Thermal efficiency obtained when considered the pump work is

$$\eta_{th1} = 0.3718$$

Thermal efficiency obtained when neglecting the pump work is

$$\eta_{th2} = 0.378$$

Error caused in the thermal efficiency is

Thermal efficiency obtained when considered the pump work is

$\eta_{th1} = 0.3718$

Thermal efficiency obtained when neglecting the pump work is

$\eta_{th2} = 0.378$

Error caused in the thermal efficiency is

$$error = \frac{\eta_{th2} - \eta_{th1}}{\eta_{th1}}$$

$$error = \frac{0.378\text{-}0.3718}{0.3718} \times 100$$

$$\boxed{error = 1.66\%}$$

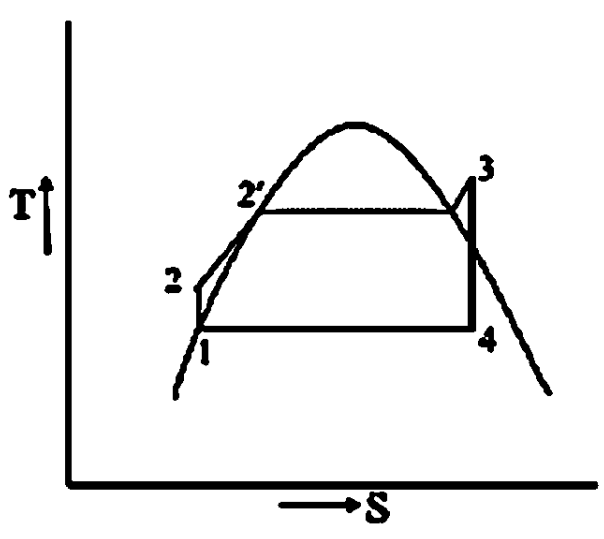
Question: 9.121P

Consider a steam power plant that operates on a simple ideal Rankine cycle and has a net power output of 45 MW. Steam enters the turbine at 7 MPa and 500°C and is cooled in the condenser at a pressure of 10 kPa by running cooling water from a lake through the tubes of the condenser at a rate of 2000 kg/s. Show the cycle on a *T-s* diagram with respect to saturation lines, and determine *(a)* the thermal efficiency of the cycle, (b) the mass flow rate of the steam, and (c) the temperature rise of the cooling water.

Step 1 of 13

Given

Turbine inlet pressure $P_3 = 7\text{MPa}$



Turbine inlet temperature $T_3 = 500^0\text{C}$

Condenser pressure $P_4 = P_1 = 10\text{kPa}$

Net power output $W_{net} = 45\text{MW}$

Mass flow rate of cooling water $\dot{m}_w = 2000\text{kg/s}$

Step 2 of 13

Step 3 of 13

At $P_1 = 10\text{kPa}$ from saturated water tables

$h_1 = h_{f,10kPa} = 191.81\text{ kJ/kg}$

$v_1 = v_{f,10kPa} = 0.00101\text{ m}^3\text{/kg}$

$h_{fg} = 2392.1\text{kJ/kg}$

$s_f = 0.6492\text{kJ/kg.K}$

$s_{fg} = 7.4996\text{kJ/kg.K}$

Step 4 of 13

Pump work during the process 1-2 is

$w_{pump} = -v_1(P_2 - P_1)$

$w_{pump} = -0.00101 \times (7000 - 10)$

$w_{pump} = -7.06\text{kJ/kg}$

Step 5 of 13

Applying first law to the process 1-2

$h_1 = h_2 + w_{pump}$

$h_2 = h_1 - w_{pump}$

$h_2 = 191.81 + 7.06$

$h_2 = 198.87\text{ kJ/kg}$

Step 6 of 13

At $P_3 = 7\text{MPa}$ and $T_3 = 500^0\text{C}$ from superheated water tables

$h_3 = 3411.4\text{ kJ/kg}$

$s_3 = 6.8\text{ kJ/kg.K}$

Step 7 of 13

Process 3-4 is isentropic expansion

$s_3 = s_4$

$s_3 = s_f + x_4 s_{fg}$

$x_4 = \dfrac{(s_3 - s_f)}{s_{fg}}$

$x_4 = \dfrac{(6.8 - 0.649)}{7.4996}$

$x_4 = 0.82$

Step 8 of 13

Enthalpy at state-4

$h_4 = h_f + x_4 h_{fg}$

$h_4 = 191.81 + (0.82 \times 2392.1)$

$h_4 = 2153.332\text{ kJ/kg}$

Step 9 of 13

Heat addition is given by

$q_{in} = h_3 - h_2$

$q_{in} = 3411.4 - 198.87$

$q_{in} = 3212.53\text{ kJ/kg}$

Step 10 of 13

Heat rejected in the condenser is

$q_{out} = h_4 - h_1$

$q_{out} = 2153.332 - 191.81$

$q_{out} = 1961.522\text{ kJ/kg}$

Step 11 of 13

(a)

Thermal efficiency of the cycle,

$\eta_{th} = \dfrac{w_{net}}{q_{in}}$

$\eta_{th} = \dfrac{q_{in} - q_{out}}{q_{in}}$

$\eta_{th} = \dfrac{3212.53 - 1961.522}{3212.53}$

$= 0.3894$

$\boxed{\eta_{th} = 38.94\%}$

Step 12 of 13

(b)

Steam mass flow rate is given by

$\dot{m} = \dfrac{W_{net}}{w_{net}}$

$\dot{m} = \dfrac{W_{net}}{q_{in} - q_{out}}$

$\dot{m} = \dfrac{45000}{3212.53 - 1961.522}$

$\boxed{\dot{m} = 35.97\text{ kg/s}}$

Step 13 of 13

(c)

Mass flow rate of the water

By applying energy balance to the condenser

$Q_{out} = m_w \times C_y \Delta T_{coolingwater}$

Where specific heat of water is

$C_y = 4.18\text{kJ/kg.K}$

The temperature rise of water is

$\Delta T_{coolingwater} = \dfrac{Q_{out}}{m_w \times C_y}$

$\Delta T_{coolingwater} = \dfrac{\dot{m} q_{out}}{m_w \times C_y}$

$\Delta T_{coolingwater} = \dfrac{35.97 \times 1961.522}{2000 \times 4.18}$

$\boxed{\Delta T_{coolingwater} = 8.439^0\text{C}}$

Question: 9.122P pg 1

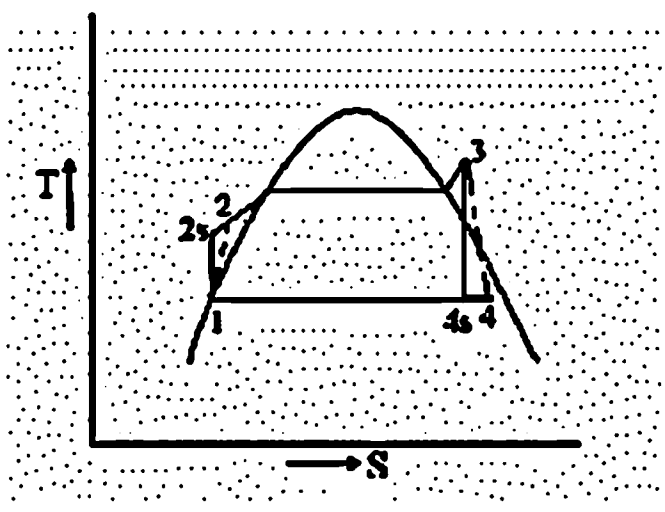
Repeat Prob. 9–121 assuming an isentropic efficiency of 87 percent for both the turbine and the pump

Step 1 of 15

Given

Turbine inlet pressure $P_3 = 7\text{MPa}$

Turbine inlet temperature $T_3 = 500^0\text{C}$



Condenser pressure $P_4 = P_1 = 10\text{kPa}$

Net power output $W_{net} = 45\text{MW}$

Mass flow rate of cooling water $\dot{m}_w = 2000\text{kg/s}$

Isentropic efficiency of turbine and pump is $\eta_T = \eta_p = 87\%$

Step 2 of 15

Step 3 of 15

At $P_1 = 10\text{kPa}$ from saturated water tables

$h_1 = h_{f,10kPa} = 191.81\text{ kJ/kg}$

$v_1 = v_{f,10kPa} = 0.00101\text{ m}^3\text{/kg}$

$h_{fg} = 2392.1\text{kJ/kg}$

$s_f = 0.6492\text{kJ/kg.K}$

$s_{fg} = 7.4996\text{kJ/kg.K}$

Step 4 of 15

Isentropic pump work during the process 1-2s is

$w_{isenp} = -v_1(P_{2s} - P_1)$

$w_{isenp} = -0.00101 \times (7000 - 10)$

$w_{isenp} = -7.06\text{kJ/kg}$

Step 5 of 15

Isentropic efficiency of the pump is

$$\eta_p = \frac{w_{isenp}}{w_{actp}}$$

$$0.87 = \frac{-7.06}{w_{actp}}$$

$$w_{actp} = -8.114\text{kJ/kg}$$

Step 6 of 15

Applying first law to the process 1-2

$h_1 = h_2 + w_{actp}$

$h_2 = h_1 - w_{actp}$

$h_2 = 191.81 + 8.114$

$h_2 = 199.924\text{ kJ/kg}$

Step 7 of 15

At $P_3 = 7\text{MPa}$ and $T_3 = 500^0\text{C}$ from superheated water tables

$h_3 = 3411.4\text{ kJ/kg}$

$s_3 = 6.8\text{ kJ/kg.K}$

Step 8 of 15

Process 3-4s is isentropic expansion

$s_3 = s_{4s}$

$s_3 = s_f + x_{4s}s_{fg}$

$$x_{4s} = \frac{(s_3 - s_f)}{s_{fg}}$$

$$x_{4s} = \frac{(6.8 - 0.649)}{7.4996}$$

$x_{4s} = 0.82$

Step 9 of 15

Enthalpy at state-4s

$h_{4s} = h_f + x_{4s}h_{fg}$

$h_{4s} = 191.81 + (0.82 \times 2392.1)$

$h_{4s} = 2153.332\text{ kJ/kg}$

Step 10 of 15

Isentropic efficiency of the turbine is

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$0.87 = \frac{3411.4 - h_4}{3411.4 - 2153.332}$$

$h_4 = 2316.88\text{kJ/kg}$

Step 11 of 15

$$h_4 = \frac{3411.4 - 2153.332}{}$$
$h_4 = 2316.88\,\text{kJ/kg}$

9.122P pg 2

Step 11 of 15

Heat addition is given by

$$q_{in} = h_3 - h_2$$
$$q_{in} = 3411.4 - 199.924$$
$$q_{in} = 3211.476\,\text{kJ/kg}$$

Step 12 of 15

Heat rejected in the condenser is

$$q_{out} = h_4 - h_1$$
$$q_{out} = 2316.88 - 191.81$$
$$q_{out} = 2125.07\,\text{kJ/kg}$$

Step 13 of 15

(a)
Thermal efficiency of the cycle,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$
$$\eta_{th} = \frac{q_{in} - q_{out}}{q_{in}}$$
$$\eta_{th} = \frac{3211.476 - 2125.07}{3211.476}$$
$$= 0.3382$$
$$\boxed{\eta_{th} = 33.82\%}$$

Step 14 of 15

(b)
Steam mass flow rate is given by

$$\dot{m} = \frac{W_{net}}{w_{net}}$$
$$\dot{m} = \frac{W_{net}}{q_{in} - q_{out}}$$
$$\dot{m} = \frac{45000}{3211.476 - 2125.07}$$
$$\boxed{\dot{m} = 41.42\,\text{kg/s}}$$

Step 15 of 15

(c)
Mass flow rate of the water
By applying energy balance to the condenser

$$Q_{out} = m_w \times C_p \Delta T_{coolingwater}$$

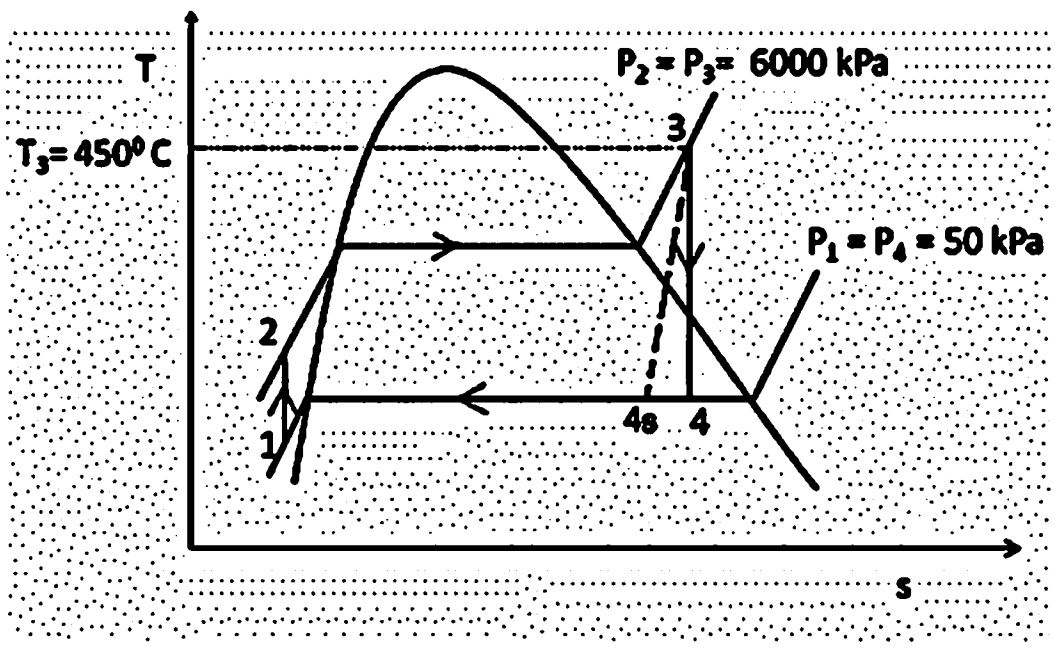
Where specific heat of water is

$$C_p = 4.18\text{kJ/kg.K}$$

The temperature rise of water is

$$\Delta T_{coolingwater} = \frac{Q_{out}}{m_w \times C_p}$$
$$\Delta T_{coolingwater} = \frac{\dot{m} q_{out}}{m_w \times C_p}$$
$$\Delta T_{coolingwater} = \frac{41.42 \times 2125.07}{2000 \times 4.18}$$
$$\boxed{\Delta T_{coolingwater} = 10.528^0\text{C}}$$

Question: 9.123P pg 1



A simple Rankine cycle uses water as the working fluid. The boiler operates at 6000 kPa and the condenser at 50 kPa. At the entrance to the turbine, the temperature is 450°C. The isentropic efficiency of the turbine is 94 percent, pressure and pump losses are negligible, and the water leaving the condenser is subcooled by 6.3°C. The boiler is sized for a mass flow rate of 20 kg/s. Determine the rate at which heat is added in the boiler, the power required to operate the pumps, the net power produced by the cycle, and the thermal efficiency. Answers:59,660 kW, 122 kW, 18,050 kW, 30.3 percent.

Step 1 of 12

Given:
Process: Rankine cycle.
Working fluid: water.
The boiler operates Pressure $P_2 = P_3 = 6000\,\text{kPa}$.
The condenser operating pressure $P_1 = P_4 = 50\text{kPa}$.
Turbine inlet temperature $T_3 = 450\,^\circ\text{C}$.
Isentropic efficiency of the turbine $\eta_T = 0.94$.
Water leaving the condenser is sub cooled by 6.3^0C.
Mass flow rate $m = 20\ \text{kg}/s$.
Pressure drop across the boiler $P_{drop} = 50\text{kPa}$.

Step 2 of 12

The Ideal Rankin cycle

Step 3 of 12

State1:
From the Saturated water pressure table
$P_1 = 50\ \text{kPa}$
$(T_{sat}) = 81.32^\circ\text{C}$
$(h_f) = 340.54\ \text{kJ/kg}$
$(v_f) = 0.001030\ \text{m}^3/\text{kg}$
From the above quantities,
At this pressure and temperature is sub cooled by 6.3^0C,
Then,
$T_1 = T_{sat} - 6.3^\circ\text{C}$
$= 81.3 - 6.3$
$= 75^\circ\text{C}$
Now from the Saturated water temperature table
At $T_1 = 75^\circ\text{C}$
$h_1 = h_f = 314.03\ \text{kJ/kg}$

Step 4 of 12

State 2:
Exit pressure of the pump $P_2 = 6000\ \text{kPa}$
The work done in the compression process is given by,
$w_{pump} = v_1 \times (P_2 - P_1)$
$w_{pump} = 0.001030 \times (6000\ \text{kPa} - 50\ \text{kPa})$
$w_{pump} = 6.12\text{kJ/kg}$

Step 5 of 12

Enthalpy at state 2 is
$h_2 = h_1 + w_{pump}$
$= 314.03 + 6.1$
$= 320.15\text{kJ/kg}$

Step 6 of 12

State 3:
From the superheated water table
At $P_3 = P_2 = 6000\ \text{kPa}$ And $T_3 = 450^\circ\text{C}$
$h_3 = 3302.9\ \text{kJ/kg}$
$s_3 = 6.7219\ \text{kJ/kg} \cdot \text{K}$

Step 7 of 12

State4:
Ideally the expansion in turbine is isentropic in nature, then $s_4 = s_3 = 6.7219\ \text{kJ/kg} \cdot \text{K}$
From the saturated water pressure table
At $P_4 = P_1 = 50\ \text{kPa}$ and $s_4 = s_3 = 6.7219\ \text{kJ/kg} \cdot \text{K}$
$s_4 = s_f + x_4 s_{fg}$
$6.7219 = 1.0912 + x_4 (6.5019)$
$x_4 = 0.866$
$h_4 = h_f + x_4 h_{fg}$
$= 340.54 + 0.866(2304.7)$
$= 2336.410\text{kJ/kg}$

Step 8 of 12

Work obtained from the turbine (ideally)

$= 2336.410 \text{ kJ/kg}$

Step 8 of 12

Work obtained from the turbine (ideally)

$W_{Ts} = 20 \times (3302.76 - 2336.41)$

$= 19327 \text{ kW}$

$= 19.32 \text{ MW}$

But it is given that the turbine is only 94% efficient, hence the actual work obtained from the turbine is,

$W_{Ta} = \eta_T \times W_{Ts}$

$W_{Ta} = 0.94 \times 19.32 \text{ MW}$

$= 18.17 \text{ MW}$

Step 9 of 12

Work done in pump is

$\dot{W}_{pump} = \dot{m} W_{pump}$

$= 20 \times 6.1$

$= 122 \text{ kJ/sec}$

$= 122 \text{ kW}$

Step 10 of 12

The net output of the Rankin cycle is given by,

$W_{net} = W_{Ta} - W_{pump}$

$= 18.17 - 0.122 \text{ MW}$

$= 18.05 \text{ M}$

$\boxed{W_{net} = 18.05 \text{ MW}}$

Step 11 of 12

The Rate at which heat added is,

$Q_{in} = \dot{m} (h_3 - h_2)$

$Q_{in} = 20 \times (3302.76 - 320.15)$

$= 59652.2 \text{ kJ/s}$

$= 59.65 \text{ MW}$

$\boxed{Q_{in} = 59.65 \text{ MW}}$

Step 12 of 12

Thermal efficiency of the Rankin cycle is given by,

$$\eta_{Rankin} = \frac{W_{net}}{Q_{in}}$$

$$= \frac{18.05 \text{ MW}}{59.65 \text{ MW}}$$

$= 0.303$

$= 30.3 \%$

$\boxed{\eta_{Rankin} = 30.3\%}$

Question: 9.124P

 Using EES (or other) software, determine how much the thermal efficiency of the cycle in Prob. 9–123 would change if there were a 50 kPa pressure drop across the boiler.

We don't have the solution to this problem yet.

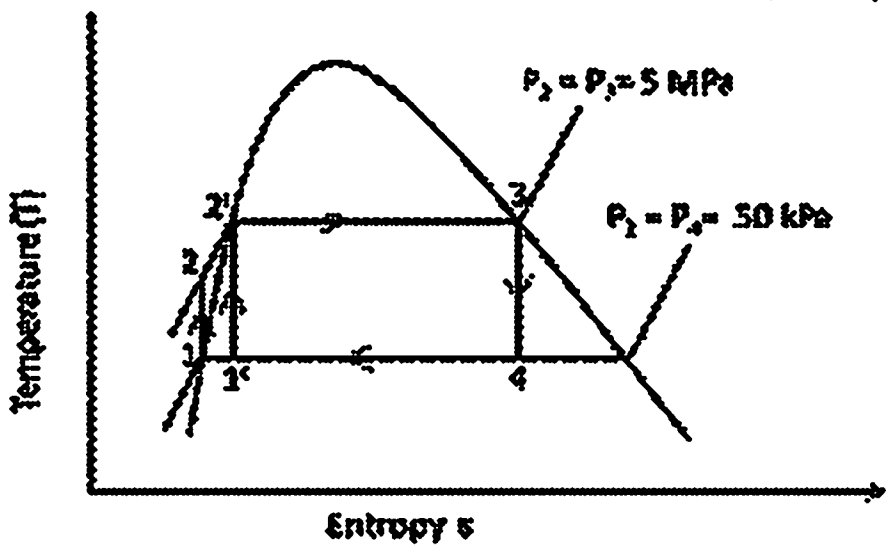
Question:



The net work output and the thermal efficiency for the Carnot and the simple ideal Rankine cycles with steam as the working fluid are to be calculated and compared. Steam enters the turbine in both cases at 5 MPa as a saturated vapor, and the condenser pressure is 50 kPa. In the Rankine cycle, the condenser exit state is saturated liquid and in the Carnot cycle, the boiler inlet state is saturated liquid. Draw the *T-s* diagrams for both cycles.

Step 1 of 15

Given,
Both the Rankin and Carnot cycles are operated between same pressure limits.
Boiler pressure = 5 MPa,
Condenser pressure = 50 kPa.
In both the cases stem is entering the turbine as saturated vapor.
In Rankin cycle the condenser exit is saturated liquid, where as in Carnot cycle boiler nlet is saturated liquid.

Step 2 of 15

The Ideal Rankin cycle and Carnot cycle operating between the given conditions is shown below.

Step 3 of 15

a) **Carnot Cycle:**

State 2^1:

$P_{2'} = 5\ \text{MPa} = 5000\ \text{kPa}$ and the liquid entering the boiler is saturated liquid, hence

$h_{2'} = 1154.5\ \text{kJ/kg}$

$s_2 = 2.9207\ \text{kJ/kg}\cdot\text{K}$

Step 4 of 15

State 3:

$P_3 = P_{2'} = 5\ \text{MPa} = 5000\ \text{kPa}$

the liquid entering the turbine is saturated vapor.

$h_3 = h_g = 2794.3\ \text{kJ/kg}$

$s_3 = s_g = 5.973\ \text{kJ/kg}\cdot\text{K}$

Step 5 of 15

State 4:

Since the expansion is isentropic $s_4 = s_3$ and $P_4 = 50\ \text{kPa}$

At these conditions the enthalpy is calculated using the steam tables and is given by,

From the saturated water pressure table

At $P_4 = P_1 = 50\ \text{kPa}$ and $s_4 = s_3 = 5.973\ \text{kJ/kg}\cdot\text{K}$

$$s_4 = s_f + x_4 s_{fg}$$

$$5.973 = 1.0912 + x_4(6.5019)$$

$$x_4 = 0.75$$

$$h_4 = h_f + x_4 h_{fg}$$

$$= 340.54 + 0.75(2304.7)$$

$$= 2070.9\ \text{kJ/kg}$$

Step 6 of 15

State 1^1:

Since the expansion is isentropic $s_{1'} = s_2 = 2.9207\ \text{kJ/kg}\cdot\text{K}$

From the saturated water pressure table

$P_{1'} = 50\ \text{kPa}$

$$s_1 = s_f + x_4 s_{fg}$$

$$2.9207 = 1.0912 + x_4(6.5019)$$

$$x_1 = 0.28$$

$$h_1 = h_f + x_4 h_{fg}$$

$$= 340.54 + 0.2814(2304.7)$$

$$= 989.082\ \text{kJ/kg}$$

Step 7 of 15

The net work output from the Carnot cycle is given by,

$$W_{net} = (h_3 - h_4) - (h_{2'} - h_1)$$

$$W_{net} = (2794.3 - 2070.9) - (1154.5 - 989.082)$$

$$W_{net} = 557.982\ \text{kJ/kg}$$

Step 8 of 15

The efficiency of the Carnot cycle is given by,

$$\eta_{Carnot} = \frac{W_{net}}{Q_{sup}}$$

$$= \frac{(h_3 - h_4) - (h_{2'} - h_1)}{(h_3 - h_{2'})}$$

$$= \frac{557.982}{}$$

$$\eta_{Carnot} = \frac{Q_{sup}}{}$$

$$= \frac{(h_3 - h_4) - (h_2 - h_1)}{(h_3 - h_2)}$$

$$= \frac{557.982}{(2794.3 - 1154.5)}$$

$$= 0.340$$

$$\boxed{\eta_{Carnot} = 0.340}$$

Step 9 of 15

b) Rankin cycle:

State 1:

$P_1 =$ 50 kPa And the water is at saturated liquid condition. At these conditions the enthalpy is calculated using the steam tables and is given by,

$h_1 =$ 340.54 kJ/kg

$v_1 =$ 0.001030 m^3/kg

Step 10 of 15

State 2:

$P_2 =$ 5 MPa = 5000 kPa

The work done in the compression process is given by,

$w_{pump} = v_1 \times (P_2 - P_1)$

$w_{pump} = 0.001030 \times (5000\ \text{kPa} - 50\ \text{kPa})$

$w_{pump} = 5.0985$kJ/kg

Step 11 of 15

Enthalpy at state 2 is

$h_2 = h_1 + w_{pump}$

$= 340.54 + 5.0985$

$=345.638$kJ/kg

Step 12 of 15

State 3:

$P_3 = 5$ MPa = 5000 kPa And the liquid entering the turbine is saturated vapor.

$h_3 =$ 2794.2 kJ/kg

$s_3 =$ 5.9737 kJ/kg K

Step 13 of 15

State 4:

Since the expansion is isentropic $s_4 = s_3$ and $P_4 = 50$ kPa

At these conditions the enthalpy is calculated using the steam tables and is given by,

From the saturated water pressure table

At $P_4 = P_1 = 50$ kPa and $s_4 = s_3 =$ 5.973 kJ/kg·K

$s_4 = s_f + x_4 s_{fg}$

$5.973 = 1.0912 + x_4 (6.5019)$

$x_4 = 0.75$

$h_4 = h_f + x_4 h_{fg}$

$= 340.54 + 0.75(2304.7)$

$= 2070.9$kJ/kg

Step 14 of 15

The net work output from the Rankin cycle is given by,

$W_{net} = (h_3 - h_4) - (h_2 - h_1)$

$W_{net} = (2794.3 - 2070.9) - (345.638 - 340.54)$

$= 718.302$kJ/kg

$\boxed{W_{net} = 718.302\text{kJ/kg}}$

Step 15 of 15

The efficiency of the Rankin cycle is given by,

$$\eta_{Rankin} = \frac{W_{net}}{Q_{sup}}$$

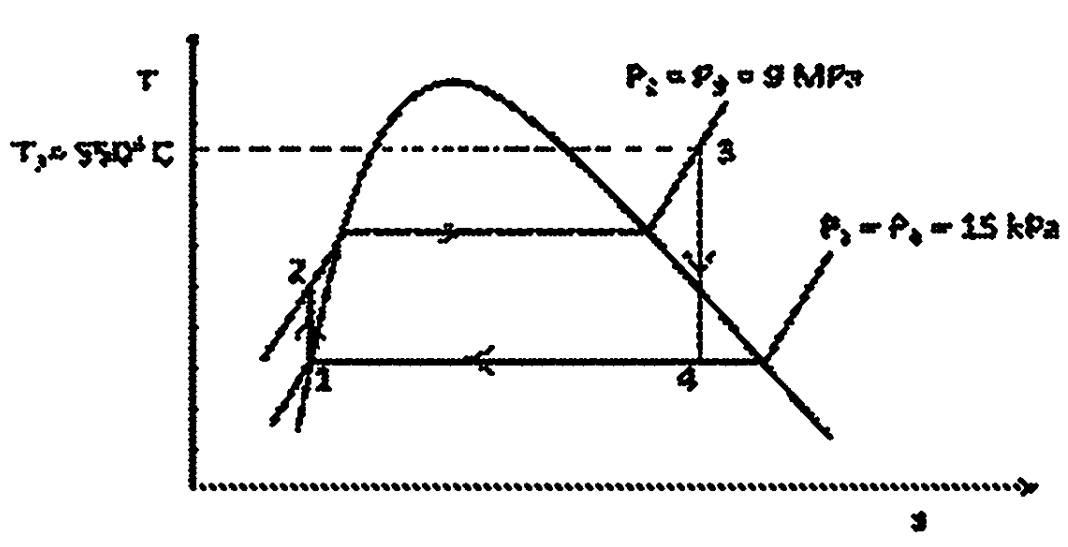
$$= \frac{(h_3 - h_4) - (h_2 - h_1)}{(h_3 - h_2)}$$

$$= \frac{718.302}{(2794.3 - 345.638)}$$

$$= 0.293$$

$$\boxed{\eta_{Rankin} = 0.293}$$

Question: 9.126P



Consider a coal-fired steam power plant that produces 120 MW of electric power. The power plant operates on a simple ideal Rankine cycle with turbine inlet conditions of 9 MPa and 550°C and a condenser pressure of 15 kPa. The coal has a heating value (energy released when the fuel is burned) of 29,300 kJ/kg. Assuming that 75 percent of this energy is transferred to the steam in the boiler and that the electric generator has an efficiency of 96 percent, determine (a) the overall plant efficiency (the ratio of net electric power output to the energy input as fuel) and *(b)* the required rate of coal supply.

Step 1 of 11

Given,
Working fluid: water.
The boiler operating pressure $P_2=P_3=9\,\text{MPa}$.
the condenser operating pressure $P_1=P_4=15\,\text{kPa}$.
Turbine inlet temperature $T_3=550^\circ\text{C}$
The heating value of coal $C_v=29300\,\text{kJ/kg}$
It is mentioned that only 75 % of the energy is transferred to boiler.
Electric generator efficiency $\eta_g=0.96$.

Step 2 of 11

The Ideal Rankin cycle operating between the given conditions is shown below.

Step 3 of 11

State1:
From the Saturated water pressure table
$P_1 = 15\,\text{kPa}$
$h_1 = 225.94\,\text{kJ/kg}$
$v_1 = 0.001014\,\text{m}^3/\text{kg}$

Step 4 of 11

State 2:
The boiler operating pressure $P_2 = 9000\,\text{kPa}$
The work done in the compression process is given by,

$$w_{pump} = v_1 \times (P_2 - P_1)$$
$$w_{pump} = 0.001014 \times (9000 - 15)$$
$$= 9.11\,\text{kJ/kg}$$

And we know that

$$h_2 = h_1 + w_{pump}$$
$$= 225.93 + 9.11$$
$$= 235.04\,\text{kJ/kg}$$

Step 5 of 11

State 3:
From the superheated water
$P_3 = P_2 = 9000\,\text{kPa}$ And $T_3 = 550^0\,\text{C}$
$h_3 = 3512.0\,\text{kJ/kg}$
$s_3 = 6.81164\,\text{kJ/kg}\cdot\text{K}$

Step 6 of 11

State4:
Ideally the expansion in turbine is isentropic in nature,
Then $s_4 = s_3 = 6.81164\,\text{kJ/kg}\cdot\text{K}$
From the Saturated water pressure table
At $P_4 = P_1 = 15\,\text{kPa}$ and $s_4 = s_3 = 6.81164\,\text{kJ/kg}\cdot\text{K}$

$$h_4 = h_f + x_4 h_{fg}$$
$$= 225.94 + 0.8358(2372.3)$$
$$= 2208.708\,\text{kJ/kg}$$

Step 7 of 11

Work obtained from the turbine

$$W_T = (3512.0 - 2208.708)$$
$$= 1303.29\,\text{kJ/kg}$$

But it is given that the electric generator is only 96% efficient, The power obtained is 120 MW, hence,

$$120\text{MW} = m_{steam} \times W_T \times \eta_g$$
$$m_{steam} = \frac{120 \times 10^6}{0.96 \times 1303.2 \times 10^3}$$
$$= 95.917\,\text{kg/s}$$

Step 8 of 11

Heat supplied in the boiler is given by,

$$Q_{in} = \dot{m}\,(h_3 - h_2)$$
$$Q_{in} = 95.917 \times (3512.0 - 235.04)$$
$$= 314.316\,\text{MW}$$

Step 9 of 11

Since, only 75% of the energy is transferred to the boiler, total heat supplied by the steam is,

$$Q_{sup} = \frac{314.316}{0.75}$$
$$= 419.088\,\text{MW}$$

Step 10 of 11

The overall plant efficiency is given by,

$$\eta_{Overall} = \frac{W_T}{Q_{sup}}$$
$$= \frac{120}{419.088}$$
$$= 0.286$$

$$\boxed{\eta_{Overall} = 0.286}$$

Step 11 of 11

(b)

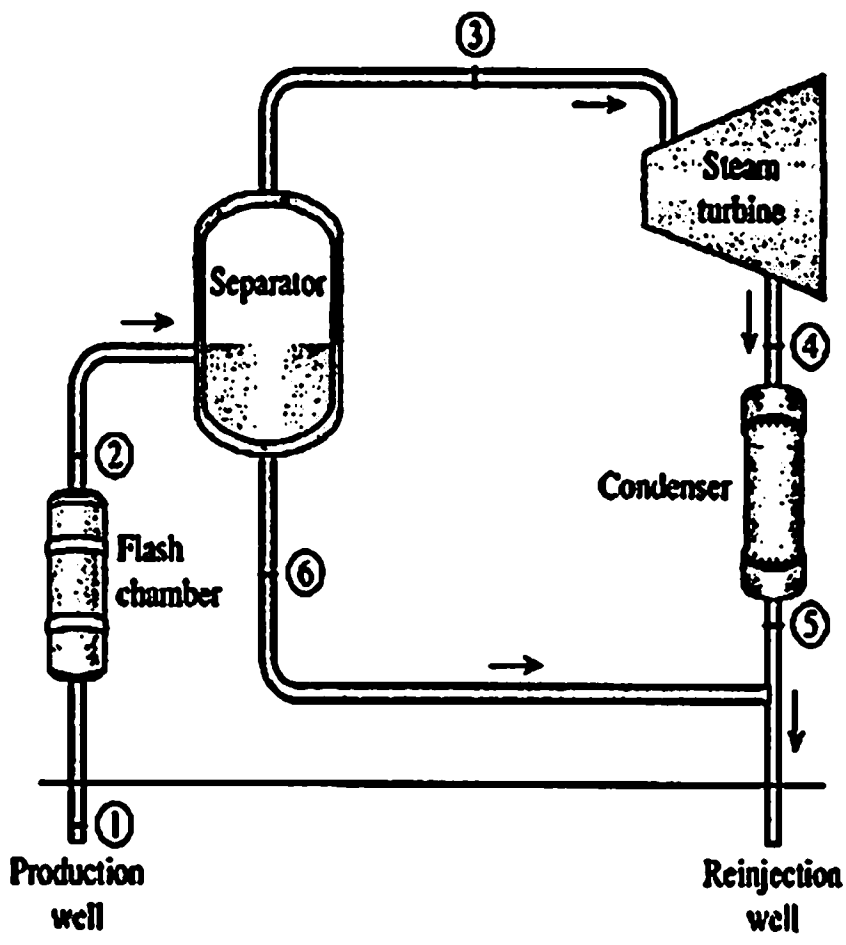
The required rate of coal is calculated by using following relation.

$$m_{coal} \times CV_{coal} = Q_{sup}$$
$$m_{coal} = \frac{419.088\text{MW}}{29300\,\text{kJ/kg}}\left(\frac{10^3\,\text{kJ/s}}{1\,\text{MW}}\right)$$
$$= 14.303\,\text{kg/s} \times \left(\frac{1\,\text{t}}{1000\,\text{kg}}\right) \times \left(\frac{3600\,\text{s}}{1\,\text{h}}\right)$$
$$= 51.49\,\text{t/h}$$

$$\boxed{m_{coal} = 51.49\,\text{t/h}}$$

Question: 9.127P pg 1

The schematic of a single-flash geothermal power plant with state numbers is given in Fig. P9-127. Geothermal resource exists as saturated liquid at 230°C. The geothermal liquid is withdrawn from the production well at a rate of 230 k.g/ s and is flashed to a pressure of 500 kPa by an essentially lisenthalpic flashing process where the resulting vapor is seprated from the liquid in a separator and directed to the turbine. The steam leaves the turbine at 10 kPa with a moisture content of 10 percent and enters the condenser where it is condensed and routed to a reinjection well along with the liquid coming off the separator. Determine (a) the mass flow rate of steam through the turbine, *(b)* the isentropic efficienc of the turbine, (c) the power output of the turbine, and *(d)* thermal efficiency of the plant (the ratio of the turbine work output to the energy of the geothermal fluid relative to standard ambient conditions).



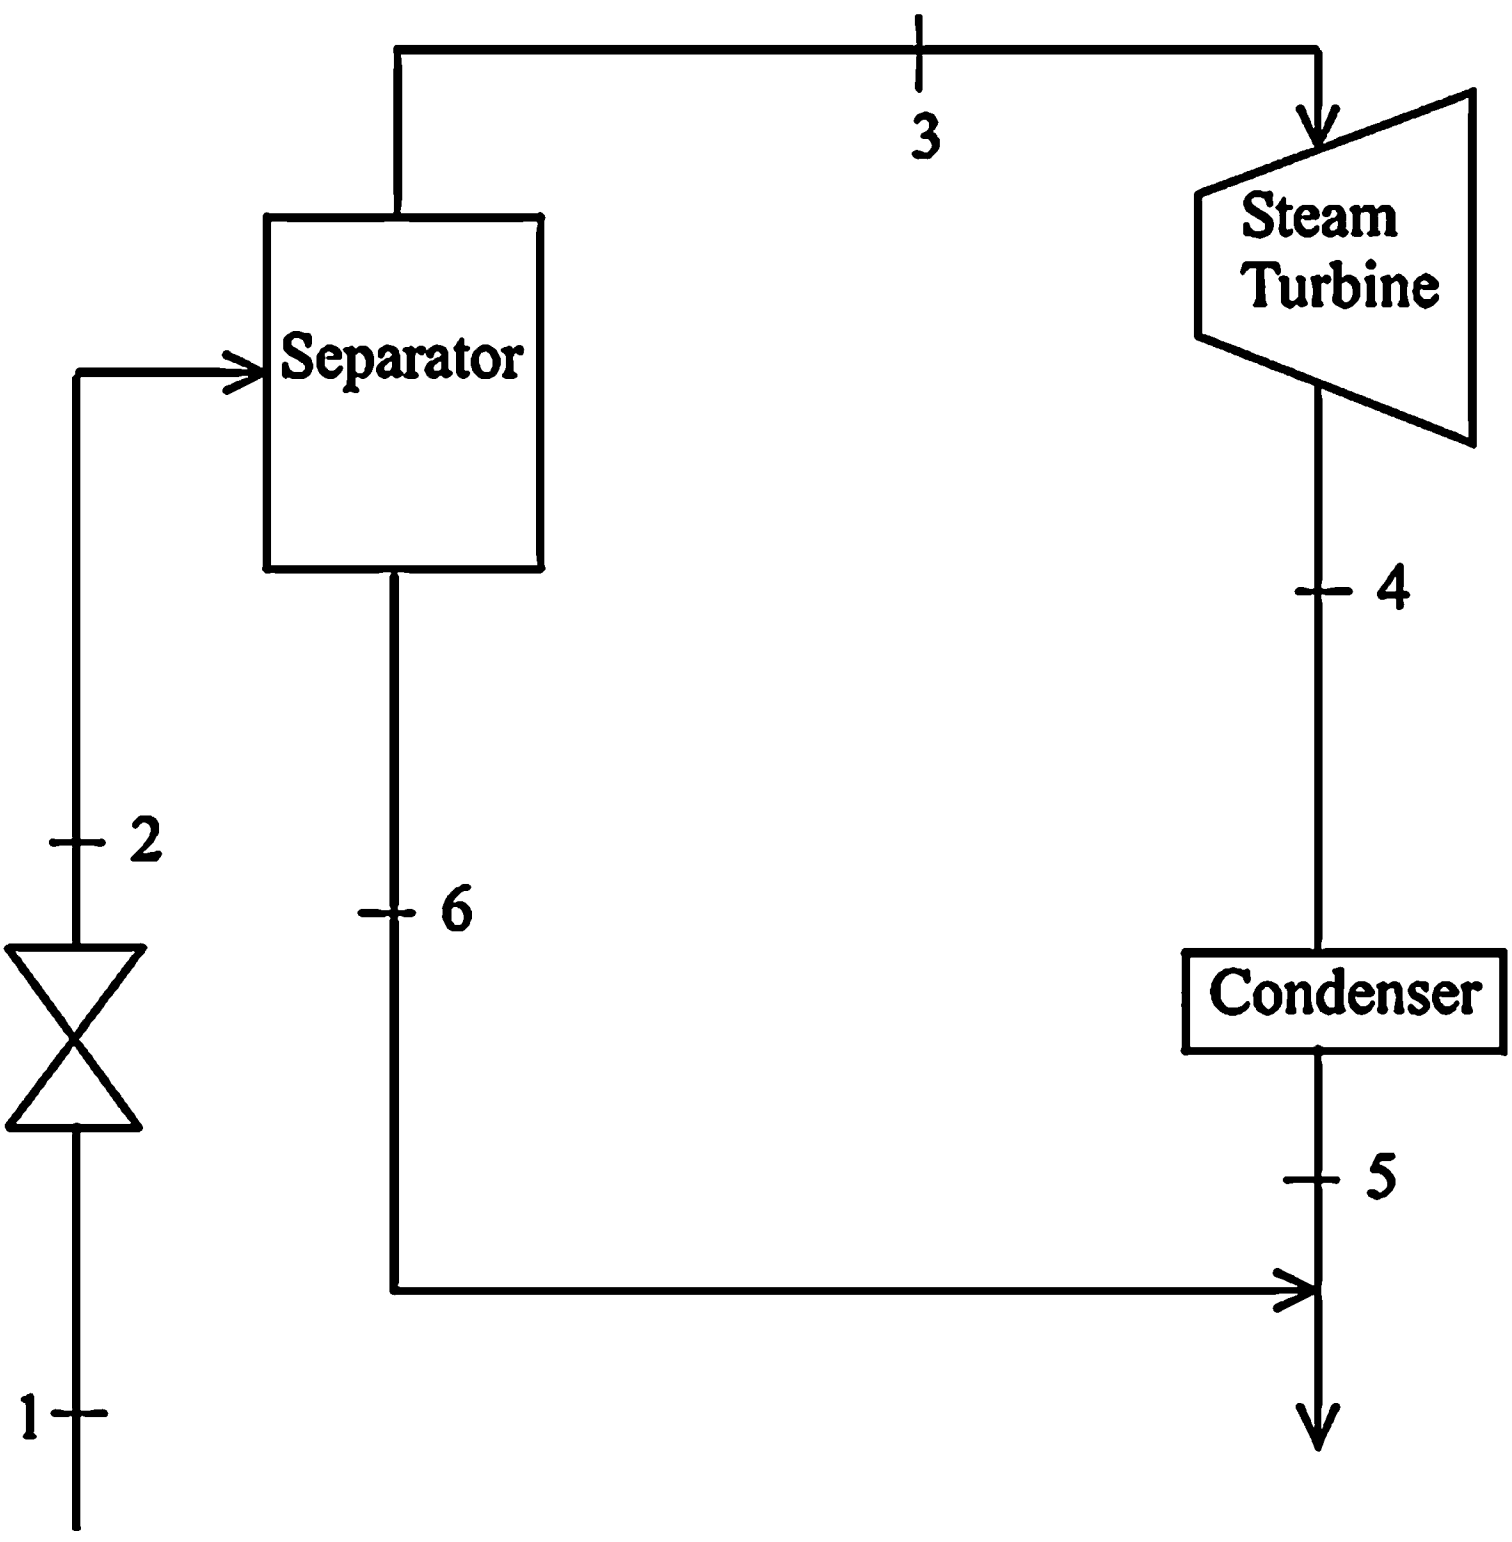


FIGURE P9–127

Step 1 of 6

Consider the schematic diagram of a single-flash geothermal power plant.

Step 2 of 6

Obtain the properties of steam from the table A.4, "Properties of saturated water-temperature table" at temperature, 230^0C .

Specific enthalpy, $h_1 = h_f = 990.14\ \text{kJ/kg}$

In the flash chamber, the enthalpy remains constant.

$$h_1 = h_2$$

Obtain the properties of steam from the table A.4, "Properties of saturated water-pressure table" at pressure, 500 kPa.

$$h_{f@500\text{kPa}} = 640.09\,\text{kJ/kg}$$

$$h_{fg@500\text{kPa}} = 2108\,\text{kJ/kg}$$

Determine the dryness fraction at state 2.

$$h_2 = h_{f@500\text{kPa}} + x_2 h_{fg@500\text{kPa}}$$

$$990.14 = 640.09 + x_2 \times 2108.0$$

$$x_2 = 0.166$$

Step 3 of 6

Determine the mass flow rate of steam through the turbine.

$$x_2 = \frac{\dot{m}_3}{\dot{m}_2}$$

$$x_2 = \frac{\dot{m}_3}{\dot{m}_1}$$

$$\dot{m}_3 = x_2 \times \dot{m}_1$$

Substitute 0.166 for x_2 , and $230\,\text{kg/s}$ for $\dot{m}_1$.

$\dot{m}_1$

$\dot{m}_3 = x_2 \times \dot{m}_1$

Substitute 0.166 for x_2 , and 230kg/s for $\dot{m}_1$.

$$\dot{m}_3 = 0.166 \times 230$$
$$= 38.18\text{kg/s}$$

Hence, the mass flow rate of steam through the turbine is, $\boxed{\dot{m}_3 = 38.18\text{kg/s}}$.

Step 4 of 6

(b)

Obtain the properties of saturated vapor from the table A.4, "Properties of saturated water-pressure table" at pressure, 500 kPa.

$h_3 = 2748.1\text{ kJ/kg}$

$s_3 = 6.8207\text{ kJ/kg.K}$

Obtain the properties of saturated vapor from the table A.4, "Properties of saturated water-pressure table" at pressure, 10 kPa.

$h_{f@10\text{kPa}} = 191.81\text{kJ/kg}$

$h_{fg@10\text{kPa}} = 2392.1\text{kJ/kg}$

Calculate the enthalpy at pressure , 10 kPa and dryness fraction, 0.9.

$h_4 = h_{f@10\text{kPa}} + x_4 h_{fg@10\text{kPa}}$

$h_4 = 191.81 + (0.9 \times 2392.1)$

$h_4 = 2344.7\text{ kJ/kg}$

Step 5 of 6

Obtain the properties of saturated vapor from the table A.4, "Properties of saturated water-pressure table" at pressure, 10 kPa.

$s_{f@10\text{kPa}} = 0.6492\text{kJ/kgK}$

$s_{fg@10\text{kPa}} = 7.4996\text{kJ/kgK}$

As the process 3-4s is reversible isentropic process,

$s_3 = s_{4s}$

$s_{4s} = s_{f@10\text{kPa}} + x_{4s} s_{fg@10\text{kPa}}$

$6.8207 = 0.6492 + x_{4s} \times 7.4996$

$x_{4s} = 0.8229$

Determine the enthalpy at state 4s.

$h_{4s} = h_{f@10\text{kPa}} + x_{4s} h_{fg@10\text{kPa}}$

$h_{4s} = 191.81 + 0.8229 \times 2392.1$

$h_{4s} = 2160.269\text{kJ/kg}$

Determine the isentropic efficiency of the turbine.

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$\eta_T = \frac{2748.1 - 2344.7}{2748.1 - 2160.269}$$

$\eta_T = 0.686$

$\boxed{\eta_T = 0.686}$

(c)

Determine the power output from the turbine.

$W_T = \dot{m}_3 (h_3 - h_4)$

$W_T = 38.18 \times (2748.1 - 2344.7)$

$W_T = 15401.812\text{kW}$

Hence, the power output of the turbine is, $\boxed{W_T = 15.401\text{ MW}}$.

Step 6 of 6

(d)

Obtain the properties of saturated water from the table A.4, "Properties of saturated water-temperature table" at temperature, 25°C .

$h_0 = h_f = 104.83\text{ kJ/kg}$

Determine the total energy of the geothermal fluid.

$E_{in} = m_1 (h_1 - h_0)$

$E_{in} = 230 \times (990.14 - 104.83)$

$E_{in} = 203621.3\text{kW}$

Determine the thermal efficiency of the plant.

$$\eta_{th} = \frac{W_T}{E_{in}}$$

$$\eta_{th} = \frac{15401.812}{203621.3}$$

$= 0.07563$

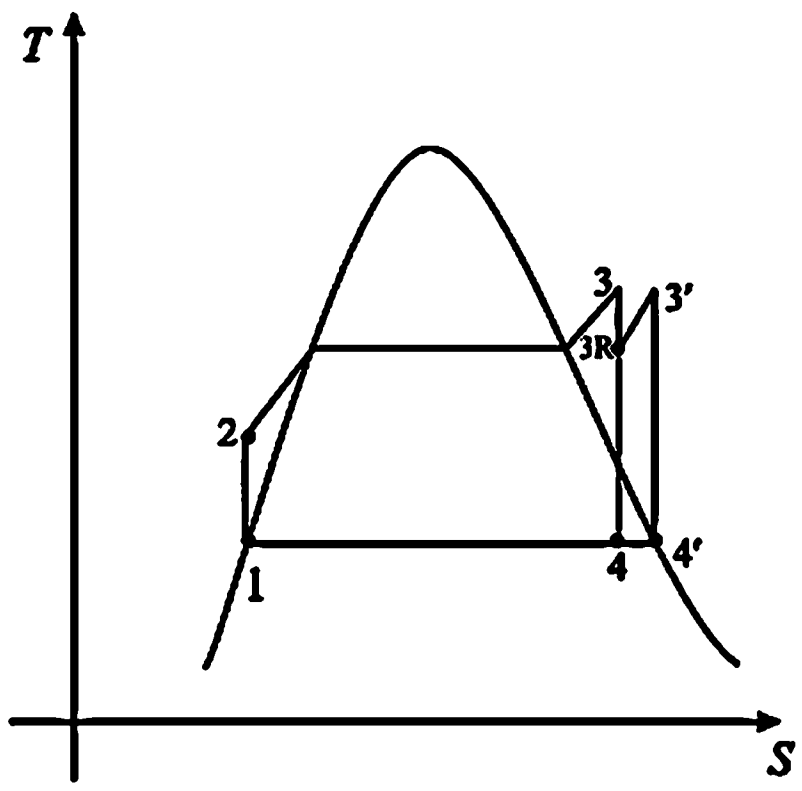
Hence, the thermal efficiency of the plant is

$$\eta_{th} = \frac{15401.812}{203621.3}$$

$$= 0.07563$$

Hence, the thermal efficiency of the plant is, $\boxed{\eta_{th} = 7.563\%}$.

Question: 9.128P



How do the following quantities change when a simple ideal Rankine cycle is modified with reheating? Assume the mass flow rate is maintained the same.

Pump work input:	(*a*) increases, (*b*) decreases, (c)remains the same
Turbine work ouput:	(*a*) increases (b) decreases, (c) remains the same
Heat supplied:	(*a*) increases (b) decreases, (c) remains the same
Heat rejected:	(*a*) increases, (b) decreases, (c) remains the same
Moisture content at turbine exit:	(*a*) increases, (b) decreases, (c) remains the same

Step 1 of 7

Given: Mass flow rate is constant

Step 2 of 7

Step 3 of 7

Pump work input: (c) remains the same

In reheating process $1-2$ will not change and hence pump work remains same

Step 4 of 7

Turbine work output: (a) increases

In reheating work output in turbine will take place in two stages first stage from $3-3R$ and second stage from $3'-4'$ and hence turbine work output increases

Step 5 of 7

Heat supplied: (a) increases

As it is reheat cycle additional heat is supplied and hence heat supplied increases

Step 6 of 7

Heat rejected: (a) increases

In reheat cycle turbine outlet point moves towards superheated region and hence heat rejected increases

Step 7 of 7

Moisture content at turbine exit: (b) decreases

In reheat cycle turbine outlet point moves towards superheated region and hence moisture content at turbine decreases

Question: 9.129P

Is there an optimal pressure for reheating the steam of a Rankine cycle? Explain.

Step 1 of 2

An optimal pressure for reheating generally allows for decrease of the moisture content of the steam at the low-pressure turbine exit. In general optimum reheat pressure is about the one-fourth of the maximum cycle pressure.

Step 2 of 2

The average temperature during the reheat process can be increased by increasing the number of expansion and reheat stages. As the number of stages is increased, the expansion and reheat processes approach an isothermal process at the maximum temperature. The use of more than two reheat stages, however, is not practical. The theoretical improvement in efficiency from the second reheat is about half of that which results from a single reheat. If the turbine inlet pressure is not high enough, double reheat would result in superheated exhaust. This is undesirable as it would cause the average temperature for heat rejection to increase and thus the cycle efficiency to decrease. Therefore, double reheat is used only on supercritical-pressure ($P > 22.06$ MPa) power plants. A third reheat stage would increase the cycle efficiency by about half of the improvement attained by the second reheat. This gain is too small to justify the added cost and complexity.

Question: 9.130P

Consider a simple ideal Rankine cycle and an ideal Rankine cycle with three reheat stages. Both cycles operate between the same pressure limits. The maximum temperature is 700°C in the simple cycle and 450°C in the reheat cycle. Which cycle do you think will have a higher thermal efficiency?

Step 1 of 2

The thermal efficiency of the simple ideal Rankine cycle will probably be higher when compared to ideal Rankine cycle in three stages since the average temperature at which heat (700°C) is added will be higher in simple cycle.

Step 2 of 2

Reason:
In ideal rankine cycle on addition of third reheat stage it would increase the cycle efficiency by about half of the improvement attained by the second reheat but gain is too small to justify the added cost and complexity. And also the average temperature at which heat added is low compared to simple ideal Rankine cycle.

Question: 9.131P

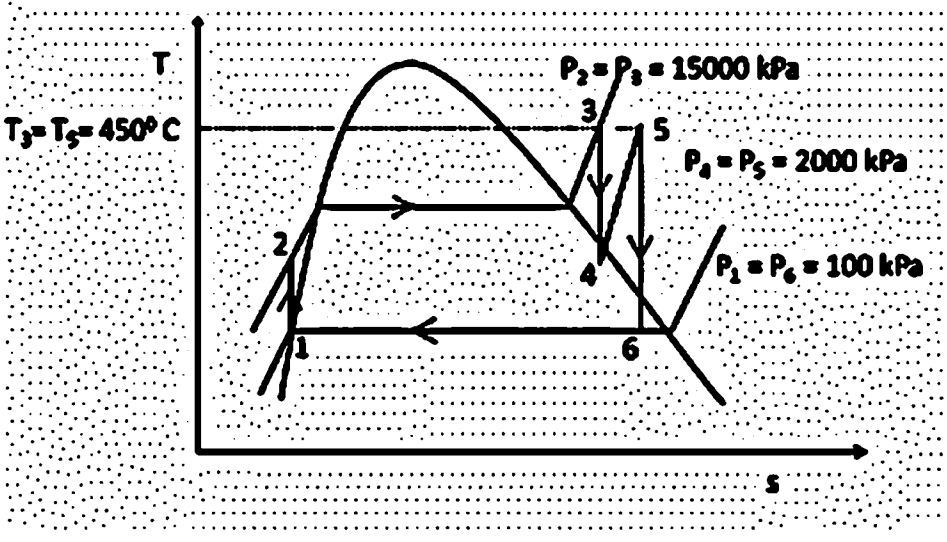
An ideal reheat Rankine cycle with water as the working fluid operates the inlet of the high-pressure turbine at 8000 kPa and 450T; the inlet of the low-pressure turbine at 500 kPa and 500°C; and the condenser at 10 kPa. Determine the mass flow rate through the boiler needed for this system to produce a net 5000 kW of power and the thermal efficiency of the cycle.

We don't have the solution to this problem yet.

Get help from a Chegg subject expert.

Ask an expert

Question:



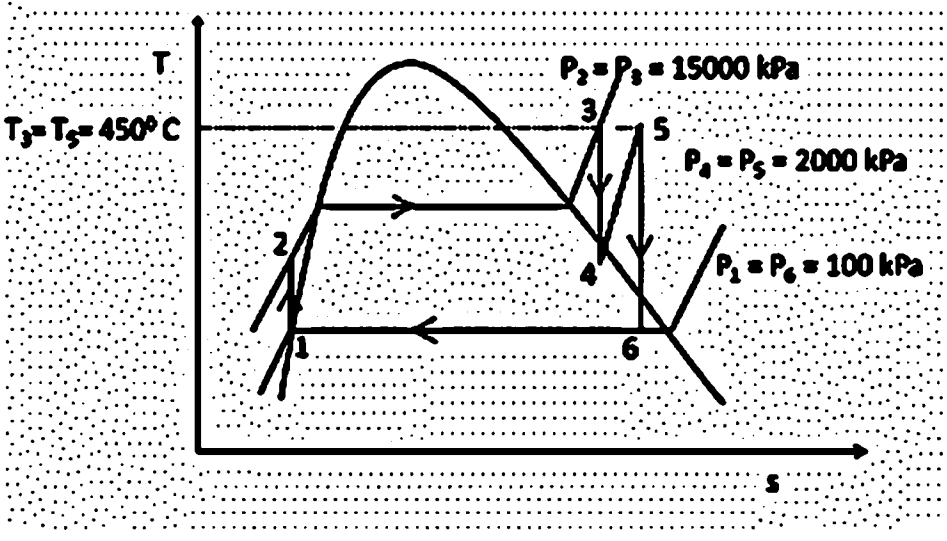
An ideal reheat Rankine cycle with water as the working fluid operates the boiler at 15,000 kPa, the reheater at 2000 kPa, and the condenser at 100 kPa. The temperature is 450CC at the entrance of the high-pressure and low-pressure turbines. The mass flow rate through the cycle is 1.74 kg/s. Determine the power used by pumps, the power produced by the cycle, the rate of heat transfer in the reheater, and the thermal efficiency of this system.

Step 1 of 13

Given,
Working fluid: water.
Pressure at the inlet of the high-pressure turbine $P_2 = P_3 = 15000$ kPa.
Temperature at the inlet of the high-pressure turbine $T = 450^0$C.
Pressure at the inlet of the low-pressure turbine $P_4 = P_5 = 2000$ kPa.
Temperature at the inlet of the low-pressure turbine $T = 450^0$C.
Condenser Pressure $P_1 = P_6 = 100$ kPa.
Mass flow rate $m = 1.74$ kg / s.

Step 2 of 13

The Ideal Reheat Rankin cycle operating between the given conditions is shown below.



Step 3 of 13

State 1:
From the saturated water pressure table
$P_1 = 100$ kPa And saturated liquid, at these conditions
$h_1 = 417.51$ kJ/kg
$v_1 = 0.001043$ m^3/kg

Step 4 of 13

Step 2 of 13

The Ideal Reheat Rankin cycle operating between the given conditions is shown below.

Step 3 of 13

State 1:
From the saturated water pressure table
$P_1 = 100$ kPa And saturated liquid, at these conditions
$h_1 = 417.51$ kJ/kg
$v_1 = 0.001043$ m^3/kg

Step 7 of 13

State 3:
From the superheated water
$P_3 = P_2 = 15000$ kPa And $T_3 = 450^0$C
$h_3 = 3157.9$ kJ/kg
$s_3 = 6.1434$kJ/kg · K

Step 8 of 13

State 4:
From the saturated water pressure table
$P_4 = 2000$ kPa and $s_4 = s_3 = 6.143$ kJ/kg · K

$$s_4 = s_f + x_4 s_{fg}$$
$$6.143 = 2.4467 + x_4 (3.8923)$$
$$x_4 = 0.9497$$
$$h_4 = h_f + x_4 h_{fg}$$
$$= 908.47 + 0.9497(1889.8)$$
$$= 2703.321\text{kJ/kg}$$

Step 9 of 13

State 5:
From the superheated water
$P_5 = 2000$ kPa and $T_5 = 450^0$C
By using interpolation,

$$h_5 = 3248.4 + \frac{(450-400)(3468.3-3248.3)}{(500-400)}$$
$$= 3358.4\text{kJ/kg}$$

By using interpolation,

$$h_5 = 3248.4 + \frac{(450-400)(3468.3-3248.3)}{(500-400)}$$

$$= 3358.4\,\text{kJ/kg}$$

$$s_5 = 7.1292 + \frac{(450-400)(7.4337-7.1292)}{(500-400)}$$

$$= 7.281\,\text{kJ/kg}\cdot\text{K}$$

Step 10 of 13

State 6:

From the saturated water pressure table

$P_6 = 100\,\text{kPa}$ and $s_6 = s_5 = 7.281\,\text{kJ/kg}\cdot\text{K}$

$$s_6 = s_f + x_6 s_{fg}$$

$$7.281 = 1.3028 + x_6(6.0562)$$

$$x_6 = 0.9871$$

$$h_6 = h_f + x_6(h_{fg})$$

$$= 417.51 + 0.9871(2257.5)$$

$$= 2645.88\,\text{kJ/kg}$$

Step 11 of 13

Net power output is given by,

$$W_{net} = \dot{m} \times \left((h_3 - h_4) + (h_5 - h_6) - (h_2 - h_1)\right)$$

$$W_{net} = 1.74\left((3157.9 - 2703.32) + (3358.4 - 2645.88) - (432.97 - 417.51)\right)$$

$$= 2003.85\,\text{kW}$$

Step 12 of 13

Rate of heat transfer is given by,

$$Q_{in} = \dot{m} \times \left((h_3 - h_2) + (h_5 - h_4)\right)$$

$$Q_{in} = 1.74 \times \left((3157.9 - 432.97) + (3358.4 - 2703.321)\right)$$

$$= 5881.215\,\text{kJ/s}$$

$$= 5881.215\,\text{kW}$$

Step 13 of 13

Efficiency of the cycle is given by,

$$\eta_{Rankin} = \frac{W_{net}}{Q_{in}}$$

$$= \frac{2000\,\text{kW}}{5881.215\,\text{kW}}$$

Step 11 of 13

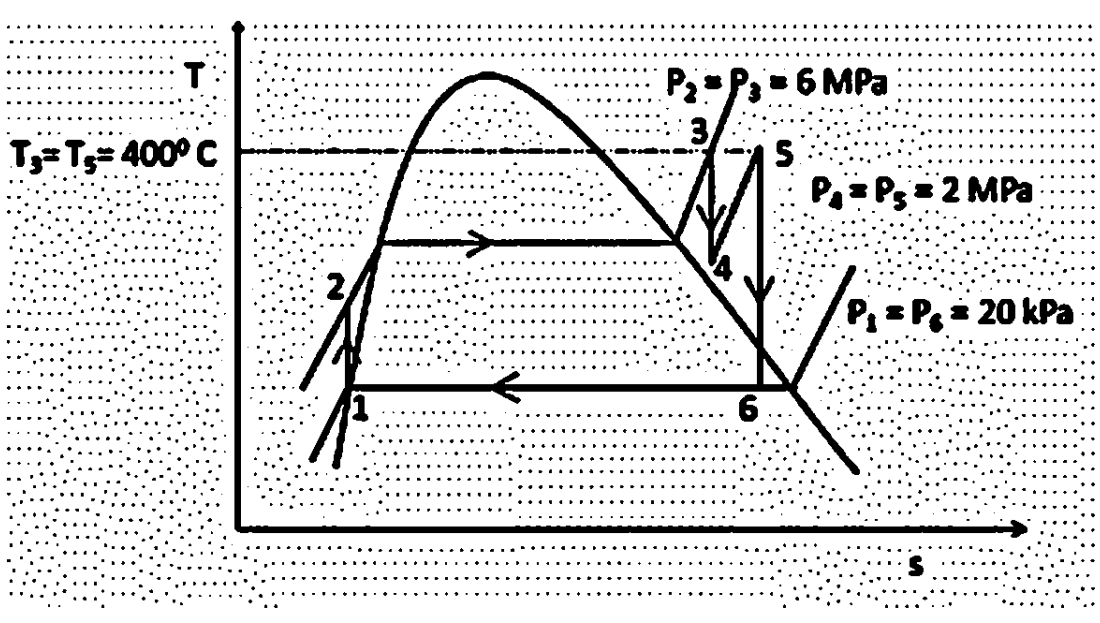
Net power output is given by,

$$W_{net} = \dot{m} \times \left((h_3 - h_4) + (h_5 - h_6) - (h_2 - h_1)\right)$$

$$W_{net} = 1.74\left((3157.9 - 2703.32) + (3358.4 - 2645.88) - (432.97 - 417.51)\right)$$

$$= 2003.85\,\text{kW}$$

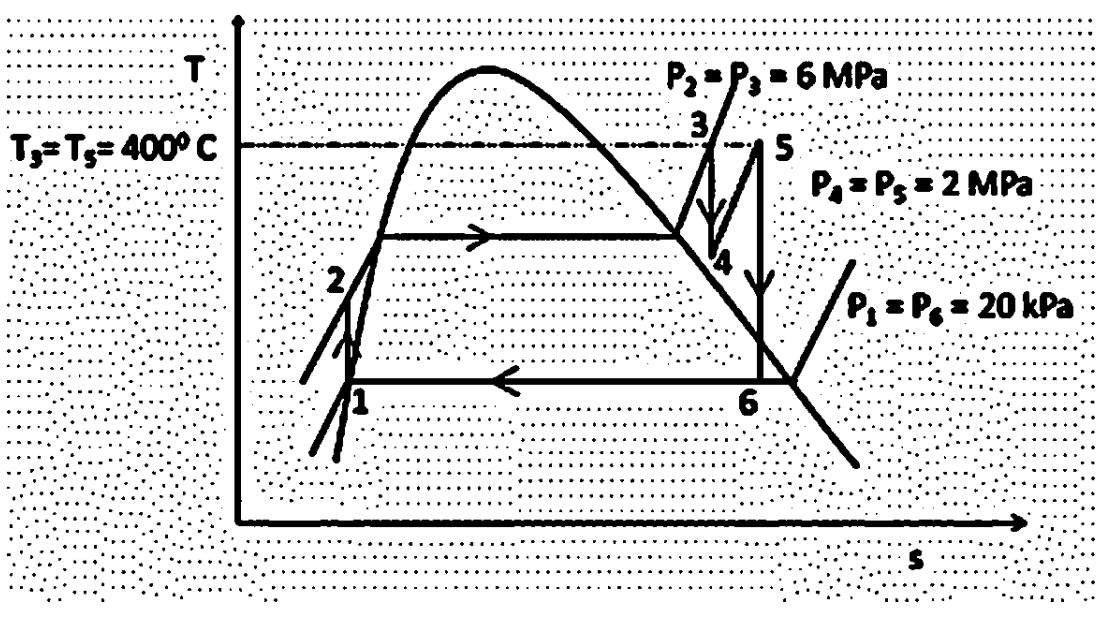
Question: 9.133P



A steam power plant operates on the ideal reheat Rankine cycle. Steam enters the high-pressure turbine at 6 MPa and 400°C and leaves at 2 MPa. Steam is then reheated at constant pressure to 400°C before it expands to 20 kPa in the low-pressure turbine. Determine the turbine work output, in kJ/kg. and the thermal efficiency of the cycle. Also, show the cycle on a *T-s* diagram with respect to saturation lines.

Step 1 of 13

Given,
Working fluid: water.
Pressure at the inlet of the high-pressure turbine $P_2 = P_3 = 6$ MPa.
Temperature at the inlet of the high-pressure turbine $T_3 = 400^0$C
Pressure at the inlet of the low-pressure turbine $P_4 = P_5 = 2$ MPa.
Temperature at the inlet of the low-pressure turbine $T_5 = 400^0$C.
Condenser Pressure $P_1 = P_6 = 20$ kPa.



Step 2 of 13

The Ideal Reheat Rankin cycle operating between the given conditions is shown below.

Step 2 of 13

The Ideal Reheat Rankin cycle operating between the given conditions is shown below.

Step 3 of 13

State 1:
From the saturated water pressure table
$P_1 = 20$ kPa And saturated liquid,
$h_1 = 251.42$ kJ/kg
$v_1 = 0.001017$ m^3/kg

Step 3 of 13

State 1:
From the saturated water pressure table
$P_1 = 20$ kPa And saturated liquid,
$h_1 = 251.42$ kJ/kg
$v_1 = 0.001017$ m^3/kg

Step 7 of 13

State 4:
From the superheated water pressure table
$P_4 = 2$ MPa and $s_4 = s_3 = 6.5432$ kJ/kg·K

$$h_4 = 2836.1 + \frac{(6.5432 - 6.4160)(2903.3 - 2836.1)}{(6.5475 - 6.4160)}$$

$h_4 = 2901.10$ kJ/kg

Step 8 of 13

State 5:
From the superheated water pressure table
$P_5 = 2$ MPa and $T_5 = 400^0$C
$h_5 = 3248.4$ kJ/kg
$s_5 = 7.1292$ kJ/kg·K

Step 9 of 13

State 6:
From the saturated water pressure table
$P_6 = 20$ kPa and $s_6 = s_5 = 7.1292$ kJ/kg·K

$$s_6 = s_f + x_6(s_{fg})$$

$$7.1292 = 0.8320 + x_6(7.0752)$$

$$x_6 = 0.8900$$

$$h_6 = h_f + x_6(h_{fg})$$

$$= 251.42 + 0.8900(2357.5)$$

$$= 2349.685 \text{ kJ/kg}$$

Step 7 of 13

State 4:
From the superheated water pressure table
$P_4 = 2$ MPa and $s_4 = s_3 = 6.5432$ kJ/kg·K

$$h_4 = 2836.1 + \frac{(6.5432 - 6.4160)(2903.3 - 2836.1)}{(6.5475 - 6.4160)}$$

$h_4 = 2901.10$ kJ/kg

Step 8 of 13

State 5:
From the superheated water pressure table
$P_5 = 2$ MPa and $T_5 = 400^0$C
$h_5 = 3248.4$ kJ/kg
$s_5 = 7.1292$ kJ/kg·K

Step 10 of 13

Turbine work output is given by,

$$W_T = (h_3 - h_4) + (h_5 - h_6)$$

$$W_T = (3178.3 - 2901.10) + (3248.7 - 2349.685)$$

$$W_T = 1176.215 \text{ kJ/kg}$$

Step 11 of 13

Net work output is given by,

$$W_{net} = W_T - W_{pump}$$

$$W_{net} = 1176.215 - 6.08$$

$$= 1170.135 \text{ kJ/kg}$$

Question: 9.134DIAGR-CH

Reconsider Prob. 9–133. Using EES (or other) software, solve this problem by the diagram window data entry feature of EES. Include the effects of the turbine and pump efficiencies and also show the effects of reheat on the steam quality at the low-pressure turbine exit. Plot the cycle on a *T-s* diagram with respect to the saturation lines. Discuss the results of your parametric studies.

Ask an expert

Question:

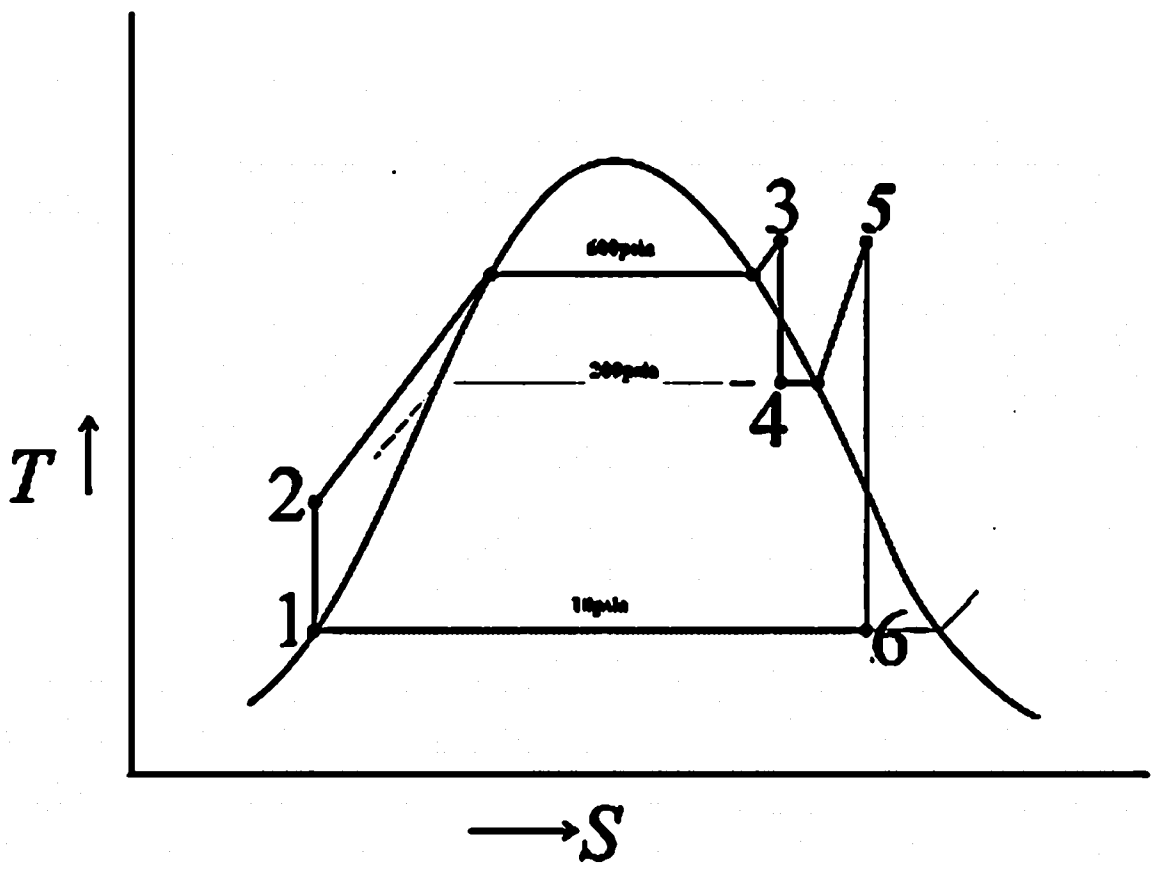
Consider a steam power plant that operates on the ideal reheat Rankine cycle. The plant maintains the inlet of the high-pressure turbine at 600 psia and 600°F, the inlet of the low-pressure turbine at 200 psia and 600°F, and the condenser at 10 psia. The net power produced by this plant is 5000 kW. Determine the rate of heat addition and rejection and the thermal efficiency of the cycle.

Step 1 of 18

Given:

Inlet pressure of high pressure turbine $P_3 = 600\,\text{psia}$

Inlet temperature of high pressure turbine $T_1 = 600^0\,\text{F}$



Inlet pressure of low pressure turbine $P_5 = 200\,\text{psia}$

Inlet temperature of low pressure turbine $T_5 = 600^0\,\text{F}$

Condenser pressure $P_6 = P_1 = 10\,\text{psia}$

Net power produced $W_{net} = 5000\,\text{kW}$

Step 2 of 18

Step 3 of 18

At $P_1 = 10\,\text{psia}$ from saturated water tables

$h_1 = h_f = 161.25\,\text{Btu/lbm}$

$v_1 = v_{f,10psia} = 0.01659\,\text{ft}^3/\text{lbm}$

Step 4 of 18

Pump work

$$w_{pump} = -v_1(P_2 - P_1) \qquad (\because P_2 = P_3)$$

$$w_{pump} = -0.01659\,\frac{\text{ft}^3}{\text{lbm}} \times (600-10)\frac{\text{lbf}}{\text{in}^2} \times 144\frac{\text{in}^2}{\text{ft}^2} \times \frac{1}{778}\frac{\text{Btu}}{\text{ft-lbf}}$$

$$w_{pump} = -1.81\,\text{Btu/lbm}$$

Step 5 of 18

Applying first law to the process 1-2

$h_1 = h_2 + w_{pump}$

$h_2 = h_1 - w_{pump}$

$h_2 = 161.25 + 1.81$

$h_2 = 163.1\,\text{Btu/lbm}$

Step 6 of 18

At $P_3 = 600\,\text{psia}$ and $T_3 = 600^0\,\text{F}$ from superheated water tables

$h_3 = 1289.9\,\text{Btu/lbm}$

$s_3 = 1.5325\,\text{Btu/lbm.R}$

Step 7 of 18

Process 3-4 is isentropic process

$s_4 = s_3$

At $P_4 = 200\,\text{psia}$ from saturated water tables

$s_4 = s_{f@200psia} + x_4 s_{fg@200psia}$

$1.5325 = 0.54379 + x_4 \times 1.00219$

$x_4 = 0.986$

Step 8 of 18

Enthalpy at state-4,

$h_4 = h_{f@200psia} + x_4 h_{fg@200psia}$

$h_4 = 355.46 + 0.986 \times 843.33$

$h_4 = 1186.98\,\text{Btu/lbm}$

Step 9 of 18

At state-5:

From superheated water tables at $P_5 = 200\,\text{psia}$ and $T_5 = 600^0\,\text{F}$

$h_5 = 1322.3\,\text{Btu/lbm}$

$s_5 = 1.6771\,\text{Btu/lbm.R}$

Step 10 of 18

Process 5-6 is isentropic expansion

$s_5 = s_6$

$s_5 = s_{f@10psia} + x_6 s_{fg@10psia}$

$1.6771 = 0.28362 = x_6 \times 1.50391$

$x_6 = 0.927$

Step 11 of 18

$1.6771 = 0.28362 = x_6 \times 1.50391$

$x_6 = 0.927$

Step 11 of 18

Enthalpy at state-6

$h_6 = h_{f@10\,psia} + x_6 h_{fg@psia}$

$h_6 = 161.25 + 0.927 \times 981.82$

$h_6 = 1071.39$ kJ/kg

Step 12 of 18

The heat input is

$q_{in} = (h_3 - h_2) + (h_5 - h_4)$

$q_{in} = (1289.9 - 163.1) + (1322.3 - 1186.98)$

$q_{in} = 1262.12$ Btu/lbm

Step 13 of 18

The heat rejected in the condenser is

$q_{out} = (h_6 - h_1)$

$q_{out} = (1071.39 - 161.25)$

$q_{out} = 910.14$ Btu/lbm

Step 14 of 18

Net power output

$w_{net} = q_{in} - q_{out}$

$w_{net} = 1262.12 - 910.14$

$w_{net} = 351.98$ Btu/lbm

Step 15 of 18

Mass flow rate

$$m_{steam} = \frac{W_{net}}{w_{net}}$$

$$m_{steam} = \frac{5000 \text{ kJ/s}}{351.98 \text{ Btu/lbm}} \times \frac{0.9478 \text{ Btu}}{1 \text{ kJ}}$$

$m_{steam} = 13.46$ lbm/s

Step 16 of 18

Rate of heat addition is

$Q_{in} = m_{steam} \times q_{in}$

$Q_{in} = 13.46 \times 1262.12$

$\boxed{Q_{in} = 16988.135 \text{Btu/s}}$

Step 17 of 18

Rate of heat rejection is

$Q_{out} = m_{steam} \times q_{out}$

$Q_{out} = 13.46 \times 910.14$

$\boxed{Q_{out} = 12250.48 \text{ Btu/s}}$

Step 18 of 18

Thermal efficiency of the cycle,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$\eta_{th} = \frac{351.98}{1262.12}$$

$\boxed{\eta_{th} = 27.88\%}$

Question: 9.136P pg 1

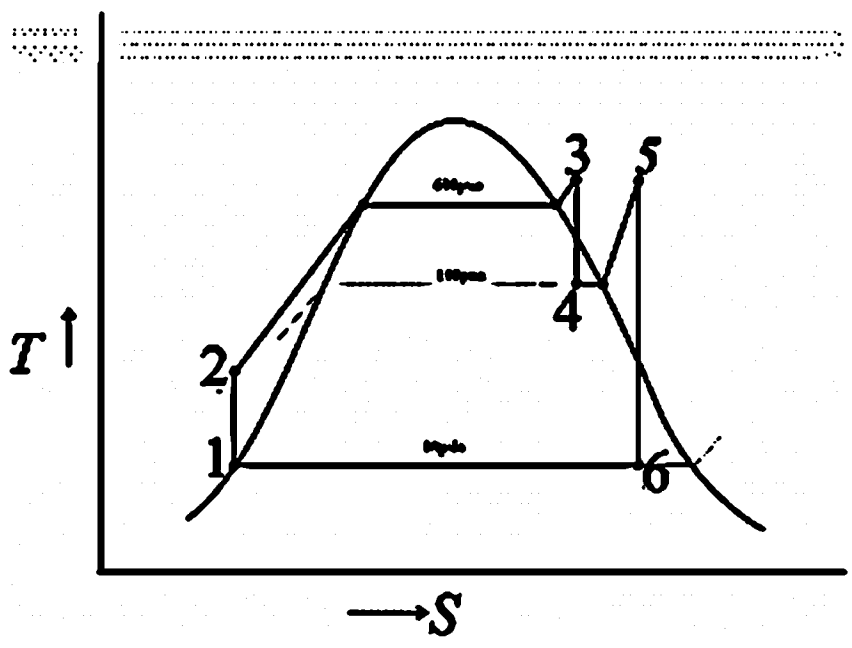
In Prob, 9-135E, is there any advantage to operating the reheat section of the boiler at 100 psia rather than 200 psia while maintaining the same low-pressure turbine inlet temperature?

Step 1 of 26

Given:

Inlet pressure of high pressure turbine $P_3 = 600\,\text{psia}$

Inlet temperature of high pressure turbine $T_1 = 600^0\,\text{F}$



Inlet pressure of low pressure turbine $P_5 = 100\,\text{psia}$

Inlet temperature of low pressure turbine $T_5 = 600^0\,\text{F}$

Condenser pressure $P_6 = P_1 = 10\,\text{psia}$

Net power produced $W_{net} = 5000\,\text{kW}$

Step 2 of 26

Step 3 of 26

At $P_1 = 10\,\text{psia}$ from saturated water tables

$h_1 = h_f = 161.25\,\text{Btu/lbm}$

$v_1 = v_{f,10psia} = 0.01659\,\text{ft}^3/\text{lbm}$

Step 4 of 26

Pump work

$$w_{pump} = -v_1(P_2 - P_1) \qquad (\because P_2 = P_3)$$

$$w_{pump} = -0.01659\ \frac{\text{ft}^3}{\text{lbm}} \times (600-10)\frac{\text{lbf}}{\text{in}^2} \times 144\frac{\text{in}^2}{\text{ft}^2} \times \frac{1}{778}\frac{\text{Btu}}{\text{ft-lbf}}$$

$$w_{pump} = -1.81\,\text{Btu/lbm}$$

Step 5 of 26

Applying first law to the process 1-2

$h_1 = h_2 + w_{pump}$

$h_2 = h_1 - w_{pump}$

$h_2 = 161.25 + 1.81$

$h_2 = 163.1\,\text{Btu/lbm}$

Step 6 of 26

At $P_3 = 600\,\text{psia}$ and $T_3 = 600^0\,\text{F}$ from superheated water tables

$h_3 = 1289.9\,\text{Btu/lbm}$

$s_3 = 1.5325\,\text{Btu/lbm.R}$

Step 7 of 26

Process 3-4 is isentropic process

$s_4 = s_3$

From steam tables at $P_4 = 100\,\text{psia}$ and $s_4 = s_3 = 1.5325\,\text{Btu/lbm.R}$

$s_3 = s_{f@100psia} + x_4 s_{fg@100psia}$

$1.5325 = 0.47427 + x_4 \times 1.12888$

$x_4 = 0.937$

Step 8 of 26

Enthalpy at state-4

$h_4 = h_{f@100psia} + x_4 h_{fg@100psia}$

$h_4 = 298.51 + 0.937 \times 888.9$

$h_4 = 1131.409\,\text{Btu/lbm}$

Step 9 of 26

At state-5:

From steam tables at $P_5 = 100\,\text{psia}$ and $T_5 = 600^0\,\text{F}$

Enthalpy at state-5, $h_5 = 1329.4\,\text{Btu/lbm}$

Entropy at state-5, $s_5 = 1.7586\,\text{Btu/lbm.R}$

Step 10 of 26

Process 5-6 is isentropic expansion

$s_5 = s_6$

$s_5 = s_{f@10psia} + x_6 s_{fg@10psia}$

$1.7586 = 0.28362 + x_6 \times 1.50391$

$x_6 = 0.9807$

Step 11 of 26

Enthalpy at state-6,

$h_6 = h_{f@10psia} + x_6 h_{fg@10psia}$

$h_6 = 161.25 + 0.9807 \times 981.82$

$h_6 = 1124.12\,\text{kJ/kg}$

Enthalpy at state-6,

$h_6 = h_{f@10psia} + x_6 h_{fg@10psia}$

$h_6 = 161.25 + 0.9807 \times 981.82$

$h_6 = 1124.12$ kJ/kg

Step 12 of 26

The heat input is

$q_{in} = (h_3 - h_2) + (h_5 - h_4)$

$q_{in} = (1289.9 - 163.1) + (1329.4 - 1131.409)$

$q_{in} = 1324.791$ Btu/lbm

Step 13 of 26

The heat rejected in the condenser is

$q_{out} = (h_6 - h_1)$

$q_{out} = (1124.12 - 161.25)$

$q_{out} = 962.87$ Btu/lbm

Step 14 of 26

Net power output

$w_{net} = q_{in} - q_{out}$

$w_{net} = 1324.791 - 962.87$

$w_{net} = 361.921$ Btu/lbm

Step 15 of 26

Mass flow rate

$$m_{steam} = \frac{W_{net}}{w_{net}}$$

$$m_{steam} = \frac{5000 \text{ kJ/s}}{361.921 \text{ Btu/lbm}} \times \frac{0.9478 \text{ Btu}}{1 \text{ kJ}}$$

$m_{steam} = 13.094$ lbm/s

Step 16 of 26

Rate of heat addition is

$Q_{in} = m_{steam} \times q_{in}$

$Q_{in} = 13.094 \times 1324.791$

$\boxed{Q_{in} = 17346.813 \text{ Btu/s}}$

Step 17 of 26

Rate of heat rejection is

$Q_{out} = m_{steam} \times q_{out}$

$Q_{out} = 13.094 \times 962.87$

$\boxed{Q_{out} = 12607.819 \text{ Btu/s}}$

Step 18 of 26

Thermal efficiency of the cycle,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$\eta_{th} = \frac{361.921}{1324.791}$$

$= 0.2731$

$\boxed{\eta_{th} = 27.31\%}$

Step 19 of 26

If the reheat pressure is 200psia

Process 3-4 is isentropic process

$s_4 = s_3$

At $P_4 = 200$ psia from saturated water tables

$s_4 = s_{f@200psia} + x_4 s_{fg@200psia}$

$1.5325 = 0.54379 + x_4 \times 1.00219$

$x_4 = 0.986$

Step 20 of 26

Enthalpy at state-4,

$h_4 = h_{f@200psia} + x_4 h_{fg@200psia}$

$h_4 = 355.46 + 0.986 \times 843.33$

$h_4 = 1186.98$ Btu/lbm

Step 21 of 26

At state-5:

From superheated water tables at $P_5 = 200$ psia and $T_5 = 600^0$F

$h_5 = 1322.3$ Btu/lbm

$s_5 = 1.6771$ Btu/lbm.R

Step 22 of 26

Process 5-6 is isentropic expansion

$s_5 = s_6$

$s_5 = s_{f@10psia} + x_6 s_{fg@10psia}$

$1.6771 = 0.28362 = x_6 \times 1.50391$

$x_6 = 0.927$

Enthalpy at state-6

$h_6 = h_{f@10psia} + x_6 h_{fg@psia}$

$h_6 = 161.25 + 0.927 \times 981.82$

$h_6 = 1071.39$ kJ/kg

$h_6 = h_{f@10\,psia} + x_6 h_{fg@psia}$

$h_6 = 161.25 + 0.927 \times 981.82$

$h_6 = 1071.39$ kJ/kg

Step 23 of 26

The heat input is

$q_{in} = (h_3 - h_2) + (h_5 - h_4)$

$q_{in} = (1289.9 - 163.1) + (1322.3 - 1186.98)$

$q_{in} = 1262.12$ Btu/lbm

Step 24 of 26

The heat rejected in the condenser is

$q_{out} = (h_6 - h_1)$

$q_{out} = (1071.39 - 161.25)$

$q_{out} = 910.14$ Btu/lbm

Step 25 of 26

Net power output

$w_{net} = q_{in} - q_{out}$

$w_{net} = 1262.12 - 910.14$

$w_{net} = 351.98$ Btu/lbm

Step 26 of 26

Thermal efficiency of the cycle,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

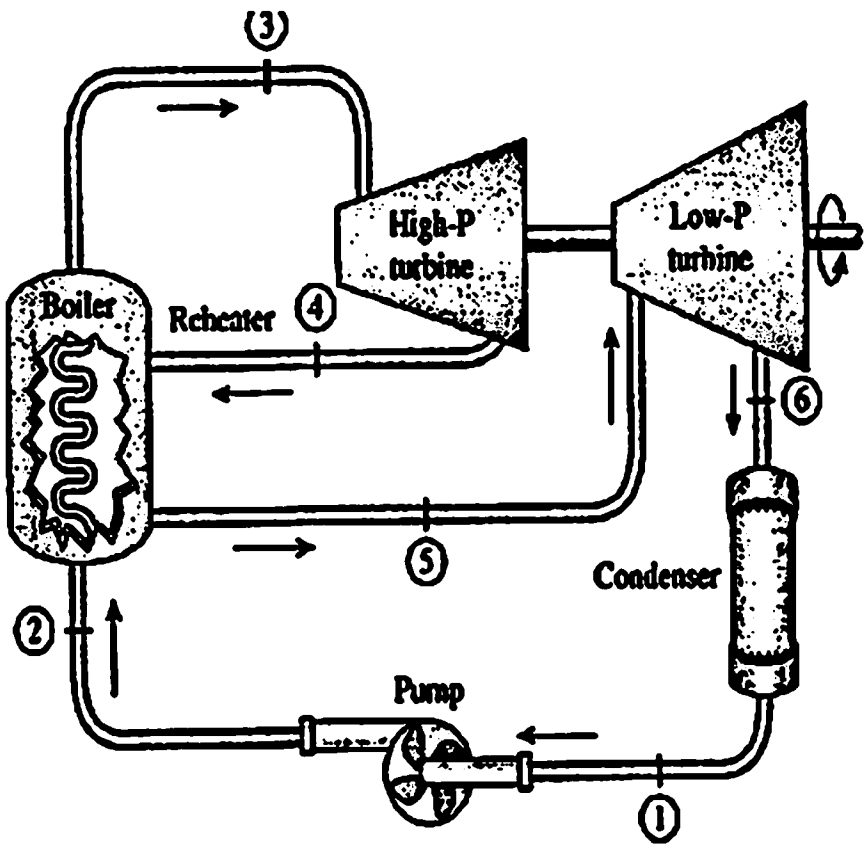
$$\eta_{th} = \frac{351.98}{1262.12}$$

$$\boxed{\eta_{th} = 27.88\%}$$

Therefore there is a slight decrease in thermal efficiency if the pressure is decreased from 200psia to 100psia

Question: 9.137P pg 1

Consider a steam power plant that operates on the ideal reheat Rankine cycle. The plant maintains the boiler at 7000 kPa, the reheat section at 800 kPa, and the condenser at 10 kPa. The mixture quality at the exit of both turbines is 93 percent. Determine the temperature at the inlet of each turbine and the cycle's thermal efficiency. Answers:373°C, 416°C, 37.6 percent



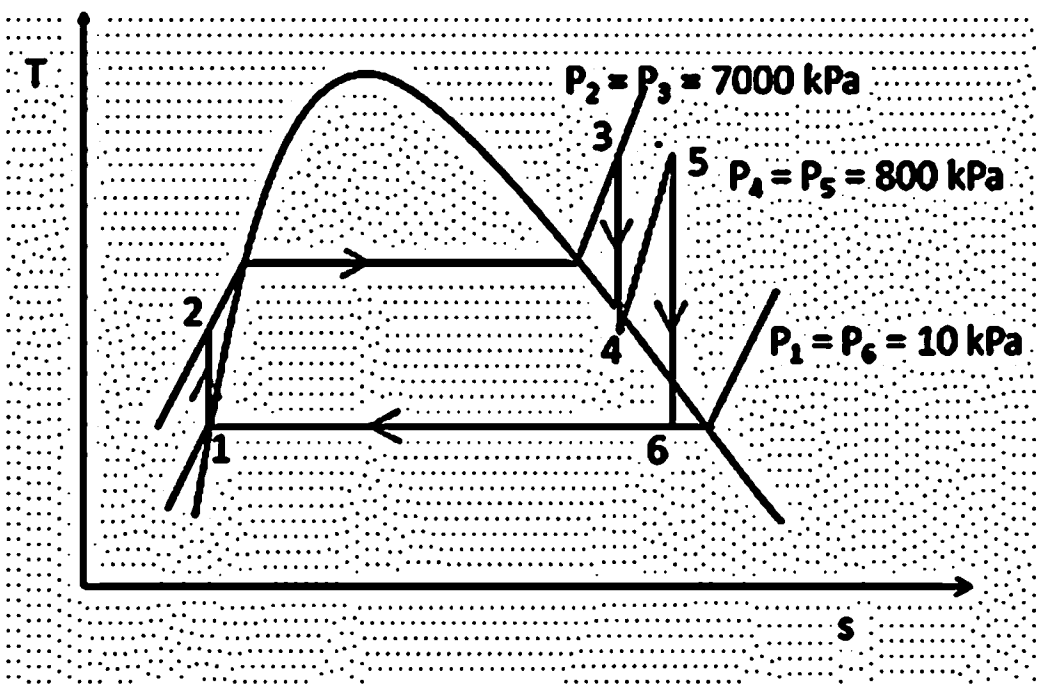


FIGURE P9–137

Step 1 of 13

Given,
Working fluid: water.
Pressure at the inlet of the high-pressure turbine $P_2 = P_3 = 7000$ kPa.
Pressure at the inlet of the low-pressure turbine $P_4 = P_5 = 800$ kPa.
Condenser Pressure $P_1 = P_6 = 10$ kPa.
The mixture quality at the exit of both the turbines is $x_r = 93\%$.

Step 2 of 13

The Ideal Reheat Rankin cycle operating between the given conditions is shown below.

Step 3 of 13

State1:
From the saturated water
$P_1 = 10$ kPa And saturated liquid,
$h_1 = h_f = 191.81$ kJ/kg
$v_1 = v_f = 0.001010\ m^3/kg$

Step 4 of 13

State 2:
$P_2 = 7000$ kPa
The work done in the compression process is given by,
$w_{pump} = v_1 \times (P_2 - P_1)$
$w_{pump} = 0.001010 m^3/kg \times (7000\ kPa - 10\ kPa) \times (1kJ/1\ kPa\ m^3)$
$w_{pump} = 7.06$ kJ/kg

Step 5 of 13

Enthalpy at state 2 is
$h_2 = h_1 + w_{pump}$
$= 191.81 + 7.06$
$= 198.87$ kJ/kg

Step 6 of 13

State 6:
$P_6 = P_1 = 10$ kPa and quality of steam after expension through turbine is 0.93
At these conditions,
$h_6 = h_f + x_6 h_{fg}$
$= 191.81 + 0.93(2392.1)$
$= 2416.463 kJ/kg$
And entropy is
$s_6 = s_f + x_6(s_{fg})$
$= 0.6492 + 0.93(7.4996)$
$= 7.623 kJ/kg \cdot K$

Step 7 of 13

State 5:
Since process 5-6 isentropic process.
From the superheated water
$P_5 = 800$ kPa and $s_5 = s_6 = = 7.623 kJ/kg \cdot K$
$$h_5 = 3267.7 + \frac{(7.623 - 7.5735)(3267.7 - 3162.2)}{(7.8692 - 7.5735)}$$
$= 3285.360 kJ/kg$

$P_5 = 800\,\text{kPa}$ and $s_5 = s_6 = = 7.629\,\text{kJ/kg}\,\text{K}$ P pg 2

$$h_5 = 3267.7 + \frac{(7.623 - 7.5735)(3267.7 - 3162.2)}{(7.8692 - 7.5735)}$$

$$= 3285.360\,\text{kJ/kg}$$

$$T_5 = 400 + \frac{(7.623 - 7.5735)(3267.7 - 3162.2)}{(7.8692 - 7.5735)}$$

$$= 417.66^\circ\text{C}$$

Temperature at the inlet of low pressure turbine inlet $\boxed{T_5 = 417.66^\circ\text{C}}$

Step 8 of 13

State 4:

$P_4 = 800\,\text{kPa}$ and and quality of steam after expension through turbine is 0.93 at these conditions,

From the saturated water pressure table

At $P_4 = 800\,\text{kPa}$

$$h_4 = h_f + x_4(h_{fg})$$

$$= 720.87 + 0.93(2047.5)$$

$$= 2625.0\,\text{kJ/kg}$$

And entropy is

$$s_4 = s_f + x_4(s_{fg})$$

$$= 2.0457 + 0.93(4.6160)$$

$$= 6.3385\,\text{kJ/kg}\cdot\text{K}$$

Step 9 of 13

State 3:

From the superheated water

$P_3 = 7000\,\text{kPa}$ and $s_3 = s_4 = 6.338\,\text{kJ/kg}\cdot\text{K}$

$$h_5 = 3016.9 + \frac{(6.3385 - 6.2305)(3159.2 - 3016.9)}{(6.4502 - 6.2305)}$$

$$= 3086.851\,\text{kJ/kg}$$

$$T_3 = 350 + \frac{(6.3385 - 6.2305)(400 - 350)}{(6.4502 - 6.2305)}$$

$$= 374.578^\circ\text{C}$$

Temperature at the inlet of high pressure turbine inlet $\boxed{T_5 = 374.578^0\text{C}}$

Step 10 of 13

Turbine work output is given by,

$$W_T = (h_3 - h_4) + (h_5 - h_6)$$

$$W_T = (3086.851 - 2625) + (3285.360 - 2416.463\ )$$

$$= 1330.748\,\text{kJ/kg}$$

Step 11 of 13

Net work output is given by,

$$W_{net} = W_T - W_{pump}$$

$$W_{net} = 1330.748\ - 7.06$$

$$= 1323.288\,\text{kJ/kg}$$

Step 12 of 13

Heat supplied is given by,

$$Q_{in} = (h_3 - h_2) + (h_5 - h_4)$$

$$= (3086.851 - 198.87) + (3285.360 - 2625)$$

$$= 3548.341\,\text{kJ/kg}$$

Step 13 of 13

Efficiency of the cycle is given by,

$$\eta_{Rankin} = \frac{W_{net}}{Q_{in}} = \frac{1323.288}{3548.341}$$

$$= 0.377$$

$\boxed{\eta_{Rankin} = 0.377}$

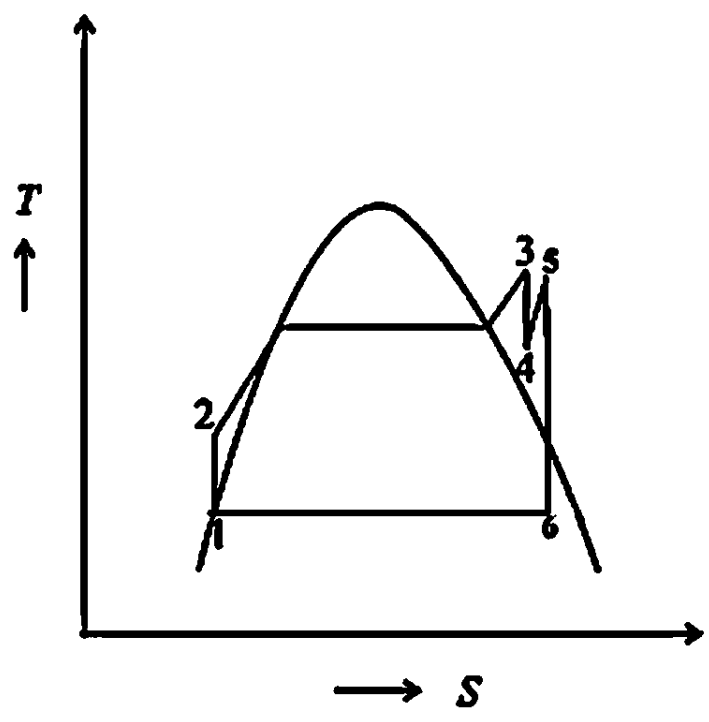
Question: 9.138P

A steam power plant operates on an ideal reheat Rankine cycle between the pressure limits of 15 MPa and 10 kPa. The mass flow rate of steam through the cycle is 12 kg/s. Steam enters both stages of the turbine at 500°C. If the moisture content of the steam at the exit of the low-pressure turbine is not to exceed 10 percent, determine *(a)* the pressure at which reheating takes place, *(b)* the total rate of heat input in the boiler, and (c) the thermal efficiency of the cycle. Also, show the cycle on a *T-s* diagram with respect to saturation lines.

Step 1 of 13

Given:

Pressure in the boiler $P_3 = P_2 = 15\text{MPa}$



Condenser pressure $P_6 = P_1 = 10\text{kPa}$

Mass flow rate of steam $\dot{m} = 12\text{kg/s}$

Steam enters both stages of the turbine at temperature $T_3 = T_5 = 500^0\text{C}$

Dryness fraction at the exit of the low pressure turbine is $x_6 = 90\%$

Step 2 of 13

Step 3 of 13

At $P_6 = P_1 = 10\text{kPa}$ from saturated water tables

$h_1 = h_f = 191.81\text{ kJ/kg}$

$v_1 = v_f = 0.00101\text{ m}^3\text{/kg}$

Pump work

$w_{pump} = -v_1(P_2 - P_1)$

$w_{pump} = -0.00101 \times (15000 - 10)$

$w_{pump} = -15.14\text{ kJ/kg}$

Step 4 of 13

By applying first law to the process 1-2

$h_1 = h_2 + w_{pump}$

$h_2 = h_1 - w_{pump}$

$h_2 = 191.81 + 15.14$

$h_2 = 206.95\text{ kJ/kg}$

Step 5 of 13

At $P_3 = 15000\text{ kPa}$ and $T_3 = 500^0\text{C}$ from superheated water tables

$h_3 = 3310.8\text{ kJ/kg}$

$s_3 = 6.348\text{ kJ/kg.K}$

Step 6 of 13

Process 5-6 is isentropic expansion

$s_6 = s_5$

At $P_6 = 10\text{ kPa}$ from saturated water tables

$s_6 = s_{f@10kPa} + x_6 s_{fg@10kPa}$

$s_6 = 0.6492 + 0.9 \times 7.4996$

$s_6 = 7.3988\text{ kJ/kg.K}$

Enthalpy at state-6

$h_6 = h_f + x_6 h_{fg}$

$h_6 = 191.81 + 0.9 \times 2392.1$

$h_6 = 2344.7\text{ kJ/kg}$

Step 7 of 13

(a)

Process 5-6 is isentropic expansion

$s_5 = s_6$

At $T_5 = 500^0\text{C}$ and $s_5 = s_6 = 7.3988\text{kJ/kg.K}$ from superheated tables

$$P_5 = 2000 + (2500 - 2000)\left(\frac{7.3988 - 7.4337}{7.3254 - 7.4337}\right)$$

Pressure at state-5

$\boxed{P_5 = 2161.126\text{ kPa}}$

Step 8 of 13

Enthalpy at state-5

$$h_5 = 3468.3 + (3462.8 - 3468.3)\left(\frac{7.3988 - 7.4337}{7.3254 - 7.4337}\right)$$

$h_5 = 3466.527\text{ kJ/kg}$

Step 9 of 13

At $P_4 = P_5 = 2161.126\text{ kPa}$ and $s_4 = s_3 = 6.348\text{kJ/kg.K}$ by using EES software

Enthalpy at state-4

$h_4 = 2818.5\text{ kJ/kg}$

Step 10 of 13

Net work output from the turbine is

$w_{net} = (h_3 - h_4) + (h_5 - h_6)$

$w_{net} = (3310.8 - 2818.5) + (3466.527 - 2344.7)$

$w_{net} = 1614.127\text{ kJ/kg}$

Step 11 of 13

The heat input is

$q_{in} = (h_3 - h_2) + (h_5 - h_4)$

$q_{in} = (3310.8 - 206.95) + (3466.527 - 2818.5)$

$q_{in} = 3751.87\text{ kJ/kg}$

Step 12 of 13

The total rate of heat input in the boiler is

$Q_{in} = m_{steam} \times q_{in}$

$Q_{in} = 12 \times 3751.87$

$\boxed{Q_{in} = 45022.44\text{kW}}$

Step 13 of 13

(c)

Thermal efficiency of the cycle,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

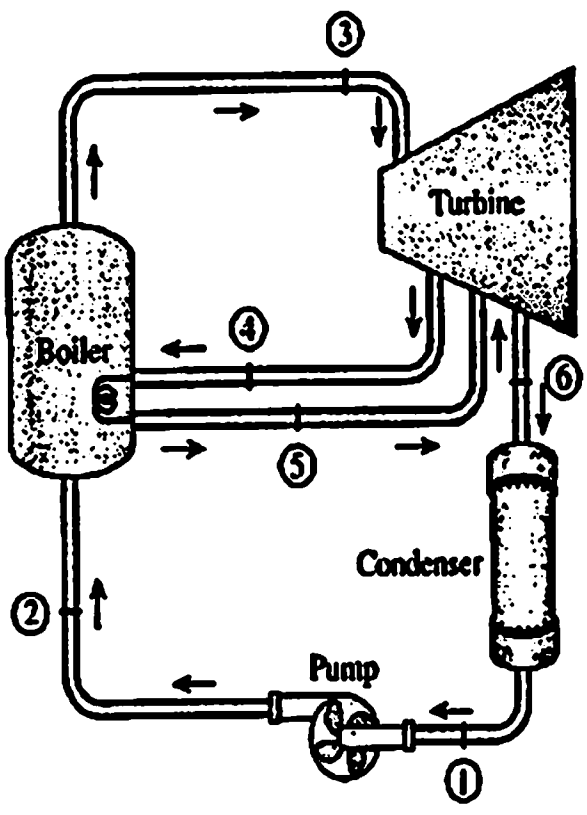
$$\eta_{th} = \frac{1614.127}{3751.87}$$

$$= 0.4302$$

$\boxed{\eta_{th} = 43.02\%}$

Question: 9.139P pg 1

A steam power plant operates on the reheat Rankine cycle. Steam enters the high-pressure turbine at 12.5 MPa and 550°C at a rate of 7.7 kg/s and leaves at 2 MPa. Steam is then reheated at constant pressure to 450°C before it expands in the low-pressure turbine. The isentropic efficiencies of the turbine and the pump are 85 percent and 90 percent, respectively. Steam leaves the condenser as a saturated liquid. If the moisture content of the steam at the exit of the turbine is not to exceed 5 percent, determine (a) the condenser pressure, *(b)* the net power output, and *(c)* the thennal efficiency



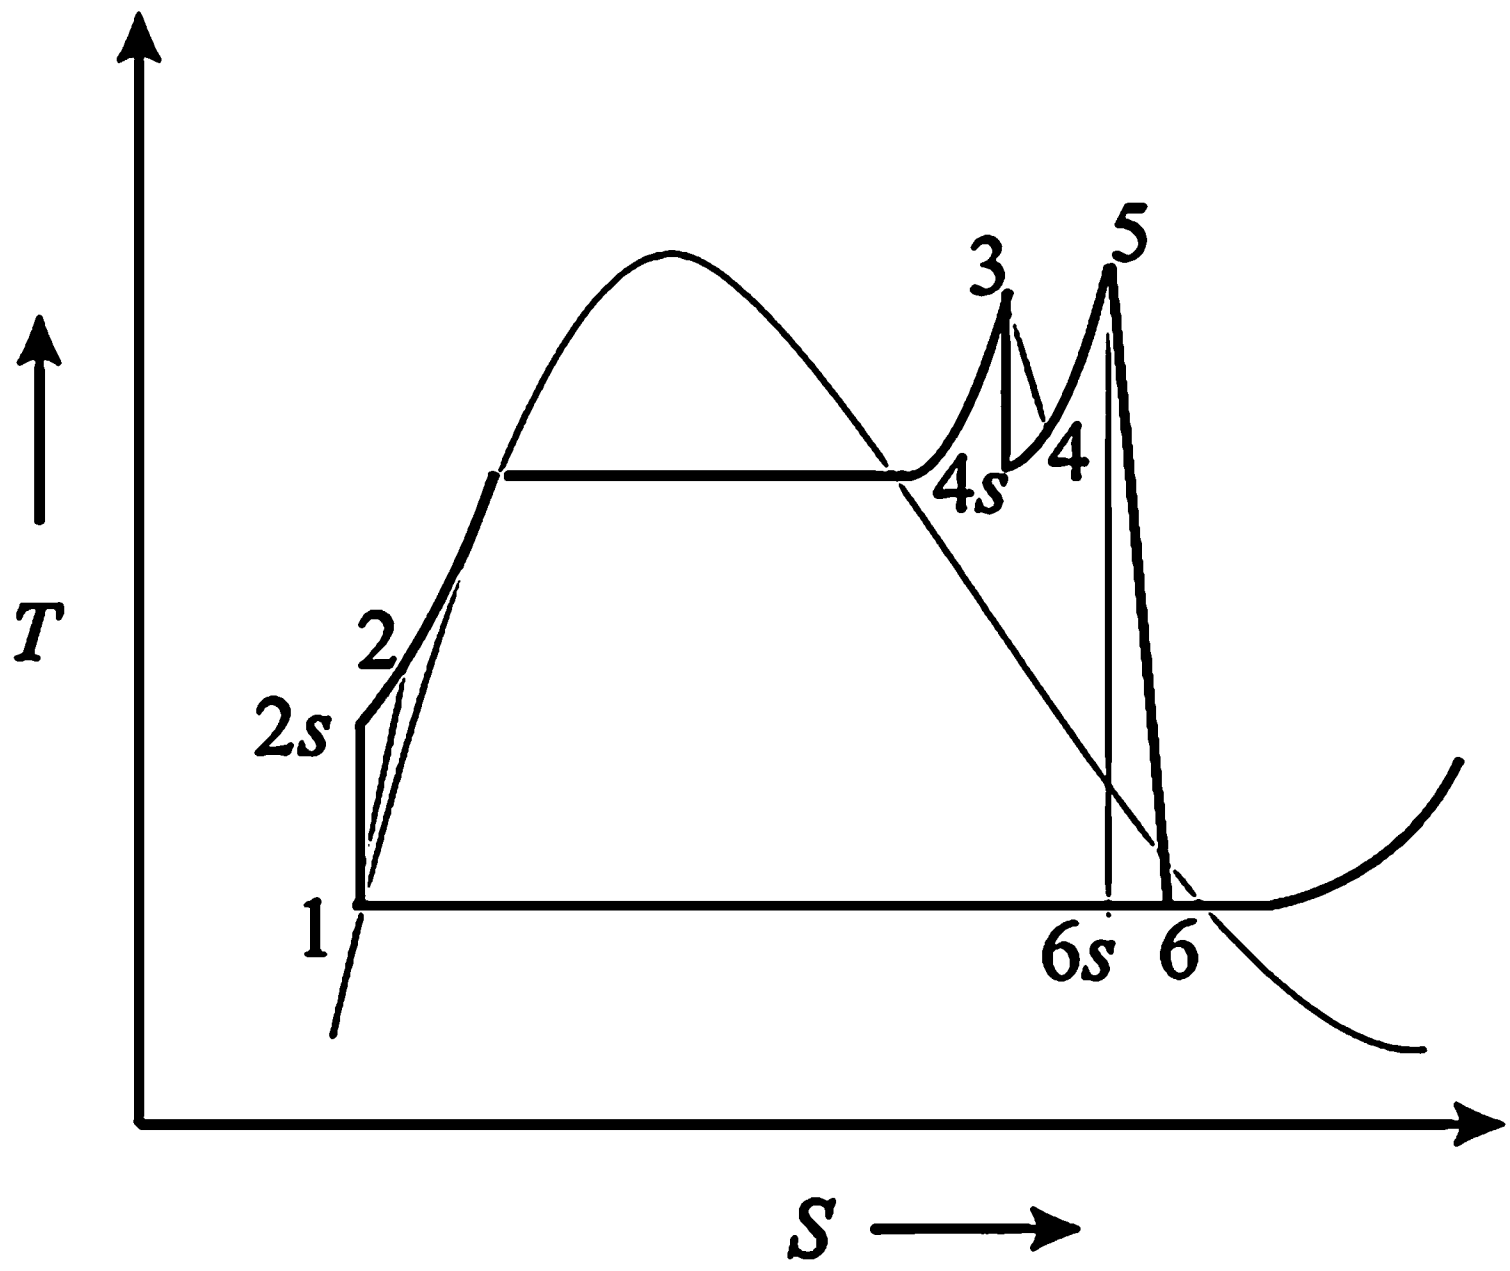


FIGURE P9–139

Step 1 of 12

Draw the *T-s* Diagram of the thermodynamic cycle is as follows:

Step 2 of 12

Obtain the properties of super-heated water vapor at $P_3 = 12.5\,\text{MPa}$ and $T_3 = 550\,^\circ\text{C}$ from Table A-6, "Properties of superheated vapor", from the text book.

Specific enthalpy, $h_3 = 3476.5\ \text{kJ/kg}$

Specific entropy, $s_3 = 6.6317\ \text{kJ/kg.K}$

Since the process 3-4*s* is isentropic process, entropies remains constant.

$$s_{4s} = s_3$$
$$= 6.6317\ \text{kJ/kg.K}$$

Obtain the properties of super-heated water vapor at $P_4 = 2\,\text{MPa}$ and $s_{4s} = 6.6317\ \text{kJ/kg.K}$ from Table A-6, "Properties of superheated vapor", from the text book by using interpolation between 250°C and 300°C.

$$\frac{h_{4s} - 2903.3}{3024.2 - 2903.3} = \frac{6.6317 - 6.5475}{6.7684 - 6.5475}$$
$$h_{4s} = 2949.38\ \text{kJ/kg}$$

Step 3 of 12

Calculate the actual enthalpy at state 4 by using following relation:

$$\eta_t = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

Substitute $3476.5\ \text{kJ/kg}$ for h_3, $2949.38\ \text{kJ/kg}$ for h_{4s}, and 0.85 for η_t.

$$0.85 = \frac{3476.5 - h_4}{3476.5 - 2949.38}$$
$$h_4 = 3028.44\ \text{kJ/kg}$$

Obtain the properties of super-heated water vapor at $P_5 = 2\,\text{MPa}$ and $T_5 = 450\,^\circ\text{C}$ from Table A-6, "Properties of superheated vapor", from the text book by using interpolation between 400°C and 500°C.

Specific enthalpy:

$$\frac{h_5 - 3248.4}{3468.3 - 3248.4} = \frac{450 - 400}{500 - 400}$$
$$h_5 = 3358.35\ \text{kJ/kg}$$

Specific entropy:

$$\frac{s_5 - 7.1292}{7.4337 - 7.1292} = \frac{450 - 400}{500 - 400}$$
$$s_5 = 7.28145\ \text{kJ/kg}$$

$$\frac{s_5 - 7.1292}{7.4337 - 7.1292} = \frac{450 - 400}{500 - 400}$$
$$s_5 = 7.28145 \text{ kJ/kg}$$

Step 4 of 12

(a)

Assume the pressure at condenser is 9 kPa and condition of the steam is 0.95.

Since the process 3-4*s* is isentropic process, entropies remains constant.

$$s_{6s} = s_5$$
$$= 7.2814 \text{ kJ/kg.K}$$

Obtain the isentropic enthalpy at exit of the second turbine at 9 kPa and $s_{6s} = 7.2814 \text{ kJ/kg.K}$ from the EES.

Specific enthalpy, $h_{6s} = 2293.4 \text{ kJ/kg}$

Obtain the properties of saturated water at 9 kPa from Table A-5, "Properties of saturated water", from the text book.

Specific enthalpy of saturated liquid, $h_f = 183.2 \text{ kJ/kg}$

Specific enthalpy of vaporization, $h_{fg} = 2396.9 \text{ kJ/kg}$

Step 5 of 12

Calculate the value of actual enthalpy at exit of the second turbine.

$$h_6 = h_{f6} + x_6 h_{fg6}$$

Substitute 183.2 kJ/kg for h_{f6}, 0.95 for x_6 and 2396.9 kJ/kg for h_{fg6}

$$h_6 = 183.2 + (0.95 \times 2396.9)$$
$$= 2460.255 \text{ kJ/kg}$$

Write the relation for isentropic efficiency of the turbine.

$$\eta_t = \frac{h_5 - h_6}{h_5 - h_{6s}}$$

Substitute 3358.35 kJ/kg for h_5, 2293.4 kJ/kg for h_{6s}, and 2460.255 kJ/kg for h_6.

$$\eta_t = \frac{3358.35 - 2460.255}{3358.35 - 2293.4}$$
$$= 0.843$$
$$\neq 0.85$$

Step 6 of 12

Assume the pressure at condenser is 10 kPa and condition of the steam is 0.95.

Since the process 3-4*s* is isentropic process, entropies remains constant.

$$s_{6s} = s_5$$
$$= 7.2814 \text{ kJ/kg.K}$$

Obtain the isentropic enthalpy at exit of the second turbine at 10 kPa and $s_{6s} = 7.2814 \text{ kJ/kg.K}$ from the EES.

Specific enthalpy, $h_{6s} = 2307 \text{ kJ/kg}$

Obtain the properties of saturated water at 10 kPa from Table A-5, "Properties of saturated water", from the text book.

Specific enthalpy of saturated liquid, $h_f = 191.81 \text{ kJ/kg}$

Specific enthalpy of vaporization, $h_{fg} = 2392.1 \text{ kJ/kg}$

Step 7 of 12

Calculate the value of actual enthalpy at exit of the second turbine.

$$h_6 = h_{f6} + x_6 h_{fg6}$$

Substitute 183.2 kJ/kg for h_{f6}, 0.95 for x_6 and 2396.9 kJ/kg for h_{fg6}

$$h_6 = 191.8 + (0.95 \times 2392.1)$$
$$= 2464.295 \text{ kJ/kg}$$

Write the relation for isentropic efficiency of the turbine.

$$\eta_t = \frac{h_5 - h_6}{h_5 - h_{6s}}$$

Substitute 3358.35 kJ/kg for h_5, 2307 kJ/kg for h_{6s}, and 2464.295 kJ/kg for h_6.

$$\eta_t = \frac{3358.35 - 2464.295}{3358.35 - 2307}$$
$$= 0.8503$$
$$\neq 0.85$$

Step 8 of 12

Therefore condenser pressure will be between 9 kPa and 10 kPa.

Calculate the condenser pressure by using interpolation between 9 kPa and 10 kPa:

$$\frac{0.85 - 0.843}{0.8503 - 0.843} = \frac{P_6 - 9}{10 - 9}$$
$$P_6 = 9.9 \text{ kPa}$$

Therefore the condenser pressure is, $\boxed{9.9 \text{ kPa}}$.

Step 9 of 12

Therefore the condenser pressure is, $\boxed{9.9\text{ kPa}}$ 9P pg 3

Step 9 of 12

Obtain the properties of the water at exit of the condenser at $P_6 = 9.9\text{ kPa}$ from Table A-5, "Properties of saturated water", from the text book.

Specific enthalpy, $h_1 = 190.9\text{ kJ/kg}$

Specific entropy, $s_1 = 0.646\text{ kJ/kg.K}$

Specific volume, $v_1 = 0.001\text{ m}^3\text{/kg}$

Calculate the work done by the pump by using the following relation:

$$w_p = v_1(P_2 - P_6)$$

Substitute $0.001\text{ m}^3\text{/kg}$ for v_1, 9.9 kPa for P_6, and 12.5 MPa for P_2.

$$\begin{aligned} w_p &= 0.001\left[\left(12.5\times10^3\right)-9.9\right] \\ &= 12.49\text{ kJ/kg} \end{aligned}$$

Step 10 of 12

Calculate the isentropic enthalpy at exit of the pump by using the following relation:

$$w_p = h_{2s} - h_1$$

Substitute 190.9 kJ/kg for h_1, and 12.49 kJ/kg for w_p.

$$\begin{aligned} 12.49 &= h_{2s} - 190.9 \\ h_{2s} &= 12.49 + 190.9 \\ h_{2s} &= 203.39\text{ kJ/kg} \end{aligned}$$

Calculate the actual enthalpy at exit of the pump by using the following relation:

$$\eta_p = \frac{h_{2s} - h_1}{h_2 - h_1}$$

Substitute 203.39 kJ/kg for h_{2s}, 190.9 kJ/kg for h_1, and 0.9 for η_p.

$$\begin{aligned} 0.9 &= \frac{203.39-190.9}{h_2-190.9} \\ h_2 &= 204.78\text{ kJ/kg} \end{aligned}$$

Step 11 of 12

(b)

Calculate the net power output.

$$P_{net} = \dot{m}\left[\left(h_3 - h_4\right)+\left(h_5 - h_6\right)\right]$$

Here, $\dot{m}$ is the mass flow rate of the steam.

Substitute 7.7 kg/s for $\dot{m}$, 3358.35 kJ/kg for h_5, 2464.295 kJ/kg for h_6, 3476.5 kJ/kg for h_3, and 3028.44 kJ/kg for h_4.

$$\begin{aligned} P_{net} &= 7.7\left[\left(3476.5-3028.44\right)+\left(3358.35-2464.295\right)\right] \\ &= 10334.2\text{ kW} \\ &= 10.3\text{ MW} \end{aligned}$$

Therefore, net power output is, $\boxed{10.4\text{ MW}}$.

Step 12 of 12

(c)

Calculate the thermal efficiency by using the following relation:

$$\begin{aligned} \eta_{th} &= \frac{P_{net}}{Q_{in}} \\ &= \frac{P_{net}}{\dot{m}\left[\left(h_3 - h_2\right)+\left(h_5 - h_4\right)\right]} \end{aligned}$$

Here, Q_{in} is the amount of heat supplied.

Substitute 7.7 kg/s for $\dot{m}$, 10468 kW for P_{net}, 3476.5 kJ/kg for h_3, 3358.35 kJ/kg for h_5, 204.78 kJ/kg for h_2, and 3028.44 kJ/kg for h_4.

$$\begin{aligned} \eta_{th} &= \frac{10334.2}{7.7\left[\left(3476.5-204.78\right)+\left(3358.35-3028.44\right)\right]} \\ &= \frac{10334.2}{27732.55} \\ &= 37\% \end{aligned}$$

Therefore, thermal efficiency of the cycle is, $\boxed{37\%}$.

Question: 9.140P

Why do we study the reversed Carnot cycle even though it is not a realistic model for refrigeration cycles?

Step 1 of 2

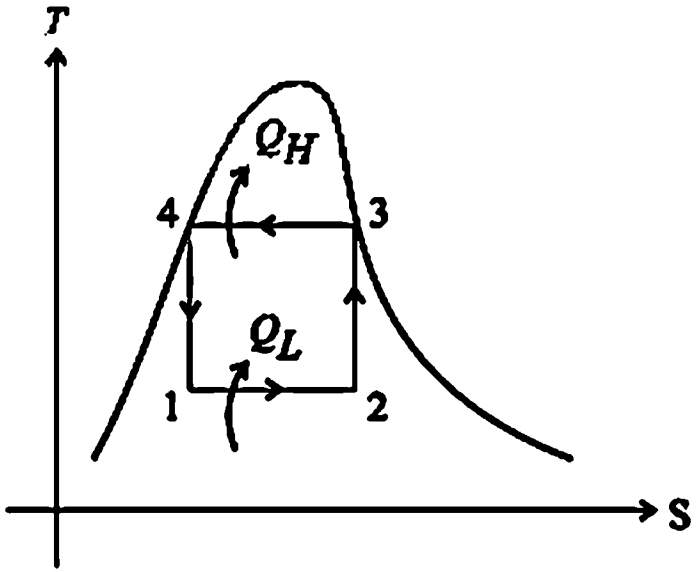
Carnot cycle is totally reversible cycle that consists of two reversible isothermal and two reversible isentropic processes. It has a maximum efficiency for given temperature limits. The two isothermal heat transfer processes are not difficult to achieve in practice since maintaining the constant pressure automatically fixes the temperature of a two phase mixture at the saturation value. So, it is difficult to maintain isothermal conditions during the heat absorption and heat rejection processes. Therefore we conclude that reverse Carnot cycle cannot be approximated in actual device and it is not realistic model for refrigeration cycle.

Step 2 of 2

And reverse Carnot cycle is most effective refrigeration cycle operating between two specified temperature levels. So it can serve as a standard against which actual refrigeration cycles are compared.

Question:

9.141P



Why is the reversed Carnot cycle executed within the saturation dome not a realistic model for refrigeration cycles?

Step 1 of 1

The reversed Carnot cycle executed within the saturation dome is not a realistic model for refrigeration cycles.

Reason:

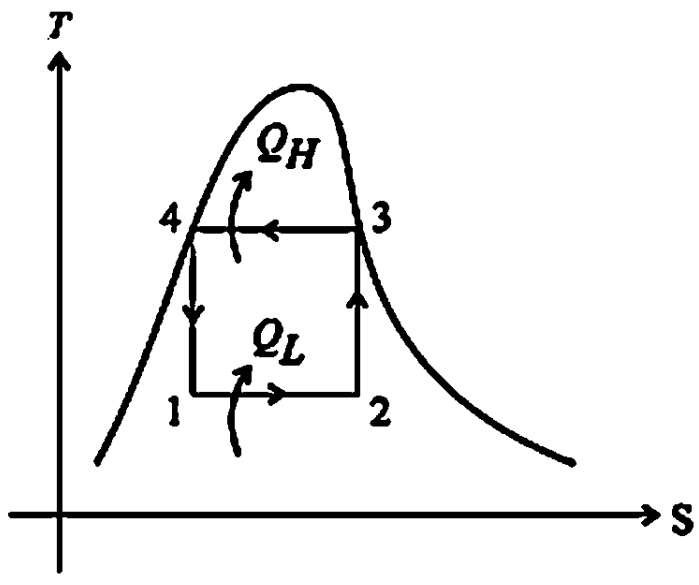
The two isothermal heat transfer processes (Processes 1-2 and 3-4) are not difficult to achieve in practice. The processes 2-3 and 4-1 cannot be approximated closely in practice. This is because process 2-3 involves the compression of a liquid-vapor mixture, which requires a compressor that will handle two phases, and process 4-1 involves the expansion of high-moisture content refrigerant in a turbine.

Question: 9.142P

A steady-flow Carnot refrigeration cycle uses refrigerant- 134a as the working fluid. The refrigerant changes from saturated vapor to saturated liquid at 40°C in the condenser as it rejects heat. The evaporator pressure is 100 kPa. Show the cycle on a *T-s* diagram relative to saturation lines, and determine *(a)* the coefficient of performance, *(b)* the amount of heat absorbed from the refrigerated space, and *(c)* the net work input. Answer: (a) 3.72, *(b)*128 kJ/kg, (c) 34.6 kJ/kg

Step 1 of 7

Given:



Refrigeration fluid: R-134a

Temperature of the condenser $T_H = 40^\circ C$

Pressure of evaporator $P_L = 100 kPa$

Step 2 of 7

T-S diagram for reversed Carnot refrigeration cycle :

Step 3 of 7

Condenser temperature

$T_H = 40^\circ C$

$= 273 + 40$

$= 313K$

Evaporator temperature

From the saturated refrigerant R-134a pressure table

At $P_L = 100 kPa$

$T_L = -26.37^\circ C$

$= 273 - 26.37^\circ C$

$= 246.63K$

Step 4 of 7

(a) Coefficient of performance of reversed Carnot refrigeration cycle is

$$(COP)_{R.C} = \frac{T_L}{T_H - T_L}$$

$$= \frac{246.63}{313 - 246.63}$$

$$= 3.715$$

$$\boxed{(COP)_{RC} = 3.715}$$

Step 5 of 7

b) Amount of heat absorbed from the refrigerant space, from the saturated refrigerant R-134a Temperature table

At $40^\circ C$

$$h_3 = h_g = 271.27 \frac{kJ}{kg}$$

$$h_4 = h_f = 108.26 \frac{kJ}{kg}$$

Thus,

Heat transferred is

$$q_H = h_3 - h_4$$

$$= \left(271.27 \frac{kJ}{kg}\right) - \left(108.26 \frac{kJ}{kg}\right)$$

$$= 163.01 \frac{kJ}{kg}$$

Step 6 of 7

Since reversed Carnot refrigeration cycle operates between the two temperature limits, so amount of heat supplied and rejection occurs at respective the temperature limits.

It gives

$$\frac{q_H}{q_L} = \frac{T_H}{T_L}$$

$$q_L = \frac{T_L}{T_H}(q_H)$$

$$= \frac{(246.63K)}{(313K)}\left(163.01 \frac{kJ}{kg}\right)$$

$$= 128.44 \frac{kJ}{kg}$$

$$\boxed{q_L = 128.44 \frac{kJ}{kg}}$$

Step 7 of 7

(c) The net work input

$$W_{net} = q_H - q_L$$

$$= \left(163.01 \frac{kJ}{kg}\right) - \left(128.44 \frac{kJ}{kg}\right)$$

$$= 34.57 \frac{kJ}{kg}$$

$$= 34.57 \frac{kJ}{kg}$$

$$\boxed{W_{net} = 34.57 \frac{kJ}{kg}}$$

Question: 9.143P

Refrigerant-134a enters the condenser of a steady-flow Carnot refrigerator as a saturated vapor at 90 psia, and it leaves with a quality of 0.05. The heat absorption from the refrigerated space takes place at a pressure of 30 psia. Show the cycle on a *T-s* diagram relative to saturation lines, and determine *(a)* the coefficient of performance, *(b)* the quality at the beginning of the heat-absorption process, and (c) the net work input.

Step 1 of 7

Given:
Working fluid: Refrigerant-134a
Pressure at warm space = 90 psia
Temperature of warm space,

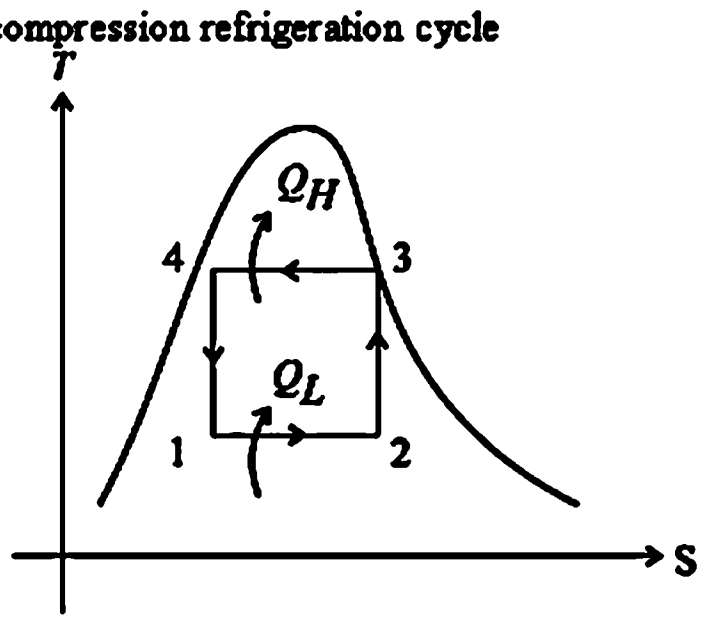
$T_H = T_{sat@90psia} = 72.78^\circ F$

$T_H = 72.78+460.02\ R$

$T_H = 532.8\ R$

Pressure at refrigerated space = 30 psia
Temperature of refrigerated space,

$T_L = T_{sat\ @\ 30psia} = 15.37^\circ F$



$T_L = 15.37+460.02R$

$T_L = 475.4\ R$

Given, quality $x_4 = 0.05$

Step 2 of 7

T-S diagram of vapor-compression refrigeration cycle

Step 3 of 7

From Saturated refrigerant-134a – Pressure table,

$s_{f@90psia} = 0.07481$ Btu/lbm.R

$s_{fg@90psia} = 0.14525$ Btu/lbm.R

$s_{g@90psia} = 0.22006$ Btu/lbm·R

$s_{f@30psia} = 0.03793$ Btu/lbm.R

$s_{fg@30psia} = 0.18589$ Btu/lbm.R

Step 4 of 7

Assumptions:

1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 5 of 7

(a) Coefficient of performance:
Coefficient of performance

$$COP = \frac{1}{\frac{T_H}{T_L}-1}$$

$$COP = \frac{1}{\frac{532.8}{475.4}-1}$$

$$COP = \frac{1}{0.12074}$$

$$\boxed{COP = 8.282}$$

Step 6 of 7

(b) The quality at the beginning of the heat-absorption process, x_1:
For the process 4-1,

$s_1 = s_4 = \left(s_f + x_4 \times s_{fg}\right)_{@90psia}$

$s_1 = 0.07481+0.05\times0.14525$

$s_1 = 0.0820725$ Btu/lbm.R

We know that

$s_1 = \left(s_f + x_1 \times s_{fg}\right)_{@30psia}$

$0.0820725 = 0.03793 + x_1 \times 0.18589$

$$x_1 = \frac{(0.0820725-0.03793)}{0.18589}$$

$$\boxed{x_1 = 0.2374}$$

Step 7 of 7

(c) Net work input:
Net work input = Area enclosed in the T-s diagram

$w_{net} = (T_H - T_L)\times(s_3 - s_4)$

Where $s_3 = s_{g\ @\ 90psia} = 0.22006$ Btu/lbm·R

$w_{net} = (532.8-475.4)\times(0.22006-0.0820725)$

$w_{net} = (57.4)\times(0.1379875)$

$$\boxed{w_{net} = 7.9205\ \text{Btu/lbm}}$$

Question: 9.144P

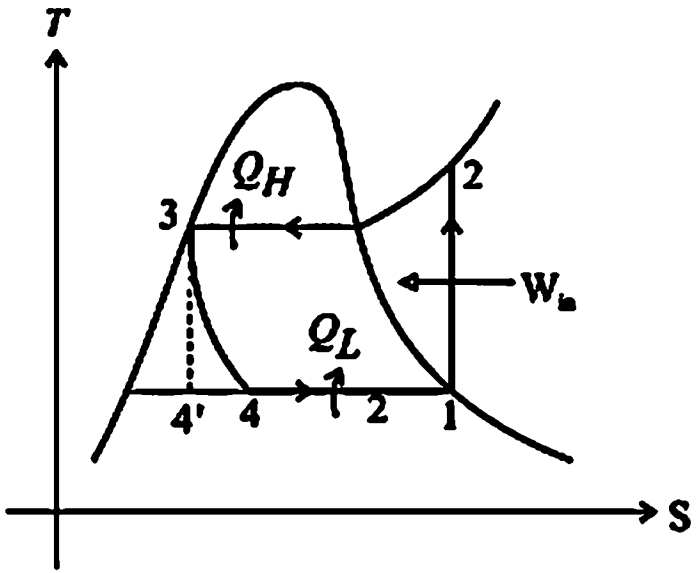
Does the ideal vapor-compression refrigeration cycle involve any internal irreversibilities?

Step 1 of 1

Yes. The ideal vapor-compression refrigeration cycle involves one irreversible process (throttling).

Explanation:
Unlike other ideal cycles (Carnot cycle), the ideal vapor compression refrigeration cycle is not an internally reversible cycle since it involves an irreversible (throttling) process. This process is maintained in the cycle to make it a more realistic model for the actual vapor-compression refrigeration cycle.

Question: 9.145P



Why is the throttling valve not replaced by an isentropic turbine in the ideal vapor-compression refrigeration cycle?

Step 1 of 2

Replacing the expansion valve by a turbine is not practical.

Explanation:
If the throttling device were replaced by an isentropic turbine, the refrigerant would enter the evaporator at state $4'$ instead of state 4. As a result, the refrigeration capacity would increase and the net work input would decrease by the amount of work output of turbine. Even though there are benefits on adding the turbine but the added cost and complexity make it unpractical

Step 2 of 2

Question: 9.146P

It is proposed to use water instead of refrigerant-134a as the working fluid in air-conditioning applications where the minimum temperature never falls below the freezing point. Would you support this proposal? Explain.

Step 1 of 1

We can't use water instead of refrigerant R-134a.

Explanation:
For the refrigerants in evaporator saturated pressure for given temperature is very low which is not practical to maintain with water.

Question: 9.147P

In a refrigeration system, would you recommend condensing the refrigerant-134a at a pressure of 0.7 or 1.0 MPa if heat is to be rejected to a cooling medium at 15°C?Why?

Step 1 of 1

We must recommend the pressure of 0.7 MPa.

Explanation:
We must maintain minimum temperature difference of 10°C for effective heat transfer. Given that cooling medium is at 15°C. So, we must maintain condensation temperature of the refrigerant as 25°C. The saturation pressure corresponding to 25°C is very much near to 0.7 MPa (From Saturated refrigerant R-134a temperature table)

Question: 9.148P

Docs the area enclosed by the cycle on a *T-s* diagram represent the net work input for the reversed Carnot cycle? How about for the ideal vapor-compression refrigeration cycle?

Step 1 of 1

Yes, the area enclosed by the cyclic curve on a *T-s* diagram represents the net work input for the reversed Carnot cycle but not for the ideal vapor-compression refrigeration cycle.

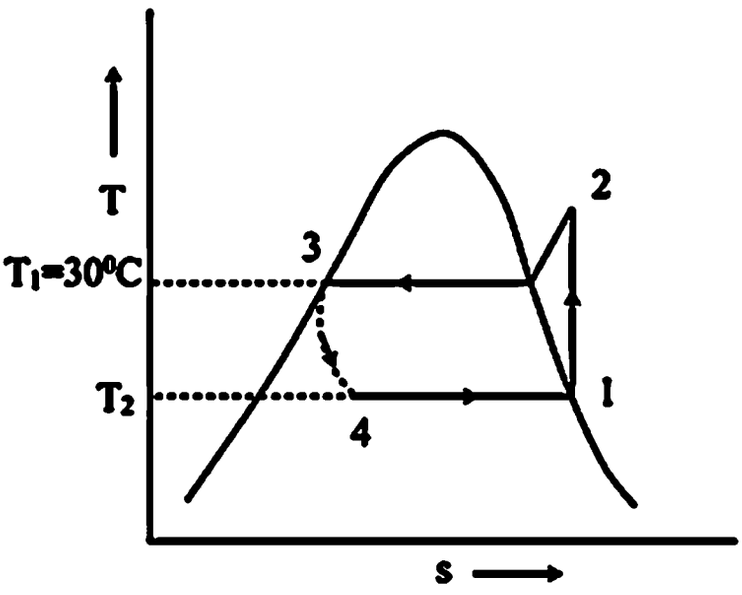
Explanation:

The area enclosed by the cyclic curve on a *T-s* diagram represents the net work input for the reversed Carnot cycle as it contains all internally reversible processes where the ideal vapor-compression refrigeration cycle involves one irreversible process (throttling).

Question:

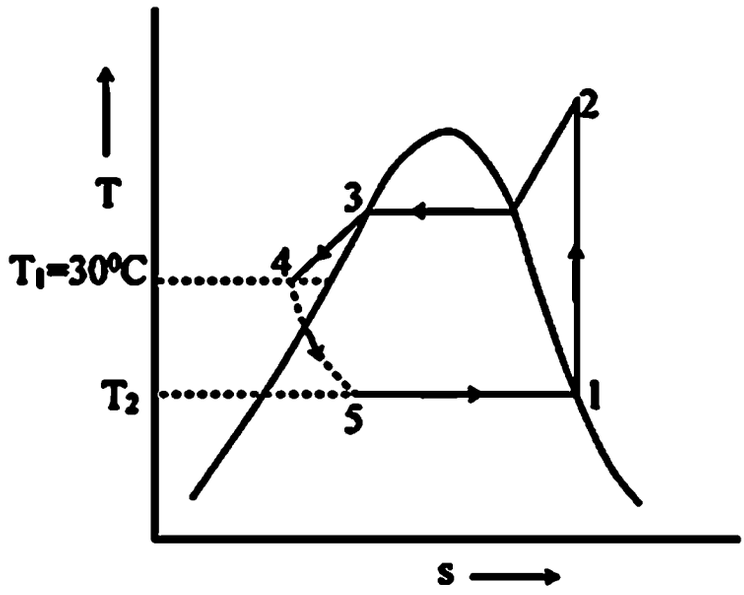
9.149P

Consider two vapor-compression refrigeration cycles. The refrigerant enters the throttling valve as a saturated liquid at 30°C in one cycle and as subcooled liquid at 30°C in the other one. The evaporator pressure for both cycles is the same. Which cycle do you think will have a higher COP?



Step 1 of 3

Consider two vapor-compression refrigeration cycles. The refrigerant enters the throttling valve as a saturated liquid at 30°C in one cycle and as sub cooled liquid at 30°C in the other one. The evaporator pressure for both cycles is the same.



The cycle that involves saturated liquid at 30°C will have a higher COP than the cycle that involves sub cooled liquid at 30°C.

Step 2 of 3

Draw the T-s diagrams for the two cycles.

(A) Saturated vapour

(B) sub cooled vapour

Step 3 of 3

Explanation:

It require a smaller work input for the same refrigeration capacity if we use the cycle that involves saturated liquid at 30°C than the cycle that involves sub cooled liquid at 30°C.

COP can be defined as

$$COP_R = \frac{\text{Cooling effect}}{\text{Work input}}$$

So, The cycle that involves saturated liquid at 30°C will have a higher COP.

Question: 9.150P

The COP of vapor-compression refrigeration cycles improves when the refrigerant is subcooled before it enters the throttling valve. Can the refrigerant be subcooled indefinitely to maximize this effect, or is there a lower limit? Explain.

Step 1 of 1

It is undesirable to route the refrigerant to the throttling valve before the refrigerant is completely condensed. Therefore, the refrigerant is sub cooled somewhat before it enters the throttling valve. The COP of vapor-compression refrigeration cycles improves when the refrigerant is sub cooled before it enters the throttling valve.

But we can't sub cool the refrigerant indefinitely to maximize this effect. The reason is that heat has to be transferred from the refrigerant to cooling medium, so the minimum temperature to which the refrigerant can be sub cooled is the temperature of the cooling medium. As the temperature of the coolant cannot be at indefinite low temperature, sub cooling the refrigerant indefinitely is not possible. Hence the minimum temperature of the coolant is the lower limit.

Question:

9.151P

A refrigerator operates on the ideal vapor-comprcssion refrigeration cycle and uses refrigerant -134a as the working fluid. The condenser operates at 300 psia and the evaporator 20°F. If an adiabatic, reversible expansion device were avail able and used to expand the liquid leaving the condenser. how much would the COP improve by using this device instead of the throttle device?

Step 1 of 8

Given:
Working fluid: Refrigerant-134a
Pressure at condenser, P_2 =300 psia
Temperature at evaporator, T_1 =20°F

Step 2 of 8

T-S diagram of vapor-compression refrigeration cycle

Question:

A refrigerator operates on the ideal vapor-comprcssion refrigeration cycle and uses refrigerant -134a as the working fluid. The condenser operates at 300 psia and the evaporator 20°F. If an adiabatic, reversible expansion device were avail able and used to expand the liquid leaving the condenser. how much would the COP improve by using this device instead of the throttle device?

Step 1 of 8

Given:
Working fluid: Refrigerant-134a
Pressure at condenser, P_2 =300 psia
Temperature at evaporator, T_1 =20°F

Step 2 of 8

T-S diagram of vapor-compression refrigeration cycle

Step 5 of 8

From saturated refrigerant-134a pressure table
P_2 =300 psia, Saturated liquid,
$h_3 = h_{f@300\,psia} = 66.339$ Btu/lbm
$s_3 = s_{f@300\,psia} = 0.12715$ Btu/lbm.R
For throttling, $h_4 = h_3 = 66.339$ Btu/lbm
If we use adiabatic, reversible expansion device, $s_{4s} = s_3$
$h_{4s} = 59.8$ Btu/lbm

Step 6 of 8

Assumptions:
1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 7 of 8

If we use throttling device, $COP_1 = \dfrac{h_1 - h_4}{h_2 - h_1}$

$COP_1 = \dfrac{105.98 - 66.339}{125.68 - 105.98}$

$COP_1 = 2.01223$

Step 5 of 8

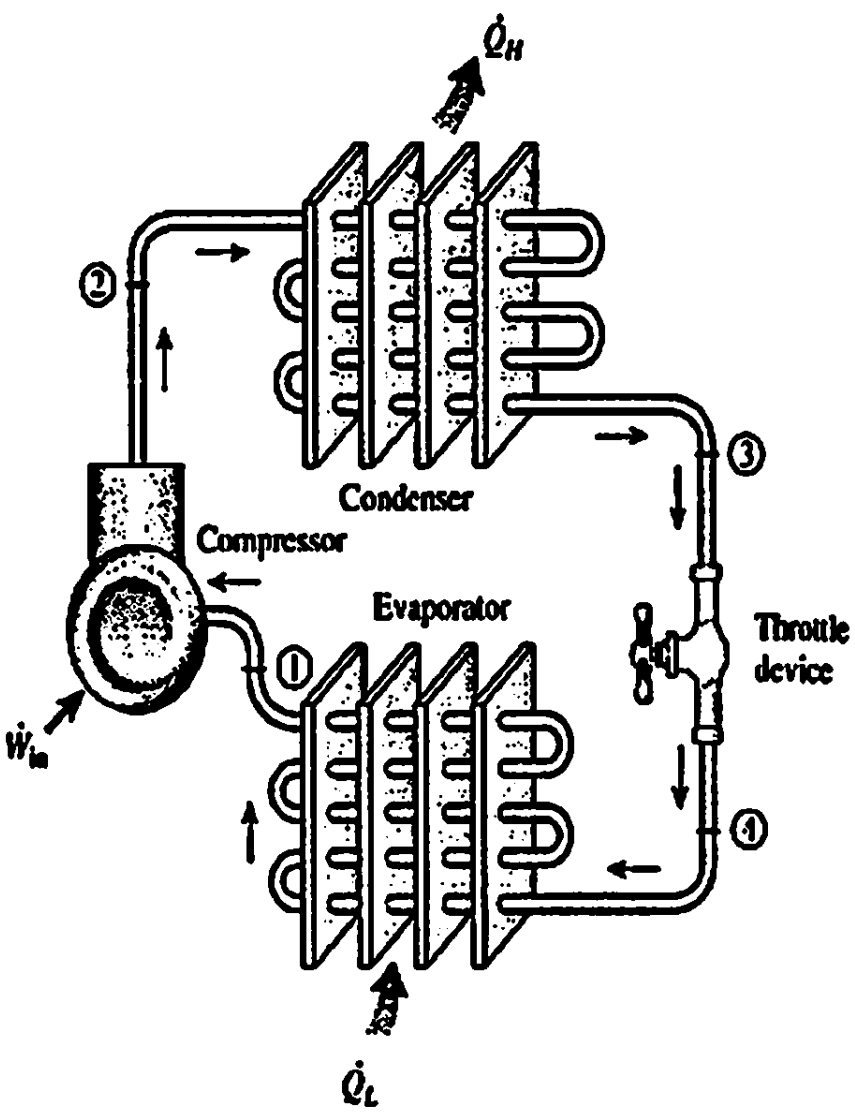
From saturated refrigerant-134a pressure table
P_2 =300 psia, Saturated liquid,
$h_3 = h_{f@300\,psia} = 66.339$ Btu/lbm
$s_3 = s_{f@300\,psia} = 0.12715$ Btu/lbm.R
For throttling, $h_4 = h_3 = 66.339$ Btu/lbm
If we use adiabatic, reversible expansion device, $s_{4s} = s_3$
$h_{4s} = 59.8$ Btu/lbm

Step 6 of 8

Assumptions:
1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Question: 9.152P

An ideal vapor-compression refrigeration cycle that uses refrigerant-134a as its working fluid maintains a condenser at 1000 kPa and the evaporator at 4°C. Determine this! system's COP and the amount of power required to service a400 kW cooling load.



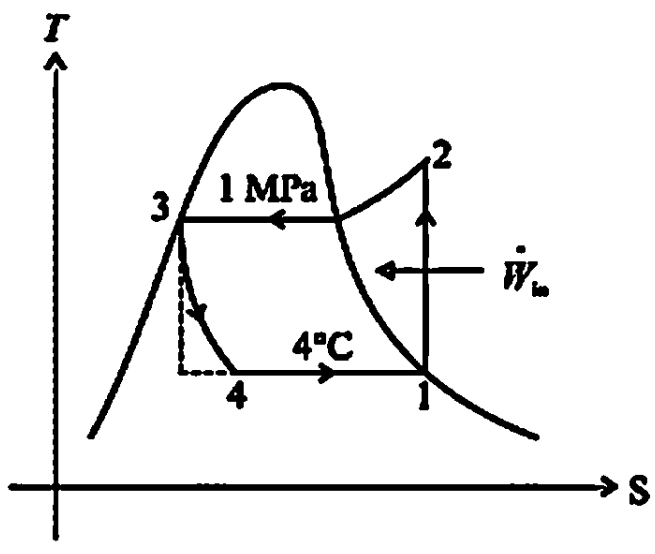


FIGURE P9–152

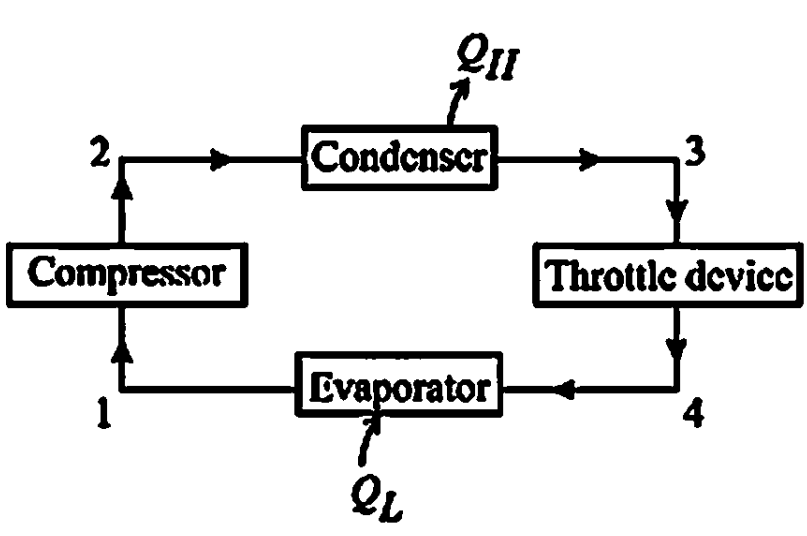
Step 1 of 9

Given:
Working fluid: Refrigerant-134a
Cooling load, $\dot{Q}_L = 400\ \text{kW}$
Pressure at condenser, $P_2 = 1\text{MPa}$
Temperature at evaporator, $T_1 = 4°\text{C}$



Step 2 of 9

T-S diagram of vapor-compression refrigeration cycle

Step 3 of 9

Block diagram of vapor-compression refrigeration cycle

Step 4 of 9

From Saturated refrigerant −134a temperature table
At $T_1 = 4°C$ saturated vapor,
$h_1 = h_{g@4°C} = 252.77\ \text{kJ/kg}$
$s_1 = s_{g@4°C} = 0.92927\ \text{kJ/kg.K}$

Step 5 of 9

From superheated refrigerant -134a table
$P_2 = 1\text{MPa}, s_2 = s_1 = 0.92927\ \text{kJ/kg.K}$

$$h_2 = 271.71 + \frac{0.92927 - 0.9179}{0.9525 - 0.9179} \times (282.74 - 271.71)$$

$h_2 = 275.3\ \text{kJ/kg}$

Step 6 of 9

From saturated refrigerant -134a pressure table
$P_2 = 1\text{MPa}$, Saturated liquid,
$h_3 = h_{f@1MPa} = 107.32\ \text{kJ/kg}$
For throttling, $h_4 = h_3 = 107.32\ \text{kJ/kg}$

Step 7 of 9

Assumptions:
1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 8 of 9

We know that cooling load, $\dot{Q}_L = \dot{m} \times (h_1 - h_4)$

So, Mass flow rate, $\dot{m} = \dfrac{\dot{Q}_L}{(h_1 - h_4)}$

$$\dot{m} = \frac{400}{(252.77 - 107.32)}$$

$\dot{m} = 2.75\ \text{kg/s}$

Power required, $\dot{W}_{in} = \dot{m} \times (h_2 - h_1)$

$\dot{W}_{in} = 2.75 \times (275.3 - 252.77)$

Power required, $\boxed{\dot{W}_{in} = 61.95\ \text{kW}}$

Step 9 of 9

COP of the refrigerator:

Coefficient of performance, $\text{COP} = \dfrac{\dot{Q}_L}{\dot{W}_{in}}$

$$\text{COP} = \frac{400}{61.95}$$

$\text{COP} = 6.4568$

$\boxed{\text{COP} = 6.46}$

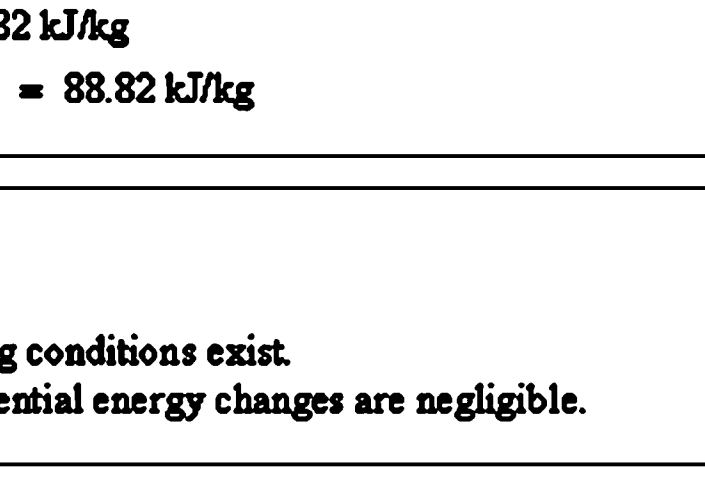
Question: 9.153P

A refrigerator uses refrigerant-134a as the working fluid and operates on an ideal vapor-compression refrigeration cycle between 0.12 and 0.7 MPa. The mass flow rate of the refrigerant is 0.05 kg/s. Show the cycle on a *T-s* diagram with respect to saturation lines. Determine *(a)* the rate of heat removal from the refrigerated space and the power input to the compressor, *(b)* the rate of heat rejection to the environment, and *(c)* the coefficient of performance. Answers:(a) 7.41 kW, 1.83 kW, *(b)*9.23 kW, (c) 4.06

Step 1 of 9

Given:

Working fluid: Refrigerant-134a



Mass flow rate of refrigerant, $\dot{m}_r = 0.05\ kg/s$

Pressure at condenser, $P_2 = 0.7\ MPa$

Pressure at evaporator, $P_1 = 0.12\ MPa$

Step 2 of 9

T-S diagram of vapor-compression refrigeration cycle

Step 3 of 9

From saturated refrigerant – 134a table

At $P_1 = 0.12\ MPa$ and saturated vapor,

$h_1 = h_{g@120\ kPa} = 236.97\ kJ/kg$

$s_1 = s_{g@120\ kPa} = 0.94779\ kJ/kg.K$

Step 4 of 9

From superheated refrigerant – 134a table

At $P_2 = 0.7\ MPa$, $s_2 = s_1 = 0.94779\ kJ/kg.K$

$$h_2 = 268.45 + \frac{0.94779 - 0.9313}{0.9641 - 0.9313} \times (278.57 - 168.45)$$

$h_2 = 273.5\ kJ/kg$

Step 5 of 9

At $P_2 = 0.7\ MPa$, Saturated liquid,

$h_3 = h_{f@0.7\ MPa} = 88.82\ kJ/kg$

For throttling, $h_4 = h_3 = 88.82\ kJ/kg$

Step 6 of 9

Assumptions:

1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 7 of 9

(a) Rate of heat removal from the refrigerated space, $\dot{Q}_L = \dot{m} \times (h_1 - h_4)$

$\dot{Q}_L = 0.05 \times (236.97 - 88.82)$

$\dot{Q}_L = 7.4075\ kW$

Rate of heat removal from the refrigerated space, $\boxed{\dot{Q}_L = 7.41\ kW}$

Power required, $\dot{W}_{in} = \dot{m} \times (h_2 - h_1)$

$\dot{W}_{in} = 0.05 \times (273.5 - 236.97)$

$\dot{W}_{in} = 1.8265$

Power required, $\boxed{\dot{W}_{in} = 1.83\ kW}$

Step 8 of 9

(b) The rate of heat rejection to the environment, $\dot{Q}_H = \dot{W}_{in} + \dot{Q}_L$

$\dot{Q}_H = 1.83 + 7.41$

$\boxed{\dot{Q}_H = 9.23\ kW}$

Step 9 of 9

(c) COP of the refrigerator:

Coefficient of performance, $COP = \dfrac{\dot{Q}_L}{\dot{W}_{in}}$

$$COP = \frac{7.41}{1.83}$$

$\boxed{COP = 4.05}$

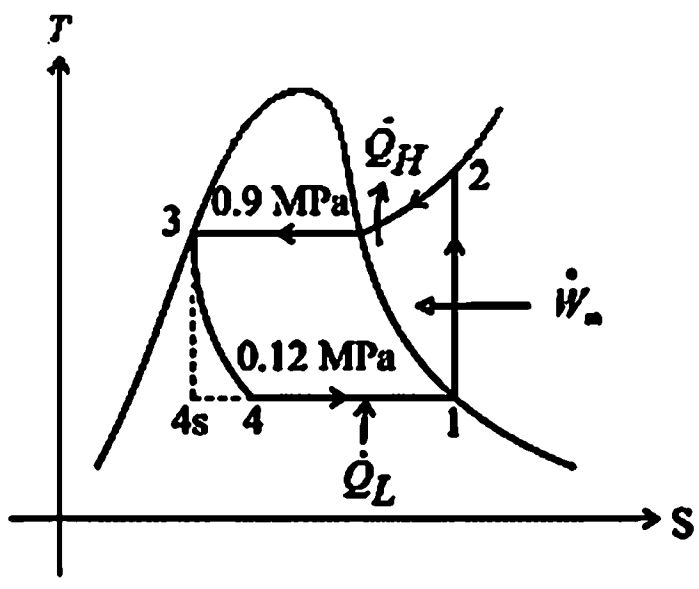
Question: 9.154P

Repeat Prob. 9–153 for a condenser pressure of 0.9 MPa.

Step 1 of 9

Given:

Working fluid: Refrigerant-134a



Mass flow rate of refrigerant, $\dot{m}_r = 0.05\ kg/s$

Pressure at condenser, $P_2 = 0.9\ MPa$

Pressure at evaporator, $P_1 = 0.12\ MPa$

Step 2 of 9

T-S diagram of vapor-compression cycle

Step 3 of 9

From saturated refrigerant- 134a pressure table

At $P_1 = 0.12\ MPa$ and saturated vapor,

$h_1 = h_{g@120\ kPa} = 236.97\ kJ/kg$

$s_1 = s_{g@120\ kPa} = 0.94779\ kJ/kg.K$

Step 4 of 9

At $P_2 = 0.9\ MPa$, $s_2 = s_1 = 0.94779\ kJ/kg.K$

$$h_2 = 274.17 + \frac{0.94779 - 0.9327}{0.966 - 0.9327} \times (284.77 - 274.17)$$

$h_2 = 278.97\ kJ/kg$

Step 5 of 9

At $P_2 = 0.9\ MPa$, Saturated liquid,

$h_3 = h_{f@0.9\ MPa} = 101.61\ kJ/kg$

For throttling, $h_4 = h_3 = 101.61\ kJ/kg$

Step 6 of 9

Assumptions:

1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 7 of 9

(a) Rate of heat removal from the refrigerated space, $\dot{Q}_L = \dot{m} \times (h_1 - h_4)$

$\dot{Q}_L = 0.05 \times (236.97 - 101.61)$

$\dot{Q}_L = 6.768\ kW$

Rate of heat removal from the refrigerated space, $\boxed{\dot{Q}_L = 6.768\ kW}$

Power required, $\dot{W}_{in} = \dot{m} \times (h_2 - h_1)$

$\dot{W}_{in} = 0.05 \times (278.97 - 236.97)$

$\dot{W}_{in} = 2.1 kW$

Power required, $\boxed{\dot{W}_{in} = 2.1\ kW}$

Step 8 of 9

(b) The rate of heat rejection to the environment, $\dot{Q}_H = \dot{W}_{in} + \dot{Q}_L$

$\dot{Q}_H = 2.1 + 6.768$

$\boxed{\dot{Q}_H = 8.868\ kW}$

Step 9 of 9

(c) COP of the refrigerator:

Coefficient of performance, $COP = \dfrac{\dot{Q}_L}{\dot{W}_{in}}$

$$COP = \frac{6.768}{2.1}$$

$\boxed{COP = 3.223}$

Question:

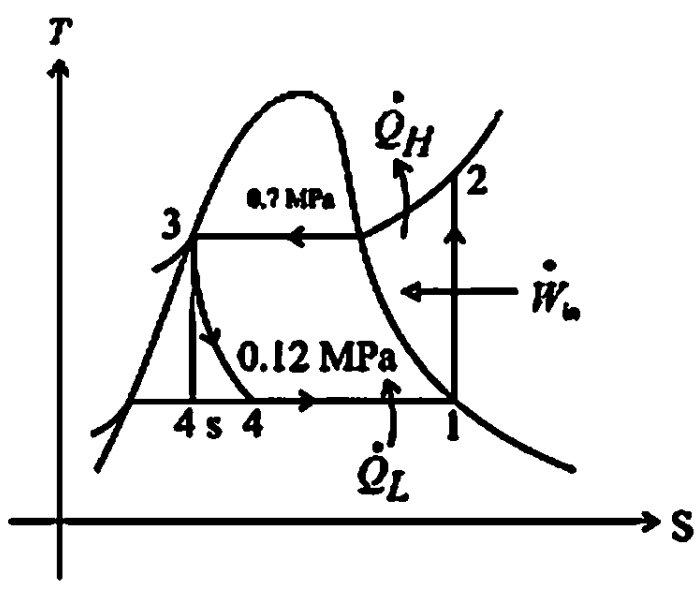
9.155P

If the throttling valve in Prob. 9–153 is replaced by an isentropic turbine, determine the percentage increase in the COP and in the rate of heat removal from the refrigerated space. Answers: 4.2 percent, 4.2 percent

Step 1 of 13

Given:

Working fluid: Refrigerant-134a



Mass flow rate of refrigerant, $\dot{m}_r = 0.05\ kg/s$

Pressure at condenser, $P_2 = 0.7\ MPa$

Pressure at evaporator, $P_1 = 0.12\ MPa$

Step 2 of 13

T-S diagram of vapor-compression refrigeration cycle

Step 3 of 13

From saturated refrigerant- 134a pressure table

At $P_1 = 0.12\ MPa$ and saturated vapor,

$h_1 = h_{g@120\ kPa} = 236.97\ kJ/kg$

$s_1 = s_{g@120\ kPa} = 0.94779\ kJ/kg.K$

Step 4 of 13

From superheated refrigerant- 134a table

$P_2 = 0.7\ MPa, s_2 = s_1 = 0.94779\ kJ/kg.K$

$$h_2 = 268.45 + \frac{0.94779 - 0.9313}{0.9641 - 0.9313} \times (278.57 - 168.45)$$

$h_2 = 273.5\ kJ/kg$

Step 5 of 13

From saturated refrigerant- 134a pressure table

$P_2 = 0.7\ MPa$, Saturated liquid,

$h_3 = h_{f@0.7\ MPa} = 88.82\ kJ/kg$

For throttling, $h_4 = h_3 = 88.82\ kJ/kg$

Step 6 of 13

Assumptions:

1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 7 of 13

The throttling valve is replaced by an isentropic turbine.

$(s_4)_{turbine} = s_3 = s_{f@0.7\ MPa} = 0.3323\ kJ/kg.K$

$s_{f@120kPa} = 0.09275\ kJ/kg.K$

$s_{fg@120kPa} = 0.85503\ kJ/kg.K$

$h_{f@120kPa} = 22.49\ kJ/kg$

$h_{fg@120kPa} = 214.48\ kJ/kg$

But $s_3 = s_{f@120kPa} + (x_4)_{turbine} \times s_{fg@120kPa}$

$$(x_4)_{turbine} = \frac{0.3323 - 0.09275}{0.85503}$$

$(x_4)_{turbine} = 0.280166$

Step 8 of 13

Enthalpy at turbine exit, $(h_4)_{turbine} = h_{f@120\ kPa} + (x_4)_{turbine} \times h_{fg@120kPa}$

$(h_4)_{turbine} = 22.49 + 0.280166 \times 214.48$

$(h_4)_{turbine} = 82.58\ kJ/kg$

Step 9 of 13

For throttling valve: Rate of heat removal from the refrigerated space,

$\dot{Q}_L = \dot{m} \times (h_1 - h_4)$

$\dot{Q}_L = 0.05 \times (236.97 - 88.82)$

$\dot{Q}_L = 7.4075\ kW$

For turbine: Rate of heat removal from the refrigerated space,

$(\dot{Q}_L)_{turbine} = \dot{m} \times (h_1 - (h_4)_{turbine})$

$(\dot{Q}_L)_{turbine} = 0.05 \times (236.97 - 82.58)$

$(\dot{Q}_L)_{turbine} = 7.7195\ kW$

Step 10 of 13

$$\text{Increase in } \dot{Q}_L = \frac{(\dot{Q}_L)_{turbine} - \dot{Q}_L}{\dot{Q}_L}$$

$$\%\dot{Q}_L = \frac{7.7195 - 7.41}{7.41}$$

$\%\dot{Q}_L = 4.18\%$

$\boxed{\%\dot{Q}_L = 4.2\%}$

Step 11 of 13

Power required, $\dot{W}_{in} = \dot{m} \times (h_2 - h_1)$

$\dot{W}_{in} = 0.05 \times (273.5 - 236.97)$

$\dot{W}_{in} = 1.8265$

Step 12 of 13

COP of the refrigerator if it is throttling valve:

Coefficient of performance, $COP = \frac{\dot{Q}_L}{\dot{W}_{in}}$

$$COP = \frac{7.41}{1.83}$$

$COP = 4.05$

COP of the refrigerator if it is turbine:

$$(COP)_{turbine} = \frac{(\dot{Q}_L)_{turbine}}{\dot{W}_{in}}$$

$$(COP)_{turbine} = \frac{7.7195}{1.83}$$

$(COP)_{turbine} = 4.2183$

Step 13 of 13

$$\text{Increase in COP, } = \frac{(COP)_{turbine} - COP}{COP}$$

$$\%COP = \frac{4.2183 - 4.05}{4.05}$$

$\boxed{\%COP = 4.2\%}$

Question: 9.156P

Refrigerant-134a enters the compressor of a refrigerator as superheated vapor at 0.20 MPa and −5°C at a rate of 007 kg/s, and it leaves at 1.2 MPa and 70°C. The refrigerant is cooled in the condenser to 44°C and 1.15 MPa, and it is throttled to 0.21 MPa. Disregarding any heat transfer and pressure drops in the connecting lines between the components, show the cycle on a *T-s* diagram with respect to saturation lines, and determine *(a)* the rate of heat removal from the refrigerated space and the power input to the compressor, *(b)* the isentropic efficiency of the compressor, and *(c)* the COP of the refrigerator.

Step 1 of 10

Given:

Working fluid: R-134a

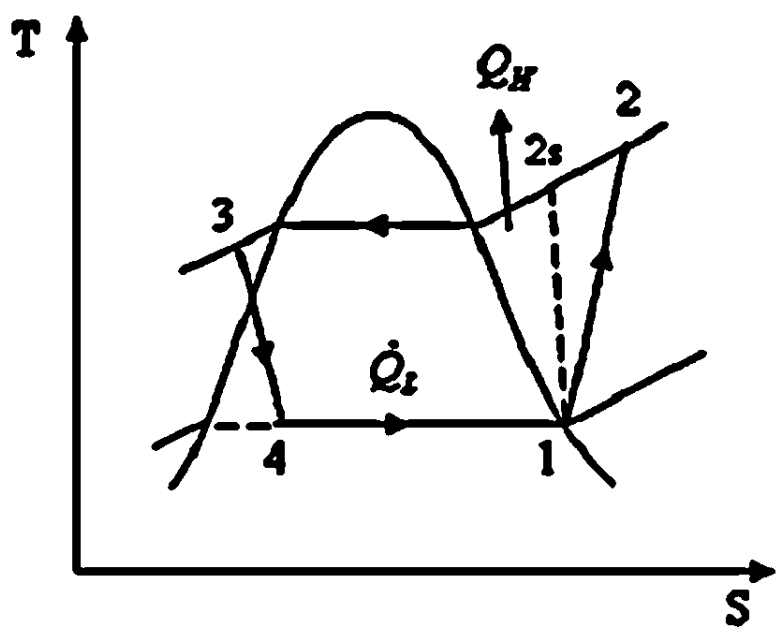
Inlet pressure of the compressor $P_1 = 0.20\,\text{MPa}$

Inlet temperature of the compressor $T_1 = -5^\circ\text{C}$

Mass flow rate of the refrigerant $m = 0.07\,\frac{\text{kg}}{s}$

Exit pressure of the compressor $P_2 = 1.2\,\text{MPa}$

Exit temperature of the compressor $T_2 = 70^\circ\text{C}$



Exit pressure of the condenser $P_3 = 1.15\,\text{MPa}$

Exit temperature of the condenser $T_3 = 44^\circ\text{C}$

Throttled pressure $P_4 = 0.21\,\text{MPa}$

Step 2 of 10

T-S Diagram:

Step 3 of 10

State1:

Since refrigerant leaves the compressor is saturated liquid

From the Superheated refrigerant R-134a

At P_1=0.2MPa , $T_1 = -5^\circ\text{C}$

Using the interpolation

$$h_1 = 244.54 + \frac{(-10-(-5))(253.05-244.54)}{(-10-0)}$$

$$h_1 = 248.795\,\frac{\text{kJ}}{\text{kg}}$$

Entropy

At $T_1 = -5^\circ\text{C}$ and P_1=0.2MPa

Using the method of interpolation

$$s_1 = 0.9380 + \frac{(-10-(-5))(0.9698-0.9380)}{(-10-0)}$$

$$s_1 = 0.9539\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 4 of 10

State2:

Since refrigerant leaves the compressor in the form of saturated liquid

From the Superheated refrigerant R-134a

At $P_2 = 1.2\,\text{MPa}$ and $T_2 = 70^\circ\text{C}$

$$h_2 = 300.61\,\frac{\text{kJ}}{\text{kg}}$$

Step 5 of 10

State3:

Since refrigerant leaves the condenser in form of saturated liquid.

So, from the saturated refrigerant R-134a temperature table

$T_3 = 44^\circ\text{C}$ And P_3=1.15MPa

$$h_3 = h_f = 114.28\,\frac{\text{kJ}}{\text{kg}}$$

State4:

In throttling process, enthalpy remains constant.

$h_4 \cong h_3$ (Throttling)

$$h_3 = 114.28\,\frac{\text{kJ}}{\text{kg}}$$

Step 6 of 10

(a) The rate of heat removal from the refrigerated space and the power input to the compressor are determined from their definitions.

$$\dot{Q}_L = \dot{m}(h_1 - h_4)$$

$$= \left(0.07\,\frac{\text{kg}}{s}\right)\left(\left(248.795\,\frac{\text{kJ}}{\text{kg}}\right)-\left(114.28\,\frac{\text{kJ}}{\text{kg}}\right)\right)$$

$$= 9.41\,\frac{\text{kJ}}{s}$$

$$\boxed{Q_L = 9.41\,\text{kW}}$$

Step 7 of 10

Work input is

$$\dot{W}_{in} = \dot{m}(h_2 - h_1)$$

$$= 0.07\,\frac{\text{kg}}{s}\left(\left(300.61\,\frac{\text{kJ}}{\text{kg}}\right)-\left(248.795\,\frac{\text{kJ}}{\text{kg}}\right)\right)$$

$$= 3.627\,\frac{\text{kJ}}{s}$$

$$\boxed{W_{in} = 3.627\,\text{kW}}$$

Step 8 of 10

(b) The isentropic efficiency of the compressor is determined from

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

Where the enthalpy at state $2s$ is

From the superheated refrigerant R-134a

$$P_{2s} = 1.2\,\text{MPa and } s_{2s} = s_2 = 0.9539\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$h_{2s} = = 278.27 + \frac{(0.9539-0.9297)(289.64-278.27)}{(0.9614-0.9267)}$$

$$h_{2s} = 286.199\,\frac{\text{kJ}}{\text{kg}}$$

Step 9 of 10

Isentropic efficiency of the compressor is

$$\eta_c = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$= \frac{(286.199-248.795)}{(300.61-248.795)}$$

$$= 0.721$$

$$\boxed{\eta_C = 72.1\%}$$

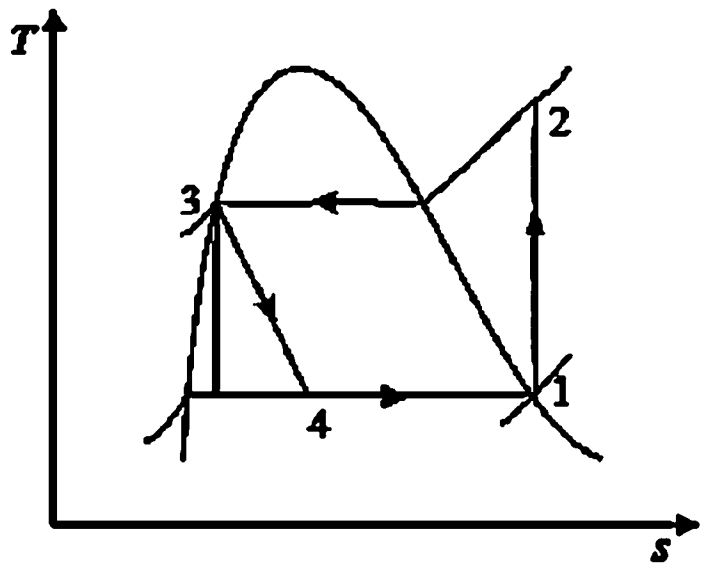
Step 10 of 10

(c) The COP of the refrigerator is determined from

$$(COP)_R = \frac{Q_L}{\dot{W}_{in}}$$

$$= \frac{9.41}{3.627}$$

$$= 2.59$$



$$\boxed{\text{COP} = 2.59}$$

Question: 9.157P

A refrigerator uses refrigerant-134a as its working fluid and operates on the ideal vapor-compression refrigeration cycle. The refrigerant evaporates at 5°F and condenses at 180 psia. This unit serves a 45,000 Btu/h cooling load. Determine the mass flow rate of the refrigerant and the power that this unit will require.

Step 1 of 6

Draw the different processes on T-s diagram as shown below:

Process 1-2 is isentropic compression
Process 2-3 is condensation process
Process 3-4 is throttling expansion
Process 4-1 is evaporation

Step 2 of 6

The refrigerant enters into the compressor is saturated Vapor, and refrigerant leaves the condenser is saturated liquid.

Obtain the properties of refrigerant from "saturated refrigerant R-134a temperature tables" at $T_1 = 5°\text{F}$

Specific enthalpy of saturated vapor $h_1 = h_g = 103.82 \frac{\text{Btu}}{\text{lbm}}$

Specific entropy of saturated vapor $s_1 = s_g = 0.22485 \frac{\text{Btu}}{\text{lbm} \cdot \text{R}}$

Step 3 of 6

Process 1-2 is isentropic compression process, entropy remains constant.

$$s_1 = s_2$$

Obtain the properties at state 2 from "superheated refrigerant R-134a pressure table" at $P_2 = 180\text{psia}$ and $s_2 = 0.22485 \frac{\text{Btu}}{\text{lbm} \cdot \text{R}}$

$$h_2 = 118.63 + (124.17 - 118.63)\left(\frac{0.22485 - 0.21910}{0.22850 - 0.21910}\right)$$

$$= 122.01 \frac{\text{Btu}}{\text{lbm}}$$

Step 4 of 6

Obtain the properties at state 3 "from saturated refrigerant R-134a pressure table" at condenser pressure $P_3 = 180\text{psia}$

Specific enthalpy of saturated liquid $h_3 = h_f = 51.497 \frac{\text{Btu}}{\text{lbm}}$

In process 3-4 enthalpy remains constant. Since it is a throttling process

$$h_3 = h_4$$

$$h_4 = 51.497 \frac{\text{Btu}}{\text{lbm}}$$

Step 5 of 6

Find the mass flow rate of refrigerant by using the equation,

$$\dot{Q}_L = \dot{m}(h_1 - h_4)$$

Here, $\dot{Q}_L$ is cooling load capacity

$$\dot{m} = \frac{\dot{Q}_L}{(h_1 - h_4)}$$

Substitute $45{,}000\,\text{Btu/h}$ for $\dot{Q}_L$

$$\dot{m} = \frac{45000}{(103.82 - 51.497)}$$

$$= 860.042\,\text{lbm/h}$$

Therefore, mass flow rate of the refrigerant is $\boxed{860.042 \frac{\text{lbm}}{\text{h}}}$

Step 6 of 6

Calculate the power input to the compressor by using the equation,

$$\dot{W}_{in} = \dot{m}(h_2 - h_1)$$

$$= \left(860.0424 \frac{\text{lbm}}{\text{h}}\right)\left(\left(122.01 \frac{\text{Btu}}{\text{lbm}}\right) - \left(103.82 \frac{\text{Btu}}{\text{lbm}}\right)\right)\left(\frac{1\text{kW}}{3412.14 \frac{\text{Btu}}{\text{h}}}\right)$$

$$= 4.58\text{kW}$$

Therefore, power required to the compressor is $\boxed{4.58\text{kW}}$

Question: 9.158P

Using EES for other) software, repeat *mM* Prob. 9-157E if ammonia is used in place of refrigerant-134a.

Step 1 of 10

Given:
Working fluid: ammonia
Operating temperature of the evaporator $T_1=5°F$
Operating pressure of the condenser $P_2=180\,\text{psia}$
Cooling load $Q_L=45000\frac{\text{Btu}}{\text{h}}$

Step 2 of 10

The problem is solved using EES, and the solution is given below.

```
"Given"
x[1]=1
T[1]=5 [F]
x[3]=0
P[3]=180 [psia]
Q_dot_L=45000 [Btu/h]
```

Step 3 of 10

```
"Analysis"
Fluid$='ammonia'
"compressor"
h[1]=enthalpy(Fluid$, T=T[1], x=x[1])
s[1]=entropy(Fluid$, T=T[1], x=x[1])
s[2]=s[1]
P[2]=P[3]
h[2]=enthalpy(Fluid$, P=P[2], s=s[2])
```

Step 4 of 10

```
"expansion valve"
h[3]=enthalpy(Fluid$, P=P[3], x=x[3])
h[4]=h[3]
m_dot_R=Q_dot_L/(h[1]-h[4])
W_dot_in=m_dot_R×(h[2]-h[1])×Convert(Btu/h, kW)
```

Step 5 of 10

Solution for ammonia

```
Fluid$='ammonia'
m_dot_R=33 [Btu/h]
Q_dot_L=45000 [Btu/h]
W_dot_in=-1.196 [kW]
```

Step 6 of 10

Given:
Working fluid: R-134a
Operating temperature of the evaporator $T_1=5°F$
Operating pressure of the condenser $P_2=180\,\text{psia}$
Cooling load $Q_L=45000\frac{\text{Btu}}{\text{h}}$

Step 7 of 10

The problem is solved using EES, and the solution is given below.

```
"Given"
x[1]=1
T[1]=5 [F]
x[3]=0
P[3]=180 [psia]
Q_dot_L=45000 [Btu/h]
```

Step 8 of 10

```
"Analysis"
Fluid$='ammonia'
"compressor"
h[1]=enthalpy(Fluid$, T=T[1], x=x[1])
s[1]=entropy(Fluid$, T=T[1], x=x[1])
s[2]=s[1]
P[2]=P[3]
h[2]=enthalpy(Fluid$, P=P[2], s=s[2])
```

Step 9 of 10

```
"expansion valve"
h[3]=enthalpy(Fluid$, P=P[3], x=x[3])
h[4]=h[3]
m_dot_R=Q_dot_L/(h[1]-h[4])
W_dot_in=m_dot_R×(h[2]-h[1])×Convert(Btu/h, kW)
```

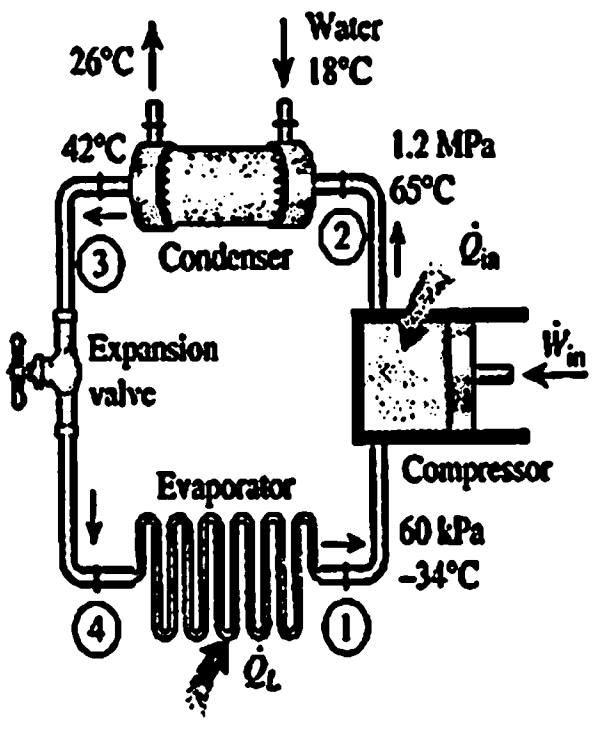
Step 10 of 10

Solution for R-134a

```
Fluid$='R134a'
m_dot_R=206 [Btu/h]
Q_dot_L=45000 [Btu/h]
W_dot_in=-0.8038 [kW]
```

Question: 9.159P pg 1

A commercial refrigerator with refrigerant-134a as the working fluid is used to keep the refrigerated space at −30°C by rejecting its waste heat to cooling water that enters the condenser at 18°C at a rate of 0.25 kg/s and leaves at 26°C. The refrigerant enters the condenser at 1.2 MPa and 65°C and leaves at 42°C. The inlet state of the compressor is 60 kPa and −34°C and the compressor is estimated to gain a net heat of 450 W from the surroundings. Determine *(a)* the quality of the refrigerant at the evaporator inlet, *(b)* the refrigeration load, (c) the COP of the refrigerator, and *(d)* the theoretical maximum refrigeration load for the same power input to the compressor.



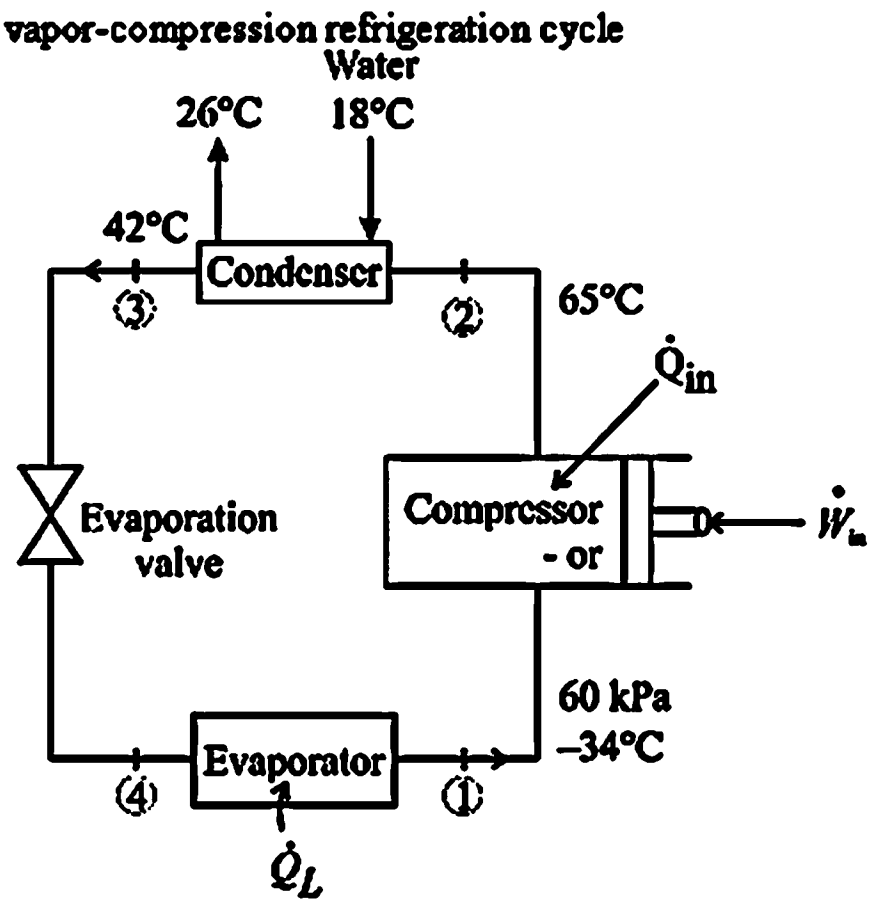


FIGURE P9–159

Step 1 of 12

Given:
Working fluid: Refrigerant-134a
Mass flow rate of water, $\dot{m}_w = 0.25\ kg/s$
The compressor is estimated to gain a net heat of 450 W from the surroundings, $\dot{Q}_{in} = 450\ W$

Step 2 of 12

Block diagram of vapor-compression refrigeration cycle

Step 3 of 12

From Superheated refrigerant- 134a table
At $P_1 = 60kPa$, $T_1 = -34°C$

$$h_1 = 227.79 + \frac{(-34-(-36.95))}{(-20-(-34))}(240.76-227.79)$$

$$h_1 = 230.5 kJ/kg$$

Step 4 of 12

From Superheated refrigerant- 134a table
At $P_2 = 1200kPa$, $T_2 = 65°C$

$$h_2 = 289.64 + \frac{(65-60)}{(70-60)}(300.61-289.64)$$

$$h_2 = 295.12\ kJ/kg$$

Step 5 of 12

At $P_3 = 1200kPa$, $T_3 = 42°C$

$h_3 \cong h_{f@42°C} = 111.26$ kJ/kg (From saturated refrigerant – 134a temperature table)

Step 6 of 12

Enthalpy of water before entering the condenser,
$h_{w\,before} = h_{f@18°C} = 75.47$ kJ/kg (From saturated water-temperature table)
Enthalpy of water after leaving the condenser,
$h_{w\,after} = h_{f@26°C} = 108.94$ kJ/kg (From saturated water-temperature table)

Step 7 of 12

Assumptions:
1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 8 of 12

(a) The quality of the refrigerant at the evaporator inlet:
From the diagram,
$h_4 = h_3 = 111.26$ kJ/kg
From saturated refrigerant – 134a pressure table
$P_4 = 60kPa$, $h_4 = 111.26$ kJ/kg

$$h_4 = h_{f4} + x_4 h_{fg4}$$

$$111.26 = 3.841 + x_4(223.95)$$

$h_4 = h_3 = 111.26$ kJ/kg

9.159P pg 2

From saturated refrigerant – 134a pressure table

$P_4 = 60$kPa, $h_4 = 111.26$ kJ/kg

$h_4 = h_{f4} + x_4 h_{fg4}$

$111.26 = 3.841 + x_4 (223.95)$

$$x_4 = \frac{111.26 - 3.841}{223.95}$$

$\boxed{x_4 = 0.4796}$

Step 9 of 12

(b) The refrigeration load:

Mass flow rate of the refrigerant, $\dot{m}_r = \dfrac{h_{w\text{-}after} - h_{w\text{-}before}}{h_2 - h_3} \times \dot{m}_w$

$$\dot{m}_r = \frac{108.94 - 75.47}{295.12 - 111.26} \times 0.25$$

$\dot{m}_r = 0.04551$ kg/s

Heat rejected to atmosphere, $\dot{Q}_H = \dot{m}_r \times (h_2 - h_3)$

$\dot{Q}_H = 0.04551 \times (295.12 - 111.26)$

$\dot{Q}_H = 8.3674$ kW

Step 10 of 12

Compressor power input, $\dot{W}_{in} = \dot{m}_r \times (h_2 - h_1) - \dot{Q}_{in}$

$\dot{W}_{in} = 0.04551 \times (295.12 - 230.5) - 0.45$

$\dot{W}_{in} = 2.9408 - 0.45$

$\dot{W}_{in} = 2.4908$ kW

Refrigeration load, $\dot{Q}_L = \dot{Q}_H - \dot{W}_{in}$

$\dot{Q}_L = 8.3674 - 2.4908$

$\boxed{\dot{Q}_L = 5.8766 \text{ kW}}$

Step 11 of 12

(c) COP of the refrigerator:

Coefficient of performance, $COP = \dfrac{\dot{Q}_L}{\dot{W}_{in}}$

$$COP = \frac{5.8766}{2.4908}$$

$\boxed{COP = 2.359}$

Step 12 of 12

(d) Theoretical maximum refrigeration load:

Maximum COP, $COP_{max} = \dfrac{1}{\dfrac{T_H}{T_L} - 1}$

$$COP_{max} = \frac{1}{\frac{291}{243} - 1}$$

$COP_{max} = 5.0625$

Theoretical maximum refrigeration load, $(\dot{Q}_L)_{max} = COP_{max} \times \dot{W}_{in}$

$(\dot{Q}_L)_{max} = 5.0625 \times 2.4908$

$\boxed{(\dot{Q}_L)_{max} = 12.609 \text{ kW}}$

Question: 9.160P pg 1

Refrigerant-134a enters the compressor of a refrigerator at 100 kPa and −20°C at a rate of 0.5 m3/min and leaves at 0.8 MPa. The isentropic efficiency of the compressor is 78 percent. The refrigerant enters the throttling valve at 0.75 MPa and 26°C and leaves the evaporator as saturated vapor at −26°C. Show the cycle on a T-s diagram with respect to saturation lines, and determine *(a)* the power input to the compressor, *(b)* the rate of heat removal from the refrigerated space, and (c) the pressure drop and rate of heat gain in the line between the evaporator and the compressor.

Step 1 of 11

Given:

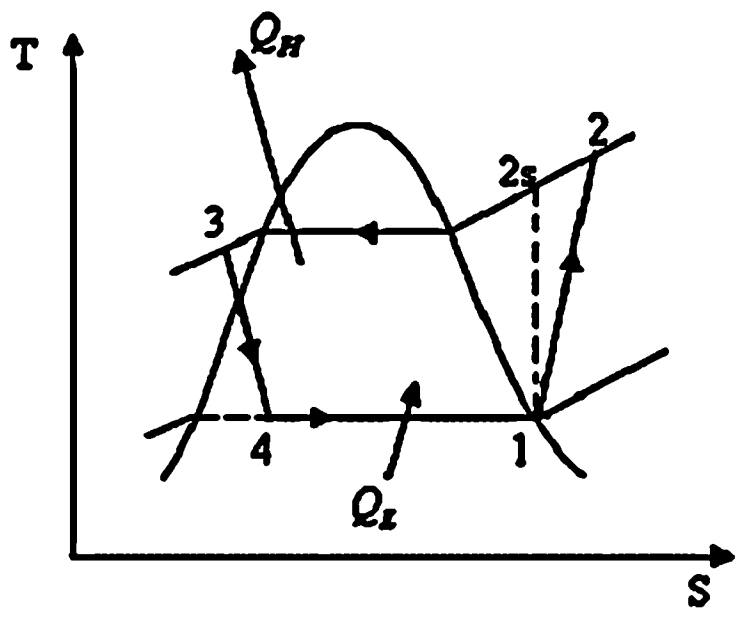
Working fluid: R-134a

Inlet pressure of the compressor $P_1 = 100\text{kPa}$

Inlet Temperature of the compressor $T_1 = -20^\circ\text{C}$

Volume flow rate in compressor $V_1 = 0.5\dfrac{\text{m}^3}{\text{min}}$

Exit pressure of the compressor $P_2 = 0.8\text{MPa}$



Inlet pressure of the throttle $P_3 = 0.75\text{MPa}$

Inlet temperature of the throttle $T_3 = 26^\circ\text{C}$

Inlet temperature of the evaporator $T_5 = -26^\circ\text{C}$

Step 2 of 11

T-S Diagram:

Step 3 of 11

(a)

State1:

Refrigerant enters into the compressor is superheated state. So

From the superheated refrigerant R-134a

At $P_1 = 100\text{kPa}$ and $T_1 = -20^\circ\text{C}$

$$v_1 = 0.19841\frac{\text{m}^3}{\text{kg}}$$

$$h_1 = 239.50\frac{\text{kJ}}{\text{kg}}$$

$$s_1 = 0.9721\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 4 of 11

State2:

Refrigerant leaves the compressor is superheated sate.

From the superheated refrigerant R-134a

At $P_2 = 0.8MPa$

And $s_{2s} = s_1 = 0.9721\dfrac{\text{kJ}}{\text{kg}\cdot\text{K}}$

Using method of interpolation

$$h_{2s} = 276.45 + \frac{(0.9721-0.9480)(286.69-276.45)}{(0.9802-0.9480)}$$

$$h_{2s} = 284.11\frac{\text{kJ}}{\text{kg}}$$

Step 5 of 11

State3:

Refrigerant leaves the condenser is saturated liquid

From the saturated refrigerant R-134a Temperature table

At $P_3 = 0.75\text{MPa}, T_3 = 26^\circ\text{C}$

$$h_3 = h_f = 87.83\frac{\text{kJ}}{\text{kg}}$$

Throttling:

Since inn throttling enthalpy remains constant.

$$h_3 = h_4 = 87.83\frac{\text{kJ}}{\text{kg}}$$

Step 6 of 11

State5:

Leaving temperature of the evaporator is saturated vapor.

From the saturated refrigerant R-134a Temperature table

$T_5 = -26^\circ\text{C}$

$P_5 = P_{sat} = 101.73\text{kPa}$

$$h_5 = h_g = 234.68\frac{\text{kJ}}{\text{kg}}$$

Step 7 of 11

Then the mass flow rate of the refrigerant is

$$\dot{m} = \frac{V_1}{v_1}$$

$$= \frac{\left(\dfrac{0.5\,\text{m}^3}{60\,\text{sec}}\right)}{\left(0.19841\dfrac{\text{m}^3}{\text{kg}}\right)}$$

$$= 0.042\frac{\text{kg}}{s}$$

$$= \frac{\left(0.042\frac{\text{kg}}{\text{s}}\right)}{\left(0.19841\frac{\text{m}^3}{\text{kg}}\right)}$$

$$= 0.042\frac{\text{kg}}{\text{s}}$$

Step 8 of 11

The power input to the compressor is

$$\dot{W}_{in} = \frac{\dot{m}(h_{2s} - h_1)}{\eta_c}$$

$$= \frac{\left(0.042\frac{\text{kg}}{\text{s}}\right)\left(\left(284.11\frac{\text{kJ}}{\text{kg}}\right) - \left(239.50\frac{\text{kJ}}{\text{kg}}\right)\right)}{0.78}$$

$$= 2.40\frac{\text{kJ}}{\text{s}}$$

$$\boxed{\dot{W}_{in} = 2.40\text{kW}}$$

Step 9 of 11

(b) The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}(h_5 - h_4)$$

$$= \left(0.042\frac{\text{kg}}{\text{s}}\right)\left(\left(234.68\frac{\text{kJ}}{\text{kg}}\right) - \left(87.83\frac{\text{kJ}}{\text{kg}}\right)\right)$$

$$= 6.167\frac{\text{kJ}}{\text{s}}$$

$$\boxed{\dot{Q}_L = 6.167\text{kW}}$$

Step 10 of 11

(c) The pressure drop and the heat gain in the line between the evaporator and the compressor are

$$\Delta P = P_5 - P_1$$

$$= 101.73\text{kPa} - 100\text{kPa}$$

$$= 1.73\text{kPa}$$

$$\boxed{\Delta P = 1.73\text{kPa}}$$

Step 11 of 11

Rate of heat in between evaporator and compressor is

$$\dot{Q}_{gain} = \dot{m}(h_1 - h_5)$$

$$= \left(0.042\frac{\text{kg}}{\text{s}}\right)\left(\left(239.50\frac{\text{kJ}}{\text{kg}}\right) - \left(234.68\frac{\text{kJ}}{\text{kg}}\right)\right)$$

$$= 0.20244\frac{\text{kJ}}{\text{s}}$$

$$\boxed{\dot{Q}_{gain} = 0.20244\text{kW}}$$

Question:

Reconsider Prob. 9–160. Using EES (or other) software, investigate the effects of varying the compressor isentropic efficiency over the range 60 to 100 percent and the compressor inlet volume flow rate from 0.1 to 1.0 m3/min on the power input and the rate of refrigeration. Plot the rate of refrigeration and the power input to the compressor as functions of compressor efficiency for compressor inlet volume flow rates of 0.1, 0.5, and 1.0 mVmin, and discuss the results.

Step 1 of 22

Given:

Working fluid: R-134a

Inlet pressure of the compressor $P_1 = 100\text{kPa}$

Inlet Temperature of the compressor $T_1 = -20^\circ\text{C}$

Volume flow rate in compressor varies from $V_1 = 0.1\frac{\text{m}^3}{\text{min}}$ to $1\frac{\text{m}^3}{\text{min}}$

Exit pressure of the compressor $P_2 = 0.8\text{MPa}$

Inlet pressure of the throttle $P_3 = 0.75\text{MPa}$

Inlet temperature of the throttle $T_3 = 26^\circ\text{C}$

Inlet temperature of the evaporator $T_5 = -26^\circ\text{C}$

Step 2 of 22

```
P[1]=100 [kPa]
T[1]=-20 [C]

Question: 9.162P

A refrigerator uses refrigerant-134a as the working fluid and operates on the ideal vapor-compression refrigeration cycle except for the compression process. The refrigerant enters the evaporator at 120 kPa with a quality of 30 percent and leaves the compressor at 60°C. If the compressor consumes 450 W of power, determine (a) the mass flow rate of the refrigerant, *(b)* the condenser pressure, and (c) the COP of the refrigerator.

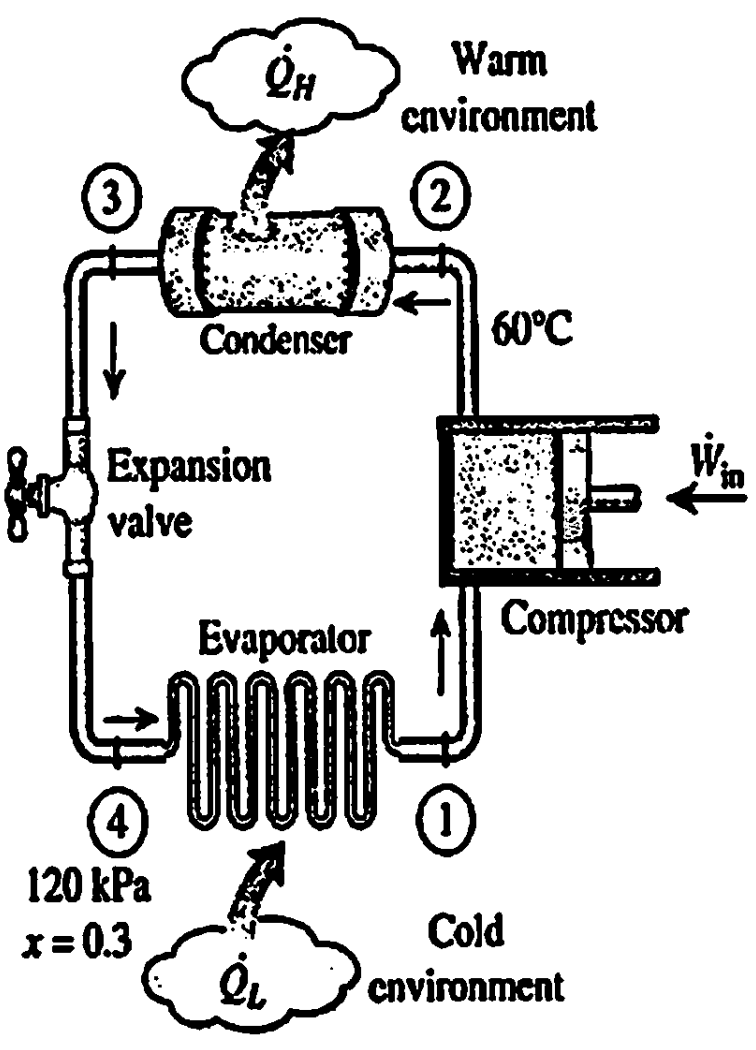

FIGURE P9–162

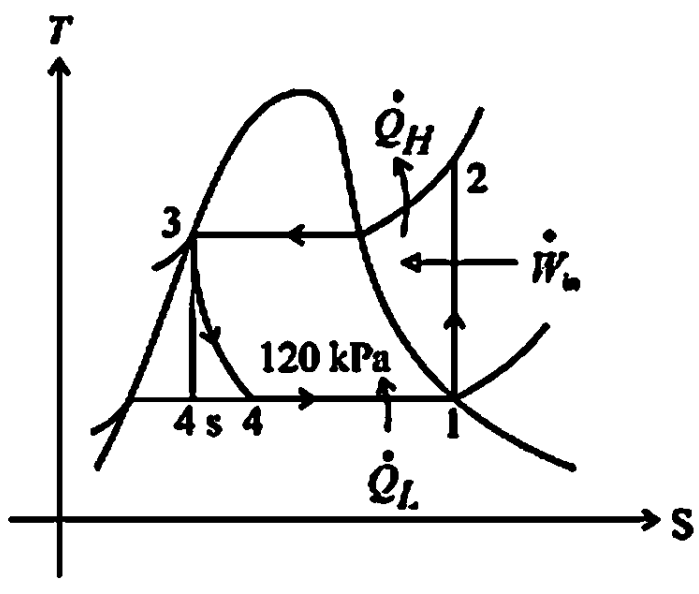
Step 1 of 11

Given:

Working fluid: Refrigerant-134a

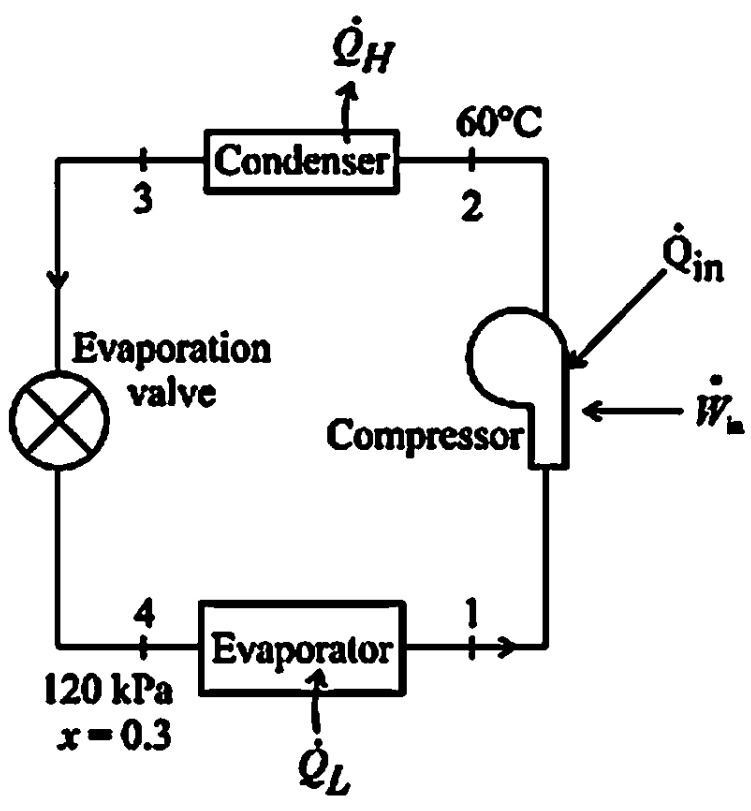
Pressure of refrigerant at entrance of evaporator, $P_4 = 120$ kPa



Quality $x_4 = 0.3$

It leaves the compressor at $T_2 = 60°C$

Power of compressor, $\dot{W}_{in} = 450$ W



Step 2 of 11

T-S diagram of vapor-compression refrigeration cycle

Step 3 of 11

Block diagram of vapor-compression refrigeration cycle

Step 4 of 11

From Saturated refrigerant- 134a pressure table

At $P_4 = 120$ kPa and $x_4 = 0.3$

$h_4 = 22.49 + (0.3)(214.48)$

$h_3 = h_4 = 86.83$ kJ/kg

Step 5 of 11

From saturated refrigerant-134a pressure table

At $h_3 = 86.83$ kJ/kg, saturated liquid

$$P_3 = 650 + \frac{(86.83 - 85.26)}{(88.82 - 85.26)}(700 - 650)$$

$P_2 = P_3 = 672$ kPa

Step 6 of 11

From superheated refrigerant-134a table

At $P_2 = 672$ kPa, $T_2 = 60°C$

$$h_2 = 299.98 - \frac{(672 - 600)}{(700 - 600)}(299.98 - 298.42)$$

$h_2 = 298.85$ kJ/kg

Step 7 of 11

From saturated refrigerant-134a pressure table

At $P_1 = 120$ kPa, saturated vapor

$h_1 = 236.97$ kJ/kg

Step 8 of 11

Assumptions:

1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 9 of 11

(a) Mass flow rate of the refrigerant:

Mass flow rate of refrigerant, $\dot{m}_r = \dfrac{\dot{W}_{in}}{h_2 - h_1}$

$$\dot{m}_r = \frac{0.45}{298.85 - 236.97}$$

$\boxed{\dot{m}_r = 7.27 \times 10^{-3} \text{ kg/s}}$

Step 10 of 11

(b) The condenser pressure

Condenser pressure $\boxed{P_3 = 672 \text{ kPa}}$

Step 11 of 11

(c) COP of the refrigerator

Cooling load, $\dot{Q}_L = \dot{m}_r \times (h_1 - h_4)$

$\dot{Q}_L = 0.00727 \times (236.97 - 86.83)$

$\dot{Q}_L = 1.0915$ kW

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{in}}$$

$$\text{COP} = \frac{1.0915}{0.45}$$

$\boxed{\text{COP} = 2.425}$

Question: 9.163P

The manufacturer of an air conditioner claims a seasonal energy efficiency ratio (SEER) of 16 (Btu/h)/W for one of its units. This unit operates on the normal vapor compression refrigeration cycle and uses refrigerant-22 as the working fluid. This SEER is for the operating conditions when the evaporator saturation temperature is -5°C and the condenser saturation temperature is 45°C. Selected data for refrigerant-22 are provided in the table below.

T, °C	P_{sat}, kPa	h_f, kJ/kg	h_g, kJ/kg	s_g, kJ/kg·K
−5	421.2	38.76	248.1	0.9344
45	1728	101	261.9	0.8682

(*a*) Sketch the hardware and the *T*-*s* diagram for this air conditioner.

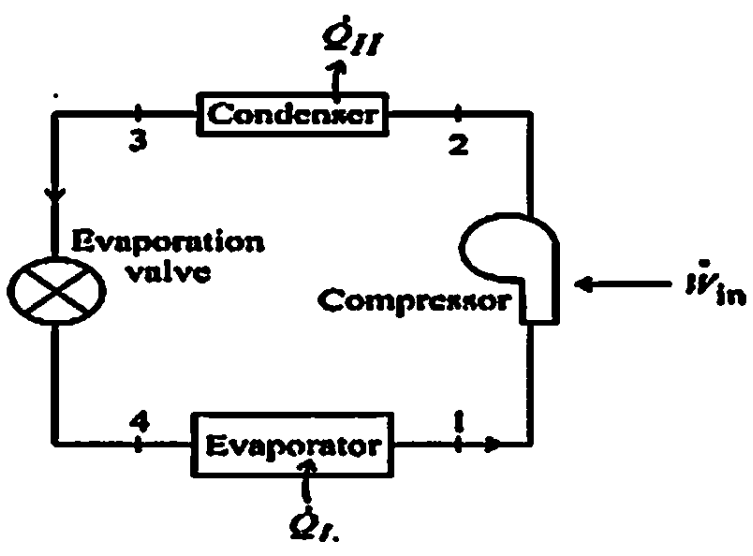
(*b*) Determine the heat absorbed by the refrigerant in the evaporator per unit mass of refrigeranl-22, in kJ/kg.

(*c*) Determine the work input to the compressor and the heat rejected in the condenser per unit mass of refrigerant-22, in kJ/kg.

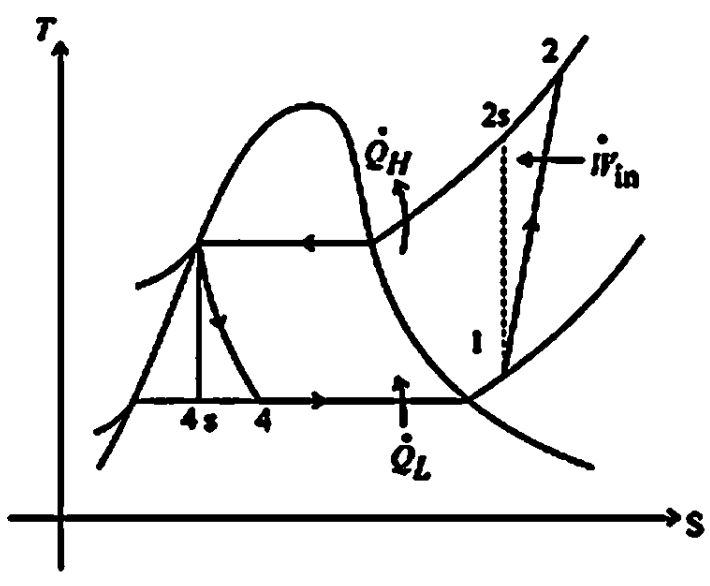
Step 1 of 7

Given:

Working fluid: $R-22$



Seasonal energy efficiency $SEER = 16\dfrac{\text{Btu}}{\text{h}}$



Saturation temperature of evaporator $T_1 = T_4 = -5^\circ C$

Saturation temperature of the condenser $T_3 = 45^\circ C$

Step 2 of 7

a)

Step 3 of 7

(b) State 3:

From the saturation temperature table

$$h_3 = h_f = 101\frac{\text{kJ}}{\text{kg}}$$

State4:

Since Throttling process enthalpy remains constant

$$h_4 = h_3 = 101\frac{\text{kJ}}{\text{kg}}$$

Step 4 of 7

State 1:

From the saturated refrigerant-22

At

$$h_1 = h_g = 248.1\frac{\text{kJ}}{\text{kg}}$$

The heat absorbed by the refrigerant in the evaporator is

$$q_L = h_1 - h_4$$
$$= 248.1 - 101$$
$$= 147.1\frac{\text{kJ}}{\text{kg}}$$

$$\boxed{q_L = 147.1\frac{\text{kJ}}{\text{kg}}}$$

Step 5 of 7

(c) The COP of the air conditioner is

$$\text{COP}_R = SEER\left(\frac{1W}{3.412Btu/h}\right)$$
$$= \left(16\frac{Btu/h}{W}\right)\left(\frac{1W}{3.412Btu/h}\right)$$
$$= 4.689$$

Step 6 of 7

The work input to the compressor is

$$\text{COP}_R = \frac{q_L}{w_{in}}$$

$$\Rightarrow w_{in} = \frac{q_L}{COP_R}$$
$$= \frac{\left(147.1\frac{\text{kJ}}{\text{kg}}\right)}{4.689}$$
$$= 31.36\frac{\text{kJ}}{\text{kg}}$$

$$\boxed{W_{in} = 31.36\frac{\text{kJ}}{\text{kg}}}$$

Step 7 of 7

The enthalpy at the compressor exit is

$$w_{in} = h_2 - h_1$$
$$\Rightarrow h_2 = h_1 + w_{in}$$
$$= \left(248.1\frac{\text{kJ}}{\text{kg}}\right) + \left(31.36\frac{\text{kJ}}{\text{kg}}\right)$$
$$= 279.5\frac{\text{kJ}}{\text{kg}}$$

The heat rejected from the refrigerant in the condenser is then

$$q_H = h_2 - h_3$$
$$= \left(279.5\frac{\text{kJ}}{\text{kg}}\right) - \left(101\frac{\text{kJ}}{\text{kg}}\right)$$
$$= 178.5\frac{\text{kJ}}{\text{kg}}$$

$$\boxed{q_H = 178.5\frac{\text{kJ}}{\text{kg}}}$$

Question: 9.164P

An actual refrigerator operates on the vapor-compression refrigeration cycle with refrigerant-22 as the working fluid. The refrigerant evaporates at -15°C and condenses at 40°C. The isentropic efficiency of the compressor is 83 percent. The refrigerant is superheated by 5°C at the compressor inlet and subcooled by 5°C at the exit of the condenser. Determine (a) the heat removed from the cooled space and the work input, in kJ/kg and the COP of the cycle. Determine (*b*) the same parameters if the cycle operated on the ideal vapor-compression refrigeration cycle between the same evaporating and condensing temperatures.

The properties of R-22 in the case of actual operation are:*h*1 =402.49 kJ/kg. *h*2=454.00 U/kg. *h*3 = 243.19 kJ/kg

The properties of R-22 in the case of ideal operation are: *h*1 =399.04 kJ/kg, *h*2 = 440.71 Id/kg, *h*3, =249.80 kJ/kg Note: state 1: compressor inlet, state 2: compressor exit, state 3: condenser exit, state 4: evaporator inlet.

Step 1 of 9

Given:

Working fluid: $R-22$

Temperature of the evaporator $T_1 = T_4 = -15^\circ C$

Temperature of the condenser $T_2 = 40^\circ C$

Exit temperature of the condenser $T_3 = 5^\circ C$

Properties of $R-22$:

Enthalpy	Actual condition	Ideal condition
h_1	$402.49\frac{kJ}{kg}$	$399.04\frac{kJ}{kg}$
h_2	$454.00\frac{kJ}{kg}$	$440.71\frac{kJ}{kg}$
h_3	$243.19\frac{kJ}{kg}$	$249.80\frac{kJ}{kg}$

Step 2 of 9

Actual refrigerator:

(a) Heat removed from the cold space is

From the properties of $R-22$

$$h_1 = 402.49\frac{kJ}{kg}$$

$$h_4 = 243.19\frac{kJ}{kg}$$

$$\dot{Q}_L = h_1 - h_4$$

$$= \left(402.49\frac{kJ}{kg}\right) - \left(243.19\frac{kJ}{kg}\right)$$

$$= 159.3\frac{kJ}{kg}$$

$$\boxed{\dot{Q}_L = 159.3\frac{kJ}{kg}}$$

Step 3 of 9

Work input to the compressor

From the properties of $R-22$

$$h_2 = 454\frac{kJ}{kg}$$

$$h_1 = 402.49\frac{kJ}{kg}$$

$$W_{in} = h_2 - h_1$$

$$= \left(454\frac{kJ}{kg}\right) - \left(402.49\frac{kJ}{kg}\right)$$

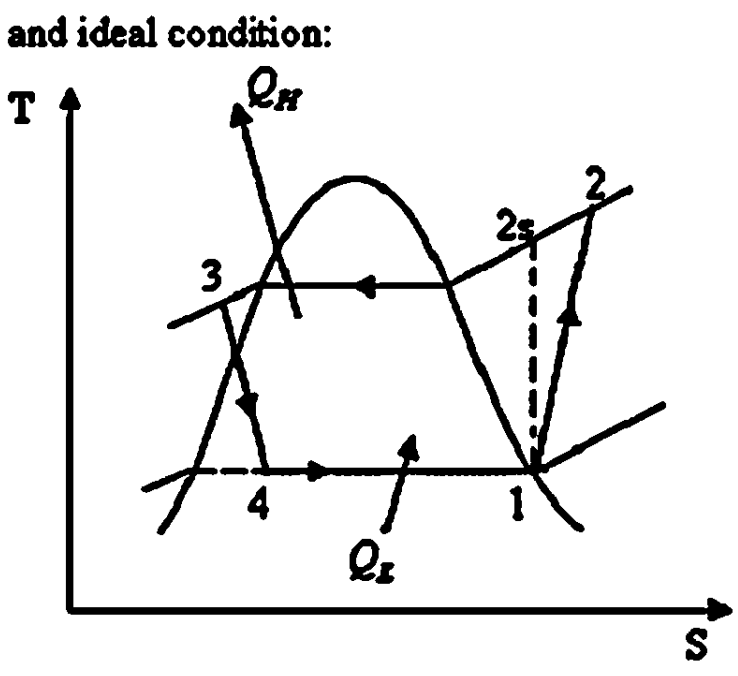
$$= 51.51\frac{kJ}{kg}$$

$$\boxed{W_{in} = 51.51\frac{kJ}{kg}}$$

Step 4 of 9

COP of the cycle

$$(COP)_{actual} = \frac{Q_L}{W_{in}}$$



$$= \frac{159.3}{51.51}$$

$$= 3.092$$

$$\boxed{(COP)_{actual} = 3.092}$$

Step 5 of 9

T-*s* Diagram for actual and ideal condition:

Step 6 of 9

Ideal Cycle:

Heat removed from the refrigerated space

From the properties of $R-22$

$$h_1 = 399.04\frac{kJ}{kg}$$

$$h_4 = 249.8\frac{kJ}{kg}$$

Step 7 of 9

$$\dot{Q}_L = h_1 - h_4$$

$$= \left(399.04\frac{kJ}{kg}\right) - \left(249.8\frac{kJ}{kg}\right)$$

$$= 149.24\frac{kJ}{kg}$$

$$\boxed{\dot{Q}_L = 149.24\frac{kJ}{kg}}$$

Step 8 of 9

Work input to compressor

From the properties of $R-22$

$$h_1 = 399.04\frac{kJ}{kg}$$

$$h_2 = 440.71\frac{kJ}{kg}$$

$$W_{in} = (h_2 - h_1)$$

$$= \left(440.71\frac{kJ}{kg}\right) - \left(399.04\frac{kJ}{kg}\right)$$

$$= 41.67\frac{kJ}{kg}$$

$$\boxed{W_{in} = 41.67\frac{kJ}{kg}}$$

Step 9 of 9

COP of the ideal cycle

$$(COP)_{ideal} = \frac{Q_L}{W_{in}}$$

$$= \frac{149.24}{41.67}$$

$$= 3.58147$$

$$\boxed{(COP)_{ideal} = 3.58147}$$

Question:

A refrigerator uses refrigerant-134a as the working fluid and operates on the vapor-compression refrigeration cycle. The evaporator and condenser pressures are 200 kPa and 1400 kPa, respectively. The isentropic efficiency of the compressor is 88 percent. The refrigerant enters the compressor at a rate of 0.025 kg/s superheated by 10.1°C and leaves the condenser sub cooled by 4.4°C. Determine (*a*) the rate of cooling provided by the evaporator, the power input, and the COP. Determine (*b*) the same parameters if the cycle operated on the ideal vapor-compression refrigeration cycle between the same pressure limits.

Step 1 of 17

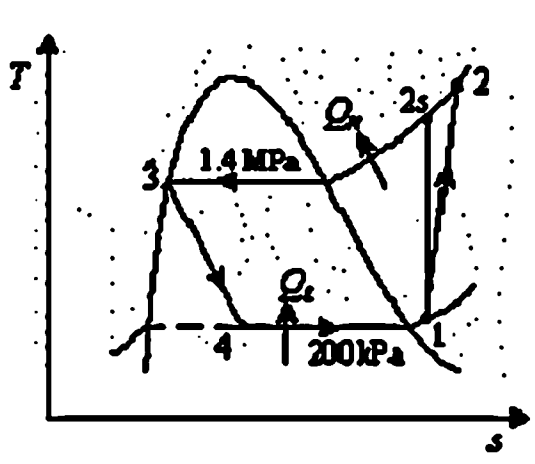
Given:

Working fluid: $R-134a$

Evaporator pressure $P_1 = P_4 = 200\text{kPa}$

Condenser pressure $P_2 = P_3 = 1400\text{kPa}$

Isentropic efficiency of the compressor $\eta_C = 0.88$



Mass flow rate to compressor $m = 0.025\dfrac{\text{kg}}{s}$

Superheat temperature $T_2 = 10.1^\circ\text{C}$

Sub cooled temperature $T_{3'} = 4.4^\circ\text{C}$

Step 2 of 17

T-s Diagram:

Step 3 of 17

(a)

State 1:

Since refrigerant enters into the compressor is superheated state. So

From the superheated refrigerant $R-134a$

At $P_1 = 200\text{kPa}$

$T_{sat} = -10.09^\circ\text{C}$

$\cong -10.1^\circ\text{C}$

$T_1 = (-10.1^\circ\text{C}) + (10.1^\circ\text{C})$

$= 0^\circ\text{C}$

Now take the properties at $T_1 = 0^\circ\text{C}$ and $P_1 = 200\text{kPa}$

$h_1 = 253.05\dfrac{\text{kJ}}{\text{kg}}$

$s_1 = 0.9698\dfrac{\text{kJ}}{\text{kg}\cdot\text{K}}$

Step 4 of 17

State 2:

From the superheated refrigerant $R-134a$

At $P_2 = 1400\text{kPa}$ And $s_1 = s_2 = 0.9698\dfrac{\text{kJ}}{\text{kg}\cdot\text{K}}$

Using the interpolation

$$h_{2s} = 285.47 + \frac{(0.9698-0.9389)(297.10-285.47)}{(0.9733-0.9389)}$$

$h_{2s} = 295.91\dfrac{\text{kJ}}{\text{kg}}$

$T_{sat} = 52.40^\circ\text{C}$

Step 5 of 17

State 3 and State 4:

$P_3 = 1400kPa$

$T_3 = 52.40^\circ\text{C} - T_{3'}$

$= 52.40^\circ\text{C} - 4.4^\circ\text{C}$

$= 48^\circ\text{C}$

From the Saturated refrigerant $R-134a$ Temperature table

At $T_3 = 48^\circ\text{C}$

$h_3 \cong h_f = 120.39\dfrac{\text{kJ}}{\text{kg}}$

Since state 3 to state 4 is the throttling process so enthalpy remains constant.

$h_4 = h_3 = 120.39\dfrac{\text{kJ}}{\text{kg}}$

Step 6 of 17

Isentropic efficiency of the compressor is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.88 = \frac{\left(295.91\dfrac{\text{kJ}}{\text{kg}}\right) - \left(253.05\dfrac{\text{kJ}}{\text{kg}}\right)}{h_2 - \left(253.05\dfrac{\text{kJ}}{\text{kg}}\right)}$$

$$\Rightarrow h_2 = 301.75\frac{\text{kJ}}{\text{kg}}$$

Step 7 of 17

Amount of heat removed in evaporator

$\dot{Q}_L = \dot{m}(h_1 - h_4)$

$= \left(0.025\dfrac{\text{kg}}{s}\right)\left(253.05\dfrac{\text{kJ}}{\text{kg}} - 120.39\dfrac{\text{kJ}}{\text{kg}}\right)$

$= 3.317\dfrac{\text{kJ}}{s}$

$$= \left(0.025\frac{\text{kg}}{s}\right)\left(253.05\frac{\text{kJ}}{\text{kg}} - 120.39\frac{\text{kJ}}{\text{kg}}\right)$$

$$= 3.317\frac{\text{kJ}}{s}$$

$$= 3.317\text{kW}$$

$$\boxed{\dot{Q}_L = 3.317\text{kW}}$$

Step 8 of 17

Amount of heat removed in condenser

$$\dot{Q}_H = \dot{m}(h_2 - h_3)$$

$$= \left(0.025\frac{\text{kg}}{s}\right)\left(301.75\frac{\text{kJ}}{\text{kg}} - 120.39\frac{\text{kJ}}{\text{kg}}\right)$$

$$= 4.534\frac{\text{kJ}}{s}$$

$$= 4.534\text{kW}$$

$$\dot{W}_{in} = \dot{m}(h_2 - h_1)$$

$$= \left(0.025\frac{\text{kg}}{s}\right)\left(301.75\frac{\text{kJ}}{\text{kg}} - 253.05\frac{\text{kJ}}{\text{kg}}\right)$$

$$= 1.217\frac{\text{kJ}}{s}$$

$$= 1.217\text{kW}$$

$$\boxed{\dot{W}_{in} = 1.217\text{kW}}$$

Step 9 of 17

$$COP = \frac{\dot{Q}_L}{\dot{W}_{in}}$$

$$= \frac{(3.317\text{kW})}{(1.217\text{kW})}$$

$$= 2.725$$

$$\boxed{(COP)_{actual} = 2.725}$$

Step 10 of 17

(b)

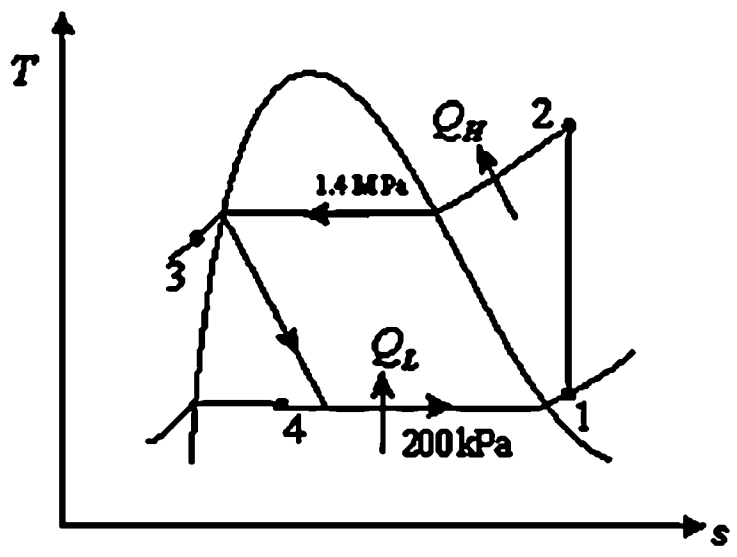
Ideal vapor-compression refrigeration cycle

State 1:

Since refrigerant enters into the compressor is superheated state. So

From the superheated refrigerant $R-134a$

At $P_1 = 200\text{kPa}$



$$x_1 = 1$$

$$h_1 = 244.46\frac{\text{kJ}}{\text{kg}}$$

$$s_1 = 0.9377\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 11 of 17

T-s Diagram:

Step 12 of 17

State 2:

From the superheated $R-134a$ table

$$P_2 = 1400\text{kPa}$$

$$s_1 = s_2 = 0.9377\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Using the interpolation

$$h_2 = 276.12 + \frac{(0.9377 - 0.9105)(285.47 - 276.12)}{(0.9389 - 0.9105)}$$

$$h_2 = 285.08\frac{\text{kJ}}{\text{kg}}$$

Step 13 of 17

State 3:

From the Saturated refrigerant $R-134a$ Pressure table

$$P_3 = 1400kPa$$

$$x_1 = 0$$

$$h_3 = h_g = 127.22\frac{\text{kJ}}{\text{kg}}$$

Since state 3 to state 4 is the throttling process so enthalpy remains constant

$$h_4 = h_3 = 127.22\frac{\text{kJ}}{\text{kg}}$$

Step 14 of 17

Amount of heat removed in evaporator

$$\dot{Q}_L = \dot{m}(h_1 - h_4)$$

$$= \left(0.025\frac{\text{kg}}{s}\right)\left(244.46\frac{\text{kJ}}{\text{kg}} - 127.22\frac{\text{kJ}}{\text{kg}}\right)$$

$$= 2.931\frac{\text{kg}}{s}$$

$$= 2.931\text{kW}$$

$$= \left(0.025\frac{kg}{s}\right)\left(244.46\frac{kJ}{kg} - 127.22\frac{kJ}{kg}\right)$$

$$= 2.931\frac{kg}{s}$$

$$= 2.931 kW$$

$$\boxed{\dot{Q}_L = 2.931 kW}$$

9.165P pg 3

Step 15 of 17

Amount of heat rejection in condenser

$$\dot{Q}_H = \dot{m}(h_2 - h_3)$$

$$= \left(0.025\frac{kg}{s}\right)\left(285.08\frac{kJ}{kg} - 127.22\frac{kJ}{kg}\right)$$

$$= 3.947\frac{kg}{s}$$

$$= 3.947 kW$$

Step 16 of 17

Work input to the compressor

$$\dot{W}_H = \dot{m}(h_2 - h_1)$$

$$= \left(0.025\frac{kg}{s}\right)\left(285.08\frac{kJ}{kg} - 244.46\frac{kJ}{kg}\right)$$

$$= 1.016\frac{kJ}{s}$$

$$= 1.016 kW$$

$$\boxed{\dot{W}_H = 1.016 kW}$$

Step 17 of 17

COP of the ideal refrigeration cycle

$$COP = \frac{\dot{Q}_L}{\dot{W}_{in}}$$

$$= \frac{(2.931 kW)}{(1.016 kW)}$$

$$= 2.884$$

$$\boxed{COP = 2.884}$$

Question: 9.166P

Do you think a heat pump system will be more cost-effective in New York or in Miami? Why?

Step 1 of 1

Heat pumps are most competitive in areas that have a large cooling load during the cooling season and a relatively small heating load during the heating season, such as in Miami. In these areas, the heat pump can meet the entire cooling and heating needs of residential or commercial buildings. The heat pump is least competitive in areas where the heating load is very large and the cooling load is small, such as in New York.

Question: 9.167P

What is a water-source heat pump? How does the COP of a water-source heat pump system compare to that of an air-source system?

Step 1 of 1

A water-source heat pump is a heat pump in which water is used as energy source for the heat pump instead of air. Water-source systems usually use well water from depths of up to 80 m in the temperature range of 5 to 18°C, and they do not have a frosting problem. They typically have higher COPs but are more complex and require easy access to a large body of water such as underground water.

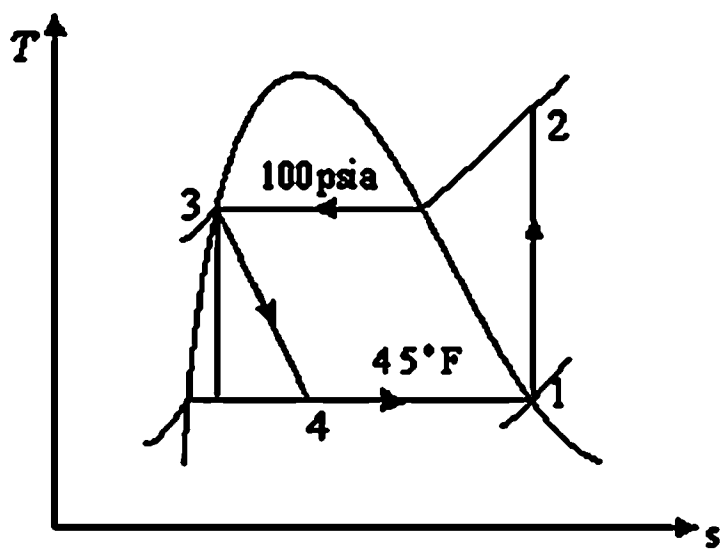
Question:

9.168P

A heat pump uses refrigerant-134a as the working fluid and operates on the ideal vapor-compression refrigeration cycle. The condenser pressure is 100 psia while the evaporator temperature is 40°F. What is the COP of this heat pump?

Step 1 of 7

Given:



Working fluid: $R-134a$

Pressure of the condenser $P_3 = P_2 = 100\,\text{psia}$

Temperature of evaporator $T_1 = 40^\circ\text{F}$

Step 2 of 7

T-s Diagram:

Step 3 of 7

State 1:

Since refrigerant enters into the compressor is saturated vapor, So

From the Saturated refrigerant -134a Temperature table

At $T_1 = 40^\circ\text{F}$

$$h_1 = h_g = 108.78\frac{\text{Btu}}{\text{lbm}}$$

$$s_1 = 0.22189\frac{\text{Btu}}{\text{lbm}\cdot\text{R}}$$

Step 4 of 7

Sate 2:

Since ideal refrigeration cycle so entropy remains constant. And also refrigerant leaving to the compressor superheated condition.

$$s_2 = s_1 = 0.22189\frac{\text{Btu}}{\text{lbm}\cdot\text{R}}$$

From the Superheated refrigerant-134a

At $P_2 = 100\text{psia}$ and $s_2 = 0.22189\frac{\text{Btu}}{\text{lbm}\cdot\text{R}}$

By using the interpolation

$$h_2 = 114.05 + \frac{(0.22189-0.22016)(118.90-114.05)}{(0.22900-0.22016)}$$

$$h_2 = 114.99\frac{\text{Btu}}{\text{lbm}}$$

Step 5 of 7

State 3:

Since refrigerant leaves the condenser is saturated liquid.

From the saturated refrigerant -134a pressure table

$P_3 = 100\text{psia}$

$$h_3 = h_f = 37.869\frac{\text{Btu}}{\text{lbm}}$$

Step 6 of 7

State 4:

Since process 3 to 4 throttling so enthalpy remains constant.

$$h_4 = h_3 = 37.869\frac{\text{Btu}}{\text{lbm}}$$

$$\frac{\text{Btu}}{\text{lbm}\cdot\text{R}}$$

From the Superheated refrigerant-134a

At $P_2 = 100\text{psia}$ and $s_2 = 0.22189\frac{\text{Btu}}{\text{lbm}\cdot\text{R}}$

By using the interpolation

$$h_2 = 114.05 + \frac{(0.22189-0.22016)(118.90-114.05)}{(0.22900-0.22016)}$$

$$h_2 = 114.99\frac{\text{Btu}}{\text{lbm}}$$

Step 5 of 7

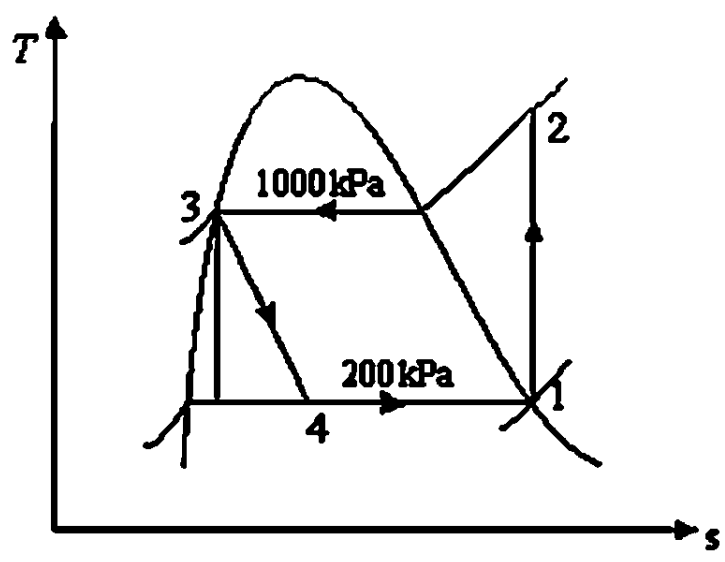
Question: 9.169P

A heat pump operates on the ideal vapor-compression refrigeration cycle and uses refrigerant-134a as the working fluid. The condenser operates at1000 kPa and the evaporator at 200 kPa. Determine this system's COP and the rate of heat supplied to the evaporator when the compressor consumes 6 kw.

Step 1 of 9

Given:

Working fluid: $R-134a$



Operating pressure of the condenser $P_2 = P_3 = 1000\text{kPa}$

Operating pressure of the evaporator $P_1 = P_4 = 200\text{kPa}$

Power input to the compressor $W_{in} = 6\text{kW}$

Step 2 of 9

T-s diagram:

Step 3 of 9

State 1:

Since refrigerant enters into the compressor is saturated vapor, so

From the Saturated refrigerant -134a Pressure table

At $P_1 = 200\text{kPa}$

$$h_1 = h_g = 244.46\frac{\text{kJ}}{\text{kg}}$$

$$s_1 = s_g = 0.93773\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 4 of 9

Sate 2:

Since ideal refrigeration cycle so entropy remains constant. And also refrigerant leaving to the compressor superheated condition.

$$s_1 = s_2 = 0.93773\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

From the superheated refrigerant-134a

At $P_2 = P_3 = 1000\text{kPa}$ and $s_1 = s_2 = 0.93773\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$

Using method of interpolation

$$h_2 = 271.71 + \frac{(0.93773 - 0.9179)(282.74 - 271.71)}{(0.9525 - 0.9179)}$$

$$h_2 = 278.031\frac{\text{kJ}}{\text{kg}}$$

Step 5 of 9

Mass flow rate in to the compressor is

$$\dot{W}_{in} = \dot{m}(h_2 - h_1)$$

$$\Rightarrow \dot{m} = \frac{\dot{W}_{in}}{(h_2 - h_1)}$$

$$= \frac{6\text{kW}}{\left(277.031\frac{\text{kJ}}{\text{kg}} - 244.46\frac{\text{kJ}}{\text{kg}}\right)}$$

$$= 0.1842\frac{\text{kg}}{s}$$

Step 6 of 9

State 3:

Since refrigerant leaves the condenser is saturated liquid.

From the saturated refrigerant -134a pressure table

$P_3 = 1000\text{kPa}$

$$h_3 = h_f = 107.32\frac{\text{kJ}}{\text{kg}}$$

Step 7 of 9

State 4:

Since process 3 to 4 throttling so enthalpy remains constant.

$$h_4 = h_3 = 107.32\frac{\text{kJ}}{\text{kg}}.$$

Step 8 of 9

Rate of heat supplied to the evaporator

$$\dot{Q}_L = \dot{m}(h_1 - h_4)$$

$$= \left(0.1842\frac{\text{kg}}{s}\right)\left(244.46\frac{\text{kJ}}{\text{kg}} - 107.32\frac{\text{kJ}}{\text{kg}}\right)$$

$$= 25.26\frac{\text{kJ}}{s}$$

$$\boxed{\dot{Q}_L = 25.26\text{kW}}$$

Step 9 of 9

COP of the heat pump is

$$(COP)_{HP} = \frac{\dot{Q}_H}{\dot{W}_{in}}$$

$$COP = \frac{h_2 - h_3}{h_2 - h_1}$$

$$COP = \frac{278.031 - 107.32}{278.031 - 244.46}$$

$$= 5.085$$

$$\boxed{COP = 5.085}$$

Question: 9.170P

A heat pump operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid. This heat pump is used to keep a space at 25°C by absorbing heat at the rate of 2.7 kW from geothermal water flowing through the evaporator. The evaporator operates at 20°C. and the condenser operates at 1400 kPa. The compressor receives work equal to 20 kJ for each kilogram of refrigerant flowing into it

(*a*) Sketch the hardware and the *T-s* diagram for this heat pump

(*b*) Determine the rate of heat transfer to the heated space at 25°C.

(*c*) Determine the COP of the heat pump.

Refrigerant-134a data: *T*= 20°C: *hf*= 79.3 kJ/kg

hg= 261.6 kJ/kg: *P*= 1400 kPa: *hf*= 127.2 kJ/kg

hg =276.2 kJ/kg

Step 1 of 9

Given:

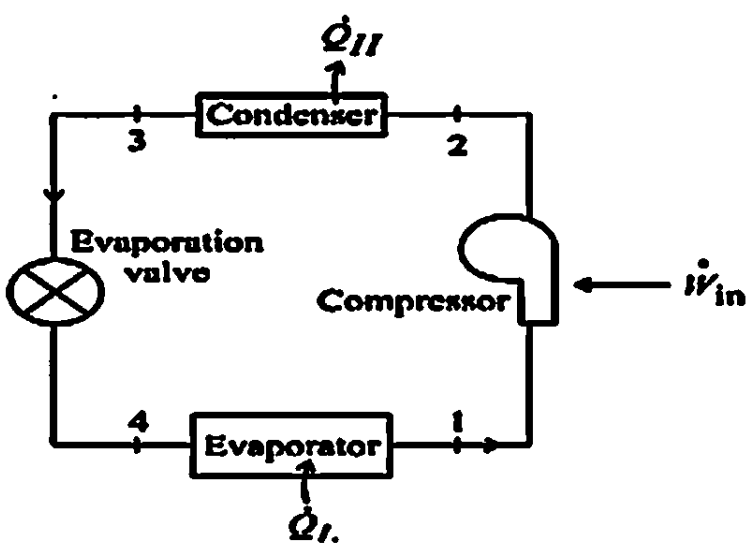
Working fluid: $R-134a$

Temperature of heated space $T_R = 25^\circ C$

Rate of heat gain $\dot{Q}_L = 2.7 kW$

Operating temperature of the evaporator $T_{evap} = 20^\circ C$

Operating Pressure of the condenser $P_2 = P_3 = 1400 kPa$



Compressor work $W_{in} = 20 kJ$

Properties R-134a:

At T=20°C	At P=1400kPa
$h_f = 79.3 \frac{kJ}{kg}$	$h_f = 127.2 \frac{kJ}{kg}$
$h_g = 261.6 \frac{kJ}{kg}$	$h_g = 276.2 \frac{kJ}{kg}$

Step 2 of 9

A) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic; the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure.

Step 3 of 9

(b) State 1:

Since refrigerant enters in to the compressor is saturated vapor, so

From the above table

At $T_{evap} = 20^\circ C$

$$h_1 = h_g = 261.6 \frac{kJ}{kg}$$

Step 4 of 9

State 3:

From the above table

At $P_2 = P_3 = 1400 kPa$

$$h_3 = h_f = 127.2 \frac{kJ}{kg}$$

Step 5 of 9

State 4:

Process 3 to 4 throttling Process so enthalpy remains constant.

$$h_4 = h_3 = 127.2 \frac{kJ}{kg}$$

Step 6 of 9

The enthalpy at the compressor exit is

$$w_{in} = h_2 - h_1$$

$$\Rightarrow h_2 = h_1 + w_{in}$$

$$= 261.6 \frac{kJ}{kg} + 20 \frac{kJ}{kg}$$

$$= 281.6 \frac{kJ}{kg}$$

Step 7 of 9

The mass flow rate through the cycle is

$$\dot{Q}_L = \dot{m}(h_1 - h_4)$$

$$\Rightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4}$$

$$= \frac{2.7 \frac{kJ}{s}}{\left(261.6 \frac{kJ}{kg} - 127.2 \frac{kJ}{kg}\right)}$$

$$= 0.02009 \frac{kg}{s}$$

Step 8 of 9

The rate of heat transfer to the heated space is

$$\dot{Q}_H = \dot{m}(h_2 - h_3)$$

$$= \left(0.02009 \frac{kg}{s}\right)\left(281.6 \frac{kJ}{kg} - 127.2 \frac{kJ}{kg}\right)$$

$$= 3.10 \frac{kJ}{s}$$

$$= 3.10 kW$$

$$\boxed{\dot{Q}_H = 3.10 kW}$$

Step 9 of 9

(c) The COP of the heat pump is

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{in}}$$

$$= \frac{\dot{Q}_H}{\dot{m} w_{in}}$$

$$= \frac{3.10 kW}{\left(0.02009 \frac{kg}{s}\right)\left(20 \frac{kJ}{kg}\right)}$$

$$= 7.72$$

$$\boxed{(COP)_{HP} = 7.72}$$

Question: 9.171P pg 1

A building requires a 2-ton heat pump for maintaining the interior space at 27°C when the outside temperature is 5°C. The heat pump operates on the normal vapor compression refrigeration cycle and uses refrigerant-134a as the working fluid. The heat pump operating conditions require an evaporator pressure of 240 kPa and a condenser pressure of 1600 kPa while the compressor has an isentropic efficiency] of 85 percent. Selected data for refrigerant-134a are provided in the table below.

P, kPa	T_{sat}, °C	h_f, kJ/kg	h_g, kJ/kg	s_g, kJ/kg·K
240	−5.37	43	244	0.9222
1600	57.92	134	275	0.8982

For R-134a at P = 1600 kPa and s = 0.9222 kJ/kg·K, h = 285 kJ/kg. Also, 1 ton = 211 kJ/min.

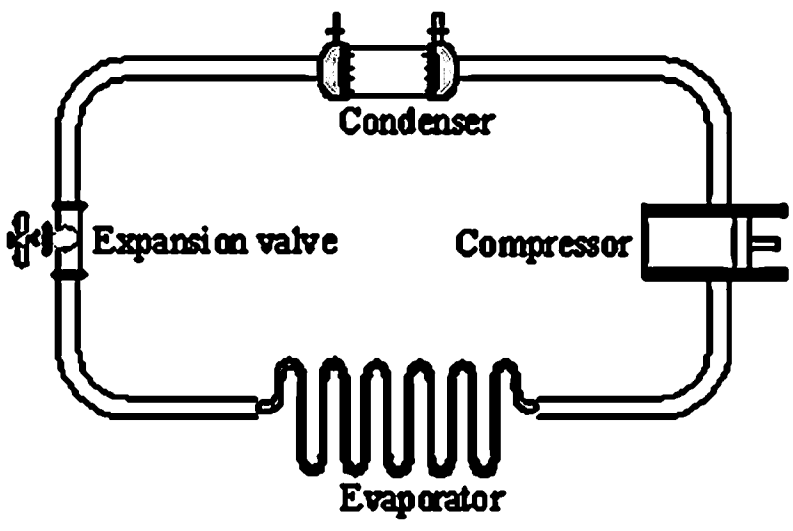
(*a*) Sketch the hardware and the *T*-*s* diagram for this heat pump system.

(*b*) Determine the power required to drive the heat pump, in kW and the COP.

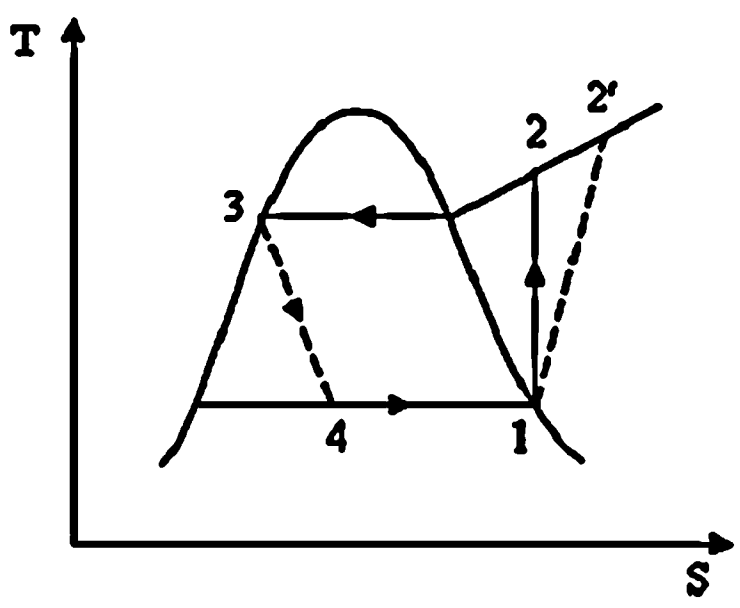
Step 1 of 9

Given:
Working fluid: $R-134a$
Capacity of the heat pump $Q_H = 2\,\text{ton}$
Highest temperature $T_H = 27^\circ\text{C}$
Lowest temperature $T_L = 5^\circ\text{C}$
Operating pressure of evaporator $P_1 = P_4 = 240\,\text{kPa}$
Operating pressure of Condenser $P_2 = P_3 = 1600\,\text{kPa}$
Isentropic efficiency of the compressor $\eta_C = 0.85$
Properties of R-134a:

P,kPa	T_{sat},°C	h_f, kJ/kg	h_g, kJ/kg	s_g, kJ/kg·K
240	-5.37	43	244	0.92222
1600	57.92	134	275	0.8982



Superheated conditions:



For R-134a at $P = 1600\,\text{kPa}$ and $s = 0.9222\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$

$h_{sup} = 285\,\frac{\text{kJ}}{\text{kg}}$ And $1\text{Ton} = 210\,\frac{\text{kJ}}{\text{min}} = 3.5\text{kW}$

Step 2 of 9

A)

Step 3 of 9

b) State1:
Since refrigerant enters into the compressor Saturated vapor ,so
From the above table
At $P_1 = P_4 = 240\,\text{kPa}$

$h_1 = h_g = 244\,\frac{\text{kJ}}{\text{kg}}$

$s_1 = s_g = 0.9222\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$

Step 4 of 9

State 2:
Since refrigerant leaving to the compressor is superheated conditions.So
From the above table
At $P = 1600\,\text{kPa}$

$h_2 = h_{sup} = 285\,\frac{\text{kJ}}{\text{kg}}$

Step 5 of 9

State 3:
Refrigerant leaving to the condenser is saturated liquid, So
From the above table
At $P = 1600\,\text{kPa}$

$h_3 = h_f = 134\,\frac{\text{kJ}}{\text{kg}}$

Step 6 of 9

We know that
Efficiency of the compressor

Step 6 of 9

We know that
Efficiency of the compressor

$$\eta_c = \frac{h_2 - h_1}{h_{2'} - h_1}$$

$$0.85 = \frac{\left(285\frac{kJ}{kg} - 244\frac{kJ}{kg}\right)}{\left(h_{2'} - 244\frac{kJ}{kg}\right)}$$

$$\Rightarrow h_{2'} = 292.24\frac{kJ}{kg}$$

Step 7 of 9

Capacity of the heat pump $Q_H = 2\text{ton}$
And we also know that

$$1\text{Ton} = 210\frac{kJ}{min}$$
$$= 3.5kW$$
$$\dot{Q}_H = 2\times 3.5kW$$
$$= 7\,kW$$

$$\dot{Q}_H = \dot{m}(h_{2'} - h_3)$$
$$\Rightarrow \dot{m} = \frac{7kW}{\left(292.24\frac{kJ}{kg} - 134\frac{kJ}{kg}\right)}$$
$$= 0.04424\frac{kg}{s}$$

Step 8 of 9

Power required for driving the pump

$$\dot{W}_{in} = \dot{m}(h_{2'} - h_1)$$
$$= 0.04424\frac{kg}{s}\left(292.24\frac{kJ}{kg} - 244\frac{kJ}{kg}\right)$$
$$= 2.134\frac{kJ}{s}$$

$$\boxed{\dot{W}_{in} = 2.134kW}$$

Step 9 of 9

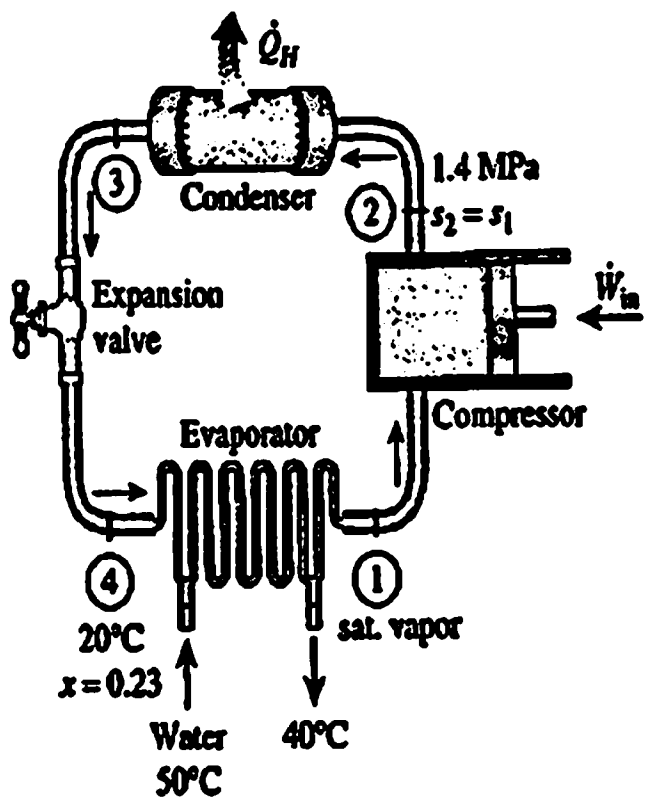
COP of the heat pump is

$$(COP)_{HP} = \frac{\dot{Q}_H}{\dot{W}_{in}}$$
$$= \frac{7}{2.134}$$
$$= 3.28$$

$$\boxed{COP = 3.28}$$

Question: 9.172P pg 1

A heat pump with refrigerant-134a as the working ' fluid is used to keep a space at 25°C by absorbing heat from geothermal water that enters the evaporator at 50°C at a rate of 0.065 kg/s and leaves at 40°C. The refrigerant enters the evaporator at 20°C with a quality of 23 percent and leaves at the inlet pressure as saturated vapor. The refrigerant loses 300 W of heat to the surroundings as it flows through the compressor and the refrigerant leaves the compressor at 1.4 MPa at the same entropy as the inlet. Determine (*a*) the degrees of subcooling of the refrigerant in the condenser, (*b*) the mass flow rate of the refrigerant, (*c*) the heating load and the COP of the heat pump, and (*d*) the theoretical minimum power input to the compressor for the same heating load.



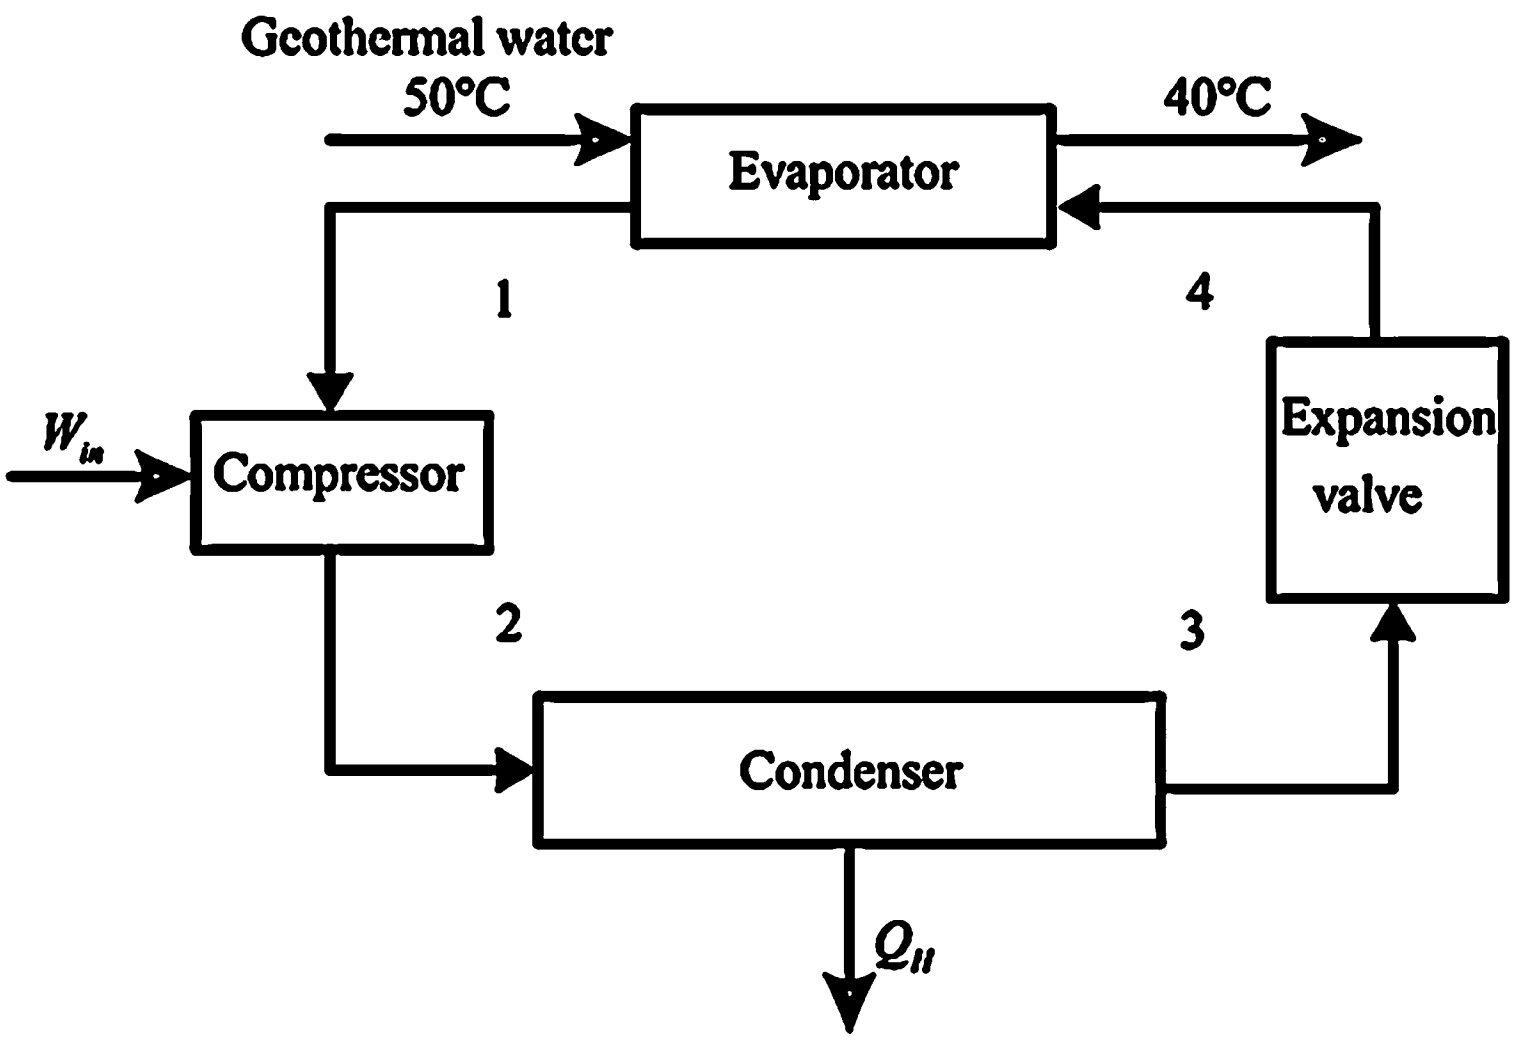


FIGURE P9–172

Step 1 of 12

Sketch the block diagram showing heat pump cycle:

Step 2 of 12

(a)

Calculate the enthalpy at the entry of the evaporator:

Obtain the enthalpies from the table A-11, "Saturated refrigerant-134a-Temperature Table" in the textbook.

The enthalpy of a saturated liquid h_{f4} is $79.32\left(\frac{\text{kJ}}{\text{kg}}\right)$.

The enthalpy of the evaporation h_{fg4} is $182.27\left(\frac{\text{kJ}}{\text{kg}}\right)$.

The saturated pressure P_4 is $572.07\ \text{kPa}$.

Hence substitute $79.32\left(\text{kJ}/\text{kg}\right)$ for h_{f4} and $182.27\left(\text{kJ}/\text{kg}\right)$ for h_{fg4}.

$$h_4 = h_{f4} + x_4 h_{fg4}$$

Here, h_{f4} is the enthalpy of a saturated liquid, h_{fg4} is enthalpy of the evaporation, and x_4 is the quality of the refrigerant at the entry of evaporator.

Substitute $79.32\,\text{kJ}/\text{kg}$ for h_{f4}, $182.27\left(\text{kJ}/\text{kg}\right)$ for h_{fg4} and 0.23 for x_4.

$$\begin{aligned} h_4 &= 79.32 + (0.23 \times 182.27) \\ &= 121.24\,\text{kJ/kg} \end{aligned}$$

Step 3 of 12

The pressure remains constant when refrigerant leaves the evaporator in a saturated stage. Hence the pressures at the inlet and the outlet are equal.

$$\begin{aligned} P_4 &= P_1 \\ &= 572.07\,\text{kPa} \end{aligned}$$

At saturated stage the enthalpy at the inlet of the compressor is equal to the enthalpy of the saturated vapor.

Hence $h_1 = h_{g1}$

$$= 261.59\,\text{kJ/kg}$$

And at the saturated stage the entropy at the inlet of the compressor is equal to the enthalpy of the saturated vapor.

Hence $s_1 = s_{g1}$

$$= 0.92234\,\text{kJ/kg}\cdot\text{K}$$

Step 4 of 12

Calculate the enthalpy at the exit of the compressor pressure by interpolation method:

Step 4 of 12

Calculate the enthalpy at the exit of the compressor pressure by interpolation method:

For h_{avg}, at $h_{max} = 285.47\ \text{kJ/kg}$ and $s_{max} = 0.9389\ \text{kJ/kg.k}$, $h_{min} = 276.12\ \text{kJ/kg}$ and $s_{min} = 0.9015\ \text{kJ/kg.k}$.

The formula for interpolation is follows:

$$h_{avg} = h_{min} + (h_{max} - h_{min})\left(\frac{s_{avg} - s_{min}}{s_{max} - s_{min}}\right)$$

$$h_2 = h_{0.9105} + (h_{0.9389} - h_{0.9105})\left(\frac{0.924 - 0.9105}{0.9389 - 0.9105}\right)$$

$$= 276.12 + (285.47 - 276.12)\left(\frac{0.924 - 0.9105}{0.9389 - 0.9105}\right)$$

$$= 280.56\ \text{kj/kg}$$

Therefore, the enthalpy at the exit of the compressor is $280.56\ \text{kJ/kg}$

Step 5 of 12

Obtain the enthalpy values for the geothermal water inlet and outlet respectively:
From the saturated water temperature table A-4 the values of enthalpy for the geothermal water inlet and outlet are follows;

$$\text{At } T_{GI} = 50°\text{C ; enthalpy } h_{GI} = 209.34\ \text{kJ/kg}$$
$$\text{At } T_{GO} = 40°\text{C ; enthalpy } h_{GO} = 167.53\ \text{kJ/kg}$$

From the A-12 saturated refrigerant of R134-a pressure table the saturated temperature at pressure of 1400 kPa the temperature is $T_{sat} = 52.4°\text{C}$.

We know that enthalpy is constant in expansion valve therefore, $h_4 = h_3$. Also inlet and outlet pressure are constant therefore, $P_2 = P_3 = 1.4\text{MPa}$.

Step 6 of 12

Calculate the temperature at state 3 by interpolation as follows:

Obtain the enthalpies at the following temperatures from the table A-11, "Saturated refrigerant -134a- Temperature table" in the textbook.

$$h_{@48°\text{C}} = 120.39\ \text{kJ/kg}$$
$$h_{@52°\text{C}} = 126.59\ \text{kJ/kg}$$

Use interpolation and find temperature at state 3 as follows:

$$T_3 = 48 + \left(\frac{52 - 48}{126.59 - 120.39}\right)(121.24 - 120.39)$$
$$= 48.6°\text{C}$$

Calculate the degree of sub cooling as follows:

$$T_{subcooling} = T_{sat} - T_3$$

Substitute $52.4°\text{C}$ for T_{sat} and $48.6°\text{C}$ for T_3.

$$T_{subcooling} = 52.4 - 48.6$$
$$= 3.8°\text{C}$$

Step 7 of 12

Therefore, the degree of sub cooling is $\boxed{3.8°\text{C}}$.

Step 8 of 12

(b)

Calculate the heat absorbed from geothermal water as follows.

$$\dot{Q} = \dot{m}(h_{GI} - h_{GO})$$

Here, $\dot{m}$ is the mass flow rate, h_{GI} is the enthalpy of the geo water inlet, and h_{GO} is the enthalpy of the geo water outlet.

Substitute 0.0065 for $\dot{m}$, $209.34\ \text{kJ/kg}$ for h_{GI} and $167.53\ \text{kJ/kg}$ for h_{GO}.

$$\dot{Q} = 0.065 \times (209.34 - 167.53)$$
$$= 2.71\ \text{kW}$$

Calculate the mass flow rate of the refrigerant R134-a as follows.

$$\dot{m}_R = \frac{\dot{Q}}{h_1 - h_4}$$

Here, $\dot{m}_R$ is the mass flow rate of the refrigerant, h_1 is the enthalpy at the entry of the compressor and h_4 is the enthalpy at the entry of the evaporator and is the heat absorbed by the geothermal water $\dot{Q}$.

Substitute, 2.71 kW for $\dot{Q}$, $261.59\ \text{kJ/kg}$ for h_1, and $121.74\ \text{kJ/kg}$ for h_4.

$$\dot{m}_R = \frac{2.71}{260.03 - 121.74}$$
$$= 0.01965\ \text{kg/s}$$

Therefore, mass flow rate of the refrigerant is $\boxed{0.01965\ \text{kg/s}}$.

Step 9 of 12

(c)

Calculate the Power input to the heat pump as follows.

$$\dot{W}_{in} = \dot{m}_R(h_2 - h_1) + \dot{Q}_{II}$$

Here, $\dot{m}_R$ mass flow rate of the refrigerant, h_2, h_1 is the enthalpy at the entry of the compressor and the exit of the compressor and $\dot{Q}_{II}$ is the heat loss through the compressor.

Calculate the Power input to the heat pump as follows:

$$w_{in} = \dot{m}_R (h_2 - h_1) + Q_H$$

Here, $\dot{m}_R$ mass flow rate of the refrigerant, h_2, h_1 is the enthalpy at the entry of the compressor and the exit of the compressor and Q_H is the heat loss through the compressor.

Substitute, $0.01965\,^{kg}/_{s}$ for $\dot{m}_R$, $261.59\,^{kJ}/_{kg}$ for h_1, $280.5\,^{kJ}/_{kg}$ for h_2 and $0.3\,kW$ for Q_H.

$$\begin{aligned} w_{in} &= 0.01965(280.5 - 261.59) + 0.3 \\ &= 0.671\,kW \end{aligned}$$

Step 10 of 12

Calculate the heating effect of the condenser:

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3)$$

Here, $\dot{Q}_H$ is the heating effect of the condenser, h_2, h_3 is the enthalpy at the entry of the compressor and the exit of the condenser and $\dot{m}_R$ is the mass flow rate of the refrigerant.

Substitute $0.01965\,^{kg}/_{s}$ for $\dot{m}_R$, $280.5\,^{kJ}/_{kg}$ for h_2, and $121.74\,^{kJ}/_{kg}$ for h_4

$$\begin{aligned} \dot{Q}_H &= 0.01965 \times (280.5 - 121.74) \\ &= 3.119\,kW \end{aligned}$$

Therefore, the heating load is $\boxed{3.119\,kW}$.

Step 11 of 12

Calculate the coefficient of performance of the heat pump:

$$COP = \frac{\dot{Q}_H}{w_{in}}$$

Here, *COP* is the coefficient of performance, $\dot{Q}_H$ is the heating effect of the condenser and w_{in} is the work input.

Substitute 3.119 kW for $\dot{Q}_H$ and 0.671 kW for w_{in}.

$$\begin{aligned} COP &= \frac{3.119}{0.671} \\ &= 4.648 \end{aligned}$$

Therefore, COP of the heat pump is $\boxed{4.648}$.

Step 12 of 12

(d)

Calculate the reversible COP as follows:

$$COP_{rev} = \frac{1}{1 - \frac{T_L}{T_H}}$$

Substitute 298 K for T_L and 323 K for T_H.

$$\begin{aligned} COP_{rev} &= \frac{1}{1 - \frac{298}{323}} \\ &= 12.29 \end{aligned}$$

Calculate the minimum power input as follows:

$$w_{in-min} = \frac{\dot{Q}_H}{COP_{rev}}$$

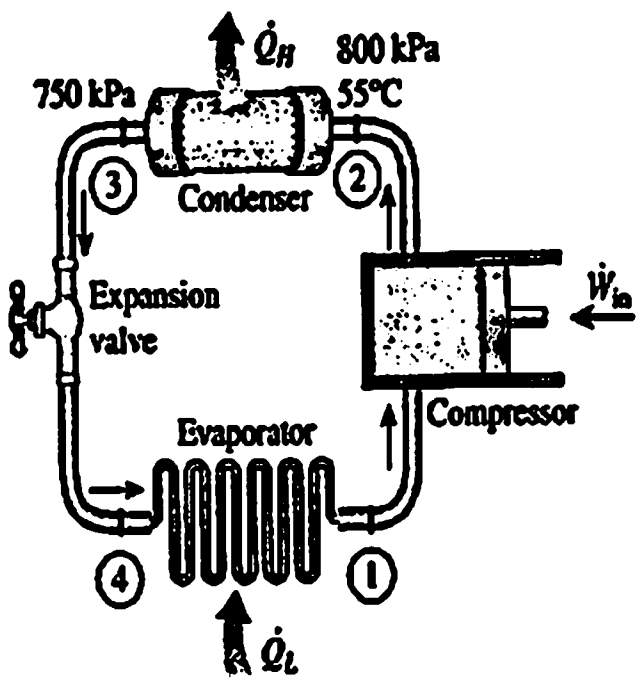
Substitute 3.119 kW for $\dot{Q}_H$ and 12.29 for COP_{rev}.

$$\begin{aligned} w_{in-min} &= \frac{3.119}{12.92} \\ &= 0.241\,kW \end{aligned}$$

Therefore, the minimum power input to the compressor is $\boxed{0.241\,kW}$.

Question: 9.173P pg 1

Refrigerant-134a enters the condenser of a residential heat pump at 800 kPa and 55°C at a rate of 0.018 kg/s and leaves at 750 kPa subcooled by 3°C. The refrigerant enters the compressor at 200 kPa superheated by 4°C. Determine (*a*) the isentropic efficiency of the compressor, (*b*) the rate of heat supplied to the heated room, and (*c*) the COP of the heat pump. Also, determine (*d*) the COP and the rate of heat supplied to the heated room if this heat pump operated on the ideal vapor-compression cycle between the pressure limits of 200 and 800 kPa.



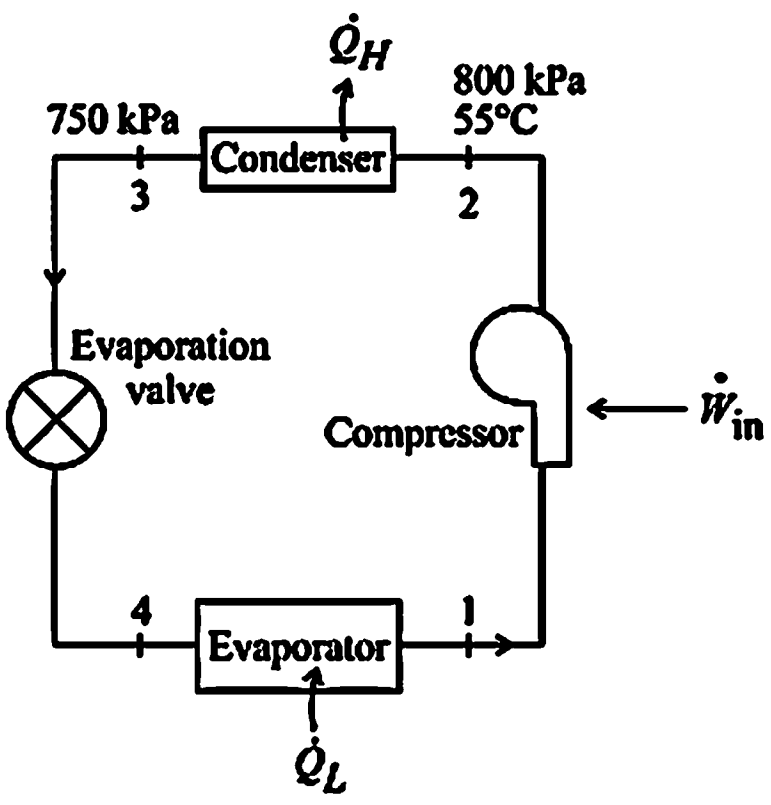


FIGURE P9–173

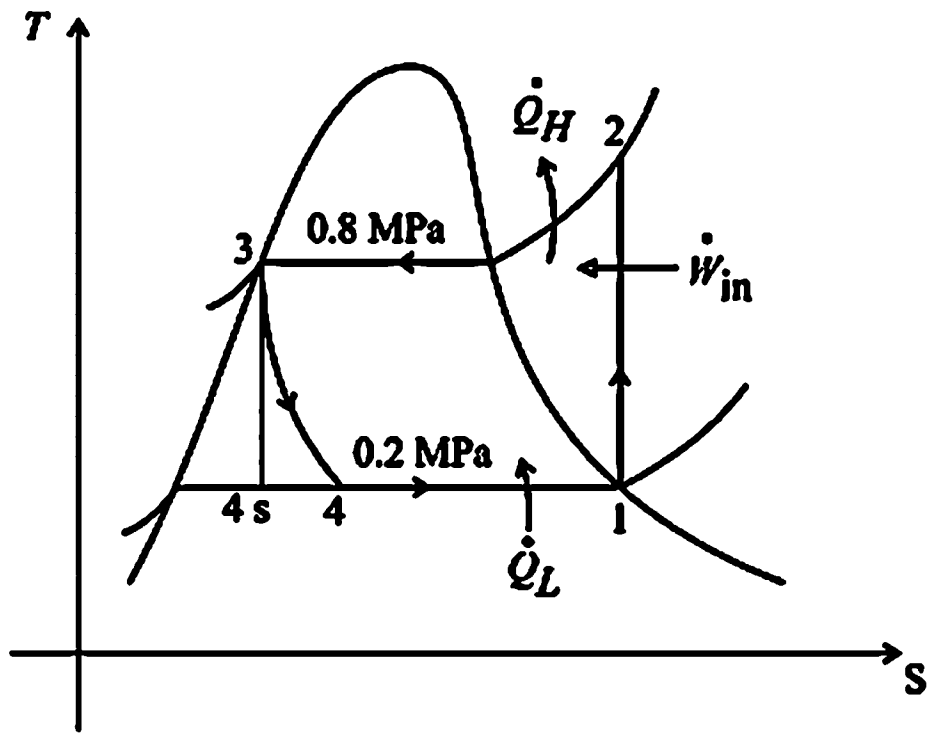
Step 1 of 16

Given:
Working fluid: R-134a
Pressure at the inlet of condenser $P_2 = 800\ \text{kPa}$
Temperature at the inlet of condenser $T_2 = 55°\text{C}$
Pressure at the exit of condenser $P_3 = 750\ \text{kPa}$
Pressure at the exit of evaporator $P_1 = 200\ \text{kPa}$
Mass flow rate $\dot{m} = 0.018\ \text{kg/s}$



Step 2 of 16

Block diagram of vapor-compression refrigeration cycle

Step 3 of 16

T-S diagram of vapor-compression refrigeration cycle

Step 4 of 16

From superheated refrigerant-134a table

At $P_2 = 800\ \text{kPa}, T_2 = 55°\text{C}$

$$h_2 = 286.69 + \frac{(55-50)}{(60-50)}(296.81-286.69)$$

$$h_2 = 291.75\ \text{kJ/kg}$$

Step 5 of 16

From saturated refrigerant-134a pressure table

$T_{sat@750kPa} = 29.06°\text{C}$

At $P_3 = 750\ \text{kPa}$ and $T_3 = (29.06-3)°\text{C} = 26.06°\text{C}$

From saturated refrigerant-134a temperature table

$$h_{3@26.06°C} = 87.83 + \left(\frac{26.06-26}{28-26}\right)(90.69-87.83)$$

$$h_{3@26.06°C} = 87.91\ \text{kJ/kg}$$

Step 6 of 16

For throttling, $h_4 = h_3 = 87.91\ \text{kJ/kg}$

From saturated refrigerant-134a pressure table

$T_{sat@200kPa} = -10.09°\text{C}$

Step 7 of 16

From superheated refrigerant-134a table

$T_{sat@200kPa} = -10.09\,^{\circ}C$

Step 7 of 16

From superheated refrigerant-134a table

At $P_1 = 200\,kPa, T_1 = (-10.09+4)^{\circ}C = -6.09^{\circ}C$

$$h_1 = 244.54 + \frac{(-6.09-(-10))}{(0-(-10))}(253.05-244.54)$$

$$h_1 = 247.87\,kJ/kg$$

$$s_1 = 0.9380 + \frac{(-6.09-(-10))}{(0-(-10))}(0.9698-0.9380)$$

$$s_1 = 0.9504\,kJ/kg.K$$

Step 8 of 16

From superheated refrigerant-134a table

At $P_2 = 800\,kPa, s_2 = s_1 = 0.9504\,kJ/kg.K$

$$h_{2s} = 276.45 + \frac{(0.9504-0.9480)}{(0.9802-0.9480)}(286.69-276.45)$$

$$h_{2s} = 277.21\,kJ/kg$$

Step 9 of 16

Assumptions:

1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 10 of 16

(a) Isentropic efficiency of the compressor:

Isentropic efficiency of the compressor, $\eta_C = \dfrac{h_{2s}-h_1}{h_2-h_1}$

$$\eta_C = \frac{277.21-247.87}{291.75-247.87}$$

$$\boxed{\eta_C = 0.6686}$$

Step 11 of 16

(b) Rate of heat supplied to the room:

Rate of heat supplied to the room, $\dot{Q}_H = \dot{m}\times(h_2-h_3)$

$$\dot{Q}_H = 0.018\times(291.75-87.91)$$

$$\boxed{\dot{Q}_H = 3.67\,kW}$$

Step 12 of 16

(c) COP:

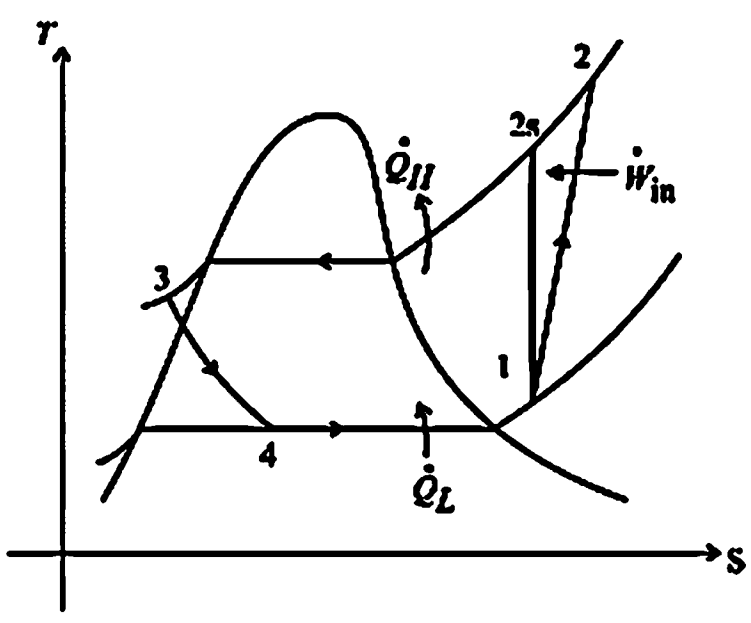
Power input, $\dot{W}_{in} = \dot{m}\times(h_2-h_1)$

$$\dot{W}_{in} = 0.018\times(291.75-247.87)$$

$$\dot{W}_{in} = 0.79\,kW$$

But, $COP = \dfrac{\dot{Q}_H}{\dot{W}_{in}}$

$$COP = \frac{3.67}{0.79}$$



$$\boxed{COP = 4.646}$$

Step 13 of 16

(d) COP and the rate of heat supplied to the heated room if this heat pump operated on the ideal vapor-compression cycle between the pressure limits 200 kPa and 800 kPa:

Step 14 of 16

T-S diagram of vapor-compression refrigeration cycle

Step 15 of 16

From saturated refrigerant-134a pressure table

$h_1 = h_{g@200kPa} = 244.46\,kJ/kg$

$s_1 = s_{g@200kPa} = 0.9377\,kJ/kg.K$

From superheated refrigerant-134a table

At $P_2 = 800\,kPa, s_2 = s_1 = 0.9377\,kJ/kg.K$

$$h_2 = 267.29 + \frac{(0.9377-0.9183)}{(0.9480-0.9183)}(276.45-267.29)$$

$$h_2 = 273.27\,kJ/kg$$

$h_4 = h_3 = h_{f@800kPa} = 95.47\,kJ/kg$

But, $COP = \dfrac{\dot{Q}_H}{\dot{W}_{in}}$

$$COP = \frac{(h_2-h_3)}{(h_2-h_1)}$$

$$COP = \frac{273.27-95.47}{273.27-244.46}$$

$$\boxed{COP = 6.171}$$

$$COP = \frac{273.27-95.47}{273.27-244.46}$$

$$\boxed{COP = 6.171}$$

Rate of heat supplied to the room, $\dot{Q}_H = \dot{m} \times (h_2 - h_3)$

$$\dot{Q}_H = 0.018 \times (273.27-95.47)$$

$$\boxed{\dot{Q}_H = 3.2\ \text{kW}}$$

Step 16 of 16

Question:

9.174P

An Otto cycle with a compression ratio of 7 begins its compression at 90 kPa and 15°C. The maximum cycle temperature is 1000°C. Utilizing air-standard assumptions, determine the thermal efficiency of this cycle using (*a*) constant specific heats at room temperature and(*b*) variable specific heats

Step 1 of 6

Given:

Compression ratio of the Otto cycle is $r = 7$

Initial Temperature (before compression), $T_1 = 15^0\text{C}$

Initial Pressure (before compression), $P_1 = 90\ \text{kPa}$

Specific heat at constant pressure, $C_P = 1.005\ \text{kJ/KgK}$

Specific heat at constant temperature, $C_V = 0.7\ \text{kJ/KgK}$

Gas constant of air, $R = 0.3\ \text{kJ/KgK}$

Specific heat ratio, $k = 1.4$

Step 2 of 6

(a)

With Constant specific heats, the efficiency of the Otto cycle is given as

$$\eta_{otto} = 1 - \left(\frac{1}{r}\right)^{k-1}$$

$$= 1 - \left(\frac{1}{7}\right)^{k-1}$$

$$= 1 - 0.4591$$

$$= 0.5409$$

Hence the thermal efficiency of Otto cycle is $\boxed{\eta_{otto} = 54.09\%}$

Step 3 of 6

(b)

From ideal gas properties table of air at $T_1\,(288\ \text{K})$,

$V_{r1} = 688.1$ and

$u_1 = 205.48\ \text{kJ/kg}$

But compression ratio, $r = \frac{V_1}{V_2} = \frac{V_{r1}}{V_{r2}}$ Hence

$$V_{r2} = \frac{V_{r1}}{r}$$

$$= \frac{688.1}{7}$$

$$= 98.3$$

From ideal gas properties table of air, the internal energy corresponding to V_{r2} is

$$u_2 = 477.62\ \text{kJ/kg}$$

Step 4 of 6

Temperature after constant volume heat addition is $T_3 = 1273\ \text{K}$

From ideal gas properties table of air at T_3,

$$V_{r3} = 12.045 \text{ and}$$

$$u_3 = 998.51\ \text{kJ/kg}$$

Hence amount of heat added is

$$q_{in} = u_3 - u_2$$

$$= 998.51 - 447.62$$

$$= 550.89\ \text{kJ/kg}$$

Step 5 of 6

From compression ratio, $r = \frac{V_4}{V_3} = \frac{V_{r4}}{V_{r3}}$ Hence

$$V_{r4} = rV_{r3}$$

$$= 7 \times 12.045$$

$$= 84.32$$

From ideal gas properties table of air, the internal energy corresponding to V_{r4} is

$$u_4 = 475.54\ \text{kJ/kg}$$

Hence amount of heat rejected is

$$q_{out} = u_4 - u_1$$

$$= 475.54 - 205.48$$

$$= 270.06\ \text{kJ/kg}$$

Step 6 of 6

Efficiency of the cycle,

$$\eta_{Otto} = 1 - \frac{q_{out}}{q_{in}}$$

$$= 1 - \frac{270.06}{550.89}$$

$$= 0.5098$$

Hence efficiency of Otto cycle is $\boxed{\eta_{Otto} = 50.98\%}$

Question: 9.175P

A Diesel cycle has a compression ratio of 20 and begins its compression at 13 psia and 45°F. The maximum cycle temperature is 1800°F. Utilizing air-standard assumptions, determine the thermal efficiency of this cycle using (*a*) constant specific heats at room temperature and (*b*) variable specific heats.

Step 1 of 9

Given:
Compression ratio of the Diesel cycle, $r = 20$
Initial temperature (before compression), $T_1 = 45^0\text{F}$
Initial pressure (before compression), $P_1 = 13$ psia
Maximum cycle temperature, $T_{max} = 1800^0\text{F}$
Specific heat at constant pressure, $C_p = 0.24$ Btu/lbmR
Specific heat at constant temperature, $C_v = 0.171$ Btu/lbmR
Specific heat ratio, $k = 1.4$

Step 2 of 9

(a)
For Isentropic Compression,

$$T_2 = T_1\left(\frac{V_1}{V_2}\right)^{k-1}$$
$$= T_1(r)^{k-1}$$
$$= (45+460)(7)^{1.4-1}$$
$$= 1673.8\text{ R}$$

For constant pressure heat addition,

$$V_3 = \frac{T_3}{T_2}V_2$$
$$= \frac{2260}{1673.8}\times V_2$$
$$= 1.35\times V_2$$

Step 3 of 9

For isentropic expansion,

$$T_4 = T_3\left(\frac{V_3}{V_4}\right)^{k-1}$$
$$= T_3\left(\frac{1.35\times V_2}{V_1}\right)^{k-1}$$
$$= (2260)\left(\frac{1.35}{20}\right)^{1.4-1}$$
$$= 768.8\text{ R}$$

Heat added to the cycle is

$$q_{in} = C_p(T_3 - T_2)$$
$$= (0.24)(2260-1673.8)$$
$$= 140.7\text{ Btu/lbm}$$

Heat rejected from the cycle is

$$q_{out} = C_v(T_4 - T_1)$$
$$= (0.171)(768.8-505)$$
$$= 45.11\text{ Btu/lbm}$$

Step 4 of 9

Efficiency of the cycle is

$$\eta_{Diesel} = 1 - \frac{q_{out}}{q_{in}}$$
$$= 1 - \frac{45.11}{140.7}$$
$$= 0.6784$$

Hence the efficiency of the diesel cycle is $\boxed{\eta_{Diesel} = 67.84\%}$

Step 5 of 9

(b)
From Ideal gas properties of air, at $T_1\,(505\text{ R})$

$$V_{r1} = 170.82 \text{ and}$$
$$u_1 = 86.06\text{ Btu/lbm}$$

But compression ratio, $r = \frac{V_1}{V_2} = \frac{V_{r1}}{V_{r2}}$ Hence

$$V_{r2} = \frac{V_{r1}}{r}$$
$$= \frac{170.82}{20}$$
$$= 8.541$$

Step 6 of 9

From ideal gas properties table of air, the internal energy corresponding to V_{r2} is

$$T_2 = 1582.3\text{ R}$$
$$h_2 = 391.01\text{ Btu/lbm}$$

Temperature after constant pressure heat addition is

$$T_3 = 2260\text{ R}$$

Hence volume after constant pressure heat addition is

$$V_3 = \left(\frac{T_3}{T_2}\right)V_2$$
$$= \left(\frac{2260}{1582.3}\right)V_2$$
$$= 1.428\times V_2$$

Step 7 of 9

From ideal gas properties table of air at T_3,

$$V_{r3} = 2.922 \text{ and}$$
$$h_3 = 577.52\text{ Btu/lbm}$$

Hence amount of heat added is

$$q_{in} = h_3 - h_2$$
$$= 577.52 - 86.06$$
$$= 186.51\text{ Btu/lbm}$$

Step 8 of 9

For isentropic expansion process,

$$V_{r4} = \left(\frac{V_4}{V_3}\right)V_{r3}$$
$$= \left(\frac{V_1}{1.428\times V_2}\right)V_{r3}$$
$$= \left(\frac{20}{1.428}\right)2.922$$
$$= 40.92$$

From ideal gas properties table of air, the internal energy corresponding to V_{r4} is

$$u_4 = 152.65\text{ Btu/lbm}$$

Hence amount of heat rejected is

$$q_{out} = u_4 - u_1$$
$$= 152.65 - 86.06$$
$$= 66.59\text{ Btu/lbm}$$

Step 9 of 9

Efficiency of the cycle,

$$\eta_{Diesel} = 1 - \frac{q_{out}}{q_{in}}$$
$$= 1 - \frac{66.59}{186.51}$$
$$= 0.643$$

Hence efficiency of Diesel cycle is $\boxed{\eta_{Diesel} = 64.3\%}$

Question: 9.176P

A Brayton cycle with a pressure ratio of 12 operates with air entering the compressor at 13 psia and 20°F, and the turbine at 1000°F. Calculate the net specific work produced by this cycle treating the air as an ideal gas with (*a*) constant specific heats at room temperature and (*b*) variable specific heats.

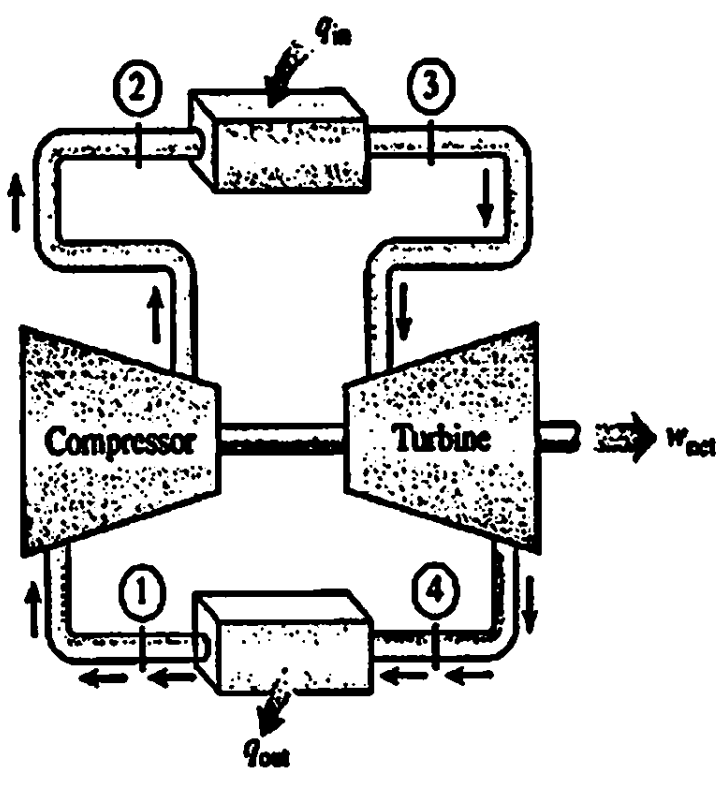


FIGURE P9–176E

Step 1 of 5

Obtain the properties of air at room temperature from properties of air table

Specific heat of air at constant pressure $c_p = 0.24\,\text{Btu/lbm}\cdot\text{R}$

Ratio of specific heats $k = 1.4$

(a)

Find the net specific work by using constant specific heats:

Find the exit temperature of the compressor by using isentropic relation of the process 1- 2

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Here, T_1, T_2 are the temperatures of compressor inlet, exit and P_1, P_2 are the pressures of compressor inlet, exit.

Substitute pressure ratio, $\frac{P_2}{P_1} = 12$ and $20°\text{F} = 480\,\text{R}$ for T_1

$$\frac{T_2}{480} = (12)^{\frac{1.4-1}{1.4}}$$
$$T_2 = 976.28\,\text{R}$$

Step 2 of 5

Find the exit temperature of turbine by using isentropic expansion of the turbine of the process 3-4

$$\frac{T_3}{T_4} = \left(\frac{P_3}{P_4}\right)^{\frac{k-1}{k}}$$
$$= \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} \qquad (\text{since } P_3 = P_2, P_4 = P_1)$$

Here, a point 3 and 4 indicates turbine inlet and exit respectively.

Find T_4 by substituting $1000°\text{F} = 1460\,\text{R}$ for T_3

$$\frac{1460}{T_4} = 12^{\frac{1.4-1}{1.4}}$$
$$T_4 = 717.81\,\text{R}$$

Step 3 of 5

Find the specific work output by the Brayton cycle by using the expression,

$$w_{net} = w_{turbine} - w_{compressor}$$
$$= c_p(T_3 - T_4) - c_p(T_2 - T_1)$$
$$= 0.24(1460 - 717.81) - 0.24(976.28 - 480)$$
$$= 178.125 - 119.107$$
$$= 59.018\,\text{Btu/lbm}$$

Therefore, net specific work produced by the cycle by using constant specific heats is **59.018 Btu/lbm**

Step 4 of 5

(b)

Find the net specific work by using variable specific heats:

Obtain the properties of air at compressor inlet temperature at $T_1 = 480\,\text{R}$ from table "Ideal gas properties of air"

Enthalpy $h_1 = 114.69\,\text{Btu/lbm}$

Relative pressure $P_{r1} = 0.9182$

Similarly obtain the properties of air at turbine inlet temperature at $T_3 = 1460\,\text{R}$

Specific enthalpy

$$h_3 = 353.37 + (363.89 - 353.37)\left(\frac{1460 - 1440}{1480 - 1440}\right)$$
$$= 358.63\,\text{Btu/lbm}$$

Relative pressure

$$P_{r3} = 47.74 + (53.04 - 47.75)\left(\frac{1460 - 1440}{1480 - 1440}\right)$$
$$= 50.385$$

Step 5 of 5

Find the relative pressure at compressor exit by using the relation,

$$P_{r2} = \frac{P_2}{P_1} P_{r1}$$
$$= 12 \times 0.9182$$
$$= 11.0184$$

Find the enthalpy at $P_{r2} = 11.0184$ from ideal gas properties of air table,

$$h_2 = 231.06 + (236.02 - 231.06)\left(\frac{11.0184 - 10.61}{11.43 - 10.61}\right)$$
$$= 233.53\,\text{Btu/lbm}$$

Find the relative pressure at turbine exit by using the relation,

$$P_{r4} = \frac{P_4}{P_3} P_{r3}$$
$$= \frac{P_1}{P_2} P_{r3}$$
$$= \frac{1}{12} \times 50.385$$
$$= 4.1987$$

Find the enthalpy at $P_{r4} = 4.1987$ from ideal gas properties of air table,

$$h_4 = 177.23 + (182.08 - 177.23)\left(\frac{4.1987 - 4.193}{4.607 - 4.193}\right)$$
$$= 177.296\,\text{Btu/lbm}$$

Find the specific work output by the Brayton cycle by using the expression,

$$w_{net} = w_{turbine} - w_{compressor}$$
$$= (h_3 - h_4) - (h_2 - h_1)$$
$$= (358.63 - 177.296) - (233.53 - 114.69)$$
$$= 181.361 - 118.84$$
$$= 62.521\,\text{Btu/lbm}$$

Therefore, net specific work produced by the cycle by using variable specific heats is **62.521 Btu/lbm**

Question: 9.177P

A four-stroke turbocharged V-16 diesel engine built by GE Transportation Systems to power fast trains produces 3500 hp at 1200 rpm. Determine the amount of power produced per cylinder per (*a*) mechanical cycle and (*b*) thermodynamic cycle.

Step 1 of 3

Given

Power produced $P = 3500\,\text{hp}$

Speed of train $N = 1200\,\text{rpm}$

Number of cylinders $n = 16$

Step 2 of 3

(a) Mechanical cycle

$$P_{mech} = \frac{\text{Total power}}{(\text{Number of cylinders})(\text{Number of mechanical cycles})}$$

$$= \frac{3500 \times 746}{(16)\left(\frac{1200}{60}\right)} \qquad (\text{Since } 1\text{hp} = 746 \text{ watts})$$

$$= 8159.375\,\text{J/cycle}$$

$$\boxed{P_{mech} = 8.16\,\text{kJ/cycle}}$$

Step 3 of 3

(b) Thermodynamic cycle

$$P_{ther} = \frac{\text{Total power}}{(\text{Number of cylinders})(\text{Number of thermodynamic cycles})}$$

$$= \frac{3500 \times 746}{(16)\left(\frac{1200}{2 \times 60}\right)}$$

$$= 16318.75\,\text{J/cycle}$$

$$\boxed{P_{ther} = 16.318\,\text{kJ/cycle}}$$

Question: 9.178P

Consider a simple ideal Brayton cycle operating between the temperature limits of 300 and 1500 K. Using constant specific heats at room temperature, determine the pressure ratio for which the compressor and the turbine exit temperatures of air are equal.

Step 1 of 4

Given

Initial temperature $T_1 = 300\text{K}$

Maximum temperature $T_3 = 1500\text{K}$

Considering $k = 1.4$ (specific heat ratio)

Step 2 of 4

During the process isentropic compression (1-2)

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_2}{T_1} = \left(r_p\right)^{\frac{k-1}{k}}$$

$$T_2 = T_1\left(r_p\right)^{\frac{k-1}{k}} \text{ ---------- (1)}$$

Step 3 of 4

Similarly during the process isentropic expansion (3-4)

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

Since $\frac{P_2}{P_1} = \frac{P_3}{P_4} = r_p$

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{T_3} = \left(\frac{1}{r_p}\right)^{\frac{k-1}{k}}$$

$$T_4 = T_3\left(\frac{1}{r_p}\right)^{\frac{k-1}{k}} \text{ ---------- (2)}$$

Step 4 of 4

If compressor and the turbine exit temperatures of air are equal then

$T_2 = T_4$

Therefore from expressions (1) and (2)

$$T_1\left(r_p\right)^{\frac{k-1}{k}} = T_3\left(\frac{1}{r_p}\right)^{\frac{k-1}{k}}$$

$$\frac{T_3}{T_1} = \left(r_p\right)^{\frac{2(k-1)}{k}}$$

$$r_p = \left(\frac{T_3}{T_1}\right)^{\frac{k}{2(k-1)}}$$

$$r_p = \left(\frac{1500}{300}\right)^{\frac{1.4}{2(1.4-1)}}$$

$$\boxed{r_p = 16.718}$$

Question: 9.179P

A four-cylinder spark-ignition engine has a compression ratio of 10.5, and each cylinder has a maximum volume of 0.4 L. At the beginning of the compression process, the air is at 98 kPa and 37°C, and the maximum temperature in the cycle is 2100 K. Assuming the engine to operate on the ideal Otto cycle, determine (*a*) the amount of heat supplied per cylinder, (*b*) the thermal efficiency, and (*c*) the number of revolutions per minute required for a net power output of 45 kW. Assume variable specific heats for air.

Step 1 of 4

Obtain the properties of air at compressor inlet temperature $T_1 = 37°C = 310\,K$ from ideal gas properties of air.

Specific internal energy $u_1 = 221.25\,kJ/kg$

Relative volume $v_{r1} = 572.3$

Find the relative volume at state 2 by applying the isentropic relation during the compression process 1-2

$$\frac{v_{r2}}{v_{r1}} = \frac{v_2}{v_1}$$

Here, $\frac{v_1}{v_2}$ is compression ratio

Substitute 10.5 for $\frac{v_1}{v_2}$

$$\frac{v_{r2}}{v_{r1}} = \frac{1}{\frac{v_1}{v_2}}$$

$$\frac{v_{r2}}{572.3} = \frac{1}{10.5}$$

$$v_{r2} = 54.50$$

Step 2 of 4

Obtain the internal energy at state 2 at $v_{r2} = 54.50$ from ideal gas properties of air

$$u_2 = 560.01 + (576.12 - 560.01)\left(\frac{54.50 - 55.54}{51.64 - 55.54}\right)$$

$$= 564.306\,kJ/kg$$

Similarly obtain the properties of air at maximum temperature in the cycle $T_3 = 2100\,K$

Specific internal energy $u_3 = 1775.3\,kJ/kg$

Relative volume $v_{r3} = 2.356$

By using the isentropic relation during the expansion process 3-4, find the relative volume v_{r4}

$$\frac{v_{r4}}{v_{r3}} = \frac{v_4}{v_3}$$

$$\frac{v_{r4}}{v_{r3}} = \frac{v_1}{v_2} \qquad (\text{since } v_4 = v_1 \text{ and } v_3 = v_2)$$

$$\frac{v_{r4}}{2.356} = 10.5$$

$$v_{r4} = 24.738$$

Obtain the internal energy at state 4 at $v_{r4} = 24.738$ from ideal gas properties of air

$$u_4 = 758.94 + (776.10 - 758.94)\left(\frac{24.738 - 25.17}{23.72 - 25.17}\right)$$

$$= 764.052\,kJ/kg$$

Find mass of air by using ideal gas equation,

$m = \frac{P_1 V_1}{R T_1}$ Here, P_1 is initial pressure, V_1 is initial volume, R is gas constant and T_1 is initial temperature

Substitute 98 kPa for P_1, $0.4 \times 10^3\,m^3$ for V_1, $0.287\,kJ/kg \cdot K$ for R and $310\,K$ for T_1

$$m = \frac{98 \times 0.4 \times 10^{-3}}{0.287 \times 310}$$

$$= 0.00044\,kg$$

Step 3 of 4

(a) Find the amount of heat supplied per cylinder by using the equation,

$$Q_{2-3} = m(u_3 - u_2)$$

$$= 0.00044(1775.3 - 564.306)$$

$$= 0.5328\,kJ$$

Therefore, the amount of heat supplied per cylinder is $\boxed{0.5328\,kJ}$

Step 4 of 4

(b)

Find the amount of heat rejection during the cycle by using the equation,

$$Q_{4-1} = m(u_4 - u_1)$$

$$= 0.00044(764.052 - 221.25)$$

$$= 0.2388\,kJ$$

Find the net work done by using the equation,

$$W_{net} = Q_{2-3} - Q_{4-1}$$

$$= 0.5328 - 0.2388$$

$$= 0.294\,kJ$$

Find the thermal efficiency of the cycle by using the equation,

$$\eta = \frac{W_{net}}{Q_{2-3}}$$

$$= \frac{0.294}{0.5328}$$

$$= 0.5518$$

$$= 53.18\%$$

Therefore, thermal efficiency of the cycle is $\boxed{53.18\%}$

(c)

Find the number of revolutions per minute by using the equation,

$$\dot{n} = 2\frac{\dot{W}_{net}}{n_{cyl} W_{net}}$$

Here, $\dot{W}_{net}$ is net power output, n_{cyl} is number of cylinders

Substitute 45 kW for $\dot{W}_{net}$ and 4 for n_{cyl}

$$\dot{n} = 2 \times \frac{45}{4 \times 0.294}$$

$$= 76.53\,rps$$

$$= 76.53 \times 60$$

$$= 4591.836\,rpm$$

Therefore, the number of revolutions per minute is $\boxed{4591.836\,rpm}$

Question: 9.180P

Reconsider Prob. 9–179. Using EES (or other) software, study the effect of varying the compression ratio from 5 to 11 on the net work done and the efficiency of the cycle. Plot the *P-v* and *T-s* diagrams for the cycle, and discuss the results.

Step 1 of 3

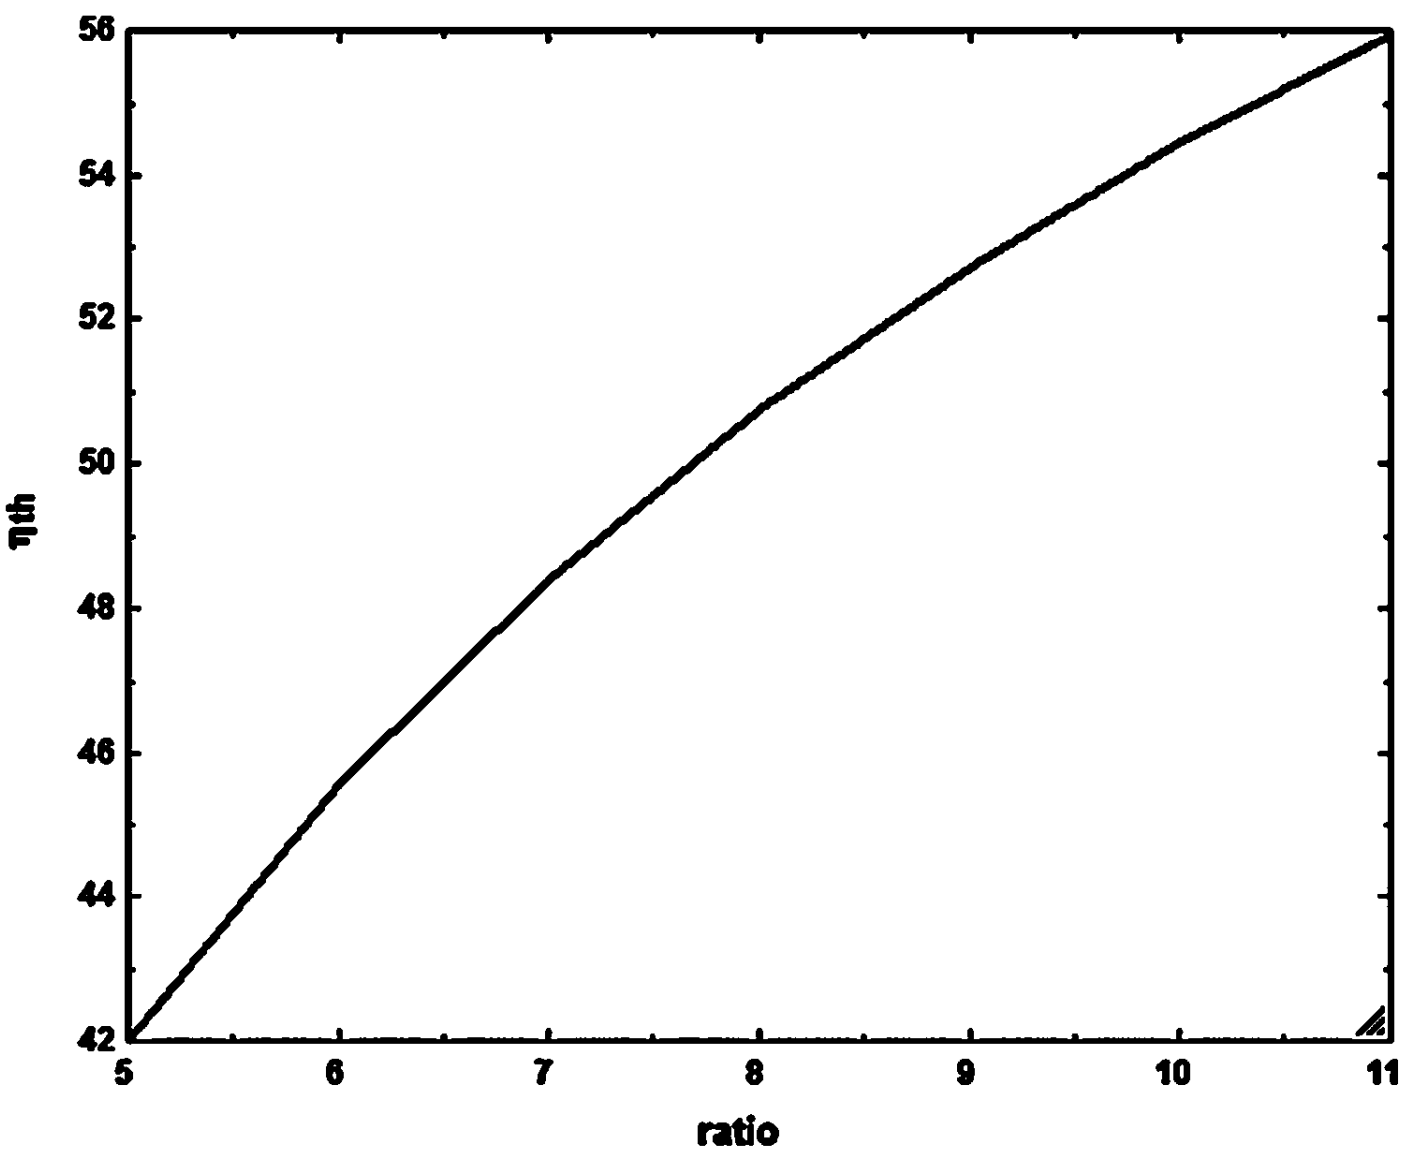
Now to solve the equation for a range of compression ratio, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.

A dailog box will open. Now, select "No. of Runs" = 7

Select "variables in equations" as ratio , Eta_th and w_net

Press 'Add' and then press 'ok'

A table will appear and enter the values of compression ration 'ratio' as 5, 6, 7, 8, 9, 10, and 11. Then click on 'Solve table' of 'Calculate' menu.



The Solution will appear as follows:

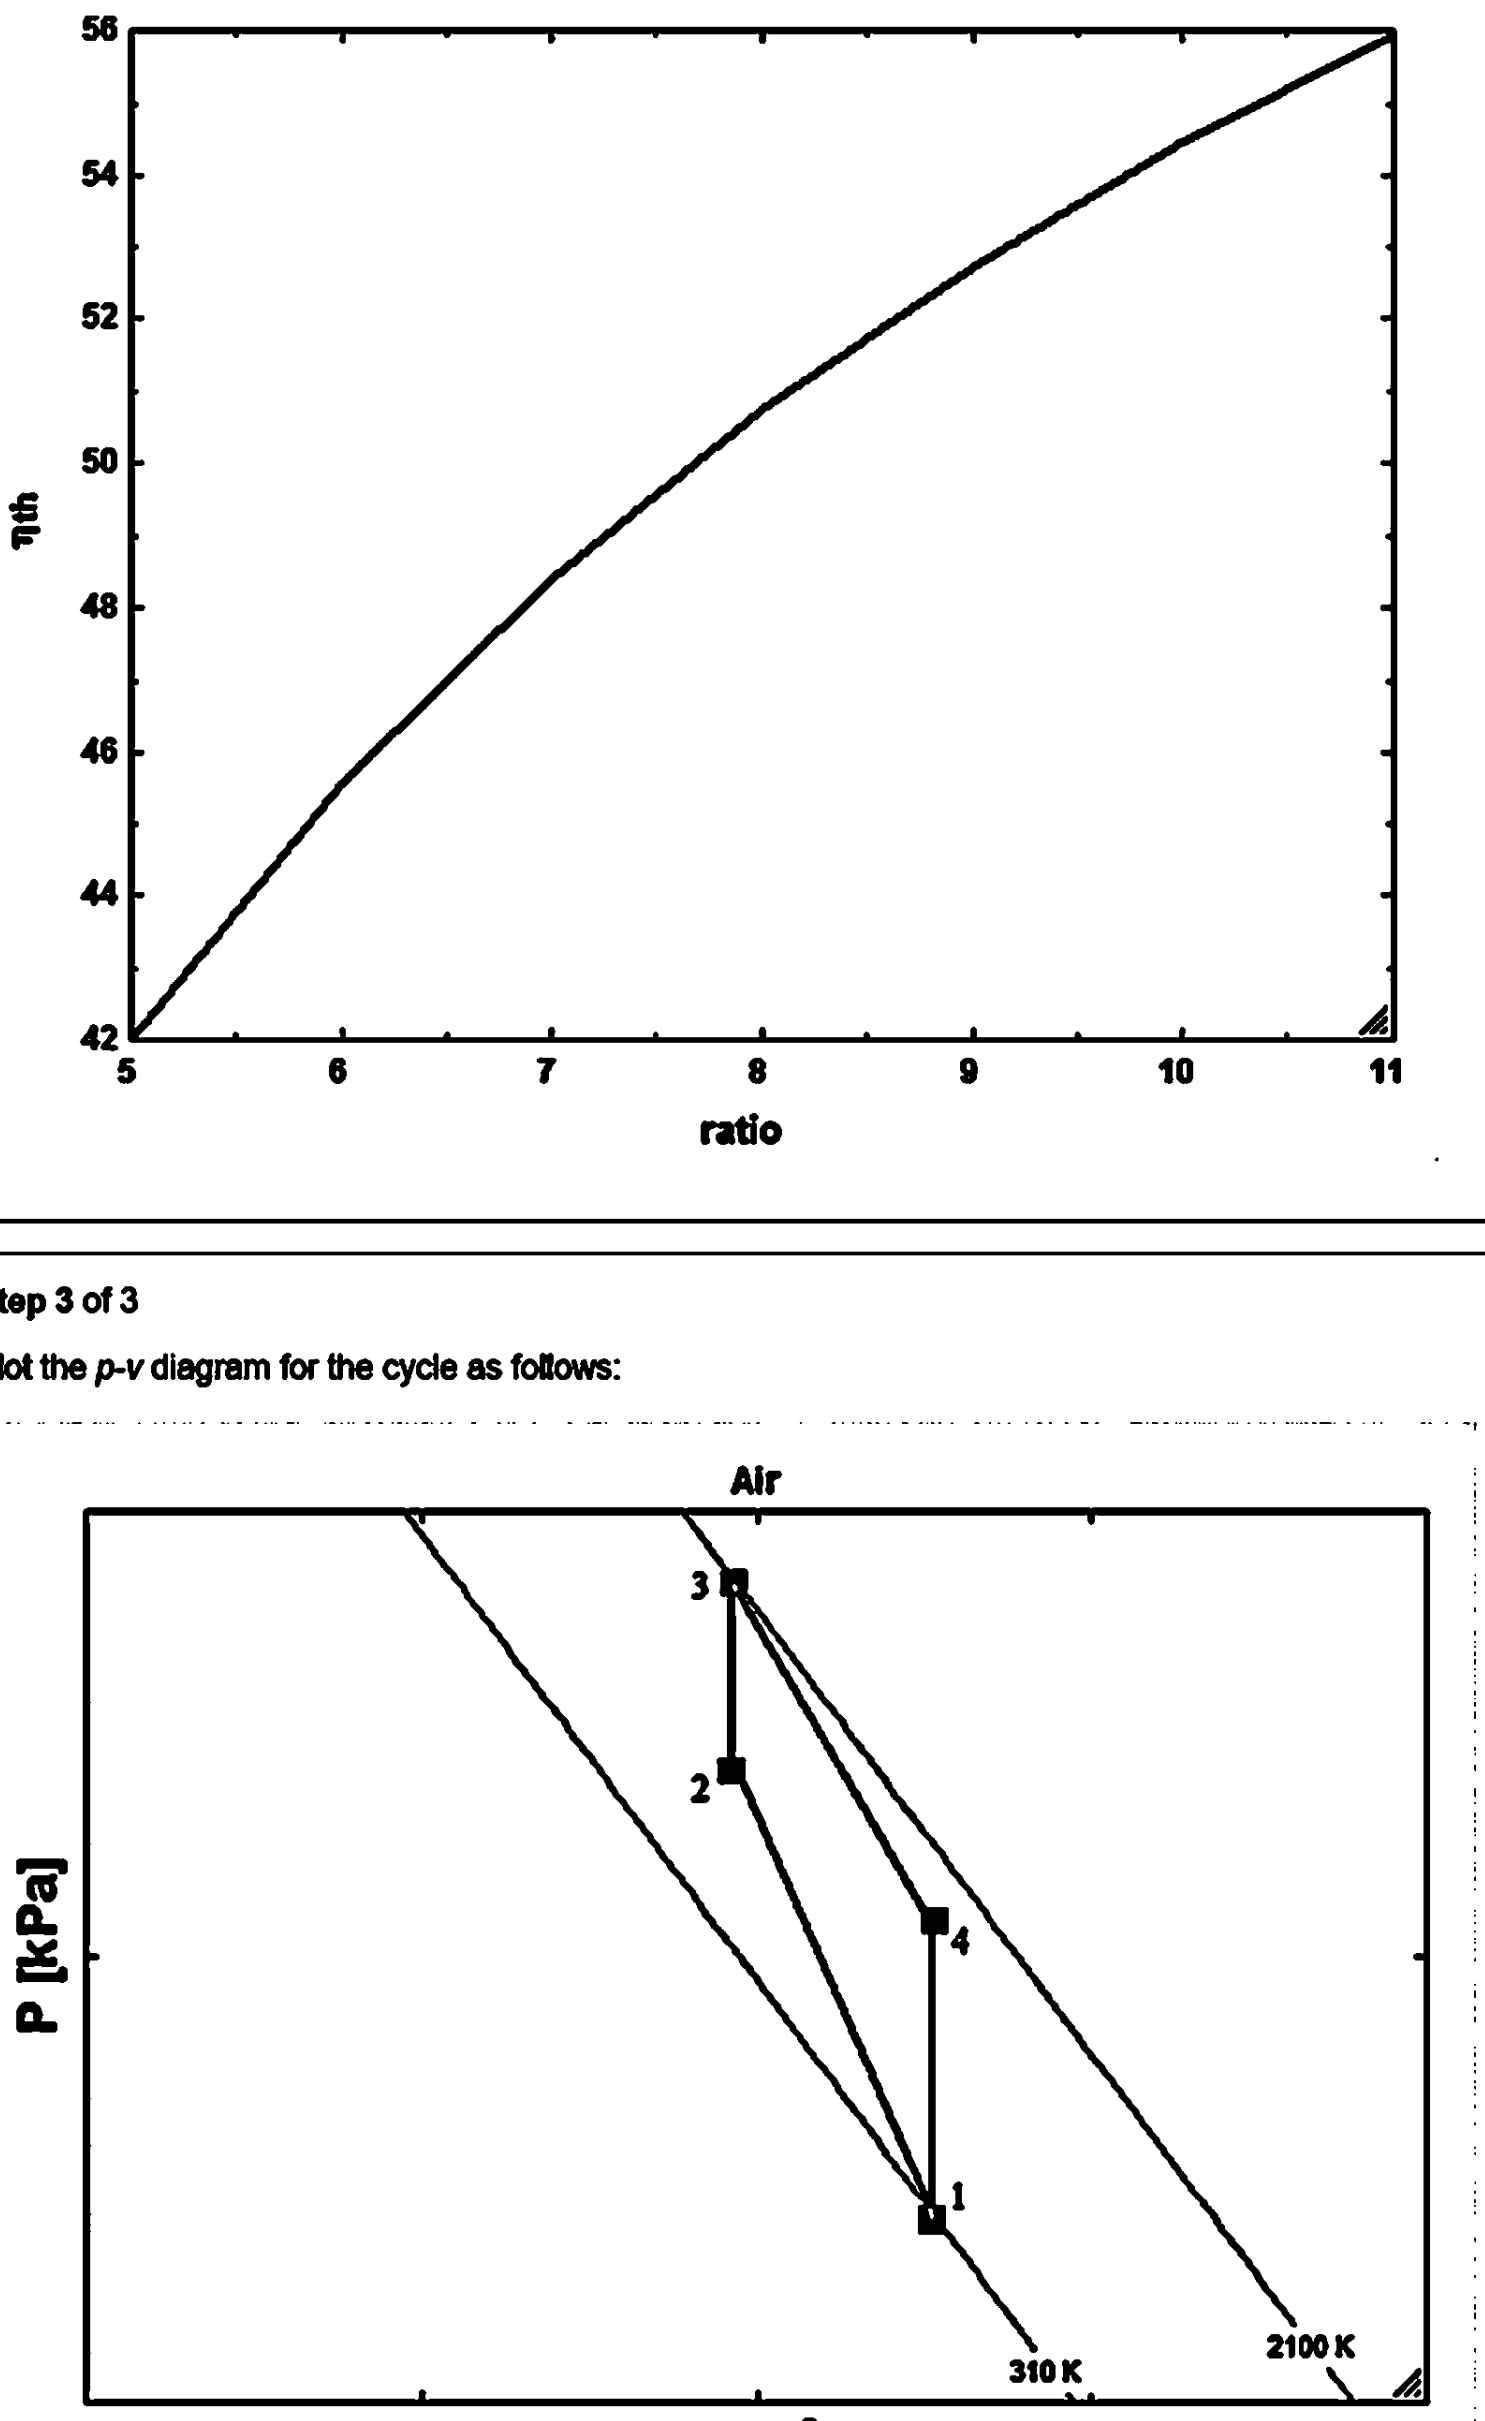
1..7	1 ratio	2 η_{th}	3 w_{net}
Run 1	5	42.01	568.3
Run 2	6	45.56	602
Run 3	7	48.4	625.8
Run 4	8	50.75	643
Run 5	9	52.73	655.5
Run 6	10	54.45	664.7
Run 7	11	55.95	671.3

In order to find the variation of thermal efficiency with compression ratio, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.

Select X-axis as ratio and Y-axis as Eta_th. Press OK

The Graph will be plotted as follows:

Step 2 of 3



Inorder to find the variation of thermal efficiency with compression, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.

Select X-axis as ratio and Y-axis as Eta_th. Press OK

The Graph will be plotted as follows:

Step 3 of 3

Plot the *p-v* diagram for the cycle as follows:

Plot the *T-s* diagram for the cycle as follows:

Question: 9.181P

An ideal gas Carnot cycle uses helium as the working fluid and rejects heat to a lake at 15°C. Determine the pressure ratio, compression ratio, and minimum temperature of the heat source for this cycle to have a thermal efficiency of 50 percent.

Step 1 of 4

Given

Thermal efficiency $\eta_{th} = 0.5$

Low temperature reservoir $T_L = 15°C = 15+273 = 288K$

Step 2 of 4

The efficiency of a Carnot cycle is defined as

$$\eta = 1 - \frac{T_{min}}{T_{max}}$$

$$\eta = 1 - \frac{T_L}{T_H}$$

$$0.5 = 1 - \frac{288}{T_H}$$

$$T_H = 576K$$

Temperature of heat source

$$\boxed{T_H = 576K}$$

Step 3 of 4

The pressure ratio is defined as

$$\frac{P_2}{P_1} = \left(\frac{T_2}{T_1}\right)^{\frac{k}{k-1}}$$

$$\frac{P_2}{P_1} = \left(\frac{T_H}{T_L}\right)^{\frac{k}{k-1}}$$

Specific heat ratio for helium is taking from ideal gas specific heats of various common gases table

$k = 1.667$

$$\frac{P_2}{P_1} = \left(\frac{576}{288}\right)^{\frac{1.667}{1.667-1}}$$

$$= 5.6539$$

Pressure ratio

$$\boxed{\frac{P_2}{P_1} = 5.6539}$$

Step 4 of 4

Compression ratio

$$\frac{v_1}{v_2} = \left(\frac{P_2}{P_1}\right)^{1/k}$$

$$\frac{v_1}{v_2} = (5.6539)^{1/1.667}$$

$$= 2.8269$$

Compression ratio

$$\boxed{\frac{v_1}{v_2} = 2.83}$$

Question: 9.182P

Repeat Prob. 9–181 when the lake is at 60°F and the Carnot cycle's thermal efficiency is to be 60 percent

Step 1 of 4

Given

Thermal efficiency $\eta_{th} = 0.6$

Low temperature reservoir $T_L = 60°F = 60+460 = 520R$

Step 2 of 4

The efficiency of a Carnot cycle is defined as

$$\eta = 1 - \frac{T_{min}}{T_{max}}$$

$$\eta = 1 - \frac{T_L}{T_H}$$

$$0.6 = 1 - \frac{520}{T_H}$$

$$T_H = 1300R$$

Temperature of heat source

$$\boxed{T_H = 1300R}$$

Step 3 of 4

The pressure ratio is defined as

$$\frac{P_2}{P_1} = \left(\frac{T_2}{T_1}\right)^{\frac{k}{k-1}}$$

Specific heat ratio for helium is taking from ideal gas specific heats of various common gases table

$k = 1.667$

$$\frac{P_2}{P_1} = \left(\frac{1300}{520}\right)^{\frac{1.667}{1.667-1}}$$

$$\boxed{\frac{P_2}{P_1} = 9.875}$$

Step 4 of 4

Compression ratio

$$\frac{v_1}{v_2} = \left(\frac{P_2}{P_1}\right)^{1/k}$$

$$\frac{v_1}{v_2} = (9.875)^{1/1.667}$$

$$\frac{v_1}{v_2} = 3.95$$

Compression ratio

$$\boxed{\frac{v_1}{v_2} = 3.95}$$

Question: 9.183P

A typical hydrocarbon fuel produces 43,000 kJ/kg of heat when used in a spark-ignition engine. Determine the compression ratio required for an ideal Otto cycle to use 0.035 grams of fuel to produce 1 kJ of work. Use constant specific heats at room temperature.

Step 1 of 2

Determine the heat energy of hydrocarbon fuel by using the equation,

$$Q = mq$$

Here, m is mass of fuel and q is specific energy of hydrocarbon fuel.

Substitute $0.035\,\text{grams} = 0.035\times10^{-3}\,\text{kg}$ for m and $43,000\,\text{kJ/kg}$ for q

$$\begin{aligned} Q &= 0.035\times10^{-3}\times43,000 \\ &= 1.505\,\text{kJ} \end{aligned}$$

Step 2 of 2

Write the thermal efficiency of a heat engine,

$$\eta = \frac{W}{Q_{in}} \quad \text{..... (1)}$$

Here, W is work output from the engine and Q_{in} is heat supplied to the engine

Also, write the thermal efficiency of an ideal Otto cycle in terms of compression ratio,

$$\eta = 1 - \frac{1}{r^{k-1}} \quad \text{..... (2)}$$

Here, r is compression ratio and k is specific heat ratio.

Equate equations (1) and (2)

$$\eta = \frac{W}{Q_{in}} = 1 - \frac{1}{r^{k-1}}$$

$$\frac{W}{Q_{in}} = 1 - \frac{1}{r^{k-1}}$$

Substitute 1 kJ for W and 1.4 for k

$$\frac{1}{1.505} = 1 - \frac{1}{r^{1.4-1}}$$

$$0.664 = 1 - \frac{1}{r^{0.4}}$$

$$0.336 = \frac{1}{r^{0.4}}$$

$$r^{0.4} = 2.976$$

$$r = 15.27$$

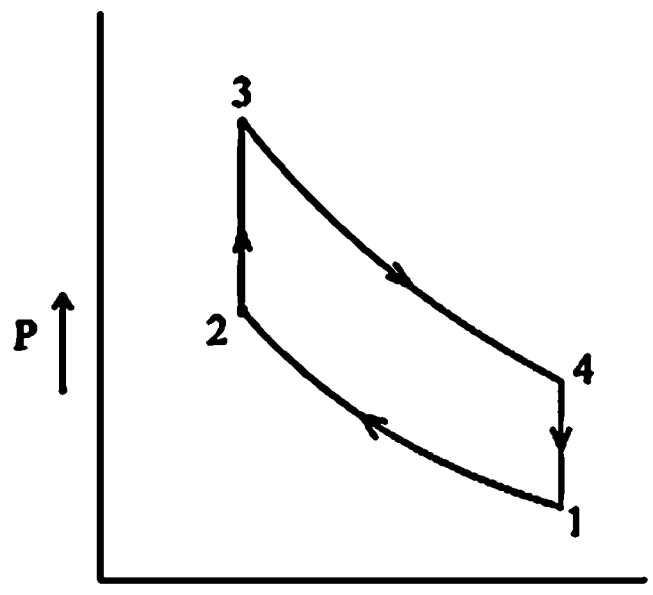
Therefore, compression ratio of Otto cycle is $\boxed{15.27}$

Question:

An ideal Otto cycle has a compression ratio of 9.2 and uses air as the working fluid. At the beginning of the compression process, air is at 98 kPa and 27°C. The pressure is doubled during the constant-volume heat-addition process. Accounting for the variation of specific heats with temperature, determine (*a*) the amount of heat transferred to the air,(*b*) the net work output, (*c*) the thermal efficiency, and.(*d*) the mean effective pressure for the cycle.

Step 1 of 16

Given



Compression ratio $r = 9.2$

Initial pressure $P_1 = 98\ \text{kPa}$

Initial temperature $T_1 = 27°\text{C} = 27 + 273 = 300\text{K}$

Pressure during the constant volume heat addition process is $P_3 = 2P_2$

Step 2 of 16

Step 3 of 16

a)

Since we are considering variable specific heats the specific heat at constant pressure and specific heat at constant volume will be different at different temperatures.

At $T_1 = 300\text{K}$ from ideal gas properties of air

$u_1 = 214.07\ \text{kJ/kg}$

$v_{r1} = 621.2$

Step 4 of 16

Process 1-2 is isentropic compression process

$$\frac{v_{r_1}}{v_{r_2}} = \frac{v_2}{v_1}$$

$$v_{r2} = v_{r1}\frac{v_2}{v_1}$$

$$= 621.2 \times \frac{1}{9.2}$$

$$v_{r_2} = 67.52$$

Step 5 of 16

At $v_{r_2} = 67.52$ from ideal gas properties of air

$$u_2 = 512.33 + (520.23 - 512.33)\left(\frac{67.52 - 69.76}{67.07 - 69.76}\right)$$

$$u_2 = 518.9\text{kJ/kg}$$

$$T_2 = 700 + (710 - 700)\left(\frac{67.52 - 69.76}{67.07 - 69.76}\right)$$

$$T_2 = 708.32\text{K}$$

Step 6 of 16

Applying ideal gas equation to process 1-2

$$\frac{P_1 v_1}{T_1} = \frac{P_2 v_2}{T_2}$$

$$P_2 = \frac{v_1}{v_2}\frac{T_2}{T_1}P_1$$

$$= (9.2) \times \frac{708.32}{300} \times 98$$

$$P_2 = 2128.737\ \text{kPa}$$

Step 7 of 16

Process 2-3 is constant volume heat addition

$$\frac{T_3}{T_2} = \frac{P_3}{P_2}$$

$$T_3 = \frac{P_3}{P_2} \times T_2$$

$$T_3 = 2(708.32)$$

$$T_3 = 1416.64\text{K}$$

Step 8 of 16

At $T_3 = 1416.64\text{K}$ from ideal gas properties of air

$$u_3 = 1113.52 + (1131.77 - 1113.52)\left(\frac{1416.64 - 1400}{1420 - 1400}\right)$$

$$u_3 = 1128.704\ \text{kJ/kg}$$

$$v_{r_3} = 8.919 + (8.526 - 8.919)\left(\frac{1416.64 - 1400}{1420 - 1400}\right)$$

$$v_{r3} = 8.592$$

Step 9 of 16

(a) The amount of heat transferred to the air is

$$q_{in} = (u_3 - u_2)\ \text{kJ/kg}$$

$$= (1128.704 - 518.9)$$

(a) The amount of heat transferred to the air is

$$q_{in} = (u_3 - u_2) \text{ kJ/kg}$$
$$= (1128.704 - 518.9)$$
$$\boxed{q_{in} = 609.804 \text{ kJ/kg}}$$

Step 10 of 16

(b) The net work output

Process 3-4 is isentropic expansion

$$\frac{v_{r4}}{v_{r3}} = \frac{v_4}{v_3}$$
$$v_{r4} = \frac{v_4}{v_3} v_{r3}$$
$$v_{r4} = \frac{v_1}{v_2} v_{r3}$$
$$= 9.2(8.592)$$
$$v_{r_4} = 79.0464$$

Step 11 of 16

At $v_{r_4} = 79.0464$ from ideal gas properties of air

$$u_4 = 481.01 + (488.81 - 481.01)\left(\frac{79.0464 - 81.89}{78.61 - 81.89}\right)$$
$$u_4 = 487.77 \text{ kJ/kg}$$

Step 12 of 16

The amount of heat rejection is expressed as

$$q_{out} = (u_4 - u_1) \text{ kJ/kg}$$
$$= (487.77 - 214.07)$$
$$q_{out} = 273.7 \text{ kJ/kg}$$

Step 13 of 16

The net work output

$$w_{net} = q_{in} - q_{out}$$
$$= 609.804 - 273.7$$
$$\boxed{w_{net} = 336.104 \text{ kJ/kg}}$$

Step 14 of 16

(c) The thermal efficiency

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$
$$= \frac{336.104}{609.804}$$
$$= 0.551$$
$$\boxed{\eta_{th} = 55.1\%}$$

Step 15 of 16

(d) The mean effective pressure for the cycle is

$$MEP = \frac{w_{net}}{v_1 - v_2}$$
$$MEP = \frac{w_{net}}{v_1\left(1 - \frac{v_2}{v_1}\right)}$$

Where v_1 can be calculated by using ideal gas equation

$$v_1 = \frac{RT_1}{P_1}$$
$$= \frac{(0.287)(300)}{98}$$
$$v_1 = 0.8785 \text{ m}^3/\text{kg}$$

Step 16 of 16

Mean effective pressure is

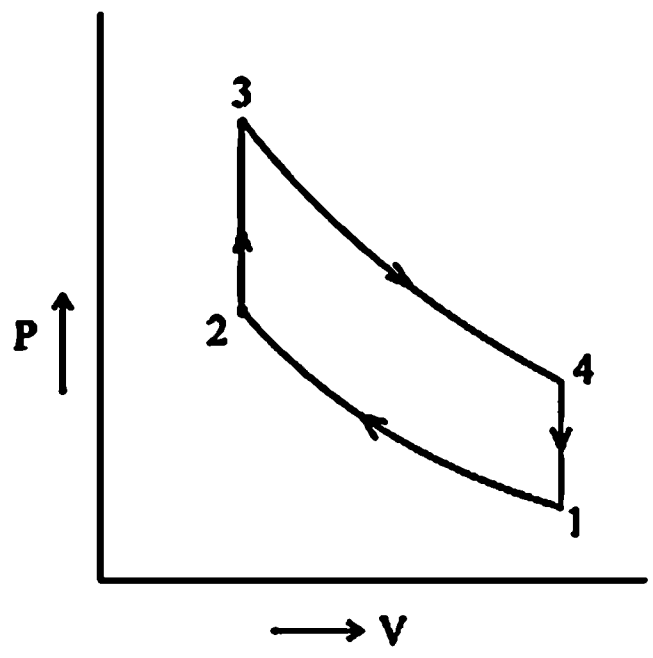
$$MEP = \frac{w_{net}}{v_1\left(1 - \frac{v_2}{v_1}\right)}$$
$$MEP = \frac{336.104}{0.8785\left(1 - \frac{1}{9.2}\right)}$$
$$\boxed{MEP = 429.245 \text{ kPa}}$$

Question: 9.185P pg 1

Repeat Prob. 9–184 using constant specific heats at room temperature.

Step 1 of 13

Given



Compression ratio $r = 9.2$

Initial pressure $P_1 = 98\ \text{kPa}$

Initial temperature $T_1 = 27°\text{C} = 27 + 273 = 300\text{K}$

Pressure during the constant volume heat addition process is $P_3 = 2P_2$

Step 2 of 13

Step 3 of 13

a) The amount of heat supplied

Considering constant specific heats at room temperature

From table ideal gas specific heats of various common gases

Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4\,(\text{specific heat ratio})$

Step 4 of 13

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 300(9.2)^{1.4-1}$$

$$T_2 = 728.847\text{K}$$

Step 5 of 13

Applying ideal gas equation to process 1-2

$$\frac{P_1 v_1}{T_1} = \frac{P_2 v_2}{T_2}$$

$$P_2 = \frac{v_1}{v_2}\frac{T_2}{T_1}P_1$$

$$= (9.2)\frac{728.847}{300} \times 98$$

$$P_2 = 2190.428\ \text{kPa}$$

Step 6 of 13

Process 2-3 is constant volume heat addition

$$\frac{T_3}{T_2} = \frac{P_3}{P_2}$$

$$T_3 = \frac{P_3}{P_2} \times T_2$$

$$T_3 = 2(728.847)$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 300(9.2)^{1.4-1}$$

$$T_2 = 728.847\text{K}$$

Step 5 of 13

Applying ideal gas equation to process 1-2

$$\frac{P_1 v_1}{T_1} = \frac{P_2 v_2}{T_2}$$

$$P_2 = \frac{v_1}{v_2}\frac{T_2}{T_1}P_1$$

$$= (9.2)\frac{728.847}{300} \times 98$$

$$P_2 = 2190.428\ \text{kPa}$$

Step 6 of 13

Process 2-3 is constant volume heat addition

$$\frac{T_3}{T_2} = \frac{P_3}{P_2}$$

$$T_3 = \frac{P_3}{P_2} \times T_2$$

$$T_3 = 2(728.847)$$

$$\boxed{q_{in} = 523.312\ \text{kJ/kg}}$$

Step 9 of 13

(b) The net work output

The amount of heat rejection during the process 4-1 is

$$q_{out} = (u_4 - u_1)\ \text{kJ/kg}$$

Step 9 of 13

(b) The net work output

The amount of heat rejection during the process 4-1 is

$$q_{out} = (u_4 - u_1)\ \text{kJ/kg}$$

$$= c_v (T_4 - T_1)$$

$$= 0.718(600 - 300)$$

$$q_{out} = 215.4\ \text{kJ/kg}$$

Step 10 of 13

The net work output

$$w_{net} = q_{in} - q_{out}$$

$$= 523.312 - 215.4$$

$$\boxed{w_{net} = 307.912\ \text{kJ/kg}}$$

Step 11 of 13

c)

The thermal efficiency is defined as

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$= \frac{307.912}{523.312}$$

$$= 0.588$$

$$\boxed{\eta_{th} = 58.8\%}$$

Step 12 of 13

(d) Mean effective pressure

We know that

$$MEP = \frac{w_{net}}{v_1 - v_2}$$

$$MEP = \frac{w_{net}}{v_1\left(1 - \frac{v_2}{v_1}\right)}$$

Where v_1 can be calculated by using ideal gas equation

$$v_1 = \frac{RT_1}{P_1}$$

$$= \frac{(0.287)(300)}{98}$$

$$v_1 = 0.8785\ \text{m}^3/\text{kg}$$

Step 13 of 13

Mean effective pressure is

$$MEP = \frac{w_{net}}{v_1\left(1 - \frac{v_2}{v_1}\right)}$$

$$MEP = \frac{w_{net}}{v_1\left(1 - \frac{1}{r}\right)}$$

$$= \frac{307.912}{0.8785\left(1 - \frac{1}{9.2}\right)}$$

$$= 393.062\text{kPa}$$

$$\boxed{MEP = 393.062\ \text{kPa}}$$

Question: 9.186P

An ideal dual cycle has a compression ratio of 14 and uses air as the working fluid. At the beginning of the compression process, air is at 14.7 psia and 120°F, and occupies a volume of 98 in 3. During the heat-addition process, 0.6 Btu of heat is transferred to air at constant volume and 1.1 Btu at constant pressure. Using constant specific heats evaluated at room temperature, determine the thermal efficiency of the cycle.

Step 1 of 7

Obtain the properties of air at room temperature from table "Properties of ideal gases"

Gas constant of air $R = 0.3704\,\text{psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$

Specific heat at constant pressure $c_p = 0.24\,\text{Btu/lbm}\cdot\text{R}$

Specific heat at constant volume $c_v = 0.171\,\text{Btu/lbm}\cdot\text{R}$

Specific heat ratio, $k = 1.4$

Draw the different processes of Dual cycle on *T-s* diagram as shown below:

Question:

An ideal dual cycle has a compression ratio of 14 and uses air as the working fluid. At the beginning of the compression process, air is at 14.7 psia and 120°F, and occupies a volume of 98 in 3. During the heat-addition process, 0.6 Btu of heat is transferred to air at constant volume and 1.1 Btu at constant pressure. Using constant specific heats evaluated at room temperature, determine the thermal efficiency of the cycle.

Step 1 of 7

Obtain the properties of air at room temperature from table "Properties of ideal gases"

Gas constant of air $R = 0.3704\,\text{psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$

Specific heat at constant pressure $c_p = 0.24\,\text{Btu/lbm}\cdot\text{R}$

Specific heat at constant volume $c_v = 0.171\,\text{Btu/lbm}\cdot\text{R}$

Specific heat ratio, $k = 1.4$

Draw the different processes of Dual cycle on *T-s* diagram as shown below:

Here, $\frac{V_1}{V_2}$ is compression ratio.

Substitute 14 for $\frac{V_1}{V_2}$

$$\frac{T_2}{580} = 14^{1.4-1}$$
$$T_2 = 1666.78\,\text{R}$$

Step 4 of 7

Find the temperature at state 3 after constant volume heat addition process,

$$Q_{2-3} = mc_v(T_3 - T_2)$$

Here, Q_{2-3} heat addition in constant volume process

Substitute 0.6 Btu for Q_{2-3}

$$0.6 = 0.00388 \times 0.171 \times (T_3 - 1666.78)$$
$$T_3 = 2571.10\,\text{R}$$

Step 5 of 7

Find the temperature at state 4 after constant pressure heat addition process,

Here, $\frac{V_1}{V_2}$ is compression ratio.

Substitute 14 for $\frac{V_1}{V_2}$

$$\frac{T_2}{580} = 14^{1.4-1}$$
$$T_2 = 1666.78\,\text{R}$$

Step 4 of 7

Find the temperature at state 3 after constant volume heat addition process,

$$Q_{2-3} = mc_v(T_3 - T_2)$$

Here, Q_{2-3} heat addition in constant volume process

Substitute 0.6 Btu for Q_{2-3}

$$0.6 = 0.00388 \times 0.171 \times (T_3 - 1666.78)$$
$$T_3 = 2571.10\,\text{R}$$

Step 5 of 7

Find the temperature at state 4 after constant pressure heat addition process,

$$Q_{3-4} = mc_p(T_4 - T_3)$$

Here, Q_{3-4} heat addition in constant volume process

Substitute 1.1 Btu for Q_{3-4}

$$1.1 = 0.00388 \times 0.24 \times (T_4 - 2571.10)$$
$$T_4 = 3752.37\,\text{R}$$

Find the temperature at state 5 by using the isentropic relation,

$$\frac{T_4}{T_5} = \left(\frac{V_5}{V_4}\right)^{k-1}$$
$$= \left(\frac{V_1}{V_4}\right)^{k-1} \qquad (\text{Since } V_5 = V_1)$$
$$= \left(\frac{V_1}{V_2} \times \frac{V_2}{V_4}\right)^{k-1}$$
$$= \left(\frac{V_1}{V_2} \times \frac{V_3}{V_4}\right)^{k-1} \qquad (\text{Since } V_2 = V_3)$$

Substitute the relation $\frac{V_3}{V_4} = \frac{T_3}{T_4}$, since the process 3-4 is constant pressure heat addition process.

$$\frac{T_4}{T_5} = \left(\frac{V_1}{V_4} \times \frac{T_3}{T_4}\right)^{k-1}$$
$$= \frac{Q_{2-3} + Q_{3-4} - Q_{5-1}}{Q_{2-3} + Q_{3,4}}$$
$$= \frac{0.6 + 1.1 - 0.6229}{0.6 + 1.1}$$
$$= 0.6335$$

Therefore, thermal efficiency of the ideal dual cycle is **63.35%**

$$= \frac{Q_{2-3} + Q_{3-4} - Q_{5-1}}{Q_{2-3} + Q_{3,4}}$$
$$= \frac{0.6 + 1.1 - 0.6229}{0.6 + 1.1}$$
$$= 0.6335$$

Therefore, thermal efficiency of the ideal dual cycle is **63.35%**

Question:

Consider a simple ideal Brayton cycle with air as the working fluid. The pressure ratio of the cycle is 6, and the minimum and maximum temperatures are 300 and 1300 K, respectively. Now the pressure ratio is doubled without changing the minimum and maximum temperatures in the cycle. Determine the change in (*a*) the net work output per unit mass and (*b*) the thermal efficiency of the cycle as a result of this modification. Assume variable specific heats for air.

Step 1 of 18

Given Data:

Pressure ratio of the cycle, $r_p = 6$

The minimum temperature of the cycle, $T_1 = 300\ \text{K}$

The maximum temperature of the cycle, $T_3 = 1300\ \text{K}$

Step 2 of 18

The *T*-*s* diagram for the given ideal Brayton cycle is shown:

Question:

Consider a simple ideal Brayton cycle with air as the working fluid. The pressure ratio of the cycle is 6, and the minimum and maximum temperatures are 300 and 1300 K, respectively. Now the pressure ratio is doubled without changing the minimum and maximum temperatures in the cycle. Determine the change in (*a*) the net work output per unit mass and (*b*) the thermal efficiency of the cycle as a result of this modification. Assume variable specific heats for air.

Step 1 of 18

Given Data:

Pressure ratio of the cycle, $r_p = 6$

The minimum temperature of the cycle, $T_1 = 300\ \text{K}$

The maximum temperature of the cycle, $T_3 = 1300\ \text{K}$

Step 2 of 18

The *T*-*s* diagram for the given ideal Brayton cycle is shown:

The pressure ratio is given by,

$$r_p = \frac{P_2}{P_1}$$

$$r_p = \frac{P_{r_2}}{P_{r_1}}$$

$$6 = \frac{P_{r_2}}{1.3860}$$

$$P_{r_2} = 8.316$$

Step 5 of 18

By interpolating the values, enthalpy h_2 is calculated as follows:

$$\frac{7.824 - P_{r_2}}{7.824 - 8.411} = \frac{h_{7824} - h_2}{h_{7824} - h_{8.411}}$$

$$\frac{7.824 - 8.316}{7.824 - 8.411} = \frac{492.74 - h_2}{492.74 - 503.02}$$

$$h_2 = 501.36\ \text{kJ/kg}$$

Step 6 of 18

The pressure ratio is given by,

$$\frac{1}{} = \frac{P_4}{}$$

The pressure ratio is given by,

$$r_p = \frac{P_2}{P_1}$$

$$r_p = \frac{P_{r_2}}{P_{r_1}}$$

$$6 = \frac{P_{r_2}}{1.3860}$$

$$P_{r_2} = 8.316$$

Step 5 of 18

By interpolating the values, enthalpy h_2 is calculated as follows:

$$\frac{7.824 - P_{r_2}}{7.824 - 8.411} = \frac{h_{7824} - h_2}{h_{7824} - h_{8.411}}$$

$$\frac{7.824 - 8.316}{7.824 - 8.411} = \frac{492.74 - h_2}{492.74 - 503.02}$$

$$h_2 = 501.36\ \text{kJ/kg}$$

Step 6 of 18

The pressure ratio is given by,

$$\frac{1}{} = \frac{P_4}{}$$

Heat energy out of the system per unit mass is given by,

$$q_{out} = h_4 - h_1$$

$$= 855.27 - 300.19$$

$$= 555.08\ \text{kJ/kg}$$

Step 9 of 18

Work done by the system per unit mass is given by,

$= 555.08 \text{ kJ/kg}$

Step 9 of 18

Work done by the system per unit mass is given by,

$$w_{net} = q_{in} - q_{out}$$
$$= 894.61 - 555.08$$
$$= 339.53 \text{ kJ/kg}$$

Thermal efficiency of the system is given by,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$
$$= \frac{339.53}{894.61}$$
$$= 37.95\%$$

Step 10 of 18

Since, the pressure ratio of the cycle is doubled. Therefore, the pressure ratio of the system, $r_p' = 12$

From ideal gas properties of air tables,

At temperature $T_1 = 300 \text{ K}$ the following values are obtained:

Enthalpy $h_1 = 300.19 \text{ kJ/kg}$, reduced pressure, $P_{r_1} = 1.3860$

At temperature $T_3' = 1300 \text{ K}$ the following values are obtained:

Enthalpy $h_3' = 1395.97 \text{ kJ/kg}$, reduced pressure, $P_{r_3}' = 330.90$

Step 11 of 18

The pressure ratio is given by,

$$r_p' = \frac{P_2'}{P_1}$$

$$r_p' = \frac{P_{r_2}'}{P_{r_1}}$$

$$12 = \frac{P_{r_2}'}{1.3860}$$

$$P_{r_2}' = 16.6320$$

Step 12 of 18

By interpolating the values, enthalpy h_2' is calculated as follows:

$$\frac{16.28 - P_{r_2}'}{16.28 - 17.30} = \frac{h_{16.28} - h_2'}{h_{16.28} - h_{17.30}}$$

$$\frac{16.28 - 16.6320}{16.28 - 17.30} = \frac{607.02 - h_2}{607.02 - 617.53}$$

$$h_2' = 610.65 \text{ kJ/kg}$$

Step 13 of 18

The pressure ratio is given by,

$$\frac{1}{r_p'} = \frac{P_4'}{P_3'}$$

$$\frac{1}{r_p} = \frac{P_{r_4}'}{P_{r_3}'}$$

$$\frac{1}{12} = \frac{P_{r_4}'}{330.90}$$

$$P_{r_4}' = 27.575$$

Step 14 of 18

By interpolating the values, enthalpy h_4' is calculated as follows:

$$\frac{27.29 - P_{r_2}'}{16.28 - 17.30} = \frac{h_{16.28} - h_2'}{h_{16.28} - h_{17.30}}$$

$$\frac{16.28 - 16.6320}{16.28 - 17.30} = \frac{607.02 - h_2}{607.02 - 617.53}$$

$$h_2' = 610.65 \text{ kJ/kg}$$

Step 13 of 18

The pressure ratio is given by,

$$\frac{1}{r_p'} = \frac{P_4'}{P_3'}$$

$$\frac{1}{r_p} = \frac{P_{r_4}'}{P_{r_3}'}$$

$$\frac{1}{12} = \frac{P_{r_4}'}{330.90}$$

$$P_{r_4}' = 27.575$$

Step 14 of 18

By interpolating the values, enthalpy h_4' is calculated as follows:

$27.29 - P_{r_2}'$ h $- h'$

Thermal efficiency of the system is given by,

$$\eta_{th}' = \frac{w_{net}'}{q_{in}'}$$

27.29 – P. 4 –4' 9.187P pg 3

Thermal efficiency of the system is given by,

$$\eta_{th}' = \frac{w_{net}'}{q_{in}'}$$
$$= \frac{380.96}{785.32}$$
$$= 48.51\%$$

Step 17 of 18

(a)

Change in the net work output per unit mass of the cycle due to this modification is given by,

$$\Delta w_{net} = w_{net}' - w_{net}$$
$$= 380.96 - 339.53$$
$$= 41.43 \text{ kJ/kg}$$

Therefore, the change in the net work output per unit mass of the cycle due to this modification, $\boxed{\Delta w_{net} = 41.43 \text{ kJ/kg}}$

Step 18 of 18

(b)

Change in thermal efficiency of the cycle due to this modification is given by,

Thermal efficiency of the system is given by,

$$\eta_{th}' = \frac{w_{net}'}{q_{in}'}$$
$$= \frac{380.96}{785.32}$$
$$= 48.51\%$$

$$\Delta \eta_{th} = \eta_{th}' - \eta_{th}$$
$$= 48.51 - 37.95$$
$$= 10.56\%$$

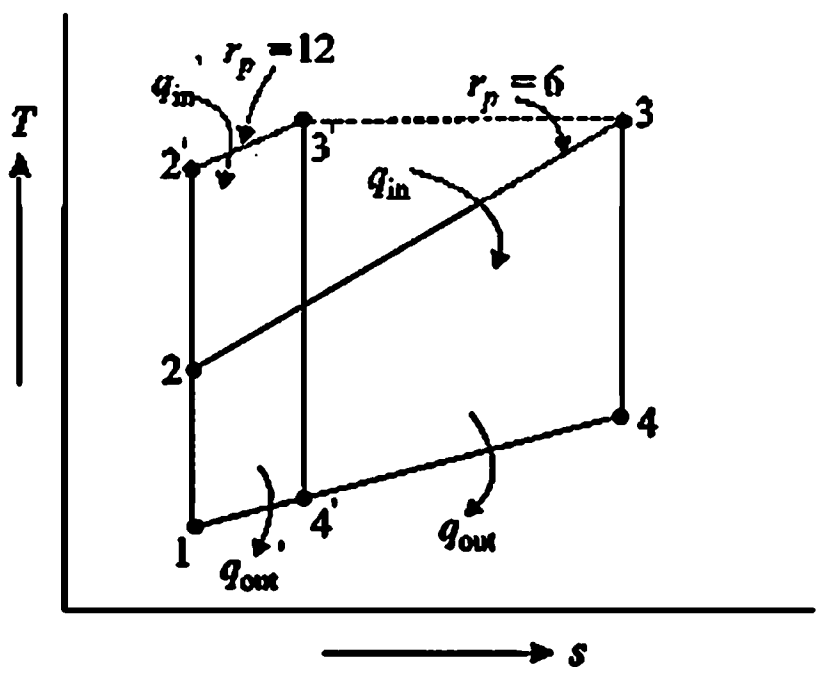
Therefore, the change in thermal efficiency of the cycle due to this modification, $\boxed{\Delta \eta_{th} = 10.56\%}$

Question: 9.188P pg 1

Repeat Prob. 9–187 using constant specific heats at room temperature.

Step 1 of 13

Given Data:



Pressure ratio of the cycle, $r_p = 6$

The minimum temperature of the cycle, $T_1 = 300\ \text{K}$

The maximum temperature of the cycle, $T_3 = 1300\ \text{K}$

Step 2 of 13

The T-s diagram for the given ideal Brayton cycle is shown:

Step 3 of 13

From ideal-gas specific heats of various common gases tables; the properties of air are,

Gas constant, $R = 0.2870\ \text{kJ/kg}\cdot\text{k}$

Specific heat at constant pressure, $c_p = 1.005\ \text{kJ/kg}\cdot\text{k}$

Specific heat at constant volume, $c_v = 0.718\ \text{kJ/kg}\cdot\text{k}$

Specific heat ratio, $k = 1.400$

The pressure ratio is given by,

$$r_p = \frac{P_2}{P_1} = \frac{P_3}{P_4}$$

Step 4 of 13

Process 1-2:

During the process 1-2, isentropic compression of the gas takes place. Therefore,

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{(k-1)/k}$$

$$\frac{T_2}{300} = \left(r_p\right)^{(1.4-1)/1.4}$$

$$T_2 = 300\times(6)^{0.4/1.4}$$

$$= 500.5531\ \text{K}$$

Step 5 of 13

Process 3-4:

During the process 3-4, isentropic expansion of the gas takes place. Therefore,

$$\frac{T_3}{T_4} = \left(\frac{P_3}{P_4}\right)^{(k-1)/k}$$

$$\frac{1300}{T_4} = \left(r_p\right)^{(1.4-1)/1.4}$$

$$\frac{1300}{T_4} = (6)^{0.4/1.4}$$

$$T_4 = 779.1381\ \text{K}$$

Step 6 of 13

Heat energy given to the system per unit mass is given by,

$$q_{in} = c_p\left(T_3 - T_2\right)$$

$$= 1.005(1300 - 500.5531)$$

$$= 803.4441\ \text{kJ/kg}$$

Heat energy given out of the system per unit mass is given by,

$$q_{out} = c_p\left(T_4 - T_1\right)$$

$$= 1.005(779.1381 - 300)$$

$$= 481.5338\ \text{kJ/kg}$$

Step 7 of 13

The net work done by the system per unit mass is given by,

$$w_{net} = q_{in} - q_{out}$$

$$= 803.4441 - 481.5338$$

$$= 321.9103\ \text{kJ/kg}$$

Thermal efficiency of the system is given by,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$= \frac{321.9103}{803.9103}$$

$$= 40.07\%$$

Step 8 of 13

Since, the pressure ratio of the cycle is doubled. Therefore, the pressure ratio of the system, $r_p' = 12$

The pressure ratio is given by,

$$r_p' = \frac{P_2'}{P_1} = \frac{P_3'}{P_4'}$$

system, $r_p' = 12$

The pressure ratio is given by,

$$r_p' = \frac{P_2'}{P_1} = \frac{P_3'}{P_4'}$$

During the process $1\text{-}2'$, isentropic compression of the gas takes place. Therefore,

$$\frac{T_2'}{T_1} = \left(\frac{P_2'}{P_1}\right)^{(k-1)/k}$$

$$\frac{T_2'}{300} = \left(r_p'\right)^{(1.4-1)/1.4}$$

$$T_2' = 300 \times (12)^{0.4/1.4}$$

$$= 610.1811 \text{ K}$$

Step 9 of 13

During the process $3'\text{-}4'$, isentropic expansion of the gas takes place. Therefore,

$$\frac{T_3'}{T_4'} = \left(\frac{P_3'}{P_4'}\right)^{(k-1)/k}$$

$$\frac{1300}{T_4'} = \left(r_p'\right)^{(1.4-1)/1.4}$$

$$\frac{1300}{T_4} = (12)^{0.4/1.4}$$

$$T_4 = 639.1545 \text{ K}$$

Step 10 of 13

Heat energy given to the system per unit mass is given by,

$$q_{in}' = c_p\left(T_3 - T_2'\right)$$

$$= 1.005(1300 - 610.1811)$$

$$= 693.2680 \text{ kJ/kg}$$

Heat energy out of the system per unit mass is given by,

$$q_{out}' = c_p\left(T_4' - T_1'\right)$$

$$= 1.005(639.1545 - 300)$$

$$= 340.8502 \text{ kJ/kg}$$

Step 11 of 13

Work done by the system per unit mass is given by,

$$w_{net}' = q_{in}' - q_{out}'$$

$$= 693.2680 - 340.8502$$

$$= 352.4178 \text{ kJ/kg}$$

Thermal efficiency of the system is given by,

$$\eta_{th}' = \frac{w_{net}'}{q_{in}'}$$

$$= \frac{352.4178}{693.2680}$$

$$= 50.83\%$$

Step 12 of 13

(a)

Change in the net work output per unit mass of the cycle due to this modification is given by,

$$\Delta w_{net} = w_{net}' - w_{net}$$

$$= 352.4178 - 321.9103$$

$$= 30.51 \text{ kJ/kg}$$

Therefore, the change in the net work output per unit mass of the cycle due to this modification, $\boxed{\Delta w_{net} = 30.51 \text{ kJ/kg}}$

Step 13 of 13

(b)

Change in thermal efficiency of the cycle due to this modification is given by,

$$\Delta \eta_{th} = \eta_{th}' - \eta_{th}$$

$$= 50.83 - 40.07$$

$$= 10.76\%$$

Therefore, the change in thermal efficiency of the cycle due to this modification, $\boxed{\Delta \eta_{th} = 10.76\%}$

Question:

A steam power plant operating on a simple ideal Rankine cycle maintains the boiler at 6000 kPa, the turbine inlet at 600°C, and the condenser at 50 kPa. Compare the thermal efficiency of this cycle when it is operated so that the liquid enters the pump as a saturated liquid against that when the liquid enters the pump 11.3°C cooler than a saturated liquid at the condenser pressure.

Step 1 of 17

Given:

Boiler pressure $P_3 = 6000\text{kPa}$

Inlet temperature of the turbine $T_3 = 600°\text{C}$

Condenser pressure $P_1 = 50\text{kPa}$

Step 2 of 17

T-s Diagram:

Step 3 of 17

At state-1:

At $P_1 = 50\text{ kPa}$ and $x_1 = 0$

Since saturated liquid

Enthalpy at state-1,

$$h_1 = h_f = 340.54\ \frac{\text{kJ}}{\text{kg}}$$

Specific volume at -1,

$$v_1 = 0.001030\ \frac{\text{m}^3}{\text{kg}}$$

Work of pump

$$w_{pump} = v_1(P_2 - P_1)$$

$$w_{pump} = 0.001030\ \frac{\text{m}^3}{\text{kg}}(6000-50)\text{kPa} \times \left(\frac{1\text{kJ}}{1\text{kPa.m}^3}\right)$$

$$w_{pump} = 6.12\ \frac{\text{kJ}}{\text{kg}}$$

Step 4 of 17

At state-2:

Enthalpy at state-2

$$h_2 = h_1 + w_{pump}$$

$$h_2 = (340.54 + 6.12)$$

$$h_2 = 346.66\ \frac{\text{kJ}}{\text{kg}}$$

Step 5 of 17

At state-3:

From the superheated water

At $P_3 = 6000\text{ kPa}$ and $T_3 = 600°\text{C}$

Enthalpy at state-3,

$$h_3 = 3658.8\ \frac{\text{kJ}}{\text{kg}}$$

Entropy at state-3,

$$s_3 = 7.1693\ \frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 6 of 17

At state-4:

At $P_4 = 50\text{ kPa}$ and $s_4 = s_3 = 7.1693\ \frac{\text{kJ}}{\text{kg}\cdot\text{K}}$

It's an isentropic process

From the saturated water

At $P_4 = 50\text{ kPa}$

$$s_f = 1.0912\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$s_{fg} = 6.5019\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Entropy at state-4,

$$s_4 = 7.169\text{ kJ/kg.K}$$

Dryness fraction at state-4,

$$s_4 = s_f + x_4 s_{fg}$$

$$\Rightarrow x_4 = \frac{s_4 - s_f}{s_{fg}}$$

$$x_4 = \frac{7.169 - 1.0912}{6.5019}$$

$$x_4 = 0.934$$

Step 7 of 17

Enthalpy at state-4,

From the saturated water

At $P_4 = 50\text{ kPa}$

$$h_f = 340.54\frac{\text{kJ}}{\text{kg}}$$

$$h_{fg} = 2304.7\frac{\text{kJ}}{\text{kg}}$$

$$h_f = 340.54 \frac{\text{kJ}}{\text{kg}}$$

$$h_{fg} = 2304.7 \frac{\text{kJ}}{\text{kg}}$$

$$h_4 = h_f + x_4 h_{fg}$$

$$h_4 = 340.5 + 0.934 \times 2304.7$$

$$h_4 = 2494.87 \ \frac{\text{kJ}}{\text{kg}}$$

Step 8 of 17

Total heat addition in the cycle occurs at process 2-3, so
Heat input per unit mass,

$$q_{in} = (h_3 - h_2)$$

$$q_{in} = (3658.8 - 346.66)\text{kJ/kg}$$

$$q_{in} = 3312.14 \ \frac{\text{kJ}}{\text{kg}}$$

Step 9 of 17

Heat rejected during process 4-1, so
Heat rejected per unit mass,

$$q_{out} = h_4 - h_1$$

$$q_{out} = (2494.87 - 340.54)$$

$$q_{out} = 2154.33 \ \frac{\text{kJ}}{\text{kg}}$$

Step 10 of 17

Total work output from the three turbines,

$$w_{turbine} = q_{in} - q_{out}$$

$$w_{turbine} = (3312.14 - 2154.33)$$

$$w_{turbine} = 1157.81 \ \frac{\text{kJ}}{\text{kg}}$$

Step 11 of 17

Thermal efficiency of the plant is

$$\eta_{th} = \frac{w_{turbine}}{q_{in}}$$

$$\eta_{th} = \frac{1157.81}{3312.14}$$

$$= 0.349$$

$$= 34.9\%$$

$$\boxed{\eta_{th} = 34.9\%}$$

Step 12 of 17

Case 2:
When liquid enters the pump at a temperature 11.3°C cooler than $T_{1,50kPa} = 81.3^\circ\text{C}$
At state-1:
At $P_1 = 50\ \text{kPa}$
Saturation temperature at $P_1 = 50\ \text{kPa}$ is $T_{1,50kPa} = 81.3$
So temperature at -1,

$$T_1 = T_{1,50kPa} - 11.3^\circ\text{C}$$

$$T_1 = 81.3^\circ\text{C} - 11.3^\circ\text{C}$$

$$T_1 = 70^\circ\text{C}$$

From the saturated water
At $T_1 = 70^\circ\text{C}$
Enthalpy at state-1,

$$h_1 = h_f = 293.07 \ \frac{\text{kJ}}{\text{kg}}$$

Specific volume at -1,

$$v_1 = 0.001023 \ \frac{\text{m}^3}{\text{kg}}$$

Step 13 of 17

Work of pump,

$$w_{pump} = v_1 (P_2 - P_1)$$

$$w_{pump} = 0.001023 \ \frac{\text{m}^3}{\text{kg}} (6000 - 50)\text{kPa} \times \left(\frac{1\text{kJ}}{1\text{kPa.m}^3} \right)$$

$$w_{pump} = 6.09 \ \frac{\text{kJ}}{\text{kg}}$$

Step 14 of 17

At state-2:
Enthalpy at state-2, $h_2 = h_1 + w_{pump}$

$$h_2 = (293.1 + 6.09)$$

$$h_2 = 299.2 \ \frac{\text{kJ}}{\text{kg}}$$

Step 15 of 17

Total heat addition in the cycle occurs at process 2-3, So
Heat input per unit mass,

$$q_{in} = (h_3 - h_2)$$

$$q_{in} = (3658.8 - 299.2)$$

$$q_{in} = 3359.6 \ \frac{\text{kJ}}{\text{kg}}$$

Step 16 of 17

Heat rejected during process 4-1, so

Step 16 of 17

Heat rejected during process 4-1, so
Heat rejected per unit mass,

$$q_{out} = h_4 - h_1$$

$$q_{out} = (2494.87 - 293.07)$$

$$q_{out} = 2201.8 \ \frac{kJ}{kg}$$

Total work output from the three turbines,

$$w_{turbine} = q_{in} - q_{out}$$

$$w_{turbine} = (3359.6 - 2201.8)$$

$$w_{turbine} = 1157.8 \ \frac{kJ}{kg}$$

Step 17 of 17

Thermal efficiency of the plant is

$$\eta_{th} = \frac{w_{turbine}}{q_{in}}$$

$$\eta_{th} = \frac{1157.8}{3359.6}$$

$$= 0.345$$

$$= 34.5\%$$

$$\boxed{\eta_{th} = 34.5\%}$$

So η_{th} slightly decreases as a effect of sub-cooling liquid at pump.

Question: 9.190P

The Stillwater geothermal power plant in Nevada, which started full commercial operation in 1986, is designedto operate with seven identical units. Each of these seven units consists of a pair of power cycles, labeled Level I and Level II, operating on the simple Rankine cycle using anorganic fluid as the working fluid.

The heat source for the plant is geothermal water (brine) entering the vaporizer (boiler) of Level I of each unit at 325°F at a rate of 384,286 lbm/h and delivering 22.79 MBtu/h ("M" stands for "million"). The organic fluid that enters the vaporizer at 202.2°C at a rate of 157,895 lbm/h leaves it at 282.4°F and 225.8 psia as saturated vapor. This saturated vapor expands in the turbine to 95.8°F and 19.0 psia and produces 1271 kW of electric power. About 200 kW of this power is used by the pumps, the auxiliaries, and the six fans of the condenser- Subsequently, the organic working fluid is condensed ■ an air-cooled condenser by air that enters the condenser at 55°F at a rate of 4,195,100 lbm/h and leaves at 84.5°C. The working fluid is pumped and then preheated in a preheater to 202.2°F by absorbing 11.14 MBtu/h of heat from the geothermal water (coming from the vaporizer of Level II) entering the preheater at 211.8°F and leaving at 154.0°F.

Taking the average specific heat of the geothermal water to be 1.03 Btu/lbm °F, determine (*a*) the exit temperature of the geothermal water from the vaporizer, (*b*) the rate of heat rejection from the working fluid to the air in the condenser, (*c*) the mass flow rate of the geothermal water at the preheater, and (*d*) the thermal efficiency of the Level I cycle of this geothermal power plant.

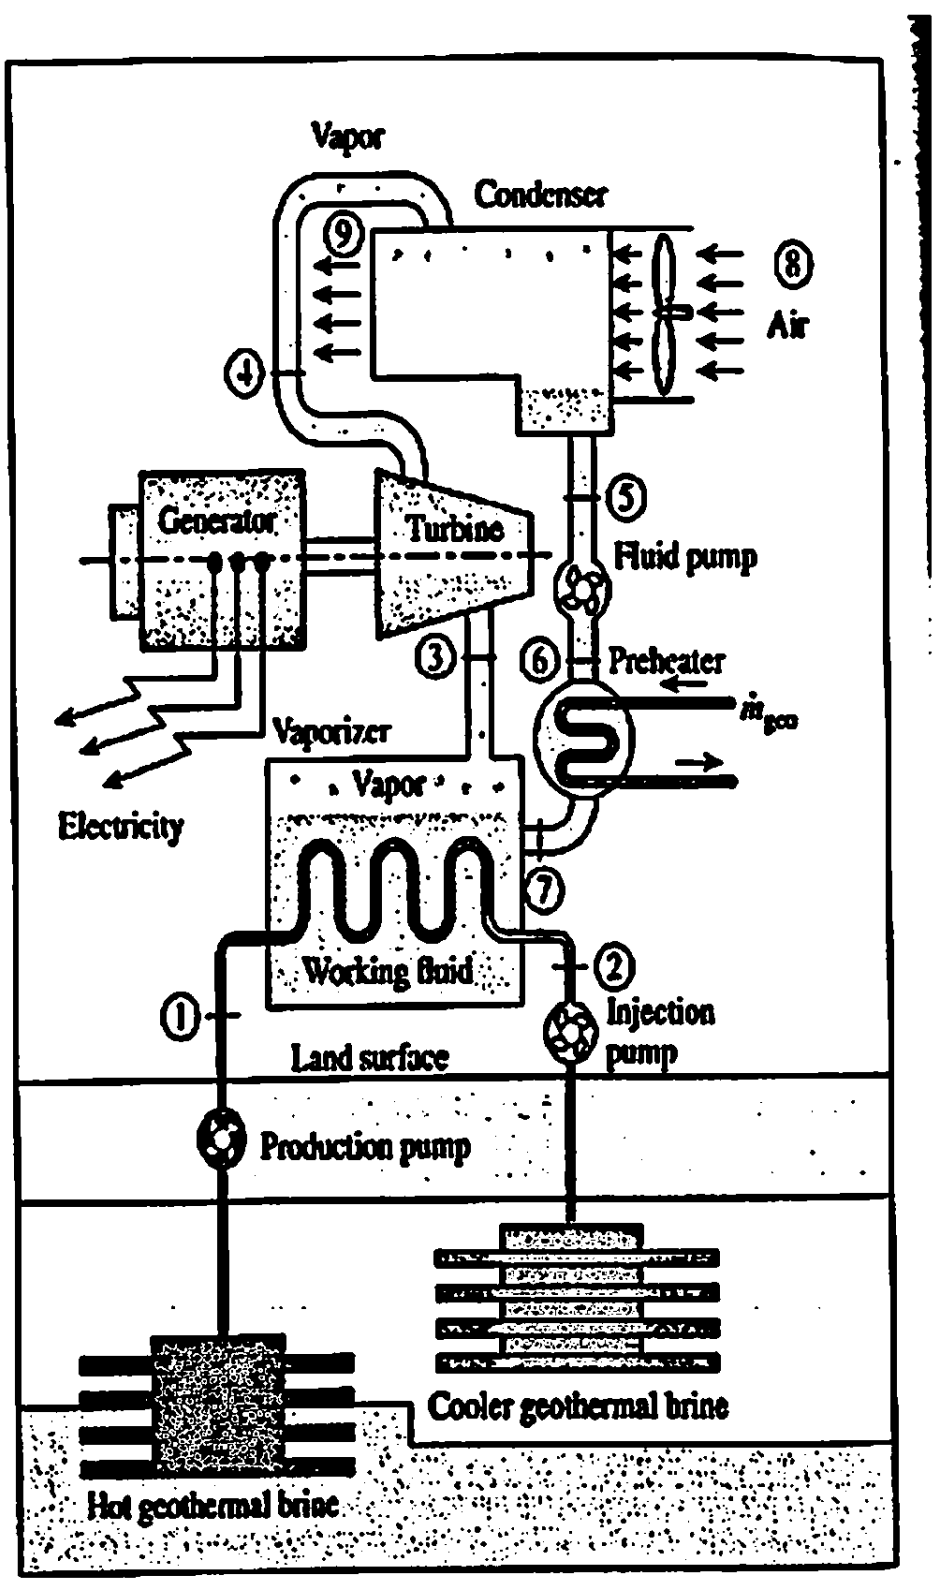


Figure P9-190

Schematic of a binary geothermal power plant.

Step 1 of 7

Given data:

Geothermal water entering the vaporizer at temperature $T_1 = 325^0\text{F}$

Mass flow rate of geothermal water $\dot{m}_{geowater} = 384286\text{lbm/h}$

Amount of heat delivered from geothermal water $Q_{geowater} = -22.79\text{MBtu/h}$

Specific heat of geothermal water $c_p = 1.03\text{Btu/lbm}$

Work output from the turbine $W_T = 1271\text{kW}$

Power used by the pumps, the auxiliaries and fans are $W_p = -200\text{kW}$

Air enters the condenser at temperature $T_8 = 55^0\text{F}$

Mass flow rate of air $\dot{m}_{air} = 4195100\text{lbm/h}$

Air leaves the condenser at temperature $T_9 = 84.5^0\text{C}$

The amount of heat absorbed to the working fluid $Q_{working\,fluid} = 11.14\text{MBtu/h}$

Geothermal water entering the preheater at temperature $T_6 = 211.8^0\text{F}$

Geothermal water leaving the preheater at temperature $T_7 = 154.0^0\text{F}$

Step 2 of 7

(a)

The exit temperature of the geothermal water from the vaporizer is determined using the steady flow energy balance on the geothermal water

$$Q_{geowater} = m_{geowater} \times c_p \times (T_2 - T_1)$$

$$-22790000 = 384286 \times 1.03 \times (T_2 - 325)$$

$$\boxed{T_2 = 267.42^0\text{F}}$$

Step 3 of 7

(b)

The rate of heat rejection from the working fluid to the air in the condenser

Applying steady flow energy balance on air

$$Q_{air} = m_{air} \times c_p \times (T_9 - T_8)$$

$$Q_{air} = 4195100 \times 0.24 \times (84.5 - 55)$$

$$Q_{air} = 29701308\text{Btu/hr}$$

$$\boxed{Q_{air} = 29.7\text{ MBtu/hr}}$$

Step 4 of 7

(c)

The mass flow rate of geothermal water at the preheater

Applying steady flow energy balance on the geothermal water in preheater

$$Q_{geo} = m_{geo} \times c_{p,geo} \times (T_{out} - T_{in})$$

We know the amount of heat absorbed by working fluid is equal to the amount of heat rejected by the geothermal water

$$-11140000 = m_{geo} \times 1.03 \times (154 - 211.8)$$

$$\boxed{m_{geo} = 187119.96\text{ lbm/hr}}$$

Step 5 of 7

(d)

The heat addition is given by,

$$Q_{in} = Q_{vaporizer} + Q_{preheater}$$

$$Q_{in} = 22790000 + 11140000$$

$$Q_{in} = 33930000\text{ Btu/hr.}$$

Step 6 of 7

The network output is

$$W_{net} = W_T + W_p$$

$$W_{net} = 1271 - 200$$

$$W_{net} = 1071\text{ kW}$$

Step 7 of 7

Thermal efficiency of the level I cycle of this geothermal power plant is

$$\eta_{th} = \frac{W_{net}}{Q_{in}}$$

$$\eta_{th} = \frac{1071\text{ kW}}{33930000\text{ Btu/hr}}$$

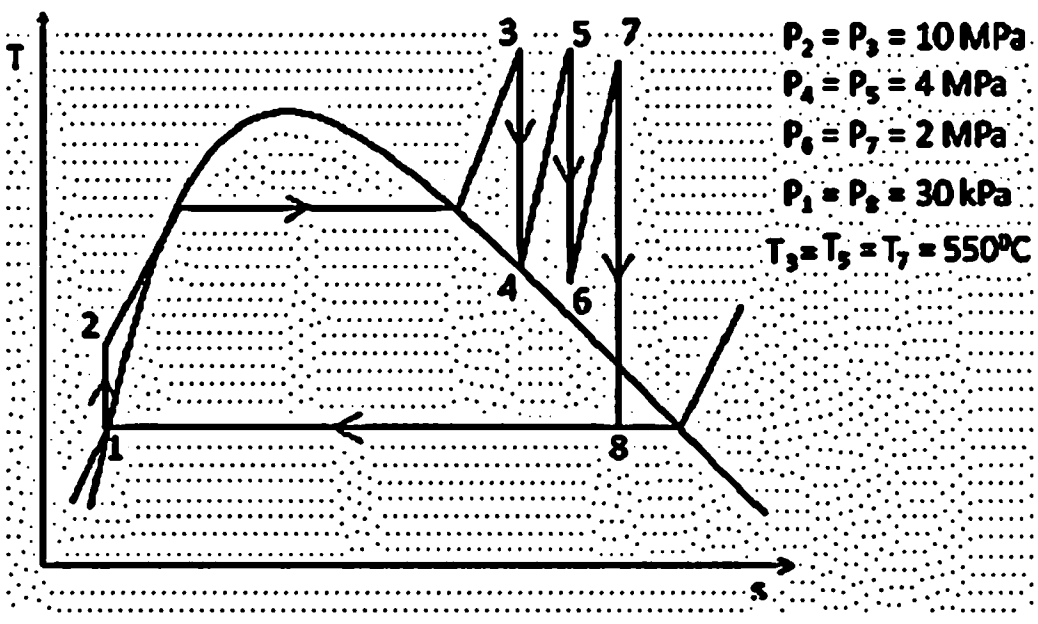
Since we know that $1\text{kWhr} = 3412.14\text{Btu}$

$$\eta_{th} = \frac{1071\text{ kW}}{33930000\text{ Btu/hr}} \times \frac{3412.14\text{Btu}}{1\text{kWhr}}$$

$$\eta_{th} = 0.1077$$

$$\boxed{\eta_{th} = 10.77\%}$$

Question: 9.191P



A steam power plant operates on an ideal Rankine cycle with two stages of reheat and has a net power output of 75 MW. Steam enters all three stages of the turbine at 550°C. The maximum pressure in the cycle is 10 MPa, and the minimum pressure is 30 kPa. Steam is reheated at 4 MPa the first time and at 2 MPa the second time. Show the cycle on a *T-s* diagram with respect to saturation lines, and determine (*a*) the thermal efficiency of the cycle, and (*b*) the mass flow rate of the steam.

Step 1 of 7

Given,
The net output of the power plant, $W_{net} = 75\ \text{MW}$,
Steam enters all three stages of the turbine at 550^0C
The maximum pressure in the cycle = 10 MPa,
The minimum pressure in the cycle = 30 kPa,

Step 2 of 7

The Ideal Reheat Rankin cycle operating between the given conditions is shown below.

Step 3 of 7

From saturated steam tables, at State-1 (30 kPa)

$$h_1 = \left(h_f\right)_{\text{at } 30\text{ kPa}} = 289.22\ \text{kJ/kg}$$

$$v_1 = \left(v_f\right)_{\text{at } 30\text{ kPa}} = 0.001022\ \text{m}^3\text{/kg}$$

The work done in the compression process is given by,

$$w_{pump} = v_1 \times (P_2 - P_1)$$
$$= \left(0.001022\ \text{m}^3\text{/kg}\right) \times (10000\ \text{kPa} - 30\ \text{kPa})$$
$$= 10.2\ \text{kJ/kg}$$
$$h_2 = h_1 + w_{pump}$$
$$= 289.22 + 10.2$$
$$= 299.42\ \text{kJ/kg}$$

Step 4 of 7

From superheated steam tables at State-3 (10 MPa and 550^0C)

$h_3 = 3501.9\ \text{kJ/kg}$

$s_3 = 6.7583\ \text{kJ/kgK}$

For isentropic expansion, $s_4 = s_3 = 6.7583\ \text{kJ/kgK}$

From superheated steam tables at State-4 (4 MPa and $s_4 = 6.7583\ \text{kJ/kgK}$)

$h_4 = 3205.7\ \text{kJ/kg}$

From superheated steam tables at State-5 (4 MPa and 550^0C)

$h_5 = 3560.2\ \text{kJ/kg}$

$s_5 = 7.2352\ \text{kJ/kgK}$

Step 5 of 7

For isentropic expansion, $s_6 = s_5 = 7.2352\ \text{kJ/kgK}$

From superheated steam tables at State-6 (2 MPa and $s_6 = 7.2352\ \text{kJ/kgK}$)

$h_6 = 3321.5\ \text{kJ/kg}$

From superheated steam tables at State-7 (2 MPa and 550^0C)

$h_7 = 3578.9\ \text{kJ/kg}$

$s_7 = 7.5723\ \text{kJ/kgK}$

For isentropic expansion, $s_8 = s_7 = 7.5723\ \text{kJ/kgK}$

From saturated steam tables at State-8 (30 kPa and $s_8 = 7.5723\ \text{kJ/kgK}$)

$h_8 = 2557.8\ \text{kJ/kg}$

Step 6 of 7

(b)

Now net work output is given as

$$W_{net} = \dot{m}\left[(h_3 - h_4) + (h_5 - h_6) + (h_7 - h_8) - (h_2 - h_1)\right]$$
$$75000 = \dot{m}[(3501.9 - 3205.7) + (3560.2 - 3321.5) + (3578.9 - 2557.8) - (299.42 - 289.22)]$$
$$75000 = \dot{m} \times 1545.8$$
$$\dot{m} = 48.51\ \text{kg/s}$$

Hence the mass flow rate is $\boxed{\dot{m} = 48.51\ \text{kg/s}}$

Step 7 of 7

(a)

Heat supplied to the cycle is

$$Q_{in} = \dot{m} \times \left[(h_3 - h_2) + (h_5 - h_4) + (h_7 - h_6)\right]$$
$$= 48.51 \times \left[(3501.9 - 299.42) + (3560.2 - 3205.7) + (3578.9 - 3321.5)\right]$$
$$= 185\ \text{MW}$$

The thermal efficiency of the Rankin cycle is given by,

$$\eta_{th} = \frac{W_{net}}{Q_{in}}$$
$$= \frac{75}{185}$$
$$= 0.405$$

Hence thermal efficiency of the cycle is $\boxed{\eta_{th} = 40.5\%}$

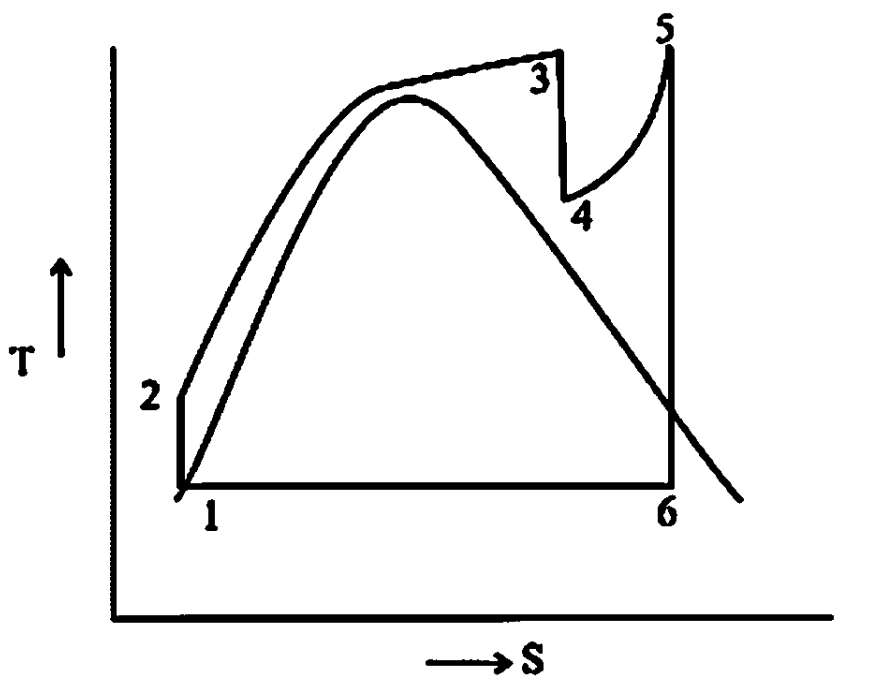
Question: 9.192P

Consider a steam power plant operating on the ideal Rankine cycle with reheat between the pressure limits of 25 MPa and 10 kPa with a maximum cycle temperature of 600°C and a moisture content of 8 percent at the turbine exit. For a reheat temperature of 600°C, determine the reheat pressures of the cycle for the cases of (*a*) single and (*b*) double reheat.

Step 1 of 7

Given data:

Maximum pressure in the cycle $P_3 = 25\,\text{MPa}$



Minimum pressure in the cycle $P_1 = 10\,\text{kPa}$

Maximum cycle temperature $T_3 = 600^0\,\text{C}$

Reheat temperature $T_5 = 600^0\,\text{C}$

Dryness fraction at the turbine exit $x_6 = 0.92$

Step 2 of 7

Step 3 of 7

(a)

For a single reheat cycle

At $P_6 = 10\,\text{kPa}$ and $x_6 = 0.92$

Enthalpy at state -6 is given by

$h_6 = h_f + x_6 h_{fg}$

$h_6 = 191.81 + (0.92 \times 2392.1)$

$h_6 = 2392.54\ \text{kJ/kg}$

Entropy at state-6 is given by

$s_6 = s_f + x_6 s_{fg}$

$s_6 = 0.6492 + (0.92 \times 7.4996)$

$s_6 = 7.5488\ \text{kJ/kg.K}$

Step 4 of 7

Process 5-6 is isentropic expansion then entropy remains constant

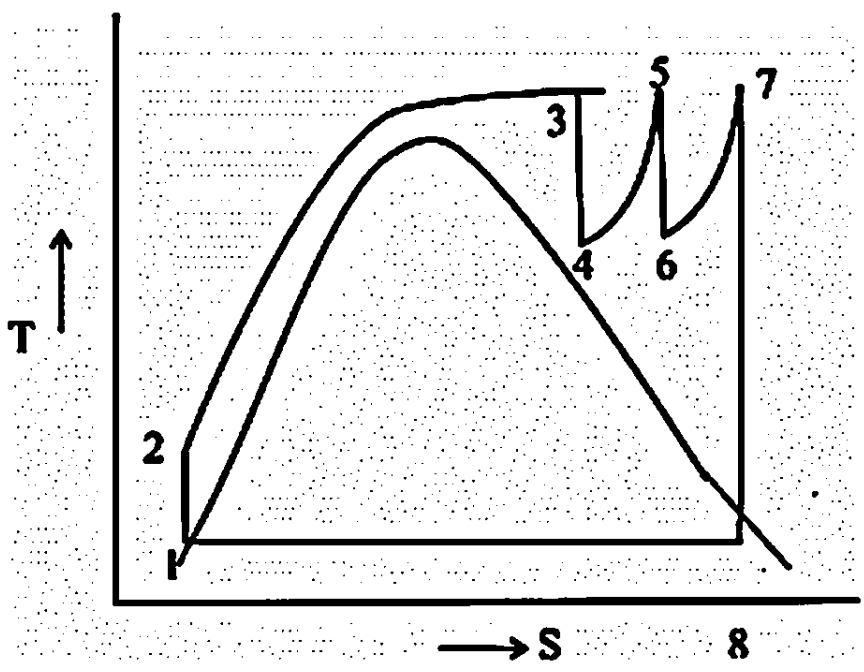
$s_5 = s_6$

At $T_6 = 600^0\,\text{C}$ and $s_6 = s_5 = 7.5488\,\text{kJ/kg.K}$ from superheated water tables

$$P_6 = 2500 + (3000 - 2500)\left(\frac{7.5488 - 7.5979}{7.5103 - 7.5979}\right)$$

$P_6 = 2780.251\,\text{kPa}$

Therefore reheat pressure of the cycle for the case of single reheat is



$\boxed{P_5 = 2780.251\ \text{kPa}}$ Or

$\boxed{P_5 = 2.780\ \text{MPa}}$

Step 5 of 7

(b)

Double reheat cycle:

Step 6 of 7

At $P_8 = 10\ \text{kPa}$ and $x_8 = 0.92$

Enthalpy at state -8 is given by

$h_8 = h_f + x_8 h_{fg}$

$h_8 = 191.81 + (0.92 \times 2392.1)$

$h_8 = 2392.54\ \text{kJ/kg}$

Entropy at state-8 is given by

$s_8 = s_f + x_8 s_{fg}$

$s_8 = 0.6492 + (0.92 \times 7.4996)$

$s_8 = 7.5488\ \text{kJ/kg.K}$

Step 7 of 7

Process 7-8 is isentropic expansion then entropy remains constant

$s_7 = s_8$

At $T_7 = 600^0\,\text{C}$ and $s_7 = s_8 = 7.5488\,\text{kJ/kg.K}$ from superheated water tables

$$P_7 = 2500 + (3000 - 2500)\left(\frac{7.5488 - 7.5979}{7.5103 - 7.5979}\right)$$

$P_7 = 2780.251\,\text{kPa}$

$P_7 = 2.78\,\text{MPa}$

Any pressure P_x selected between the limits of 25Mpa and 2.78Mpa will satisfy the requirements, and can be used for the double reheat pressure.

Question:

Using EES (or other) software, investigate the effect of the condenser pressure on the performance of a simple ideal Rankine cycle. Turbine inlet conditions of steam are maintained constant at 10 MPa and 550°C while the condenser pressure is varied from 5 to 100 kPa. Determine the thermal efficiency of the cycle and plot it against the condenser pressure, and discuss the results.

Step 1 of 6

The procedure for developing solution by using EES software: Open the new equations window EES software and type all the information which is used to solve the problem For developing table: 1) Click on table followed by new parametric table and add the variables, which are varying variable and required answer variable, then one table will form with that variables 2) Click on the variable which is varying and enter initial value and final value. 3) For getting the required answer variable values corresponding to the varying variable values click on the green colour button and then the table will form with required answers For developing graph: 1) Click on plot followed by new plot window followed by x-y plot. 2) Select the x-axis variable and y-axis variable and then press ok, then the graph will form with the given values.

Step 2 of 6

Write the program for the given system in EES software:

EES Limited Academic Version: C:\EES (LIMITED ACADEMIC)\HELLO.TXT - [Equations ...

```

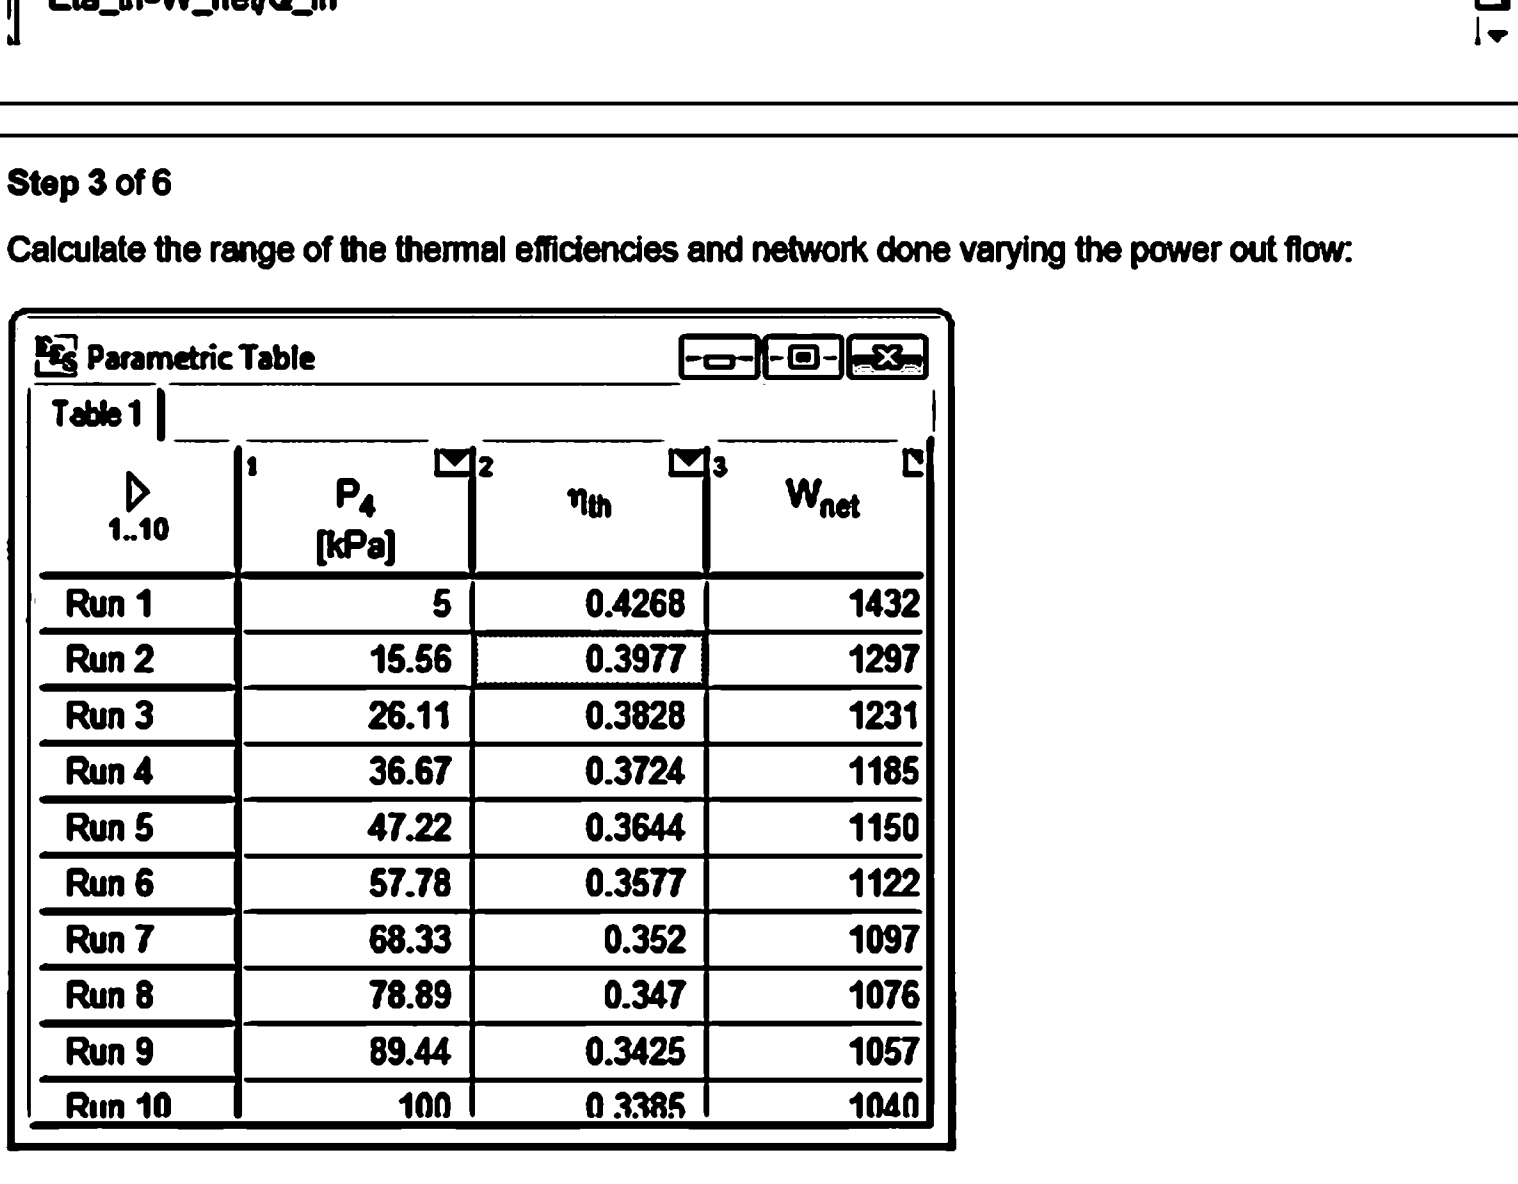
Step 3 of 6

Calculate the range of the thermal efficiencies and network done varying the power out flow:



Parametric Table

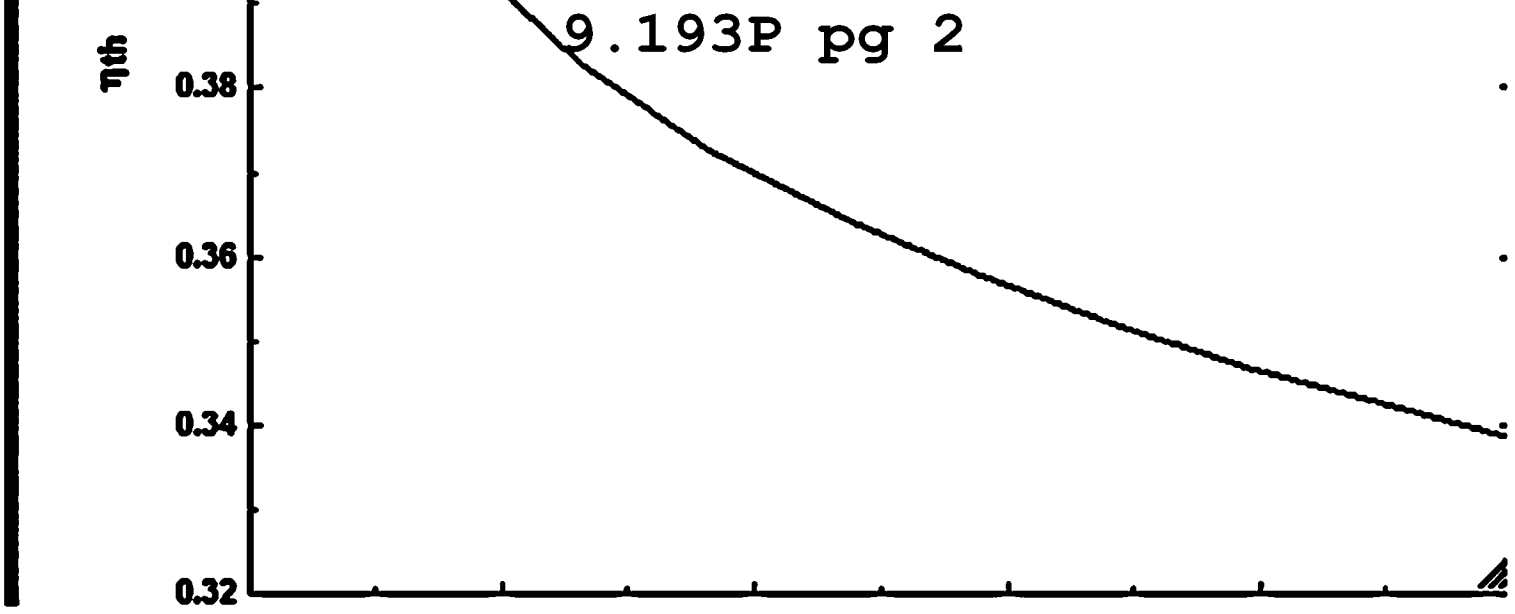


Table 1

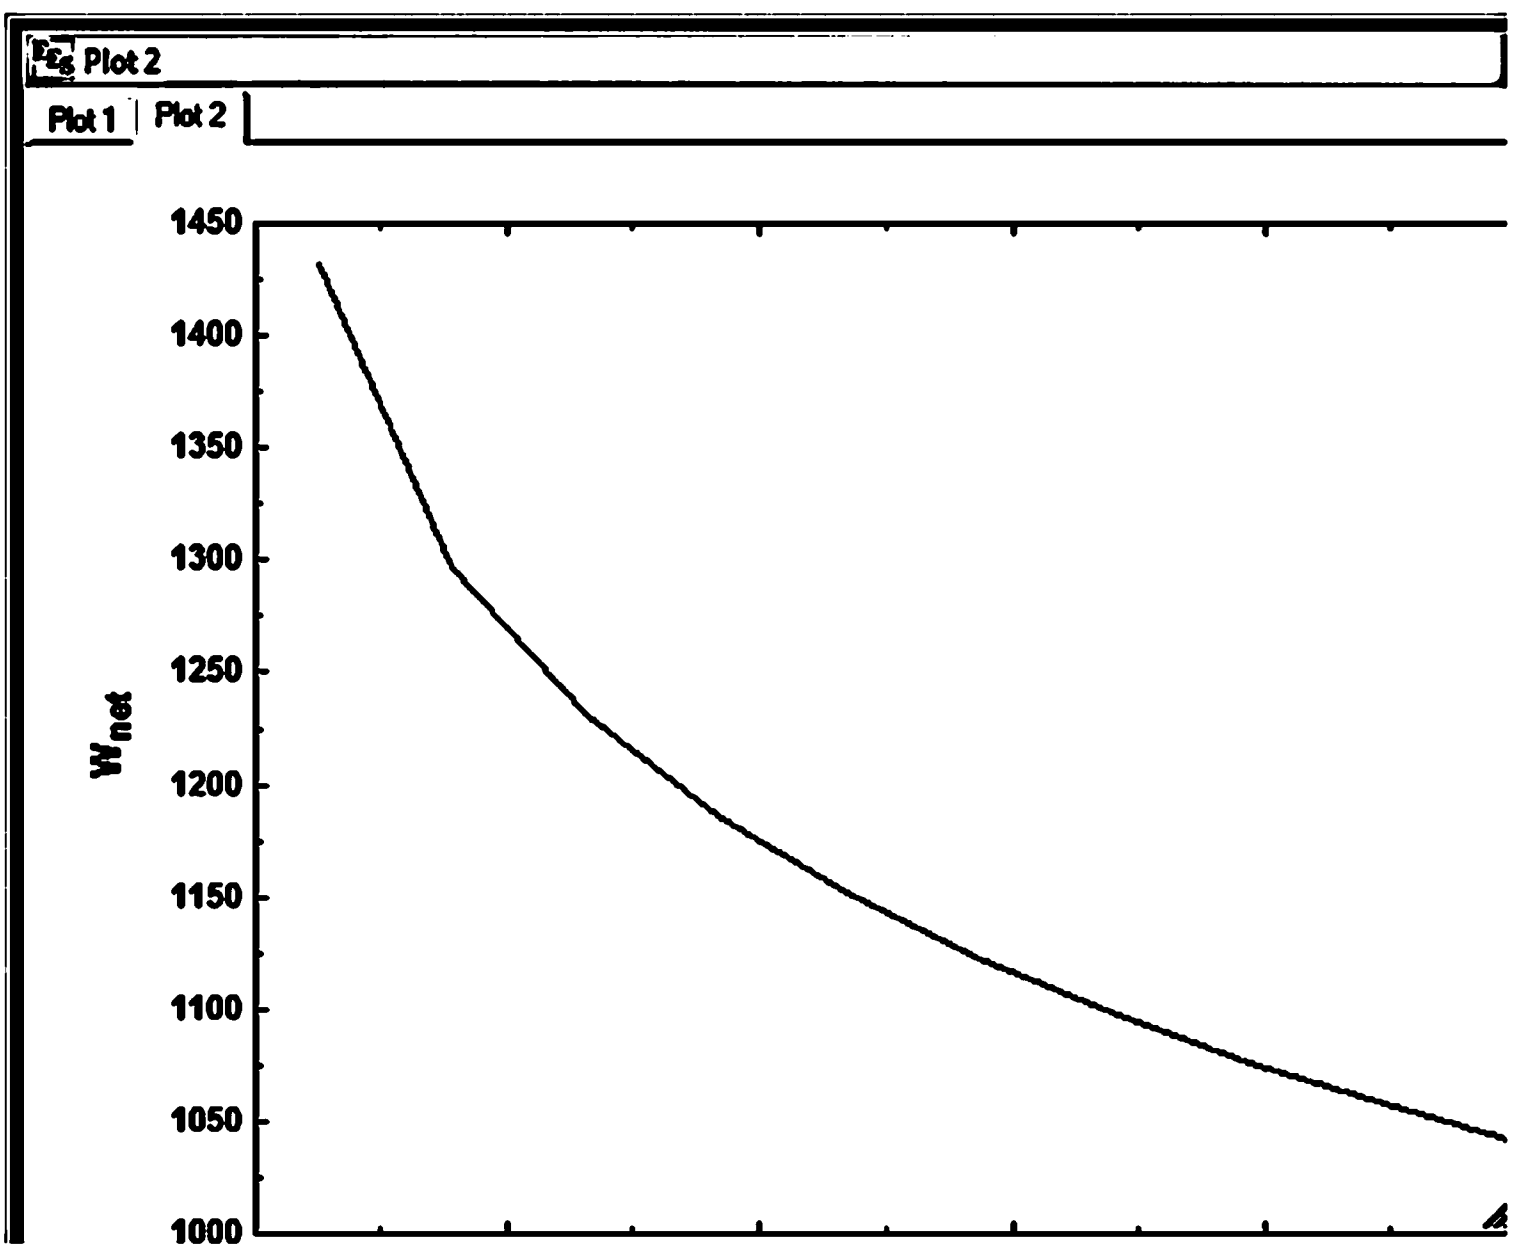
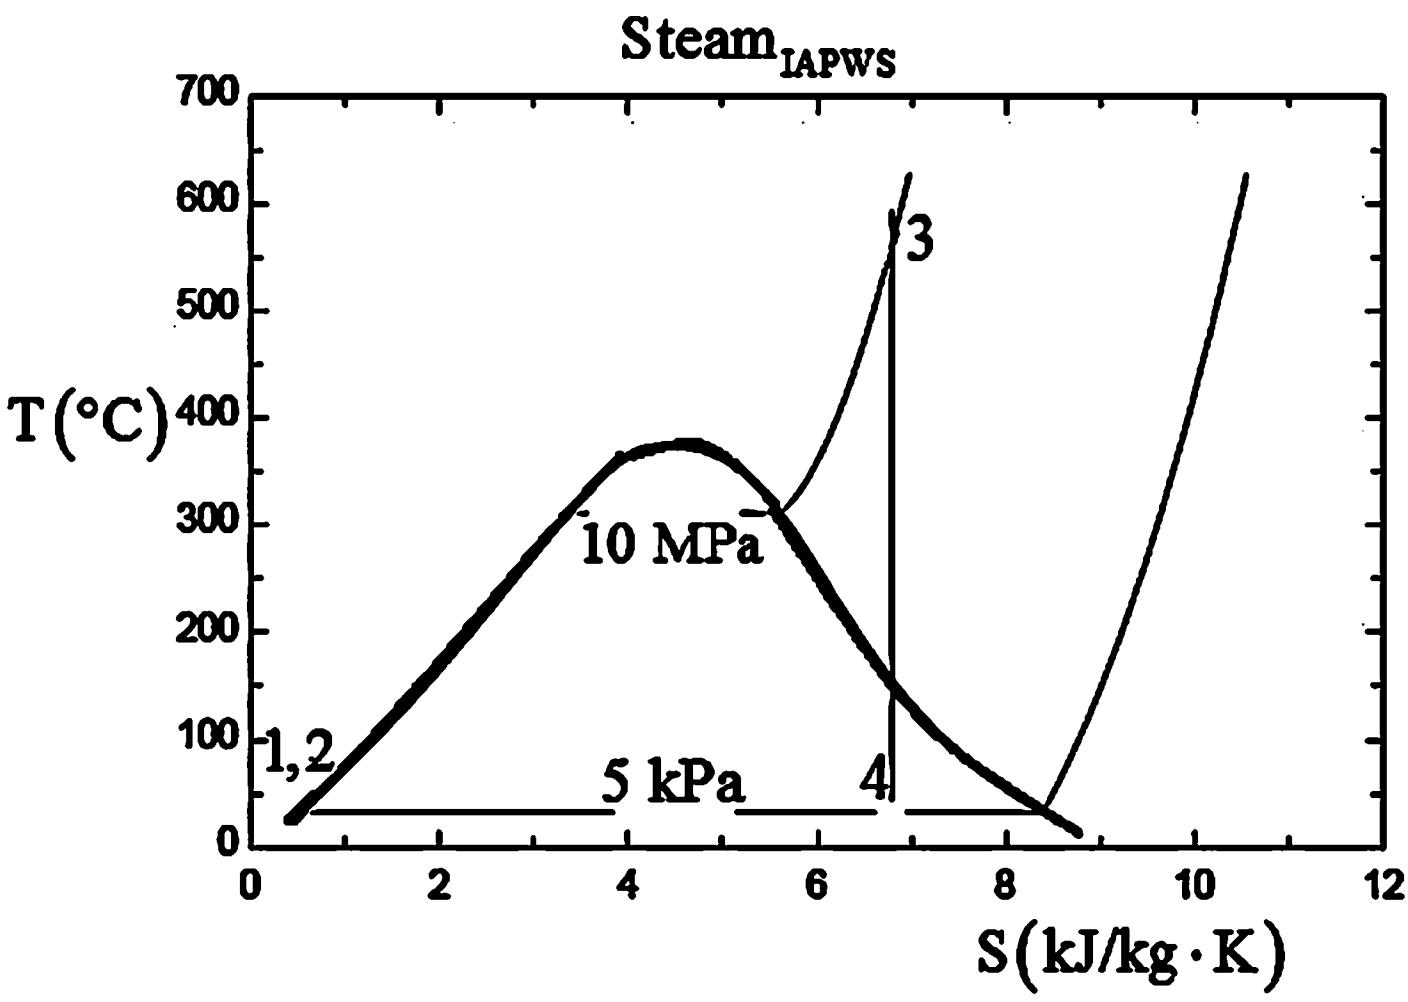
1..10	1 P_4 [kPa]	2 η_{th}	3 W_{net}
Run 1	5	0.4268	1432
Run 2	15.56	0.3977	1297
Run 3	26.11	0.3828	1231
Run 4	36.67	0.3724	1185
Run 5	47.22	0.3644	1150
Run 6	57.78	0.3577	1122
Run 7	68.33	0.352	1097
Run 8	78.89	0.347	1076
Run 9	89.44	0.3425	1057
Run 10	100	0.3385	1040

Step 4 of 6



Plot the graph between the pressure at point at point 4 and the thermal efficiency:



Step 5 of 6

Plot the graph between the pressure at point at point 4 and the network done:

Step 6 of 6

Draw the graph between the temperature and the entropy:

Question: 9.194P

Using EES (or other) software, investigate the effect of superheating the steam on the performance of a simple ideal Rankine cycle. Steam enters the turbine at 3 MPa and exits at 10 kPa. The turbine inlet temperature is varied from 250 to 1100°C. Determine the thermal efficiency of the cycle and plot it against the turbine inlet temperature, and discuss the results.

We don't have the solution to this problem yet.

Get help from a Chegg subject expert.

Ask an expert

Question: 9.195P

Using EES (or other) software, investigate the effect of number of reheat stages on the performance of an ideal Rankine cycle. The maximum and minimum pressures in the cycle are 15 MPa and 10 kPa, respectively, and steam enters all stages of the turbine at 500°C. For each case, maintain roughly the same pressure ratio across each turbine stage. Determine the thermal efficiency of the cycle and plot it against the number of reheat stages 1, 2, 4, and 8, and discuss the results.

We don't have the solution to this problem yet.

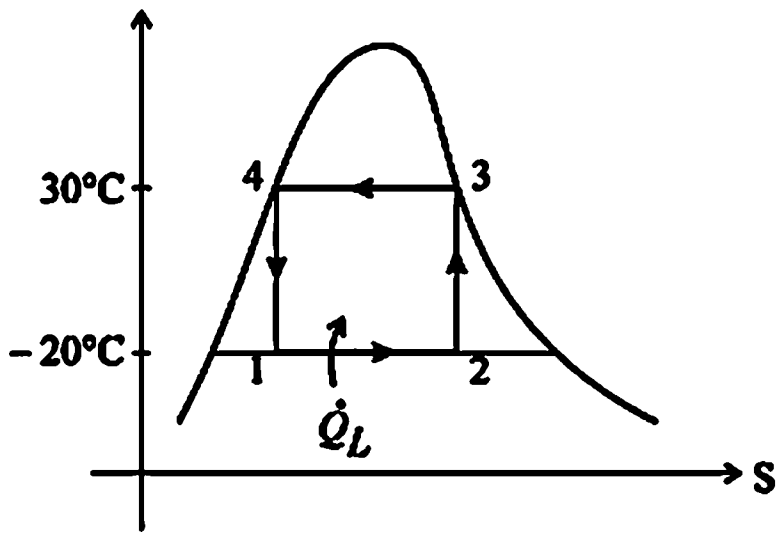
Question: 9.196P

Consider a steady-flow Carnot refrigeration cycle that uses refrigerant-134a as the working fluid. The maximum and minimum temperatures in the cycle are 30 and -20°C. respectively. The quality of the refrigerant is 0.15 at the beginning of the heat absorption process and 0.80 at the end. Show the cycle on a *T*-*s* diagram relative to saturation lines, and determine (*a*) the coefficient of performance, (*b*) the condenser and evaporator pressures, and (*c*) the net work input.

Step 1 of 8



Given:
Working fluid: R-134a
Maximum temperature $T_H = 30°C = 30+273 = 303K$
Minimum temperature $T_L = -20°C = -20+273 = 253K$

Step 2 of 8

Assumptions:
1. Steady operating conditions exist.
2. Kinetic and potential energy changes are negligible.

Step 3 of 8

T-S diagram of carnot refrigeration cycle

Step 4 of 8

From Saturated water-temperature table
$P_{sat@-20°C} = 132.82\ kPa$
$P_{sat@30°C} = 770.64\ kPa$
$h_{f@-20°C} = 25.49\ kJ/kg$
$h_{fg@-20°C} = 212.91\ kJ/kg$

Step 5 of 8

(a) COP of refrigeration cycle:

$$COP = \frac{1}{\frac{T_H}{T_L} - 1}$$

$$COP = \frac{1}{\frac{303}{253} - 1}$$

$$\boxed{COP = 5.06}$$

Step 6 of 8

(b) Condenser and evaporator pressures:
From Saturated water-temperature table
Pressure of condenser, $\boxed{P_c = P_{sat@30°C} = 770.64\ kPa}$
Pressure of evaporator, $\boxed{P_e = P_{sat@-20°C} = 132.82\ kPa}$

Step 7 of 8

(c) Net work input:

$$h_1 = h_{f@-20°C} + x_1 \times h_{fg@-20°C}$$
$$h_1 = 25.49 + 0.15 \times 212.91$$
$$h_1 = 57.4265\ kJ/kg$$
$$h_2 = h_{f@-20°C} + x_2 \times h_{fg@-20°C}$$
$$h_2 = 25.49 + 0.8 \times 212.91$$
$$h_2 = 195.818\ kJ/kg$$

Step 8 of 8

$$\text{But, } COP = \frac{\dot{Q}_L}{\dot{W}_{in}}$$

$$COP = \frac{(h_2 - h_1)}{\dot{W}_{in}}$$

$$\dot{W}_{in} = \frac{195.818 - 57.4265}{5.06}$$

$$\boxed{\dot{W}_{in} = 27.35\ kJ/kg}$$

Question:

9.197P

Rooms with floor areas of up to 15-m2 are cooled adequately by window air conditioners whose cooling capacity is 5000 Btu/h. Assuming the COP of the air conditioner to be 3.5, determine the rate of heat gain of the room, in Btu/h, when the air conditioner is running continuously to maintain a constant room temperature.

Step 1 of 2

Assumptions:

1. The heat gain includes heat transfer through walls and the roof, infiltration heat gain, solar heat gain etc.
2. Steady Operation condition exist

Step 2 of 2

The rate of heat gain of the room in steady operation is equal to the cooling rate of the air conditioning system.

So, $\boxed{\dot{Q}_{\text{heat gain}} = \dot{Q}_{\text{cooling rate}} = 5000\text{Btu/h}}$

Question:

9.198P

A heat pump water heater (HPWH) heats water by absorbing heat from the ambient air and transferring it to water. The heat pump has a COP of 3.4 and consumes 6 kW of electricity when running. Determine if this heat pump can be used to meet the cooling needs of a room most of the time for "free" by absorbing heat from the air in the room. The rate of heat gain of a room is usually less than 45,000 kJ/h.

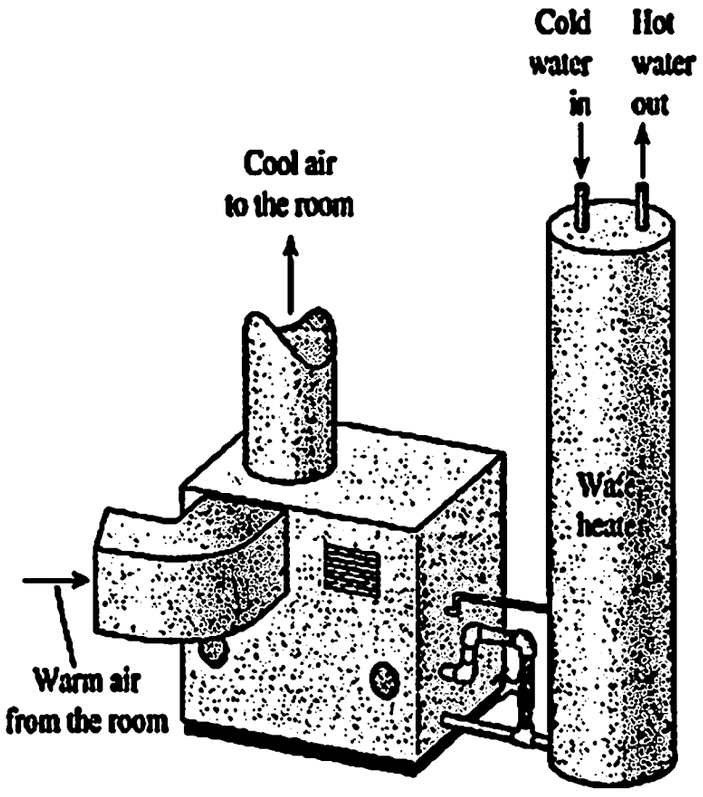


FIGURE P9–198

Step 1 of 3

Given:

COP of the heat pump $(COP)_{HP} = 3.4$

Work input to the compressor $W_{in} = 6\,\text{kW}$

Rate of heat gain $Q_H = 45000\,\frac{\text{kJ}}{\text{h}}$

Step 2 of 3

We know that

Coefficient of performance

$$COP = \frac{Q_H}{W_{in}}$$

$$\Rightarrow \dot{Q}_H = \dot{W}_{in} \times COP$$

$$= 6 \times 3.4$$

$$= 20.4\,\text{kW}$$

Step 3 of 3

But according to problem, we have

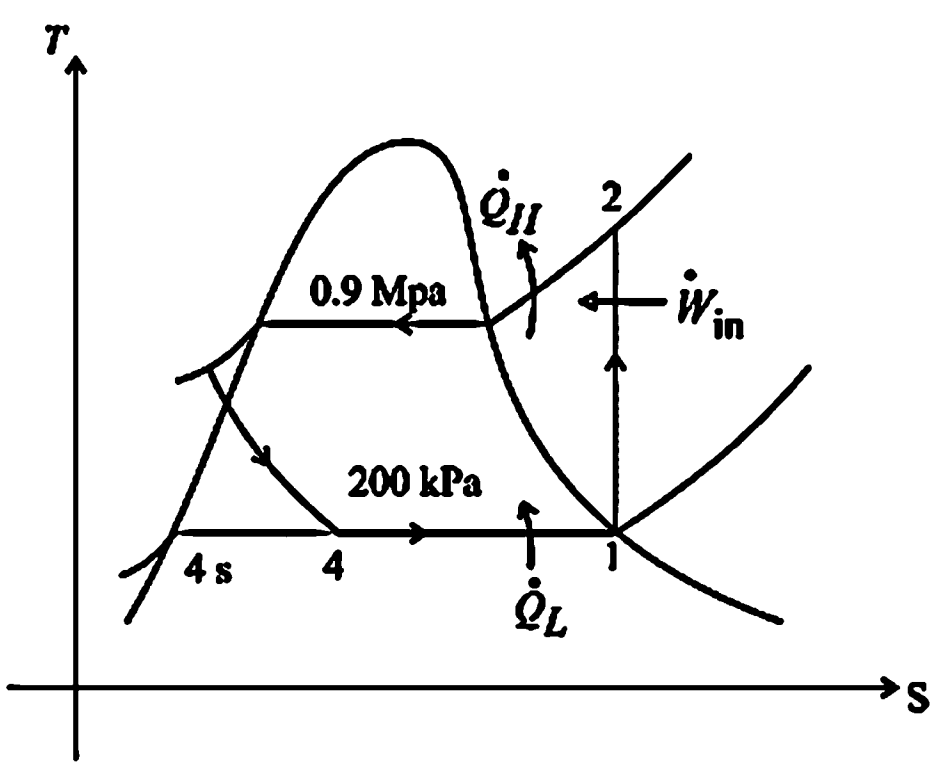
$$\dot{Q}_H = 45000\,\frac{\text{kJ}}{\text{h}}$$

$$= 12.5\,\text{kW}$$

$$Q_H = 20.4\,\text{kW} > Q_{\text{rabbum}}$$

So, heat pump can be used to meet the cooling need of the room most of the time.

Question: 9.199P



A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a is used to heat a house. The mass flow rate of the refrigerant is 0.32 kg/s. The condenser and evaporator pressures are 900 and 200 kPa, respectively. Show the cycle on a *T-s* diagram with respect to saturation lines, and determine (*a*) the rate of heat supply to the house, (*b*) the volume flow rate of the refrigerant at the compressor inlet, and (*c*) the COP of this heat pump.

Step 1 of 7

Given:
Working fluid: R-134a
Mass flow rate = 0.32 kg/s
Condenser pressure $P_2 = 900\,\text{kPa}$
Evaporator pressure $P_1 = 200\,\text{kPa}$

Step 2 of 7

T-S diagram of vapor compression cycle

Step 3 of 7

From saturated water-pressure table
At $P_1 = 200$ kPa and saturated vapor,
$h_1 = h_{g@200kPa} = 244.46$ kJ/kg,
$s_1 = s_{g@200kPa} = 0.93773$ kJ/kg.K,
$v_1 = v_{g@200kPa} = 0.099867\ \text{m}^3/\text{kg}$
At $P_2 = 900$ kPa and $s_2 = s_1 = 0.93773$ kJ/kg.K,

$$h_2 = 274.17 + \frac{0.93773 - 0.9327}{0.9660 - 0.9327} \times (284.77 - 274.17)$$

$h_2 = 275.77$ kJ/kg,
At $P_3 = P_2 = 900$ kPa and saturated liquid,
$h_3 = h_{f@0.9MPa} = 101.61$ kJ/kg,
For throttling, $h_4 = h_3 = 101.61$ kJ/kg,

Step 4 of 7

Assumptions:
1. Steady operating conditions exist.
2 Kinetic and potential energy changes are negligible.

Step 5 of 7

(a) Rate of heat supply to the house:
Rate of heat supply to the house, $\dot{Q}_H = \dot{m} \times (h_2 - h_3)$
$\dot{Q}_H = 0.32 \times (275.77 - 101.61)$
$\boxed{\dot{Q}_H = 55.7312\ \text{kW}}$

Step 6 of 7

(b) Volume flow rate of the refrigerant at the compressor inlet:
Volume flow rate of the refrigerant at the compressor inlet, $\dot{V}_1 = \dot{m} \times v_1$
$\dot{V}_1 = 0.32 \times 0.099867$
$\boxed{\dot{V}_1 = 0.03196\ \text{m}^3/\text{s}}$

Step 7 of 7

(c) COP of the heat pump:
COP of the heat pump, $\text{COP} = \dfrac{\dot{Q}_L}{\dot{W}_{in}}$

$$\text{COP} = \frac{h_2 - h_3}{h_2 - h_1}$$

$$\text{COP} = \frac{275.77 - 101.61}{275.77 - 244.46}$$

$\boxed{\text{COP} = 5.5624}$

Question: 9.200P

A ground-coupled heat pump operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid. This heat pump has a COP equal to 6 in this cooling mode and maintains a space at 25°C when absorbing heat from the space at the rate of 18 kW in the evaporator. The evaporator operates at 20°C, and the condenser operates at 1400 kPa. Ground water taken from a well at the rate of 0.32 kg/s absorbs the heat transferred from the refrigerant in the condenser.

(a) Sketch the hardware and the *T-s* diagram for this heat pump,

(b) If the ground water enters the condenser at 10°C, what will be the temperature of the cooling water as it is returned to the ground? Take *cp*= 4.18 kJ/kg.K for cooling water.

(c) Determine the COP of the heat pump.

RefrigeranM34a data: *T*= 20°C: *hf* =79.3 kJ/kg, *hg* = 261.6 kJ/kg; *P* =1400 kPa: *hf* = *Mil* kJ/kg,

hg =276.2 kJ/kg

Step 1 of 7

Given:

Working fluid: R-134a

COP of the heat pump $(COP)_R = 6$

Refrigeration space temperature $T_1 = 25^\circ C$

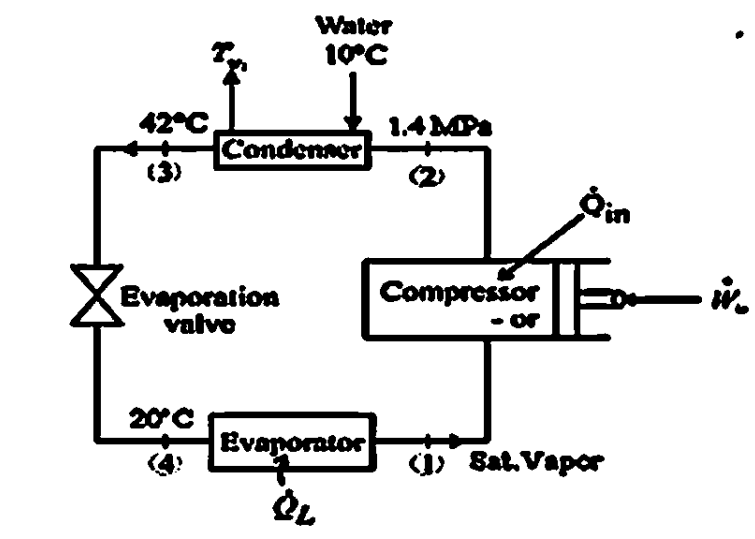
Capacity of the evaporator $Q_L = 18\,kW$

Operating temperature of evaporator $T_4 = 20^\circ C$

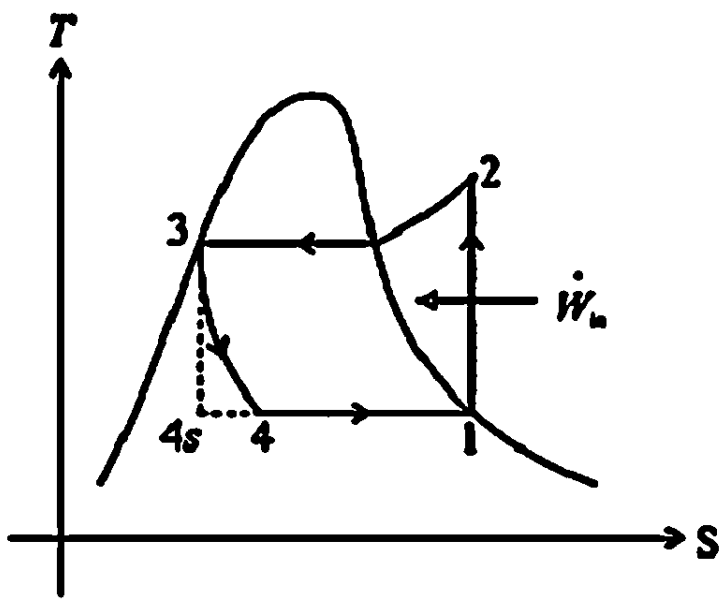
Operating pressure of condenser $P_2 = P_3 = 1400\,kPa$

Mass flow rate of water $m = 0.32\frac{kg}{s}$

Inlet temperature of the ground water $T_{w1} = 10^\circ C$



Specific heat of water $C_p = 4.18\frac{kJ}{kg \cdot K}$



Properties of R-134a

$T = 20^\circ C$	$h_f = 79.3\frac{kJ}{kg}$	$h_g = 261.6\frac{kJ}{kg}$
$P_2 = P_3 = 1400\,kPa$	$h_f = 127.2\frac{kJ}{kg}$	$h_g = 276.2\frac{kJ}{kg}$

Step 2 of 7

(a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic; the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure.

Step 3 of 7

(b) State 3:

From the properties of R-134a

At $P_2 = P_3 = 1400\,kPa$

$$h_3 = h_f = 127.2\frac{kJ}{kg}$$

Step 4 of 7

State 4:

Since process 3 to 4 is throttling so enthalpy remains constant.So

$$h_4 = h_3 = 127.2\frac{kJ}{kg}$$

State1:

Since refrigerant enters into the compressor is saturated Vapor. So

$$h_1 = h_g = 261.6\frac{kJ}{kg}$$

Step 5 of 7

The rate of heat transfer in the condenser is determined from

$$COP = \frac{\dot{Q}_L}{\dot{Q}_H - \dot{Q}_L}$$

$$\Rightarrow \dot{W}_{in} = \frac{\dot{Q}_L}{COP_R}$$

$$\Rightarrow \dot{Q}_H - \dot{Q}_L = \frac{\dot{Q}_L}{COP_R}$$

$$\dot{Q}_H = \dot{Q}_L\left(1 + \frac{1}{COP_R}\right)$$

$$= (18)\left(1 + \frac{1}{6}\right)$$

$$= 21\,kW$$

Step 6 of 7

An energy balance on the condenser gives

Heat supplied is equal to the heat gain.

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = \dot{m}_w c_{pw}(T_{2w} - T_{1w})$$

$$T_{2w} = T_{1w} + \frac{\dot{Q}_H}{\dot{m}_w c_{pw}}$$

$$= 10^\circ C + \frac{21\,kW}{\left(0.32\frac{kg}{s}\right)\left(4.18\frac{kJ}{kg \cdot K}\right)}$$

$$= 25.69^\circ C$$

$$\boxed{T_{2w} = 25.69^\circ C}$$

Step 7 of 7

(c) The COP of the heat pump is

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{Q}_H - \dot{Q}_L}$$

$$= \frac{21}{21 - 18}$$

$$= 7$$

$$\boxed{COP_{HP} = 7}$$

Question: 9.201P pg 1

A refrigeration unit operates on the ideal vapor compression refrigeration cycle and uses refrigerant-22 as the working fluid. The operating conditions for this unit are evaporator saturation temperature of -5°C and the condenser saturation temperature of 45°C. Selected data for refrigerant-22 are provided in the table below.

T, °C	P_{sat}, kPa	h_f, kJ/kg	h_g, kJ/kg	s_g, kJ/kg·K
−5	421.2	38.76	248.1	0.9344
45	1728	101	261.9	0.8682

For R-22 at P =1728 kPa and s =0.9344 kJ/kg-K,

T =68.15T and h =283.7 kJ/kg. Also, take

cp,air =1.005 kJ/kg-K.

(*a*) Sketch the hardware and the *T-s* diagram for this heat pump application.

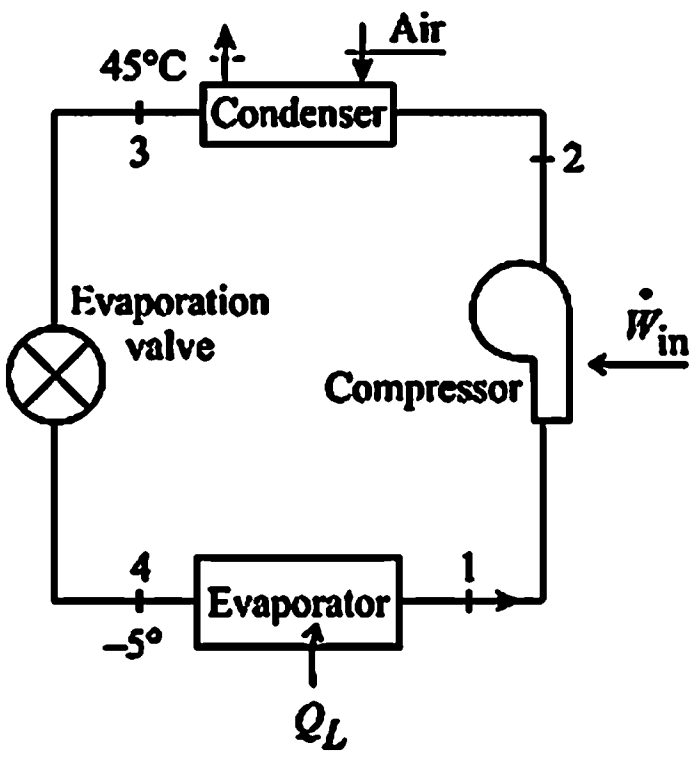
(*b*) Determine the COP for this refrigeration unit.

(*c*)The evaporator of this unit is located inside the air handler of the building. The air flowing through the air handler enters the air handler at 27°C and is limited to a 20°C temperature drop. Determine the ratio of volume flow rate of air entering the air handler (*m*3air/min) to mass flow rate of R-22 (kgR-22/s) through the air handler, in $(m^3_{air}/\text{min})/(\text{kg}_{R\text{-}22}/\text{s})$. Assume the air pressure is 100 kPa.

Step 1 of 7

Given:

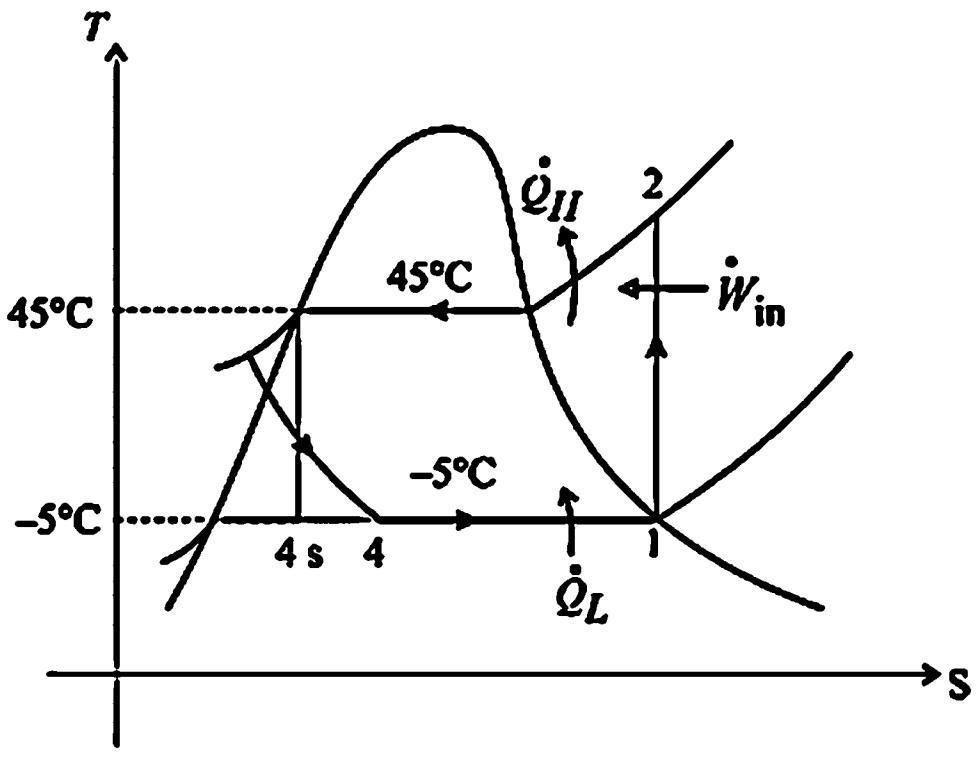
Evaporation saturation temperature $T_1 = -5°C$



Condenser saturation temperature $T_2 = 45°C$

Air flowing through air handler is limited to $\Delta T = 20°C$

Step 2 of 7



(a)

Hardware for heat pump application

Step 3 of 7

T-S diagram of heat pump application

Step 4 of 7

(b)

From the refrigerant-22 table

At $T_1 = -5°C$, saturated vapor

$h_1 = h_{g@-5°C} = 248.1 \text{kJ/kg}$, $s_1 = s_{g@-5°C} = 0.9344 \text{kJ/kg.K}$

At $P_2 = 1728 \text{kPa}$, $s_2 = s_1 = 0.9344 \text{kJ/kg.K}$

$h_2 = 283.7 \text{kJ/kg}$

At $P_3 = 1728 \text{kPa}$, saturated liquid

$h_3 = h_{f@1728\text{kPa}} = 101 \text{kJ/kg}$

For Throttling, $h_4 \cong h_3 = 101 \text{kJ/kg}$

Step 5 of 7

COP of the heat pump:

$$\text{COP}_{HP} = \frac{q_H}{w_{in}}$$

$$\text{COP}_{HP} = \frac{h_2 - h_3}{h_2 - h_1}$$

$$\text{COP}_{HP} = \frac{283.7 - 101}{283.7 - 248.1}$$

$$\boxed{\text{COP}_{HP} = 5.132}$$

Step 6 of 7

(c)

Ratio of volume flow rate of air entering the air handler to mass flow rate of R-22 through the air handler:

Energy balance on the condenser, $\dot{Q}_H = \dot{m}_R (h_2 - h_3)$ and $\dot{Q}_H = \dot{m}_a c_p \Delta T$

$$\dot{m}_R (h_2 - h_3) = \frac{\dot{V}_a}{v_a} c_p \Delta T$$

through the air handler: 9.201P pg 2

Energy balance on the condenser, $\dot{Q}_H = \dot{m}_R (h_2 - h_3)$ and $\dot{Q}_H = \dot{m}_a c_p \Delta T$

$$\dot{m}_R (h_2 - h_3) = \frac{\dot{V}_a}{v_a} c_p \Delta T$$

$$\frac{\dot{V}_a}{\dot{m}_R} = \frac{(283.7 - 101)}{(1/0.847) \times (1.005) \times (20)}$$

$$\frac{\dot{V}_a}{\dot{m}_R} = \frac{182.7}{23.7308}$$

$$\frac{\dot{V}_a}{\dot{m}_R} = 7.699 \left(m^3 air / s \right) / (kg R22 / s)$$

$$\boxed{\frac{\dot{V}_a}{\dot{m}_R} = 461.94 \left(m^3 air / \min \right) / (kg R22 / s)}$$

Step 7 of 7

Question: 9.202P

Consider an ice producing plant that operates on the ideal vapor-compression refrigeration cycle and uses refrigerant-134a as the working fluid. The refrigeration cycle operating conditions require an evaporator pressure of 140 kPa and the condenser pressure of 1200 kPa. Cooling water flows through the water jacket surrounding the condenser and is supplied at the rate of 200 kg/s. The cooling water has a 10°C temperature rise as it flows through the water jacket. To produce ice, potable water is supplied to the chiller section of the refrigeration cycle. For each kg of ice produced,333 kj of energy must be removed from the potable water supply |

(*a*)Sketch the hardware for all three working fluids of this refrigerant-ice making system and the *T-s* diagram for refrigeration cycle.

(*b*)Determine the mass flow rate of the refrigerant, in kg/s

(*c*)Determine the mass flow rate of the potable water supply, in kg/s.

Step 1 of 8

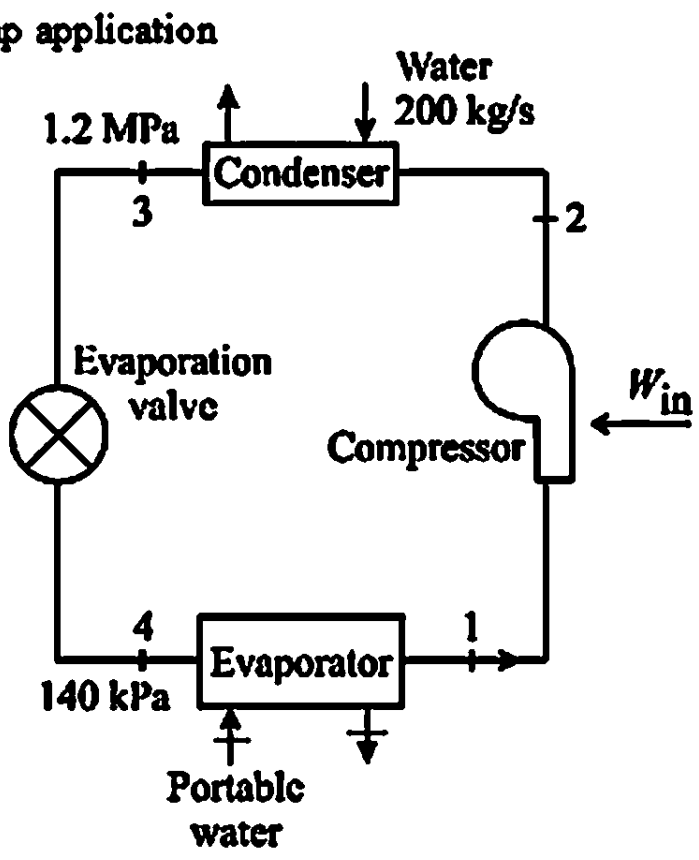
Given:

Working fluid: R-134a

Evaporator pressure $P_1 = P_4 = 140\text{kPa}$

Condenser pressure $P_2 = P_3 = 1200\text{kPa}$

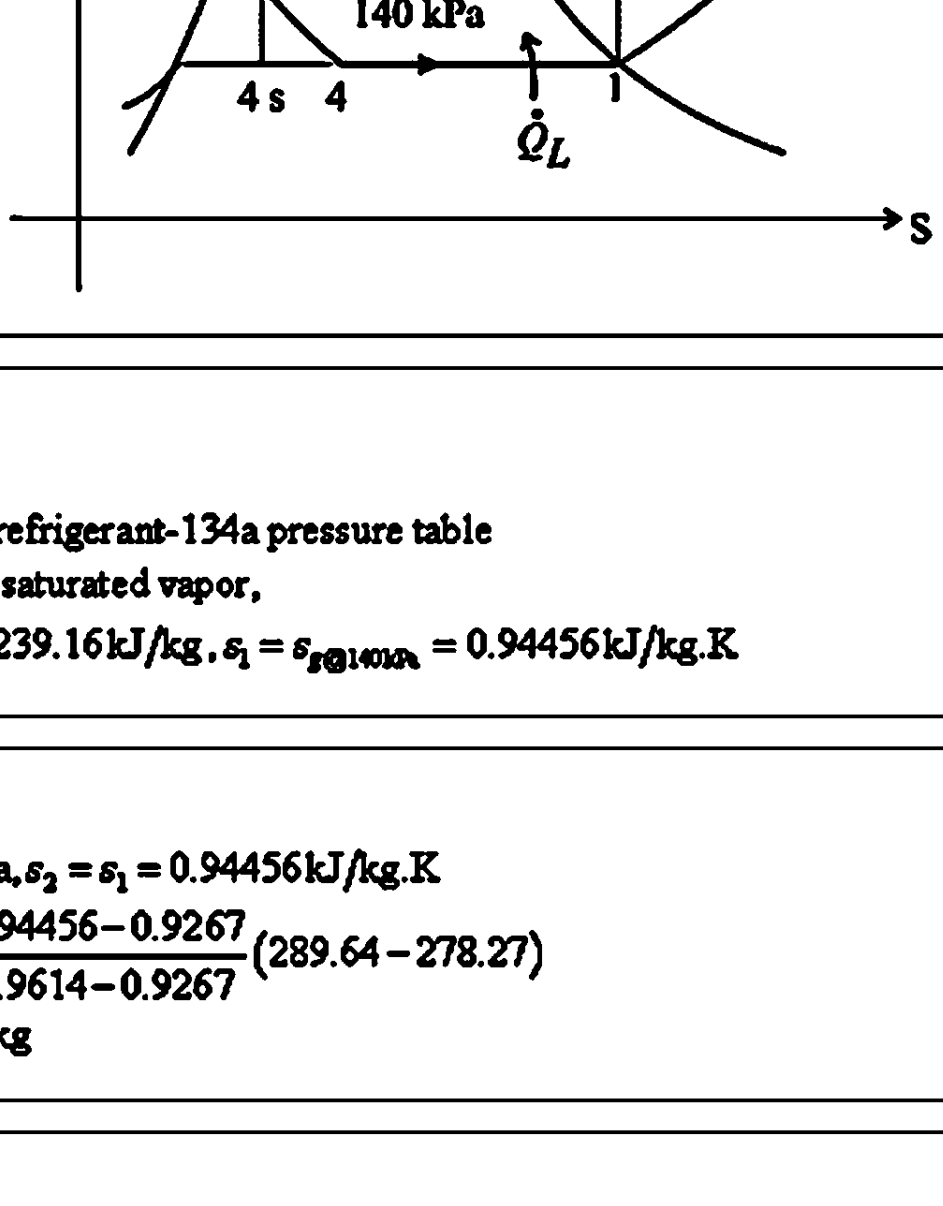
Mass flow rate of water $\dot{m}_w = 200\text{kg/s}$



Rise in temperature of water $\Delta T = 10°\text{C}$

Amount of energy to be removed for each kg of ice $h_{if} = 333\text{kJ/kg}$

Step 2 of 8



(a)

Hardware for Heat pump application

Step 3 of 8

T-S diagram of heat pump application

Step 4 of 8

(b)

From saturated refrigerant-134a pressure table

At $P_1 = 140\text{kPa}$, saturated vapor,

$h_1 = h_{g@140\text{kPa}} = 239.16\text{kJ/kg}$, $s_1 = s_{g@140\text{kPa}} = 0.94456\text{kJ/kg.K}$

Step 5 of 8

At $P_2 = 1200\text{kPa}$, $s_2 = s_1 = 0.94456\text{kJ/kg.K}$

$$h_2 = 278.27 + \frac{0.94456 - 0.9267}{0.9614 - 0.9267}(289.64 - 278.27)$$

$$h_2 = 284.12\text{kJ/kg}$$

Step 6 of 8

From saturated refrigerant-134a pressure table

At $P_3 = 1200\text{kPa}$, saturated liquid

$h_3 = h_{f@1200\text{kPa}} = 117.77\text{kJ/kg}$

For Throttling, $h_4 \cong h_3 = 117.77\text{kJ/kg}$

Step 7 of 8

Mass flow rates of the refrigerant:

Energy balance on the condenser, $\dot{Q}_H = \dot{m}_R(h_2 - h_3) = \dot{m}_w c_p \Delta T$

$$\dot{m}_R = \frac{\dot{m}_w c_p \Delta T}{h_2 - h_3}$$

$$\dot{m}_R = \frac{(200)\times(4.18)(10)}{(284.12 - 117.77)}$$

$$\dot{m}_R = \frac{8360}{166.35}$$

$$\boxed{\dot{m}_R = 50.255\text{ kg/s}}$$

Step 8 of 8

(c)

Mass flow rate of the potable water:

Energy balance on the evaporator, $\dot{Q}_L = \dot{m}_R(h_1 - h_4) = \dot{m}_w h_{if}$

$$\dot{m}_w = \frac{\dot{m}_R(h_1 - h_4)}{h_{if}}$$

$$\dot{m}_w = \frac{50.271\times(239.16 - 117.77)}{333}$$

$$\dot{m}_w = \frac{6102.39}{333}$$

$$\boxed{\dot{m}_w = 18.325\text{ kg/s}}$$

CHAPTER 10
SOLUTIONS

Question: 10.001P

Define internal, external, and open-channel flows.

Step 1 of 3

External flow: The flow of an unbounded fluid over a surface is known as external flow. The flow of water in river is example for external flow.

Step 2 of 3

Internal flow: If the fluid is completely bounded by a solid surface, then the flow is known as internal flow. Water flow in a pipe is example for internal flow.

Step 3 of 3

Open channel flow

The flow of liquids in a duct is called open channel flow, if the duct is partially filled liquid and there is a free surface. Internal flows are dominated by the influence of viscosity, where as in solid fluids viscous effects are limited to boundaries.

Discussion: Classification of flows is useful in flow analysis.

Question: 10.002P

Define incompressible flow and incompressible fluid. Must the flow of a compressible fluid necessarily be treated as compressible?

Step 1 of 2

Incompressible Flow:

Flow is incompressible means; the fluid density remains constant throughout. If the density changes in a flow, the density of such a fluid (like liquid) is practically independent.

Incompressible flow is satisfy the below equation

$$\frac{\partial \rho}{\partial t}+\frac{\partial \rho u}{\partial x}+\frac{\partial \rho v}{\partial y}+\frac{\partial \rho w}{\partial z}=0$$

If flow is satisfy the continuity equation then flow is called incompressible.

Step 2 of 2

Compressible Flow:

Flow is compressible means the density of the fluid changes in the fluid flow due to change in temperature and pressure.

Example: Gases are considered compressible fluid.

If flow is not satisfy the continuity equation then flow is called compressible.

Question: 10.003P

Consider the flow of air over the wings of an aircraft. Is this flow internal or external? How about the flow of gases through a ajet engine?

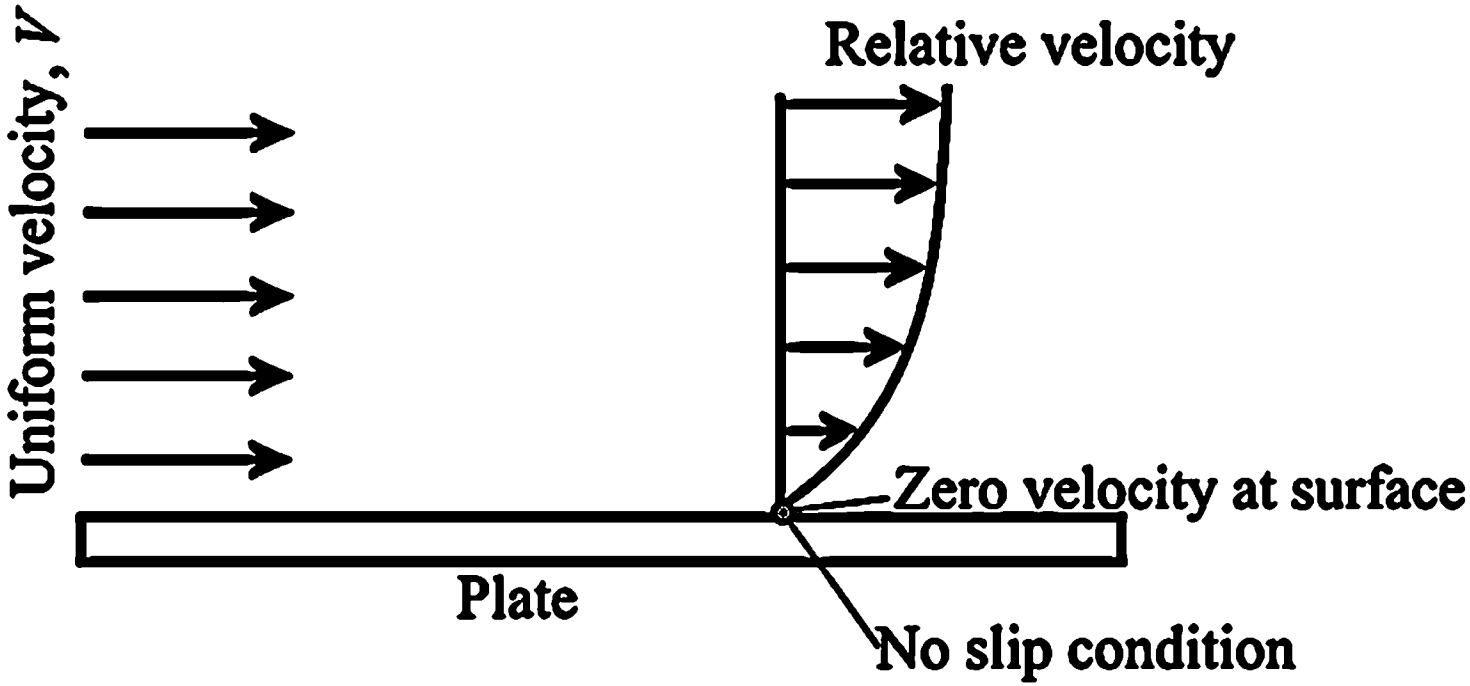
Step 1 of 2

External flow: The flow of an unbounded fluid over a surface is known as External flow. The flow of water in river is an example for external flow.

Therefore we can say that the air flow over the wings of aircraft is external flow. Here the flow is over unbounded surface.

Step 2 of 2

Internal flow: If the fluid is completely bounded by a solid surface, then the flow is known as internal flow. Water flow in a pipe is example for internal flow.



Flow of gases through jet engine is internal flow because in engines, fluids (gases) are bounded by solid surface.

Question: 10.004P

What is the no-slip condition? What causes it?

Step 1 of 2

Sketch the no slip condition exits, when a fluid flows over the plate.

Step 2 of 2

Consider the surface up on which the fluid flows as nonporous. Thus when the fluid in motion comes in contact with a nonporous surface then the fluid approaches to a complete stop at the surface and considers a zero velocity relative to the surface. That is a fluid in direct contact with solid, sticks to the surface, and there will be no slip occurs on the surface. This condition is called to be as no-slip condition.

Viscosity of the fluid is responsible for no-slip condition to occur.

Question: 10.005P

What is forced flow? How does it differ from natural flow? Is flow caused by winds forced or natural flow?

Step 1 of 1

Forced Flow:
If a fluid is forced to flow over a surface or in a pipe by means of external source such as pump or fan, then the flow is known as forced flow.

Natural Flow:
In natural flow, the fluid motion is due to natural means such as buoyancy effect. Flow caused by winds is natural flow. This flow is due to change in temperatures and pressures in the atmosphere, so the flow of wind is natural flow.

Question: 10.006P

What is a boundary layer? What causes a boundary layer to develop?

Step 1 of 2

Boundary layer:
At the surface, the fluid is at rest. The velocity of the fluid is zero at the surface and gradually increases. The flow region adjacent to the wall in which the viscous effects are significant is called the boundary layer.

Step 2 of 2

Boundary layer is developed due to the no-slip condition. No slip condition means, the fluid motion is zero at the contact surface of the solid. The property viscosity is responsible for no slip condition and development of boundary layer. Viscosity gives the relation between rate of deformation and shear stress. It is the main cause of boundary layer.

Question: 10.007P

What is vapor pressure? How is it related to saturation pressure?

Step 1 of 1

The vapor pressure of a pure substance is defined as the pressure exerted by its vapor in an equilibrium phase with its liquid at a given temperature. It is denoted as P_v. At a given temperature, the pressure at which the substance changes its phase is known as the saturation pressure, P_{sat}.

Relation between both is given as

$P_v = P_{sat}$ for pure vapor.

Question: 10.008P

Does water boil at higher temperatures at higher pressures? Explain.

Step 1 of 1

The saturation temperature of the pure substance depends upon pressure; when pressure increases saturation temperature also increases.

For example: Water boils at 134° C in a pressure cooker operating at 3 atm absolute pressure, but it boils at 93° C in an ordinary pan at 2000 m elevation where the atmospheric pressure is 0.8 atm. Therefore the vapour pressure increases with temperature.

Question: 10.009P

If the pressure of a substance is increased during a boiling process, will the temperature also increase or will it remain constant? Why?

Step 1 of 1

Analysis:

If the pressure of the substance increases during a boiling process, the temperature will also increase.

During boiling, the liquid is converted into vapor so we can apply the ideal gas equation. Here the pressure and temperature are linearly proportional, therefore as pressure increases, the temperature also increases.

Question: 10.010P

What is cavitation? What causes it?

Step 1 of 1

Cavitation is the phenomenon of formation of vapor bubbles of a flowing liquid in a region where the pressure of the liquid falls below its vapor pressure at that temperature and the sudden collapsing of these vapor bubbles in a region of higher pressure. When these vapor bubbles collapse, a very high pressure is created which causes pitting on the metallic surfaces termed as cavitation.

Question: 10.011P

In a piping system, the water temperature remains under 35°C. Determine the minimum pressure allowed in the system to avoid cavitation.

Step 1 of 1

Given data:

The temperature of water, $t = 35^\circ C$

Let the minimum pressure that can exist in the piping system to avoid cavitations be P_{min}.

The vapor pressure of water at, $t = 35^\circ C$ is

$P = 5.63 kPa$.

i.e. $P_{min} = 5.63\ kPa$

Therefore the pressure should not be maintained more than $P = 5.63 kPa$ in given water piping system to avoid cavitation.

Question: 10.012P

The analysis of a propeller that operates in water at 20°C shows that the pressure at the tips of the propeller drops to 2 kPa at high speeds. Determine if there is a dange of cavitation for this propeller.

Step 1 of 6

Given data :

The temperature of water, $t = 20°C$

The actual pressure at the tip of the propeller, $P_{act} = 2\,kPa$

Step 2 of 6

Obtain the saturation pressure of water $20°C$ from table A-4, "Saturated water-temperature table "from the textbook.

$P = 2.34\,kPa$

Step 3 of 6

At the given temperature, to avoid cavitation, the pressure in the flow must be greater than the vapor (or saturation) pressure.

Step 4 of 6

Since the actual pressure $P_{act} = 2\,kPa$ is less than the vapor pressure of the water at $20°C$, there is a chance of cavitation.

Step 5 of 6

Hence, there is a danger of cavitation for this propeller.

Step 6 of 6

Question: 10.013P

The analysis of a propeller that operates in water at 70°F shows that the pressure at the tips of the propeller drops to 0.1 psia at high speeds. Determine if there is a danger of cavitation for this propeller.

Step 1 of 2

Given data:

The temperature of water, $t = 70°F$

The actual pressure at the tip of the propeller, $P_{act} = 0.1 psia$

Step 2 of 2

From the saturated water temperature table at $t = 70°F$ the given values of saturated pressure is $P_{sat} = 0.3632$ psia

At the given temperature, to avoid cavitation, pressure in the flow must be greater than the vapour (or saturation) pressure.

There is danger of cavitation in the pump because the minimum pressure in the pump is $P_{act} = 0.1 psia$. This is less than the vapour pressure.

Question: 10.014P

What is viscosity? What is the cause of it in liquids and in gases? Do liquids or gases have higher dynamic viscosities?

Step 1 of 1

Viscosity is defined as the property of fluid which offers resistance to the movement of one layer of the fluid over another adjacent layer.

The viscous forces in a fluid are due to cohesive forces and momentum transfer. In liquids, the cohesive force predominates the molecular momentum transfer, due to closely packed molecules and with the increase in temperature, the cohesive force decreases with the result of decreasing viscosity.

In case of gases, the cohesive forces are small and molecular momentum transfer predominates. With the increase in temperature, molecular momentum transfer increases and hence viscosity increases.

Viscosity is the measure of resistance of fluid. Viscosity of liquids is more than viscosity of gases.

Question: 10.015P

What is a Newtonian fluid? Is water a Newtonian fluid?

Step 1 of 1

Fluid which satisfy the Newton's law of viscosity is known as Newtonian fluid. Newton's law of viscosity states that a fluid's shear stress is proportional to its velocity gradient.

$$\tau = \mu \frac{du}{dy}$$

Here

μ : Coefficient of viscosity or dynamic viscosity of the fluid.

Water is an example of Newtonian fluid.

Question: 10.016P

Consider two identical small glass balls dropped into two identical containers, one filled with water and the other with oil. Which ball will reach the bottom of the container first? Why?

Step 1 of 1

From the property of viscosity ball is dropped in the water container will reach faster to the bottom than the ball dropped in oil container.

The viscosity of water is less than oil. So the viscosity of oil restricts the motion of ball.

Question: 10.017P

How does the dynamic viscosity of (*a*) liquids and (*b*) gases vary with temperature?

Step 1 of 1

Dynamic viscosity is depends upon temperature.

Dynamic Viscosity of liquids decreases with increases in temperature, where as in gases dynamic viscosity increases with increase in temperature. In liquids cohesive force dominates the molecular momentum. In gases molecular momentum dominates the cohesive force.

When temperature increases cohesive force decreases in liquids so dynamic viscosity decreases.

In gases molecular momentum increases with increase in temperature so the dynamic viscosity increases.

Question: 10.018P

How does the kinematic viscosity of (*a*) liquids and (*b*) gases vary with temperature?

Step 1 of 1

Kinematics viscosity is depends on the temperature .Kinematic Viscosity of liquids reduces with raise in temperature, where as in gases kinematic viscosity raises with raise in temperature.

Question: 10.019P

For flow over a plate, the variation of velocity with vertical distance y from the plate is given as $u(y) = ay - by2$ where a and b are constants. Obtain a relation for the wall shear stress in terms of a, b, and μ.

Step 1 of 1

The velocity distribution is given as

$$u(y) = ay - by^2$$

Now, the velocity gradient is

$$\frac{du}{dy} = a - 2by$$

Shear stress would be:

$$\tau = \mu \frac{du}{dy}$$

The shear stress $\boxed{\tau = \mu(a - 2by)}$

Question: 10.020P

A 50-cm × 30-cm × 20-cm block weighing 150 N is to be moved at a constant velocity of 0.8 m/s on an inclined surface with a friction coefficient of 0.27. (*a*) Determine the force *F* that needs to be applied in the horizontal direction. (*b*) If a 0.4-mm-thick oil film with a dynamic viscosity of 0.012 Pa•s is applied between the block and inclined surface, determine the percent reduction in the required force.

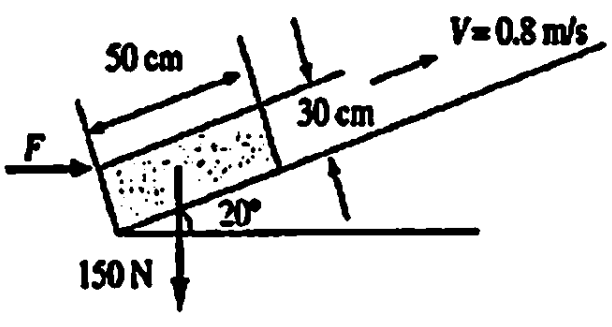


FIGURE P10–20

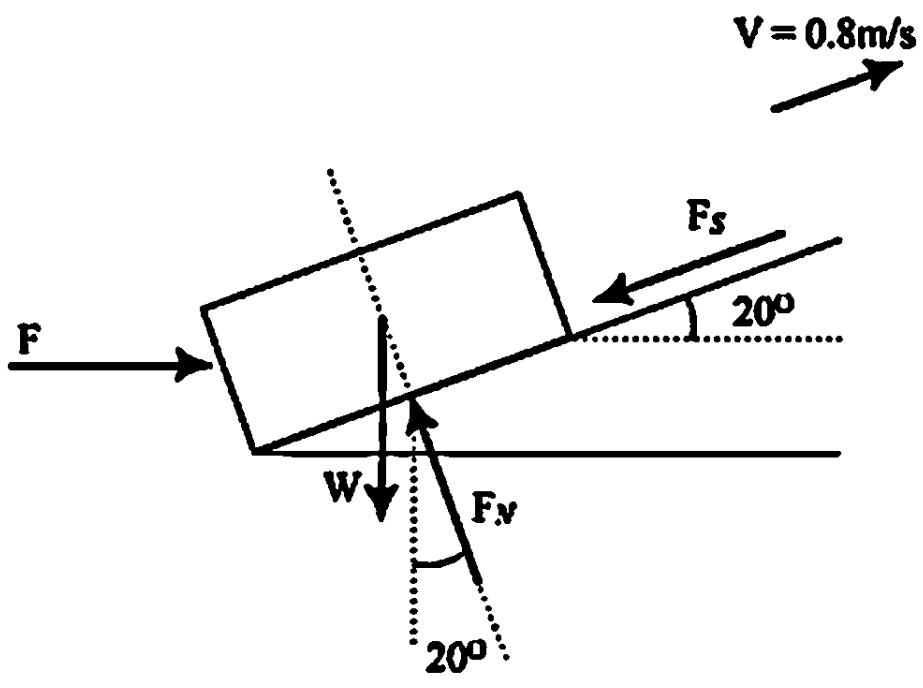
Step 1 of 9

Given data:

The weight of the block is $W = 150\ \text{N}$.

The velocity of the block is constant and is $v = 0.8\ \text{m/s}$.

The coefficient of friction of the surface is $\mu_s = 0.27$.



The thickness of the oil film is $\ell = 0.4\ \text{mm}$.

The dynamic viscosity between the block and inclined surface is $\mu = 0.012\ \text{Pa}\cdot\text{s}$.

The velocity $V = 0.8\ \text{m/s}$.

Step 2 of 9

Let us draw the free body diagram of the block.

Step 3 of 9

(a) Apply the condition of equilibrium.

Then

$$+\uparrow \sum F_y = 0$$

$$F_N \cos 20° - W - F_S \sin 20° = 0$$

Where

The frictional force applied by the surface

$$F_S = \mu_s F_N$$

Then

$$F_N \cos 20° - W - \mu_s F_N \sin 20° = 0$$

$$0.939F_N - (0.27)F_N(0.342) = 150$$

$$F_N = 177.16\ \text{N}$$

Step 4 of 9

And

$$+\rightarrow \sum F_x = 0$$

$$F - F_N \sin 20° - F_S \cos 20° = 0$$

Then

$$F = F_N \sin 20° + \mu_s F_N \cos 20°$$

$$= (0.342 + 0.27 \times 0.939)F_N$$

$$= 105.5\ \text{N}$$

Hence the required horizontal force to be applied is $\boxed{F = 105.5\ \text{N}}$.

Step 5 of 9

(b)

An oil film of thickness 4 mm and dynamic viscosity of $\mu = 0.012\ \text{Pa}\cdot\text{s}$ is introduced between the block and surface.

The shear force exerted

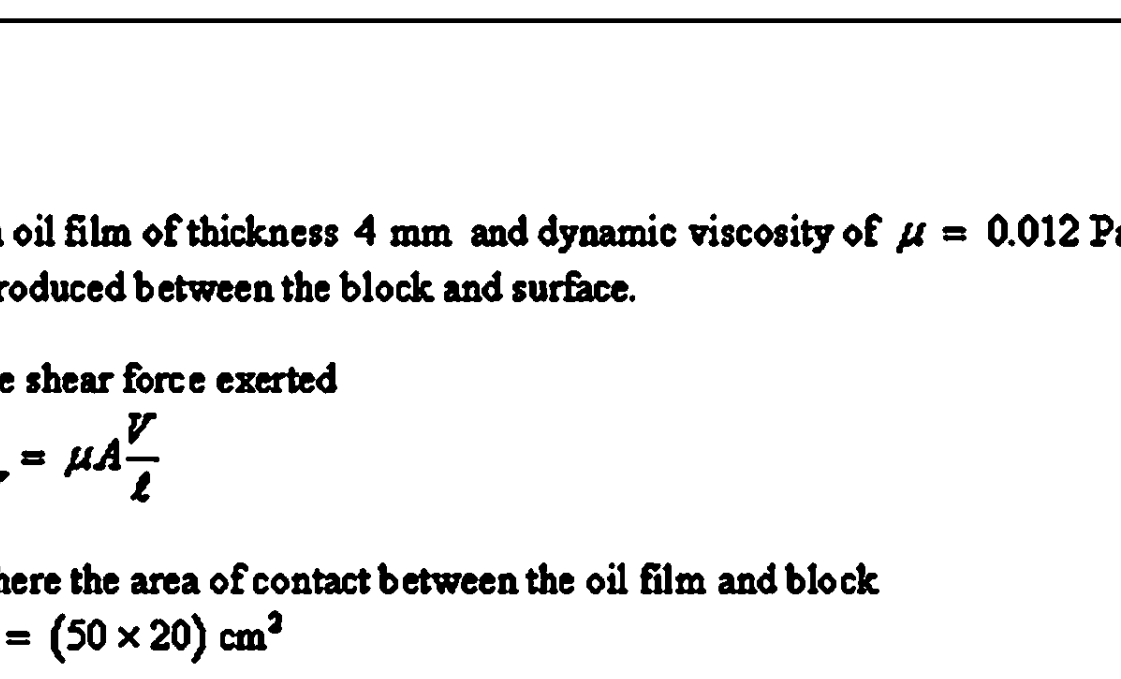
$$F_{sf} = \mu A \frac{V}{\ell}$$

Where the area of contact between the oil film and block

$$A = (50 \times 20)\ \text{cm}^2$$

$$= 1000\ \text{cm}^2$$

$$= 0.1\ \text{m}^2$$



Then

$$F_{sf} = (0.012)(0.1)\frac{0.8}{(0.4 \times 10^{-3})}$$

$$= 2.4\ \text{N}$$

Step 6 of 9

Let us draw the free body diagram

Step 7 of 9

Apply the condition of equilibrium.

Then

$$+\uparrow \sum F_y = 0$$

$$F_N \cos 20° - W - F_{sf} \sin 20° = 0$$

$$F_N \cos 20° - 150 - 2.4 \sin 20° = 0$$

$$F_N = 160.5\ \text{N}$$

Step 8 of 9

And

$$+\rightarrow \sum F_x = 0$$

$$F - F_N \sin 20° - F_{sf} \cos 20° = 0$$

Then

$$F = F_N \sin 20° + F_{sf} \cos 20°$$

$$= 160.5 \sin 20° + 2.4 \cos 20°$$

$$= 57.14\ \text{N}$$

The required horizontal force to be applied when the oil film is used,

$F = 57.14\ \text{N}$.

Step 9 of 9

The percentage reduction in applied force is

$$\%\text{reduction} = \left(\frac{105.5\ \text{N} - 57.14\ \text{N}}{105.5\ \text{N}}\right) \times 10$$

$$= 45.83\%$$

Hence the percentage reduction in the applied force when the oil film is used is

$\boxed{\text{Percentage of reduction} = 45\%}$.

Question: 10.021P

Consider the flow of a fluid with viscosity μ through a circular pipe. The velocity profile in the pipe is given as $u(r) = u\max(1 - rn/Rn)$, where $u\max$ is the maximum flow velocity, which occurs at the centerline; r is the radial distance from the centerline; and $u(r)$ is the flow velocity at any position r. Develop a relation for the drag force exerted on the pipe wall by the fluid in the flow direction per unit length of the pipe.

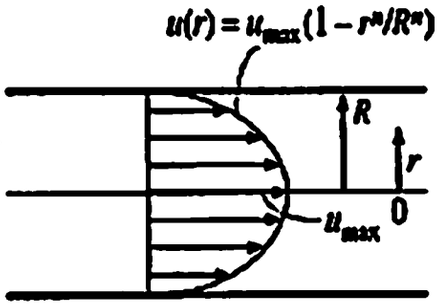


FIGURE P10–21

Step 1 of 2

Velocity profile in the pipe, $u(r) = u_{max}\left(1 - \frac{r^n}{R^n}\right)$

Drag force, $F = \mu A \frac{u}{y}$

μ is the coefficient of viscosity

Area of the profile $A = 2\pi Rl$

Velocity gradient

$$\frac{u}{y} = \frac{du}{dy}$$

$$= -\frac{du}{dr}$$

$$= -\frac{d}{dr}\left[u_{max}\left(1 - \frac{r^n}{R^n}\right)\right]$$

$$= -u_{max}\left(\frac{-nr^{n-1}}{R^n}\right)_{r=R}$$

$$= \frac{u_{max} n}{R}$$

Step 2 of 2

So drag force becomes;

$$F = \mu(2\pi RL)\left(\frac{u_{max} n}{R}\right)$$

$$= 2\pi n u_{max} \mu L$$

$$\frac{F}{L} = 2\pi n u_{max} \mu$$

Therefore drag force per unit length is $\boxed{2\pi n u_{max} \mu}$

Question: 10.022P

A thin 40-cm × 40-cm flat plate is pulled at 2 m/s horizontally through a 3.6-mm-thick oil layer sandwiched between two plates, one stationary and the other moving at a constant velocity of 0.3 m/s, as shown in Fig. P10–22. The dynamic viscosity of oil is 0.027 Pa·s. Assuming the velocity in each oil layer to vary linearly, (*a*) plot the velocity profile and find the location where the oil velocity is zero and (*b*) determine the force that needs to be applied on the plate to maintain this motion.

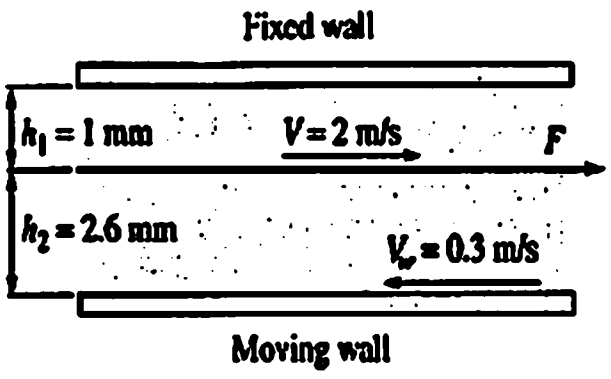

FIGURE P10–22

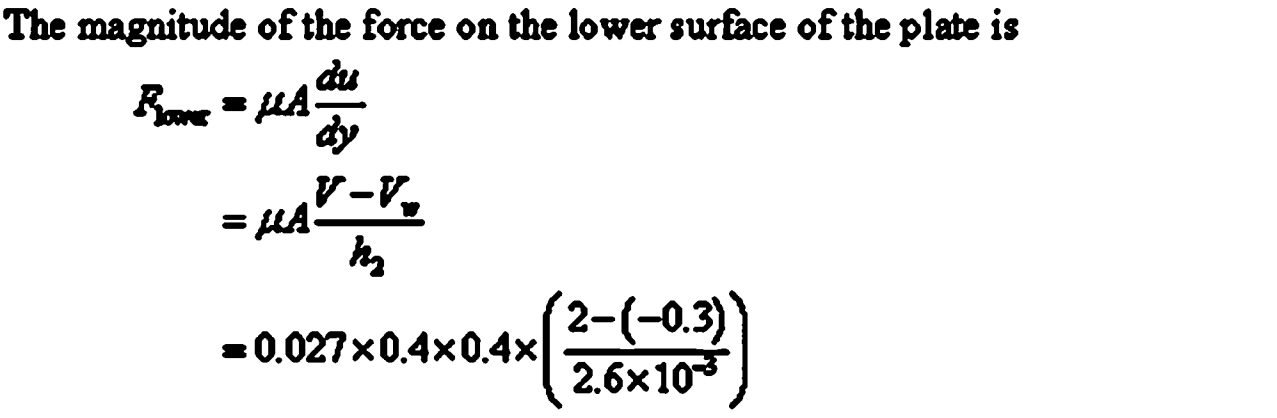
Step 1 of 5

Given data:

Dimensions of the thin flat plate, 40 cm ×40 cm

The velocity of the thin plate, $V = 2\,m/s$



Thickness of the oil layer, 3.6 mm

Dynamic viscosity of oil, $\mu = 0.027\,N.s/m^2$

Velocity of the moving plate, $V_w = 0.3\,m/s$

Step 2 of 5

a) Consider a point O at a distance of x from the moving wall where the velocity is zero as shown in figure

Step 3 of 5

By symmetric triangles below the thin plate

$$\frac{2.6-x}{x} = \frac{2}{0.3}$$

$$(2.6-x)\times 0.3 = 2x$$

$$0.78 - 0.3x = 2x$$

$$0.78 = 2.3x$$

$$x = \frac{0.78}{2.3}$$

$$\boxed{x = 0.339 \text{ mm}}$$

Therefore the location where the oil velocity is zero, $x = 0.339$ mm .

Step 4 of 5

(b) The magnitude of the force on the upper surface of the plate

$$F_{upper} = \mu A \frac{du}{dy}$$

$$= \mu A \left(\frac{V-0}{h_1}\right)$$

$$= 0.027\times 0.4\times 0.4\times \left(\frac{2}{1\times 10^{-3}}\right)$$

$$F_{upper} = 8.64\text{ N}$$

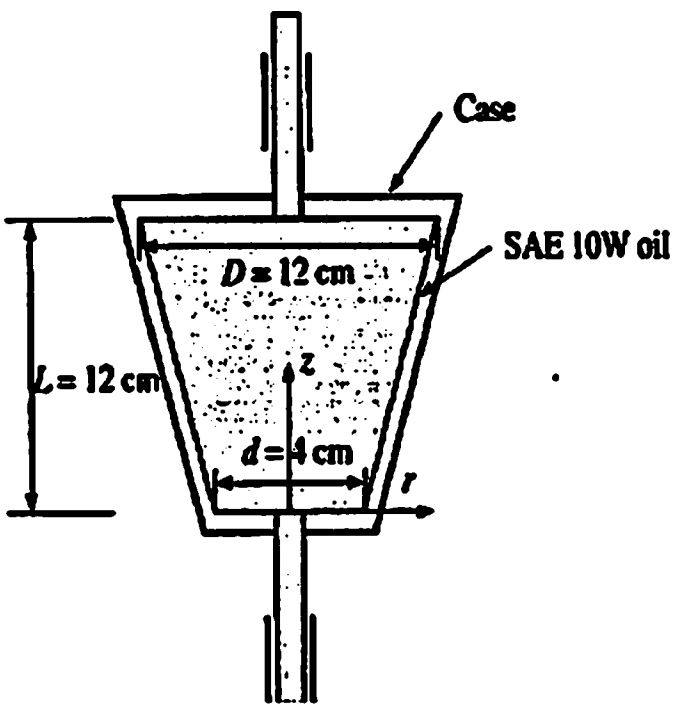
Therefore force on the upper surface of the plate, $\boxed{F_{upper} = 8.64\text{ N}}$.

Step 5 of 5

The magnitude of the force on the lower surface of the plate is

$$F_{lower} = \mu A \frac{du}{dy}$$

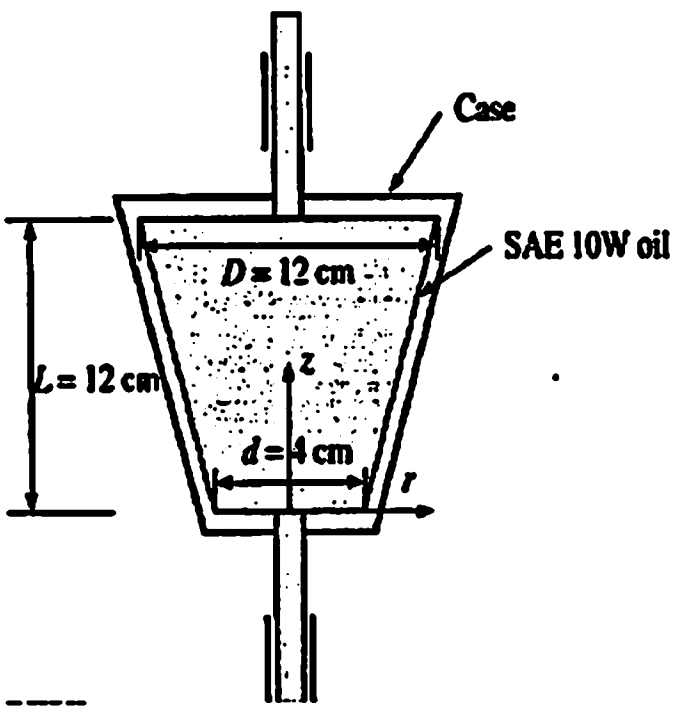
$$= \mu A \frac{V - V_w}{h_2}$$



$$= 0.027\times 0.4\times 0.4\times \left(\frac{2-(-0.3)}{2.6\times 10^{-3}}\right)$$

$$F_{lower} = 3.82\text{ N}$$

Therefore force on the lower surface of the plate, $\boxed{F_{lower} = 3.82\text{ N}}$



Question: 10.023P pg 1

A frustum-shaped body is rotating at a constant angular speed of 200 rad/s in a container filled with SAE 10W oil at 20°C ($\mu = 0.1$ Pa·s), as shown in Fig. P10–23. If the thickness of the oil film on all sides is 1.2 mm, determine the power required to maintain this motion. Also determine the reduction in the required power input when the oil temperature rises to 80°C ($\mu = 0.0078$ Pa·s).

Question:

A frustum-shaped body is rotating at a constant angular speed of 200 rad/s in a container filled with SAE 10W oil at 20°C ($\mu = 0.1$ Pa·s), as shown in Fig. P10–23. If the thickness of the oil film on all sides is 1.2 mm, determine the power required to maintain this motion. Also determine the reduction in the required power input when the oil temperature rises to 80°C ($\mu = 0.0078$ Pa·s).

$$\tau = \mu\frac{du}{dr}$$
$$= \mu\frac{V}{h}$$
$$= \mu\frac{\omega r}{h} \qquad \ldots\ldots (1)$$

Step 3 of 10

The shear force acting on the surface is
$F = \tau A$
Consider an area dA on which the shear force acts.
Then expression can be written as
$dF = \tau dA \qquad \ldots\ldots (2)$
Substituting equation (1) in equation (2), we get
$$dF = \mu\frac{\omega r}{h}dA$$
Using relation,
The torque is given by
$T = FR$
For a radius $R = r$ and force dF, the torque generated is
$dT = (dF)(r) \qquad \ldots\ldots (3)$
Substitute the dF in equation (3), we get
$$dT = \left(\mu\frac{\omega r}{h}dA\right)(r)$$
$$= \mu\frac{\omega r^2}{h}dA$$

Step 4 of 10

We have for power,
$P = T\omega \qquad \ldots\ldots (4)$
Where
Where
$$T = \int dT$$
$$= \int \mu\frac{\omega r^2}{h}dA$$
Substituting T in equation (4), we get
$$P = \left(\int \mu\frac{\omega r^2}{h}dA\right)\omega$$
$$= \int \mu\frac{\omega^2 r^2}{h}dA$$
$$= \mu\frac{(\omega r)^2}{h}\int dA$$

Step 5 of 10

Consider the side surface of the frustum shaped body.

We can express the power as
$$P_{side} = \mu\frac{(\omega r)^2}{h}\int dA \qquad \ldots\ldots (5)$$
Where
$dA = (2\pi r)dz$
The mean radius for the body can be expressed as
$$r = \frac{d}{2} + \frac{D-d}{2}$$

$$P_{side} = \mu\frac{(\omega r)^2}{h}\int dA \qquad \ldots\ldots (5)$$

Where

$$dA = (2\pi r)dz$$

The mean radius for the body can be expressed as

$$r = \frac{d}{2} + \frac{D-d}{2L}$$

Differentiating r with respect to z

$$dr = \frac{D-d}{2L}dz$$

$$dz = \frac{2L}{D-d}dr$$

Step 6 of 10

Substituting dz in dA, we get

$$dA = 2\pi r(dz)$$

$$= 2\pi r\left(\frac{2L}{D-d}dr\right)$$

$$= (rdr)\left(\frac{4L\pi}{D-d}\right)$$

Substituting r and dA in equation (5), we get

$$P_{side} = \mu\frac{(\omega r)^2}{h}\int dA$$

The top radius is $D/2$ and the bottom radius is $d/2$.

$$P_{side} = \mu\frac{(\omega r)^2}{h}\int_{d/2}^{D/2} dA$$

$$= \mu\frac{(\omega r)^2}{h}\int_{d/2}^{D/2}(rdr)\left(\frac{4L\pi}{D-d}\right)$$

$$= \frac{\mu\omega^2}{h}\left(\frac{4L\pi}{D-d}\right)\int_{d/2}^{D/2} r^3 dr$$

Step 7 of 10

Applying the limits to integration, we get

$$P_{side} = \frac{\mu\omega^2}{h}\left(\frac{4L\pi}{D-d}\right)\left(\frac{r^4}{4}\right)_{d/2}^{D/2}$$

$$= \frac{\mu\omega^2\pi L}{h(D-d)}\left(\frac{D^4-d^4}{16}\right)$$

Consider the top surface.
We can express the power as

$$P_{top} = \mu\frac{(\omega r)^2}{h}\int dA \qquad \ldots\ldots (6)$$

Where the area

$$dA = (2\pi r)dr$$

Substituting dA in equation (6), we get

$$P_{top} = \mu\frac{(\omega r)^2}{h}\int 2\pi r dr$$

The top radius is $D/2$ and the bottom radius is 0.

$$P_{top} = \mu\frac{(\omega r)^2}{h}\int_0^{D/2} 2\pi r dr$$

$$= \mu\frac{2\pi\omega^2}{h}\left(\frac{r^4}{4}\right)_0^{D/2}$$

$$= \mu\frac{\pi\omega^2 D^4}{32h}$$

Step 8 of 10

Consider the bottom surface.
We can express the power as

$$P_{bottom} = \mu\frac{(\omega r)^2}{h}\int dA \qquad \ldots\ldots (7)$$

Where the area

$$dA = (2\pi r)dr$$

Substituting dA in equation (7), we get

$$P_{top} = \mu\frac{(\omega r)^2}{h}\int 2\pi r dr$$

The top radius is $d/2$ and the bottom radius is 0.

$$P_{top} = \mu\frac{(\omega r)^2}{h}\int_0^{d/2} 2\pi r dr$$

$$= \mu\frac{2\pi\omega^2}{h}\left(\frac{r^4}{4}\right)_0^{d/2}$$

$$= \mu\frac{\pi\omega^2 d^4}{32h}$$

Step 9 of 10

The total power required to maintain the motion is

$$P_{total} = P_{side} + P_{top} + P_{bottom}$$

$$= \left[\frac{\mu\omega^2\pi L}{h(D-d)}\left(\frac{D^4-d^4}{16}\right)\right] + \left[\mu\frac{\pi\omega^2 D^4}{32h}\right] + \left[\mu\frac{\pi\omega^2 d^4}{32h}\right]$$

$$= \frac{\mu\omega^2\pi}{16h}\left[L\frac{(D^4-d^4)}{D-d} + \left(\frac{D^4+d^4}{2}\right)\right]$$

Substituting the given values in P_{total}, we get

$$P_{total} = \frac{(0.1)(200)^2\pi}{16(0.0012)}\left[(0.12)\frac{(0.12^4-0.04^4)}{0.12-0.04} + \left(\frac{0.12^4+0.04^4}{2}\right)\right]$$

$$= 269.75\ \text{W}$$

The power required to maintain the motion at 20°C is

$$\boxed{(P_{total})_{20} = 269.75\ \text{W}}$$

$= 269.75\ \text{W}$

The power required to maintain the motion at 20°C is

$$\boxed{(P_{\text{total}})_{20} = 269.75\ \text{W}}$$

Step 10 of 10

The power required to maintain the motion when $\mu = 0.0078\ \text{Pa}\cdot s$ and the temperature 80°C can be expressed as

The power associated is directly proportional to the viscosity of the fluid.

$$\frac{(P_{\text{total}})_{20}}{(P_{\text{total}})_{80}} = \frac{\mu_{20}}{\mu_{80}}$$

$$\frac{(P_{\text{total}})_{20}}{(P_{\text{total}})_{80}} = \frac{0.1}{0.0078}$$

$$\frac{(P_{\text{total}})_{80}}{269.75} = \frac{0.0078}{0.1}$$

$$(P_{\text{total}})_{80} = \frac{0.0078}{0.1}(269.75)$$

$$= 21.04\ \text{W}$$

The reduction in the required power input when the oil temperature is 80°C

$$\boxed{(P_{\text{total}})_{80} = 21.04\ \text{W}}.$$

Question: 10.024P

The clutch system shown in Fig. P10–24 is used to transmit torque through a 2-mm-thick oil film with μ = 0.38 N·s/m2 between two identical 30-cm-diameter disks. When the driving shaft rotates at a speed of 1450 rpm, the driven shaft is observed to rotate at 1398 rpm. Assuming a linear velocity profile for the oil film, determine the transmitted torque.

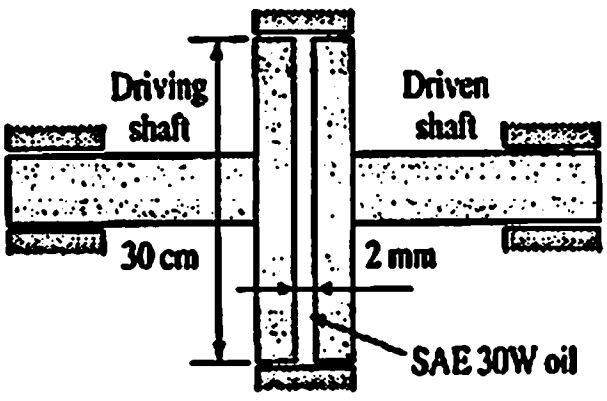


FIGURE P10–24

Step 1 of 4

Given data:

Oil film thickness, $h = 2\text{mm} = 0.002\text{m}$

The absolute viscosity of SAE30 oil is $\mu = 0.38\text{N.s/m}^2$

The Speed of the driving shaft, $n_1 = 1450\text{rpm}$

The Speed of the driven shaft, $n_2 = 1398\text{rpm}$

The diameter of a clutch $D = 30\text{cm} = 0.3\text{m}$

Step 2 of 4

Assume that one of the plate is stationary, linear velocity of other plate $V = (\omega_1 - \omega_2)r$

Consider a small area dA on the surface of the disc.

Then the shear force on the disc is on the area dA is $dF = \mu(dA)\dfrac{V}{h}$

Here $dA = (2\pi r)dr$

Now

$$dF = \mu(dA)\frac{V}{h}$$

$$= \mu(2\pi r)\frac{(\omega_1 - \omega_2)r}{h}dr$$

Now the torque on the small area dA is $dT = (dF)r$

Now $dT = \mu(2\pi)\dfrac{(\omega_1 - \omega_2)r^3}{h}dr$

Step 3 of 4

By integrating the dT we get torque on the disc

$$T = \int_{r=0}^{D/2} dT$$

$$= \int_{r=0}^{D/2} \mu 2\pi \frac{(\omega_1 - \omega_2)r^3}{h}dr$$

$$= \mu 2\pi \frac{(\omega_1 - \omega_2)}{h}\int_0^{D/2} r^3 dr$$

$$= \mu 2\pi \frac{(\omega_1 - \omega_2)}{h}\left(\frac{r^4}{4}\right)_0^{D/2}$$

$$T = \frac{\pi\mu(\omega_1 - \omega_2)D^4}{32h}$$

Step 4 of 4

Calculating:

$$\omega_1 - \omega_2 = 2\pi(n_1 - n_2)$$

$$= 2\pi(1450 - 1398)\frac{1}{60}$$

$$= 5.445\text{rad/s}$$

Also absolute viscosity of SAE30 oil is $0.38\text{N}\cdot\text{s/m}^2$

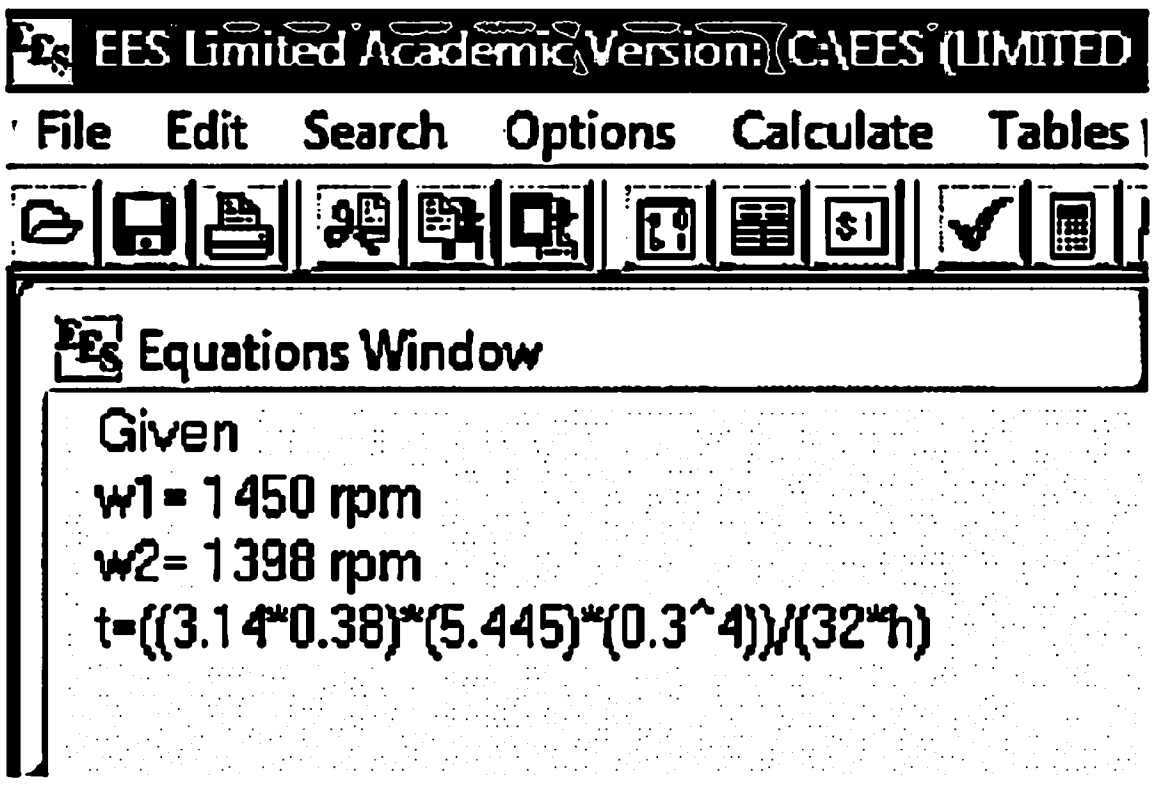
By substituting the values we get

$$T = \frac{\pi\mu(\omega_1 - \omega_2)D^4}{32h}$$

$$= \frac{0.38\pi \times 5.445 \times (0.3)^4}{32 \times 0.002}$$

$$= 0.823\text{N}\cdot\text{m}$$

Therefore transmitted torque is $\boxed{T = 0.823\text{N}\cdot\text{m}}$



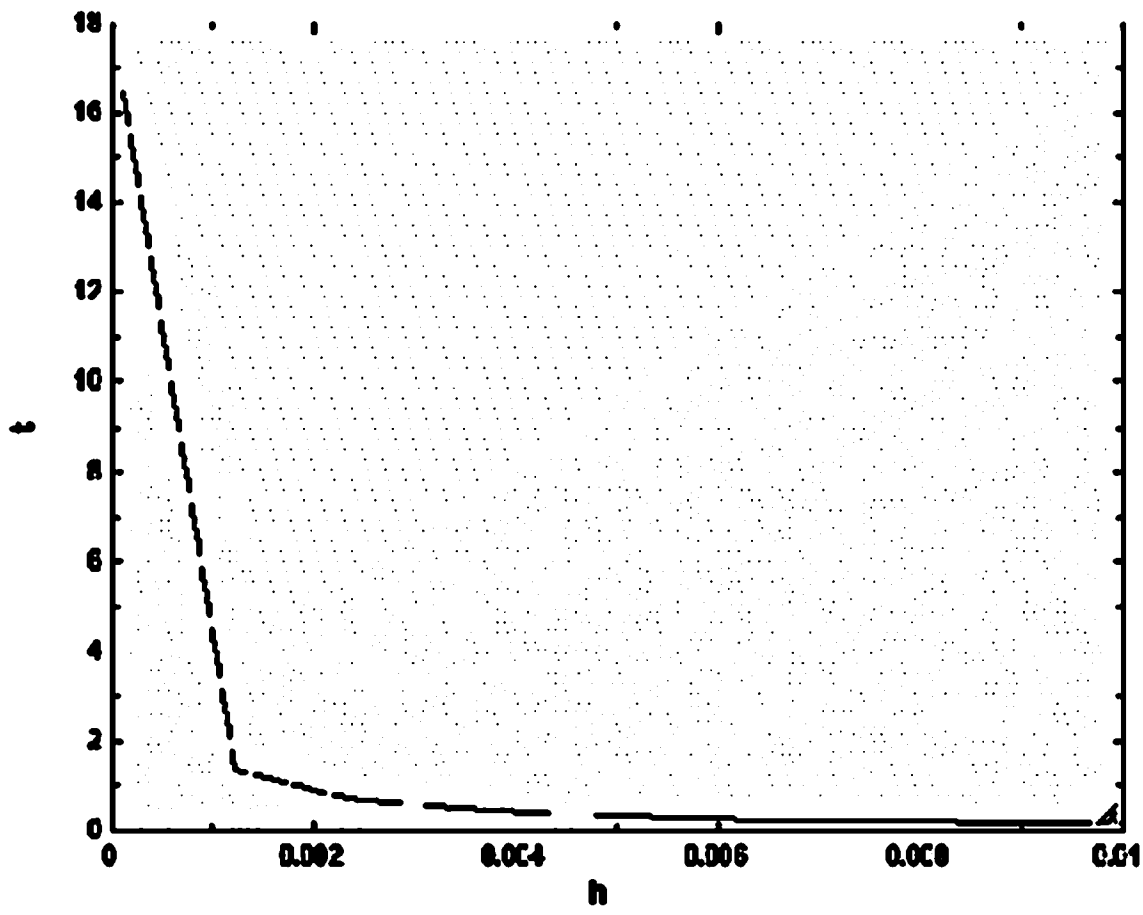
Question: 10.025P

Reconsider Prob. 10–24. Using EES (or other) software, investigate the effect of oil film thickness on the torque transmitted. Let the film thickness vary from 0.1 mm to 10 mm. Plot your results, and state your conclusions.

Step 1 of 3

The equation used is $T = \frac{\pi\mu(\omega_1 - \omega_2)D^4}{32h}$

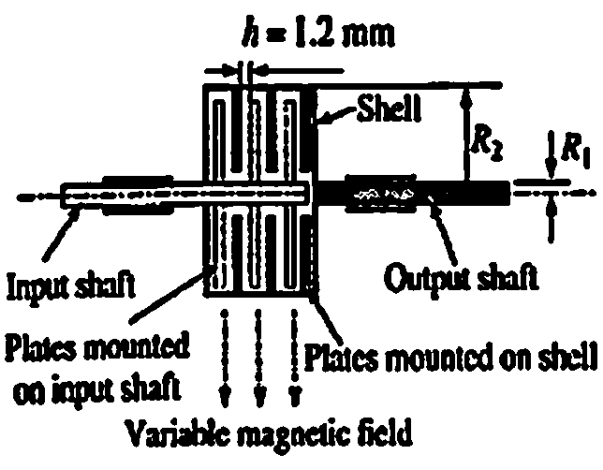
By Using the EES software, we have to write the above equation in new window.



Step 2 of 3

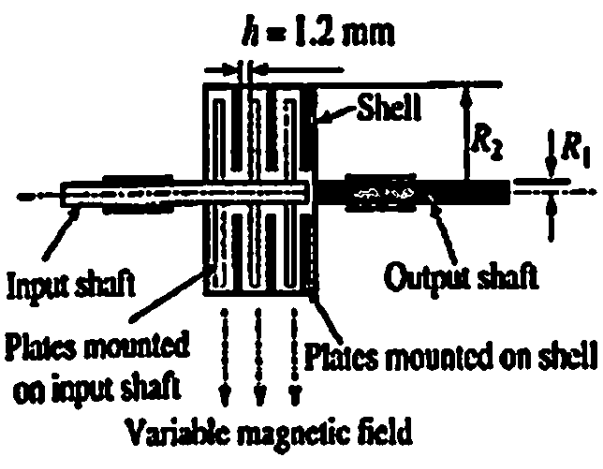
After writing the equations in the Equation window then click on table in menu bar. Then select new parameter table. Then varying the h value from 0.0001 to 0.01m we get

1..10	h	t
Run 1	0.0001	16.45
Run 2	0.0012	1.37
Run 3	0.0023	0.715
Run 4	0.0034	0.4837
Run 5	0.0045	0.3655
Run 6	0.0056	0.2937
Run 7	0.0067	0.2455
Run 8	0.0078	0.2108
Run 9	0.0089	0.1848
Run 10	0.01	0.1645



Step 3 of 3

By plotting the graph between torque Vs thickness of oil film:



Question: 10.026P

The viscosity of some fluids changes when a strong electric field is applied on them. This phenomenon is known as the electrorheological (ER) effect, and fluids that exhibit such behavior are known as ER fluids. The Bingham plastic model for shear stress, which is expressed as $\tau = \tau_y + \mu(du/dy)$ is widely used to describe ER fluid behavior because of its simplicity. One of the most promising applications of ER fluids is the ER clutch. A typical multidisk ER clutch consists of several equally spaced steel disks of inner radius $R1$ and outer radius $R2$, N of them attached to the input shaft. The gap h between the parallel disks is filled with a viscous fluid. (*a*) Find a relationship for the torque generated by the clutch when the output shaft is stationary and (*b*) calculate the torque for an ER clutch with $N = 11$ for $R1 = 50$ mm, $R2 = 200$ mm, and $\dot{n} = 2400$ rpm if the fluid is SAE 10 with $\mu = 0.1$ Pa•s, $\tau_y = 2.5$ kPa, and $h = 1.2$ mm.

Question:

The viscosity of some fluids changes when a strong electric field is applied on them. This phenomenon is known as the electrorheological (ER) effect, and fluids that exhibit such behavior are known as ER fluids. The Bingham plastic model for shear stress, which is expressed as $\tau = \tau_y + \mu(du/dy)$ is widely used to describe ER fluid behavior because of its simplicity. One of the most promising applications of ER fluids is the ER clutch. A typical multidisk ER clutch consists of several equally spaced steel disks of inner radius $R1$ and outer radius $R2$, N of them attached to the input shaft. The gap h between the parallel disks is filled with a viscous fluid. (*a*) Find a relationship for the torque generated by the clutch when the output shaft is stationary and (*b*) calculate the torque for an ER clutch with $N = 11$ for $R1 = 50$ mm, $R2 = 200$ mm, and $\dot{n} = 2400$ rpm if the fluid is SAE 10 with $\mu = 0.1$ Pa•s, $\tau_y = 2.5$ kPa, and $h = 1.2$ mm.

We have,

$$\tau = \tau_y + \mu\left(\frac{du}{dy}\right)$$

$$= \tau_y + \mu\left(\frac{V}{h}\right) \qquad \ldots\ldots (1)$$

Where,
The velocity of the input shaft is
$V = r\omega$
Substituting V in equation (1), we get

$$\tau = \tau_y + \mu\left(\frac{r\omega}{h}\right)$$

Step 3 of 6

Consider an area dA on the plate surface.
Then the force can be written as
$dF = \tau dA$
Substituting τ in dF, we get

$$dF = \left[\tau_y + \mu\left(\frac{r\omega}{h}\right)\right](2\pi r\,dr)$$

The torque generated can write as
$dT = r\,dF$
Integrating on both sides
$\int dT = \int r\,dF$
Substituting dF in dT, we get
We have,

$$\tau = \tau_y + \mu\left(\frac{du}{dy}\right)$$

$$= \tau_y + \mu\left(\frac{V}{h}\right) \qquad \ldots\ldots (1)$$

Where,
The velocity of the input shaft is
$V = r\omega$
Substituting V in equation (1), we get

$$\tau = \tau_y + \mu\left(\frac{r\omega}{h}\right)$$

Step 3 of 6

Consider an area dA on the plate surface.
Then the force can be written as
$dF = \tau dA$
Substituting τ in dF, we get

$$dF = \left[\tau_y + \mu\left(\frac{r\omega}{h}\right)\right](2\pi r\,dr)$$

The torque generated can write as
$dT = r\,dF$
Integrating on both sides
$\int dT = \int r\,dF$
Substituting dF in dT, we get

$$\int dT = \int_{R_1}^{R_2} r\left[\tau_y + \mu\left(\frac{\omega r}{h}\right)\right](2\pi r\,dr)$$

$$= 2\pi\left(\tau_y \int_{R_1}^{R_2} r^2\,dr + \frac{\mu\omega}{h}\int_{R_1}^{R_2} r^3\,dr\right)$$

Step 4 of 6

Applying limits of integration, we get
The torque generated by a single surface of the plate

$$T = 2\pi\left[\frac{\tau_y}{3}\left(R_2^3 - R_1^3\right) + \frac{\mu\omega}{4h}\left(R_2^4 - R_1^4\right)\right]$$

The torque generated by both surfaces of the plate

$$T = 2\left\{2\pi\left[\frac{\tau_y}{3}\left(R_2^3 - R_1^3\right) + \frac{\mu\omega}{4h}\left(R_2^4 - R_1^4\right)\right]\right\}$$

$$= 4\pi\left[\frac{\tau_y}{3}\left(R_2^3 - R_1^3\right) + \frac{\mu\omega}{4h}\left(R_2^4 - R_1^4\right)\right]$$

For N number of clutch plates, the torque generated is

$$T = 4\pi N\left[\frac{\tau_y}{3}\left(R_2^3 - R_1^3\right) + \frac{\mu\omega}{4h}\left(R_2^4 - R_1^4\right)\right]$$

The torque generated by the clutch when the output shaft is stationary is

$$\boxed{T = 4\pi N\left[\frac{\tau_y}{3}\left(R_2^3 - R_1^3\right) + \frac{\mu\omega}{4h}\left(R_2^4 - R_1^4\right)\right]}$$

Step 5 of 6

(b)
Given data:
The number of clutch plates, $N = 11$
The inner radius of clutch plate, $R_1 = 50$ mm.
The outer radius of clutch plate, $R_2 = 200$ mm.
The speed of the input shaft is, $\dot{n} = 2400$ rpm.
The viscosity of fluid *SAE* 10, $\mu = 0.1\ \text{Pa}\cdot\text{s}$

$$= 4\pi(11)\left[\frac{(2.5\times 10^{3})}{3}\left(0.2^3 - 0.05^3\right) + \frac{(0.1)(251.32)}{4(0.0012)}\left(0.2^4 - 0.05^4\right)\right]$$

$$= 4\pi(11)[6.5625 + 8.3446]$$

$$= 2060.61\ \text{N}\cdot\text{m}$$

The torque for an ER clutch is $\boxed{T = 2060.61\ \text{N}\cdot\text{m}}$

Question: 10.027P

The viscosity of some fluids, called magnetorheological (MR) fluids, changes when a magnetic field is applied. Such fluids involve micron-sized magnetizable particles suspended in an appropriate carrier liquid, and are suitable for use in controllable hydraulic clutches. See Fig. P10–26. The MR fluids can have much higher viscosities than the ER fluids, and they often exhibit shear-thinning behavior in which the viscosity of the fluid decreases as the applied shear force increases. This behavior is also known as pseudoplastic behavior, and can be successfully represented by Herschel-Bulkley constitutive model expressed as $\tau = \tau y + K(du/dy)m$. Here τ is the shear stress applied, τv is the yield stress, K is the consistency index, and m is the power index. For a Herschel-Bulkley fluid with τy = 900 Pa, K = 58 Pa·sm, and m = 0.82, (*a*) find a relationship for the torque transmitted by an MR clutch for N plates attached to the input shaft when the input shaft is rotating at an angular speed of ω while the output shaft is stationary and (*b*) calculate the torque transmitted by such a clutch with N = 11 plates for $R1$ = 50 mm, $R2$ = 200 mm, $\dot{n} = 3000$ rpm, and h = 1.5 mm.

Step 1 of 8

Given data:

The fluid used in the clutches is MR fluid.

The yield stress, $\tau_y = 900\,\text{Pa}$

The consistency index, $K = 58\,\text{Pa}\cdot s^m$

The power index, $m = 0.82$

The shear stress used for The Herschel-Bulkley constitutive model is

$$\tau = \tau_y + K\left(\frac{du}{dy}\right)^m$$

Step 2 of 8

(a)

The number of clutch plates attached to input shaft are N.

The angular speed of the input shaft is ω.

The output shaft is stationary.

We know that velocity gradient

$$\frac{V}{l} = \frac{du}{dy}$$

Here, The fluid thickness $l = h$

$$\frac{V}{h} = \frac{du}{dy}$$

Step 3 of 8

We have,

$$\tau = \tau_y + \mu\left(\frac{du}{dy}\right)^m$$

$$= \tau_y + \mu\left(\frac{V}{h}\right)^{0.82} \qquad \ldots\ldots (1)$$

Where,

The velocity of the input shaft is

$V = r\omega$

Substituting V in equation (1), we get

$$\tau = \tau_y + \mu\left(\frac{r\omega}{h}\right)^{0.82}$$

Step 4 of 8

Consider an area dA on the plate surface.

Then the force can be written as

$dF = \tau dA$

Substituting τ in dF, we get

$$dF = \left[\tau_y + \mu\left(\frac{r\omega}{h}\right)^{0.82}\right](2\pi r dr)$$

The torque generated can write as

$dT = rdF$

Integrating on both sides

$\int dT = \int rdF$

Substituting dF in dT, we get

$$\int dT = \int rdF$$

$$= \int_{R_1}^{R_2} r\left[\tau_y + K(\omega r/h)^{0.82}\right](2\pi r dr)$$

$$= 2\pi\left[\tau_y \int_{R_1}^{R_2} r^2 dr + K\left(\frac{\omega}{h}\right)^{0.82} \int_{R_1}^{R_2} r^{2.82} dr\right]$$

Step 5 of 8

Applying limits of integration, we get

The torque generated by a single surface of the plate

$$T = 2\pi\left[\tau_y\left(\frac{1}{3}\right)\left(R_2^3 - R_1^3\right) + K\left(\frac{\omega}{h}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(R_2^{3.82} - R_1^{3.82}\right)\right]$$

The torque generated by both surfaces of the plate

$$T = (2)\left\{2\pi\left[\tau_y\left(\frac{1}{3}\right)\left(R_2^3 - R_1^3\right) + K\left(\frac{\omega}{h}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(R_2^{3.82} - R_1^{3.82}\right)\right]\right\}$$

$$= 4\pi\left[\tau_y\left(\frac{1}{3}\right)\left(R_2^3 - R_1^3\right) + K\left(\frac{\omega}{h}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(R_2^{3.82} - R_1^{3.82}\right)\right]$$

For N number of clutch plates, the torque generated is

$$T = (N)\left\{4\pi\left[\tau_y\left(\frac{1}{3}\right)\left(R_2^3 - R_1^3\right) + K\left(\frac{\omega}{h}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(R_2^{3.82} - R_1^{3.82}\right)\right]\right\}$$

$$= 4\pi N\left[\tau_y\left(\frac{1}{3}\right)\left(R_2^3 - R_1^3\right) + K\left(\frac{\omega}{h}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(R_2^{3.82} - R_1^{3.82}\right)\right]$$

The torque generated by the MR clutch when the output shaft is stationary is

$$\boxed{T = 4\pi N\left[\tau_y\left(\frac{1}{3}\right)\left(R_2^3 - R_1^3\right) + K\left(\frac{\omega}{h}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(R_2^{3.82} - R_1^{3.82}\right)\right]}$$

Step 6 of 8

(b)

Given data:

The number of clutch plates, $N = 11$

The inner radius of clutch plate, $R_1 = 50$ mm

The outer radius of clutch plate, $R_2 = 200$ mm

The speed of the input shaft is, $\dot{n} = 3000$ rpm.

The fluid thickness, $h = 1.5$ mm

Step 7 of 8

The angular speed of the shaft is

$$\omega = \frac{2\pi\dot{n}}{60}$$

$$= \frac{2\pi(2400)}{60}$$

$$= 251.32\,\text{rad/s}$$

Step 8 of 8

The torque for an MR clutch is given by

$$T = 4\pi N\left[\tau_y\left(\frac{1}{3}\right)\left(R_2^3 - R_1^3\right) + K\left(\frac{\omega}{h}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(R_2^{3.82} - R_1^{3.82}\right)\right]$$

$$= 4\pi(11)\left[(900)\left(\frac{1}{3}\right)\left(0.2^3 - 0.05^3\right) + (58)\left(\frac{314.15}{0.0015}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(0.2^{3.82} - 0.05^{3.82}\right)\right]$$

$$= 4\pi(11)\left[(900)\left(\frac{1}{3}\right)\left(0.2^3 - 0.05^3\right) + (58)\left(\frac{314.15}{0.0015}\right)^{0.82}\left(\frac{1}{3.82}\right)\left(0.2^{3.82} - 0.05^{3.82}\right)\right]$$

$$= 4\pi(11)[2.3625 + 745.373]$$

$T = 103359.53\,\text{N}\cdot\text{m}$

Torque transmitted by the clutch is $\boxed{T = 103359.53\,\text{N}\cdot\text{m}}$

Question: 10.028P

The viscosity of a fluid is to be measured by a viscometer constructed of two 75-cm-long concentric cylinders. The outer diameter of the inner cylinder is 15 cm, and the gap between the two cylinders is 1 mm. The inner cylinder is rotated at 300 rpm, and the torque is measured to be 0.8 N·m. Determine the viscosity of the fluid.

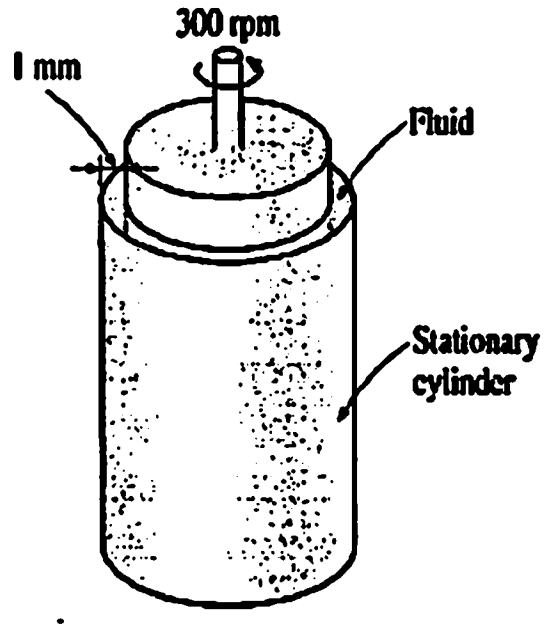


FIGURE P10–28

Step 1 of 3

Given data:

Length of cylinders, $L = 75\text{ cm} = 0.75\text{ m}$

Outer diameter of the inner cylinder, $d = 15\text{ cm} = 0.15\text{ m}$

Therefore the radius, $r = 0.075\text{ m}$

Gap between the cylinders, $dy = 1\text{ mm} = 10^{-3}\text{m}$

Speed of the inner cylinder, $N = 300\text{ rpm}$

Torque, $T = 0.8\text{ N}\cdot\text{m}$

Step 2 of 3

Area is given by

$$A = \pi dL$$
$$= \pi \times 0.15 \times 0.75$$
$$= 0.35325\text{ m}^2$$

Velocity is given by

$$u = \frac{\pi dN}{60}$$
$$= \frac{\pi \times 0.15\text{ m} \times 300\text{ rpm}}{60}$$
$$= 2.356\text{ m/s}$$

Step 3 of 3

Force acting is given by

$$F = \frac{T}{r}$$
$$= \frac{0.8\text{ N}\cdot\text{m}}{0.075\text{ m}}$$
$$= 10.66\text{ N}$$

We know that

$$F = \mu A \frac{du}{dy}$$

$$(10.66\text{ N}) = \frac{\mu \times (0.35325\text{ m}^2) \times (2.356\text{ m/s})}{(10^{-3}\text{ m})}$$

$$\mu = 0.0128\text{kg/m}\cdot\text{s}$$

Therefore the Viscosity of the fluid is $\boxed{\mu = 0.0128\text{kg/m}\cdot\text{s}}$

Question: 10.029P

The viscosity of a fluid is to be measured by a viscometer constructed of two 3-ft-long concentric cylinders. The inner diameter of the outer cylinder is 6 in, and the gap between the two cylinders is 0.05 in. The outer cylinder is rotated at 250 rpm, and the torque is measured to be 1.2 lbf-ft. Determine the viscosity of the fluid.

Step 1 of 3

Given data:

Length of cylinders, $L = 3\,\text{ft}$

Outer diameter of the inner cylinder, $d = 6\text{ in} = 0.5\,\text{ft}$

Therefore the radius, $r = 0.25\,\text{ft}$

Gap between the cylinders, $dy = 0.05\text{in} = 0.00416\,\text{ft}$

Speed of the inner cylinder, $N = 300\,\text{rpm}$

Torque, $T = 1.2\,\text{lbf}\cdot\text{ft}$

Step 2 of 3

Area is given by

$$A = \pi dL$$
$$= \pi \times 0.5 \times 3$$
$$= 4.71\,\text{ft}^2$$

Velocity is given by

$$u = \frac{\pi dN}{60}$$
$$= \frac{\pi \times 0.5 \times 250}{60}$$
$$= 6.54\,\text{ft/s}$$

Step 3 of 3

Force acting is given by

$$F = \frac{T}{r}$$
$$= \frac{1.2}{0.25}$$
$$= 4.8\,\text{lbf}$$

We know that

$$F = \mu A \frac{du}{dy}$$
$$4.8 = \frac{\mu \times 4.71 \times 6.54}{0.00416}$$
$$\mu = 0.000648\,\text{lb}\cdot\text{s/ft}$$

Therefore the Viscosity of the fluid is $\boxed{\mu = 0.000648\,\text{lb}\cdot\text{s/ft}}$

Question: 10.030P

In regions far from the entrance, fluid flow through a circular pipe is one-dimensional, and the velocity profile for laminar flow is given by$u(r)$= $u$max(1 −$r2/R2$), where$R$ is the radius of the pipe, r is the radial distance from the center of the pipe, and$u$max is the maximum flow velocity, which occurs at the center. Obtain (*a*) a relation for the drag force applied by the fluid on a section of the pipe of length$L$ and (*b*) the value of the drag force for water flow at 20°C with R = 0.08 m, L = 30 m, $u$max = 3 m/s, and μ = 0.0010 kg/m·s.

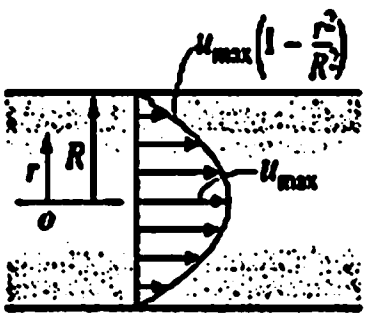

FIGURE P10–30

Step 1 of 5

Given data:

Velocity profile in the pipe, $u(r)=u_{max}\left(1-\frac{r^2}{R^2}\right)$

Step 2 of 5

(a)

We know that

Drag force, $F=\mu A\frac{u}{y}$

Where

The area $A=2\pi Rl$

And

$$\frac{u}{y}=\frac{du}{dy}$$
$$=-\frac{du}{dr}$$
$$=-\frac{d}{dr}\left[u_{max}\left(1-\frac{r^2}{R^2}\right)\right]$$
$$=-u_{max}\left(\frac{-2r^{2-1}}{R^2}\right)_{r=R}$$
$$=\frac{2u_{max}}{R}$$

Step 3 of 5

So drag force becomes;

$$F=\mu(2\pi RL)\left(\frac{2u_{max}}{R}\right)$$
$$=4\pi u_{max}\mu L$$

$$\boxed{F=4\pi u_{max}\mu L}$$

Therefore drag force per unit length is $F=4\pi u_{max}\mu L$

Step 4 of 5

(b) Given data:

The radius of the pipe $R=0.08\,\mathrm{m}$

The length of the pipe $L=30\,\mathrm{m}$

The maximum flow velocity $u_{max}=3\,\mathrm{m/s}$

The dynamic viscosity of fluid $\mu=0.0010\,\mathrm{kg/m\cdot s}$

Step 5 of 5

By substituting the given values:

$$F=4\pi u_{max}\mu L$$
$$=4\pi\times3\times0.001\times30$$
$$=1.131\,\mathrm{N}$$

$$\boxed{F=1.131\,\mathrm{N}}$$

Therefore the value of drag force is $1.131\,\mathrm{N}$

Question: 10.031P

Repeat Prob. 10–30 for *u*max = 7 m/s.

Step 1 of 5

Given data:

Velocity profile in the pipe, $u(r) = u_{max}\left(1-\frac{r^2}{R^2}\right)$

Step 2 of 5

(a)
We know that

Drag force, $F = \mu A\frac{u}{y}$

Where
The area $A = 2\pi Rl$
And

$$\frac{u}{y} = \frac{du}{dy}$$
$$= -\frac{du}{dr}$$
$$= -\frac{d}{dr}\left[u_{max}\left(1-\frac{r^2}{R^2}\right)\right]$$
$$= -u_{max}\left(\frac{-2r^{2-1}}{R^2}\right)_{r=R}$$
$$= \frac{2u_{max}}{R}$$

Step 3 of 5

So drag force becomes;

$$F = \mu(2\pi RL)\left(\frac{2u_{max}}{R}\right)$$
$$= 4\pi u_{max}\mu L$$
$$\boxed{F = 4\pi u_{max}\mu L}$$

Therefore drag force per unit length is $F = 4\pi u_{max}\mu L$

Step 4 of 5

(b) Given data:
The radius of the pipe $R = 0.08\text{m}$
The length of the pipe $L = 30\text{m}$
The maximum flow velocity $u_{max} = 7\text{m/s}$
The dynamic viscosity of fluid $\mu = 0.0010\text{kg/m}\cdot\text{s}$

Step 5 of 5

By substituting the given values:

$$F = 4\pi u_{max}\mu L$$
$$= 4\pi\times 7\times 0.001\times 30$$
$$= 2.64\text{N}$$
$$\boxed{F = 2.64\text{N}}$$

Therefore the value of drag force is 2.64N

Question: 10.032P

What is surface tension? What is it caused by? Why is the surface tension also called surface energy?

Step 1 of 1

Surface tension:

Surface tension is a property of a liquid due to unbalanced molecular cohesive forces at or near the surface.

The main reason for surface tension is cohesion of molecules. The pulling force that causes this tension is due to the attractive forces between the molecules. The unit for surface tension is N/m. It is also written as N-m/m^2 i.e. surface energy per unit area. Surface tension is also defined as work done per unit increase in the surface area.

Question: 10.033P

Consider a soap bubble. Is the pressure inside the bubble higher or lower than the pressure outside?

Step 1 of 1

The air trapped inside a soap bubble will add a pressure to the soap film from the inside and the air surrounding the bubble will add a pressure to the soap film from the outside. This means that the soap bubble is acted by pressure from two sides i.e. from inner and outer.

We know that in a closed area, density of air will be larger than the normal surrounding area. The pressure inside the bubble will be larger than the pressure outside the soap bubble. It is represented as:

$$P_i - P_e = \frac{8\sigma}{d}$$

P_i = Pressure inside the bubble

P_e = Pressure outside the bubble

d = Diameter of soap bubble

σ = Surface tension

Question: 10.034P

What is the capillary effect? What is it caused by? How is it affected by the contact angle?

Step 1 of 1

Capillarity is defined as a phenomenon of rise or fall of a liquid surface in a small tube relative to the adjacent general level of liquid when the tube is held vertically in the liquid.

The property of rise or fall of a liquid in capillary (small diameter tube) inserted in the liquid is known as a capillary effect.
The main cause of capillary effect is due to the adhesive forces (The forces between unlike molecules like glass and water). If the adhesive force dominates the cohesive force then there will be a capillary rise.
If the cohesive force dominates the adhesive forces there will be a capillary fall of the liquid.

The strength of capillary effect is quantified by contact angle ϕ defined as the angle that tangent to the liquid surface makes with the solid surface at the point of contact. If $\phi < 90^\circ$ capillary rise will occur and if $\phi > 90^\circ$ capillary fall will occur.

Wet surface and dry surface depends upon the contact angle.

Question: 10.035P

A small-diameter tube is inserted into a liquid whose contact angle is 110°. Will the level of liquid in the tube be higher or lower than the level of the rest of the liquid? Explain.

Step 1 of 2

Capillary effect:

Capillary effect is a rise or fall of a liquid in a small diameter tube when inserted into a liquid.
It is known that the contact angle is 110°.

Step 2 of 2

If the contact angle is more than 90 degrees, the liquid in the tube is lower than the rest of the liquid.

So, $110^{\circ} > 90^{\circ}$

This means that the level of the liquid in the tube will be lower than the level of the rest of the fluid.

If $\phi > 90^{\circ}$, h is negative value due to capillary drop.

Question: 10.036P

Is the capillary rise greater in small- or large-diameter tubes?

Step 1 of 1

The capillary rise h is given by the relation:

$$h = \frac{2\sigma_s}{\rho g R}\cos\phi$$

Where

R: Radius

ϕ : Capillary rising angle

σ_s : Surface tension

ρ : Density

From the above relation it is clear that

$$h \propto \frac{1}{R}$$

$$h \propto \frac{1}{D}$$

Capillary height is inversely proportional to the diameter of tube.

So, capillary rise will be greater in small diameter tubes and lesser in large diameter tubes.

Question: 10.037P

Consider a 0.2-mm diameter air bubble in a liquid. Determine the pressure difference between the inside and outside of the air bubble if the surface tension at the air-liquid interface is (*a*) 0.08 N/m and (*b*) 0.12 N/m.

Step 1 of 3

Given data:

Diameter of the air bubble, $D = 0.2\,\text{mm}$

$= 0.2\times10^{-3}\,\text{m}$

So the radius of the air bubble, $R = 0.1\times10^{-3}\,\text{m}$

Step 2 of 3

(a)

Surface Tension, $\sigma_s = 0.08\,\text{N/m}$

The pressure difference between inside and outside of the bubble is given as

$$P_i - P_o = \frac{2\sigma_s}{R}$$

$$= \frac{2\times0.08\,\text{N/m}}{0.1\times10^{-3}\,\text{m}}$$

$$= 1600\,\text{N/m}^2$$

Thus the pressure difference of the air bubble, $\boxed{P_i - P_o = 1600\,\text{N/m}^2}$

Step 3 of 3

(b)

Surface Tension, $\sigma_s = 0.12\,\text{N/m}$

$$P_i - P_o = \frac{2\sigma_s}{R}$$

$$= \frac{2\times0.12\,\text{N/m}}{0.1\times10^{-3}\,\text{m}}$$

$$= 2400\,\text{N/m}^2$$

Thus the pressure difference of the air bubble, $\boxed{P_i - P_o = 2400\,\text{N/m}^2}$

Question: 10.038P

A 0.03-in-diameter glass tube is inserted into kerosene at 68°F. The contact angle of kersene with a glass surface is 26°. Determine the capillary rise of kerosene in the tube.

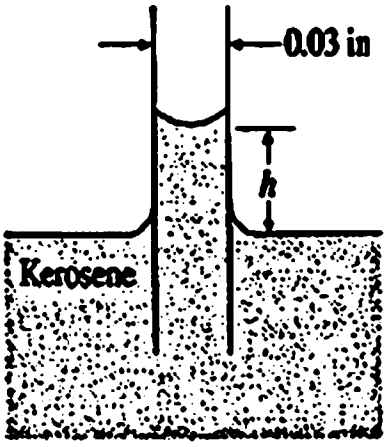

FIGURE P10–38

Step 1 of 2

Given data:

Glass tube diameter, $D = 0.03\text{in.}$

Radius of capillary tube, $R = 0.015\text{in.}$

$= 0.00125\text{ft}$

Kerosene at 20^0 C is the liquid.

Contact angle, $\phi = 26^0$

Step 2 of 2

From properties of liquid tables

Surface tension of kerosene at 60^0 F, $\sigma_s = 1.91856 \times 10^{-3}$ lb/ft

Density of kerosene, $\rho = 51.2\text{lbm/ft}^3$

Capillary raise is given by

$$h = \frac{2\sigma_s}{\rho g R}\cos\phi$$

$$= \frac{2 \times 1.91856 \times 10^{-3} \times \cos 26^\circ}{\frac{51.2}{32.17} \times 32.2 \times 0.00125}$$

$$= 0.05384\text{ft}$$

$$= 0.646\text{in.}$$

Therefore, height of mercury rise is $\boxed{h = 0.65\text{in.}}$

Question: 10.039P

A 1.2-mm-diameter tube is inserted into an unknown liquid whose density is 960 kg/m3, and it is observed that the liquid rises 5 mm in the tube, making a contact angle of 15°. Determine the surface tension of the liquid.

Step 1 of 2

Given data:

Glass tube diameter, $D = 1.2$ mm

Contact angle, $\phi = 15°$

Capillary rise, $h = 5$ mm

$= 0.005$ m

Density of liquid, $\rho = 960$ kg/m^3

Radius of capillary tube, $R = \frac{D}{2}$

$= 1.2/2$

$= 0.6$ mm

$= 0.6 \times 10^{-3}$ m

Step 2 of 2

Capillary raise is given by

$$h = \frac{2\sigma_s}{\rho g R}\cos\phi$$

$$= \frac{2(\sigma_s \text{ N/m})}{(960)\text{ kg/m}^3\,(9.81\text{ m/s}^2)(0.6\times10^{-3}\text{ m})}\cos 15°$$

$$= 0.342\sigma_s$$

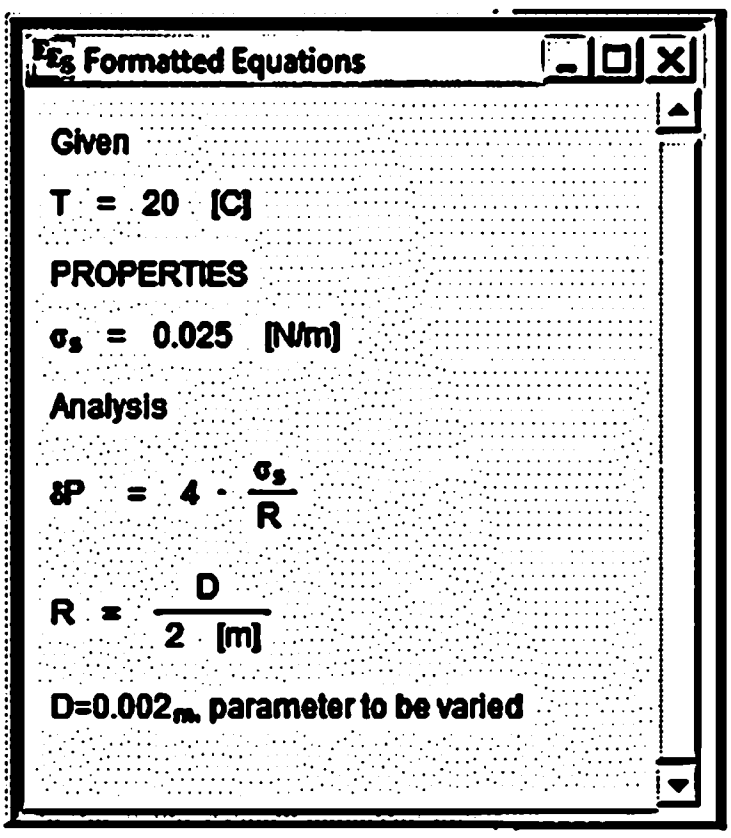
$$(0.005\text{ m}) = 0.342\sigma_s$$

$$\sigma_s = 0.01462\text{ N/m}$$

Therefore, Surface Tension $\boxed{\sigma_s = 0.0146\text{ N/m}}$

Question: 10.040P

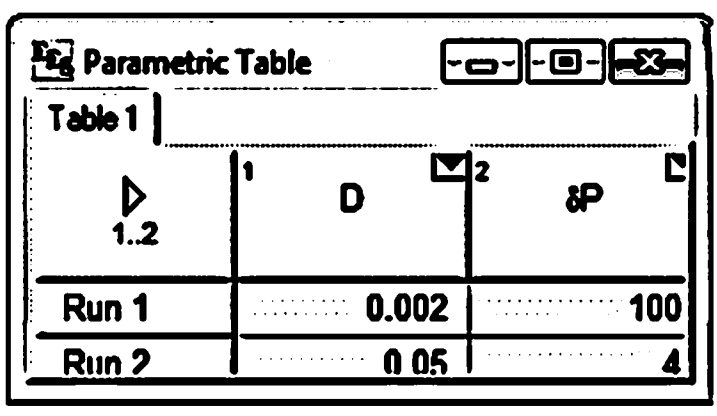
Determine the gage pressure inside a soap bubble of diameter (*a*) 0.2 cm and (*b*) 5 cm at 20°C.



Step 1 of 2

The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box



```
"Given"
T=20[C]
"PROPERTIES"
sigma_s=0.025[N/m]
"Analysis"
DeltaP=4*sigma_s/R
R=D/2[m]
"D=0.002[m], parameter to be varied"
```

Now check the mathematical representation of the equations entered in the code by pressing 'Formatted equations' of the 'Windows' tab. The equations will be displayed as shown.

Step 2 of 2

Now to solve the equation for two diameters, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 2
Select variables in equations as D and δP press 'Add' and then press 'ok'
A table will appear and enter the values of diameter under 'D' as 0.002 and 0.05 in the D column.
Then click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below

Thus the gauge pressure inside a 0.2 cm soap bubble is $\boxed{\Delta p = 100\,\mathrm{N/m^2}}$ and

The gauge pressure inside a 5 cm soap bubble is $\boxed{\Delta p = 4\,\mathrm{N/m^2}}$

Question: 10.041P

Nutrients dissolved in water are carried to upper parts of plants by tiny tubes partly because of the capillary effect. Determine how high the water solution will rise in a tree in a 0.002-mm-diameter tube as a result of the capillary effect. Treat the solution as water at 20°C with a contact angle of 15°.

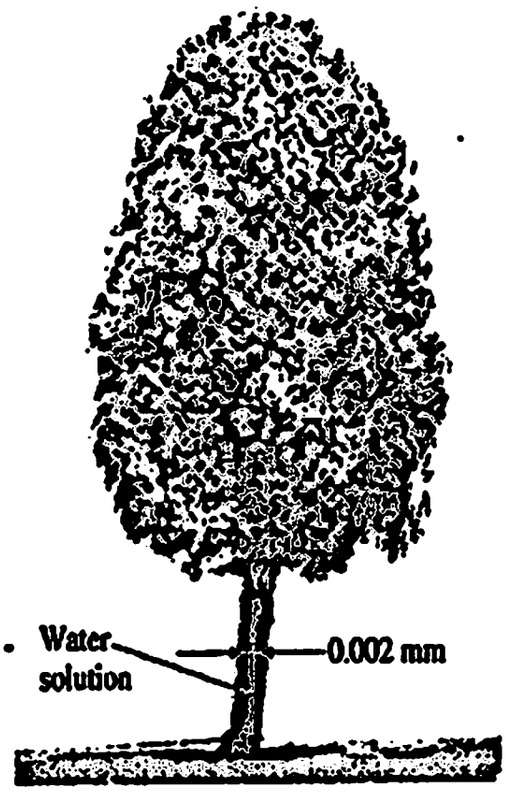


FIGURE P10–41

Step 1 of 2

Given data:

Tube diameter, $D = 0.002\ \text{mm}$

Contact angle, $\phi = 15°$

Density of water, $\rho = 998.21\ \text{kg/m}^3$

Surface tension of water at 20°C, $\sigma_s = 0.073\ \text{N/m}$

Radius of capillary tube, $R = \dfrac{D}{2}$

$$= \frac{0.002}{2}$$

$$= 0.001\ \text{mm}$$

$$= 1\times10^{-6}\ \text{m}$$

Step 2 of 2

Capillary raise is given by

$$h = \frac{2\sigma_s}{\rho g R}\cos\phi$$

$$= \frac{2(0.073\ \text{N/m})}{(998.21\ \text{kg/m}^3)(9.81\ \text{m/s}^2)(1\times10^{-6}\ \text{m})}\cos 15°$$

$$= 14.4\ \text{m}$$

Therefore the capillary rise is $\boxed{h = 14.4\ \text{m}}$.

Question: 10.042P

The surface tension of a liquid is to be measured using a liquid film suspended on a U-shaped wire frame with an 8-cm-long movable side. If the force needed to move the wire is 0.024 N, determine the surface tension of this liquid in air.

Step 1 of 2

Given data:

Movable side length, $b = 8\,\text{cm}$

$= 0.08\,\text{m}$

Force required, $F = 0.024\,\text{N}$

Step 2 of 2

We know that surface tension

$$\sigma_s = \frac{F}{2b}$$

Putting values in the above equation

$$\sigma_s = \frac{0.024\,\text{N}}{2 \times 0.08\,\text{m}}$$

$$= 0.15\,\text{N/m}$$

Thus surface tension $\boxed{\sigma_s = 0.15\,\text{N/m}}$

Question: 10.043P

Contrary to what you might expect, a solid steel ball can float on water due to the surface tension effect. Determine the maximum diameter of a steel ball that would float on water at 20°C. What would your answer be for an aluminum ball? Take the densities of steel and aluminum balls to be 7800 kg/m3 and 2700 kg/m3, respectively.

Step 1 of 3

Surface tension of water at 20°C, $\sigma = 0.073\,\text{N/m}$

When the board has to float, the force should be equal to the weight of the ball.

$$\pi D\sigma_s = mg$$

$$\pi D\sigma_s = \rho Vg$$

$$\pi D\sigma_s = \rho\pi\frac{D^3}{6}g$$

$$\sigma_s = \rho\frac{D^2}{6}g$$

$$D^2 = \frac{6\sigma_s}{\rho g}$$

$$D = \sqrt{\frac{6\sigma_s}{\rho g}}$$

Here σ_s is surface tension, ρ is density of fluid and g is acceleration due to gravity.

Step 2 of 3

Substitute: $\sigma = 0.073\,\text{N/m}$, $\rho_{steel} = 7800\,\text{kg/m}^3$ and $g = 9.81\,\text{m/s}^2$

Diameter of a steel ball:

$$D_{steel} = \sqrt{\frac{6\times 0.073\,\text{N/m}}{7800\,\text{kg/m}^3\times 9.81}}$$

$$= 2.39\times 10^{-3}\,\text{m}$$

Thus diameter of steel ball is $\boxed{2.39\times 10^{-3}\,\text{m}}$

Step 3 of 3

Substitute: $\sigma = 0.073\,\text{N/m}$, $\rho_{Al} = 2700\,\text{kg/m}^3$ and $g = 9.81\,\text{m/s}^2$

Diameter of an aluminum ball:

$$D_{Al} = \sqrt{\frac{6\times 0.073\,\text{N/m}}{2700\,\text{kg/m}^3\times 9.81}}$$

$$= 4.1\times 10^{-3}\,\text{m}$$

Thus diameter of steel ball is $\boxed{4.1\times 10^{-3}\,\text{m}}$

Question:

10.044P

The pressure on the suction side of pumps is typically low, and the surfaces on that side of the pump are susceptible to cavitation, especially at high fluid temperatures. If the minimum pressure on the suction side of a water pump is 0.95 psia absolute, determine the maximum water temperature to avoid the danger of cavitation.

Step 1 of 2

Given data:

Type of pump: Water pump

Operating pressure of the water pump, $P = 0.95\,\text{psia}$

Step 2 of 2

From the table of "saturated water temperature"

At $P = 0.95\,\text{psia}$

Saturation temperature of the water is $T_{sat} = 100°\text{F}$

So we have to avoid cavitations in water pump, we maintained the temperature of the water below saturation temperature of the water.

Therefore, maximum water temperature to avoid cavitations is $\boxed{T_{max} = 100°\text{F}}$.

Question: 10.045P

A closed tank is partially filled with water at 80°C. If the air above the water is completely evacuated, determine the absolute pressure in the evacuated space. Assume the temperature to remain constant.

Step 1 of 2

Given data:

The closed tank is partially filled with water.

All the air is removed from the tank.

The temperature of the water is $T = 80^\circ C$.

The temperature remains constant.

Step 2 of 2

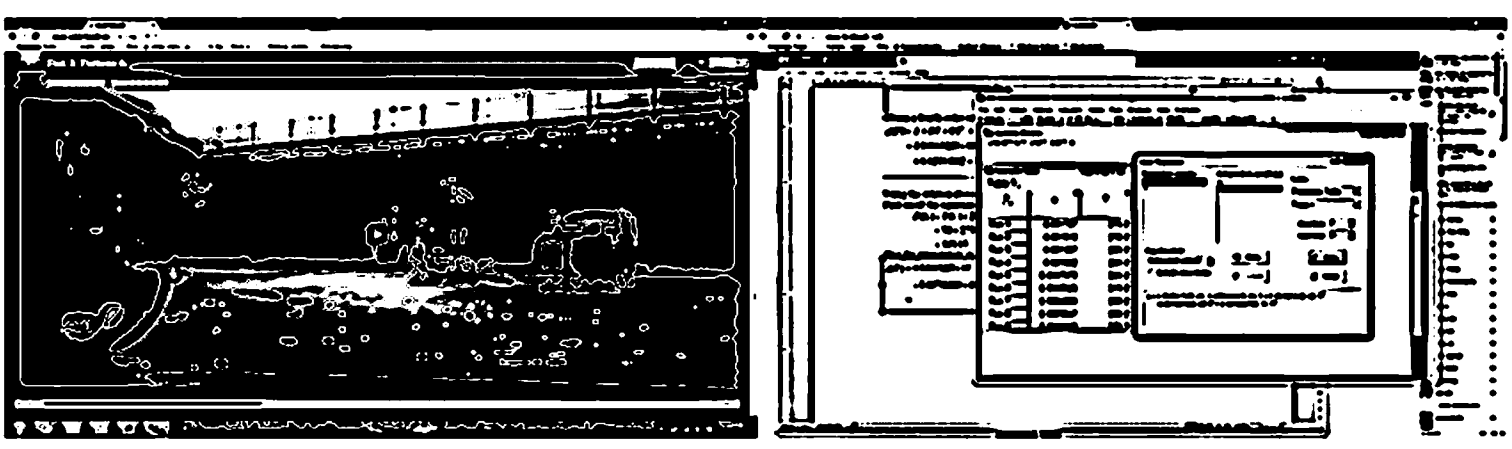
The atmospheric pressure inside the vessel is zero hence the absolute pressure inside the tank will be equal to the vapor pressure of water at $T = 80^\circ C$.

The vapor pressure of water at $T = 80^\circ C$.

$P_w = 355.1$ mm of Hg

Absolute pressure in the evacuated space is $\boxed{P_w = 355.1 \text{ mm of Hg}}$.

Question: 10.046P



The variation of the dynamic viscosity of water with absolute temperature is given as

T,K	μ, Pa·s
273.15	1.787 × l0−3
278.15	1.519 × 10−3
283.15	1.307 × 10−3
293.15	1.002 × 10−3
303.15	7.975 × 10−4
313.15	6.529 × 10−4
333.15	4.665 × 10−4
353.15	3.547 × 10−4
373.15	2.828 × 10−4

Using tabulated data, develop a relation for viscosity in the form of$\mu = \mu(T) = A + BT + CT2 + DT3 + ET4$ .Using the relation developed, predict the dynamic viscosity of water at 50°C at which the reported value is 5.468 × 10−4 Pa·s. Compare your result with the results of Andrade's equation, which is given in the form of$\mu = D \cdot eB/T$, where$D$ and$B$ are constants whose values are to be determined using the viscosity data given.

Step 1 of 5

Using EES, generate a parametric table for the given information. Then calculate a fourth order linear regression with the dynamic viscosity is the dependent variable and the temperature as the independent variable.

Step 2 of 5

Obtain a fourth order relation for viscosity as a function of temperature.

$$\mu(T) = A + BT + CT^2 + DT^3 + ET^4$$
$$= 4.8291758 \times 10^{-1} - 5.68904387 \times 10^{-3} T + 2.49152104 \times 10^{-5} T^2 - 4.86155745 \times 10^{-8} T^3 + 3.56198079 \times 10^{-11} T^4$$

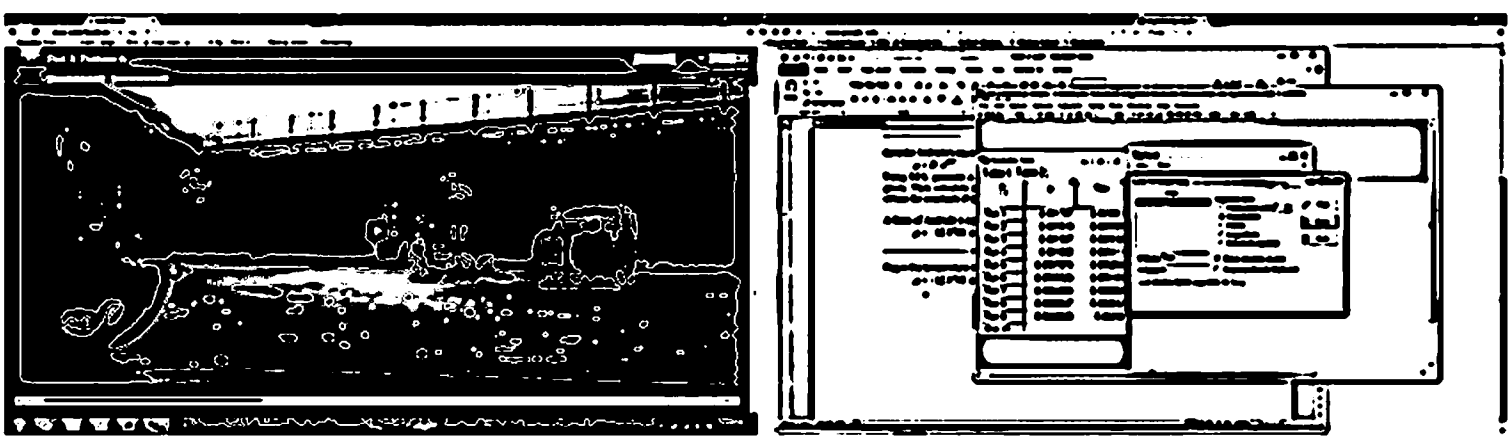
Using the relation above, calculate the dynamic viscosity at 50°C.

First recall the equation to convert temperature in Celsius to Kelvin.

$$T(\mathrm{K}) = T(\mathrm{C}) + 273.15$$
$$= 50 + 273.15$$
$$= 323.15$$

Plug the temperature in Kelvin into the function for dynamic viscosity.

$$\mu(T) = 4.8291758 \times 10^{-1} - 5.68904387 \times 10^{-3} \times (323.15) + 2.49152104 \times 10^{-5} \times (323.15)^2 - 4.86155745 \times 10^{-8} \times (323.15)^3 + 3.56198079 \times 10^{-11} T^4 \times (323.15)^4$$
$$= 5.529 \times 10^{-4}\ \mathrm{Pa \cdot s}$$



The relation developed predicts a dynamic viscosity of $5.529 \times 10^{-4}\ \mathrm{Pa \cdot s}$ of water at 50°C, which is very close to the report value of $5.468 \times 10^{-4}\ \mathrm{Pa \cdot s}$.

Step 3 of 5

Consider Andrade's equation.

$$\mu = D \cdot e^{B/T}$$

Using EES, generate a plot of dynamic viscosity vs. the inverse of time using the data given. Then calculate an exponential curve fit with the form of Andrade's equation to obtain the constants D and B.

Step 4 of 5

A form of Andrade's equation is obtained.

$$\mu = 0.00000172655 \cdot e^{1876.74/T}$$

Step 5 of 5

Plug in the temperature in Kelvin.

$$\mu = 0.00000172655 \cdot e^{1876.74/323.15}$$
$$= 5.7465 \times 10^{-4}\ \mathrm{Pa \cdot s}$$

The value of dynamic viscosity obtained using Andrade's equation is $5.7465 \times 10^{-4}\ \mathrm{Pa \cdot s}$, which is close to the value obtained using the fourth order relation previously as well as the reported value.

Question: 10.047P

Consider laminar flow of a Newtonian fluid of viscosity μ between two parallel plates. The flow is one-dimensional, and the velocity profile is given as $u(y) = 4u\text{max}\,[y/h - (y/h)2]$, where y is the vertical coordinate from the bottom surface,h is the distance between the two plates, and $u$max is the maximum flow velocity that occurs at midplane. Develop a relation for the drag force exerted on both plates by the fluid in the flow direction per unit area of the plates.

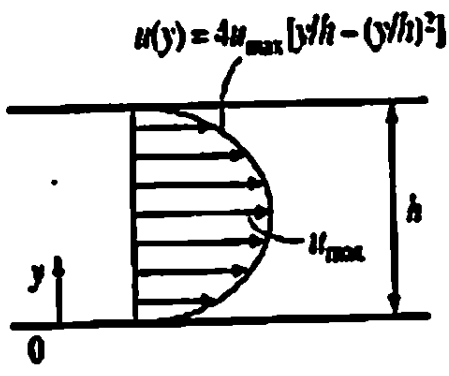


FIGURE P10–47

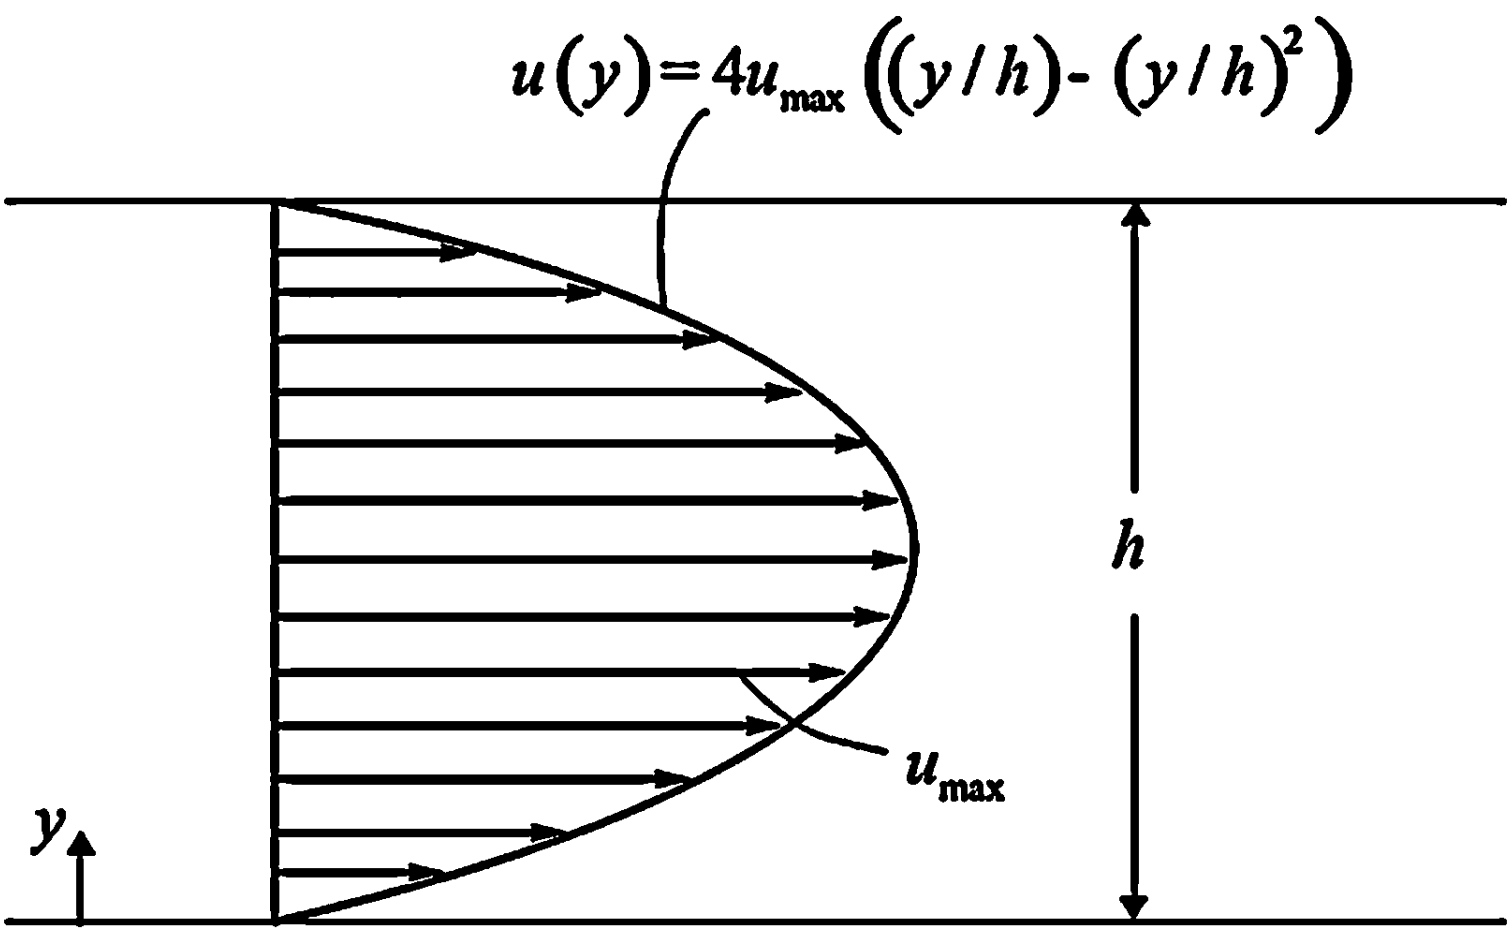
Step 1 of 4

Given data:

The velocity profile is $u(y) = 4u_{max}\left[(y/h)-(y/h)^2\right]$.

The distance between the plates is h.



The maximum flow velocity is u_{max}.

The fluid flow is one dimensional.

The fluid is of Newtonian nature.

Step 2 of 4

Given figure:

The velocity profile given in the problem is symmetric. Hence we can assume that the shear stress acting on the bottom plate will be equal to the shear stress acting on the top plate.

Step 3 of 4

The shear stress acting on the bottom of the plate,

$$\tau_{Bottom} = \mu\frac{du}{dy}$$

$$\tau_{Bottom} = \mu\frac{d}{dy}\left(4u_{max}\left[(y/h)-(y/h)^2\right]\right)$$

$$= 4u_{max}\mu\frac{d}{dy}\left[(y/h)-(y/h)^2\right]$$

Differentiating the above equation, we get

$$\tau_{Bottom} = 4u_{max}\left[(1/h)-(2y/h^2)\right]$$

At bottom of the plate $y = 0$.

$$\tau_{Bottom} = 4\mu u_{max}\left[\frac{1}{h}-\frac{2(0)}{h^2}\right]$$

$$= \frac{4\mu u_{max}}{h}$$

Due to symmetry,

Shear stress at top plate is equal to shear stress at bottom plate.

$$\tau_{Top} = \tau_{Bottom}$$

$$= \frac{4\mu u_{max}}{h}$$

Step 4 of 4

The shear force acting on the upper and lower plates can be expressed as

$$F = \left(\tau_{Bottom}A + \tau_{Top}A\right)$$

$$= \frac{4\mu u_{max}}{h} + \frac{4\mu u_{max}}{h}$$

$$F = \frac{8\mu u_{max}A}{h} \quad \text{..... (1)}$$

Where,

A = Area of plate

The friction drag per unit area is

From equation (1)

$$\frac{F}{A} = \frac{8\mu u_{max}}{h}$$

The drag force exerted on both plates by the fluid in the flow direction per unit area is

$$\boxed{\frac{F}{A} = \frac{8\mu u_{max}}{h}}.$$

Question: 10.048P

Some non-Newtonian fluids behave as a Bingham plastic for which shear stress can be expressed as $\tau = \tau_y + \mu(du/dr)$. For laminar flow of a Bingham plastic in a horizontal pipe of radius R, the velocity profile is given as $u(r)=(\Delta P/4\mu L)(r2-R2)+(\tau y/\mu)(r- R)$, where $\Delta P/L$ is the constant pressure drop along the pipe per unit length, μ is the dynamic viscosity, r is the radial distance from the centerline, and τy is the yield stress of Bingham plastic. Determine (*a*) the shear stress at the pipe wall and (*b*) the drag force acting on a pipe section of length L.

Step 1 of 4

Given data:

The shear stress, $\tau = \tau_y + \mu(du/dr)$.

The velocity profile, $u(r) = (\Delta P/4\mu L)(r^2 - R^2) + (\tau_y/\mu)(r - R)$.

The constant pressure drop per unit length is $\Delta P/L$.

The dynamic viscosity is μ.

The radial distance from center line is r.

The yield stress of Bingham plastic is τ_y.

Step 2 of 4

(a)

The fluid considered is non-Newtonian and behaves like Bingham plastic.

The flow is laminar taking place inside a pipe.

The radial distance is along the y-coordinate.

The shear stress at pipe wall can be written as

$$\begin{aligned}\tau_r &= \mu\frac{du}{dr}\\ &= \mu\left[\frac{d}{dr}\left(\frac{\Delta P}{4\mu L}(r^2 - R^2) + \frac{\tau_y}{\mu}(r - R)\right)\right]\\ &= \mu\left[\left(\frac{\Delta P}{4\mu L}\right)\frac{d}{dr}(r^2 - R^2) + \left(\frac{\tau_y}{\mu}\right)\frac{d}{dr}(r - R)\right]\end{aligned}$$

Step 3 of 4

Differentiating the above equation, we get

$$\begin{aligned}\tau_r &= \mu\left(\frac{2R\Delta P}{4\mu L} + \frac{\tau_y}{\mu}\right)\\ &= \mu\left(\frac{R\Delta P}{2\mu L} + \frac{\tau_y}{\mu}\right)\end{aligned}$$

The shear stress acting on the pipe wall can be expressed as

$$\begin{aligned}\tau &= \tau_y + \tau_r\\ &= \tau_y + \mu\left(\frac{r\Delta P}{2\mu L} + \frac{\tau_y}{\mu}\right)\\ &= 2\tau_y + \frac{R\Delta P}{2L}\end{aligned}$$

The shear stress acting on the pipe wall is

$$\boxed{\tau = 2\tau_y + \frac{R\Delta P}{2L}}.$$

Step 4 of 4

(b)

The area of the pipe exposed to the fluid is,

$$A = 2\pi rL$$

The drag force exerted on the pipe surface is

$$\begin{aligned}F_D &= \tau A\\ &= \left(2\tau_y + \frac{R\Delta P}{2L}\right)(2\pi rL)\end{aligned}$$

The drag force exerted on a pipe section of length L is

$$\boxed{F_D = \left(2\tau_y + \frac{R\Delta P}{2L}\right)(2\pi rL)}.$$

Question: 10.049P

A 0.018-in-diameter glass tube is inserted into mercury, which makes a contact angle of 140° with glass. Determine the capillary drop of mercury in the tube at 68°F.

Step 1 of 2

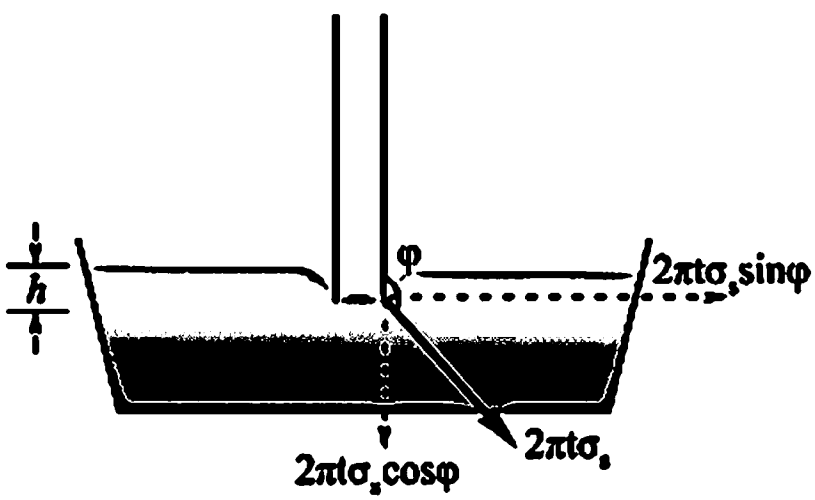
Given data:

Diameter of the glass is tube, $d = 0.018\text{in}$

Radius of the glass is tube, $R = 2.286\text{m}$

Contact angle made by the mercury, $\phi = 140°$

Temperature of the mercury is $t = 68°\text{F} = 20°\text{C}$



Surface tension of the mercury at 20°C $\sigma_s = 0.44\,\text{N/m}$

Density of the mercury, $\rho = 13600\,\text{kg/m}^3$

Acceleration due to gravity $g = 9.81\,\text{m/s}^2$

Step 2 of 2

Figure showing forces acting near the meniscus of mercury,

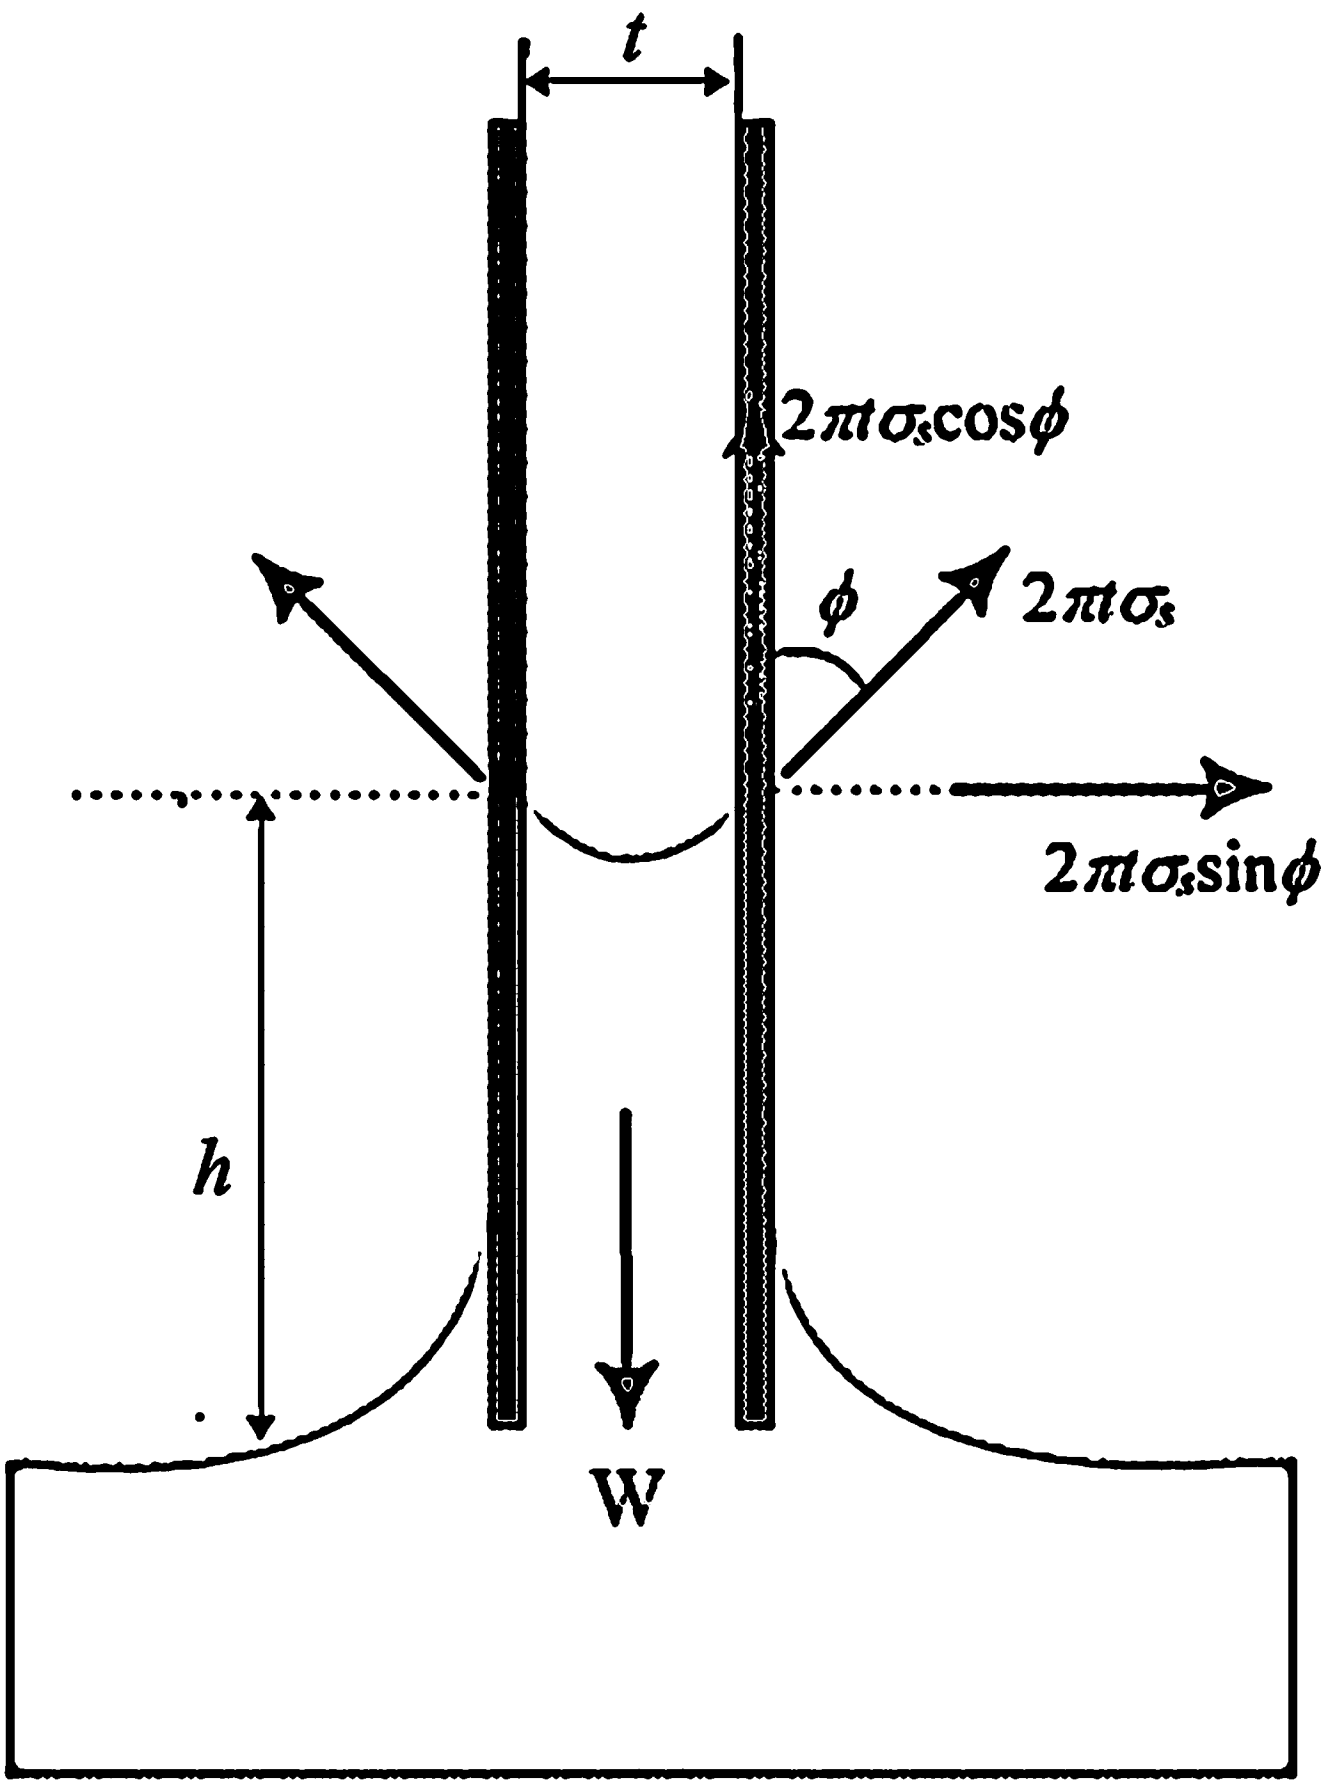
We know that capillary drop is given by,

$$h = \frac{2\sigma\cos\phi}{\rho g R}$$

$$= \frac{2\times(0.44\,\text{N/m})\times(\cos 140°)}{(13600\,\text{kg/m}^3)\times(9.81\,\text{m/s}^2)\times(2.286\times10^{-4}\,\text{m})}$$

$$= -0.022\,\text{m}$$

$$= -0.8701\,\text{in.}$$



The capillary drop in mercury is obtained as $\boxed{h = -0.8701\,\text{in.}}$.

Question: 10.050P

Derive a relation for the capillary rise of a liquid between two large parallel plates a distance *t* apart inserted into the liquid vertically. Take the contact angle to be ϕ.

Step 1 of 3

Let us draw the diagram:

Step 2 of 3

Let us assume that the water and the plate surfaces are free from impurities and the experiment takes place in atmospheric pressure.

From the figure we know that the bottom of the liquid is at the same level as the free surface of the reservoir where the atmospheric pressure acts. The same pressure will be acting on the top of the liquid column. Thus the two effects cancel each other.

The weight of the liquid column is

$W = mg$ ..... (1)

Where,

m = Mass of the liquid

$= \rho V$

ρ = Density of liquid

V = Volume of the liquid

$= b \times t \times h$

Step 3 of 3

Substituting the values in equation (1)

$$W = (\rho V) g$$
$$= \rho g (b \times t \times h)$$

Let us equate the vertical component of surface tension and weight.

$$W = F_{surface}$$
$$\rho g (b \times t \times h) = 2\pi t \sigma_s \cos\phi$$
$$h = \frac{2\pi\sigma_s}{\rho g b} \cos\phi$$

The required capillary rise is $\boxed{h = \frac{2\pi\sigma_s}{\rho g b} \cos\phi}$

Question: 10.051P

Consider a 40-cm-long journal bearing that is lubricated with oil whose viscosity is 0.1 kg/m·s at 20°C at the beginning of operation and 0.008 kg/m·s at the anticipated steady operating temperature of 80°C. The diameter of the shaft is 8 cm, and the average gap between the shaft and the journal is 0.08 cm. Determine the torque needed to overcome the bearing friction initially and during steady operation when the shaft is rotated at 800 rpm.

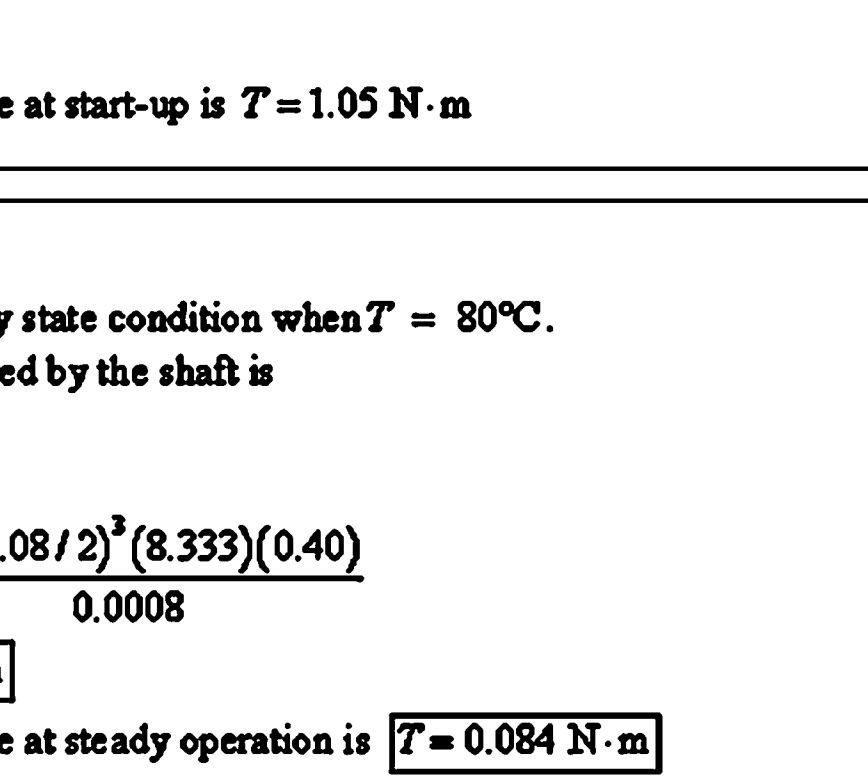
Step 1 of 5

Given data:

The length of the journal bearing, $L = 40$ cm

The viscosity of the lubricant at 20°C, $\mu_{20} = 0.1\ \text{kg/m} \cdot \text{s}$

The viscosity of the lubricant at 80°C, $\mu_{80} = 0.008\ \text{kg/m} \cdot \text{s}$



The velocity of the shaft, $n = 800$ rpm

The diameter of the shaft, $d = 0.08$ m

The average gap between the shaft and journal, $l = 0.08$ cm

Step 2 of 5

Let us draw the diagram:

Step 3 of 5

Let us assume that the fluid is Newtonian and the end effects are negligible.

The velocity of the shaft is

$n = 800$ rpm

$$= \left(\frac{800}{60}\right) \text{rps}$$

$$= 8.333 \text{ rps}$$

The torque generated by the shaft can be written as,

$$T = \mu \frac{4\pi^2 R^3 n L}{l}$$

Step 4 of 5

Consider the start-up condition when $T = 20°\text{C}$.

The torque generated by the shaft is

$$T = \mu_{20} \frac{4\pi^2 R^3 n L}{l}$$

$$= (0.1) \frac{4\pi^2 (0.08/2)^3 (8.333)(0.40)}{0.0008}$$

$$\boxed{T = 1.05\ \text{N} \cdot \text{m}}$$

The required torque at start-up is $T = 1.05\ \text{N} \cdot \text{m}$

Step 5 of 5

Consider the steady state condition when $T = 80°\text{C}$.

The torque generated by the shaft is

$$T = \mu_{80} \frac{4\pi^2 R^3 n L}{l}$$

$$= (0.008) \frac{4\pi^2 (0.08/2)^3 (8.333)(0.40)}{0.0008}$$

$$\boxed{T = 0.084\ \text{N} \cdot \text{m}}$$

The required torque at steady operation is $\boxed{T = 0.084\ \text{N} \cdot \text{m}}$

Question: 10.052P

The diameter of one arm of a U-tube is 5 mm while the other arm is large. If the U-tube contains some water, and both surface are exposed to atmospheric pressure, determine the difference between the water levels in the two arms.

Step 1 of 4

Given data:

A U-tube manometer is used.

The diameter of one arm is $D = 5\text{ mm}$

$= 0.005\text{ m}$

The diameter of the other arm is large.

The water surfaces in both arms are exposed to atmospheric pressure.

Step 2 of 4

Let us assume that there are no impurities in water and no contamination on the tube surfaces.

Let us assume the temperature to be $T = 20^\circ\text{C}$

At $T = 20^\circ\text{C}$ the properties of water are

Surface tension, $\sigma_s = 0.073\text{ N/m}$

And the contact angle is approximately $\phi = 0^\circ$

Consider the arm with very large diameter.

Since the diameter is large the capillary rise h will be negligible. Hence we can assume h will be zero in the arm having large diameter.

Then

$h_1 = 0$

Step 3 of 4

Consider the tube of diameter $D_1 = 0.005\text{ m}$.

The capillary rise is,

$$h_2 = \frac{2\sigma_s}{\rho g R}\cos\phi \qquad \ldots\ldots (1)$$

Where,

R = Radius of the tube

$$= \frac{D}{2}$$

$$= \frac{0.005}{2}$$

$$= 2.5\times10^{-3}\text{ m}$$

ρ = Density of water

$= 1000\text{ kg/m}^3$.

g = acceleration due to gravity

$= 9.81\text{ m/s}^2$.

Step 4 of 4

Substituting the above values in equation (1), we get

$$h_2 = \frac{2(0.073\text{ N/m})}{(1000\text{ kg/m}^3)(9.81\text{ m/s}^2)(2.5\times10^{-3}\text{ m})}\cos 0^\circ$$

$$= 0.0593\text{ m}$$

The difference between the water levels in the two arms is

$\Delta h = h_2 - h_1$

$= 0.0593 - 0$

$= 0.0593$

$\boxed{\Delta h = 0.0593\text{ m}}$

The difference between the water levels in the two arms is $\boxed{\Delta h = 0.0593\text{ m}}$.

Question: 10.053P

Some rocks or bricks contain small air pockets in them and have a spongy structure. Assuming the air spaces form columns of an average diameter of 0.004 mm, determine how high water can rise in such a material. Take the surface tension of the air-water interface in that material to be 0.085 N/m.

Step 1 of 3

Given data:

The average diameter of the columns, $D = 0.004$ mm

$= 0.004 \times 10^{-3}$ m

The surface tension of the air water interface, $\sigma_s = 0.085$ N/m

Let us assume the water is not contaminated, the walls of the columns are free from impurities and the pressure in the air spaces is equal to the atmospheric pressure.

Step 2 of 3

The capillary rise is given by

$$h = \frac{2\sigma_s}{\rho g R}\cos\phi \qquad \text{..... (1)}$$

Where,

R = Radius of the tube

$$= \frac{D}{2}$$

$$= \frac{0.004 \times 10^{-3}}{2}$$

$$= 0.002 \times 10^{-3} \text{ m}$$

Density of water, $\rho = 1000$ kg/m^3.

Acceleration due to gravity $g = 9.81$ m/s^2.

Contact angle $\phi = 0^\circ$

Step 3 of 3

Substituting the values in equation (1), we get

$$h = \frac{2(0.085)}{1000 \times 9.81 \times 0.002 \times 10^{-3}}\cos 0^\circ$$

$$= 8.66 \text{ m}$$

The rise of water in the material is $\boxed{h = 8.66 \text{ m}}$.

CHAPTER 11

SOLUTIONS

Question: 11.001P

Define the resultant hydrostatic force acting on a submerged surface, and the center of pressure.

Step 1 of 2

The hydrostatic pressure is defined as

$$P = \rho g h \qquad \ldots\ldots (1)$$

Here ρ is the fluid density. g Is the acceleration due to gravity. And h is the distance from the liquid surface.

As no shear stress exists in a static fluid, all hydrostatic forces on any element of a submerged surface must act in a direction normal to the surface.

Step 2 of 2

The above equation (1) shows that pressure distribution varies linearly over the any liquid surface.

The magnitude of the resultant hydrostatic force of a submerged plane is equal to the product of pressure P_c at the centroid of the surface and area A of the surface.

$$F_R = P_C A$$

The point of application of resultant force on the plane surface is known as centre of pressure.

Question: 11.002P

Someone claims that she can determine the magnitude of the hydrostatic force acting on a plane surface submerged in water regardless of its shape and orientation if she knew the vertical distance of the centroid of the surface from the free surface and the area of the surface. Is this a valid claim? Explain.

Step 1 of 2

For an inclined surface if we know the vertical distance and area of the surface we can determine the magnitude of resultant force.

Yes. It is a valid claim.

Step 2 of 2

Whatever may be the inclination of the submerged plane surface to the free liquid, the magnitude of the resultant hydrostatic force equals the product of area and the pressure at the centroid of the area.

Find the resultant force.

$$F_R = P_c A$$

$$= P_{avg} A$$

Here:

$P_c = P_0 + \rho g h_c$ is the pressure at the centroid of the surface.

This is equivalent to the average pressure P_{avg} on the surface.

$h_c = y_c + \sin\theta$ is the vertical distance of the centroid from the free surface of the liquid.

Question: 11.003P

A submerged horizontal flat plate is suspended in water by a string attached at the centroid of its upper surface. Now the plate is rotated 45° about an axis that passes through its centroid. Discuss the change on the hydrostatic force acting on the top surface of this plate as a result of this rotation. Assume the plate remains submerged at all times.

Step 1 of 1

The magnitude of the resultant hydrostatic force equals the product of area and the pressure at the centroid of the surfaces, i.e.

$F = P_c A$

On rotating of the plate about the axis passing through the centroid of the plate, whatever may be the inclination, the pressure force remains constant.

Therefore there will be no change in the magnitude of hydrostatic force on the surface when it is rotated by 45°.

Question: 11.004P

You may have noticed that dams are much thicker at the bottom. Explain why dams are built that way.

Step 1 of 1

Basic equation for pressure

$P = \gamma h$

Pressure is directly proportional to height. So when height increases pressure also increases.

To withstand high pressure at the bottom of the dam, basements are built much wider than the top. So the bottom of the dam will be thicker.

Question: 11.005P

Consider a submerged curved surface. Explain how you would determine the horizontal component of the hydrostatic force acting on this surface.

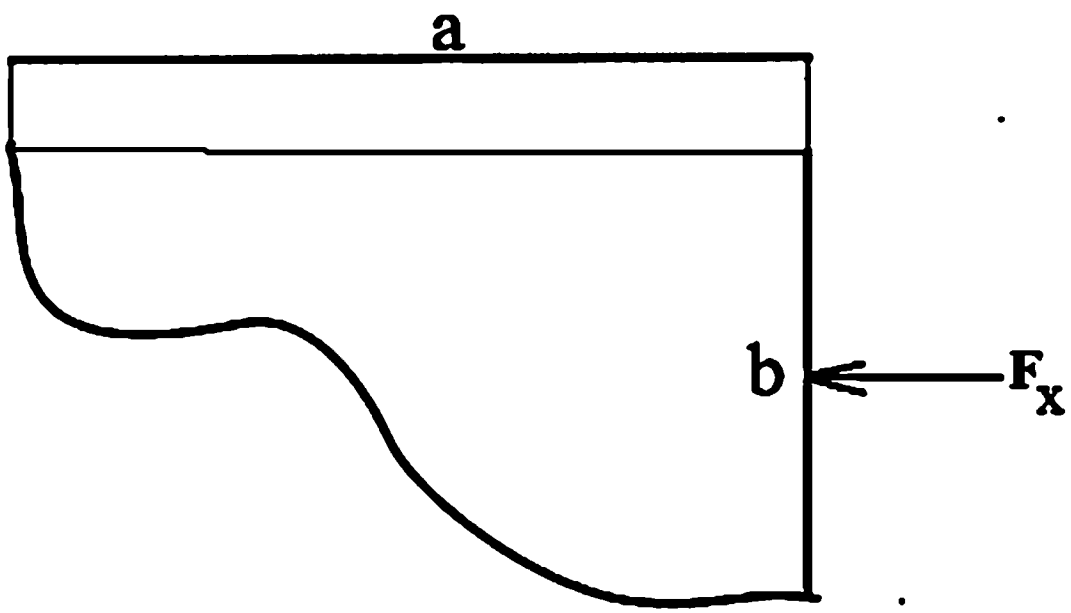
Step 1 of 2

The horizontal component of the hydrostatic force acting on a curved surface is equal to the hydrostatic force acting on the vertical projection of the curved surface.

Horizontal component of curved surface,

$F_H = F_x$

$F_H = \rho g A h_c$



Here

h_c **is the centroidal distance of the surface from the free surface.**

A **is the cross sectional area of the curved surface.**

h_c **and** A **are depends on curved surface of the object.**

Step 2 of 2

In the above figure:

a is the horizontal projection of the curved surface.

b is the vertical projection of the curved surface.

Question: 11.006P

Consider a submerged curved surface. Explain how you would determine the vertical component of the hydrostatic force acting on this surface.

Step 1 of 2

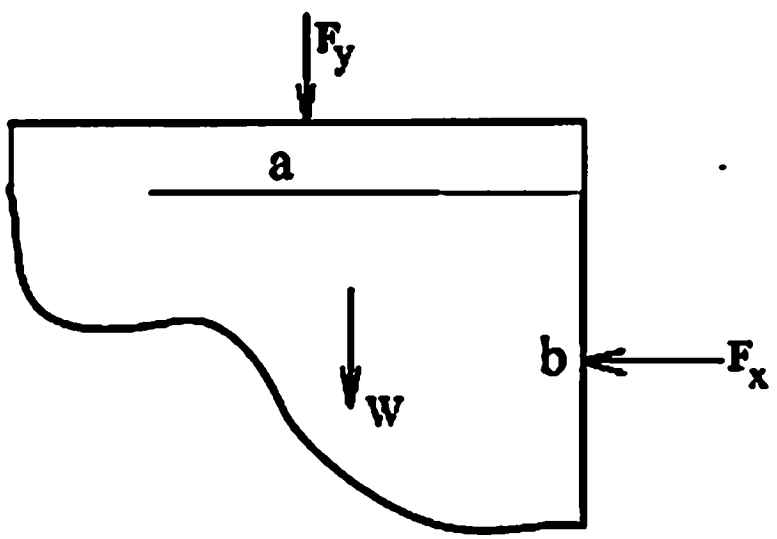
The vertical component of the hydrostatic force acting on a curved surface is equal to the hydrostatic force acting on the horizontal projection of the curved surface, plus weight of the fluid block. (Direction of the weight of the fluid block should be taken into consideration).

Vertical force component of curved surface

$$F_v = F_y \pm W$$

It is a vector addition if both F_y and W act in the same direction, and subtract if they act in opposite directions.

$$F_v = \rho g A h_c \pm W$$



Where

h_c is the centroidal distance of the surface from the free surface.

A is the cross sectional area of the curved surface.

h_c and A are depends on curved surface of the object.

Step 2 of 2

In the above figure:

a is the horizontal projection of the curved surface.

b is the vertical projection of the curved surface.

Question: 11.007P

Consider a circular surface subjected to hydrostatic forces by a constant density liquid. If the magnitudes of the horizontal and vertical components of the resultant hydrostatic force are determined, explain how you would find the line of action of this force.

Step 1 of 2

When the curved surface is circular, the resultant of hydrostatic force acting on the surface always passes through the centre of the circle. This is because, as the pressure forces are normal to the surface, all the lines which are normal to the surface of a circle pass through the center of the circle.

As the pressure forces form a concurrent force system, it can be taken as a single equivalent force at that point.

Step 2 of 2

When magnitudes of the horizontal and vertical components of the resultant hydrostatic forces are given, then the line of action is given as

$$\tan\theta = \frac{F_V}{F_H}$$

Here θ is the angle made by the line of action, F_H is the horizontal force component of hydrostatic force and F_V is the vertical force component of hydrostatic force.

Question: 11.008P

Consider a heavy car submerged in water in a lake with a flat bottom. The driver's side door of the car is 1.1 m high and 0.9 m wide, and the top edge of the door is 10 m below the water surface. Determine the net force acting on the door (normal to its surface) and the location of the pressure center if (*a*) the car is well-sealed and it contains air at atmospheric pressure and (*b*) the car is filled with water.

Step 1 of 5

Given data:

Height of driver's side door, $b = 1.1\,\text{m}$
Width of driver's side door, $w = 0.9\,\text{m}$
Height of the car door top edge from the water surface, $s = 10\,\text{m}$
Density of water, $\rho = 1000\,\text{kg/m}^3$
Acceleration due to gravity, $g = 9.81\,\text{m/s}^2$
The distance of centroid of car door from the surface of water,

$$h_c = s + \frac{b}{2}$$
$$= 10 + \frac{1.1}{2}$$
$$= 10.55\,\text{m}$$

Step 2 of 5

(a)
The door can be considered as a vertical rectangular plate.
The average pressure acting on the car door,

$$P_{avg} = \rho g h_c$$
$$= 1000 \times 9.81 \times 10.55$$
$$= 103495.5\,\text{N/m}^2$$
$$= 103.495\,\text{kN/m}^2$$

Area of the rectangular car door,

$$A = b \times w$$
$$= 1.1 \times 0.9$$
$$= 0.99\,\text{m}^2$$

Step 3 of 5

The resultant hydrostatic force on the car door,

$$F_R = P_{avg} \times A$$
$$= 103.495 \times 0.99$$
$$= 102.46\,\text{kN}$$

Therefore the resultant hydrostatic force on the car door, $\boxed{F_R = 102.46\ \text{kN}}$.
The moment of inertia of rectangle about x-axis,

$$I_{xx} = \frac{wb^3}{12}$$
$$= \frac{0.9 \times 1.1^3}{12}$$
$$= 0.099\,\text{m}^4$$

Step 4 of 5

The perpendicular distance between hydrostatic force and surface of water, $y_c = h_c = 10.55\,\text{m}$
The line of action of the hydrostatic force from the free surface of the water,

$$y_p = y_c + \frac{I_{xx}}{h_c A}$$
$$= 10.55 + \frac{0.099}{10.55 \times 0.99}$$
$$= 10.55 + 9.478 \times 10^{-3}$$
$$= 10.559\,\text{m}$$

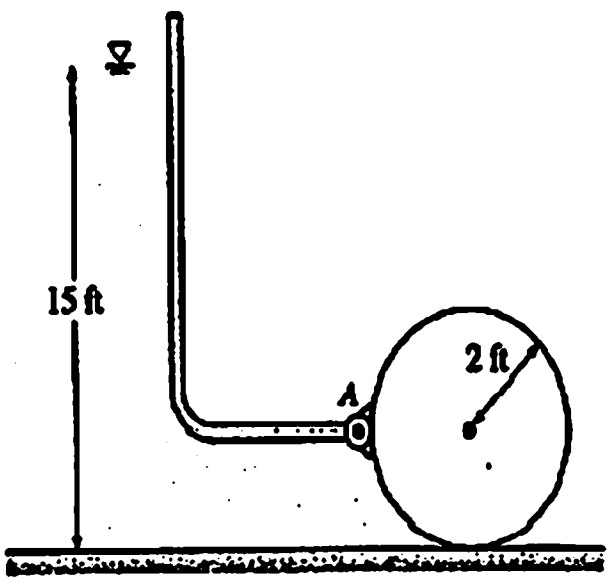
Therefore the line of action of the hydrostatic force from the free surface of the water, $\boxed{y_p = 10.559\ \text{m}}$.

Step 5 of 5

(b)
The net force acting on the door is zero when the car is filled with water, because the door is having water on both sides, therefore both inside and outside forces will get neutralized and the net force acing on the door will become zero.

Question: 11.009P pg 1

A long, solid cylinder of radius 2 ft hinged at point *A* is used as an automatic gate, as shown in Fig. P11–9E. When the water level reaches 15 ft, the cylindrical gate opens by turning about the hinge at point *A*. Determine (*a*) the hydrostatic force acting on the cylinder and its line of action when the gate opens and (*b*) the weight of the cylinder per ft length of the cylinder.



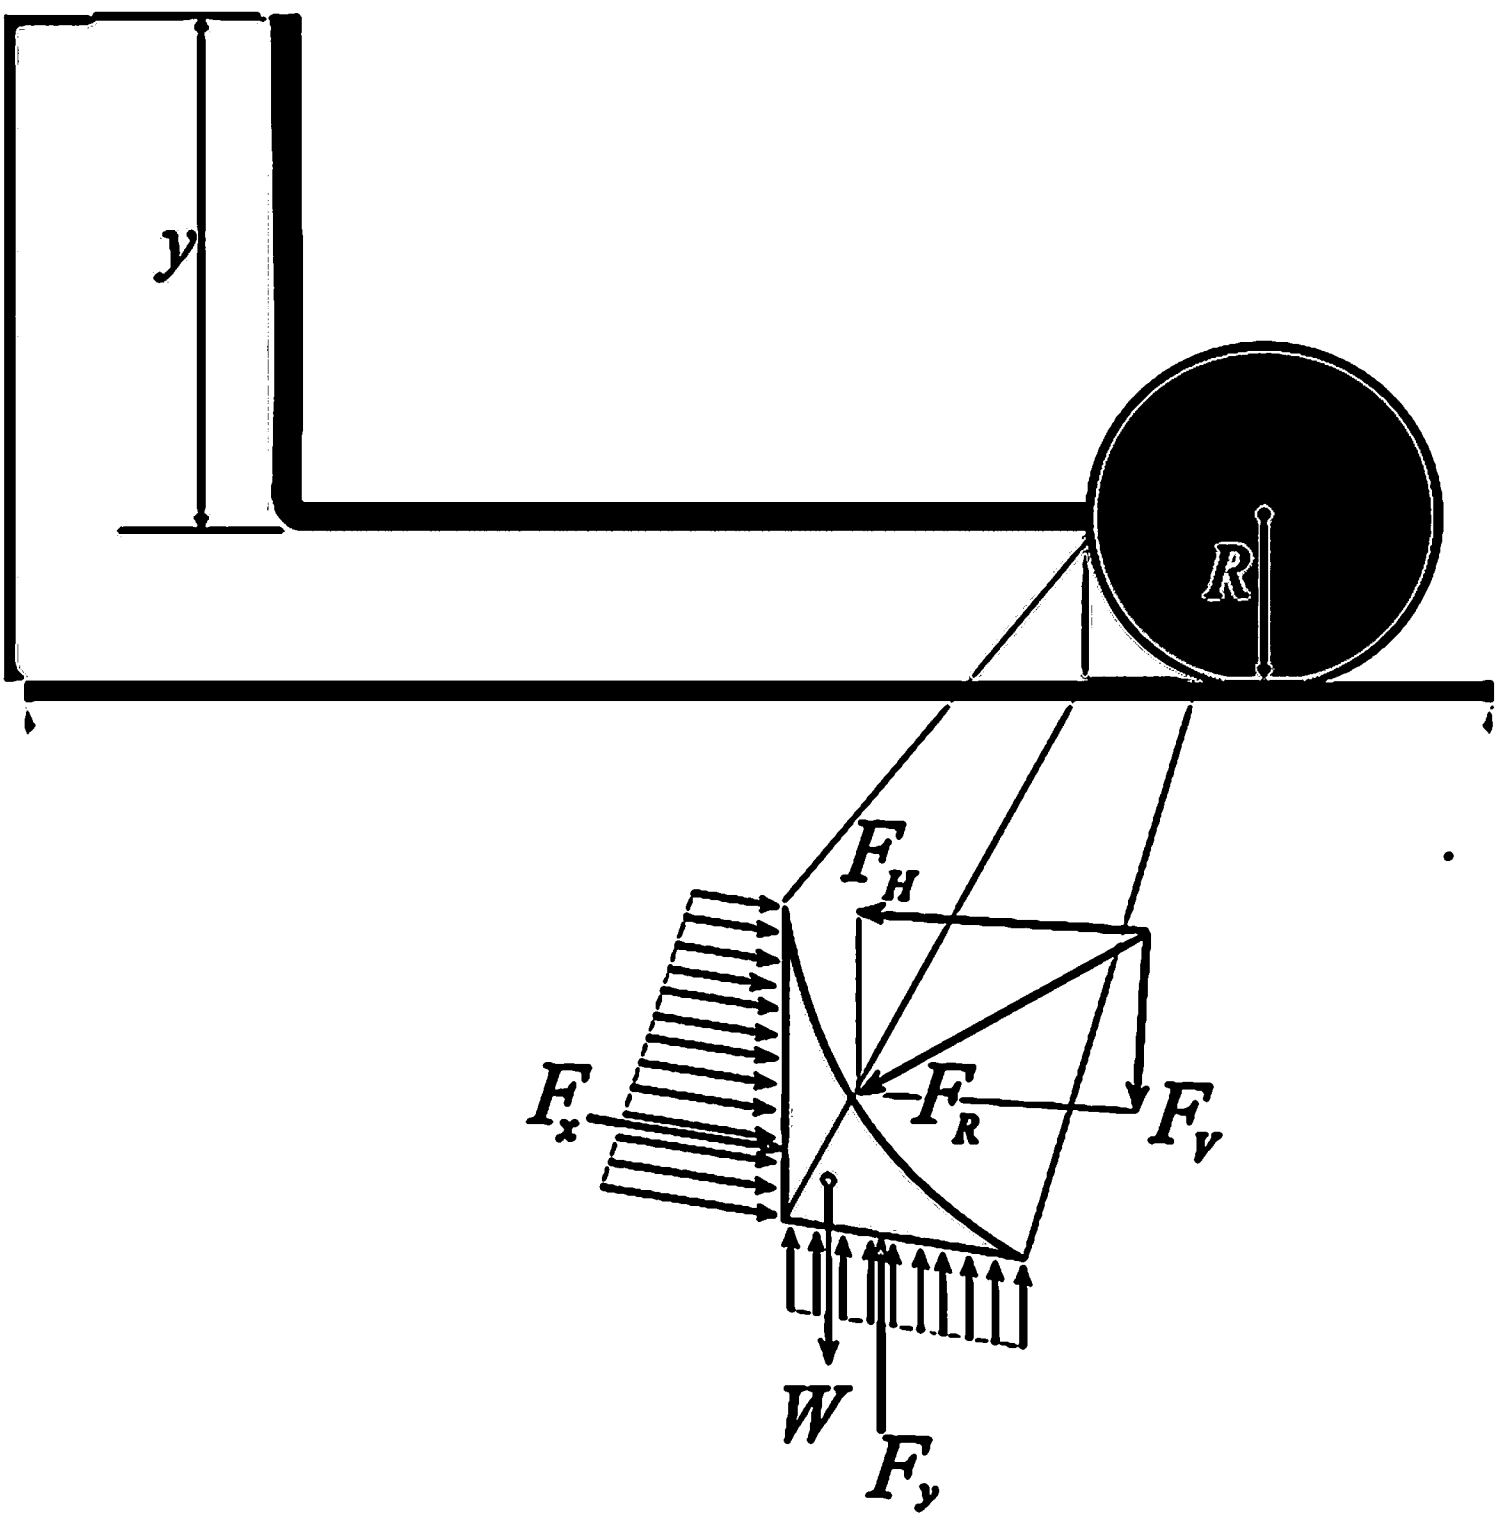


FIGURE P11-9E

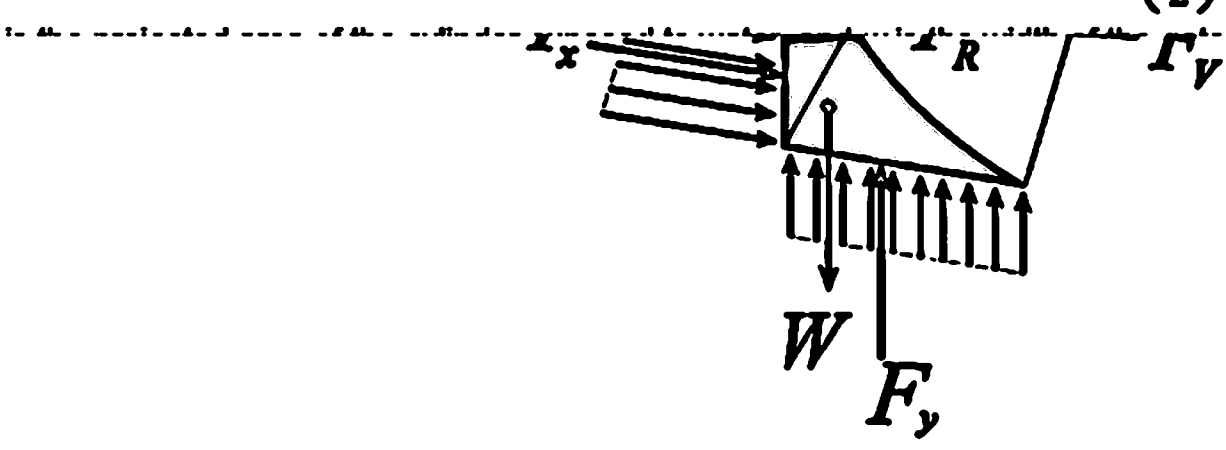
Step 1 of 9

Draw the schematic diagram of the automatic gate:



Step 2 of 9

Consider the liquid part enclosed by the cylinder and the vertical projection of the cylinder shown in the figure:

Calculate the horizontal force acting on the projection of enclosed element (on to the vertical surface) $\left(F_H\right)$:

$$F_H = F_x$$
$$= \rho g h_C A$$
$$= \rho g\left(y+\frac{R}{2}\right)(R\times w)$$

Here, ρ is the density of water, *g* is the acceleration due gravity, *R* is the radius of the cylinder, h_C is the distance between the centre of the gravity of vertical projection of the cylinder $\left(\frac{R}{2}\right)$ and the free surface, *A*

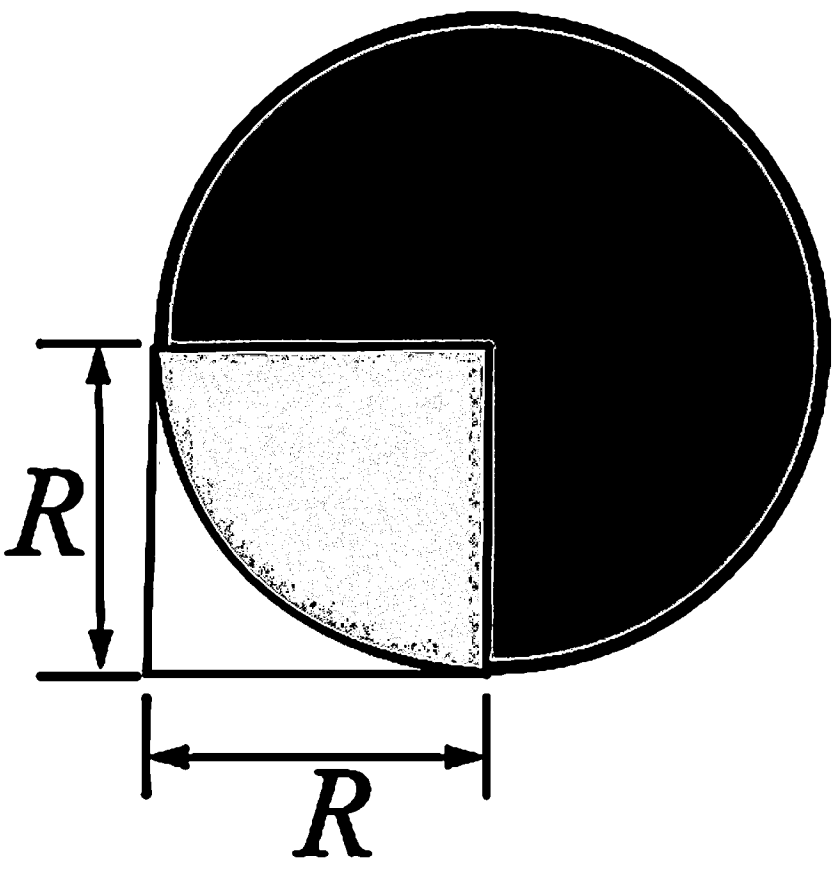
Step 2 of 9

Consider the liquid part enclosed by the cylinder and the vertical projection of the cylinder shown in the figure:

Calculate the horizontal force acting on the projection of enclosed element (on to the vertical surface) $\left(F_H\right)$:

$$F_H = F_x$$
$$= \rho g h_C A$$
$$= \rho g\left(y+\frac{R}{2}\right)(R\times w)$$

Here, ρ is the density of water, *g* is the acceleration due gravity, *R* is the radius of the cylinder, h_C is the distance between the centre of the gravity of vertical projection of the cylinder $\left(\frac{R}{2}\right)$ and the free surface, *A*



Step 4 of 9

Draw the volume of the enclosed element, (*V*) per unit width using the following figure.

Step 4 of 9

Draw the volume of the enclosed element, (V) per unit width using the following figure.

Step 5 of 9

Calculate the volume of the enclosed element using the following equation.

$$V=\left(R^2-\frac{\pi R^2}{4}\right)w$$

Substitute 1 ft for w.

$$V=\left(2^2-\frac{\pi\times 2^2}{4}\right)\times 1$$
$$=0.854\ \text{ft}^3$$

Step 6 of 9

Calculate the weight of the enclosed element per unit width of the gate.

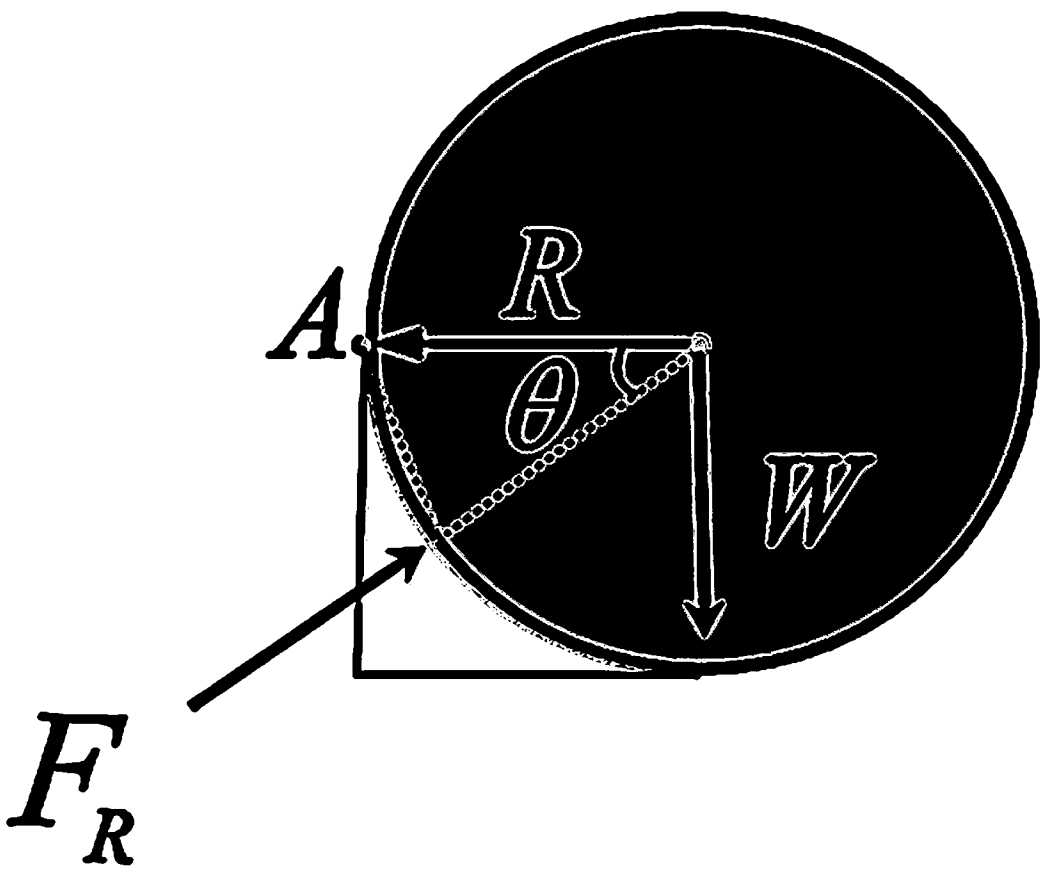
$$W=mg$$
$$=\rho Vg$$
$$=62.4\times 0.858\times 32.2$$
$$=1723962.24\ \text{lbm}\cdot\text{ft/s}^2\times\frac{1\ \text{lbf}}{32.174\ \text{lbm}\cdot\text{ft/s}^2}$$
$$=53.54\ \text{lbf}$$

Calculate the resultant vertical force acting on the enclosed element.

$$F_v=F_y-W$$
$$=1873.51-53.54$$
$$=1819.97\ \text{lbf}$$

Step 7 of 9

Calculate the hydrostatic force acing on the gate, $\left(F_R\right)$ using the following relation.



$$F_R=\sqrt{F_H{}^2+F_V{}^2}$$
$$=\sqrt{1748.61^2+1819.97^2}$$
$$=2523.87\ \text{lbf}$$

Calculate the direction of the hydrostatic force using the following equation.

$$\theta=\tan^{-1}\left(\frac{F_V}{F_H}\right)$$
$$=\tan^{-1}\left(\frac{1819.97}{1748.61}\right)$$
$$=46.15^\circ$$

Step 8 of 9

Consider that the gate is about lift:

Step 9 of 9

Take moment about the hinge A:

$$\sum M_{hinge}=0$$
$$F_R R\sin\theta-W_{cylinder}R=0$$
$$\left(2523.87\times 2\times\sin 46.15^\circ\right)-\left(W_{cylinder}\times 2\right)=0$$
$$W_{cylinder}\times 2=3640.20$$
$$W_{cylinder}=1820.1\ \text{lbf}$$

Therefore, the weight of the cylinder per unit width is $\boxed{1820.1\ \text{lbf}}$.

$W_{cylinder} \times 2 = 3640.20$

$W_{cylinder} = 1820.1 \text{ lbf}$

11.009P pg 3

Therefore, the weight of the cylinder per unit width is $\boxed{1820.1 \text{ lbf}}$.

Question: 11.010P

Consider a 4-m-long, 4-m-wide, and 1.5 aboveground swimming pool that is filled with water to their rim. (*a*) Determine the hydrostatic force on each wall and distance of the line of action of this force from the (*b*) If the height of the walls of the pool is doubled and pool is filled, will the hydrostatic force on each wall double or quadruple? Why?

Step 1 of 5

Given:

Length of swimming pool $= 4\text{m}$

Width of swimming pool $= 4\text{m}$

Height of swimming pool $= 1.5\text{m}$

Step 2 of 5

Specific weight of water, $\gamma = 9810\text{N/m}^3$

Area, $A = 4 \times 1.5$

$= 6\text{m}^2$

The distance from free surface of water to centroid of the wall:

$$h_c = \frac{h}{2}$$
$$= \frac{1.5}{2}$$
$$= 0.75\text{m}$$

Step 3 of 5

(a)

Hydrostatic force on the wall:

$$F = \gamma A h_c$$
$$= 9810 \times 6 \times 0.75$$
$$= 44145\text{N}$$
$$= 44.145\text{kN}$$

Thus the hydrostatic force on each wall is $\boxed{F = 44.145\text{kN}}$

Step 4 of 5

Distance of line of action from the ground:

$$y = \frac{h}{3}$$
$$= \frac{1.5}{3}$$
$$= 0.5\text{m}$$

Thus the distance of line of action from the ground is $\boxed{0.5\text{m}}$.

Step 5 of 5

(b)

Hydrostatic force on the wall when the height of the pool is doubled:

$$F = \gamma A h_c$$
$$= \gamma \frac{2h}{2}(2h \times w)$$
$$= 4\left[\gamma \frac{h}{2}(h \times w)\right]$$

Thus the hydrostatic force quadruples.

Question:

11.011P

Consider a 200-ft-high, 1200-ft-wide dam filled capacity. Determine (*a*) the hydrostatic force on the dam and (*b*) the force per unit area of the dam near the top and near the bottom.

Step 1 of 4

Find the area of the dam wall by using the following formula:

$$A = wh$$

Here, w is the width of the dam and h is the height of the dam.

Substitute 1200 ft for w and 200 ft for h.

$$\begin{aligned} A &= (1200)(200) \\ &= 240000\ \text{ft}^2 \end{aligned}$$

Step 2 of 4

Question:

Consider a 200-ft-high, 1200-ft-wide dam filled capacity. Determine (*a*) the hydrostatic force on the dam and (*b*) the force per unit area of the dam near the top and near the bottom.

Step 1 of 4

Find the area of the dam wall by using the following formula:

$$A = wh$$

Here, w is the width of the dam and h is the height of the dam.

Substitute 1200 ft for w and 200 ft for h.

$$\begin{aligned} A &= (1200)(200) \\ &= 240000\ \text{ft}^2 \end{aligned}$$

Step 2 of 4

$F = F_{avg}$

Substitute $6240\ \text{lb/ft}^2$ for γ and $240000\ \text{ft}^2$ for A.

$$\begin{aligned} F &= 6240 \times 240000 \\ &= 1497600000\ \text{lbf} \\ &= 14.976 \times 10^8\ \text{lbf} \end{aligned}$$

Therefore, the hydrostatic force acting on dam is $\boxed{14.976 \times 10^8\ \text{lbf}}$.

Step 4 of 4

b)

The force per unit area at the top of the dam is $\boxed{\text{zero}}$.

Find the force per unit area at the bottom of the dam by using the following formula:

$$\overline{F} = \gamma h$$

Substitute $6240\ \text{lb/ft}^2$ for γ and 200 ft for h.

$$\begin{aligned} \overline{F} &= 6240 \times 200 \\ &= 1248000\ \text{lbf} \end{aligned}$$

Therefore, the force per unit area at the bottom of the dam is $\boxed{1248000\ \text{lbf}}$.

Question: 11.012P

A room in the lower level of a cruise ship has a 30-cm-diameter circular window. If the midpoint of the window is 4 m below the water surface, determine the hydrostatic force acting on the window, and the pressure center. Take the specific gravity of seawater to be 1.025.

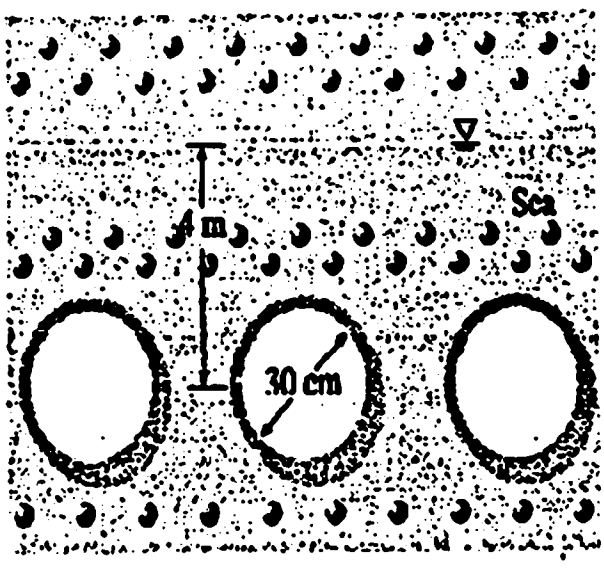


FIGURE P11–12

Step 1 of 4

Given data:

Diameter of the window, $d = 30\,\text{cm} = 0.3\,\text{m}$

The vertical distance between the free surface of water to the centre of window, $h_c = 4\,\text{m}$

Specific gravity of sea water, $SG = 1.025$

Density of sea water,

$$\rho = SG \times \rho_{water}$$
$$= 1.025 \times 1000$$
$$= 1025\,\text{kg/m}^3$$

Step 2 of 4

Area of the window,

$$A = \frac{\pi}{4} d^2$$
$$= \frac{\pi}{4}(0.3)^2$$
$$= 0.07069\,\text{m}^2$$

The average pressure acting on the circular plate,

$$P_{avg} = \rho g h_c$$
$$= 1025 \times 9.81 \times 4$$
$$= 40221\,\text{N/m}^2$$

Step 3 of 4

Hydrostatic force acting on window,

$$F = P_{avg} \times A$$
$$= 40221 \times 0.07069$$
$$= 2843.222\,\text{N}$$

Therefore hydrostatic force acting on window, $\boxed{F = 2843.222\,\text{N}}$.

Moment of inertia of a circular plate about x-axis,

$$I_{xx} = \frac{\pi}{64} d^4$$
$$= \frac{\pi}{64}(0.3)^4$$
$$= 3.976 \times 10^{-4}\,\text{m}^4$$

Step 4 of 4

The perpendicular distance between hydrostatic force and center of window, $y_c = h_c = 4\,\text{m}$

Centre of pressure,

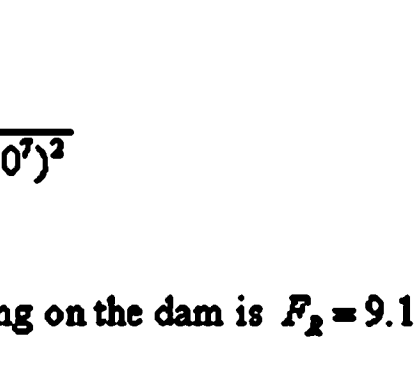
$$y_p = y_c + \frac{I_{xx}}{A y_c}$$
$$= 4 + \frac{3.976 \times 10^{-4}}{0.07069 \times 4}$$
$$= 4 + 1.406 \times 10^{-3}$$
$$= 4.001\,\text{m}$$

Therefore the center of pressure, $\boxed{y_p = 4.001\,\text{m}}$.

Question: 11.013P

The water side of the wall of a 100-m-long dam is a quarter circle with a radius of 10 m. Determine the hydrostatic force on the dam and its line of action when the dam is filled to the rim.

Step 1 of 4



Given data:-

Width of the dam is $w = 100\ \text{m}$

Radius of the quarter circle is $R = 10\ \text{m}$

Step 2 of 4

Consider the free body diagram of the liquid block.

Step 3 of 4

Horizontal force on the vertical surface is

$$F_H = F_x = \rho g h_c A$$

$$= 1000 \times 9.81 \times \frac{10}{2} \times (10 \times 100)$$

$$F_H = 4.905 \times 10^7\ \text{N}$$

Vertical force component on curved surface is

$$F_V = F_y + W$$

Here F_y is zero since it coincides with the free surface of the water.

$$F_y = 0$$

Then weight of the fluid block per meter length is

$$F_V = W = \rho g V$$

$$= 1000 \times 9.81 \times \left(w \times \frac{\pi R^2}{4} \right)$$

$$= 1000 \times 9.81 \times \left(100 \times \frac{\pi \times 10^2}{4} \right)$$

$$F_V = 7.705 \times 10^7\ \text{N}$$

Step 4 of 4

The resultant force on the dam is

$$F_R = \sqrt{F_H^2 + F_V^2}$$

$$= \sqrt{(4.905 \times 10^7)^2 + (7.705 \times 10^7)^2}$$

$$\boxed{F_R = 9.13 \times 10^7\ \text{N}}$$

Therefore the resultant force acting on the dam is $F_R = 9.13 \times 10^7\ \text{N}$

Line of action of the resultant force is

$$\tan\theta = \frac{F_V}{F_H}$$

$$= \frac{7.705 \times 10^7}{4.905 \times 10^7}$$

$$= 1.571$$

$$\boxed{\theta = 57.5^0}$$

Therefore, the line of action of the resultant force is $\theta = 57.5^0$.

Question: 11.014P

A 6-m-high, 5-m-wide rectangular plate blocks the end of a 5-m-deep freshwater channel, as shown in Fig. P11–14. The plate is hinged about a horizontal axis along its upper edge through a point *A* and is restrained from opening by a fixed ridge at point *B*. Determine the force exerted on the plate by the ridge.

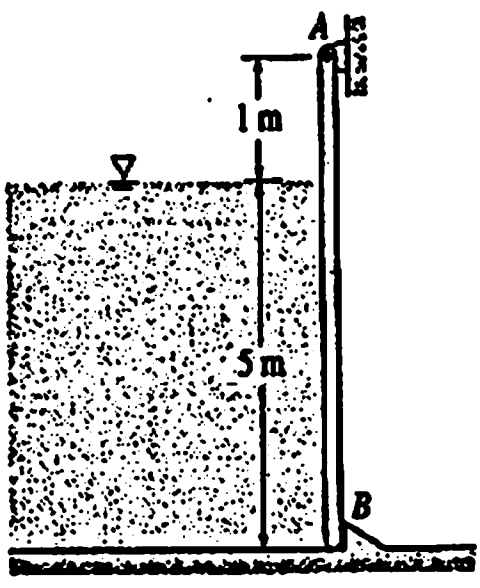


FIGURE P11–14

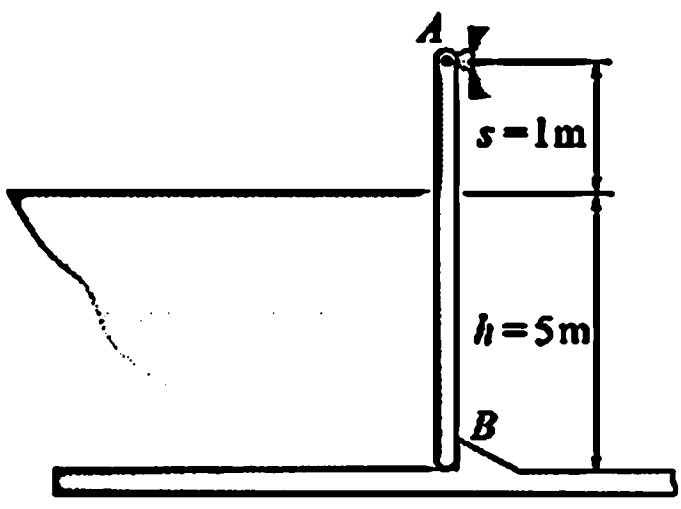
Step 1 of 6

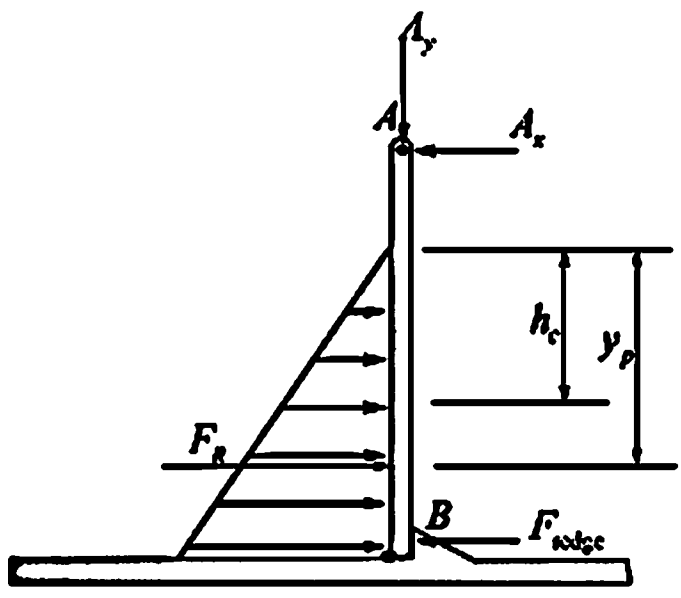
Given data:



Height of rectangular plate, $l = 6\,\text{m}$

Width of rectangular plate, $b = 5\,\text{m}$

Height of fresh water, $h = 5\,\text{m}$



Step 2 of 6

Given figure:

Step 3 of 6

The free body diagram of given figure is as shown in figure-2:

Step 4 of 6

Density of water, $\rho = 1000\,\text{kg/m}^3$

Acceleration due to gravity, $g = 9.81\,\text{m/s}^2$

Area of hydraulic pressure acts on rectangular plate,

$$A = h \times b$$
$$= 5 \times 5$$
$$= 25\,\text{m}^2$$

The centroid of area of hydraulic pressure from the surface of water,

$$h_c = \frac{h}{2}$$
$$= \frac{5}{2}\,\text{m}$$

Step 5 of 6

The average pressure acting on the rectangular plate,

$$P_{avg} = \rho g h_c$$
$$= 1000 \times 9.81 \times \frac{5}{2}$$
$$= 24525\,\text{N/m}^2$$

The hydrostatic force due to water on the plate,

$$F_R = P_{avg} \times A$$
$$= 24525 \times 25$$
$$= 613125\,\text{N}$$
$$= 613.125\,\text{kN}$$

Step 6 of 6

The line of action of the hydrostatic force on rectangular plate,

$$y_p = \frac{2h}{3}$$
$$= \frac{2(5)}{3}$$
$$= 3.33\,\text{m}$$

By taking moment about A, we get $\sum M_A = 0$

$$F_R(s + y_p) - F_{ridge}(\overline{AB}) = 0$$
$$(613.125)(1 + 3.33) - F_{ridge}(6) = 0$$
$$F_{ridge} = 442.47\,\text{kN}$$

Therefore the reaction force at point B, $\boxed{F_{ridge} = 442.47\,\text{kN}}$.

Question: 11.015P

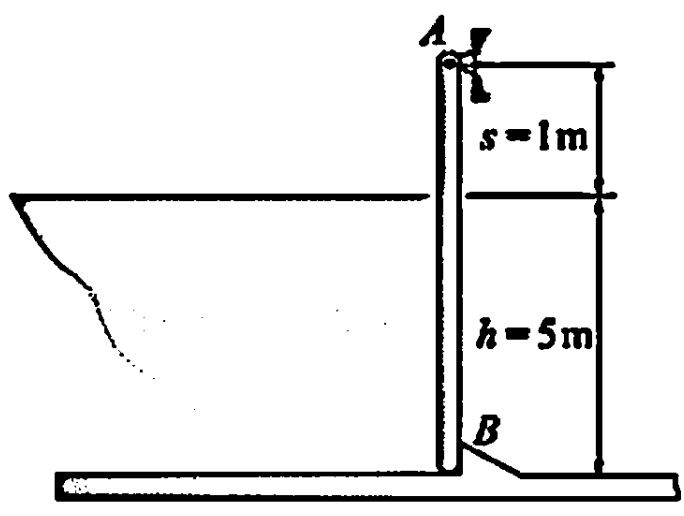
Reconsider Prob. 11–14. Using EES (or other) software, investigate the effect of water depth on the force exerted on the plate by the ridge. Let the water depth vary from 0 to 5 m in increments of 0.5 m. Tabulate and plot your results.

Step 1 of 7

Given data:

Height of rectangular plate above the water surface, $s = 1\text{m}$

Width of rectangular plate, $w = 5\text{m}$



Height of fresh water, $h = 5\text{m}$

Using EES software, investigate the effect of water depth on the force exerted on the plate by the ridge.

The water depth is varying from $0\text{to}5\text{m}$ in increments of 0.5m.

Step 2 of 7

Given figure:

Step 3 of 7

The procedure for developing solution by using EES software:
Open the new equations window EES software and type all the information which is used to solve the problem
For developing table:
1) Click on table followed by new parametric table and add the variables, which are varying variable and required answer variable, then one table will form with that variables
2) Click on the variable which is varying and enter initial value and final value.
3) For getting the required answer variable values corresponding to the varying variable values click on the green color button and then the table will form with required answers
For developing graph:
1) Click on plot followed by new plot window followed by x-y plot.
2) Select the x-axis variable and y-axis variable and then press ok, then the graph will form with the given values.

Step 4 of 7

The equations which are using in EES software for developing the solution are given in equations window is as shown below

Equations Window

```
g=9.81 "m/s^2"
rho=1000 "kg/m^3"
s=1"m"
w=5 "m"
A=w*h
P_ave=rho*g*h/2000 "kPa"
F_R=P_ave*A "kN"
y_p=2*h/3
F_ridge=(s+y_p)*F_R/(s+h)
```

Step 5 of 7

The EES software will convert the equations in equations window to equations in formatting window is as shown below

Formatted Equations

$$g = 9.81 \quad \text{m/s2}$$

$$\rho = 1000 \quad \text{kg/m3}$$

$$s = 1 \quad \text{m}$$

$$w = 5 \quad \text{m}$$

$$A = w \cdot h$$

$$P_{ave} = \rho \cdot g \cdot \frac{h}{2000} \quad \text{kPa}$$

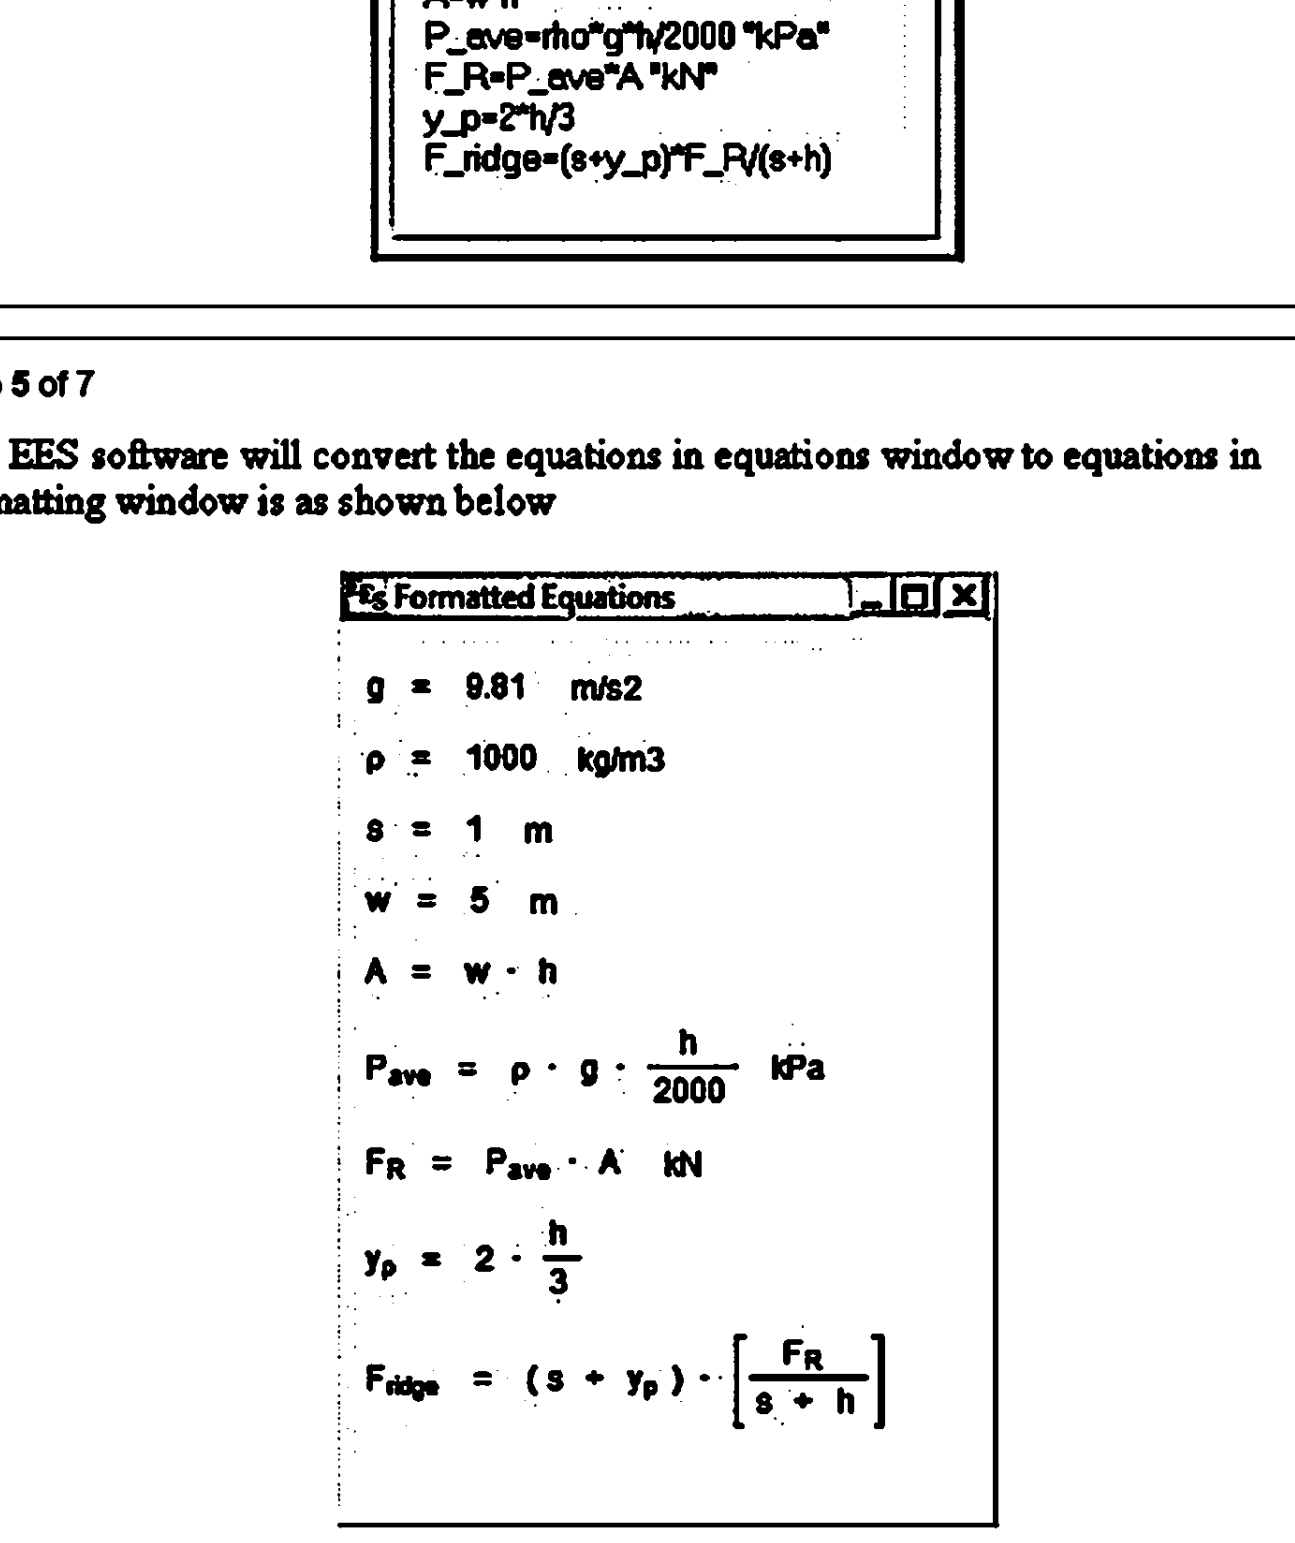
$$F_R = P_{ave} \cdot A \quad \text{kN}$$

$$y_p = 2 \cdot \frac{h}{3}$$

$$F_{ridge} = (s + y_p) \cdot \left[\frac{F_R}{s + h}\right]$$

Step 6 of 7

The EES software is developing the table for F_{ridge} corresponding to the h values is as shown below,



Parametric Table

Table 1

1..11	F_{ridge}	h
Run 1	0	0
Run 2	5.45	0.5
Run 3	20.44	1
Run 4	44.15	1.5
Run 5	76.3	2
Run 6	116.8	2.5
Run 7	165.5	3
Run 8	222.5	3.5
Run 9	287.8	4
Run 10	361.2	4.5
Run 11	442.8	5

Step 7 of 7

The EES software is developing the graph between F_{ridge} and h is as shown below,

Question: 11.016P

The flow of water from a reservoir is controlled by a 5-ft-wide L-shaped gate hinged at point *A*, as shown in Fig. P11–16E. If it is desired that the gate open when the water height is 12 ft, determine the mass of the required weight *W*.

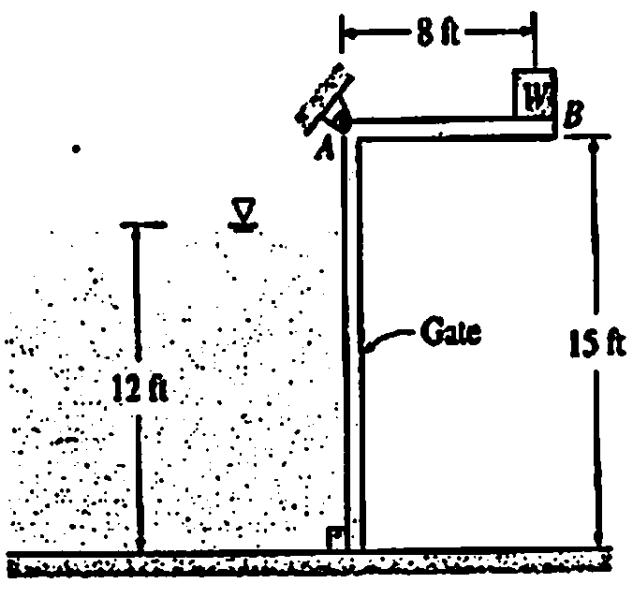


FIGURE P11–16E

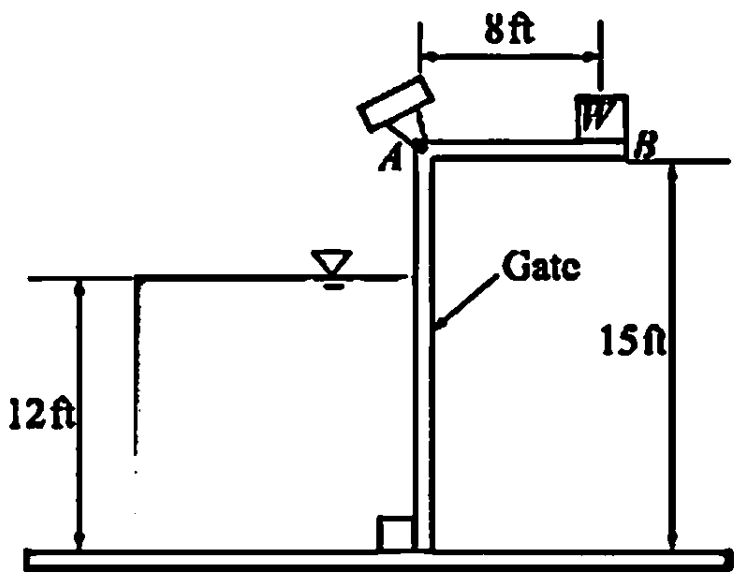
Step 1 of 6

Given data:

Width of the gate, $w = 5\text{ft}$

Height of water, $h = 12\text{ft}$



Height of gate above the water surface, $s = 3\text{ft}$

Density of water, $\rho = 62.4\text{lb/ft}^3$

Acceleration due to gravity, $g = 32.174\text{ft/s}^2$

Step 2 of 6

Given figure:

Step 3 of 6

Area of gate up to water level,

$$A = wh$$
$$= 5\times12$$
$$= 60\text{ft}^2$$

The vertical distance from the top of water to centroid of dam wall,

$$h_c = \frac{h}{2}$$
$$= \frac{12}{2}$$
$$= 6\text{ft}$$

Step 4 of 6

The average pressure acting on the gate,

$$P_{avg} = \rho g h_c$$
$$= 62.4\times32.174\times6$$
$$= 12045.945\text{lbf/ft}^2$$

Hydrostatic force acting on the gate,

$$F = P_{avg}\times A$$
$$= 12045.945\times60$$
$$= 722756.7\text{lbf}$$

Step 5 of 6

Moment of inertia about x-axis at the centroid of gate,

$$I_{xc} = \frac{wh^3}{12}$$
$$= \frac{(5)(12)^3}{12}$$
$$= 720\text{ft}^4$$

Centre of pressure acting on the gate,

$$h_p = h_c + \frac{I_{xc}}{Ah_c}$$
$$= 6 + \frac{720}{60\times6}$$
$$= 8\text{ft}$$

Step 6 of 6

Now taking the moment about A, we get

$$\sum M_A = 0$$
$$W\times8 = 722756.7\times(3+8)$$
$$W = 993790.462\text{lbf}$$

The mass of applied weight,

$$m = \frac{W}{g}$$
$$= \frac{993790.462}{32.174}$$
$$= 30887.998\text{lbm}$$

The mass of applied weight, $\boxed{m = 30887.998\text{lbm}}$.

Question: 11.017P

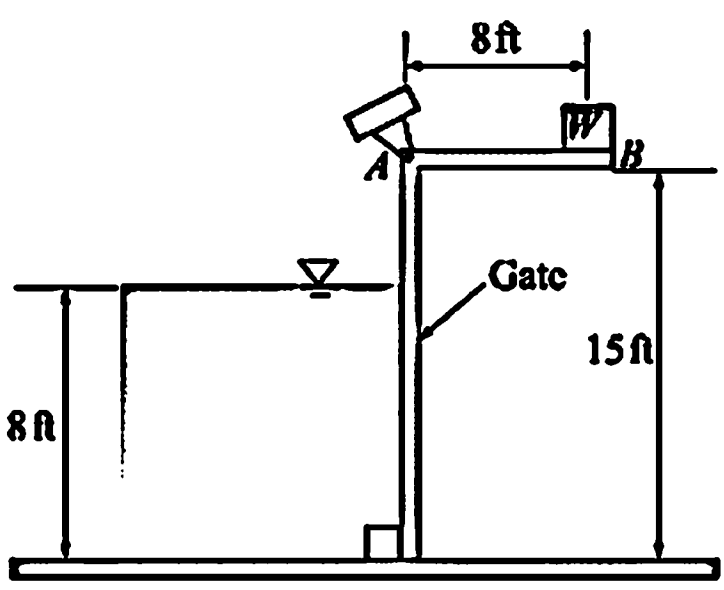
Repeat Prob. 11–16E for a water height of 8 ft.

Step 1 of 6

Given data:

Width of the gate, $w = 5\text{ft}$

Height of water, $h = 8\text{ft}$



Height of gate above the water surface, $s = 7\text{ft}$

Density of water, $\rho = 62.4\text{lb/ft}^3$

Acceleration due to gravity, $g = 32.174\text{ft/s}^2$

Step 2 of 6

Given figure:

Step 3 of 6

Area of gate up to water level,

$$A = wh$$
$$= 5\times 8$$
$$= 40\text{ft}^2$$

The vertical distance from the top of water to centroid of dam wall,

$$h_c = \frac{h}{2}$$
$$= \frac{8}{2}$$
$$= 4\text{ft}$$

Step 4 of 6

The average pressure acting on the gate,

$$P_{avg} = \rho g h_c$$
$$= 62.4\times 32.174\times 4$$
$$= 8030.6304\text{lbf/ft}^2$$

Hydrostatic force acting on the gate,

$$F = P_{avg}\times A$$
$$= 8030.6304\times 40$$
$$= 321225.216\text{lbf}$$

Step 5 of 6

Moment of inertia about x-axis at the centroid of gate,

$$I_{xc} = \frac{wh^3}{12}$$
$$= \frac{(5)(8)^3}{12}$$
$$= 213.333\text{ft}^4$$

Centre of pressure acting on the gate,

$$h_p = h_c + \frac{I_{xc}}{Ah_c}$$
$$= 4 + \frac{213.333}{40\times 4}$$
$$= 5.333\text{ft}$$

Step 6 of 6

Now taking the moment about A, we get

$$\sum M_A = 0$$
$$W\times 8 = 321225.216\times(3+5.333)$$
$$W = 334596.215\text{lbf}$$

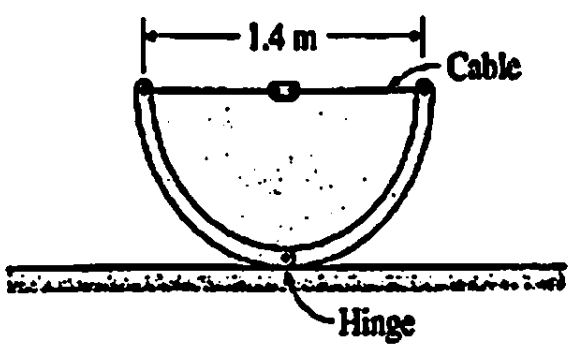
The mass of applied weight,

$$m = \frac{W}{g}$$
$$= \frac{334596.215}{32.174}$$
$$= 10399.5831\text{lbm}$$

The mass of applied weight, $\boxed{m = 10399.5831\text{lbm}}$.

Question: 11.018P

A water trough of semicircular cross section of radius 0.7 m consists of two symmetric parts hinged to each other at the bottom, as shown in Fig. P11–18. The two parts are held together by a cable and turnbuckle placed every 3 m along the length of the trough. Calculate the tension in each cable when the trough is filled to the rim.



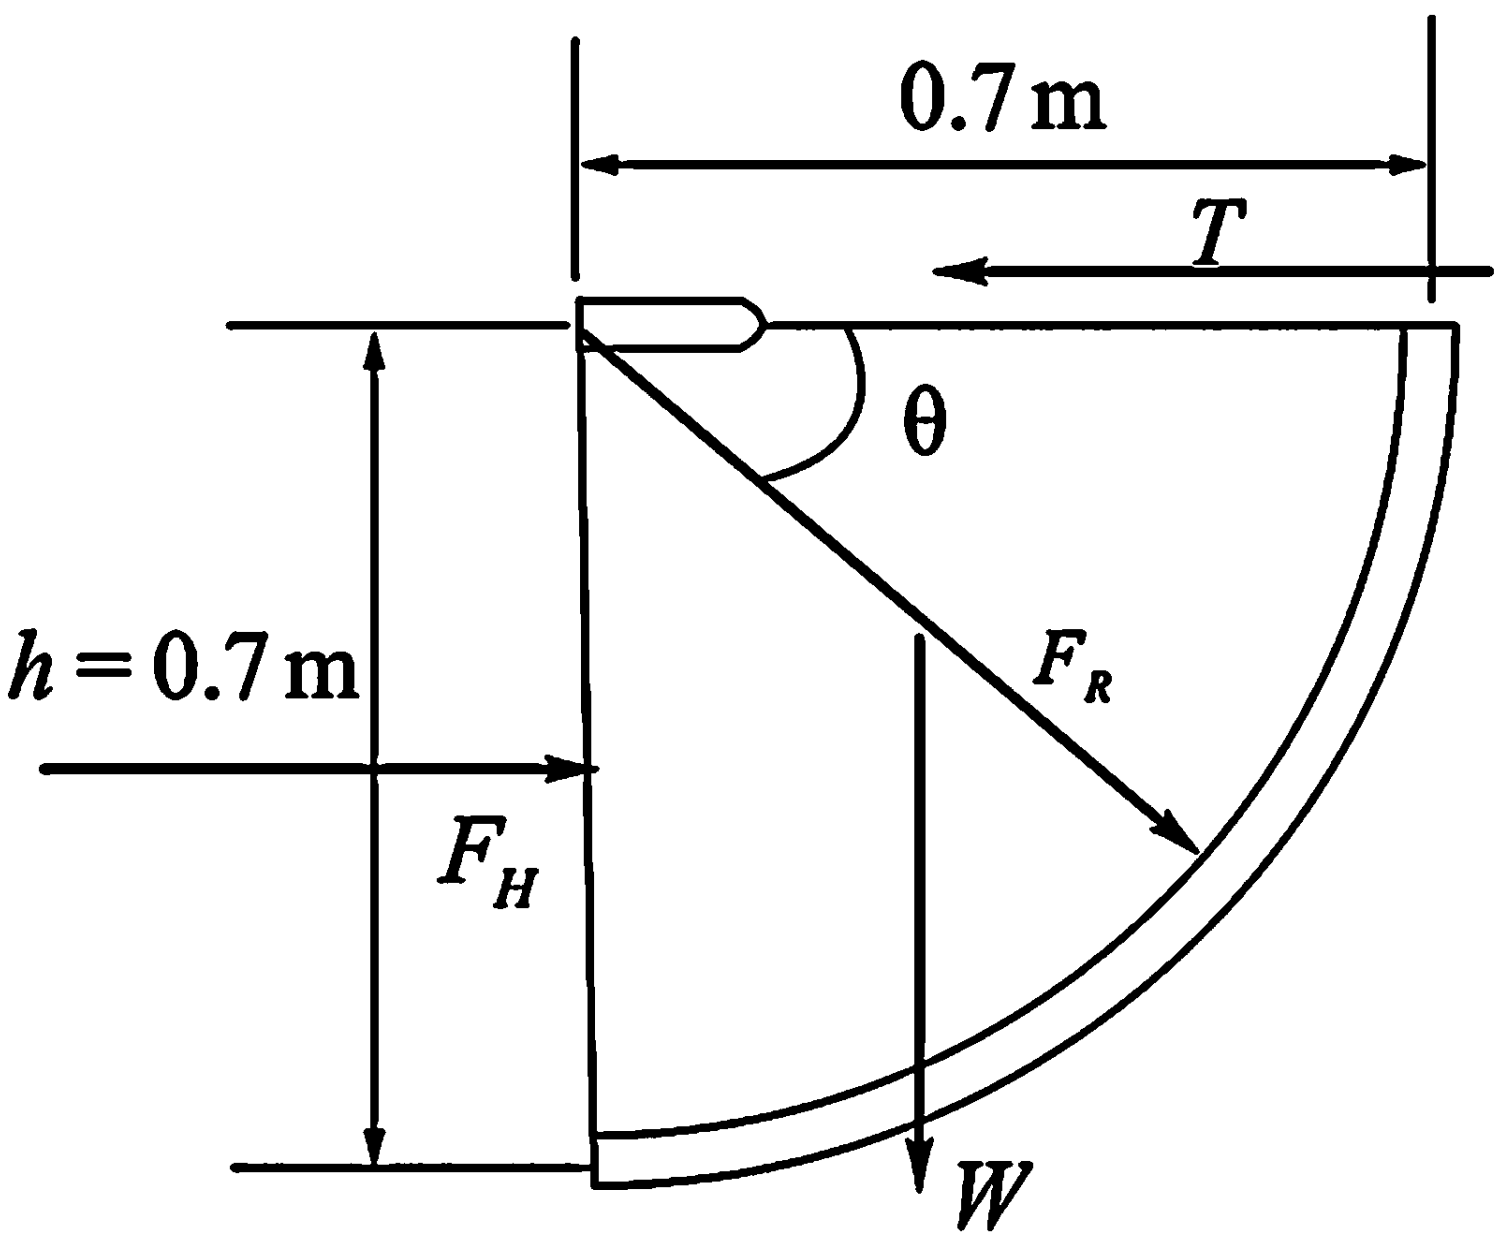


FIGURE P11–18

Step 1 of 4

Consider half of the trough which is in quarter circular shape is as shown in figure:

Step 2 of 4

Find the distance of centroid of rectangle from the surface of water.

$$h_c = \frac{h}{2}$$

Here, h is the height.

Substitute 0.7 m for h.

$$h_c = \frac{0.7}{2}$$
$$= 0.35\,\text{m}$$

Find the cross-sectional area.

$$A_R = rl$$

Here, r is the radius and l is the length.

Substitute 0.7 m for r and 3 m for l.

$$A_R = (0.7)(3)$$
$$= 2.1\,\text{m}^2$$

Find the horizontal hydrostatic force.

$$F_H = \rho g h_c A_R$$

Here, ρ is the density of water and g is the acceleration due to gravity.

Substitute $1000\,\text{kg/m}^3$ for ρ, $9.81\,\text{m/s}^2$ for g, 0.35 m for h_c, and $2.1\,\text{m}^2$ for A_R.

$$F_H = (1000)(9.81)(0.35)(2.1)$$
$$= 7210.35\,\text{N}$$

Step 3 of 4

Find the area of the quarter circle block.

$$A_C = \frac{\pi}{4} r^2$$

Substitute 0.7 m for r.

$$A_C = \frac{\pi}{4}(0.7)^2$$
$$= 0.384845\,\text{m}^2$$

Find the volume of quarter circle block.

$$V = lA_C$$

Substitute 3 m for l and $0.384845\,\text{m}^2$ for A_C.

$$V = (3)(0.384845)$$
$$= 1.1545\,\text{m}^3$$

Find the weight of fluid in the $3\,\text{m}$ block.

$$W = \rho g V$$

Substitute $1000\,\text{kg/m}^3$ for ρ, $9.81\,\text{m/s}^2$ for g and $1.1545\,\text{m}^3$ for V.

$$W = 1000 \times 9.81 \times 1.1545$$
$$= 11325.645\,\text{N}$$

The vertical force is the weight of the fluid in the first quarter circular $3\,\text{m}$ block.

$$F_V = W$$
$$= 11325.645\,\text{N}$$

Step 4 of 4

Find the resultant force acting on the surface of quarter circle.

$$F_R = \sqrt{F_H^2 + F_V^2}$$

Substitute $7210.35\,\text{N}$ for F_H and $11325.645\,\text{N}$ for F_V.

$$F_R = \sqrt{7210.35^2 + 11325.645^2}$$
$$= 13426.07\ \text{N}$$

Find the direction of action of the resultant force.

$$\theta = \tan^{-1}\frac{F_V}{F_H}$$

Substitute $7210.35\,\text{N}$ for F_H and $11325.645\,\text{N}$ for F_V.

$$\theta = \tan^{-1}\left(\frac{11325.645}{7210.35}\right)$$
$$= 57.52°$$

Find the tension in the cable by taking the moments about the point A.

$$\sum M_A = 0$$
$$F_R r \sin(90-\theta)° = Tr$$
$$F_R \sin(90-\theta)° = T$$

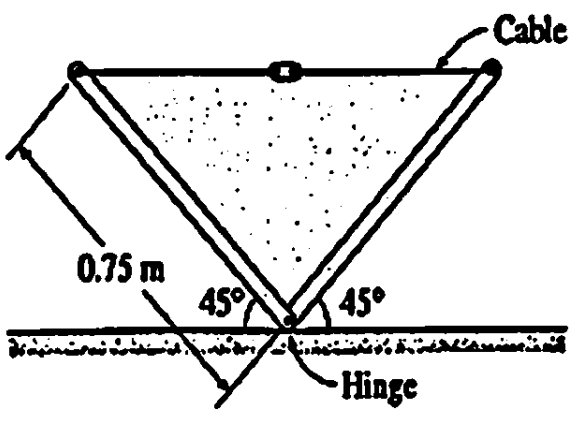
Substitute $13426.07\,\text{N}$ for F_R and $57.52°$ for θ.

$$13426.07 \sin(90-57.52)° = T$$
$$T = 7209.87\,\text{N}$$

Therefore, the tension in the cable is $\boxed{7209.87\,\text{N}}$.

Question: 11.019P

The two sides of a V-shaped water trough are hinged to each other at the bottom where they meet, as shown in Fig. P11–19, making an angle of 45° with the ground from both sides. Each side is 0.75 m wide, and the two parts are held together by a cable and turnbuckle placed every 6 m along the length of the trough. Calculate the tension in each cable when the trough is filled to the rim.



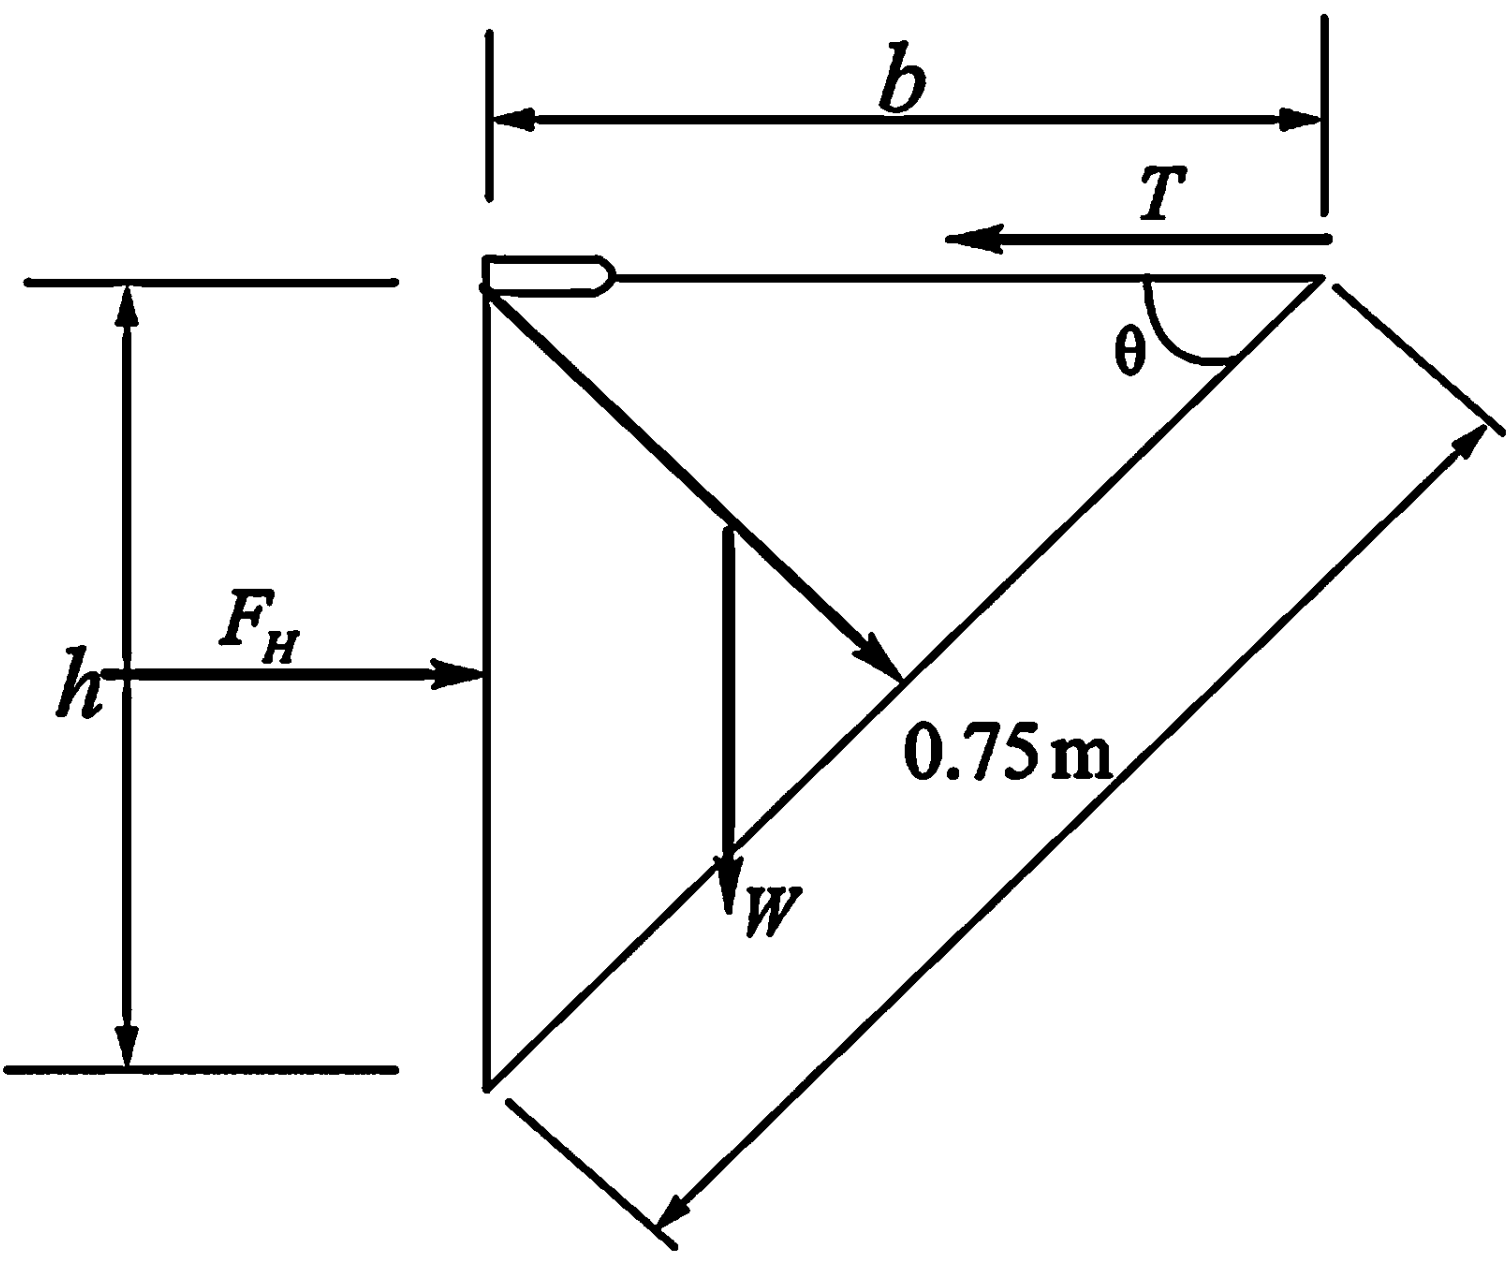


FIGURE P11–19

Step 1 of 8

Consider half of the trough which is in triangular shape is as shown in figure:

Step 2 of 8

Calculate the height of the water with the help of the above figure.

$$h = (0.75)\sin 45°$$
$$= 0.530 \text{ m}$$

Calculate the breadth of the water with the help of the above figure.

$$b = (0.75)\cos 45°$$
$$= 0.530 \text{ m}$$

Calculate the distance of centroid of projected area of water trough; this is a rectangle, from the surface of water.

$$h_c = \frac{h}{2}$$
$$= \frac{0.53}{2}$$
$$= 0.265 \text{ m}$$

Step 3 of 8

Calculate the horizontal hydrostatic force acting on the projected area of the trough.

$$F_H = P_{avg} A_R$$

Here, the average pressure acting the projected area is P_{avg} and the projected area is A_R .

Step 4 of 8

On further continuing, $F_H = (\rho g h_c)(h \times l)$ Here, the density of water is ρ , the acceleration due to gravity is g and the length of first block of trough is l .

Step 5 of 8

Substitute 1000 kg/m^3 for ρ , 9.81 m/s^2 for g and 6 m for l and all the corresponding values in the above equation.

Step 6 of 8

$$F_H = (1000)(9.81)(0.265)(0.530 \times 6)$$
$$= 8266.88 \text{ N}$$

Step 7 of 8

Calculate the vertical force considering the fact that the vertical force is the weight of liquid column itself.

$$F_V = W$$

Here, the weight of the fluid body is W .

Now calculate the weight of fluid body.

$$W = \rho g V$$
$$= (1000)(9.81)\left(6 \times \frac{bh}{2}\right)$$
$$= 9810 \times 6 \times \frac{0.530 \times 0.530}{2}$$
$$= 8266.88 \text{ N}$$

So, the vertical force,

$$F_V = 8266.88 \text{ N}$$

Step 8 of 8

Now, calculate the magnitude of the resultant force.

$$F_R = \sqrt{F_H^2 + F_V^2}$$
$$= \sqrt{8266.8^2 + 8266.8^2}$$
$$= 11691.02 \text{ N}$$

Also, calculate the direction of action of the resultant force,

$$\theta = \tan^{-1}\left(\frac{F_V}{F_H}\right)$$
$$= \tan^{-1}\left(\frac{8266.8}{8266.8}\right)$$
$$= 45°$$

Now take the moments about the point A and equating it to zero we

$$\sum M_A = 0$$
$$T(h) = F_R \cos 45° \times \left(\frac{2h}{3}\right)$$
$$T = \frac{2}{3}(11691.02 \times \cos 45°)$$
$$T = 5511.19 \text{ N}$$

Therefore the tension in each cable, T , is $\boxed{5511.19 \text{ N}}$.

Question: 11.020P

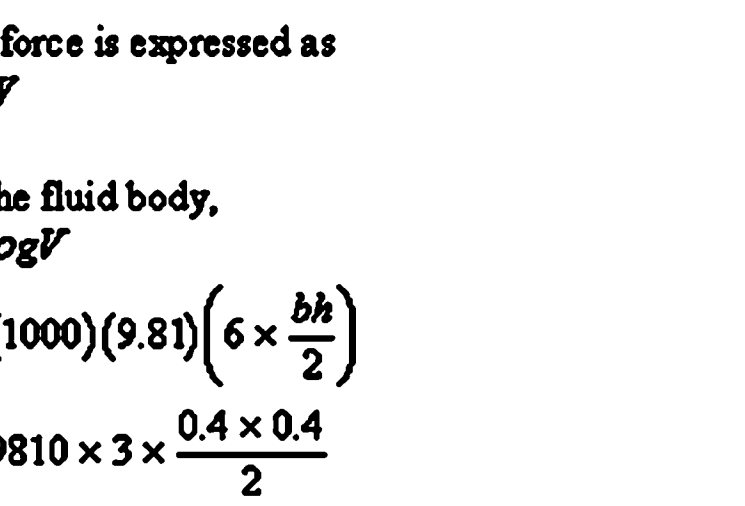
Repeat Prob. 11–19 for the case of a partially filled trough with a water height of 0.4 m directly above the hinge.

Step 1 of 8

Given data:

The trough is partially filled.

The height of the water body from the hinge point is $h = 0.4$ m



The cable and turnbuckle are placed at 6 m intervals along the trough.

The density of water is $\rho = 1000\ \text{kg/m}^3$

Step 2 of 8

Let us assume that the atmospheric pressure acts on both sides of the trough and gets cancelled. The weight of the trough is negligible.

Let us draw the figure for a section of the triangular trough.

Step 3 of 8

From the figure,

The height of the water body,

$h = 0.4$ m

The breadth of the water body,

$b = 0.4$ m

Step 4 of 8

The average pressure on the vertical surface is the pressure value at the centroid of the surface.

$$P_{avg} = P_C$$
$$= \rho g h_C$$

Consider the horizontal force acting on the vertical surface,

$$F_H = P_{avg} A$$
$$= \rho g h_C A$$
$$= (1000)(9.81)\left(\frac{0.4}{2}\right)(0.4 \times 3)$$
$$= 2354.4\ \text{N}$$

Step 5 of 8

The force acting on the horizontal coincides with the free surface of water hence can be neglected.

Therefore the vertical force is expressed as

$$F_V = W$$

Where the weight of the fluid body,

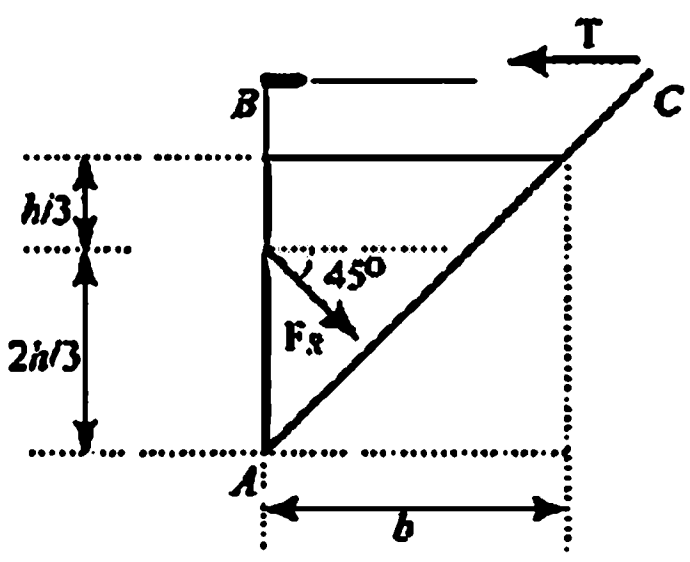
$$W = \rho g V$$
$$= (1000)(9.81)\left(6 \times \frac{bh}{2}\right)$$
$$= 9810 \times 3 \times \frac{0.4 \times 0.4}{2}$$
$$= 2354.4\ \text{N}$$

Therefore the vertical force is $F_V = 2354.4$ N

Step 6 of 8

The magnitude of the resultant force,

$$F_R = \sqrt{F_H^2 + F_V^2}$$
$$= \sqrt{2354.4^2 + 2354.4^2}$$
$$= 3329.6\ \text{N}$$



Step 7 of 8

The direction of action of the force,

$$\theta = \tan^{-1}\left(\frac{F_V}{F_H}\right)$$
$$= \tan^{-1}\left(\frac{2354.4}{2354.4}\right)$$
$$= 45°$$

Step 8 of 8

Let us draw the figure

Question: 11.021P

A retaining wall against a mud slide is to be constructed by placing 1.2-m-high and 0.25-m-wide rectangular concrete blocks (ρ = 2700 kg/m3) side by side, as shown in Fig. P11–21. The friction coefficient between the ground and the concrete blocks is f = 0.3, and the density of the mud is about 1800 kg/m3. There is concern that the concrete blocks may slide or tip over the lower left edge as the mud level rises. Determine the mud height at which (*a*) the blocks will overcome friction and start sliding and (*b*) the blocks will tip over.

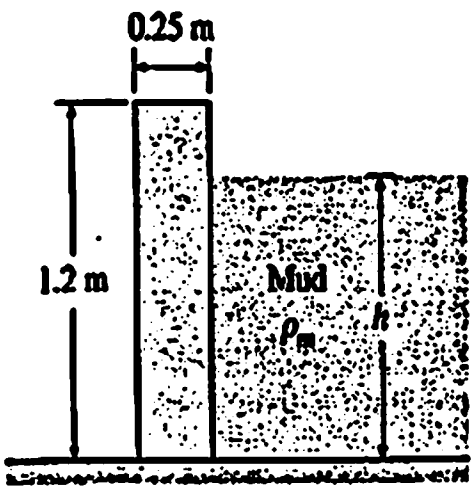


FIGURE P11–21

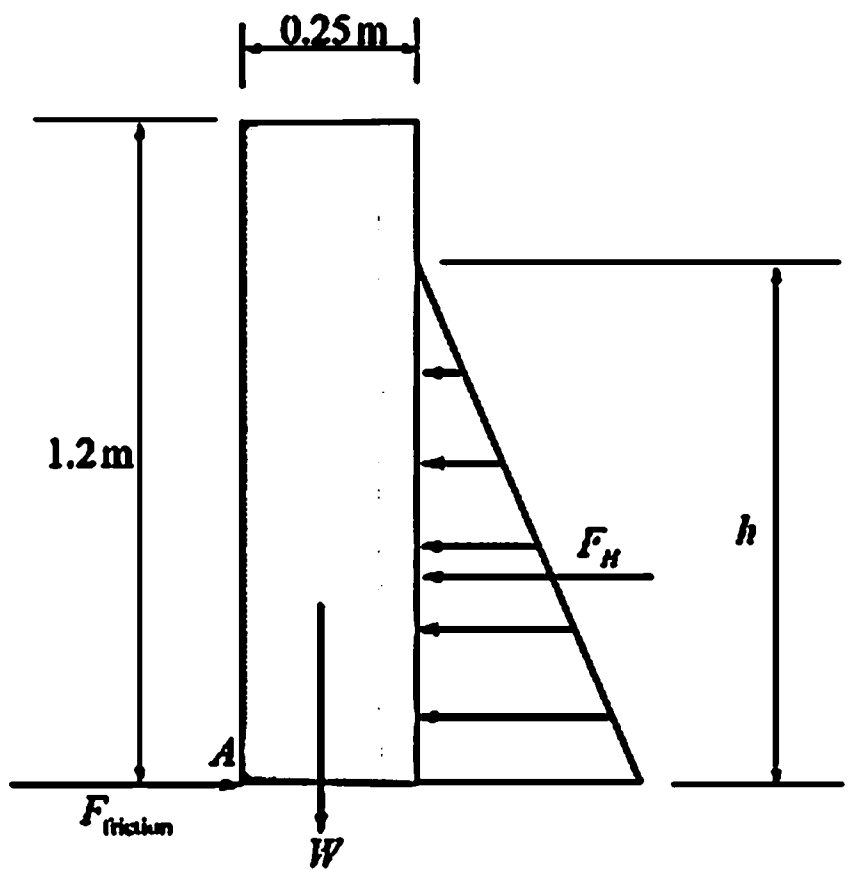
Step 1 of 6

Given data:

The height of rectangular concrete block, $H = 1.2\,\text{m}$

The width of rectangular concrete block, $w = 0.25\text{m}$

The coefficient of friction between ground and concrete blocks, $f = 0.3$



Density of mud is 1800 kg/m^3.

Density of concrete is 2700 kg/m^3.

The height of mud is h

Step 2 of 6

The free body diagram of the given figure is as shown below,

Step 3 of 6

The weight of the concrete wall per unit length

$W = \rho g V$

$= (2700)(9.81)(w \times H \times 1)$

$= (2700)(9.81)(0.25 \times 1.2 \times 1)$

$= 7946.1\text{N}$

Frictional force between the wall and ground

$F_{friction} = fW$

$= (0.3)(7946.1)$

$= 2383.83\text{N}$

Step 4 of 6

The shape of mud at the contact of mud and wall is rectangular shape,

Now the centroid of that rectangle from the surface of mud, $h_c = \dfrac{h}{2}$

Hydrostatic force exerted by mud on the wall

$F_H = (\rho g h_c) A$

$= [(1800\text{kg/m}^3)(9.81\ \text{m/s}^2)(h/2)](h \times 1)$

$= 8829h^2$

Step 5 of 6

a)

For the height of mud to start sliding of block:

When the horizontal hydrostatic force is equal to frictional force then the block will start sliding, therefore,

$F_H = F_{friction}$

$8829h^2 = 2384$

$h = 0.5196\,\text{m}$

Therefore the height of mud to start sliding of block, $\boxed{h = 0.5196\,\text{m}}$

Step 6 of 6

b)

For the height of mud to tip over the block:

The line of action of F_H is $2h/3$ from the mud surface.

Taking moments about point A and equate it to zero.

$\sum M_A = 0$

$W(0.125) = F_H(h/3)$

$(7946.1)(0.125) = (8829h^2)(h/3)$

$h = 0.6962\,\text{m}$

Therefore, the height of mud to tip over the block, $\boxed{h = 0.6962\,\text{m}}$

Question: 11.022P

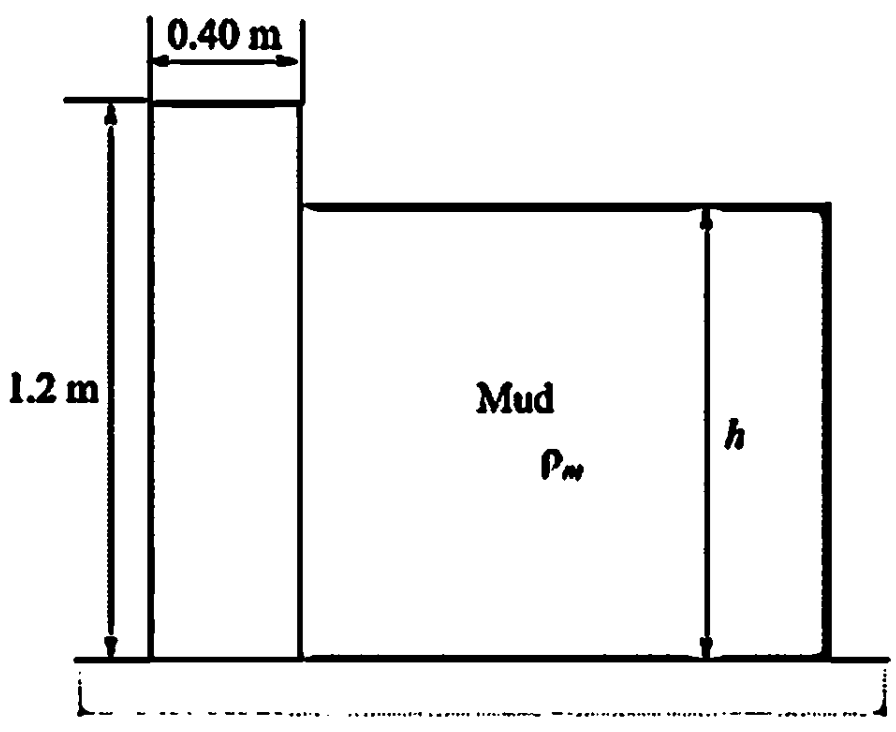
Repeat Prob. 11–21 for 0.4-m-wide concrete blocks.

Step 1 of 8

Given Data:

Density of mud, $\rho_m = 1800\ \text{kg/m}^3$.

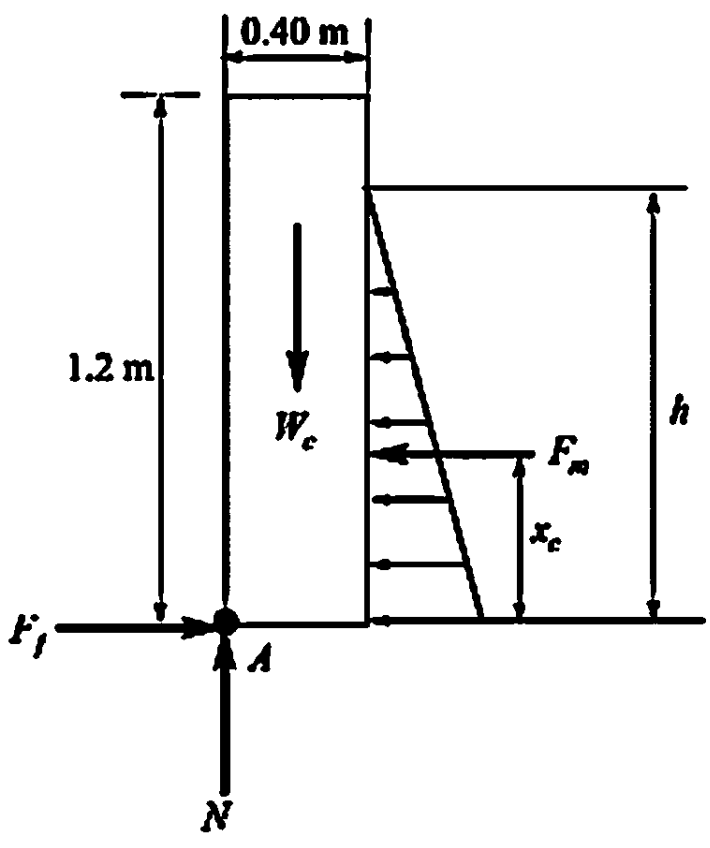
Density of concrete, $\rho_c = 2700\ \text{kg/m}^3$.



Width of the concrete block, $w = 0.4\ \text{m}$.

Height of the concrete block, $h_c = 1.2\ \text{m}$.

Coefficient of friction between the ground and the concrete block, $f = 0.3$



Step 2 of 8

Given figure is shown:

Step 3 of 8

Forces acting on the retaining wall are shown:

Step 4 of 8

Volume of the concrete block per unit length is given by,

$$V_c = l \times h_c \times w$$
$$= 1 \times 1.2 \times 0.4$$
$$= 0.48\ \text{m}^3$$

Weight of the concrete block per unit length is given by,

$$W_c = \rho_c g V_c$$
$$= 2700 \times 9.81 \times 0.48$$
$$= 12713.76\ \text{N}$$

Step 5 of 8

Normal reaction between the wall and the wall is given by,

$$N = W_c$$
$$= 12713.76\ \text{N}$$

Frictional force between the ground and the concrete wall is given by,

$$F_f = f \times N$$
$$= 0.3 \times 12713.76$$
$$= 3814.128\ \text{N}$$

Step 6 of 8

Pressure acting by the hydrostatic mud on the retaining wall is given by,

$$P_m = \frac{1}{2} \times \rho_m g h$$
$$= \frac{1}{2} \times 1800 \times 9.81 \times h$$
$$= 8829h$$

The hydrostatic force acting on the retaining wall due to the mud per unit length is given by,

$$F_m = P_m \times h \times 1$$
$$= 8829h \times h \times 1$$
$$= 8829h^2$$

The height of the hydrostatic force acting on the retaining wall due to the mud from the ground is given by,

$$x_m = h \times \frac{1}{3}$$
$$= \frac{h}{3}$$

Step 7 of 8

(a)

For the block to start sliding:

$$F_f = F_m$$

$$3814.128 = 8829h^2$$

$$h = 0.657\ \text{m}$$

Therefore, the blocks will over come friction and start sliding at height of mud,

$\boxed{h = 0.657\ \text{m}}$

Step 8 of 8

(b)

For the blocks to tip over:

$$\sum M_A = 0$$

$$-W_c \times \left(\frac{0.4}{2}\right) + F_m \times x_m = 0$$

$$-12713.76 \times 0.2 + 8829h^2 \times \frac{h}{3} = 0$$

$$h = 0.952\ \text{m}$$

Therefore, the blocks will tip over at height of mud, $\boxed{h = 0.952\ \text{m}}$

Question: 11.023P

A 4-m-long quarter-circular gate of radius 3 m and of negligible weight is hinged about its upper edge *A*, as shown in Fig. P11–23. The gate controls the flow of water over the ledge at *B*, where the gate is pressed by a spring. Determine the minimum spring force required to keep the gate closed when the water level rises to *A* at the upper edge of the gate.

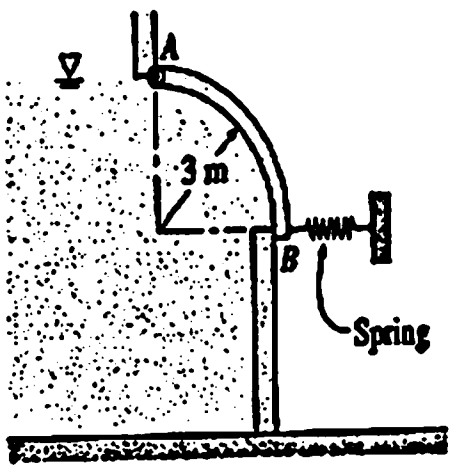


FIGURE P11–23

Step 1 of 5

Given data:

Length of the quarter circular plate=4 m

Radius of the quarter circular plate=3 m

Step 2 of 5

Horizontal force on the vertical surface

$$F_H = \rho g h_c A$$
$$= (1000\text{kg/m}^3)(9.81\text{m/s}^2)(3/2\text{m})(4\text{m}\times 3\text{m})$$
$$= 176.58\text{kN}$$

Vertical force on horizontal surface

$$F_y = \rho g h_{bottom} A$$
$$= (1000\text{kg/m}^3)(9.81\text{m/s}^2)(3\text{m})(4\text{m}\times 3\text{m})$$
$$= 353.2\text{kN}$$

Step 3 of 5

Weight of the fluid block per 4 m length

$$W = \rho g V$$
$$= (1000\text{kg})(9.81\text{m/s}^2)(w\times \pi R^2/4)$$
$$= (1000\text{kg})(9.81\text{m/s}^2)(4\times \pi(3)^2/4)$$
$$= 277.37\text{N}$$

The net upward force

$$F_V = F_y - W$$
$$= 353.2 - 277.37$$
$$= 75.83\text{kN}$$

Step 4 of 5

The resultant force

$$F_R = \sqrt{F_H^2 + F_V^2}$$
$$= \sqrt{(176.58)^2 + (75.83)^2}$$
$$= 192.17\text{kN}$$

$$\tan\theta = \frac{F_V}{F_H}$$
$$= \frac{75.83}{176.58}$$
$$= 0.429$$
$$\theta = 23.24^\circ$$

Step 5 of 5

The minimum spring force is determined by taking the moment about the hinge A.

$$\sum M_A = 0$$
$$F_R R\sin(90-\theta) - F_{spring} R = 0$$
$$F_R R\sin(90-\theta) = F_{spring} R$$
$$192.17\sin(90-23.24) = F_{spring}$$
$$F_{spring} = 176.57\text{kN}$$

Therefore the minimum spring force required is $\boxed{F_{spring} = 176.57\text{kN}}$.

Question: 11.024P

Repeat Prob. 11–23 for a radius of 4 m for the gate.

Step 1 of 4

Given data:-

Radius of the gate is $r = 4$ m

Step 2 of 4

Horizontal force on the vertical surface is

$$F_H = \rho g h_c A$$
$$= 1000 \times 9.81 \times \frac{4}{2} \times (4 \times 4)$$
$$= 314 \text{ kN}$$

Vertical force on horizontal surface is

$$F_V = \rho g h_{bottom} A$$
$$= 1000 \times 9.81 \times 4 \times (4 \times 4)$$
$$= 627.8 \text{ kN}$$

Step 3 of 4

Weight of the fluid block per 4 m length is

$$W = \rho g V$$
$$= 1000 \times 9.81 \times \left(w \times \frac{\pi r^2}{4} \right)$$
$$= 9810 \times \left(4 \times \frac{\pi \times 4^2}{4} \right)$$
$$= 493.104 \text{ kN}$$

The net upward force is

$$F_V = F_y - W$$
$$= 627.8 - 493.104$$
$$= 135 \text{ kN}$$

Step 4 of 4

The resultant force is

$$F_R = \sqrt{F_H^2 + F_V^2}$$
$$= \sqrt{(314)^2 + (135)^2}$$
$$= 341.8 \text{ kN}$$
$$\tan\theta = \frac{F_V}{F_H}$$
$$= \frac{135}{314}$$
$$= 0.429$$
$$\theta = 23.2^0$$

The minimum spring force is determined by taking the moment about the hinge A.

$$\sum M_A = 0$$
$$F_R R \sin(90 - \theta) - F_{spring} R = 0$$
$$F_{spring} = F_R \sin(90 - 23.2)$$
$$F_{spring} = F_R \sin(66.8)$$
$$\boxed{F_{spring} = 314 \text{ kN}}.$$

Therefore the minimum spring force required to keep the gate closed is $F_{spring} = 314$ kN.

Question: 11.025P

What is buoyant force? What causes it? What is the magnitude of the buoyant force acting on a submerged body whose volume is V? What are the direction and the line of action of the buoyant force?

Step 1 of 1

The force exerted by the fluid on an immersed body is known as buoyant force.
The main reason for buoyancy force is when the depth increases, the pressure of water increases. The magnitude of buoyant force on a submerged body whose volume is V is:

$$F_B = \rho_f g V$$

The direction of the buoyancy force is towards upwards and its line of action passes through the centroid of the displaced volume.

Question: 11.026P

Consider two identical spherical balls submerged in water at different depths. Will the buoyant forces acting on these two balls be the same or different? Explain.

Step 1 of 1

The buoyant force on the two spheres is same when submerged at different depths. The magnitude of buoyant force does not depend upon the depth of water as it is clear from the formula:

$F_B = \rho_f g V$

Where F_B is buoyant force

ρ_f is density of fluid

g is gravitational constant

V is volume

Question: 11.027P

Consider two 5-cm-diameter spherical ballsone made of aluminum, the other of iron—submerged in water. Will the buoyant forces acting on these two balls be the same or different? Explain.

Step 1 of 1

The buoyant force acting on the iron and aluminum balls are same. This is because buoyant force depends on the density of fluid, but not on the density of immersed body.

Buoyant force is given as

$$F_B = \rho_f g V$$

where F_B is buoyant force

ρ_f is density of fluid

g is gravitational constant

V is volume

Question: 11.028P

Consider a 3-kg copper cube and a 3-kg copper ball submerged in a liquid. Will the buoyant forces acting on these two bodies be the same or different? Explain.

Step 1 of 1

The buoyant force acting on copper cube and copper ball are same. Buoyant force depends on the volume, but not on the shape of body. Buoyant force is:

$$F_B = \rho_f g V$$

Where F_B is buoyant force

ρ_f is density of fluid

g is gravitational constant

V is volume

Question: 11.029P

Discuss the stability of (*a*) a submerged and (*b*) a floating body whose center of gravity is above the center of buoyancy.

Step 1 of 2

a) A submerged body whose centre of gravity G is above the center of buoyancy B is unstable.

Step 2 of 2

b) For a floating body, when G is above B, it is stable. The centroid of the displaced volume shifts to the side to a point B during a rotational disturbance while the centre of gravity G of the body remains unchanged. Hence the floating body will be stable when G is above B.

Question: 11.030P

The density of a liquid is to be determined by an old 1-cm-diameter cylindrical hydrometer whose division marks are completely wiped out. The hydrometer is first dropped in water, and the water level is marked. The hydrometer is then dropped into the other liquid, and it is observed that the mark for water has risen 0.6 cm above the liquid–air interface (Fig. P11–30). If the height of the original water mark is 13.6 cm, determine the density of the liquid.

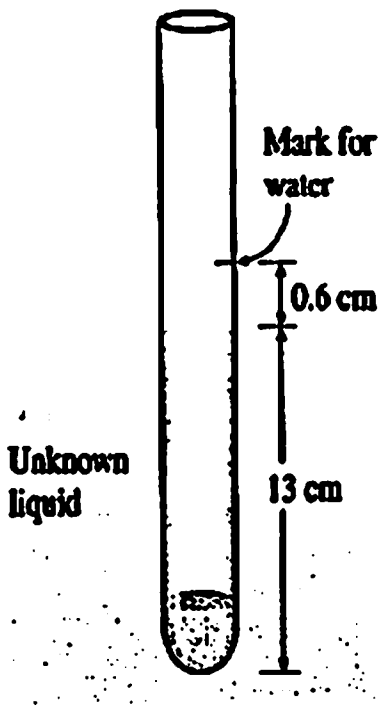

FIGURE P11–30

Step 1 of 4

Given Data:

Diameter of the cylindrical hydrometer, $d = 1$ cm

The height of the water mark when it is dropped in water, $h_{water} = 13.60$ cm

Difference between the height of the water mark and the liquid mark,

$h_{water} - h_{liquid} = 0.6$ cm

Step 2 of 4

Density of water, $\rho_{water} = 1000\ \text{kg/m}^3$

Let the cross-sectional area of the hydrometer be A.

Height of the water mark is given by,

$$h_{liquid} = h_{water} - 0.60$$
$$= 3.60 - 0.60$$
$$= 3.0 \text{ cm}$$

Volume of the hydrometer submerged in water is given by

$$V_{water} = A \times h_{water}$$
$$= A \times 13.6$$

Volume of the hydrometer submerged in liquid is given by

$$V_{liquid} = A \times h_{liquid}$$
$$= A \times 13.0$$

Step 3 of 4

Buoyancy force exerted by the water on the hydrometer is given by

$$F_{B_{water}} = \rho_{water} g V_{water}$$
$$= 1000 \times g \times A \times 13.6$$
$$= 13600 \times g \times A$$

Buoyancy force exerted by the liquid on the hydrometer is given by

$$F_{B_{liquid}} = \rho_{liquid} g V_{liquid}$$
$$= \rho_{liquid} \times g \times A \times 13.0$$
$$= 13.0 \times \rho_{liquid} \times g \times A$$

Step 4 of 4

The buoyancy force exerted by the liquid on the hydrometer must be equal to the buoyancy force exerted by the water on the hydrometer.

$$F_{B_{liquid}} = F_{B_{water}}$$

$$13.0 \times \rho_{liquid} \times g \times A = 13600 \times g \times A$$

$$\rho_{liquid} = \frac{13600}{13.0}$$
$$= 1046.15\ \text{kg/m}^3$$

Therefore, the density of the liquid, $\boxed{\rho_{liquid} = 1046.15\ \text{kg/m}^3}$

Question: 11.031P

A crane is used to lower weights into a lake for an underwater construction project. Determine the tension in rope of the crane due to a 3-ft-diameter spherical steel block(density = 494 lbm/ft3) when it is (*a*) suspended in the air and (*b*) completely immersed in water.

Step 1 of 5

Given Data:

Diameter of the spherical steel block, $d = 3\,\text{ft}$

Density of the spherical steel block, $\rho_s = 494\ \text{lbm/ft}^3$

Volume of the spherical steel block is given by,

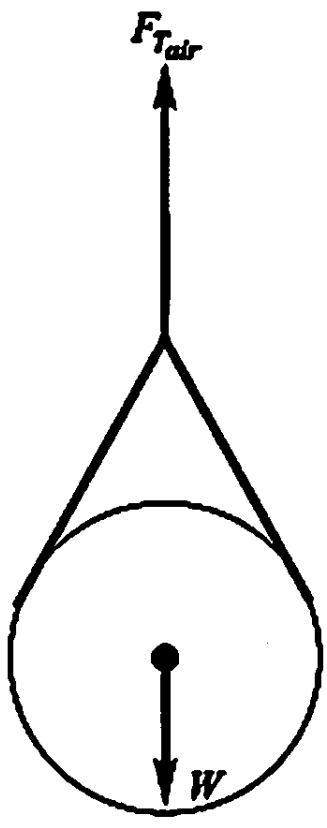
$$V = \frac{4}{3}\pi\left(\frac{d}{2}\right)^3$$

$$= \frac{4}{3}\times\pi\times\left(\frac{3}{2}\right)^3$$

$$= 14.1372\,\text{ft}^3$$

Weight of the spherical steel block is given by,

$$W = \rho_s \times g \times V$$



$$= 494\times 32.174\times 14.1372$$

$$= 224696.0348\ \text{lbm}\cdot\text{ft/sec}^2\left|\frac{1\,\text{lbf}}{32.174\ \text{lbm}\cdot\text{ft/sec}^2}\right|$$

$$= 6983.78\,\text{lbf}$$

Step 2 of 5

Free body diagram of the spherical block when it is suspended in water is shown:

Step 3 of 5

(a)

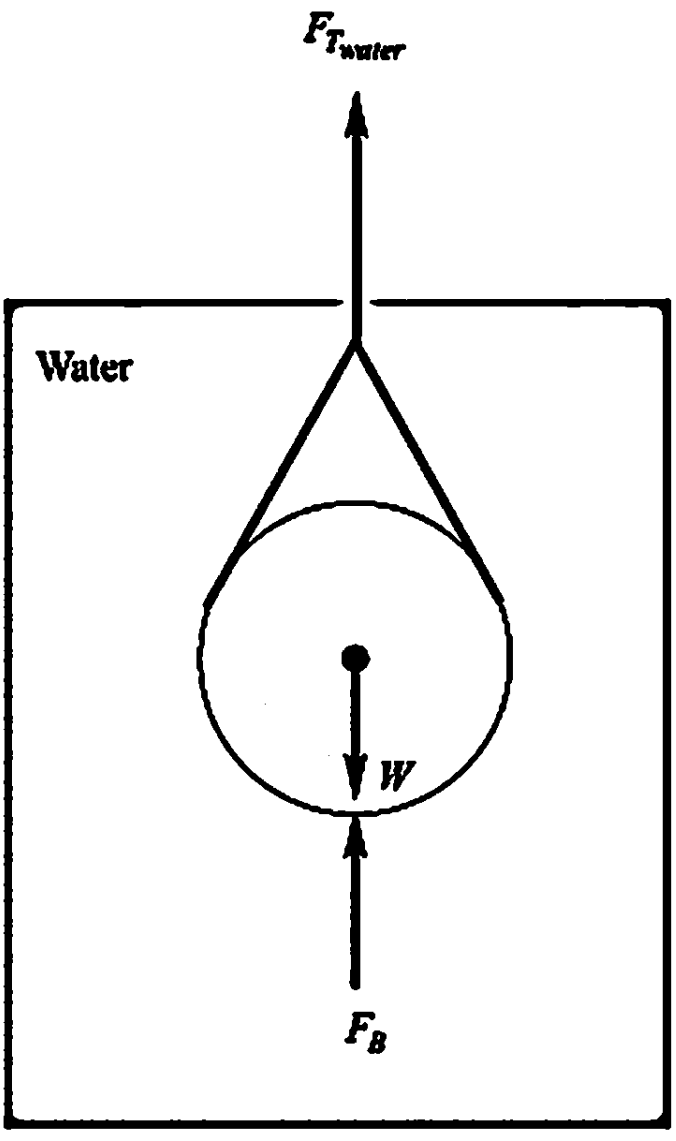
When the spherical steel block is suspended in air:

Since the buoyancy force due to air is negligible. Therefore, the tension in the rope is equal to the weight of the spherical steel block.

The tension in the rope is given by,

$$F_{T_{air}} = W$$

$$= 6983.78\,\text{lbf}$$



Therefore, the tension in the rope when the spherical block is suspended in air,

$$\boxed{F_{T_{air}} = 6983.78\,\text{lbf}}$$

Step 4 of 5

(b)

Free body diagram of the spherical block when it is suspended in water is shown:

Step 5 of 5

When the spherical steel block is suspended in water:

Buoyancy force acting on the spherical steel block is given by,

$$F_B = \rho_w \times g \times V$$

$$= 62.4\times 32.174\times 14.1372$$

$$= 28382.6570\ \text{lbm}\cdot\text{ft/sec}^2\left|\frac{1\,\text{lbf}}{32.174\ \text{lbm}\cdot\text{ft/sec}^2}\right|$$

$$= 882.27\,\text{lbf}$$

From the free body diagram, the tension in the rope is given by,

$$F_{T_{water}} = W - F_B$$

$$= 6983.78 - 882.27$$

$$= 6101.511\text{bf}$$

Therefore, the tension in the rope when the spherical block is suspended in air,

$$\boxed{F_{T_{water}} = 6101.511\text{bf}}$$

Question: 11.032P

The volume and the average density of an irregularly shaped body are to be determined by using a spring scale. The body weighs 7200 N in air and 4790 N in water. Determine the volume and the density of the body. State your assumptions.

Step 1 of 3

Mass of the body

$$m = \frac{W_{air}}{g}$$

Here W_{air} is the Weight of the body in air; g is acceleration due to gravity.

Substitute $7200\,\text{N}$ for W_{air}, and $9.81\,\text{m/s}^2$ for g

$$m = \frac{7200\,\text{N}}{9.81\,\text{m/s}^2}$$
$$= 733.944\,\text{kg}$$

Step 2 of 3

Buoyancy force is the difference between the weights of the body in water and air.

$$F_B = W_{air} - W_{Water}$$

Here W_{air} is the Weight of the body in air; W_{Water} is the Weight of the body in water.

Substitute $7200\,\text{N}$ for W_{air}, $4790\,\text{N}$ and for W_{Water}.

$$F_B = 7200 - 4790$$
$$= 2410\,\text{N}$$

The Buoyancy force

$$F_B = \rho g V$$

Here ρ is the Density of water; g is acceleration due to gravity, and V is the volume the body.

Substitute $1000\,\text{kg}$ for ρ, $9.81\,\text{m/s}^2$ for g, and 2410 for F_B

$$2410\,\text{N} = (1000\,\text{kg/m}^3)(9.81\,\text{m/s}^2)V$$
$$V = 0.2456\,\text{m}^3$$

The volume of a body $\boxed{0.2456\,\text{m}^3}$

Step 3 of 3

Now density of the body

$$\rho_{body} = \frac{m}{V}$$

Here m is the mass of the body, and V is the volume the body.

Substitute $734\,\text{kg}$ for m, and 0.2456 for V

$$\rho_{body} = \frac{734\,\text{kg}}{0.2456\,\text{m}^3}$$
$$= 2988.5\,\text{kg/m}^3$$

Density of the body $\boxed{2988.5\,\text{kg/m}^3}$

Question: 11.033P

Consider a large cubic ice block floating in seawater. The specific gravities of ice and seawater are 0.92 and 1.025, respectively. If a 15-cm-high portion of the ice block extends above the surface of the water, determine the height of the ice block below the surface.

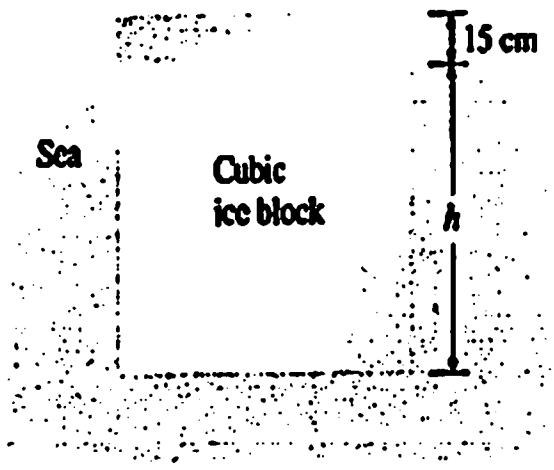


FIGURE P11–33

Step 1 of 4

Given Data:

Specific gravity of ice is $SG_{ice} = 0.92$

Specific gravity of seawater is $SG_{seawater} = 1.025$

Height of the block above the surface, $x = 15\text{cm}$

Step 2 of 4

To find the height of the ice under sea water

The density of sea water is given by,

$$\rho_{seawater} = 1000 \times SG_{seawater}$$
$$= (1000)(1.025)$$
$$= 1025\,\text{kg/m}^3$$

The density of ice is given by,

$$\rho_{ice} = 1000 \times SG_{ice}$$
$$= (1000)(0.92)$$
$$= 920\,\text{kg/m}^3$$

Step 3 of 4

Let the cross-sectional area of the ice block be A.

Total volume of the ice block is given by,

$$V_{total} = A \times (h + x)$$
$$= A \times (h + 15)$$

Volume of the submerged ice block is given by,

$$V_{sub} = A \times h$$

Weight of the ice block is given by,

$$W = \rho_{ice} \times g \times V_{total}$$

Buoyancy force acting on the ice block is given by,

$$F_B = \rho_{seawater} \times g \times V_{sub}$$

Step 4 of 4

The weight of the block is equal to buoyancy force.

$$W = F_B$$
$$\rho_{ice} \times g \times V_{total} = \rho_{seawater} \times g \times V_{sub}$$
$$920 \times g \times A \times (h + 15) = 1025 \times g \times A \times h$$
$$920 \times (h + 15) = 1025 \times h$$
$$105 \times h = 138000$$
$$h = 131.4\ \text{cm}$$
$$= 1.1314\ \text{m}$$

Therefore, the height of the ice block below the surface of water, $\boxed{h = 1.31\text{m}}$

Question: 11.034P

It is estimated that 90 percent of an iceberg's volume is below the surface, while only 10 percent is visible above the surface. For seawater with a density of 1025 kg/m3, estimate the density of the iceberg.

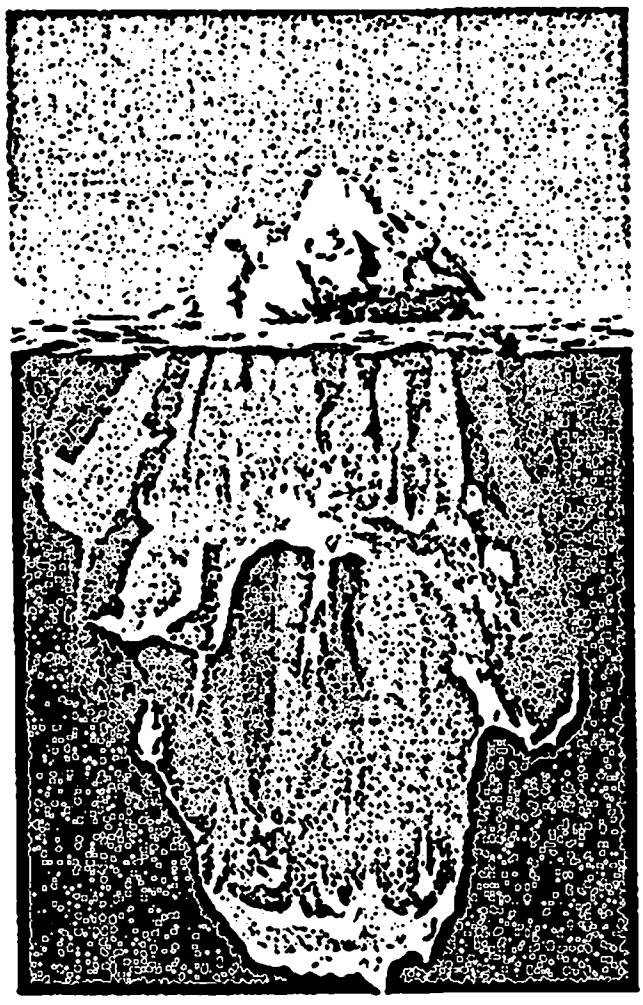

FIGURE P11–34

Step 1 of 3

Given Data:

Percentage of volume of iceberg below the water surface is 90%, $V_{sub} = 0.9V$

Percentage of volume of iceberg above the water surface is 10%, $V_{above} = 0.1V$

Density of sea water, $\rho_{seawater} = 1025 kg/m^3$.

Step 2 of 3

Let the density of the iceberg be $\rho_{iceberg}$

Total weight of the iceberg is given by,

$W = \rho_{iceberg} \times g \times V$

Buoyancy force acting on the iceberg is given by,

$$F_B = \rho_{seawater} \times g \times V_{sub}$$
$$= 1025 \times g \times (0.9V)$$
$$= 922.50 \times g \times V$$

Step 3 of 3

The weight of the block is equal to buoyancy force

$W = F_B$

$\rho_{iceberg} \times g \times V = 922.50 \times g \times V$

$\rho_{iceberg} = 922.50 \ kg/m^3$

Therefore, the density of the iceberg, $\boxed{\rho_{iceberg} = 922.50 kg/m^3}$

Question: 11.035P

A 170-kg granite rock (ρ = 2700 kg/m3) is dropped into a lake. A man dives in and tries to lift the rock. Determine how much force the man needs to apply to lift it from the bottom of the lake. Do you think he can do it?

Step 1 of 3

Weight of the rock in air

$$W = mg$$

Here m is the Mass of the granite; g is acceleration due to gravity.

Substitute $170\,\text{kg}$ for m, and 9.81m/s^2 for g

$$W = (170\,\text{kg})(9.81\text{m/s}^2)$$
$$= 1667.7\text{N}$$

Volume of the rock in air

$$V = \frac{m}{\rho}$$

Here m is the Mass of the granite; ρ_{Granit} is Density of the granite.

Substitute $170\,\text{kg}$ for m, and $2700\,\text{kg/m}^3$ for ρ_{Granit}

$$V = \frac{170\,\text{kg}}{2700\,\text{kg/m}^3}$$
$$= 0.06296\,\text{m}^3$$

Step 2 of 3

The buoyancy force acting on the rock is

$$F_B = \rho_{water} gV$$

Here ρ_{water} is the Density of water; g is acceleration due to gravity, and V is the volume of the rock.

Substitute $1000\,\text{kg}$ for ρ_{water}, 9.81m/s^2 for g, and $0.06296\,\text{m}^3$ for V

$$F_B = (1000\,\text{kg/m}^3)(9.81\text{m/s}^2)(0.06296\,\text{m}^3)$$
$$= 617.6376\text{N}$$

Force required equal to weight of the rock in water

$$W_{Water} = W_{air} - F_B$$
$$= 1667.7 - 617.6376$$
$$= 1050.06\text{N}$$

Weight of the rock in water $\boxed{1050.06\text{N}}$

Step 3 of 3

The force corresponding to mass is

$$m = \frac{W_{water}}{g}$$
$$= \frac{1050.06}{9.81}$$
$$= 107.0397\,\text{kg}$$

The weight of the granite in water is

$$\text{Lift Percentage (\%)} = \frac{1667.7 - 617.6376}{1667.7}$$
$$= 0.6296\% \text{ of water}$$

Mass of the granite in water

$$m_{gra} = 0.6296 \times 170$$
$$= 107.032\,\text{kg}$$

Therefore a person can lift a rock of 107.032kg on earth, so he can lift the rock in water also, as $m_{gra} < m$.

Question: 11.036P

It is said that Archimedes discovered his principle during a bath while thinking about how he could determine if King Hiero's crown was actually made of pure gold. While in the bathtub, he conceived the idea that he could determine the average density of an irregularly shaped object by weighing it in air and also in water. If the crown weighed 3.20 kgf (= 31.4 N) in air and 2.95 kgf (= 28.9 N) in water, determine if the crown is made of pure gold. The density of gold is 19,300 kg/m3. Discuss how you can solve this problem without weighing the crown in water but by using an ordinary bucket with no calibration for volume. You may weigh anything in air.

Step 1 of 4

Given Data:

Weight of the crown in air, $W_a = 31.4\ \text{N}$

Weight of the crown in water, $W_w = 28.9\ \text{N}$

Density of gold, $\rho_g = 19300\ \text{kg/m}^3$

Step 2 of 4

Let us assume that the buoyant force in air is negligible.

The buoyant force acting on the crown by the water is given by,

$$\begin{aligned} F_B &= W_a - W_w \\ &= 31.4 - 28.9 \\ &= 2.5\ \text{N} \end{aligned}$$

Mass of the crown is given by,

$$\begin{aligned} m_c &= \frac{W_a}{g} \\ &= \frac{31.4}{9.81} \\ &= 3.2\ \text{kg} \end{aligned}$$

Step 3 of 4

Buoyant force is equal to the weight of the volume of water displaced.

$$F_B = \rho_{water} \times g \times V$$
$$2.5 = 1000 \times 9.81 \times V$$
$$V = 2.55 \times 10^{-4}\ \text{m}^3$$

The volume of the water displaced is equal to the volume of the crown.

Let the average density of the crown be ρ_{avg}.

Average density of the crown is given by,

$$\begin{aligned} \rho_{avg} &= \frac{m}{V} \\ &= \frac{3.2}{2.55 \times 10^{-4}} \\ &= 12549.02\ \text{kg/m}^3 \end{aligned}$$

Since, $\rho_{avg} < \rho_g$. Therefore, we can conclude that the crown is not made of pure gold.

Step 4 of 4

If the weight of the crown in water is not known:

A bucket which is half filled with water is taken. The weight of the bucket is weighted and be W_1.

Now the crown is completed immersed into the water. After marking the new water level in the bucket, the crown is taken out.

Now, water is filled in the bucket upto the new water mark and is weighed. Let it be W_2.

The volume of the crown is calculated by,

$$V = \frac{W_2 - W_1}{\rho_{water} \times g}.$$

The weight of the crown in air is known as W_a.

The average density of the crown is calculated as follows:

$$\rho_{avg} = \frac{W_a}{V \times g}$$

Question: 11.037P

One of the common procedures in fitness programs is to determine the fat-to-muscle ratio of the body. This is based on the principle that the muscle tissue is denser than the fat tissue, and, thus, the higher the average density of the body, the higher is the fraction of muscle tissue. The average density of the body can be determined by weighing the person in air and also while submerged in water in a tank. Treating all tissues and bones (other than fat) as muscle with an equivalent density of ρmuscle,obtain a relation for the volume fraction of body fat $x$fat.

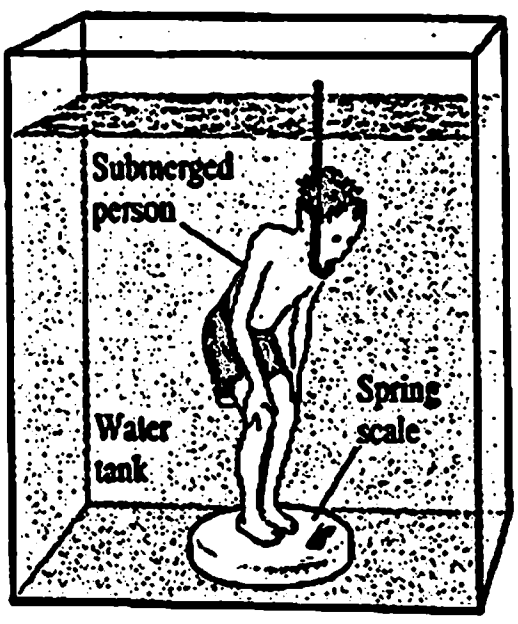

FIGURE P11-37

Step 1 of 3

Let the total volume of the body be

Let the average density of the body be

Let the density of the fat tissue be ρ_{fat}

Volume of the fat tissue is given by,

$$V_{fat} = x_{fat} \times V$$

Volume of the muscle tissue is given by,

$$\begin{aligned} V_{muscle} &= V - V_{fat} \\ &= V - x_{fat} \times V \\ &= V(1 - x_{fat}) \end{aligned}$$

Step 2 of 3

Mass of the fat tissue is given by,

$$\begin{aligned} m_{fat} &= V_{fat} \times \rho_{fat} \\ &= x_{fat} \times V \times \rho_{fat} \end{aligned}$$

Mass of the muscle tissue is given by,

$$\begin{aligned} m_{muscle} &= V_{muscle} \times \rho_{muscle} \\ &= V(1 - x_{fat}) \times \rho_{muscle} \end{aligned}$$

Total mass of the body is given by,

$$m = V \times \rho_{avg}$$

Step 3 of 3

The total mass of the body is equal to the sum of mass of the fat tissue and muscle tissue. Therefore,

$$m = m_{fat} + m_{muscle}$$

$$V \times \rho_{avg} = (x_{fat} \times V \times \rho_{fat}) + (V(1 - x_{fat}) \times \rho_{muscle})$$

$$\rho_{avg} = x_{fat} \times \rho_{fat} + (1 - x_{fat}) \times \rho_{muscle}$$

$$\rho_{avg} = x_{fat} \times \rho_{fat} + \rho_{muscle} - x_{fat} \times \rho_{muscle}$$

$$x_{fat}(\rho_{muscle} - \rho_{fat}) = \rho_{muscle} - \rho_{avg}$$

$$x_{fat} = \frac{\rho_{muscle} - \rho_{avg}}{\rho_{muscle} - \rho_{fat}}$$

Therefore, the volume fraction of the body fat, $\boxed{x_{fat} = \frac{\rho_{muscle} - \rho_{avg}}{\rho_{muscle} - \rho_{fat}}}$.

Question: 11.038P

The hull of a boat has a volume of 180 m3, and the total mass of the boat when empty is 8560 kg. Determine how much load this boat can carry without sinking (*a*) in a lake and (*b*) in seawater with a specific gravity of 1.03.

Step 1 of 4

Given Data:

Volume of boat hull, $V = 180\ \text{m}^3$

Mass of the boat, $m = 8560\ \text{kg}$

The weight of the empty boat is given by,

$$\begin{aligned} W_{boat} &= mg \\ &= (8560\,\text{kg})(9.81\,\text{m/s}^2) \\ &= 83.97\times10^3\ \text{N} \\ &= 83.97\,\text{kN} \end{aligned}$$

Step 2 of 4

(a) To find the load that can carry by the boat without sinking in the lake.

Density of lake water, $\rho_{lake} = 1000\ \text{kg/m}^3$

Buoyancy force acting on the boat in lake is given by,

$$\begin{aligned} F_{B,lake} &= \rho_{lake} g V \\ &= (1000\,\text{kg/m}^3)(9.81\,\text{m/s}^2)(180) \\ &= 1765.80\times10^3\ \text{N} \\ &= 1765.8\,\text{kN} \end{aligned}$$

The load that can be carried by this boat without sinking in lake is given by,

$$\begin{aligned} W_{load,lake} &= F_{B,lake} - W_{boat} \\ &= 1765.8 - 83.97 \\ &= 1681.83\,\text{kN} \end{aligned}$$

Therefore, the load that can be carried by this boat without sinking in lake,

$$\boxed{W_{load,lake} = 1681.83\ \text{kN}}$$

Step 3 of 4

(b) To find the load that can carry by the boat without sinking in the sea.

Specific gravity of sea water, $SG = 1.03$

Density of sea water is given by,

$$\begin{aligned} \rho_{sea} &= SG \times \rho_{water} \\ &= 1.03\times1000 \\ &= 1030\ \text{kg/m}^3 \end{aligned}$$

Buoyancy force acting on the boat in sea is given by,

$$\begin{aligned} F_{B,sea} &= \rho_{sea} g V \\ &= (1030\,\text{kg/m}^3)(9.81\,\text{m/s}^2)(180) \\ &= 1818.77\times10^3\ \text{N} \\ &= 1818.77\,\text{kN} \end{aligned}$$

Step 4 of 4

The load that can be carried by this boat without sinking in sea is given by,

$$\begin{aligned} W_{load,sea} &= F_{B,sea} - W_{boat} \\ &= 1818.77 - 83.97 \\ &= 1734.80\,\text{kN} \end{aligned}$$

Therefore, the load that can be carried by this boat without sinking in sea,

$$\boxed{W_{load,sea} = 1734.80\ \text{kN}}$$

Question: 11.039P

An air-conditioning system requires a 20-m-long section of 15-cm-diameter ductwork to be laid underwater. Determine the upward force the water will exert on the duct. Take the densities of air and water to be 1.3 kg/m3 and 1000 kg/m3, respectively.

Step 1 of 3

Given data:

Length of the section, $L = 20\ \text{m}$

Diameter of the duct, $D = 15\ \text{cm} = 0.15\ \text{m}$

Density of air, $\rho_{air} = 1.3\ \text{kg/m}^3$

Density of water, $\rho_{water} = 1000\ \text{kg/m}^3$

Step 2 of 3

To find the buoyant force acting on the duct.

Volume of the duct under the water is

$$V = \frac{\pi}{4} D^2 L$$

$$= \frac{\pi}{4} \times 0.15^2 \times 20$$

$$= 0.3534\ \text{m}^3$$

The buoyancy force acting on the duct is given by,

$$F_B = \rho g V$$

$$= 1000 \times 9.81 \times 0.3534$$

$$= 3466.854\ \text{N}$$

Step 3 of 3

Neglecting the air density, the upward force on the duct is equal to the buoyancy force.

Therefore, the upward force acting on the duct is given by,

$$F = F_B$$

$$= 3466.854\ \text{N}$$

Therefore, the upward force that the water will exert on the duct, $\boxed{F = 3466.854\ \text{N}}$.

Question: 11.040P

The density of a floating body can be determined by tying weights to the body until both the body and the weights are completely submerged, and then weighing them separately in air. Consider a wood log that weighs 1540 N in air. If it takes 34 kg of lead (ρ = 11,300 kg/m3) to completely sink the log and the lead in water, determine the average density of the log.

Step 1 of 5

Given data:

The weight of the wooden log, $W_l = 1540$ N

The mass of lead used to submerge the log, $m_d = 34$ kg

The density of lead, $\rho_d = 11{,}300\ \text{kg/m}^3$

Step 2 of 5

Assume

The body is submerged and in a suspended state

We know for a body in suspended state,

$\rho = \rho_f$

Where

ρ is the average density of the body

ρ_f is the density of water

Step 3 of 5

The total mass of the body,

$$\begin{aligned} m &= m_d + m_l \\ &= m_d + \frac{W_l}{g} \\ &= 34 + \frac{1540}{9.81} \\ &= 190.98\ \text{kg} \end{aligned}$$

Step 4 of 5

The mass of the log,

$$\begin{aligned} m_l &= \frac{W_l}{g} \\ &= \frac{1540}{9.81} \\ &= 156.98\ \text{kg} \end{aligned}$$

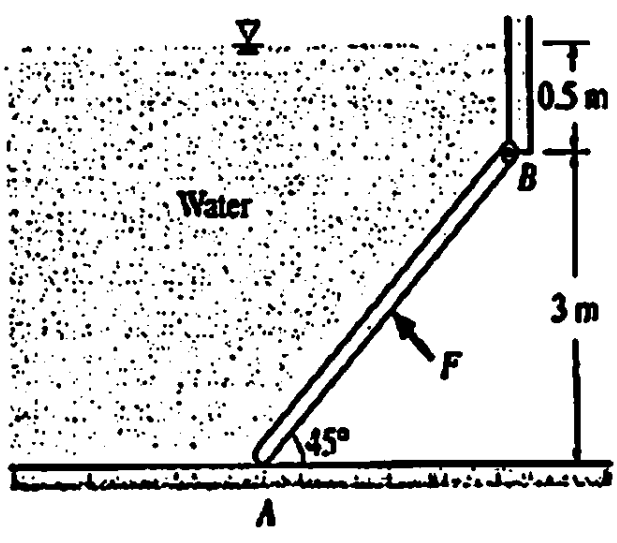
Step 5 of 5

The volume of lead used,

$$\begin{aligned} \rho_d &= \frac{m_d}{\rho_d} \\ &= \frac{34}{11300}\ \text{m}^3 \end{aligned}$$

Question: 11.041P

The 280-kg, 6-m-wide rectangular gate shown in Fig. P11–41 is hinged at *B* and leans against the floor at *A* making an angle of 45° with the horizontal. The gate is to be opened from its lower edge by applying a normal force at its center. Determine the minimum force *F* required to open the water gate.



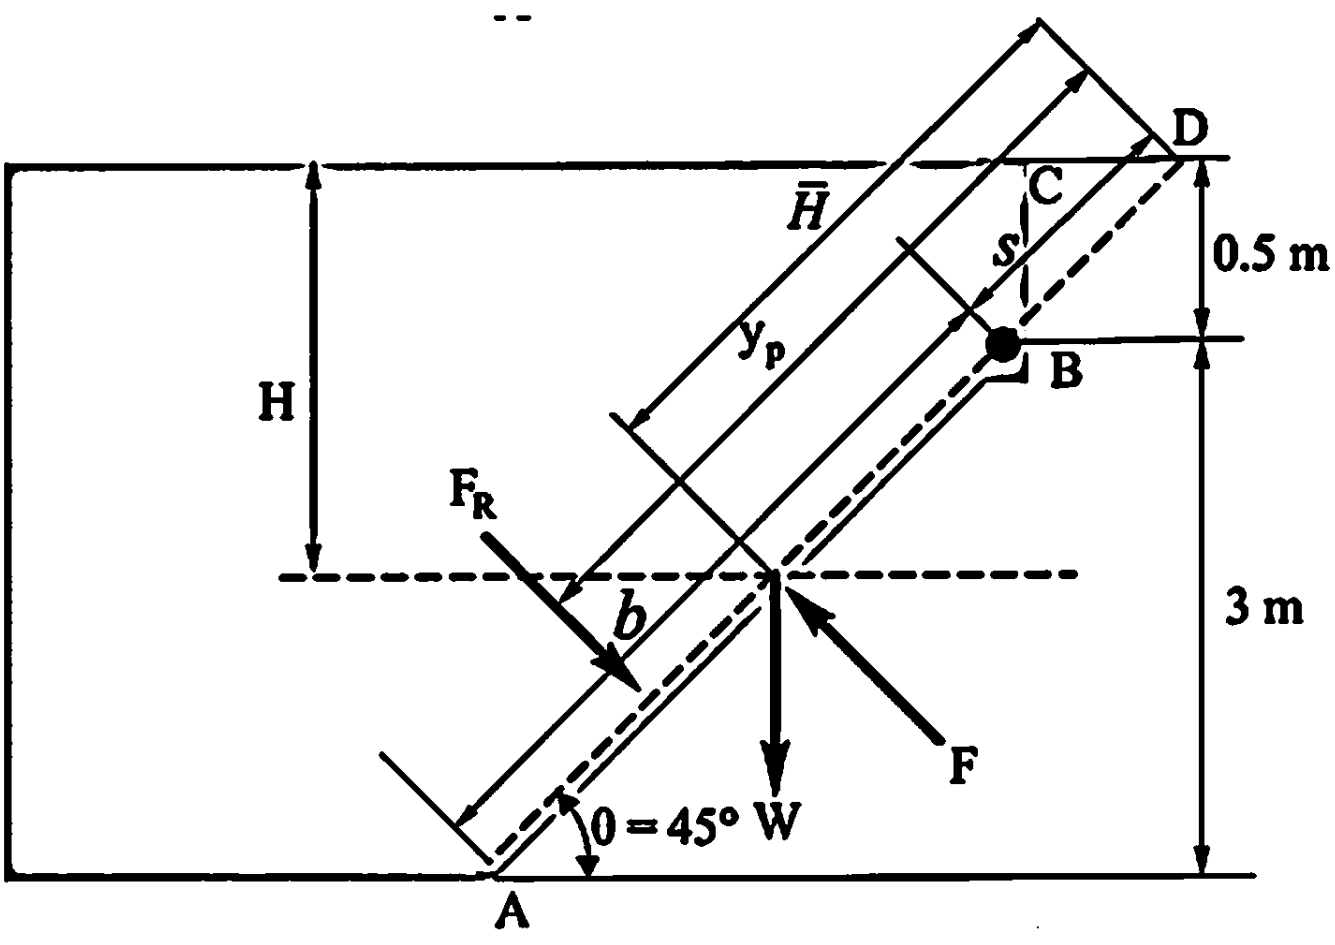


FIGURE P11–41

Step 1 of 6

Show the forces acting on the rectangular gate:

Step 2 of 6

Calculate the point of center of pressure acting on the gate due to the liquid.

$$y_p = \bar{H} + \frac{I}{A\bar{H}}$$

$$= \left(\frac{s+b}{2}\right) + \frac{\frac{b^3 d}{12}}{b \times d\left(\frac{s+b}{2}\right)}$$

$$= \left(\frac{s+b}{2}\right) + \frac{b^2 d}{12\left(\frac{s+b}{2}\right)}$$

Here, s is the length of the gate (AB), $\bar{H}$ is the inclined distance of the centroid from the surface, b is the distance from point B to D, and d is the width of the gate.

Calculate the vertical centroid distance of the gate from the water surface.

$$H = \bar{H}\sin 45°$$

$$= \left(\frac{s+b}{2}\right)\sin 45°$$

Step 3 of 6

Calculate the resultant force acting on the gate due to water.

$$F_R = \rho g H \times A$$

Here ρ is the density of the water, and A is the cross sectional area of the gate.

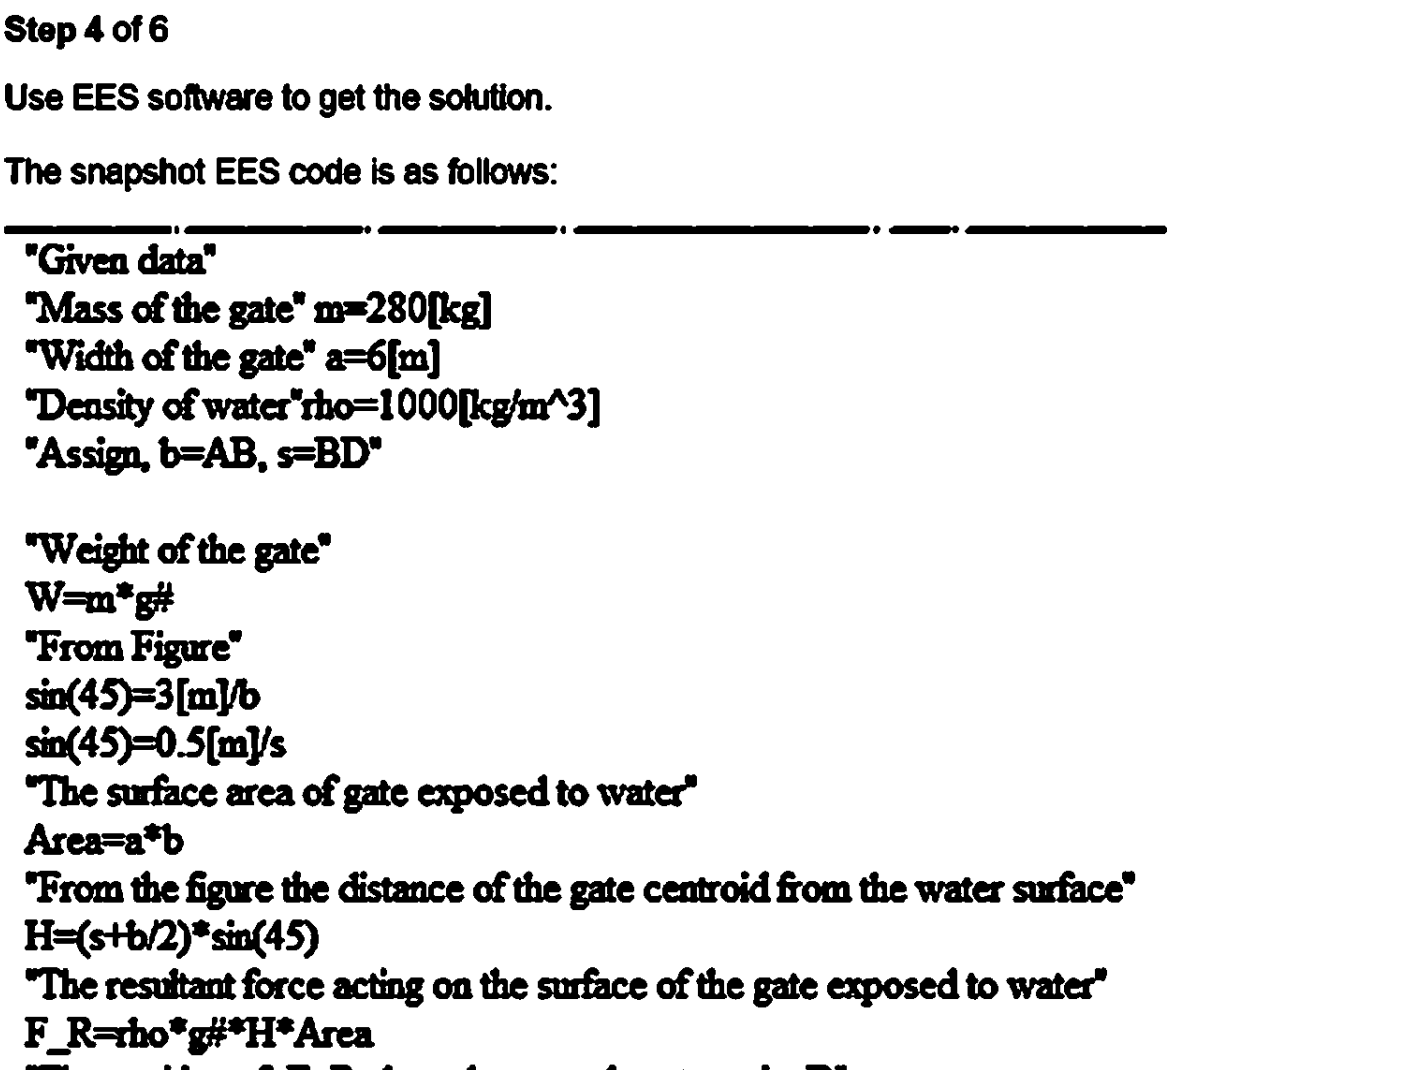
Take moments about B.

$$F_R\left(y_p - s\right) + W\left(\frac{b}{2}\cos 45°\right) = F \times \frac{b}{2}$$

Here, W is the weight of the gate.

Step 4 of 6

Use EES software to get the solution.



The snapshot EES code is as follows:

```
"Given data"
"Mass of the gate" m=280[kg]
"Width of the gate" a=6[m]
"Density of water"rho=1000[kg/m^3]
"Assign, b=AB, s=BD"

"Weight of the gate"
W=m*g#
"From Figure"
sin(45)=3[m]/b
sin(45)=0.5[m]/s
"The surface area of gate exposed to water"
Area=a*b
"From the figure the distance of the gate centroid from the water surface"
H=(s+b/2)*sin(45)
"The resultant force acting on the surface of the gate exposed to water"
F_R=rho*g#*H*Area
"The position of  F_R along the gate plane to point D"
y_p=s+b/2+b^2/(12*(s+b/2))
"Taking moment about the point B"
F_R*(y_p-s)-F*(b/2)+W*(b*cos(45)/2)=0
```

Step 5 of 6

After writing the EES code, press "F2" key on the keyboard. The solution window pops up. The screen shot of the solution window appears as follows:

Step 6 of 6

From the solution window, the force required to open the gate is as follows:

$$F = 626055\ \text{kg}\cdot\text{m/s}^2$$

$$= 626.055 \times 10^3\ \text{N}$$

$$= 626.055\ \text{kN}$$

Therefore, the minimum force required to open the water gate, is **626.055 kN**.

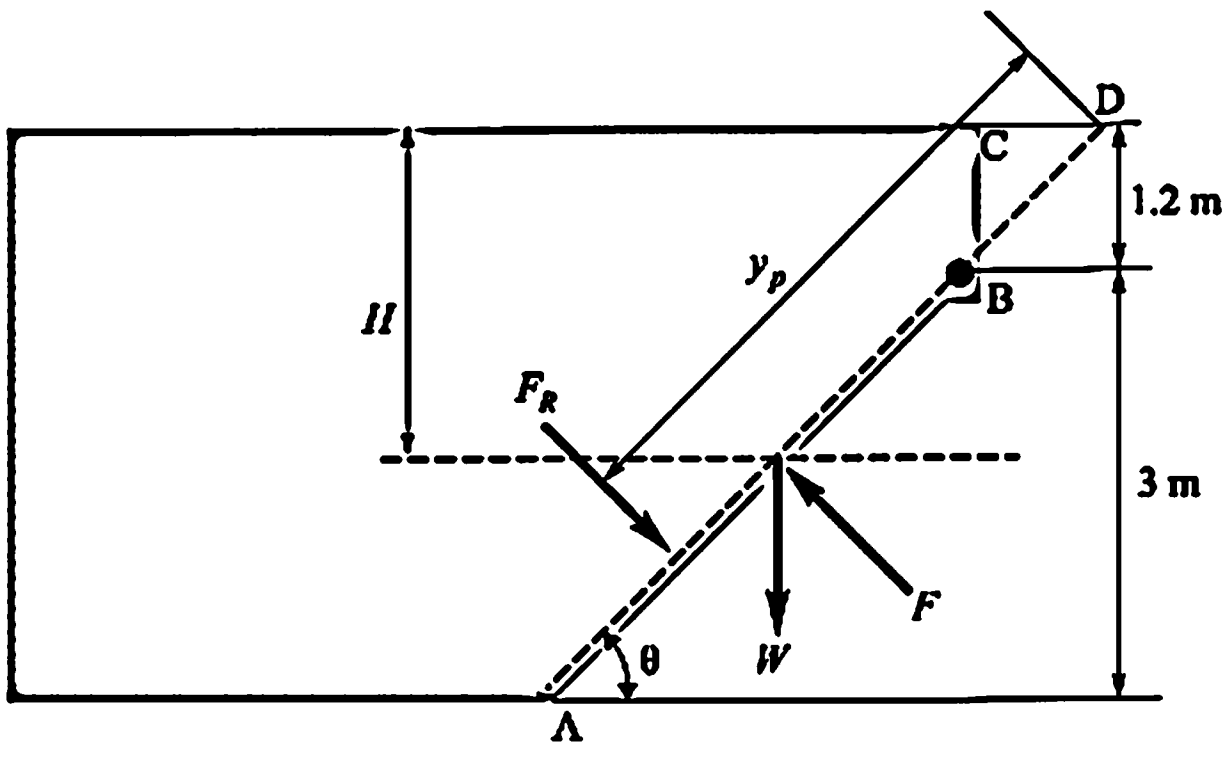
Question: 11.042P

Repeat Prob. 11–41 for a water height of 1.2 m above the hinge at *B*.

Step 1 of 6

Given Data:

The mass of the gate, $m = 280$ kg



The width of the gate, $a = 6$ m

The angle made by the gate with horizontal, $\theta = 45°$

A normal force is applied at the center of the gate from below.

Step 2 of 6

The forces acting on the gate is shown:

Step 3 of 6

Assign $AB = b$ and $BD = s$

From the figure

$$\sin 45° = \frac{3\text{ m}}{b}$$

$$b = \frac{3}{\sin 45°}$$

$$= 4.2426\text{ m}$$

From the figure,

$$\sin 45° = \frac{1.2\text{ m}}{s}$$

$$s = \frac{1.2}{\sin 45°}$$

$$= 1.697\text{ m}$$

Step 4 of 6

The surface area of the gate exposed to water,

$$A = a \times b$$

$$= 6\text{ m} \times 4.2426\text{ m}$$

$$= 25.4556\text{ m}^2$$

From the figure the distance of the gate centroid from the water surface,

$$H = (s + b/2) \times \sin 45°$$

$$= (1.697 + 4.2426/2) \times \sin 45°$$

$$= 2.699\text{ m}$$

The resultant force acting on the surface of the gate exposed to water,

$$F_R = \rho g H A$$

$$= (1000)(9.81)(2.699)(25.4556)$$

$$= 674.268 \times 10^3\text{ N}$$

Step 5 of 6

The position of F_R along the gate plane to point *D*,

$$y_p = s + (b/2) + \frac{ab^3}{12\left[s + b/2 + P_0/(\rho g \sin\theta)\right]ab}$$

The atmospheric pressure is neglected.

$$y_p = s + (b/2) + \frac{b^2}{12[s + b/2]}$$

$$= 1.697 + (4.2426/2) + \frac{4.2426^2}{1.697 + 4.2426/2}$$

$$= 4.2111\text{ m}$$

Weight of the gate is given by,

$$W = mg$$

$$= 280 \times 9.81$$

$$= 2746.8\text{ N}$$

Step 6 of 6

Taking moment about the point *B*,

$$\sum M_B = 0$$

$$F_R(y_p - s) - F\left(\frac{b}{2}\right) + W\left(\frac{b \times \cos 45°}{2}\right) = 0$$

$$F = \frac{2}{b}\left(F_R(y_p - s) + W\left(\frac{b \times \cos 45°}{2}\right)\right)$$

$$= \frac{2}{4.2426}\left(674.268 \times 10^3 (4.211 - 1.697) + 2746.8\left(\frac{4.2426 \times \cos 45°}{2}\right)\right)$$

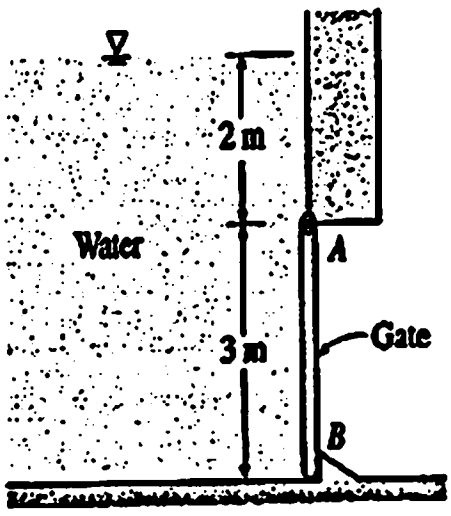
$$= 800.71 \times 10^3\text{ N}$$

$$= 800.71\text{ kN}$$

Therefore the applied force, $\boxed{F = 800.71\text{ kN}}$.

Question: 11.043P

A 3-m-high, 6-m-wide rectangular gate is hinged at the top edge at *A* and is restrained by a fixed ridge at *B*. Determine the hydrostatic force exerted on the gate by the 5-m-high water and the location of the pressure center.



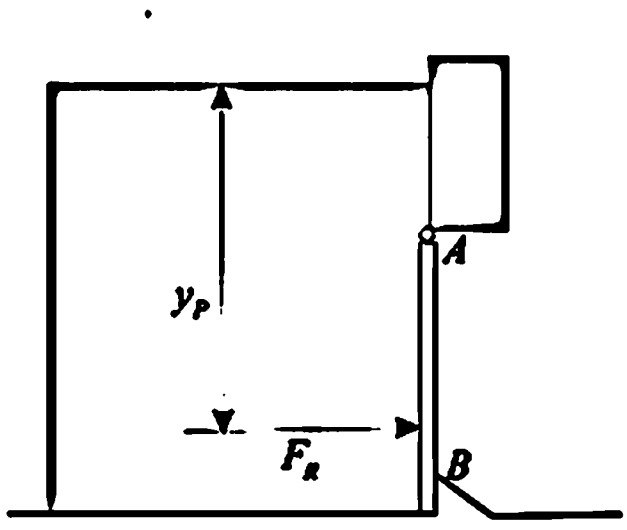


FIGURE P11–43

Step 1 of 3

Step 2 of 3

Center of gravity from the free surface of the water is

$$h_c = 2 + \frac{3}{2}$$
$$= 3.5\,\text{m}$$

Resultant hydrostatic force on the gate is

$$F_R = \rho g h_c A$$

Here ρ is the Density of water; g is acceleration due to gravity, and h_c is the Center of gravity from the free surface of the water.

Substitute 1000kg for ρ, $9.81\,\text{m/s}^2$ for g, and 3.5m for h_c

$$F_R = \left(1000\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)(3.5\,\text{m})\left(3\times 6\,\text{m}^2\right)\left(\frac{1\,\text{kN}}{1000\,\text{kg}\cdot\text{m/s}^2}\right)$$
$$= 618\,\text{kN}$$

Resultant hydrostatic force on the gate is $\boxed{618\,\text{kN}}$

Step 3 of 3

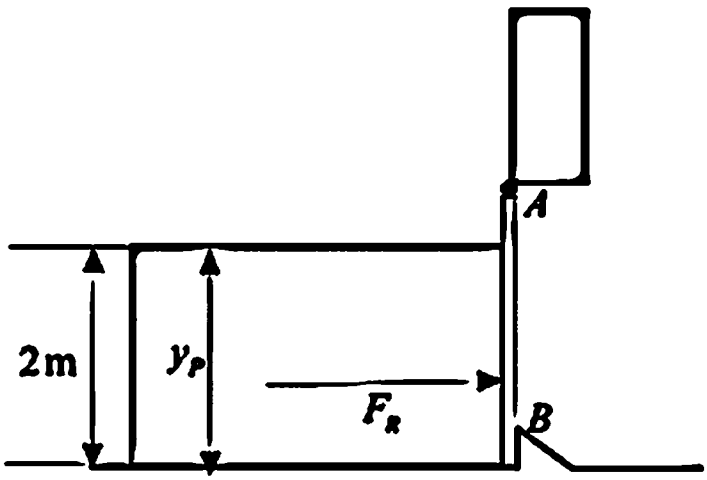
The force acting at a vertical distance of $h_p = y_p$ from the free surface directly beneath the centroid of the plate is

$$y_p = s + \frac{b}{2} + \frac{b^2}{12\left(s + \frac{b}{2} + P_0(\rho g)\right)}$$

The free surface of the water is put $P_0 = 0$, then

$$y_p = s + \frac{b}{2} + \frac{b^2}{12\left(s + \frac{b}{2}\right)}$$

Substituting the values, we get the vertical distance of the pressure center from the free surface of water as



$$y_p = 2 + \frac{3}{2} + \frac{3^2}{12\left(2 + \frac{3}{2}\right)}$$
$$= 3.71\,\text{m}$$

The vertical distance of the pressure center from the free surface of water is $\boxed{3.71\,\text{m}}$

Question: 11.044P

Repeat Prob. 11–43 for a total water height of 2 m.

Step 1 of 3

Step 2 of 3

Center of gravity from the free surface of the water is

$$h_c = \frac{2}{2}$$
$$= 1\,\text{m}$$

Resultant hydrostatic force on the gate is

$$F_R = \rho g h_c A$$

Here ρ is the Density of water; g is acceleration due to gravity, and h_c is the Center of gravity from the free surface of the water.

Substitute 1000kg for ρ, $9.81\,\text{m/s}^2$ for g, and 1m for h_c

$$F_R = \left(1000\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)(1\,\text{m})\left(2\times 6\,\text{m}^2\right)\left(\frac{1\,\text{kN}}{1000\,\text{kg}\cdot\text{m/s}^2}\right)$$
$$= 118\,\text{kN}$$

Resultant hydrostatic force on the gate is $\boxed{118\,\text{kN}}$

Step 3 of 3

The vertical distance of the pressure center from the free surface of water is

$$y_p = \frac{2(2\,\text{m})}{3}$$
$$= 1.33\,\text{m}$$

The vertical distance of the pressure center from the free surface of water is $\boxed{1.33\,\text{m}}$

Question: 11.045P

A semicircular 40-ft-diameter tunnel is to be built under a 150-ft-deep, 800-ft-long lake, as shown in Fig. P11–45E. Determine the total hydrostatic force acting on the roof of the tunnel.

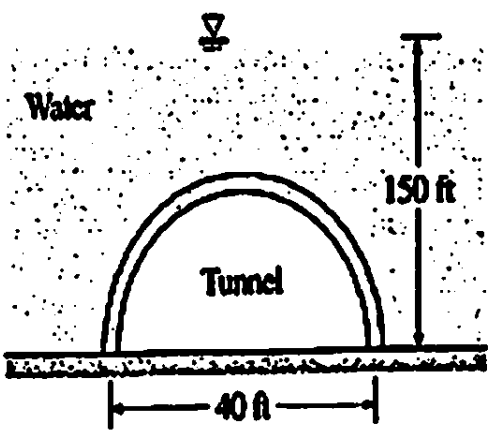


FIGURE P11–45E

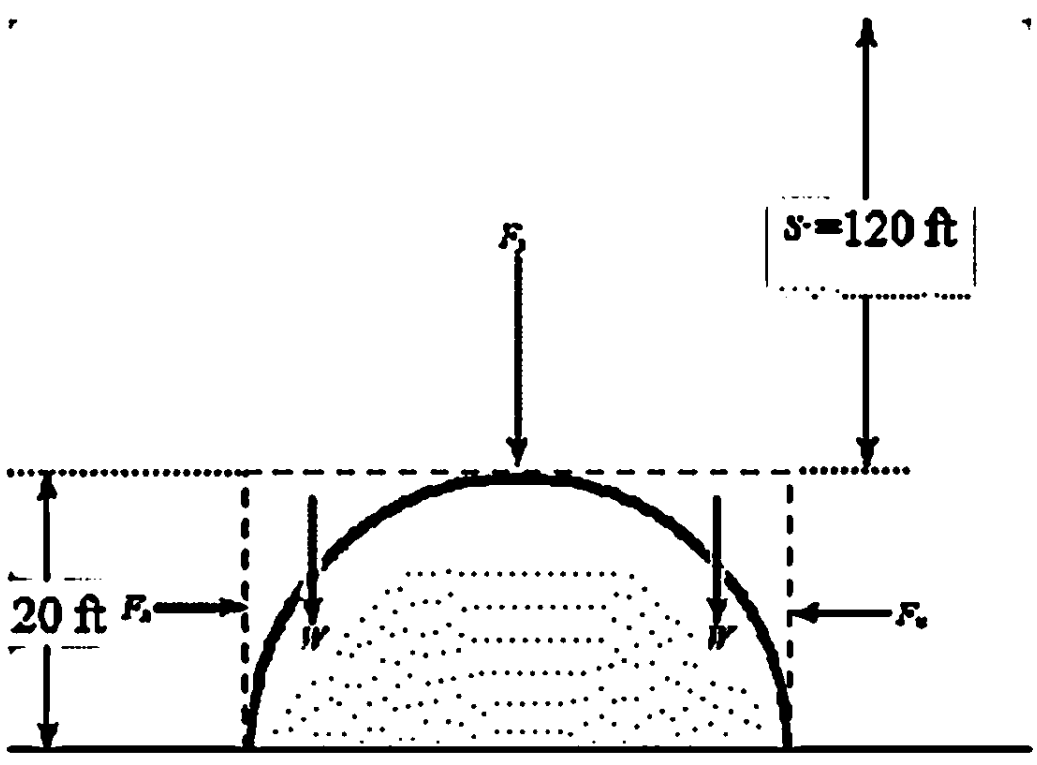
Step 1 of 8

Given data:



The depth of the lake $h_l = 150\text{ft}$

The length of the lake $l = 800\text{ft}$

The diameter of the tunnel $D = 40\text{ft}$

Step 2 of 8

The free body diagram semicircular tunnel is:

Where

F_y is force acting on horizontal surface

F_x is force acting on each vertical surface

W is the weight of the fluid acting on each side

Step 3 of 8

The tunnel has been enclosed in a rectangular fluid block of height equal to the radius of the tunnel, $R = 20\text{ft}$

Consider the rectangular fluid block with the tunnel.

Consider the horizontal forces on a vertical side.

$$F_x = P_{avg}A$$
$$= \rho g h_C A$$
$$= \rho g\left(s + \frac{R}{2}\right)A$$

Where area A on vertical surface is

$$A = 20\times 800$$
$$= 16000\,\text{ft}^2$$

Step 4 of 8

Substituting the required values:

The horizontal force acting on each vertical side of the tunnel

$$F_x = \left(62.4\frac{\text{lbm}}{\text{ft}^3}\right)\left(32.2\frac{\text{ft}}{\text{sec}^2}\right)\left(130 + \frac{20}{2}\right)\text{ft}\times 16000\,\text{ft}^2\times\frac{1\text{lbf}}{32.2\text{lbm}.\frac{\text{ft}}{\text{sec}^2}}$$

$$= 139.776\times 10^6\,\text{lbf}$$

Since horizontal force acting on the right side and left side of the tunnel is equal and opposite then the net total force acting on the tunnel in horizontal direction is zero.

$$F_X = F_x - F_x$$
$$= 0$$

Step 5 of 8

The vertical force acting on horizontal side of the tunnel is

$$F_y = \rho g h_C A$$
$$= \rho g s\left(D\times l\right)$$
$$= 62.4\frac{\text{lbm}}{\text{ft}^3}\times 32.2\frac{\text{ft}}{\text{sec}^2}\times 130\text{ft}\times(40\times 800)\text{ft}^2\times\frac{1\text{lbf}}{32.2\text{lbm}.\frac{\text{ft}}{\text{sec}^2}}$$
$$= 259.584\times 10^6\,\text{lbf}$$

Step 6 of 8

Weight of the fluid acting on one side of the tunnel is

$$W = \rho g V$$
$$= \rho g\left(R^2 - \frac{\pi R^2}{4}\right)l$$
$$= 62.4\frac{\text{lbm}}{\text{ft}^3}\times 32.2\frac{\text{ft}}{\text{sec}^2}\left(20^2 - \frac{\pi\times 20^2}{4}\right)\text{ft}^2\times 800\text{ft}\times\frac{1\text{lbf}}{32.2\text{lbm}\cdot\frac{\text{ft}}{\text{sec}^2}}$$
$$= 4.285\times 10^6\,\text{lbf}$$

Step 7 of 8

The total vertical force acting on the top of the tunnel

$$F_Y = F_y + W + W$$
$$F_Y = F_y + 2W$$
$$= 259.584\times 10^6 + 2\times 4.285\times 10^6$$
$$= 268.154\times 10^6\,\text{lbf}$$

Step 8 of 8

The total force acting on the tunnel is

$$F = \sqrt{F_X^2 + F_Y^2}$$
$$= \sqrt{F_Y^2}$$
$$= F_Y$$
$$= 268.154\times 10^6$$

Therefore, the total force acting on the tunnel $\boxed{F = 268.154\times 10^6}$

Question: 11.046P

A 50-ton, 6-m-diameter hemispherical dome on a level surface is filled with water, as shown in Fig. P11–46. Someone claims that he can lift this dome by making use of Pascal's law by attaching a long tube to the top and filling it with water. Determine the required height of water in the tube to lift the dome. Disregard the weight of the tube and the water in it.

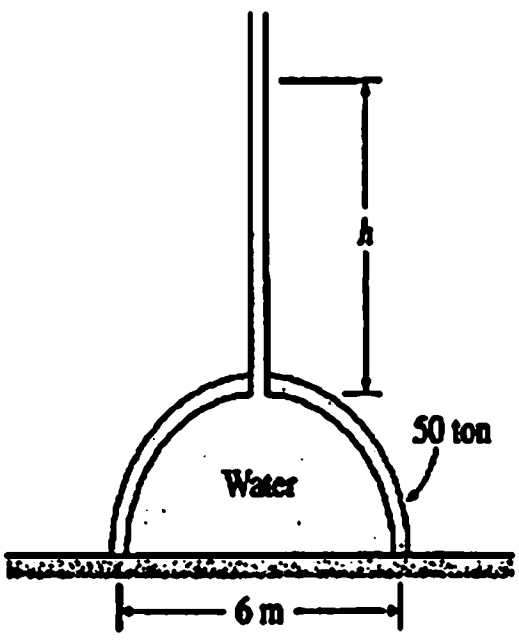


FIGURE P11–46

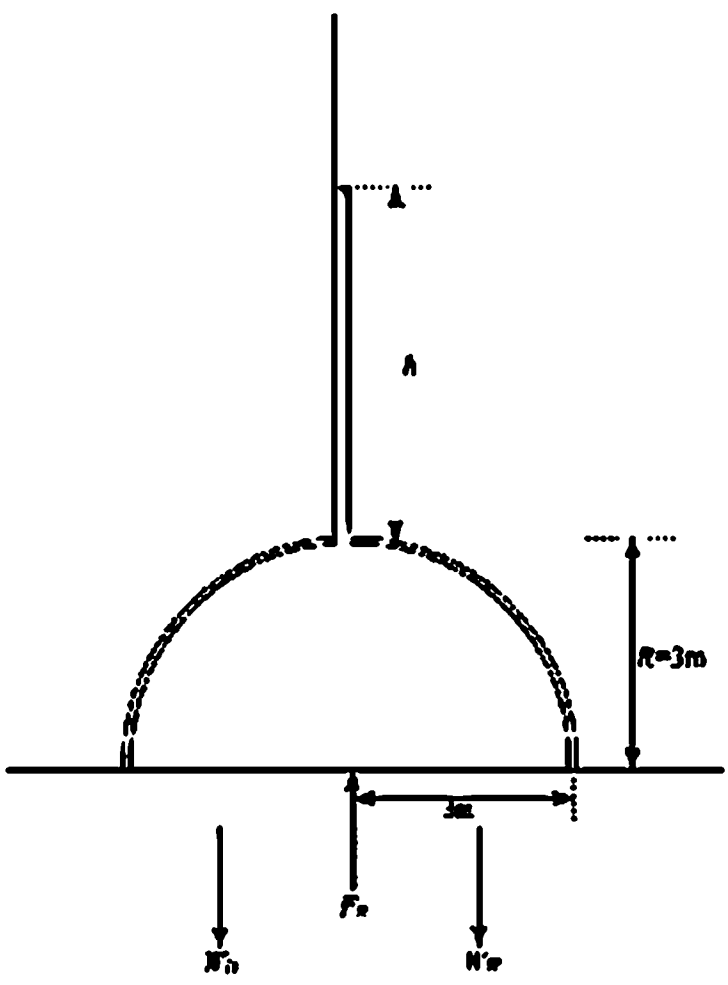
Step 1 of 4

Given data:

The mass of hemispherical dome, $m_D = 50 \times 10^3 \text{ kg}$

The diameter of the dome, $D = 6 \text{ m}$



Radius of the dome, $R = \frac{D}{2} = 3\text{m}$

The weight of the tube and the water in it can be neglected.

Assuming atmospheric pressure acts on both sides of the dome and can be neglected.

Step 2 of 4

The hemispherical dome is as shown in figure:

The volume of water inside the hemispherical dome,

$$V_W = \frac{2}{3}\pi R^3$$

Step 3 of 4

Consider the vertical forces.

Applying the equilibrium condition:

$$\sum F_y = 0$$

$$F_R - W_W - W_D = 0$$

Where W_D is the weight of the dome and

W_W is the weight of water inside the dome

F_R is the hydrostatic force acting from bottom

Then

$$F_R = W_W + W_D$$

$$\rho(h+R)\pi R^2 g = m_D g + m_{water} g$$

$$\rho\pi R^2 (h+R) = m_D + m_{water}$$

$$h = \frac{m_D + m_{water}}{\rho\pi R^2} - R$$

Step 4 of 4

Then substituting the known values

$$h = \frac{m_D + \rho_{water} V_W}{\rho\pi R^2} - R$$

$$= \frac{m_D + \rho_{water}\left(\frac{2}{3}\pi R^3\right)}{\rho\pi R^2} - R$$

$$= \frac{\left(50 \times 10^3\right) + \left(1000\right)\left(\frac{2}{3}\pi \times 3^3\right)}{1000\pi \times 3^2} - 3$$

$$= \frac{50000 + 56548.66}{28274.33} - 3$$

$$= 0.768 \text{ m}$$

Therefore the required height of water in the tube is $\boxed{h = 0.77 \text{ m}}$

Question: 11.047P

The water in a 25-m-deep reservoir is kept inside by a 150-m-wide wall whose cross section is an equilateral triangle, as shown in Fig. P11–47. Determine (*a*) the total for * (hydrostatic + atmospheric) acting on the inner surface of the wall and its line of action and (*b*) the magnitude of the? horizontal component of this force. Take *P*atm = 100 kPa.

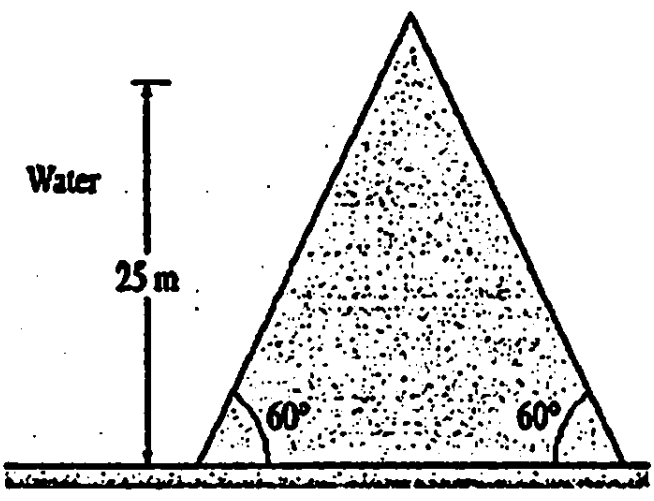


FIGURE P11–47

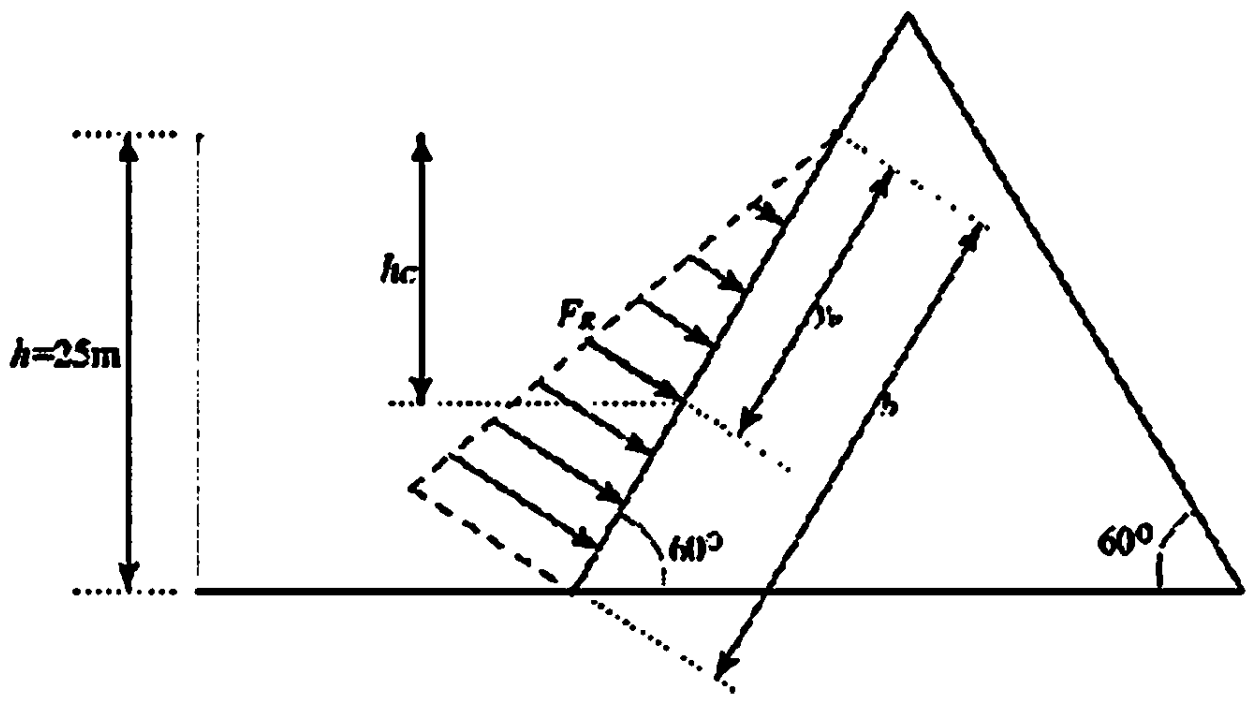
Step 1 of 7

Given data:



The depth of the reservoir, $d = 25\ \text{m}$

The atmospheric pressure, $P_{atm} = 100\ \text{kPa}$

Width of the wall, $w = 150\ \text{m}$

Step 2 of 7

The figure representing reservoir wall whose cross section is triangle is as shown below:

Step 3 of 7

Assuming:

Atmospheric pressure is acting on both sides of the gate, which cancels each other.

From the above figure,

$$b = \frac{h}{\sin 60^\circ}$$
$$= \frac{25}{\sin 60^\circ}$$
$$= 28.867\ \text{m}$$

Step 4 of 7

The vertical distance of the centroid from the free surface of the liquid is

$$h_C = \frac{h}{2}$$
$$= \frac{25}{2}$$
$$= 12.5\text{m}$$

Step 5 of 7

a)

The hydrostatic force acting on the wall is

$$F_R = P_{avg} A$$
$$= (P_{atm} + \rho g h_C) A$$

Where area of the surface is

$$A = w \times b$$
$$= 150 \times 28.867$$
$$= 4330.05\text{m}^2$$

Substituting the known values in the above equation

$$F_R = \left((100 \times 10^3) + (1000 \times 9.81 \times 12.49) \right) 4330.05$$
$$= 9.635 \times 10^8\text{N}$$

Therefore, the total force acting on the inner surface of the wall $\boxed{F_R = 9.635 \times 10^8\text{N}}$

Step 6 of 7

The line of action of the total force is

$$y_p = s + \frac{b}{2} + \frac{b^2}{12\left(s + \frac{b}{2} + \frac{P_0}{\rho g \sin\theta}\right)}$$
$$= 0 + \frac{28.867}{2} + \frac{28.867^2}{12\left(0 + \frac{28.867}{2} + \frac{100 \times 10^3}{1000 \times 9.81 \times \sin 60^\circ}\right)}$$
$$= 14.4335 + 2.650$$
$$= 17.08\ \text{m}$$

Therefore, line of action of the centre of pressure acting along the wall surface,

$\boxed{y_p = 17.08\ \text{m}}$

Step 7 of 7

b)

The horizontal component of hydrostatic force,

$$F_H = F_R \sin 60^\circ$$
$$= \left(9.635 \times 10^8\right) \sin 60^\circ$$
$$= 8.334 \times 10^8\text{N}$$

Therefore the horizontal component of hydrostatic force $\boxed{F_H = 8.334 \times 10^8\text{N}}$

Question: 11.048P pg 1

An elastic air balloon having a diameter of 30 cm is attached to the base of a container partially filled with water at +4°C, as shown in Fig. P11–48. If the pressure of air above water is gradually increased from 100 kPa to 1.6 MPa, will the force on the cable change? If so, what is the percent change in the force? Assume the pressure on the free surface and the diameter of the balloon are related by $P = CD^n$, where C is a constant and $n = -2$. The weight of the balloon and the air in it is negligible.

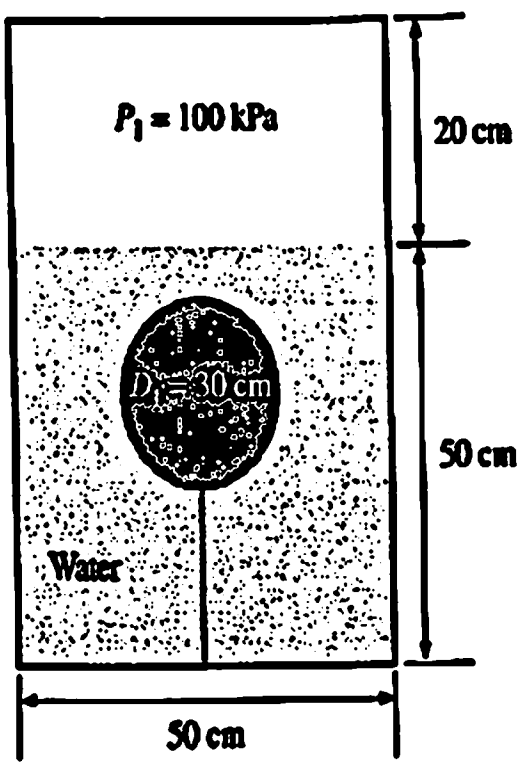


FIGURE P11–48

Step 1 of 9

Given data:

The diameter of the balloon, $D_1 = 0.3$ m.

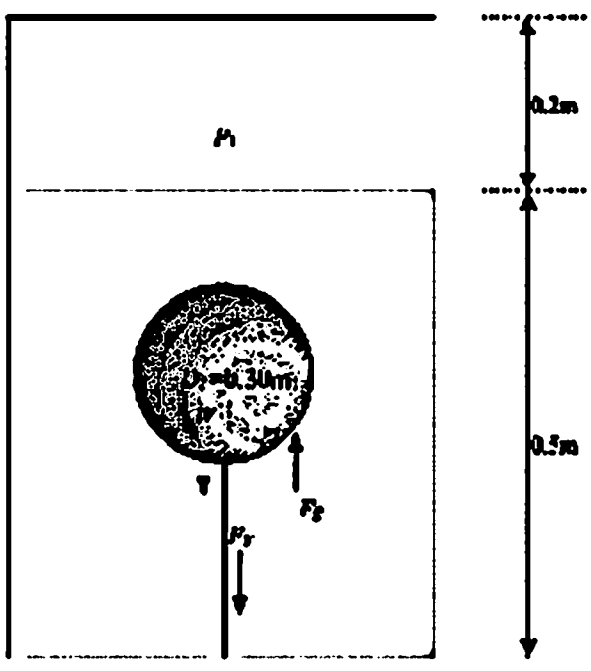
The initial pressure of air above water $p_1 = 100$ kPa

The final pressure of air above water $p_2 = 1.6$ MPa

The pressure on the surface and diameter of balloon is related by $P = CD^n$.

C is a constant and $n = -2$.

Step 2 of 9



Assuming:

The weight of the balloon and air in it is negligible.

The effect of atmospheric pressure is neglected.

Step 3 of 9

An elastic air balloon is attached to the base of a container is as shown below:

Step 4 of 9

The pressure on the surface and diameter of balloon is related by

$$P = CD^n$$

$$C = \frac{P}{D^n}$$

At initial state 1

$$C = \frac{P_1}{D_1^n}$$

$$= \frac{P_1}{D_1^{-2}}$$

$$C = P_1 D_1^2 \quad \text{..... (1)}$$

And at final state 2

$$C = \frac{P_2}{D_2^n}$$

$$= \frac{P_2}{D_2^{-2}}$$

$$C = P_2 D_2^2 \quad \text{..... (2)}$$

Comparing equations (1) and (2)

$$P_1 D_1^2 = P_2 D_2^2 \quad \text{..... (3)}$$

Step 5 of 9

From equation (3) the final diameter of the balloon when the pressure $P_2 = 1.6$ MPa is

$$P_1 D_1^2 = P_2 D_2^2$$

$$D_2 = D_1 \sqrt{\frac{P_1}{P_2}}$$

$$= (0.3) \sqrt{\frac{100 \times 10^3}{1.6 \times 10^6}}$$

$$= 0.075 \text{ m}$$

Step 6 of 9

From the diagram,

The tension in the cable

$$F_T = F_B - W$$

Where

F_B is the buoyant force on the balloon.

W is the weight of the balloon which is negligible.

Then

$$F_T = F_B$$

For buoyant force,

F_B is the buoyant force on the balloon.
W is the weight of the balloon which is negligible.
Then
$F_T = F_B$
For buoyant force,
$F_B = \rho_{water} g V_{balloon}$

Step 7 of 9

Volume of the balloon when diameter, $D_1 = 0.3$ m

$$V_{balloon} = \frac{4}{3}\pi r_1^3$$
$$= \frac{4}{3}\pi\left(\frac{D_1}{2}\right)^3$$
$$= \frac{\pi D_1^3}{6}$$
$$= \frac{\pi \times 0.3^3}{6}$$
$$= 0.0141\ \text{m}^3$$

Step 8 of 9

Then buoyant force
$$F_{B_1} = (1000)(9.81)(0.0141)$$
$$= 138.32\ \text{N}$$

Volume of the balloon when diameter when the diameter, $D_2 = 0.075$ m

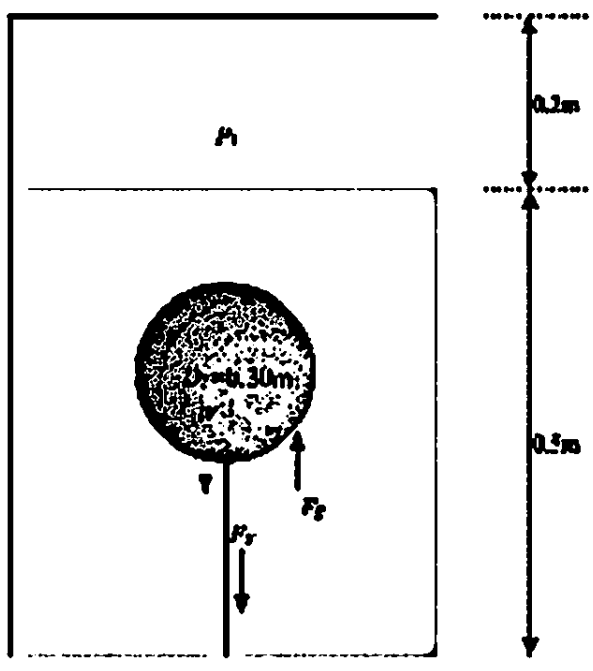
$$V_{balloon} = \frac{\pi D_2^3}{6}$$
$$= \frac{\pi \times 0.075^3}{6}$$
$$= 2.2 \times 10^{-4}\ \text{m}^3$$

Then buoyant force
$$F_{B_2} = (1000)(9.81)\left(2.2 \times 10^{-4}\right)$$
$$= 2.1582\ \text{N}$$

Step 9 of 9

The percentage decrease in cable tension

$$\%\,\text{decrease} = \frac{F_{B_1} - F_{B_2}}{F_{B_1}}$$
$$= \frac{138.32 - 2.1582}{138.32}$$
$$= 0.9843$$
$$= 98.43\%$$



Therefore the cable tension decreases by a margin of $\boxed{98.43\%}$.

Question: 11.049P

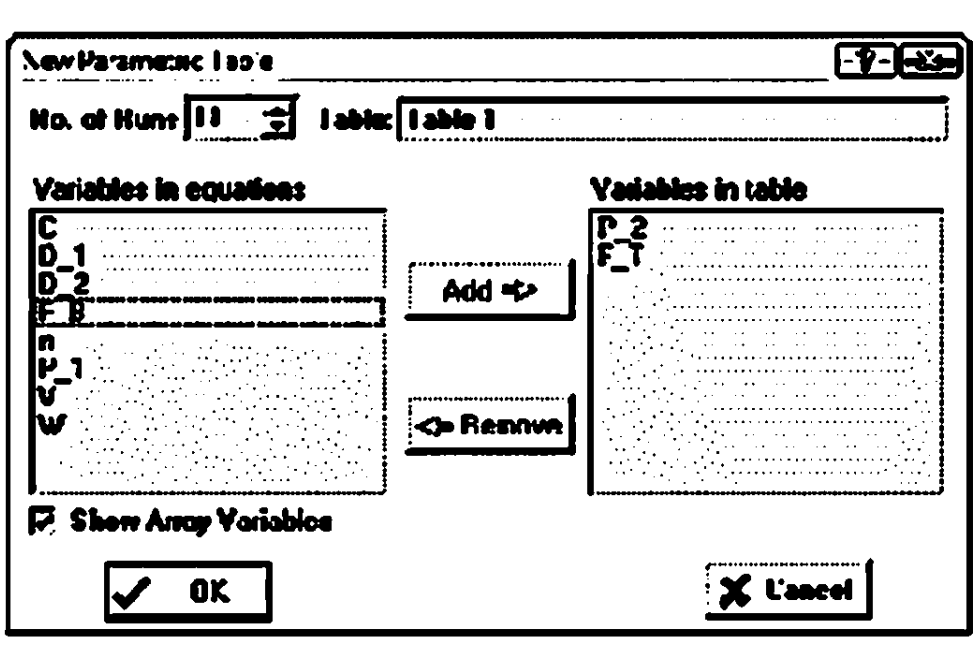
Reconsider Prob. 11-48. Using EES (or other) software, investigate the effect of air pressure above water on the cable force. Let this pressure vary from 0.5 MPa to 15 MPa. Plot the cable force versus the air pressure.

Step 1 of 6

An elastic air balloon is attached to the base of a container is as shown below:

Step 2 of 6

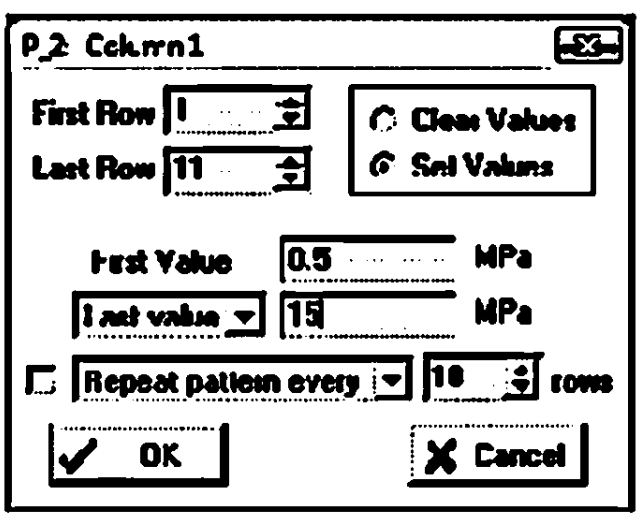
The given problem can be solved using EES software by following the below steps.



1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
"Given Data"
D_1=0.30[m]                          "Diameter of ballon"
"P_2 is varying from 0.5[MPa] to 15[MPa]"
W=0                                  "Weight of the ballon is negligible"
P_1=0.1[MPa]
"P=CD^n"
n=-2

P_1=C*D_1^n                          "At pressure P_1"
P_2=C*(D_2^n)                        "At pressure P_2"
V=abs(pi*(D_2)^3/6)                  "Volume of the ballon at diameter D_2"
F_B=1000*g#*V                        "Buoyant force acting on ballon"
F_T=F_B-W                            "Tesnion in the cable"
```



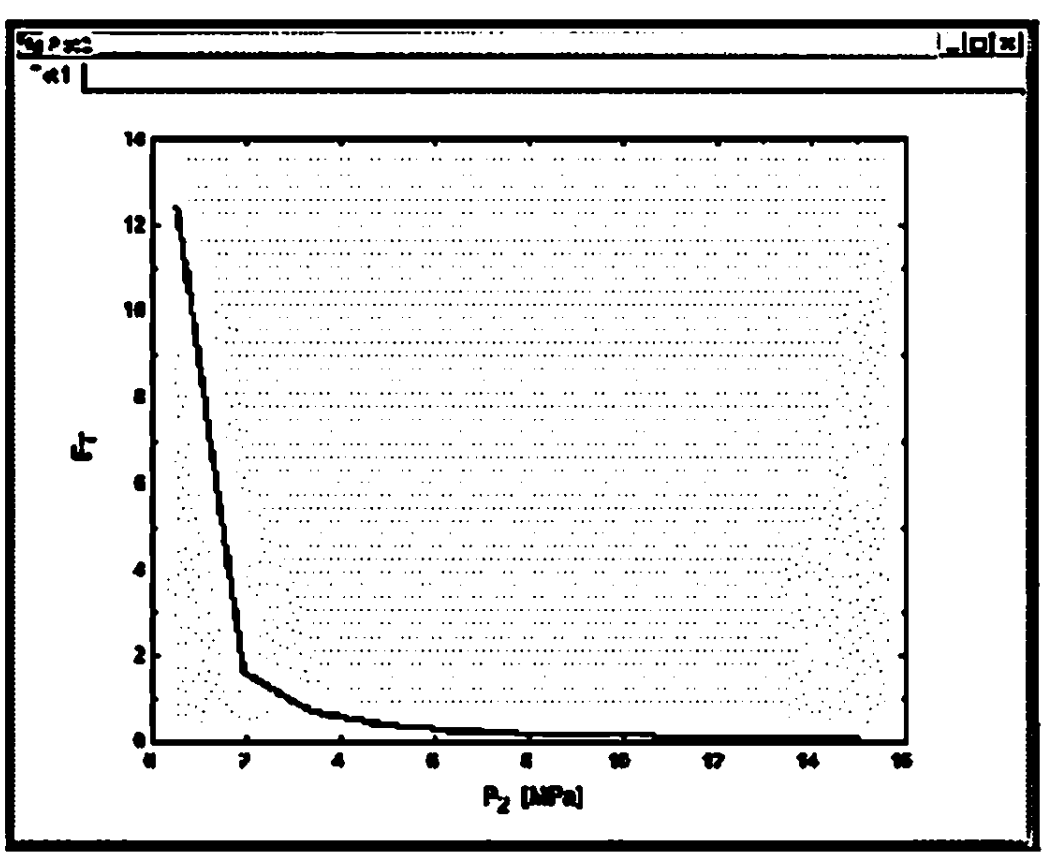
Step 3 of 6

Now to solve the equation for a range of pressure values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "P_2" and "F_T" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 4 of 6

To enter the values in the "P_2" column click on the drop tab in "P_2" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 5 of 6



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	1 P_2 [MPa]	2 F_T
Run 1	0.5	12.1
Run 2	1.95	1.61
Run 3	3.4	0.6993
Run 4	4.85	0.4105
Run 5	6.3	0.2773
Run 6	7.75	0.2032
Run 7	9.2	0.1571
Run 8	10.65	0.1261
Run 9	12.1	0.1042
Run 10	13.55	0.0879
Run 11	15	0.07547

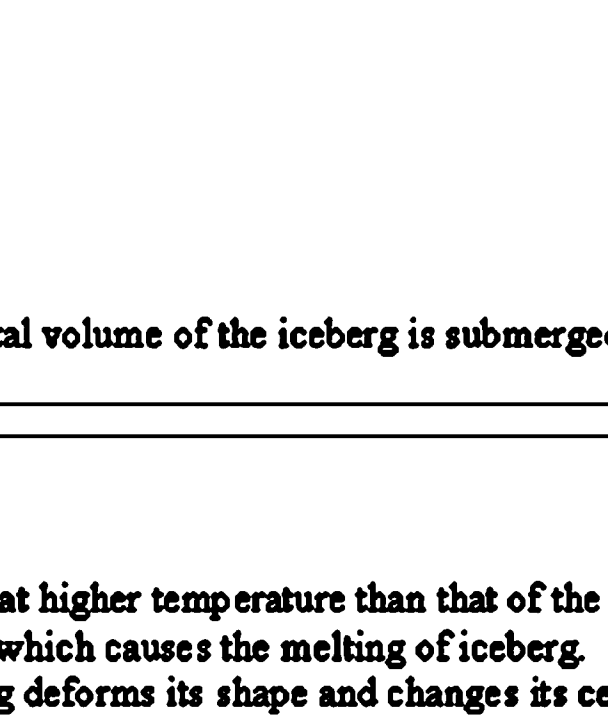
Step 6 of 6

Inorder to plot the cable force versus the air pressure, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Select X-axis as "P_2" and Y-axis as "F_T" and press 'OK'
The Graph will be plotted as shown below:

Question: 11.050P

The average density of icebergs is about 917 kg/m3. (*a*) Determine the percentage of the total volume of an iceberg submerged in seawater of density 1042 kg/m3. (*b*) Although icebergs are mostly submerged, they are observed to turn over. Explain how this can happen. (*Hint:*Consider the temperatures of icebergs and seawater.)

Step 1 of 5



Given data:

The average density of seawater, $\rho_w = 1042\ kg/m^3$

The density of ice berg, $\rho_i = 917\ kg/m^3$

Step 2 of 5

Consider the iceberg in sea water as shown in figure:

Step 3 of 5

a)

Assume W_i is the weight of the iceberg and F_B is the buoyant force which keeps it afloat.

Then by force equilibrium,

$W_i = F_B$

$\rho_i g V_i = \rho_w g V_{sub}$

Where V_i is the volume of the iceberg and

V_{sub} Is the volume of the submerged portion of the iceberg

Step 4 of 5

Then from above equation

$\rho_i g V_i = \rho_w g V_{sub}$

$$\frac{V_i}{V_{sub}} = \frac{\rho_i}{\rho_w}$$

$$= \frac{917}{1042}$$

$$= 0.880$$

$$= 88\%$$

$V_i = 0.88(V_{sub})$

Therefore $\boxed{88\%}$ of the total volume of the iceberg is submerged in sea water.

Step 5 of 5

b)

We know the sea water is at higher temperature than that of the iceberg. This causes heat transfer from water to ice which causes the melting of iceberg.

The melting of the ice berg deforms its shape and changes its centre of mass which causes turning over of the iceberg.

CHAPTER 12
SOLUTIONS

Question: 12.001P

What is streamwise acceleration? How does it differ from normal acceleration? Can a fluid particle accelerate in steady How?

Step 1 of 2

Streamwise acceleration:

The acceleration of a fluid particle along a stream line in a flow can be termed as Streamwise acceleration.

Step 2 of 2

Difference between Streamwise and Normal acceleration

In Streamwise acceleration the fluid particles accelerates along the stream line. But in normal acceleration the fluid particles accelerates in a direction normal to the streamline which is usually created due to change in direction of flow.

Question: 12.002P

Express the Bernoulli equation in three different ways using (*a*) energies, (*b*) pressures, and (*c*) heads.

Step 1 of 3

(a) Bernoulli's equation in terms of energies for unit mass

$$\boxed{\frac{P}{\rho}+\frac{V^2}{2}+gz = \text{constant}}$$

Where,

The flow energy of the fluid is $\frac{P}{\rho}$

The kinetic energy of the fluid is $\frac{V^2}{2}$

The potential energy of the fluid is gz

Step 2 of 3

(b) **Bernoulli's equation in terms of pressures**

We have

$$\frac{P}{\rho}+\frac{V^2}{2}+gz = \text{constant}$$

Divide the equation with density (ρ)

Then we get the Bernoulli's equation in terms of pressures for unit mass as

$$\boxed{P+\rho\frac{V^2}{2}+\rho gz = \text{constant}}$$

Where

The static pressure head is P

The dynamic pressure is $\rho\frac{V^2}{2}$

The hydrostatic pressure is ρgz

Step 3 of 3

(c) **Bernoulli's equation in terms of heads**

We have

$$\frac{P}{\rho}+\frac{V^2}{2}+gz = \text{constant}$$

Divide the equation with acceleration due to gravity, (g)

$$\boxed{\frac{P}{\rho g}+\frac{V^2}{2g}+z = \text{constant}}$$

Where

The pressure head is $\frac{P}{\rho g}$

The velocity head is $\frac{V^2}{2g}$

The elevation head is z

Question: 12.003P

What are the three major assumptions used in the derivation of the Bernoulli equation?

Step 1 of 1

The three major assumptions for the derivation of Bernoulli's Equation

(1) The fluid flow is steady.

(2) The fluid flow is incompressible.

(3) The frictional forces are negligible.

Question: 12.004P

Define static, dynamic, and hydrostatic pressure. Under what conditions is their sum constant for a flow stream?

Step 1 of 2

Static pressure (P):

The static pressure is the actual thermodynamic pressure of the fluid. This pressure does not take into account any dynamic effects and is the same pressure used in property tables.

Dynamic pressure:

The dynamic pressure $\left(\rho V^2/2\right)$ of the fluid can be defined as the pressure developed when the fluid motion is brought to a stop in an isentropic manner

Hydrostatic pressure:

The pressure exerted by a liquid column of height h under the effect of gravity over specified area can be termed as hydrostatic pressure.

It is expressed as

$P_h = \rho g h$

Or

$P_h = \rho g z$

Where z is the elevation

Step 2 of 2

We have the Bernoulli's equation for pressures in term of unit mass,

$$P + \rho\frac{V^2}{2} + \rho g z = \text{constant}$$

The equation represents the sum of static, dynamic and hydrostatic pressures are constant. This is possible when the following conditions are satisfied

(1) The fluid flow is steady.

(2) The fluid flow is incompressible.

(3) The frictional forces are negligible.

Therefore static, dynamic and hydrostatic pressures have been defined and the conditions for the sum of static, dynamic and hydrostatic pressures to be constant have been specified.

Question: 12.005P

What is stagnation pressure? Explain how it can be measured.

Step 1 of 2

Stagnation pressure:
The pressure developed at a point where the fluid has been brought to rest in an isentropic manner can be termed as stagnation pressure.
The stagnation pressure is expressed as

$$P_{stag} = P + \rho\frac{V^2}{2}$$

Where
The static pressure is P

The dynamic pressure is $\rho\frac{V^2}{2}$

Step 2 of 2

The stagnation pressure can be measured by using a Pitot tube. The Pitot tube is a device in the form of a small tube with one end open which is pointed directly into the fluid flow. The moving fluid is brought to rest or stagnates due to the absence of an outlet. The pressure developed can be measured by using this instrument is the stagnation pressure.

Question: 12.006P

Define pressure head, velocity head, and elevation head for a fluid stream and express them for a fluid stream whose pressure is P, velocity is V, and elevation is z.

Step 1 of 3

Pressure head:

Pressure head can be defined as the height of a fluid column that produces a static pressure.

It is represented as $\frac{P}{\rho g}$

Where

The pressure is P

The density of fluid is ρ

The acceleration due to gravity is g

Step 2 of 3

Velocity head:

The elevation that is required for a fluid to attain a velocity V in a frictionless fall can be termed as the velocity head of that fluid.

It is represented as $\frac{V^2}{2g}$

Where

The velocity to be attained is V

Step 3 of 3

Elevation head:

The height at which the stored which also represents the potential energy of the fluid can be termed as elevation head

The elevation head is represented as z.

Consider a fluid under a pressure P, velocity V and elevation z

The pressure head, velocity head and elevation head can be combined to form the Bernoulli equation expressed in terms of head as

$$\frac{P}{\rho g} + \frac{V^2}{2g} + z = \text{constant}$$

Question: 12.007P

What is the hydraulic grade line? How does it differ from the energy grade line? Under what conditions do both lines coincide with the free surface of a liquid?

Step 1 of 3

Hydraulic grade line (HGL):

The line that represents the sum of static pressure head and elevation head can be termed as Hydraulic grade line.

Hydraulic grade line can be represented as

$$\frac{P}{\rho g} + z$$

Where

The static pressure head is $\frac{P}{\rho g}$

The elevation head is z

Step 2 of 3

Energy grade line (EGL):

The energy grade line represents the sum of static pressure, dynamic pressure and elevation pressure heads.

It is represented as

$$\frac{P}{\rho g} + \frac{V^2}{2g} + z$$

Where

The static pressure head is P

The dynamic pressure is $\rho\frac{V^2}{2}$

The elevation head is z

Step 3 of 3

Difference between Hydraulic grade and Energy grade line

The difference between Hydraulic grade and Energy grade line is the presence of the dynamic pressure head term $\left(\frac{V^2}{2g}\right)$ in the Energy grade line.

The energy grade line coincides with the hydraulic grade line when the velocity is zero and the static (gage) pressure is zero.

Then the elevation of the free surface z will represent both HGL and EGL.

Examples: Stationary lakes and reservoirs.

Question: 12.008P

How is the location of the hydraulic grade line determined for open-channel flow? How is it determined at the outlet of a pipe discharging to the atmosphere?

Step 1 of 3

The Hydraulic grade line represents the sum of the static pressure and the elevation head and it is denoted with letter HGL

$$\text{HGL} = \frac{P}{\rho g} + z$$

where P is the pressure at one point

Density of the fluid is ρ

Acceleration due to gravity is g

Elevation head is z

Step 2 of 3

In case of open channel flow the atmospheric pressure acts at the free surface of the liquid. Then the hydraulic grade line, HGL coincides with the free surface of the liquid.

Step 3 of 3

When fluid is discharging from the pipe to the atmosphere, atmospheric pressure acts at the exit of the pipe then the hydraulic grade line coincides with the pipe outlet.

Question: 12.009P

In a certain application, a siphon must go over a high wall. Can water or oil with a specific gravity of 0.8 go over a higher wall? Why?

Step 1 of 5

Given data:

The specific gravity of oil is $SG_O = 0.8$.

The oil and water is to be siphoned over a high wall.

Step 2 of 5

Assumption:

The siphoning is to be carried out under the normal atmospheric pressure of $P_{atm} = 1.013$ bar.

The water used is of density $\rho_w = 1000\ kg/m^3$.

Step 3 of 5

Consider water is being used,

We have

$P_{atm} = \rho_w g h_w$

The maximum height to which water can be siphoned when $P_{atm} = 1.013$ bar

$$h_w = \frac{P_{atm}}{\rho_w g}$$

$$= \frac{1.013 \times 10^5}{(1000)(9.81)}$$

$$= 10.32\ m$$

We can conclude that if the height of the high wall is equal to or below 10.32 m , the water can be siphoned over it.

Step 4 of 5

Consider oil is being used,

The density of oil,

$$\rho_O = SG_O(\rho_w)$$

$$= (0.8)(1000)$$

$$= 800\ kg/m^3$$

Step 5 of 5

We have

$P_{atm} = \rho_O g h_O$

The maximum height to which oil can be siphoned when $P_{atm} = 1.013$ bar

$$h_O = \frac{P_{atm}}{\rho_O g}$$

$$= \frac{1.013 \times 10^5}{(800)(9.81)}$$

$$= 12.9\ m$$

We can conclude that if the height of the high wall is equal to or below 12.9 m , the oil can be siphoned over it.

Question: 12.010P

Explain how and why a siphon works. Someone proposes siphoning cold water over a 7-m-high wall. Is this feasible? Explain.

Step 1 of 3

The difference in elevation and the corresponding pressure difference between the inlet and exit of a tube cause the phenomenon of siphoning.

The exit of a siphon tube is positioned at an elevation below that of the free surface of the liquid, this elevation difference causes the flow of liquid inside the tube.

Step 2 of 3

Write the equation for the atmospheric pressure.

$$P_{atm} = \rho_{water} g h_{water}$$

Here, P_{atm} is the atmospheric pressure, ρ_{water} is the density of water, g is the acceleration due to the gravity, and h_{water} is the height to which water can be siphoned.

Substitute $1.013 \times 10^5 \text{ N/m}^2$ for P_{atm}, 9.81 m/s^2 for g, and 1000 kg/m^3 for ρ_{water}.

$$1.013 \times 10^5 = 1000 \times 9.81 \times h_{water}$$

$$h_{water} = \frac{1.013 \times 10^5}{1000 \times 9.81}$$
$$= 10.326 \text{ m}$$

So, the maximum height to which water can be siphoned when it is exposed to the atmospheric pressure is 10.326 m.

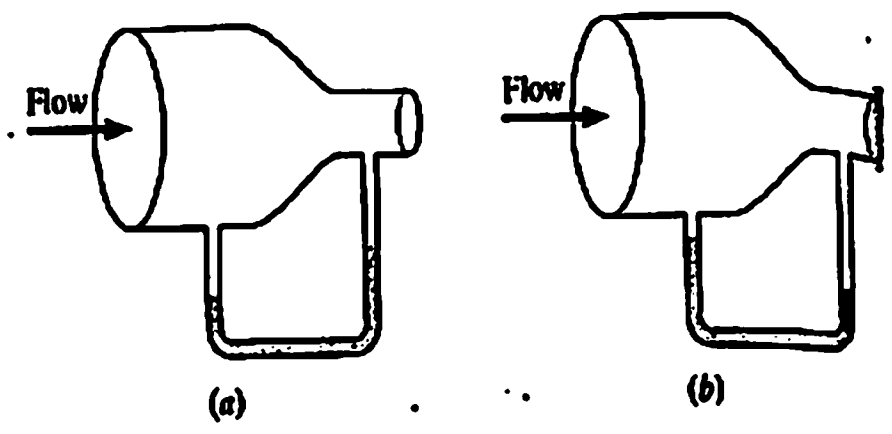
Step 3 of 3

As the proposed height for siphoning cold water is 7 m, which is less than 10.326 m.

Thus, it is **feasible** to siphon cold water over a 7 m high wall.

Question: 12.011P pg 1

A glass manometer with oil as the working fluid is connected to an air duct as shown in Fig. P12—J1C. Will the oil levels in the manometer be as in Fig. P12—1 IC*a* or *b*Explain. What would your response be if the How direction is reversed.



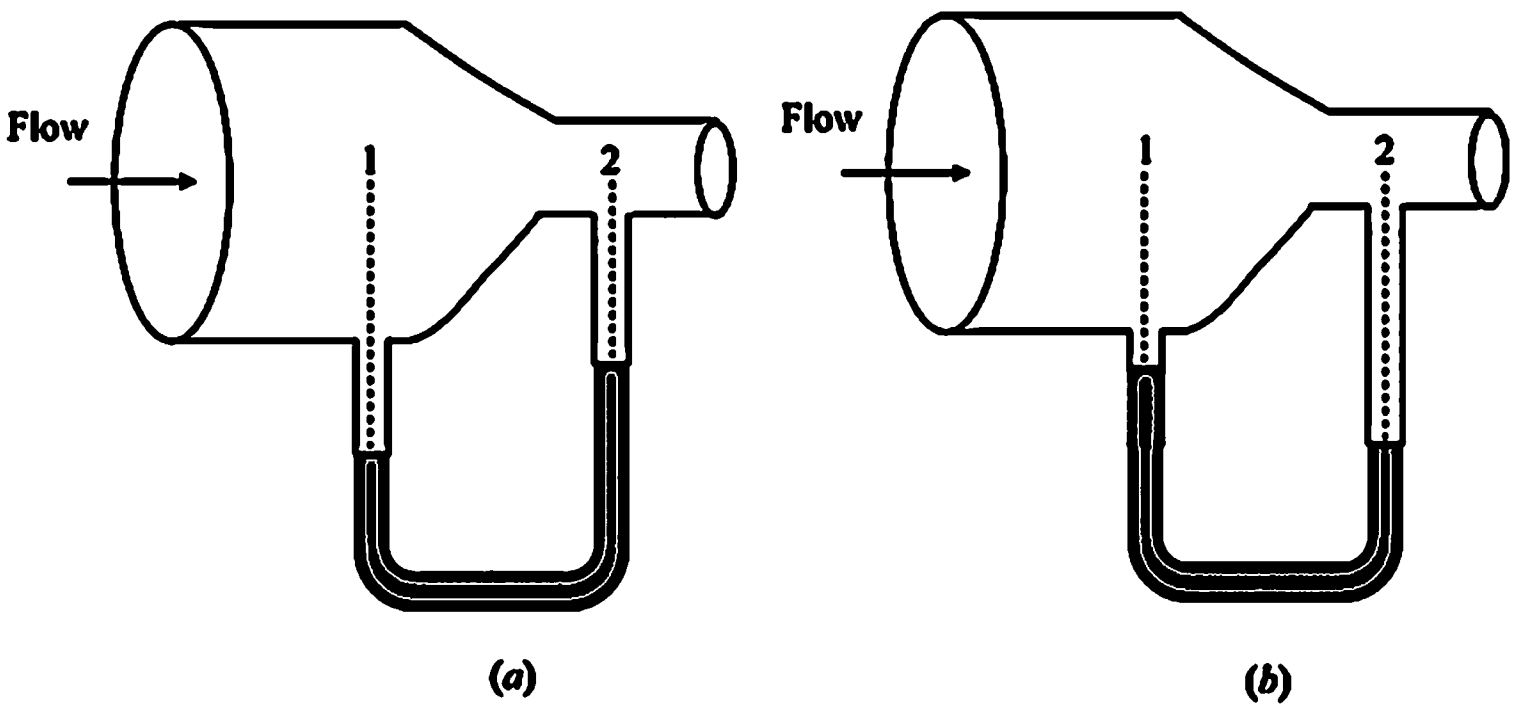


FIGURE P12-11C

Step 1 of 8

Draw the diagram for the given configurations.

Step 2 of 8

Assume the flow is steady, incompressible, and inviscid.

Write the equation for mass flow rate.

$$\dot{m} = \rho V A_c$$

Here, $\dot{m}$ is the mass flow rate, V is the flow velocity, A_c is the area of cross-section, and ρ is the density of the fluid.

As the flow is assumed to be constant, $\dot{m}$ and ρ are constant.

$$V = \frac{\dot{m}}{\rho A_c}$$

$$V \propto \frac{1}{A_c}$$

Therefore, the velocity varies inversely with the area of cross section.

Step 3 of 8

From the above figure, as the flow is from left to right, the area of cross section decreases from section 1 to section 2.

$$A_1 > A_2$$

Here, A_1 is the area at section 1 and A_2 is the area at section 2.

As the velocities are inversely proportional to area of cross section,

$$V_1 < V_2$$

Here, V_1 is the velocity at section 1 and V_2 is the velocity at section 2.

Step 4 of 8

Apply the Bernoulli's equation at section 1 and section 2.

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 \quad \text{..... (1)}$$

Here, P_1 is the pressure at section 1, P_2 is the pressure at section 2, V_1 is the velocity at section 1, V_2 is the velocity at the section 2, z_1 is the elevation at section 1, z_2 is the elevation at section 2, ρ is the density of the fluid, and g is the acceleration due to the gravity.

From the figure, section 1 and section 2 are at same levels of elevation.

$$z_1 = z_2$$

Substitute z_2 for z_1 in equation (1).

$$P_1 = P_2 + \frac{1}{2}\rho\left(V_2^2 - V_1^2\right)$$

Step 5 of 8

Find the pressure at the section 2.

$$\frac{P_2}{\rho g} = \frac{P_1}{\rho g} + \frac{V_1^2}{2g} - \frac{V_2^2}{2g}$$

$$P_2 = P_1 + \frac{1}{2}\rho\left(V_1^2 - V_2^2\right)$$

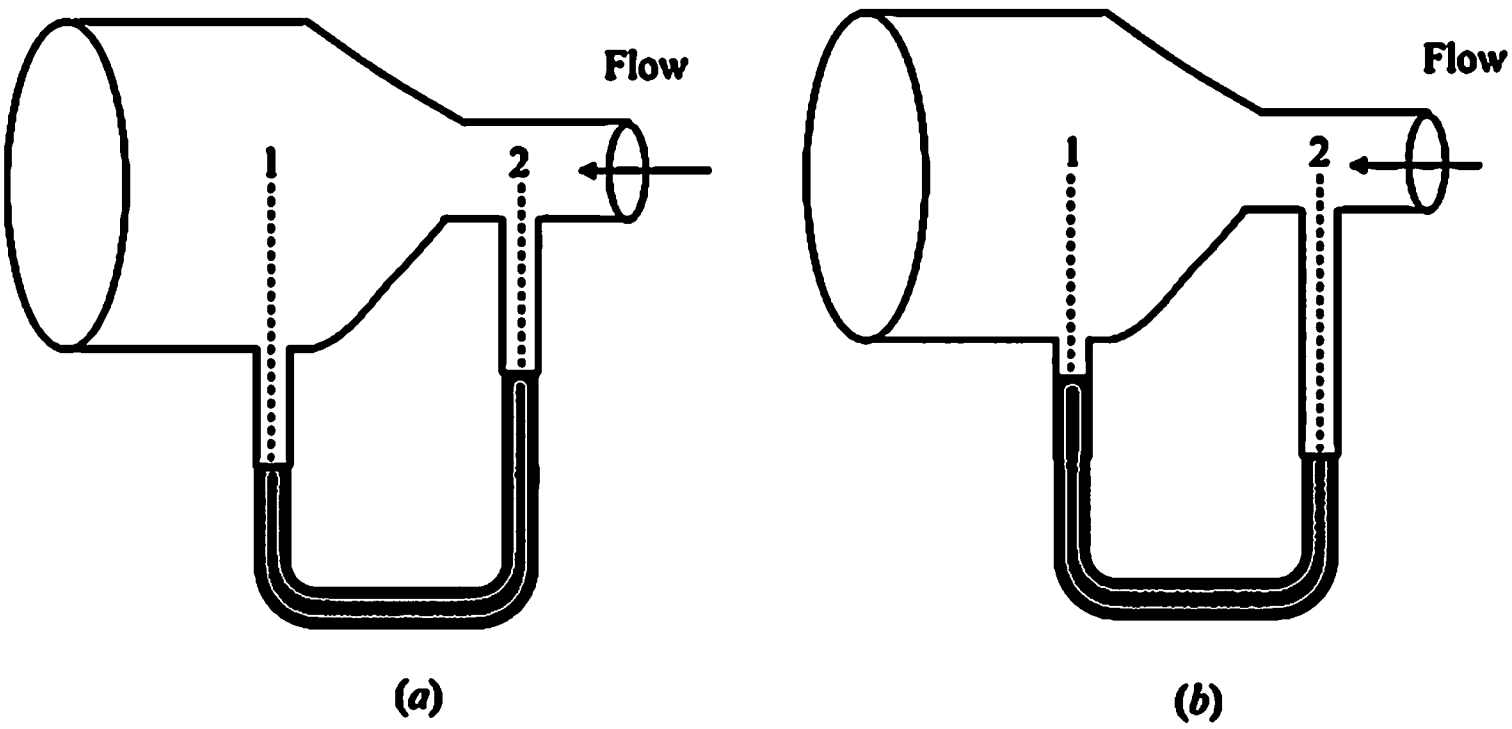
As $V_1 < V_2$, V_1^2 is less than V_2^2.

Hence, the term $V_1^2 - V_2^2$ is negative and $V_2^2 - V_1^2$ is positive.

$$P_2 = P_1 - \frac{1}{2}\rho\left(V_2^2 - V_1^2\right)$$

So, the pressure at section 2 is less than the pressure at section 1.

$$P_2 = P_1 - \frac{1}{2}\rho\left(V_2^2 - V_1^2\right)$$



So, the pressure at section 2 is less than the pressure at section 1.

As the pressure in section 2 is less than the pressure in section 1, the fluid will rise in section 2.

Therefore, the correct configuration is figure $\boxed{(a)}$.

Step 6 of 8

Now consider the flow direction to be reversed.

(a) (b)

Step 7 of 8

Here, in the reversed flow configuration the area of cross section increases from section 2 to section 1.

$$A_2 < A_1$$

As the velocities are inversely proportional to area of cross section,

$$V_2 > V_1$$

Step 8 of 8

Apply the Bernoulli's equation at section 1 and section 2.

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

From the figure, section 1 and section 2 are at same levels of elevation.

$$z_1 = z_2$$

Substitute z_2 for z_1 .

$$P_1 = P_2 + \frac{1}{2}\rho\left(V_2^2 - V_1^2\right)$$

As the term $V_2^2 - V_1^2$ is positive, the pressure at 1 is greater than pressure at 2.

So, the fluid at section 1 will depress.

Therefore, the correct configuration for reversed direction of the flow is $\boxed{(a)}$.

Question: 12.012P

The velocity of a fluid flowing in a pipe is to be measured by two different Pito-type mercury manometers shown in Fig. P12-12C. Would you expect both manometers to predict the same velocity for flowing water? If not, which would be more accurate? Explain. What would your response be if air were flowing in the pipe instead of water?

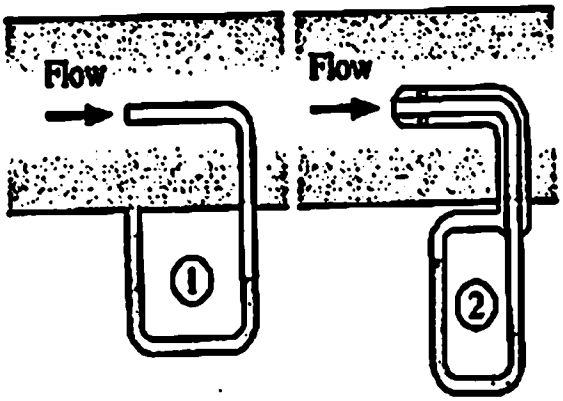


FIGURE P12–12C

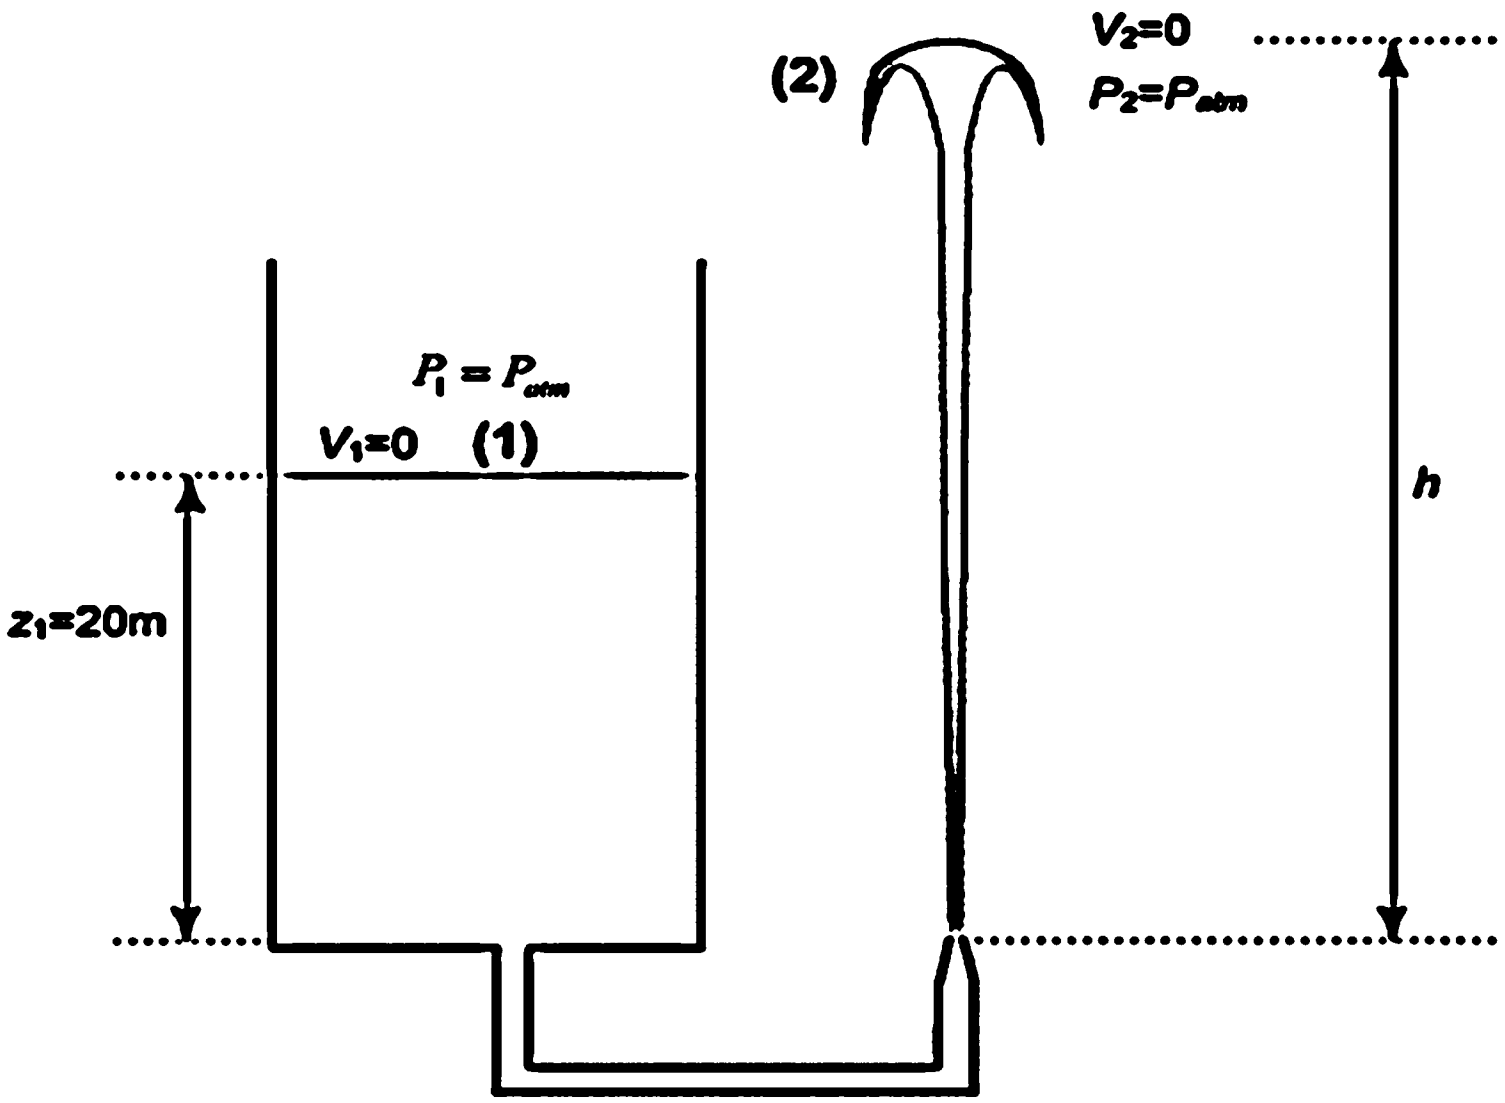
Step 1 of 1

Pitot tubes are used to indicate the fluid flow velocity by measuring the difference between the static and dynamic pressures in fluids. From the two different Pitot-type mercury manometers shown, arrangement 2 can be considered to be more accurate because it measures both stagnation pressure and static pressure at same location along the pipe centerline. Whereas in arrangement 1, the stagnation pressure is measured at pipe centerline, along with a static pressure tap that measures static pressure at the bottom of the pipe.



Static pressure in a pipe varies with elevation across the pipe cross section which is similar to hydrostatics (change of pressure with respect to height). Hence we can say that even arrangement is 1 is accurate as the elevation difference between the Pitot probe and static pressure tap is compensated by the change in hydrostatic pressure. Hence there will be no change in the analysis when the water is replaced by air as elevation changes are not important.

Question: 12.013P

The water level of a tank on a building roof is 20 m above the ground. A hose leads from the tank bottom to the ground. The end of the hose has a nozzle, which is pointed straight up. What is the maximum height to which the water could rise? What factors would reduce this height?

Step 1 of 3

Draw the schematic diagram of the tank.

Step 2 of 3

Apply Bernoulli's equation between the points (1) and (2).

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2$$

Substitute P_{atm} for P_1, 0 for V_1, $20\,\text{m}$ for z_1, P_{atm} for P_2, 0 for V_2 and 0 for z_2.

$$\frac{P_{atm}}{\rho g}+\frac{0}{2g}+20=\frac{P_{atm}}{\rho g}+\frac{0}{2g}+z_2$$

$$z_2=20\ \text{m}$$

Therefore, the maximum height to which water can rise from the nozzle is $\boxed{z_2=20\ \text{m}}$.

Step 3 of 3

The following are the factors that can reduce the height of the jet:

- Frictional effects being present in the system.
- Lower pressure at the water surface in the tank.

Question: 12.014P

A student siphons water over a 8.5-m-high wall at :sea level. She then climbs to the summit of Mount Shasta (elevation 4390 m, *P*atm = 58.5 kPa) and attempts the same experiment. Comment on her prospects for success.

Step 1 of 3

Given data:

The atmospheric pressure at Mt Shasta, $P_{atm} = 58.5\ \text{kPa}$.

The elevation of Mt Shasta summit, $z = 4390\ \text{m}$.

The height over which water has to be siphoned, $h_s = 8.5\ \text{m}$.

Step 2 of 3

The height to which water can be raised under a pressure of $P_{atm} = 58.5\ \text{kPa}$,

$$h = \frac{P_{atm}}{\rho g}$$

$$= \frac{58.5 \times 10^3}{(1000)(9.81)}$$

$$= 5.963\ \text{m}$$

We get $h < h_s$

Therefore, we can conclude that it is not possible for the person to siphon water over a wall of height $h_s = 8.5$ m at the summit of Mt Shasta.

Step 3 of 3

The pressure required to siphon water over a wall of height $h_s = 8.5$ m at the summit of Mt Shasta,

$$P = \rho g h_s$$

$$= (1000)(9.81)(8.5)$$

$$= 83.385 \times 10^3 \text{Pa}$$

$$= 83.385 \text{kPa}$$

Therefore, a pressure of $\boxed{P = 83.4\ \text{kPa}}$ is required for the siphoning process to occur.

Question: 12.015P

In a hydroelectric power plant, water enters the turbine nozzles at 800 kPa absolute with a low velocity. If the nozzle outlets are exposed to atmospheric pressure of 100 kPa, determine the maximum velocity to which water can be accelerated by the nozzles before striking the turbine blades.

Step 1 of 3

Given data:

Inlet pressure of the nozzle, $P_1 = 800$ kPa

$= 800000$ kPa.

Outlet pressure of the nozzle, $P_2 = 100$ kPa

$= 100000$ kPa.

Step 2 of 3

Let us apply the Bernoulli's equation between the Inlet and outlet

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 \qquad \ldots\ldots (1)$$

where

The elevation, $z_1 = z_2 = 0$.

Inlet velocity, $V_1 = 0$.

Density water, $\rho = 1000$ kg/m^3.

Step 3 of 3

By substituting the required values in equation (1), we get

$$\frac{P_1}{\rho g} + 0 + 0 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + (0)$$

$$\frac{V_2^2}{2g} = \frac{P_1}{\rho g} - \frac{P_2}{\rho g}$$

$$V_2^2 = \frac{2(P_1 - P_2)}{\rho}$$

$$= \frac{2(800000 - 100000)}{1000}$$

$$= 1400$$

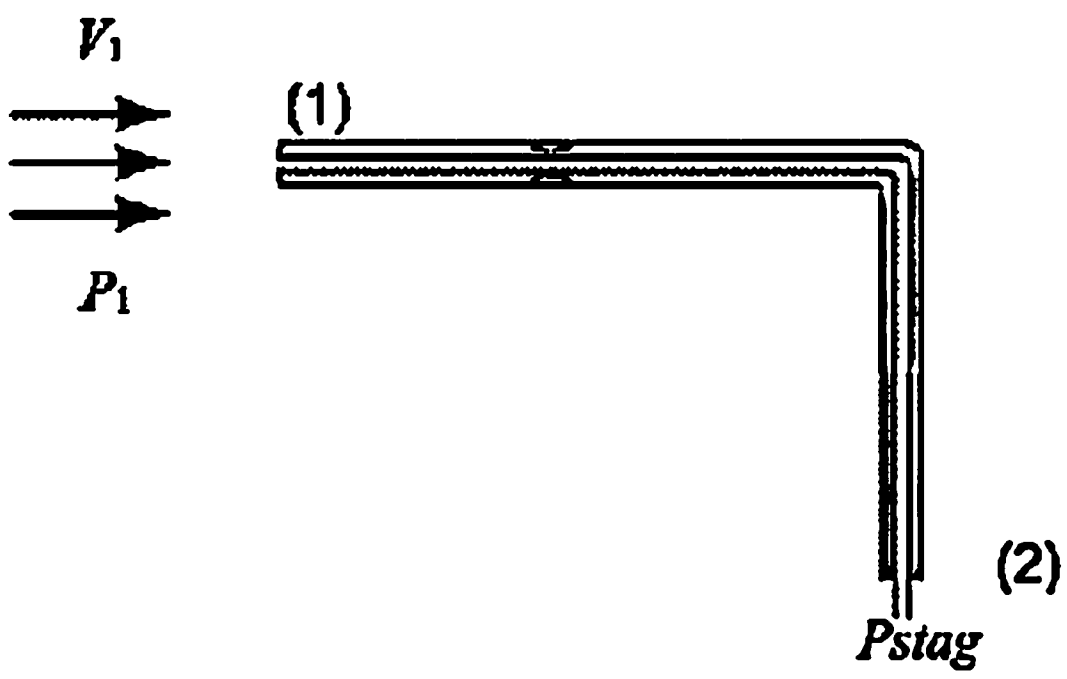
$$V_2 = \sqrt{1400}$$

$$= 37.42 \text{ m/s}$$

Therefore, the maximum velocity to which water can be accelerated by the nozzle is $\boxed{V_2 = 37.42 \text{ m/s}}$.

Question: 12.016P

A Pilot-static probe is used to measure the speed of an aircraft flying at 3000 m. If the differential pressure reading is 3 kPa, determine the speed of the aircraft.



Step 1 of 3

Given data:

Flying height of the aircraft, $h = 3000$ m.

The differential pressure reading, $P_{diff} = 3$ kPa.

Let us draw the figure.

Step 2 of 3

We have,

$$P_{diff} = P_{stag} - P_1$$
$$= 3 \text{ kPa}$$

Let us apply the Bernoulli's equation between the two points,

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 \qquad \ldots\ldots (1)$$

where

The elevation, $z_1 = z_2$

The velocity at stagnation point (2), $V_2 = 0$

Step 3 of 3

By substituting the above values in equation (1), we get

$$\frac{V_1^2}{2g} = \frac{P_{stag}}{\rho g} - \frac{P_1}{\rho g}$$

$$\frac{V_1^2}{2} = \frac{P_{stag} - P_1}{\rho}$$

Substitute the required values,

$$\frac{V_1^2}{2} = \frac{3 \times 10^3}{0.909}$$

$$V_1 = \sqrt{6600.66}$$
$$= 81.24 \text{ m/s}$$

Therefore, the velocity of the aircraft is $\boxed{V_1 = 81.2 \text{ m/s}}$.

Question: 12.017P

While traveling on a dirt road, the bottom of a car kits a sharp rock and a small hole develops at the bottom of its tank. If the height of the gasoline in the tank is 40 cm, determine the initial velocity of the gasoline at the hole. Discuss how the velocity will change with time and how the flow will be affected if the lid of the tank is closed tightly.

Step 1 of 3

Given data:

The height of the gasoline in the tank, $z_1 = 0.4$ m.

Let us apply the Bernoulli's equation between the surface of gasoline and exit,

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 \qquad \ldots\ldots (1)$$

Where

The elevation at exit

$z_2 = 0$

Step 2 of 3

By substitute the required values in equation (1), we get

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + (0.40\text{ m}) = \frac{P_{atm}}{\rho g} + \frac{V_2^2}{2g} + (0)$$

$$\frac{V_2^2}{2g} = 0.4$$

$$V_2 = \sqrt{2(9.81)(0.4)}$$

$$= 2.8014\text{ m/s}$$

Therefore, the exit velocity of the gasoline is $\boxed{V_2 = 2.80\text{ m/s}}$.

Step 3 of 3

When the lid of the gasoline tank is tightly sealed, the pressure at the surface will be minimum or much less than the atmospheric pressure. We also know that the exit velocity is proportional to the square root of the height of the fluid.

Then as the height decreases and along with the absence or negligible pressure on the surface the exit velocity will be lower than 2.80 m/s.

Question: 12.018P

The drinking water needs of an office are by large water bottles. One end of a 0.25-in-diameter plastic hose is inserted into the bottle placed on a high stand, while the other end with an on/off valve is maintained 2 ft below the bottom of the bottle. If the water level in the bottle is 1.5 ft when it is full, determine how long it will take at the minimum to fill an 8-oz glass (= 0.00835 ft3) (*a*) when the bottle is first opened and (*b*) when the bottle is almost empty. Neglect frictional losses.

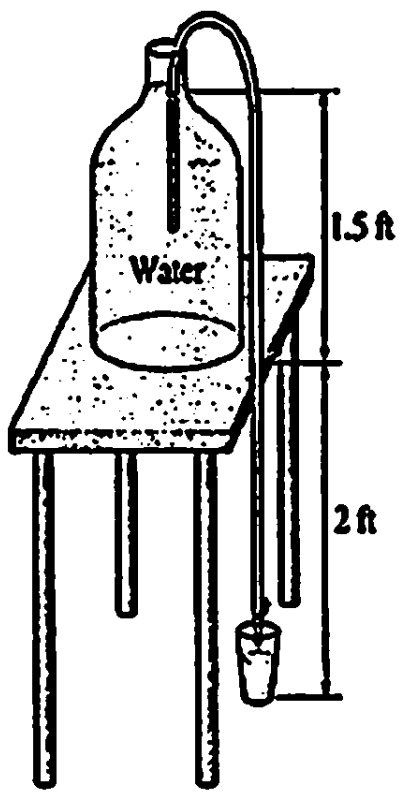


FIGURE P12–18E

Step 1 of 5

Let us apply the Bernoulli's equation,

$$\frac{P_1}{\rho g}+\frac{v_1^2}{2g}+z_1=\frac{P_2}{\rho g}+\frac{v_2^2}{2g}+z_2$$

Where

Inlet open is atmosphere, $p_1 = p_{atm}$

Discharge is also in atmosphere, $p_2 = p_{atm}$

The elevation $z_2 = 0$

The bottle is very large is compare to the tube diameter.

Step 2 of 5

Substituting the required values,

$$\frac{P_{atm}}{\rho g}+0+z_1=\frac{P_{atm}}{\rho g}+\frac{v_2^2}{2g}+0$$

$$v_2^2 = 2gz_1$$

$$v_2 = \sqrt{2gz_1}$$

Step 3 of 5

a)

When the bottle is first opened (Full bottle),

$$z_1 = 3.5\,\text{ft}$$

The flow velocity at outlet,

$$v_2 = \sqrt{2\times 32.2\times 3.5}$$

$$= 15.01\ \text{ft/s}$$

Area of the hose $A=\frac{\pi}{4}d^2$

Here d is the diameter of the hose.

Substitute $d = 0.25$ in. in above equation.

$$A=\frac{\pi}{4}\left(0.25\text{in.}\times\frac{1}{12}\frac{\text{ft}}{\text{in.}}\right)^2$$

$$=0.0003409\,\text{ft}^2$$

Step 4 of 5

Time taken at the minimum to fill the glass,

$$\Delta t=\frac{V}{Q}$$

$$=\frac{V}{Av_2}$$

Here V is the volume of the bottle.

Substitute $V = 0.00835\,\text{ft}^3$, $A = 0.0003409\,\text{ft}^2$ and $v_2 = 15.01\,\text{ft/s}$ in above equation.

$$\Delta t=\frac{0.00835}{0.0003409\times 15.01}$$

$$=1.6318\text{s}$$

Time taken at the minimum to fill the glass is $\boxed{1.63\text{s}}$

Step 5 of 5

b)

When the bottle is almost empty (Full empty)

$$z_1 = 2\,\text{ft}$$

The flow velocity at outlet,

$$v_2 = \sqrt{2\times 32.2\times 2}$$

$$= 11.35\ \text{ft/s}$$

Time taken at the minimum to fill the glass,

$$\Delta t=\frac{V}{Q}$$

$$=\frac{V}{Av_2}$$

Here V is the volume of the bottle.

Substitute $V = 0.00835\,\text{ft}^3$, $A = 0.0003409\,\text{ft}^2$ and $v_2 = 11.35\,\text{ft/s}$ in above equation.

$$\Delta t=\frac{0.00835}{0.0003409\times 11.35}$$

$$=2.158\text{s}$$

Time taken at the minimum to fill the glass is $\boxed{2.16\text{s}}$

Question: 12.019P

A piezometer and a Pilot tube are tapped into a 4-cm-diameter horizontal water pipe, and the height of the water columns are measured to be 26 cm in the piezometer and 35 cm in the Pitot tube (both measured from the top surface of the pipe). Determine the velocity at the center of the pipe.

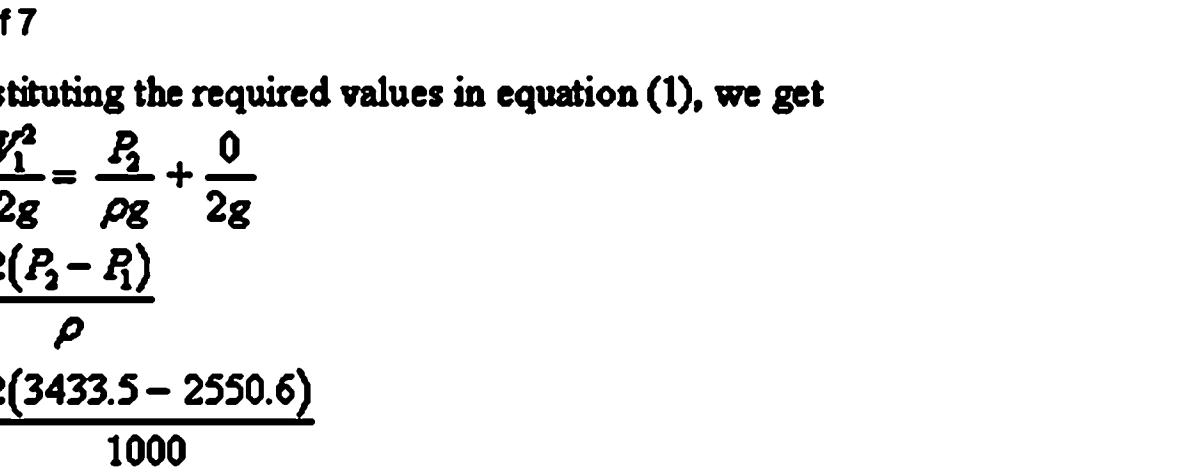
Step 1 of 7

Given data:

The diameter of the pipe, $D = 4$ cm

$= 0.04$ m.

The height of water column in piezometer, $z_1 = 26$ cm



$= 0.26$ m.

The height of water column in Pitot tube, $z_2 = 35$ cm

$= 0.35$ m.

Step 2 of 7

Let us draw the figure.

Step 3 of 7

Consider the piezometer at section (1),

The pressure,

$P_1 = \rho g h_1$

$= (1000)(9.81)(0.26)$

$= 2550.6$ Pa

Step 4 of 7

Consider the Pitot tube at section (2),

$P_2 = \rho g h_2$

$= (1000)(9.81)(0.35)$

$= 3433.5$ Pa

Step 5 of 7

Let us apply the Bernoulli's between the points (1) and (2).

Then,

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 \qquad \ldots\ldots (1)$$

where

The elevation

$z_1 = z_2$

The velocity at the stagnation point (2)

$V_2 = 0$

Step 6 of 7

By substituting the required values in equation (1), we get

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} = \frac{P_2}{\rho g} + \frac{0}{2g}$$

$$V_1^2 = \frac{2(P_2 - P_1)}{\rho}$$

$$= \frac{2(3433.5 - 2550.6)}{1000}$$

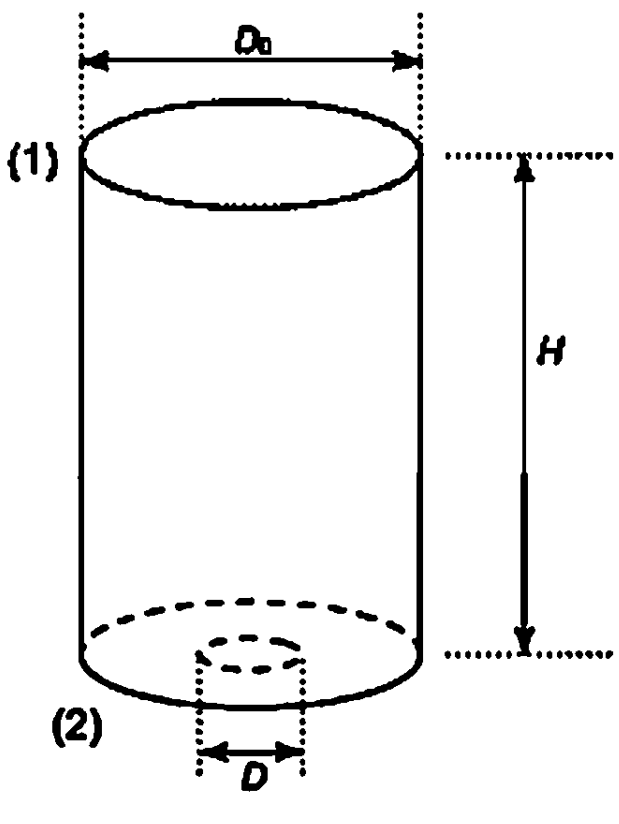
$= 1.7658$

Step 7 of 7

The flow velocity at the center of the pipe,

$V_1 = \sqrt{1.7658}$

$= 1.32$ m/s



Therefore, the flow velocity is $\boxed{V_1 = 1.32 \text{ m/s}}$.

Question: 12.020P

The diameter of a cylindrical water tank is D_0 and its height is H. The tank is filled with water, which is open to the atmosphere. An orifice of diameter D with a smooth entrance (i.e., negligible losses) is open at the bottom. Develop a relation for the time required for the tank (*a*) to empty halfway and (*b*) to empty completely.

Step 1 of 6

Let us draw the figure

Step 2 of 6

The flow rate,

$$\dot{V} = AV$$

where

A is the area

V is the velocity of fluid

Then flow rate at the orifice,

$$\dot{V} = A_2 V_2$$

$$= \left(\frac{\pi D^2}{4}\right) V_2$$

Step 3 of 6

Let us apply the Bernoulli's equation between (1) and (2).

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

The pressures

$$P_1 = P_2 = P_{atm}$$

P_{atm} is the atmospheric pressure.

The velocity of water at (1),

$$V_1 = 0$$

Then

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + z_1 = \frac{P_{atm}}{\rho g} + \frac{V_2^2}{2g} + 0$$

$$V_2 = \sqrt{2gz_1}$$

Step 4 of 6

Substituting $V_2 = \sqrt{2gz_1}$ in $\dot{V} = \left(\frac{\pi D^2}{4}\right) V_2$ then

$$\dot{V} = \left(\frac{\pi D^2}{4}\right)\sqrt{2gz_1}$$

We have $\dot{V} = \frac{V}{\Delta t}$

Where

V is the volume of water removed

Δt is the time period.

The volume, $V = \pi \frac{D_0^2}{4} z$

where z is the height of water removed from the cylindrical tank.

Then we can write,

$$\left(\frac{\pi D^2}{4}\right)\sqrt{2gz_1} = \frac{V}{\Delta t}$$

$$\left(\frac{\pi D^2}{4}\right)\sqrt{2gz_1} = \pi \frac{D_0^2}{4\Delta t} z$$

Step 5 of 6

a)

The water level is half way

$$\left(\frac{\pi D^2}{4}\right)\sqrt{2gz_1} = \pi \frac{D_0^2}{4\Delta t} z$$

Where

$$z_1 = H \text{ and } z = \frac{H}{2}$$

Then

$$\left(\frac{\pi D^2}{4}\right)\sqrt{2gH} = \pi \frac{D_0^2}{4\Delta t} \frac{H}{2}$$

$$\left(\frac{D_0^2}{D^2}\right)\frac{H}{\sqrt{8gH}} = \Delta t$$

Therefore, the time required is $\boxed{\Delta t = \left(\frac{D_0^2}{D^2}\right)\frac{H}{\sqrt{8gH}}}$.

Step 6 of 6

b)

The tank is completely empty.

We have

$$\left(\frac{\pi D^2}{4}\right)\sqrt{2gz_1} = \pi \frac{D_0^2}{4\Delta t} z$$

Where

$$z_1 = H \text{ and } z = H$$

Then

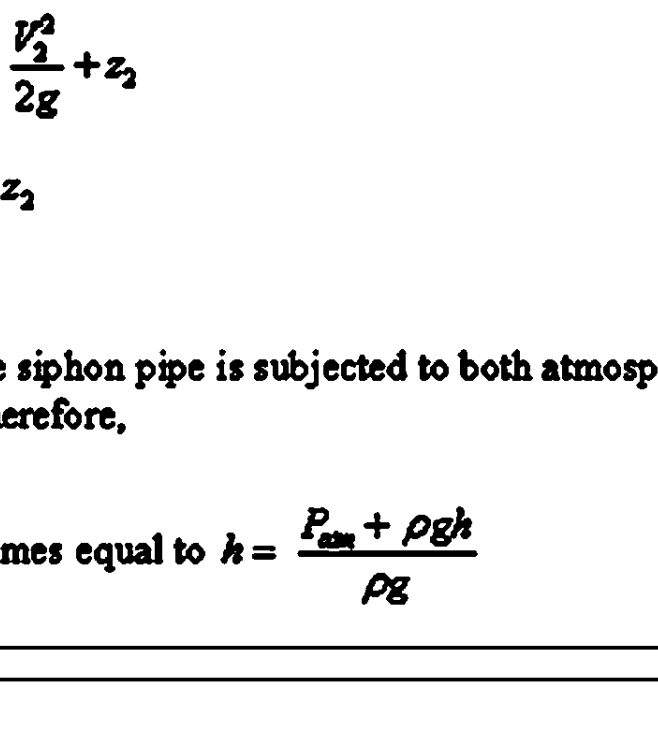
$$\left(\frac{\pi D^2}{4}\right)\sqrt{2gH} = \pi \frac{D_0^2}{4\Delta t} H$$

$$\left(\frac{D_0^2}{D^2}\right)\frac{H}{\sqrt{2gH}} = \Delta t$$

Therefore, the time required is $\boxed{\Delta t = \left(\frac{D_0^2}{D^2}\right)\frac{H}{\sqrt{2gH}}}$.

Question: 12.021P

A siphon pumps water from a large reservoir to a lower tank that is initially empty. The tank also has a rounded orifice 20 ft below the reservoir surface where the water leaves the tank. Both the siphon and the orifice diameters are 2 in. Ignoring frictional losses, determine to what height the water will rise in the tank at equilibrium.



Step 1 of 9

Given data:

Diameters of siphon and orifice, $d = 2\text{in.}$

Step 2 of 9

Schematic of diagram of siphon system:

Step 3 of 9

The pressure at point (1) and (3) is equal to the atmospheric pressure, P_{atm}.

The velocity at point (1) and (3) is negligible or equal to zero.

Apply the Bernoulli's equation between reservoir surface (1) and siphon exit (2).

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

Let us set the orifice point as the reference level.

From the figure

$z_2 = z_4$

Step 4 of 9

Then

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$\frac{P_{atm}}{\rho g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

Where

Since pressure exit of the siphon pipe is subjected to both atmospheric pressure and pressure of the water. Therefore,

$P_2 = P_{atm} + \rho g h$

Then pressure head becomes equal to $h = \frac{P_{atm} + \rho g h}{\rho g}$

Step 5 of 9

Then, simplifying the above expression, we get

$$\frac{P_{atm}}{\rho g} + z_1 = \frac{P_{atm} + \rho g h}{\rho g} + \frac{V_2^2}{2g} + 0$$

$$0 + z_1 = h + \frac{V_2^2}{2g} + 0$$

$$\frac{V_2^2}{2g} = z_1 - h$$

$$V_2 = \sqrt{2g(z_1 - h)}$$

Step 6 of 9

Applying Bernoulli's equation between tank surface (3) and orifice exit (4).

$$\frac{P_3}{\rho g} + \frac{V_3^2}{2g} + z_3 = \frac{P_4}{\rho g} + \frac{V_4^2}{2g} + z_4$$

Since atmospheric pressure acting at surface (3), therefore

$P_3 = P_{atm}$

And set the orifice point as the reference level.

So from the figure

$z_3 = h$

Then, substituting the values in above expression, we get

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + z_3 = \frac{P_4}{\rho g} + \frac{V_4^2}{2g} + 0$$

$$\frac{P_{atm}}{\rho g} + h = \frac{P_4}{\rho g} + \frac{V_4^2}{2g} + 0$$

Where

$P_4 = P_{atm} + \rho g h$

Step 7 of 9

Then, velocity at exit of orifice is

$$\frac{P_{atm}}{\rho g} + h = \frac{P_{atm} + \rho g h}{\rho g} + \frac{V_4^2}{2g} + 0$$

$$h = \frac{V_4^2}{2g}$$

$$V_4 = \sqrt{2gh}$$

Step 8 of 9

We know that when the diameters of the orifice and the siphon tube are equal to each other, their flow rates will also be equal to each other.

Then

$\dot{V}_2 = \dot{V}_4$

$A_{siphon} V_2 = A_{orifice} V_4$

$V_2 = V_4$

Substitute the known values in above expression, we get

$$\sqrt{2g(z_1 - h)} = \sqrt{2gh}$$

$$2g(z_1 - h) = 2gh$$

$$h = \frac{z_1}{2}$$

Step 9 of 9

The height to which water rises in the tank

$$h = \frac{z_1}{2}$$

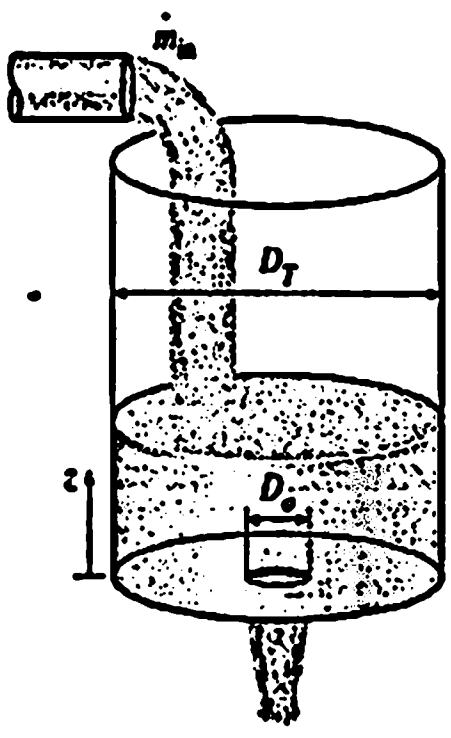
$$= \frac{20}{2}$$

$$= 10\text{ft}$$

Therefore, height of the water rises in bottom tank is $\boxed{h = 10\text{ft}}$.

Question: 12.022P pg 1

Water enters a tank of diameter *DT*steadily at a mass flow rate of *m*in An orifice at the bottom with diameter *D*oallows water to escape. The orifice has a rounded entrance, so the frictional losses are negligible. If the tank is initially empty, (*a*) determine the maximum height that the water will reach in the tank and (*b*) obtain a relation for water height *z* as a function of time.



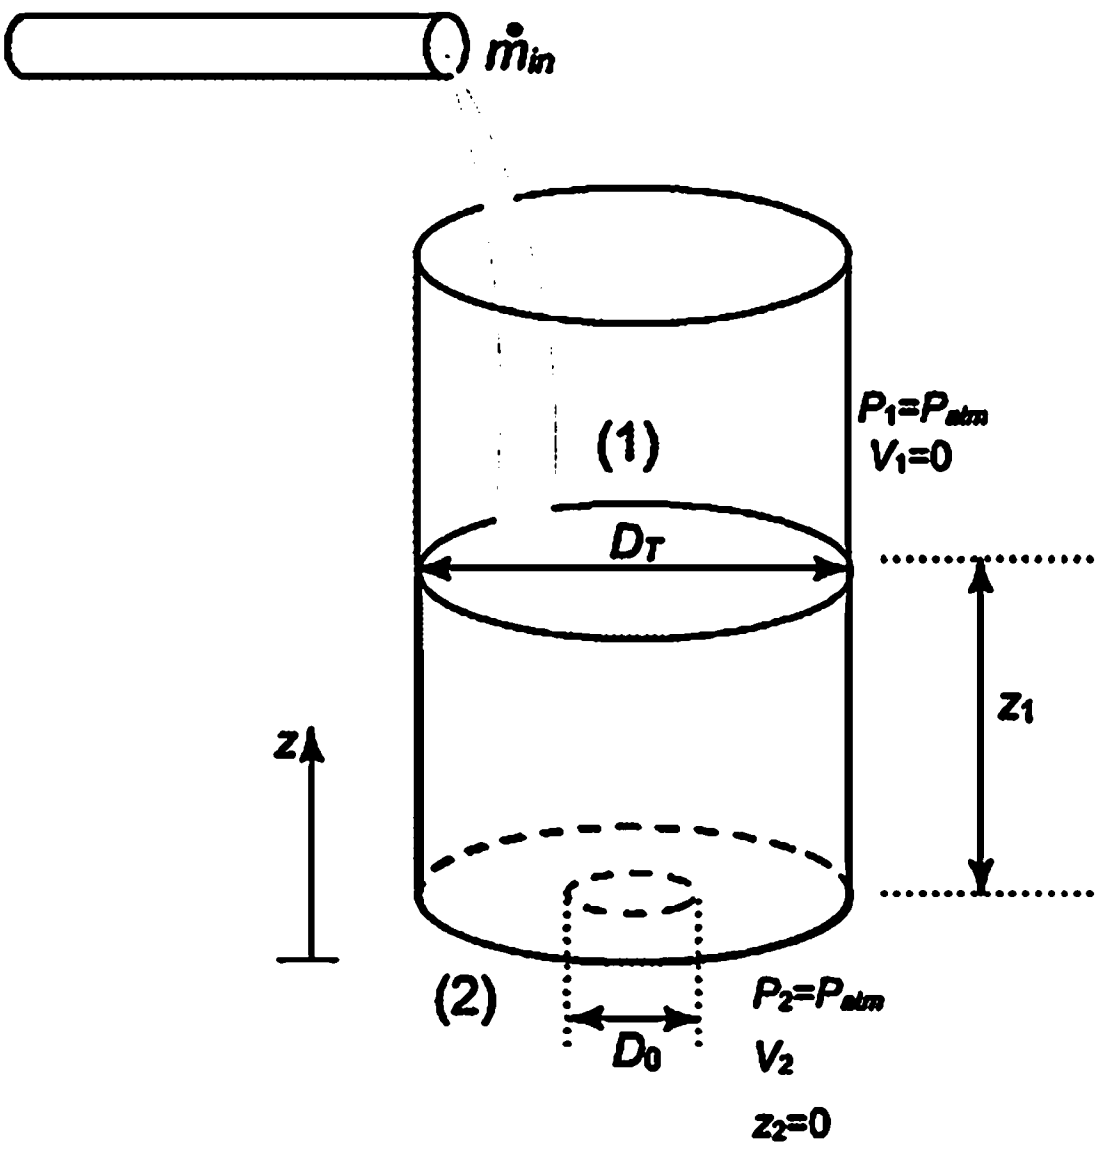


FIGURE P12-22

Step 1 of 7

Draw the schematic diagram of water tank system.

Step 2 of 7

(a)

Apply the Bernoulli's theorem between the points (1) and (2), by setting the bottom of the tank as datum, to find out the expression for the velocity at the exit.

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2$$

Here, the pressure at points 1 and 2 are P_1 and P_2 respectively, velocity of points 1 and 2 are V_1 and V_2 respectively, and the height of points 1 and 2 above datum head is z_1 and z_2 respectively.

Substitute 0 for V_1 and 0 for z_2 .

$$\frac{P_{atm}}{\rho g}+\frac{0}{2g}+z=\frac{P_{atm}}{\rho g}+\frac{V_2^2}{2g}+0$$

$$\frac{V_2^2}{2g}=z$$

$$V_2=\sqrt{2gz} \quad \text{..... (1)}$$

Step 3 of 7

Calculate the mass flow rate at the point-2 at orifice.

$$\dot{m}_{orifice}=\rho A_{orifice}V_2 \quad \text{..... (2)}$$

Here, the density of the water is ρ , the area of the orifice is $A_{orifice}$, and the velocity at point 2 is V_2 .

Substitute $\left(\frac{\pi D_0^2}{4}\right)$ for $A_{orifice}$ and equation (1) in equation (2).

$$\dot{m}_{orifice}=\rho\left(\frac{\pi D_0^2}{4}\right)\sqrt{2gz}$$

Here, the diameter of the orifice is D_0 .

Square the equation on both sides.

$$\left(\dot{m}_{orifice}\right)^2=\rho^2\left(\frac{\pi D_0^2}{4}\right)^2 2gz$$

$$z=\frac{\left(\dot{m}_{orifice}\right)^2}{\rho^2\left(\frac{\pi D_0^2}{4}\right)^2 2g}$$

When the water is at maximum height, it is equal to $z=z_{max}$ and the flow rate $\dot{m}_{orifice}=\dot{m}_{in}$.

$$z_{max}=\frac{\left(\dot{m}_{in}\right)^2}{\rho^2\left(\frac{\pi D_0^2}{4}\right)^2 2g}$$

$$z_{max} = \frac{(\dot{m}_{in})^2}{\rho^2\left(\frac{\pi D_0^2}{4}\right)^2 2g}$$

Therefore, the maximum height reached by the water in the tank is $\boxed{\frac{(\dot{m}_{in})^2}{\rho^2\left(\frac{\pi D_0^2}{4}\right)^2 2g}}$.

Step 4 of 7

(b)
Apply the principle of conservation of mass for the control volume undergoing a change during period of time dt.

$$dm_{cv} = \dot{m}_{in}dt - \dot{m}_{orifice}dt$$

$$\rho\left(\frac{\pi D_T^2}{4}\right)dz = \dot{m}_{in}dt - \rho\left(\frac{\pi D_0^2}{4}\right)\sqrt{2gz}dt$$

$$dt = \frac{\rho\left(\frac{\pi D_T^2}{4}\right)}{\dot{m}_{in} - \rho\left(\frac{\pi D_0^2}{4}\right)\sqrt{2gz}}dz$$

$$= \frac{1}{\dot{m}_{in}}\left(\frac{\rho\left(\frac{\pi D_T^2}{4}\right)}{1 - \frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2gz}}\right)dz$$

$$= \frac{\rho\left(\frac{\pi D_T^2}{4}\right)}{\dot{m}_{in}}\left(\frac{1}{1 - \left(\frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2g}\right)z^{1/2}}\right)dz$$

Substitute b for $\left(\frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2g}\right)$ and a for $\frac{\rho\left(\frac{\pi D_T^2}{4}\right)}{\dot{m}_{in}}$.

$$dt = a\left(\frac{1}{1 - bz^{1/2}}\right)dz \quad \text{..... (3)}$$

Step 5 of 7

Consider the following expression.

$$z = x^2 \quad \text{..... (4)}$$

$$dz = 2xdx$$

Substitute x^2 for z and $2xdx$ for dz in equation (3).

$$dt = a\left(\frac{1}{1 - bz^{1/2}}\right)dz$$

$$= a\left(\frac{1}{1 - b\left(x^2\right)^{1/2}}\right)(2xdx) \quad \text{..... (5)}$$

$$= a\left(\frac{2xdx}{1 - bx}\right)$$

Dissolve the fraction using the following method.

$$\text{Numerator} = A \times (\text{denominator}) + B \times \frac{d}{dt}(\text{denominator})$$

$$2x = A \times (1 - bx) + B \times \frac{d}{dx} \times (1 - bx) \quad \text{..... (6)}$$

$$2x = A \times (1 - bx) - bB$$

Equate the coefficients of t on the left hand side and right hand side and find out the variables A and B.

$$A = \frac{-2}{b}$$

$$A - bB = 0$$

$$A = bB$$

$$-\frac{2}{b} = bB$$

$$B = -\frac{2}{b^2}$$

Step 6 of 7

Substitute $\left(-\frac{2}{b^2}\right)$ for B and $-\frac{2}{b}$ for A in equation (6).

$$2x = \frac{-2}{b} \times (1 - bx) - \frac{-2}{b^2}b$$

$$2x = \frac{-2}{b} \times (1 - bx) + \frac{2}{b}$$

Substitute $\left(\frac{-2}{b} \times (1 - bx) + \frac{2}{b}\right)$ for $2x$ in equation (5).

$$dt = a\left(\frac{\frac{-2}{b} \times (1 - bx) + \frac{2}{b}}{\quad}\right)dx$$

Substitute $\left(\frac{-2}{b}\times(1-bx)+\frac{2}{b}\right)$ for $2x$ in equation (5).

12 022R.pg 3

$$dt=a\left(\frac{\frac{-2}{b}\times(1-bx)+\frac{2}{b}}{1-bx}\right)dx$$

$$dt=\frac{2a}{b}\left(\frac{1}{1-bx}-1\right)dx$$

Step 7 of 7

Integrate the equation on both sides.

$$\int dt=\int\frac{2a}{b}\left(\frac{1}{1-bx}-1\right)dx$$

$$t=\frac{2a}{b}\left(\ln(1-bx)-x\right)$$

Substitute the equation (4).

$$t=\frac{2a}{b}\left(\ln\left(1-bz^{1/2}\right)-z^{1/2}\right)\quad\ldots\ldots\ (7)$$

Substitute $\left(\frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2g}\right)$ for b and $\frac{\rho\left(\frac{\pi D_T^2}{4}\right)}{\dot{m}_{in}}$ for a in the equation (7).

$$t=\frac{2\frac{\rho\left(\frac{\pi D_T^2}{4}\right)}{\dot{m}_{in}}}{\left(\frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2g}\right)}\left(\ln\left(1-\left(\frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2g}\right)z^{1/2}\right)-z^{1/2}\right)$$

$$=2\frac{D_T^2}{\sqrt{2g}D_0^2}\left(\left(\ln\left(1-\frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2g}\right)z^{1/2}\right)-z^{1/2}\right)$$

Therefore, the relation between the time and height is,

$$\boxed{t=2\frac{D_T^2}{\sqrt{2g}D_0^2}\left(\left(\ln\left(1-\frac{\rho\left(\frac{\pi D_0^2}{4}\right)}{\dot{m}_{in}}\sqrt{2g}\right)z^{1/2}\right)-z^{1/2}\right)}.$$

Question: 12.023P

Water flows through a horizontal pipe at a rate of 1 gal/s. The pipe consists of two sections of diameters 4 in and 2 in with a smooth reducing section. The pressure difference between the two pipe sections is measured by a mercury manometer. Neglecting frictional effects, determine the differential height of mercury between the two pipe sections.

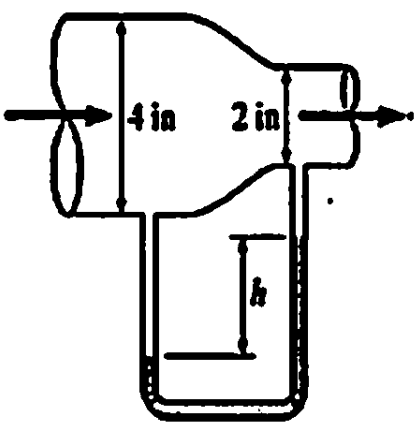

FIGURE P12–23E

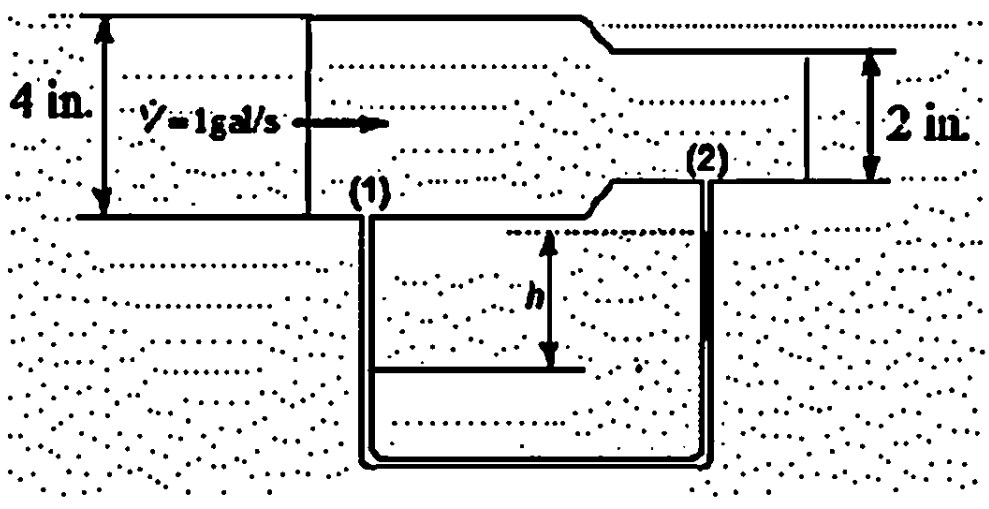
Step 1 of 7

Given data:



Flow rate of water though a horizontal pipe, $\dot{V} = 1\text{gal/s}$

Diameter of horizontal pipe at section (1), $D_1 = 4\text{in.}$

Diameter of horizontal pipe at section (2), $D_2 = 2\text{in.}$

Step 2 of 7

Schematic diagram of manometer arrangement in a horizontal pipe:

Step 3 of 7

From the continuity equation, rate of flow through a horizontal pipe section is given as

$$\dot{V} = A_1V_1 = A_2V_2$$

Where,

A_1 is the area of the pipe section (1)

A_2 Is the area of the pipe section (2)

V_1 is the velocity of water at section (1)

V_2 is the velocity water at section (2)

Then, velocity of water in a pipe section (1) is

$$\dot{V} = A_1V_1$$

$$V_1 = \frac{\dot{V}}{A_1}$$

$$= \frac{(1\text{gal/s})\left(\frac{231\text{in}^3}{1\text{gal}}\right)}{\frac{\pi}{4}(4\text{in.})^2}$$

$$= 18.38\text{in./s}$$

$$= 18.38\text{in./s} \times 1\text{ft}/12\text{in.}$$

$$= 1.53\text{ft/s}$$

Step 4 of 7

Similarly, velocity of water in a pipe section (2) is

$$\dot{V} = A_2V_2$$

$$V_2 = \frac{\dot{V}}{A_2}$$

$$= \frac{(1\text{gal/s})\left(\frac{231\text{in}^3}{1\text{gal}}\right)}{\frac{\pi}{4}(2\text{in.})^2}$$

$$= 73.52\text{in./s}$$

$$= 73.52\text{in./s} \times 1\text{ft}/12\text{in.}$$

$$= 6.126\text{ft/s}$$

Step 5 of 7

Applying the Bernoulli's flow equation between the points (1) and (2):

$$\frac{P_1}{\rho_w} + \frac{V_1^2}{2} + gz_1 = \frac{P_2}{\rho_w} + \frac{V_2^2}{2} + gz_2$$

$$P_1 - P_2 = \rho_w\left(\frac{V_2^2}{2} - \frac{V_1^2}{2}\right)$$

Since pipe placed along the horizontal direction, therefore datum head becomes equal to zero.

Pressure difference between inlet and exit of the pipe is equivalent to pressure of water.

$$P_1 - P_2 = \gamma_{mercury}h$$

Then we can write,

$$\gamma_{mercury}h = \rho_w\left(\frac{V_2^2 - V_2^2}{2g}\right)$$

Step 6 of 7

From the table of "ideal gas, specific heats of various fluids"

For mercury,

Specific weight $\gamma_{mercury} = 62.41\text{lbm/ft}^3$

Pressure head of mercury in terms of pressure head of water is determined by multiplying to 12.6

Step 7 of 7

Then, The height of water column

$$\gamma_{mercury}h = \rho_w\frac{\left(V_2^2 - V_2^2\right)}{2g}$$

$$\left(62.41\text{lbm/ft}^3 \times 12.6\right)h = 62.41\text{lbm/ft}^3\left(\frac{\left((6.126\text{ft/s})^2 - (1.53\text{ft/s})^2\right)}{2\left(32.2\text{ft/s}^2\right)}\right)$$

$$= 0.0433\text{ft}$$

$$= 0.0433\text{ft} \times \frac{12\text{in.}}{1\text{ft}}$$

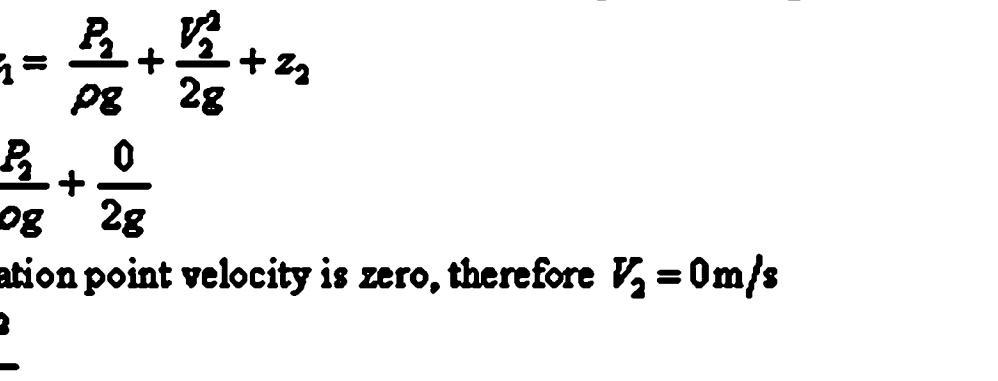
$$= 0.52\text{in.}$$

Therefore, the differential height of the water column is $\boxed{h = 0.52\text{in.}}$

Question: 12.024P

An airplane is flying at an altitude of 12,000 m. Determine the gage pressure at the stagnation point on the nose of the plane if the speed of the plane is 300 km/h. How would you solve this problem if the speed were. 1050 km/h? Explain.

Step 1 of 6



Given data:

The altitude of the airplane, $h = 12000$ m

The speed of the aircraft, $V = 300$ km/h

Step 2 of 6

Schematic diagram of airplane nose:

Step 3 of 6

The aircraft moves at a speed of $V = 300$ km/h through the atmosphere. Then we can assume that the airflow over the aircraft will be having a velocity of 300 km/h .

The stagnation point at the tip of the nose cone is point (2) and point where air has a velocity of 300 km/h before stagnation is represented as point (1).

Applying Bernoulli's equation between the points (1) and (2)

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

The points are at the same level, therefore $z_1 = z_2$

From the table of "properties of air table"

The density of air at 12000 m is $\rho = 0.312$ kg/m^3 .

The velocity at point (1),

$$V_1 = 300 \text{ km/h}$$

$$= 300 \text{ km/h} \times \frac{5}{18} \text{m/s}$$

$$= 83.33 \text{ m/s}$$

Step 4 of 6

Substituting the known values in the Bernoulli's equation, we get,

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} = \frac{P_2}{\rho g} + \frac{0}{2g}$$

Since at stagnation point velocity is zero, therefore $V_2 = 0$ m/s

$$P_2 - P_1 = \frac{\rho V_1^2}{2}$$

$$P_2 - P_1 = \frac{(0.312)(83.33)^2}{2}$$

$$= 1083.24 \text{ Pa}$$

Then the gage pressure at stagnation point,

$$P_{gage} = P_2 - P_1$$

$$= 1083.24 \text{ Pa}$$

Therefore, the gage pressure at the stagnation point is $\boxed{1083.24 \text{ Pa}}$.

Step 5 of 6

The aircraft is at a speed of 1050 km/h .

We can assume that the airflow speed over the aircraft is 1050 km/h .

Then,

$$V_1 = 1050 \text{ km/h}$$

$$= 1050 \text{ km/h} \times \frac{\frac{5}{18} \text{m/s}}{1 \text{km/h}}$$

$$= 291.66 \text{ m/s}$$

Step 6 of 6

The mach number of the aircraft,

$$Ma = \frac{V_1}{c}$$

Where,

c be taken is the velocity of sound approximated to 340 m/s

Then

$$Ma = \frac{291.66}{340}$$

$$= 0.85$$

We know that for the flow to be considered incompressible when the Mach number $Ma \leq 0.3$. But our value for Mach number of the aircraft is $Ma = 0.85$ which is greater than 0.3

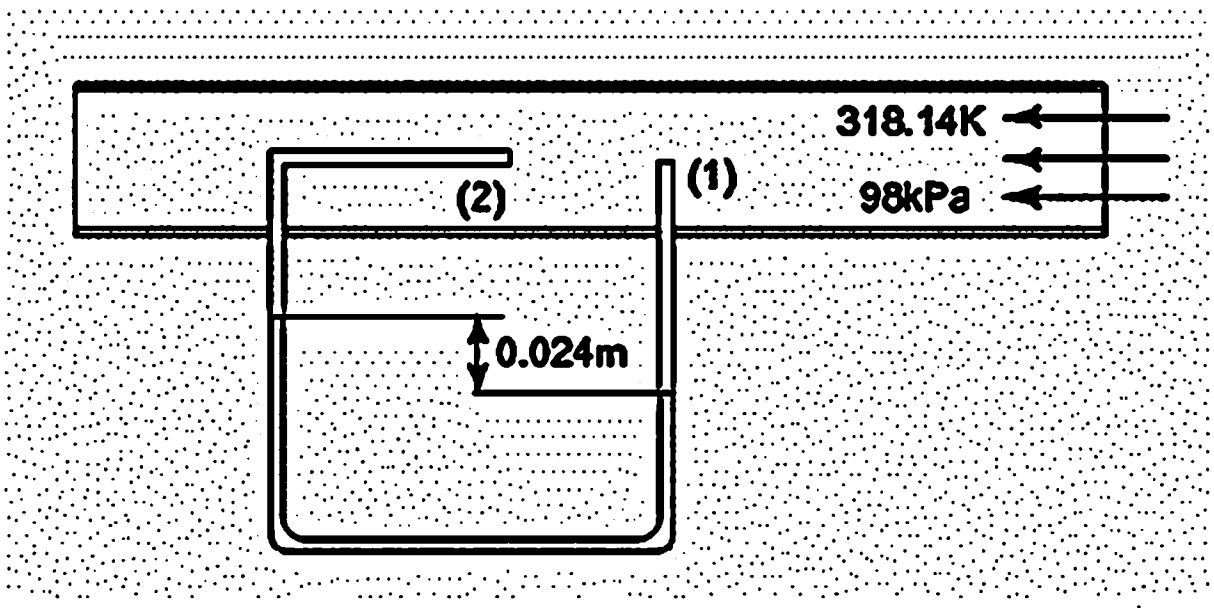
Therefore the flow in this case is compressible. So the problem should be solved using the Bernoulli's equation for steady, compressible, isentropic flow.

Question: 12.025P

The air velocity in the duct of a heating system is to be measured by a Pitot-static probe inserted into the duet parallel to the flow. If the differential height between the water columns connected to the two outlets of the probe is 2.4 cm, determine (*a*) the flow velocity and (*b*) the pressure rise at the tip of the probe. The air temperature and pressure in the duct are 45°C and 98 kPa, respectively.

Step 1 of 6

Given data:



The air temperature in the duct $T = 45°C = 318.15K$

The air pressure in the duct $P_{air} = 98\ kPa$

The differential height between the water columns $\Delta h = 2.4\ cm = 0.024\ m$

Step 2 of 6

Schematic diagram of pitot-static probe:

The points (1) and (2) are at same elevation, $z_1 = z_2$

The velocity at stagnation point (2), $V_2 = 0$

Step 3 of 6

From the ideal gas equation, we have

$P = \rho_{air} RT$

Where

The pressure $P_{air} = 98\ kPa$

The temperature $T = 318.15\ K$

The gas constant $R = 0.287\ kJ/kg \cdot K$

Then the density of air in duct,

$$\rho_{air} = \frac{(98 \times 10^3\ Pa)}{(0.287 \times 10^3\ kJ/kg \cdot K)(318.14\ K)}$$

$$= 1.073\ kg/m^3$$

Step 4 of 6

Applying Bernoulli's equation between the points (1) and (2)

$$\frac{P_1}{\rho_{air} g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho_{air} g} + \frac{V_2^2}{2g} + z_2$$

Substituting the required values and simplifying the above relation

$$\frac{V_1^2}{2} = \frac{P_2}{\rho_{air}} - \frac{P_1}{\rho_{air}}$$

$$V_1 = \sqrt{\frac{2(P_2 - P_1)}{\rho_{air}}}$$

Step 5 of 6

(b)

The pressure difference can be expressed as,

$$P_2 - P_1 = \rho_{water} g h$$

$$= (1000)(9.81)(0.024)$$

$$= 235.44\ Pa$$

Therefore the pressure rise, $\boxed{P_2 - P_1 = 235.44\ Pa}$

Step 6 of 6

a)

The flow velocity,

$$V_1 = \sqrt{\frac{2(P_2 - P_1)}{\rho_{air}}}$$

$$= \sqrt{\frac{2(235.44)}{1.073}}$$

$$= 20.94\ m/s$$

Therefore, the flow velocity is $\boxed{V_1 = 20.94\ m/s}$

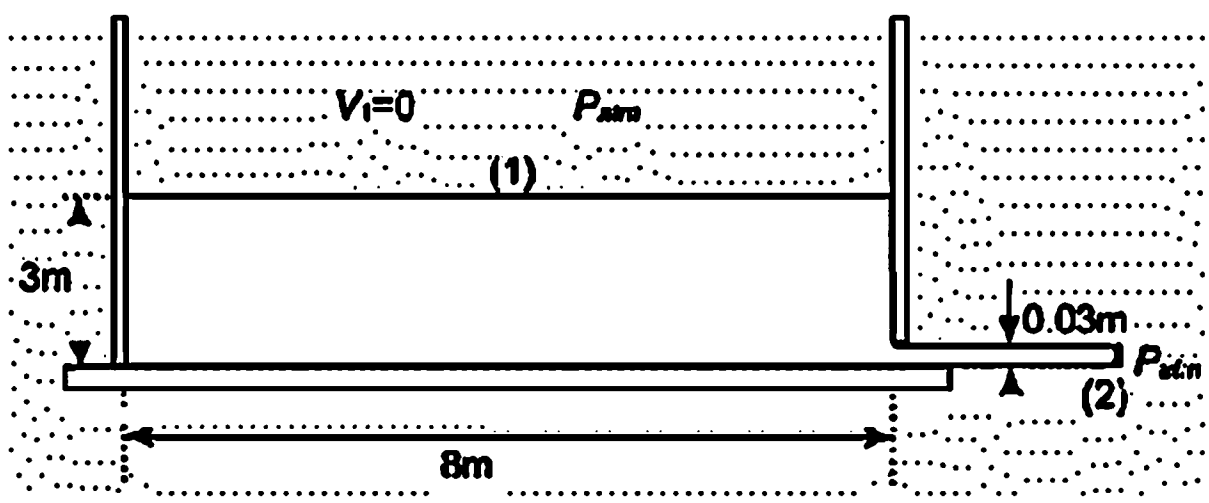
Question: 12.026P

The water in a 8-m-diameter, 3-m-high aboveground swimming pool is to be emptied by unplugging a 3-cm-diameter, 25-m-long horizontal pipe attached to the bottom of the pool. Determine the maximum discharge rate of water through the pipe. Also, explain why the actual flow rate will be less.

Step 1 of 4

Given data:

The diameter of the swimming pool $D = 8$ m



The pool is at an elevation from ground level $h = 3$ m

The diameter of the exit pipe $d = 3\text{cm} = 0.03\text{m}$

Length of pipe $L = 25\text{m}$

Step 2 of 4

Schematic diagram of the swimming pool:

Step 3 of 4

Let us set point (2) as the reference point.

Applying Bernoulli's equation between points (1) and (2)

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

Substitute the known values in above expression, we get

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + z_1 = \frac{P_{atm}}{\rho g} + \frac{V_2^2}{2g} + 0$$

$$V_2^2 = 2gz_1$$

$$V_2 = \sqrt{2gz_1}$$

From the above equation it is evident that the exit velocity is maximum, when the head z_1 is maximum.

Step 4 of 4

The discharge of water through orifice is

$$\dot{V} = A_{orifice} V_2$$

$A_{orifice}$ Is the area of the orifice.

The maximum discharge is when $z_1 = 3$ m

Then,

$$\dot{V}_{max} = \left(\frac{\pi}{4} D_{orifice}^2\right)\sqrt{2gz_1}$$

$$= \left(\frac{\pi}{4} \times 0.03^2\right)\sqrt{2(9.81)(3)}$$

$$= 5.423 \times 10^{-3}\ \text{m}^3/\text{s}$$

Therefore, the maximum discharge rate of water through the pipe

$$\boxed{\dot{V}_{max} = 5.42 \times 10^{-3}\ \text{m}^3/\text{s}}$$

The actual flow rate is less than the theoretical flow rate because we have not taken frictional effects into account. Presence of frictional effects always reduces the flow rate in a system.

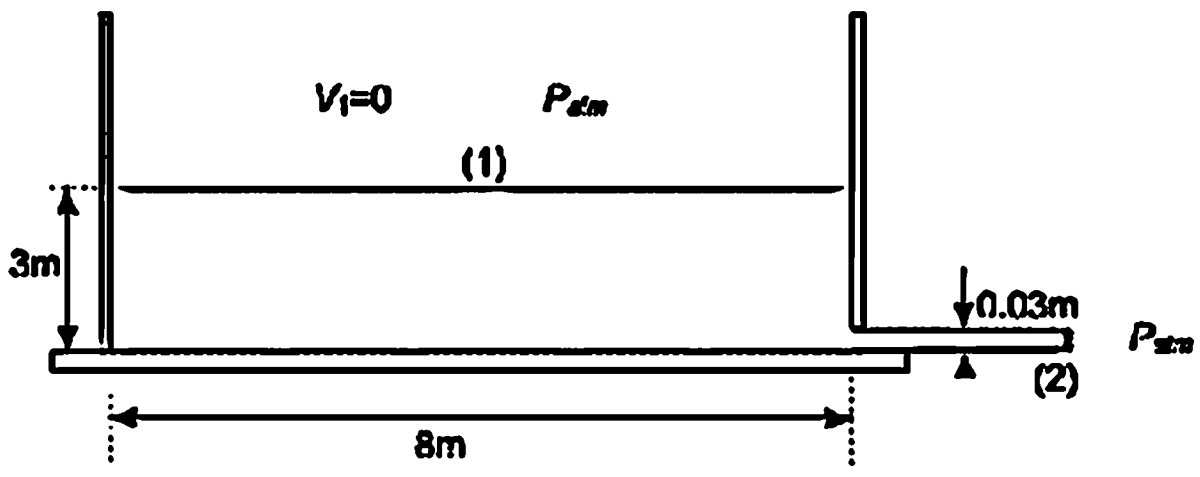
Question: 12.027P

Reconsider Prob. 12–26. Determine how long it will take to empty the swimming pool completely.

Step 1 of 7

Given data:

The diameter of the swimming pool $D = 8$ m



The pool is at an elevation from ground level $h = 3$ m

The diameter of the exit pipe $d = 3\text{cm} = 0.03\text{m}$

Length of pipe, $L = 25\text{m}$

Step 2 of 7

Schematic diagram of the swimming pool:

Step 3 of 7

Let us set point (2) as the reference point.

Applying Bernoulli's equation between points (1) and (2)

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

Substituting the known values

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + z_1 = \frac{P_{atm}}{\rho g} + \frac{V_2^2}{2g} + 0$$

$$V_2^2 = 2gz_1$$

$$V_2 = \sqrt{2gz_1}$$

Step 4 of 7

The discharge,

$$\dot{V} = A_{orifice} V_2$$

$A_{orifice}$ is the area of the orifice

The discharge of water during a time period dt is,

$$\dot{V} = \frac{dV}{dt}$$

$$dV = \dot{V} dt$$

$$dV = AV_2 dt$$

$$= \frac{\pi D^2}{4}\sqrt{2gz_1}dt$$

Where z_1 varies from h to 0 when the tank is emptied completely.

Step 5 of 7

Applying the principle of conservation of mass.

Then the discharge dV must be equal to the volume of water removed from the cylinder during the period dt

Then

$$dV = A_{tank}(-dz)$$

Where

'dz'is the height change and negative sign represents the decrease in elevation

A_{tank} is the area of the tank

Step 6 of 7

Then

$$A_{tank}(-dz) = \frac{\pi D^2}{4}\sqrt{2gz_1}dt$$

$$\left(\frac{\pi}{4}D_0^2\right)(-dz) = \frac{\pi D^2}{4}\sqrt{2gz_1}dt$$

$$dt = -\left(\frac{D_0^2}{D^2}\right)\frac{(dz)}{\sqrt{2gz_1}}$$

Integrating the above equation we get

$$t = -\int_h^0 \left(\frac{D_0^2}{D^2}\right)\frac{(dz)}{\sqrt{2gz_1}}$$

$$= -\frac{1}{\sqrt{2g}}\left(\frac{D_0^2}{D^2}\right)\int_h^0 (z_1)^{-1/2} dz$$

$$= -\frac{1}{\sqrt{2g}}\left(\frac{D_0^2}{D^2}\right)\left(z_1^{1/2}\right)_h^0$$

$$= \frac{1}{\sqrt{2g}}\left(\frac{D_0^2}{D^2}\right)\left(\frac{h^{1/2}}{1/2}\right)$$

Step 7 of 7

Then the time required draining the tank,

$$t = \frac{1}{\sqrt{2g}}\left(\frac{D_0^2}{D^2}\right)\left(h^{1/2}\right)$$

$$= \left(\frac{8^2}{0.03^2}\right)\left(\sqrt{\frac{2h}{g}}\right)$$

$$= \left(\frac{8^2}{0.03^2}\right)\left(\sqrt{\frac{2\times 3}{9.81}}\right)$$

$$= 55613.289\ s$$

$$= 15.44\text{hr}$$

Therefore, the time required to empty the tank $\boxed{t = 15.44\text{hr}}$

Question: 12.028P

Reconsider Prob. 12–27. Using EES (or other) software, investigate the effect of the discharge pipe diameter on the time required to empty the pool completely. Let the diameter vary from 1 to 10 cm in increments of 1 cm. Tabulate and plot the results.

Step 1 of 4

Given data:

The diameter of the swimming pool $D = 8$ m

The pool is at an elevation from ground level $h = 3$ m

The diameter of the exit pipe $d = 3\text{cm} = 0.03\text{m}$

Length of pipe, $L = 25\text{m}$

Step 2 of 4

Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

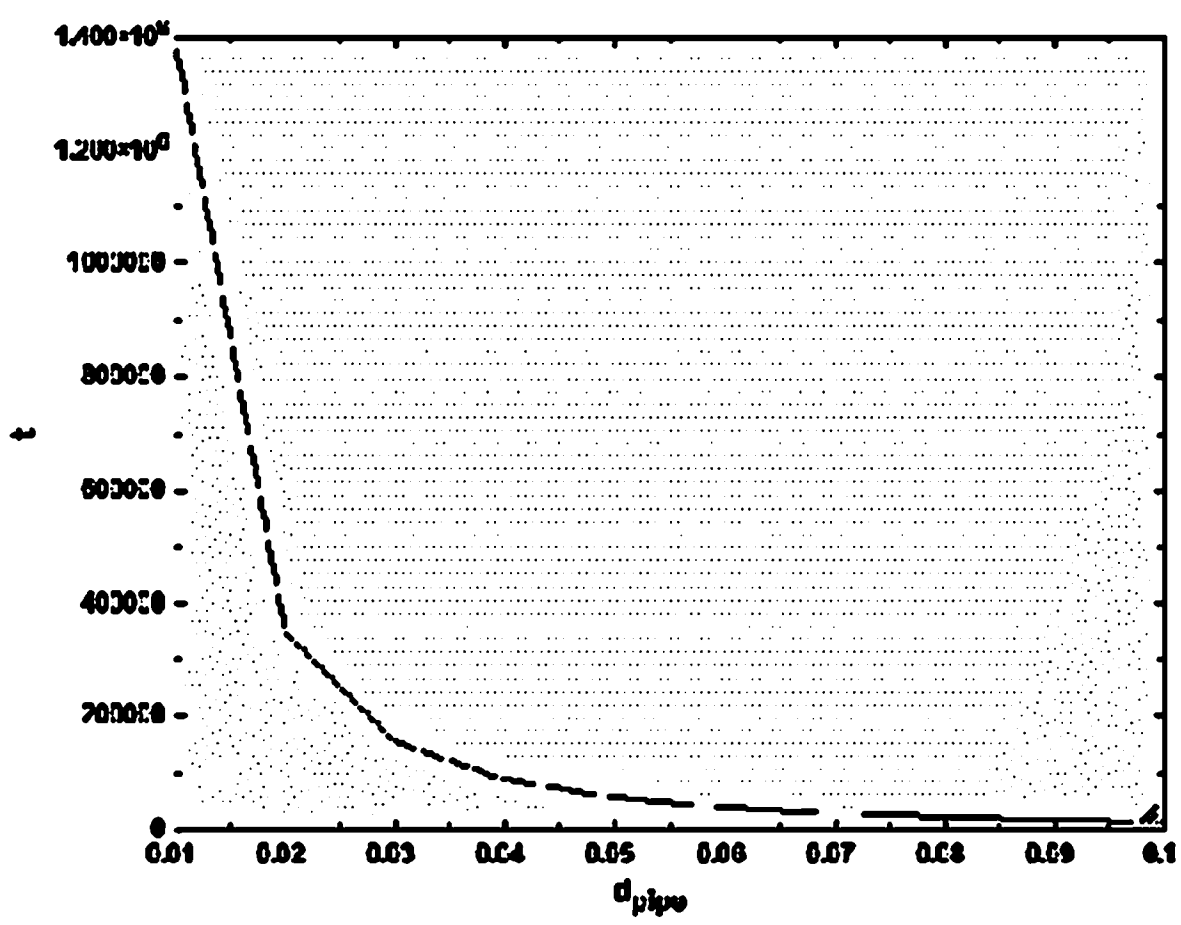
File Edit Search Options Calculate Tables

Equations Window

```
g=9.81 "m/s2"
rho=1000 "kg/m3"
h=3 "m"
D=d_pipe/100 "m"
D_pool=8 "m"
V_initial=SQRT(2*g*h) "m/s"
Ac=pi*D^2/4
V_dot=Ac*V_initial*1000 "m3/s"
t=(D_pool/D)^2*SQRT(2*h/g)/3600 "hour"
```

Step 3 of 4

After writing the equation in equation window, then select table on menu bar, then click new parameter table.



The dialog box will be appeared, then select the diameter of pipe and time, then click ADD, then click OK button.

Then the following results are displayed

1..10	d_{pipe}	t
Run 1	0.01	1.390E+06

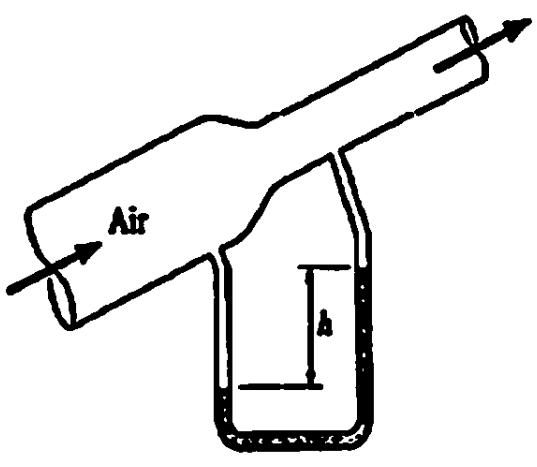
Select the plot on menu bar, then click x-y plot .Dialog box will appeared, then select variables to draw graph, then click ok button.

Question: 12.029P

Air at 110 kPa and 50°C flows upward through a 6-cm-diameter inclined duct at a rate of 45 L/s. The duct diameter is then reduced to 4 cm through a reducer. The pressure change across the reducer is measured by a water manometer. The elevation difference between the two points on the pipe where the two arms of the manometer are attached is 0.20 m. Determine the differential height between the fluid levels of the two arms of the manometer.



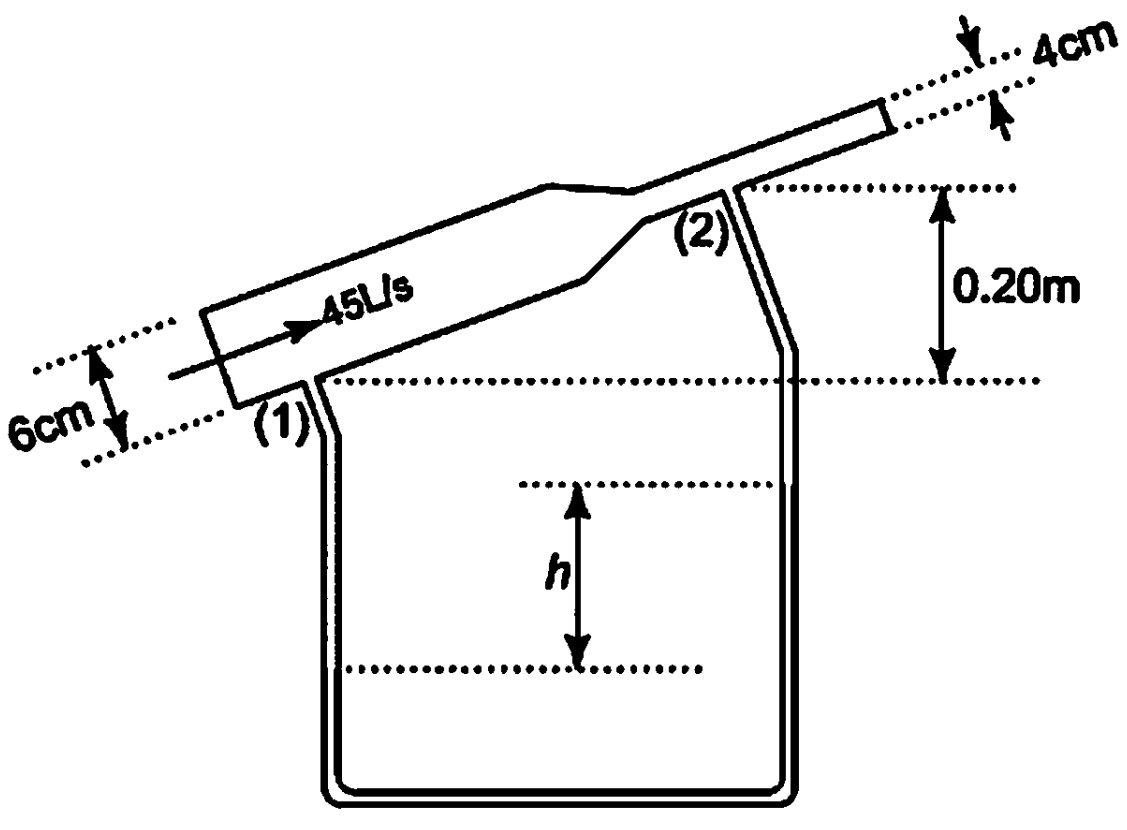


FIGURE P12–29

Step 1 of 5

Free body diagram of pipe and manometer system is as shown below:

Step 2 of 5

Use the ideal gas equation to find out the density of air.

$$P = \rho RT$$

Here, the gas constant is R, density of air is ρ_{air}, the temperature of air is T and the pressure of air is P.

Substitute $0.287\ \text{kJ/kg.K}$ for R, $323.15\ \text{K}$ for T and $110\ \text{kPa}$ for P in the above equation.

$$110 = \rho_{air}(0.287)(323.15)$$
$$\rho_{air} = 1.186\ \text{kg/m}^3$$

Step 3 of 5

Use the continuity equation, to calculate the velocity of flow at point-1.

$$\dot{V} = A_1 v_1$$
$$v_1 = \frac{\dot{V}}{A_1}$$
$$= \frac{\dot{V}}{\frac{\pi}{4} \times d_1^2}$$

Here, the velocity at the point-1 is v_1, the volumetric flow rate is $\dot{V}$ and the area of the duct at point-1 is A_1 and the diameter of the pipe at section-1 is d_1.

Substitute $0.045\ \text{m}^3/\text{s}$ for $\dot{V}$ and $0.06\ \text{m}$ for d_1 in the above equation.

$$v_1 = \frac{0.045}{\frac{\pi}{4}(0.06)^2}$$
$$= 15.91\ \text{m/s}$$

Step 4 of 5

Now calculate the velocity at point (2).

$$v_2 = \frac{\dot{V}}{A_2}$$
$$= \frac{\dot{V}}{\frac{\pi}{4} \times d_2^2}$$

Here, the velocity at the point-2 is v_2, the area of cross-section at point-2 is A_2 and the diameter of the point-2 is d_2.

Substitute $0.04\ \text{m}$ for d_2 and all the corresponding values in the above equation.

$$v_2 = \frac{0.045\ \text{m}^3/\text{s}}{\frac{\pi}{4}(0.04)^2}$$
$$= 35.809\ \text{m/s}$$

Step 5 of 5

Apply the Bernoulli's equation between points (1) and (2), keeping point-1 as the reference point.

$$\frac{P_1}{\rho_{air} g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho_{air} g} + \frac{V_2^2}{2g} + z_2$$

Here, the pressure at point-1 is P_1, the pressure at point-2 is P_2, the height above the datum head at point-1 and 2 are z_1 and z_2 respectively and the acceleration due to gravity is g.

Substitute 0 for z_1 and $0.20\ \text{m}$ for z_2 and all the corresponding values in the above equation.

$$\frac{P_1}{\rho_{air}} + \frac{V_1^2}{2} + 0 = \frac{P_2}{\rho_{air}} + \frac{V_2^2}{2} + 0.20$$
$$\frac{P_1 - P_2}{\rho_{air}} = \frac{V_2^2 - V_1^2}{2} + 0.20$$

$$P_1 - P_2 = \rho_{air}\left(\frac{V_2^2 - V_1^2}{2} + 0.20\right)$$
$$= 1.186\left(\frac{35.809^2 - 15.91^2}{2} + 0.20\right)$$
$$= 610.526\ \text{Pa}$$

The pressure difference between the points is $P_1 - P_2 = 610.526\ \text{Pa}$

Calculate the differential height taking into account that the pressure difference in duct is equal to differential height of manometer.

$$P_2 - P_1 = \rho_w g h_w$$

Here the density of water is ρ

Substitute $1000\ \text{kg/m}^3$ for ρ and all the corresponding values in the above equation.

$$h = \frac{P_2 - P_1}{\rho_w g}$$
$$= \frac{610.526}{(1000)(9.81)}$$
$$= 0.0622\ \text{m}$$

Therefore, the differential height of the manometer, h, is $\boxed{0.0622\ \text{m}}$

Question: 12.030P

Air is flowing through a venturi meter whose diameter is 2.6 in at the entrance part (location 1) and 1.8 in at the throat (location 2). The gage pressure is measured to be 12.2 psia at the entrance and 11.8 psia at the throat. Neglecting frictional effects, show that the volume flow rate can be expressed as

$$\dot{V} = A_2\sqrt{\frac{2(P_1 - P_2)}{\rho(1 - A_2^2/A_1^2)}}$$

and determine the flow rate of air. Take the air density to be 0.075 lbm/ft3.

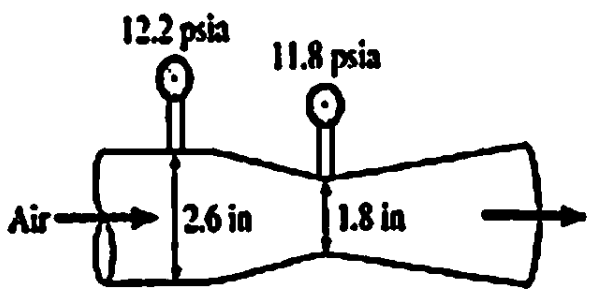

FIGURE P12–30E

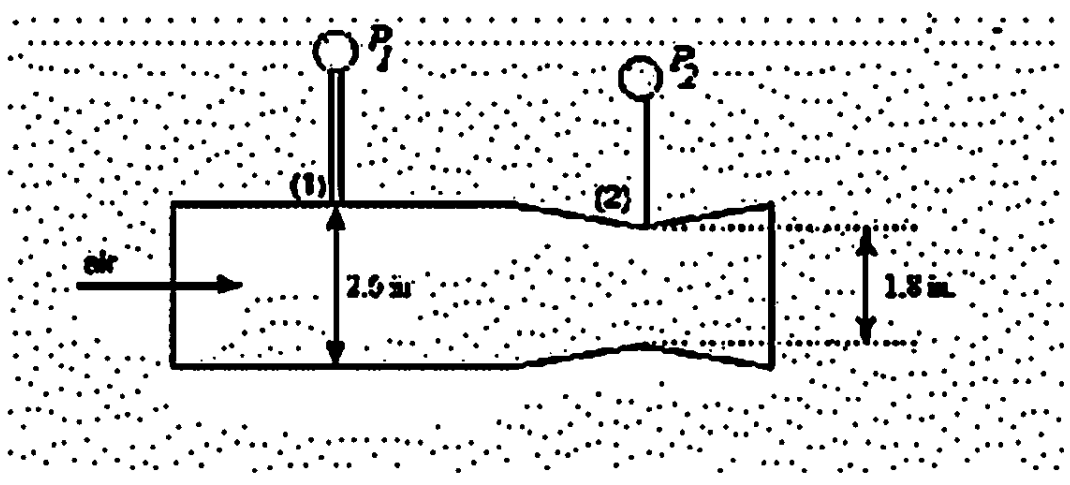
Step 1 of 7

Given data:

Inlet diameter of the venturi meter, $D_1 = 2.6\text{in.}$

Throat diameter, $D_2 = 1.8\text{in}$



Inlet pressure of the venturi meter, $P_1 = 12.2\text{psia}$

Throat pressure, $P_2 = 11.8\text{psia}$

Density of the air, $\rho = 0.075\text{lbm/ft}^3$

Step 2 of 7

Schematic diagram of venturi meter:

Step 3 of 7

The flow is steady, incompressible and irrotational.
The frictional effects can be neglected.
The points (1) and (2) are at the same elevation.
By apply the Bernoulli's equation between the points (1) and (2).

$$\frac{P_1}{\rho_{air}g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho_{air}g} + \frac{V_2^2}{2g} + z_2$$

Substitute the required values and simplify.

$$\frac{P_1}{\rho} + \frac{V_1^2}{2} + 0 = \frac{P_2}{\rho} + \frac{V_2^2}{2} + 0$$

$$P_1 - P_2 = \frac{\rho}{2}\left(V_2^2 - V_1^2\right)$$

Step 4 of 7

From the continuity equation,
Flow velocities at (1) and (2),

$$V_1 = \frac{\dot{V}}{A_1} \text{ And } V_2 = \frac{\dot{V}}{A_2}$$

Where

$\dot{V}$ Is the flow rate and A is the area at respective position.

Step 5 of 7

$$A_2 = \frac{\pi}{4}D_2^2$$

$$= \frac{\pi}{4}(1.8)^2$$

$$= 2.54\text{in.}^2$$

Step 7 of 7

Then, volume flow rate though a venturi meter is given as

$$\dot{V} = A_2\sqrt{\frac{2(P_1 - P_2)}{\rho\left(1 - \frac{A_2^2}{A_1^2}\right)}}$$

Substituting the all known values above expression, we get

$$\dot{V} = 2.54\sqrt{\frac{2(12.2 - 11.8)}{\left(0.075\text{lbm/ft}^3 \times \left(\frac{1\text{ft}}{12\text{in.}}\right)^3\right)\left(1 - \frac{2.54^2}{5.30^2}\right)}}$$

$$= 392.90\text{in}^3/\text{s}$$

$$= 0.227\text{ft}^3/\text{s}$$

Therefore, volume flow rate though a venturi meter is $\boxed{\dot{V} = 0.227\text{ft}^3/\text{s}}$

Question: 12.031P

The water pressure in the mains of a city at a particular location is 350 kPa gage. Determine if this main can serve water to neighborhoods that are 50 m above this location

Step 1 of 3

Given data:

The gage pressure of water in the mains, $P_{gage} = 350$ kPa.

The height to which water is to be served, $h = 50$ m.

Step 2 of 3

From the properties of various fluids table

For water, the density of water is $\rho = 1000\ \text{kg/m}^3$.

From the expression of gauge pressure

$P_{gage} = \rho g h_{water}$

Where,

h_{water} is the height of water column corresponding to the pressure P_{gage}.

Step 3 of 3

By substitute the known values in above equation, we get

$350 \times 10^3 \text{Pa} = \left(1000\ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right) h_{water}$

$h_{water} = 35.677$ m

Here $h_{water} < h$

Therefore we can conclude that the pressure in the mains is insufficient to supply the water to a height of 50 m.

Question: 12.032P

A pressurized tank of water has a 10-cm-diameter orifice at the bottom, where water discharges to the atmosphere. The water level is 2.5 m above the outlet. The lank air 1 pressure above the water level is 250 kPa (absolute) white the atmospheric pressure is 100 kPa. Neglecting frictional effects, determine the initial discharge rate of water from the tank.

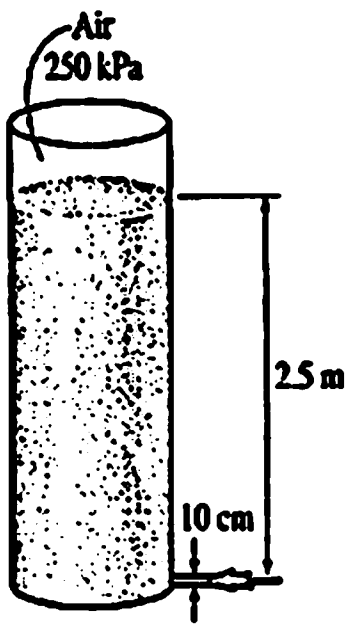


FIGURE P12-32

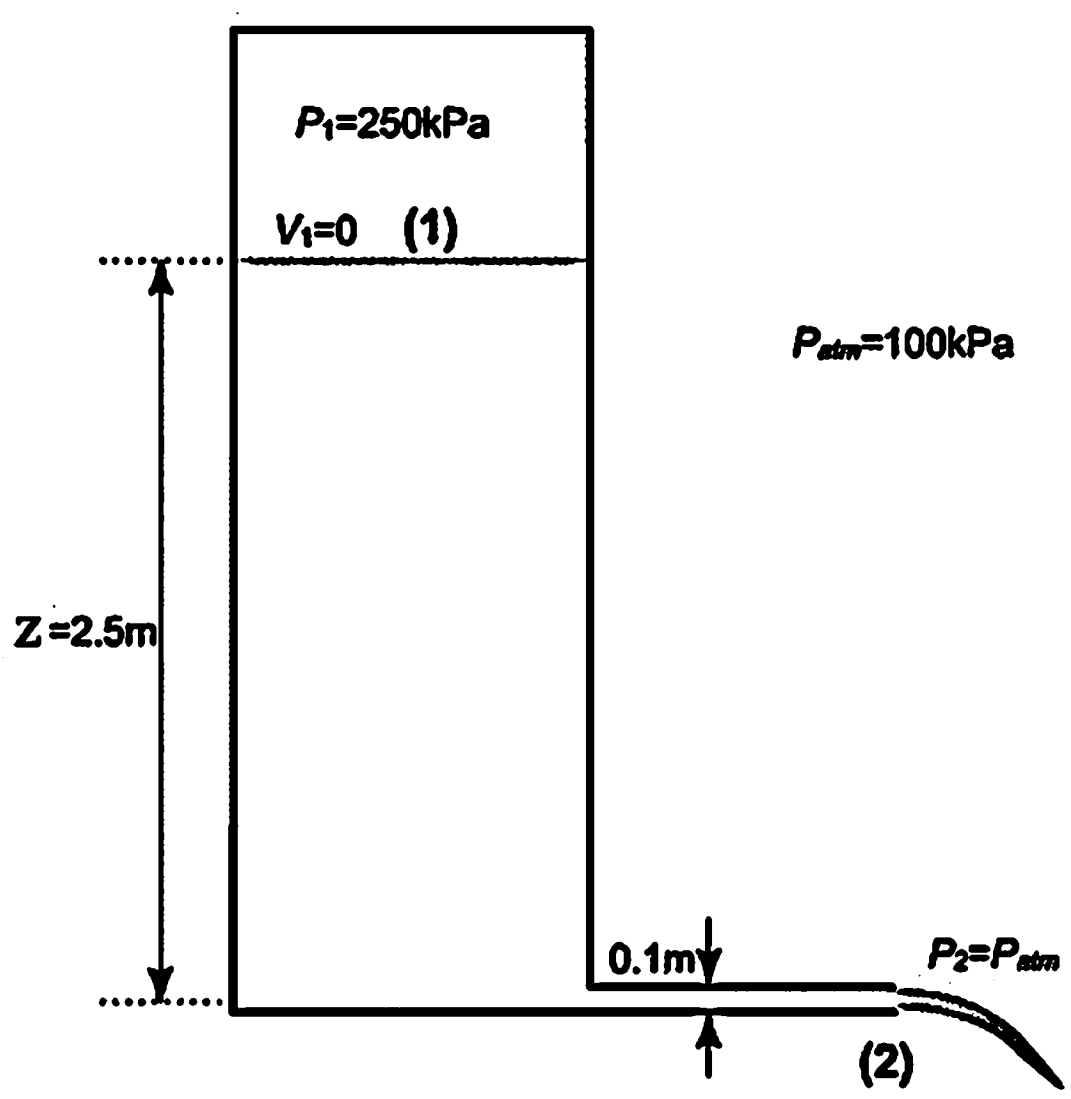
Step 1 of 4

Given data:-

The diameter of the orifice, $D_0 = 10\,\text{cm} = 0.1\,\text{m}$.



The absolute pressure at the top of the water surface, $P_1 = 250\,\text{kPa}$.

The atmospheric pressure, $P_{atm} = 100\,\text{kPa}$.

The height of water column, $z_1 = 2.5\,\text{m}$.

Step 2 of 4

Schematic diagram of tank system:

Point (2) is set as the reference point.

Step 3 of 4

By apply the Bernoulli's equation between the points (1) and (2).

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2$$

Substitute the known values and simplify.

$$\frac{250\times10^3}{1000\times9.81}+\frac{0}{2\times9.81}+z_1=\frac{100\times10^3}{1000\times9.81}+\frac{V_2^2}{2\times9.81}+z_2$$

$$\frac{250\times10^3}{1000\times9.81}+\frac{0}{2\times9.81}+2.5=\frac{100\times10^3}{1000\times9.81}+\frac{V_2^2}{2\times9.81}+0$$

$$\frac{V_2^2}{2\times9.81}=17.79$$

$$V_2=\sqrt{349.05}$$

$$=18.682\,\text{m/s}$$

Step 4 of 4

The flow rate at point (2),

$$\dot{V}=A_{orifice}V_2$$

$$=\left(\frac{\pi}{4}D_0^2\right)(18.682)$$

$$=\left(\frac{\pi}{4}0.1^2\right)(18.682)$$

$$=0.1467\,\text{m}^3/\text{s}$$

Therefore the flow rate through the orifice is $\boxed{\dot{V}=0.1467\,\text{m}^3/\text{s}}$.

Question: 12.033P

Reconsider Prob. 12–32. Using EES (or other) software, investigate the effect of water height in the tank on the discharge velocity. .Let the water height vary from 0 to 5 m in increments of 0.5 m. Tabulate and plot the results.

Step 1 of 4

Given data:

The diameter of the orifice, $D_0 = 10\ \text{cm} = 0.1\ \text{m}$.

The absolute pressure at the top of the water surface, $P_1 = 250\ \text{kPa}$.

The atmospheric pressure, $P_{atm} = 100\ \text{kPa}$.

The height of water column, $z_1 = 2.5\ \text{m}$.

Step 2 of 4

Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

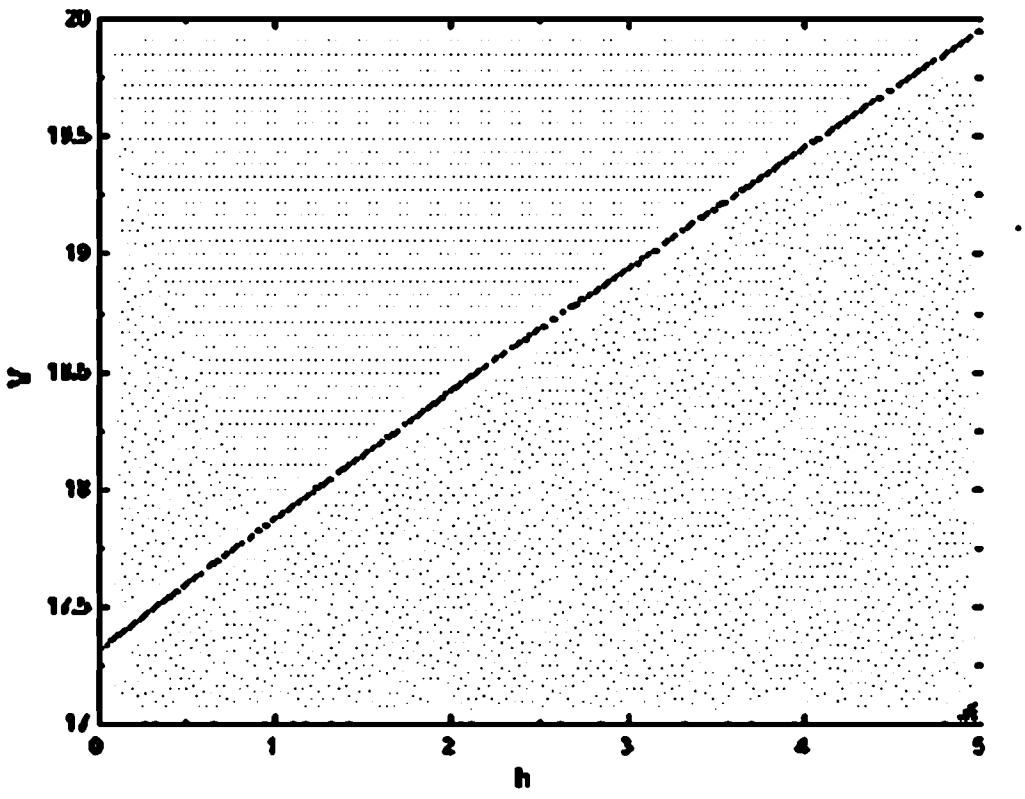
```
g=9.814 " m/s2"
rho=1000 "kg/m3'
"d=0.10 "m"
P1=250 "kPa"
P_atm=100 "kPa"
V=SQRT(2*(P1-P_atm)*1000/rho+2*g*h)
Ac=pi*D^2/4
V_dot=Ac*V
```

Step 3 of 4

After writing the equation in equation window, then select table on menu bar, then click new parameter table.

The dialog box will be appeared, then select the diameter of pipe and time, then click ADD, then click OK button.

The following results are displayed



1..11	h	V̇	V
Run 1	0	0.136	17.32
Run 2	0.5	0.1382	17.6
Run 3	1	0.1404	17.88
Run 4	1.5	0.1426	18.15
Run 5	2	0.1447	18.42
Run 6	2.5	0.1467	18.68

Run 9	4	0.1528	19.46
Run 10	4.5	0.1548	19.71
Run 11	5	0.1567	19.95

Step 4 of 4

Select the plot on menu bar, then click x-y plot .Dialog box will appeared, then select variables to draw graph, then click ok button.

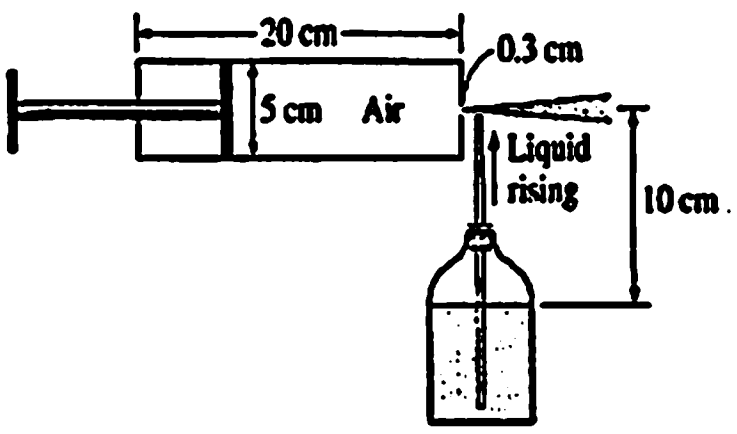
The graph will appeared

By plotting the graph between velocity and height:

Question:

12.034P

A hand held bicycle pump can be used as an atomizer to generate a fine mist of paint or pesticide by forcing air at a high velocity through a small hole and placing a short tube between the liquid reservoir and the high-speed air jet. The pressure across a subsonic jet exposed to the atmosphere is nearly atmospheric, and the surface of the liquid in the reservoir is also open to atmospheric pressure. In light of this, explain how the liquid is sucked up the tube. *Hint:* Read Sec. 12–1 carefully.



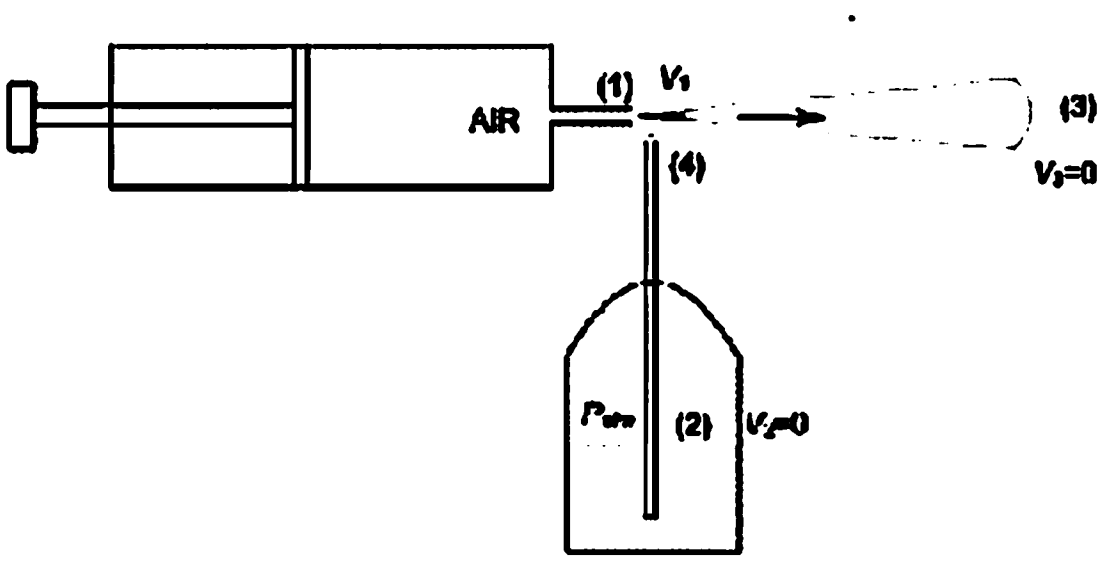


FIGURE P12–34

Step 1 of 3

Let us draw the figure:

Step 2 of 3

The flow is steady, incompressible and irrotational.
The frictional effects in the entire system are negligible.
The elevation difference between the points (1), (3) and (4) are negligible.

By considering points (2) and (4):
By applying the Bernoulli's flow equations between the two points:

$$\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2=\frac{P_4}{\rho g}+\frac{V_4^2}{2g}+z_4$$

$$\frac{P_{atm}}{\rho_{water} g}+\frac{0}{2g}+h=\frac{P_4}{\rho_{water} g}+\frac{0}{2g}+0$$

$$\frac{P_4}{\rho_{water} g}=\frac{P_{atm}}{\rho_{water} g}-h$$

$$P_4=P_{atm}-\rho_{water} g h$$

Hence, the pressure at point (4) must be less than the atmospheric pressure P_{atm} for the water to move up the tube.

Step 3 of 3

The low pressure at point (4) is created due to the high velocity air moving out from the orifice at point (1). Points (1) and (4) are at close proximity hence their pressures will be also equal to create the upward flow of water into the air flow
Therefore

$$P_1=P_4$$

$$=P_{atm}-\rho_{water} g h$$

Therefore, we can conclude that the presence of below atmospheric pressure at point (1) causes the liquid to be sucked up the tube.

Question: 12.035P

The water level in a tank is 15 m above the ground. A hose is connected to the bottom of the tank, and the nozzle at the end of the hose is pointed straight up. The tank cover is airtight, and the air pressure above the water surface is 3 atm gage. The system is at sea level. Determine the maximum height to which the water stream could rise.

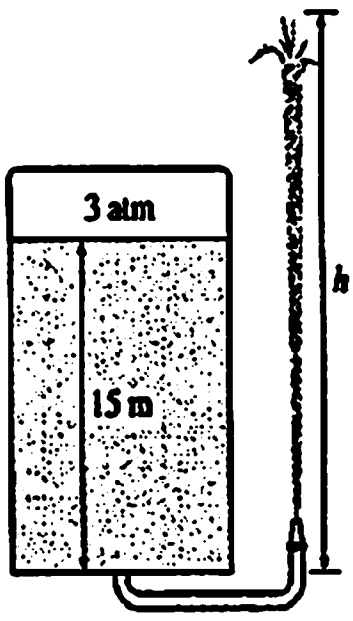

FIGURE P12–35

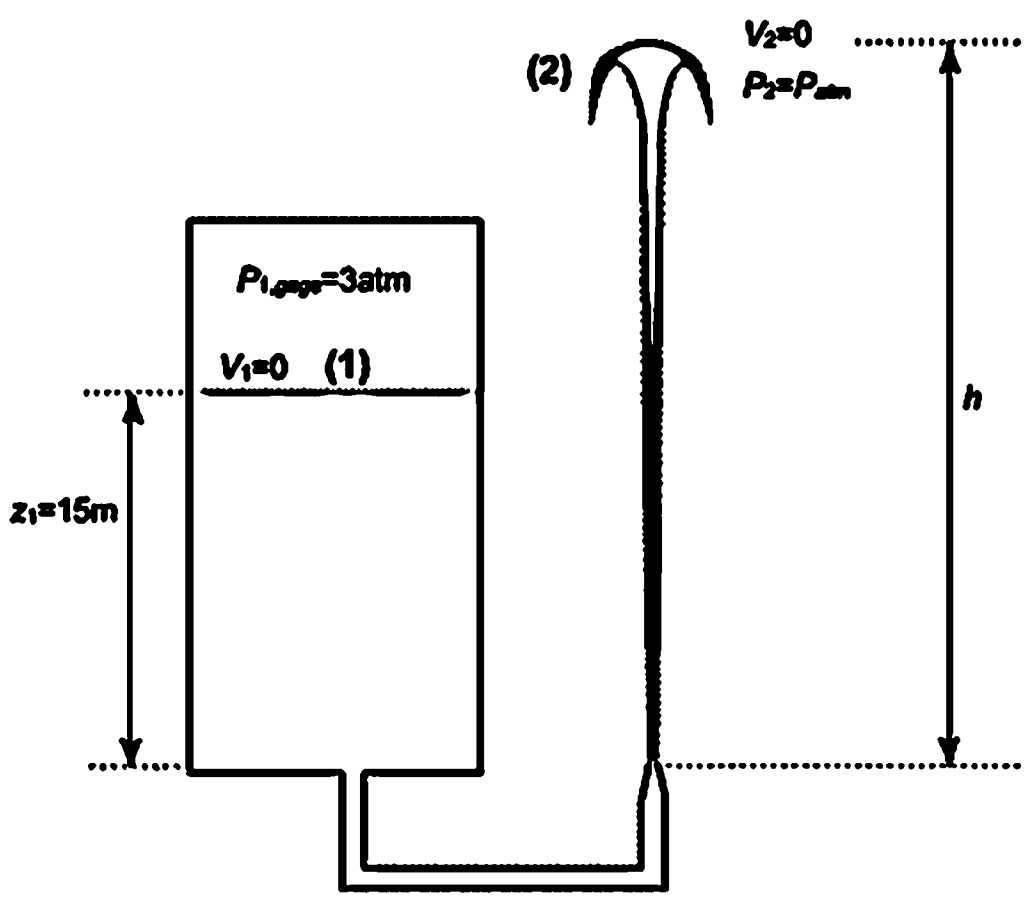
Step 1 of 4



Given data:-

The height of water level in the tank, $h_1 = z_1 = 15$ m.

The pressure at the water surface in the tank, $P_{1,gage} = 3$ atm.

Step 2 of 4

Let us draw the figure.

Step 3 of 4

The pressure at point (1),

$P_1 = 3$ atm

$= 3.039\times10^5$ Pa

The atmospheric pressure,

$P_{atm} = 1.013\times10^5$ Pa

By applying the Bernoulli's equation between the points (1) and (2), we get

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2$$

$$\frac{P_1}{\rho g}+\frac{0}{2g}+15=\frac{P_{atm}}{\rho g}+\frac{0}{2g}+h$$

Step 4 of 4

Then, maximum height of water rise to which the water stream could rise is

$$h=\left[\frac{1}{(1000)(9.81)}(P_1-P_{atm})\right]+15$$

$$=\left[\frac{1}{(1000)(9.81)}(P_{1,gage})\right]+15$$

$$=\left[\frac{1}{(1000)(9.81)}(3.039\times10^5)\right]+15$$

$$= 45.97 \text{ m}$$

Therefore, the height to which water rises is $\boxed{h = 45.97 \text{ m}}$.

Question: 12.036P

A Pitot-static probe connected to a water manometer is used to measure the velocity of air. If the deflection (the vertical distance between the fluid levels in the two arms) is 7.3 cm, determine the air velocity. Take the density of air to be 1.25 kg/m3.

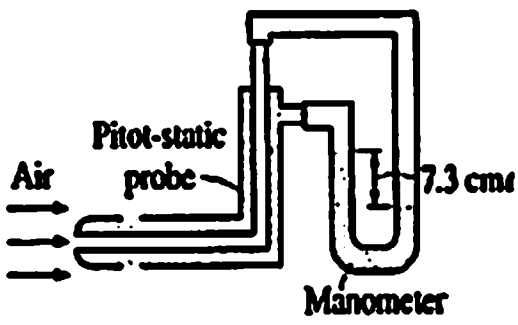


FIGURE P12-36

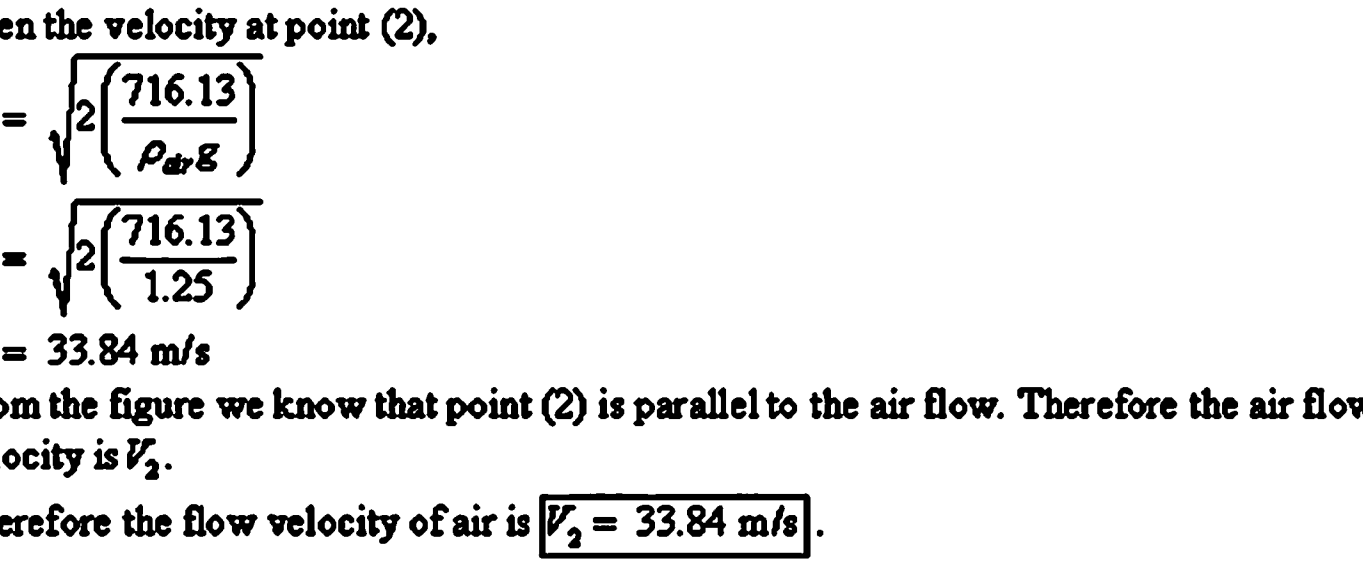
Step 1 of 4



Given data:-

The density of air, $\rho_{air} = 1.25\ \text{kg/m}^3$.

The differential height of fluid in the probe, $h = 0.073\ \text{m}$.

Step 2 of 4

Let us draw the figure

Step 3 of 4

Consider point (1) which is the stagnation point.

The velocity, $V_1 = 0$

Apply the Bernoulli's equation between the points (1) and (2).

$$\frac{P_1}{\rho_{air} g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho_{air} g} + \frac{V_2^2}{2g} + z_2$$

Substitute the required values and simplify.

$$\frac{P_1}{\rho_{air} g} + \frac{0}{2g} = \frac{P_2}{\rho_{air} g} + \frac{V_2^2}{2g}$$

$$V_2 = \sqrt{2\left(\frac{P_1 - P_2}{\rho_{air}}\right)}$$

The pressure difference between the two points can be expressed as,

$$\begin{aligned} P_1 - P_2 &= \rho_{water} g h \\ &= 1000(9.81)(0.073) \\ &= 716.13\ \text{Pa} \end{aligned}$$

Step 4 of 4

Then the velocity at point (2),

$$\begin{aligned} V_2 &= \sqrt{2\left(\frac{716.13}{\rho_{air} g}\right)} \\ &= \sqrt{2\left(\frac{716.13}{1.25}\right)} \\ &= 33.84\ \text{m/s} \end{aligned}$$

From the figure we know that point (2) is parallel to the air flow. Therefore the air flow velocity is V_2.

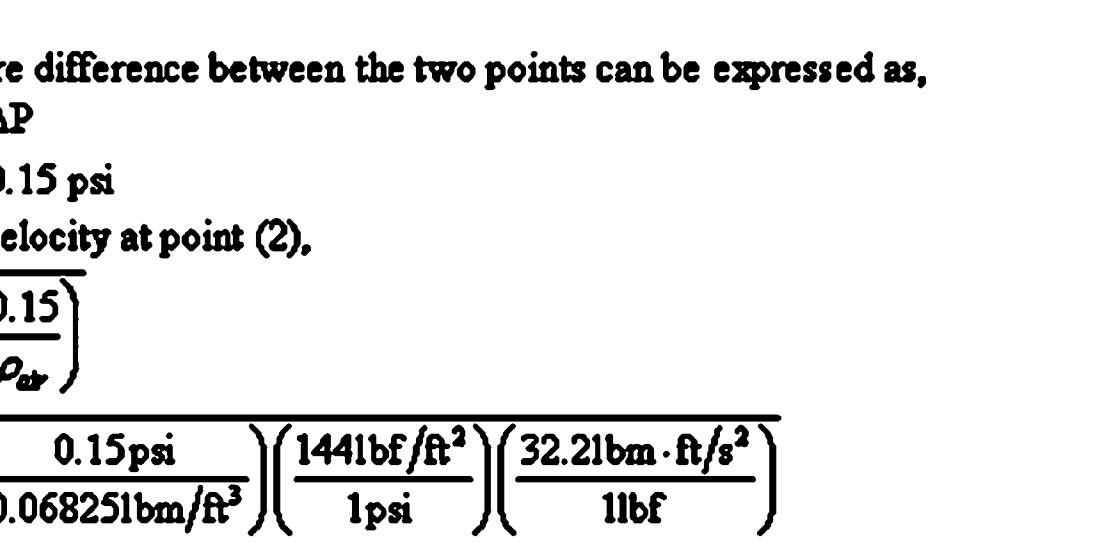
Therefore the flow velocity of air is $\boxed{V_2 = 33.84\ \text{m/s}}$.

Question: 12.037P

The air velocity in a duct is measured by a Pitot-static probe connected to a differential pressure gage. If the air is at 13.4 psia absolute and 70°F and the reading of the differential pressure gage is 0.15 psi, determine the air velocity.

Step 1 of 4

Given data:



The absolute pressure of air, $P_{abs} = 13.4$ psia.

The air is at a temperature, $T = 70°F$.

The differential pressure gage reading, $\Delta P = 0.15$ psia.

Step 2 of 4

Let us draw the figure:

Step 3 of 4

We have,

$$P_{abs} = \rho_{air} RT$$

$$13.4 = \rho_{air}(0.3704)(70+460\text{R})$$

$$\rho_{air} = 0.06825 \text{ lbm/ft}^3$$

Consider point (1) which is the stagnation point.

The velocity, $V_1 = 0$

Apply the Bernoulli's equation between the points (1) and (2).

$$\frac{P_1}{\rho_{air} g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho_{air} g} + \frac{V_2^2}{2g} + z_2$$

Substitute the required values and simplify.

$$\frac{P_1}{\rho_{air} g} + \frac{0}{2g} = \frac{P_2}{\rho_{air} g} + \frac{V_2^2}{2g}$$

$$V_2 = \sqrt{2\left(\frac{P_1 - P_2}{\rho_{air}}\right)}$$

Step 4 of 4

The pressure difference between the two points can be expressed as,

$$P_1 - P_2 = \Delta P$$

$$= 0.15 \text{ psi}$$

Then, the velocity at point (2),

$$V_2 = \sqrt{2\left(\frac{0.15}{\rho_{air}}\right)}$$

$$= \sqrt{2\left(\frac{0.15\text{psi}}{0.06825\text{lbm/ft}^3}\right)\left(\frac{144\text{lbf/ft}^2}{1\text{psi}}\right)\left(\frac{32.2\text{lbm}\cdot\text{ft/s}^2}{1\text{lbf}}\right)}$$

$$= 143 \text{ ft/s}$$

From the figure we know that point (2) is parallel to the air flow.

Therefore, the air flow velocity is $\boxed{V_2 = 143\text{ft/s}}$.

Question: 12.038P

In cold climates, water pipes may freeze and burst if proper precautions are not taken. In such an occurrence, the exposed part of a pipe on the ground ruptures, and water shoots up to 42 m. Estimate the gage pressure of water in the pipe. State your assumptions and discuss if the actual pressure is more or less than the value you predicted.

Step 1 of 2

Given data:-

The maximum height to which water shoots up, $h = 42\ \text{m}$.

The density of water is at maximum at 4°C or 277.14 K is beyond which it becomes less dense leading to the solidification into ice at 0°C with corresponding expansion. This expansion during this process is the cause of pipe rupture in cold climates.

Step 2 of 2

The density of water at temperature 273.14 K,

$\rho_{water} = 999.8395\ \text{kg/m}^3$

The water rises to a height of 42 m due to the pressure in the line.

Then we have,

$$P_{line} = \rho_{water} g h$$
$$= 999.9395 \times 9.81 \times 42$$
$$= 411.953\ \text{kPa}$$

Therefore, the gage pressure in the line is $\boxed{P_{line} = 411.953\ \text{kPa}}$.

Question: 12.039P

What is irreversible head loss? How is it related to the mechanical energy loss?

Step 1 of 2

Irreversible head loss (h_L) is the loss in head due to the effect of irreversibilities, like friction in piping, and it does not include the losses that occur within the pump or turbine.

Mechanical energy loss is the loss of head due to irreversibilities such as friction in pump or turbine. Mechanical energy loss is dissipated in the form of thermal energy.

Step 2 of 2

The relation between Irreversible head loss (h_L) and mechanical energy loss is expressed by the relation,

$$h_L = \frac{e_{mech\ loss}}{g}$$
$$= \frac{\dot{E}_{mech\ loss}}{\dot{m}g}$$

Here, $e_{mech\ loss}$ is the total mechanical energy loss, $\dot{E}_{mech\ loss}$ is the total mechanical power loss, and $\dot{m}$ is the mass flow rate.

Question: 12.040P

What is useful pump head? How is it related to the power input to the pump?

Step 1 of 1

Useful pump head

The useful power given as input to a pump, which expresses as fluid head can be termed as useful pump head.

Useful pump head and power input can be related by the following equation,

$$h_{pump} = \frac{w_{pump,u}}{g} = \frac{\dot{W}_{pump,u}}{\dot{m}g}$$

Where,

$h_{pump,u}$ is the useful pump head.

$w_{pump,u}$ is the useful work input.

$\dot{W}_{pump,u}$ is the useful power input.

Question: 12.041P

What is the kinetic energy correction factor? Is it significant?

Step 1 of 1

Kinetic energy correction factor (α)

The kinetic energy obtained from average velocity and that obtained from actual velocity is not equal to each other. To correct this error the kinetic energy term $(V^2/2)$ in the energy equation is replaced by the term $\alpha V_{avg}^2/2$.

Where,

α is the kinetic energy correction factor.

V_{avg} is the average velocity.

The energy equation when the kinetic energy correction factor is included,

For a pump turbine system

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L$$

Where,

$h_{pump,u}$ is the useful pump head.

$h_{turbine,e}$ is the extracted head removed from the fluid by the turbine.

h_L is the irreversible head loss.

Question: 12.042P

The water level in a tank is 20 m above the ground. A hose is connected to the bottom of the tank, and the nozzle at the end of the hose is pointed straight up. The water stream from the nozzle is observed to rise 25 m above the ground. Explain what may cause the water from the hose to rise above the tank level.

Step 1 of 2

Given data:-

The water surface is at a height of 20 m from the ground level.

The water stream from the nozzle rises to a height of 25 m from the ground level.

Step 2 of 2

We know that the maximum height to which water can rise from the nozzle of the hose must be equal to the height of the water surface which is 20 m

In the present situation the water rises to 25 m . This is possible only if the water is pressurized above atmospheric pressure at some point.

This can be achieved by

- Pressurizing at the water surface inside the tank.
- Installing a pumping unit along the flow before the exit which will pressurize the water flow

Thus we can conclude that the difference in height between the water jet rise from the hose and the tank water level surface is due to pressurization.

Question: 12.043P

A person is filling a knee-high bucket with water using a garden hose and holding it such that water discharges from the hose at the level of his waist. Someone suggests that the bucket will fill faster if the hose is lowered such that water discharges from the hose at the knee level. Do you agree with this suggestion? Explain. Disregard any frictional effects.

Step 1 of 2

It is given that the frictional effects are neglected.
We have the Bernoulli's equation

$$\frac{P_1}{\rho_{water} g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho_{water} g} + \frac{V_2^2}{2g} + z_2 \qquad \text{..... (1)}$$

Let us set the ground level as the reference position, then $z_1 = 0$

Let the pressure at exit P_2 be equal to the atmospheric pressure.

Then re-arranging the equation (1) for exit velocity

$$\frac{P_1}{\rho_{water} g} + \frac{V_1^2}{2g} + 0 = \frac{P_2}{\rho_{water} g} + \frac{V_2^2}{2g} + z_2$$

$$\frac{V_2^2}{2} = \frac{P_1 - P_{atm}}{\rho_{water}} + \frac{V_1^2}{2} - z_2$$

$$V_2 = \sqrt{2\left(\frac{P_1 - P_{atm}}{\rho_{water}} + \frac{V_1^2}{2} - z_2\right)} \qquad \text{..... (2)}$$

Step 2 of 2

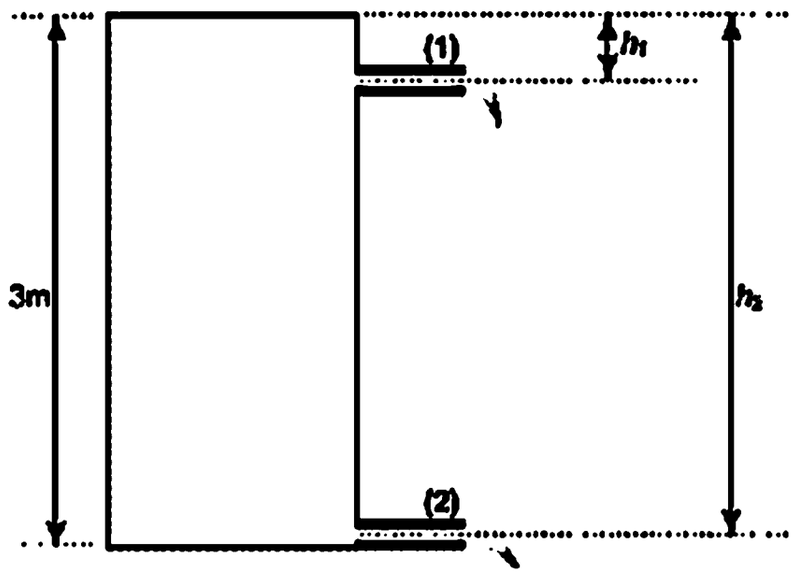
From the above expression (2) for exit velocity it is evident that the velocity will decrease with the increase in the elevation z_2.

We know that mass low rate,

$\dot{m} = A_{pipe} V_2$

Where A_{pipe} is the area of the pipe

Thus it is evident that the mass flow decreases with increasing elevation.



Therefore if the hose is held at knee level rather than at the waist level of the person the bucket will fill faster due to increased discharge.

Question: 12.044P

A 3-m-high tank filled with water has a discharge valve near the bottom and another near the top. (*a*) If these two valves are opened, will there be any difference between the discharge velocities of the two water streams? (*b*) If a hose whose discharge end is left open on the ground is first connected to the lower valve and then to the higher valve, will there be any difference between the discharge rates of water for the two cases? Disregard any frictional effects.

Step 1 of 3

Figure representing the 3 m high tank

Step 2 of 3

(a)

The relation for pressure is expressed as

$P = \rho g h$

Where h is height of the water column above the point considered

Since we know that with increase in applied pressure the flow rate through an orifice increases, we can conclude that as the height h decreases the flow rate will also decrease

Both the valves at (1) and (2) are open

We know from the figure that $h_1 < h_2$

Then the velocities at the valves is $V_1 < V_2$

Therefore we can say that the discharge velocities will be different at valves (1) and (2).

Step 3 of 3

(b)

The discharge rate is expressed as $\dot{m} = AV$

Where V is the velocity and A is the area

Then the flow rates at the valves will be $\dot{m}_1 < \dot{m}_2$

Because the velocities at the valves are $V_1 < V_2$

The mass flow rate of water through the hose when connected to valve (1) will be less than mass flow rate when connected to valve (2).

Question: 12.045P

In a hydroelectric power plant, water flows from an elevation of 240 ft to a turbine, where electric power is generated. For an overall turbine-generator efficiency of 83 percent, determine the minimum flow rate required to generate 100 kW of electricity.

Step 1 of 3

Given data:

Elevation from which the water flows, $H = 240$ ft

Overall turbine-generator efficiency, $\eta = 83\%$

Minimum power to be generated by the plant, $P = 100$ KW

Density of water, $\rho = 62.2$ lb/ft^3

Step 2 of 3

The power to be generated is $P = 100$ KW

From the conversion table we get 1 KW $= 737.56$ lbf.ft/s

Thus using the conversion factor we get the power in English units as

$P = 100 \times 737.56$ lbf.ft/s

$= 73756$ lbf.ft/s

Let us first calculate the flow rate of water using the formula for efficiency of a turbine and then determine the mass flow rate. Thus the relation for efficiency of a turbine is

$$\eta_t = \frac{P}{WQH}$$

Re-arranging for Q we get

$$Q = \frac{P}{WH\eta_t} \qquad \text{..... (1)}$$

Step 3 of 3

Now substituting the given values in the equation (1) we get

$$Q = \frac{P}{WH\eta_t}$$

$$= \frac{73756}{62.2 \times 240 \times 0.83}$$

$$= \frac{73756}{12390.24}$$

$$= 5.95 \text{ ft}^3/\text{s}$$

The mass flow rate is expressed as

$$\dot{m} = \rho AV$$

$$= \rho Q$$

$$= 62.2 \times 5.95$$

$$= 370.26 \text{ lbm/s}$$

Therefore the mass flow rate of water is $\boxed{\dot{m} = 370.26 \text{ lbm/s}}$

Question: 12.046P

Reconsider Prob. 12-45E. Determine the flow rate of water if the irreversible head loss of the piping system between the free surfaces of the source and the sink is 36 ft.

Step 1 of 4

Elevation from which the water flows, $H = 240$ ft
Overall turbine-generator efficiency, $\eta = 83\%$
Minimum power to be generated by the plant, $P = 100$ KW
Density of water, $\rho = 62.2$ lb/ft^3
Head loss of the system from source to the sink, $h_L = 36$ ft

Step 2 of 4

Applying the steady head form of the energy equation we get

$$\frac{P_1}{\rho g}+\alpha_1\left(\frac{V_1^2}{2g}\right)+z_1-h_{turbine}=\frac{P_2}{\rho g}+\alpha_2\left(\frac{V_2^2}{2g}\right)+z_2+h_L$$

Since the water level at the source and the sink remain constant so $V_1 = V_2 \approx 0$ and also the pressure at the source and sink are equal to the atmospheric pressure $P_1 = P_2 = P_{atm}$.

Hence the above equation reduces to

$$\frac{P_{atm}}{\rho g}+\alpha_1(0)+z_1-h_{turbine}=\frac{P_{atm}}{\rho g}+\alpha_2(0)+z_2+h_L$$

$$h_{turbine} = (z_1 - z_2) - h_L$$
$$= 240 - 36$$
$$= 204 \text{ ft}$$

Step 3 of 4

The power to be generated is $P = 100$ KW
From the conversion table we get 1 KW = 737.56 lbf.ft/s
Thus using the conversion factor we get the power in English units as
$P = 100 \times 737.56$ lbf.ft/s
$= 73756$ lbf.ft/s

Let us first calculate the flow rate of water using the formula for efficiency of a turbine and then determine the mass flow rate. Thus the relation for efficiency of a turbine is

$$\eta_t = \frac{P}{WQh_{turbine}}$$

Re-arranging for Q we get

$$Q = \frac{P}{Wh_{turbine}\eta_t} \qquad \text{..... (1)}$$

Step 4 of 4

Now substituting the given values in the equation (1) we get

$$Q = \frac{P}{Wh_{turbine}\eta_t}$$
$$= \frac{73756}{62.2 \times 204 \times 0.83}$$
$$= \frac{73756}{10531.704}$$
$$= 7 \text{ ft}^3/\text{s}$$

The mass flow rate is expressed as

$$\dot{m} = \rho AV$$
$$= \rho Q$$
$$= 62.2 \times 7$$
$$= 435.6 \text{ lbm/s}$$

Therefore the mass flow rate of water is $\boxed{\dot{m} = 435.6 \text{ lbm/s}}$

Question: 12.047P

A fan is to be selected to ventilate a bathroom whose dimensions are 2 m × 3 m × 3 m. The air velocity is not to exceed 8 m/s to minimize vibration and noise. The combined efficiency of the fan-motor unit to be used can be taken to be 50 percent. If the fan is to replace the entire volume of air in 10 min, determine (*a*) the wattage of the fan-motor unit to be purchased, (*b*) the diameter of the fan casing, and (*c*) the pressure difference across the fan. Take the air density to be 1.25 kg/m3 and disregard the effect of the kinetic energy correction factors.

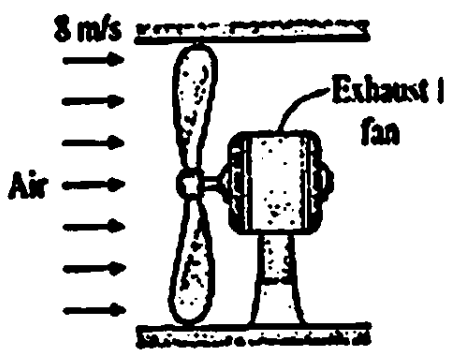


FIGURE P12–47

Step 1 of 4

(a)

The total volume of air (V) in the bathroom is as follows

$$V = 2\text{ m} \times 3\text{ m} \times 3\text{ m}$$
$$= 18\text{ m}^3$$

Use this volume to calculate the volume flow rate ($\dot{V}$) using the time it takes to replace the entire volume of air (t).

$$\dot{V} = \frac{V}{t}$$

Substitute $18\,\text{m}^3$ for V and $10\,\text{min}$ for t in the above equation and obtain the flow rate as follows

$$\dot{V} = \frac{18\text{ m}^3}{10\text{ min}} \times \frac{1\text{ min}}{60\text{ s}}$$
$$= 0.03\text{ m}^3/\text{s}$$

Next calculate the mass flow rate ($\dot{m}$) using the density of air as follows

$$\dot{m} = \rho\dot{V}$$

Substitute $1.25\,\text{kg/m}^3$ for ρ and $0.03\,\text{m}^3/\text{s}$ for $\dot{V}$ in the above relation

$$\dot{m} = 1.25\text{ kg/m}^3 \times 0.03\text{ m}^3/\text{s}$$
$$= 0.0375\text{ kg/s}$$

Step 2 of 4

Apply the energy equation for steady, incompressible flow relating pressure (P), velocity (V), and height (z) between the inlet side of the fan (point 1) and the exit side of the fan (point 2).

$$\dot{m}\left(\frac{P_1}{\rho} + \alpha_1\frac{V_1^2}{2} + z_1 g\right) + \dot{W}_{pump} = \dot{m}\left(\frac{P_2}{\rho} + \alpha_2\frac{V_2^2}{2} + z_2 g\right) + \dot{W}_{turbine} + \dot{E}_{mech,loss}$$

Because both points are open to the atmosphere both P_1 and P_2 are equal to the atmospheric pressure. Notice that both points are at the same height, so $z_1 = z_2$.

Also, consider point 1 far enough from the fan so that the flow velocity is zero. The effective power of the fan is equal to the difference between the pump and the mechanical loss.

$$\dot{W}_{pump} - \dot{E}_{mech,loss} = \dot{m}\alpha_2\frac{V_2^2}{2}$$

$$\dot{W}_{fan,eff} = \dot{m}\alpha_2\frac{V_2^2}{2}$$

Recall that the electric power rating of the fan is equal to the effective power divided by the power rating.

$$\dot{W}_{fan,elect} = \frac{1}{\eta}\dot{m}\alpha_2\frac{V_2^2}{2}$$

Substitute $0.0375\,\text{m}^3/\text{s}$ for $\dot{m}$, $8\,\text{m/s}$ for V_2 and 0.5 for η in the above equation. Recall that, since the effect of the kinetic energy correction factors is negligible, $\alpha_2 = 1$

$$\dot{W}_{fan,elect} = \frac{1}{0.5} \times 0.0375\text{ kg/s} \times 1 \times \frac{(8\text{ m/s})^2}{2}$$
$$= 2.4\text{ W}$$

Therefore, the electric power rating of the fan is $2.4\,\text{W}$.

Step 3 of 4

(b)

Define the volume flow rate as calculated previously with the diameter of the fan (D) and the velocity flow (V) as follows

$$\dot{V} = A_2 V_2$$
$$= \pi\left(\frac{D}{2}\right)^2 V_2$$

Plug in the given velocity and the calculated volume flow rate. Solve for the diameter using the relation below

$$D = \sqrt{\frac{4\dot{V}}{\pi V_2}}$$

Substitute $0.03\,\text{m}^3/\text{s}$ for $\dot{V}$ and $8\,\text{m/s}$ for V_2 in the above relation

$$D = \sqrt{\frac{4 \times 0.03\text{ m}^3/s}{\pi \times 8\text{ m/s}}}$$
$$= 6.9\text{ cm}$$

In order for the mean velocity of air to remain below the specified value, the diameter of the fan casing can only be at most $6.9\,\text{cm}$.

Step 4 of 4

(c)

Consider now a point 3 immediately before the fan and a point 4 immediate after the fan. Apply the energy equation as follows

$$\dot{m}\left(\frac{P_3}{\rho} + \alpha_3\frac{V_3^2}{2} + z_3 g\right) + \dot{W}_{pump} = \dot{m}\left(\frac{P_4}{\rho} + \alpha_4\frac{V_4^2}{2} + z_4 g\right) + \dot{W}_{turbine} + \dot{E}_{mech,loss}$$

Note that both points are at the same height and have the same flow velocity. Solve for the difference in pressures.

$$\dot{m}\frac{P_3}{\rho} + \dot{W}_{fan,eff} = \dot{m}\frac{P_4}{\rho}$$

$$P_4 - P_3 = \frac{\dot{W}_{fan,eff}}{\dot{m}/\rho}$$
$$= \frac{\dot{W}_{fan,eff}}{\dot{V}}$$

Plug in the calculated volume flow rate and effective fan power.

$$P_4 - P_3 = \frac{1.2\text{ W}}{0.03\text{ m}^3/\text{s}}$$
$$= 40\text{ Pa}$$

Therefore, the pressure difference across the fan is $40\,\text{Pa}$.

Question: 12.048P

Water is being pumped from a large lake to a reservoir 25 m above at a rate of 25 L/s by a 10-kW (shaft) pump.If the irreversible head loss of the piping system is 5 m,determine the mechanical efficiency of the pump.

Step 1 of 3

Given data:-

Height of the tank from the reservoir, $z_2 = 25\ \text{m}$

The flow rate, $\dot{V} = 25\ \text{L/s} = 0.025\ \text{m}^3/\text{s}$

The power input for the pump, $\dot{W}_{shaft,in} = 10\ \text{kW}$

The irreversible head loss for the piping system, $h_L = 5\ \text{m}$

Step 2 of 3

The mass flow rate of water is determined by using the relation

$$\begin{aligned}\dot{m} &= \rho\dot{V}\\ &= \left(1000\ \text{kg/m}^3\right)\left(25\times10^{-3}\ \text{m}^3/\text{s}\right)\\ &= 25\ \text{kg/s}\end{aligned}$$

The relation for mass flow rate can be expressed as

$$\dot{m} = \frac{\dot{W}_{pump,in}}{gz_2 + gh_L}$$

$$\dot{W}_{pump,in} = \left(gz_2 + gh_L\right)\dot{m}$$

Substituting the values of $z_2 = 25\ \text{m}$, $h_L = 5\ \text{m}$ and $\dot{m} = 25\ \text{kg/s}$ in the above relation we get

$$\begin{aligned}\dot{W}_{pump,in} &= g(25+5)25\\ &= 9.81(25+5)25\\ &= 7357.5\ \text{W}\end{aligned}$$

Step 3 of 3

Thus the efficiency of the pump is determined by

$$\begin{aligned}\eta_{pump} &= \frac{\dot{W}_{pump,in}}{\dot{W}_{shaft,in}}\\ &= \frac{7357.5}{10\times10^3}\\ &= 0.73575\\ &= 73.57\ \%\end{aligned}$$

Therefore the efficiency of the pump is $\boxed{\eta_{pump} = 73.57\ \%}$

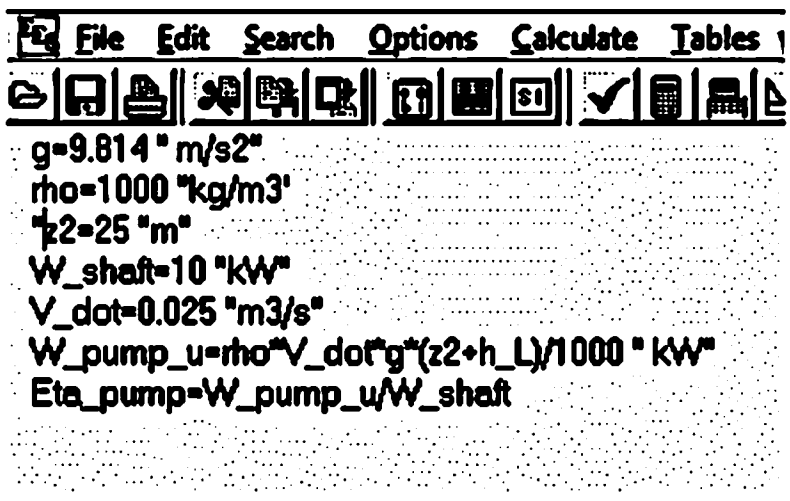
Question: 12.049P

Reconsider Prob. 12–48. Using EES (or other) software, investigate the effect of irreversible head loss on the mechanical efficiency of the pump. Let the head loss vary from 0 to 15 m in increments of 1 m. Plot the results, and discuss them.

Step 1 of 4

Given data:

Height of the tank from the reservoir, $z_2 = 25\ \text{m}$



The flow rate, $\dot{V} = 25\ \text{L/s} = 0.025\ \text{m}^3/\text{s}$

The power input for the pump, $\dot{W}_{shaft,in} = 10\ \text{kW}$

The irreversible head loss for the piping system, $h_L = 5\ \text{m}$

Step 2 of 4

Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

Step 3 of 4

After writing the program in equation window select table on menu bar and click new parameter table. Now the dialog box will be appeared on the screen and then select the efficiency, head loss and work done by the pump. Finally click ADD, then click OK button.

The following results are displayed;

Parametric Table

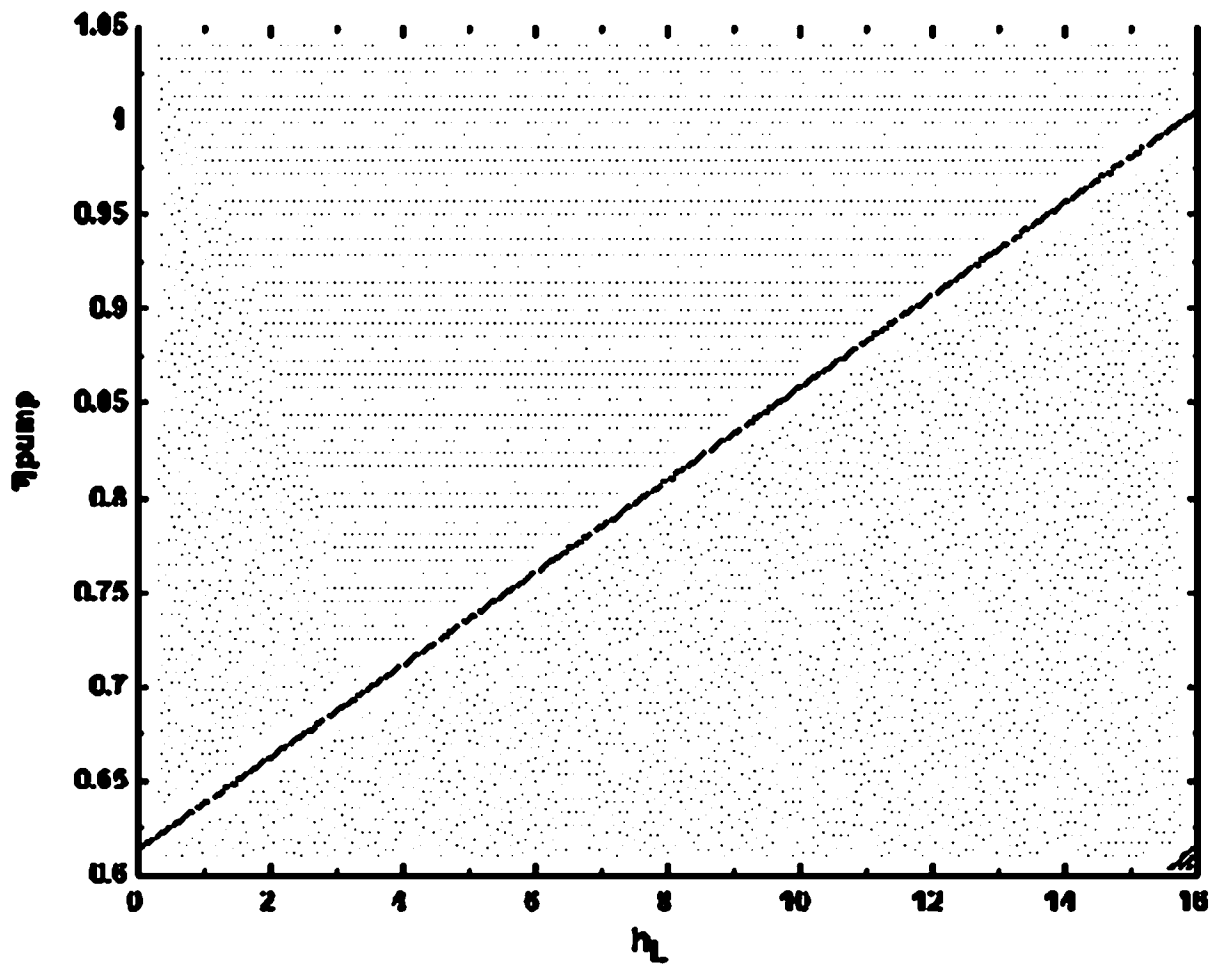


Table 1 | Table 2 | Table 3 | Table 4

1..16	η_{pump}	h_L	$W_{pump,u}$
Run 1	0.6134	0	6.134
Run 2	0.6395	1.067	6.395
Run 3	0.6657	2.133	6.657
Run 4	0.6919	3.2	6.919

Run 16	1.006	16	10.06

Step 4 of 4

Select the plot on menu bar, then click x-y plot .Dialog box will be appeared and select variables to draw graph, then click OK button.

By plotting the graph between efficiency of pump and head loss:

Question: 12.050P

A 7-hp (shaft) pump is used to raise water to a 15-m higher elevation. If the mechanical efficiency of the pump is 82 percent, determine the maximum volume flow rate of water.

Step 1 of 2

Convert the units of the input shat power,

$$\begin{aligned}\dot{W}_{shaft,in} &= 7\ \text{hp} \\ &= 7\,\text{hp} \times \left(\frac{745.69\,\text{W}}{1\,\text{hp}}\right) \\ &= 5219.83\,\text{W}\end{aligned}$$

Consider the relation for efficiency of the pump.

$$\eta_{pump} = \frac{\dot{W}_{pump,u}}{\dot{W}_{shaft,in}}$$

$$\dot{W}_{pump,u} = \eta_{pump}\left(\dot{W}_{shaft,in}\right)$$

Substitute 0.82 for η_{pump}, and $5219.83\,\text{W}$ for $\dot{W}_{shaft,in}$.

$$\begin{aligned}\dot{W}_{pump,u} &= (0.82)(5219.83) \\ &= 4280.26\,\text{W}\end{aligned}$$

Step 2 of 2

Calculate the mass flow rate

$$\dot{m} = \frac{\dot{W}_{pump,u}}{gz_2}$$

Here, g is acceleration due to gravity and z_2 is the elevation.

Substitute $15\,\text{m}$ for z_2 and $4280.26\,\text{W}$ for $\dot{W}_{pump,u}$.

$$\begin{aligned}\dot{m} &= \frac{4280.26}{9.81(15)} \\ &= 29.08\,\text{kg/s}\end{aligned}$$

Calculate the volume flow rate.

$$\dot{V} = \frac{\dot{m}}{\rho}$$

Substitute $29.08\,\text{kg/s}$ for $\dot{m}$ and $1000\,\text{kg/m}^3$ for ρ.

$$\begin{aligned}\dot{V} &= \frac{29.08}{1000} \\ &= 0.02908\ \text{m}^3/\text{s}\end{aligned}$$

Therefore the flow rate is $\boxed{0.02908\ \text{m}^3/\text{s}}$.

Question: 12.051P

Water flows at a rate of 0.035 m3/s in a horizontal pipe whose diameter is reduced from 15 cm to 8 cm by a reducer. If the pressure at the centerline is measured to be 480 kPa and 445 kPa before and after the reducer, respectively, determine the irreversible head loss in the reducer. Take the kinetic energy correction factors to be 1.05.

Step 1 of 3

Given data:

The flow rate, $\dot{V} = 0.035\ m^3/s$

The diameter of the reducer varies from 15 cm to 8cm

The pressure after the reducer, $P_2 = 480$ kPa

The pressure before the reducer is $P_1 = 445$ kPa

The kinetic energy correction factor, $\alpha = 1.05$

Let the flow velocity be V

The area be A

Step 2 of 3

We know that flow velocity

$$V = \frac{\dot{V}}{A}$$

So before the reducer the velocity where area is A_1 is

$$V_1 = \frac{\dot{V}}{A_1}$$

$$= \frac{0.035}{\frac{\pi}{4}(0.15)^2}$$

$$= 1.980\ m/s$$

After the reducer the velocity where area is A_2

$$V_2 = \frac{\dot{V}}{A_2}$$

$$= \frac{0.035}{\frac{\pi}{4}(0.08)^2}$$

$$= 6.96\ m/s$$

Step 3 of 3

Let us apply the Bernoulli's equation for steady incompressible flow between the entrance and exit of the reducer. We get

$$\frac{P_1}{\rho g} + \alpha \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \alpha \frac{V_2^2}{2g} + z_2 + h_L$$

We know that flow velocity

$$V = \frac{\dot{V}}{A}$$

So before the reducer the velocity where area is A_1 is

$$V_1 = \frac{\dot{V}}{A_1}$$

$$= \frac{0.035}{\frac{\pi}{4}(0.15)^2}$$

$$= 1.980\ m/s$$

After the reducer the velocity where area is A_2

$$V_2 = \frac{\dot{V}}{A_2}$$

Question: 12.052P

The water level in a tank is 20 m above the ground. A hose is connected to the bottom of the tank, and the nozzle at the end of the hose is pointed straight up. The tank is at sea level, and the water surface is open to the atmosphere. In the line leading from the tank to the nozzle is a pump, which increases the pressure of water. If the water jet rises to a height of 27 m from the ground, determine the minimum pressure rise supplied by the pump to the water line.

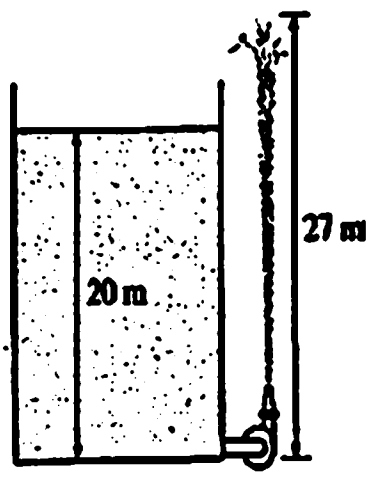

FIGURE P12-52

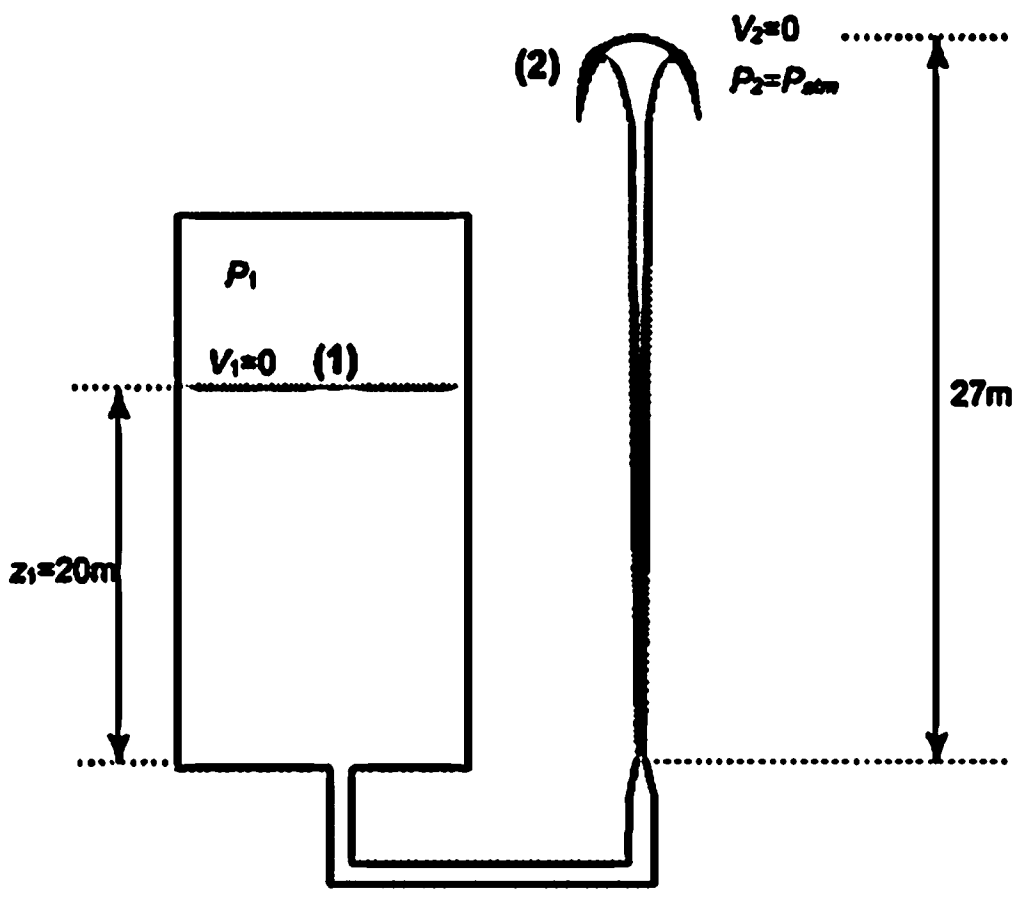
Step 1 of 5

Given data:

The height to which the water jet rises from the nozzle, $z_j = 27$ m.

The height of water surface in the tank from nozzle, $z_s = 20$ m.



Step 2 of 5

Assumptions are

- The flow is steady, incompressible and irrotational.
- The frictional effects are neglected.
- The pressure outside is atmospheric pressure, P_{atm}.

Step 3 of 5

Figure showing a water tank with nozzle fitted at its bottom,

Step 4 of 5

The atmospheric pressure,

$$P_{atm} = P_2$$
$$= 1.013 \times 10^5 \text{Pa}$$

Applying the Bernoulli's equation between the points (1) and (2):

Then

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$\frac{P_1}{\rho g} + \frac{0}{2g} + 20 = \frac{P_{atm}}{\rho g} + \frac{0}{2g} + 27$$

Step 5 of 5

Then

$$\frac{1}{(1000)(9.81)}(P_1 - P_{atm}) = 27 - 20$$

$$\frac{1}{(1000)(9.81)}(P_{1,gage}) = 27 - 20$$

$$P_{1,gage} = 68670 \text{ Pa}$$

Therefore the gage pressure required to raise the water jet to a height of 27 m is

$\boxed{P_{1,gage} = 68670 \text{ Pa}}$.

$$\frac{1}{(1000)(9.81)}(P_1 - P_{atm}) = 27 - 20$$

$$\frac{1}{(1000)(9.81)}(P_{1,gage}) = 27 - 20$$

$$P_{1,gage} = 68670 \text{ Pa}$$

Therefore the gage pressure required to raise the water jet to a height of 27 m is

$\boxed{P_{1,gage} = 68670 \text{ Pa}}$.

Question: 12.053P

A hydraulic turbine has 85 m of head available at a flow rate of 0.25 m3/s. and its overall turbine-generator efficiency is 78 percent. Determine the electric power outputof this turbine.

Step 1 of 3

Given data:

The available head for the hydraulic turbine, $h_{turbine} = 85$ m

The flow rate is $\dot{V} = 0.25\ m^3/s$

The overall turbine generator efficiency, $\eta_{turbine-gen} = 78\ \%$

Step 2 of 3

We know that efficiency is given by

$$\eta_{turbine-gen} = \frac{\dot{W}_{electric}}{\dot{W}_{turbine,e}} \qquad \text{..... (1)}$$

Also the Electric power output,

$$\dot{W}_{electric} = \eta_{turbine-gen}\dot{W}_{turbine,e}$$

We have,

$$\eta_{turbine} = \frac{\dot{W}_{turbine,e}}{\dot{m}g}$$

$$\dot{W}_{turbine,e} = \eta_{turbine}\dot{m}g$$

$$= \eta_{turbine}\left(\dot{V}\rho\right)g$$

$$= (85)(0.25 \times 1000)(9.81)$$

$$= 208.46 \times 10^3\ W$$

Step 3 of 3

Substituting these values in equation (1) we have,

$$\dot{W}_{electric} = \eta_{turbine-gen}\dot{W}_{turbine,e}$$

$$= 0.78\left(208.46 \times 10^3\right)$$

$$= 162.60 \times 10^3\ W$$

Therefore the electric power output of the turbine is $\boxed{\dot{W}_{electric} = 162.6 \times 10^3\ W}$.

Question: 12.054P pg 1

An oil pump is drawing 25 kW of electric power while pumping oil with ρ =860 kg/m3 at a rate of 0.1m3sThe inlet and outlet diameters of the pipe are 8 cm and 12 cm respectively. If the pressure rise of oil in the pump is mea sured to be 250 kPa and the motor efficiency is 90 percent; determine the mechanical efficiency of the pump. Take the kinetic energy correction factor to be 1.05.

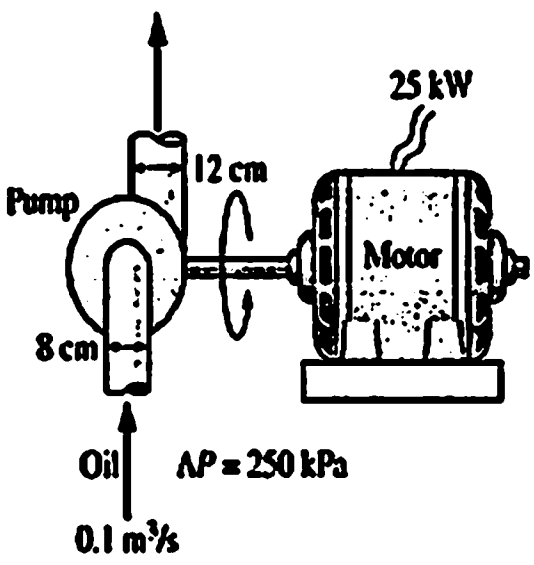


FIGURE P12–54

Step 1 of 6

Given data:

The input electric power, $\dot{W}_{electric,in} = 25\ \text{kW}$

The motor efficiency, $\eta_{motor} = 90\ \%$

The flow rate, $\dot{V} = 0.1\ \text{m}^3/\text{s}$

The pressure rise in the pump, $\Delta P = 250\ \text{kPa}$

The kinetic energy correction factor, $\alpha = 1.05$

The inlet diameter, $D_1 = 0.08\ \text{m}$

The outlet diameter, $D_2 = 0.12\ \text{m}$

Step 2 of 6

Calculation of mechanical efficiency of the pump:

In order to calculate the mechanical efficiency, let us calculate the change in mechanical energy and shaft work.

Let us set the inlet zone as point (1) and exit zone of the pump as point (2).

The inlet area,

Step 1 of 6

Given data:

The input electric power, $\dot{W}_{electric,in} = 25\ \text{kW}$

The motor efficiency, $\eta_{motor} = 90\ \%$

The flow rate, $\dot{V} = 0.1\ \text{m}^3/\text{s}$

The pressure rise in the pump, $\Delta P = 250\ \text{kPa}$

The kinetic energy correction factor, $\alpha = 1.05$

The inlet diameter, $D_1 = 0.08\ \text{m}$

The outlet diameter, $D_2 = 0.12\ \text{m}$

Step 2 of 6

Calculation of mechanical efficiency of the pump:

In order to calculate the mechanical efficiency, let us calculate the change in mechanical energy and shaft work.

Let us set the inlet zone as point (1) and exit zone of the pump as point (2).

The inlet area,

$$A_1 = \frac{\pi}{4} D_1^2$$

$$= \frac{\pi}{4} \times 0.08^2$$

$$= 5.026 \times 10^{-3}\ \text{m}^2$$

The exit area,

$$A_2 = \frac{\pi}{4} D_2^2$$

$$= \frac{\pi}{4} \times 0.12^2$$

$$= 11.30 \times 10^{-3}\ \text{m}^2$$

Step 3 of 6

We have,

$$\dot{V} = A_2 V_2$$

$$0.1 = \left(11.30 \times 10^{-3}\right) \times V_2$$

$$V_2 = 8.849\ \text{m/s}$$

And

$$\dot{V} = A_1 V_1$$

$$0.1 = \left(5.026 \times 10^{-3}\right) V_2$$

$$V_1 = 19.896\ \text{m/s}$$

Step 4 of 6

Let us apply the energy equation between the two points.

Step 4 of 6

Let us apply the energy equation between the two points.

Then,

$$\frac{P_1}{\rho g}+\alpha_1\frac{V_1^2}{2g}+z_1+h_{pump,u}=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+z_2+h_{turbine,e}+h_L$$

$$\alpha_1\frac{V_1^2}{2g}-\alpha_2\frac{V_2^2}{2g}+z_1+h_{pump,u}=\frac{P_2}{\rho g}-\frac{P_1}{\rho g}+z_2+h_{turbine,e}+h_L$$

The difference in elevation between the inlet (1) and exit (2) is negligible,

$$z_1-z_2=0.$$

And the head loss due to turbine is also negligible.

Now substitute the required values,

$$\alpha\left(\frac{V_1^2}{2g}-\frac{V_2^2}{2g}\right)+h_{pump,u}=\frac{1}{\rho g}(P_2-P_1)$$

$$\frac{1.05}{2(9.81)}\left(19.896^2-8.849^2\right)+h_{pump,u}=\frac{1}{860(9.81)}\left(250\times10^3\right)$$

$$h_{pump,u}=12.63\text{ m}$$

Step 5 of 6

We know that,

The efficiency of a motor,

$$\eta_{motor}=\frac{\dot{W}_{shaft}}{\dot{W}_{electric,in}}$$

$$\dot{W}_{shaft}=\eta_{motor}\dot{W}_{electric,in}$$

$$=0.90\left(25\times10^3\right)$$

$$=22.5\times10^3\text{ W}$$

The change in mechanical energy,

$$\Delta E=\dot{m}h_{pump,u}$$

The mechanical efficiency of the pump,

$$\eta_{pump}=\frac{\Delta\dot{E}_{mech}}{\dot{W}_{shaft}}$$

$$=\frac{1086.18}{\left(22.5\times10^3\right)}$$

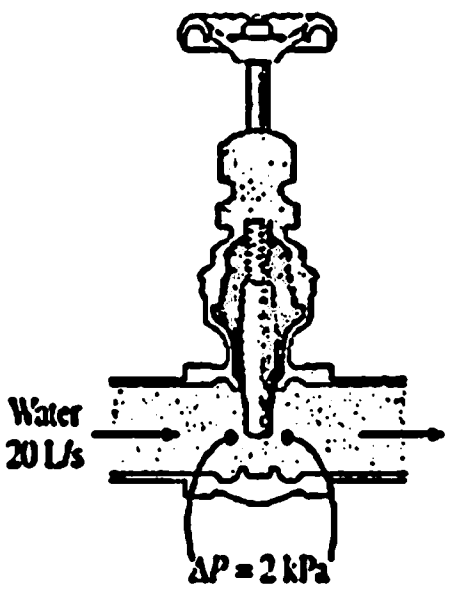
$$=0.048$$

$$=4.8\%$$

Therefore, the mechanical efficiency of the pump is, $\boxed{\eta_{pump}=4.8\%}$

Question: 12.055P

Water flows at a rate of 20 L/s through a horizontal pipe whose diameter is constant at 3 cm. The pressure drop across a valve in the pipe is measured to be 2 kPa, as shown in Fig PI2-55. Determine the irreversible head loss of the valve, and the useful pumping power needed to overcome the resulting pressure drop.



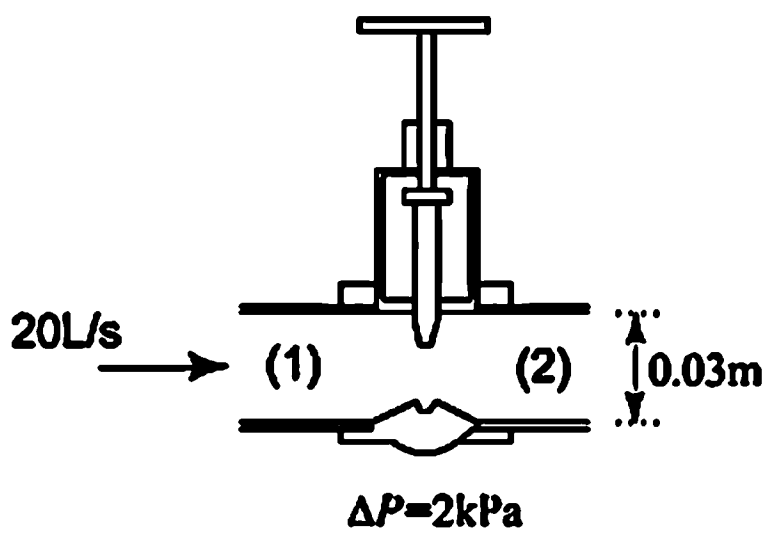


FIGURE P12–55

Step 1 of 5

Figure showing the flow of fluid through the pipe,

Step 2 of 5

Apply Bernoulli's equation for steady incompressible flow between the points (1) and (2):

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1+h_{pump,u}=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2+h_{turbine,e}+h_L$$

Here, head loss in pump is $h_{pump,u}$, head loss in turbine is $h_{turbine,e}$, the irreversible head loss h_L, the pressure at section 1 and 2 are P_1, P_2 respectively, velocity at section 1 and 2 are V_1, V_2 respectively and , height of the flow from datum at section 1 and 2 are z_1, z_2 respectively.

Step 3 of 5

Since the head loss in pump and turbine are absent,

$$h_{turbine,e}=h_{pump,u}=0$$

There is no change in height between sections (1) and (2) and the flow occurs in a horizontal path hence,

$$z_1=z_2$$

There is no change in velocity at section 1 and 2, since the diameter of the pipe remains constant.

$$V_1=V_2$$

From the mentioned conditions the Bernoulli equation modifies as,

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1+h_{pump,u}=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2+h_{turbine,e}+h_L$$

$$\frac{P_1}{\rho g}=\frac{P_2}{\rho g}+h_L$$

$$h_L=\frac{1}{\rho g}(P_1-P_2)$$

$$h_L=\frac{1}{\rho g}(\Delta P) \qquad \text{..... (1)}$$

Step 4 of 5

Substitute 2 kPa for ΔP, 9.81 m/s^2 for g and 1000 kg/m^3 for ρ in the equation (1),

$$h_L=\frac{1}{\rho g}(\Delta P)$$

$$=\frac{1}{(1000)(9.81)}(2\times10^3)$$

$$=0.2038 \text{ m}$$

Therefore the irreversible head loss h_L is $\boxed{0.2038 \text{ m}}$.

Step 5 of 5

Find the power required to overcome this pressure loss using the formula,

$$W_{pump}=\dot{m}\rho h_L$$

Here, mass flow rate is denoted by $\dot{m}$, density of water by ρ and, head loss by h_L.

Substitute 20 L/s for $\dot{m}$, 1000 kg/m^3 for ρ and 0.2038 m for h_L in the equation,

$$W_{pump}=\dot{m}\rho g h_L$$

$$=20 \text{ (L/s)}\times1000 \text{ kg/m}^3\times9.81 \text{ m/s}^2\times0.2038 \text{ m}$$

$$=\frac{20}{1000}\text{ (m}^3\text{/s)}\times1000 \text{ kg/m}^3\times9.81 \text{ m/s}^2\times0.2038 \text{ m}\times\left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right)$$

$$=0.03998 \text{ kW}$$

$$=39.98 \text{ W}$$

Therefore, the power required to overcome the pressure loss is $\boxed{39.98 \text{ W}}$.

Question: 12.056P

The water level in a tank is 66 ft above the ground. a hose is connected to the bottom of the tank at the ground level and the nozzle at the end of the hose is pointed straight up The tank cover is airtight, but the pressure over the water surface is unknown. Determine the minimum tank air pressure (gage) that will cause a water stream from the nozzle to rise 90 ft from the ground.

Step 1 of 3

Given data:

The height of the water in the tank from ground level, $z_s = 66\text{ft}$

The height to which the water jet rises, $z_j = 90\text{ft}$

The pressure at tank surface and maximum height of the jet is atmospheric, P_{atm}

Step 2 of 3

Consider Bernoulli's equation for steady incompressible flow between the tank surface and point of maximum height of the water jet, we get

$$\frac{P_s}{\rho g} + \alpha_1 \frac{V_s^2}{2g} + z_s + h_{pump,u} = \frac{P_j}{\rho g} + \alpha_2 \frac{V_j^2}{2g} + z_j + h_{turbine,e} + h_L$$

We know that

$P_s = P_j = P_{atm}$

And the velocity of fluid at the surface and maximum height is zero,

$V_s = V_j = 0$

Step 3 of 3

The useful pump head is

$$\begin{aligned} h_{pump,u} &= z_j - z_s \\ &= 90 - 66 \\ &= 24\text{ft} \end{aligned}$$

Then the pressure rise can be expressed as

$$\begin{aligned} \Delta P &= \rho g h_{pump,u} \\ &= (62.22) \times (32.174) \times (24) \\ &= 480044.79 \\ &= 48.00\text{ksf} \end{aligned}$$

or

$$= 333.64\text{psi}$$

Therefore the minimum pressure rise required is $\boxed{\Delta P = 48.00\text{ksf}}$.

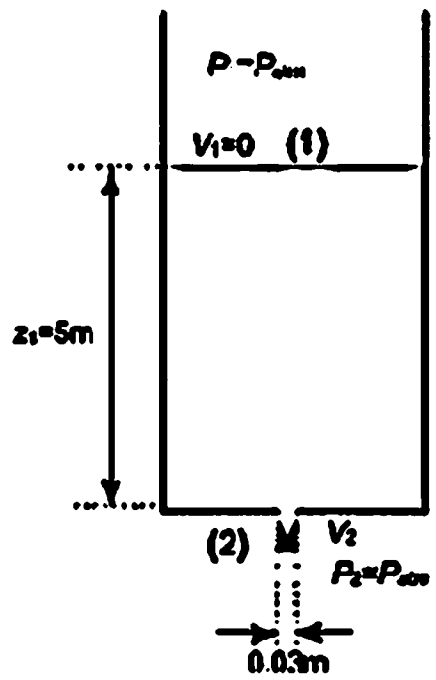
Question: 12.057P

A large tank is initially filled with water 5 m above the center of a sharp-edged 10-cm-diameter orifice. The tank water surface is open to the atmosphere, and the orifice drains to the atmosphere. If the total irreversible head loss in the system is 0.3 m, determine the initial discharge velocity of water from the tank. Take the kinetic energy correction factor at the orifice to be 1.2.

Step 1 of 4

Given data:

The diameter of the orifice, $D_2 = 0.1\,\text{m}$.



The irreversible head loss, $h_L = 0.3\,\text{m}$.

The free surface of water in the tank is at a height of from the orifice is $z_1 = 5\,\text{m}$.

The kinetic energy correction factor at orifice is $\alpha_2 = 1.2$.

Step 2 of 4

Figure showing a tank fitted with orifice,

Step 3 of 4

The exit at the orifice is set as the reference point. Applying the Bernoulli's equation for steady incompressible flow between the points (1) and (2):

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine} + h_L$$

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_L$$

Step 4 of 4

Substituting the required values and on simplifying, we get

$$\frac{P_{atm}}{\rho g} + 0 + 5 = \frac{P_{atm}}{\rho g} + (1.2)\frac{V_2^2}{2g} + 0 + 0.3$$

$$V_2^2 = \frac{(2 \times 9.81)(5 - 0.3)}{1.2}$$

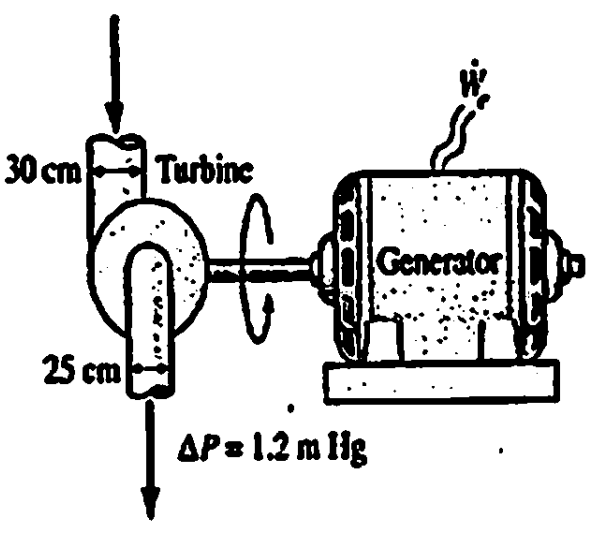
$$V_2 = \sqrt{76.845}$$

$$= 8.76\ \text{m/s}$$

Therefore the initial discharge velocity is $\boxed{V_2 = 8.76\ \text{m/s}}$.

Question: 12.058P

Water enters a hydraulic turbine through a 30-cm-diameter pipe at a rate of 0.6 m3s and exits through a 25-cm-diameter pipe. The pressure drop in the turbine is measured by a mercury manometer to be 1.2 m. For a combined turbine-generator efficiency of 83 percent, determine the net electric power output. Disregard the effect of the kinetic energy correction factors.



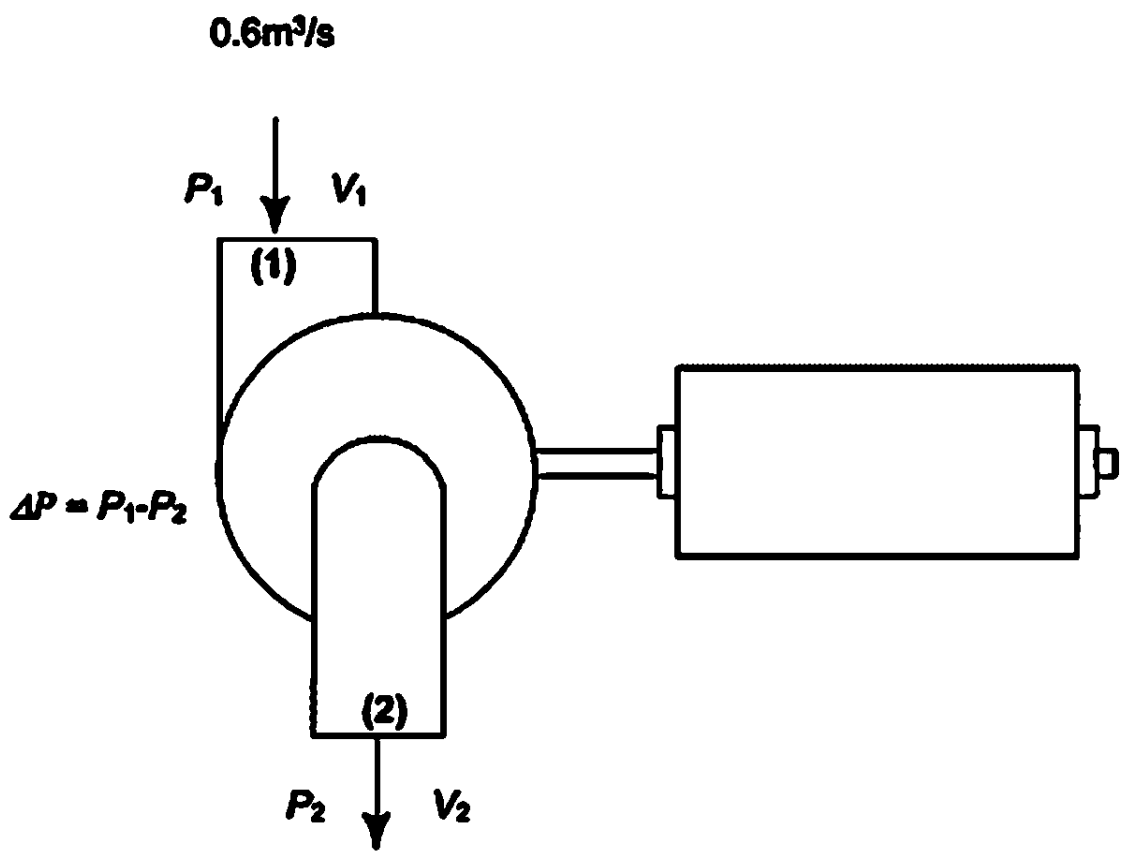


FIGURE P12–58

Step 1 of 5

Sketch the schematic diagram of the pump.

Step 2 of 5

Calculate the mass flow rate of the pump using the following relation

$$\dot{V} = A_1 V_1$$
$$= \frac{\dot{V}}{A_1}$$
$$= \frac{\dot{V}}{\left(\frac{\pi}{4} D_1^2\right)}$$

Here, A is the area of flow, D_1 is the diameter at the inlet and V_1 is the inlet velocity of flow.

Substitute $0.6\ \text{m}^3/\text{s}$ for $\dot{V}$ and 0.3 m for D_1

$$V_1 = \frac{0.6}{\frac{\pi}{4}(0.3)^2}$$
$$= \frac{0.6 \times 4}{\pi \times (0.3)^2}$$
$$= 8.48\ \text{m/s}$$

Step 3 of 5

Calculate the exit velocity using the following relation

$$V_2 = \frac{\dot{V}}{A_2}$$
$$= \frac{\dot{V}}{\frac{\pi}{4} D_2^2}$$

Here, D_2 is the diameter at the outlet.

Substitute 0.25 m for D_2

$$V_2 = \frac{0.6}{\frac{\pi}{4}(0.25)^2}$$
$$= \frac{0.6 \times 4}{\pi (0.25)^2}$$
$$= 12.22\ \text{m/s}$$

Step 4 of 5

Calculate the pressure drop using the following relation

$$\Delta P = \rho_{Hg} g h_{Hg}$$

Here, ρ_{Hg} are the densities of mercury and water respectively and h_{Hg} is the drop in pressure head.

Substitute $13{,}600\ \text{kg/m}^3$ for ρ_{Hg} , $9.81\ \text{m/s}^2$ for g and 1.2 for h_{Hg}

$$\Delta P = 13{,}600 \times 9.81 \times (1.2)$$
$$= 160 \times 10^3\ \text{Pa}$$

Step 5 of 5

Applying the Bernoulli's flow equation between (1) and (2):

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L$$
$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + 0 + 0 = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + 0 + h_{turbine,e} + 0$$
$$h_{turbine,e} = \frac{P_1}{\rho g} - \frac{P_2}{\rho g} + \alpha\left(\frac{V_1^2}{2g} - \frac{V_2^2}{2g}\right)$$
$$= \frac{\Delta P}{\rho g} + \alpha\left(\frac{V_1^2}{2g} - \frac{V_2^2}{2g}\right)$$

Here, P is the pressure, ρ is the density of water, g is the acceleration due to gravity, α is the correction factor, $h_{turbine,e}$ is the turbine head and $h_{pump,u}$ is the pump head.

Substitute 1 for α and $1000\ \text{kg/m}^3$ for ρ

$$h_{turbine,e} = \frac{160 \times 10^3}{1000 \times 9.81} + (1.0)\left(\frac{8.48^2 - 12.22^2}{2(9.81)}\right)$$
$$= 12.36\ \text{m}$$

Calculate the electric power output using the following equation

$$\dot{W}_{turbine} = \eta_{turb-gen} \times \rho \dot{V} g h_{turbine,e}$$

Here, $\eta_{turb-gen}$ is the turbine – generator efficiency.

Substitute 0.83 for $\eta_{turb-gen}$

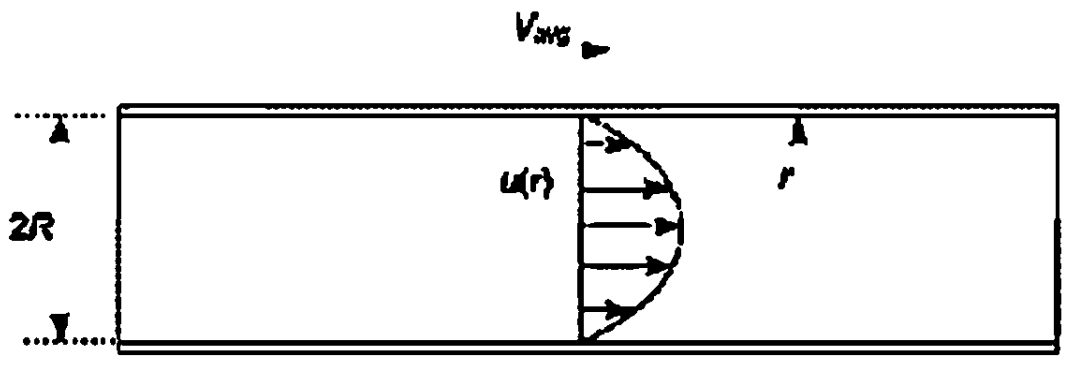
$$\dot{W}_{turbine} = 0.83 \times 1000 \times 0.6 \times 9.81 \times 12.36$$
$$= 60.383 \times 10^3\ \text{W}$$

Therefore, the net electric power output of the turbine is $\boxed{60.383\ \text{kW}}$.

Question: 12.059P

The velocity profile for turbulent flow in a circular pipe is approximated as $u(r)=umax(1-r/R)1/n$ where $n=7$. Determine the kinetic energy correction factor for this flow.

Step 1 of 8



Given data:

The velocity profile of the fluid flow, $u(r) = u_{max}(1 - r/R)^{1/n}$.

Where $n = 7$

Step 2 of 8

Let us draw the figure.

Step 3 of 8

We have

$$\alpha = \frac{1}{A}\int_A \left[\frac{V(r)}{V_{avg}}\right]^3 dA$$

$$= \frac{1}{\pi R^2}\int_A \left[\frac{u(r)}{V_{avg}}\right]^3 dA$$

$$= \frac{u_{max}^3}{\pi R^2 V_{avg}^3}\int_0^R \left[(1 - r/R)^{1/n}\right]^3 (2\pi r)dr$$

$$= \frac{2u_{max}^3}{R^2 V_{avg}^3}\int_0^R \left[(1 - r/R)^{1/n}\right]^3 (r)dr$$

Step 4 of 8

We have for average velocity,

$$V_{avg} = \frac{1}{A}\int_A V(r)dA$$

$$= \frac{1}{A}\int_A u(r)dA$$

$$= \frac{1}{\pi R^2}\int_0^R u_{max}(1 - r/R)^{1/n} 2\pi r dr$$

$$= \frac{2u_{max}}{R^2}\int_0^R (1 - r/R)^{1/n} r dr$$

Step 5 of 8

Where

$$\int_0^R \left(1 - \frac{r}{R}\right)^{1/n} r dr = \left\{\frac{\left(1 - \frac{r}{R}\right)^{(1/n)+2}}{\frac{1}{R^2}\left[(1/n)+2\right]} - \frac{\left(1 - \frac{r}{R}\right)^{(1/n)+1}}{\frac{1}{R^2}\left[(1/n)+1\right]}\right\}_0^R$$

$$= \frac{\left(1 - \frac{R}{R}\right)^{(1/n)+2}}{\frac{1}{R^2}\left[(1/n)+2\right]} - \frac{\left(1 - \frac{r}{R}\right)^{(1/n)+1}}{\frac{1}{R^2}\left[(1/n)+1\right]}$$

$$= \frac{n^2 R^2}{(n+1)(2n+1)}$$

Step 6 of 8

Then

$$V_{avg} = \frac{2u_{max}}{R^2}\frac{n^2 R^2}{(n+1)(2n+1)}$$

We have $n = 7$

$$V_{avg} = \frac{2u_{max}}{R^2}\frac{7^2 R^2}{(7+1)(2\times 7+1)}$$

$$= 0.81667u_{max}$$

Step 7 of 8

We have

$$\alpha = \frac{2u_{max}^3}{R^2 V_{avg}^3}\int_0^R \left[(1 - r/R)^{1/n}\right]^3 r dr$$

$$= \frac{2u_{max}^3}{R^2(0.81667u_{max})^3}\int_0^R \left[(1 - r/R)^{1/n}\right]^3 r dr$$

Where

$$\int_A \left[(1 - r/R)^{1/n}\right]^3 r dr = \left[\frac{\left(1 - \frac{r}{R}\right)^{(3/n)+2}}{(1/R^2)\left(\frac{3}{n}+2\right)} - \frac{\left(1 - \frac{r}{R}\right)^{(3/n)+1}}{(1/R^2)\left(\frac{3}{n}+1\right)}\right]_0^R$$

$$= \frac{\left(1 - \frac{R}{R}\right)^{(3/n)+2}}{(1/R^2)\left(\frac{3}{n}+2\right)} - \frac{\left(1 - \frac{R}{R}\right)^{(3/n)+1}}{(1/R^2)\left(\frac{3}{n}+1\right)}$$

$$= \frac{n^2 R^2}{(n+3)(2n+3)}$$

Step 8 of 8

Then

$$\alpha = \frac{2u_{max}^3}{R^2(0.81667u_{max})^3}\frac{n^2 R^2}{(n+3)(2n+3)}$$

$$= \frac{2u_{max}^3}{R^2(0.81667u_{max})^3}\frac{7^2 R^2}{(7+3)(2\times 7+3)}$$

$$= 1.058$$

Therefore the kinetic energy correction factor is $\boxed{\alpha = 1.058}$.

Question: 12.060P

Water is pumped from a lower reservoir to a higher reservoir by a pump that provides 20 kW of useful mechanical power to the water. The free surface of the upper reservoir is 45 m higher than the surface of the lower reservoir. If the flow rate of water is measured to be 0.03 m3/s, determine the irreversible head loss of the system and the lost mechanical power during this process.

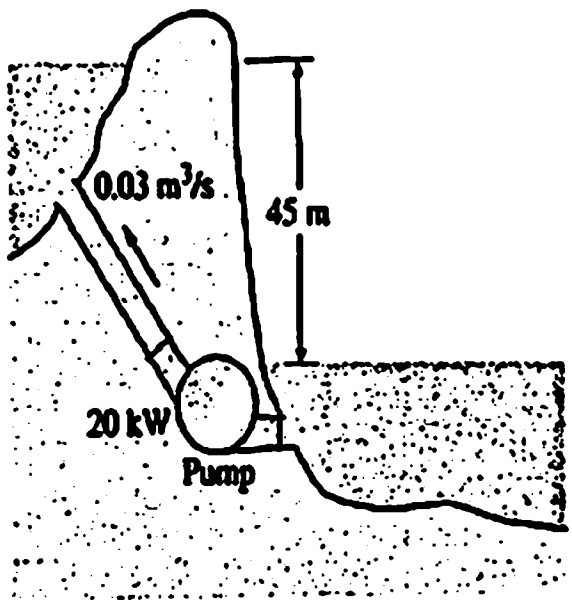


FIGURE P12–60

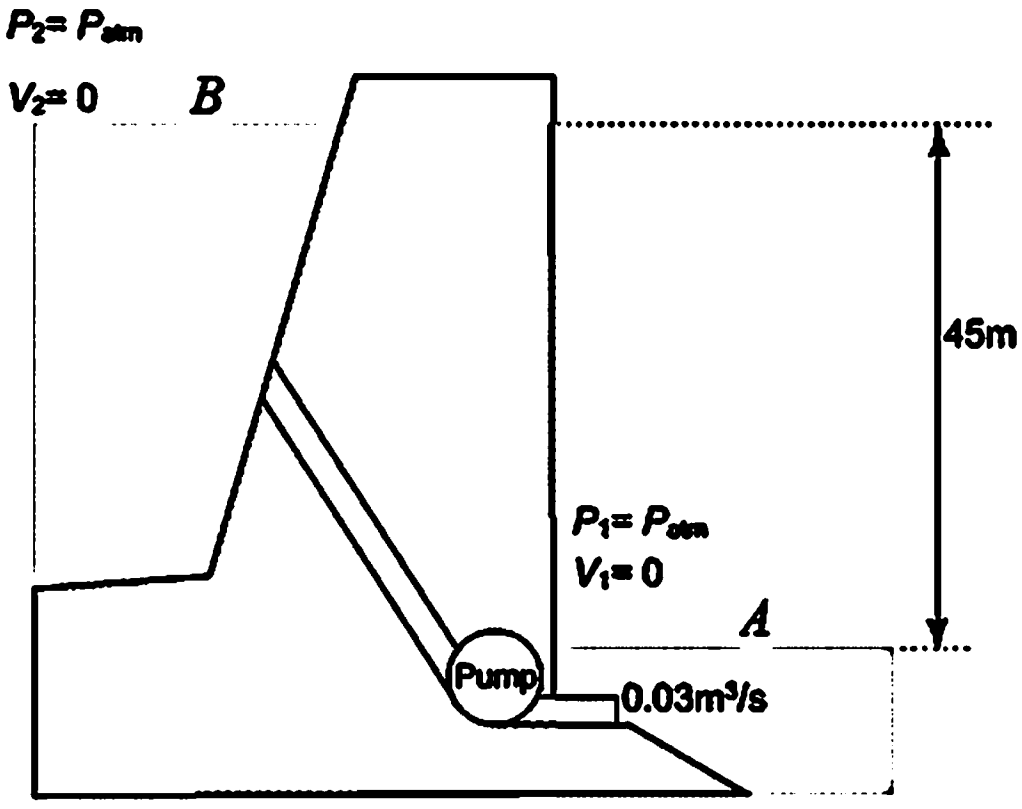
Step 1 of 5

Given data:



The useful mechanical power given by the pump, $\dot{W}_{pump,u} = 20\ \text{kW}$.

The free surface of upper reservoir is $45\ \text{m}$ above the lower reservoir.

The flow rate, $\dot{V} = 0.03\ \text{m}^3/\text{s}$.

Step 2 of 5

Figure showing different levels reservoir;

Step 3 of 5

We know that mass flow rate,

$$\dot{m} = \rho\dot{V}$$
$$= (1000)0.03$$
$$= 30\ \text{kg/s}$$

Step 4 of 5

Applying the Bernoulli's flow equation between the points *A* and *B*:

$$\dot{m}\left(\frac{P_1}{\rho g} + \alpha_1\frac{V_1^2}{2g} + gz_1\right) + \dot{W}_{pump} = \dot{m}\left(\frac{P_2}{\rho g} + \alpha_2\frac{V_2^2}{2g} + gz_2\right) + \dot{W}_{turbine} + \dot{E}_{mech,loss}$$

$$\dot{m}\left(\frac{P_1}{\rho g} + gz_1\right) + \dot{W}_{pump} = \dot{m}\left(\frac{P_2}{\rho g} + gz_2\right) + \dot{E}_{mech,loss}$$

$$(300)\left(\frac{P_{atm}}{\rho g} + g\times 0\right) + \left(20\times 10^3\right) = (30)\left(\frac{P_{atm}}{\rho g} + g\times 45\right) + \dot{E}_{mech,loss}$$

$$\dot{E}_{mech,loss} = 6756.5\ \text{W}$$

Therefore, the mechanical power loss during the process is $\boxed{\dot{E}_{mech,loss} = 6756.5\ \text{W}}$

Step 5 of 5

Then the irreversible head loss,

$$h_L = \frac{\dot{E}_{mech,loss}}{\dot{m}g}$$
$$= \frac{6756.5}{(30)(9.81)}$$
$$= 22.95\ \text{m}$$

Therefore, the irreversible head loss is $\boxed{h_L = 22.72\ \text{m}}$.

Question: 12.061P

Water in a partially filled large tank is to be supplied to the roof top, which is 8 m above the water level in the tank, through a 2.5-cm-internal-diameter pipe by maintaining a constant air pressure of 300 kPa (gage) in the tank. If the head loss in the piping is 2 m of water, determine the discharge rate of the supply of water to the roof top.

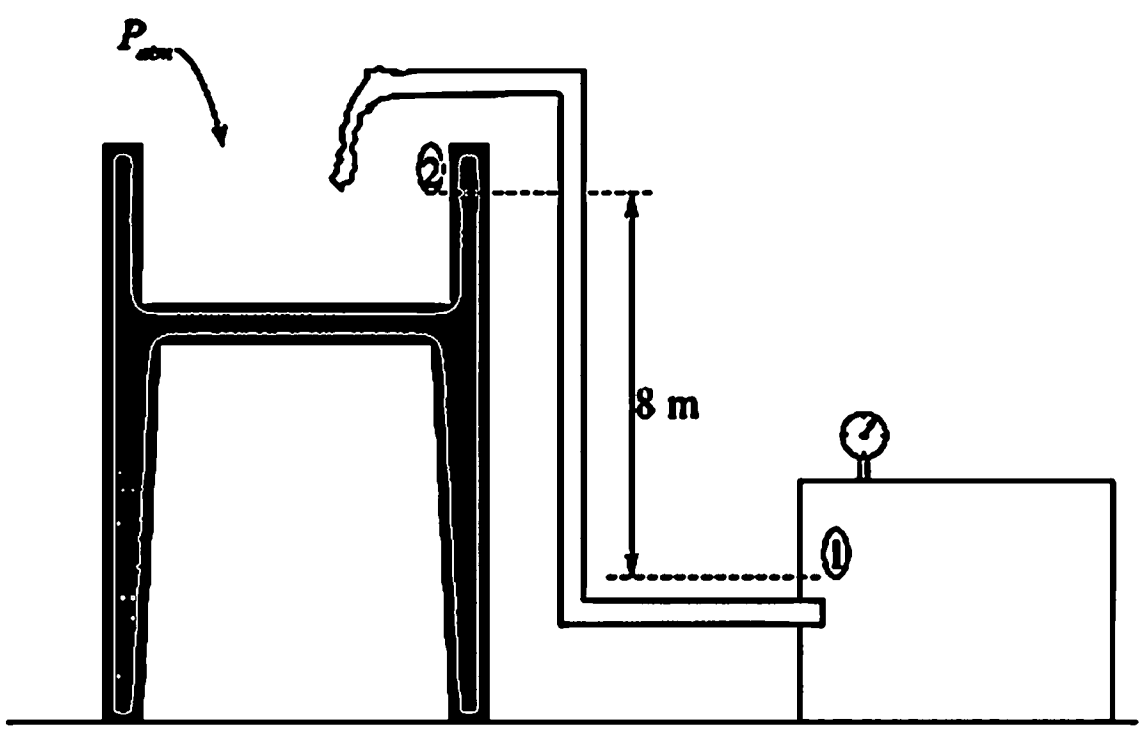
Step 1 of 4

Given data:

The water has to be supplied to a height, $h = 8$ m

The internal diameter of the pipe, $d = 2.5$ cm

The gage pressure in the tank, $P_{gage} = 300$ kPa



The head loss in the pipe, $h_L = 2$ m

Initial velocity of the water in the tank, $V_1 = 0$

Density of the water is taken as $\rho = 1000\ \text{kg/m}^3$

Step 2 of 4

Water supplied from partially filled tank to the top of the roof as shown below.

Step 3 of 4

Applying the Bernoulli's flow equation between the points (1) and (2) we get

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1+h_{pump,u}=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2+h_{turbine}+h_L$$

Substituting the required values and simplify:

$$\frac{P_{abs}}{\rho g}+0+z_1+0=\frac{P_{atm}}{\rho g}+\frac{V_2^2}{2g}+z_2+h_L$$

$$\frac{V_2^2}{2g}=\left(\frac{P_{abs}}{\rho g}-\frac{P_{atm}}{\rho g}\right)+z_1-z_2-h_L$$

$$=\frac{P_{gage}}{\rho g}+z_1-z_2-h_L$$

$$=\frac{300\times10^3}{(1000)(9.81)}+0-8-2$$

$$=20.581$$

$$V_2=\sqrt{2g\times20.581}$$

$$=20.10\ \text{m/s}$$

Velocity of the water discharging on to the top of the roof is $V_2 = 20.10$ m/s

Step 4 of 4

Area of the pipe is given by

$$A_2=\frac{\pi}{4}\times d^2$$

$$=\frac{\pi}{4}(0.025)^2$$

$$=4.909\times10^{-4}\ \text{m}^2$$

The discharge rate of the supply of water to the roof top,

$$\dot{V}=AV_2$$

$$=4.909\times10^{-4}\times20.10$$

$$=9.869\times10^{-3}\ \text{m}^3/\text{s}$$

Therefore the discharge rate of the supply of water to the roof top is $\boxed{\dot{V} = 9.869\times10^{-3}\text{m}^3/\text{s}}$

Question: 12.062P pg 1

Underground water is to be pumped by a 78 percent efficient 5-kW submerged pump to a pool whose free surface is 30 m above the underground water level. The diameter of the pipe is 7 cm on the intake side and 5 cm on the discharge side. Determine (*a*) the maximum flow rate of water and (*b*) the pressure difference across the pump. Assume the elevation difference between the pump inlet and the outlet and the effect of the kinetic energy correction factors to be negligible.

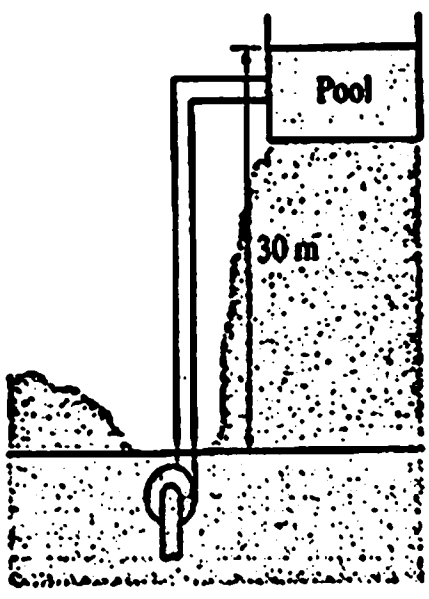


FIGURE P12–62

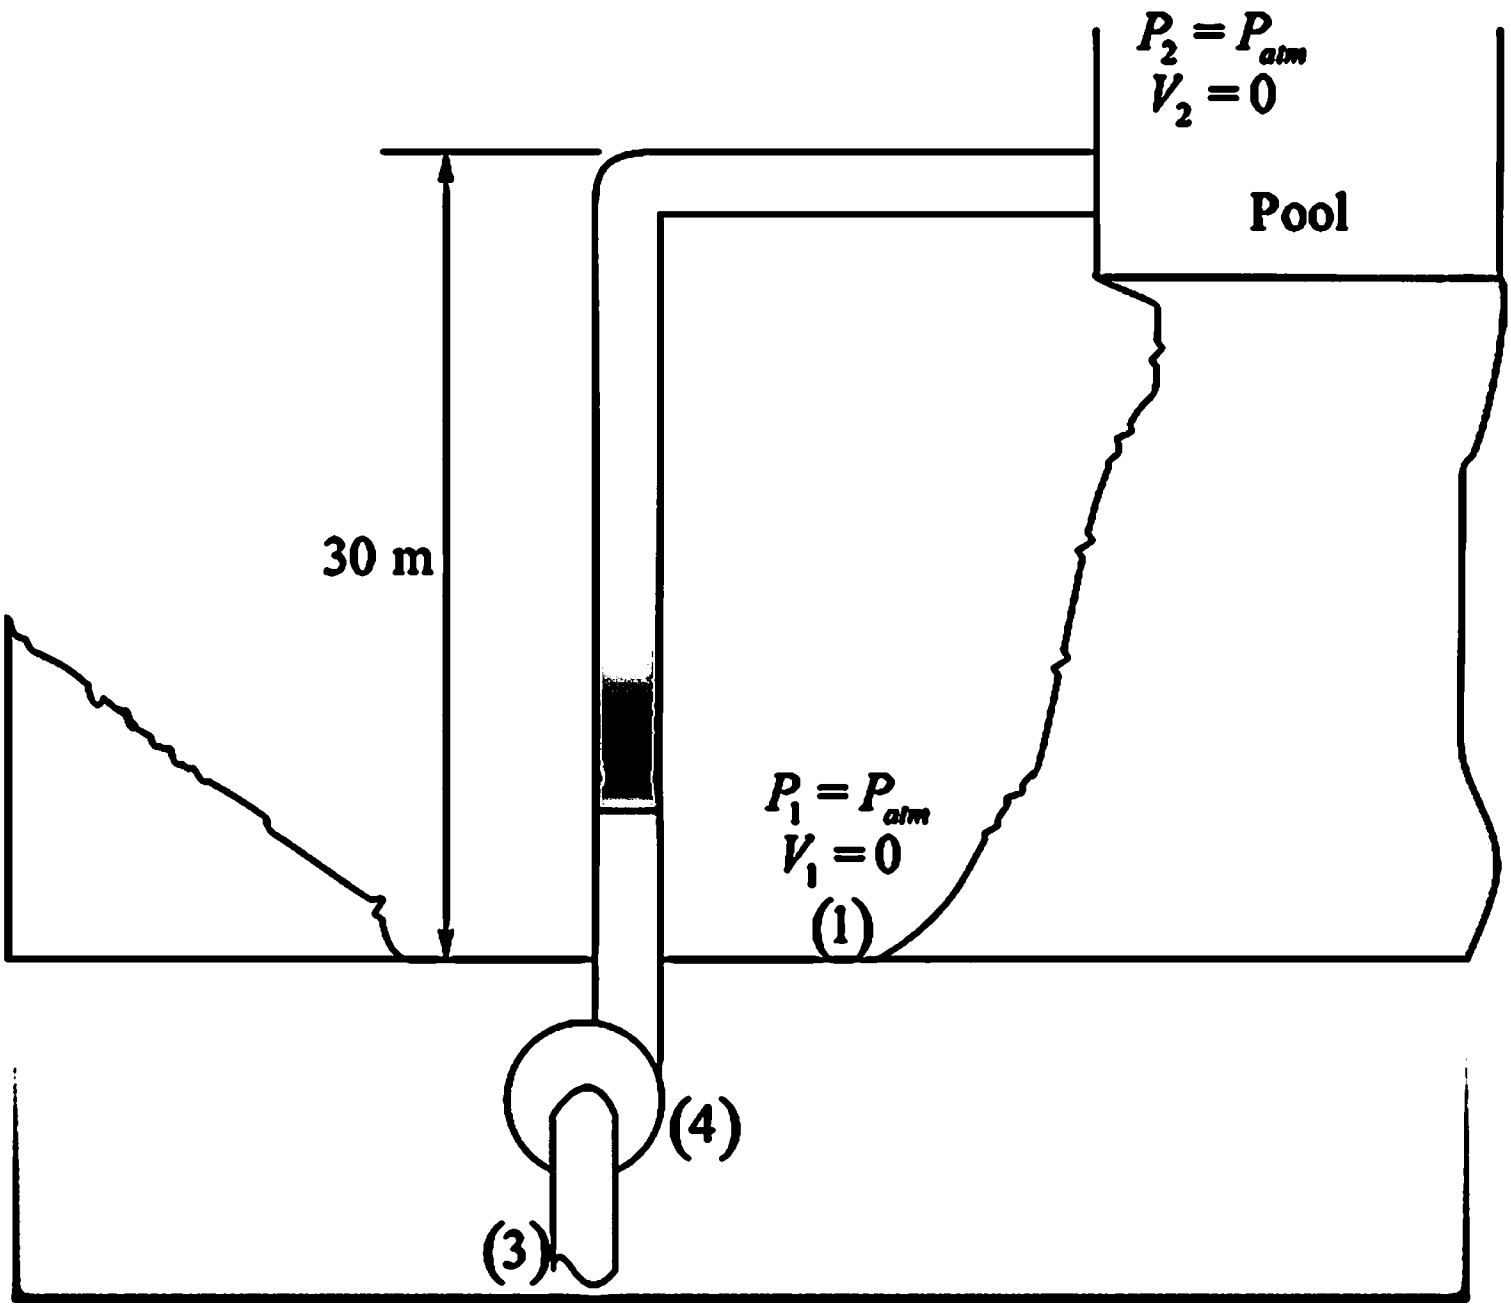
Step 1 of 8

Given data:

The pump efficiency, $\eta_{pump} = 78\%$

The power delivered by the submerged pump, $\dot{W}_{pump} = 5\ \text{kW}$

Height of the pool from the under water surface, $h = 30\ \text{m}$



Diameter of the pipe on the intake side, $d_3 = 0.07\ \text{m}$

Diameter of the pipe on the discharge side, $d_4 = 0.05\ \text{m}$

Assume the elevation difference between the pump inlet and the outlet and the effect of the kinetic energy correction factor to be negligible.

Step 2 of 8

Under ground water is supplied by a pump to the pool as shown in the figure below.

Step 3 of 8

The mechanical efficiency of the pump is given by

$$\eta_{pump} = \frac{\dot{W}_{pump,u}}{\dot{W}_{pump}}$$

$$\dot{W}_{pump,u} = \eta_{pump}\dot{W}_{pump}$$
$$= 0.78(5)$$
$$= 3.9\ \text{kW}$$

Step 4 of 8

Applying the Bernoulli's equation for steady flow between the points (1) and (2), we get

$$\dot{m}\left(\frac{P_1}{\rho} + \alpha_1\frac{V_1^2}{2} + gz_1\right) + \dot{W}_{pump,u} = \dot{m}\left(\frac{P_2}{\rho} + \alpha_2\frac{V_2^2}{2} + gz_2\right) + \dot{W}_{turbine,e} + E_{mech,loss}$$

Since the work done by the turbine and mechanical losses is zero then the equation is given by

$$\dot{m}\frac{P_{atm}}{\rho} + \dot{m}g(0) + \dot{W}_{pump,u} = \dot{m}\frac{P_{atm}}{\rho} + \dot{m}gz_2 \quad \text{..... (1)}$$

From the equation the mass flow rate of the water through the pump is given by

$$\dot{W}_{pump,u} = \dot{m}gz_2$$
$$\dot{m} = \frac{3.9\times10^3}{(9.81)(30)}$$
$$\dot{m} = 13.25\ \text{kg/s}$$

Step 5 of 8

a)

The maximum flow rate of the water through the pump is given by

$$\dot{m} = \rho\dot{V}$$

a)

The maximum flow rate of the water through the pump is given by

$$\dot{m} = \rho \dot{V}$$

$$\dot{V} = \frac{\dot{m}}{\rho}$$

$$= \frac{13.25}{1000}$$

$$= 0.01325 \text{ m}^3/\text{s}$$

Therefore, the maximum flow rate of the water through the pump is $\boxed{\dot{V} = 0.01325 \text{ m}^3/\text{s}}$

Step 6 of 8

Area of the pipe at the intake side of the water is given by

$$A_3 = \frac{\pi d_3^2}{4}$$

$$= \frac{\pi (0.07)^2}{4}$$

$$= 3.848 \times 10^{-3} \text{ m}^2$$

Discharge of the water through the pipe at the intake side is given by

$$V_3 = \frac{\dot{V}}{A_3}$$

$$= \frac{0.01325}{3.848 \times 10^{-3}}$$

$$= 3.443 \text{ m/s}$$

The velocity of the water at the intake side of the pipe is $V_3 = 3.443$ m/s

Area of the pipe at the discharge side of the water is given by

$$A_4 = \frac{\pi d_4^2}{4}$$

$$= \frac{\pi (0.05)^2}{4}$$

$$= 1.963 \times 10^{-3} \text{ m}^2$$

Discharge of the water through the pipe at the discharge side is given by

$$V_4 = \frac{\dot{V}}{A_4}$$

$$= \frac{0.01325}{1.963 \times 10^{-3}}$$

$$= 6.749 \text{ m/s}$$

The velocity of the water at the discharge side of the pipe is $V_4 = 6.749$ m/s

Step 7 of 8

Applying the Bernoulli's equation for steady flow between the points (3) and (4):

$$\frac{P_3}{\rho g} + \alpha_1 \frac{V_3^2}{2g} + z_3 + h_{pump,u} = \frac{P_4}{\rho g} + \alpha_2 \frac{V_4^2}{2g} + z_4 + h_{turbine,u} + h_L$$

$$\frac{P_3}{\rho g} + \frac{V_3^2}{2g} + h_{pump,u} = \frac{P_4}{\rho g} + \frac{V_4^2}{2g}$$

$$\frac{P_3}{\rho g} - \frac{P_4}{\rho g} = \frac{1}{2g}\left(V_4^2 - V_3^2\right) - h_{pump,u}$$

$$P_4 - P_3 = \rho\left[\frac{\dot{W}_{pump,u}}{\dot{m}g} - \frac{1}{2}\left(V_4^2 - V_3^2\right)\right]$$

Step 8 of 8

b)

Pressure difference across the pump is given by

$$P_4 - P_3 = \rho\left[\frac{\dot{W}_{pump,u}}{\dot{m}g} - \frac{1}{2}\left(V_4^2 - V_3^2\right)\right]$$

$$= (1000)\left[\frac{3.9 \times 10^3}{13.25 \times 9.81} - \frac{1}{2}\left(6.749^2 - 3.443^2\right)\right]$$

$$= 1000[30.004 - 16.85]$$

$$= 13154.04 \text{ Pa}$$

Therefore, the pressure difference across the pump is $\boxed{P_4 - P_3 = 13154.04 \text{ Pa}}$

Question: 12.063P

Reconsider Prob. 12–62. Determine the flow rate of water and the pressure difference across the pump if the irreversible head loss of the piping system is 4 m.

Step 1 of 9

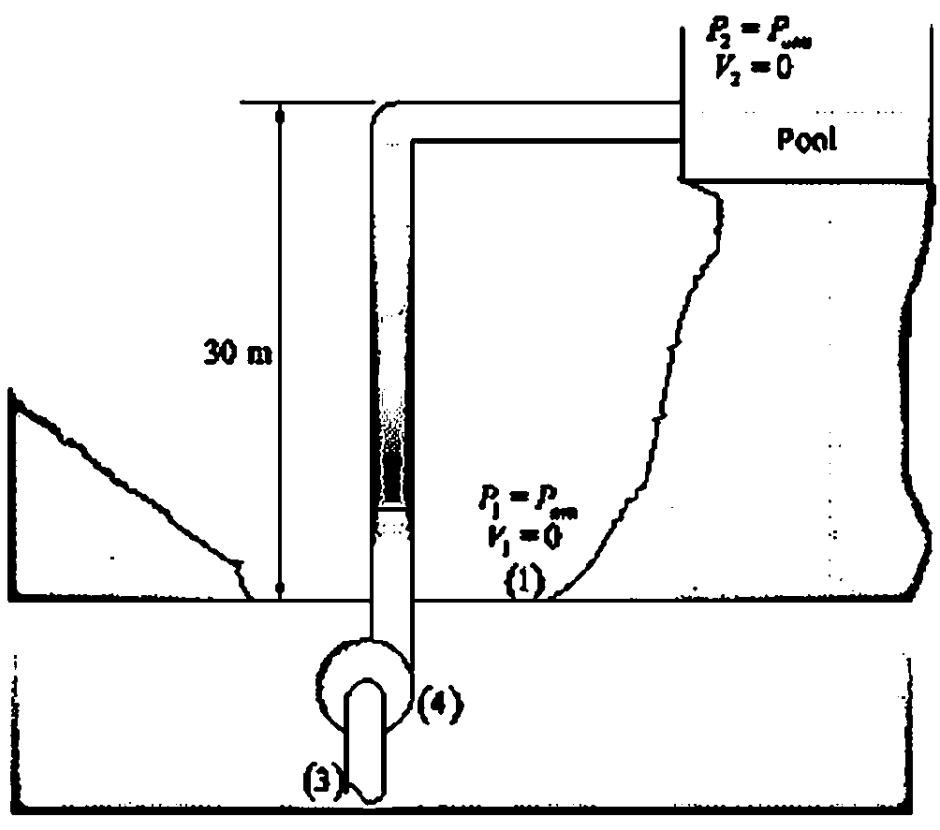
Given data:

The pump efficiency, $\eta_{pump} = 78\%$

The power delivered by the submerged pump, $\dot{W}_{pump} = 5$ kW

Height of the pool from the under water surface, $h = 30$ m

Diameter of the pipe on the intake side, $d_3 = 0.07$ m



Diameter of the pipe on the discharge side, $d_4 = 0.05$ m

Irreversible head loss in the pipe system, $h_L = 4$ m

Assume the elevation difference between the pump inlet and the outlet and the effect of the kinetic energy correction factor to be negligible.

Step 2 of 9

Under ground water is supplied by a pump to the pool as shown in the figure below.

Step 3 of 9

The mechanical efficiency of the pump is given by

$$\eta_{pump} = \frac{\dot{W}_{pump,u}}{\dot{W}_{pump}}$$

$$\dot{W}_{pump,u} = \eta_{pump}\dot{W}_{pump}$$
$$= 0.78(5)$$
$$= 3.9 \text{ kW}$$

Step 4 of 9

Applying the Bernoulli's equation for steady flow between the points (1) and (2), we get

$$\dot{m}\left(\frac{P_1}{\rho} + \alpha_1\frac{V_1^2}{2} + gz_1\right) + \dot{W}_{pump,u} = \dot{m}\left(\frac{P_2}{\rho} + \alpha_2\frac{V_2^2}{2} + gz_2\right) + \dot{W}_{turbine,e} + \dot{E}_{mech,loss}$$

Since the work done by the turbine and mechanical losses is zero then the equation is given by

$$\dot{m}\frac{P_{atm}}{\rho} + \dot{m}g(0) + \dot{W}_{pump,u} + \dot{E}_{mech,loss} = \dot{m}\frac{P_{atm}}{\rho} + \dot{m}gz_2 \qquad \ldots\ldots (1)$$

From the equation (1), the mass flow rate of the water through the pump is given by

$$\dot{W}_{pump,u} = \dot{m}gz_2 + \dot{E}_{mech,loss}$$
$$= \dot{m}gz_2 + \dot{m}gh_L$$
$$3.9 \times 10^3 = \dot{m}\left((9.81)(30) + (9.81)(4)\right)$$
$$\dot{m} = 11.69 \text{ kg/s}$$

Step 5 of 9

a)

The maximum flow rate of the water through the pump is given by

$$\dot{m} = \rho\dot{V}$$

$$\dot{V} = \frac{\dot{m}}{\rho}$$
$$= \frac{11.69}{1000}$$
$$= 0.01169 \text{ m}^3/\text{s}$$

Therefore, the maximum flow rate of the water through the pump is $\boxed{\dot{V} = 0.01169 \text{ m}^3/\text{s}}$

Step 6 of 9

Area of the pipe at the intake side of the water is given by

$$A_3 = \frac{\pi d_3^2}{4}$$
$$= \frac{\pi(0.07)^2}{4}$$
$$= 3.848\times10^{-3} \text{ m}^2$$

Discharge of the water through the pipe at the intake side is given by

$$V_3 = \frac{\dot{V}}{A_3}$$
$$= \frac{0.01169}{3.848\times10^{-3}}$$
$$= 3.038 \text{ m/s}$$

The velocity of the water at the intake side of the pipe is $V_3 = 3.038$ m/s

Step 7 of 9

Area of the pipe at the discharge side of the water is given by

$$A_4 = \frac{\pi d_4^2}{4}$$
$$= \frac{\pi(0.05)^2}{4}$$
$$= 1.963\times10^{-3} \text{ m}^2$$

Discharge of the water through the pipe at the discharge side is given by

$$V_4 = \frac{\dot{V}}{A_4}$$
$$= \frac{0.01169}{1.963\times10^{-3}}$$
$$= 5.955 \text{ m/s}$$

The velocity of the water at the discharge side of the pipe is $V_4 = 5.955$ m/s

Step 8 of 9

Applying the Bernoulli's equation for steady flow between the points (3) and (4):

$$\dot{m}\left(\frac{P_1}{\rho} + \alpha_1\frac{V_1^2}{2} + gz_1\right) + \dot{W}_{pump,u} = \dot{m}\left(\frac{P_2}{\rho} + \alpha_2\frac{V_2^2}{2} + gz_2\right) + \dot{W}_{turbine,e} + \dot{E}_{mech,loss}$$

We can neglect frictional effects due to piping when we consider the pump only, $\dot{E}_{mech,loss} = 0$.

Then

$$\left(\frac{P_3}{\rho} + \frac{V_3^2}{2}\right) + \frac{\dot{W}_{pump,u}}{\dot{m}} = \left(\frac{P_4}{\rho} + \frac{V_4^2}{2}\right)$$

$$\frac{P_4}{\rho} - \frac{P_3}{\rho} = \frac{\dot{W}_{pump,u}}{\dot{m}} - \left(\frac{V_4^2}{2} - \frac{V_3^2}{2}\right)$$

Step 9 of 9

b)

Pressure difference across the pump is given by

$$P_4 - P_3 = \rho\left[\frac{\dot{W}_{pump,u}}{\dot{m}} - \frac{1}{2}\left(V_4^2 - V_3^2\right)\right]$$
$$= (1000)\left[\frac{3.9\times10^3}{11.69} - \frac{1}{2}\left(5.955^2 - 3.038^2\right)\right]$$
$$= 1000[333.62 - 13.12]$$
$$= 320503.7 \text{ Pa}$$

Therefore, the pressure difference across the pump is $\boxed{P_4 - P_3 = 320504 \text{ Pa}}$

Question: 12.064P

A fireboal is to fight fires at coastal areas by drawing seawater with a density of 1030 kg/m3 through a 20-cm-diameter pipe at a rate of 0.1 m3/s and discharging it through a hose nozzle with an exit diameter of 5 cm. The total irreversible head loss of the system is 3 m, and the position of the nozzle is 3 m above sea level. For a pump efficiency of 70 percent, determine the required shaft power input to the pump and the water discharge velocity.

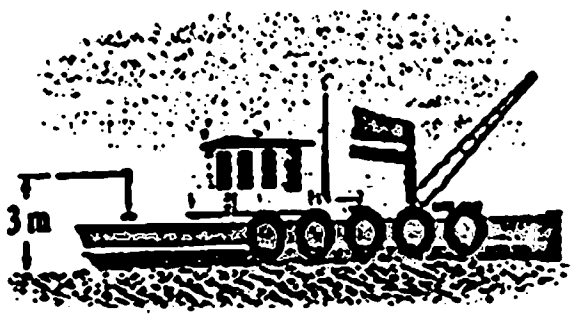


FIGURE P12–64

Step 1 of 6

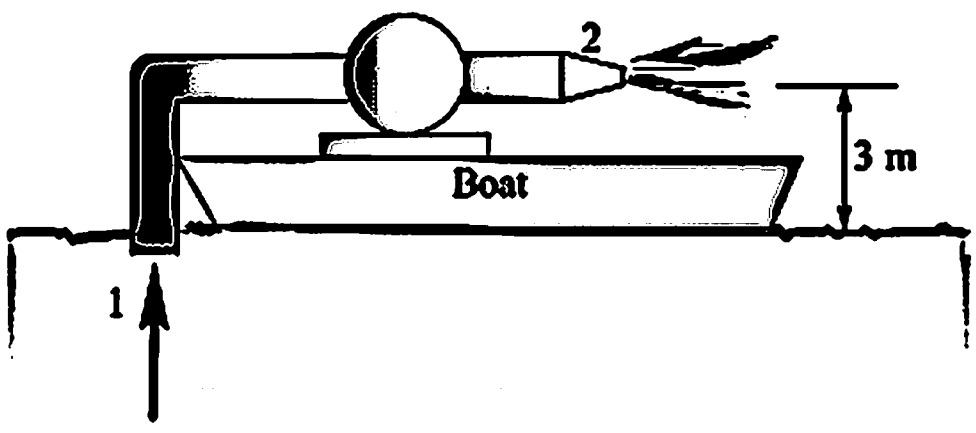
Given data:

The density of seawater, $\rho = 1030\ \text{kg/m}^3$

The pipe diameter, $D_p = 0.20\ \text{m}$

The flow rate through the pipe, $\dot{V} = 0.1\ \text{m}^3/\text{s}$

The exit diameter of the nozzle, $D_{out} = 0.05\ \text{m}$



The irreversible head loss of the system, $h_L = 3\ \text{m}$

Height the nozzle above the sea level is $z_2 = 3\ \text{m}$

The mechanical efficiency of the pump is $\eta_{pump} = 70\%$

Step 2 of 6

A fire boat is to fight fires at the coastal areas from the nozzle as shown in the figure below.

Step 3 of 6

Let us set the suction point at sea level as point (1) and the discharge point at the nozzle as point (2).

Consider point (1) where the suction taking place.

Velocity of the water at point (1) is given by

$$\dot{V} = A_1 V_1$$

$$V_1 = \frac{\dot{V}}{A_2}$$

$$= \frac{0.1}{\frac{\pi}{4}(0.2^2)}$$

$$= 3.183\ \text{m/s}$$

Step 4 of 6

And the velocity of the water discharging at point (2) is given by

$$V_2 = \frac{\dot{V}}{A_2}$$

$$= \frac{0.1}{\frac{\pi}{4}(0.05^2)}$$

$$= 50.93\ \text{m/s}$$

Therefore, the discharge velocity of the water is $\boxed{V_2 = 50.93\ \text{m/s}}$

Step 5 of 6

Applying the Bernoulli's equation for steady incompressible flow between the points (1) and (2):

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L$$

$$\frac{P_{atm}}{\rho g} + (1)\frac{3.183^2}{2g} + 0 + h_{pump,u} = \frac{P_{atm}}{\rho g} + (1)\frac{50.93^2}{2g} + 3 + 0 + 3$$

$$h_{pump,u} = 137.69\ \text{m}$$

Step 6 of 6

The efficiency of the pump is given by

$$\eta_{pump} = \frac{\dot{W}_{pump,u}}{\dot{W}_{shaft,in}}$$

$$\dot{W}_{shaft,in} = \frac{\left(\rho \dot{V} g h_{pump,u}\right)}{\eta_{pump}}$$

$$= \frac{1030(0.1)(9.81)(137.69)}{0.7}$$

$$= 198.75 \times 10^3\ \text{W}$$

$$= 199\ \text{kW}$$

Therefore, the required shaft power input to the pump is $\boxed{\dot{W}_{shaft,in} = 199\ \text{kW}}$

Question: 12.065P

Air flows through a pipe at a rate of 170 L/s. The pipe consists of two sections of diameters 18 cm and 10 cm with a smooth reducing section that connects them. The pressure difference between the two pipe sections is measured by a water manometer. Neglecting frictional effects, determine the differential height of water between the two pipe sections. Take the air density to be 1.20 kg/m3.

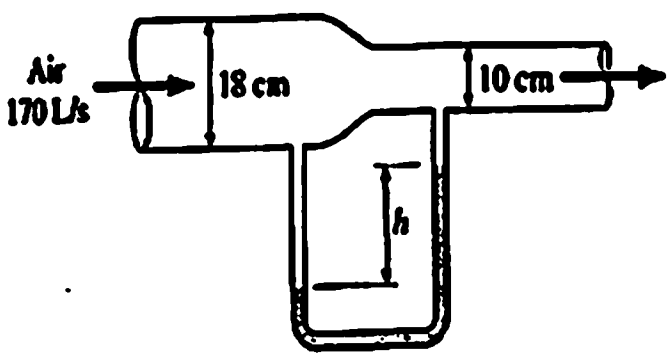


FIGURE P12-65

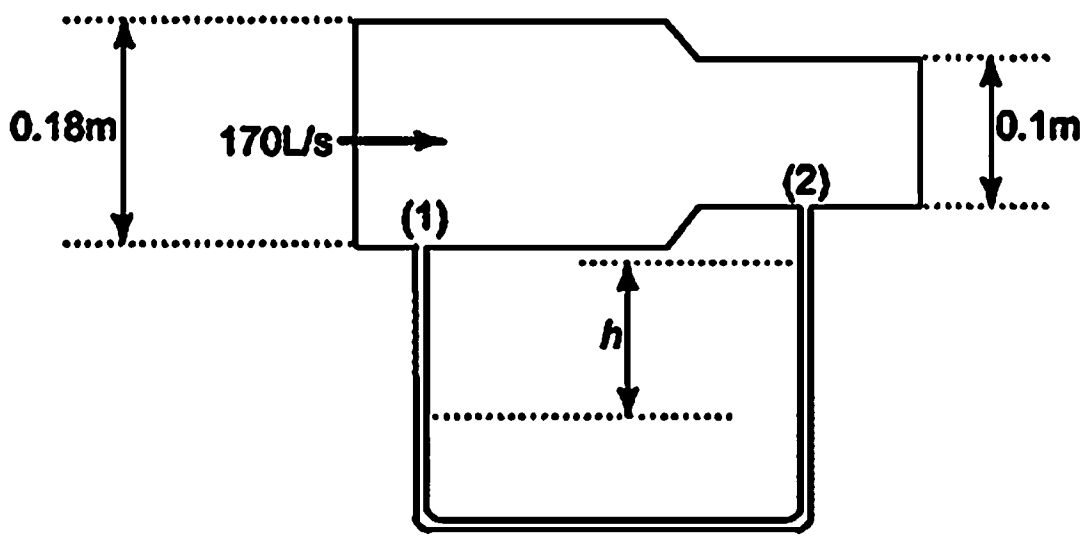
Step 1 of 7

Given data:

The flow rate of the air through the pipe,

$\dot{V} = 170\ \text{L/s}$

$= 0.17\ \text{m}^3/\text{s}$



The inlet diameter of the pipe, $D_1 = 0.18\ \text{m}$

The exit diameter of the pipe, $D_2 = 0.1\ \text{m}$

The density of the air, $\rho_a = 1.2\ \text{kg/m}^3$

Step 2 of 7

Air flows through the pipe consisting of two different sections and a water manometer as shown below.

Step 3 of 7

Discharge through the pipe at the two sections is given by

$\dot{V} = A_1V_1 = A_2V_2$

Where A is the area of the pipe and V is the velocity of the water

Then the velocity of the water at the inlet of the pipe is given by

$$V_1 = \frac{\dot{V}}{A_1}$$

$$= \frac{0.17}{\frac{\pi}{4}(0.18)^2}$$

$$= 6.6805\ \text{m/s}$$

Step 4 of 7

Velocity of the water at the exist of the pipe is given by

$$V_2 = \frac{\dot{V}}{A_2}$$

$$= \frac{0.17}{\frac{\pi}{4}(0.10)^2}$$

$$= 21.645\ \text{m/s}$$

Step 5 of 7

Applying the Bernoulli's flow equation between the points (1) and (2):

$$\frac{P_1}{\rho_a} + \frac{V_1^2}{2} + gz_1 = \frac{P_2}{\rho_a} + \frac{V_2^2}{2} + gz_2$$

$$P_1 - P_2 = \rho_a\left(\frac{V_2^2}{2} - \frac{V_1^2}{2}\right) \qquad \ldots\ldots (1)$$

Step 6 of 7

The pressure force acting in the water manometer is given by

$$P_1 - P_2 = \rho_{water}gh \qquad \ldots\ldots (2)$$

By substituting the equation (2) in (1), we get

$$\rho_{water}gh = \rho_a\frac{V_2^2 - V_1^2}{2}$$

Step 7 of 7

The differential height of water between the two pipes is given by

$$h = \rho_a\frac{V_2^2 - V_1^2}{2g\rho_{water}}$$

$$= (1.20)\frac{\left(21.645^2 - 6.6805^2\right)}{2(9.81)(1000)}$$

$$= 0.026\ \text{m}$$

$$= 2.6\ \text{cm}$$

Therefore, the differential height of the water between the two pipes is $\boxed{h = 2.6\ \text{cm}}$.

Question: 12.066P

Air at 100 kPa and 25°C flows in a horizontal duct of variable cross section. The water column in the manometer that measures the difference between two sectiqns has a vertical displacement of 8 cm. If the velocity in the first section is low and the friction is negligible, determine the velocity at the second section. Also, if the manometer reading has a possible error of ±2 mm, conduct an error analysis to estimate the range of validity for the velocity found.

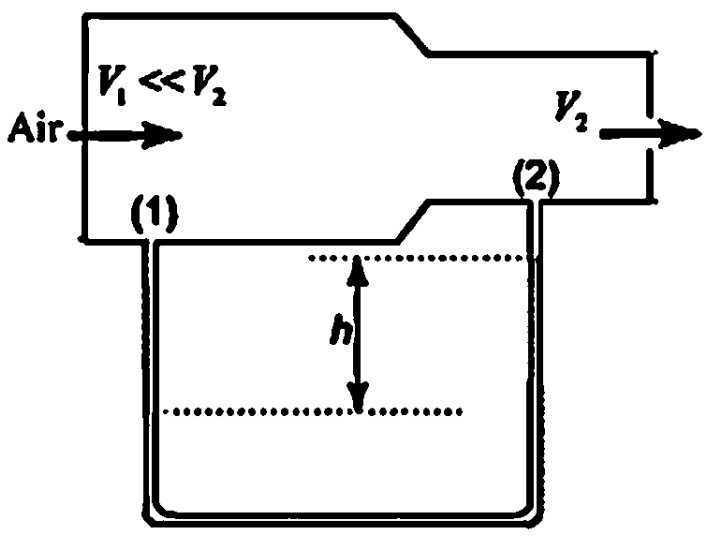
Step 1 of 7

Given data:

Air flowing through the horizontal duct at a pressure, $P = 100\ \text{kPa}$.

The difference in the heights of the water column manometers, $h = 0.08\ \text{m}$.

The density of the water, $\rho_w = 1000\ \text{kg/m}^3$.



Possible error in the manometer, $h_e = \pm 0.02\ \text{m}$.

The universal gas constant, $R = 0.2870\ \text{kJ/kg}\cdot\text{K}$.

Temperature of the air flowing in the duct, $T = 25\ ^\circ\text{C}$.

Step 2 of 7

Air flows through the horizontal duct of variable cross section with a water column manometer as shown below.

Step 3 of 7

The density of the air in the tank is given by

$$\rho_a = \frac{P}{RT}$$

$$= \frac{100 \times 10^3}{(0.287 \times 10^3)(298)}$$

$$= 1.17\ \text{kg/m}^3$$

Step 4 of 7

Applying the Bernoulli's flow equation between the points (1) and (2):

$$\frac{P_1}{\rho_a} + \frac{V_1^2}{2} + gz_1 = \frac{P_2}{\rho_a} + \frac{V_2^2}{2} + gz_2 \qquad \ldots\ldots (1)$$

The effect of elevation can be neglected between the two points because they lie on the same ground and the initial velocity of the air is very small it can be negligible.Then from equation (1)

$$\frac{P_1}{\rho_a} + 0 + 0 = \frac{P_2}{\rho_a} + \frac{V_2^2}{2} + 0$$

$$V_2^2 = \frac{2(P_1 - P_2)}{\rho_a}$$

$$V_2 = \sqrt{\frac{2(P_1 - P_2)}{\rho_a}} \qquad \ldots\ldots (2)$$

Step 5 of 7

The pressure force acting in the water manometer is given by

$$P_1 - P_2 = \rho_{water} g h \qquad \ldots\ldots (3)$$

By substituting the equation (3) in (2), we get

$$V_2 = \sqrt{\frac{2\rho_{water} g h}{\rho_a}}$$

The velocity of the air at the exit is given by

$$V_2 = \sqrt{\frac{2\rho_{water} g h}{\rho_a}}$$

$$= \sqrt{\frac{2 \times 1000 \times 9.81 \times 0.08}{1.17}}$$

$$= 36.63\ \text{m/s}$$

Therefore, the velocity of the air at the second section is $\boxed{V_2 = 36.63\ \text{m/s}}$.

Step 6 of 7

Error analysis

The velocity is proportional to the square root of the differential height of the manometer fluid. That is, $V_2 = k\sqrt{h}$

Differentiating on both sides we get

$$dV_2 = \frac{1}{2} k \frac{dh}{\sqrt{h}}$$

Now dividing both sides by V_2 we get

$$\frac{dV_2}{V_2} = \frac{\frac{1}{2} k \frac{dh}{\sqrt{h}}}{V_2}$$

$$\frac{dV_2}{V_2} = \frac{\frac{1}{2} k \frac{dh}{\sqrt{h}}}{k\sqrt{h}}$$

$$\frac{dV_2}{V_2} = \frac{dh}{2h}$$

$$= \frac{\pm 0.02}{2 \times 0.08}$$

$$= \pm 0.013$$

Step 7 of 7

$$dV_2 = \pm(0.013 \times V_2)$$

$$= \pm(0.013 \times 36.6)$$

$$= \pm 0.4758\ \text{m/s}$$

$$= \pm 0.5\ \text{m/s}$$

Therefore, after conducted the error analysis the estimated validity of the velocity is expressed as $\boxed{V_2 = 36.6 \pm 0.5\ \text{m/s}}$

Question: 12.067P

A very large tank contains air at 102 kPa at a location where the atmospheric air is at 100 kPa and 20°C Now a 2-cm-diamcter tap is opened. Determine the maximum flow rate of air through the hole. What would your response be r| air is discharged through a 2-m-long. 4-cm-diameter tube with 2-cm-diameter nozzle? Would you solve the problem same way if the pressure in the storage tank were 300 kPa|

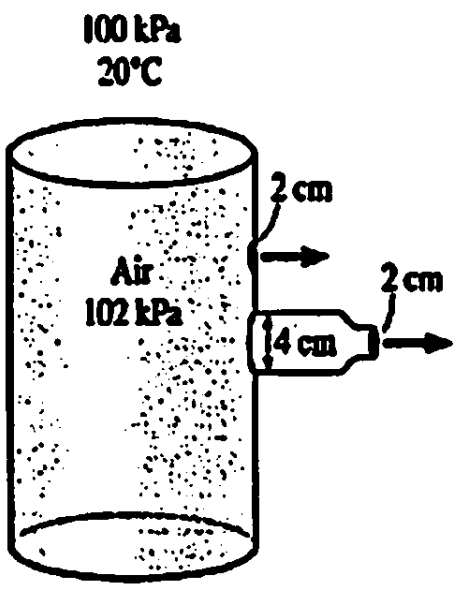


FIGURE P12–67

Step 1 of 6

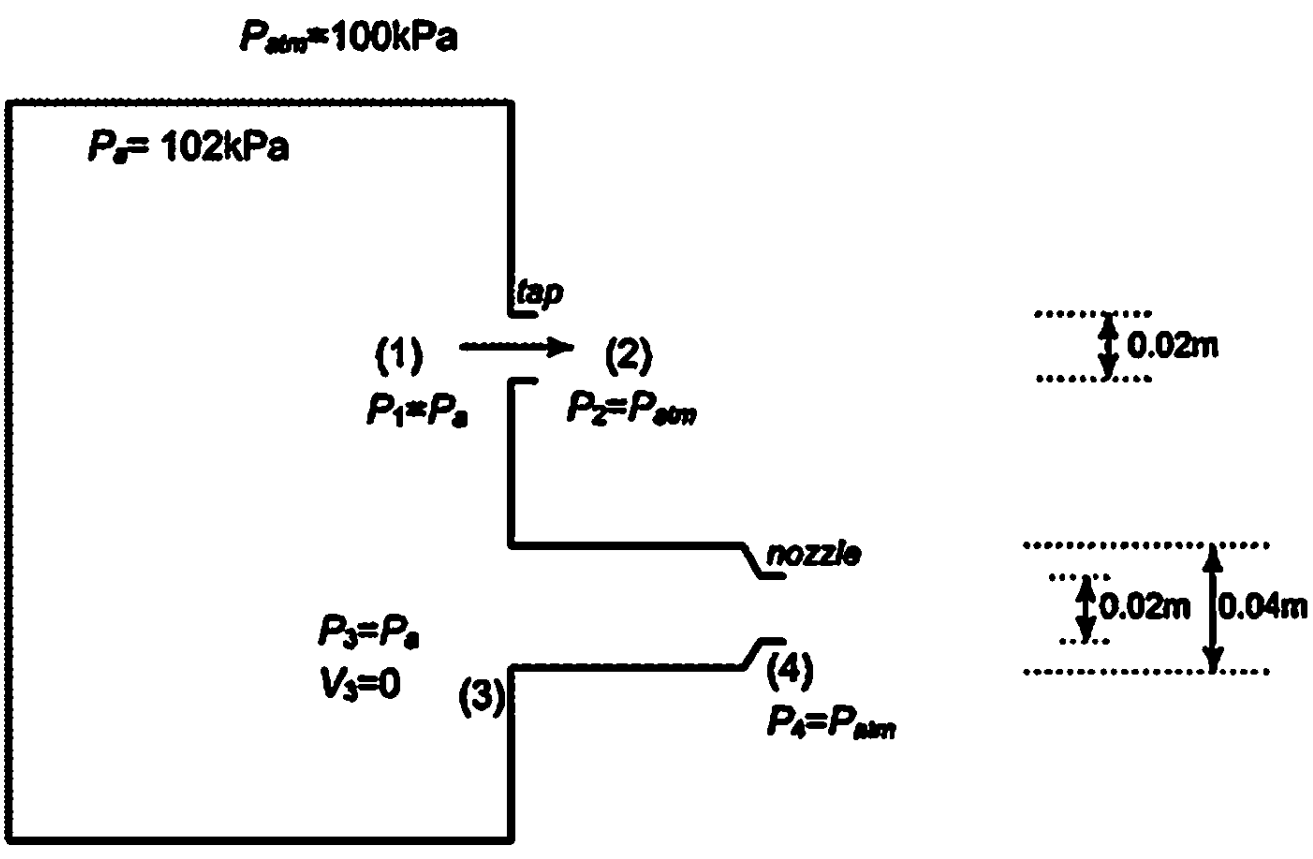
Given data:

The pressure of the air inside the tank, $P_a = P_1 = 102\ \text{kPa}$.

The atmospheric pressure outside the tank, $P_{atm} = P_2 = 100\ \text{kPa}$.

The diameter of the tap, $D_t = 0.02\ \text{m}$.

Temperature of the air in the tank, $T = 20\ ^\circ\text{C}$.



The universal gas constant $R = 0.2870\ \text{kJ/kg}\cdot\text{K}$

Air escapes through a hose of diameter, $d_{hose} = 0.04\ \text{m}$

Diameter of the nozzle end, $d_{noz} = 0.02\ \text{m}$

Step 2 of 6

Let us draw the figure.

Step 3 of 6

Applying the Bernoulli's flow equation between the tank and the tap, points (1) and (2):

$$\frac{P_1}{\rho_a} + \frac{V_1^2}{2} + gz_1 = \frac{P_2}{\rho_a} + \frac{V_2^2}{2} + gz_2 \quad \text{..... (1)}$$

The effect of elevation can be neglected between the two points because they lie on the same ground and the velocity of the air in the tank is zero

Then from equation (1)

$$\frac{P_1}{\rho_a} + 0 + 0 = \frac{P_2}{\rho_a} + \frac{V_2^2}{2} + 0$$

$$V_2^2 = \frac{2(P_1 - P_2)}{\rho_a}$$

$$V_2 = \sqrt{\frac{2(P_1 - P_2)}{\rho_a}} \quad \text{..... (2)}$$

Step 4 of 6

The density of the air in the tank is given by

$$\rho_a = \frac{P}{RT}$$

$$= \frac{102 \times 10^3}{(0.287 \times 10^3)(293)}$$

$$= 1.2129\ \text{kg/m}^3$$

Step 5 of 6

From equation (2), the velocity of the air exerting out from the tap to the atmosphere is given by

$$V_2 = \sqrt{\frac{2(P_1 - P_2)}{\rho_a}}$$

$$= \sqrt{\frac{2(102 - 100)}{1.2129}}$$

$$= \sqrt{3.298}$$

$$= 1.816\ \text{m/s}$$

Step 6 of 6

The discharge rate of the air through the tap is given by

$$\dot{V}_{tap} = A_{tap} V_2$$

$$= \left(\frac{\pi}{4} \times 0.02^2\right)(1.816)$$

$$= 5.705 \times 10^{-4}\ \text{m}^3/\text{s}$$

The maximum flow rate is $\boxed{\dot{V}_{tap} = 5.705 \times 10^{-4}\ \text{m}^3/\text{s}}$

The air escapes through a hose of diameter 0.04m, length 2m with an end nozzle of diameter 0.02cm.

Let us assume the flow is steady, incompressible and irrotational having the frictional effects inside the hose and at nozzle are negligible.

The discharge rate through the hose shall not vary due to the increased size and length because as the area increases there will be corresponding decrease in pressure and the frictional effects are neglected throughout the entire length of the hose.

This can be expressed as

$$\dot{V}_{hose} = A_3 V_3 = A_4 V_4$$

Where we can express based on our knowledge

$$\dot{V}_{tap} = \dot{V}_{hose}$$

When the pressure in the storage tank is $P = 300\ \text{kPa}$ then there occur pressure change between the tank and atmosphere. Since the air density is no longer remains same as in the tank and the atmosphere the flow is not incompressible. Thus it can be solved using the theory of compressible flow.

Question: 12.068P

Water is flowing through a Venturi meter whose 1 diameter is 7 cm at the entrance part and 4 cm at the throat 1 The pressure is measured to be 380 kPa at the entrance and J 150 kPa at the throat. Neglecting frictional effects, determine 1 the flow rate of water.

Step 1 of 4

Given data:

The inlet diameter of the Venturi meter, $D_1 = 0.07$ m .

The throat diameter of the Venturi meter, $D_2 = 0.04$ m .

The inlet pressure, $P_1 = 380$ kPa .

The throat pressure, $P_2 = 150$ kPa .

The frictional effects can be neglected.

Step 2 of 4

Let us assume the flow is steady, incompressible and irrotational.

Let the inlet section be point (1) and throat section is point (2).

Both the points are at the same elevation $z_1 = z_2 = 0$.

Flow rate of the water is given by

$$\dot{V} = A_1V_1 = A_2V_2$$

Then we can express

$$V_1 = \frac{\dot{V}}{A_1} \qquad \ldots\ldots (1)$$

And

$$V_2 = \frac{\dot{V}}{A_2} \qquad \ldots\ldots (2)$$

Step 3 of 4

Applying the Bernoulli's flow equation between the points (1) and (2):

$$\frac{P_1}{\rho} + \frac{V_1^2}{2} + gz_1 = \frac{P_2}{\rho} + \frac{V_2^2}{2} + gz_2$$

$$\frac{P_1 - P_2}{\rho} = \frac{V_2^2 - V_1^2}{2}$$

Now by substituting equation (1) and (2) in (3), we get

$$\frac{P_1 - P_2}{\rho} = \frac{1}{2}\left[\left(\frac{\dot{V}}{A_2}\right)^2 - \left(\frac{\dot{V}}{A_1}\right)^2\right]$$

Step 4 of 4

The flow rate of the water is given by

$$\dot{V} = \frac{\pi D_2^2}{4}\sqrt{\frac{2(P_1 - P_2)}{\rho\left[1 - \left(\frac{A_2}{A_1}\right)^2\right]}}$$

$$= \frac{\pi D_2^2}{4}\sqrt{\frac{2(P_1 - P_2)}{\rho\left[1 - \left(\frac{D_2}{D_1}\right)^4\right]}}$$

$$= \frac{\pi(0.04)^2}{4}\sqrt{\frac{2(380 - 150)}{1000\left[1 - \left(\frac{4}{7}\right)^4\right]}\left(\frac{1000}{1}\right)}$$

$$= \frac{\pi(0.04)^2}{4} \times 22.69$$

$$= 0.0285 \text{ m}^3/\text{s}$$

Therefore the flow rate of the water is $\boxed{\dot{V} = 0.0285 \text{ m}^3/\text{s}}$.

Question: 12.069P

Water flows at a rate of 0.025 m3/s in a horizontal pipe whose diameter increases from 6 to 11 cm by an 1 enlargement section. If the head loss across the enlargement section is 0.45 m and the kinetic energy correction factor at 1 both the inlet and the outlet is 1.05. determine the pressure 1 change.

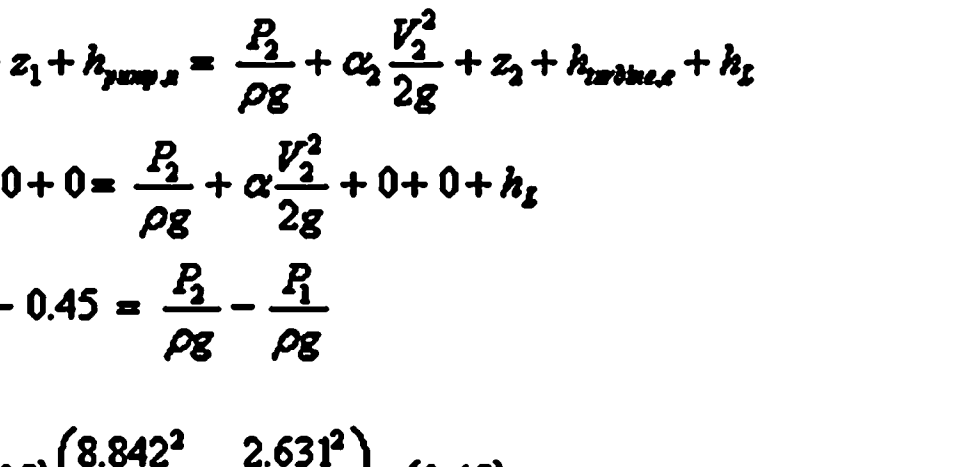
Step 1 of 4

Given data:

The flow rate of the water, $\dot{V} = 0.025\ \text{m}^3/\text{s}$.

The initial diameter of the pipe section, $D_1 = 0.06\ \text{m}$.

The final diameter of the pipe section, $D_2 = 0.11\ \text{m}$.



The head loss, $h_L = 0.45\ \text{m}$.

The kinetic energy correction factor at inlet and outlet, $\alpha_1 = \alpha_2 = 1.05$.

The frictional effects are neglected.

Step 2 of 4

Water flows in a pipe whose diameter is varying as shown in the figure below.

Step 3 of 4

Let us assume the flow is steady and incompressible and the inlet and exit are at the same elevation.

Velocity of the water at point (1) is given by

$$V_1 = \frac{\dot{V}}{A_1}$$

$$= \frac{0.025}{\frac{\pi}{4}(0.06^2)}$$

$$= 8.842\ \text{m/s}$$

And

Velocity of the water at point (2) is given by

$$V_2 = \frac{\dot{V}}{A_2}$$

$$= \frac{0.025}{\frac{\pi}{4}(0.11)^2}$$

$$= 2.631\ \text{m/s}$$

Step 4 of 4

Applying the Bernoulli's equation for steady flow between the points (1) and (2):

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine} + h_L$$

$$\frac{P_1}{\rho g} + \alpha \frac{V_1^2}{2g} + 0 + 0 = \frac{P_2}{\rho g} + \alpha \frac{V_2^2}{2g} + 0 + 0 + h_L$$

$$\alpha \frac{V_1^2}{2g} - \alpha \frac{V_2^2}{2g} - 0.45 = \frac{P_2}{\rho g} - \frac{P_1}{\rho g}$$

Then,

$$P_2 - P_1 = \rho(1.05)\left(\frac{8.842^2}{2} - \frac{2.631^2}{2}\right) - (0.45)\rho g$$

$$= 1000(1.05)\left(\frac{8.842^2}{2} - \frac{2.631^2}{2}\right) - 0.45(1000)(9.81)$$

$$= 32.996 \times 10^3\ \text{Pa}$$

$$= 32.996\ \text{kPa}$$

Therefore the pressure change in the pipe is $\boxed{\Delta P = 32.996\ \text{kPa}}$.

Question: 12.070P

A 3-m-high large tank is initially filled with water. The tank water surface is open to the atmosphere, and a sharp-edged 10-cm-diameter orifice at the bottom drains to the atmosphere through a horizontal 80-m-long pipe. If the total irreversible head loss of the system is determined to he 1.5 m. determine the initial velocity of the water from the tank. Disregard the effect of the kinetic energy correction factors.

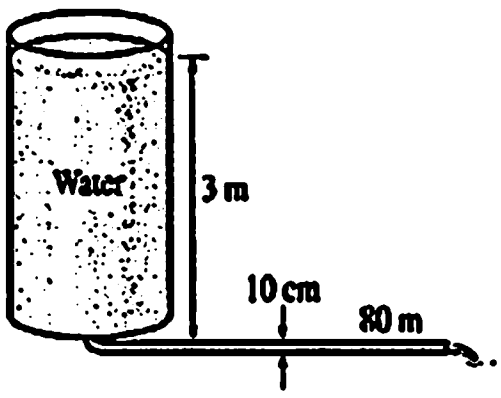


FIGURE P12–70

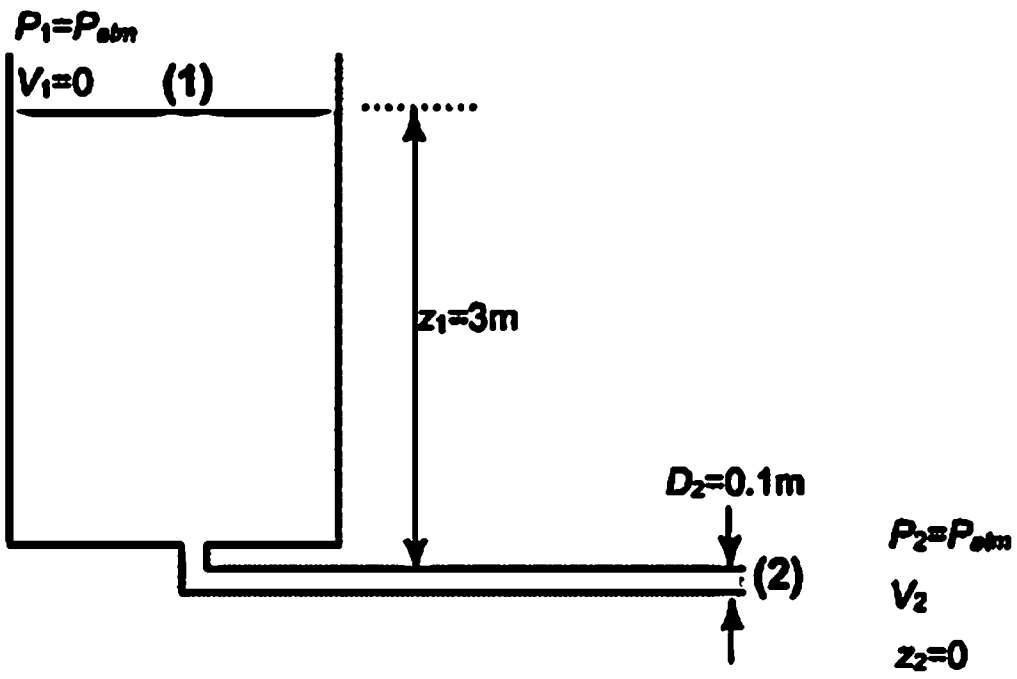
Step 1 of 5

Given data:

The total irreversible head loss, $h_L = 1.5$ m.

Height of the water in the tank from the surface, $Z_1 = 3$ m.



The tank has the orifice at the bottom of the pipe having diameter, $d = 0.1$ m.

The length of the pipe, $L = 80$ m

The kinetic energy corrections can be neglected.

Step 2 of 5

A tank filled of water is orifice at the bottom of the tank as shown in the figure below.

Step 3 of 5

Let us assume

1. The fluid is incompressible and the flow is steady.
2. The frictional effects can be neglected.
3. The kinetic energy correction factors can be neglected, $\alpha_1 = \alpha_2 = 1$.

Step 4 of 5

Applying the Bernoulli's flow equation between the points (1) and (2):

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,s} + h_L$$

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + 3 + 0 = \frac{P_{atm}}{\rho g} + (1)\frac{V_2^2}{2g} + 0 + 0 + 1.5$$

$$\frac{V_2^2}{2g} = 1.5$$

Step 5 of 5

Then the outlet velocity of the water is given by

$$V_2 = \sqrt{1.5(2g)}$$

$$= \sqrt{1.5(2 \times 9.81)}$$

$$= 5.425 \text{ m/s}$$

Therefore the outlet velocity of the water $\boxed{V_2 = 5.425 \text{ m/s}}$

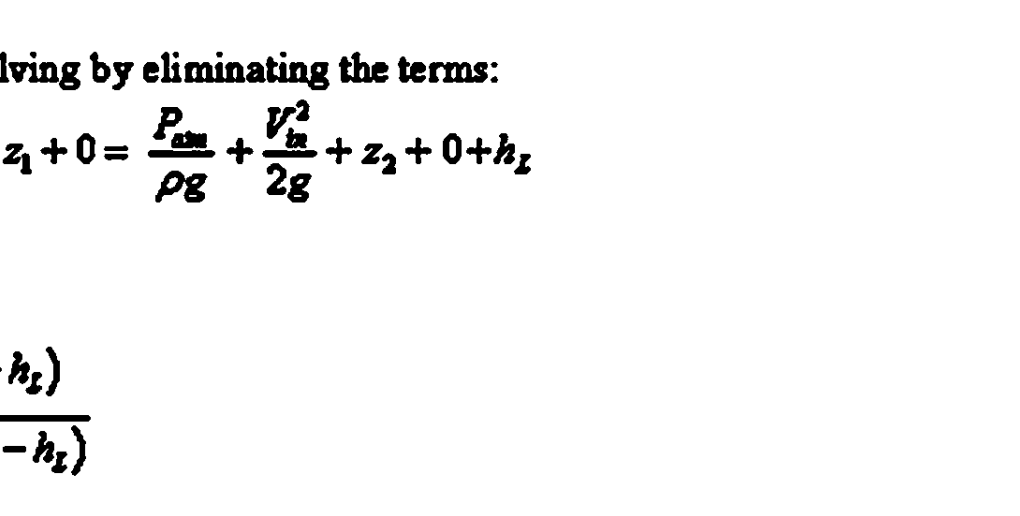
Question: 12.071P

Reconsider Prob. 12-70. Using EES (or other) software, investigate the effect of the tank : - height on the initial discharge velocity of water from the complexly filled tank. Let the tank height vary from 2 to 15 m in increments of 1 m, and assume the irreversible head loss to remain constant. Tabulate and plot the results.

Step 1 of 8

Given data:

The total irreversible head loss, $h_L = 1.5\ \text{m}$.



Acceleration due to gravity, $g = 9.81\ \text{m/s}^2$.

Density of water, $\rho = 1000\ \text{kg/m}^3$

Diameter of orifice, $D = 0.1\ \text{m}$

Step 2 of 8

Free body diagram of the tank:

Step 3 of 8

By applying the Bernoulli's flow equation between the points (1) and (2).

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L$$

where, p is pressure at points (1) and (2).

ρ is density of fluid.

g is acceleration due to gravity

V is velocity at points (1) and (2).

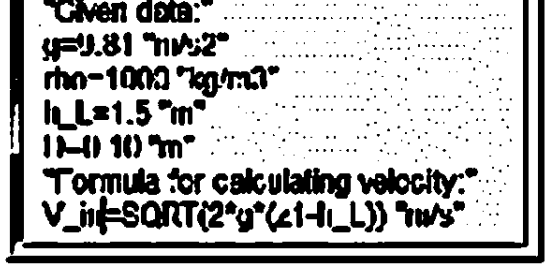
z is elevation at points (1) and (2).

h is head at pump, turbine and total head.

Step 4 of 8

On further solving by eliminating the terms:

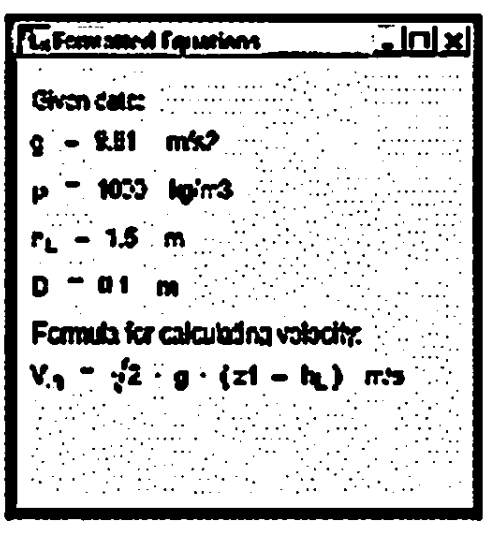
$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + z_1 + 0 = \frac{P_{atm}}{\rho g} + \frac{V_{in}^2}{2g} + z_2 + 0 + h_L$$



$$\frac{V_{in}^2}{2g} = z_1 - h_L$$

$$V_{in}^2 = 2g(z_1 - h_L)$$

$$V_{in} = \sqrt{2g(z_1 - h_L)}$$

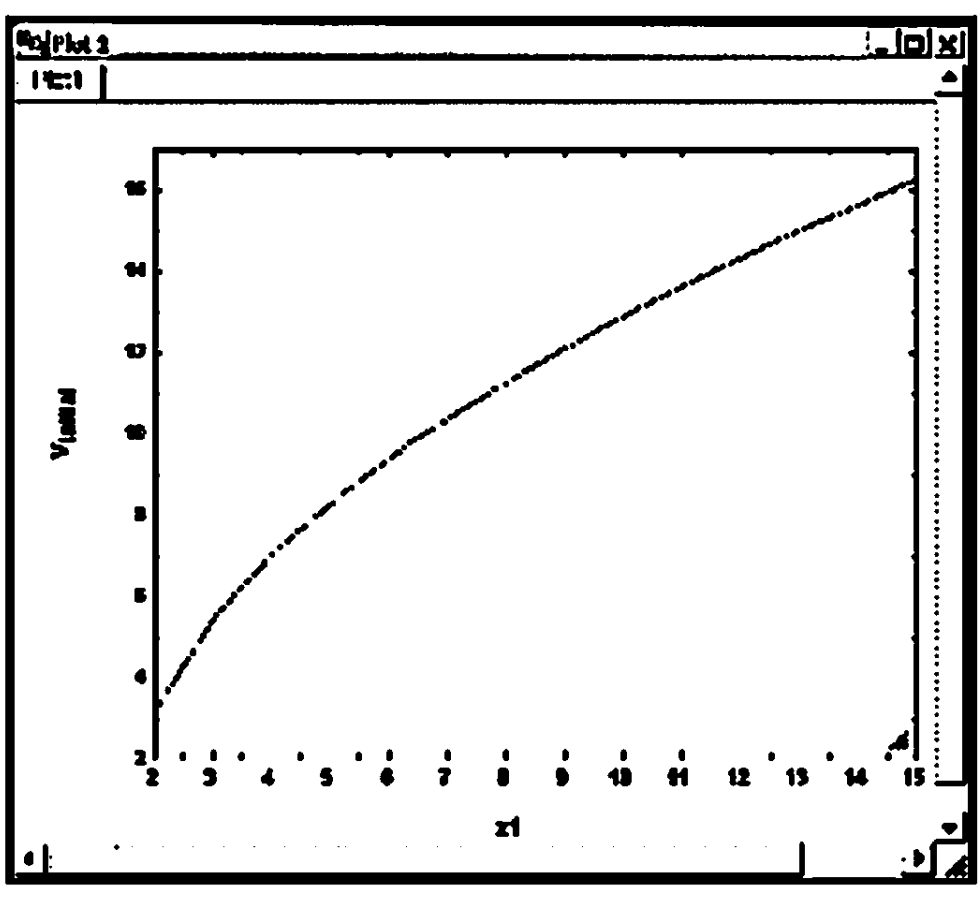


Step 5 of 8

Using the above formula and by EES software, we give the inputs in equation window as shown below:

Step 6 of 8

The equations in the formatted window are shown below:



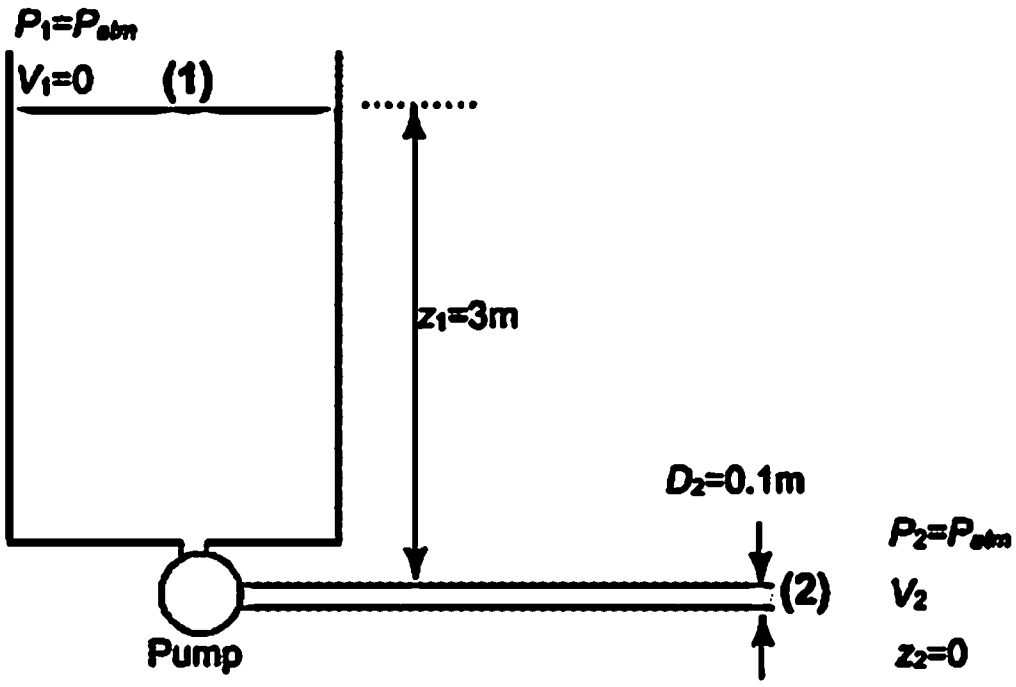
Step 7 of 8

The tabulated values are shown below as in EES varying the tank height from 2m to 15m with increments of 1m:

	z1	V_{inmm}	h_L
Run 1	2	3.132	1.5
Run 2	3.083	5.574	1.5
Run 3	4.167	7.233	1.5
Run 4	5.25	8.578	1.5
Run 5	6.333	9.738	1.5
Run 6	7.417	10.77	1.5
Run 7	8.5	11.72	1.5
Run 8	9.583	12.59	1.5
Run 9	10.67	13.41	1.5
Run 10	11.75	14.18	1.5
Run 11	12.83	14.91	1.5
Run 12	13.92	15.61	1.5
Run 13	15	16.27	1.5

Step 8 of 8

The plot obtained from the above table is shown as:



Question: 12.072P

Reconsider Prob. 12–70. In order to drain the tank faster, a pump is installed near the tank exit. Determine the pump head input necessary to establish an average water velocity of 6.5 m/s when the tank is full.

Step 1 of 3

Free body diagram of the tank:

Step 2 of 3

Given data:

The total irreversible head loss, $h_L = 1.5\ \text{m}$.

The exit velocity, $V_2 = 6.5\ \text{m/s}$.

By applying the Bernoulli's flow equation between the points (1) and (2):

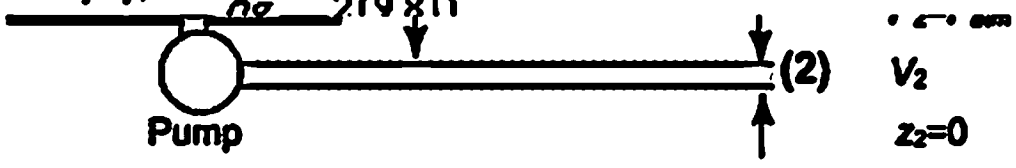
$$\frac{p_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{p_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine} + h_L \qquad \ldots\ldots (1)$$

Where, p is pressure at points (1) and (2).

ρ is density of fluid.

g is acceleration due to gravity.

V is velocity at points (1) and (2).



z is elevation at points (1) and (2).

h is head at pump, turbine and total head.

Step 3 of 3

By substituting the given values in (1):

$$\frac{P_{atm}}{\rho g} + \frac{0}{2g} + 3 + h_{pump,u} = \frac{P_{atm}}{\rho g} + \frac{(6.5)^2}{2(9.81)} + 0 + 0 + 1.5$$

Step 2 of 3

Given data:

The total irreversible head loss, $h_L = 1.5\ \text{m}$.

The exit velocity, $V_2 = 6.5\ \text{m/s}$.

Question: 12.073P

The water level in a tank is 120 ft above the ground. A hose is connected to the bottom of the tank, and the nozzle at the end of the hose is pointed straight up. The tank is at sea level, and the water surface is open to the atmosphere. In the line leading from the tank to the nozzle is a pump, which increases the water pressure by 10 psia. Determine the maximum height to which the water stream could rise.

Step 1 of 4

Given data:

The height of the water in the tank from ground level, $z_s = 120\ \text{ft}$.

The pressure rise, $\Delta P = 10\ \text{psia} = 1440\ \text{lbf/ft}^2$.

The pressure at tank surface and maximum height of the jet is atmospheric, P_{atm}.

Step 2 of 4

Density of water,

$$\rho = 62.4\ \text{lbm/ft}^3$$

$$= \frac{62.4}{32.2}\ \text{lbf.s}^2/\text{ft}^4$$

Acceleration due to gravity, $g = 32.2\ \text{ft/s}^2$

The pressure rise is expressed as,

$$\Delta P = \rho g h_{pump,u}$$

Rewriting the above equation:

$$h_{pump,u} = \frac{\Delta P}{\rho g}$$

$$= \frac{1440}{\frac{62.4}{32.2} \times 32.2}$$

$$= 23.08\ \text{ft}$$

Step 3 of 4

By applying the Bernoulli's equation for steady incompressible flow between the tank surface and point of maximum height of the water jet,

$$\frac{P_s}{\rho g} + \alpha_1 \frac{V_s^2}{2g} + z_s + h_{pump,u} = \frac{P_j}{\rho g} + \alpha_2 \frac{V_j^2}{2g} + z_j + h_{minor,e} + h_L$$

Where, the pressures

$$P_s = P_j = P_{atm}$$

The velocity at the surface and maximum height is zero,

$$V_s = V_j = 0$$

Step 4 of 4

The useful pump head:

$$h_{pump,u} = z_j - z_s$$

By substituting values in the above equation:

$$23.08 = z_j - 120$$

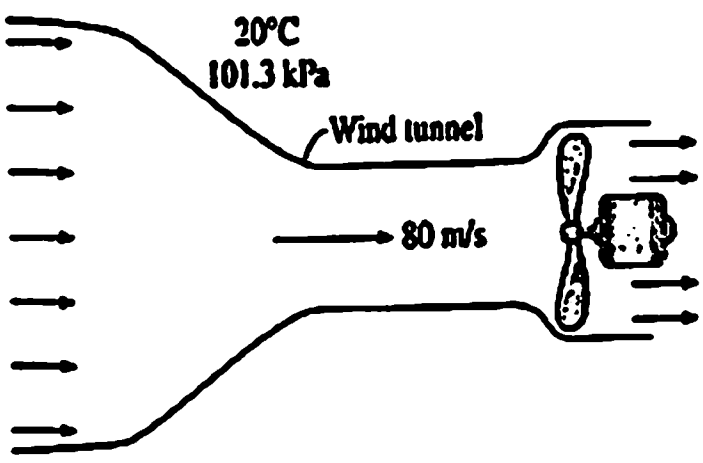
$$z_j = 23.08 + 120$$

$$= 143.08$$

Therefore the maximum height to which the water rises is $\boxed{z_j = 143.08\ \text{ft}}$.

Question: 12.074P

A wind tunnel draws atmospheric air at 20°C and 101.3 kPa by a large fan located near the exit of the tunnel. If the air velocity in the tunnel is 80 m/s, determine the pressure in the tunnel.



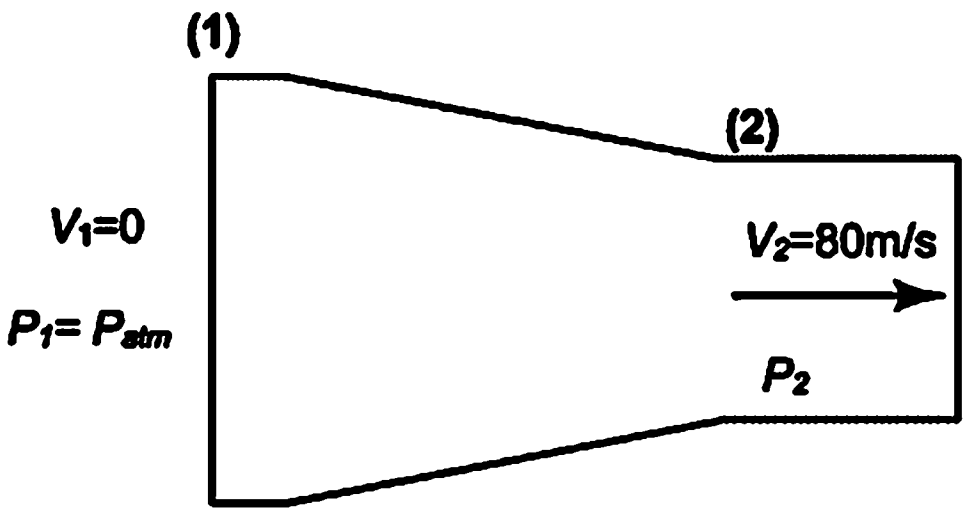


FIGURE P12–74

Step 1 of 3

Draw the wind tunnel showing the velocities and pressures at state 1 and state2.

Step 2 of 3

Find the density of air by using ideal gas equation.

$$\rho=\frac{P_1}{RT_1}$$

Here, P_1 is atmospheric air at state 1, R is gas constant of air, and T_1 is temperature of air at state 1.

Substitute $101.3\,\text{kPa}$ for P_1, $0.287\,\text{kJ/kg.K}$ for R, and $(20+273.14)\,\text{K}$ for T_1

$$\rho_1=\frac{101.3}{(0.287)(293.15)}$$
$$=1.204\,\text{kg/m}^3$$

Step 3 of 3

Apply Bernoulli's equation between the points (1) and (2).

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2$$

Here, $\frac{P}{\rho g}$ indicates pressure head, $\frac{V^2}{2g}$ is velocity head, and z is datum head.

Assume there is no change in datum head at section 1 and 2. Then the modified Bernoulli's equation becomes,

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}$$
$$\frac{P_1}{\rho}+\frac{V_1^2}{2}=\frac{P_2}{\rho}+\frac{V_2^2}{2}$$

Substitute 101.3kPa for P_1, 0 m/s for V_1, 80 m/s for V_2, and $9.81\,\text{m/s}^2$ for g.

$$\frac{101.3\times10^3}{1.204}+0=\frac{P_2}{1.204}+\frac{(80)^2}{2}$$
$$84.136\times10^3=\frac{P_2}{1.204}+3200$$
$$P_2=97446.94\,\text{Pa}$$
$$P_2=97.446\,\text{kPa}$$

Therefore, the pressure inside the wind tunnel is $\boxed{97.446\,\text{kPa}}$

CHAPTER 13
SOLUTIONS

Question: 13.001P

Is momentum a vector? If so, in what direction does it point?

Step 1 of 1

The momentum of a body is defined as the product of the mass and the velocity of a body.
Le the mass of a body is m
The velocity of a body is V
Then the momentum of a body is mV

The velocity is a vector quantity. As the momentum is a constant multiple of velocity, momentum of a body is also a vector and the direction of the momentum is in the direction of velocity of that body.

Question: 13.002P

Express the conservation of momentum principle. What can you say about the momentum of a body if the net force acting on it is zero?

Step 1 of 1

The conservation of momentum principle states that for a system, the total momentum remains constant provided no external resultant force acts on the system. Thus the moment of an isolated system remains constant.

Total initial momentum = Total final momentum.
If no external force is acting on a body then the momentum of the body remains constant.

Question: 13.003P

Express Newton's first, second, and third laws.

Step 1 of 1

Newton's first law states that every object in a state of rest or uniform motion remains in that state unless an external force is applied on it. Newton's first law is also called as the law of inertia.

Newton's second law states that the rate of change of momentum of an object is directly proportional to the resultant force acting on it

For a rigid body of mass m, Newton's second law is expressed as

$$\vec{F} = m\vec{a} = m\frac{d\vec{V}}{dt} = \frac{d\left(m\vec{V}\right)}{dt}$$

Where $\vec{F}$ is the net force acting on the body and $\vec{a}$ is the acceleration of the body under the influence of $\vec{F}$

Newton's third law states that for every action, there is an equal and opposite reaction.

Question: 13.004P

Express Newton's second law of motion for rotating bodies. What can you say about the angular velocity and angular momentum of a rotating nonrigid body of constant mass if the net torque acting on it is zero?

Step 1 of 1

Angular momentum is the product of the moment of inertia and angular velocity. The angular momentum remains constant if the net external torque acting on the system is zero. Newton's second law of motion for rotating bodies states that the rate of change of the angular momentum of the body is equal to the net torque acting it.

If the net torque acting on a rotating a non-rigid body with constant mass is zero then the angular momentum of the body remains constant and the angular velocity will change.

Question: 13.005P

Describe body forces and surface forces, and explain how the net force acting on a control volume is determined. Is fluid weight a body force or surface force? How about pressure?

Step 1 of 1

Body forces are forces that act throughout the entire body of the control volume. Some examples of body forces are gravitational force, magnetic force etc. Forces which act on the point of contact are called surface forces. Some examples of surface forces are pressure, reaction force etc.

In a control volume the net force is the sum of body forces and surface forces.

Fluid weight is a body force, which acts throughout the entire body. Force acting per unit area is pressure. Thus pressure is a surface force.

Question: 13.006P

How do surface forces arise in the momentum analysis of a control volume? How can we minimize the number of surface forces exposed during analysis?

Step 1 of 1

Surface forces are generated when the control volume is isolated from its surroundings for the purpose of analysis.

When the control volume is detached the effect of any detached object from the volume is accounted by a force at that location.

When choosing a control volume, care should be taken to expose only the forces such as reaction forces that are required for analysis and minimum number of other forces.

Question: 13.007P

Explain the importance of the Reynolds transport theorem in fluid mechanics, and describe how the linear momentum equation is obtained from it.

Step 1 of 1

Reynolds transport theorem the relationship between the time rates of change of an extensive property for a system and a control volume. The linear momentum equation is obtained from Reynolds transport theorem by setting $b = \vec{V}$, thus $B = m\vec{V}$ in the Reynolds transport theorem.

Question: 13.008P

What is the importance of the momentum-flux correction factor in the momentum analysis of flow systems? For which type(s) of flow is it significant and must it be considered in analysis: laminar flow, turbulent flow, or jet flow?

Step 1 of 1

The momentum flux can be expressed in terms of the mass flow rate and average flow velocity by using the momentum-flux correction factor (◊).

$$\beta = \frac{1}{A_c}\int_{A_c}\left(\frac{V}{V_{avg}}\right)^2 dA_c$$

For fully developed laminar pipe flows the value of ◊◊ is about 1.33. Thus ◊ cannot be ignored and is significant and should be considered in laminar flow. But for fully developed turbulent flow, the value of ◊◊ is very close to unity so it can be neglected. Also for jet flow the value of ◊ is unity. So for jet flows the momentum flux correction factor can be neglected.

Question: 13.009P

Write the momentum equation for steady one- dimensional flow for the case of no external forces and explain the physical significance of its terms.

Step 1 of 2

The momentum equation for steady one dimensional flow is expressed as,

$$\sum \vec{F} = \sum_{in} \beta \dot{m} \vec{V} - \sum_{out} \beta \dot{m} \vec{V} \quad \text{..... (1)}$$

Here, $\vec{F}$ is the net force acting on the control volume, $\sum_{in} \beta \dot{m} \vec{V}$ represents the incoming momentum flux, $\sum_{out} \beta \dot{m} \vec{V}$ represents the net outgoing momentum flow flux, β is the momentum correction factor, $\dot{m}$ is the mass flow rate, and $\vec{V}$ is the velocity of flow.

Step 2 of 2

As the flow is of steady, one-dimensional, and of no external forces,

$$\sum \vec{F} = 0$$

Substitute 0 for $\sum \vec{F}$ in equation (1).

$$\sum_{in} \beta \dot{m} \vec{V} - \sum_{out} \beta \dot{m} \vec{V} = 0$$

Therefore, the momentum equation for steady, one-dimensional flow for the case of no external forces is $\boxed{\sum_{in} \beta \dot{m} \vec{V} - \sum_{out} \beta \dot{m} \vec{V} = 0}$.

As it is a case of general momentum equation, since there are no external forces acting,

Conservation of momentum holds good.

Question: 13.010P

In the application of the momentum equation, explain why we can usually disregard the atmospheric pressure and work with gage pressures only.

Step 1 of 1

Atmospheric pressure tends to act in all directions. As a result, individual atmospheric forces tend to cancel out each other when taken into analysis.

Due to the above reason we disregard atmospheric pressure and consider the gage pressures only during the application of momentum equation.

Question: 13.011P

A rocket in space (no friction or resistance to motion) can expel gases relative to itself at some high velocity *V*. Is *V* the upper limit to the rocket's ultimate velocity?

Step 1 of 1

When there is no friction the velocity of the rocket will continue to increase. Thus *V* is not the upper limit to the rocket's ultimate velocity. So if there is no resistance to motion, then the rocket will accelerate continuously.

Question: 13.012P

Describe in terms of momentum and airflow how a helicopter is able to hover.

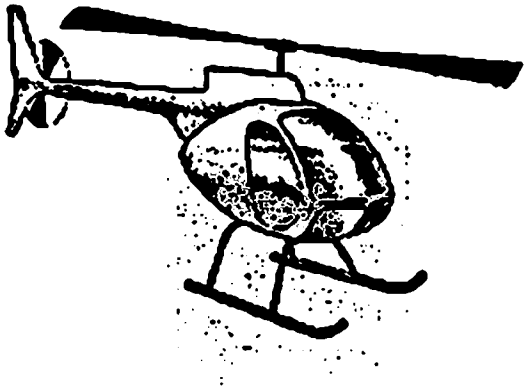

FIGURE P13–12C

Step 1 of 1

The propeller blades of a helicopter spins, hence it creates a downdraft of air. This pushes the helicopter. The air beneath the blades thus, has greater pressure than the air above them. This momentum in the air creates a lift. To hover a helicopter the momentum created by the flow of air must be balanced by the lift force of the helicopter.

Question: 13.013P

Does it take more, equal, or less power for a helicopter to hover at the top of a high mountain than it does at sea level? Explain.

Step 1 of 1

At higher altitudes the density of the air decreases, so more air must be forced into the downdraft by the helicopter blades in order to provide the same lift force as of the sea level. Thus, it requires more power for a helicopter to hover on the top of a high mountain than it does at sea level.

Question: 13.014P

In a given location, would a helicopter require more energy in summer or winter to achieve a specified performance? Explain.

Step 1 of 1

In summer season the density of the air is less. So in order to create lift, more air must be forced into the downdraft by the helicopter blades. In winter the density of the air is high compared to that of summer. Therefore, less air must be forced into the downdraft by the helicopter blades to provide the same lift.

Thus a helicopter requires more energy in summer than in winter to achieve a specified performance.

Question: 13.015P

A horizontal water jet from a nozzle of constant exit cross section impinges normally on a stationary vertical flat plate. A certain force F is required to hold the plate against the water stream. If the water velocity is doubled, will the necessary holding force also be doubled? Explain.

Step 1 of 3

The following assumptions are made for explanation:

(1) The flow of water at the nozzle outlet is steady.
(2) The water splatters in direction normal to the approach of the water jet.
(3) The water jet is exposed to atmosphere, thus the pressure of water jet and splattered water is atmospheric which is neglected.
(4) The vertical forces and momentum fluxes are not considered since they have no effect on horizontal reaction force.
(5) The effect of momentum flux correction factor is negligible, $\beta \cong 1$

Step 2 of 3

For the total reaction force, we have

$$\begin{aligned} F_R &= \beta \dot{m} V \\ &= \dot{m} V \\ &= (\rho A V) V \\ &= \rho A V^2 \end{aligned}$$

Step 3 of 3

When the velocity is doubled,

$$\begin{aligned} F_R &= \rho A (2V)^2 \\ &= 4 \rho A V^2 \end{aligned}$$

From the above result we can conclude that when the velocity is doubled the resultant force increases by a factor of four rather than being doubled.

Question: 13.016P

Two firefighters are fighting a fire with identical water hoses and nozzles, except that one is holding the hose straight so that the water leaves the nozzle in the same direction it comes, while the other holds it backward so that the water makes a U-turn before being discharged. Which firefighter will experience a greater reaction force?

Step 1 of 3

Given data:

Fire fighter (1) holds the hose straight so that water leaves in the same direction as it comes.

Fire fighter (2) holds the hose straight backwards so that water makes a U-turn before leaving the nozzle.

Step 2 of 3

Consider the case of fire fighter (2).

The water is discharged after undergoing a turn of 180°. This is similar to the discharge of water from a reversing elbow.

We know the reaction force in this case,

$$F_{Rx} = -\beta \dot{m}(V_2 + V_1) - P_{1,gage} A_1 \qquad \ldots\ldots (3)$$

Step 3 of 3

Consider the case of fire fighter (1).

The water is discharged from the nozzle along the direction of flow. That is in the positive x-direction.

We know the reaction force in this case,

$$F_{Rx} = \beta \dot{m}(V_2 + V_1) - P_{1,gage} A_1 \qquad \ldots\ldots (4)$$

On comparing the equations (3) and (4),

We can conclude that the fire fighter (2) will be experiencing greater reaction force than fire fighter (1).

Question: 13.017P

A constant-velocity horizontal water jet from a stationary nozzle impinges normally on a vertical flat plate that rides on a nearly frictionless track. As the water jet hits the plate, it begins to move due to the water force. Will the acceleration of the plate remain constant or change? Explain.

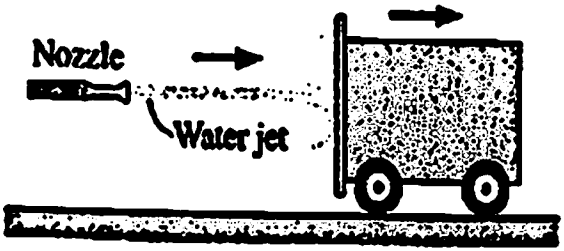

FIGURE P13–17C

Step 1 of 1

The impulse force exerted by the water on the plate, $F = \dot{m}V$

Where V is the relative velocity between water and the plate

We know mass flow rate, $\dot{m} = \rho AV$

Thus the impulse force becomes

$$F = (\rho AV)V$$

$$= \rho AV^2$$

Now, as the water jet hits the plate, it moves. Thus the relative velocity will decrease as the plate moves. As the relative velocity decreases the impulse force will also decrease.

The acceleration of the plate

$$a = \frac{F}{m}$$

Since the force decrease the acceleration of the plate will also decrease.

Therefore the acceleration of the plate is not constant.

Question: 13.018P

A horizontal water jet of constant velocity V from a stationary nozzle impinges normally on a vertical flat plate that rides on a nearly frictionless track. As the water jet hits the plate, it begins to move due to the water force. What is the highest velocity the plate can attain? Explain.

Step 1 of 2

Write the equation for impulse force exerted by the water jet on the plate.

$$F = \dot{m}(V-u)$$

Here, $(V-u)$ is the relative velocity between water and the plate, V is the velocity of jet and u is the velocity of plate.

Write the equation for mass flow rate.

$$\dot{m} = \rho A(V-u)$$

Here, ρ is the density and A is the cross sectional area.

Substitute $\rho A(V-u)$ for $\dot{m}$.

$$\begin{aligned} F &= \dot{m}(V-u) \\ &= (\rho A(V-u))(V-u) \\ &= \rho A(V-u)^2 \end{aligned}$$

Now, as the water jet hits the plate, it moves. Thus the relative velocity will decrease as the plate moves. As the relative velocity decreases the impulse force will also decrease.

Step 2 of 2

The maximum force exerted by the water jet on the plate can be obtained at the velocity of plate is zero. As the velocity of plate increases the relative velocity decreases, thereby the force exerted on the plate decreases. The minimum force on the plate can be obtained at the velocity of plate is equal to the velocity of jet. If the velocity of plate is more than the velocity of jet, then the force exerted on the plate becomes negative, which is impossible case.

Therefore, the maximum velocity of the plate is equal to the velocity of jet.

Question: 13.019P

A horizontal water jet of constant velocity V impinges normally on a vertical flat plate and splashes off the sides in the vertical plane. The plate is moving toward the oncoming water jet with velocity 1/2 V. If a force F is required to maintain the plate stationary, how much force is required to move the plate toward the water jet?

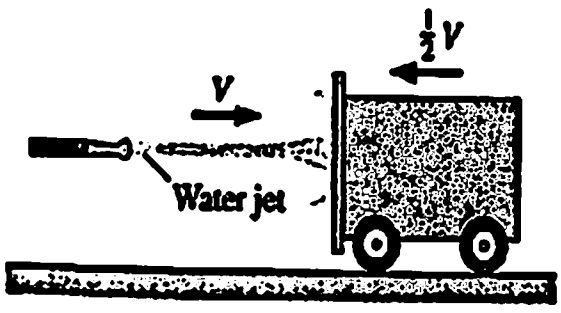

FIGURE P13–19

Step 1 of 4

The Schematic representation of the given system is shown below.

CV

Question:

A horizontal water jet of constant velocity V impinges normally on a vertical flat plate and splashes off the sides in the vertical plane. The plate is moving toward the oncoming water jet with velocity 1/2 V. If a force F is required to maintain the plate stationary, how much force is required to move the plate toward the water jet?

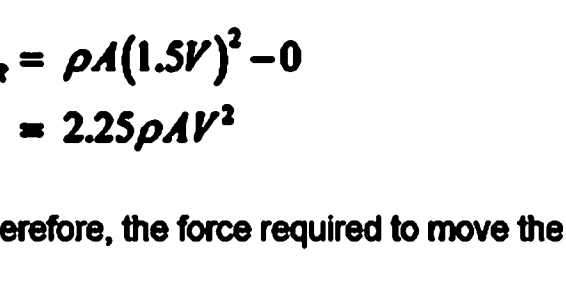

FIGURE P13–19

Step 1 of 4

The Schematic representation of the given system is shown below.

The effect of momentum flux correction factor is negligible.

CV

Step 3 of 4

When the plate is moving with a velocity $0.5V$ against the jet of velocity V, the relative velocity of the jet with respect to the plate can be represented as

$$\begin{aligned} V_{in} &= V-(-0.5V) \\ &= 1.5V \end{aligned}$$

Calculate the reaction force by applying momentum equation as shown below.

$$\begin{aligned} \sum \overline{F_R} &= \sum_{in} \beta \dot{m} \overline{V} - \sum_{out} \beta \dot{m} \overline{V} \\ &= \dot{m}V_{in} - \dot{m}V_{out} \\ &= (\rho A V_{in})(V_{in}) - (\rho A V_{out})(V_{out}) \\ &= \left[\rho A (V_{in})^2\right] - \left[\rho A (V_{out})^2\right] \end{aligned}$$

Step 4 of 4

Substitute $1.5V$ for V_{in} and 0 for V_{out}.

$$\begin{aligned} F_R &= \rho A (1.5V)^2 - 0 \\ &= 2.25\rho A V^2 \end{aligned}$$

Therefore, the force required to move the plate towards the jet is $\boxed{2.25\rho A V^2}$.

Question: 13.020P

A 90° elbow in a horizontal pipe is used to direct water flow upward at a rate of 30 kg/s. The diameter of the entire elbow is 10 cm. The elbow discharges water into the atmosphere, and thus the pressure at the exit is the local atmospheric pressure. The elevation difference between the centers of the exit and the inlet of the elbow is 40 cm. The weight of the elbow and the water in it is considered to be negligible. Determine (*a*) the gage pressure at the center of the inlet of the elbow and (b) the anchoring force needed to hold the elbow in place. Take the momentum-flux correction factor to be 1.03 at both the inlet and the outlet.

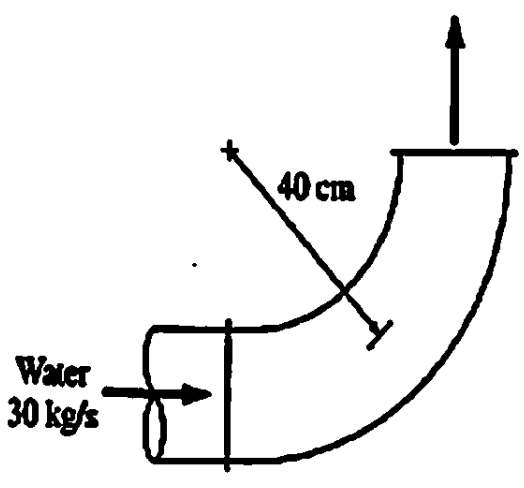

FIGURE P13–20

Step 1 of 8

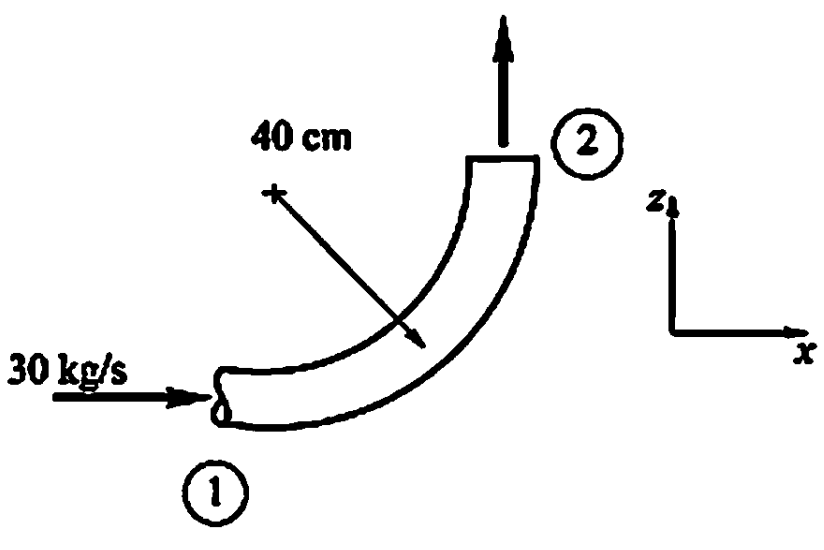
Given data:

The upward flow rate, $\dot{m}_1 = 30\ \text{kg/s}$

The diameter of the elbow, $D = 10\text{cm} = 0.1\text{m}$

The momentum-flux correction factor for each inlet and outlet, $\beta = 1.03$

Step 2 of 8



Assumptions:

1. The flow is steady, frictionless, incompressible, and irrotational.
2. Water is discharged to the atmosphere, and thus the gage pressure at the outlet is zero.
3. The weight of the elbow and the water in it is negligible.

Properties: Take the density of water as 1000 kg/m^3.

Step 3 of 8

A 90^0 elbow is as shown in figure:

Step 4 of 8

(a)

Consider elbow as the control volume.

Now, the inlet is at point 1 and the outlet at point 2.

Since the flow is steady, we have

$\dot{m}_1 = \dot{m}_2 = \dot{m} = 30\ \text{kg/s}$

Mass flow rate,

$\dot{m} = \rho V A$

$$V = \frac{\dot{m}}{\rho\left(\frac{\pi D^2}{4}\right)}$$

$$= \frac{30\ \text{kg/s}}{(1000\ \text{kg/m}^3)\frac{\pi(0.1\ \text{m})^2}{4}}$$

$V = 3.82\ \text{m/s}$

Step 5 of 8

The mean inlet and outlet velocities of water, $V = V_1 = V_2 = 3.82\ \text{m/s}$

From Bernoulli's equation, we have

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$P_1 - P_2 = \rho g(z_2 - z_1)$$

Hence gage pressure at section 1, we have

$$P_{1\text{gage}} = \rho g(z_2 - z_1)$$

$$= (1000\ \text{kg/m}^3)(9.81\ \text{m/s}^2)(0.4\ \text{m})\left(\frac{1\ \text{kN}}{1000\ \text{kg}\cdot\text{m/s}^2}\right)$$

$$= 3.924\ \text{kN/m}^2$$

$$= 3.924\ \text{kPa}$$

Thus, the gage pressure, $\boxed{P_{1\text{gage}} = 3.92\ \text{kPa}}$

Step 6 of 8

(b)

Let the anchoring force of the elbow in x direction be F_{Rx} and anchoring force of the elbow in z direction be F_{Rz}

The momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}.$$

Now, the components of the equation in x direction,

$$F_{Rx} + P_{1\text{gage}} A_1 = 0 - \beta \dot{m}(+V_1)$$

$$= -\beta \dot{m}(+V_1)$$

On substituting the known values in the above equation, we have

$$F_{Rx} = -\beta \dot{m}(+V_1) - P_{1\text{gage}} A_1$$

$$= -1.03(30\ \text{kg/s})(3.82\ \text{m/s})\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) - (3924\ \text{N/m}^2)\frac{\pi(0.1\ \text{m})^2}{4}$$

$$= -118.038\ \text{N} - 30.819\ \text{N}$$

$$= -148.86\ \text{N}$$

Step 7 of 8

The components of the equation in z direction,

$$F_{Rz} = \beta \dot{m}(+V_2)$$

$$= \beta \dot{m} V_2$$

Substituting the known values in the above equation, we have

$$F_{Rz} = \beta \dot{m} V_2$$

$$= 1.03(30\ \text{kg/s})(3.81\ \text{m/s})\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right)$$

$$= 117.729\ \text{N}$$

Step 8 of 8

The resultant force of the given system, we have

$$F_R = \sqrt{F_{Rx}^2 + F_{Rz}^2}$$

$$= \sqrt{(-148.86)^2 + 117.729^2}$$

$$= 189.78\ \text{N}$$

The angle for the force acting in the positive x direction,

$$\theta = \tan^{-1}\left(\frac{F_{Rz}}{F_{Rx}}\right)$$

$$= \tan^{-1}\left(\frac{117.729}{-148.86}\right)$$

$$= -38.34^\circ$$

Therefore, the anchoring force, $\boxed{F_R = 189.78\ \text{N}}$

The force is acting at an angle $\boxed{141.66^\circ}$ from the positive x direction.

Question: 13.021P

Repeat Prob. 13-20 for the case of another (identical) elbow attached to the existing elbow so that the fluid makes a U-turn.

Step 1 of 7

Given data:

The upward flow rate, $\dot{m}_1 = 30\ \text{kg/s}$

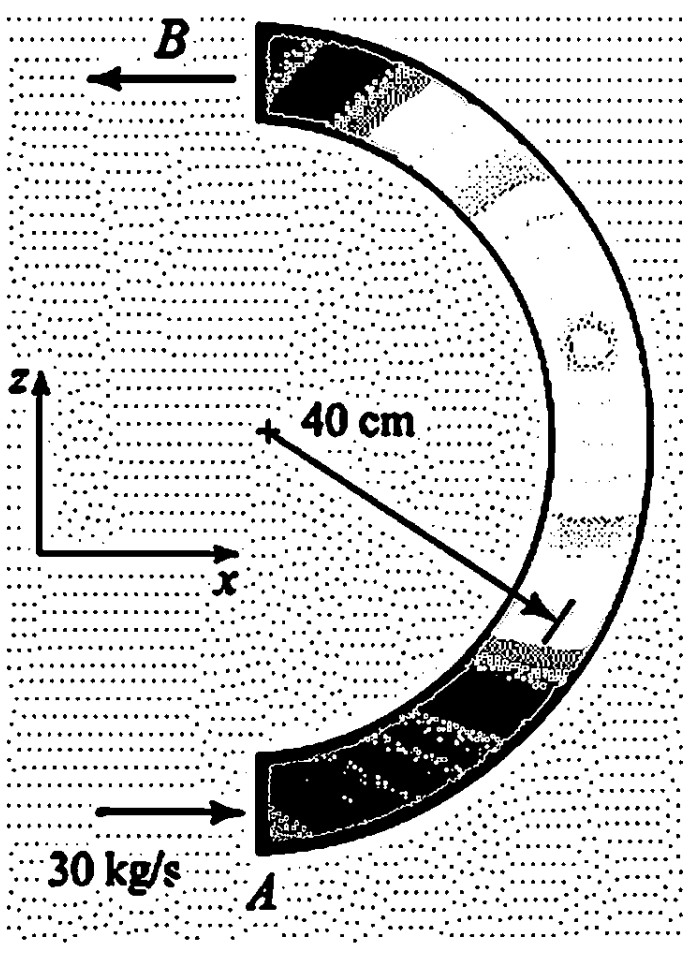
The diameter of the elbow, $D = 10\text{cm} = 0.1\text{m}$

The momentum-flux correction factor for each inlet and outlet, $\beta = 1.03$

Density of water is taken as $1000\ \text{kg/m}^3$

Step 2 of 7

Assumptions:



A. The flow is steady, frictionless, incompressible, irrotational and one dimensional.

B. Water is discharged to the atmosphere, and thus the gage pressure at the outlet is zero.

C. The weight of the elbow and the water in it is negligible.

Step 3 of 7

Figure showing the elbow bend,

Step 4 of 7

a) Let us consider the elbow as a control volume and water enters at point A and the outlet at point B.

Now, $\dot{m}_1 = \dot{m}_2 = \dot{m} = 30\ \text{kg/s}$, since the flow is steady.

And mass flow rate is given by, $\dot{m} = \rho VA$

Calculating volume;

$$V = \frac{\dot{m}}{\rho\left(\frac{\pi D^2}{4}\right)}$$

$$= \frac{30\ \text{kg/s}}{\left(1000\ \text{kg/m}^3\right)\frac{\pi(0.1\ \text{m})^2}{4}}$$

The volume, $V = 3.82\ \text{m/s}$

Step 5 of 7

The mean inlet and outlet velocities of water are $V = V_1 = V_2 = 3.81\ \text{m/s}$.

Using the Bernoulli's equation,

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$P_1 - P_2 = \rho g(z_2 - z_1)$$

Thus,

$$P_{\text{gage}} = \rho g(z_2 - z_1)$$

$$= \left(1000\ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right)(0.8\ \text{m})\left(\frac{1\ \text{kN}}{1000\ \text{kg}\cdot\text{m/s}^2}\right)$$

$$= 7.848\ \text{kN/m}^2$$

$$= 7.848\ \text{kPa}$$

Thus, the gage pressure is $\boxed{P_{\text{gage}} = 7.85\ \text{kPa}}$.

Step 6 of 7

b)

Let the anchoring force of the elbow in x direction be F_{Rx} and anchoring force of the elbow in z direction be F_{Rz}. The momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m}\vec{V} - \sum_{in} \beta \dot{m}\vec{V}.$$

Step 7 of 7

The components of the equation in x direction is

$$F_{Rx} + P_{\text{gage}}A_1 = \beta \dot{m}(-V_2) - \beta \dot{m}(+V_1)$$

$$= -2\beta \dot{m}V$$

$$F_{Rx} = -2\beta \dot{m}V - P_{\text{gage}}A_1$$

$$= -2(1.03)(30\ \text{kg/s})(3.82\ \text{m/s})\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) - \left(7848\ \text{N/m}^2\right)\frac{\pi(0.1\ \text{m})^2}{4}$$

$$= -236.058\ \text{N} - 61.63\ \text{N}$$

$$= -297.688\ \text{N}$$

The components of the equation in z direction is zero thus, $F_{Rz} = 0$. Thus

$$F_R = F_{Rx} = -297.688\ \text{N}$$

Therefore, the anchoring force is $\boxed{F_R = 298\ \text{N}}$. The force is acting at negative x direction.

Question: 13.022P

A horizontal water jet impinges against a vertical flat plate at 25 ft/s and splashes off the sides in the vertical plane. If a horizontal force of 350 lbf is required to hold the plate against the water stream, determine the volume flow rate of the water.

Step 1 of 3

Given data:

The mass flow rate of water, $\dot{m} = 25\,\text{ft/s}$

The horizontal force required to hold the plate against the water stream,

$$\begin{aligned} F_{Rx} &= 350\,\text{lbf} \\ &= 350 \times 32.2 \quad \left(\text{since}, 1\,\text{lbf} = 32.2\,\text{lbm}\cdot\text{ft/s}^2\right) \\ &= 11270\,\text{lbm}\cdot\text{ft/s}^2 \end{aligned}$$

The density of water, $\rho = 62.4\,\text{lbm/ft}^3$

Step 2 of 3

By using moment equation for steady one-dimensional flow in x -direction, we get

$$\sum F = \sum_{\text{out}} \beta \dot{m} V - \sum_{\text{in}} \beta \dot{m} V$$

$$-F_{Rx} = -\dot{m} V_1$$

$$F_{Rx} = \dot{m} V_1$$

$$\dot{m} = \frac{F_{Rx}}{V_1}$$

$$= \frac{11270}{25}$$

$$= 450.8\,\text{ft/s}$$

Step 3 of 3

By using the formula for volume flow rate, we get

$$\dot{V} = \frac{\dot{m}}{\rho}$$

$$= \frac{450.8}{62.4}$$

$$= 7.224\,\text{ft}^3/\text{s}$$

Therefore, the volume flow rate, $\boxed{\dot{V} = 7.224\,\text{ft}^3/\text{s}}$.

Question: 13.023P

A reducing elbow in a horizontal pipe is used to deflect water flow by an angle $\theta = 45°$ from the flow direction while accelerating it. The elbow discharges water into the atmosphere. The cross-sectional area of the elbow is 150 cm2 at the inlet and 25 cm2 at the exit. The elevation difference between the centers of the exit and the inlet is 40 cm. The mass of the elbow and the water in it is 50 kg. Determine the anchoring force needed to hold the elbow in place. Take the momentum- flux correction factor to be 1.03 at both the inlet and outlet.

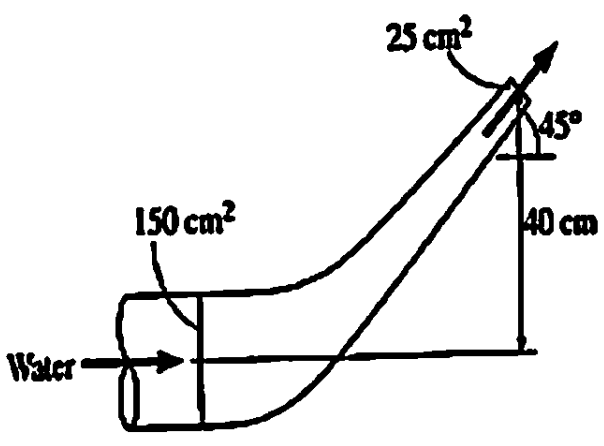


FIGURE P13–23

Step 1 of 8

Given data:-

The cross sectional area at inlet is $A_1 = 150\ \text{cm}^2 = 0.015\text{m}^2$.

The cross sectional area at exit is $A_1 = 25\ \text{cm}^2 = 0.0025\text{m}^2$.

The elevation difference is $z_2 - z_1 = 40\,\text{cm} = 0.4\,\text{m}$.

The angle is $\theta = 45°$.

The mass of elbow and the water in it is $m = 50\ \text{kg}$.

The momentum-flux correction factor for each inlet and outlet is $\beta = 1.03$.

Step 2 of 8

Assumptions

1. The flow is steady, frictionless, incompressible, and irrotational.
2. Water is discharged to the atmosphere, and thus the gage pressure at the outlet is zero.
3. Let the mass flow rate be $\dot{m} = 30\ \text{kg/s}$

Properties: Take the density of water as $1000\ \text{kg/m}^3$.

Step 3 of 8

Take the elbow as the control volume. Now, the inlet is at point 1 and the outlet at point 2.

Now, $\dot{m}_1 = \dot{m}_2 = \dot{m} = 30\ \text{kg/s}$,

Since the flow is steady. Also, $\dot{m} = \rho VA$.

Now, the inlet velocity is

$$V_1 = \frac{\dot{m}}{\rho A_1}$$

$$= \frac{30\ \text{kg/s}}{(1000\ \text{kg/m}^3)(0.015\ \text{m}^2)}$$

$$= 2\ \text{m/s}$$

Now, the outlet velocity is

$$V_2 = \frac{\dot{m}}{\rho A_2}$$

$$= \frac{30\ \text{kg/s}}{(1000\ \text{kg/m}^3)(0.0025\ \text{m}^2)}$$

$$= 12\ \text{m/s}$$

Step 4 of 8

Now, use Bernoulli's equation,

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$P_1 - P_2 = \rho g\left[\frac{V_2^2 - V_1^2}{2g} + (z_2 - z_1)\right]$$

Thus,

$$P_{1,\text{gage}} = \rho g\left[\frac{V_2^2 - V_1^2}{2g} + (z_2 - z_1)\right]$$

$$= (1000\ \text{kg/m}^3)(9.81\ \text{m/s}^2)\left[\frac{(12\ \text{m/s})^2 - (2\ \text{m/s})^2}{2(9.81\ \text{m/s}^2)} + 0.4\right]\left(\frac{1\,\text{kN}}{1000\ \text{kg}\cdot\text{m/s}^2}\right)$$

$$= 73.92\ \text{kN/m}^2$$

$$= 73.92\ \text{kPa}$$

Step 5 of 8

Let the anchoring force of the elbow in x direction be F_{Rx} and anchoring force of the elbow in z direction be F_{Rz}. Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m}\vec{V} - \sum_{in} \beta \dot{m}\vec{V}.$$

Now, the components of the equation in x direction is

$$F_{Rx} + P_{1,\text{gage}} A_1 = \beta \dot{m} V_2 \cos\theta - \beta \dot{m} V_1$$

$$F_{Rx} = \beta \dot{m}(V_2 \cos\theta - V_1) - P_{1,\text{gage}} A_1$$

$$= 1.03(30\ \text{kg/s})\left[(12\ \text{m/s})\cos 45° - 2\ \text{m/s}\right]\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) - (73920\ \text{N/m}^2)(0.015)$$

$$= 200.40\ \text{N} - 1108.8\ \text{N}$$

$$= -908.4\ \text{N}$$

Step 6 of 8

Now, the components of the equation in z direction is

$$F_{Rz} - W = \beta \dot{m} V_2 \sin\theta$$

$$F_{Rz} = \beta \dot{m} V_2 \sin\theta + W$$

Now, weight of the elbow and the water in it is

$$W = mg$$

$$= (50\ \text{kg})(9.81\ \text{m/s}^2)$$

$$= 490.5\ \text{N}$$

Step 7 of 8

Now, substitute the known values and solve F_{Rx}.

$$F_{Rx} = 1.03(30\ \text{kg/s})\left[(12\ \text{m/s})\sin 45°\right]\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) + (490.5\ \text{N})$$

$$= 752.69\ \text{N}$$

Now,

The resultant force

$$F_R = \sqrt{F_{Rx}^2 + F_{Rz}^2}$$

$$= \sqrt{(-908.4)^2 + (752.69)^2}$$

$$= 1179.72\ \text{N}$$

Step 8 of 8

Now, the angle,

$$\theta = \tan^{-1}\left(\frac{F_{Rz}}{F_{Rx}}\right)$$

$$= \tan^{-1}\left(\frac{752.69}{-908.4}\right)$$

$$= -39.64°$$

Therefore, the anchoring force is $\boxed{F_R = 1179.72\ \text{N}}$. The force is acting at an angle $\boxed{140.36°}$ from the positive x direction.

Question: 13.024P

Repeat Prob. 13-23 for the case of $\theta = 110°$.

Step 1 of 8

Given data:-

The cross sectional area at inlet is $A_1 = 150\ \text{cm}^2 = 0.015\,\text{m}^2$.

The cross sectional area at exit is $A_1 = 25\ \text{cm}^2 = 0.0025\,\text{m}^2$.

The elevation difference is $z_2 - z_1 = 40\,\text{cm} = 0.4\,\text{m}$.

The angle is $\theta = 110°$.

The mass of elbow and the water in it is $m = 50\ \text{kg}$.

The momentum-flux correction factor for each inlet and outlet is $\beta = 1.03$.

Step 2 of 8

Assumptions

1. The flow is steady, frictionless, incompressible, and irrotational.
2. Water is discharged to the atmosphere, and thus the gage pressure at the outlet is zero.
3. Let the mass flow rate be $\dot{m} = 30\ \text{kg/s}$

Properties: Take the density of water as $1000\ \text{kg/m}^3$.

Step 3 of 8

Take the elbow as the control volume. Now, the inlet is at point 1 and the outlet at point 2.

Now, $\dot{m}_1 = \dot{m}_2 = \dot{m} = 30\ \text{kg/s}$, since the flow is steady. Also, $\dot{m} = \rho V A$.

Now, the inlet velocity is

$$V_1 = \frac{\dot{m}}{\rho A_1}$$

$$= \frac{30\ \text{kg/s}}{(1000\ \text{kg/m}^3)(0.015\ \text{m}^2)}$$

$$= 2\ \text{m/s}$$

Now, the outlet velocity is

$$V_2 = \frac{\dot{m}}{\rho A_2}$$

$$= \frac{30\ \text{kg/s}}{(1000\ \text{kg/m}^3)(0.0025\ \text{m}^2)}$$

$$= 12\ \text{m/s}$$

Step 4 of 8

Now, use Bernoulli's equation,

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$P_1 - P_2 = \rho g\left[\frac{V_2^2 - V_1^2}{2g} + (z_2 - z_1)\right]$$

Thus,

$$P_{1,\text{gage}} = \rho g\left[\frac{V_2^2 - V_1^2}{2g} + (z_2 - z_1)\right]$$

$$= (1000\ \text{kg/m}^3)(9.81\ \text{m/s}^2)\left[\frac{(12\ \text{m/s})^2 - (2\ \text{m/s})^2}{2(9.81\ \text{m/s}^2)} + 0.4\right]\left(\frac{1\,\text{kN}}{1000\ \text{kg}\cdot\text{m/s}^2}\right)$$

$$= 73.92\ \text{kN/m}^2$$

$$= 73.92\ \text{kPa}$$

Step 5 of 8

Let the anchoring force of the elbow in x direction be F_{Rx} and anchoring force of the elbow in z direction be F_{Rz}. Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}.$$

Now, the components of the equation in x direction is

$$F_{Rx} + P_{1,\text{gage}} A_1 = \beta \dot{m} V_2 \cos\theta - \beta \dot{m} V_1$$

$$F_{Rx} = \beta \dot{m}(V_2 \cos\theta - V_1) - P_{1,\text{gage}} A_1$$

$$= 1.03(30\ \text{kg/s})\left[(12\ \text{m/s})\cos 110° - 2\ \text{m/s}\right]\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) - (73920\ \text{N/m}^2)(0.015)$$

$$= -188.62\ \text{N} - 1108.8\ \text{N}$$

$$= -1297.42\ \text{N}$$

Step 6 of 8

Now, the components of the equation in z direction is

$$F_{Rz} - W = \beta \dot{m} V_2 \sin\theta$$

$$F_{Rz} = \beta \dot{m} V_2 \sin\theta + W$$

Now, weight of the elbow and the water in it is

$$W = mg$$

$$= (50\ \text{kg})(9.81\ \text{m/s}^2)$$

$$= 490.5\ \text{N}$$

Step 7 of 8

Now, substitute the known values and solve F_{Rz}.

$$F_{Rz} = 1.03(30\ \text{kg/s})\left[(12\ \text{m/s})\sin 110°\right]\left(\frac{1\ \text{N}}{1\ \text{kg}\cdot\text{m/s}^2}\right) + (490.5\ \text{N})$$

$$= 838.94\ \text{N}$$

Now,

The resultant force

$$F_R = \sqrt{F_{Rx}^2 + F_{Rz}^2}$$

$$= \sqrt{(-1297.42)^2 + (838.94)^2}$$

$$= 1545.03\ \text{N}$$

Step 8 of 8

Now, the angle,

$$\theta = \tan^{-1}\left(\frac{F_{Rz}}{F_{Rx}}\right)$$

$$= \tan^{-1}\left(\frac{838.94}{-1297.42}\right)$$

$$= -32.89°$$

Therefore, the anchoring force is $\boxed{F_R = 1545\ \text{N}}$. The force is acting at an angle $\boxed{147°}$ from the positive x direction.

Question: 13.025P

Water accelerated by a nozzle to 20 m/s strikes the vertical back surface of a cart moving horizontally at a constant velocity of 5 m/s in the flow direction. The mass flow rate of water through the stationary nozzle is 30 kg/s. After the strike, the water stream splatters off in all directions in the plane of the back surface, (*a*) Determine the force that needs to be applied by the brakes of the cart to prevent it from accelerating. (*b*) If this force were used to generate power instead of wasting it on the brakes, determine the maximum amount of power that could ideally be generated.

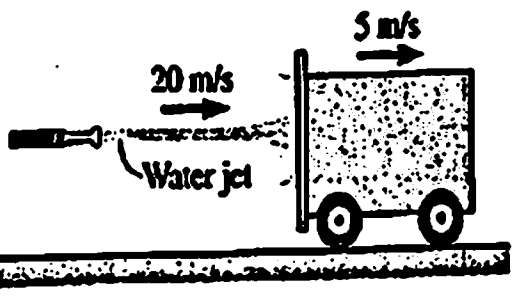

FIGURE P13–25

Step 1 of 5

Given data:-

The velocity of water, $v_{jet} = 20\ \text{m/s}^2$

The velocity of the cart, $v_{cart} = 5\ \text{m/s}^2$

The mass flow rate, $\dot{m}_{jet} = 30\ \text{kg/s}$

Step 2 of 5

Assumptions are

1. The flow is steady, frictionless and incompressible.
2. Water is discharged to the atmosphere, and thus it is not considered.
3. The flow is jet flow so the momentum-flux correction factor is unity.
4. Neglect the friction.

Step 3 of 5

Consider the cart as the control volume.

The relative velocity between cart and the water jet,

$$\begin{aligned} V_r &= V_{jet} - V_{cart} \\ &= (20\ \text{m/s}) - (5\ \text{m/s}) \\ &= 15\ \text{m/s} \end{aligned}$$

The mass flow rate with respect to the relative velocity is

$$\begin{aligned} \dot{m}_r &= \frac{V_r}{V_{jet}} \dot{m}_{jet} \\ &= \frac{15\ \text{m/s}}{20\ \text{m/s}} (30\ \text{kg/s}) \\ &= 22.5\ \text{kg/s} \end{aligned}$$

Step 4 of 5

Let F_{Rx} be in positive x direction. Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}.$$

Thus, $F_{Rx} = \dot{m} V$. Now, the braking force is

$$\begin{aligned} F_{brake} &= -\dot{m}_r V_r \\ &= -(22.5\ \text{kg/s})(15\ \text{m/s}) \left(\frac{1\ \text{N}}{1\ \text{kg} \cdot \text{m/s}^2} \right) \\ &= -337.5\ \text{N} \end{aligned}$$

Therefore, the braking force is $\boxed{F_{brake} = -338\ \text{N}}$

Step 5 of 5

Power dissipated by the brake is

$$\begin{aligned} P &= F_{brake} V_{cart} \\ &= (337.5\ \text{N})(5\ \text{m/s}) \\ &= 1687.5\ \text{N} \cdot \text{m/s} \\ &= 1687.5\ \text{W} \end{aligned}$$

Therefore, the maximum power that could be generated is $\boxed{P = 1.69\ \text{kW}}$

Question: 13.026P

Reconsider Prob.13-25 .If the mass of the cart is 400 kg and the brakes fail, determine the acceleration of the cart when the water first strikes it.Assume the mass of water that wets the back surface is negligible.

Step 1 of 4

Given data:

The velocity of water, $v_{jet} = 20\ \text{m/s}^2$

The velocity of the cart, $v_{cart} = 5\ \text{m/s}^2$

The mass flow rate, $\dot{m}_{jet} = 30\ \text{kg/s}$

The mass of the cart, $m = 400\ \text{kg}$

Step 2 of 4

Assumptions are

- The flow is steady, frictionless and incompressible.
- Water is discharged to the atmosphere, and thus the pressure is not considered.
- The flow is jet flow so the momentum-flux correction factor is unity.
- Neglect the friction.

Step 3 of 4

Consider the cart as the control volume.

Now, the relative velocity between cart and the water jet,

$$\begin{aligned} V_r &= V_{jet} - V_{cart} \\ &= (20\ \text{m/s}) - (5\ \text{m/s}) \\ &= 15\ \text{m/s} \end{aligned}$$

Now, the mass flow rate with respect to the relative velocity is

$$\begin{aligned} \dot{m}_r &= \frac{V_r}{V_{jet}} \dot{m}_{jet} \\ &= \frac{15\ \text{m/s}}{20\ \text{m/s}} (30\ \text{kg/s}) \\ &= 22.5\ \text{kg/s} \end{aligned}$$

Step 4 of 4

Let F_{Rx} be in positive x direction. Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}.$$

Thus,

$$\begin{aligned} F_{Rx} &= \dot{m}_r V_r \\ &= (22.5\ \text{kg/s})(15\ \text{m/s}) \left(\frac{1\ \text{N}}{1\ \text{kg} \cdot \text{m/s}^2} \right) \\ &= 337.5\ \text{N} \end{aligned}$$

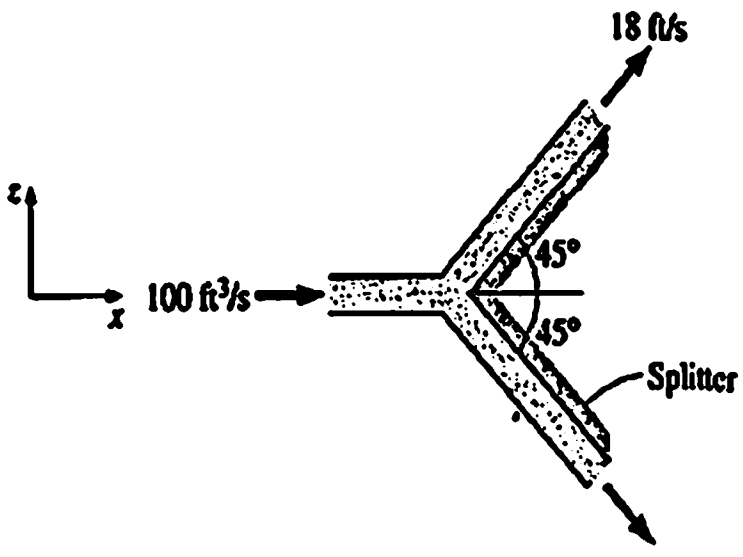
Now, as the break fails the force of the water jet will accelerate the cart. Thus, the acceleration is

$$\begin{aligned} a &= \frac{F}{m_{cart}} \\ &= \frac{337.5\ \text{N}}{400\ \text{kg}} \\ &= 0.8437\ \text{m/s}^2 \end{aligned}$$

Therefore, the acceleration of the cart is $\boxed{a = 0.844\ \text{m/s}^2}$.

Question: 13.027P pg 1

A 100-ft3/s water jet is moving in the positive *x*-direction at 18 ft/s. The stream hits a stationary splitter such that half of the flow is diverted upward at 45° and the other half is directed downward, and both streams have a final speed of 18 ft/s. Disregarding gravitational effects, determine the *x*- and *z*-components of the force required to hold the splitter in place against the water force.



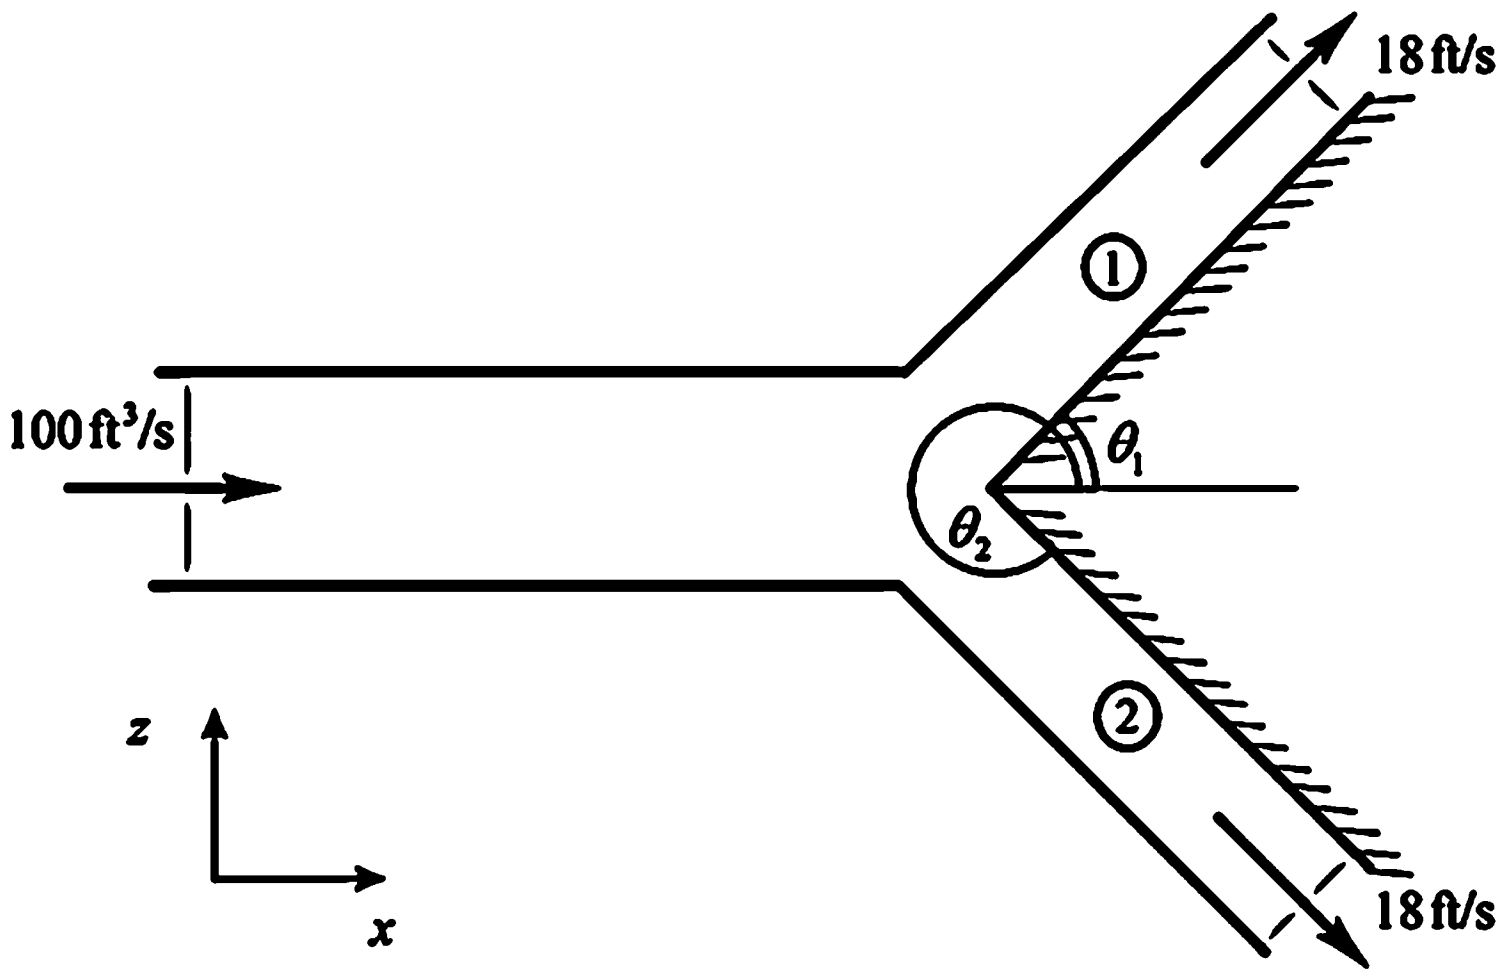


FIGURE P13–27E

Step 1 of 7

Draw the Figure that showing flow of water through the channel,

Step 2 of 7

Find the mass flow rate at the entrance of the channel,

$\dot{m} = \rho \dot{V}$

Here, density of water is denoted as ρ and, velocity of flow as $\dot{v}$.

Substitute $62.37\,\text{lb/ft}^3$ for ρ and, $100\,\text{ft}^3/\text{s}$ for $\dot{v}$ in the equation,

$$\begin{aligned}\dot{m} &= \rho \dot{V} \\ &= 62.37 \times 100 \\ &= 62.37 \times 10^2\ \text{lb/s}\end{aligned}$$

Step 3 of 7

Since the bifurcated channels are identical the mass flow rates are equal in both the sections.

$\dot{m}_1 = \dot{m}_2$

Here, mass flow rate of the section 1 is $\dot{m}_1$ and, mass flow rate of the section 2 is $\dot{m}_2$.

The flow is considered to be steady state, frictionless and the fluid to be incompressible. Applying the law of conservation of mass to the flow,

$$\begin{aligned}\dot{m} &= \dot{m}_1 + \dot{m}_2 \\ &= 2\dot{m}_1 \qquad (\text{since, } \dot{m}_1 = \dot{m}_2) \\ \dot{m}_1 &= \frac{1}{2}\dot{m}\end{aligned}$$

Step 4 of 7

Apply the momentum equation for steady one-dimensional flow,

$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}$.

Consider the momentum equations along the $x-$ axis,

$F_{Rx} = \dot{m}_1 V_1 \cos\theta_1 + \dot{m}_2 V_2 \cos\theta_2 - \dot{m} V$

Here, mass flow rate before hitting the splitter is $\dot{m}$, velocity of flow before hitting the splitter is V , mass flow rate channel 1 is $\dot{m}_1$, velocity of flow channel 1 is V_1 , angle my the split channel 1 with horizontal is θ_1 , mass flow rate channel 2 is $\dot{m}_2$, velocity of flow channel 2 is V_2 and, angle my the split channel 2 with horizontal is θ_2 .

Step 5 of 7

On simplification of above equation,

$$\begin{aligned}F_{Rx} &= \dot{m}_1 V_1 \cos\theta_1 + \dot{m}_2 V_2 \cos\theta_2 - \dot{m} V \\ &= \frac{\dot{m}}{2} V_1 \cos\theta_1 + \frac{\dot{m}}{2} V_2 \cos\theta_2 - \dot{m} V \qquad \left(\text{since, } \dot{m}_1 = \dot{m}_2 = \frac{\dot{m}}{2}\right) \\ &= \left(\frac{1}{2}\dot{m}\right) V \left(\cos\theta_1 + \cos\theta_2\right) - \dot{m} V \qquad (\text{also, } V_1 = V_2 = V)\end{aligned}$$

$$F_{Rx} = \dot{m} V \left[\frac{\left(\cos\theta_1 + \cos\theta_2\right)}{2} - 1\right] \quad \ldots\ldots (1)$$

Step 6 of 7

$F_{Rx} = \dot{m}V\left[\frac{(\cos\theta_1+\cos\theta_2)}{2}-1\right]$ 13(1027P pg 2

Step 6 of 7

Substitute 62.37×10^2 lb/s for $\dot{m}$, 45° for θ_1, 315° for θ_2 and, 18 ft/s^2 and V in the equation (1),

$$F_{Rx} = \dot{m}V_1\left[\frac{(\cos\theta_1+\cos\theta_2)}{2}-1\right]$$
$$= 62.37\times10^2\times18\times\left[\frac{(\cos45°+\cos315°)}{2}-1\right]$$
$$= 62.37\times10^2\times18\times[0.707-1]$$
$$= -32{,}893.938 \text{ lb}$$

Therefore, the force required in *x*-direction to keep the splitter in position is $\boxed{32{,}893.938 \text{ lb}}$ (the opposite direction of the water jet)

Apply the momentum equation for steady one-dimensional flow,

$$\sum\vec{F} = \sum_{out}\beta\dot{m}\vec{V} - \sum_{in}\beta\dot{m}\vec{V}.$$

Consider the momentum equations along the z– axis,

$$F_{Rz} = (\dot{m}_1V_1\sin\theta_1 + \dot{m}_2V_2\sin\theta_2) - 0$$
$$= \frac{\dot{m}}{2}V_1\sin\theta_1 + \frac{\dot{m}}{2}V_2\sin\theta_2 \qquad \left(\text{since}, \dot{m}_1 = \dot{m}_2 = \frac{\dot{m}}{2}\right)$$
$$= \frac{\dot{m}}{2}V_1\sin\theta_1 + \frac{\dot{m}}{2}V_1\sin\theta_2 \qquad (\text{also}, V_1 = V_2)$$

$$= \frac{\dot{m}}{2}V_1(\sin\theta_1+\sin\theta_2) \quad \text{..... (2)}$$

Here, mass flow rate channel 1 is $\dot{m}_1$, velocity of flow channel 1 is V_1, angle my the split channel 1 with horizontal is θ_1, mass flow rate channel 2 is $\dot{m}_2$, velocity of flow channel 2 is V_2 and, angle my the split channel 2 with horizontal is θ_2.

Step 7 of 7

Substitute 62.37×10^2 lb/s for $\dot{m}$, 45° for θ_1, 315° for θ_2 and, 18 ft/s for V_1 in the equation(2).

$$F_{Rz} = \frac{\dot{m}}{2}V_1(\sin\theta_1+\sin\theta_2)$$
$$= \frac{62.37\times10^2}{2}\times18\times(\sin45°+\sin315°)$$
$$= \frac{62.37\times10^2}{2}\times18\times(0.7071-0.7071)$$
$$= 0$$

There is no force required in *z*-axis direction. Since, the bifurcated forces are equal and opposite in direction to each other.

Question: 13.028P

Reconsider Prob. 13-27E. Using EES (or other) software, investigate the effect of the splitter angle on the force exerted on the splitter in the incoming flow direction. Let the half splitter angle vary from 0° to 180° in increments of 10°. Tabulate and plot your results, and draw some conclusions.

Step 1 of 7

Given data:

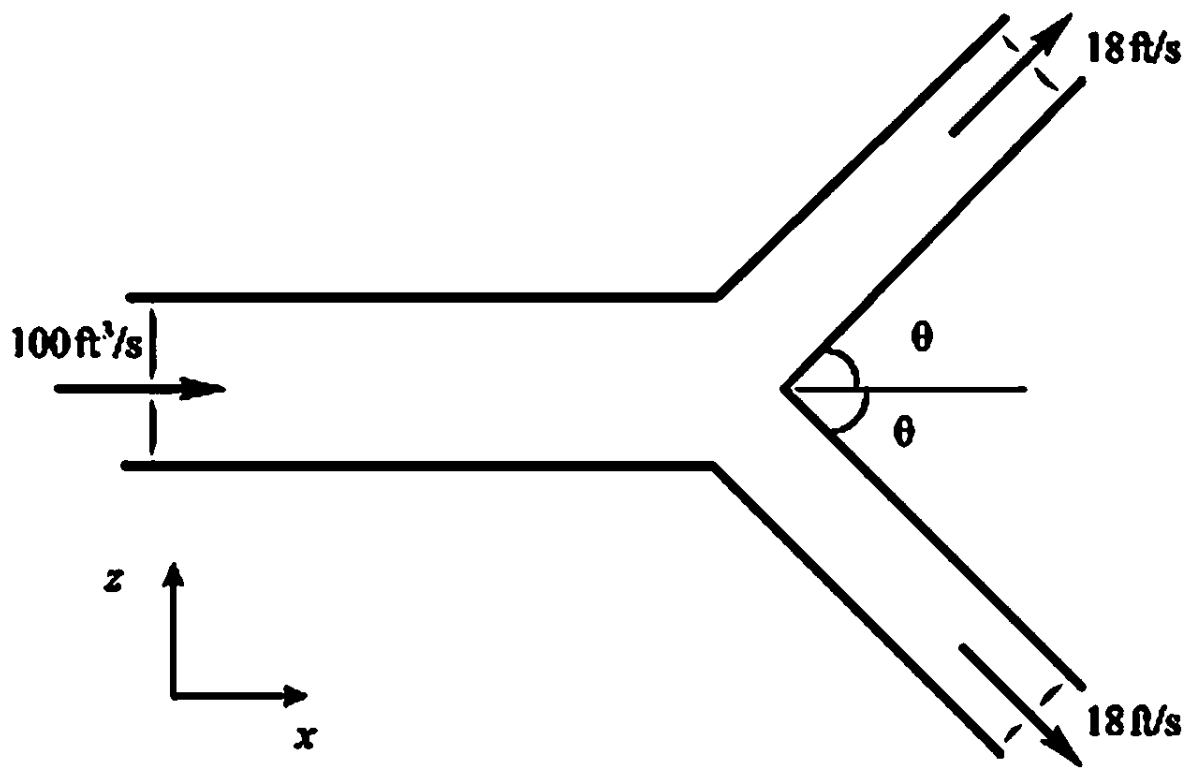
The velocity of water, $V_1 = 18\ \text{ft/s}^2$

The velocity of water in the splitter, $V_2 = 18\ \text{ft/s}^2$

The angle varies form, $\theta = 0°\text{to}180°$

The discharge, $\dot{V} = 100\text{ft}^3/s$

The density of water, $\rho = 62.37\text{lb/ft}^3$.



Step 2 of 7

Assumptions are

1. The flow is steady, frictionless and incompressible.
2. Water is discharged to the atmosphere, and thus the pressure is not considered.
3. The flow is jet flow so the momentum-flux correction factor is unity.

Step 3 of 7

Given figure is,

Step 4 of 7

Splitter is taken as the control volume. We have,

The mass flow rate is given by, $\dot{m}_2 = \frac{1}{2}\dot{m}$

Now, the mass flow rate of water,

$$\dot{m} = \rho\dot{V}$$
$$= 62.37 \times 1000$$
$$= 62.37 \times 10^3\ \text{lb/s}$$

Step 5 of 7

Now, the momentum equation for steady one-dimensional flow,

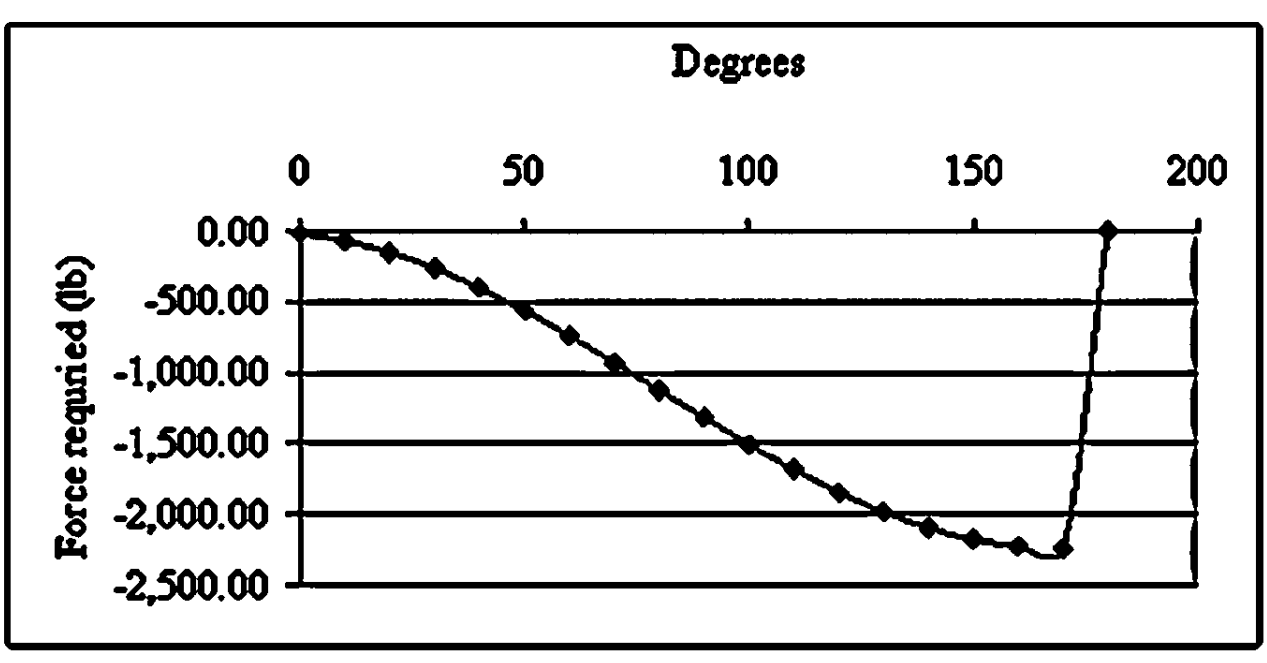
$$\sum \vec{F} = \sum_{out} \beta\dot{m}\vec{V} - \sum_{in} \beta\dot{m}\vec{V}.$$

Thus, the momentum equations along the x - axis is

$$F_{Rx} = 2\dot{m}_2 V_2 \cos\theta - \dot{m}V_1$$
$$= 2\left(\frac{1}{2}\dot{m}\right)V_2 \cos\theta - \dot{m}V_1$$
$$= \dot{m}(V_2 \cos\theta - V_1)$$

Step 6 of 7

Now, substituting the known values, we get,



$$F_{Rx} = 62.37 \times 10^3 (18\cos\theta° - 18)$$

For various values of splitter angle the force required is tabulated below;

Splitter angle (degrees)	Force required (lb)
0	-17,069.43
10	-67,758.64
20	-150,526.24
30	-262,855.36
40	-401,330.18
50	-561,739.85
60	-739,206.48
70	-928,333.51
80	-1,123,369.80
90	-1,318,384.50
100	-1,507,447.43
110	-1,684,809.40
120	-1,845,077.03
130	-1,983,376.76
140	-2,095,503.04
150	-2,178,046.23
160	-2,228,496.30
170	-2,245,319.10
180	0.00

Step 7 of 7

The Splitter angle versus Force required for holding the splitter is plotted on the graph show below:

The graph shows us the force required to apply on the splitter increases with the increase in angle.

Question: 13.029P

A horizontal 5-cm-diameter water jet with a velocity of 18 m/s impinges normally upon a vertical plate of mass 1000 kg. The plate rides on a nearly frictionless track and is initially stationary. When the jet strikes the plate, the plate begins to move in the direction of the jet. The water always splatters in the plane of the retreating plate. Determine (*a*) the acceleration of the plate when the jet first strikes it (time = 0), (*b*) the time it takes for the plate to reach a velocity of 9 m/s, and (*c*) the plate velocity 20 s after the jet first strikes the plate. For simplicity, assume the velocity of the jet is increased as the cart moves such that the impulse force exerted by the water jet on the plate remains constant.

Step 1 of 7

Given data: The diameter of the jet is $d = 5$ cm

The velocity of water is $V = 18$ m/s

The mass of the plate is $m_{plate} = 1000$ kg

The density of water is $1000\ \text{kg/m}^3$

Step 2 of 7

Assumptions are

- The flow is steady, frictionless and incompressible.
- Water is discharged to the atmosphere, and thus the pressure is not considered.
- The flow is jet flow so the momentum-flux correction factor is unity.
- The motion of water jet and the cart are horizontal.
- The relative velocity remains constant.

Step 3 of 7

a)

Take the vertical plate on the frictionless

Track as the control volume.

Now, the mass flow rate of water,

$$\dot{m} = \rho A V$$

$$= (1000\ \text{kg/m}^3)(18\ \text{m/s})\frac{\pi(0.05\ \text{m})^2}{4}$$

$$= 35.34\ \text{kg/s}$$

Step 4 of 7

Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}.$$

Thus, the momentum equations along the x - axis is

$$F_{flx} = -\dot{m}_i V_i$$

$$= -(35.34\ \text{kg/s})(18\ \text{m/s})$$

$$= -636.12\ \text{kg} \cdot \text{m/s}^2$$

$$= -636.12\ \text{N}$$

Step 5 of 7

Thus, the force on the plate is $F = -F_{flx} = 636.12$ N. Now, the initial acceleration of the plate,

$$a = \frac{F}{m_{plate}}$$

$$= \frac{636.12\ \text{kg} \cdot \text{m/s}^2}{1000\ \text{kg}}$$

$$= 0.636\ \text{m/s}^2$$

Therefore, the acceleration is $\boxed{a = 0.636\ \text{m/s}^2}$.

Step 6 of 7

b)

We know, $a = \frac{\Delta V}{\Delta t}$. Also,

The final velocity is given as 9 m/s. So,

$$\Delta t = \frac{(9\ \text{m/s} - 0)}{0.636\ \text{m/s}^2}$$

$$= 14.15\ \text{s}$$

Therefore, the time taken to reach the velocity of 9 m/s is $\boxed{t = 14.15\ \text{s}}$.

Step 7 of 7

c)

We know, $V_{final} = V_{initial} + at$. Also,

The time is given as 20 s.

Thus,

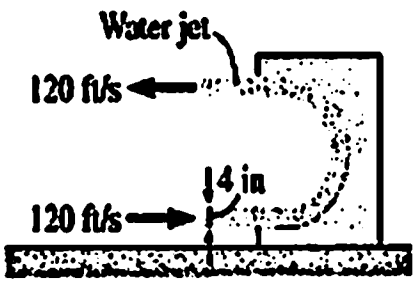
$$V_{final} = 0 + (0.636\ \text{m/s})(20\ \text{s})$$

$$= 12.7\ \text{m/s}$$

Therefore, the velocity of the plate after 20 s is $\boxed{V_{plate} = 12.7\ \text{m/s}}$.

Question: 13.030P

A 4-in-diameter horizontal water jet having a velocity of 120 ft/s strikes a curved plate, which deflects the water 180° at the same speed. Ignoring the frictional effects, determine the force required to hold the plate against the water stream.



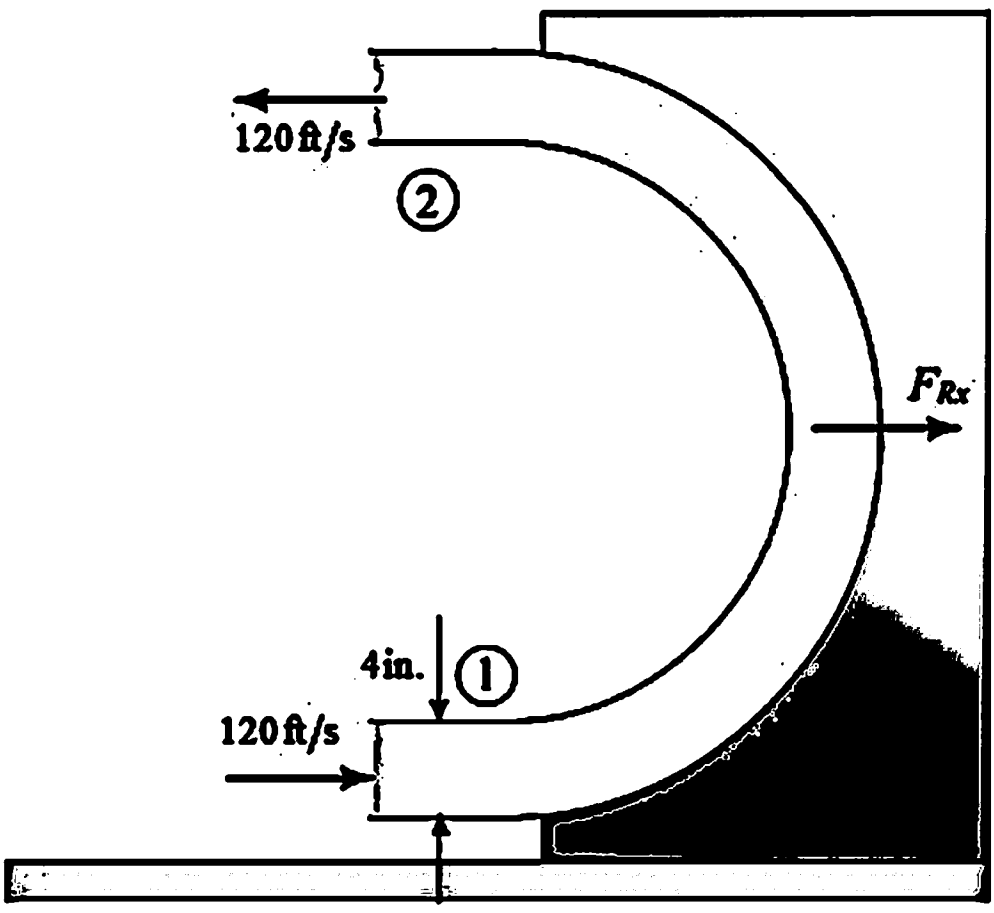


FIGURE P13–30E

Step 1 of 3

Draw the diagram that represents the horizontal water jet strikes on the curved plate.

Here, F_{Rx} is the force exerted by water on the curved plate.

Step 2 of 3

Assume mass flow rate remains constant at the entrance and leaving of the curved plate.

$$\dot{m} = \dot{m}_1 = \dot{m}_2$$

Find the mass flow rate of water by using the following equation:

$$\dot{m} = \rho V A$$

$$= \rho V \frac{\pi}{4} D^2$$

Here, ρ is density of water, V is velocity of water jet, A is the cross sectional area of the jet, and D is diameter of the jet.

Substitute $62.4\,\text{lbm/ft}^3$ for ρ , 120 ft/s for V, and $\frac{4}{12}$ ft for D.

$$\dot{m} = (62.4) \times (120) \times \frac{\pi \left(\frac{4}{12}\right)^2}{4}$$

$$= 653.45\,\text{lb/s}$$

Step 3 of 3

Apply the momentum equation for steady one-dimensional flow.

$$\sum \vec{F} = \sum_{\text{out}} \beta \dot{m} \vec{V} - \sum_{\text{in}} \beta \dot{m} \vec{V}$$

$$F_{Rx} = \beta \dot{m}(-V_2) - \beta \dot{m}(+V_1)$$

Here, β is the momentum correction factor, V_1 is the velocity of water jet at inlet in positive x direction, and V_2 is the velocity of water jet at outlet in negative x direction,

Substitute 1 for β, $653.45\,\text{lb/s}$ for $\dot{m}$, $120\,\text{ft/s}$ for V_1, V_2

$$F_{Rx} = \beta \dot{m}(-V_2) - \beta \dot{m}(V_1)$$

$$= \left(1 \times 653.45 \frac{\text{lbm}}{\text{s}} \times (-120) \frac{\text{ft}}{\text{s}} - 1 \times 653.45 \frac{\text{lbm}}{\text{s}} \times (120) \frac{\text{ft}}{\text{s}}\right) \times \frac{1\,\text{lbf}}{32.2\,\text{lbm.ft/s}^2}$$

$$= 4870.434\,\text{lbf}$$

Therefore, the force applied in the negative x direction to hold the curved plate is **4870.434 lbf**

Question: 13.031P

A 3-in-diameter horizontal jet of water, with velocity 140 ft/s, strikes a bent plate, which deflects the water by 135° from its original direction. How much force is required to hold the plate against the water stream and what is its direction? Disregard frictional and gravitational effects.

Step 1 of 5

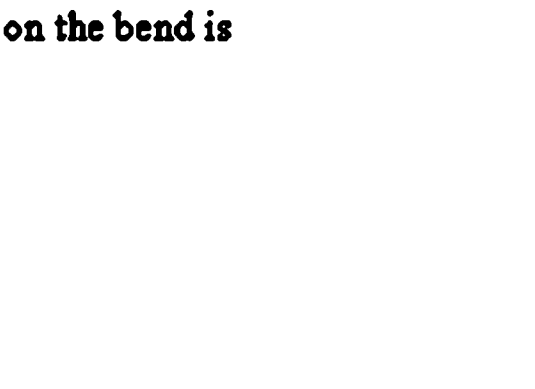
Diameter of the water jet $D = 3\text{in.}$

Velocity of water $V = 140\text{ft/s}$

Water is deflected from its initial position is $\theta = 135°$

Step 2 of 5

The mass flow rate of water can be calculated as,



$$\dot{m} = \rho AV$$

$$= \left(62.4\text{lbm/ft}^3\right) \times \frac{\pi\left(\frac{3}{12}\right)^2}{4}\text{ft}^2 \times 140\text{ft/s}$$

$$= 428.827\text{lbm/s}$$

Step 3 of 5

The velocity triangle at the exit is as shown in figure:

Step 4 of 5

The momentum equation for steady flow in x direction is

$$\sum \vec{F}_x = \dot{m}\left(V_{out} - V_{in}\right)_x$$

$$= \dot{m} \times \left(-V\cos 45° - V\right)$$

$$= -\dot{m}V\left(\cos 45° + 1\right)$$

$$= -428.827 \times 140 \times (1.707)$$

$$= -102481.07\text{lbf}$$

The momentum equation for steady flow in y direction is

$$\sum \vec{F}_y = \dot{m}\left(V_{out} - V_{in}\right)_y$$

$$= \dot{m}\left(V\sin 45° - 0\right)$$

$$= 428.827 \times 140 \times \sin 45°$$

$$= 42451.707\text{lbf}$$

Step 5 of 5

Now the resultant force acting on the bend is

$$F = \sqrt{F_x^2 + F_y^2}$$

$$= \sqrt{(-102481.07)^2 + 42451.707^2}$$

$$= 110925.72\text{lbf}$$

Therefore, the force required to hold the plate in place is $\boxed{110925.72\text{lbf}}$

Direction of the force acting on the bend is

$$\alpha = \tan^{-1}\left(\frac{F_y}{F_x}\right)$$

$$= \tan^{-1}\left(\frac{42451.707}{-102481.07}\right)$$

$$= -22.501°$$

$$\boxed{\alpha = -22.501°}$$

Question: 13.032P

Firefighters are holding a nozzle at the end of a hose while trying to extinguish a fire. If the nozzle exit diameter is 6 cm and the water flow rate is 5 m3/min, determine (*a*) the average water exit velocity and (*b*) the horizontal resistance force required of the firefighters to hold the nozzle.

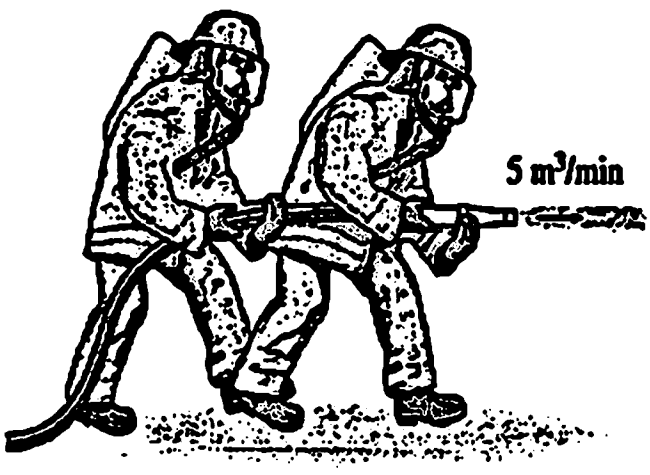


FIGURE P13–32

Step 1 of 4

Given data:-

The exit diameter of the nozzle is $D = 6\,\text{cm}$.

The water flow rate is $\dot{V} = 5\,\text{m}^3/\text{min}$.

Step 2 of 4

Assumptions

1. The flow is steady, frictionless and incompressible.
2. Water is discharged to the atmosphere, and thus the pressure is not considered.
3. The flow is jet flow so the momentum-flux correction factor is unity.
4. The gravitational force is not considered.

Step 3 of 4

a) The density of water is $1000\,\text{kg/m}^3$. Take the nozzle and horizontal portion of the hose as the control volume.

$$V = \frac{\dot{V}}{A}$$

$$= \frac{5\,\text{m}^3/\text{min}}{\frac{\pi(0.06\,\text{m})^2}{4}}\left(\frac{1}{60\,\text{s}}\right)$$

$$= 29.47\,\text{m/s}$$

Therefore, the average exit velocity of water is $\boxed{V = 29.5\,\text{m/s}}$.

Step 4 of 4

b) Now, the mass flow rate,

$$\dot{m} = \rho\dot{V}$$

$$= \left(1000\,\text{kg/m}^3\right)\left(5\,\text{m}^3/\text{min}\right)\left(\frac{1}{60\,\text{s}}\right)$$

$$= 83.33\,\text{kg/s}$$

Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta\dot{m}\vec{V} - \sum_{in} \beta\dot{m}\vec{V}.$$

Now, the momentum equations along the x - axis is

$$F_{in} = \dot{m}V_{out}$$

$$= (83.33\,\text{kg/s})(29.47\,\text{m/s})$$

$$= 2455.83$$

Therefore, the horizontal force required to hold the nozzle is $\boxed{F = 2456\,\text{N}}$.

Question: 13.033P

A 5-cm-diameter horizontal jet of water with a velocity of 40 m/s relative to the ground strikes a flat plate that is moving in the same direction as the jet at a velocity of 10 m/s. The water splatters in all directions in the plane of the plate. How much force does the water stream exert on the plate?

Step 1 of 4

The relative velocity of water $V_{jet} = 40$ m/s

The velocity of the plate $V_{plate} = 10$ m/s

The diameter of the jet $D = 5$ cm

Step 2 of 4

Assumptions

1. The flow is steady, frictionless and incompressible.
2. Water is discharged to the atmosphere, and thus it is not considered.
3. The flow is jet flow so the momentum-flux correction factor is unity.
4. Neglect the friction.
5. The vertical forces are not considered since they have no effect on the horizontal force exerted on the plate.

Step 3 of 4

Consider the plate as the control volume.

Now, the relative velocity between plate and the water jet,

$$\begin{aligned} V_r &= V_{jet} - V_{plate} \\ &= (40 \text{ m/s}) - (10 \text{ m/s}) \\ &= 30 \text{ m/s} \end{aligned}$$

Now, the mass flow rate with respect to the relative velocity is

$$\begin{aligned} \dot{m}_r &= \rho A V_r \\ &= \rho \times \frac{\pi}{4} D^2 \times V_r \\ &= (1000 \text{ kg/m}^3) \times \frac{\pi (0.05 \text{ m})^2}{4} \times (30 \text{ m/s}) \\ &= 58.9 \text{ kg/s} \end{aligned}$$

Step 4 of 4

Let F_{Rx} be in positive x direction. Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}.$$

Thus, $F_{Rx} = \dot{m} V_1$,

$$\begin{aligned} F_{Rx} &= \dot{m}_r V_r \\ &= (58.9 \text{ kg/s})(30 \text{ m/s}) \\ &= 1767 \text{ kg} \cdot \text{m/s} \\ &= 1767 \text{ N} \end{aligned}$$

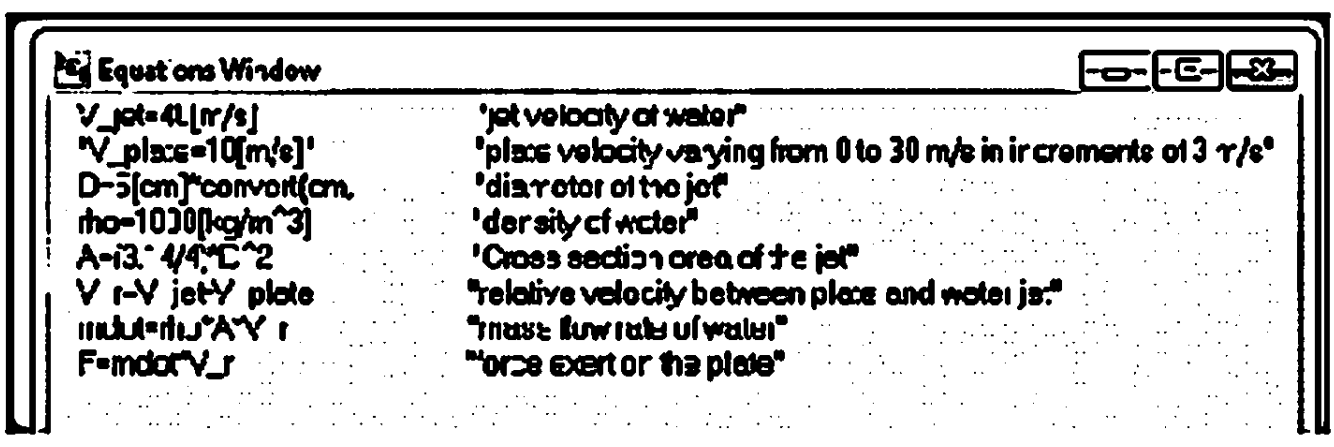
Therefore, the force exerted by the water on the plate is $\boxed{F = 1767 \text{ N}}$

Question: 13.034P

Reconsider Prob. 13-33. Using EES (or other) software, investigate the effect of the plate velocity on the force exerted on the plate. Let the plate velocity vary from 0 to 30 m/s, in increments of 3 m/s. Tabulate and plot your results.

Step 1 of 5

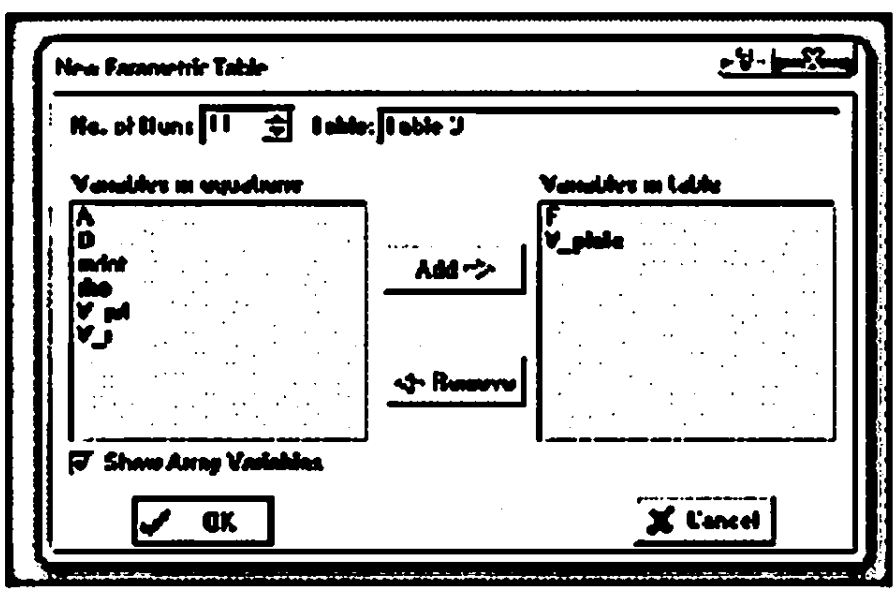
The relative velocity of water $V_{jet} = 40$ m/s



The velocity of the plate $V_{plate} = 10$ m/s

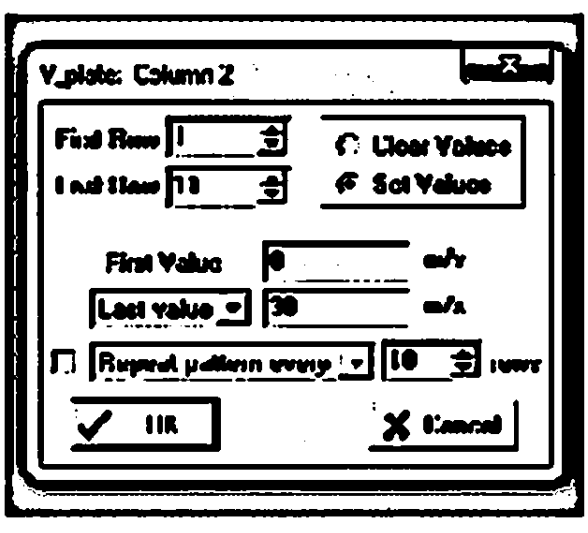
The diameter of the jet $D = 5$ cm

Step 2 of 5



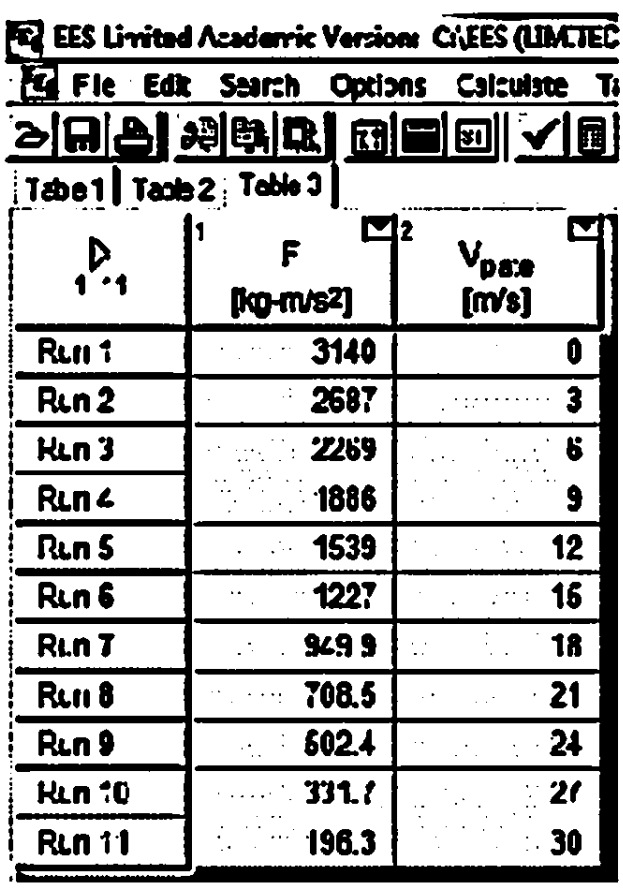
The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box



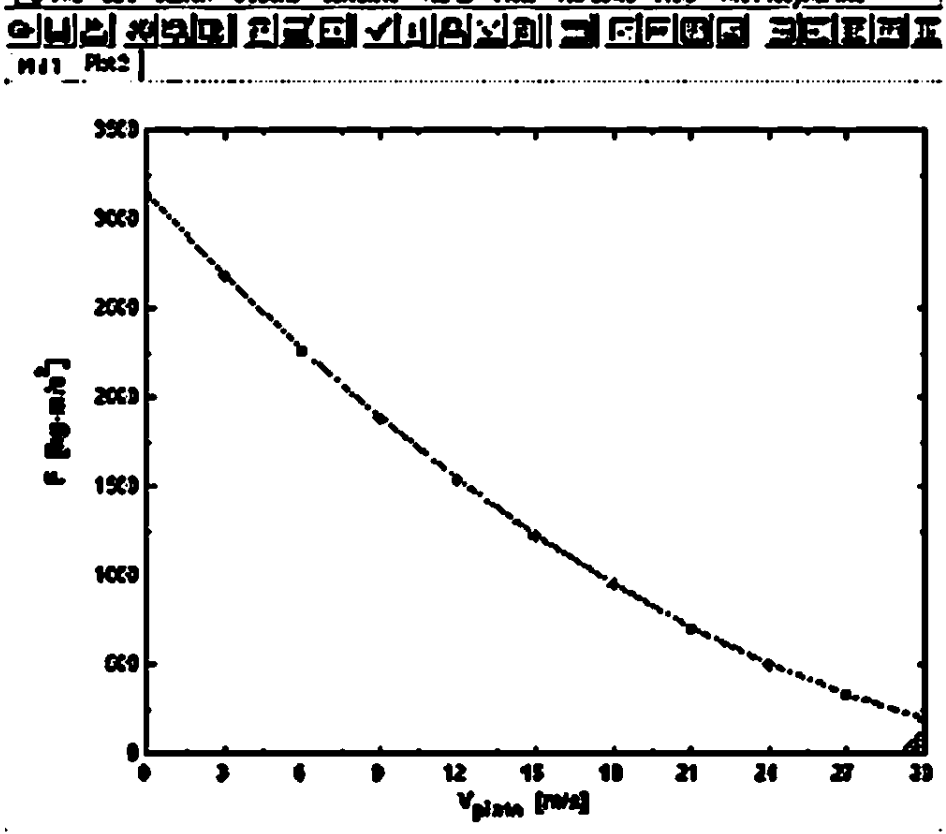
Step 3 of 5

Now to solve the equation for a range of plate velocity,use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "V_plate", "F", press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:



To enter the values in the "V_plate" column, click on the drop tab in "V_plate" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 5



Now click on 'Solve' of 'Calculate' menu.
The Solution will appear as shown below:

	1 F [kg-m/s2]	2 V_{plate} [m/s]
Run 1	3140	0
Run 2	2687	3
Run 3	2269	6
Run 4	1886	9
Run 5	1539	12
Run 6	1227	15
Run 7	949.9	18
Run 8	708.5	21
Run 9	502.4	24
Run 10	331.7	27
Run 11	196.3	30

Inorder to plot the plate velocity and force exerted on plate, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the plot showing the force exerted on plate and plate velocity is shown:

Step 5 of 5

Question: 13.035P

A fan with 24-in-diameter blades moves 2000 cfm (cubic feet per minute) of air at 70°F at sea level. Determine (*a*) the force required to hold the fan and (*b*) the minimum power input required for the fan. Choose a control volume sufficiently large to contain the fan, with the inlet sufficiently far upstream so that the gage pressure at the inlet is nearly zero. Assume air approaches the fan through a large area with negligible velocity and air exits the fan with a uniform velocity at atmospheric pressure through an imaginary cylinder whose diameter is the fan blade diameter.

Step 1 of 10

The diameter of the fan blade, $D = 24\text{in.}$

The flow rate of air, $\dot{V} = 2000\,\text{cfm}$

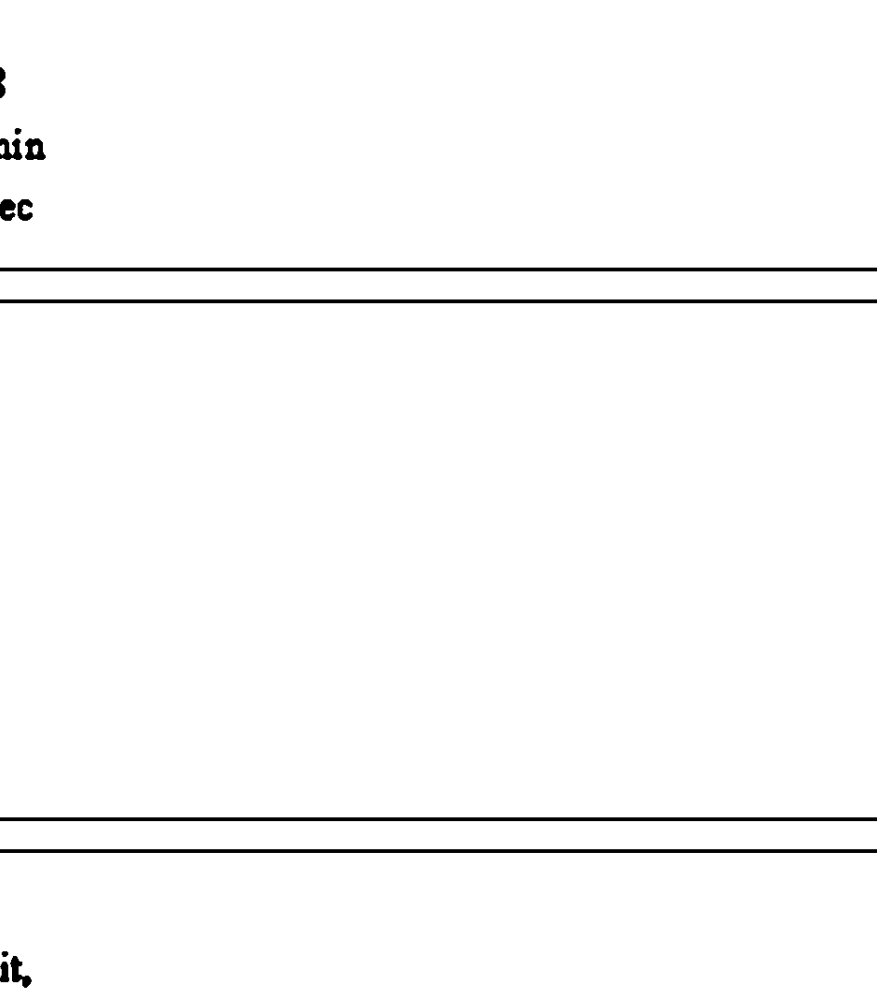
The temperature of air, $T = 70°\text{F} = 530°\text{R}$

Step 2 of 10

Assumptions:

The flow is steady and incompressible.

The frictional effects are negligible.



Air approaches the fan through a large area with negligible velocity.

The pressures at inlet and exit are atmospheric.

The wind flow is uniform upstream and downstream, $\beta \cong 1$.

Step 3 of 10

A fan with 24 in. diameter blades is shown in figure,

Step 4 of 10

Density of air can be calculated by using ideal gas equation,

$$\rho = \frac{P}{RT}$$

$$= \frac{(14.7\times144)}{(53.35)(530)}$$

$$= 0.0748\,\text{lb/ft}^3$$

Step 5 of 10

The mass flow rate of air,

$$\dot{m} = \rho\dot{V}$$

$$= 62.4\times0.0748$$

$$= 4.667\,\text{slug/min}$$

$$= 0.0777\,\text{slug/sec}$$

Step 6 of 10

The exit area,

$$A_2 = \frac{\pi D^2}{4}$$

$$= \frac{\pi\left(\frac{24}{12}\right)^2}{4}$$

$$= 3.1415\text{ft}^2$$

Step 7 of 10

The velocity at exit,

$$V_2 = \frac{\dot{V}}{A_2}$$

$$= \frac{2000\times\frac{1}{60}}{3.1415}$$

$$= 10.61\,\text{ft/s}$$

Step 8 of 10

a) We have,

$$\sum F_R = \sum \beta\dot{m}\vec{V}_{out} - \sum \beta\dot{m}\vec{V}_{in}$$

Then

$$F_R = \sum \beta\dot{m}\vec{V}_{out} - \sum \beta\dot{m}\vec{V}_{in}$$

$$= \dot{m}V_2 - \dot{m}V_1$$

$$= 0.0777\times10.61 - 0$$

$$= 0.8243\text{lbf}$$

Therefore, the force required to hold the fan is $\boxed{F_R = 0.8243\text{lbf}}$

Step 9 of 10

b) Apply the conservation of energy principle for the control volume between the inlet and exit

Then the equation can be expressed as

$$\dot{m}\left(\frac{P_1}{\rho}+\frac{V_1^2}{2}+gz_1\right)+\dot{W}_{fan} = \dot{m}\left(\frac{P_2}{\rho}+\frac{V_2^2}{2}+gz_2\right)+\dot{W}_{turbine}+\dot{E}_{mech,loss}$$

We know,

$P_1 = P_2 = P_{atm}$,

$z_1 = z_2$ and

$V_1 = 0$

Step 10 of 10

Power required is

$$\dot{W}_{fan} = \frac{\dot{m}V_2^2}{2}$$

$$= \frac{0.0777\left(10.61^2\right)}{2}$$

$$= 4.373\frac{\text{lbf}\cdot\text{ft}}{\text{sec}}$$

$$= 4.373\frac{\text{lbf}\cdot\text{ft}}{\text{sec}}\times\frac{1000\,\text{W}}{737.56\frac{\text{lbf}\cdot\text{ft}}{\text{sec}}}$$

$$= 5.92\,\text{W}$$

Therefore, the minimum power required for the fan is $\boxed{\dot{W}_{fan} = 5.92\,\text{W}}$

inlet and exit

Then the equation can be expressed as

Question: 13.036P pg 1

An unloaded helicopter of mass 10,000 kg hovers at sea level while it is being loaded. In the unloaded hover mode, the blades rotate at 400 rpm. The horizontal blades above the helicopter cause a 18-m-diameter air mass to move downward at an average velocity proportional to the overhead blade rotational velocity (rpm). A load of 14,000 kg is loaded onto the helicopter, and the helicopter slowly rises. Determine (*a*) the volumetric airflow rate downdraft that the helicopter generates during unloaded hover and the required power input and (*b*) the rpm of the helicopter blades to hover with the 14,000-kg load and the required power input. Take the density of atmospheric air to be 1.18 kg/m3. Assume air approaches the blades from the top through a large area with negligible velocity and air is forced by the blades to move down with a uniform velocity through an imaginary cylinder whose base is the blade span area.

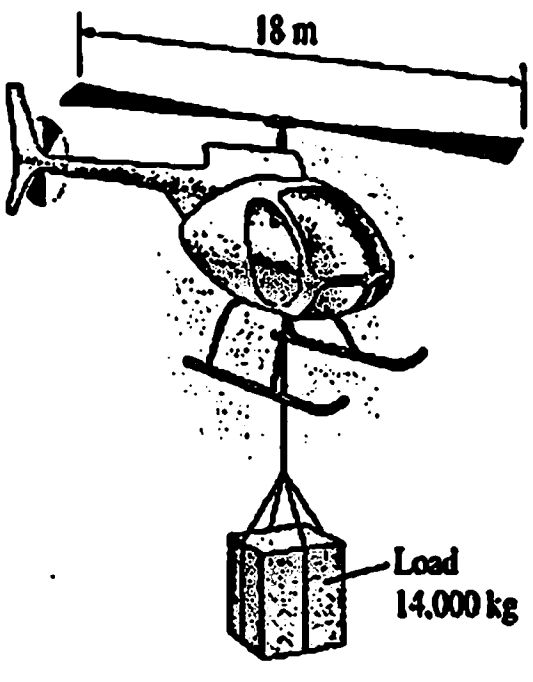


FIGURE P13–36

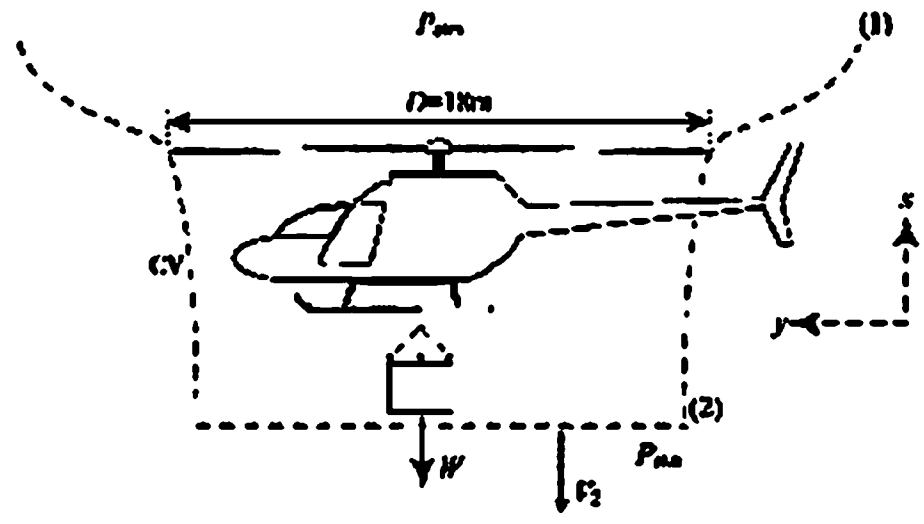
Step 1 of 17

The diameter of the rotor blade, $D = 18$ m

The mass of the helicopter alone, $m_h = 10000$ kg

The mass of the load alone, $m_l = 14000$ kg

The angular velocity of rotor during unloaded hover mode, $n_{UL} = 400$ rpm.



The density of air, $\rho = 1.18$ kg/m^3

Step 2 of 17

Assumptions:
The flow is steady and incompressible.
The frictional effects are negligible.
Air approaches the rotor through a large area with negligible velocity.
The pressures at inlet and exit are atmospheric.
The wind flow is uniform upstream and downstream, $\beta \cong 1$.

Step 3 of 17

The control volume of the helicopter and a load is as shown in figure:

Step 4 of 17

The weight of the helicopter alone,

$$W_h = m_h g$$
$$= (10000)(9.81)$$
$$= 98100 \text{ N}$$

Step 5 of 17

The weight of the load alone,

$$W_l = m_l g$$
$$= (14000)(9.81)$$
$$= 137340 \text{ N}$$

Step 6 of 17

a)
Consider the unloaded hover mode:

The total force acting on the helicopter is equal to the weight of the helicopter.
Then

$$\sum F_{hx} = -W$$
$$= -W_h$$

We have,

$$\sum F_{hx} = \sum \beta \dot{m} \vec{V}_{out} - \sum \beta \dot{m} \vec{V}_{in}$$

Where,

$\dot{m} = \rho A V$,

$V_{in} = 0$ and

$\beta \cong 1$

Then

$$-W_h = -(\rho A V_2) V_2$$
$$W_h = \rho A V_2^2$$

Step 7 of 17

The exit velocity can be expressed as

$$V_2 = \sqrt{\frac{W_h}{\rho A}}$$
$$= \sqrt{\frac{W_h}{\rho\left(\frac{\pi D^2}{4}\right)}}$$
$$= \sqrt{\frac{98100}{}}$$

$$= \sqrt{\frac{W_h}{\rho\left(\frac{\pi D^2}{4}\right)}}$$

$$= \sqrt{\frac{98100}{1.18\left(\frac{\pi \times 18^2}{4}\right)}}$$

$$= 18.0749 \text{ m/s}$$

Step 8 of 17

The mass flow rate of air

$$\dot{m} = \rho A V_2$$

$$= 1.18\left(\frac{\pi \times 18^2}{4}\right)18.0749$$

$$= 5427.412 \text{ kg/s}$$

Step 9 of 17

Volumetric flow rate of air can be calculated as

$$\dot{V} = \frac{\dot{m}}{\rho}$$

$$= \frac{5427.412}{1.18}$$

$$= 4599.50 \text{ m}^3/\text{s}$$

Therefore, the volumetric down flow rate is $\boxed{\dot{V} = 4599.50 \text{ m}^3/\text{s}}$

Step 10 of 17

Apply the conservation of energy principle between the inlet and exit of control volume
We have

$$\dot{m}\left(\frac{P_1}{\rho} + \frac{V_1^2}{2} + gz_1\right) + \dot{W}_{rotor} = \dot{m}\left(\frac{P_2}{\rho} + \frac{V_2^2}{2} + gz_2\right) + \dot{W}_{turbine} + \dot{E}_{mech,loss}$$

Let us assume the elevation difference between the two points is negligible.
We have,

$P_1 = P_2 = P_{atm}$, $z_1 = z_2$ and $V_1 = 0$

Then

$$\dot{W}_{rotor} = \frac{\dot{m}V_2^2}{2}$$

$$= \frac{5427.414\left(18.0749^2\right)}{2}$$

$$= 886.573 \times 10^3 \text{ W}$$

Therefore, the required power input is $\boxed{\dot{W}_{rotor} = 886.573 \times 10^3 \text{ W}}$

Step 11 of 17

b)
Consider the loaded hover mode of the helicopter.
The total weight of the helicopter,

$$W = W_h + W_l$$

$$= 98100 + 137340$$

$$= 235440 \text{ N}$$

The total force acting on the helicopter is equal to the weight of the helicopter and the load.
Then

$$\sum F_{in} = -W$$

We have,

$$\sum F_{in} = \sum \beta \dot{m} \vec{V}_{out} - \sum \beta \dot{m} \vec{V}_{in}$$

Where,

$\dot{m} = \rho A V$,

$V_{in} = 0$ and

$\beta \cong 1$

Then

$$-W = -(\rho A V_2) V_{2L}$$

$$W = \rho A V_{2L}^2$$

Step 12 of 17

The exit velocity during loaded mode can be expressed as

$$V_{2L} = \sqrt{\frac{W}{\rho A}}$$

$$= \sqrt{\frac{W}{\rho\left(\frac{\pi D^2}{4}\right)}}$$

$$= \sqrt{\frac{235440}{1.18\left(\frac{\pi \times 18^2}{4}\right)}}$$

$$= 28.00 \text{ m/s}$$

Step 13 of 17

The mass flow rate,

$$\dot{m}_L = \rho A V_{2L}$$

$$= 1.18\left(\frac{\pi \times 18^2}{4}\right)28$$

$$= 8407.655 \text{ kg/s}$$

Step 14 of 17

Apply the conservation of energy principle between the inlet and exit of control volume
We have

$$\dot{m}_L\left(\frac{P_1}{\rho} + \frac{V_1^2}{2} + gz_1\right) + \dot{W}_{rotor,L} = \dot{m}_L\left(\frac{P_2}{\rho} + \frac{V_{2L}^2}{2} + gz_2\right) + \dot{W}_{turbine,L} + \dot{E}_{mechloss,L}$$

Let us assume the elevation difference between the two points is negligible.
We have,

We have

$$\dot{m}_L\left(\frac{P_1}{\rho}+\frac{V_1^2}{2}+gz_1\right)+\dot{W}_{rotor,L}=\dot{m}_L\left(\frac{P_2}{\rho}+\frac{V_{2L}^2}{2}+gz_2\right)+\dot{W}_{turbine,L}+\dot{E}_{mech\,loss,L}$$

Let us assume the elevation difference between the two points is negligible.
We have,

$P_1 = P_2 = P_{atm}$,

$z_1 = z_2$ and

$V_1 = 0$

Step 15 of 17

Then

$$\dot{W}_{rotor,L}=\frac{\dot{m}_L V_{2L}^2}{2}$$

$$=\frac{8407.655(28^2)}{2}$$

$$=3295.8\times10^3\,\text{W}$$

Therefore, the required power input is $\boxed{\dot{W}_{rotor,L}=3295.8\times10^3\,\text{W}}$.

Step 16 of 17

We know that the velocity is proportional to the overhead rotor rpm.

Then we can express for unloaded mode as,

$$\dot{m}_L\left(\frac{P_1}{\rho}+\frac{V_1^2}{2}+gz_1\right)+\dot{W}_{rotor,L}=\dot{m}_L\left(\frac{P_2}{\rho}+\frac{V_{2L}^2}{2}+gz_2\right)+\dot{W}_{turbine,L}+\dot{E}_{mech\,loss,L}$$

Let us assume the elevation difference between the two points is negligible.
We have,

$P_1 = P_2 = P_{atm}$,

$z_1 = z_2$ and

$V_1 = 0$

Step 15 of 17

Then

$$\dot{W}_{rotor,L}=\frac{\dot{m}_L V_{2L}^2}{2}$$

$$=\frac{8407.655(28^2)}{2}$$

$$=3295.8\times10^3\,\text{W}$$

Therefore, the required power input is $\boxed{\dot{W}_{rotor,L}=3295.8\times10^3\,\text{W}}$.

Step 16 of 17

We know that the velocity is proportional to the overhead rotor rpm.

Question: 13.037P pg 1

Reconsider the helicopter in Prob. 13-36, except that it is hovering on top of a 2800-m-high mountain where the air density is 0.928 kg/m3. Noting that the unloaded helicopter blades must rotate at 400 rpm to hover at sea level, determine the blade rotational velocity to hover at the higher altitude. Also determine the percent increase in the required power input to hover at 3000-m altitude relative to that at sea level.

Step 1 of 15

The diameter of the rotor blade, $D = 18$ m

The mass of the helicopter, $m = 10000$ kg

The altitude of the helicopter at mountain top, $z_{mnt} = 2800$ m

The density of air at mountain top, $\rho_{mnt} = 0.928\ \text{kg/m}^3$

The final altitude of the helicopter, $z_2 = 3000$ m

The rotational velocity of rotor at sea level, $n_{sea} = 400$ rpm

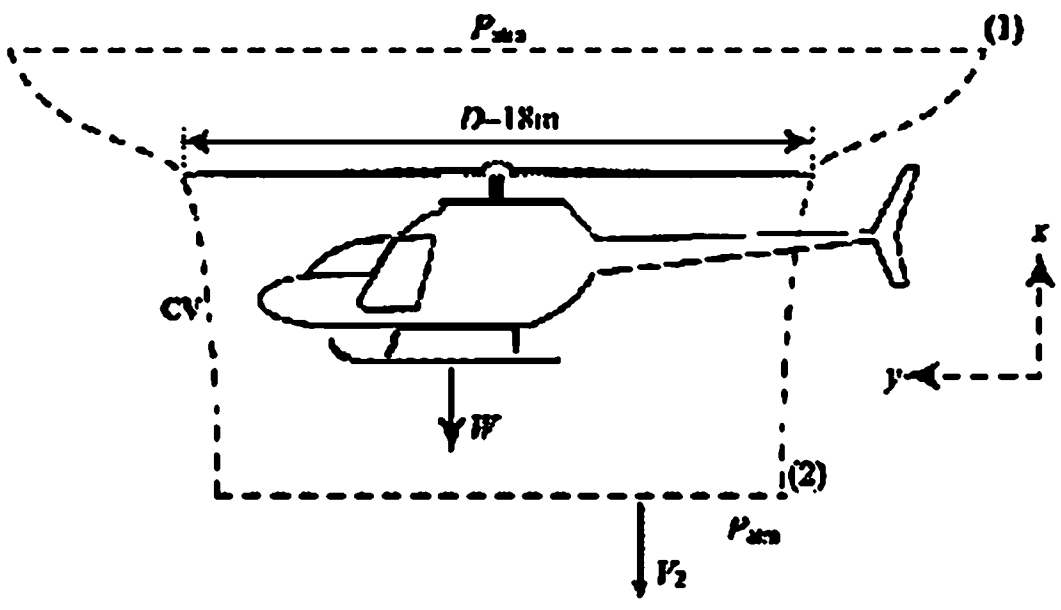
The exit velocity is proportional to the rotational velocity of blade.

Step 2 of 15

Assumptions:

The flow is steady and incompressible.

The frictional effects are negligible.



Air approaches the rotor through a large area with negligible velocity.

The pressures at inlet and exit are atmospheric.

The wind flow is uniform upstream and downstream, $\beta \cong 1$.

Step 3 of 15

The control volume of the helicopter and a load is as shown in figure:

Step 4 of 15

The weight of the helicopter,

$W = mg$

$= (10000)(9.81)$

$= 98100$ N

Step 5 of 15

The total force acting on the helicopter is equal to the weight of the helicopter.

Then

$\sum F_{fy} = -W$

We have,

$\sum F_{fx} = \sum \beta \dot{m} \vec{V}_{out} - \sum \beta \dot{m} \vec{V}_{in}$

Where,

$\dot{m} = \rho A V$,

$V_{in} = 0$ and

$\beta \cong 1$

Then

$-W = -(\rho A V_2) V_2$

$W = \rho A V_2^2$

Step 6 of 15

The exit velocity can be expressed as

$$V_2 = \sqrt{\frac{W}{\rho A}}$$

Consider the unloaded hover mode at sea level,

$$V_{2,sea} = \sqrt{\frac{W}{\rho_{sea} A}}$$

Consider the unloaded hover mode at the mountain top.

$$V_{2,mnt} = \sqrt{\frac{W}{\rho_{mnt} A}}$$

Step 7 of 15

Then

$$\frac{V_{2,mnt}}{V_{2,sea}} = \frac{\sqrt{\rho_{sea}}}{\sqrt{\rho_{mnt}}}$$

$$= \sqrt{\frac{1.18}{0.928}}$$

$$= 1.127$$

Step 8 of 15

We know the exit velocity is proportional to blade velocity.

Then

$n_{mnt} \propto V_{2mnt}$

$= aV_{2mnt}$

And

$n_{sea} \propto V_{2sea}$

$= aV_{2sea}$

Step 9 of 15

Then

$$\frac{n_{mnt}}{n_{sea}} = \frac{V_{2mnt}}{V_{2sea}}$$

Step 9 of 15

Then

$$\frac{n_{mtn}}{n_{sea}} = \frac{V_{2mtn}}{V_{2sea}}$$
$$= 1.1276$$

Step 10 of 15

Then

$$n_{mtn} = 1.1276(400)$$
$$= 451 \text{ rpm}$$

The rotor velocity at mountain top, $\boxed{n_{mtn} = 451.04 \text{ rpm}}$

Step 11 of 15

The mass flow rate,

$$\dot{m} = \rho A V_{2,sea}$$
$$= 0.928\left(\frac{\pi \times 18^2}{4}\right)20.381$$
$$= 4812.91 \text{ kg/s}$$

Step 12 of 15

Apply the conservation of energy principle between the inlet and exit of control volume at sea level

We have

$$\dot{m}\left(\frac{P_1}{\rho} + \frac{V_{1sea}^2}{2} + gz_1\right) + \dot{W}_{rotor,sea} = \dot{m}\left(\frac{P_2}{\rho} + \frac{V_{2sea}^2}{2} + gz_2\right) + \dot{W}_{turbine,sea} + \dot{E}_{mechloss,sea}$$

Let us assume the elevation difference between the two points is negligible.

We have,

$P_1 = P_2 = P_{atm}$,

$z_1 = z_2$ and

$V_1 = 0$

Then

$$\dot{W}_{rotor,sea} = \frac{\dot{m}V_{2sea}^2}{2}$$
$$= \frac{\rho_{sea} A V_{2sea} V_{2sea}^2}{2}$$
$$= \frac{\rho_{sea} A}{2}\left(\sqrt{\frac{W}{A\rho_{sea}}}\right)^3$$
$$= \frac{\rho_{sea}}{2\sqrt{\rho_{sea}}^3}\left(\sqrt{\frac{W}{A}}\right)^3$$

Step 13 of 15

Similarly for the altitude of 3000 m

$$\dot{W}_{rotor,a} = \frac{\dot{m}V_{2a}^2}{2}$$
$$= \frac{\rho_a A V_{2a} V_{2a}^2}{2}$$
$$= \frac{\rho_a A}{2}\left(\sqrt{\frac{W}{A\rho_a}}\right)^3$$
$$= \frac{\rho_a}{2\sqrt{\rho_a}^3}\left(\sqrt{\frac{W}{A}}\right)^3$$

Step 14 of 15

Then

$$\frac{\dot{W}_{rotor,sea}}{\dot{W}_{rotor,a}} = \frac{\frac{\rho_{sea}}{2\sqrt{\rho_{sea}}^3}\left(\sqrt{\frac{W}{A}}\right)^3}{\frac{\rho_a}{2\sqrt{\rho_a}^3}\left(\sqrt{\frac{W}{A}}\right)^3}$$
$$= \frac{\sqrt{\rho_a}}{\sqrt{\rho_{sea}}}$$
$$= \frac{\sqrt{0.897}}{\sqrt{1.18}}$$
$$= 0.8718$$

That is

$$\dot{W}_{rotor,sea} = 0.8718\dot{W}_{rotor,a}$$

Step 15 of 15

Then

$$\left(\Delta\dot{W}\right) = \dot{W}_{rotor,a} - \dot{W}_{rotor,sea}$$
$$= 1 - 0.8718$$
$$= 0.128$$
$$= 12.8\%$$

Therefore, the power required for the helicopter at an altitude of 3000 m is $\boxed{12.8\%}$ greater than the power required at an altitude at sea level.

Question: 13.038P

A sluice gate, which controls flow rate in a channel by simply raising or lowering a vertical plate, is commonly used in irrigation systems. A force is exerted on the gate due to the difference between the water heights *y*1, and *y*2 and the flow velocities *V*1 and *V*2 upstream and downstream from the gate, respectively. Take the width of the sluice gate (into the page) to be *w*. Wall shear stresses along the channel walls may be ignored, and for simplicity, we assume steady, uniform flow at locations 1 and 2. Develop a relationship for the force *FR* acting on the sluice gate as a function of depths *y*1, and *y*2, mass flow rate *m*, gravitational constant *g*, gate width *w*, and water density *ρ*.

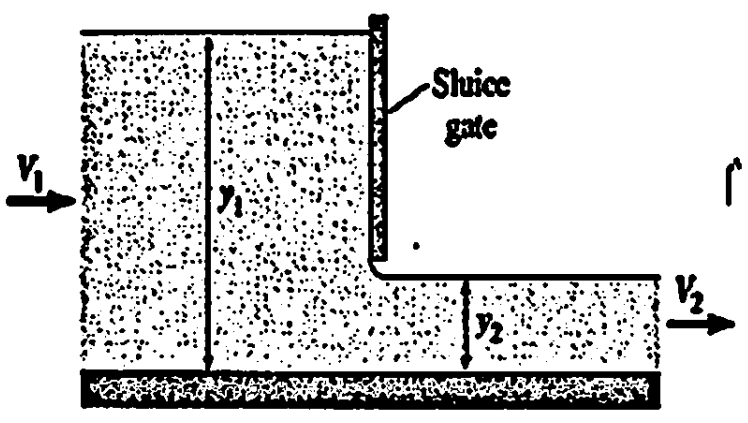


FIGURE P13–38

Step 1 of 4

Apply the Bernoulli's equation between the inlet and exit

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+y_1=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+y_2$$

Here, P_1, P_2 are pressures at inlet and exit, ρ is the density of water, V_1, V_2 are the velocities at the inlet and exit, and y_1, y_2 are the water heights.

Substitute P_{atm} for P_1, P_2 .

$$\frac{P_{atm}}{\rho g}+\frac{V_1^2}{2g}+y_1=\frac{P_{atm}}{\rho g}+\frac{V_2^2}{2g}+y_2 \quad \text{..... (1)}$$
$$V_2^2-V_1^2=2g(y_1-y_2)$$

Mass flow rate is constant though out the flow.

$$\dot{m}=\rho A_1 V_1=\rho A_2 V_2$$

Where, A_1 and A_2 is the inlet and exit flow areas.

$$A_1V_1=A_2V_2=\dot{V}$$

Here, $\dot{V}$ is the volumetric flow rate.

Step 2 of 4

Substitute $\frac{\dot{V}}{A_1}$ for V_1 , wy_1 for A_1 , wy_2 for A_2 , and $\frac{\dot{V}}{A_2}$ for V_2 in equation (1).

$$V_2^2-V_1^2=2g(y_1-y_2)$$
$$\left(\frac{\dot{V}}{A_2}\right)^2-\left(\frac{\dot{V}}{A_1}\right)^2=2g(y_1-y_2)$$
$$\left(\frac{\dot{V}}{wy_2}\right)^2-\left(\frac{\dot{V}}{wy_1}\right)^2=2g(y_1-y_2)$$

$$\dot{V}=\sqrt{w^2\frac{y_1y_2}{y_1^2-y_2^2}(y_1-y_2)}$$
$$=w\sqrt{2g\frac{(y_2-y_1)y_1y_2}{(y_2-y_1)(y_2+y_1)}}$$
$$=w\sqrt{2g\frac{y_1y_2}{(y_2+y_1)}}$$

Step 3 of 4

Find the initial velocity.

$$V_1=\frac{\dot{V}}{A_1}$$
$$=\frac{w}{A_1}\sqrt{2g\frac{y_1y_2}{(y_2+y_1)}}$$

Substitute $w\sqrt{2g\frac{y_1y_2}{(y_2+y_1)}}$ for $\dot{V}$ and wy_1 for A_1 .

$$V_1=\frac{w}{A_1}\sqrt{2g\frac{y_1y_2}{(y_2+y_1)}}$$

Find the final velocity.

$$V_2=\frac{\dot{V}}{A_2}$$
$$=\frac{w}{A_2}\sqrt{2g\frac{y_1y_2}{(y_2+y_1)}}$$

Substitute $w\sqrt{2g\frac{y_1y_2}{(y_2+y_1)}}$ for $\dot{V}$ and wy_2 for A_2 .

$$V_2=\frac{w}{A_2}\sqrt{2g\frac{y_1y_2}{(y_2+y_1)}}$$

Step 4 of 4

Write the force balance for the system.

$$\sum F_{fix}=\sum\beta\dot{m}\vec{V}_{out}-\sum\beta\dot{m}\vec{V}_{in}$$
$$\sum F_{fix}=P_1A_1-P_2A_2-F_R$$
$$\dot{m}(V_2-V_1)=\left(\rho g\frac{y_1}{2}A_1-\rho g\frac{y_2}{2}A_2\right)-F_R$$
$$\left(\rho g\frac{y_1}{2}A_1-\rho g\frac{y_2}{2}A_2\right)-F_R=\dot{m}\frac{\dot{V}}{A_2}-\dot{m}\frac{\dot{V}}{A_1}$$
$$\left(\rho g\frac{y_1}{2}A_1-\rho g\frac{y_2}{2}A_2\right)-F_R=\frac{\rho}{A_2}-\frac{\rho}{A_1}$$

$$F_R=\left(\rho g\frac{y_2}{2}A_2-\rho g\frac{y_1}{2}A_1\right)-\left(\frac{\rho}{A_2}-\frac{\rho}{A_1}\right)$$
$$=\left(\rho g\frac{y_2}{2}wy_2-\rho g\frac{y_1}{2}wy_1\right)-\left(\frac{\rho}{A_2}-\frac{\rho}{A_1}\right)$$
$$=\rho gw\left(\frac{y_2^2}{2}-\frac{y_1^2}{2}\right)-\rho\left(\frac{1}{A_2}-\frac{1}{A_1}\right)$$

Therefore, the reaction force can be expressed as $\boxed{\rho gw\left(\frac{y_2^2}{2}-\frac{y_1^2}{2}\right)-\rho\left(\frac{1}{A_2}-\frac{1}{A_1}\right)}$.

Question: 13.039P

Water enters a centrifugal pump axially at atmospheric pressure at a rate of 0.12 m3/s and at a velocity of 7 m/s, and leaves in the normal direction along the pump casing, as shown in Fig. PI3-39. Determine the force acting on the shaft (which is also the force acting on the bearing of the shaft) in the axial direction.

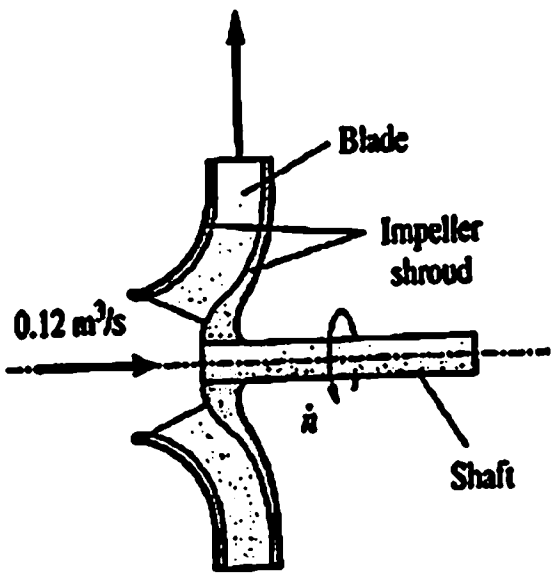

FIGURE P13–39

Step 1 of 5

Given data:-

The velocity of water is $V = 7\ \text{m/s}$.

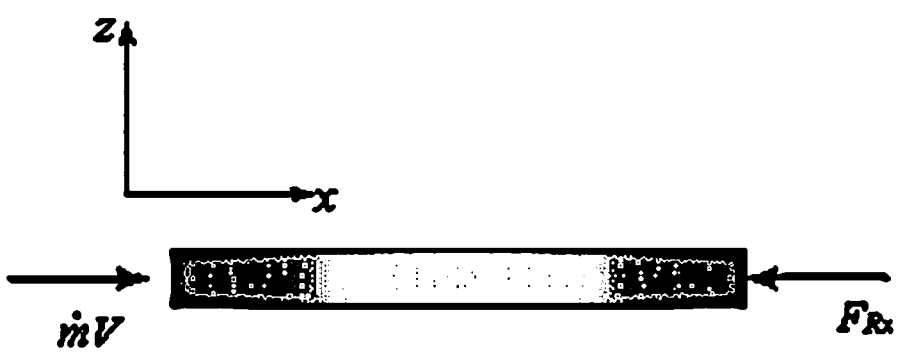
The water flow rate is $\dot{V} = 0.12\ \text{m}^3/\text{s}$.

Step 2 of 5

Assumptions

1. The flow is steady, frictionless and incompressible.
2. Atmosphere pressure is not considered.
3. The momentum-flux correction is neglected.

Step 3 of 5



Take the centrifugal pump as the control volume.

Now, the mass flow rate is

$$\begin{aligned}\dot{m} &= \rho\dot{V} \\ &= (1000\ \text{kg/m}^3)(0.12\ \text{m}^3/\text{s}) \\ &= 120\ \text{kg/s}\end{aligned}$$

Step 4 of 5

Draw the free-body diagram of the shaft.

Step 5 of 5

Let F_{Rx} be in positive x direction. Now, the momentum equation for steady one-dimensional flow,

$$\sum \vec{F} = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}.$$

Thus, $-F_{Rx} = -\dot{m}V_i$,

$$\begin{aligned}F_{Rx} &= \dot{m}V_i \\ &= (120\ \text{kg/s})(7\ \text{m/s}) \\ &= 840\ \text{kg}\cdot\text{m/s} \\ &= 840\ \text{N}\end{aligned}$$

Therefore, the force acting on the shaft is $\boxed{F = 840\ \text{N}}$.

Question: 13.040P

An incompressible fluid of density ρ and viscosity μ, flows through a curved duct that turns the flow 180°. The duct cross-sectional area remains constant. The average velocity, momentum flux correction factor, and gage pressure are known at the inlet (1) and outlet (2), as in Fig. P13–40. (a) Write an expression for the horizontal force Fx of the fluid on the walls of the duct in terms of the given variables. (b) Verify your expression by plugging in the following values: ρ = 998.2 kg/m3, μ, = 1.003 × 10-3 kg/m-s, $A1$, = $A2$ = 0.025 m2, $\beta 1$ = 1.01, $\beta 2$ = 1.03, $V1$ = 10 m/s, $P1$,gage= 78.47 kPa, and $P2$,gage = 65.23 kPa.

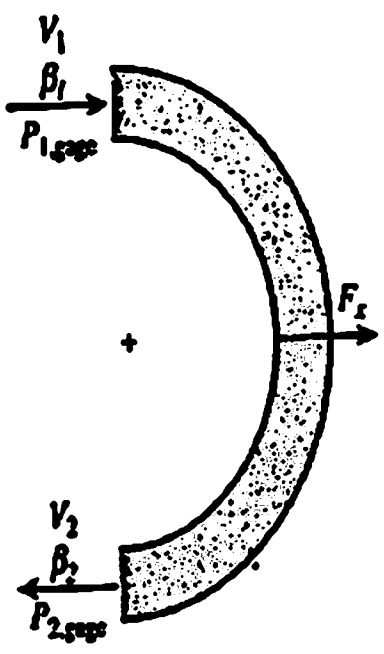


FIGURE P13–40

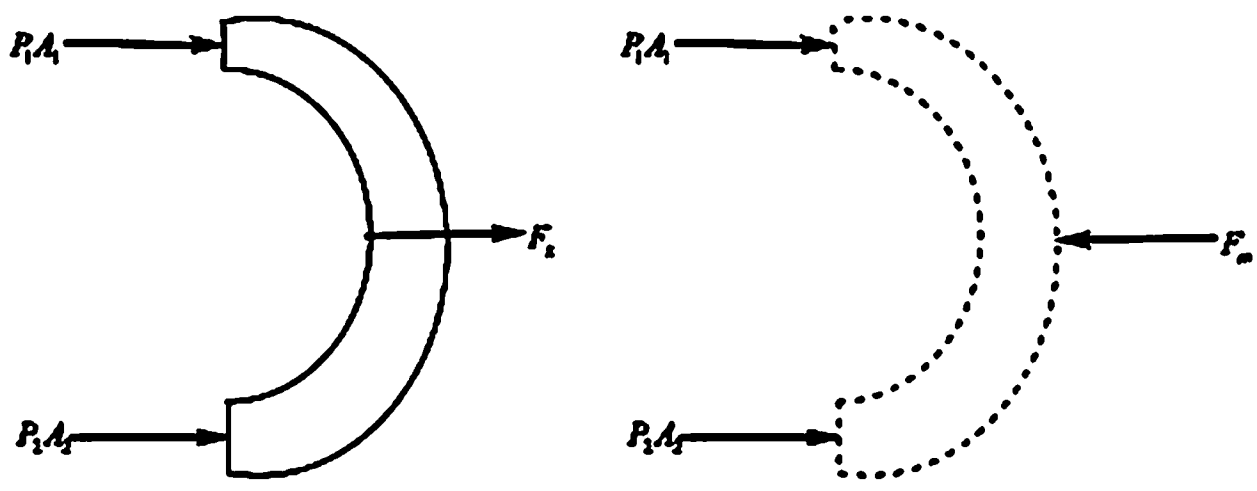
Step 1 of 5

Density of the fluid ρ

Fluid viscosity μ

The average velocity at inlet is V_1



Average velocity at exit is V_2

Momentum flux correction factor at inlet and exit is β_1, β_2

Gage pressure at the inlet and exit is P_1, P_2

Step 2 of 5

The fluid flows through a curved duct that turns the flow 180^0 is shown below:
The curved surface indicates control volume of water

Where

F_x Represents force acting by the fluid on the walls of the duct

F_m Represents reaction force by the walls of the duct on the water

Step 3 of 5

The pressure force acting at inlet is P_1A_1

The pressure force acting at exit is P_2A_2

By applying momentum equation on this control volume the net thrust force acting on the body can be determined as,

$$\sum F = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}$$

$$-F_m + P_1A_1 + P_2A_2 = \beta \dot{m}(-V_{out}) - \beta \dot{m} V_{in}$$

$$-F_m = \dot{m}(-\beta_2 V_{out} - \beta_1 V_{in}) - P_1A_1 - P_2A_2$$

Therefore, the fluid force F_x acting on the walls of the curved duct is

$$F_x = -F_m$$

$$\boxed{F_x = \dot{m}(-\beta_2 V_{out} - \beta_1 V_{in}) - P_1A_1 - P_2A_2}$$

Step 4 of 5

(b)

Density of the fluid $\rho = 998.2 \text{kg/m}^3$

Dynamic viscosity of the fluid $\mu = 1.003 \times 10^{-3} \text{kg/m} \cdot \text{s}$

Cross sectional area of the duct at inlet and exit is $A_1 = A_2 = 0.025 \text{m}^2$

Momentum flux correction factor at inlet $\beta_1 = 1.01$

Momentum flux correction factor at exit $\beta_2 = 1.03$

Velocity at inlet $V_1 = 10 \text{m/s}$

Gage pressure at inlet is $P_{1,gage} = 78.47 \text{kPa}$

Gage pressure at exit is $P_{2,gage} = 65.23 \text{kPa}$

Step 5 of 5

Since duct area remains constant, there is no change in velocity at inlet and exit

$V_1 = V_2 = 10 \text{m/s}$

Mass flow rate of incompressible fluid is

$$\dot{m} = \rho A_1 V_1$$
$$= 998.2 \times 0.025 \times 10$$
$$= 249.55 \text{kg/sec}$$

Substituting the known values in force F_m

$$F_m = \dot{m}(\beta_2 V_{out} - \beta_1 V_{in}) - P_1A_1 - P_2A_2$$
$$= 249.55(-1.03 \times 10 - 1.01 \times 10) - 78.47 \times 10^3 \times 0.025 - 65.23 \times 10^3 \times 0.025$$
$$= -5090.82 - 1961.75 - 1630.75$$
$$= -8683.32 \text{N}$$

Therefore, the fluid force acting on the walls of the duct is

$$\boxed{F_x = -F_m = 8683.32 \text{N}}$$

Question: 13.041P

Consider the curved duct of Prob. 13-40, except allow the cross-sectional area to vary along the duct ($A1 \neq A2$). (*a*) Write an expression for the horizontal force *Fx* of the fluid on the walls of the duct in terms of the given variables. (*b*) Verify your expression by plugging in the following values: ρ = 998.2 kg/m3, *A*1 = 0.025 m2, *A*2 = 0.015 m2, $\beta 1$ = 1.02, $\beta 2$= 1.04, *V*1 = 20 m/s, *P*1,gage = 88.34 kPa, and *P*2,gage = 67.48 kPa.

Step 1 of 5

Given data:

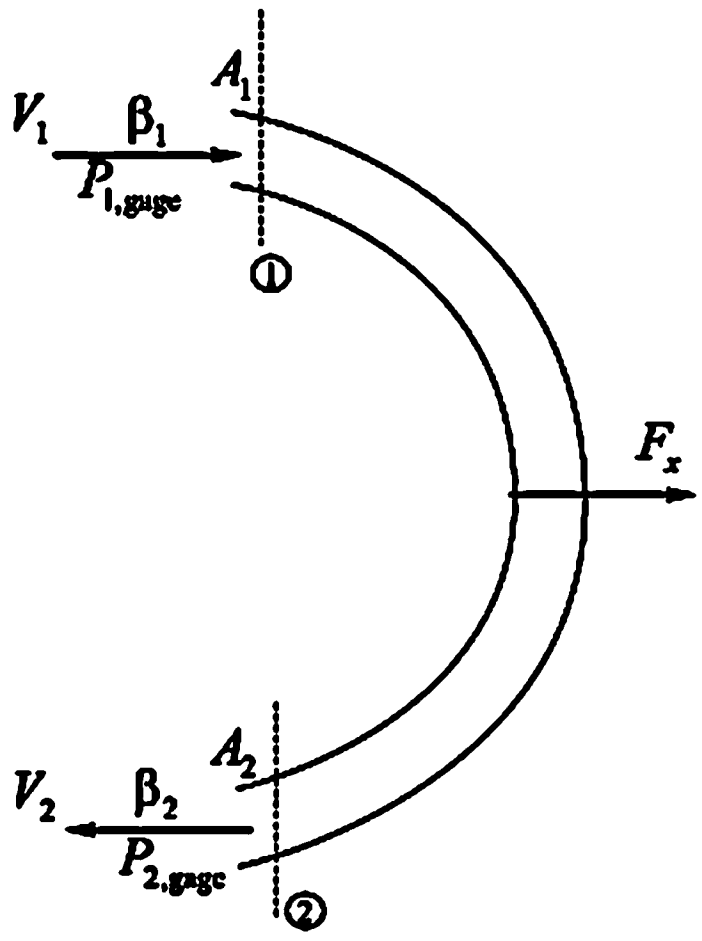
Inlet velocity of the fluid, $V_1 = 20$ m/s

Momentum flux correction factor at inlet, $\beta_1 = 1.02$

Gage pressure at inlet, $P_{1,gage} = 88.34$ kPa

Inlet area, $A_1 = 0.025$ m^2

Momentum flux correction factor at exit, $\beta_2 = 1.04$



Gage pressure at outlet, $P_{2,gage} = 67.48$ kPa

Outlet area, $A_2 = 0.015$ m^2

Density of the fluid, $\rho = 998.2$ kg/m^3

Step 2 of 5

The curved duct is as shown in figure:

Step 3 of 5

Mass flow rate of the fluid at inlet,

$\dot{m} = \rho A_1 V_1$

$= 998.2 \times 0.025 \times 20$

$= 499.1$ kg/sec

Mass flow is constant throughout the duct,

Therefore,

$\dot{m}_{inlet} = \dot{m}_{outlet}$

$\rho A_1 V_1 = \rho A_2 V_2$

$499.1 = 998.2 \times 0.015 \times V_2$

$V_2 = 33.333$m/sec

Step 4 of 5

(a)

Steady flow momentum equation with external force,

$$\sum F = \sum_{out} \beta \dot{m} V - \sum_{in} \beta \dot{m} V$$

$$F_x + P_{1,gage} A_1 + P_{2,gage} A_2 = \beta_2 \dot{m}(-V_2) - \beta_1 \dot{m} V_1$$

$$F_x = \beta_2 \dot{m}(-V_2) - \beta_1 \dot{m} V_1 - \left(P_{1,gage} A_1 + P_{2,gage} A_2\right)$$

Therefore,

The expression for the horizontal force,

$$\boxed{F_x = \beta_2 \dot{m}(-V_2) - \beta_1 \dot{m} V_1 - \left(P_{1,gage} A_1 + P_{2,gage} A_2\right)}$$

Step 5 of 5

(b)

Steady flow momentum equation with external force,

$$F_x + P_{1,gage} A_1 + P_{2,gage} A_2 = \beta_2 \dot{m}(-V_2) - \beta_1 \dot{m} V_1$$

Therefore, horizontal force,

$$F_x = -\beta_2 \dot{m} V_2 - \beta_1 \dot{m} V_1 - P_{1,gage} A_1 - P_{2,gage} A_2$$

$$= -(1.04 \times 499.1 \times 33.333) - (1.02 \times 499.1 \times 20) - 88.34 \times 10^3 \times 0.025 - 67.48 \times 10^3 \times 0.015$$

$$= -30704.3 \text{ N}$$

Therefore, the horizontal force of the fluid on the walls of the duct, $\boxed{F_x = -30704.3 \text{ N}}$

Question: 13.042P

Water flowing in a horizontal 25-cm-diameter at 8 m/s and 300 kPa gage enters a 90° bend reducing section, which connects to a 15-cm-diameter vertical pipe.The inlet of the bend is 50 cm above the exit. Neglecting any frictional and gravitational effects, determine the net results force exerted on the reducer by the water. Take the momentum -flux correction factor to be 1.04.

Step 1 of 8

Given data:

Inlet velocity of the fluid, $V_1 = 8\ m/s$

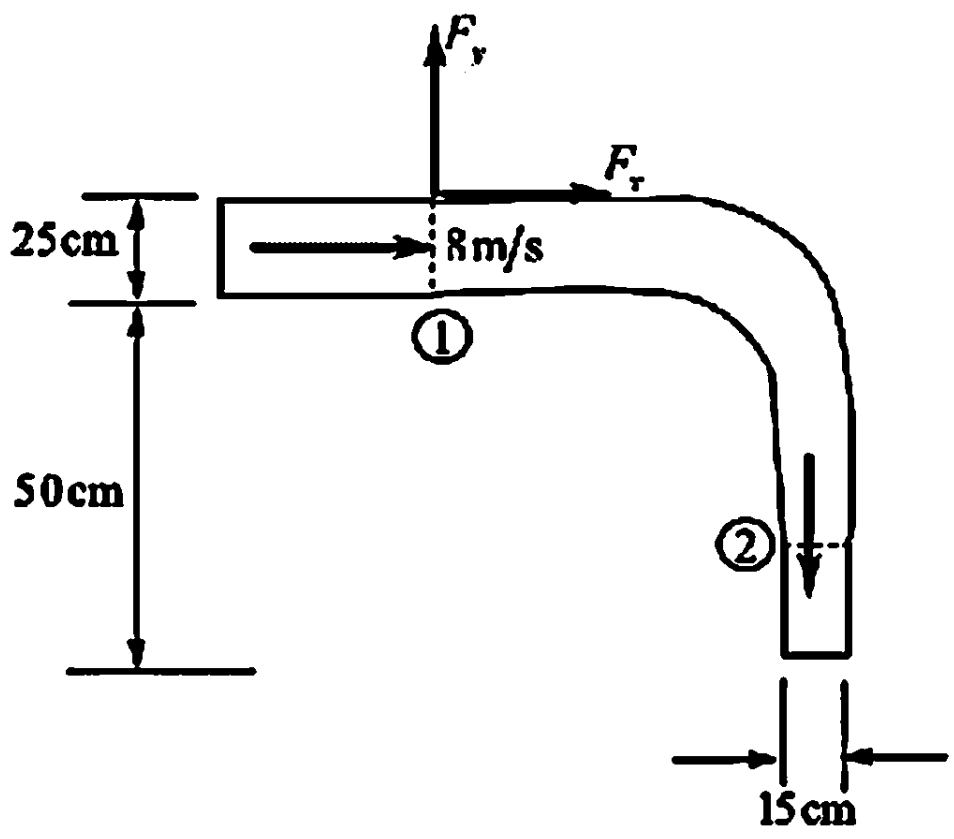
Gage pressure at inlet, $P_{1,gage} = 300\ kPa = 300\times10^3\ Pa$

Inlet diameter, $d_1 = 25\ cm = 0.25\ m$

The height of inlet of pipe from datum, $z_1 = 50\ cm = 0.05\ m$

The height of outlet of pipe from datum, $z_2 = 0\ cm = 0\ m$

Outlet diameter, $d_2 = 15\ cm = 0.15\ m$



Density of the fluid, $\rho = 1000\ kg/m^3$

Momentum flux correction factor, $\beta = 1.04$

Acceleration due to gravity, $g = 9.81 m/s^2$

Step 2 of 8

The reducer is as shown in figure:

Step 3 of 8

Mass flow rate of the fluid at inlet,

$$\dot{m} = \rho A_1 V_1$$

$$= 1000\times\frac{\pi}{4}\times d_1^2\times 8$$

$$= 1000\times\frac{\pi}{4}\times 0.25^2\times 8$$

$$= 392.699\ m/s$$

Step 4 of 8

Mass flow is constant throughout the duct,

Therefore,

$$\dot{m}_{inlet} = \dot{m}_{outlet}$$

$$\rho A_1 V_1 = \rho A_2 V_2$$

$$392.699 = 1000\times\frac{\pi}{4}\times d_2^2\times V_2$$

$$392.699 = 1000\times\frac{\pi}{4}\times 0.15^2\times V_2$$

$$V_2 = 22.22\ m/s$$

Step 5 of 8

By using Bernoulli equation, we have

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1 = \frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2$$

$$\frac{300\times1000}{1000\times9.81}+\frac{8^2}{2\times9.81}+0.05 = \frac{P_2}{1000\times9.81}+\frac{(22.222)^2}{2\times9.81}+0$$

$$30.581+3.261+0.05 = \frac{P_2}{1000\times9.81}+25.169$$

$$P_2 = 85572.63\ Pa$$

$$= 85.572\ kPa$$

Step 6 of 8

Steady flow momentum equation with external force

$$\sum F = \sum_{ex}\beta\dot{m}V - \sum_{in}\beta\dot{m}V$$

By using the moment equation along x-axis,

$$F_x + P_{1,gage}A_1 = 0 - \beta\dot{m}V_1$$

$$F_x = -\beta\dot{m}V_1 - P_{1,gage}A_1$$

$$F_x = -1.04\times392.699\times8 - 300\times1000\times\frac{\pi}{4}\times0.25^2$$

$$= -17993.471\ N$$

$$= -17.993\ kN$$

Step 7 of 8

By using the moment equation along y-axis,

$$F_y - P_{2,gage}A_2 = \beta\dot{m}(-V_2) - 0$$

$$F_y = -\beta\dot{m}V_2 + P_{2,gage}A_2$$

$$F_y = -1.04\times392.699\times22.222 + 85.572\times1000\times\frac{\pi}{4}\times0.15^2$$

$$F_y = -7563.437\ N$$

$$= -7.563\ kN$$

The net resultant force acting on the reducer by the water,

$$F_R = \sqrt{F_x^2+F_y^2}$$

$$= \sqrt{(-17.993)^2+(-7.563)^2}$$

$$= 19.517\ kN$$

Therefore, the net resultant force acting on the reducer by the water, $\boxed{F_R = 19.517\ kN}$.

Step 8 of 8

The angle of resultant force with positive x-axis,

$$\theta = \tan^{-1}\left(\frac{F_y}{F_x}\right)$$

$$= \tan^{-1}\left(\frac{-7.563}{-17.993}\right)$$

$$= 22.798°$$

Therefore, the angle of resultant force with positive x-axis, $\boxed{\theta = 22.798°}$.

Question: 13.043P

Commercially available large wind turbines have blade span diameters as large as 100 m and generate over 3 MW of electric power at peak design conditions. Consider a wind turbine with a 90-m blade span subjected to 25-km/h steady winds. If the combined turbine-generator efficiency of the wind turbine is 32 percent determine (*a*) the power generated by the turbine and (*b*) the horizontal force exerted by the wind on the supporting mast of the turbine. Take the density of air to be 1.25 kg/m3, and disregard frictional effect.

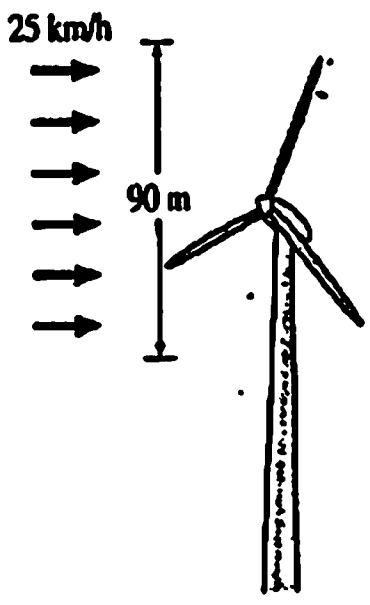


FIGURE P13–43

Step 1 of 5

Diameter of the span, $d = 90\,\text{m}$

Power generated by the electric generator, $W_{act} = 3\,\text{MW}$

Initial velocity of the blade,

$$V_1 = 25\ \text{km/h}$$
$$= 25\times\left(\frac{5}{18}\right)$$
$$= 6.94\ \text{m/s}$$

Generator efficiency,

$$\eta_{gen} = 32\%$$
$$= 0.32$$

Density of air, $\rho = 1.25\ \text{kg/m}^3$

Step 2 of 5

$$\dot{m} = \rho A_1 V_1$$

Mass flow rate,
$$= 1.25\times\frac{\pi(90)^2}{4}\times 6.94$$
$$= 55187.96\ \text{m/s}$$

Step 3 of 5

Turbine efficiency,

$$\eta_{turbine} = \frac{W_{act}}{W_{max}}$$
$$0.32 = \frac{3}{W_{max}}$$
$$W_{max} = \frac{3}{0.32}$$
$$= 9.37\ \text{MW}$$

Therefore, the power developed by the turbine is $\boxed{W_{max} = 5.12\ \text{MW}}$

Step 4 of 5

The exit velocity of blade for wind turbine is determined as,

$$V_2 = V_1\sqrt{(1-\eta_{turbine})}$$
$$= 6.94\sqrt{(1-0.32)}$$
$$= 5.72\ \text{m/s}$$

Step 5 of 5

The moment equation, we have

$$\sum\vec{F} = \sum_{out}\beta\dot{m}\vec{V} - \sum_{in}\beta\dot{m}\vec{V} \quad \text{..... (1)}$$

Where,

Moment flux correction factor for study flow is $\beta = 1$

The equation (1) can be re-written as,

$$\vec{F} = \beta\dot{m}V_2 - \beta\dot{m}V_1$$
$$= \beta\dot{m}(V_2 - V_1)$$
$$= 1\times 55187.96\times(5.72-6.94)$$
$$= -67329.31\ \text{N}$$

Therefore, the horizontal force exerted by the wind is $\boxed{\vec{F} = -67329.31\ \text{N}}$

Question: 13.044P pg 1

Water enters vertically and steadily at a rate of 15 L/s into the sprinkler shown in Fig. P13-44. Both water jets have a diameter of 1.2 cm. Disregarding any frictional effects, determine (*a*) the rotational speed of the sprinkler in rpm and (*b*) the torque required to prevent the sprinkler from rotating.

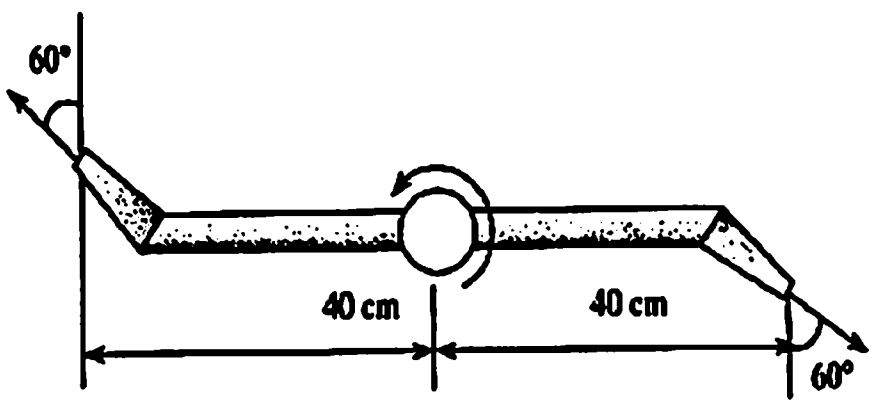

FIGURE P13–44

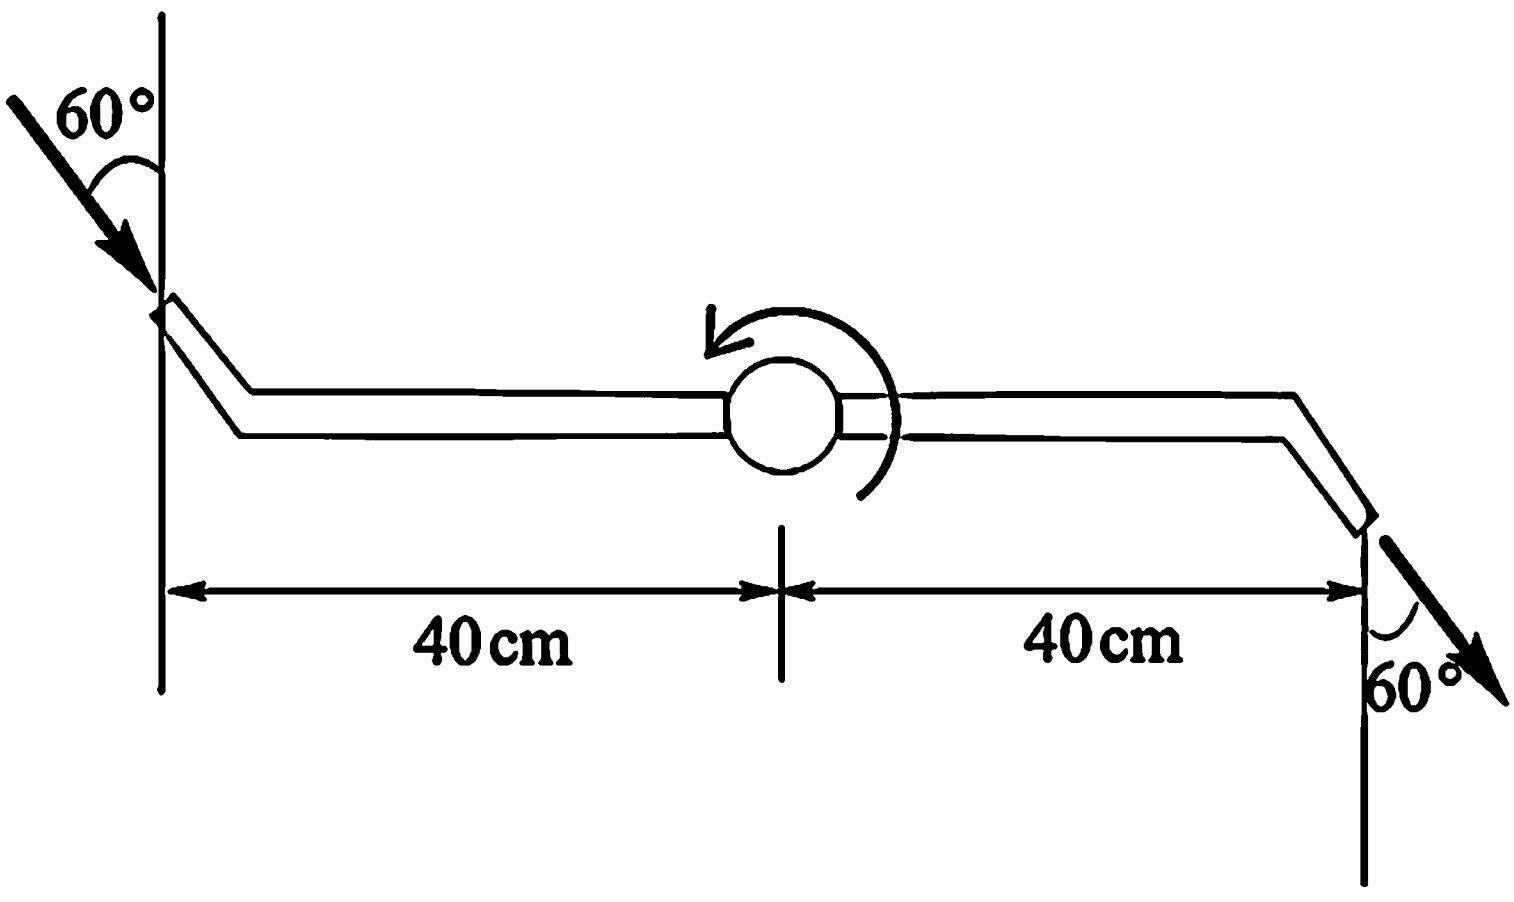
Step 1 of 9

Given data:



The mass flow rate of water along the vertical pipe,

$$\dot{m}_v = 15 \text{ L/s}$$
$$= 14.4 \text{ kg/s}$$

The diameter of water jets, $D = 1.2 \text{ cm}$

Step 2 of 9

Given figure:

Step 3 of 9

The density of water is $\rho = 1000 \text{ kg/m}^3$.

Since, both the nozzles are identical and at equal distance from the center.

Then,

$$\dot{m}_1 = \dot{m}_2 = \frac{\dot{m}_v}{2}$$

Therefore, mass flow rate,

$$\dot{m} = \frac{\dot{m}_v}{2}$$
$$= \frac{14.4}{2}$$
$$= 7.2 \text{ kg/s}$$

Step 4 of 9

The volumetric flow rate,

$$\dot{V} = \frac{\dot{m}}{\rho}$$
$$= \frac{7.2}{1000}$$
$$= 0.0072 \text{ m}^3/\text{s}$$

Step 5 of 9

The velocity of jet,

$$V_{jet} = \frac{\dot{V}}{A_{jet}}$$
$$= \frac{0.0072}{2\left[\frac{\pi}{4}(0.012^2)\right]}$$
$$= 31.83 \text{ m/s}$$

Step 6 of 9

The angular momentum equation can be expressed as,

$$\sum M = \left(\sum rmV_{out}\right) - \left(\sum rmV_{in}\right)$$

We know that there are no external moments acting on the system. Then the momentum equation about the axis of rotation becomes

$$0 = -2rmV_r \cos\theta$$

Therefore the relative velocity of the jet $V_r = 0$

Step 7 of 9

Therefore the relative velocity of the jet, V_r = 13.044P pg 2

Step 7 of 9

We also know,

$$V_r = V_{jet,s} - V_{nozzle}$$

Then

$$V_{jet,s} - V_{nozzle} = 0$$
$$V_{jet,s} = V_{nozzle}$$
$$V_{jet}\cos 60^\circ = V_{nozzle}$$

$$V_{nozzle} = V_{jet}\cos 60^\circ$$
$$= 31.83 \times \cos 60^\circ$$
$$= 15.915 \text{ m/s}$$

Step 8 of 9

(a)

Calculation of rotational speed of the sprinkler:

We know that,

$$V_{nozzle} = \omega \frac{D}{2}$$

Then, rate of rotation or angular velocity is,

$$\omega = \frac{V_{nozzle}}{(D/2)}$$
$$= \frac{15.915}{(0.4/2)}$$
$$= 79.575 \text{ rad/s}$$

The rotational speed,

$$\dot{n} = \frac{\omega \times 60}{2\pi}$$
$$= \frac{79.575 \times 60}{2\pi}$$
$$= 759.9 \text{ rpm}$$

Therefore, the rotational speed of the system is $\boxed{\dot{n} = 759.9 \text{ rpm}}$

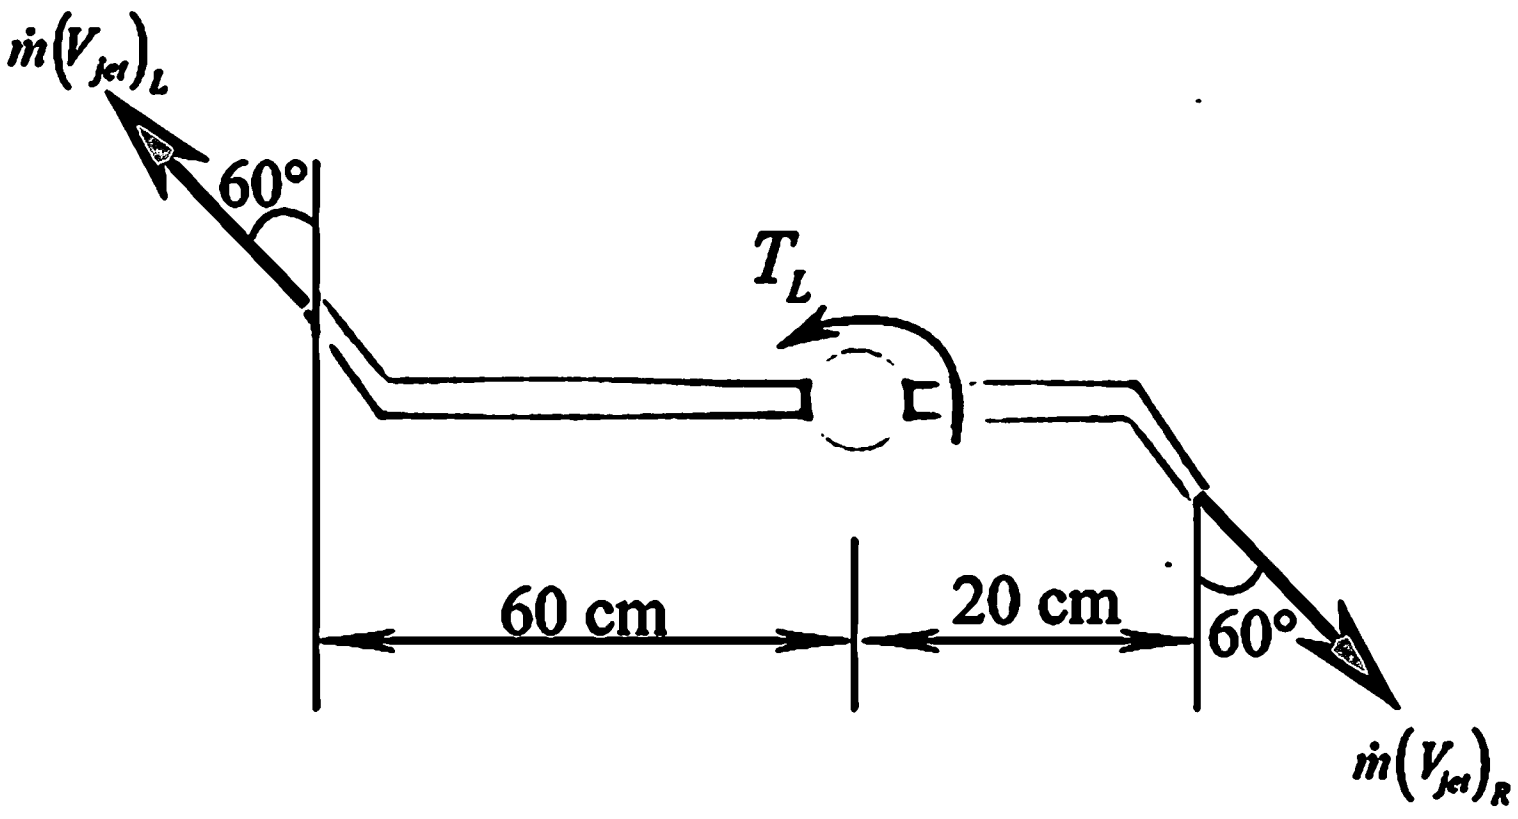
Step 9 of 9

(b)

The torque required to prevent the sprinkler from rotating:

The torque can be expressed as,

$$T_{shaft} = r\dot{m}_v V_{jet}$$
$$= (0.2)(14.4)(31.83)$$
$$= 91.67 \text{ N} \cdot \text{m}$$



Therefore, the torque required is $\boxed{T_{shaft} = 91.67 \text{ N} \cdot \text{m}}$

Question: 13.045P pg 1

Repeat Prob. 13-44 for the case of unequal arms —the left one being 60 cm and the right one 20 cm from the axis of rotation.

Step 1 of 9

Draw the schematic diagram of the sprinkler.

Step 2 of 9

Convert the units of volume flow rate of water L/s to m^3/s.

$$1\ L/s = 10^{-3}\ m^3/s$$

$$Q = 15\ L/s$$
$$= 15\times10^{-3}\ m^3/s$$

Find the mass flow rate of water by using the equation.

$$\dot{m} = \rho Q$$

Here, Q is volume flow rate of water, and ρ is the density of water.

Substitute $15\times10^{-3}\ m^3/s$ for Q, and $1000\ kg/m^3$ for ρ.

$$\dot{m} = 1000\times15\times10^{-3}$$
$$= 15\ kg/s$$

Step 3 of 9

Find the cross sectional area for left section of the sprinkler using the equation.

$$A_L = \frac{\pi}{4}d^2$$

Here, d is the diameter of the jet.

Substitute 0.012 m for the value d.

$$A_L = \frac{\pi}{4}\times0.012^2$$
$$= 1.13\times10^{-4}\ m^2$$

Find the cross sectional area for right section of the sprinkler using the equation.

$$A_R = \frac{\pi}{4}d^2$$

Substitute 0.012 m for the value d.

$$A_R = \frac{\pi}{4}\times0.012^2$$
$$= 1.13\times10^{-4}\ m^2$$

Step 4 of 9

Find the velocity at left section of the sprinkler using the equation.

$$\frac{Q}{2} = A_L V_L$$

Here, A_L is the cross sectional area at left section of the sprinkler and V_L is the velocity at larger section of the sprinkler.

Substitute $15\times10^{-3}\ m^3/s$ for Q and $1.13\times10^{-4}\ m^2$ for A_L.

$$\frac{15\times10^{-3}}{2} = 1.13\times10^{-4}V_L$$
$$V_L = 66.37\ m/s$$

Find the velocity along the vertical direction at left jet.

$$(V_L)_V = V_L\cos\theta$$

Here, θ is the inclination.

Substitute $66.37\ m/s$ for V_L, and $60°$ for θ.

$$(V_L)_V = 66.37\cos60°$$
$$= 33.18\ m/s$$

Step 5 of 9

Find the velocity at right section of the sprinkler using the equation.

$$\frac{Q}{2} = A_R V_R$$

Here, A_R is the cross sectional area at right section of the sprinkler and V_R is the velocity of the sprinkler.

Substitute $15\times10^{-3}\ m^3/s$ for Q and $1.13\times10^{-4}\ m^2$ for A_R.

2

Here, A_R is the cross sectional area at right section of the sprinkler and V_R is the velocity of the sprinkler.

Substitute $15\times10^{-3}\ \text{m}^3/\text{s}$ for Q and $1.13\times10^{-4}\ \text{m}^2$ for A_R.

$$\frac{Q}{2}=A_RV_R$$
$$\frac{15\times10^{-3}}{2}=1.13\times10^{-4}V_R$$
$$V_R=66.37\ \text{m/s}$$

Step 6 of 9

Find the velocity along the vertical direction at right jet.

$$(V_R)_V=V_R\cos\theta$$

Substitute $66.37\ \text{m/s}$ for V_L, and $60°$ for θ.

$$(V_R)_V=66.37\cos60°$$
$$=33.18\ \text{m/s}$$

Find the velocity of the nozzle with respect to left jet using the equation,

$$(V_{nozzle})_L=r_L\omega$$

Here, r_L is the arc length and ω is the angular speed of sprinkler.

Substitute 0.6 m for r_L.

$$(V_{nozzle})_L=0.6\omega$$

Find the velocity of the nozzle with respect to right jet using the equation.

$$(V_{nozzle})_R=r_R\omega$$

Here, r_R is the arc length.

Substitute 0.2 m for r_R.

$$(V_{nozzle})_R=0.2\omega$$

Step 7 of 9

Find the absolute velocity of water at left jet.

$$(V_{jet})_L=(V_L)_V-(V_{nozzle})_L$$

Substitute $33.18\ \text{m/s}$ for $(V_L)_V$ and (0.6ω) for $(V_{nozzle})_L$.

$$(V_{jet})_L=33.18-0.6\omega$$

Find the absolute velocity water at right jet.

$$(V_{jet})_R=(V_R)_V-(V_{nozzle})_R$$

Substitute $33.18\ \text{m/s}$ for $(V_R)_V$ and (0.2ω) for $(V_{nozzle})_R$.

$$(V_{jet})_R=33.18-0.2\omega$$

Step 8 of 9

(a)

Apply angular momentum equation for no external moments acting on the system.

$$\sum M=\sum rmV_{out}-\sum rmV_{in}$$
$$0=r_L\dot{m}(V_{jet})_R-r_R\dot{m}(V_{jet})_L$$

Substitute $(33.18-0.6\omega)$ for $(V_{jet})_L$, $15\ \text{kg/s}$ for $\dot{m}$, 0.6 m for r_L, 0.2 for r_R and $(33.18-0.2\omega)$ for $(V_{jet})_R$.

$$0=r_L\dot{m}(V_{jet})_R-r_R\dot{m}(V_{jet})_L$$
$$0=0.6\times15\times(33.18-0.6\omega)-0.2\times15\times(33.18-0.2\omega)$$
$$9(33.18-0.6\omega)=3(33.18-0.2\omega)$$
$$199.08=4.8\omega$$
$$\omega=41.47\ \text{rad/s}$$

Find the rotations speed of sprinkler using the equation.

$$n=\frac{\omega\times60}{2\pi}$$

Substitute $41.47\ \text{rad/s}$ for ω.

$$n=\frac{41.47\times60}{2\pi}$$
$$=396\ \text{rpm}$$

Therefore, the rotational speed of sprinkler is $\boxed{396\ \text{rpm}}$.

(b)

Find the absolute velocity of water on the sprinkler due to the left jet.

$$(V_{jet})_L=33.18-0.6\omega$$

Substitute $41.47\ \text{rad/s}$ for ω.

$$(V_{jet})_L=33.18-(0.6\times41.47)$$
$$=8.29\ \text{N}\cdot\text{m}$$

Find the absolute velocity of water on the sprinkler due to the right jet.

$$(V_{jet})_R=33.18-0.2\omega$$

$= 8.29\ \text{N}\cdot\text{m}$

Find the absolute velocity of water on the sprinkler due to the right jet.

$$\left(V_{jet}\right)_R = 33.18 - 0.2\omega$$

Substitute $41.47\ \text{rad/s}$ for ω.

$$\left(V_{jet}\right)_R = 33.18 - (0.2 \times 41.47)$$
$$= 24.88\ \text{N}\cdot\text{m}$$

Step 9 of 9

Find the torque on the sprinkler due to the left jet.

$$T_L = r_L \dot{m} \left(V_{jet}\right)_L$$

Substitute $8.29\ \text{m/s}$ for $\left(V_{jet}\right)_L$, $15\ \text{kg/s}$ for $\dot{m}$ and 0.6 m for r_L.

$$T_L = 0.6 \times 15 \times 8.29$$
$$= 74.61\ \text{N}\cdot\text{m}$$

Find the torque on the sprinkler due to the right jet.

$$T_R = r_R \dot{m} \left(V_{jet}\right)_R$$

Substitute $24.88\ \text{m/s}$ for $\left(V_{jet}\right)_R$, $15\ \text{kg/s}$ for $\dot{m}$ and 0.35 m for r_R.

$$T_R = 0.35 \times 15 \times 24.88$$
$$= 130.62\ \text{N}\cdot\text{m}$$

Find the total torque required to prevent sprinkler from rotating.

$$T = T_L + T_R$$
$$= 74.61 + 130.62$$
$$= 205.23\ \text{N}\cdot\text{m}$$

Therefore, the total torque required to prevent sprinkler from rotating is

$\boxed{205.23\ \text{N}\cdot\text{m}}$.

Question: 13.046P

A 60-kg ice skater is standing on ice with ice skates (negligible friction). She is holding a flexible hose (essentially weightless) that directs a 2-cm-diameter stream of water horizontally parallel to her skates. The water velocity at the hose outlet is 10 m/s relative to the skater. If she is initially standing still, determine (*a*) the velocity of the skater and the distance she travels in 5 s and (*b*) how long it will take to move 5 m and the velocity at that moment.

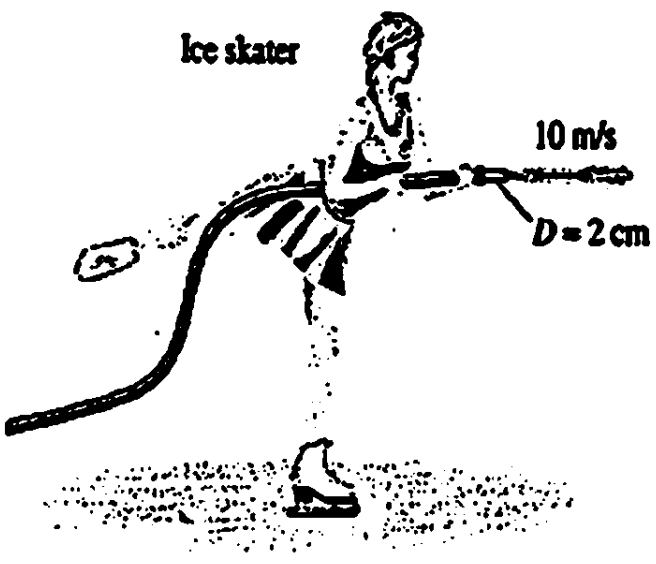


FIGURE P13–46

Step 1 of 4

(a)

Calculate the mass flow rate of water through the hose by using the following equation

$$\dot{m} = \rho A V$$

Here, density of water is ρ , the cross-sectional area of the hose is A and the velocity of the water at the hose outlet V

Substitute $1000\,\text{kg/m}^3$ for ρ, $\frac{\pi(0.02\,\text{m})^2}{4}$ for A and $10\,\text{m/s}$ for V in the equation

$$\dot{m} = (1000\,\text{kg/m}^3)\frac{\pi(0.02\,\text{m})^2}{4}(10\,\text{m/s})$$
$$= 3.14\,\text{kg/s}$$

Step 2 of 4

The force exerted on the skater by the water stream (F) is the momentum flux of the water stream acting opposite to the direction of water flow.

$$F = \dot{m}V$$
$$= (3.14\,\text{kg/s})(10\,\text{m/s})$$
$$= 31.4\,\text{N}$$

(*a*)

Find the acceleration of the skater

$$a = \frac{F}{m}$$

Substitute $31.4\,\text{N}$ for F and $60\,\text{kg}$ for m in the equation

$$a = \frac{F}{m}$$
$$= \frac{31.4\,\text{N}}{60\,\text{kg}}$$
$$= 0.523\,\text{m/s}^2$$

Find the velocity of the skater after 5 seconds

$$V_{skater} = at$$
$$= (0.523\,\text{m/s}^2)(5\,\text{s})$$
$$= 2.62\,\text{m/s}$$

The velocity of the skater after 5 s is $2.62\,\text{m/s}$.

Step 3 of 4

Determine the distance traveled by the skater (x) after 5 s.

$$x = \frac{1}{2}at^2$$
$$= \frac{1}{2}(0.523\,\text{m/s}^2)(5\,\text{s})^2$$
$$= 6.54\,\text{m}$$

The distance traveled by the skater after 5 s is $6.54\,\text{m}$.

Step 4 of 4

(b)

Use kinematics to determine the time it takes to move 5 meters distance.

$$t = \sqrt{\frac{2x}{a}}$$

Here, distance moved is x

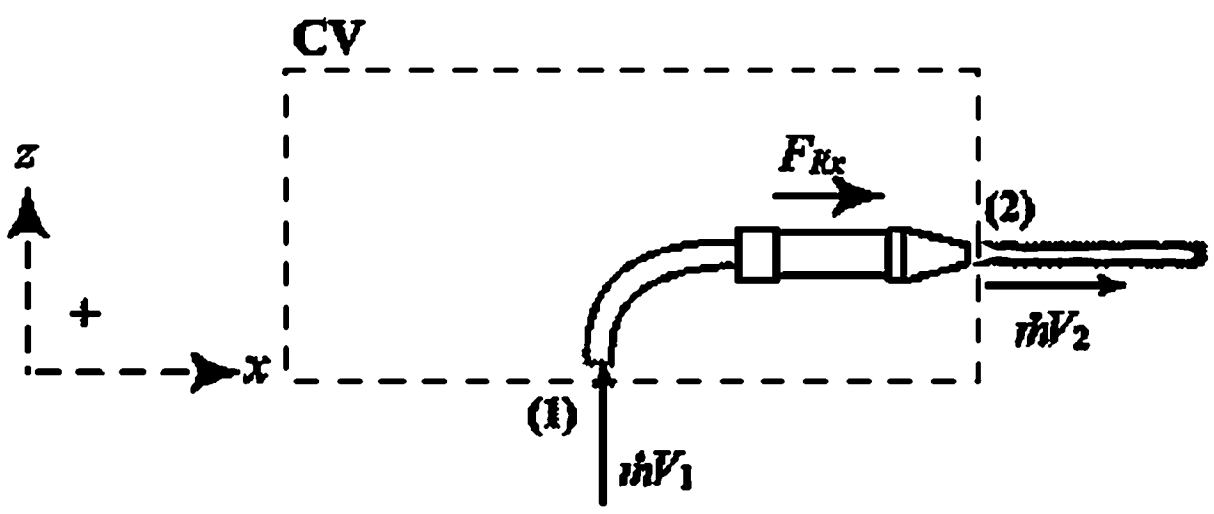
Substitute $5\,\text{m}$ for x and $0.523\,\text{m/s}^2$ for a in the equation

$$t = \sqrt{\frac{2(5\,\text{m})}{0.523\,\text{m/s}^2}}$$
$$= 4.4\,\text{s}$$

Therefore, the time taken for the skater to travel 5 m distance is $4.4\,\text{s}$

Use kinematics to determine the velocity of the skater after she has traveled 5 m.

$$V_{skater} = at$$
$$= (0.523\,\text{m/s}^2)(4.4\,\text{s})$$
$$= 2.3\,\text{m/s}$$



Therefore, the velocity of the skater after she has traveled 5 m is $2.3\,\text{m/s}$.

Question: 13.047P

Show that the force exerted by a liquid jet on a stationary nozzle as it leaves with a velocity *V* is proportional to *V* 2 or, alternatively, to *m*2. Assume the jet stream is perpenticular to the incoming liquid flow line.

Step 1 of 5

Schematic representation of jet, nozzle and direction of forces:

Step 2 of 5

Let us prove that, the force exerted by the jet is proportional to square of velocity of jet:
The momentum equation for steady one dimensional flow in the horizontal direction can be expressed as,

$$\sum F = \sum \beta \dot{m} V_{out} - \sum \beta \dot{m} V_{in}$$

From the figure, the inlet components are in the vertical direction. Since, we can get the reaction force with horizontal components alone, we can neglect the inlet components.

Step 3 of 5

Then the above momentum equation becomes,

$$F_{Rx} = \dot{m}V_2 - 0$$

Since,

$$\dot{m} = \rho A V$$

The momentum equation, $F_{Rx} = \rho A V_2^2$

Thus, the nozzle exerts a reaction force $F_{Rx} = \rho A V_2^2$ against the jet or the jet exerts a force of magnitude equal to the reaction force in the opposite direction.

That is $\boxed{F_{jet} = \rho A V_2^2}$.

Hence proved, that the force exerted by the jet is proportional to V_2^2.

Step 4 of 5

Let us prove that, the force exerted by the jet is proportional to
From Newton's law, we have

$$F_{Rx} = \dot{m}V_2$$

We also know that,

$$V_2 = \frac{\dot{m}}{\rho A}$$

Step 5 of 5

Then, the reaction force,

$$F_{Rx} = \dot{m}\left(\frac{\dot{m}}{\rho A}\right)$$

$$= \frac{\dot{m}^2}{\rho A}$$

The nozzle exerts a reaction force $F_{Rx} = \frac{\dot{m}^2}{\rho A}$ against the jet or the jet exerts a force of magnitude equal to the reaction force in the opposite direction.

$$\boxed{F_{jet} = \frac{\dot{m}^2}{\rho A}}.$$

Hence proved, that the force exerted by the jet is proportional to $\dot{m}^2$.

Question: 13.048P

A tripod holding a nozzle, which directs a 5-cm-diameter stream of water from a hose, is shown in Fig. P13-48. The nozzle mass is 10 kg when filled with water. The tripod is rated to provide 1800 N of holding force. A firefighter was standing 60 cm behind the nozzle and was hit by the nozzle when the tripod suddenly failed and released the nozzle. You have been hired as an accident reconstructionist and, after testing the tripod, have determined that as water flow rate increased, it did collapse at 1800 N. In your final report you must state the water velocity and the flow rate consistent with the failure and the nozzle velocity when it hit the firefighter. For simplicity, ignore pressure and momentum effects in the upstream portion of the hose.

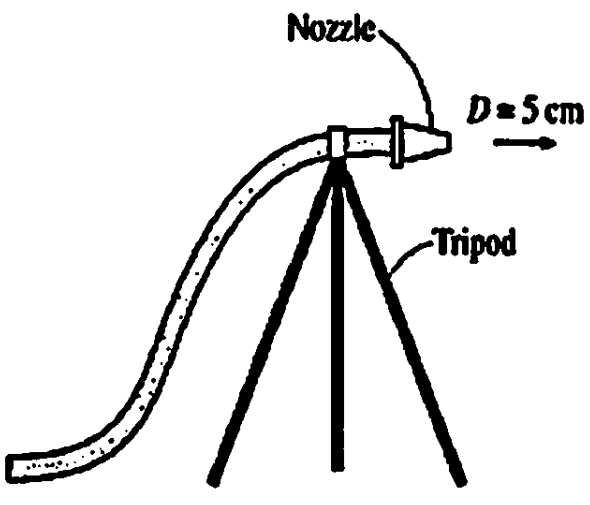


FIGURE P13–48

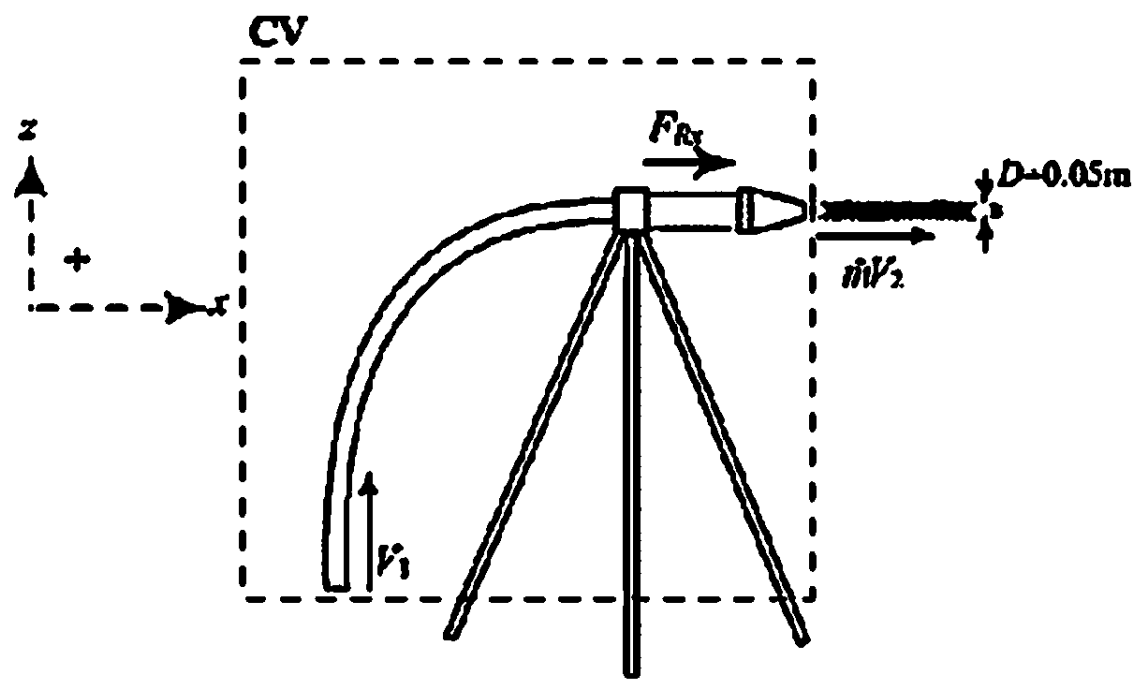
Step 1 of 7

Given data:

The reaction force offered by the tripod in horizontal direction, $F_{Rx} = 1800$ N



The mass of the nozzle, $m_N = 10$ kg

The distance between the nozzle and firefighter, $d = 0.6$ m

The diameter of water stream at nozzle, $D = 0.05$ m

Step 2 of 7

Given figure:

Step 3 of 7

Calculation of exit velocity of the stream:

The velocity of the stream at exit is,

$$V_2 = \sqrt{\frac{F_{Rx}}{\rho A}} \qquad \ldots\ldots (1)$$

The area of water stream at exit,

$$A = \pi\frac{D^2}{4}$$
$$= \pi\frac{0.05^2}{4}$$
$$= 0.0019634 \text{ m}^2$$

Step 4 of 7

The momentum equation for steady one dimensional flow in the horizontal direction can be expressed as,

$$\sum F = \sum \beta \dot{m} V_{out} - \sum \beta \dot{m} V_{in}$$

Since, the momentum flux correction factor is negligible and $V_1 = 0$

Then,

$$F_{Rx} = \dot{m}V_2 - 0$$
$$F_{Rx} = \rho A V_2^2 \qquad (\text{since, } \dot{m} = \rho A)$$

By substituting the known values in equation (1), we get

$$V_2 = \sqrt{\frac{F_{Rx}}{\rho A}}$$
$$= \sqrt{\frac{1800}{1000 \times 0.0019634}}$$
$$= 30.27 \text{ m/s}$$

Therefore, the exit velocity of the stream is $\boxed{V_2 = 30.27 \text{ m/s}}$

Step 5 of 7

Calculation of flow rate of water:

Flow rate of water can be calculated as,

$$\dot{V} = AV_2$$
$$= (0.0019634)(30.27)$$
$$= 0.05944 \text{ m}^3/\text{s}$$

Therefore, the volumetric flow rate is $\boxed{\dot{V} = 0.05944 \text{ m}^3/\text{s}}$

Step 6 of 7

Calculation of the velocity of the nozzle when it strikes the fire fighter:

From Newton's law we have, the holding force,

$$F_{Rx} = m_N a$$

Then,

$$a = \frac{F_{Rx}}{m_N}$$
$$= \frac{1800}{10}$$
$$= 180 \text{ m/s}^2$$

We have the equation for motion

$$s = V_0 t + \frac{1}{2}at^2$$

For the nozzle,

$$0.6 = 0 + \frac{1}{2}(180)t^2$$

Then

$$t = \sqrt{\frac{2 \times 0.6}{180}}$$
$$= 0.0816 \text{ s}$$

Step 7 of 7

The final velocity of nozzle,

$$V = V_0 + at$$
$$= 0 + (180)(0.0816)$$
$$= 14.7 \text{ m/s}$$

Therefore, the velocity of the nozzle when it strikes the fire fighter is, $\boxed{V = 14.7 \text{ m/s}}$

Question: 13.049P

Consider an airplane with a jet engine attached to the tail section that expels combustion gases at a rate of 18 kg/s with a velocity of $V = 300$ m/s relative to the plane. During landing, a thrust reverser (which serves as a brake for the aircraft and facilitates landing on a short runway) is lowered in the path of the exhaust jet, which deflects the exhaust from rearward to 150°. Determine (*a*) the thrust (forward force) that the engine produces prior to the insertion of the thrust reverser and (*b*) the braking force produced after the thrust reverser is deployed.

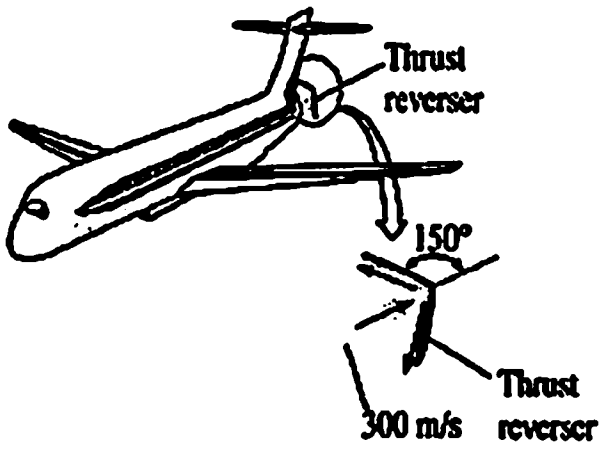


FIGURE P13–49

Step 1 of 3

Given data:

The mass flow rate of combustion gases, $\dot{m} = 18\ \text{kg/s}$

The velocity of exhaust gases, $V = 300\ \text{m/s}$

The angle of exhaust from rearward, $\alpha = 150°$

Step 2 of 3

a)

By using formula for the thrust force exerted on the air plane, we get

$$\begin{aligned} F_{\text{thrust}} &= \dot{m}V \\ &= 18 \times 300 \\ &= 5400\ \text{N} \end{aligned}$$

Therefore, the thrust force exerted on the air plane, $\boxed{F_{\text{thrust}} = 5400\ \text{N}}$

Step 3 of 3

b)

By using the moment equation for steady one-dimensional flow in x -direction, we get

$$\sum F = \sum_{\text{out}} \beta \dot{m} V - \sum_{\text{in}} \beta \dot{m} V$$

$$\begin{aligned} F_{Rx} &= \dot{m}(-V)\cos(180° - \alpha) + \dot{m}(-V)\cos(180° - \alpha) - \dot{m}V \\ &= 18(-300)\cos(180° - \alpha) + 18(-300)\cos(180° - \alpha) - 18 \times 300 \\ &= 18(-300)\cos(180° - 150) + 18(-300)\cos(180° - 150) - 18 \times 300 \\ &= -14753.074\ \text{N} \end{aligned}$$

The braking force acting on the air plane is equal and opposite of the force F_{Rx}.

Therefore the braking force acting on the plane, $\boxed{F_{\text{braking}} = -14753.074\ \text{N}}$.

Question: 13.050P

Reconsider Prob. 13-49. Using EES (or other) software, investigate the effect of / thrust reverser angle on the braking force exerted on the airplane. Let the reverser angle vary from 0° (no reversing) to 180° (full reversing) in increments of 10°. Tabulate and plot your results and draw conclusions.

Step 1 of 5

The procedure for developing solution by using EES software:
Open the new equations window EES software and type all the information which is used to solve the problem
For developing table:
1) Click on table followed by new parametric table and add the variables, which are varying variable and required answer variable, then one table will form with that variables
2) Click on the variable which is varying and enter initial value and final value.
3) For getting the required answer variable values corresponding to the varying variable values click on the green color button and then the table will form with required answers
For developing graph:
1) Click on plot followed by new plot window followed by x-y plot.
2) Select the x-axis variable and y-axis variable and then press ok, then the graph will form with the given values.

Step 2 of 5

The equations which are using in EES software for developing the solution are given in equations window is as shown below

Equations Window

```
V_jet=300 "m/s"
m_dot=18 "Kg/s"
F_Rx=-(1-2*cos(alpha))*m_dot*V_jet "N"
```

Step 3 of 5

The EES software will convert the equations in equations window to equations in formatting window is as shown below

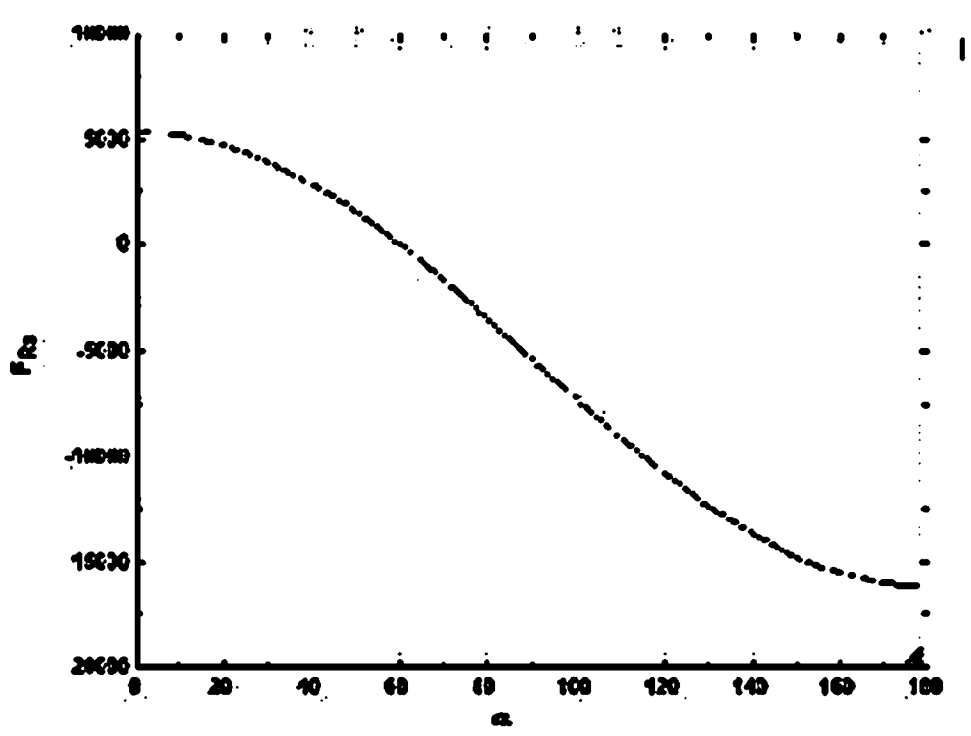
Formatted Equations

$V_{jet} = 300 \ m/s$

$\dot{m} = 18 \ Kg/s$

$F_{Rx} = -(1 - 2 \cdot \cos(\alpha)) \cdot \dot{m} \cdot V_{jet} \ N$

Step 4 of 5



The EES software is developing the table for F_{Rx} corresponding to the α values is as shown below,

Table 1

1..19	1 α	2 F_{Rx}
Run 1	0	5400
Run 2	10	5236
Run 3	20	4749
Run 4	30	3953
Run 5	40	2873
Run 6	50	1542
Run 7	60	-6.446E-10
Run 8	70	-1706
Run 9	80	-3525
Run 10	90	-5400
Run 11	100	-7275
Run 12	110	-9094
Run 13	120	-10800
Run 14	130	-12342
Run 15	140	-13673
Run 16	150	-14753

Step 5 of 5

The EES software is developing the graph between F_{Rx} and α is as shown below,

Question: 13.051P

A spacecraft cruising in space at a constant velocity of 1500 ft/s has a mass of 18,000 lbm. To slow down the spacecraft, a solid fuel rocket is fired, and the combustion gases leave the rocket at a constant rate of 150 lbm/s at a velocity of 5000 ft/s in the same direction as the spacecraft for a period of 5 s. Assuming the mass of the spacecraft remains constant, determine (*a*) the deceleration of the spacecraft during this 5-s period, (*b*) the change of velocity of the spacecraft during this time period, and (c) the thrust exerted on the spacecraft.

Question: 13.052P

A 6-cm-diameter horizontal water jet having a velocity of 25 m/s strikes a vertical stationary flat plate. The water splatters in all directions in the plane of the plate. How much force is required to hold the plate against the water stream?

We don't have the solution to this problem yet.

Get help from a Chegg subject expert.

Ask an expert

Question: 13.053P

A 5-cm-diameter horizontal jet of water, with velocity 30 m/s, strikes the tip of a horizontal cone, which deflects the water by 45° from its original direction. How much force is required to hold the cone against the water stream?

Step 1 of 2

Calculate the mass flow rate by using the following equation

$$\dot{m} = \rho A V$$

Here, density of water is ρ , cross-sectional area is A and the velocity of jet is V.

Substitute $1000\ \text{kg/m}^3$ for ρ, $\frac{\pi(0.05\ \text{m})^2}{4}$ for A and $30\ \text{m/s}$ for V in the equation

$$\dot{m} = (1000\ \text{kg/m}^3)\frac{\pi(0.05\ \text{m})^2}{4}(30\ \text{m/s})$$
$$= 58.90\ \text{kg/s}$$

Step 2 of 2

Consider the momentum flux equation

$$\sum F = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}$$

Here, momentum flux correction factor is β, mass flow rate is $\dot{m}$ and velocity is V

There are two forces acting on the cone, the anchoring forces in each direction (F_{Rx}, F_{Ry}). There is one source of mass into the region, the jet, and one source of mass out of the region, the deflected water.

Now consider the anchoring force in the x direction, the water velocity of the jet is the same as the water velocity of the deflected water.

$$F_{Rx} = \dot{m} V \cos\theta - \dot{m} V$$

Substitute $58.90\ \text{kg/s}$ for $\dot{m}$, $45°$ for θ and $30\ \text{m/s}$ for V in the equation

Plug in the calculated mass flow rate, the given velocity, and the angle of 45°.

$$F_{Rx} = (58.90\ \text{kg/s})(30\ \text{m/s})(\cos 45° - 1)$$
$$= -518\ \text{N}$$

The anchoring force in the y direction is zero because of symmetry

$$F_{Ry} = 0\ \text{N}$$

Therefore a force of $518\ \text{N}$ must be applied to hold the cone against the water stream.

Question: 13.054P

Water is flowing into and discharging from a pipe U-section as shown in Fig. PI3-54. At flange (1), the total absolute pressure is 200 kPa, and 42 kg/s flows into the pipe. At flange (2), the total pressure is 150 kPa. At location (3), 10 kg/s of water discharges to the atmosphere, which is at 100 kPa. Determine the total *x*- and *z*-forces at the two flanges connecting the pipe. Discuss the significance of gravity force for this problem. Take the momentum-flux correction factor to be 1.03 throughout the pipes.

Question: 13.055P

Indiana Jones needs to ascend a 10-m-high building. There is a large hose filled with pressurized water hanging down from the building top. He builds a square platform and mounts four 4-cm-diameter nozzles pointing down at each corner. By connecting hose branches, a water jet with 15-m/s velocity can be produced from each nozzle. Jones, the platform, and the nozzles have a combined mass of 150 kg. Determine (*a*) the minimum water jet velocity needed to raise the system, (*b*) how long it takes for the system to rise 10 m when the water jet velocity is 18 m/s and the velocity of the platform at that moment, and (*c*) how much higher will the momentum raise Jones if he shuts off the water at the moment the platform reaches 10 m above the ground. How much time does he have to jump from the platform to the roof?

Question: 13.056P

An engineering student considers using a fan as a levitation demonstration. She plans to face the box-enclosed fan so the air blast is directed face down through a 3-ft-diameter blade span area. The system weighs 5 lbf, and the student will secure the system from rotating. By increasing the power to the fan, she plans to increase the blade rpm and air exit velocity until the exhaust provides sufficient upward force to cause the box fan to hover in the air. Determine (*a*) the air exit velocity to produce 5 lbf, (*b*) the volumetric flow rate needed, and (*c*) the minimum mechanical power that must be supplied to the airstream. Take the air density to be 0.078 lbm/ft3.

Question: 13.058P

A 7-cm diameter vertical water jet is injected upwards by a nozzle at a speed of 15 m/s. Determine the maximum weight of a flat plate that can be supported by this water jet at a height of 2 m from the nozzle.

Step 1 of 5

Find the time to reach height 2m from the nozzle using the equation.

$$s = ut - \frac{1}{2}gt^2$$

Here, u is the initial velocity of the jet, h is the height from the nozzle, and g is the acceleration due to gravity.

Substitute $15\ \text{m/s}$ for u, $9.81\ \text{m/s}^2$ for g, and 2 m for s.

$$s = ut - \frac{1}{2}gt^2$$

$$2 = 15t - \frac{1}{2}\times 9.81 \times t^2$$

$$4.9t^2 - 15t + 2 = 0$$

$$t = 0.139\ \text{s}$$

Step 2 of 5

Find the velocity at height 2m from the nozzle using the equation.

$$v = u - gt$$

Substitute $15\ \text{m/s}$ for u and $9.81\ \text{m/s}^2$ for g.

$$v = u - gt$$
$$= 15 - 9.81\times 0.139$$
$$= 13.63\ \text{m/s}$$

Find the area of the jet using the equation.

$$A = \frac{\pi}{4}d^2$$

Here, d is the diameter of the jet.

Substitute $0.07\ \text{m}$ for d.

$$A = \frac{\pi}{4}d^2$$
$$= \frac{\pi}{4}(0.07)^2$$
$$= 0.00384\ \text{m}^2$$

Step 3 of 5

Find the volume flow rate of water using the continuity equation.

$$Q = Av$$

Here, area of the jet A.

Substitute $0.00384\ \text{m}^2$ for A and $13.63\ \text{m/s}$ for v.

$$Q = Av$$
$$= 0.00384\times 13.63$$
$$= 0.05233\ \text{m}^3/\text{s}$$

Find the mass flow rate of water using the equation.

$$\dot{m} = Q\rho$$

Here, density of the water is ρ.

Substitute $1000\ \text{kg/m}^3$ for ρ.

$$\dot{m} = Q\rho$$
$$= 0.05233\times 1000$$
$$= 52.33\ \text{kg/s}$$

Step 4 of 5

Apply the momentum equation with external force for steady flow,

$$\sum F = \sum_{out} \dot{m}V - \sum_{in} \dot{m}V$$
$$W = \dot{m}(V_{out}) - \dot{m}V_{in}$$

Here, W is the weight of the flat plate, V_{out} is the velocity after striking, and V_{in} is the velocity before striking.

Substitute $13.63\ \text{m/s}$ for $(V_{out} = v)$, 0 for V_{in} and $52.33\ \text{kg/s}$ for $\dot{m}$.

$$W = \dot{m}(V_{out}) - \dot{m}V_{in}$$
$$= 52.33\times 13.63 - 52.33\times 0$$
$$= 52.33\times 13.63$$
$$= 713.2579\ \text{N}$$

Therefore, the weight of the flat plate is $\boxed{713.2579\ \text{N}}$.

Step 5 of 5

Find the mass of the flat plate using the equation.

$$W = mg$$

Here, m is the mass of the flat plate.

Substitute $713.2579\ \text{N}$ for W.

$$W = mg$$
$$713.2579 = m\times 9.81$$
$$m = \frac{713.2579}{9.81}$$
$$= 72.7\ \text{kg}$$

Therefore, the mass of the flat plate is $\boxed{72.7\ \text{kg}}$.

Question: 13.059P

A soldier jumps from a plane and opens his parachute when his velocity reaches the terminal velocity *VT*. The parachute slows him down to his landing velocity of *VF*. After the parachute is deployed, the air resistance is proportional to the velocity squared (i.e., $F = kV2$). The soldier, his parachute, and his gear have a total mass of *m*. Show that $k = mg/V_F^2$ and develop a relation for the soldier's velocity after he opens the parachute at time $t = 0$.

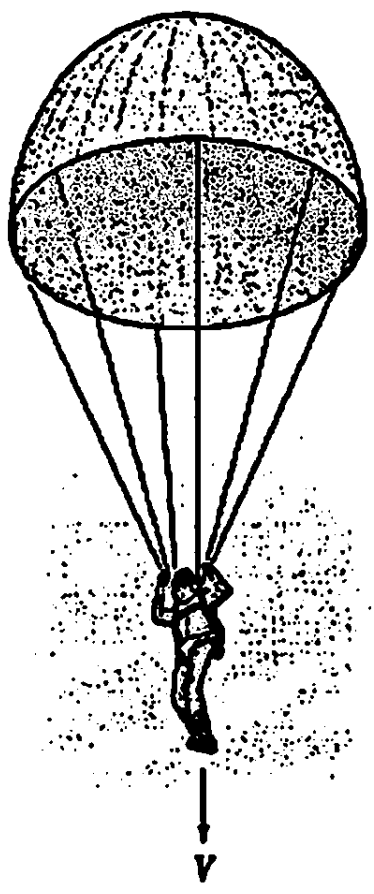

FIGURE P13–59

Step 1 of 5

As the Air resistance force is proportional to the square of the landing velocity when parachute is deployed,

$$F_{\text{air resistance}} = kV_F^2 \quad \text{..... (1)}$$

Here, constant is k, V_F is the landing velocity, and $F_{\text{air resistance}}$ is the force due to the air resistance.

Step 2 of 5

Landing velocity occurs when the air resistance is equal to the weight of the object.

Calculate the air resistance.

As the system is to be in equilibrium,

$$F_{\text{air resistance}} = W \quad \text{..... (2)}$$

Here, $F_{\text{air resistance}}$ is the force due to the air resistance and W is the total weight of the system.

Step 3 of 5

From equations (1) and (2), obtain the value of constant k.

$$mg = kV_F^2$$

$$k = \frac{mg}{V_F^2}$$

Therefore, the value of the constant is $\boxed{k = \frac{mg}{V_F^2}}$.

Step 4 of 5

Calculate the net force developed by parachute when the soldier has a velocity V.

$$F_{net} = W - F_{\text{air resistance}}$$

Here, F_{net} is the net force acting on the system.

Substitute mg for W and kV^2 for $F_{\text{air resistance}}$.

$$F_{net} = mg - kV^2$$

Substitute $\frac{mg}{V_F^2}$ for k.

$$F_{net} = mg - \frac{mg}{V_F^2} \times V^2$$

$$= mg\left(1 - \frac{V^2}{V_F^2}\right)$$

Step 5 of 5

According Newton's 2nd law

$$F_{net} = m\frac{dV}{dt}$$

$$mg\left(1 - \frac{V^2}{V_F^2}\right) = m\frac{dV}{dt}$$

Integrate to calculate the velocity,

Here $V = V_T$ when $t = 0$.

$$\frac{dV}{\left(1 - V^2/V_F^2\right)} = g\,dt$$

$$\int_{V_T}^{V} \frac{dV}{\left(V_F^2 - V^2\right)} = \frac{g}{V_F^2}\int_0^t dt$$

$$\frac{1}{2V_F}\left(\int_{V_T}^{V}\left(\frac{1}{(V_F + V)} + \frac{1}{(V_F - V)}\right)dV\right) = \frac{g\int_0^t dt}{V_F^2}$$

$$\frac{1}{2V_F}\left(\ln(V_F + V) + \ln(V_F - V)\right)_{V_T}^{V} = \frac{g(t)_0^t}{V_F^2}$$

Up on substituting the integrands, obtain the equation for the velocity of the soldier.

Therefore, velocity of soldier as a function of time is $V = V_F \frac{V_T + V_F + (V_T - V_F)e^{-2gt/V_F}}{V_T + V_F - (V_T - V_F)e^{-2gt/V_F}}$.

Question: 13.060P

Nearly frictionless vertical guide rails maintain a plate of mass *mp* in a horizontal position, such that it can slide freely in the vertical direction. A nozzle directs a water stream of area *A* against the plate underside. The water jet splatters in the plate plane, applying an upward force against the plate. The water flow rate *m* (kg/s) can be controlled. Assume that distances are short, so the velocity of the rising jet can be considered constant with height, (*a*) Determine the minimum mass flow rate $\dot{m}_{min}$ necessary to just levitate the plate and obtain a relation for the steady-state velocity of the upward moving plate for $\dot{m} > \dot{m}_{min}$ (*b*) At time *t* = 0, the plate is at rest, and the water jet with $\dot{m} > \dot{m}_{min}$ is suddenly turned on. Apply a force balance to the plate and obtain the integral that relates velocity to time (do not solve).

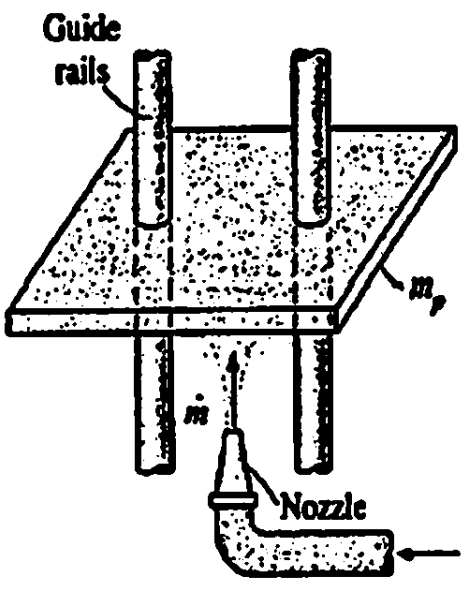

FIGURE P13–60

Step 1 of 3

a) Take the plate as the system. Recall the steady linear momentum equation relating force (*F*), the momentum flux correction factor (ß), mass flow rate ($\dot{m}$), and the velocity (*V*).

$$F = \sum_{out} \beta \dot{m} \vec{V} - \sum_{in} \beta \dot{m} \vec{V}$$

There is only one force acting on the system, the weight of the plate (*W*). There is no mass flow out but there is a source of mass flow in from the water jet.

$$W = \dot{m} V_j$$

The mass flow rate can be defined as the product of the density of water (*?*), the cross-sectional area of the jet (*A*), and the water velocity (V_J).

$$\dot{m} = \rho A V_j$$

$$V_j = \frac{\dot{m}}{\rho A} \quad \text{..... (1)}$$

The weight of the plate is defined as the product of its mass (*m*) and the gravitational constant (*g*).

$$mg = \frac{\dot{m}^2}{\rho A}$$

$$\dot{m} = \sqrt{\rho A m g}$$

Thus, the minimum mass flow rate necessary to just levitate the plate is $\boxed{\sqrt{\rho A m g}}$

Step 2 of 3

Now consider that the plate has some constant velocity. The momentum equation is then changed to reflect the relative velocity.

$$W = \dot{m}(V_j - V)$$

Recall the definitions of the water jet velocity, the mass flow rate, and the weight and rearrange to solve for the velocity of the plate.

$$mg = \rho A (V_j - V)^2$$

$$(V_j - V)^2 = \frac{mg}{\rho A}$$

Apply root on both sides.

$$(V_j - V)^2 = \frac{mg}{\rho A}$$

$$V_j - V = \sqrt{\frac{mg}{\rho A}}$$

Substitute (1) in above equation.

$$V_j - V = \sqrt{\frac{mg}{\rho A}}$$

$$V = \frac{\dot{m}}{\rho A} - \sqrt{\frac{mg}{\rho A}}$$

Thus, the relation for the steady-state velocity of the upward moving plate is $\boxed{\frac{\dot{m}}{\rho A} - \sqrt{\frac{mg}{\rho A}}}$

Step 3 of 3

b) Now consider a force balance on the plate. There are two forces acting on the plate, one from the momentum impulse and one from the weight. These two forces cause an acceleration of the plate (*a*).

$$\dot{m}(V_j - V) - W = ma$$

$$a = \frac{\rho A (V_j - V)^2}{m} - g$$

$$\frac{mdV}{\rho A (V_j - V)^2 - mg} = dt$$

Integrate both sides.

$$\int_0^V \frac{mdV}{\rho A (V_j - V)^2 - mg} = \int_0^t dt$$

$$t = \int_0^V \frac{mdV}{\rho A (V_j - V)^2 - mg}$$

Therefore, the integral that relates velocity to time is $\boxed{t = \int_0^V \frac{mdV}{\rho A (V_j - V)^2 - mg}}$

CHAPTER 14
SOLUTIONS

Question: 14.001P

What is hydraulic diameter? How is it defined? What is it equal to for a circular pipe of diameter D?

Step 1 of 1

Hydraulic diameter is defined as it is ratio of cross sectional area of the pipe to wetted perimeter of the pipe. This parameter useful to determined the Reynolds number for laminar or turbulent flow.

$$D_h = \frac{4A_c}{p}$$

Where,

A_c is the cross sectional area of the pipe

p is the perimeter of the pipe

For circular pipe:

$$D_{hc} = \frac{4A_c}{P}$$

$$= \frac{4\left(\frac{\pi}{4}D_c^2\right)}{\pi D_c}$$

$$= D_c$$

Hence, for circular pipe hydraulic diameter is reduced to diameter of the circular pipe.

Question: 14.002P

How is the hydrodynamic entry length defined for flow in a pipe? Is the entry length longer in laminar or turbulent flow?

Step 1 of 1

The region from the inlet of pipe to the point, at which the velocity profile is fully developed (where the boundary layer merges at the centerline) is called hydrodynamic entry region. The length of the hydrodynamic entry region is called hydrodynamic entry length. It is denoted by L_h

The entry length is longer in laminar flow when compared to the turbulent flow. But if the Reynolds number is very low, the boundary length will also be low.

Question: 14.003P

Why are liquids usually transported in circular pipes?

Step 1 of 1

The pipes with circular cross section can withstand large pressure differences between the inside and the outside without undergoing any distortion. Also the circular shape contains the largest cross sectional area to perimeter ratio, and less frictional losses.

Question: 14.004P

What is the physical significance of the Reynolds number? How is it defined for (*a*) flow in a circular pipe of inner diameter *D* and (*b*) flow in a rectangular duct of cross section *a* × *b*?

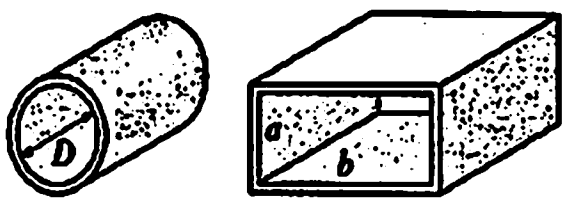

FIGURE P14–4C

Step 1 of 4

Reynolds number is the ratio of the inertial forces to viscous forces in the fluid. The flow regime depends on the Reynolds number.

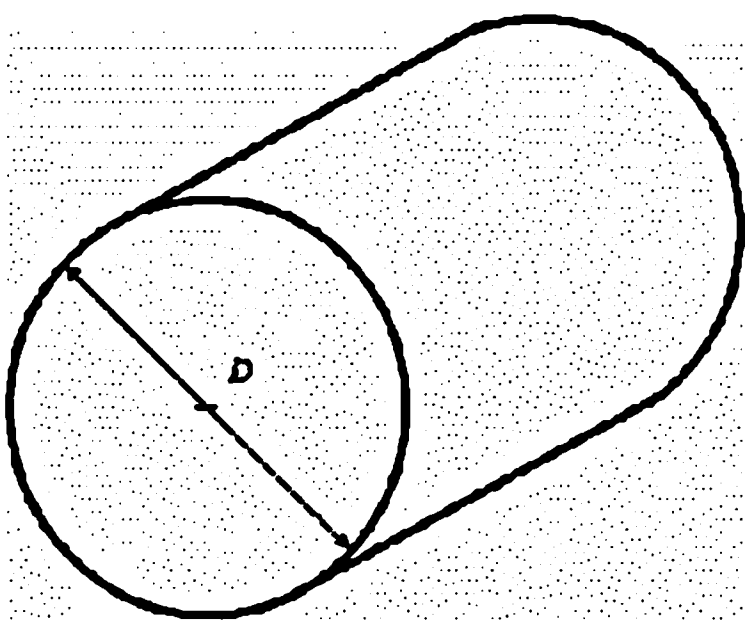
The Reynolds number is given by $\mathrm{Re} = \dfrac{VD_h}{\nu}$

Where

V is the velocity of fluid

D_h is the hydraulic diameter and

ν is the kinematic viscosity



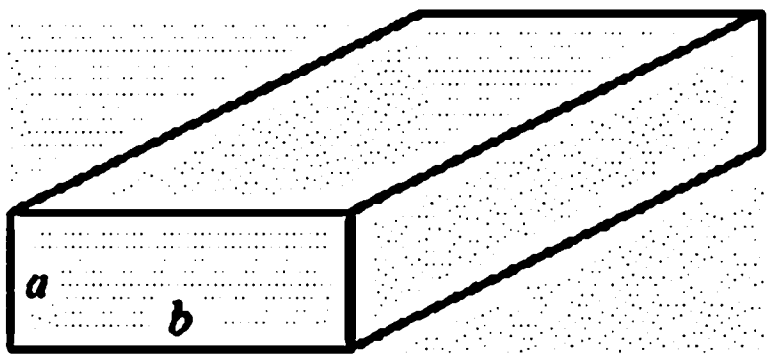
Step 2 of 4

The inertial forces in a fluid are proportional to the fluid density and square of the fluid velocity. For large Reynolds number, the inertial forces are large relative to the viscous forces. So the viscous forces cannot prevent the random and rapid fluctuations of the fluid. Therefore, the flow will be turbulent.

For small or moderate Reynolds number, the viscous forces are larger than the inertial forces. Thus it suppress the fluctuations of the fluid thereby keep the fluid inline. Thus, the flow will be laminar.

Step 3 of 4

a) Consider the flow in a circular pipe of diameter D.



For circular pipe, the hydraulic diameter, $D_h = D$

Then, the Reynolds number, $\boxed{\mathrm{Re} = \dfrac{VD}{\nu}}$

Step 4 of 4

b) Consider the flow in a rectangular duct of cross section $a \times b$

For rectangular duct, the hydraulic diameter,

$$D_h = \frac{2ab}{a+b}$$

Then,

$$\mathrm{Re} = \frac{VD_h}{\nu}$$

$$= \frac{V\left(\dfrac{2ab}{a+b}\right)}{\nu}$$

$$= \frac{V}{\nu}\left(\frac{2ab}{a+b}\right)$$

Therefore, the Reynolds number, $\boxed{\mathrm{Re} = \dfrac{V}{\nu}\left(\dfrac{2ab}{a+b}\right)}$

Question: 14.005P

Consider a person walking first in air and then in water at the same speed. For which motion will the Reynolds number be higher?

Step 1 of 3

Let (1) and (2) denote the inlet and outlet of the manometer respectively.

The area of section (1) is more than the area of section (2).

$$A_1 > A_2$$

Hence, the velocity of section (2) is more than the velocity of section (1).

$$V_2 > V_1$$

Write the Bernoulli's equation.

$$\frac{p}{\rho}+\frac{V^2}{2}+gz=C$$

Here, p is the pressure, ρ is the density of the working fluid, V is the velocity of flow, g is the acceleration due to gravity, z is the elevation and C is a constant.

Step 2 of 3

Write the Bernoulli's equation for the inlet and the outlet.

$$\frac{p_1}{\rho}+\frac{V_1^2}{2}+gz_1=\frac{p_2}{\rho}+\frac{V_2^2}{2}+gz_2=C$$

The elevations are equal for both sections.

$$z_1 = z_2$$

$$\frac{p_1}{\rho}+\frac{V_1^2}{2}=\frac{p_2}{\rho}+\frac{V_2^2}{2}=C$$

Since $V_2 > V_1$, for the constant to hold good:

$$p_1 > p_2$$

Therefore, figure *a* is correct.

Step 3 of 3

If the flow is reversed, the conditions pertaining to the area and the velocity remain the same. Only the direction of flow changes.

Therefore, figure *a* is correct.

Question: 14.006P

Show that the Reynolds number for flow in a circular pipe of diameter D can be expressed as $Re = 4\dot{m}/(\pi D\mu)$.

Step 1 of 3

The diameter of the circular pipe is D.

The cross-sectional flow area $A_c = \frac{\pi}{4}D^2$

The Reynolds number for a circular tube is given by $Re = \frac{\rho VD}{\mu}$ .....(1)

Step 2 of 3

The average velocity is given by $V = \frac{\dot{m}}{\rho A_c}$

Where,

$\dot{m}$ is the mass flow rate and

ρ is the density of the fluid

Substitute the known expressions.

$$V = \frac{\dot{m}}{\rho\left(\frac{\pi}{4}D^2\right)}$$

$$= \frac{4\dot{m}}{\pi\rho D^2} \qquad \text{.....(2)}$$

Step 3 of 3

Now substituting the value of velocity from equation (2) in (1) we get

$$Re = \frac{\rho\left(\frac{4\dot{m}}{\pi\rho D^2}\right)D}{\mu}$$

$$= \frac{4\dot{m}}{\pi D\mu}$$

Therefore, the Reynolds number for flow in a circular pipe is $\boxed{Re = \frac{4\dot{m}}{\pi D\mu}}$

Question: 14.007P

Which fluid at room temperature requires a larger pump to flow at a specified velocity in a given pipe: water or engine oil? Why?

Step 1 of 1

At room temperature, engine oil requires a larger pump than for water to flow at a specified velocity in a given pipe. This is because engine oil has more viscosity than that of water.

Question: 14.008P

Consider the flow of air and water in pipes of the same diameter, at the same temperature, and at the same mean velocity. Which flow is more likely to be turbulent? Why?

Step 1 of 3

Reynolds number is the ratio of inertial force to viscous force in the fluid.

We can write, the Reynolds number, $\mathrm{Re} = \dfrac{\rho V_{avg} D}{\mu} = \dfrac{V_{avg} D}{\nu}$,

Here, V_{avg} is the average flow velocity, D is the characteristic length of the geometry, μ is the dynamic viscosity, ρ is the density of the flowing fluid, and ν is the kinematic viscosity.

Thus, Reynolds number is inversely proportional to the kinematic viscosity, for a fluid with constant velocity and constant diameter.

Step 2 of 3

Consider the conditions at $25°\mathrm{C}$.

From the table of properties of saturated water at $25°\mathrm{C}$,

$$\rho_{water} = 997\ \mathrm{kg/m^3}$$
$$\mu_{water} = 0.891 \times 10^{-3}\ \mathrm{kg/m \cdot s}$$

Calculate the kinematic viscosity for water by using the following relations.

$$\nu_{water} = \frac{\mu_{water}}{\rho_{water}}$$
$$= \frac{0.891 \times 10^{-3}}{997}$$
$$= 8.937 \times 10^{-7}\ \mathrm{m^2/s}$$

Step 3 of 3

And from the table of properties of air at 1 atm pressure and $25°\mathrm{C}$, we get $\nu_{air} = 1.562 \times 10^{-5}\ \mathrm{m^2/s}$.

Here, water has the smallest kinematic viscosity. So, motion of water has the highest Reynolds number. Therefore, the water flow is more likely to be turbulent.

The density and the dynamic viscosity of water are greater than that of air. But the density is much greater when compared to the dynamic viscosity. So, the kinematic viscosity of water will be smaller than that of air.

Question: 14.009P

Consider laminar flow in a circular pipe. Is the wall shear stress *tw* higher near the inlet of the pipe or near the exit? Why? What would your response be if the flow were turbulent?

Step 1 of 1

For laminar uniform flow in a circular pipe, the highest wall shear stress will be at the inlet of the tube, where the boundary layer thickness is almost zero.

Also for the turbulent uniform flow, the highest wall shear stress will be at the inlet of the tube.

Question: 14.010P

How does surface roughness affect the pressure drop in a pipe flow is turbulent? What would your response be if the flow were laminar?

Step 1 of 1

The pressure drop in turbulent flow is

$$\Delta P = f \frac{L}{D} \frac{\rho V_{avg}^2}{2}$$

$\Delta P \propto f$

Where,

V_{avg} is the average flow velocity,

D is the characteristic length of the geometry,

ρ is the density of the flowing fluid and

L is the length of the pipe

f is friction factor

Here pressure drop is directly proportional to the friction factor and friction factor is more for rough surfaced pipes when compared to smooth surface.
Therefore, when the surface roughness is more the pressure drop will also be more.

In case of laminar flow effect of surface roughness on the friction factor is negligible and thus the pressure drop is also negligible.

Question: 14.011P

Shown here is a cool picture of water being released at 300,000 gallons per second in the spring of 2008. This was part of a revitalization effort for the ecosystem of the Grand Canyon and the Colorado River. Estimate the Reynolds number of the pipe flow. Is it laminar or turbulent? (Hint: For a length scale, approximate the height of the man directly above the pipe to be 6 ft.)

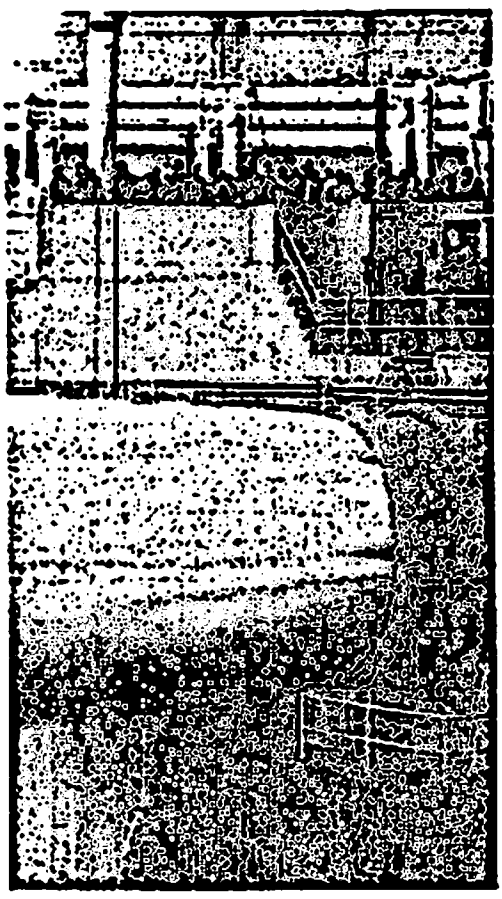


FIGURE P14–11E

Photo courtesy of Don Becker, U.S. Geological Survey.

Step 1 of 4

Given data:

The flow rate of the water in pipe, $\dot{V} = 300{,}000$ gal/s

The height of the man, $h = 6$ ft

Step 2 of 4

The diameter of the pipe is nearly 2.5 times the height of man. Hence

$$D = 1.5h$$
$$= 1.5 \times 6$$
$$= 9 \text{ ft}$$

The area of the pipe is

$$A = \frac{\pi}{4} D^2$$
$$= \frac{\pi}{4} (9 \text{ ft})^2$$
$$= 63.62 \text{ ft}^2$$

Step 3 of 4

The flow rate of the water in pipe,

$$\dot{V} = 300{,}000 \text{ gal/s}$$
$$= 300{,}000 \text{ gal/s} \left(\frac{0.13368 \text{ ft}^3/\text{s}}{1 \text{ gal/s}} \right)$$
$$= 40104 \text{ ft}^3/\text{s}$$

The velocity of the flow in pipe is

$$V = \frac{\dot{V}}{A}$$
$$= \frac{300{,}000 \text{ gal/s}}{63.62 \text{ ft}^2}$$
$$= \frac{40104 \text{ ft}^3/\text{s}}{63.62 \text{ ft}^2}$$
$$= 630.37 \text{ ft/s}$$

Step 4 of 4

From the properties table of water,

$$\rho = 62.4 \text{ lbm/ft}^3$$
$$\mu = 8.781 \times 10^{-4} \text{ lbm/ft} \cdot \text{s}$$

The Reynolds number of the given flow is

$$\text{Re} = \frac{\rho V D}{\mu}$$
$$= \frac{62.4 \times 630.37 \times 9}{8.781 \times 10^{-4}}$$
$$= 403 \times 10^6$$

Hence the estimated Reynolds number is $\boxed{\text{Re} = 403 \times 10^6}$

As the Reynolds number is greater than 4000, the flow is turbulent.

Question: 14.012P

Someone claims that the shear stress at the center of a circular pipe during fully developed laminar flow is zero. Do you agree with this claim? Explain.

Step 1 of 1

The shear stress is proportional to the velocity gradient. At the center of the pipe, the velocity gradient is zero. Thus, the shear stress will be zero at the center of the pipe. Therefore, the claim that "the shear stress at the center of a circular pipe during fully developed laminar flow is zero" is correct.

Question: 14.013P

Someone claims that in fully developed turbulent flow in a pipe, the shear stress is a maximum at the pipe wall. Do you agree with this claim? Explain.

Step 1 of 1

The shear stress is proportional to the velocity gradient. At the pipe wall, the velocity gradient is maximum. Thus, the shear stress will maximum at the pipe wall. Therefore, the claim that " in fully developed turbulent flow in a pipe, the shear stress is maximum at the pipe wall" is zero correct.

Question: 14.014P

How does the wall shear stress *tw* vary along the flow direction in the fully developed region in (*a*) laminar flow and (*b*) turbulent flow?

Step 1 of 2

a) For laminar flow, the wall shear stress τ_w remains constant along the flow direction in the fully developed region.

Step 2 of 2

b) For turbulent flow, the wall shear stress τ_w remains constant along the flow direction in the fully developed region.

Question: 14.015P

In the fully developed region of flow in a circular pipe, does the velocity profile change in the flow direction?

Step 1 of 1

The thickness of the boundary layer inside a pipe increases in the flow direction until it reaches the pipe center and it fills the entire pipe. A little further downstream the velocity becomes fully developed and remains constant. It occurs when the normalized temperature profile remains unchanged as the pipe is not heated or cooled during the flow process.

Therefore in the fully developed region of flow in a circular pipe, the velocity profile does not change in the flow direction.

Question: 14.016P

How is the friction factor for flow in a pipe related to the pressure loss? How is the pressure loss related to the pumping power requirement for a given mass flow rate?

Step 1 of 2

The pressure loss for fully developed internal flow is given by $\Delta P_L = f \frac{L}{D} \frac{\rho V_{avg}^2}{2}$,

Where,
f is the Darcy friction factor,
L is the length of the pipe,
D is the diameter of the pipe,
ρ is the density of the flowing fluid,
V_{avg} is the average velocity and
$\frac{\rho V_{avg}^2}{2}$ is called the dynamic pressure

Thus, the friction factor is directly proportional to the pressure loss, for a specified fluid flowing in a particular velocity through a pipe having constant length and diameter.

Step 2 of 2

The pumping power required for the internal flow is given by $\dot{W}_{pump} = \dot{V} \Delta P_L$,

The volume flow rate is given by $\dot{V} = \frac{\dot{m}}{\rho}$,

Where, $\dot{V}$ is the volume flow rate
Where, $\dot{m}$ is the mass flow rate

Therefore, the pumping power required, $\dot{W}_{pump} = \frac{\dot{m} \Delta P_L}{\rho}$

Thus, the pressure loss is directly proportional to the pumping power required.

Question: 14.017P

Discuss whether fully developed pipe flow is one-, two-, or three-dimensional.

Step 1 of 1

In a fully developed laminar flow, the fluid particle moves along a streamline at constant axial velocity. And, there is no motion in the radial direction. Thus, we can say that the fully developed fluid flow is one dimensional.

Question:

14.018P

Consider fully developed flow in a circular pipe with negligible entrance effects. If the length of the pipe is doubled, the head loss will (*a*) double, (*b*) more than double, (*c*) less than double, (*d*) reduce by half, or (*e*) remain constant.

Step 1 of 2

The head loss for fully developed internal flow is given by $\Delta h_L = f\dfrac{L}{D}\dfrac{V^2}{2g}$

Where,
f is the Darcy friction factor,
L is the length of the pipe,
D is the diameter of the pipe,
V is the average velocity and
g is the gravitational acceleration.

Step 2 of 2

The new head loss, when the length of the pipe is doubled $(L = 2L)$

$$\begin{aligned}\Delta h_L' &= f\frac{(2L)}{D}\frac{V^2}{2g}\\ &= 2\left(f\frac{L}{D}\frac{V^2}{2g}\right)\\ &= 2\Delta h_L\end{aligned}$$

Therefore, when the length of the pipe is doubled, the head loss is also doubled.

The new head loss, when the length of the pipe is doubled $(L = 2L)$

$$\begin{aligned}\Delta h_L' &= f\frac{(2L)}{D}\frac{V^2}{2g}\\ &= 2\left(f\frac{L}{D}\frac{V^2}{2g}\right)\\ &= 2\Delta h_L\end{aligned}$$

Therefore, when the length of the pipe is doubled, the head loss is also doubled.

Question: 14.019P

Someone claims that the volume flow rate in a circular pipe with laminar flow can be determined by measuring the velocity at the centerline in the fully developed region, multiplying it by the cross-sectional area, and dividing the result by 2. Do you agree? Explain.

Step 1 of 2

We know, the volume flow rate,

$\dot{V} = V_{avg} A_c$,

where, V_{avg} is the average flow velocity and

A_c is the cross-sectional area of the pipe.

But, the average flow velocity,

$V_{avg} = \frac{u_{max}}{2}$,

where, u_{max} is the maximum velocity of flow which is through the centerline in the fully developed region.

Step 2 of 2

Then, the volume flow rate,

$\dot{V} = \frac{u_{max}}{2} A_c$.

Therefore, the claim that "the volume flow rate in a circular pipe with laminar flow can be determined by measuring the velocity at the centerline in a fully developed region, multiplying it by the cross sectional area, and dividing the result by 2" is correct.

Step 2 of 2

Then, the volume flow rate,

$\dot{V} = \frac{u_{max}}{2} A_c$.

Therefore, the claim that "the volume flow rate in a circular pipe with laminar flow can be determined by measuring the velocity at the centerline in a fully developed region, multiplying it by the cross sectional area, and dividing the result by 2" is correct.

Question: 14.020P

Someone claims that the average velocity in a circular pipe in fully developed laminar flow can be determined by simply measuring the velocity at $R/2$ (midway between the wall surface and the centerline). Do you agree? Explain.

Step 1 of 2

The velocity profile in fully developed laminar flow in circular pipe is

$$u(r) = u_{max}\left(1 - \frac{r^2}{R^2}\right),$$

where, u_{max} is the maximum velocity of flow which is through the centerline in the fully developed region.

When $r = R/2$,

$$u(R/2) = u_{max}\left(1 - \frac{(R/2)^2}{R^2}\right)$$

$$= u_{max}\left(1 - \frac{1}{4}\right)$$

$$= \frac{3}{4}u_{max}$$

Step 2 of 2

The average velocity,

$$V_{avg} = \frac{u_{max}}{2}$$

Now, $u(R/2) \neq V_{avg}$.

Therefore, the claim that "the average velocity in a circular pipe in fully developed laminar flow can be determined by simply measuring the velocity at $R/2$" is wrong.

Question: 14.021P

Consider fully developed laminar flow in a circular pipe. If the diameter of the pipe is reduced by half while the flow rate and the pipe length are held constant, the head loss will (*a*) double, (*b*) triple, (*c*) quadruple, (*d*) increase by a factor of 8, or (*e*) increase by a factor of 16.

Step 1 of 6

Given data:
The flow through the circular channel is fully developed and laminar.
The flow rate and pipe length are held constant.

Step 2 of 6

The head loss for fully developed internal flow is given by $\Delta h_L = f\frac{L}{D}\frac{V^2}{2g}$

Where,
f is the Darcy friction factor,
L is the length of the pipe,
D is the diameter of the pipe,
V is the average velocity and
g is the gravitational acceleration.

Step 3 of 6

The Reynolds number is given by $\mathrm{Re} = \frac{VD}{\nu}$,
Where, ν is the kinematic viscosity of the flowing fluid
The friction factor,

$$f = \frac{64}{\mathrm{Re}} = \frac{64}{(VD/\nu)} = \frac{64\nu}{VD}$$

Step 4 of 6

The cross sectional flow area, $A_c = \frac{\pi}{4}D^2$
The flow rate is given by $\dot{V} = VA_c$
Then,

$$V = \frac{\dot{V}}{A_c} = \frac{\dot{V}}{\left(\frac{\pi}{4}D^2\right)} = \frac{4\dot{V}}{\pi D^2}$$

Step 5 of 6

Thus, the head loss can be written as

$$\Delta h_L = \left(\frac{64\nu}{VD}\right)\frac{L}{D}\frac{V^2}{2g} = \frac{64\nu L}{D^2}\frac{V}{2g} = \frac{64\nu L}{D^2}\frac{\left(4\dot{V}/\pi D^2\right)}{2g} = \frac{128\nu L\dot{V}}{\pi D^4 g}$$

Thus, we get that the head loss is inversely proportional to the fourth power of the diameter of the pipe.

Step 6 of 6

When the diameter is reduced by half,

$$\Delta h_L' = \frac{128\nu L\dot{V}}{\pi(D/2)^4 g} = 16\left(\frac{128\nu L\dot{V}}{\pi D^4 g}\right) = 16h_L$$

Therefore, when the diameter is reduced by half the head loss will increase by a factor of 16.

Question: 14.022P

What is the physical mechanism that causes the friction factor to be higher in turbulent flow?

Step 1 of 1

The fluid in turbulent flow is subjected to enhanced mixing due to swirling eddies. This results in increased mass transfer or quicker transport of mass to all regions. All this would increase the friction and hence the turbulent flow is associated with much higher values of friction factor.

Question: 14.023P

What is turbulent viscosity? What causes it?

Step 1 of 1

Turbulent viscosity is the viscosity due to the momentum transport by the turbulent eddies. It is the property of the flow and is denoted by μ_t

The relation between turbulent shear stress (τ_{turb}) and the turbulent viscosity (μ_t) is

$$\tau_{turb} = -\rho\overline{u'v'}$$

$$= \mu_t \frac{\partial \bar{u}}{\partial y}$$

where, u' and v' are the fluctuating components of velocity,

ρ is the density and

$\bar{u}$ is the mean velocity in the direction of flow.

Question: 14.024P

Consider fully developed laminar flow in a circular pipe. If the viscosity of the fluid is reduced by half by heating while the flow rate is held constant, how does the head loss change?

Step 1 of 4

Obtain the relation for the pressure drop for a fully developed laminar flow in a circular pipe.

$$\Delta P = \frac{8\mu L V_{avg}}{R^2} = \frac{32\mu L V_{avg}}{D^2} \quad \text{..... (1)}$$

Here, L is the length is the pipe, μ is the dynamic viscosity, V_m is the mean velocity, and D is the diameter.

Since the area of the pipe remains constant, the length and diameter of the pipe can be considered as constants in the equation (1).

$$L = D = C$$

Step 2 of 4

Write the equation for flow rate.

$$Q = AV_{avg}$$

Here, A is the area of the pipe.

Since area of the pipe remains same, the flow arte equation becomes as follows:

$$Q \propto V_{avg}$$

Since, flow rate is kept constant, thus the mean velocity becomes constant. As the flow rate is directly proportional to mean velocity. Thus,

$$V_{avg} = C$$

Step 3 of 4

Hence pressure is directly proportional to viscosity.

$$\Delta P \propto \mu$$

Write the equation for head loss as follows:

$$h_L = \frac{\Delta P}{\rho g} \quad \text{..... (2)}$$

Here, ρ is the density and g is the acceleration due to gravity.

From the relation it is clear that, head loss is proportional to viscosity.

$$h_L \propto \mu$$

Hence if the viscosity is reduced by half then head loss is also reduced by half. It can be proved as follows:

Substitute equation (1) for ΔP in equation (2).

$$h_L = \frac{\Delta P}{\rho g} = \frac{\left(\frac{32\mu L V_{avg}}{D^2}\right)}{\rho g} \quad \text{..... (2)} = \frac{32\mu L V_{avg}}{\rho g D^2}$$

Step 4 of 4

When the viscosity of the fluid is reduced by half, obtain the relation for new head loss as follows:

Substitute $\left(\frac{\mu}{2}\right)$ for μ in equation (2).

$$\Delta h_L' = \frac{32(\mu/2) L V_{avg}}{\rho g D^2} = \frac{1}{2}\left(\frac{32\mu L V_{avg}}{\rho g D^2}\right)$$

Substitute h_L for $\left(\frac{32\mu L V_{avg}}{\rho g D^2}\right)$.

$$\Delta h_L' = \frac{1}{2} h_L$$

Therefore, when the viscosity of the fluid is reduced by half, the head loss will be reduced by half.

Question: 14.025P

How is head loss related to pressure loss? For a given fluid, explain how you would convert head loss to pressure loss.

Step 1 of 2

The relation between the head loss (Δh_L) and the pressure loss (ΔP_L) is given by

$$\Delta h_L = \frac{\Delta P_L}{\rho g},$$

Where,

ρ is the density of the flowing fluid and

g is the gravitational acceleration.

Step 2 of 2

Then, the pressure loss,

$$\Delta P_L = \rho g \Delta h_L$$

Therefore, the pressure loss is obtained by multiplying the head loss with the density of the fluid and the gravitational acceleration.

Question: 14.026P

Consider laminar flow of air in a circular pipe with perfectly smooth surfaces. Do you think the friction factor for this flow is zero? Explain.

Step 1 of 1

For laminar flow in a circular pipe, the friction factor is given by the formula

$$f = \frac{64\mu}{\rho D V_{avg}} \qquad \ldots\ldots (1)$$

The relation for Reynolds number is given by the formula

$$\mathrm{Re} = \frac{\rho D V_{avg}}{\mu} \qquad \ldots\ldots (2)$$

Hence from equations (1) and (2) , we get the relation for friction factor as below.

$$f = \frac{64}{\mathrm{Re}}$$

Thus, the friction factor is independent of the surface roughness of the pipe. And hence the friction factor for perfectly smooth surfaces is not zero.

Question: 14.027P

Explain why the friction factor is independent of the Reynolds number at very large Reynolds numbers.

Step 1 of 1

Friction factor depends on Reynolds number to some extent only, but for large values of Reynolds number, it is not true. This can be explained as follows:

Friction factor is a function of Reynolds number and relative roughness.

$$f = \text{func}\left(\text{Re}, \frac{\varepsilon}{D}\right)$$

From FIGURE 14-22, at very large Reynolds numbers, the friction factor curves in the Moody chart are all almost horizontal. Friction factor here depends only on the relative roughness but not the Reynolds numbers.

Therefore, it can be concluded that friction factor is independent of Reynolds number for larger value of Reynolds numbers.

Question: 14.028P

Water at 10°C (ρ = 999.7 kg/m3 and μ = 1.307 × 10-3 kg/m-s) is flowing steadily in a 0.20-cm-diameter, 15-long pipe at an average velocity of 1.2 m/s. Determine (*a*) the pressure drop, (*b*) the head loss, and (*c*) the pumping power requirement to overcome this pressure drop.

Step 1 of 6

Given data:

Water is flowing at 10°C through a pipe.

The density, $\rho = 999.7\ \text{kg/m}^3$

The dynamic viscosity, $\mu = 1.307 \times 10^{-3}\ \text{kg/m} \cdot \text{s}$

The length of the pipe, $L = 15\ \text{m}$

The diameter of pipe, $D = 0.20\ \text{cm} = 2 \times 10^{-3}\ \text{m}$

The average velocity, $V = 1.2\ \text{m/s}$

Step 2 of 6

The flow is assumed to be steady, fully developed and incompressible.

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{(999.7\ \text{kg/m}^3)(1.2\ \text{m/s})(2 \times 10^{-3}\ \text{m})}{1.307 \times 10^{-3}\ \text{kg/m} \cdot \text{s}}$$

$$= 1835.7$$

Here, Re < 2300 Therefore, the flow is laminar.

Step 3 of 6

The friction factor,

$$f = \frac{64}{\text{Re}}$$

$$= \frac{64}{1835.7}$$

$$= 0.03486$$

Step 4 of 6

a) The pressure drop,

$$\Delta P_L = f \frac{L}{D} \frac{\rho V^2}{2}$$

$$= 0.03486 \left[\frac{15\ \text{m}}{2 \times 10^{-3}\ \text{m}}\right]\left[\frac{(999.7\ \text{kg/m}^3)(1.2\ \text{m/s})^2}{2}\right]$$

$$= 188.187 \times 10^3\ \text{Pa}$$

$$= 188.187\ \text{kPa}$$

Therefore, the pressure drop is $\boxed{188.187\ \text{kPa}}$

Step 5 of 6

b) The head loss is given by $h_L = \frac{\Delta P_L}{\rho g}$,

Where, g is the gravitational acceleration.

Substituting the known values.

$$h_L = \frac{188.187 \times 10^3\ \text{Pa}}{(999.7\ \text{kg/m}^3)(9.81\ \text{m/s}^2)}$$

$$= 19.19\ \text{m}$$

Therefore, the head loss, $\boxed{h_L = 19.2\ \text{m}}$

Step 6 of 6

c) The cross sectional flow area,

$$A_c = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(2 \times 10^{-3}\ \text{m})^2$$

$$= 3.1416 \times 10^{-6}\ \text{m}^2$$

The flow rate,

$$\dot{V} = V A_c$$

$$= (1.2\ \text{m/s})(3.1416 \times 10^{-6}\ \text{m}^2)$$

$$= 3.77 \times 10^{-6}\ \text{m}^3\text{/s}$$

Question: 14.029P

Water at 15°C (ρ = 999.1 kg/m3 and μ = 1.138 X 10-3 kg/m-s) is flowing steadily in a 30-m-long and 5-cm-diameter horizontal pipe made of stainless steel at a rate of 9 L/s. Determine (*a*) the pressure drop, (*b*) the head loss, and (*c*) the pumping power requirement to overcome this pressure drop.

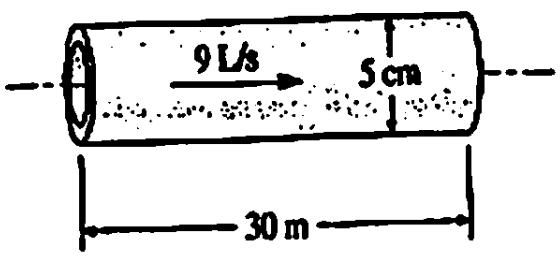

FIGURE P14–29

Step 1 of 7

Given data:

The temperature of the water in pipe $T = 15^{\circ}\text{C}$

The density of water $\rho = 999.1\,\text{kg/m}^3$

The dynamic viscosity of water $\mu = 1.138 \times 10^{-3}\,\text{kg/m}\cdot\text{s}$

The length of the pipe $L = 30\,\text{m}$

The diameter of pipe $D = 5\,\text{cm} = 5 \times 10^{-2}\,\text{m}$

The volumetric flow rate of water $\dot{V} = 9\,\text{L/s} = 9 \times 10^{-3}\,\text{m}^3/\text{s}$

Step 2 of 7

The cross sectional area of pipe

$$A_c = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}\left(5 \times 10^{-2}\,\text{m}\right)^2$$

$$= 1.963 \times 10^{-3}\,\text{m}^2$$

The average flow velocity,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{9 \times 10^{-3}\,\text{m}^3/\text{s}}{1.963 \times 10^{-3}\,\text{m}^2}$$

$$= 4.585\,\text{m/s}$$

Step 3 of 7

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{\left(999.1\,\text{kg/m}^3\right)\left(4.585\,\text{m/s}\right)\left(5 \times 10^{-2}\,\text{m}\right)}{1.138 \times 10^{-3}\,\text{kg/m}\cdot\text{s}}$$

$$= 2.0127 \times 10^5$$

Here, Re > 4000. Therefore, the flow is turbulent.

Step 4 of 7

For turbulent flow, the Colebrook's equation is given by

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D_h}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

where, f is the friction factor.

ε is the surface roughness.

For stainless steel, the surface roughness is $\varepsilon = 0.002\,\text{mm} = 2 \times 10^{-6}\,\text{m}$

By substituting the known values in Colebrook's equation

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{2 \times 10^{-6}\,\text{m}/5 \times 10^{-2}\,\text{m}}{3.7} + \frac{2.51}{\left(2.0127 \times 10^5\right)\sqrt{f}}\right)$$

$$= -2.0 \log\left(1.0811 \times 10^{-5} + \frac{1.2421 \times 10^{-5}}{\sqrt{f}}\right)$$

By solving the equation for f, we get $f = 0.0159$

Step 5 of 7

(a) The pressure drop in flow

$$\Delta P_L = f\frac{L}{D}\frac{\rho V^2}{2}$$

$$= 0.0159\left[\frac{30\,\text{m}}{5 \times 10^{-2}\,\text{m}}\right]\left[\frac{\left(999.1\,\text{kg/m}^3\right)\left(4.585\,\text{m/s}\right)^2}{2}\right]$$

$$= 100.185 \times 10^3\,\text{Pa}$$

$$= 100.185\,\text{kPa}$$

Therefore, the pressure drop ΔP_L is $\boxed{100.185\,\text{kPa}}$

Step 6 of 7

(b) The head loss in the flow

$$h_L = \frac{\Delta P_L}{\rho g}$$

$$= \frac{100.185 \times 10^3\,\text{Pa}}{\left(999.1\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)}$$

$$= 10.22\,\text{m}$$

Therefore, the head loss h_L in pipe is $\boxed{10.22\,\text{m}}$

Step 7 of 7

(c) The required pumping power

$$\dot{W}_{\text{pump}} = \dot{V}\Delta P_L$$

$$= \left(9 \times 10^{-3}\,\text{m}^3/\text{s}\right)\left(100.185 \times 10^3\,\text{Pa}\right)$$

$$= 901.665\,\text{W}$$

Therefore, the power $\dot{W}_{\text{pump}}$ required to overcome the pressure loss is $\boxed{901.665\,\text{W}}$

Question: 14.030P

Heated air at 1 atm and 100°F is to be transported in a 400-ft-long circular plastic duct at a rate of 12 ft3/s. If the head loss in the pipe is not to exceed 50 ft, determine the minimum diameter of the duct.

Step 1 of 2

Write the velocity profile equation for fully developed laminar flow.

$$u(r)=4\left(1-\frac{r^2}{R^2}\right)$$

Here, r is the element radius and R is the radius of profile.

Compare the profile equation with fully developed laminar flow profile equation (8.17).

$$2V_{avg}=4$$

$$V_{avg}=\frac{4}{2}$$

$$=2\,\text{m/s}$$

Therefore, the average velocity is $\boxed{2\,\text{m/s}}$.

Step 2 of 2

Find the maximum velocity by using the following formula.

$$u_{max}=2V_{avg}$$

Substitute 2 m/s for V_{avg} .

$$u_{max}=2(2)$$

$$=4\,\text{m/s}$$

Therefore, the maximum velocity is $\boxed{4\,\text{m/s}}$.

Find the volume flow rate by using the following formula.

$$\dot{V}=V_{avg}A_c$$

$$=V_{avg}\left(\pi R^2\right)$$

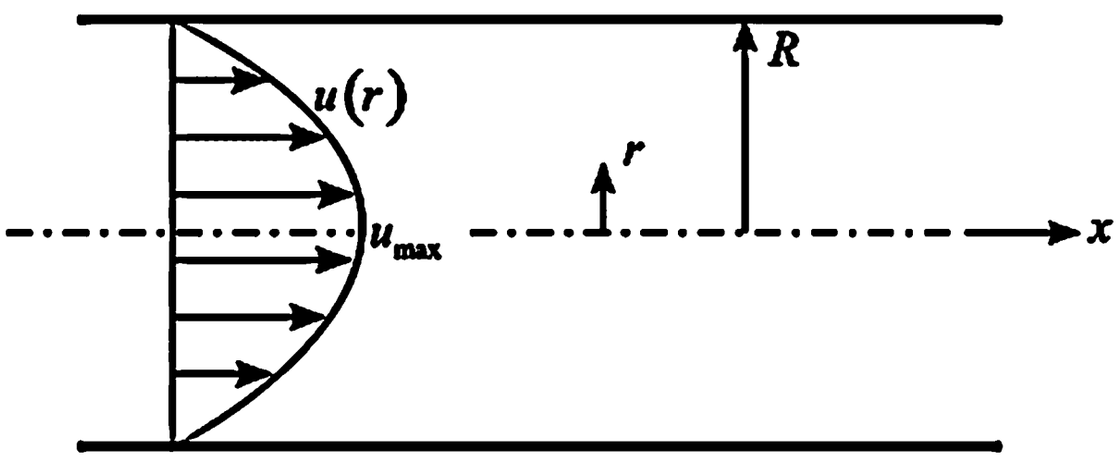
Substitute 2 m/s for V_{avg} and 2 cm for R.

$$\dot{V}=(2)\left(\pi\left(2\,\text{cm}\times10^{-2}\,\frac{\text{m}}{\text{cm}}\right)^2\right)$$

$$=0.0025143\,\text{m}^3/\text{s}$$

Therefore, the volume flow rate is $\boxed{0.0025143\,\text{m}^3/\text{s}}$.

Question: 14.031P



In fully developed laminar flow in a circular pipe, the velocity at $R/2$ (midway between the wall surface and the centerline) is measured to be 8 m/s. Determine the velocity at the center of the pipe.

Step 1 of 3

Given data:

The velocity at a position $R/2$, $u(R/2) = 8\ \text{m/s}$.

Velocity profile of the flow is as shown below.

Step 2 of 3

The velocity profile of the fully developed laminar flow for a circular channel is given by

$$u(r) = u_{max}\left(1 - \frac{r^2}{R^2}\right) \qquad \ldots\ldots (1)$$

where, r is the radius of the differential fluid element $r = (R/2)$

R is the radius of the pipe and

u_{max} is the maximum velocity, at the center of the pipe.

Step 3 of 3

By substituting the known values in equation (1), we get

$$u(r) = u_{max}\left(1 - \frac{(R/2)^2}{R^2}\right)$$

$$u(R/2) = u_{max}\left(1 - \frac{(R/2)^2}{R^2}\right)$$

$$8\ \text{m/s} = u_{max}\left(1 - \frac{(R/2)^2}{R^2}\right)$$

$$8\ \text{m/s} = \frac{3}{4}(u_{max})$$

$$u_{max} = \frac{4}{3}(8\ \text{m/s})$$

$$= 10.7\ \text{m/s}$$

Therefore, the velocity at the center of the pipe is $\boxed{u_{max} = 10.7\ \text{m/s}}$

Question: 14.032P

The velocity profile in fully developed laminar flow in a circular pipe of inner radius $R = 2$ cm, in m/s, is given by $u(r) = 4(1 - r2/R2)$. Determine the average and maximum velocities in the pipe and the volume flow rate.

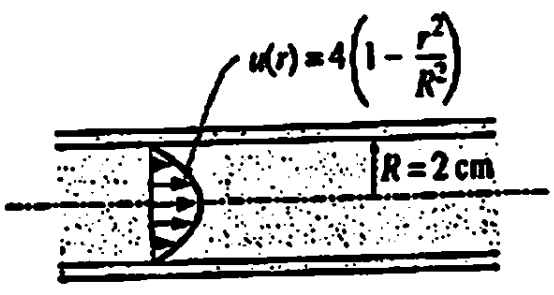


FIGURE P14–32

Step 1 of 4

Obtain the properties of air at 1 atm pressure from the "Properties of air table".

The density of air at $45°C$, $\rho = 1.109\ \text{kg/m}^3$

The dynamic viscosity at $45°C$, $\mu = 1.941 \times 10^{-5}\ \text{kg/m}\cdot\text{s}$

The kinematic viscosity at $45°C$, $\nu = 1.750 \times 10^{-5}\ \text{m}^2/\text{s}$

For glass, the roughness, $\varepsilon = 0$

Find the cross-sectional flow area between glass cover using the following formula:

$$A_c = bl$$

Here, b is the width of the solar collector and $0.03\ \text{m}$ for l.

Substitute 1 m for b and 0.03 m for b.

$$\begin{aligned} A_c &= (1\ \text{m})(0.03\ \text{m}) \\ &= 0.03\ \text{m}^2 \end{aligned}$$

Find the perimeter using the following formula:

$$p = 2(b + l)$$

Substitute 1 m for b and 0.03 m for b.

$$\begin{aligned} p &= 2(1\ \text{m} + 0.03\ \text{m}) \\ &= 2.06\ \text{m} \end{aligned}$$

Step 2 of 4

Find the hydraulic diameter using the following formula:

$$D_h = \frac{4A_c}{p}$$

Substitute $0.03\ \text{m}^2$ for A_c and 2.06 m for p.

$$\begin{aligned} D_h &= \frac{4(0.03\ \text{m}^2)}{2.06\ \text{m}} \\ &= 0.05825\ \text{m} \end{aligned}$$

Find the average velocity of air using the following formula:

$$V = \frac{\dot{V}}{A_c}$$

Here, $\dot{V}$ is rate of discharge of air.

Substitute $0.03\ \text{m}^2$ for A_c and $0.15\ \text{m}^3/\text{s}$ for $\dot{V}$.

$$\begin{aligned} V &= \frac{0.15}{0.03} \\ &= 5\ \text{m/s} \end{aligned}$$

Step 3 of 4

Find the Reynolds number using following formula:

$$\text{Re} = \frac{VD_h}{\nu}$$

Substitute 5 m/s for V, $0.05825\ \text{m}$ for D_h and $1.750 \times 10^{-5}\ \text{m}^2/\text{s}$ for ν.

$$\begin{aligned} \text{Re} &= \frac{(5)(0.05825)}{1.750 \times 10^{-5}} \\ &= 16642.86 \end{aligned}$$

$\text{Re} > 4000$, the flow is turbulent

Find the friction factor using the Colebrook equation.

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

Substitute 0 for ε and 16642.86 for Re.

$$\begin{aligned} \frac{1}{\sqrt{f}} &= -2.0\log\left(\frac{0/D}{3.7} + \frac{2.51}{(16642.86)\sqrt{f}}\right) \\ &= -2.0\log\left(\frac{0.1508 \times 10^{-3}}{\sqrt{f}}\right) \\ f &= 0.0271 \end{aligned}$$

Step 4 of 4

Find the pressure drop using the following formula:

$$\Delta P_L = f\frac{L}{D_h}\frac{\rho V^2}{2}$$

Substitute 0.0271 for f, 5 m for L, $0.05825\ \text{m}$ for D_h, $1.109\ \text{kg/m}^3$ for ρ, and 5 m/s for V.

$$\begin{aligned} \Delta P_L &= 0.0271\left[\frac{5}{0.05825}\right]\left[\frac{(1.109)(5)^2}{2}\right] \\ &= 32.25\ \text{Pa} \end{aligned}$$

Therefore, the pressure drop in the collector is $\boxed{32.25\ \text{Pa}}$.

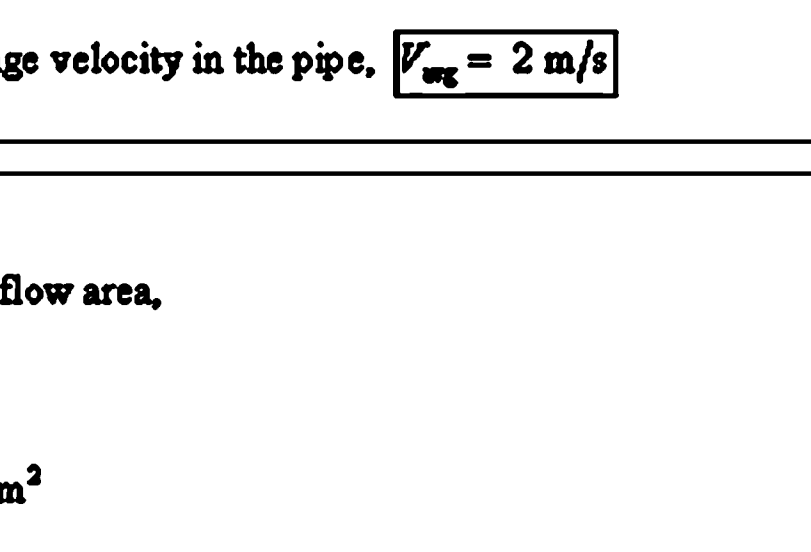
Question: 14.033P

Repeat Prob. 14-32 for a pipe of inner radius 7 cm.

Step 1 of 5

Given data:

The inner radius of the circular pipe, $R = 7\text{ cm}$



$= 0.07\text{ m}$

The velocity profile of the fully developed laminar flow for the given circular channel,

$$u(r) = 4\left(1 - \frac{r^2}{R^2}\right)$$

Step 2 of 5

Let us draw the velocity profile.

Step 3 of 5

The velocity profile of the fully developed laminar flow for a circular channel is given by

$$u(r) = u_{max}\left(1 - \frac{r^2}{R^2}\right)$$

Where, r is the radius of the differential fluid element.

Compare the given expression and the general expression of the velocity profile of the fully developed laminar flow,

$$u_{max}\left(1 - \frac{r^2}{R^2}\right) = 4\left(1 - \frac{r^2}{R^2}\right)$$

$$u_{max} = 4\text{ m/s}$$

Therefore, the maximum velocity in the pipe, $\boxed{u_{max} = 4\text{ m/s}}$

Step 4 of 5

The average velocity,

$$V_{avg} = \frac{u_{max}}{2}$$

$$= \frac{4\text{ m/s}}{2}$$

$$= 2\text{ m/s}$$

Therefore, the average velocity in the pipe, $\boxed{V_{avg} = 2\text{ m/s}}$

Step 5 of 5

The cross-sectional flow area,

$$A_c = \pi R^2$$

$$= \pi(0.07\text{ m})^2$$

$$= 15.393 \times 10^{-3}\text{ m}^2$$

The volume flow rate,

$$\dot{V} = V_{avg} A_c$$

$$= (2\text{ m/s})(15.393 \times 10^{-3}\text{ m}^2)$$

$$= 30.786 \times 10^{-3}\text{ m}^3/\text{s}$$

Therefore, the volume flow rate, $\boxed{\dot{V} = 30.786 \times 10^{-3}\text{ m}^3/\text{s}}$

Question: 14.034P

Consider an air solar collector that is 1 m wide and 5 m long and has a constant spacing of 3 cm between the glass cover and the collector plate. Air flows at an average temperature of 45°C at a rate of 0.15 m3/s through the 1-m-wide edge of the collector along the 5-m-long passageway. Disregarding the entrance and roughness effects and the 90° bend, determine the pressure drop in the collector.

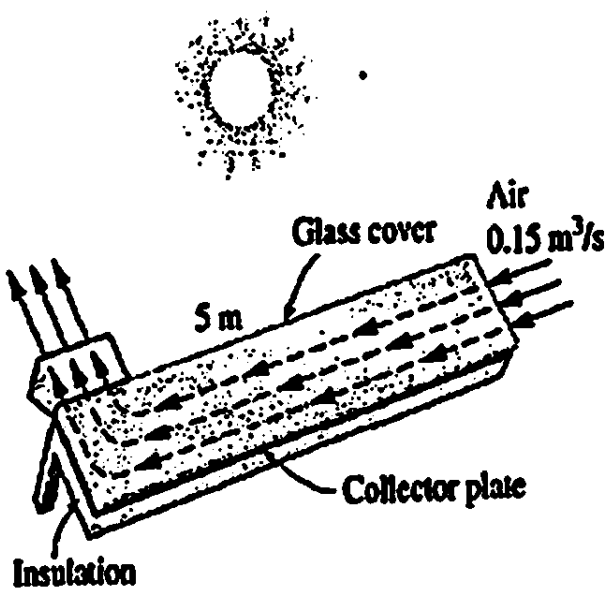


FIGURE P14–34

Step 1 of 7

Given data:

The width of the solar collector, $b = 1\text{ m}$

The length of the solar collector, $L = 5\text{ m}$

The constant spacing between the glass cover, $l = 3\text{ cm} = 0.03\text{ m}$

The temperature of the air, $T = 45°\text{C}$

The rate of discharge of air, $\dot{V} = 0.15\text{ m}^3/\text{s}$

Step 2 of 7

From the table of properties of air at 1 atm pressure,

The density of air at 45°C, $\rho = 1.109\text{ kg/m}^3$

The dynamic viscosity at 45°C, $\mu = 1.941 \times 10^{-5}\text{ kg/m}\cdot\text{s}$

The kinematic viscosity at 45°C, $\nu = 1.750 \times 10^{-5}\text{ m}^2/\text{s}$

Step 3 of 7

For glass, the roughness, $\varepsilon = 0$

The cross-sectional flow area between the glass cover,

$$A_c = bl$$
$$= (1\text{ m})(0.03\text{ m})$$
$$= 0.03\text{ m}^2$$

The perimeter,

$$p = 2(b + l)$$
$$= 2(1\text{ m} + 0.03\text{ m})$$
$$= 2.06\text{ m}$$

Step 4 of 7

The hydraulic diameter,

$$D_h = \frac{4A_c}{p}$$
$$= \frac{4(0.03\text{ m}^2)}{2.06\text{ m}}$$
$$= 0.0582\text{ m}$$

The average velocity,

$$V = \frac{\dot{V}}{A_c}$$
$$= \frac{0.15\text{ m}^3/\text{s}}{0.03\text{ m}^2}$$
$$= 5\text{ m/s}$$

Step 5 of 7

The Reynolds number,

$$\text{Re} = \frac{VD_h}{\nu}$$
$$= \frac{(5\text{ m/s})(0.0582\text{ m})}{1.750 \times 10^{-5}\text{ m}^2/\text{s}}$$
$$= 16.629 \times 10^3$$

Since Re > 4000, the flow is turbulent

Step 6 of 7

For turbulent flow, the Colebrook equation is given by $\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$,

Where, f is the friction factor.

Substituting the known values in Colebrook equation and solving the equation for f we get,

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{0/D}{3.7} + \frac{2.51}{(16.629 \times 10^3)\sqrt{f}}\right)$$
$$= -2.0\log\left(\frac{0.1509 \times 10^{-3}}{\sqrt{f}}\right)$$
$$f = 0.0271$$

Step 7 of 7

The pressure drop,

$$\Delta P_L = f\frac{L}{D_h}\frac{\rho V^2}{2}$$
$$= 0.0271\left[\frac{5\text{ m}}{0.0582\text{ m}}\right]\left[\frac{(1.109\text{ kg/m}^3)(5\text{ m/s})^2}{2}\right]$$
$$= 32.27\text{ Pa}$$

Therefore, the pressure drop in the collector, $\boxed{\Delta P_L = 32.3\text{ Pa}}$

Question: 14.035P

Consider laminar flow of a fluid through a square channel with smooth surfaces. Now the average velocity of the fluid is doubled. Determine the change in the head loss of the fluid. Assume the flow regime remains unchanged.

Step 1 of 4

Write the expression for Reynolds number.

$$\mathrm{Re} = \frac{\rho V D}{\mu}$$

Here, ρ is the density of the flowing fluid, V is the average flow velocity, D is the diameter of the pipeline and μ is the dynamic viscosity

Write the expression for friction factor.

$$f = 0.184\,\mathrm{Re}^{-0.2}$$

Substitute $\frac{\rho V D}{\mu}$ for Re.

$$f = 0.184\left(\frac{\rho V D}{\mu}\right)^{-0.2}$$

Step 2 of 4

Find the head loss using the following formula:

$$h_L = f\frac{L}{D}\frac{V^2}{2g}$$

Here, L is the length of the pipeline and g is the gravitational acceleration.

Substitute $0.184\left(\frac{\rho V D}{\mu}\right)^{-0.2}$ for f.

$$h_L = \left[0.184\left(\frac{\rho V D}{\mu}\right)^{-0.2}\right]\frac{L}{D}\frac{V^2}{2g} \quad \text{..... (1)}$$

$$= \frac{0.092L}{gD^{1.8}}\left(\frac{\rho}{\mu}\right)^{-0.2} V^{1.8}$$

Step 3 of 4

Find the new head loss when the velocity is doubled.

Substitute $2V$ for V in equation (1).

$$h_L' = \frac{0.092L}{gD^{1.8}}\left(\frac{\rho}{\mu}\right)^{-0.2}(2V)^{1.8}$$

$$= 3.48\left[\frac{0.092L}{gD^{1.8}}\left(\frac{\rho}{\mu}\right)^{-0.2} V^{1.8}\right]$$

$$= 3.48h_L$$

Therefore, the new head loss when the velocity of fluid velocity is doubled is $\boxed{3.48h_L}$.

Step 4 of 4

For fully turbulent flow in a rough pipe, the friction factor is independent of the Reynolds number.

Write the expression for head loss of the pipe.

$$h_L = f\frac{L}{D}\frac{V^2}{2g}$$

Find the new head loss when the velocity is doubled.

Substitute $2V$ for V.

$$h_L' = f\frac{L}{D}\frac{(2V)^2}{2g}$$

$$= 4\left[f\frac{L}{D}\frac{V^2}{2g}\right]$$

$$= 4h_L$$

Therefore, the new head loss for turbulent flow when the velocity of fluid velocity is doubled is $\boxed{4h_L}$.

14.036P

Question:

Repeat Prob. 14-35 for turbulent flow in smooth pipes for which the friction factor is given as $f = 0.184Re^{-0.2}$. What would your answer be for fully turbulent flow in a rough pipe?

Step 1 of 6

Given data:

The friction factor, $f = 0.184\,\mathrm{Re}^{-0.2}$

It is assumed that the flow is turbulent through out the pipe. The inner surface is assumed to be smooth.

The Reynolds number, $\mathrm{Re} = \dfrac{\rho VD}{\mu}$

Where, ρ is the density of the flowing fluid

V is the average flow velocity

D is the diameter of the pipeline and

μ is the dynamic viscosity

Step 2 of 6

Question:

Repeat Prob. 14-35 for turbulent flow in smooth pipes for which the friction factor is given as $f = 0.184Re^{-0.2}$. What would your answer be for fully turbulent flow in a rough pipe?

Step 1 of 6

Given data:

The friction factor, $f = 0.184\,\mathrm{Re}^{-0.2}$

It is assumed that the flow is turbulent through out the pipe. The inner surface is assumed to be smooth.

The Reynolds number, $\mathrm{Re} = \dfrac{\rho VD}{\mu}$

Where, ρ is the density of the flowing fluid

V is the average flow velocity

D is the diameter of the pipeline and

μ is the dynamic viscosity

Step 2 of 6

$$h_L = \frac{gD^{1.8}}{}\left(\frac{\mu}{}\right)^{\cdot\cdot\cdot}$$

$$= 3.48\left[\frac{0.092L}{gD^{1.8}}\left(\frac{\rho}{\mu}\right)^{-0.2}V^{1.8}\right]$$

$$= 3.48h_L$$

Therefore, when the velocity is doubled, the head loss is increased by 3.48 times.

Step 5 of 6

For fully turbulent flow in a rough pipe, the friction factor is independent of the Reynolds number.

Therefore, the flow velocity

Thus, in the equation of head loss, $h_L = f\dfrac{L}{D}\dfrac{V^2}{2g}$

The friction factor, length of pipeline, diameter of the pipeline and the gravitational acceleration are constant.

Step 6 of 6

When the velocity is doubled $(V = 2V)$, the new head loss,

$$h_L' = f\frac{L}{D}\frac{(2V)^2}{2g}$$

$$= 4\left[f\frac{L}{D}\frac{V^2}{2g}\right]$$

$$h_L = \frac{gD^{1.8}}{}\left(\frac{\mu}{}\right)^{\cdot\cdot\cdot}$$

$$= 3.48\left[\frac{0.092L}{gD^{1.8}}\left(\frac{\rho}{\mu}\right)^{-0.2}V^{1.8}\right]$$

$$= 3.48h_L$$

Therefore, when the velocity is doubled, the head loss is increased by 3.48 times.

Question: 14.039P

Oil with ρ = 876 kg/m3 and μ = 0.24 kg/m-s is flowing through a 1.5-cm-diameter pipe that discharges into the atmosphere at 88 kPa. The absolute pressure 15 m before the exit is measured to be 135 kPa. Determine the flow rate of oil through the pipe if the pipe is (*a*) horizontal, (*b*) inclined 8° upward from the horizontal, and (*c*) inclined 8° downward from the horizontal.

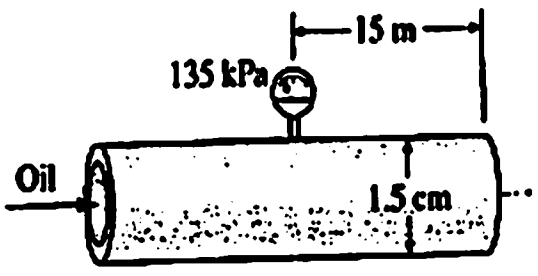

FIGURE P14–39

Step 1 of 5

Given data:

The density of oil, $\rho = 876\ \text{kg/m}^3$

The dynamic viscosity of oil, $\mu = 0.24\ \text{kg/m}\cdot\text{s}$

The diameter of pipe, $D = 1.5\ \text{cm} = 1.5\times10^{-2}\ \text{m}$

The exit pressure, $P_2 = 88\ \text{kPa}$

The absolute pressure 15 m before exit, $P_1 = 135\ \text{kPa}$

Step 2 of 5

The flow is assumed to be steady, fully developed, incompressible and laminar.

The length, $L = 15\ \text{m}$

The cross sectional flow area,

$$A_c = \frac{\pi}{4}D^2$$
$$= \frac{\pi}{4}\left(1.5\times10^{-2}\ \text{m}\right)^2$$
$$= 1.767\times10^{-4}\ \text{m}^2$$

Step 3 of 5

The pressure drop,

$$\Delta P = P_1 - P_2$$
$$= 135\ \text{kPa} - 88\ \text{kPa}$$
$$= 47\ \text{kPa}$$
$$= 47\times10^3\ \text{Pa}$$

Step 4 of 5

a) The pipe is horizontal.

The volume flow rate for horizontal pipe is given by $\dot{V} = \dfrac{\Delta P \pi D^4}{128\mu L}$

Substituting the known values, we get

$$\dot{V} = \frac{\left(47\times10^3\ \text{Pa}\right)\pi\left(1.5\times10^{-2}\ \text{m}\right)^4}{128\left(0.24\ \text{kg/m}\cdot\text{s}\right)\left(15\ \text{m}\right)}$$
$$= 1.62\times10^{-5}\ \text{m}^3/\text{s}$$

Therefore, the flow rate of oil through horizontal pipe, $\boxed{\dot{V} = 1.62\times10^{-5}\ \text{m}^3/\text{s}}$

Step 5 of 5

b) The pipe is inclined 8° upward from the horizontal. So, $\theta = 8°$

The volume flow rate for inclined pipe is given by $\dot{V} = \dfrac{\left(\Delta P - \rho g L \sin\theta\right)\pi D^4}{128\mu L}$,

Substituting the known values, we get

$$\dot{V} = \frac{\left[\Delta P - \rho g L \sin\theta\right]\pi D^4}{128\mu L}$$
$$= \frac{\left[47\times10^3\ \text{Pa} - \left(876\ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right)\left(15\ \text{m}\right)\sin\left(8°\right)\right]\pi\left(1.5\times10^{-2}\ \text{m}\right)^4}{128\left(0.24\ \text{kg/m}\cdot\text{s}\right)\left(15\ \text{m}\right)}$$
$$= 1.00\times10^{-5}\ \text{m}^3/\text{s}$$

Therefore, the flow rate of oil through horizontal pipe, $\boxed{\dot{V} = 1.00\times10^{-5}\ \text{m}^3/\text{s}}$

Question: 14.040P

Glycerin at 40°C with ρ = 1252 kg/m3 and μ = 0.27 kg/m-s is flowing through a 2-cm-diameter, 25-m- long pipe that discharges into the atmosphere at 100 kPa. The flow rate through the pipe is 0.048 L/s. (a) Determine the absolute pressure 25 m before the pipe exit. (*b*) At what angle θ must the pipe be inclined downward from the horizontal for the pressure in the entire pipe to be atmospheric pressure and the flow rate to be maintained the same?

Step 1 of 8

Given data:

The density of glycerin at 40°C, $\rho = 1252\ \text{kg/m}^3$

The dynamic viscosity, $\mu = 0.27\ \text{kg/m}\cdot\text{s}$

The diameter of pipe, $D = 2\ \text{cm}$

$= 2\times10^{-2}\ \text{m}$

The length of the pipe, $L = 25\ \text{m}$

The exit pressure, $P_2 = 100\ \text{kPa}$

The flow rate through the pipe, $\dot{V} = 0.048\ \text{lit/s}$

$= 0.048\times10^{-3}\ \text{m}^3/\text{s}$

Step 2 of 8

The flow is assumed to be steady, fully developed and incompressible.

The volume flow rate for inclined pipe is given by $\dot{V} = \dfrac{(\Delta P - \rho g L\sin\theta)\pi D^4}{128\mu L}$,

Where, ΔP is the pressure drop,

θ is the angle between the pipe and horizontal and

g is the gravitational acceleration.

Step 3 of 8

The cross sectional flow area,

$$A_c = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}\left(2\times10^{-2}\ \text{m}\right)^2$$

$$= 3.1416\times10^{-4}\ \text{m}^2$$

Therefore, the velocity of flow,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{0.048\times10^{-3}\ \text{m}^3/\text{s}}{3.1416\times10^{-4}\ \text{m}^2}$$

$$= 0.153\ \text{m/s}$$

Step 4 of 8

The Reynolds number,

$$\text{Re} = \frac{\rho VD}{\mu}$$

$$= \frac{\left(1252\ \text{kg/m}^3\right)\left(0.153\ \text{m/s}\right)\left(2\times10^{-2}\ \text{m}\right)}{0.27\ \text{kg/m}\cdot\text{s}}$$

$$= 14.189$$

Here, Re < 2300. Therefore, the flow is laminar.

Step 5 of 8

a) Here, the pipe is horizontal.

So, $\theta = 0$

Then,

$$\dot{V} = \frac{\left(\Delta P - \rho g L(\sin 0)\right)\pi D^4}{128\mu L}$$

$$= \frac{\Delta P\pi D^4}{128\mu L}$$

On rearranging,

$$\Delta P = \frac{128\mu L\dot{V}}{\pi D^4}$$

$$= \frac{128(0.27\ \text{kg/m}\cdot\text{s})(25\ \text{m})\left(0.048\times10^{-3}\ \text{m}^3/\text{s}\right)}{\pi\left(2\times10^{-2}\ \text{m}\right)^4}$$

$$= 82.506\times10^3\ \text{N/m}^2$$

$$= 82.506\ \text{kN/m}^2$$

$$= 82.506\ \text{kPa}$$

Step 6 of 8

The pressure drop is given by $\Delta P = P_1 - P_2$,

Where, P_1 is the initial pressure

Then,

$$P_1 = \Delta P + P_2$$

$$= 82.506\ \text{kPa} + 100\ \text{kPa}$$

$$= 182.506\ \text{kPa}$$

Therefore, the pressure 25 m before exit, $\boxed{P_1 = 182.506\ \text{kPa}}$

Step 7 of 8

b) The pressure in the pipe is equal to atmospheric pressure.

Now, $\Delta P = P_1 - P_2 = 0$

The flow rate, $\dot{V} = 0.048\times10^{-3}\ \text{m}^3/\text{s}$

The volume flow rate for inclined pipe,

$$\dot{V} = \frac{\left[\Delta P - \rho g L\sin\theta\right]\pi D^4}{128\mu L}$$

$$0.048\times10^{-3}\ \text{m}^3/\text{s} = \frac{\left[0 - \left(1252\ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right)(25\ \text{m})\sin\theta\right]\pi\left(2\times10^{-2}\ \text{m}\right)^4}{128(0.27\ \text{kg/m}\cdot\text{s})(25\ \text{m})}$$

$$= -\left(1.786\times10^{-4}\ \text{m}^3/\text{s}\right)\sin\theta$$

Step 8 of 8

Now calculating for θ, we get

$$0.048\times10^{-3} = -1.786\times10^{-4}(\sin\theta)$$

$$\sin\theta = -\frac{0.048\times10^{-3}}{1.786\times10^{-4}}$$

$$\sin\theta = -0.269$$

$$\theta = -15.6°$$

Therefore, the pipe must be inclined downwards at an angle $\boxed{\theta = 15.6°}$

Question: 14.041P

Oil at 80°F (ρ = 56.8 lbm/ft3 and μ = 0.0278 lbm/ft-s) jS flowing steadily in a 0.5-in-diameter, 120-ft-long pipe. During the flow, the pressure at the pipe inlet and exit is measured to be 120 psi and 14 psi, respectively. Determine the flow rate of oil through the pipe assuming the pipe is (*a*) horizontal, (*b*) inclined 20° upward, and (*c*) inclined 20° downward.

Step 1 of 5

Given data:

Temperature of the oil, $T = 80°\text{F}$

Density of the oil at temperature $T = 80°\text{F}$, $\rho = 56.8\,\text{lbm/ft}^3$

Dynamic viscosity $\mu = 0.0278\,\text{lbm/ft}\cdot\text{scc}$

Pressure at inlet of the pipe $P_1 = 120\,\text{psi}$

Pressure at exit of the pipe $P_2 = 14\,\text{psi}$

Diameter of the pipe $D = 0.5\,\text{in.}$

Length of the pipe $L = 120\,\text{ft}$

Step 2 of 5

Cross section area of the oil flow

$$\begin{aligned} A_c &= \frac{\pi}{4}D^2 \\ &= \frac{\pi}{4}(0.5)^2 \\ &= 0.196\,\text{in.}^2 \end{aligned}$$

Pressure drop in the pipe

$$\begin{aligned} \Delta P &= P_1 - P_2 \\ &= 120\,\text{psi} - 14\,\text{psi} \\ &= 106\,\text{psi} \\ &= 15264\,\text{lb/ft}^2 \end{aligned}$$

Step 3 of 5

a) The pipe is horizontal $(\theta = 0°)$

The volume flow rate for horizontal pipe is given by $\dot{V} = \dfrac{\Delta P \pi D^4}{128\mu L}$

Substituting the known values, we get

$$\begin{aligned} \dot{V} &= \frac{\left(106\frac{\text{lbf}}{\text{in.}^2}\right)\pi(0.5)^4\,\text{in.}^4}{128\left(0.0278\frac{\text{lbm}}{\text{ft}\cdot\text{sec}}\right)(120\,\text{ft})} \\ &\quad \frac{\left(106\times32.2\times12\frac{\text{lbm}\cdot\text{in}}{\text{sec}^2}\right)\pi(0.5)^4\,\text{in.}^2}{128\left(0.0278\frac{\text{lbm}}{\text{ft}\cdot\text{scc}}\right)(120\,\text{ft})} \\ &= 28.43\,\text{in.}^3/\text{sec} \end{aligned}$$

Therefore, the flow rate of oil through horizontal pipe, $\boxed{\dot{V} = 28.43\,\text{in.}^3/\text{s}}$

Step 4 of 5

b) The pipe is inclined in $20°$ upward from the horizontal. So, $\theta = 20°$

The volume flow rate for inclined pipe is given by $\dot{V} = \dfrac{(\Delta P - \rho g L \sin\theta)\pi D^4}{128\mu L}$,

Substituting the known values, we get

$$\begin{aligned} \dot{V} &= \frac{[\Delta P - \rho g L \sin\theta]\pi D^4}{128\mu L} \\ &= \frac{\left[(15264\times32.2)\frac{\text{lbm}\cdot\text{ft}}{\text{ft}^2\cdot\text{sec}^2} - \left(56.8\frac{\text{lbm}}{\text{ft}^3}\times32.2\ \text{ft/s}^2\right)(120\,\text{ft})\sin(20°)\right]\pi\left(\frac{0.5}{12}\right)^4\text{ft}^4}{128(0.0278\,\text{lbm/ft}\cdot\text{sec})(120\,\text{ft})} \\ &= 9.23\times10^{-3}\,\text{ft}^3/\text{s} \end{aligned}$$

Therefore, the flow rate of oil through horizontal pipe, $\boxed{\dot{V} = 9.23\times10^{-3}\,\text{ft}^3/\text{s}}$

Step 5 of 5

c) The pipe is inclined $8°$ downward from the horizontal. So, $\theta = -8°$

The volume flow rate for inclined pipe, $\dot{V} = \dfrac{(\Delta P - \rho g L \sin\theta)\pi D^4}{128\mu L}$

Substituting the known values, we get

$$\begin{aligned} \dot{V} &= \frac{[\Delta P - \rho g L \sin\theta]\pi D^4}{128\mu L} \\ &= \frac{\left[(15264\times32.2)\frac{\text{lbm}\cdot\text{ft}}{\text{ft}^2\cdot\text{sec}^2} - \left(56.8\frac{\text{lbm}}{\text{ft}^3}\times32.2\ \text{ft/s}^2\right)(120\,\text{ft})\sin(-20°)\right]\pi\left(\frac{0.5}{12}\right)^4\text{ft}^4}{128(0.0278\,\text{lbm/ft}\cdot\text{sec})(120\,\text{ft})} \\ &= 0.0125\,\text{ft}^3/\text{s} \end{aligned}$$

Therefore, the flow rate of oil through horizontal pipe, $\boxed{\dot{V} = 0.0125\,\text{ft}^3/\text{s}}$

Question: 14.042P

Oil with a density of 850 kg/m3 and kinematic viscosity of 0.00062 m2/s is being discharged by a 8-mm-diameter, 40-m-long horizontal pipe from a storage tank open to the atmosphere. The height of the liquid level above the center of the pipe is 4 m. Disregarding the minor losses, determine the flow rate of oil through the pipe.

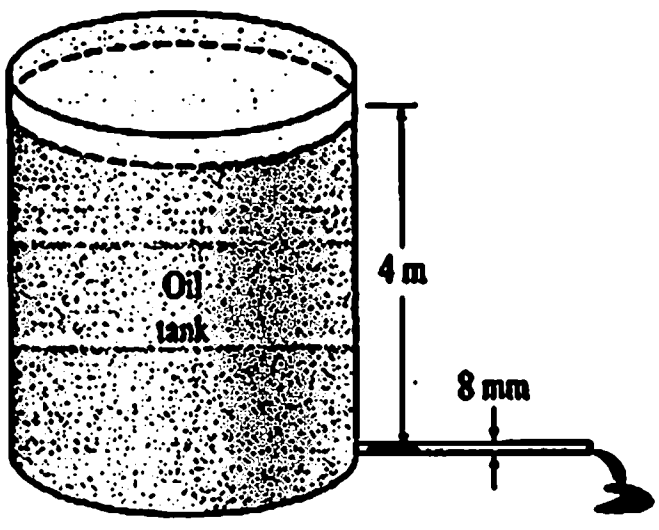

FIGURE P14–42

Step 1 of 5

Given data:

Density of the oil, $\rho = 850\ \text{kg/m}^3$

Kinetic viscosity of the oil $\nu = 0.00062\ \text{m}^2/\text{s}$

Diameter of pipe, $D = 8\ \text{mm}$

$= 8 \times 10^{-3}\ \text{m}$

The length of the pipe, $L = 40\ \text{m}$

The height of the liquid level above the centre of the pipe, $h = 4\ \text{m}$

Step 2 of 5

The volume flow rate for horizontal pipe is given by $\dot{V} = \dfrac{\Delta P \pi D^4}{128 \mu L}$,

Where, ΔP is the pressure drop and
μ is the dynamic viscosity

The pressure at the bottom open of the oil tank,

$$P_{bottom} = \rho g h$$
$$= (850\ \text{kg/m}^3)(9.81\ \text{m/s}^2)(4\ \text{m})$$
$$= 33.354 \times 10^3\ \text{N/m}^2$$

Now, the change in pressure,

$$\Delta P = P_{bottom} - P_{top}$$
$$= (3.354 \times 10^3) - 0$$
$$= 33.354 \times 10^3\ \text{N/m}^2$$

Step 3 of 5

The dynamic viscosity,

$$\mu = \rho \nu$$
$$= (850\ \text{kg/m}^3)(0.00062\ \text{m}^2/\text{s})$$
$$= 0.527\ \text{kg/m} \cdot \text{s}$$

Substitute the known values in the equation for flow rate,

$$\dot{V} = \frac{(33.354 \times 10^3\ \text{N/m}^2)\pi(8 \times 10^{-3}\ \text{m})^4}{128(0.527\ \text{kg/m} \cdot \text{s})(40\ \text{m})}$$
$$= 1.59 \times 10^{-7}\ \text{m}^3/\text{s}$$

Therefore, the flow rate of oil through horizontal pipe, $\boxed{\dot{V} = 1.59 \times 10^{-7}\ \text{m}^3/\text{s}}$

Step 4 of 5

The cross sectional flow area,

$$A_t = \frac{\pi}{4} D^2$$
$$= \frac{\pi}{4}(8 \times 10^{-3}\ \text{m})^2$$
$$= 5.026 \times 10^{-5}\ \text{m}^2$$

The velocity of flow,

$$V = \frac{\dot{V}}{A_t}$$
$$= \frac{1.59 \times 10^{-7}\ \text{m}^3/\text{s}}{5.026 \times 10^{-5}\ \text{m}^2}$$
$$= 3.16 \times 10^{-3}\ \text{m/s}$$

Step 5 of 5

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu}$$
$$= \frac{(850\ \text{kg/m}^3)(3.16 \times 10^{-3}\ \text{m/s})(8 \times 10^{-3}\ \text{m})}{0.527\ \text{kg/m} \cdot \text{s}}$$
$$= 0.0408$$

Here, Reynolds number Re <2300

Therefore, the flow is laminar and the assumption and analysis is correct.

Question: 14.043P

In an air heating system, heated air at 40°C and 105 kPa absolute is distributed through a 0.2 m × 0.3 m rectangular duct made of commercial steel at a rate of 0.5 m3/s. Determine the pressure drop and head loss through a 40-m- long section of the duct.

Step 1 of 6

Assume the flow is steady, incompressible and fully developed.

Obtain the equivalent roughness factor for commercial steel pipe from "Table 8.1 Equivalent roughness for new pipes" in the textbook.

$$\varepsilon = 0.045\,\text{mm}$$

Obtain the dynamic viscosity of air at $40°\text{C}$ from "Ideal gas properties of air" in the textbook.

$$\mu = 1.918 \times 10^{-5}\,\text{kg/m}\cdot\text{s}$$

Find the density of air.

$$\rho = \frac{P}{RT}$$

Here, P is the pressure of air, R is the characteristic gas constant of air, T is the temperature of air.

Substitute $105\,\text{kPa}$ for P, $0.287\,\text{kJ/kg-K}$ for R, and $313\,\text{K}$ for T.

$$\rho = \frac{105}{(0.287\ \text{kJ/kg}\cdot\text{K})(313\ \text{K})}$$
$$= 1.169\ \text{kg/m}^3$$

Step 2 of 6

Find the cross sectional flow area.

$$A_c = 0.2\ \text{m} \times 0.3\ \text{m}$$
$$= 0.06\ \text{m}^2$$

Find the wetted perimeter.

$$p = 2(0.2\ \text{m} + 0.3\ \text{m})$$
$$= 1\ \text{m}$$

Find the hydraulic diameter.

$$D_h = \frac{4A_c}{p}$$

Substitute $0.06\,\text{m}^2$ for A_c and $0.24\,\text{m}$ for p.

$$D_h = \frac{4(0.06)}{1}$$
$$= 0.24\ \text{m}$$

Step 3 of 6

Find the velocity of flow.

$$V = \frac{\dot{V}}{A_c}$$

Here, $\dot{V}$ is the flow rate of air.

Substitute $0.5\,\text{m}^3/\text{s}$ for $\dot{V}$ and $0.06\,\text{m}^2$ for A_c.

$$V = \frac{0.5}{0.06}$$
$$= 8.33\ \text{m/s}$$

Find the Reynolds number.

$$\text{Re} = \frac{\rho V D_h}{\mu}$$

Substitute $1.169\ \text{kg/m}^3$ for ρ, $8.33\ \text{m/s}$ for V, $0.24\ \text{m}$ for D_h, and $1.918 \times 10^{-5}\ \text{kg/m}\cdot\text{s}$ for μ.

$$\text{Re} = \frac{(1.169)(8.33)(0.24)}{1.918 \times 10^{-5}}$$
$$= 121.85 \times 10^3$$

Since $\text{Re} > 4000$, the flow is turbulent.

Step 4 of 6

Use Colebrook equation to find friction factor.

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D_h}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

Substitute $0.045\ \text{mm}$ for ε, $0.24\ \text{m}$ for D_h, and 121.85×10^3 for Re.

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{0.045\,\text{mm} \times 10^{-3}\,\frac{\text{m}}{\text{mm}} \Big/ 0.24}{3.7} + \frac{2.51}{(121.85 \times 10^3)\sqrt{f}}\right)$$
$$= -2.0 \log\left(5.067 \times 10^{-5} + \frac{2.06 \times 10^{-5}}{\sqrt{f}}\right)$$

Solve the equation for f.

$$f = 0.0183$$

Step 5 of 6

Find the pressure drop through the duct.

$$\Delta P_L = f\frac{L}{D_h}\frac{\rho V^2}{2}$$

Substitute 0.0183 for f, $40\,\text{m}$ for L, $0.24\ \text{m}$ for D_h, $1.169\ \text{kg/m}^3$ for ρ, and $8.33\ \text{m/s}$ for V.

$$\Delta P_L = f\frac{L}{D_h}\frac{\rho V^2}{2}$$
$$= 0.0183\left[\frac{40}{0.24}\right]\left[\frac{(1.169)(8.33)^2}{2}\right]$$
$$= 123.7\ \text{Pa}$$

Step 6 of 6

Find the head loss in the duct.

$$h_L = \frac{\Delta P_L}{\rho g}$$

Substitute $123.7\,\text{Pa}$ for ΔP_L, $1.169\ \text{kg/m}^3$ for ρ, and $9.81\,\text{m/s}^2$ for g.

$$h_L = \frac{123.7\ \text{Pa}}{(1.169\ \text{kg/m}^3)(9.81\ \text{m/s}^2)}$$
$$= 10.79\ \text{m}$$

Therefore, the pressure drop and the head loss in the duct is $\boxed{124\,\text{Pa}, 10.79\,\text{m}}$.

Question: 14.044P

Glycerin at 40°C with ρ = 1252 kg/m3 and μ = 0.27 kg/m-s is flowing through a 4-cm-diameter horizontal smooth pipe with an average velocity of 3.5 m/s. Determine the pressure drop per 10 m of the pipe.

Step 1 of 4

Given data:

The density of glycerin at 40°C, $\rho = 1252\ \text{kg/m}^3$

The dynamic viscosity, $\mu = 0.27\ \text{kg/m}\cdot\text{s}$

The diameter of pipe, $D = 4\ \text{cm}$

$= 4 \times 10^{-2}\ \text{m}$

The average velocity of the glycerin, $V = 3.5\ \text{m/s}$

The length of the pipe, $L = 10\ \text{m}$

Step 2 of 4

The flow is assumed to be steady, fully developed and incompressible.

The cross sectional flow area,

$$A_c = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}\left(4 \times 10^{-2}\ \text{m}\right)^2$$

$$= 1.2566 \times 10^{-3}\ \text{m}^2$$

The flow rate of the fluid,

$$\dot{V} = VA_c$$

$$= \left(3.5\ \text{m/s}\right)\left(1.2566 \times 10^{-3}\ \text{m}^2\right)$$

$$= 4.3981 \times 10^{-3}\ \text{m}^3/\text{s}$$

Step 3 of 4

The Reynolds number,

$$\text{Re} = \frac{\rho VD}{\mu}$$

$$= \frac{\left(1252\ \text{kg/m}^3\right)\left(3.5\ \text{m/s}\right)\left(4 \times 10^{-2}\ \text{m}\right)}{0.27\ \text{kg/m}\cdot\text{s}}$$

$$= 649.185$$

Here, Re < 2300. Therefore, the flow is laminar.

Step 4 of 4

The friction factor,

$$f = \frac{64}{\text{Re}}$$

$$= \frac{64}{649.185}$$

$$= 0.0986$$

The pressure drop in the pipe,

$$\Delta P_L = f\frac{L}{D}\frac{\rho V^2}{2}$$

$$= 0.0986\left[\frac{10\ \text{m}}{4 \times 10^{-2}\ \text{m}}\right]\left[\frac{\left(1252\ \text{kg/m}^3\right)\left(3.5\ \text{m/s}\right)^2}{2}\right]$$

$$= 189.028 \times 10^3\ \text{Pa}$$

$$= 189.028\ \text{kPa}$$

Therefore, the pressure drop per 10 m is $\boxed{189.03\ \text{kPa}}$

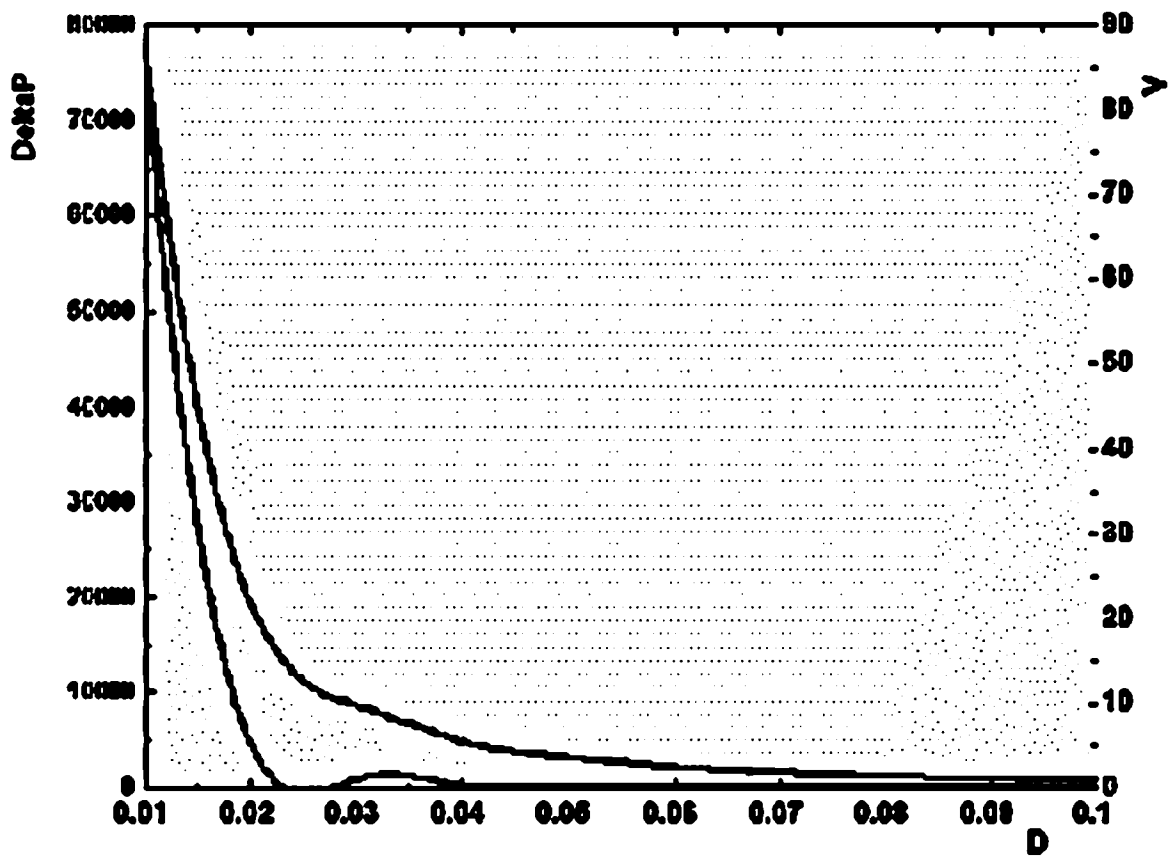
Question: 14.045P

Reconsider Prob. 14-44. Using EES (or other) software, investigate the effect of the pipe diameter on the pressure drop for the same constant flow rate. Let the pipe diameter vary from 1 to 10 cm in increments of 1 cm. Tabulate and plot the results, and draw conclusions.

Step 1 of 3

The EES code for solving the given problem is as below:

```
Vdot=3.5*pi*(0.05)^2/4          "Volumetric flow rate"
Ac=pi*D^2/4                     "Cross sectional area"
rho=1252                        "density"
nu=mu/rho                       "Kinematic viscosity"
mu=0.27                         "Dynamic viscosity"
L=10                            "Length"
V=Vdot/Ac                       "Velocity"
Re=V*D/nu                       "Reynolds number"
f=64/Re                         "friction"
DeltaP=f*(L/D)*rho*V^2/2000     "Change in pressure"
W=Vdot*DeltaP                   "Work"
```



Step 2 of 3

Now enter the values of diameter by selecting the

▷ 1..10	1 D	2 δP	3 Re	4 V
Run 1	0.01	75600	4057	87.5
Run 2	0.02	4725	2029	21.88
Run 3	0.03	933.3	1352	9.722
Run 4	0.04	295.3	1014	5.469
Run 5	0.05	121	811.5	3.5
Run 6	0.06	58.33	676.2	2.431
Run 7	0.07	31.49	579.6	1.786
Run 8	0.08	18.46	507.2	1.367
Run 9	0.09	11.52	450.8	1.08
Run 10	0.1	7.56	405.7	0.875

Step 3 of 3

The plot showing the variation of 'DeltaP' and 'V' with diameter is as below:

Question: 14.046P

Air at 1 atm and 60°F is flowing through a 1 ft × 1 ft square duct made of commercial steel at a rate of 1600 cfm. Determine the pressure drop and head loss per ft of the duct.

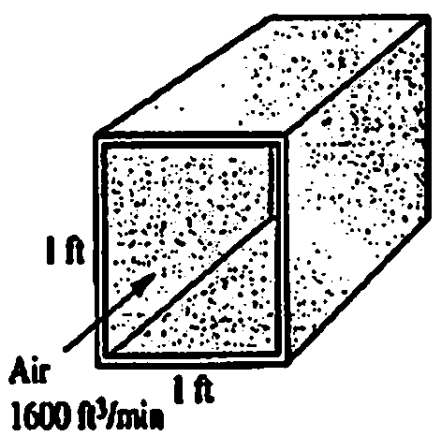


FIGURE P14–46E

Step 1 of 5

Convert the discharge rate of air from ft^3/min to ft^3/s.

Discharge of air passing through the duct,

$$\dot{V} = 1600\frac{\text{ft}^3}{\text{min}} \times \frac{1\ \text{min}}{60\ \text{sec}}$$
$$= 26.66\ \text{ft}^3/\text{s}$$

Calculate the cross sectional area of the duct.

$$A = 1 \times 1$$
$$= 1\ \text{ft}^2$$

Calculate the velocity of flow.

$$V = \dot{V} / A$$

Substitute $26.66\ \text{ft}^3/\text{s}$ for $\dot{V}$, and $1\ \text{ft}^2$ for A.

$$V = 26.66 / 1$$
$$= 26.66\ \text{ft/s}$$

Step 2 of 5

Characteristic length for a square duct,

$$D_h = a$$
$$= 1\ \text{ft}$$

Here, a is the length of a side of the square duct.

Obtain the following properties of air from table A-22E, "Properties of air at 1 atm pressure", from the textbook at 1 atm and $60°\text{F}$.

Density of air, $\rho = 0.0764\ \text{lbm/ft}^3$

Dynamic viscosity of air, $\mu = 1.135 \times 10^{-5}\ \text{lbm/ft} \cdot \text{s}$

Calculate the Reynolds number.

$$\text{Re} = \frac{\rho V D_h}{\mu}$$

Substitute $0.0764\ \text{lbm/ft}^3$ for ρ, $26.66\ \text{ft/s}$ for V, 1 ft for a, and $1.135 \times 10^{-5}\ \text{lbm/ft} \cdot \text{s}$ for μ.

$$\text{Re} = \frac{0.0764 \times 26.66 \times 1}{1.135 \times 10^{-5}}$$
$$= 179455.85$$

Since the obtained Reynolds number is more than 4000 flow is in turbulent nature.

Step 3 of 5

Equivalent roughness for commercial steel from table "Equivalent roughness values for new commercial pipes" is considered to be $\varepsilon = 0.00015$

The ducts relative roughness is given by,

$$\frac{\varepsilon}{D} = \frac{0.00015}{1}$$
$$= 0.00015$$

From Colebrook equation friction factor can be calculated as,

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon / D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$
$$= -2.0 \log\left(\frac{0.00015}{3.7} + \frac{2.51}{179455.85\sqrt{f}}\right)$$
$$= -2.0 \log\left(4.05 \times 10^{-5} + \frac{1.398 \times 10^{-5}}{\sqrt{f}}\right)$$
$$f = 0.01704$$

Step 4 of 5

Pressure drop in the duct for turbulent flow is given by,

$$\Delta P = f \frac{L}{D} \frac{\rho V^2}{2}$$

But pressure loss per unit length is given by,

$$\frac{\Delta P}{L} = f \frac{\rho V^2}{2D}$$
$$= 0.01704 \times \frac{0.0764 \times 26.66^2}{2 \times 1} \times \left(\frac{1}{32.2}\right)$$
$$= 0.0143\ \text{lbf/ft}^3$$
$$= 1 \times 10^{-4}\ \text{psi/ft}$$

Step 5 of 5

Head loss per feet is given by,

$$h_l = \frac{\frac{\Delta P}{L}}{\rho g}$$

Substitute $1 \times 10^{-4}\ \text{psi/ft}$ for $\Delta P / L$, and $0.0764\ \text{lbm/ft}^3$ for ρg.

$$h_l = \frac{1 \times 10^{-4}\ \frac{\text{psi}}{\text{ft}} \times \frac{144\ \text{in}^2}{1\ \text{ft}^2}}{0.0764\ \frac{\text{lbm}}{\text{ft}^3}}$$
$$= 0.188\ \text{ft/ft}$$

Therefore the pressure loss is obtained as $\boxed{1 \times 10^{-4}\ \text{psi/ft}}$ and the head loss is obtained as $\boxed{0.188\ \text{ft/ft}}$.

Question: 14.047P

Liquid ammonia at -20°C is flowing through a 30-m-long section of a 5-mm-diameter copper tube at a rate of 0.15 kg/s. Determine the pressure drop, the head loss, and the pumping power required to overcome the frictional losses in the tube.

Step 1 of 9

Given data:

Temperature at which liquid ammonia is flowing through a copper tube is $-20°C$.

The length of the pipe, $L = 30\,\text{m}$.

The diameter of pipe,

$$D = 5\,\text{mm} = 5\times10^{-3}\,\text{m}$$

The mass flow rate, $\dot{m} = 0.15\,\text{kg/s}$.

Step 2 of 9

The flow is assumed to be steady, fully developed and incompressible.

From the table of properties of saturated ammonia, corresponding to $-20°C$,

The density, $\rho = 665.1\,\text{kg/m}^3$.

The dynamic viscosity, $\mu = 2.361\times10^{-4}\,\text{kg/m}\cdot\text{s}$.

For copper tube, the roughness,

$$\varepsilon = 0.0015\,\text{mm} = 1.5\times10^{-6}\,\text{m}$$

Step 3 of 9

Area of the cross sectional flow,

$$A_c = \frac{\pi}{4}D^2 = \frac{\pi}{4}\left(5\times10^{-3}\right)^2 = 19.635\times10^{-6}\,\text{m}^2$$

Velocity,

$$V = \frac{\dot{m}}{\rho A_c} = \frac{0.15}{(665.1)\left(19.635\times10^{-6}\right)} = 11.486\,\text{m/s}$$

Step 4 of 9

The flow rate,

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{0.15\,\text{kg/s}}{665.1\,\text{kg/m}^3} = 2.255\times10^{-4}\,\text{m}^3/\text{s}$$

Step 5 of 9

The Reynolds number,

$$\text{Re} = \frac{\rho VD}{\mu} = \frac{(665.1)(11.486)\left(5\times10^{-3}\right)}{2.361\times10^{-4}} = 161.782\times10^3$$

Here, $\text{Re} > 4000$. Therefore, the flow is turbulent.

Step 6 of 9

For turbulent flow, the Colebrook equation is given by

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right),$$

Where f is the friction factor.

Substitute the known values.

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\left(1.5\times10^{-6}/5\times10^{-3}\right)}{3.7} + \frac{2.51}{\left(161.782\times10^3\right)\sqrt{f}}\right)$$

$$= -2.0\log\left(8.108\times10^{-5} + \left(\frac{1.55\times10^{-5}}{\sqrt{f}}\right)\right)$$

Solve the equation for f, we get

$$f = 0.01818$$

Step 7 of 9

The pressure drop,

$$\Delta P_L = f\frac{L}{D}\frac{\rho V^2}{2} = 0.01818\left[\frac{30}{5\times10^{-3}}\right]\left[\frac{(665.1)(11.486)^2}{2}\right]$$

$$= 4785.6\times10^3\,\text{Pa}$$

$$\boxed{\Delta P_L = 4785.6\,\text{kPa}}$$

Therefore, the pressure drop is $\Delta P_L = 4785.6\,\text{kPa}$.

Step 8 of 9

The head loss is given by $h_L = \frac{\Delta P_L}{\rho g}$,

Where g is the gravitational acceleration.

Substitute the known values.

$$h_L = \frac{4785.6\times10^3}{665.1\times9.81}$$

$$\boxed{h_L = 733.5\,\text{m}}$$

Therefore, the head loss, $h_L = 733.5\,\text{m}$.

Step 9 of 9

The pumping power required,

$$\dot{W}_{\text{pump}} = \dot{V}\Delta P_L = \left(2.255\times10^{-4}\right)\times\left(4785.6\times10^3\right)$$

$$= 1.079\times10^3\,\text{W}$$

$$\boxed{\dot{W}_{\text{pump}} = 1.079\,\text{kW}}$$

Therefore, the pumping power required to overcome the pressure loss, $\dot{W}_{\text{pump}} = 1.079\,\text{kW}$.

Question: 14.048P

What is minor loss in pipe flow? How is the minor loss coefficient *KL* defined?

Step 1 of 1

In typical pipe systems in addition to straight sections, there may be various fittings, valves, bends, elbows, tees, inlets, exits, expansions and contractions. These components disturb the smooth flow of the fluid, results in additional losses due to the influence of flow separation and mixing etc. These losses are called minor losses. Minor losses are expressed in terms of the loss coefficient.

The loss coefficient is given by, $K_L = \dfrac{h_L}{\left(V^2/2g\right)}$,

Where, h_L is the additional irreversible head loss,

V is the average flow velocity and

g is the gravitational acceleration.

Question: 14.049P

Define equivalent length for minor loss in pipe flow. How is it related to the minor loss coefficient?

Step 1 of 1

The presence of various fittings, valves, bends, elbows, tees, inlets, exits, expansions and contractions in a piping system cause disturbance in the smooth flow of the fluid, results in additional losses due to the influence of flow separation and mixing etc. These losses are called minor losses.

The length of a straight pipe which would give the same head loss as the minor loss component is known as the equivalent length.

The equivalent length is given by $L_{equiv} = \frac{D}{f} K_L$,

where, K_L is the loss coefficient,

D is the diameter of the pipe that contains the components and

f is the friction factor.

Question:

14.050P

The effect of rounding of a pipe inlet on the loss coefficient is (*a*) negligible, (*b*) somewhat significant, or (*c*) very significant.

Step 1 of 1

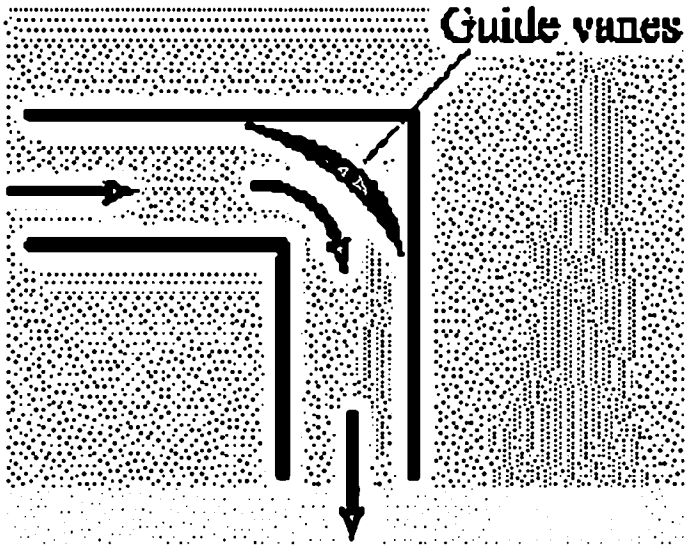
The head loss at the pipe inlet strongly depends on the geometry of the inlet. The minor loss coefficient (K_L) of reentrant pipe inlet is 0.8, sharp-edged pipe inlet is 0.5 and well-rounded pipe inlet is 0.03.

Thus, the head loss at the rounded pipe inlet is almost negligible. Therefore, the effect of rounding of the pipe inlet on the loss coefficient is very significant.

Question: 14.051P

Which has a greater minor loss coefficient during pipe flow: gradual expansion or gradual contraction? Why?

Step 1 of 1



The gradual expansion has a greater minor loss coefficient than a gradual contraction in pipe flow. This is because, in gradual expansion flow, a flow separation is occurred due to the adverse pressure gradient in the boundary layer.

Question: 14.052P

A piping system involves sharp turns, and thus large minor head losses. One way of reducing the head loss is to replace the sharp turns by circular elbows. What is another way?

Step 1 of 1

In addition to circular elbows, the head losses can be reduced by using properly placed guide vanes in sharp turns.

Question: 14.053P

During a retrofitting project of a fluid flow system to reduce the pumping power, it is proposed to install vanes into the miter elbows or to replace the sharp turns in 90° miter elbows by smooth curved bends. Which approach will result in a greater reduction in pumping power requirements?

Step 1 of 1

The loss coefficient for miter elbow with vanes, $K_L \approx 0.2$

The loss coefficient for smooth curved bend, $K_L \approx 0.9$

Since the loss coefficient is less for the miter elbow with vanes, the losses associated with it will be less. Therefore, the miter elbow with vanes will help to reduce the pumping power requirements.

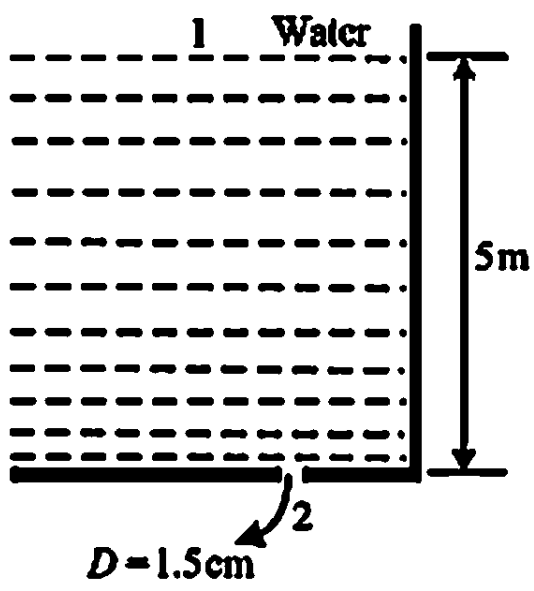
Question: 14.054P

Water is to be withdrawn from a 5-m-high water reservoir by drilling a 1.5-cm-diameter hole at the bottom surface. Disregarding the effect of the kinetic energy correction factor, determine the flow rate of water through the hole if (*a*) the entrance of the hole is well-rounded and (*b*) the entrance is sharp-edged.

Step 1 of 8

Given data:

Height of the reservoir, $H = 5\ \text{m}$



The diameter of the bottom hole,

$D = 1.5\ \text{cm}$

$= 1.5 \times 10^{-2}\ \text{m}$

Step 2 of 8

Free body diagram of the water reservoir with a hole at the bottom:

Step 3 of 8

The subscript 1 denotes the values at the free surface and subscript 2 denotes the values at the exit of the hole.

The energy equation for the two points in terms of heads,

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L$$

Step 4 of 8

Take the exit of the hole as the reference level.

Then,

$z_1 = 5\ \text{m}$

$z_2 = 0$

The pressure at both the points is equal to the atmospheric pressure,

$P_1 = P_2 = P_{\text{atm}}$

Here, the flow section does not involve any work devices such as pump or turbine. Thus,

$h_{\text{pump},u} = h_{\text{turbine},e} = 0$

The flow velocity at the free surface,

$V_1 = 0$

The effect of the kinetic energy correction factor is disregarded. So,

$\alpha_1 = \alpha_2 = 1$

Step 5 of 8

The head loss of the flow, $h_L = K_L \frac{V^2}{2g}$

Here K_L is the loss coefficient

On substituting the known values in the energy equation, we get

$$\frac{P_{\text{atm}}}{\rho g} + (1)\frac{(0)^2}{2g} + z_1 + 0 = \frac{P_{\text{atm}}}{\rho g} + (1)\frac{V_2^2}{2g} + 0 + 0 + K_L \frac{V_2^2}{2g}$$

$$z_1 = \frac{V_2^2}{2g} + K_L \frac{V_2^2}{2g}$$

$$= \frac{V_2^2}{2g}(1 + K_L)$$

$$V_2 = \sqrt{\frac{2gz_1}{1 + K_L}}$$

Step 6 of 8

The cross sectional flow area through the hole,

$$A_c = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}\left(1.5 \times 10^{-2}\ \text{m}\right)^2$$

$$= 1.767 \times 10^{-4}\ \text{m}^2$$

The flow rate through the hole,

$$\dot{V} = V_2 A_c$$

$$= \sqrt{\frac{2gz_1}{1 + K_L}} A_c$$

Step 7 of 8

(a)

For well-rounded entrance, $K_L = 0.03$

On substituting the known values in the equation for flow rate, we get

$$\dot{V} = \sqrt{\frac{2\left(9.81\ \text{m/s}^2\right)(5\ \text{m})}{1 + 0.03}}\left(1.767 \times 10^{-4}\ \text{m}^2\right)$$

$$= 9.759 \times 1.767 \times 10^{-4}$$

$$= 1.724 \times 10^{-3}\ \text{m}^3/\text{s}$$

Therefore, the flow rate through the well-rounded entrance, $\boxed{\dot{V} = 1.724 \times 10^{-3}\ \text{m}^3/\text{s}}$

(b)

Step 8 of 8

For sharp edged entrance, $K_L = 0.5$

On substituting the known values in the equation for flow rate, we get

$$\dot{V} = \sqrt{\frac{2\left(9.81\ \text{m/s}^2\right)(5\ \text{m})}{1 + 0.5}}\left(1.767 \times 10^{-4}\ \text{m}^2\right)$$

$$= 8.087 \times 1.767 \times 10^{-4}$$

$$= 1.429 \times 10^{-3}\ \text{m}^3/\text{s}$$

Therefore, the flow rate through the sharp edged entrance, $\boxed{\dot{V} = 1.429 \times 10^{-3}\ \text{m}^3/\text{s}}$

Question: 14.055P pg 1

A horizontal pipe has an abrupt expansion from $D1$ = 8 cm to $D2$ = 16 cm. The water velocity in the smaller section is 10 m/s and the flow is turbulent. The pressure in the smaller section is $P1$ = 410 kPa. Taking the kinetic energy correction factor to be 1.06 at both the inlet and the outlet, determine the downstream pressure $P2$. and estimate the error that would have occurred if Bernoulli's equation had been used.

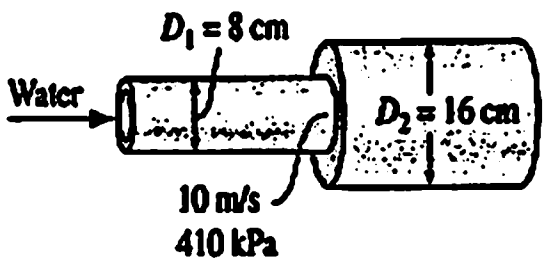


FIGURE P14–55

Step 1 of 8

Given data:

The diameter of pipe 1,

$$D_1 = 8 \text{ cm}$$
$$= 8 \times 10^{-2} \text{ m}$$

The diameter of pipe 2,

$$D_2 = 16 \text{ cm}$$
$$= 16 \times 10^{-2} \text{ m}$$

The velocity in the pipe 1, $V_1 = 10 \text{ m/s}$

The pressure in the pipe 1,

$$P_1 = 410 \text{ kPa}$$
$$= 410 \times 10^3 \text{ Pa}$$

The kinetic energy correction factor for both inlet and outlet, $\alpha_1 = \alpha_2 = 1.06$

Step 2 of 8

The flow is assumed to be steady, fully developed and incompressible.

The cross sectional flow area of pipe 1,

$$A_{C1} = \frac{\pi}{4} D_1^2$$
$$= \frac{\pi}{4}\left(8 \times 10^{-2}\right)^2$$
$$= 5.026 \times 10^{-3} \text{ m}^2$$

The cross sectional flow area of pipe 2,

$$A_{C2} = \frac{\pi}{4} D_2^2$$
$$= \frac{\pi}{4}\left(16 \times 10^{-2}\right)^2$$
$$= 20.106 \times 10^{-3} \text{ m}^2$$

Step 3 of 8

Applying the equation conservation of mass flow, we get

$$\rho V_1 A_{C1} = \rho V_2 A_{C2}$$
$$V_2 = \frac{A_{C1}}{A_{C2}} V_1$$
$$= \frac{5.026 \times 10^{-3}}{20.106 \times 10^{-3}}(10)$$
$$= 2.5 \text{ m/s}$$

The loss coefficient for sudden expansion,

$$K_L = \alpha\left(1 - \frac{A_{small}}{A_{big}}\right)^2$$
$$= 1.06\left(1 - \frac{5.026 \times 10^{-3} \text{ m}^2}{20.106 \times 10^{-3} \text{ m}^2}\right)^2$$
$$= 0.5963$$

Step 4 of 8

The head loss of the given system,

$$h_L = K_L \frac{V^2}{2g}$$

Where, g is the gravitational acceleration.

Hence the head loss,

$$h_L = K_L \frac{V_1^2}{2g}$$
$$= 0.5963\left(\frac{(10)^2}{2(9.81)}\right)$$
$$= 3.04 \text{ m}$$

Step 5 of 8

The energy equation for the expansion section in terms of heads,

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L$$

The pipe is horizontal,

$$z_1 = z_2$$

Here, the flow section does not involve any work devices such as pump or turbine.

The pipe is horizontal,

$$z_1 = z_2$$

Here, the flow section does not involve any work devices such as pump or turbine.

Thus,

$$h_{pump,u} = h_{turbine,e} = 0$$

The density of water, $\rho = 1000\ \text{kg/m}^3$

Step 6 of 8

Substitute the known values in the energy equation, we get

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + 0 = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_1 + 0 + h_L$$

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + h_L$$

$$\frac{P_2}{\rho g} = \frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} - \alpha_2 \frac{V_2^2}{2g} - h_L$$

$$P_2 = P_1 + \rho\left(\frac{\alpha_1 V_1^2}{2} - \frac{\alpha_2 V_2^2}{2} - g h_L\right)$$

On substitute the known values in the above energy equation, we get

$$P_2 = (410\times10^3) + (1000)\left(\frac{(1.06\times10^2)}{2} - \frac{(1.06\times2.5^2)}{2} - (9.81\times3.04)\right)$$

$$= 429.865\times10^3\ \text{Pa}$$

$$= 429.865\ \text{kpa}$$

$$\approx 430\ \text{kpa}$$

Therefore, the downstream pressure, $\boxed{P_2 = 430\ \text{kPa}}$

Step 7 of 8

The actual Bernoulli's equation for the given system, we have

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2$$

$$\frac{P_2}{\rho g} = \frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 - \frac{V_2^2}{2g} - z_2$$

$$= \frac{P_1}{\rho g} + \frac{V_1^2}{2g} - \frac{V_2^2}{2g}$$

$$P_2 = P_1 + \rho\left(\frac{V_1^2}{2} - \frac{V_2^2}{2}\right)$$

Step 8 of 8

On substitute the known values in the above Bernoulli's equation, we get

$$(P_2)_{\text{Bernoulli}} = (410\times10^3) + (1000)\left(\frac{10^2}{2} - \frac{2.5^2}{2}\right)$$

$$= 456.875\times10^3\ \text{Pa}$$

$$= 456.875\ \text{kPa}$$

The error in Bernoulli's equation,

$$\text{Error} = (P_2)_{\text{Bernoulli}} - P_2$$

$$= 456.875 - 429.865$$

$$= 27\ \text{kPa}$$

Therefore the error in the Bernoulli's equation, $\boxed{\text{Error} = 27\ \text{kPa}}$

Question: 14.056P

Consider flow from a water reservoir-through a circular hole of diameter D at the side wall at a vertical distance H from the free surface. The flow rate through an actual hole with a sharp-edged entrance (KL = 0.5) is considerably less than the flow rate calculated assuming "frictionless" flow and thus zero loss for the hole. Disregarding the effect of the kinetic energy correction factor, obtain a relation for the "equivalent diameter" of the sharp-edged hole for use in frictionless flow relations.

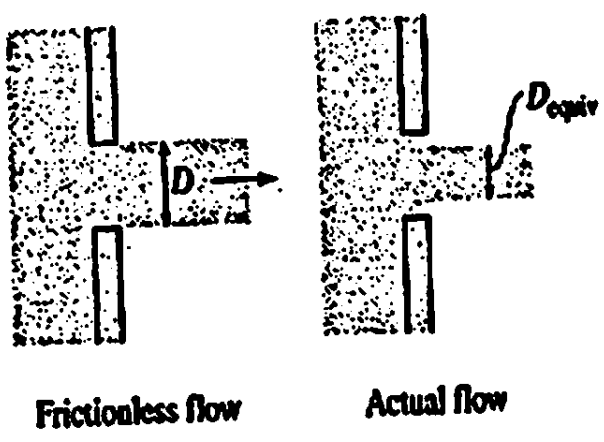

FIGURE P14–56

Step 1 of 9

Given data:

The loss coefficient, $K_L = 0.5$

The vertical distance from the hole to the free surface is H.

The diameter of the hole is D.

Step 2 of 9

The flow is assumed to be steady and incompressible.

The subscript 1 denotes the values at the free surface and subscript 2 denotes the values at the exit of the hole.

The energy equation for the two points in terms of heads is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L,$$

Step 3 of 9

Take the exit of the hole as the reference level.

Then,

$z_1 = H$

$z_2 = 0$

The pressure at both the points is equal to the atmospheric pressure. So,

$P_1 = P_2 = P_{atm}$

Step 4 of 9

Here, the flow section does not involve any work devices such as pump or turbine. Thus,

$h_{pump,s} = h_{turbine,e} = 0$

The flow velocity at the free surface,

$V_1 = 0$

The effect of the kinetic energy correction factor is disregarded. So,

$\alpha_1 = \alpha_2 = 1$

The head loss is given by $h_L = K_L \frac{V^2}{2g}$.

Step 5 of 9

Substitute the known values in the energy equation.

$$\frac{P_{atm}}{\rho g} + (1)\frac{(0)^2}{2g} + H + 0 = \frac{P_{atm}}{\rho g} + (1)\frac{V_2^2}{2g} + 0 + 0 + K_L \frac{V_2^2}{2g}$$

$$H = \frac{V_2^2}{2g} + K_L \frac{V_2^2}{2g}$$

$$= \frac{V_2^2}{2g}(1 + K_L)$$

Thus,

$$V_2 = \sqrt{\frac{2gH}{1 + K_L}}$$

Step 6 of 9

The cross sectional flow area through the hole of diameter D,

$$A_C = \frac{\pi}{4} D^2$$

The flow rate through the hole,

$$\dot{V} = V_2 A_C$$

$$= \sqrt{\frac{2gH}{1 + K_L}} \cdot \left(\frac{\pi}{4} D^2\right)$$

Step 7 of 9

The cross sectional flow area through the hole of equivalent diameter D_{equiv},

$$A_{C,equiv} = \frac{\pi}{4} D_{equiv}^2$$

For frictionless flow, $K_L = 0$.

Then, the corresponding flow velocity,

$$V_2 = \sqrt{\frac{2gH}{1 + 0}}$$

$$= \sqrt{2gH}$$

Step 8 of 9

The flow rate through the hole of equivalent diameter, D_{equiv}

$$\dot{V}_{equiv} = V_2 A_{c,equiv}$$

$$= \sqrt{2gH} \cdot \left(\frac{\pi}{4} D_{equiv}^2\right)$$

Now, the flow rate remains constant. So,

$$\dot{V} = \dot{V}_{equiv}$$

$$\sqrt{\frac{2gH}{1 + K_L}} \cdot \left(\frac{\pi}{4} D^2\right) = \sqrt{2gH} \cdot \frac{\pi}{4} D_{equiv}^2$$

Step 9 of 9

On simplifying,

$$D_{equiv}^2 = \frac{D^2}{\sqrt{1 + K_L}}$$

$$D_{equiv} = \frac{D}{(1 + K_L)^{1/4}}$$

$$= \frac{D}{(1 + 0.5)^{1/4}}$$

$$= 0.904D$$

$$\boxed{D_{equiv} = 0.904D}$$

Therefore, the relation for the equivalent diameter is $D_{equiv} = 0.904D$.

Question: 14.057P

Repeat Prob. 14-56 for a slightly rounded entrance (KL = 0.12).

Step 1 of 4

The subscript 1 denotes the values at the free surface and subscript 2 denotes the values at the exit of the hole.

Write the energy equation for steady and incompressible flow between points 1 and 2.

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L \quad \text{..... (1)}$$

Here, P_1 and P_2 are the pressures at points 1 and 2 respectively, α_1 and α_2 are the kinetic energy correction factors, V_1 and V_2 are the flow velocities, z_1 and z_2 are the distances from the reference level, ρ is the density of the fluid, g is the gravitational acceleration,

$h_{pump,u}$ is the useful pump head delivered, $h_{turbine,e}$ is the turbine head extracted from the fluid and h_L is the irreversible head loss between the two points.

Step 2 of 4

Take the exit of the hole as the reference level.

Such that:

$$z_1 = H$$
$$z_2 = 0$$

The pressure at both the points is equal to the atmospheric pressure.

$$P_1 = P_2 = P_{atm}$$

Here, the flow section does not involve any work devices such as pump or turbine.

$$h_{pump,u} = h_{turbine,e} = 0$$

The flow velocity at the free surface is zero.

$$V_1 = 0$$

The effect of the kinetic energy correction factor is disregarded.

$$\alpha_1 = \alpha_2 = 1$$

State the formula for head loss.

$$h_L = K_L \frac{V^2}{2g}$$

Step 3 of 4

Substitute P_{atm} for P_1 and P_2, 1 for α_1 and α_2, 0 for V_1, H for z_1, 0 for z_2, and 0 for $h_{pump,u}$ and $h_{turbine,e}$ in the equation (1).

$$\frac{P_{atm}}{\rho g} + (1)\frac{(0)^2}{2g} + H + 0 = \frac{P_{atm}}{\rho g} + (1)\frac{V_2^2}{2g} + 0 + 0 + K_L \frac{V_2^2}{2g}$$

$$H = \frac{V_2^2}{2g} + K_L \frac{V_2^2}{2g}$$
$$= \frac{V_2^2}{2g}(1 + K_L)$$

Rewrite the equation to derive the velocity at point 2.

$$V_2 = \sqrt{\frac{2gH}{1 + K_L}} \quad \text{..... (2)}$$

State the formula for cross sectional flow area through the hole of diameter, D.

$$A_c = \frac{\pi}{4} D^2$$

State the expression for the flow rate through the hole.

$$\dot{V} = V_2 A_c$$

$$\dot{V} = \sqrt{\frac{2gH}{1 + K_L}} \cdot \frac{\pi}{4} D^2$$

Step 4 of 4

State the formula for cross sectional flow area through the hole of equivalent diameter, D_{equiv}.

$$A_{c,equiv} = \frac{\pi}{4} D_{equiv}^2$$

State the condition for frictionless flow.

$$K_L = 0.$$

Substitute 0 for K_L in the equation (2).

$$V_2 = \sqrt{\frac{2gH}{1 + 0}}$$
$$= \sqrt{2gH}$$

State the flow rate through the hole of equivalent diameter, D_{equiv}.

$$\dot{V}_{equiv} = V_2 A_{c,equiv}$$

Substitute $\sqrt{2gH}$ for V_2, $\frac{\pi}{4} D_{equiv}^2$ for $A_{c,equiv}$.

$$\dot{V}_{equiv} = \sqrt{2gH} \cdot \frac{\pi}{4} D_{equiv}^2$$

Now, equate the flow rates as it remains constant in both cases (frictionless flow and actual flow).

$$\dot{V} = \dot{V}_{equiv}$$
$$\sqrt{\frac{2gH}{1 + K_L}} \cdot \frac{\pi}{4} D^2 = \sqrt{2gH} \cdot \frac{\pi}{4} D_{equiv}^2$$

Simplify the equation to determine equivalent diameter.

$$D_{equiv}^2 = \frac{D^2}{\sqrt{1 + K_L}}$$

$$D_{equiv} = \frac{D}{(1 + K_L)^{1/4}}$$

Substitute 0.12 for K_L.

$$D_{equiv} = \frac{D}{(1 + 0.12)^{1/4}}$$
$$= 0.972D$$

Therefore, the relation for the equivalent diameter, D_{equiv} is $\boxed{0.972D}$.

Question: 14.058P

A person filling a bucket with water using a garden hose suddenly remembers that attaching a nozzle to the hose increases the discharge velocity of water and wonders if this increased velocity would decrease the filling time of the bucket. What would happen to the filling time if a nozzle were attached to the hose: increase it, decrease it, or have no effect? Why?

Step 1 of 1

From the problem, we can say that, the nozzle is connected in series to the hose. For series connection, the flow rate is constant regardless of the diameters of the individual pipes.

The flow rate is given by, $\dot{V} = VA_c$

Where, V is the flow velocity

And A_c is the cross-sectional flow area

From the above relation the velocity and the area are inversely proportional. So, even if the velocity is increased, the cross-sectional area is reduced. So the flow rate remains the same. Therefore, there is no effect in filling time when a nozzle is connected to the hose.

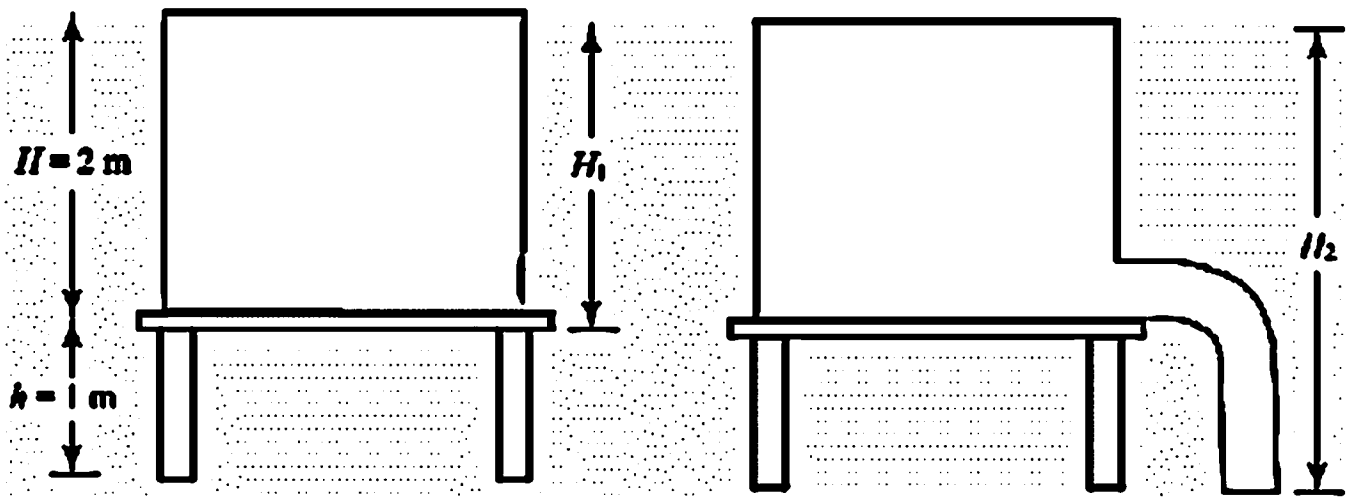
Question:

14.059P

Consider two identical 2-m-high open tanks filled with water on top of a 1-m-high table. The discharge valve of one of the tanks is connected to a hose whose other end is left open on the ground while the other tank does not have a hose connected to its discharge valve. Now the discharge valves of both tanks are opened. Disregarding any frictional loses in the hose, which tank do you think empties completely first? Why?

Step 1 of 4

Given data:



The height of the identical tanks, $H = 2\text{ m}$

The height of the table, $h = 1\text{ m}$

The frictional loss in the hose is neglected.

Step 2 of 4

The two identical tanks filled with water is shown below

Step 3 of 4

In order to find out which tank will empty first, let us calculate velocity of water of both the tanks.

From the figure,

The height of water level in first tank, $H_1 = H = 2\text{ m}$

The height of water level in the second tank,

$$H_2 = H + h$$
$$= 2\text{ m} + 1\text{ m}$$
$$= 3\text{ m}$$

Step 4 of 4

The exit velocity of water of the first tank,

$$V_{\text{tank 1}} = \sqrt{2gH_1}$$
$$= \sqrt{2\left(9.81\text{ m/s}^2\right)(2\text{ m})}$$
$$= 6.26\text{ m/s}$$

The exit velocity of water of the second tank,

$$V_{\text{tank 2}} = \sqrt{2gH_2}$$
$$= \sqrt{2\left(9.81\text{ m/s}^2\right)(3\text{ m})}$$
$$= 7.67\text{ m/s}$$

Since the exit velocity of the second tank is more than the first, the second one will empty first.

Question: 14.060P

A piping system involves two pipes of different diameters (but of identical length, material, and roughness) connected in series. How would you compare the (*a*) flow rates and (*b*) pressure drops in these two pipes?

Step 1 of 2

a) For a piping system with two pipes of different diameters connected in series, the flow rate will be constant as the pipes are of identical length, material and roughness.

Step 2 of 2

b) For a piping system with two pipes of different diameters connected in series, the pressure drop will be more for the smaller pipe compared to the bigger pipe. As the losses are more for pipe with bigger diameter.

Question: 14.061P

A piping system involves two pipes of identical diameters but of different lengths connected in parallel. How would you compare the pressure drops in these two pipes?

Step 1 of 1

For the pipes involving parallel connections, the difference in the length causes no change in the pressure drop between the pipes.

The pressure drop remains same and it does not depend on the length, diameter and roughness.

Therefore, for a piping system that involves two pipes of identical diameters and different lengths connected in parallel, the pressure drop through both pipes is the same.

Question: 14.062P

Water is pumped from a large lower reservoir to a higher reservoir. Someone claims that if the head loss is negligible, the required pump head is equal to the elevation difference between the free surfaces of the two reservoirs. Do you agree?

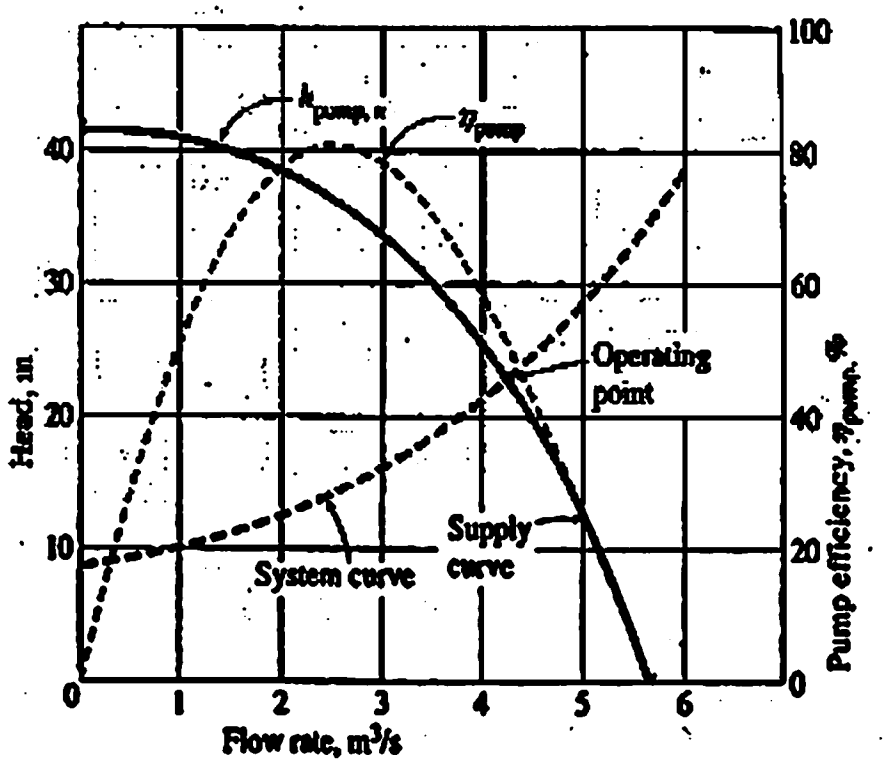
Step 1 of 1

Here, water is pumped from a lower reservoir to a higher reservoir and the head loss is negligible. So that the required pump head is equal to the elevation difference between the free surfaces of the two reservoirs is the correct statement.

Question: 14.063P

A piping system equipped with a pump is operating steadily. Explain how the operating point (the flow rate and the head loss) is established.

Step 1 of 1



A plot of required useful pump head as a function of flow rate is called system curve. A plot of experimentally determined useful pump head as a function of flow rate is called characteristic curve. The pump installed in a piping system will operate at the point of intersection of the system curve and the characteristic curve. This point of intersection is called the operating point.

Question: 14.064P

For a piping system, define the system curve, the characteristic curve, and the operating point on a head versus flow rate chart.

Step 1 of 1

4658-8-75P AID 448

System curve: A plot of required useful pump head as a function of flow rate is called system curve.

Characteristic curve: A plot of experimentally determined useful pump head as a function of flow rate is called characteristic curve.

Operating point: The pump installed in a piping system will operate at a point of intersection of the system curve and the characteristic curve which is called the operating point.

Question: 14.065P

The water needs of a small farm are to be met by pumping water from a well that can supply water continuously at a rate of 4 L/s. The water level in the well is 20 m f below the ground level, and water is to be pumped to a large tank on a hill, which is 58 m above the ground level of the well, using 5-cm internal diameter plastic pipes. The require length of piping is measured to be 420 m, and the total minor loss coefficient due to the use of elbows, vanes, etc. is estimated to be 12. Taking the efficiency of the pump to be 75 percent, determine the rated power of the pump that needs to be purchased, in kW. The density and viscosity of water at anticipated operation conditions are taken to be 1000 kg/m3 and 0.00131 kg/m-s, respectively. Is it wise to purchase a suitable pump that meets the total power requirements, or is it necessary to also pay particular attention to the large elevation head in this case? Explain.

Step 1 of 8

Given data:

The volume flow rate, $\dot{V} = 4\ \text{L/s} = 4 \times 10^{-3}\ \text{m}^3/\text{s}$

The diameter of the plastic pipe, $d = 5\ \text{cm} = 0.05\ \text{m}$

The water level in the well is 20 m below the ground level.

The water level in the tank is 58 m above the ground level.

The length of the piping, $L = 420\ \text{m}$

The total minor loss coefficient, $\sum K_L = 12$

The efficiency of the pump, $\eta_{\text{pump}} = 75\%$

The density of water, $\rho = 1000\ \text{kg/m}^3$

The dynamic viscosity, $\mu = 0.00131\ \text{kg/m} \cdot \text{s}$

Step 2 of 8

In order to calculate the total power, let us calculate the pump power as follows:

The energy equation is given by,

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L \qquad \ldots\ldots (1)$$

Here, the free surface of the well is taken as the point 1 and exit of the pipe is taken as the point 2.

Let the point 1 be reference level. So, $z_1 = 0$

Then,

$z_2 = 20 + 58$

$= 78\ \text{m}$

The kinetic energy correction factor is neglected. So, $\alpha_1 = \alpha_2 = 1$

The fluid is open to atmosphere at both points 1 and 2. So, $P_1 = P_2 = P_{\text{atm}}$

At the surface of the tank and well, the velocity is negligible. Then, $V_1 = V_2 = 0$

Here, there is no turbine. So, $h_{\text{turbine},e} = 0$

Step 3 of 8

The velocity,

$$V_2 = \frac{\dot{V}}{A_c}$$

$$= \frac{4 \times 10^{-3}}{\frac{\pi}{4}(0.05)^2}$$

$$= 2.0372\ \text{m/s}$$

Step 4 of 8

The Reynolds's number,

$$\text{Re} = \frac{\rho V_2 d}{\mu}$$

$$= \frac{1000 \times 2.0372 \times 0.05}{0.00131}$$

$$= 77{,}755.725$$

Since Re > 4000, the flow is turbulent.

Step 5 of 8

For turbulent flow, the Colebrook equation is given by

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right),$$

Where,

f is the friction factor.

For plastic tube, the roughness, $\varepsilon = 0$

Substitute the known values.

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{0/0.05\ \text{m}}{3.7} + \frac{2.51}{(77{,}755.725)\sqrt{f}}\right)$$

$$= -2.0 \log\left(\frac{3.228 \times 10^{-5}}{\sqrt{f}}\right)$$

Solving the above equation we get,

$f = 0.01897$

Step 6 of 8

We know that, the head loss,

$$h_L = \left(f\frac{L}{d} + \sum K_L\right)\frac{V_2^2}{2g}$$

$$= \left[0.01897\left(\frac{420}{0.05}\right) + 12\right]\frac{(2.0372)^2}{2(9.81)}$$

$$= 36.245\ \text{m}$$

Step 7 of 8

By substituting these known values in equation (1), we get,

$$\frac{P_{\text{atm}}}{\rho g} + (1)\frac{0^2}{2\times 9.81} + 0 + h_{\text{pump},s} = \frac{P_{\text{atm}}}{\rho g} + (1)\frac{2.0372^2}{2\times 9.81} + 78 + 0 + 36.245$$

$$h_{\text{pump},s} = 0.212 + 78 + 36.245$$

$$= 114.457\ \text{m}$$

Step 8 of 8

Now, the pump power required,

$$\dot{W}_{\text{pump},s} = \dot{V}\rho g h_{\text{pump},s}$$

$$= \left(4 \times 10^{-3}\right) \times 1000 \times 9.81 \times 114.457$$

$$= 4491.29\ \text{W}$$

The rated power of the pump,

$$\dot{W}_{\text{pump}} = \frac{\dot{W}_{\text{pump},s}}{\eta_{\text{pump}}}$$

$$= \frac{4491.29}{0.75}$$

$$= 5988.4\ \text{W}$$

$$= 5.988\ \text{kW}$$

Therefore, the required rated power of the pump, $\boxed{\dot{W}_{\text{pump}} = 5.988\ \text{kW}}$

It is wise to buy a pump which can be used for large elevation head, so that there is no need to change the pump even if the head increases due to some reason.

Question: 14.066P

Water at 70°F flows by gravity from a large reservoir at a high elevation to a smaller one through a 90-ft-long, 2-in-diameter cast iron piping system that includes four standard flanged elbows, a well-rounded entrance, a sharp-edged exit, and a fully open gate valve. Taking the free surface of the lower reservoir as the reference level, determine the elevation z1 of the higher reservoir for a flow rate of 10 ft3/min.

Step 1 of 6

The length of the pipe, $L = 90$ ft

The diameter of the pipe, $D = 2$ in. $= 0.167$ ft

The flow rate, $\dot{V} = 10\ \text{ft}^3/\text{min} = 0.167\ \text{ft}^3/\text{s}$

Water is flowing through cast iron pipe at 70°F

Step 2 of 6

The roughness of cast iron is $\varepsilon = 0.00085$ ft

From the properties table of saturated water, at 70°F

The density of water is $\rho = 62.3\ \text{lbm/ft}^3$

The dynamic viscosity is $\mu = 6.556 \times 10^{-6}\ \text{lbm/ft-s}$

The cross-sectional flow area between the glass cover,

$$A_c = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.167)^2$$

$$= 0.0219\ \text{ft}^2$$

Step 3 of 6

The average velocity,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{0.167}{0.0219}$$

$$= 7.6256\ \text{ft/s}$$

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{(62.3)(7.6256)(0.167)}{6.556 \times 10^{-6}}$$

$$= 121 \times 10^5$$

Since Re > 4000, the flow is turbulent.

Step 4 of 6

For turbulent flow, the Colebrook equation for friction factor (f) is

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{0.00085/0.167}{3.7} + \frac{2.51}{(121 \times 10^5)\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(1.3756 \times 10^{-3} + \frac{2.07 \times 10^{-7}}{\sqrt{f}}\right)$$

Solving the equation for f:

$f = 0.03053$

Step 5 of 6

For standard flanged elbows, the loss coefficient $K_{L,\,\text{elbow}} = 0.3$

For well rounded entrance, the loss coefficient $K_{L,\,\text{entrance}} = 0.03$

For sharp edged exit, the loss coefficient $K_{L,\,\text{exit}} = 1.05$

For fully opened gate valve, the loss coefficient $K_{L,\,\text{gate}} = 0.2$

Then, total loss coefficient,

$$\sum K_L = 4K_{L,\,\text{elbow}} + K_{L,\,\text{entrance}} + K_{L,\,\text{exit}} + K_{L,\,\text{gate}}$$

$$= 4(0.3) + 0.03 + 1.05 + 0.2$$

$$= 2.48$$

The total head loss in the pipe is,

$$h_L = h_{L,\,\text{major}} + h_{L,\,\text{minor}}$$

$$= \left[f\frac{L}{D} + \sum K_L\right]\frac{V^2}{2g}$$

$$= \left[(0.03053)\frac{90}{0.167} + 2.48\right]\frac{(7.6256)^2}{2(32.2)}$$

$$= 17.1\ \text{ft}$$

Step 6 of 6

Here, the points 1 and 2 are at the free surfaces of the higher and lower reservoirs respectively. Thus, the energy equation between the two points is given by

$$\frac{P_1}{\rho g} + \alpha_1\frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \alpha_2\frac{V_2^2}{2g} + z_2 + h_L \qquad \text{..... (1)}$$

The fluid at both points is open to the atmosphere. So,

$P_1 = P_2 = P_{\text{atm}}$

The fluid velocities at both points are nearly zero.

$V_1 \approx V_2 \approx 0$

The free surface of the lower reservoir is taken as the reference point. So,

$z_2 = 0$

Thus equation (1) becomes,

$$\frac{P_{\text{atm}}}{\rho g} + \alpha_1\frac{(0)^2}{2g} + z_1 = \frac{P_{\text{atm}}}{\rho g} + \alpha_2\frac{(0)^2}{2g} + 0 + h_L$$

On simplifying,

$$z_1 = h_L$$

$$= 17.1\ \text{ft}$$

Therefore, the elevation of the higher reservoir is $\boxed{z_1 = 17.1\ \text{ft}}$

Question: 14.067P

A 2.4-m-diameter tank is initially filled with water 4 m above the center of a sharp-edged 10-cm-diameter orifice. The tank water surface is open to the atmosphere, and the orifice drains to the atmosphere. Neglecting the effect of the kinetic energy correction factor, calculate (*a*) the initial velocity from the tank and (*b*) the time required to empty the tank. Does the loss coefficient of the orifice cause a significant increase in the draining time of the tank?

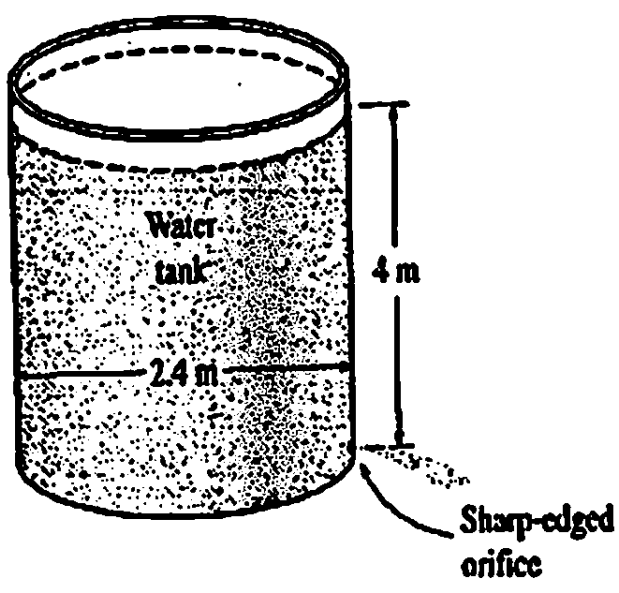


FIGURE P14–67

Step 1 of 10

Given data:

The diameter of the tank, $D = 2.4\ \text{m}$.

The initial height of the tank, $h = 4\ \text{m}$.

The diameter of the sharp edged orifice, $d = 10\ \text{cm} = 0.1\ \text{m}$.

The kinetic energy correction factor is neglected. So, $\alpha_1 = \alpha_2 = 1$.

Step 2 of 10

a)

The energy equation is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L$$

Here, free surface of the tank is taken as the point 1 and exit of the orifice is taken as the point 2.

Let the point 2 be reference level. So, $z_2 = 0$.

Step 3 of 10

The fluid is open to atmosphere at both points 1 and 2. So, $P_1 = P_2 = P_{\text{atm}}$.

At the surface of the tank, the velocity is negligible. Hence $V_1 = 0$.

Here, there is no turbine or pump. So, $h_{\text{pump},s} = h_{\text{turbine},e} = 0$.

The head loss,

$$h_L = K_L \frac{V_2^2}{2g}$$

Step 4 of 10

Then, the energy equation becomes

$$\frac{P_{\text{atm}}}{\rho g} + \frac{0^2}{2g} + z_1 + 0 = \frac{P_{\text{atm}}}{\rho g} + \frac{V_2^2}{2g} + 0 + 0 + K_L \frac{V_2^2}{2g}$$

$$z_1 = \frac{V_2^2}{2g} + K_L \frac{V_2^2}{2g}$$

$$z_1 = \frac{V_2^2}{2g}(1 + K_L)$$

$$V_2 = \sqrt{\frac{2gz_1}{1 + K_L}}$$

Step 5 of 10

Initially, the height $z_1 = h = 4\ \text{m}$.

The loss coefficient for sharp edged entrance, $K_L = 0.5$

Substitute the known values and solve for the velocity V_2.

$$V_2 = \sqrt{\frac{2(9.81\ \text{m/s}^2)(4\ \text{m})}{1 + 0.5}}$$

$$= 7.233\ \text{m/s}$$

Therefore, the initial velocity from the tank, $\boxed{V_2 = 7.233\ \text{m/s}}$.

Step 6 of 10

b)

For any time t, the velocity is given by $V_2 = \sqrt{\frac{2gz}{1 + K_L}}$.

Then, the flow rate,

$$\dot{V} = V_2 A_{\text{c. office}}$$

$$= \sqrt{\frac{2gz}{1 + K_L}} \cdot \frac{\pi}{4} d^2$$

The volume of water in tank is given by

$$dV = A_{\text{tank}}(-dz)$$

$$= -\frac{\pi D^2}{4} dz$$

The negative sign is given because the volume is decreasing when time increases.

Step 7 of 10

Then, for a differential time interval dt, the amount of flow

$$dV = \dot{V} dt$$

$$= \frac{\pi}{4} d^2 \sqrt{\frac{2gz}{1 + K_L}} \cdot dt$$

Substituting the known values

$$-\frac{\pi D^2}{4} dz = \frac{\pi}{4} d^2 \sqrt{\frac{2gz}{1 + K_L}} \cdot dt$$

$$-D^2 dz = d^2 \sqrt{\frac{2gz}{1 + K_L}} \cdot dt$$

$$dt = -\frac{D^2}{d^2} \sqrt{\frac{1 + K_L}{2gz}} \cdot dz$$

Step 8 of 10

Now, integrate the expression.

$$\int_0^t dt = \int_{z_1}^0 -\frac{D^2}{d^2} \sqrt{\frac{1 + K_L}{2gz}}\, dz$$

$$[t]_0^t = -\frac{D^2}{d^2} \sqrt{\frac{1 + K_L}{2g}} \left[\frac{z^{1/2}}{1/2}\right]_{z_1}^0$$

$$t = -\frac{D^2}{d^2} \sqrt{\frac{1 + K_L}{2g}} \left[\frac{0}{1/2} - \frac{z_1^{1/2}}{1/2}\right]$$

$$= \frac{2D^2}{d^2} \sqrt{\frac{(1 + K_L) z_1}{2g}}$$

Step 9 of 10

Then, the time required to empty the tank,

$$t = \frac{2(2.4\ \text{m})^2}{(0.1\ \text{m})^2} \sqrt{\frac{(1 + 0.5)(4\ \text{m})}{2(9.81\ \text{m/s}^2)}}$$

$$= 637.06\ \text{s}$$

$$= 10.62\ \text{min}$$

Therefore, the time required to empty the tank is $\boxed{t = 10.62\ \text{min}}$.

Step 10 of 10

If loss coefficient is neglected, the time required,

$$t = \frac{2(2.4\ \text{m})^2}{(0.1\ \text{m})^2} \sqrt{\frac{(1 + 0)(4\ \text{m})}{2(9.81\ \text{m/s}^2)}}$$

$$= 520.16\ \text{s}$$

$$= 8.67\ \text{min}$$

Thus, we got that the time required to empty the tank is less when the loss coefficient is neglected. So, the loss coefficient is significant.

Question:

A 3-m-diameter tank is initially filled with water 2 m above the center of a sharp-edged 10-cm-diameter orifice. The tank water surface is open to the atmosphere, and the orifice drains to the atmosphere through a 100-m-long pipe. The friction coefficient of the pipe is taken to be 0.015 and the effect 0f the kinetic energy correction factor can be neglected. Determine (*a*) the initial velocity from the tank and (*b*) the time required to empty the tank.

Step 1 of 9

Given data:

The diameter of the tank, $D = 3\,\text{m}$.

The initial height of the tank, $h = 2\,\text{m}$.

The diameter of the sharp edged orifice and pipe, $d = 10\,\text{cm} = 0.1\,\text{m}$.

The length of the pipe, $L = 100\,\text{m}$.

The friction coefficient of the pipe, $f = 0.015$

The kinetic energy correction factor is neglected. So, $\alpha_1 = \alpha_2 = 1$.

Step 2 of 9

a)

The energy equation is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L$$

Here, free surface of the tank is taken as the point 1 and exit of the pipe is taken as the point 2.

Let the point 2 be reference level. So, $z_2 = 0$.

Step 3 of 9

The fluid is open to atmosphere at both points 1 and 2. So, $P_1 = P_2 = P_{\text{atm}}$.

At the surface of the tank, the velocity $V_1 = 0$.

Here, there is no turbine or pump. So, $h_{\text{pump},u} = h_{\text{turbine},e} = 0$.

The head loss,

$$h_L = \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g}$$

Step 4 of 9

Then, the energy equation becomes

$$\frac{P_{\text{atm}}}{\rho g} + (1)\frac{(0)^2}{2g} + z_1 + (0) = \frac{P_{\text{atm}}}{\rho g} + (1)\frac{V_2^2}{2g} + (0) + (0) + \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g}$$

$$z_1 = \frac{V_2^2}{2g} + \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g}$$

$$z_1 = \frac{V_2^2}{2g}\left(1 + f\frac{L}{d} + K_L\right)$$

$$V_2 = \sqrt{\frac{2gz_1}{1 + f\frac{L}{d} + K_L}}$$

Step 5 of 9

Initially, the height $z_1 = h = 2\,\text{m}$.

The loss coefficient for sharp edged entrance, $K_L = 0.5$

Substitute the known values and solve for the velocity V_2.

$$V_2 = \sqrt{\frac{2(9.81\,\text{m/s}^2)(2\,\text{m})}{1 + 0.015\left(\frac{100\,\text{m}}{0.1\,\text{m}}\right) + 0.5}}$$

$$= 1.542\,\text{m/s}$$

Therefore, the initial velocity from the tank, $\boxed{V_2 = 1.542\,\text{m/s}}$.

Step 6 of 9

b)

For any time t, the velocity is given by $V_2 = \sqrt{\frac{2gz}{1 + f\frac{L}{d} + K_L}}$.

Then, the flow rate,

$$\dot{V} = V_2 A_{c,\text{pipe}}$$

$$= \sqrt{\frac{2gz}{1 + f\frac{L}{d} + K_L}} \cdot \frac{\pi}{4}d^2$$

The volume of water in tank is given by

$$dV = A_{\text{tank}}(-dz)$$

$$= -\frac{\pi D^2}{4}dz$$

The negative sign is given because the volume is decreasing when time increases.

.

Step 7 of 9

Then, for a differential time interval dt, the amount of flow

Step 7 of 9

Then, for a differential time interval dt, the amount of flow

$$dV = \dot{V}dt$$

$$= \frac{\pi}{4}d^2\sqrt{\frac{2gz}{1+f\frac{L}{d}+K_L}}\cdot dt$$

Substituting the known values,

$$-\frac{\pi D^2}{4}dz = \frac{\pi}{4}d^2\sqrt{\frac{2gz}{1+f\frac{L}{d}+K_L}}\cdot dt$$

$$-D^2dz = d^2\sqrt{\frac{2gz}{1+f\frac{L}{d}+K_L}}\cdot dt$$

$$dt = -\frac{D^2}{d^2}\sqrt{\frac{1+f\frac{L}{d}+K_L}{2gz}}\cdot dz$$

Step 8 of 9

Now, integrating the expression, we get

$$\int_0^t dt = \int_{z_1}^0 -\frac{D^2}{d^2}\sqrt{\frac{1+f\frac{L}{d}+K_L}{2gz}}\,dz$$

$$[t]_0^t = -\frac{D^2}{d^2}\sqrt{\frac{1+f\frac{L}{d}+K_L}{2g}}\left[\frac{z^{1/2}}{1/2}\right]_{z_1}^0$$

$$t = -\frac{D^2}{d^2}\sqrt{\frac{1+f\frac{L}{d}+K_L}{2g}}\left[\frac{0}{1/2}-\frac{z_1^{1/2}}{1/2}\right]$$

$$= \frac{2D^2}{d^2}\sqrt{\frac{\left(1+f\frac{L}{d}+K_L\right)z_1}{2g}}$$

Step 9 of 9

Then, the time required to empty the tank,

$$t = \frac{2(3\text{ m})^2}{(0.1\text{ m})^2}\sqrt{\frac{\left(1+0.015\left(\frac{100\text{ m}}{0.1\text{ m}}\right)+0.5\right)(2\text{ m})}{2\left(9.81\text{ m/s}^2\right)}}$$

$$= 2334.43\text{ s}$$

$$= 38.91\text{ min}$$

Therefore, the time required to empty the tank, $\boxed{t = 38.91\text{ min}}$.

Question: 14.069P

Reconsider Prob. 14-68. In order to drain the tank faster, a pump is installed near the tank exit as in Fig. P14-69. Determine how much pump power input is necessary to establish an average water velocity of 4 m/s when the tank is full at $z = 2$ m. Also, assuming the discharge velocity to remain constant, estimate the time required to drain the tank.

Someone suggests that it makes no difference whether the pump is located at the beginning or at the end of the pipe, and that the performance will be the same in either case, but another person argues that placing the pump near the end of the pipe may cause cavitation. The water temperature is 30°C, so the water vapor pressure is $Pv = 4.246$ kPa = 0.43 m-H2O, and the system is located at sea level. Investigate if there is the possibility of cavitation and if we should be concerned about the location of the pump.

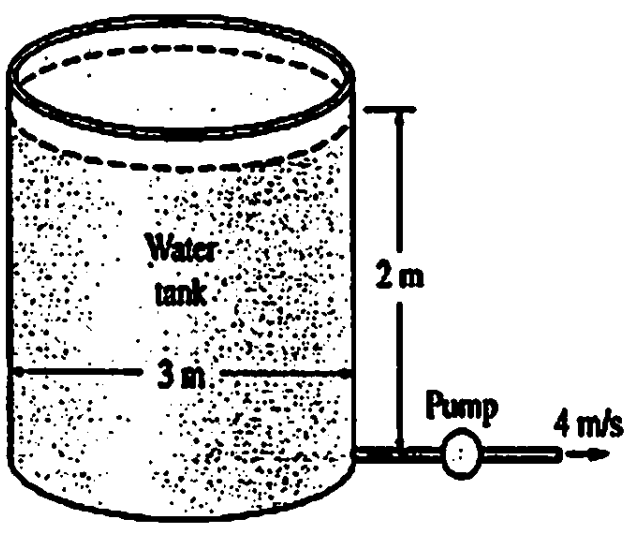

FIGURE P14-69

Step 1 of 8

Given data:

The diameter of the tank, $D = 3\,\text{m}$

The initial height of the tank, $z = h = 2\,\text{m}$

The diameter of the sharp edged orifice, $d = 10\,\text{cm} = 0.1\,\text{m}$

The length of the pipe, $L = 100\,\text{m}$

The friction coefficient of the pipe, $f = 0.015$

The kinetic energy correction factor is neglected. So, $\alpha_1 = \alpha_2 = 1$

The exit velocity, $V_2 = 4\,\text{m/s}$

Step 2 of 8

From the table of properties of water at 30°C,

The density of water at 30°C, $\rho = 996\,\text{kg/m}^3$.

The energy equation is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},a} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L$$

Here, free surface of the tank is taken as the point 1 and exit of the pipe is taken as the point 2.

Let the point 2 be reference level. So, $z_2 = 0$.

Step 3 of 8

The fluid is open to atmosphere at both points 1 and 2. So, $P_1 = P_2 = P_{\text{atm}}$.

At the surface of the tank, the velocity is $V_1 = 0$.

Here, there is no turbine. So, $h_{\text{turbine},e} = 0$.

The head loss,

$$h_L = \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g}$$

Initially, the height is $z_1 = h = 2\,\text{m}$.

Step 4 of 8

Then, the energy equation becomes

$$\frac{P_{\text{atm}}}{\rho g} + \frac{0^2}{2g} + z_1 + h_{\text{pump},a} = \frac{P_{\text{atm}}}{\rho g} + \frac{V_2^2}{2g} + 0 + 0 + \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g}$$

$$z_1 + h_{\text{pump},a} = \frac{V_2^2}{2g} + \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g}$$

$$h_{\text{pump},a} = \frac{V_2^2}{2g} + \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g} - z_1$$

$$= \left(1 + f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g} - z_1$$

$$= \left(1 + 0.015\left(\frac{100}{0.1}\right) + 0.5\right)\frac{4^2}{2\times 9.81} - 2$$

$$= 11.456\,\text{m}$$

Step 5 of 8

The mass flow rate,

$$\dot{m} = \rho A_{c,\text{pipe}} V_2$$

$$= \rho\left(\frac{\pi}{4}d^2\right)V_2$$

$$= \left(996\,\text{kg/m}^3\right)\frac{\pi}{4}(0.1\,\text{m})^2(4\,\text{m/s})$$

$$= 31.29\,\text{kg/s}$$

Now, the pump power required,

$$\dot{W}_{\text{pump},a} = \dot{m} g h_{\text{pump},a}$$

$$= (31.29\,\text{kg/s})\left(9.81\,\text{m/s}^2\right)(11.456\,\text{m})$$

$$= 3516.48\,\text{W}$$

$$= 3.516\,\text{kW}$$

Therefore, the pumping power required, $\boxed{\dot{W}_{\text{pump},a} = 3.516\,\text{kW}}$.

Step 6 of 8

Then, the flow rate is given by,

$$\dot{V} = V_2 A_{c,\text{pipe}}$$

$$= V_2\left(\frac{\pi}{4}d^2\right)$$

$$= (4\,\text{m/s})\left(\frac{\pi}{4}(0.1\,\text{m})^2\right)$$

$$= 0.0314\,\text{m}^3/\text{s}$$

Step 7 of 8

The volume of water in tank is given by

$$V = A_{\text{tank}} h$$

$$= \frac{\pi D^2}{4}h$$

$$= \frac{\pi(3\,\text{m})^2}{4}(2\,\text{m})$$

$$= 14.137\,\text{m}^3$$

Here, it is given that the discharge velocity remains constant. So, the discharge will also be constant.

Step 8 of 8

The discharge time,

$$t = \frac{V}{\dot{V}}$$

$$= \frac{14.137\,\text{m}^3}{0.0314\,\text{m}^3/\text{s}}$$

$$= 450.223\,\text{s}$$

$$= 7.504\,\text{min}$$

The required pump head of water is 11.456 m. This value exceeds the value of the atmospheric pressure at sea level (10.3 m). If the pump exit is at 1 atm, then the absolute pressure at pump inlet must be negative $(-11.4\,\text{kPa})$, which is impossible. Therefore, the system cannot work if the pump is installed near the pipe exit. Thus, the pump must be installed close to the pipe entrance.

Question: 14.070P

Water to a residential area is transported at a rate of 3 m3/s via 90-cm-internal-diameter concrete pipes with a surface roughness of 3 mm and a total length of 1500 m. In order to reduce pumping power requirements, it is proposed to line the interior surfaces of the concrete pipe with 2-cm- thick petroleum-based lining that has a surface roughness thickness of 0.04 mm. There is a concern that the reduction of pipe diameter to 86 cm and the increase in average velocity may offset any gains. Taking ρ = 1000 kg/m3 and $v = 1 \times 10\text{-}6$ m2/s for water, determine the percent increase or decrease in the pumping power requirements due to pipe frictional losses as a result of lining the concrete pipes.

Step 1 of 5

The flow rate of the water is $\dot{V} = 3\,\text{m}^3/\text{s}$

The diameter of the pipe, $D = 0.9\ \text{m}$

The surface roughness of the pipe is $\varepsilon_1 = 3\ \text{mm}$

The length of the pipe, $L = 1500\ \text{m}$

Thickness of the coating is t = 2 cm

Surface roughness of the coating is $\varepsilon_2 = 0.04\ \text{mm}$

The reduced pipe diameter, $D_r = 0.86\ \text{m}$

The density of water is $\rho = 1000\,\text{kg}/\text{m}^3$

The kinematic viscosity is $\nu = 1\times10^{-6}\,\text{m}^2/\text{s}$

Step 2 of 5

The cross sectional area of the pipe before coating is

$$A_c = \frac{\pi}{4}D^2$$
$$= \frac{\pi}{4}(0.9)^2$$
$$= 0.636\ \text{m}^2$$

The average velocity,

$$V = \frac{\dot{V}}{A_c}$$
$$= \frac{3}{0.636}$$
$$= 4.717\ \text{m/s}$$

The Reynolds number,

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{(4.717)(0.9)}{1\times10^{-6}}$$
$$= 4245300$$

Since $\text{Re} > 4000$, the flow is turbulent.

Step 3 of 5

For turbulent flow, the Colebrook equation for friction factor (f) is

$$\frac{1}{\sqrt{f_1}} = -2.0\log\left(\frac{\varepsilon_1/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f_1}}\right)$$
$$\frac{1}{\sqrt{f_1}} = -2.0\log\left(\frac{0.003/0.9}{3.7} + \frac{2.51}{(4245300)\sqrt{f_1}}\right)$$
$$\frac{1}{\sqrt{f_1}} = -2.0\log\left(9.01\times10^{-4} + \frac{5.91\times10^{-7}}{\sqrt{f_1}}\right)$$

Solving the equation for f_1 :

$$f_1 = 0.0051$$

The head loss in the pipe is,

$$h_L = f_1\frac{L}{D}\frac{V^2}{2g}$$
$$= (0.0051)\frac{1500}{0.9}\frac{4.717^2}{2\times9.81}$$
$$= 9.64\ \text{m}$$

Step 4 of 5

The cross sectional area of the pipe after coating is

$$A'_c = \frac{\pi}{4}D_r^2$$
$$= \frac{\pi}{4}(0.86)^2$$
$$= 0.581\ \text{m}^2$$

The average velocity,

$$V_r = \frac{\dot{V}}{A'_c}$$
$$= \frac{3}{0.581}$$
$$= 5.16\ \text{m/s}$$

The Reynolds number,

$$\text{Re} = \frac{V_r D_r}{\nu}$$
$$= \frac{(5.16)(0.86)}{1\times10^{-6}}$$
$$= 4437600$$

Since $\text{Re} > 4000$, the flow is turbulent.

For turbulent flow, the Colebrook equation for friction factor (f) is

$$\frac{1}{\sqrt{f_2}} = -2.0\log\left(\frac{\varepsilon_2/D_r}{3.7} + \frac{2.51}{\text{Re}\sqrt{f_2}}\right)$$
$$\frac{1}{\sqrt{f_2}} = -2.0\log\left(\frac{4\times10^{-5}/0.86}{3.7} + \frac{2.51}{(4437600)\sqrt{f_2}}\right)$$
$$\frac{1}{\sqrt{f_2}} = -2.0\log\left(1.257\times10^{-5} + \frac{5.656\times10^{-7}}{\sqrt{f_2}}\right)$$

Solving the equation for f_2 :

$$f_2 = 0.0022$$

The head loss in the pipe is,

$$h'_L = f_2\frac{L}{D_r}\frac{V_r^2}{2g}$$
$$= (0.0022)\frac{1500}{0.86}\frac{5.16^2}{2\times9.81}$$
$$= 5.207\ \text{m}$$

Step 5 of 5

By comparing the loss in pipe for both the cases, the coating will reduce the head loss and hence decreases the pumping power requirements. The percentage power reduction is

$$\%r = \frac{h'_L}{h_L}\times100$$
$$= \frac{5.207}{9.64}\times100$$
$$= 54.01\%$$

Hence the percentage decrease in the pumping power requirements is **54.01%**

Question: 14.071P

Water is transported by gravity through a 12-cm- diameter 800-m-long plastic pipe with an elevation gradient of 0.01 (i.e., an elevation drop of 1 m per 100 m of pipe length). Taking ρ = 1000 kg/m3 and v = 1 X 10-6 m2/s for water, determine the flow rate of water through the pipe. If the pipe were horizontal, what would the power requirements be to maintain the same flow rate?

Step 1 of 6

Calculate the Reynolds number by using the following equation:

$$\mathrm{Re} = \frac{Vd}{\upsilon}$$

Here, υ is the kinematic viscosity.

Substitute $0.12\,\mathrm{m}$ for d, and $1\times10^{-6}\,\mathrm{m^2/s}$ for υ.

$$\mathrm{Re} = \frac{V\times0.12}{1\times10^{-6}}$$
$$= 120000V$$

Step 2 of 6

Calculate the head loss.

$$h_L = \text{gradient}\times\text{length}$$
$$= \frac{1}{100}\times800$$
$$= 8\,\mathrm{m}$$

Write another equation of head loss.

$$h_L = \frac{fLV^2}{2gd} \quad \ldots\ldots (2)$$

Here, g is the acceleration due to gravity, L is the length of the pipe, and f is the friction factor.

Substitute $800\,\mathrm{m}$ for L, $9.81\,\mathrm{m/s^2}$ for g, $0.12\,\mathrm{m}$ for d, and $8\,\mathrm{m}$ for h_L.

$$8 = \frac{f\times800\times V^2}{2\times9.81\times0.12}$$
$$0.0235 = fV^2$$
$$V = \frac{0.153}{\sqrt{f}}$$
$$\frac{1}{\sqrt{f}} = 6.53V$$

Step 3 of 6

For smooth pipe, roughness $\varepsilon/d = 0$.

Step 4 of 6

Write the equation of friction factor for turbulent flow.

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/d}{3.7} + \frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

Substitute $120000V$ for Re, 0 for ε/d, and $6.53V$ for $\frac{1}{\sqrt{f}}$.

$$6.53V = -2.0\log\left(\frac{0}{3.7} + \frac{2.51\times6.53V}{120000V}\right)$$
$$V = \frac{(-2)\times(-3.86)}{6.53}$$
$$= 1.165\,\mathrm{m/s}$$

Step 5 of 6

Calculate the volume flow rate of water.

$$Q = AV$$
$$= \frac{\pi}{4}d^2V$$

Here, V is the average velocity of the water, A is the cross sectional area of pipe, and d is the diameter of the pipe.

Substitute $0.12\,\mathrm{m}$ for d.

$$Q = \frac{\pi}{4}0.12^2V$$
$$= 0.0113V$$

Substitute $1.165\,\mathrm{m/s}$ for V.

$$Q = 0.0113\times1.165$$
$$= 0.01317\,\mathrm{m^3/s}$$

Therefore, the flow rate of water is $\boxed{0.01317\,\mathrm{m^3/s}}$.

Step 6 of 6

Calculate the required power by using the following equation.

$$W_{pump} = Q\rho g h_L$$

Substitute $0.01317\,\mathrm{m^3/s}$ for Q, $1000\,\mathrm{kg/m^3}$ for ρ, $9.81\,\mathrm{m/s^2}$ for g and $8\,\mathrm{m}$ for h_L.

$$W_{pump} = 0.01317\times1000\times9.81\times8$$
$$= 1.033\,\mathrm{kW}$$

Therefore, the power required by the pump is $\boxed{1.033\,\mathrm{kW}}$.

Question: 14.072P pg 1

Water at 15°C is drained from a large reservoir using two horizontal plastic pipes connected in series. The first pipe is 20 m long and has a 10-cm diameter, while the second pipe is 35 m long and has a 4-cm diameter. The water level in the reservoir is 18 m above the centerline of the pipe. The pipe entrance is sharp-edged, and the contraction between the two pipes is sudden. Neglecting the effect of the kinetic energy correction factor, determine the discharge rate of water from the reservoir.

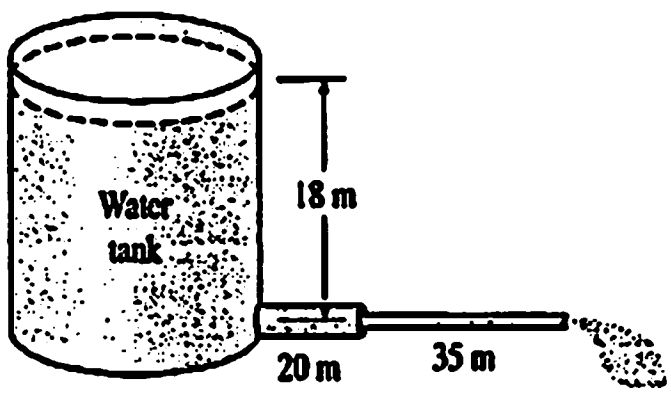

FIGURE P14–72

Step 1 of 7

Choose point 1 to be the surface of the reservoir and point 2 to be the exit of the pipe.

The energy equation between these two points:

$$\frac{P_1}{\rho g}+\frac{V_1^2}{2g}+z_1+h_{pump}=\frac{P_2}{\rho g}+\frac{V_2^2}{2g}+z_2+h_{turbine}+h_L$$

Here, pressure at point 1 and 2 is P_1 and P_2, the velocity at points 1 and 2 are V_1 and V_2, acceleration due to gravity is g

Notice that the pressures at both points are atmospheric, that the fluid velocity at point 1is zero, and that the height at point 2 is zero. There is no pump or turbine.

Substitute, 0 for P_1 and P_2, 0 for V_1, 0 for h_{pump} and $h_{turbine}$

$$z_1=\alpha_2\frac{V_2^2}{2g}+h_L$$

Substitute, 18 m for z_1, $9.81\ \text{m/s}^2$ for g

$$18\ \text{m}=\frac{V_2^2}{2(9.81\ \text{m/s}^2)}+h_L$$

Step 2 of 7

Next consider the flow velocities in each pipe. Use conservation of mass to compare flow in the two portions of the pipe.

$$V_1A_1=V_2A_2$$
$$V_1=\frac{V_2A_2}{A_1}$$

Here,

$$\frac{A_2}{A_1}=\frac{d_1^2}{d_2^2}$$
$$=\frac{4^2}{10^2}$$
$$=\frac{16}{100}$$
$$=0.16$$

Therefore,

$$V_1=\frac{V_2A_2}{A_1}$$
$$=0.16V_2$$

Step 3 of 7

Consider the head loss relationship h_L by using the following equation:

$$h_L=\left(f_1\frac{L_1}{D_1}+\sum K_{L,entrance}\right)\frac{V_1^2}{2g}+\left(f_2\frac{L_2}{D_2}+\sum K_{L,contraction}\right)\frac{V_2^2}{2g}$$

Here, loss coefficient is at entrance is $\sum K_{L,entrance}$, loss coefficient is at entrance is $\sum K_{L,contraction}$,

Substitute, $20\ \text{m}$ for L_1, $0.10\ \text{m}$ for D_1, 0.5 for $\sum K_{L,entrance}$, 0.46for $\sum K_{L,contraction}$, $20\ \text{m}$ for L_2, $0.04\ \text{m}$ for D_2

$$h_L=\left(f_1\frac{L_1}{D_1}+\sum K_{L,entrance}\right)\frac{V_1^2}{2g}+\left(f_2\frac{L_2}{D_2}+\sum K_{L,contraction}\right)\frac{V_2^2}{2g}$$
$$=\left(f_1\frac{20\ \text{m}}{0.10\ \text{m}}+0.5\right)\frac{V_1^2}{2(9.81\ \text{m/s}^2)}+\left(f_2\frac{20\ \text{m}}{0.04\ \text{m}}+0.46\right)\frac{V_2^2}{2(9.81\ \text{m/s}^2)}$$

Step 4 of 7

Express the average velocity (V) at point 2 by using the following equation:

$$V_2=\frac{\dot{V}}{A_2}$$
$$=\frac{\dot{V}}{\pi D_2^2/4}$$

Here, the volume flow rate ($\dot{V}$), the cross-sectional area (A).

$$V_2=\frac{\dot{V}}{\pi(0.04\ \text{m})^2/4}$$
$$=\frac{\dot{V}}{\pi(0.04\ \text{m})^2/4}$$

Step 5 of 7

$\pi(0.04\text{ m})^2/4$

Step 5 of 7

Calculate the Reynolds numbers (Re) by using the following equation:

$$\text{Re}_1 = \frac{\rho V_1 D_1}{\mu}$$

Here, the density of water is ρ, the viscosity of water is μ

The viscosity of water, $1.138\times10^{-3}\text{ kg/m}\cdot\text{s}$

Substitute, $1.138\times10^{-3}\text{ kg/m}\cdot\text{s}$ for μ, 0.10 m for D_1, $1.138\times10^{-3}\text{ kg/m}\cdot\text{s}$ for μ

$$\text{Re}_1 = \frac{(999.1\text{ kg/m}^3)V_1(0.10\text{ m})}{1.138\times10^{-3}\text{ kg/m}\cdot\text{s}}$$

Consider the second section of pipe.

$$\text{Re}_2 = \frac{\rho V_2 D_2}{\mu}$$
$$= \frac{(999.1\text{ kg/m}^3)V_2(0.04\text{ m})}{1.138\times10^{-3}\text{ kg/m}\cdot\text{s}}$$

Step 6 of 7

The friction factor (f). Recall that the roughness (ε) of the pipe is zero because the pipe is smooth.

Consider the first section of pipe:

The friction factor is:

$$\frac{1}{\sqrt{f_1}} = -2.0\log\left(\frac{\varepsilon/D_1}{3.7} + \frac{2.51}{\text{Re}_1\sqrt{f_1}}\right)$$
$$= -2.0\log\left(\frac{2.51}{\text{Re}_1\sqrt{f}}\right)$$

Here, the roughness factor is ε

Now consider the second section of pipe.

$$\frac{1}{\sqrt{f_2}} = -2.0\log\left(\frac{\varepsilon/D_2}{3.7} + \frac{2.51}{\text{Re}_2\sqrt{f_2}}\right)$$
$$= -2.0\log\left(\frac{2.51}{\text{Re}_2\sqrt{f_2}}\right)$$

Step 7 of 7

We now have a system of 8 equations and 8 unknowns. Use an equation solver such as EES to solve this system to find the volume flow rate. By using the EES software The discharge rate of water from the reservoir is $0.00595\text{ m}^3/\text{s}$.

Question:

A farmer is to pump water at 70°F from a river to a water storage tank nearby using a 125-ft-long, 5-in-diameter plastic pipe with three flanged 90° smooth bends. The water velocity near the river surface is 6 ft/s, and the pipe inlet is placed in the river normal to the flow direction of water to take advantage of the dynamic pressure. The elevation difference between the river and the free surface of the tank is 12 ft. For a flow rate of 1.5 ft3/s and an overall pump efficiency of 70 percent, determine the required electric power input to the pump.

Step 1 of 9

Apply the energy equation at inlet and exit.

$$\alpha_1 \frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \alpha_2 \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L \quad \text{..... (1)}$$

Here, P_1 is the inlet pressure, V_1 is the inlet velocity, z_1 is the height of the inlet from the datum, $h_{pump,u}$ is the head loss in the pump, P_2 is the exit pressure, V_2 is the exit velocity, z_2 is the height of the exit from the datum, $h_{turbine,e}$ is the heat loss at turbine exit, h_L is the head loss in the pipe, ρ is the density, and g is the acceleration due to gravity.

Let us consider the free surface river is point 1 and the position of tank is at point 2.

The water at both ends is open to atmosphere.

$$P_1 = P_{atm}$$
$$P_2 = P_{atm}$$
$$P_1 = P_2$$

The velocity at point 2 is zero.

$$V_2 = 0$$

Since, point 1 as reference level,

$$z_1 = 0$$
$$z_2 = 12\,\text{ft}$$

Step 2 of 9

Substitute P_{atm} for P_1, P_{atm} for P_2, 0 for V_2, 0 for $h_{turbine,e}$, 0 for z_1, and 12 ft for z_2 in equation (1).

$$\alpha_1 \frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 + h_{pump,u} = \alpha_2 \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L$$

$$\alpha_1 \frac{P_{atm}}{\rho g} + \frac{V_1^2}{2g} + (0) + h_{pump,u} = \alpha_2 \frac{P_{atm}}{\rho g} + \frac{0}{2g} + z_2 + 0 + h_L \quad \text{..... (2)}$$

$$\frac{V_1^2}{2g} + h_{pump,u} = z_2 + h_L$$

Step 3 of 9

Calculate the average velocity.

$$V = \dot{v}$$

Here, $\dot{v}$ is the volumetric flow rate, A is the cross sectional area.

Substitute $1.5\ \text{ft}^3/\text{s}$ for $\dot{v}$, $\frac{\pi}{4}D^2$ for A, and 5 in. for D.

$$V = \frac{1.5}{\left(\frac{\pi}{4}D^2\right)}$$
$$= \frac{1.5}{\frac{\pi}{4} \times \left(5\ \text{in} \times \frac{1\ \text{ft}}{12\ \text{in.}}\right)^2}$$
$$= 11\ \text{ft/s}$$

Here, D is the diameter.

Step 4 of 9

Obtain the density, dynamic viscosity, from the table A-15E, "Properties of Saturated Water", at temperature $70°\text{F}$.

Density, $\rho = 62.3\ \text{lbm/ft}^3$

Dynamic viscosity, $\mu = 6.556 \times 10^{-4}\ \text{lbm/ft} \cdot \text{s}$

Calculate the Reynolds number.

$$\text{Re} = \frac{\rho V D}{\mu}$$

Here, μ is the dynamic viscosity.

$$\text{Re} = \frac{\rho V D}{\mu}$$
$$= \frac{62.3 \times 11 \times 0.417}{6.556 \times 10^{-4}}$$
$$= 435890.93$$

Since, the value of Reynolds number is larger than 4000, the flow is turbulent.

Step 5 of 9

Obtain the roughness of the plastic pipe from the table 14.2, "Equivalent Roughness values for new commercial pipes", as zero.
The roughness of plastic pipe, $\varepsilon = 0$

Write an expression for the friction factor.

$$\frac{1}{\sqrt{f}} = -2.0 \log\left[\frac{\varepsilon / D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right]$$

Substitute 0 for ε, 5 in. for D.

$$\frac{1}{\sqrt{f}} = -2.0 \log\left[\frac{0}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right]$$

Substitute 0 for ε , 5 in. for D .

$$\frac{1}{\sqrt{f}} = -2.0\log\left[\frac{0}{3.7} + \frac{2.51}{\mathrm{Re}\sqrt{f}}\right]$$

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{2.51}{435890\sqrt{f}}\right)$$

$$f = 0.003$$

As the pipe is smooth for $f = 0.003$, from the table 14-21, "The friction factor is minimum for a smooth pipe, and increases with roughness", obtain the friction factor as 0.01119

$$f = 0.0119$$

Step 6 of 9

Calculate the total loss coefficient.

$$\sum K_L = K_{L,enter} + 3K_{L,elbow} + K_{L,exit} \quad \text{..... (3)}$$

Here, $K_{L,enter}$ is the entrance loss, $K_{L,elbow}$ is the loss coefficient at the smooth bends, and $K_{L,exit}$ is the exit loss.

As the pipe is smooth, the entrance losses are zero.

$$K_{L,enter} = 0$$

Obtain the loss factor at bends, from the table 14-4, "Loss coefficients of various pipe components for turbulent flow", for $90°$ flanged smooth bends.

The loss coefficient for $90°$ flanged smooth bends, $K_{L,elbow} = 0.3$

The loss coefficient at exit, $K_{L,exit} = 1.0$

Step 7 of 9

Substitute 0 for $K_{L,enter}$, 0.3 for $K_{L,elbow}$, and 1 for $K_{L,exit}$ in equation (3).

$$\begin{aligned}\sum K_L &= K_{L,enter} + 3K_{L,elbow} + K_{L,exit}\\ &= 0 + (3\times 0.3) + 1\\ &= 1.9\end{aligned}$$

Write an expression for the head loss.

$$h_L = \left(f\frac{L}{d} + K_L\right)\frac{V_2^2}{2g}$$

Substitute 0.0119 for f , 125 ft for L , 5 in for d , 1.9 for K_L , 11 ft/s for V_2 , and 32.2 ft/s² for g .

$$h_L = \left[0.0119\times\left(\frac{125}{5\text{ in.}\times\frac{1\text{ ft}}{12\text{ in}}}\right) + 1.9\right]\left[\frac{11^2}{2\times 32.2\text{ ft/s}^2}\right]$$

$$= 10.28\text{ ft}$$

Step 8 of 9

Substitute 6 ft/s for V_1 , 12 ft for z_2 , 10.28 ft for h_L , and 32.2 ft/s² for g in equation (2).

$$\frac{V_1^2}{2g} + h_{pump,u} = z_2 + h_L$$

$$\frac{6^2}{2\times 32.2} + h_{pump,u} = 12 + 10.28$$

$$h_{pump,u} = 21.72\text{ ft}$$

Step 9 of 9

Calculate the electric power required to the pump.

$$\dot{W}_{pump} = \frac{\dot{W}_{pump,u}}{\eta_{pump}}$$

Substitute $\dot{v}gh_{pump,u}$ for $\dot{W}_{pump,u}$, 1.5 ft³/s for $\dot{v}$, 32.2 ft/s² for g , 21.72 ft for $h_{pump,u}$, and 70% for η_{pump} .

$$\dot{W}_{pump} = \frac{\dot{v}gh_{pump,u}}{\eta_{pump}}$$

$$= \frac{\left(\begin{array}{l}\left(1.5\text{ ft}^3/\text{s}\right)\left(62.3\text{ lbm/ft}^3\right)\left(32.2\text{ ft/s}^2\right)\left(21.72\text{ ft}\right)\\ \times\left(\frac{1\text{ kW}}{737\text{ lbf}\cdot\text{ft/s}}\right)\times\left(\frac{1\text{ lbf}}{32.2\text{ lbm}\cdot\text{ft/s}^2}\right)\end{array}\right)}{0.7}$$

$$= \frac{2.8}{0.7}$$

$$= 4\text{ kW}$$

Therefore, the required electric power input to the pump, $\boxed{4\text{ kW}}$.

Question: 14.074P

Reconsider Prob. 14-73E. Using EES (or other) software, investigate the effect of the pipe diameter on the required electric power input to the pump. Let the pipe diameter vary from 1 to 10 in, in increments of 1 in. Tabulate and plot the results, and draw conclusions.

Step 1 of 5

The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
L=125[ft]                                   "Length of pipe"
"D_in is to be varied"                      "Diameter of pipe"
D_ft=D_in*convert(in,ft)
V_1=6[ft/s]                                 "Inlet velocity of water"
V_2=0
T=70[F]                                     "Temperature of water"
z_1=0[ft]
z_2=12[ft]
eta_pump=0.70                               "Pump efficiency"
V_dot=1.5[ft/s^3]                           "Flow rate"
n_b=3                                       "Number of 90 degrees flange bends"
K_L_b=0.3                                   "Loss Coefficient for 90 degrees flange bends"
K_L_s=1.0                                   "Sharp end"
epsilon=0.0[ft]                             "Roughness value for plastic pipe"

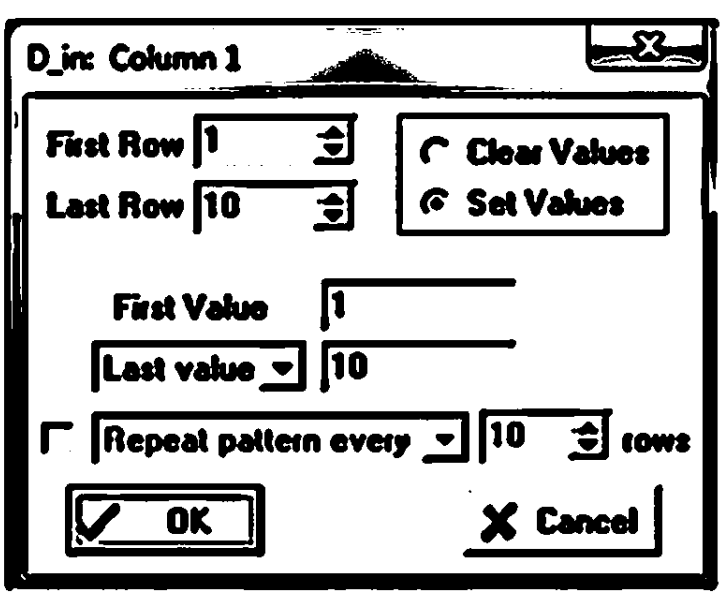
```

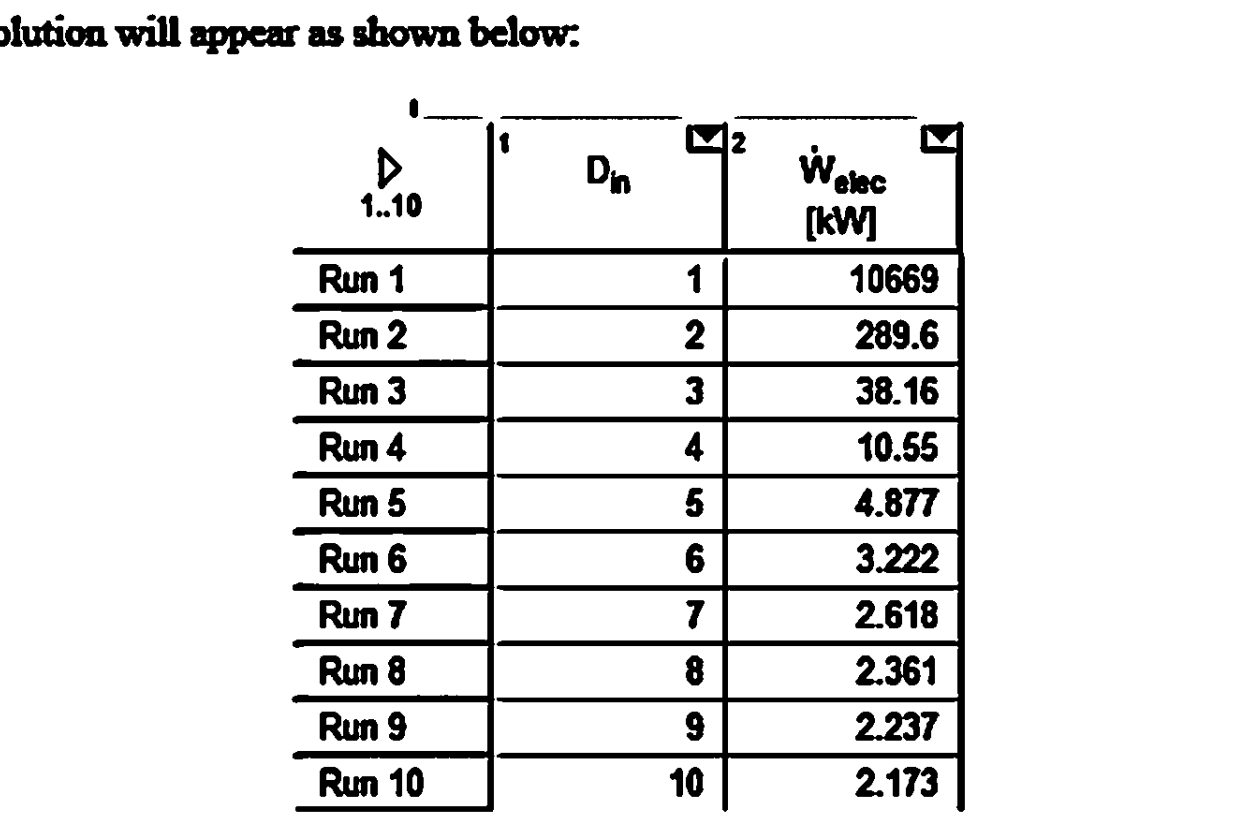


Step 2 of 5

Now to solve the equation for a range of diameter of the pipe, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 10.
Select variables in equations as "D_in" and "W_dot_elec" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 5

The diameter of the pipe is varied from 1 in. to 10 in.
To enter the values in the "D_in" column, click on the drop tab in "D_in" column. A new windows pops up, fill in the details as shown below and then press 'OK'



Step 4 of 5

Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

1..10	D_{in}	$\dot{W}_{elec}$ [kW]
Run 1	1	10669
Run 2	2	289.6
Run 3	3	38.16
Run 4	4	10.55
Run 5	5	4.877
Run 6	6	3.222
Run 7	7	2.618
Run 8	8	2.361
Run 9	9	2.237
Run 10	10	2.173

Step 5 of 5

To plot the input power as function of diameter of pipe, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the input power as function of average velocity of water flow is shown:

From the above plot we can interpret that as the diameter of the pipe increases, the electric power required to the pump decreases.

Question: 14.075P

A water tank filled with solar-heated water at 40°C is to be used for showers in a field using gravity-driven flow. The system includes 25 m of 1.5-cm-diameter galvanized iron piping with four miter bends (90°) without vanes and a wide-open globe valve. If water is to flow at a rate of 0.8 L/s through the shower head, determine how high the water level in the tank must be from the exit level of the shower. Disregard the losses at the entrance and at the shower head, and neglect the effect of the kinetic energy correction factor.

Step 1 of 8

Given data:

Temperature of the water, $T = 40°C$

Demeter of the galvanised pipe, $D = 1.5\,\text{cm} = 0.015\,\text{m}$

Length of the galvanised pipe, $L = 25\,\text{m}$

Rate of flow, $\dot{V} = 0.8\,\text{L/s} = 0.0008\,\text{m}^3/\text{s}$

Step 2 of 8

Let set discharge end of the pipe is reference line. hence $z_2 = 0$

By applying the energy balance equation from the water surface of the tank to discharge end of the pipe is given as

$$\frac{P_1}{\rho g} + \alpha \frac{V_1^2}{2g} + z_1 + h_{pump} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_L$$

Since atmospheric pressure acting on top surface of the tank and discharge end of the pipe, therefore, $P_1 = P_2 = 0$

Velocity head is negligible at free surface of the tank.

Then, simplifying the above expression, we get

$$\frac{P_1}{\rho g} + \alpha \frac{V_1^2}{2g} + z_1 + h_{pump} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_L$$

$$0 + 0 + z_1 + 0 = 0 + \alpha_2 \frac{V_2^2}{2g} + 0 + h_L$$

$$z_1 = \alpha_2 \frac{V_2^2}{2g} + h_L$$

Step 3 of 8

From the continuity equation, we have

$$\dot{V} = AV$$

$$V = \frac{\dot{V}}{A}$$

$$= \frac{\dot{V}}{\left(\frac{\pi}{4} D^2\right)}$$

$$= \frac{0.0008}{\frac{\pi}{4}(0.015)^2}$$

$$= 4.527\,\text{m/s}$$

Step 4 of 8

From the properties of the saturated water temperature table

At $T = 40°C$

Density $\rho = 992.1\,\text{kg/m}^3$

Kinematic viscosity $\mu = 0.653 \times 10^{-3}\,\text{kg/m} \cdot s$

Reynolds number is

$$\text{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{992.1 \times 4.52 \times 0.015}{0.653 \times 10^{-3}}$$

$$= 103008.238$$

Reynolds Number Is greater than The 4000,hence it is turbulent flow.

Step 5 of 8

From the table of roughness values for various pipes

For galvanised pipes,

$\varepsilon = 0.00015\text{m}$

Then roughness ratio is

$$\frac{\varepsilon}{D} = \frac{0.00015}{0.015}$$

$$= 0.01$$

Step 6 of 8

Now, friction factor of the pipe can be calculated by using the Moody chart,

At $\text{Re} = 103008.238$ and $\frac{\varepsilon}{D} = 0.01$

Friction factor is $f = 0.038$

From the table of various loss coefficient for

Now calculating the minor loss of the pipes at various section are

For entrance loss $K_{L\,entrance} = 0$

For elbow, $K_{elbow} = 1.1$

For flanged section, $K_{flanged} = 10$

Now, minor losses are

$$\sum K_L = K_{L\,entrance} + 4K_{elbow} + K_{flanged} + K_{exit}$$

$$= 0 + (4 \times 1.1) + 10 + 0$$

$$= 14.4\,\text{m}$$

Step 7 of 8

Major frictional loss are

$$h_f = \frac{fLV^2}{2gD}$$

$$= \frac{0.038 \times 25 \times 4.52^2}{2 \times 9.81 \times 0.015}$$

$$= 65.949$$

Step 8 of 8

Total losses are

$$h_L = h_f + \sum K_L$$

$$= 65.949 + 14.4$$

$$= 80.349\,\text{m}$$

Thus, elevation of the shower head is

$$z_1 = \alpha_2 \frac{V_2^2}{2g} + h_L$$

$$= \frac{1 \times 4.52^2}{2 \times 9.81} + 80.349$$

$$= 81.390\text{m}$$

Therefore, elevation of the water source is $\boxed{z_1 = 81.390\,\text{m}}$.

Question: 14.076P

Two water reservoirs *A* and *B* are connected to each other through a 40-m-long, 2-cm-diameter cast iron pipe with a sharp-edged entrance. The pipe also involves a swing check valve and a fully open gate valve. The water level in both reservoirs is the same, but reservoir *A* is pressurized by compressed air while reservoir *B* is open to the atmosphere at 88 kPa. If the initial flow rate through the pipe is 1.2 L/s, determine the absolute air pressure on top of reservoir *A*. Take the water temperature to be 10°C.

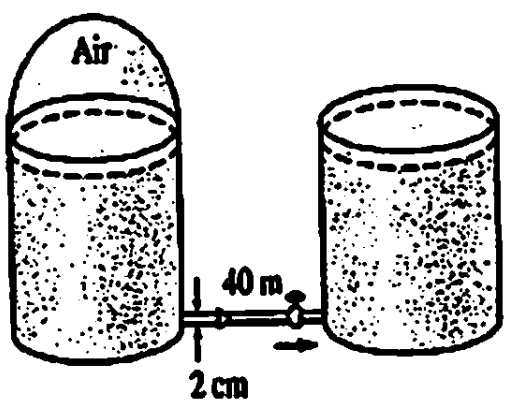


FIGURE P14–76

Step 1 of 5

Given data:

The length of the pipe, $L = 40\ \text{m}$

The diameter of the pipe, $D = 2\ \text{cm}$

$$= 2 \times 10^{-2}\ \text{m}$$

The pipe is made of cast iron.

The entrance of the pipe is sharp edged.

The pipe involves a swing check valve and fully open gate valve.

The atmospheric pressure, $P_{atm} = 88\ \text{kPa}$

The initial flow rate, $\dot{V} = 1.2\ \text{L/s}$

$$= 1.2 \times 10^{-3}\ \text{m}^3/\text{s}$$

The temperature of water is 10°C

Step 2 of 5

Assume that the flow is fully developed, incompressible and steady.

From the table of properties of saturated water, corresponding to 10°C,

The density of water, $\rho = 999.7\ \text{kg/m}^3$

The dynamic viscosity, $\mu = 1.307 \times 10^{-3}\ \text{kg/m} \cdot \text{s}$

The roughness of cast iron pipe, $\varepsilon = 0.26\ \text{mm} = 0.26 \times 10^{-3}\ \text{m}$

The energy equation for a control volume is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L \qquad \text{..... (1)}$$

Where,

Point 1 is taken as the surface of the pressurized reservoir and point 2 is taken as the surface of the open reservoir.

Step 3 of 5

Here, both the point 2 is opened to the atmosphere. So, $P_2 = P_{atm}$

The velocity at the free surfaces, $V_1 = V_2 = 0$

Let point 2 be the reference level. Then, $z_2 = 0$ and $z_1 = H$

There is no pump and turbine. So, $h_{pump,s} = h_{turbine,e} = 0$

The average velocity of flow in the pipe,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{1.2 \times 10^{-3}\ \text{m}^3/\text{s}}{\frac{\pi}{4}\left(2 \times 10^{-2}\ \text{m}\right)^2}$$

$$= 3.82\ \text{m/s}$$

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{\left(999.7\ \text{kg/m}^3\right)\left(3.82\ \text{m/s}\right)\left(2 \times 10^{-2}\ \text{m}\right)}{1.307 \times 10^{-3}\ \text{kg/m} \cdot \text{s}}$$

$$= 58.437 \times 10^3$$

Here, $\text{Re} > 4000$, therefore the flow in the pipe is turbulent.

Step 4 of 5

For turbulent flow, the Colebrook equation is $\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$,

where, f is the friction factor.

Substitute the known values.

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{0.26 \times 10^{-3}\ \text{m}/2 \times 10^{-2}\ \text{m}}{3.7} + \frac{2.51}{\left(58.437 \times 10^3\right)\sqrt{f}}\right)$$

$$= -2.0 \log\left(3.5135 \times 10^{-3} + \frac{4.2952 \times 10^{-5}}{\sqrt{f}}\right)$$

Solve the equation for f.

$f = 0.0424$

The loss coefficient for sharp edged entrance, $K_{L,1} = 0.5$

The loss coefficient for swing check valve, $K_{L,2} = 2$.

The loss coefficient for fully open gate valve, $K_{L,3} = 0.2$

The loss coefficient for exit, $K_{L,4} = 1$

The total loss coefficient,

$$\sum K_L = K_{L,1} + K_{L,2} + K_{L,3} + K_{L,4}$$

$$= 0.5 + 2 + 0.2 + 1$$

$$= 3.7$$

Step 5 of 5

The head loss,

$$h_L = \left(f \frac{L}{D} + \sum K_L\right) \frac{V^2}{2g}$$

$$= \left(0.0424 \frac{40\ \text{m}}{2 \times 10^{-2}\ \text{m}} + 3.7\right) \frac{\left(3.82\ \text{m/s}\right)^2}{2\left(9.81\ \text{m/s}^2\right)}$$

$$= 65.82\ \text{m}$$

Thus, equation (1) becomes,

$$\frac{P_1}{(999.7)(9.81)} + \alpha_1 \frac{(0)^2}{2g} + 0 + 0 = \frac{88 \times 10^3}{(999.7)(9.81)} + \alpha_2 \frac{(0)^2}{2g} + 0 + 0 + 65.82$$

$$\frac{P_1}{(999.7)(9.81)} = \frac{88 \times 10^3}{(999.7)(9.81)} + 65.82$$

$$P_1 = \left(88 \times 10^3\right) + (999.7)(9.81)(65.82)$$

$$P_1 = 733.5 \times 10^3\ \text{N/m}^2$$

$$\boxed{P_1 = 733.5\ \text{kPa}}$$

Therefore, the absolute pressure on the top of reservoir *A*, $P_1 = 733.5\ \text{kPa}$

Question: 14.077P pg 1

A vented tanker is to be filled with fuel oil with ρ = 920 kg/m3 and μ = 0.045 kg/m-s from an underground reservoir using a 25-m-long, 4-cm-diameter plastic hose with a slightly rounded entrance and two 90° smooth bends. The elevation difference between the oil level in the reservoir and the top of the tanker where the hose is discharged is 5 m. The capacity of the tanker is 18 m3 and the filling time is 30 min. Taking the kinetic energy correction factor at the hose discharge to be 1.05 and assuming an overall pump efficiency of 82 percent, determine the required power input to the pump.

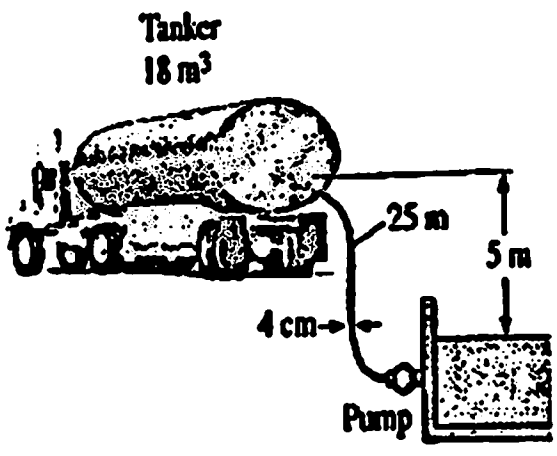

FIGURE P14–77

Step 1 of 7

Calculate the flow rate of oil by using the following equation:

$$Q = \frac{V_{tank}}{t}$$

Here, V_{tank} is the capacity of the tanker, and t is the filling time.

Substitute $18\,\text{m}^3$ for V_{tank} , $30\,\text{min}$ for t.

$$Q = \frac{18}{30\times 60}$$
$$= 0.01\,\text{m}^3/\text{s}$$

Step 2 of 7

Calculate the average velocity of the pipe by using the following equation:

$$V_{pipe} = \frac{Q}{A_p}$$
$$= \frac{Q}{\frac{\pi}{4}D^2}$$

Here, A_p is the cross sectional area of the pipe, and D is the diameter of the pipe.

Substitute $0.01\,\text{m}^3/\text{s}$ for Q , and $0.04\,\text{m}$ for d.

$$V_{pipe} = \frac{0.01}{\frac{\pi}{4}\times 0.04^2}$$
$$= 7.95\,\text{m/s}$$

Step 3 of 7

Calculate the Reynolds number by using the following equation:

$$\text{Re} = \frac{\rho V_{pipe} D}{\mu}$$

Here, ρ is the density of the oil, μ is the dynamic viscosity.

Substitute $920\,\text{kg/m}^3$ for ρ , $7.95\,\text{m/s}$ for V_{pipe} , $0.04\,\text{m}$ for D, and $0.045\,\text{kg/m}$ for μ .

$$\text{Re} = \frac{920\times 7.95\times 0.04}{0.045}$$
$$= \frac{292.56}{0.045}$$
$$= 6501.33$$

Step 4 of 7

Relative roughness of the plastic pipe is $\varepsilon/d = 0$.

From the Moody's chart for friction factor for fully developed flow in a circular pipes, obtain friction factor at $\text{Re} = 6501.33$ and $\varepsilon/d = 0$.

$$f = 0.033$$

Apply Bernoulli's equation at tank inlet and at the reservoir.

$$\frac{p_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{p_2}{\rho g} + \frac{V_2^2}{2g} + z_2 - h_p + h_L$$

Here, the pressure at points (2) and (1) are P_2 and P_1 assumed as zero, substitute, 0 for P_1 and P_2 , the average velocity of pipe (1) is $\bar{V}_1$ assumed as zero and substitute, 0 for $\bar{V}_1$ and the average velocity at exit (2) is $\bar{V}_2$, the acceleration due to gravity is g, the datum height at (2) is z_2 , The datum height at (1) is z_1 assumed as zero, substitute, z_1 for 0, the head loss due to pipe is h_p , the total head loss is h_L .

$$0+0+0 = 0+\frac{V^2}{2g}+z_2-h_p+h_L$$

$$h_p = \frac{V^2}{2g}+z_2+h_L \quad \text{..... (1)}$$

Step 5 of 7

Write the equation for the total head loss.

$$h_L = \left(f\frac{L}{D}+\sum K_L\right)\frac{V^2}{2g} \quad \text{..... (2)}$$

Here, L is the length of the pipe, $\sum K_L$ is sum of the loss coefficient, g is the acceleration due to gravity.

Calculate the sum of the loss coefficient by using the following equation:

$$h_L = \left(f\frac{L}{D} + \sum K_L\right)\frac{V^2}{2g} \quad \text{..... (2)}$$ 14.077P pg 2

Here, L is the length of the pipe, $\sum K_L$ is sum of the loss coefficient, g is the acceleration due to gravity.

Calculate the sum of the loss coefficient by using the following equation:

$$\sum K_L = K_{entrance} + 2K_{bend} \quad \text{..... (3)}$$

Here, $K_{entrance}$ is the loss coefficient at entrance, and K_{bend} is the loss coefficient at bend.

From the loss coefficient of various pipe components table, obtain:

$$K_{entrance} = 0.12$$

$$K_{bend} = 0.3$$

Substitute 0.12 for $K_{entrance}$, and 0.3 for K_{bend} in (3).

$$\begin{aligned}\sum K_L &= 0.12 + (2 \times 0.3) \\ &= 0.72\end{aligned}$$

Step 6 of 7

Substitute 0.033 for f, 0.72 for $\sum K_L$, $7.95\,\text{m/s}$ for V_{pipe}, $0.04\,\text{m}$ for D, $9.81\,\text{m/s}^2$ for g, and $25\,\text{m}$ for L in equation (2).

$$\begin{aligned}h_L &= \left(f\frac{L}{D} + \sum K_L\right)\frac{V^2}{2g} \\ &= \left(\left(0.033 \times \frac{25}{0.04}\right) + 0.72\right)\frac{7.95^2}{2 \times 9.81} \\ &= 68.75\,\text{m}\end{aligned}$$

Substitute $68.75\,\text{m}$ for h_L, $7.95\,\text{m/s}$ for V_{pipe}, $9.81\,\text{m/s}^2$ for g, and $5\,\text{m}$ for z_2 in equation (1).

$$\begin{aligned}h_p &= \frac{V^2}{2g} + z_2 + h_L \\ &= \frac{7.95^2}{2 \times 9.81} + 5 + 68.75 \\ &= 76.97\,\text{m}\end{aligned}$$

Step 7 of 7

Calculate the power required by the pump by using the following equation:

$$W_p = \frac{\rho g Q h_p}{\eta}$$

Here, η is pump efficiency.

Substitute $920\,\text{kg/m}^3$ for ρ, $9.81\,\text{m/s}^2$ for g, $0.01\,\text{m}^3/\text{s}$ for Q, $76.97\,\text{m}$ for h_p, and 0.82 for η.

$$\begin{aligned}W_p &= \frac{920 \times 9.81 \times 0.01 \times 76.97}{0.82} \\ &= \frac{6946.81}{0.82} \\ &= 8.471\,\text{kW}\end{aligned}$$

Therefore, the power required by the pump is $\boxed{8.471\,\text{kW}}$.

Question: 14.078P

Two pipes of identical length and material are connected in parallel. The diameter of pipe *A* is twice the diameter of pipe *B*. Assuming the friction factor to be the same in both cases and disregarding minor losses, determine the ratio of the flow rates in the two pipes.

Step 1 of 2

Write the equation for head loss for a steady, incompressible and fully developed flow.

$$h_L = f\frac{L}{D}\cdot\frac{V^2}{2g}$$

Here, f is the friction factor, L is the diameter, D is the diameter, V is the velocity, and g is the acceleration due to gravity.

Since, for a piping system connected in parallel, the head loss in the parallel pipes will be same.

$$(h_L)_A = (h_L)_B$$

$$f_A\frac{L_A}{D_A}\cdot\frac{V_A^2}{2g} = f_B\frac{L_B}{D_B}\cdot\frac{V_B^2}{2g} \quad \text{..... (1)}$$

Write the equation for velocity of flow through pipe *A*.

$$V_A = \frac{\dot{V}_A}{(A_c)_A} = \frac{\dot{V}_A}{\frac{\pi}{4}D_A^2}$$

Here, $\dot{V}_A$ is the flow rate in pipe A.

Substitute $2D_B$ for D_A.

$$V_A = \frac{\dot{V}_A}{\frac{\pi}{4}(2D_B)^2} = \frac{\dot{V}_A}{\pi D_B^2}$$

Step 2 of 2

Calculate the velocity of flow through pipe *B*.

$$V_B = \frac{\dot{V}_B}{(A_c)_B} = \frac{\dot{V}_B}{\frac{\pi}{4}D_B^2} = \frac{4\dot{V}_B}{\pi D_B^2}$$

Substitute the values in the equation (1), we get

$$f_B\frac{L_B}{2D_B}\cdot\left(\frac{\dot{V}_A}{\pi D_B^2}\right)^2\frac{1}{2g} = f_B\frac{L_B}{D_B}\cdot\left(\frac{4\dot{V}_B}{\pi D_B^2}\right)^2\frac{1}{2g}$$

$$\frac{\dot{V}_A^2}{2} = 16\dot{V}_B^2$$

$$\frac{\dot{V}_A^2}{\dot{V}_B^2} = 32$$

$$\frac{\dot{V}_A}{\dot{V}_B} = 5.656$$

Therefore, the ratio of flow rates in the two pipes is $\boxed{5.656}$.

Question: 14.079P

A certain part of cast iron piping of a water distribution system involves a parallel section. Both parallel pipes have a diameter of 30 cm, and the flow is fully turbulent. One of the branches (pipe *A*) is 1000 m long while the other branch (pipe *B*) is 3000 m long. If the flow rate through pipe *A* is 0.4 m3/s, determine the flow rate through pipe *B*. Disregard minor losses and assume the water temperature to be 15°C. Show that the flow is fully rough, and thus the friction factor is independent of Reynolds number.

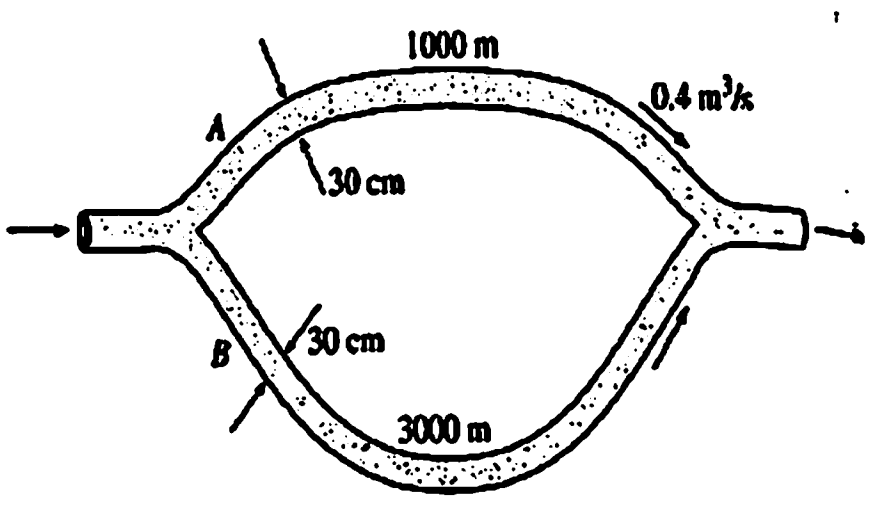

FIGURE P14–79

Step 1 of 5

Given data:

Length of the pipe *A*, $L_A = 1000$ m

Length of the pipe *B*, $L_B = 3000$ m

The diameter of the pipes, $D_A = D_B = 0.3$ m

The flow rate through the pipe *A*, $\dot{V}_A = 0.4\ \text{m}^3/s$

From the properties table of saturated water, at 15°C,

The density of water is $\rho = 999.1\ \text{kg/m}^3$

The dynamic viscosity is $\mu = 1.138 \times 10^{-3}\ \text{kg/m-s}$

Step 2 of 5

The cross sectional area of pipes *A* and *B*,

$$(A_c)_A = (A_c)_B$$
$$= \frac{\pi}{4} D_A^2$$
$$= \frac{\pi}{4}(0.3\,\text{m})^2$$
$$= 0.0707\,\text{m}^2$$

The average velocity of flow through the pipe *A*,

$$V_A = \frac{\dot{V}_A}{(A_c)_A}$$
$$= \frac{0.4\ \text{m}^3/s}{0.0707\ \text{m}^2}$$
$$= 5.658\ \text{m/s}$$

Step 3 of 5

The head loss is given by $h_L = f \frac{L}{D} \cdot \frac{V^2}{2g}$,

where, f is the friction factor,
L is the length of the pipe,
V is the average flow velocity,
D is the diameter of the pipe and
g is the gravitational acceleration.

Considering that the friction factors are same for both the pipes, the head loss will be same in the parallel piping system. Hence

$$(h_L)_A = (h_L)_B$$
$$f_A \frac{L_A}{D_A} \cdot \frac{V_A^2}{2g} = f_B \frac{L_B}{D_B} \cdot \frac{V_B^2}{2g}$$

Step 4 of 5

By substituting the values, we get

$$f_B \frac{1000}{30} \cdot \frac{(5.658)^2}{2g} = f_B \frac{3000}{30} \cdot \frac{V_B^2}{2g}$$
$$3V_B^2 = 5.658^2$$
$$V_B = 3.267\ \text{m/s}$$

The flow rate through the pipe *B*,

$$\dot{V}_B = V_B (A_c)_B$$
$$= (3.267) \times (0.0707)$$
$$= 0.231\ \text{m}^3/s$$

Therefore, the flow rate through the pipe *B*, $\boxed{\dot{V}_B = 0.231\ \text{m}^3/s}$

Step 5 of 5

The Reynolds number in pipe *A*,

$$\text{Re}_A = \frac{\rho V_A D_A}{\mu}$$
$$= \frac{(999.1\ \text{kg/m}^3)(5.658\ \text{m/s})(0.3\ \text{m})}{1.138 \times 10^{-3}\ \text{kg/m} \cdot s}$$
$$= 1.49 \times 10^6$$

Here, $\text{Re} > 4000$, therefore the flow in pipe *A* is turbulent.

The Reynolds number in pipe *B*,

$$\text{Re}_B = \frac{\rho V_B D_B}{\mu}$$
$$= \frac{(999.1\ \text{kg/m}^3)(3.267\ \text{m/s})(0.3\ \text{m})}{1.138 \times 10^{-3}\ \text{kg/m} \cdot s}$$
$$= 0.860 \times 10^6$$

Here, $\text{Re} > 4000$, therefore the flow in pipe *B* is turbulent.

Therefore, the flow in both pipes is fully turbulent, and thus the assumption that the friction factor is the same for both pipes is valid.

Question: 14.080P

Repeat Prob. 14-79 assuming pipe A has a closed gate valve ($KL = 2.1$) while pipe B has a fully open globe valve ($KL = 10$), and the other minor losses are negligible.

Step 1 of 6

Given data:

Length of the pipe A, $L_A = 1000$ m

Length of the pipe B, $L_B = 3000$ m

The diameter of the pipes, $D_A = D_B = 0.3$ m

The flow rate through the pipe A, $\dot{V}_A = 0.4\ m^3/s$

Loss coefficient of the half way closed gate valve in pipe A, $(K_L)_A = 2.1$

Loss coefficient of the fully opened globe valve in pipe B, $(K_L)_B = 10$

The roughness value of cast iron, $\varepsilon = 0.26\ mm = 2.6 \times 10^{-4}$ m

From the properties table of saturated water, at 15°C,

The density of water is $\rho = 999.1\ kg/m^3$

The dynamic viscosity is $\mu = 1.138 \times 10^{-3}$ kg/m-s

Step 2 of 6

The cross sectional area of pipes A and B,

$$(A_c)_A = (A_c)_B$$
$$= \frac{\pi}{4} D_A^2$$
$$= \frac{\pi}{4}(0.3)^2$$
$$= 0.0707\ m^2$$

The average velocity of flow through the pipe A,

$$V_A = \frac{\dot{V}_A}{(A_c)_A}$$
$$= \frac{0.4}{0.0707}$$
$$= 5.658\ m/s$$

The Reynolds number in pipe A,

$$\mathrm{Re}_A = \frac{\rho V_A D_A}{\mu}$$
$$= \frac{(999.1)(5.658)(0.3)}{1.138 \times 10^{-3}}$$
$$= 1.49 \times 10^6$$

Here, $\mathrm{Re} > 4000$, therefore the flow in pipe A is turbulent.

Step 3 of 6

For turbulent flow, the Colebrook equation is

$$\frac{1}{\sqrt{f_A}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\mathrm{Re}_A \sqrt{f_A}}\right),$$

where, f is the friction factor

ε is the roughness factor

D is the diameter of the pipe

Re is the Reynolds number of flow

Substituting the values in Colebrook equation, we get

$$\frac{1}{\sqrt{f_A}} = -2.0 \log\left(\frac{2.6 \times 10^{-4}/0.3}{3.7} + \frac{2.51}{(1.49 \times 10^6)\sqrt{f_A}}\right)$$
$$= -2.0 \log\left(2.342 \times 10^{-4} + \frac{1.685 \times 10^{-6}}{\sqrt{f_A}}\right)$$

By solving the equation for f, we get

$$f_A = 0.0192$$

Then, $f_B = f_A = 0.0192$

Step 4 of 6

The head loss is given by

$$h_L = \left(f \frac{L}{D} + K_L\right) \frac{V^2}{2g},$$

where, L is the length of the pipe,

V is the average flow velocity,

D is the diameter of the pipe and

g is the gravitational acceleration.

The head loss in pipe A,

$$(h_L)_A = \left(f_A \frac{L_A}{D_A} + (K_L)_A\right) \frac{V_A^2}{2g}$$
$$= \left((0.0192)\frac{1000}{0.3} + 2.1\right) \frac{(5.658)^2}{2(9.81)}$$
$$= 107.852\ m$$

Step 5 of 6

For a piping system, connected in parallel, the head loss in the parallel pipes is same.

$$(h_L)_A = (h_L)_B$$
$$= \left(f_B \frac{L_B}{D_B} + (K_L)_B\right) \frac{V_B^2}{2g}$$

By substituting the values, we get

$$107.852 = \left((0.0192)\frac{3000}{0.3} + 10\right) \frac{V_B^2}{2(9.81)}$$
$$107.852 = 10.296 V_B^2$$
$$V_B^2 = 10.475$$
$$V_B = 3.237\ m/s$$

Step 6 of 6

The flow rate through the pipe B,

$$\dot{V}_B = V_B (A_c)_B$$
$$= (3.237)(0.0707).$$
$$= 0.229\ m^3/s$$

Therefore, the flow rate through the pipe B, $\boxed{\dot{V}_B = 0.229\ m^3/s}$.

Question: 14.081P

Gasoline (ρ = 680 kg/m3 and v = 4.29 × 10-7m2/s) is transported at a rate of 400 L/s for a distance of 2km. The surface roughness of the piping is 0.03 mm. If the head loss due to pipe friction is not to exceed 8 m, determine the minimum diameter of the pipe.

Step 1 of 4

Given data:

Length of the pipe, $L = 2 \times 10^3 \text{ m}$

The density of gasoline, $\rho = 680 \text{kg/m}^3$

The kinematic viscosity, $\nu = 4.29 \times 10^{-7} \text{ m}^2/\text{s}$

The flow rate through the pipe, $\dot{V} = 400 \text{L/s} = 0.4 \text{m}^3/\text{s}$

The surface roughness of the piping, $\varepsilon = 3 \times 10^{-5} \text{ m}$

The head loss due to pipe friction, $h_L = 8 \text{ m}$

Step 2 of 4

The cross sectional area of pipe,

$$A_c = \frac{\pi}{4} D^2$$

The average velocity of flow through the pipe,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{4 \times 0.4}{\pi D^2}$$

$$= \frac{0.5093}{D^2}$$

The Reynolds number,

$$\text{Re} = \frac{VD}{\nu}$$

$$= \left(\frac{0.5093}{D^2}\right) \frac{D}{4.29 \times 10^{-7}}$$

$$= \frac{1.187 \times 10^6}{D}$$

Step 3 of 4

The head loss is given by the relation,

$$h_L = f \frac{L}{D} \cdot \frac{V^2}{2g}$$

where, f is the friction factor,
L is the length of the pipe,
V is the average flow velocity,
D is the diameter of the pipe and
g is the gravitational acceleration.

Substituting the known values, we get

$$8 = f \frac{(2 \times 10^3)}{D} \cdot \left(\frac{0.5093}{D^2}\right)^2 \frac{1}{2(9.81)}$$

$$8 = 26.441 \frac{f}{D^5}$$

$$f = 0.3026 \, D^5$$

Step 4 of 4

For turbulent flow, the Colebrook equation is

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

Substituting the known values, we get

$$\frac{1}{\sqrt{0.3026 D^5}} = -2.0 \log\left(\frac{3 \times 10^{-5}/D}{3.7} + \frac{2.51}{\left(\frac{1.187 \times 10^6}{D}\right)\sqrt{0.3026 D^5}}\right)$$

$$= -2.0 \log\left(\frac{8.108 \times 10^{-6}}{D} + \frac{(2.115 \times 10^{-6})D}{\sqrt{0.3026 D^5}}\right)$$

Solving the equation for D, we get

$D = 0.5232 \text{ m}$

Therefore, the minimum diameter of the pipe, $\boxed{D = 0.5232 \text{m}}$

Question: 14.082P

In large buildings, hot water in a water tank is circulated through a loop so that the user doesn't have to wait for all the water in long piping to drain before hot water starts coming out. A certain recirculating loop involves 40-m-long, 1.2-cm-diameter cast iron pipes with six 90° threaded smooth bends and two fully open gate valves. If the average flow velocity through the loop is 2 m/s, determine the required power input for the recirculating pump. Take the average water temperature to be 60°C and the efficiency of the pump to be 70 percent.

Step 1 of 7

Given data:

Length of the pipe, $L = 40\,\text{m}$

The diameter of the pipe $D = 1.2\,\text{cm} = 0.012\,\text{m}$

The average flow velocity of water $V = 2\,\text{m/s}$

The average water temperature $T = 60°\text{C}$

The efficiency of a pump $\eta_{pump-motor} = 70\% = 0.7$

Step 2 of 7

From the properties of saturated water tables at 60°C temperature the given values.

The density of water, $\rho = 983.3\,\text{kg/m}^3$

The Dynamic viscosity of water, $\mu = 0.467 \times 10^{-3}\,\text{kg/m}\cdot\text{s}$

From the loss coefficient k_L of various pipe components for turbulent flow tables the given values.

For the threaded 90° smooth bent

The loss coefficient is $k_L = 0.9$

For the full open gate valve

The loss coefficient is $k_L = 0.2$

From the Equivalent roughness values for new commercial pipes table the given values

The surface roughness of the cast iron piping, $\varepsilon = 0.26\,\text{m} = 0.00026\,\text{mm}$

Step 3 of 7

The cross sectional area of pipe,

$$A_c = \frac{\pi}{4}D^2$$

The volume flow rate and the pumping power requirements are ,

$$\dot{V} = AV_c$$

$$= \frac{\pi D^2 \times 2}{4}$$

$$= \frac{\pi \times 2 \times (0.012)^2}{4}$$

$$= 0.0002261\,\text{m}^3/\text{s}$$

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{983.3 \times 2 \times 0.012}{0.467 \times 10^{-3}}$$

$$= 50533.61$$

Step 4 of 7

Which is grater than turbulent flow =4000

The relative roughness of the pipe

$$\frac{\varepsilon}{D} = \frac{0.00026}{0.12}$$

$$= 0.0217$$

For turbulent flow, the Colebrook equation is

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

Substituting the known values, we get

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{0.0217}{3.7} + \frac{2.51}{50533.61\sqrt{f}}\right)$$

Solving the equation for f, we get

The frictional factor $f = 0.05075$

Step 5 of 7

The total head loss is given by the relation,

$$h_L = \left(f\frac{L}{D} + \sum K_L\right)\frac{V^2}{2g}$$

Where, f is the friction factor,

L is the length of the pipe,

V is the average flow velocity,

D is the diameter of the pipe and

g is the gravitational acceleration.

Substituting the known values, we get

$$h_L = \left(0.05075 \times \frac{40}{0.012} + (6 \times 0.9 + 2 \times 0.2)\right)\frac{2^2}{2 \times 9.81}$$

$$= (169.17 + 5.8)0.20$$

$$= 35\text{m}$$

Step 6 of 7

The pressure drop

$$\Delta P = \Delta P_L$$

$$= \rho g h_L$$

$$= 983.3 \times 9.81 \times 35$$

$$= 337616.055\,\text{N/m}^2$$

$$= 337.616\,\text{kN/m}^2$$

Step 7 of 7

The required pumping power

$$\dot{W}_{elect} = \frac{\dot{W}_{pump}}{\eta_{pump-motor}}$$

$$= \frac{\dot{V}\Delta P}{\eta_{pump-motor}}$$

$$= \frac{0.0002261 \times 337.616}{0.7}$$

$$= 0.111\,\text{kW}$$

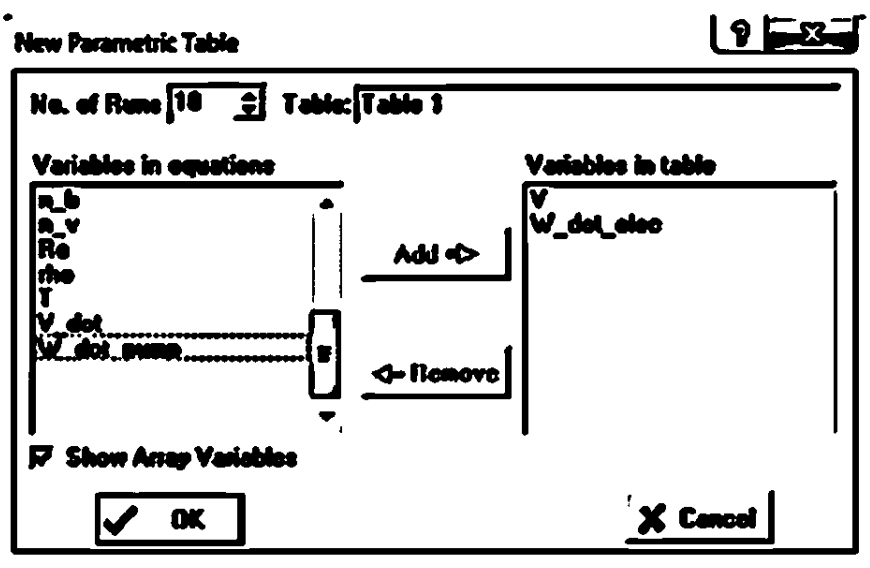
The required pumping power $\boxed{\dot{W}_{elect} = 0.111\,\text{kW}}$

Question: 14.083P

Reconsider Prob. 14-82. Using EES (or other) software, investigate the effect of the average flow velocity on the power input to the recirculating pump. Let the velocity vary from 0 to 3 m/s in increments of 0.3 m/s. Tabulate and plot the results.

Step 1 of 5

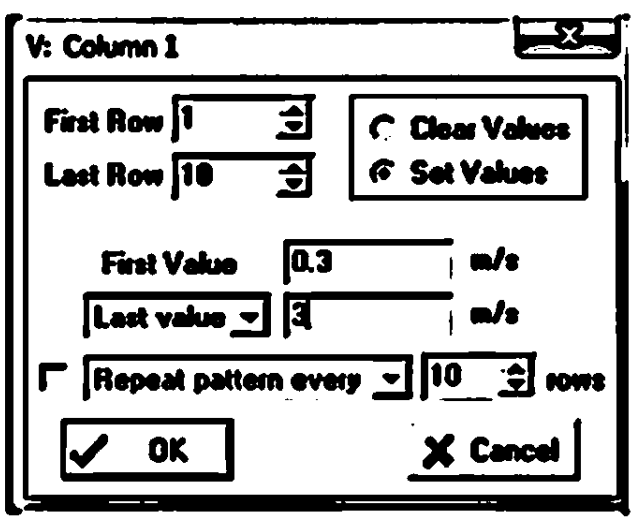
The given problem can be solved using EES software by following the below steps.



1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
L=40[m]                                  "Length of pipe"
D=1.2[cm]*convert(cm,m)                  "Diameter of pipe"
"V is varied from 0 to 3[m/s]"           "Velocity of water"
T=60[C]                                  "Temperature of water"
eta_pump=0.70                            "Pump efficiency"
epsilon=0.26[mm]*convert(mm,m)           "Roughness"
n_b=6                                    "Number of bends"
n_v=2                                    "Number of valves"

"Propertied of water at temperature T"
rho=Density(Water,T=T,P=1[atm]*convert(atm,kPa))
mu=Viscosity(Water,T=T,P=1[atm]*convert(atm,kPa))
k_L_b=0.9                                "Loss Coefficient for 90 Degrees smoothe bent"
k_L_v=0.2                                "Loss Coefficient for gate valve"
A_c=pi*D^2/4
V_dot=A_c*V                              "Flow rate"
Re=rho*V*D/mu                            "Reynolds Number"
1/sqrt(f)=-2.0*log10((epsilon/D)/3.7+2.51/(Re*sqrt(f)))
h_L=(f*L/D+K_L_b*n_b+K_L_v*n_v)*V^2/2/g#
DELTAP=rho*g#*h_L                        "Pressure drop"
W_dot_pump=V_dot*DELTAP
W_dot_elec*eta_pump=W_dot_pump
```



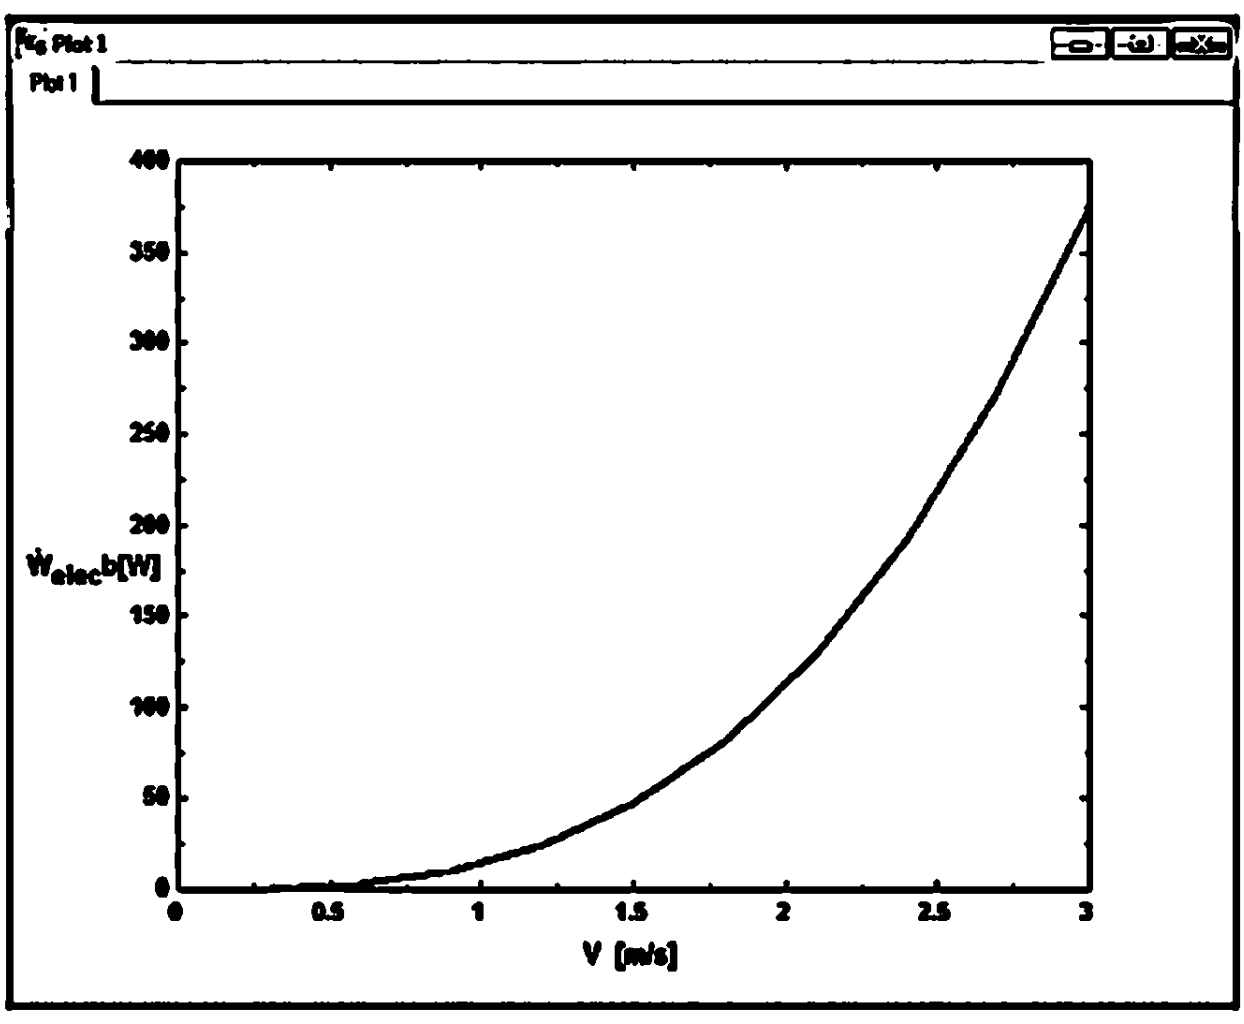
Step 2 of 5

Now to solve the equation for a range of average velocity of flow velociy, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 10.
Select variables in equations as "V" and "W_dot_elec" press 'Add' and then press 'OK'.
The screenshot of the "New Parametric Table" is shown:

Step 3 of 5

The average velocity of flow of water is varied from 0 to 3 m/s
To enter the values in the "V" column, click on the drop tab in "V" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 5



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

$\triangleright_{1..10}$	1 V [m/s]	2 $\dot{W}_{elec}$
Run 1	0.3	0.4032
Run 2	0.6	3.103
Run 3	0.9	10.32
Run 4	1.2	24.3
Run 5	1.5	47.24
Run 6	1.8	81.39
Run 7	2.1	129
Run 8	2.4	192.2
Run 9	2.7	273.3
Run 10	3	374.5

Step 5 of 5

To plot the input power as function of average velocity of water flow, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the input power as function of average velocity of water flow is shown:

From the above plot we can interpret that as the average velocity of flow of water increases the power input to the motor also increases.

Question: 14.084P

Repeat Prob. 14-82 for plastic (smooth) pipes.

Step 1 of 11

The length of cast iron pipe, $L = 40\,\text{m}$

The diameter of cast iron pipe, $D = 1.2\,\text{cm} = 0.012\,\text{m}$

The average flow velocity through the loop, $V = 2\,\text{m/s}$

The average water temperature, $T = 60°\text{C}$

The efficiency of the pump, $\eta_{\text{pump}} = 0.70$

Take density of water, $\rho = 983.3\,\text{kg/m}^3$

Acceleration due to gravity, $g = 9.81\,\text{m/s}^2$

Step 2 of 11

From the properties of saturated water table, at temperature $T = 60°$, we have

Density, $\rho = 983.3\,\text{kg/m}^3$

Dynamic viscosity, $\mu = 0.467\times10^{-3}\,\text{kg/m}\cdot\text{s}$

From the table of Equivalent roughness values for new commercial pipes, we have

The roughness value for plastic, $\varepsilon = 0$

From the table of Valves, we have

The loss of coefficient,

For threaded 90° smooth bend, $K_L = 0.9$

For fully open gate valve, $K_L = 0.2$

The plastic pipe has six 90° threaded smooth bends and two fully open gate valves.

Step 3 of 11

The water is circulating continuously, so this system is considered as control volume.

Let take the 1 and 2 points at the same point on the pipe, then the properties (pressure, velocity and elevation) will be identical at those two points.

Therefore,

Pressure, $P_1 = P_2 = P$

Velocity, $V_1 = V_2 = V$

Elevation, $z_1 = z_2 = z$

Step 4 of 11

By using the energy equation, we have

$$\frac{P_1}{\rho g}+\alpha_1\frac{V_1^2}{2g}+z_1+h_{\text{pump,u}}=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+z_2+h_{\text{turbine,e}}+h_L$$

Where,

Turbine work is not there, so we can take $h_{\text{turbine,e}} = 0$

Step 5 of 11

Then,

$$\frac{P}{\rho g}+\alpha_1\frac{V^2}{2g}+z+h_{\text{pump,u}}=\frac{P}{\rho g}+\alpha_2\frac{V^2}{2g}+z+0+h_L$$

$$h_L = h_{\text{pump,u}}$$

$$= h_{L,\text{major}}+h_{L,\text{minor}}$$

$$=\left(f\frac{L}{D}+\sum K_L\right)\frac{V_2^2}{2g}$$

$$h_L=\left(f\frac{L}{D}+\sum K_L\right)\frac{V_2^2}{2g} \qquad \ldots\ldots (1)$$

Step 6 of 11

The flow rate of water,

$$\dot{V} = VA_c$$

$$= V\left(\frac{\pi D^2}{4}\right)$$

$$=2\left(\frac{\pi(0.012)^2}{4}\right)$$

$$=2.261\times10^{-4}\,\text{m}^3/\text{s}$$

Step 7 of 11

The Reynolds number for the flow,

$$\text{Re}=\frac{\rho VD}{\mu}$$

$$=\frac{983.3\times2\times0.012}{0.467\times10^{-3}}$$

$$=50533.618$$

Re > 4000, therefore, the flow is turbulent.

Step 8 of 11

The friction factor corresponding to the relative roughness and Reynolds number can be determined by using Colebrook equation,

$$\frac{1}{\sqrt{f}}=-2.0\log\left(\frac{e/D}{3.7}+\frac{2.51}{\text{Re}\sqrt{f}}\right)$$

$$=-2.0\log\left(\frac{0/D}{3.7}+\frac{2.51}{(50533.618)\sqrt{f}}\right)$$

$$f = 0.01908$$

Step 9 of 11

By substituting f value in equation (1), we get

The total head loss,

$$h_L=\left(f\frac{L}{D}+\sum K_L\right)\frac{V_2^2}{2g}$$

$$=\left((0.01908)\frac{40}{0.012}+6\times0.9+2\times0.2\right)\frac{2^2}{2\times9.81}$$

$$=14.148\,\text{m}$$

Step 10 of 11

The pressure drop in the pipe,

$$\Delta P = \rho g h_L$$

$$=983.3\times9.81\times14.148$$

$$=136474.055\,\text{Pa}$$

$$=136.474\,\text{kPa}$$

Step 11 of 11

The required pumping power input for the recirculating pump,

$$\dot{W}_{\text{input}}=\frac{\dot{W}_{\text{pump}}}{\eta_{\text{pump}}}$$

$$=\frac{\dot{V}\Delta P}{\eta_{\text{pump}}}$$

$$=\frac{2.261\times10^{-4}\times136.474}{0.7}$$

$$=0.0441\,\text{kW}$$

Therefore, the required pumping power input for the recirculating pump is $\boxed{\dot{W}_{\text{input}} = 0.0441\,\text{kW}}$.

Question: 14.085P pg 1

Water at 20°C is to be pumped from a reservoir (zA = 2 m) to another reservoir at a higher elevation (zB = 9 m) through two 25-m-long plastic pipes connected in parallel. The diameters of the two pipes are 3 cm and 5 cm. Water is to be pumped by a 68 percent efficient motor-pump unit that draws 7 kW of electric power during operation. The minor losses and the head loss in the pipes that connect the parallel pipes to the two reservoirs are considered to be negligible. Determine the total flow rate between the reservoirs and the flow rates through each of the parallel pipes.

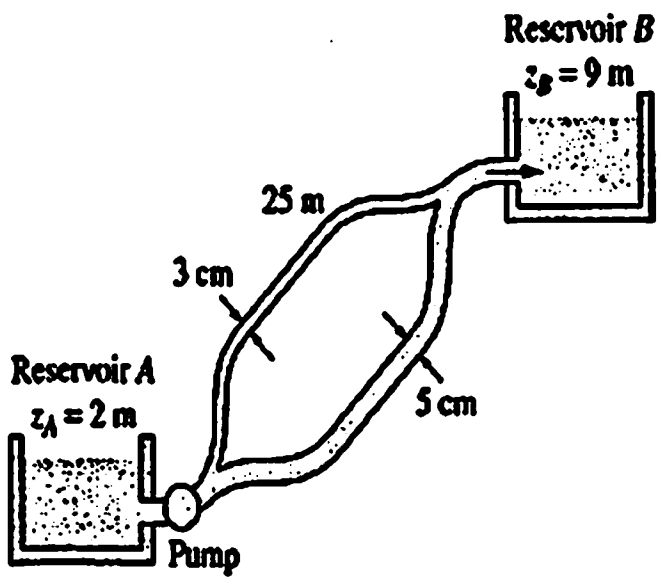


FIGURE P14–85

Step 1 of 6

From properties of saturated water tables, at temperature of $20°C$:

Density, $\rho = 998\ \text{kg/m}^3$

Dynamic viscosity, $\mu = 1.002\times10^{-3}\ \text{kg/m}\cdot\text{s}$

The electric power:

$$\dot{W} = \frac{\dot{V}\rho g h_{pump}}{\eta}$$

Here, the volume flow rate is $\dot{V}$, the density of water is, the acceleration due to gravitational is g, efficiency of the pump is *?*

Substitute, $7000\ \text{W}$ for $\dot{W}$, $998\ \text{kg/m}^3$ for *?*, $9.81\ \text{m/s}^2$ for g, 0.68 for *?*,

$$7000\ \text{W} = \frac{\dot{V}(998\ \text{kg/m}^3)(9.81\ \text{m/s}^2)h_{pump}}{0.68} \quad \text{..... (1)}$$

The energy balance equation between reservoirs is :

$$\frac{P_A}{\rho g} + \alpha_A \frac{V_A^2}{2g} + z_A + h_{pump,u} = \frac{P_B}{\rho g} + \alpha_B \frac{V_B^2}{2g} + z_B + h_L$$

Here, pressure at point 1 and 2 is P_1 and P_2, the velocity at points 1 and 2 are V_1 and V_2, acceleration due to gravity is g

Points *A* and *B* are chosen at the free surfaces of the reservoir. Since the pressures of both the liquids in the reservoir is at atmospheric pressure. Therefore, $P_A = P_B$ and the fluid velocities at both points are nearly zero, $V_A = V_B = 0$. Also z_A and z_B are 2m, 9m respectively.

$$h_{pump,u} = (z_B - z_A) + h_L \qquad h_{pump,u} = 7 + h_L \quad \text{..... (2)}$$
$$= (9-2) + h_L$$

Step 2 of 6

Since, the pipes are connected in parallel; therefore, the head loss is equal to the head loss in both the pipes.

$$h_L = h_{L,1} \quad \text{..... (3)}$$

$$h_L = h_{L,2} \quad \text{..... (4)}$$

Substitute, $0.03\ \text{m}$ for D_1 , and $0.05\ \text{m}$ for D_2 to calculate the cross-sectional area of the first pipe,

Calculate Cross-sectional area of the first pipe,

$$A_{c,1} = \frac{\pi}{4}\times D_1^2$$
$$= \frac{\pi}{4}\times 0.03^2$$
$$= 7.0685\times10^{-4}\ \text{m}^2$$

Calculate Cross-sectional area of the second pipe,

$$A_{c,2} = \frac{\pi}{4}\times D_2^2$$
$$= \frac{\pi}{4}\times 0.05^2$$
$$= 0.001\ \text{m}^2$$

Step 3 of 6

Calculate the average velocity (V) by dividing the volume flow rate ($\dot{V}$) by the cross-sectional area (A):

For First consider point 1:

$$V_1 = \frac{\dot{V}_1}{A_1}$$

$$= \frac{\dot{V}_1}{\pi(0.03\ \text{m})^2/4} \quad \text{..... (5)}$$

For point 2:

$$V_2 = \frac{\dot{V}_2}{A_2}$$

$$= \frac{\dot{V}_2}{\pi(0.03\ \text{m})^2/4} \quad \text{..... (6)}$$

$$= \frac{\dot{V}_2}{\pi (0.03\ \text{m})^2 / 4} \quad \text{..... (6)}$$

Step 4 of 6

Calculate the Reynolds numbers (Re) for first pipe by using the following equation:

$$\text{Re}_1 = \frac{\rho V_1 D_1}{\mu}$$

Here, the density of water is ?, the viscosity of water is μ

The viscosity of water, $1.002 \times 10^{-3}\ \text{kg/m} \cdot \text{s}$

Substitute, $998\ \text{kg/m}^3$ for ρ, $0.03\ \text{m}$ for D_1, and $1.002 \times 10^{-3}\ \text{kg/m} \cdot \text{s}$ for μ

$$\text{Re}_1 = \frac{\rho V_1 D_1}{\mu}$$

$$= \frac{(998\ \text{kg/m}^3) V_1 (0.03\ \text{m})}{1.002 \times 10^{-3}\ \text{kg/m} \cdot \text{s}} \quad \text{..... (7)}$$

Consider the second section of pipe.

$$\text{Re}_2 = \frac{\rho \times V_2 \times D_2}{\mu}$$

$$= \frac{998 \times V_2 \times 0.05}{1.002 \times 10^{-3}} \quad \text{..... (8)}$$

From equivalent roughness values for new commercial pipes tables, for plastic pipes, the roughness value, $\varepsilon = 0$

Frictional factor for first pipe is:

$$\frac{1}{\sqrt{f_1}} = -2.0 \log\left(\frac{\varepsilon / D_1}{3.7} + \frac{2.51}{\text{Re}_1 \sqrt{f_1}}\right)$$

$$= -2.0 \log\left(\frac{0/0.03}{3.7} + \frac{2.51}{\text{Re}_1 \sqrt{f_1}}\right)$$

$$\frac{1}{\sqrt{f_1}} = -2.0 \log\left(\frac{2.51}{\text{Re}_1 \sqrt{f_1}}\right) \quad \text{..... (9)}$$

Frictional factor for second pipe is:

$$\frac{1}{\sqrt{f_2}} = -2.0 \log\left(\frac{\varepsilon / D_2}{3.7} + \frac{2.51}{\text{Re}_2 \sqrt{f_2}}\right)$$

$$= -2.0 \log\left(\frac{0/0.05}{3.7} + \frac{2.51}{\text{Re}_2 \sqrt{f_2}}\right)$$

$$\frac{1}{\sqrt{f_2}} = -2.0 \log\left(\frac{2.51}{\text{Re}_2 \sqrt{f_2}}\right) \quad \text{..... (10)}$$

Step 5 of 6

Head loss in the first pipe is:

$$h_{L,1} = f_1 \frac{L}{D_1} \times \frac{V_1^2}{2g}$$

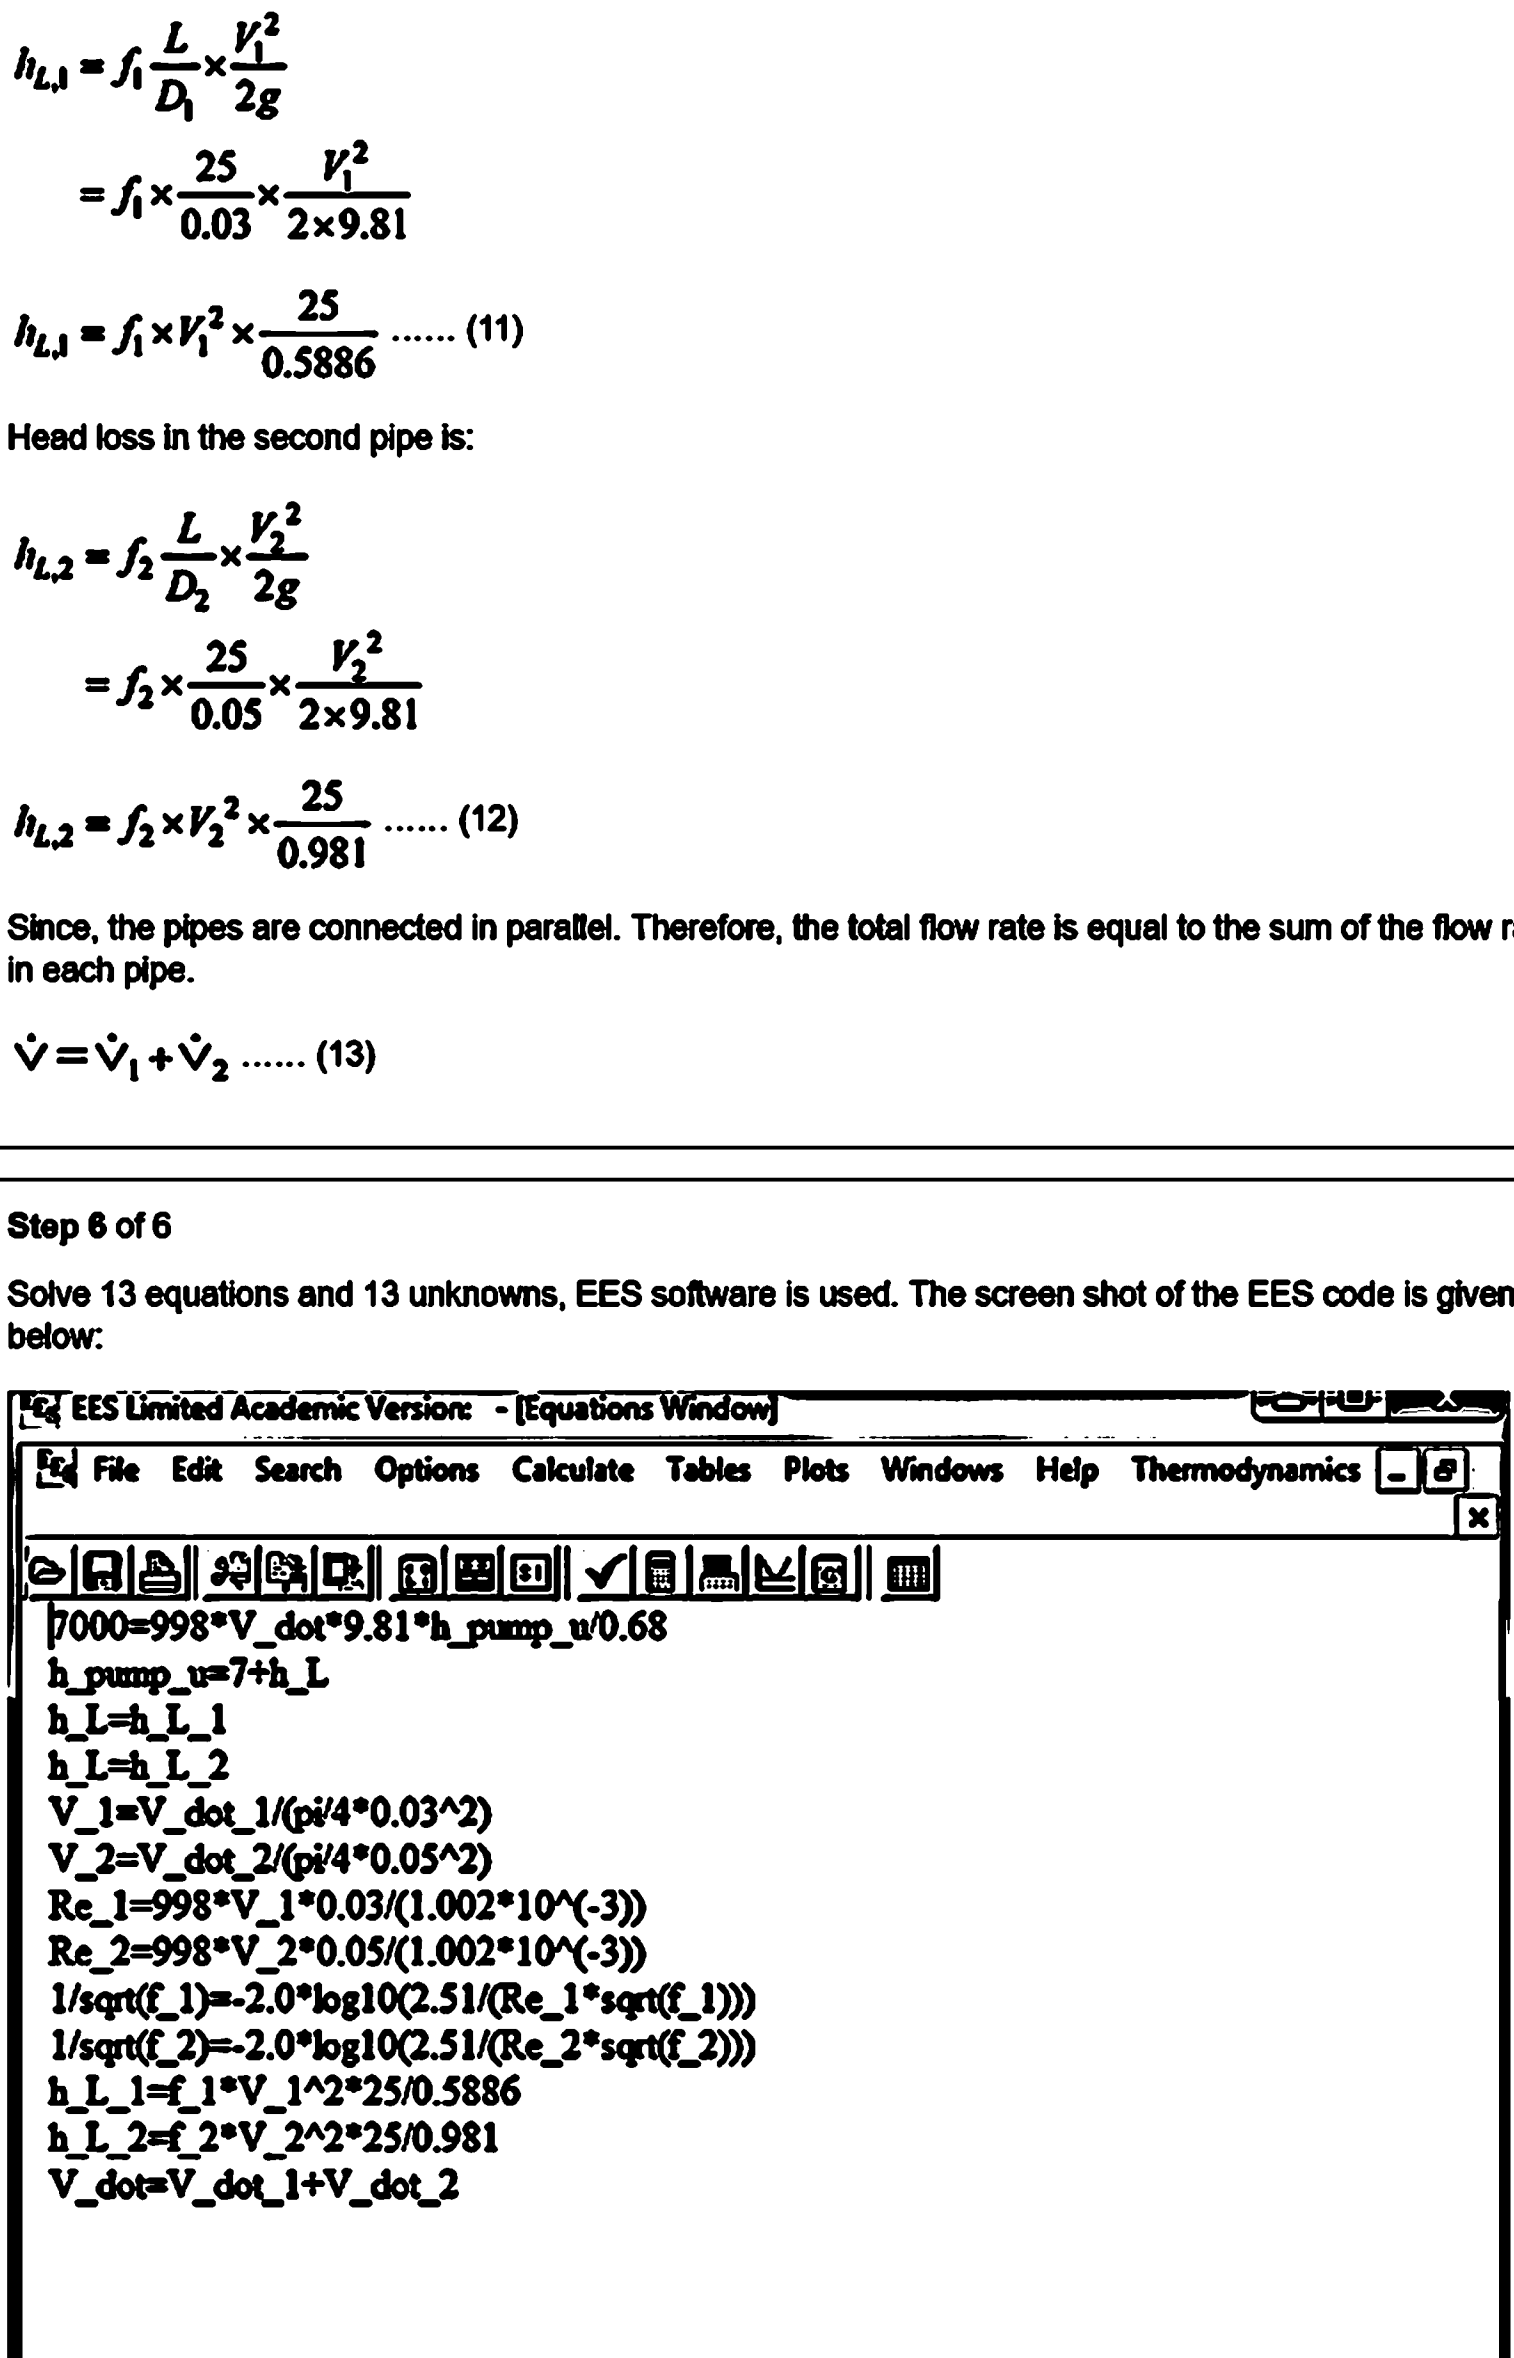
$$= f_1 \times \frac{25}{0.03} \times \frac{V_1^2}{2 \times 9.81}$$

$$h_{L,1} = f_1 \times V_1^2 \times \frac{25}{0.5886} \quad \text{..... (11)}$$

Head loss in the second pipe is:

$$h_{L,2} = f_2 \frac{L}{D_2} \times \frac{V_2^2}{2g}$$

$$= f_2 \times \frac{25}{0.05} \times \frac{V_2^2}{2 \times 9.81}$$



$$h_{L,2} = f_2 \times V_2^2 \times \frac{25}{0.981} \quad \text{..... (12)}$$

Since, the pipes are connected in parallel. Therefore, the total flow rate is equal to the sum of the flow rates in each pipe.

$$\dot{V} = \dot{V}_1 + \dot{V}_2 \quad \text{..... (13)}$$

Step 6 of 6

Solve 13 equations and 13 unknowns, EES software is used. The screen shot of the EES code is given below:

```
h_L_2=f_2*V_2^2*25/0.981
V_dot=V_dot_1+V_dot_2
```

The solution of the EES code is shown below:

EES Limited Academic Version: - [Solution]

File Edit Search Options Calculate Tables Plots Windows Help Thermodynamics

Main

Unit Settings: [kJ]/[C]/[kPa]/[kg]/[degrees]

$f_1 = 0.01638$ [m] $f_2 = 0.01391$ $h_L = 19.53$ [m]

$h_{L,1} = 19.53$ [m] $h_{L,2} = 19.53$ [m] $h_{pump,u} = 26.53$ [m]

$Re_1 = 158345$ $Re_2 = 369722$ $V_1 = 5.299$ [m/s]

$V_2 = 7.424$ [m/s] $\dot{V} = 0.01832$ [m^3/s] $\dot{V}_1 = 0.003746$ [m^3/s]

$\dot{V}_2 = 0.01458$ [m^3/s]

9 potential unit problems were detected. Check Units

Calculation time = .0 sec

Therefore, the total flow rate between the reservoirs, $\dot{V} = 0.01832$ m^3/s

The flow rate of the first pipe, $\dot{V}_1 = 0.003746$ m^3/s

The flow rate of the second pipe, $\dot{V}_2 = 0.01458$ m^3/s

Question: 14.086P pg 1

Shell-and-tube heat exchangers with hundreds of tubes housed in a shell are commonly used in practice for heat transfer between two fluids. Such a heat exchanger used in an active solar hot-water system transfers heat from a water-antifreeze solution flowing through the shell and the solar collector to fresh water flowing through the tubes at an average temperature of 60°C at a rate of 15 L/s. The heat exchanger contains 80 brass tubes 1 cm in inner diameter and 1.5 m in length. Disregarding inlet, exit, and header losses, determine the pressure drop across a single tube and the pumping power required by the tube-side fluid of the heat exchanger.

After operating a long time, 1-mm-thick scale builds up on the inner surfaces with an equivalent roughness of 0.4 mm. For the same pumping power input, determine the percent reduction in the flow rate of water through the tubes.

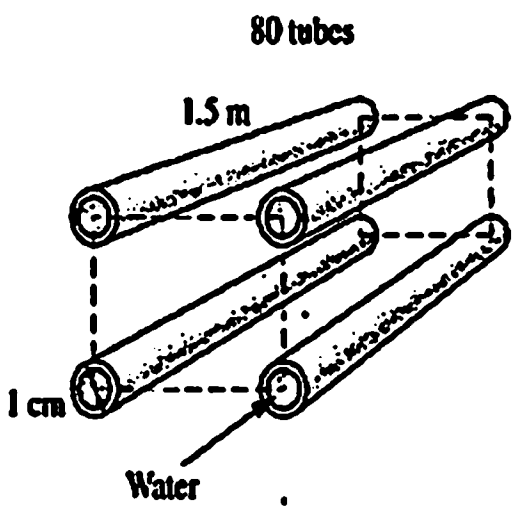


FIGURE P14–86

Step 1 of 14

The number of brass tubes, $N_{tubes} = 80$

The length of brass tubes, $L = 1.5\text{m}$

The inner diameter of brass tubes, $D = 1\text{cm} = 0.01\text{m}$

The flow rate of water, $\dot{V}_{clean} = 15\text{L/s} = 0.015\text{m/s}$

The average water temperature, $T = 60°\text{C}$

Take density of water, $\rho = 983.3\text{kg/m}^3$

Acceleration due to gravity, $g = 9.81\text{m/s}^2$

Step 2 of 14

From the properties of saturated water table, at temperature $T = 60°$, we have

Density, $\rho = 983.3\text{kg/m}^3$

Dynamic viscosity, $\mu = 0.467\times10^{-3}\,\text{kg/m}\cdot\text{s}$

From the table of Equivalent roughness values for new commercial pipes, we have

The roughness value for brass tubing, $\varepsilon = 0.0015\text{mm} = 1.5\times10^{-6}\,\text{m}$

Step 3 of 14

The average velocity of water,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{\dot{V}}{N_{tubes}\left(\frac{\pi D^2}{4}\right)}$$

$$= \frac{0.015}{80\left(\frac{\pi\times0.01^2}{4}\right)}$$

$$= 2.387\,\text{m/s}$$

Step 4 of 14

The Reynolds number for the flow,

$$\text{Re} = \frac{\rho VD}{\mu}$$

$$= \frac{983.3\times2.387\times0.01}{0.467\times10^{-3}}$$

$$= 50260$$

$\text{Re} > 4000$, therefore, the flow is turbulent.

Step 5 of 14

The relative roughness of the pipe,

$$\varepsilon/D = \frac{1.5\times10^{-6}}{0.01}$$

$$= 1.5\times10^{-4}$$

The friction factor corresponding to the relative roughness and Reynolds number can be determined by using Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

$$= -2.0\log\left(\frac{1.5\times10^{-4}}{3.7} + \frac{2.51}{(50260)\sqrt{f}}\right)$$

$$f = 0.0214$$

Step 6 of 14

The pressure drop in the pipe,

$$\Delta P = f\frac{L}{D}\frac{\rho V^2}{2000}$$

$$= 0.0214\times\frac{1.5}{0.01}\times\frac{983.3\times2.387^2}{2000}$$

$$= 8.99\text{kPa}$$

Therefore, the pressure drop in the pipe is $\boxed{\Delta P = 8.99\text{kPa}}$.

Step 7 of 14

The required pumping power input,

$$\dot{W}_{pump} = \dot{V}\Delta P$$

$$= 0.015\times8.99$$

$$= 0.13485\text{kW}$$

Therefore, the required pumping power input for overcoming the3 frictional losses

The required pumping power input

$$\dot{W}_{pump} = \dot{V}\Delta P$$
$$= 0.015 \times 8.99$$
$$= 0.13485\text{kW}$$

Therefore, the required pumping power input for overcoming the3 frictional losses is $\boxed{\dot{W}_{input} = 0.13485\text{kW}}$.

Step 8 of 14

If the 1mm thick scale builds up on the inner surface of the tubes then the 1cm diameter becomes 0.8cm .

Equivalent roughness value, $\varepsilon = 0.4\text{mm} = 0.0004\text{m}$

Assume that the flow rate and average velocity are unknowns.

Step 9 of 14

The average velocity,

$$V = \frac{\dot{V}}{A_c}$$
$$= \frac{\dot{V}}{N_{tubes}\left(\frac{\pi D^2}{4}\right)}$$
$$= \frac{\dot{V}}{80\left(\frac{\pi(0.008)^2}{4}\right)}$$
$$V = 248.679\dot{V}\ \text{m/s} \qquad \ldots\ldots (1)$$

Step 10 of 14

The Reynolds number,

$$\text{Re} = \frac{\rho VD}{\mu}$$
$$= \frac{983.3 \times V \times 0.008D}{0.467 \times 10^{-3}}$$
$$\text{Re} = 16844.539VD \qquad \ldots\ldots (2)$$

Step 11 of 14

The relative roughness of the pipe,

$$\varepsilon/D = \frac{0.0004}{0.008}$$
$$= 0.05$$

The friction factor corresponding to the relative roughness and Reynolds number can be determined by using Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$
$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{0.05}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right) \qquad \ldots\ldots (3)$$

Step 12 of 14

The pressure drop in the pipe,

$$\Delta P = f\frac{L}{D}\frac{\rho V^2}{2000}$$
$$= f \times \frac{1.5}{0.008} \times \frac{983.3 \times V^2}{2000}$$
$$\Delta P = 92.184V^2\ \text{kPa} \qquad \ldots\ldots (4)$$

The use full power input,

$$\dot{W}_{input} = 0.13485\text{kW} \qquad \ldots\ldots (5)$$

Step 13 of 14

We have five equations and five unknowns, by using trial and error approach and by assuming a velocity value, we get the unknown values as

Friction factor, $f = 0.0723$

Reynolds number, $\text{Re} = 28870$

Average velocity, $V = 1.714\text{m/s}$

Pressure drop, $\Delta P = 19.6\text{kPa}$

Flow rate, $\dot{V}_{dirty} = 0.00689\text{m}^3/\text{s} = 6.89\text{L/s}$

Step 14 of 14

The percentage reduction in the flow rate,

$$\text{Reduction ration} = \frac{\dot{V}_{clean} - \dot{V}_{dirty}}{\dot{V}_{clean}}$$
$$= \frac{15 - 6.89}{15}$$
$$= 0.54$$
$$= 54\%$$

Therefore, 54% percentage of flow rate is reduced due to the formation of scale.

Question: 14.087P

The compressed air requirements of a manufacturing facility are met by a 150-hp compressor that draws in air from the outside through an 12-m-long, 18-cm-diameter duct made of thin galvanized iron sheets. The compressor takes in air at a rate of 0.27 m3/s at the outdoor conditions of 15°C and 95 kPa. Disregarding any minor losses, determine the useful power used by the compressor to overcome the frictional losses in this duct.

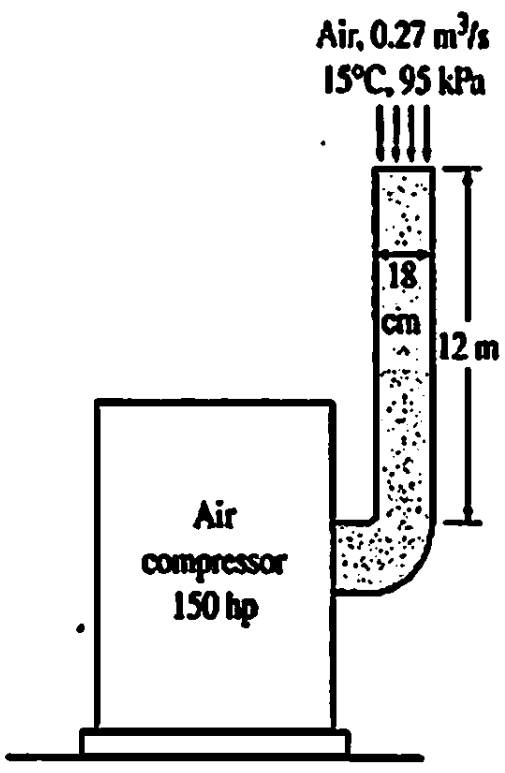

FIGURE P14–87

Step 1 of 5

Given data:

The length of the duct, $L = 12\ \text{m}$

The diameter of the duct, $D = 0.18\ \text{m}$

The rate of air intake, $\dot{V} = 0.27\ \text{m}^3/s$

The outside temperature of the air, $T = 15°\text{C}$

The outside pressure, $P = 95000\ \text{Pa}$

From the properties table of air at 1 atm (101.3 kPa) and 15°C,

The density, $\rho' = 1.225\ \text{kg}/\text{m}^3$.

The dynamic viscosity, $\mu' = 1.802 \times 10^{-5}\ \text{kg}/\text{m} \cdot s$.

Step 2 of 5

Then, the density at 95 kPa,

$$\rho = \frac{P}{P'}\rho'$$

$$= \frac{95}{101.3}(1.225)$$

$$= 1.149\ \text{kg}/\text{m}^3$$

The dynamic viscosity is independent of pressure.

So, the dynamic viscosity at 95 kPa is $\mu = 1.802 \times 10^{-5}\ \text{kg}/\text{m} \cdot s$

For galvanized iron, the roughness is $\varepsilon = 1.5 \times 10^{-4}\ \text{m}$.

The cross-sectional flow area between the glass cover,

$$A_t = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}(0.18)^2$$

$$= 25.45 \times 10^{-3}\ \text{m}^2$$

Step 3 of 5

The average velocity,

$$V = \frac{\dot{V}}{A_t}$$

$$= \frac{0.27}{25.45 \times 10^{-3}}$$

$$= 10.61\ \text{m}/s$$

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{(1.149)(10.61)\left(18 \times 10^{-2}\right)}{1.802 \times 10^{-5}}$$

$$= 121773.6$$

Since Re > 4000, the flow is turbulent.

Step 4 of 5

For turbulent flow, the friction factor (f) according to Colebrook equation is

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

$$= -2.0 \log\left(\frac{1.5 \times 10^{-4}/0.18}{3.7} + \frac{2.51}{121773.6\sqrt{f}}\right)$$

$$= -2.0 \log\left(0.2252 \times 10^{-3} + \frac{20.61 \times 10^{-6}}{\sqrt{f}}\right)$$

Solve the equation for f, we get

$$f = 0.0212$$

Step 5 of 5

The pressure drop,

$$\Delta P_L = f\frac{L}{D}\frac{\rho V^2}{2}$$

$$= 0.0212\left[\frac{12}{0.18}\right]\left[\frac{(1.149)(10.61)^2}{2}\right]$$

$$= 91.4\ \text{Pa}$$

The power required,

$$\dot{W}_{\text{pump}} = \dot{V} \times \Delta P$$

$$= (0.27)(91.4)$$

$$= 24.678\ \text{W}$$

Therefore, the power used to overcome the frictional losses is $\boxed{\dot{W}_{\text{pump}} = 24.678\ \text{W}}$

Question: 14.088P

A house built on a riverside is to be cooled in summer by utilizing the cool water of the river. A 15-m-long section of a circular stainless-steel duct of 20-cm diameter passes through the water. Air flows through the underwater section of the duct at 3 m/s at an average temperature of 15°C. For an overall fan efficiency of 62 percent, determine the fan power needed to overcome the flow resistance in this section of the duct.

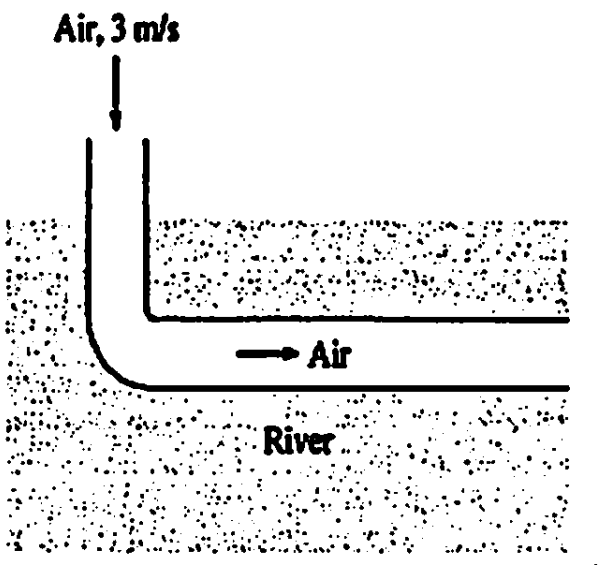

FIGURE P14–88

Step 1 of 6

Given data:

The length of the duct, $L = 15\ \text{m}$

The diameter of the duct, $D = 20\ \text{cm} = 0.2\text{m}$

The velocity of air, $V = 3\ \text{m/s}$

The temperature of the air, $T = 15°\text{C}$

The overall fan efficiency, $\eta = 62\% = 0.62$

The duct is made of stainless steel.

Step 2 of 6

The flow is assumed to be steady, incompressible and fully developed. The minor losses are neglected. The pressure of air is assumed to be 1 atm.

From the properties table of air at 1 atm pressure and 15°C

The density is $\rho = 1.225\ \text{kg/m}^3$

The dynamic viscosity is $\mu = 1.802 \times 10^{-5}\ \text{kg/m} \cdot \text{s}$

For galvanized iron, the roughness is $\varepsilon = 0.002\ \text{mm} = 2 \times 10^{-6}\ \text{m}$

Step 3 of 6

The cross-sectional flow area between the glass covers

$$A_c = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.2\ \text{m})^2$$

$$= 31.416 \times 10^{-3}\ \text{m}^2$$

The volumetric flow rate of air,

$$\dot{V} = VA_c$$

$$= (3\ \text{m/s})(31.416 \times 10^{-3}\ \text{m}^2)$$

$$= 0.0942\ \text{m}^3/\text{s}$$

Step 4 of 6

The Reynolds number,

$$\text{Re} = \frac{\rho VD}{\mu}$$

$$= \frac{(1.225\ \text{kg/m}^3)(3\ \text{m/s})(0.2\text{m})}{1.802 \times 10^{-5}\ \text{kg/m} \cdot \text{s}}$$

$$= 40.788 \times 10^3$$

Since $\text{Re} > 4000$, the flow is turbulent.

Step 5 of 6

For turbulent flow, the Colebrook equation for friction factor (f) is

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{2 \times 10^{-6}\ \text{m}/0.2\text{m}}{3.7} + \frac{2.51}{(40.788 \times 10^3)\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(2.703 \times 10^{-6} + \frac{61.54 \times 10^{-6}}{\sqrt{f}}\right)$$

By solving the above equation for f, we get the friction factor as $f = 0.0219$

Step 6 of 6

The pressure drop,

$$\Delta P_L = f \frac{L}{D} \frac{\rho V^2}{2}$$

$$= 0.0219\left[\frac{15\ \text{m}}{0.2\text{m}}\right]\left[\frac{(1.225\ \text{kg/m}^3)(3\ \text{m/s})^2}{2}\right]$$

$$= 9.054\ \text{Pa}$$

The fan power required,

$$\dot{W}_{\text{fan}} = \frac{\dot{W}_{\text{pump}}}{\eta}$$

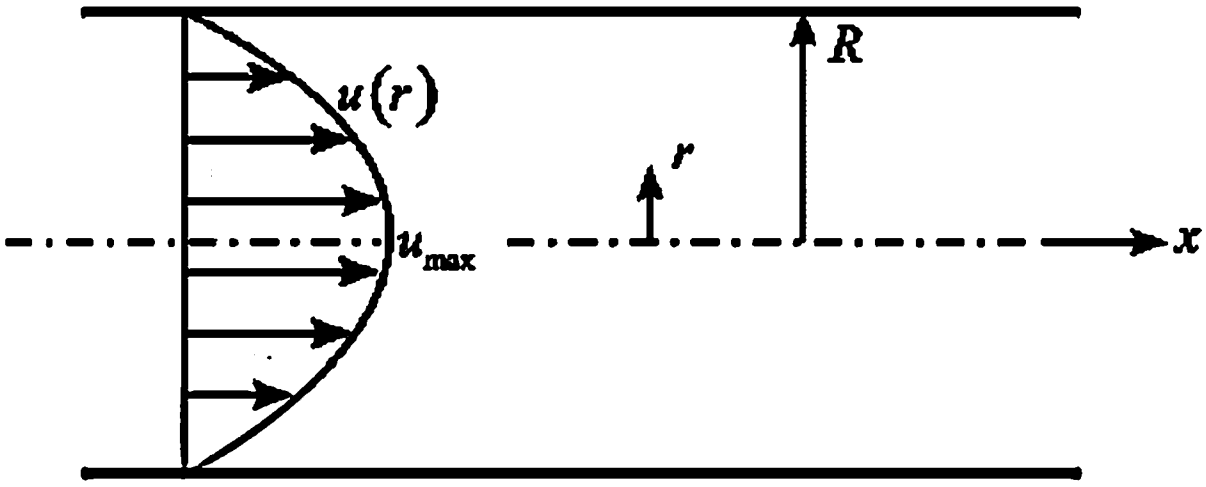
$$= \frac{(\dot{V})(\Delta P)}{\eta}$$

$$= \frac{(0.0942\ \text{m}^3/\text{s})(9.054\ \text{Pa})}{0.62}$$

$$= 1.376\ \text{W}$$

Therefore, the fan power required to overcome the flow resistance is $\boxed{\dot{W}_{\text{fan}} = 1.4\ \text{W}}$

Question: 14.089P



The velocity profile in fully developed laminar flow in a circular pipe, in m/s, is given by $u(r) = 6(1 - 100r^2)$, where r is the radial distance from the centerline of the pipe in m. Determine (*a*) the radius of the pipe, (*b*) the average velocity through the pipe, and (*c*) the maximum velocity in the pipe.

Step 1 of 4

Given data:

The velocity profile of the flow is $u(r) = 6\left(1 - 100r^2\right)$

Velocity profile of the flow is as shown below.

Step 2 of 4

(a)

The velocity profile of the fully developed laminar flow for a circular channel is given by

$$u(r) = u_{max}\left(1 - \frac{r^2}{R^2}\right) \qquad \ldots\ldots (1)$$

where, r is the radius of the differential fluid element

R is the radius of the pipe and

u_{max} is the maximum velocity, at the center of the pipe.

By comparing the given velocity profile with equation (1), we get

The maximum velocity as $u_{max} = 6$ m/s

The ratio of squares of the radii,

$$\frac{r^2}{R^2} = 100r^2$$

$$R^2 = \frac{1}{100}$$

$$R = 0.1\,\text{m}$$

Hence the radius of the pipe is $\boxed{R = 0.1\,\text{m}}$

Step 3 of 4

(b)

The average velocity of the flow is given by

$$V_{avg} = \frac{u_{max}}{2}$$

$$= \frac{6\,\text{m/s}}{2}$$

$$= 3\,\text{m/s}$$

Therefore, the average velocity through the pipe is $\boxed{V_{avg} = 3\,\text{m/s}}$

Step 4 of 4

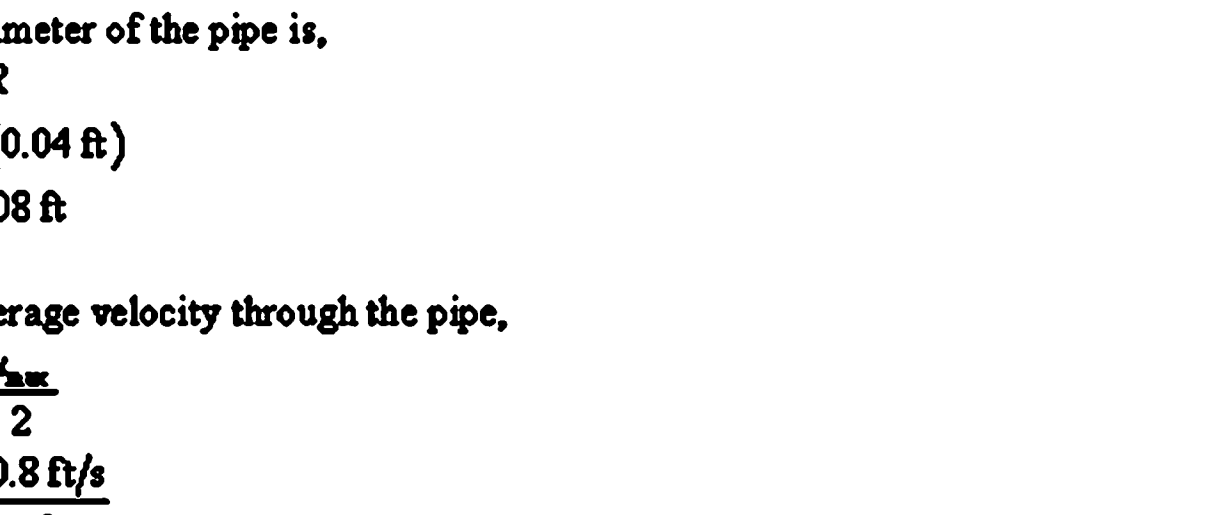
c)

By comparing the given velocity profile with equation (1), we get

The maximum velocity as $\boxed{u_{max} = 6\ \text{m/s}}$

Question: 14.090P

The velocity profile in a fully developed laminar flow of water at 40°F in a 115-ft-long horizontal circular pipe, in ft/s, is given by $u(r) = 0.8(1 - 625r2)$, where r is the radial distance from the centerline of the pipe in ft. Determine (*a*) the volume flow rate of water through the pipe,(*b*) the pressure drop across the pipe, and (*c*) the useful pumping power required to overcome this pressure drop.



Step 1 of 6

Given data:

The length of the pipe, $L = 155$ ft

The velocity profile, $u(r) = 0.8\left(1 - 625r^2\right)$

Velocity profile of the flow is as shown below.

Step 2 of 6

(a) The velocity profile of the fully developed laminar flow for a circular channel is given by

$$u(r) = u_{max}\left(1 - \frac{r^2}{R^2}\right) \qquad \ldots\ldots (1)$$

where, r is the radius of the differential fluid element

R is the radius of the pipe and

u_{max} is the maximum velocity, at the center of the pipe.

By comparing the given velocity profile with equation (1), we get

The maximum velocity as $u_{max} = 0.8$ ft/s

The ratio of squares of the radii,

$$\frac{r^2}{R^2} = 625r^2$$

$$R^2 = \frac{1}{625}$$

$$R = 0.04 \text{ ft}$$

Step 3 of 6

The diameter of the pipe is,

$$D = 2R$$
$$= 2(0.04 \text{ ft})$$
$$= 0.08 \text{ ft}$$

The average velocity through the pipe,

$$V_{avg} = \frac{u_{max}}{2}$$
$$= \frac{0.8 \text{ ft/s}}{2}$$
$$= 0.4 \text{ ft/s}$$

Step 4 of 6

The cross sectional flow area,

$$A_c = \pi R^2$$
$$= \pi(0.04 \text{ ft})^2$$
$$= 5.026 \times 10^{-3} \text{ ft}^2$$

The flow rate,

$$\dot{V} = V_{avg} A_c$$
$$= (0.4 \text{ ft/s})\left(5.026 \times 10^{-3} \text{ ft}^2\right)$$
$$= 2 \times 10^{-3} \text{ ft}^3/\text{s}$$

Therefore, the flow rate, $\boxed{\dot{V} = 2 \times 10^{-3} \text{ ft}^3/\text{s}}$

Step 5 of 6

(b) From the properties table of saturated water, at 40°F

The dynamic viscosity is $\mu = 1.308 \times 10^{-3}$ lbm/ft · s

The pressure drop for laminar flow in a horizontal pipe,

$$\Delta P = \frac{32 \mu L V_{avg}}{D^2}$$
$$= \frac{32\left(1.308 \times 10^{-3} \text{lbm/ft} \cdot \text{s}\right)(155 \text{ ft})(0.4 \text{ ft/s})}{(0.08 \text{ ft})^2}$$
$$= 405.48 \text{ lbf/ft}^2$$

Therefore, the pressure drop for laminar flow in a horizontal pipe is $\boxed{\Delta P = 405.48 \text{ lbf/ft}^2}$

Step 6 of 6

(c) The useful pumping power required,

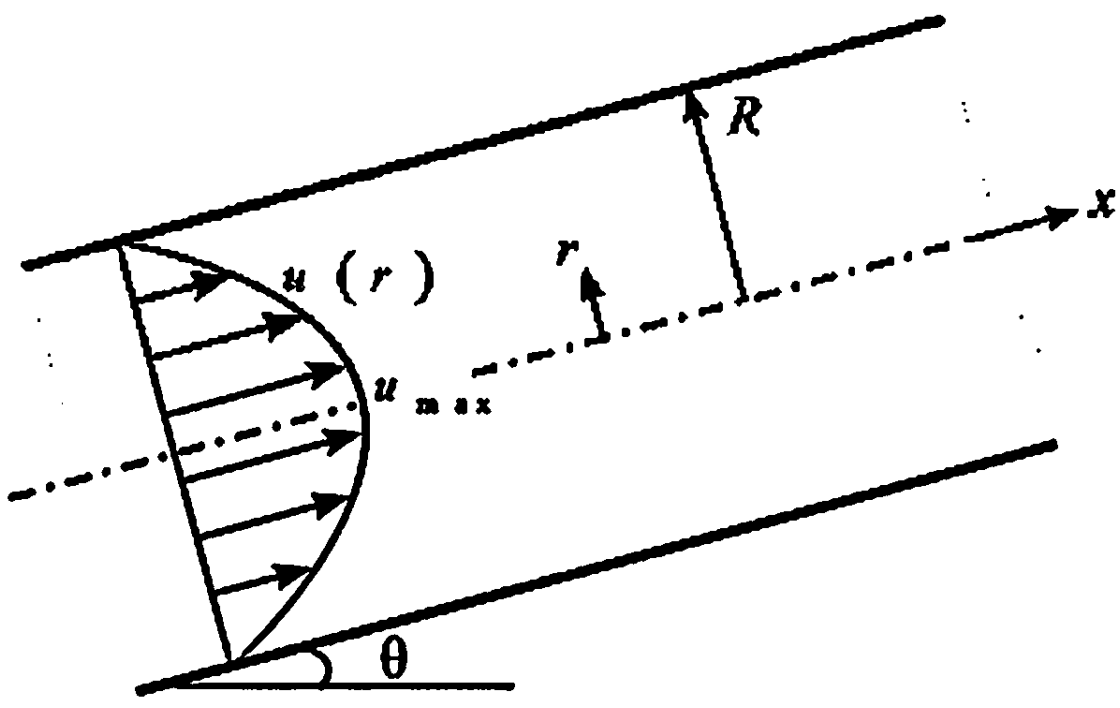
$$\dot{W}_{pump,u} = (\dot{V})(\Delta P)$$
$$= \left(2 \times 10^{-3} \text{ ft}^3/\text{s}\right)\left(405.48 \text{ lbf/ft}^2\right)$$
$$= 0.811 \text{ lbf} \cdot \text{ft/s}$$

Therefore, the useful pumping power required is $\boxed{\dot{W}_{pump,u} = 0.811 \text{lbf} \cdot \text{ft/s}}$

Question: 14.091P

Repeat Prob. 14-90E assuming the pipe is inclined 12° from the horizontal and the flow is uphill.

Step 1 of 6



Given data:

The length of the pipe, $L = 155$ ft

The velocity profile, $u(r) = 0.8\left(1 - 625r^2\right)$

The pipe is inclined at an angle of $\theta = 12°$

Velocity profile of the flow is as shown below.

Step 2 of 6

(a)

The velocity profile of the fully developed laminar flow for a circular channel is given by

$$u(r) = u_{max}\left(1 - \frac{r^2}{R^2}\right) \qquad \ldots\ldots (1)$$

where, r is the radius of the differential fluid element

R is the radius of the pipe and

u_{max} is the maximum velocity, at the center of the pipe.

By comparing the given velocity profile with equation (1), we get

The maximum velocity as $u_{max} = 0.8$ ft/s

The ratio of squares of the radii,

$$\frac{r^2}{R^2} = 625r^2$$

$$R^2 = \frac{1}{625}$$

$$R = 0.04 \text{ ft}$$

Step 3 of 6

The diameter of the pipe is,

$$D = 2R$$
$$= 2(0.04 \text{ ft})$$
$$= 0.08 \text{ ft}$$

The average velocity through the pipe,

$$V_{avg} = \frac{u_{max}}{2}$$
$$= \frac{0.8 \text{ ft/s}}{2}$$
$$= 0.4 \text{ ft/s}$$

Step 4 of 6

The cross sectional flow area,

$$A_c = \pi R^2$$
$$= \pi(0.04 \text{ ft})^2$$
$$= 5.026 \times 10^{-3} \text{ ft}^2$$

The flow rate,

$$\dot{V} = V_{avg} A_c$$
$$= (0.4 \text{ ft/s})\left(5.026 \times 10^{-3} \text{ ft}^2\right)$$
$$= 2 \times 10^{-3} \text{ ft}^3/\text{s}$$

Therefore, the flow rate, $\boxed{\dot{V} = 2 \times 10^{-3} \text{ ft}^3/\text{s}}$

Step 5 of 6

(b)

From the properties table of saturated water, at 40°F

The dynamic viscosity is $\mu = 1.308 \times 10^{-3}$ lbm/ft · s

The density of the water is $\rho = 62.42$ lbm/ft^3

The relation between pressure drop and volumetric flow rate is given by

$$\dot{V} = \frac{\left[\Delta P - \rho g L \sin\theta\right]\pi D^4}{128 \mu L}$$

$$\Delta P = \frac{128 \mu L \dot{V}}{\pi D^4} + \rho g L \sin\theta$$
$$= \frac{128\left(1.308 \times 10^{-3}\right)(155)\left(2 \times 10^{-3}\right)}{\pi(0.08)^4} + (62.42)(32.2)(155)\sin 12°$$
$$= 65175.78 \text{ lbf/ft}^2$$

Therefore, the pressure drop for laminar flow in an inclined pipe is $\boxed{\Delta P = 405.48 \text{ lbf/ft}^2}$

Step 6 of 6

(c)

The useful pumping power required,

$$\dot{W}_{pump,u} = (\dot{V})(\Delta P)$$
$$= \left(2 \times 10^{-3} \text{ ft}^3/\text{s}\right)\left(65175.78 \text{ lbf/ft}^2\right)$$
$$= 130.35 \text{ lbf} \cdot \text{ft/s}$$

Therefore, the useful pumping power required is $\boxed{\dot{W}_{pump,u} = 130.35 \text{ lbf} \cdot \text{ft/s}}$

Question: 14.092P

A highly viscous liquid discharges from a large container through a small-diameter tube in laminar flow. Disregarding entrance effects and velocity heads, obtain a relation for the variation of fluid depth in the tank with time.

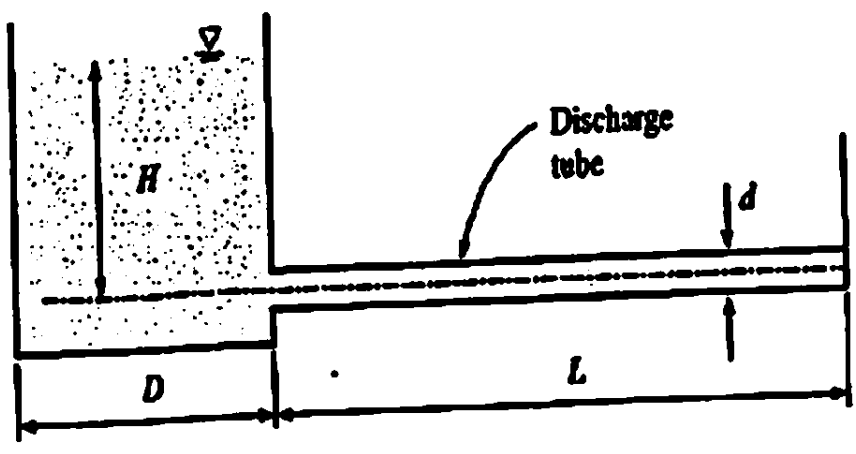


FIGURE P14-92

Step 1 of 5

Consider a tank containing incompressible fluid of height h. The liquid flows through the discharge tube of length L and diameter d. The flow is laminar.

For laminar flow, the friction factor is given by

$$f = \frac{64}{\text{Re}}$$
$$= \frac{64}{(Vd/\nu)}$$

By considering the free surface of the liquid in the tank as point-1 and the exit of the discharge pipe as point-2, from the energy balance equation for a control volume, we have

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_L \qquad \text{..... (1)}$$

Step 2 of 5

Here, both the points 1 and 2 are opened to the atmosphere. So the pressure that acts on both these points is atmospheric pressure.

$$P_1 = P_2 = P_{atm}$$

The velocity of the liquid at the free surface is zero as the fluid is stationary at the surface

$$V_1 = 0$$

The velocity head are negligible. Thus,

$$\frac{V_1^2}{2g} = \frac{V_2^2}{2g} \approx 0$$

Let point 2 be the reference level. Then,

$$z_2 = 0$$
$$z_1 = h$$

The average flow velocity,

$$V = \frac{\dot{V}}{A_c}$$
$$= \frac{4\dot{V}}{\pi d^2}$$

Step 3 of 5

By substituting the values in equation (1), we get

$$\frac{P_{atm}}{\rho g} + 0 + h = \frac{P_{atm}}{\rho g} + 0 + 0 + h_L$$
$$h = h_L$$

The expression for head loss is

$$h_L = \frac{f L V^2}{2gd}$$
$$= \frac{64L}{2(Vd/\nu)gd}\left(\frac{4\dot{V}}{\pi d^2}\right)^2$$
$$= \frac{128\nu L\dot{V}}{\pi g d^4}$$

Step 4 of 5

As the flow occurs the height of the liquid in the tank decreases. Hence the volume flow rate can be written as,

$$\dot{V} = -\left(A_{c,\text{tank}}\right)\frac{dh}{dt}$$
$$= -\left(\frac{\pi D^2}{4}\right)\frac{dh}{dt}$$

The negative sign indicates that the rate of change of liquid height is decreasing.

Now the expression for head loss becomes

$$h_L = \frac{128\nu L}{\pi g d^4}\left(-\frac{\pi D^2}{4}\frac{dh}{dt}\right)$$
$$h_L = -\frac{32\nu L D^2}{gd^4}\frac{dh}{dt}$$
$$dt = -\frac{32\nu L D^2}{gd^4}\frac{dh}{h} \qquad \text{..... (2)}$$

Step 5 of 5

By integrating the equation (2), we get

$$\int_0^t dt = -\frac{32\nu L D^2}{gd^4}\int_H^h \frac{dh}{h}$$
$$[t]_0^t = -\frac{32\nu L D^2}{gd^4}\left[\ln(h)\right]_H^h$$
$$(t-0) = -\frac{32\nu L D^2}{gd^4}\left(\ln(h) - \ln(H)\right)$$
$$t = -\frac{32\nu L D^2}{gd^4}\ln\left(\frac{h}{H}\right)$$

Therefore, the relation for the variation of fluid depth in the tank with time is

$$\boxed{t = -\frac{32\nu L D^2}{gd^4}\ln\left(\frac{h}{H}\right)}$$

Question: 14.093P

A student is to determine the kinematic viscosity of an oil using the system shown in Prob. 14-92. The initial fluid height in the tank is $H = 40$ cm, the tube diameter is $d = 6$ mm, the tube length is $L = 0.65$ m, and the tank diameter is $D = 0.63$ m. The student observes that it takes 1750 s for the fluid level in the tank to drop to 36 cm. Find the fluid viscosity.

Step 1 of 6

Given data:

The initial fluid height of the tank, $H = 40 \text{ cm} = 40 \times 10^{-2} \text{ m}$

The tube diameter, $d = 6 \text{ mm} = 6 \times 10^{-3} \text{ m}$

The tube length, $L = 0.65 \text{ m}$

The tank diameter, $D = 0.63 \text{ m}$

The final height of fluid in tank is $h = 36 \text{ cm} = 36 \times 10^{-2} \text{ m}$

The duration of discharge from tank is $t = 1750 \text{ s}$

Step 2 of 6

For laminar flow, the friction factor is given by

$$f = \frac{64}{\text{Re}} = \frac{64}{(Vd/\nu)} = \frac{64\nu}{V\left(6\times10^{-3}\right)}$$

By considering the free surface of the liquid in the tank as point-1 and the exit of the discharge pipe as point-2, from the energy balance equation for a control volume, we have

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_L \qquad \text{..... (1)}$$

Step 3 of 6

Here, both the points 1 and 2 are opened to the atmosphere. So the pressure that acts on both these points is atmospheric pressure.

$P_1 = P_2 = P_{atm}$

The velocity of the liquid at the free surface is zero as the fluid is stationary at the surface

$V_1 = 0$

The velocity head are negligible. Thus,

$$\frac{V_1^2}{2g} = \frac{V_2^2}{2g} \approx 0$$

Let point 2 be the reference level. Then,

$z_2 = 0$

$z_1 = h$

The average flow velocity,

$$V = \frac{\dot{V}}{A_c} = \frac{4\dot{V}}{\pi\left(6\times10^{-3}\right)^2} = \frac{\dot{V}}{\pi\left(9\times10^{-6}\right)}$$

Step 4 of 6

By substituting the values in equation (1), we get

$$\frac{P_{atm}}{\rho g} + 0 + h = \frac{P_{atm}}{\rho g} + 0 + 0 + h_L$$

$h = h_L$

The expression for head loss is

$$h_L = \frac{f L V^2}{2gd} = \frac{64 L V^2}{2(Vd/\nu)gd} = \frac{32\nu L V}{gd^2} = \frac{32\nu(0.65)}{g\left(6\times10^{-3}\right)^2}\left(\frac{\dot{V}}{\pi\left(9\times10^{-6}\right)}\right) = \left(2\times10^{9}\right)\left(\nu\times\dot{V}\right)$$

Step 5 of 6

As the flow occurs the height of the liquid in the tank decreases. Hence the volume flow rate can be written as,

$$\dot{V} = -\left(A_{c,\text{tank}}\right)\frac{dh}{dt} = -\left[\frac{\pi}{4}(0.63)^2\right]\frac{dh}{dt} = -0.312\frac{dh}{dt}$$

The negative sign indicates that the rate of change of liquid height is decreasing.

Now the expression for head loss becomes

$$h_L = \left(2\times10^{9}\right)(\nu)\left(-0.312\frac{dh}{dt}\right)$$

$$h = -624\times10^{6}\times\nu\frac{dh}{dt}$$

$$dt = -624\times10^{6}\times\nu\times\frac{dh}{h} \qquad \text{..... (2)}$$

Step 6 of 6

By integrating the equation (2), we get

$$\int_0^t dt = -624\times10^{6}\times\nu\int_H^h \frac{dh}{h}$$

$$[t]_0^t = -624\times10^{6}\times\nu\left[\ln(h)\right]_H^h$$

$$(t-0) = -624\times10^{6}\times\nu\left(\ln(h) - \ln(H)\right)$$

$$t = -624\times10^{6}\times\nu\ln\left(\frac{h}{H}\right)$$

$$\frac{1}{\nu} = \frac{-624\times10^{6}}{t}\ln\left(\frac{h}{H}\right)$$

$$\frac{1}{\nu} = \frac{624\times10^{6}}{1750}\ln\left(\frac{40}{36}\right)$$

$$\nu = 2.67\times10^{-5} \text{ m}^2/\text{s}$$

Therefore, the kinematic viscosity, $\boxed{\nu = 2.67\times10^{-5} \text{ m}^2/\text{s}}$

Question: 14.094P

Water is to be withdrawn from a 7-m-high water reservoir by drilling a well-rounded 4-cm-diameter hole with negligible loss near the bottom and attaching a horizontal 90° bend of negligible length. Taking the kinetic energy correction factor to be 1.05, determine the flow rate of water through the bend if (*a*) the bend is a flanged smooth bend and (*b*) the bend is a miter bend without vanes.

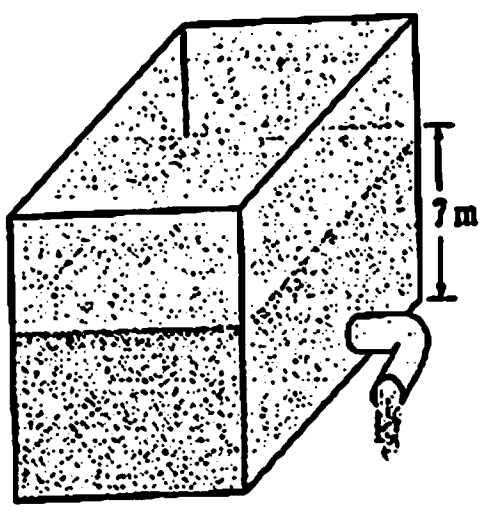

FIGURE P14–94

Step 1 of 5

Given data:

The height of the reservoir, $H = 7\text{ m}$

The diameter of the hole, $D = 4\text{ cm} = 0.04\text{ m}$

The kinetic correction factor, $\alpha_1 = \alpha_2 = 1.05$

Step 2 of 5

Consider the free surface of the reservoir as point 1 and the exit hole as point 2. Now for incompressible and steady flow, the energy balance equation for a control volume is given by

$$\frac{P_1}{\rho g}+\alpha_1\frac{V_1^2}{2g}+z_1=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+z_2+h_L \qquad \text{..... (1)}$$

Here, both the points 1 and 2 are opened to the atmosphere. So

$P_1 = P_2 = P_{atm}$

The velocity of fluid at the free surface is $V_1 = 0$

Let point 2 be the reference level, then

$z_2 = 0$ and

$z_1 = H$

$= 7\text{ m}$

The head loss in the flow is given by

$$h_L = K_L\frac{V_2^2}{2g}$$

Step 3 of 5

By substituting the values in equation (1) we get,

$$\frac{P_{atm}}{\rho g}+(1.05)\frac{(0)^2}{2g}+7=\frac{P_{atm}}{\rho g}+(1.05)\frac{V_2^2}{2g}+0+K_L\frac{V_2^2}{2g}$$

$$7=1.05\frac{V_2^2}{2g}+K_L\frac{V_2^2}{2g}$$

$$7=(1.05+K_L)\frac{V_2^2}{2g}$$

$$V_2^2=\frac{14g}{1.05+K_L}$$

$$V_2=\sqrt{\frac{14g}{1.05+K_L}}$$

The volume flow rate is given by

$$\dot{V}=V_2A_c$$

$$\dot{V}=\sqrt{\frac{14g}{1.05+K_L}}\left(\frac{\pi}{4}D^2\right) \qquad \text{..... (2)}$$

Step 4 of 5

(a) The loss coefficient for flanged smooth bend, $K_L = 0.3$

Now by substituting this value in equation (2), we get

$$\dot{V}=\sqrt{\frac{14g}{1.05+K_L}}\left(\frac{\pi}{4}D^2\right)$$

$$=\sqrt{\frac{14\times9.81}{1.05+0.3}}\left(\frac{\pi}{4}0.04^2\right)$$

$$=\sqrt{\frac{137.34}{1.35}}\left(1.257\times10^{-3}\right)$$

$$=0.01268\text{ m}^3/\text{s}$$

$$=12.68\text{ L/s}$$

Therefore, the flow rate of water through the flanged smooth bend is $\boxed{\dot{V}=12.68\text{ L/s}}$

Step 5 of 5

(b) The loss coefficient for miter bends without vanes, $K_L = 1.1$

Now by substituting this value in equation (2), we get

$$\dot{V}=\sqrt{\frac{14g}{1.05+K_L}}\left(\frac{\pi}{4}D^2\right)$$

$$=\sqrt{\frac{14\times9.81}{1.05+1.1}}\left(\frac{\pi}{4}0.04^2\right)$$

$$=\sqrt{\frac{137.34}{2.15}}\left(1.257\times10^{-3}\right)$$

$$=0.01\text{ m}^3/\text{s}$$

$$=10\text{ L/s}$$

Therefore, the flow rate of water through the miter bends without vanes is $\boxed{\dot{V}=10\text{ L/s}}$

Question: 14.095P pg 1

In a geothermal distinct heating system, 10,000 kg/s of hot water must be delivered a distance of 10 km in a horizontal pipe. The minor losses are negligible, and the only significant energy loss arises from pipe friction The friction factor is taken to be 0.015. Specifying a larger-diameter pipe would reduce water velocity, velocity head pipe friction, and thus power consumption. But a larger pipe would also cost more money initially to purchase and install. Otherwise stated, there is an optimum pipe diameter that will minimize the sum of pipe cost and future electric power cost.

Assume the system will run 24 h/day, every day for 30 years. During this time the cost of electricity remains constant at $0.06/kWh. Assume system performance stays constant over the decades (this may not be true, especially if highly mineralized water is passed through the pipeline - scale may form). The pump has an overall efficiency of 80 percent. The cost to purchase, install, and insulate a l0-km pipe depends on the diameter *D* and is given by cost = $106 *D2*, where *D* is in m. Assuming zero inflation and interest rate for simplicity and zero salvage value and zero maintenance cost, determine the optimum pipe diameter.

Step 1 of 8

Apply Bernoulli's equation between two points of the horizontal pipe.

$$\frac{P_1}{\rho g}+\alpha_1\frac{V_1^2}{2g}+z_1+h_{pump}=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+z_2+h_L \quad \text{..... (1)}$$

Here, P_1, P_2 is the pressures at points 1 and 2, V_1 , V_2 is the velocities at points 1 and 2, z_1 , z_2 is the datum heads at points 1 and 2, g is the acceleration due to gravity, ρ is the density of the hot water, and h_L is the head loss due to friction and head loss due to pump is h_{pump} , α_1 , α_2 kinetic energy correction factors at point 1 and 2.

In the loop system, the pressure at point 1 and 2 is constant.

$$P_1 = P_2 \quad \text{..... (2)}$$

In the loop system, the velocity at point 1 and 2 is constant.

$$V_1 = V_2 \quad \text{..... (3)}$$

In the loop system, the datum head at point 1 and 2 is constant.

$$z_1 = z_2 \quad \text{..... (4)}$$

Substitute the values of equations (2), (3), and (4) in equation (1).

$$\frac{P_1}{\rho g}+\alpha_1\frac{V_1^2}{2g}+z_1+h_{pump}=\frac{P_1}{\rho g}+\alpha_2\frac{V_1^2}{2g}+z_1+h_L$$
$$\alpha_1+h_{pump}=\alpha_2+h_L$$

Substitute 1 for α_1 , 1 for α_2 .

$$h_{pump}=h_L$$

Step 2 of 8

Calculate the volume flow rate.

$$\dot{V}=\frac{\dot{m}}{\rho}$$

Here, mass flow rate of the water is $\dot{m}$, and ρ is density of the water.

Substitute $10000\ \text{kg/s}$ for $\dot{m}$, and $1000\ \text{kg/m}^3$ for ρ .

$$\dot{V}=\frac{\dot{m}}{\rho}$$
$$=\frac{10000}{1000}$$
$$=10\ \text{m}^3/\text{s}$$

Consider the average velocity expression as follows:

$$V=\frac{\dot{V}}{A}$$

Here, V is the average flow velocity, $\dot{V}$ is the volume flow rate, and A is the area of the pipe.

Substitute $\left(\frac{\pi}{4}D^2\right)$ for A .

$$V=\frac{\dot{V}}{\frac{\pi}{4}D^2}$$
$$=\frac{4\dot{V}}{\pi D^2}$$

Here, D is the diameter of the pipe.

Step 3 of 8

Calculate the head loss in the pipe using the equation as follows:

$$\Delta P=f\frac{L}{D}\frac{\rho V^2}{2}$$

Substitute $\left(\frac{4\dot{V}}{\pi D^2}\right)$ for V .

$$\Delta P=f\frac{L}{D}\times\frac{\rho\left(\frac{4\dot{V}}{\pi D^2}\right)^2}{2}$$
$$=f\frac{8L\rho\dot{V}}{D^5\pi^2}$$

Here, *f* is the friction factor, and *L* is the length of the pipe.

Step 4 of 8

Calculate the pumping power using the equation as follows:

$$\dot{W}_{pump}=\frac{\text{Work done done by the pump}}{\text{Overall efficiency of the pump}}$$
$$=\frac{\dot{V}\Delta P}{}$$

Calculate the pumping power using the equation as follows:

$$\dot{W}_{pump} = \frac{\text{Work done done by the pump}}{\text{Overall efficiency of the pump}}$$
$$= \frac{\dot{V}\Delta P}{\eta_{Overall}}$$

Here, $\dot{V}$ is the volume flow rate, ΔP is the pressure difference, and $\eta_{Overall}$ is the overall efficiency.

Substitute $\left(f\frac{8L\rho\dot{V}}{D^5\pi^2}\right)$ for ΔP.

$$\dot{W}_{pump} = \frac{\dot{V}\left(f\frac{8L\rho\dot{V}^2}{D^5\pi^2}\right)}{\eta_{Overall}} \quad \text{..... (5)}$$
$$= \frac{\left(f\frac{8L\rho\dot{V}^3}{D^5\pi^2}\right)}{\eta_{Overall}}$$

Step 5 of 8

Substitute 0.015 for f, 10 km for L, $1000\ \text{kg/m}^3$ for ρ in equation (5).

$$\dot{W}_{pump} = \frac{\left(f\frac{8L\rho\dot{V}^3}{D^5\pi^2}\right)}{\eta_{Overall}}$$
$$= \frac{\left(0.015\times\frac{8\times10000\times1000\times10^3}{0.8}\right)}{\pi^2}$$
$$= 1.51\times10^8\times\frac{1}{D^5}\ \text{W}$$
$$= \frac{1.51\times10^5}{D^5}\ \text{kW}$$

Calculate the number of hours for one year to run the system.

$$\Delta t = (24\times365)$$
$$= 8760\ \text{h}$$

Step 6 of 8

Calculate the total electrical energy required for one year.

$$E_{Pump} = \dot{W}_{pump}\Delta t$$

Substitute $\left(\frac{1.51\times10^5}{D^5}\ \text{kW}\right)$ for $\dot{W}_{pump}$, $8760\ \text{h}$ for Δt.

$$E_{Pump} = \frac{1.51\times10^5}{D^5}\times8760$$
$$= \frac{13227.6}{D^5}\times10^5\ \text{kW-h}$$

Calculate the total electrical energy cost required for one year.

$$\text{Energy cost} = E_{Pump}\times\text{Unit cost}$$

Substitute $\left(\frac{13227.6}{D^5}\times10^5\right)\text{kW-h}$ for E_{Pump}, and $\$0.06/\text{kWh}$ for Unit cost.

$$\text{Energy cost} = \frac{13227.6\times10^5}{D^5}\times0.06$$
$$= \frac{793.656\times10^5}{D^5}\ \$/\text{yr}$$

Step 7 of 8

Calculate the system cost for 30 years using the equation as follows:

$$\text{System cost} = \frac{\text{Total cost}}{\text{Life time}}$$

Substitute $\$10^6D^2$ for Total cost, 30 years for Life time.

$$\text{System cost} = \frac{\$10^6D^2}{30}$$
$$= 3.3\times10^4\ D^2\ \$/\text{yr}$$

Calculate the total cost of the system using the equation as follows:

$$\text{Total cost} = \text{Energy cost} + \text{System cost}$$

Substitute $\left(\frac{793.656\times10^5}{D^5}\ \$/\text{yr}\right)$ for Energy cost, and $\left(3.3\times10^4\ D^2\ \$/\text{yr}\right)$ for System cost.

$$\text{Total cost} = \frac{793.656\times10^5}{D^5}\ \$/\text{yr} + 3.3\times10^4\ D^2\ \$/\text{yr}$$

Step 8 of 8

Calculate the diameter of the pipe by applying the condition as follows:

$$\frac{\partial(\text{Total cost})}{\partial D} = 0$$

Substitute $\left(\frac{793.656\times10^5}{D^5}\ \$/\text{yr} + 3.3\times10^4\ D^2\ \$/\text{yr}\right)$ for Total cost.

$$\frac{\partial\left(\frac{793.656\times10^5}{D^5}\ \$/\text{yr} + 3.3\times10^4\ D^2\ \$/\text{yr}\right)}{\partial D} = 0$$

$$\left(793.656\times10^5\ \$/\text{yr}\,\partial\left(\frac{1}{D^5}\right) + 3.3\times10^4\ \$/\text{yr}\,\partial\left(D^2\right)\right) = 0$$

$$\frac{\partial\left(\frac{793.656\times10^{5}\ \$/\text{yr}}{D^{5}}+3.3\times10^{4}\ \$/\text{yr}\,D^{2}\right)}{\partial D}=0$$

$$\left(793.656\times10^{5}\ \$/\text{yr}\,\partial\left(\frac{1}{D^{5}}\right)+3.3\times10^{4}\ \$/\text{yr}\,\partial\left(D^{2}\right)\right)=0$$

$$\left(793.656\times10^{5}\ \$/\text{yr}\times(-5)\left(\frac{1}{D^{6}}\right)+3.3\times10^{4}\ \$/\text{yr}\times2D\right)=0$$

$$793.656\times10^{5}\ \$/\text{yr}\times(5)\left(\frac{1}{D^{6}}\right)=3.3\times10^{4}\ \$/\text{yr}\times2D$$

$$D^{7}=\frac{396828000}{66000}$$

$$D=(6012.545)^{1/7}$$

$$=3.46\ \text{m}$$

Therefore, the optimum diameter of the pipe D is $\boxed{3.48\ \text{m}}$.

Question: 14.096P

Two pipes of identical diameter and material are connected in parallel. The length of pipe *A* is three times the length of pipe *B*. Assuming the flow is fully turbulent in both pipes and thus the friction factor is independent of the Reynolds number and disregarding minor losses, determine the ratio of the flow rates in the two pipes.

Step 1 of 4

Given data:

The diameter of pipe *A* is $D_A = D$

The diameter of pipe *B* is $D_B = D$

The length of pipe *A* is $L_A = 3L$

The length of pipe *B* is $L_B = L$

The material is identical for both the pipes.

Step 2 of 4

By considering the flow to be steady and incompressible, the velocity of flow is given by

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{\dot{V}}{\frac{\pi}{4}D^2}$$

$$= \frac{4\dot{V}}{\pi D^2}$$

Step 3 of 4

The head loss for the flow is given by

$$h_L = f\frac{L}{D}\frac{V^2}{2g}$$

$$= f\frac{L}{D}\frac{\left(4\dot{V}/\pi D^2\right)^2}{2g}$$

$$= 8f\frac{L}{g\pi^2 D^5}\dot{V}^2$$

The head loss for pipe *A* is

$$(h_L)_A = 8f\frac{L_A}{g\pi^2 D_A^5}\dot{V}_A^2$$

$$= 8f\frac{3L}{g\pi^2 D^5}\dot{V}_A^2$$

The head loss for pipe *B* is

$$(h_L)_B = 8f\frac{L_B}{g\pi^2 D_B^5}\dot{V}_B^2$$

$$= 8f\frac{L}{g\pi^2 D^5}\dot{V}_B^2$$

Step 4 of 4

For two pipes connected in parallel, the head loss for each pipe must be same. Thus we get the expression as

$$(h_L)_A = (h_L)_B$$

$$8f\frac{3L}{g\pi^2 D^5}\dot{V}_A^2 = 8f\frac{L}{g\pi^2 D^5}\dot{V}_B^2$$

$$3L\dot{V}_A^2 = L\dot{V}_B^2$$

$$\frac{\dot{V}_A}{\dot{V}_B} = \sqrt{\frac{L}{3L}}$$

$$= 0.577$$

Therefore, the ratio of flow rates in the two pipes is $\boxed{\frac{\dot{V}_A}{\dot{V}_B} = 0.577}$

Question:

A pipeline that transports oil at 40ЭC at a rate of 3 m3/s branches out into two parallel pipes made of commercial steel that reconnect downstream. Pipe *A* is 500 m long and has a diameter of 30 cm while pipe *B* is 800 m long and has a diameter of 45 cm. The minor losses are considered to be negligible. Determine the flow rate through each of the parallel pipes.

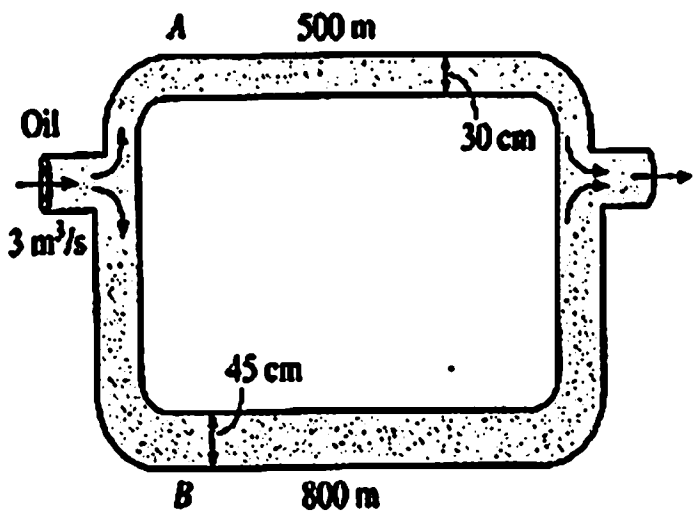

FIGURE P14–97

Step 1 of 8

Initial flow rate of the oil, $\dot{V} = 3\ \text{m}^3/\text{s}$

Length of the pipe A, $L_1 = 500\ \text{m}$

Length of the pipe B, $L_2 = 800\ \text{m}$

Diameter of the pipe A, $D_1 = 30\ \text{cm}$

Diameter of the pipe B, $D_2 = 45\ \text{cm}$

Temperature at which the oil is being transported, 40°C

The roughness of commercial steel pipes is $\varepsilon = 0.000045\ \text{m}$

From the properties table of oil at 40°C we get

Density of oil is $\rho = 876\ \text{kg/m}^3$

Dynamic viscosity of oil is $\mu = 0.2177\ \text{kg/m}\cdot\text{s}$

Step 2 of 8

In this problem let us first assume the flow to be turbulent. Also the head loss in both pipes is equal and the total flow rate must be the sum of the flow rates in the parallel branches.

$$h_{L1} = h_{L2} \qquad \ldots\ldots (1)$$

$$\dot{V} = \dot{V}_1 + \dot{V}_2 \qquad \ldots\ldots (2)$$

Now the average velocity in the pipe is determined by using the continuity equation

$$\dot{V} = AV$$

$$V = \frac{\dot{V}}{A}$$

$$= \frac{\dot{V}_1}{\pi D^2/4}$$

Step 3 of 8

Substituting the known values of pipe (1) in the above relation we get

$$V_1 = \frac{\dot{V}_1}{\pi D_1^2/4}$$

$$= \frac{\dot{V}_1}{\pi(0.3)^2/4}$$

$$= \frac{\dot{V}_1}{0.07068} \qquad \ldots\ldots (3)$$

Similarly for the pipe (2) we get

$$V_2 = \frac{\dot{V}_2}{\pi D_2^2/4}$$

$$= \frac{\dot{V}_2}{\pi(0.450.159)^2/4}$$

$$= \frac{\dot{V}_2}{0.159} \qquad \ldots\ldots (4)$$

Step 4 of 8

Now the Reynolds number for the flow in pipe (1) is

$$\text{Re}_1 = \frac{\rho V_1 D_1}{\mu}$$

$$= \frac{876 \times V_1 \times 0.3}{0.2177}$$

$$= 1207.165 \times V_1 \qquad \ldots\ldots (5)$$

Similarly the Reynolds number for the flow in pipe (2) is

$$\text{Re}_2 = \frac{\rho V_2 D_2}{\mu}$$

$$= \frac{876 \times V_2 \times 0.45}{0.2177}$$

$$= 1810.748 \times V_2 \qquad \ldots\ldots (6)$$

Step 5 of 8

For a fully developed turbulent flow, the friction factor depends upon the Reynolds number and the relative roughness ε/D

Hence the roughness value of the pipe (1) is

$$\Rightarrow \frac{\varepsilon}{D_1}$$

$$\Rightarrow \frac{0.000045}{0.3}$$

$$\Rightarrow \frac{\varepsilon}{D_1}$$

$$\Rightarrow \frac{0.000045}{0.3}$$

$$\Rightarrow 1.5\times10^{-4}$$

Similarly the roughness value of the pipe (2) is

$$\Rightarrow \frac{\varepsilon}{D_2}$$

$$\Rightarrow \frac{0.000045}{0.45}$$

$$\Rightarrow 1\times10^{-4}$$

Step 6 of 8

Now by using the Colebrook equation we shall determine the friction factor in turbulent flow. Hence the friction factor for the pipe (1) is

$$\frac{1}{\sqrt{f_1}} = -2\log\left(\frac{\varepsilon/D_1}{3.7} + \frac{2.5}{\mathrm{Re}_1\sqrt{f_1}}\right)$$

$$\frac{1}{\sqrt{f_1}} = -2\log\left(\frac{1.5\times10^{-4}}{3.7} + \frac{2.5}{(1207.165\times V_1)\sqrt{f_1}}\right) \qquad \ldots\ldots (7)$$

Similarly the friction factor for the pipe (2) is

$$\frac{1}{\sqrt{f_2}} = -2\log\left(\frac{\varepsilon/D_2}{3.7} + \frac{2.5}{\mathrm{Re}_2\sqrt{f_2}}\right)$$

$$\frac{1}{\sqrt{f_2}} = -2\log\left(\frac{1\times10^{-4}}{3.7} + \frac{2.5}{(1810.748\times V_2)\sqrt{f_2}}\right) \qquad \ldots\ldots (8)$$

Step 7 of 8

The head loss through the pipe (1) is

$$h_{f_1} = \frac{f_1 L_1 V_1^2}{2gD_1}$$

$$= \frac{f_1\times500\times V_1^2}{2\times9.81\times0.30}$$

$$= 84.94\times f_1\times V_1^2 \qquad \ldots\ldots (9)$$

Similarly the head loss for the pipe (2) is

$$h_{f_2} = \frac{f_2 L_2 V_2^2}{2gD_2}$$

$$= \frac{f_2\times800\times V_2^2}{2\times9.81\times0.45}$$

$$= 90.61\times f_2\times V_2^2 \qquad \ldots\ldots (10)$$

Step 8 of 8

Now using the equation solver, by solving the equations from (1) to (10) we get the Flow rate in pipe (1) is $\boxed{\dot{V}_1 = 0.92\ \mathrm{m}^3/\mathrm{s}}$ and the flow rate in the pipe (2) is $\boxed{\dot{V}_2 = 2.087\ \mathrm{m}^3/\mathrm{s}}$

Also the Reynolds number for the flow in pipe (1) is $\mathrm{Re}_1 = 15{,}540$ and in pipe (2) is $\mathrm{Re}_2 = 23{,}800$. This is clear that the Reynolds number is greater than 4000, hence our assumption that the flow is turbulent is correct.

Question: 14.098P

Repeat Prob. 14-97 for hot-water flow of a district heating system at 100°C.

Step 1 of 7

Given data:

Water is supplied at 20°C

The flow rate, $\dot{V} = 1.2\ m^3/s$

The length of the pipe, $L = 200\ m$

The diameter of the pipe, $D = 0.35\ m$

The pipe is made of cast iron.

The elevation difference between the free surface of the reservoir and turbine discharge, $H = 115\ m$.

The combined turbine-generator efficiency, $\eta = 80\%$

Step 2 of 7

Assuming that the flow is incompressible and steady:

From the table of properties of saturated water, corresponding to 20°C,

The density of water, $\rho = 998\ kg/m^3$

The dynamic viscosity, $\mu = 1.002 \times 10^{-3}\ kg/m \cdot s$

The roughness of cast iron pipe, $\varepsilon = 0.26\ mm = 0.26 \times 10^{-3}\ m$

The cross sectional flow area,

$$A_c = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}(0.35\ m)^2$$

$$= 96.211 \times 10^{-3}\ m^2$$

Step 3 of 7

The energy equation for a control volume is given by

$$\frac{P_1}{\rho g} + \alpha_1\frac{V_1^2}{2g} + z_1 + h_{pump,u} = \frac{P_2}{\rho g} + \alpha_2\frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L \quad \text{..... (1)}$$

where, point 1 is taken as the surface of the reservoir and point 2 is taken as the exit of the hole.

Here, both the points 1 and 2 are opened to the atmosphere. So, $P_1 = P_2$

The velocity at the points 1 and 2 is low. So, the velocities, $V_1 = V_2 = 0$

Let point 2 is the reference level. Then, $z_2 = 0$ and $z_1 = H = 115\ m$.

There is no pump. So, $h_{pump,u} = 0$.

Thus, equation (1) becomes,

$$\frac{P_1}{\rho g} + \alpha_1\frac{(0)^2}{2g} + 115\ m + 0 = \frac{P_1}{\rho g} + \alpha_2\frac{(0)^2}{2g} + 0 + h_{turbine,e} + h_L$$

$$115\ m = h_{turbine,e} + h_L \quad \text{..... (2)}$$

Step 4 of 7

The average velocity of flow in the pipe,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{1.2\ m^3/s}{96.211 \times 10^{-3}\ m^2}$$

$$= 12.47\ m/s$$

The Reynolds number,

$$\mathrm{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{(998\ kg/m^3)(12.47\ m/s)(0.35\ m)}{1.002 \times 10^{-3}\ kg/m \cdot s}$$

$$= 4.347 \times 10^6$$

Here, $\mathrm{Re} > 4000$, therefore the flow in the pipe is turbulent.

Step 5 of 7

For turbulent flow, the Colebrook equation is

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

where, f is the friction factor. By substituting the known values.

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{0.26 \times 10^{-3}\ m/0.35\ m}{3.7} + \frac{2.51}{(4.347 \times 10^6)\sqrt{f}}\right)$$

$$= -2.0\log\left(2.008 \times 10^{-4} + \frac{5.774 \times 10^{-7}}{\sqrt{f}}\right)$$

Solving the equation for f: $f = 0.0184$

Step 6 of 7

The head loss in the flow,

$$h_L = f\frac{L}{D}\frac{V^2}{2g}$$

$$= 0.0184\left(\frac{200\ m}{0.35\ m}\right)\left(\frac{(12.47\ m/s)^2}{2 \times 9.81\ m/s^2}\right)$$

$$= 83.33\ m$$

Substitute the known values in equation (2).

$$115\ m = h_{turbine,e} + 83.33\ m$$

$$h_{turbine,e} = 31.67\ m$$

Step 7 of 7

The power extracted from the water,

$$\dot{W}_{turbine,e} = \rho \dot{V} g h_{turbine,e}$$

$$= (998\ kg/m^3)(1.2\ m^3/s)(9.81\ m/s^2)(31.67\ m)$$

$$= 372.074 \times 10^3\ W$$

$$= 372.074\ kW$$

The output power of the turbine,

$$\dot{W}_{turbine\text{-}gen} = \eta \dot{W}_{turbine,e}$$

$$= \frac{80}{100}(372.074\ kW)$$

$$= 297.66\ kW$$

Therefore, the electric power output of the plant, $\boxed{\dot{W}_{turbine\text{-}gen} = 297.66\ kW}$.

Question: 14.099P pg 1

A water fountain is to be installed at a remote location by attaching a cast iron pipe directly to a water main through which water is flowing at 70°F and 60 psig. The entrance to the pipe is sharp-edged, and the 70-ft-long piping system involves three 90° miter bends without vanes, a fully open gate valve, and an angle valve with a loss coefficient of 5 when fully open. If the system is to provide water at a rate of 15 gal/min and the elevation difference between the pipe and the fountain is negligible, determine the minimum diameter of the piping system.

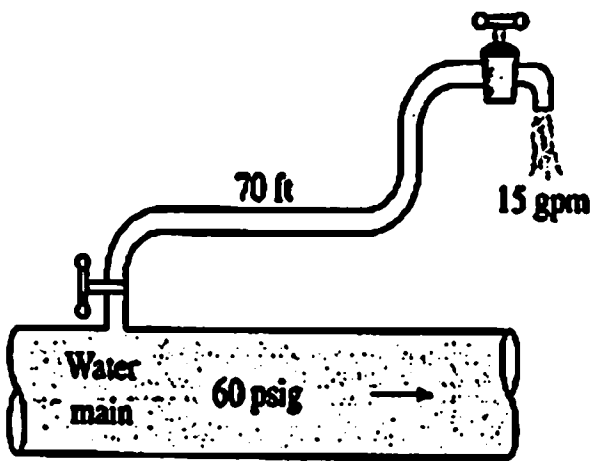

FIGURE P14–99E

Step 1 of 10

Given data:

Temperature of the water $T = 70°F$

The gage pressure, $P_1 = 60 \text{ psi}$

The pipe is having sharp edged entrance, three 90° miter bends, a fully opened gate valve and an angle valve.

The pipe is made of cast iron.

The volume flow rate, $\dot{V} = 15 \text{ gal/min} = 0.0334 \text{ ft}^3/\text{sec}$

The length of the pipe, $L = 70 \text{ ft}$

Step 2 of 10

The flow is assumed to be turbulent, fully developed and incompressible. The elevation deference between the pipe and the fountain is negligible.

From the table of properties of saturated water, corresponding to 70°F,

The density of water, $\rho_f = 62.30 \text{ lbm/ft}^3$

The dynamic viscosity, $\mu_f = 6.556 \times 10^{-4} \text{ lbm/ft-s}$

The roughness of cast iron, $\varepsilon = 0.00085 \text{ ft}$.

Step 3 of 10

Let the point in the main pipe, near the entrance, be 1. At that point the velocity is low. Let the exit be point 2. The pressure at point 2 is equal to the atmospheric pressure.

The energy equation for a control volume between two points is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L \qquad \text{..... (1)}$$

Here, there is no pump or turbine in the pipe system. So, $h_{\text{pump},u} = h_{\text{turbine},e} = 0$.

The effect of kinetic energy correction factor is assumed to be negligible. So,

$\alpha_1 = \alpha_2 = 1$.

Step 4 of 10

Elevation difference between the pipe and the fountain is assumed to be negligible. So,

$z_1 = z_2$

The velocities,

$V_1 \approx 0$

$$V_2 = \frac{\dot{V}}{A_t}$$

$$= \frac{0.0334 \text{ ft}^3/\text{s}}{\frac{\pi}{4} D^2}$$

$$= \frac{0.0425 \text{ ft}^3/\text{s}}{D^2} \qquad \text{..... (2)}$$

Step 5 of 10

The loss coefficient of sharp edged entrance, $K_{L,\text{entrance}} = 0.5$

The loss coefficient of miter bend, $K_{L,\text{bend}} = 1.1$

The loss coefficient of fully opened gate valve, $K_{L,\text{gate}} = 0.2$

The loss coefficient of fully opened angle valve, $K_{L,\text{angle}} = 5$

Total loss coefficient,

$$\sum K_L = K_{L,\text{entrance}} + 3\left(K_{L,\text{bend}}\right) + K_{L,\text{gate}} + K_{L,\text{angle}}$$

$$= 0.5 + 3(1.1) + 0.2 + 5$$

$$= 9$$

Step 6 of 10

The head loss,

$$h_L = \left(f\frac{L}{D} + \sum K_L\right)\frac{V_2^2}{2g}$$

$$= \left(f\frac{70 \text{ ft}}{D} + 9\right)\frac{\left(\frac{0.0425 \text{ ft}^3/\text{s}}{D^2}\right)^2}{2\left(32.2 \text{ ft/s}^2\right)}$$

$$= \left(f\frac{70}{D} + 9\right)\left(\frac{2.825 \times 10^{-5}}{D^4}\right) \qquad \text{.....(3)}$$

Step 7 of 10

Substituting the known values in equation (1):

$$\frac{60\frac{\text{lbm}}{(1/12)^2 \text{ ft}^2}}{(62.30 \text{ lbm/ft}^3)(32.2 \text{ ft/s}^2)} + 0 + z_1 + 0 = 0 + (1)\frac{\left(\frac{0.0425}{D^2}\right)^2}{2(32.2 \text{ ft/s}^2)} + z_1 + 0$$

Substituting the known values in equation (1):

$$\frac{60\frac{\text{lbm}}{(1/12)^2\,\text{ft}^2}}{(62.30\,\text{lbm/ft}^3)(32.2\,\text{ft/s}^2)}+0+z_1+0=0+(1)\frac{\left(\frac{0.0425}{D^2}\right)^2}{2(32.2\,\text{ft/s}^2)}+z_1+0$$

$$+\left(f\frac{70}{D}+9\right)\left(\frac{2.825\times10^{-5}}{D^4}\right)$$

$$\frac{8640}{2006.06}=\frac{2.80\times10^{-5}}{D^4}+\left(f\frac{70}{D}+9\right)\left(\frac{2.825\times10^{-5}}{D^4}\right)$$

$$4.307=\left(\frac{2.80\times10^{-5}}{D^4}\right)\left(1+f\frac{70}{D}+9\right)$$

$$=\left(\frac{2.80\times10^{-5}}{D^4}\right)\left(10+f\frac{70}{D}\right)$$

Step 8 of 10

On rearranging,

$$\frac{4.306D^4}{2.80\times10^{-5}}-10=f\frac{70}{D}$$

$$f=\left(153.78\times10^3D^4-10\right)\frac{D}{70}$$

Step 9 of 10

The Reynolds number,

$$\text{Re}=\frac{\rho VD}{\mu}$$

$$=\frac{(62.30\,\text{lbm/ft}^3)\left(\frac{0.0425\,\text{ft}^3/\text{s}}{D^2}\right)D}{6.556\times10^{-4}\,\text{lbm/ft}\cdot\text{s}}$$

$$=\frac{4038.66}{D}\qquad\text{..... (5)}$$

Step 10 of 10

For turbulent flow, the Colebrook equation is $\frac{1}{\sqrt{f}}=-2.0\log\left(\frac{\varepsilon/D}{3.7}+\frac{2.51}{\text{Re}\sqrt{f}}\right)$.

where, f is the friction factor.

Substituting the known values:

$$\frac{1}{\sqrt{\left(153.78\times10^3D^4-10\right)\frac{D}{70}}}$$

$$=-2.0\log\left(\frac{0.00085/D}{3.7}+\frac{2.51}{\frac{4038.66}{D}\sqrt{\left(153.78\times10^3D^4-10\right)\frac{D}{70}}}\right)$$

$$=-2.0\log\left(\frac{2.297\times10^{-4}}{D}+\frac{6.215\times10^{-4}D}{\sqrt{\left(153.78\times10^3D^4-10\right)\frac{D}{70}}}\right)$$

$$\frac{1}{\sqrt{\left((153780x^4)-10\right)\times\left(\frac{x}{70}\right)}}=-2\times\ln\left(\frac{(0.0002297)}{x}+\frac{(0.0006215x)}{\sqrt{\left((153780x^4)-10\right)\times\left(\frac{x}{70}\right)}}\right)$$

By solving the above equation,

$D=0.0591\,\text{ft}$

$=0.712\,\text{in.}$

Therefore, the minimum diameter of the piping system is $\boxed{D=0.71\,\text{in.}}$

Question: 14.100P

Repeat Prob. 14-99E for plastic (smooth) pipes.

Step 1 of 8

Given data:

Temperature of the water $T = 20°C$

The gage pressure, $P_1 = 400\ \text{kPa}$

The pipe is having sharp edged entrance, three 90° miter bends, a fully opened gate valve and an angle valve.

The pipe is made of plastic.

The volume flow rate, $\dot{V} = 75\ \text{L/min}$

The length of the pipe, $L = 15\ \text{m}$

Step 2 of 8

From the table of properties of saturated water, corresponding to 20°C,

The density of water, $\rho = 998\ \text{kg/m}^3$

The dynamic viscosity, $\mu = 1.002 \times 10^{-3}\ \text{kg/m} \cdot s$

The roughness of plastic, $\varepsilon = 0$

Let the point in the main pipe, near the entrance, be 1. At this point the velocity is low. Let the exit be point 2. The pressure at point 2 is equal to the atmospheric pressure.

The energy equation for a control volume between two points is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L \qquad \text{..... (1)}$$

Here, there is no pump or turbine in the pipe system. So, $h_{\text{pump},s} = h_{\text{turbine},e} = 0$.

The effect of kinetic energy correction factor is assumed to be negligible. So,

$\alpha_1 = \alpha_2 = 1$.

Step 3 of 8

Elevation difference between the pipe and the fountain is assumed to be negligible. So,

$z_1 = z_2$

The velocities,

$V_1 \approx 0$

$$V_2 = \frac{\dot{V}}{A_t} = \frac{1.25 \times 10^{-3}\ \text{m}^3/\text{s}}{\frac{\pi}{4} D^2} = \frac{1.591 \times 10^{-3}\ \text{m}^3/\text{s}}{D^2} \qquad \text{..... (2)}$$

Step 4 of 8

The loss coefficient of sharp edged entrance, $K_{L,\text{entrance}} = 0.5$

The loss coefficient of miter bend, $K_{L,\text{bend}} = 1.1$

The loss coefficient of fully opened gate valve, $K_{L,\text{gate}} = 0.2$

The loss coefficient of fully opened angle valve, $K_{L,\text{angle}} = 5$

Total loss coefficient,

$$\sum K_L = K_{L,\text{entrance}} + 3\left(K_{L,\text{bend}}\right) + K_{L,\text{gate}} + K_{L,\text{angle}} = 0.5 + 3(1.1) + 0.2 + 5 = 9$$

Step 5 of 8

The head loss in the flow,

$$h_L = \left(f\frac{L}{D} + \sum K_L\right)\frac{V_2^2}{2g} = \left(f\frac{15\ \text{m}}{D} + 9\right)\frac{\left(\frac{1.591 \times 10^{-3}\ \text{m}^3/\text{s}}{D^2}\right)^2}{2\left(9.81\ \text{m/s}^2\right)} = \left(f\frac{15}{D} + 9\right)\left(\frac{1.29 \times 10^{-7}}{D^4}\right) \qquad \text{..... (3)}$$

Step 6 of 8

Substitute the known values in equation (1).

$$\frac{400 \times 10^3\ \text{Pa}}{\left(998\ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right)} + 0 + z_1 + 0 = \left\{ 0 + (1)\frac{\left(\frac{1.591 \times 10^{-3}\ \text{m}^3/\text{s}}{D^2}\right)^2}{2\left(9.81\ \text{m/s}^2\right)} + z_1 + 0 + \left(f\frac{15}{D} + 9\right)\left(\frac{1.29 \times 10^{-7}}{D^4}\right) \right\}$$

$$40.856 = \left(\frac{1.29 \times 10^{-7}}{D^4}\right) + \left(f\frac{15}{D} + 9\right)\left(\frac{1.29 \times 10^{-7}}{D^4}\right) = \left(\frac{1.29 \times 10^{-7}}{D^4}\right)\left(f\frac{15}{D} + 9 + 1\right) = \left(\frac{1.29 \times 10^{-7}}{D^4}\right)\left(f\frac{15}{D} + 10\right)$$

Step 7 of 8

On rearranging,

$$\frac{40.856 D^4}{1.29 \times 10^{-7}} - 10 = f\frac{15}{D}$$

$$f = \left(316.71 \times 10^6 D^4 - 10\right)\frac{D}{15}$$

The Reynolds number,

$$\text{Re} = \frac{\rho V D}{\mu} = \frac{\left(998\ \text{kg/m}^3\right)\left(\frac{1.591 \times 10^{-3}\ \text{m}^3/\text{s}}{D^2}\right)D}{1.002 \times 10^{-3}\ \text{kg/m} \cdot s} = \frac{1584.65}{D} \qquad \text{..... (5)}$$

Step 8 of 8

For turbulent flow, the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

where, f is the friction factor.

Substituting the known values:

$$\frac{1}{\sqrt{\left(316.71 \times 10^6 D^4 - 10\right)\frac{D}{15}}} = -2.0 \log\left(\frac{0/D}{3.7} + \frac{2.51}{\frac{1584.65}{D}\sqrt{\left(316.71 \times 10^6 D^4 - 10\right)\frac{D}{15}}}\right)$$

$D = 0.0169\ \text{m}$

Therefore, the minimum diameter of the piping system, $\boxed{D = 0.0169\ \text{m}}$

Question: 14.101P

In a hydroelectric power plant, water at 20°C is supplied to the turbine at a rate of 1.2 m3/s through a 200-m- long, 0.35-m-diameter cast iron pipe. The elevation difference between the free surface of the reservoir and the turbine discharge is 115 m, and the combined turbine-generator efficiency is 80 percent. Disregarding the minor losses because of the large length-to-diameter ratio, determine the electric power output of this plant.

Step 1 of 8

Given data:

Temperature of the supplied water $T = 20°C$

The flow rate of the water, $\dot{V} = 1.2\ m^3/s$

The length of the pipe, $L = 200\ m$

The diameter of the pipe, $D = 0.35\ m$

The elevation difference between the free surface of the reservoir and turbine discharge, $H = 115\ m$

The combined turbine-generator efficiency, $\eta = 80\%$

The pipe is made of cast iron.

Step 2 of 8

From the table of properties of saturated water, corresponding to 20°C,

The density of water, $\rho = 998\ kg/m^3$

The dynamic viscosity, $\mu = 1.002 \times 10^{-3}\ kg/m \cdot s$

The roughness of cast iron pipe, $\varepsilon = 0.26\ mm = 0.26 \times 10^{-3}\ m$.

Step 3 of 8

The cross section of the flow area,

$$A_c = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}(0.35\ m)^2$$

$$= 96.211 \times 10^{-3}\ m^2$$

The energy equation for a control volume is given by

$$\frac{P_1}{\rho g} + \alpha_1\frac{V_1^2}{2g} + z_1 + h_{pump,e} = \frac{P_2}{\rho g} + \alpha_2\frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L \qquad \text{..... (1)}$$

Where, point 1 is taken as the surface of the reservoir
point 2 is taken as the exit of the hole.

Step 4 of 8

Here, both the points 1 and 2 are opened to the atmosphere. So, $P_1 = P_2$

The velocity at the points 1 and 2 is low. So, the velocities, $V_1 = V_2 = 0$

Let point 2 is the reference level. Then, $z_2 = 0$ and $z_1 = H = 115\ m$

There is no pump. So, $h_{pump,e} = 0$

Thus, equation (1) becomes,

$$\frac{P_1}{\rho g} + \alpha_1\frac{(0)^2}{2g} + 115\ m + 0 = \frac{P_1}{\rho g} + \alpha_2\frac{(0)^2}{2g} + 0 + h_{turbine,e} + h_L$$

$$h_{turbine,e} + h_L = 115\ m \qquad \text{..... (2)}$$

Step 5 of 8

The average velocity of flow in the pipe,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{1.2\ m^3/s}{96.211 \times 10^{-3}\ m^2}$$

$$= 12.47\ m/s$$

The Reynolds number,

$$\mathrm{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{(998\ kg/m^3)(12.47\ m/s)(0.35\ m)}{1.002 \times 10^{-3}\ kg/m \cdot s}$$

$$= 4.347 \times 10^6$$

Here, $\mathrm{Re} > 4000$, therefore the flow in the pipe is turbulent.

Step 6 of 8

For turbulent flow, the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

Where, f is the friction factor. By substituting the known values

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{0.26 \times 10^{-3}\ m/0.35\ m}{3.7} + \frac{2.51}{(4.347 \times 10^6)\sqrt{f}}\right)$$

$$= -2.0\log\left(2.008 \times 10^{-4} + \frac{5.774 \times 10^{-7}}{\sqrt{f}}\right)$$

Solving the equation for f: $f = 0.0184$

Step 7 of 8

The head loss,

$$h_L = f\frac{L}{D}\frac{V^2}{2g}$$

$$= 0.0184\left(\frac{200\ m}{0.35\ m}\right)\left(\frac{(12.47\ m/s)^2}{2 \times 9.81\ m/s^2}\right)$$

$$= 83.33\ m$$

Substitute the known values in equation (2)

$$115\ m = h_{turbine,e} + 83.33\ m$$

$$h_{turbine,e} = 31.67\ m$$

Step 8 of 8

The power extracted from the water,

$$\dot{W}_{turbine,e} = \rho\dot{V}gh_{turbine,e}$$

$$= (998\ kg/m^3)(1.2\ m^3/s)(9.81\ m/s^2)(31.67\ m)$$

$$= 372.074 \times 10^3\ W$$

$$= 372.074\ kW$$

The output power of the turbine,

$$\dot{W}_{turbine-gen} = \eta\dot{W}_{turbine,e}$$

$$= \frac{80}{100}(372.074\ kW)$$

$$= 297.66\ kW$$

Therefore, the electric power output of the plant, $\boxed{\dot{W}_{turbine-gen} = 297.66\ kW}$

Question: 14.102P pg 1

In Prob. 14-101, the pipe diameter is tripled in order to reduce the pipe losses. Determine the percent increase in the net power output as a result of this modification.

Step 1 of 14

Given data:

Temperature of the water supplied $T = 20°C$

The flow rate of the water, $\dot{V} = 1.2\ m^3/s$

The length of the pipe, $L = 200\ m$

The diameter of the pipe, $D = 0.35\ m$

The elevation difference between the free surface of the reservoir and turbine discharge, $H = 115\ m$

The combined turbine-generator efficiency, $\eta = 80\%$

The pipe is made of cast iron.

Step 2 of 14

From the table of properties of saturated water, corresponding to $20°C$,

The density of water, $\rho = 998\ kg/m^3$

The dynamic viscosity, $\mu = 1.002 \times 10^{-3}\ kg/m \cdot s$

The roughness of cast iron pipe, $\varepsilon = 0.26\ mm$

Step 3 of 14

The cross section area of the flow,

$$A_c = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.35\ m)^2$$

$$= 96.211 \times 10^{-3}\ m^2$$

Step 4 of 14

The energy equation for a control volume is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump,a} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine,e} + h_L \qquad \text{..... (1)}$$

Where, point 1 is taken as the surface of the reservoir

point 2 is taken as the exit of the hole.

Here, both the points 1 and 2 are opened to the atmosphere. So, $P_1 = P_2$

The velocity at the points 1 and 2 is low. So, the velocities, $V_1 = V_2 = 0$

Let point 2 is the reference level. Then, $z_2 = 0$ and $z_1 = H = 115\ m$.

There is no pump. So, $h_{pump,a} = 0$

Step 5 of 14

Thus, equation (1) becomes,

$$\frac{P_1}{\rho g} + \alpha_1 \frac{(0)^2}{2g} + 115\ m + 0 = \frac{P_1}{\rho g} + \alpha_2 \frac{(0)^2}{2g} + 0 + h_{turbine,e} + h_L$$

$$115\ m = h_{turbine,e} + h_L \qquad \text{..... (2)}$$

The average velocity of flow in the pipe,

$$V = \frac{\dot{V}}{A_c}$$

$$= \frac{1.2\ m^3/s}{96.211 \times 10^{-3}\ m^2}$$

$$= 12.47\ m/s$$

Step 6 of 14

The Reynolds number,

$$\mathrm{Re} = \frac{\rho V D}{\mu}$$

$$= \frac{(998\ kg/m^3)(12.47\ m/s)(0.35\ m)}{1.002 \times 10^{-3}\ kg/m \cdot s}$$

$$= 4.347 \times 10^6$$

Here, $\mathrm{Re} > 4000$, therefore the flow in the pipe is turbulent.

Step 7 of 14

For turbulent flow, the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{e/D}{3.7} + \frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

where, f is the friction factor. By substitute the known values.

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{0.26 \times 10^{-3}\ m / 0.35\ m}{3.7} + \frac{2.51}{(4.347 \times 10^6)\sqrt{f}}\right)$$

$$= -2.0 \log\left(2.008 \times 10^{-4} + \frac{5.774 \times 10^{-7}}{\sqrt{f}}\right)$$

By solving the above equation we get, $f = 0.0184$

Step 8 of 14

The head loss,

$$h_L = f \frac{L}{D} \frac{V^2}{2g}$$

$$= 0.0184\left(\frac{200\ m}{0.35\ m}\right)\left(\frac{(12.47\ m/s)^2}{2 \times 9.81\ m/s^2}\right)$$

$$= 83.33\ m$$

Substitute the known values in equation (2).

$$115\ m = h_{turbine,e} + 83.33\ m$$

$$h_{turbine,e} = 31.67\ m$$

Step 9 of 14

Substitute the known values in equation (2).

$115\text{ m} = h_{\text{turbine},e} + 83.33\text{ m}$ 14.102P pg 2

$h_{\text{turbine},e} = 31.67\text{ m}$

Step 9 of 14

Now, considering the system with diameter $3D$ The cross sectional flow area,

$$A_c = \frac{\pi}{4}(3D)^2$$
$$= \frac{9\pi}{4}(0.35\text{ m})^2$$
$$= 865.899 \times 10^{-3}\text{ m}^2$$

The energy equation for a control volume is given by

$$\frac{P_1'}{\rho g} + \alpha_1 \frac{V_1'^2}{2g} + z_1' + h_{\text{pump},s}' = \frac{P_2'}{\rho g} + \alpha_2 \frac{V_2'^2}{2g} + z_2' + h_{\text{turbine},e}' + h_L' \quad \text{..... (3)}$$

where, point 1 is taken as the surface of the reservoir and point 2 is the exit of the hole.

Here, both the points 1 and 2 are opened to the atmosphere. So, $P_1' = P_2'$.

The velocity at the points 1 and 2 is low. So, the velocities, $V_1' = V_2' = 0$.

Let point 2 be the reference level. Then, $z_2' = 0$ and $z_1' = H = 115\text{ m}$.
There is no pump. So, $h_{\text{pump},s}' = 0$.

Step 10 of 14

Thus, equation (3) becomes,

$$\frac{P_1'}{\rho g} + \alpha_1 \frac{(0)^2}{2g} + 115\text{ m} + 0 = \frac{P_1'}{\rho g} + \alpha_2 \frac{(0)^2}{2g} + 0 + h_{\text{turbine},e}' + h_L'$$
$$115\text{ m} = h_{\text{turbine},e}' + h_L' \quad \text{..... (4)}$$

The average velocity of flow in the pipe,

$$V' = \frac{\dot{V}}{A_c'}$$
$$= \frac{1.2\text{ m}^3/\text{s}}{865.899 \times 10^{-3}\text{ m}^2}$$
$$= 1.386\text{ m/s}$$

Step 11 of 14

The Reynolds number,

$$\text{Re}' = \frac{\rho V' D'}{\mu}$$
$$= \frac{(998\text{ kg/m}^3)(1.386\text{ m/s})(3 \times 0.35\text{ m})}{1.002 \times 10^{-3}\text{ kg/m} \cdot \text{s}}$$
$$= 1.449 \times 10^6$$

Here, $\text{Re}' > 4000$, therefore the flow in the pipe is turbulent.

Step 12 of 14

For turbulent flow, the Colebrook equation is

$$\frac{1}{\sqrt{f'}} = -2.0 \log\left(\frac{\varepsilon/D'}{3.7} + \frac{2.51}{\text{Re}'\sqrt{f'}}\right)$$

Substitute the known values.

$$\frac{1}{\sqrt{f'}} = -2.0 \log\left(\frac{0.26 \times 10^{-3}\text{ m}/(3 \times 0.35\text{ m})}{3.7} + \frac{2.51}{(1.449 \times 10^6)\sqrt{f'}}\right)$$
$$= -2.0 \log\left(66.924 \times 10^{-6} + \frac{1.732 \times 10^{-6}}{\sqrt{f'}}\right)$$

By solving the above equation, we get $f' = 0.0149$

Step 13 of 14

The head loss,

$$h_L' = f' \frac{L}{D'} \frac{V'^2}{2g}$$
$$= 0.0149\left(\frac{200\text{ m}}{3 \times 0.35\text{ m}}\right)\left(\frac{(1.386\text{ m/s})^2}{2 \times 9.81\text{ m/s}^2}\right)$$
$$= 0.28\text{ m}$$

Substitute the known values in equation (2).

$115\text{ m} = h_{\text{turbine},e}' + 0.28\text{ m}$

$h_{\text{turbine},e}' = 114.72\text{ m}$

Step 14 of 14

The increase in actual power output,

$$\%\text{ increse} = \frac{\eta \dot{W}_{\text{turbine},e}' - \eta \dot{W}_{\text{turbine},e}}{\eta \dot{W}_{\text{turbine},e}}$$
$$= \frac{\dot{W}_{\text{turbine},e}' - \dot{W}_{\text{turbine},e}}{\dot{W}_{\text{turbine},e}}$$
$$= \frac{\rho \dot{V} g h_{\text{turbine},e}' - \rho \dot{V} g h_{\text{turbine},e}}{\rho \dot{V} g h_{\text{turbine},e}}$$
$$= \frac{h_{\text{turbine},e}' - h_{\text{turbine},e}}{h_{\text{turbine},e}}$$
$$= \frac{114.72\text{ m} - 31.67\text{ m}}{31.67\text{ m}}$$
$$= 2.622$$
$$= 262.2\%$$

Therefore, the percentage increase in output is $\boxed{262.2\%}$.

= 262.2%

14.102P pg 3

Therefore, the percentage increase in output is **262.2%**.

Question: 14.103P pg 1

The drinking water needs of an office are met by large water bottles. One end of a 0.35-in-diameter, 6-ft-long plastic hose is inserted into the bottle placed on a high stand, while the other end with an on/off valve is maintained 3 ft below the bottom of the bottle. If the water level in the bottle is 1 ft when it is full, determine how long it would take to fill an 8-oz glass (= 0.00835 ft3) (*a*) when the bottle is first opened and (*b*) when the bottle is almost empty. Take the total minor loss coefficient, including the on/off valve, to be 2.8 when it is fully open. Assume the water temperature to be the same as the room temperature of 70°F.

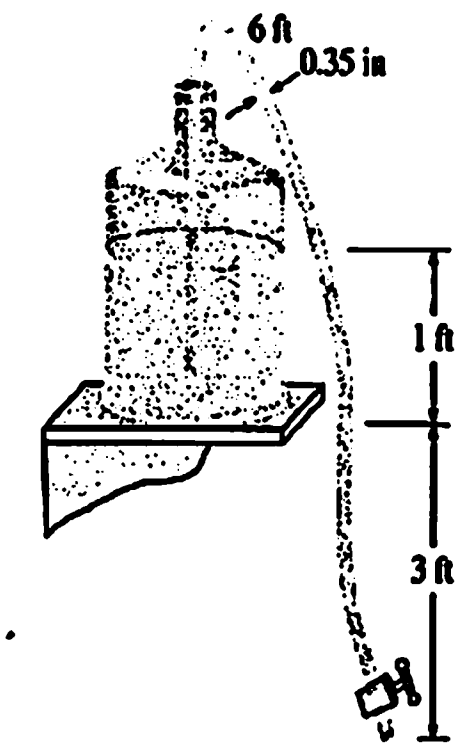

FIGURE P14–103E

Step 1 of 12

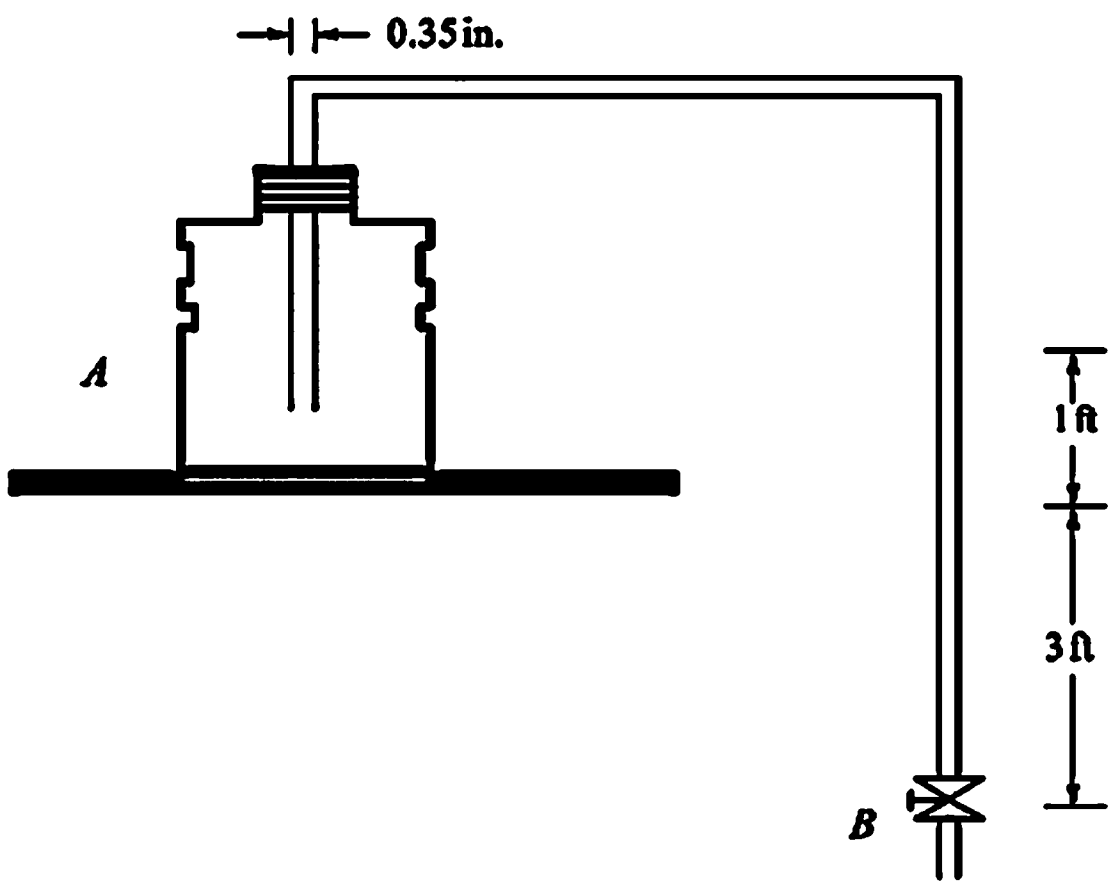
Diameter of the plastic hose, $D = 0.35\text{in.} = 0.029\text{ft}$

Total length of the plastic hose, $L = 6\text{ ft}$

Minor loss coefficient, $\sum K_l = 2.8$

Volume to be filled, $Vol = 0.00835\text{ ft}^3$

Acceleration due to gravity, $g = 32.2\text{ ft/s}^2$



Properties of water at 70°C

Density of water, $\rho = 62.3\text{lbm/ft}^3$

Dynamic viscosity of water, $\nu = 1.052\times10^{-5}\text{ ft}^2/s$

Step 2 of 12

Figure showing dinking water arrangement,

Step 3 of 12

The energy balance equation between free surface of water *A* and valve *B* is given by,

$$\frac{P_1}{\rho g}+\alpha_1\frac{V_1^2}{2g}+z_1+h_{pump}=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+z_2+h_{turbine}+h_{loss} \qquad \ldots\ldots (1)$$

The pressure acting on the free surface of the water and at the end of the pipe is atmospheric pressure only, $P_1 = P_2$

The velocity of the water at free surface is, $V_1 = 0$

We know that there is no involvement of pumps and turbines therefore,

$h_{pump} = 0,\ h_{turbine} = 0$

We know that total head losses is given by,

$$h_{loss}=\left(f\frac{L}{D}+\sum K_l\right)\frac{V_2^2}{2g}$$

$$=\left(f\frac{6}{0.029}+2.8\right)\frac{V_2^2}{2\times32.2}$$

$$=(3.21f+0.0434)V_2^2$$

Step 4 of 12

The equation (1) reduces to,

$$\frac{P_1}{\rho g}+\alpha_1\frac{0}{2g}+z_1+0=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+0+0+h_{loss}$$

$$z_1=\alpha_2\frac{V_2^2}{2g}+h_{loss}$$

$$=1\times\frac{V_2^2}{2\times32.2}+\left[(3.21f+0.0434)V_2^2\right]$$

$$z_1=(3.21f+0.0584)V_2^2 \qquad \ldots\ldots (2)$$

Step 5 of 12

Discharge by the hose is fully open is given by,

$$\dot{V}=V_2\times A$$

$$=V_2\times\frac{\pi}{4}D^2$$

$$=V_2\times\frac{\pi}{4}\times(0.029)^2$$

$$\dot{V}=6.6\times10^{-4}(V_2) \qquad \ldots\ldots (3)$$

Reynolds number is given by,

$$= V_2 \times \frac{\pi}{4} \times (0.029)^2$$

$$\dot{V} = 6.6 \times 10^{-4} (V_2) \qquad \ldots\ldots (3)$$

Reynolds number is given by,

$$\mathrm{Re} = \frac{V_2 D}{\nu}$$

$$= \frac{V_2 \times 0.029}{1.052 \times 10^{-5}}$$

$$\mathrm{Re} = 2756.65(V_2) \qquad \ldots\ldots (4)$$

Time taken for filing the glass,

$$t = \frac{Vol}{\dot{V}}$$

$$= \frac{0.00835}{6.6 \times 10^{-4} (V_2)}$$

$$t = \frac{12.64}{V_2} \qquad \ldots\ldots (5)$$

Step 6 of 12

Frictional factor is given by,

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon / D}{3.7} + \frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

$$= -2.0 \log\left(0 + \frac{2.51}{\mathrm{Re}\sqrt{f}}\right) \qquad \text{(Since roughness factor, } \varepsilon = 0\text{)}$$

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{2.51}{\mathrm{Re}\sqrt{f}}\right) \qquad \ldots\ldots (6)$$

Step 7 of 12

a) When the bottle is fist opened,

The height of the frees surface of water,

z_1 = Height from glass to bottle + Height of water free surface

$= 3 + 1$

$= 4\,\mathrm{ft}$

Equation (2) simplifies as,

$$4 = (3.21 f + 0.0584) V_2^2$$

$$f = \frac{1}{3.21}\left(\frac{4}{V_2^2} - 0.0584\right) \qquad \ldots\ldots (7)$$

$$= \frac{1.246}{V_2^2} - 0.0181$$

Step 8 of 12

Substituting in equations (4) and (7) in (6) the equation modifies as follows,

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{\frac{1.246}{V_2^2} - 0.0181}} = -2.0 \log\left(\frac{2.51}{2756.65 \times V_2 \times \sqrt{\frac{1.246}{V_2^2} - 0.0181}}\right)$$

$$V_2 = 5.19\,\mathrm{ft/s}$$

Reynolds number form equation (4),

$$\mathrm{Re} = 2756.65(V_2)$$

$$= 2756.65(5.19)$$

$$= 14307.01$$

Since the obtained Reynolds number is grater than 4000 flow is in turbulent nature.

Step 9 of 12

Time taken to fill the glass can be found form equation (5) as,

$$t = \frac{12.64}{V_2}$$

$$= \frac{12.64}{5.19}$$

$$= 2.44\,s$$

Therefore the time taken to fill the glass is $\boxed{2.44 \text{seconds}}$ when the bottle is full.

Step 10 of 12

b) When the bottle is almost empty,

The height of the frees surface of water,

z_1 = Height from glass to bottle + Height of water free surface

$= 3 + 0$

$= 3\,\mathrm{ft}$

Equation (2) simplifies as,

$$3 = (3.21 f + 0.0584) V_2^2$$

$$f = \frac{1}{3.21}\left(\frac{3}{V_2^2} - 0.0584\right) \qquad \ldots\ldots (8)$$

$$= \frac{0.9346}{V_2^2} - 0.0181$$

Step 11 of 12

Substituting in equations (4) and (7) in (6) the equation modifies as follows,

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{\frac{0.9346}{V_2^2} - 0.0181}} = -2.0 \log\left(\frac{2.51}{2756.65 \times V_2 \times \sqrt{\frac{0.9346}{V_2^2} - 0.0181}}\right)$$

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{\frac{0.9346}{V_2^2} - 0.0181}} = -2.0\log\left(\frac{2.51}{2756.65 \times V_2 \times \sqrt{\frac{0.9346}{V_2^2} - 0.0181}}\right)$$

$V_2 = 4.441 \text{ ft/s}$

Reynolds number form equation (4),

$$\begin{aligned}\mathrm{Re} &= 2756.65(V_2)\\ &= 2756.65(4.441)\\ &= 12242.28\end{aligned}$$

Since the obtained Reynolds number is grater than 4000 flow is in turbulent nature.

Step 12 of 12

Time taken to fill the glass can be found form equation (5) as,

$$\begin{aligned}t &= \frac{12.64}{V_2}\\ &= \frac{12.64}{4.441}\\ &= 2.84 s\end{aligned}$$

Therefore the time taken to fill the glass is $\boxed{t = 2.84 \text{ seconds}}$ when the bottle is almost empty.

Question:

Reconsider Prob. 14-103E. Using EES (or other) software, investigate the effect of the hose diameter on the time required to fill a glass when the bottle is full. Let the diameter vary from 0.2 to 2 in, in increments of 0.2 in. Tabulate and plot the results.

Step 1 of 9

Diameter of the plastic hose, D

Total length of the plastic hose, $L = 6$ ft

Minor loss coefficient, $\sum K_l = 2.8$

Volume to be filled, $Vol = 0.00835$ ft^3

Acceleration due to gravity, $g = 32.2$ ft/s^2

Properties of water at 70°F

Density of water, $\rho = 62.31$ lbm/ft^3

Dynamic viscosity of water, $v = 1.052 \times 10^{-5}$ ft^2/s

Step 2 of 9

This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below,

```
"Given data"
"D=0.35 [in]*convert(in,ft)"
L=6 [ft]
K_l=2.8
Vol=0.00835 [ft^3]
e=0                    "Equivalent roughness"
T_1=70 [F]
P_1=14.7 [psi]
rho_1=Density(Water,T=T_1,P=P_1)
mu_1=Viscosity(Water,T=T_1,P=P_1)
```

Step 3 of 9

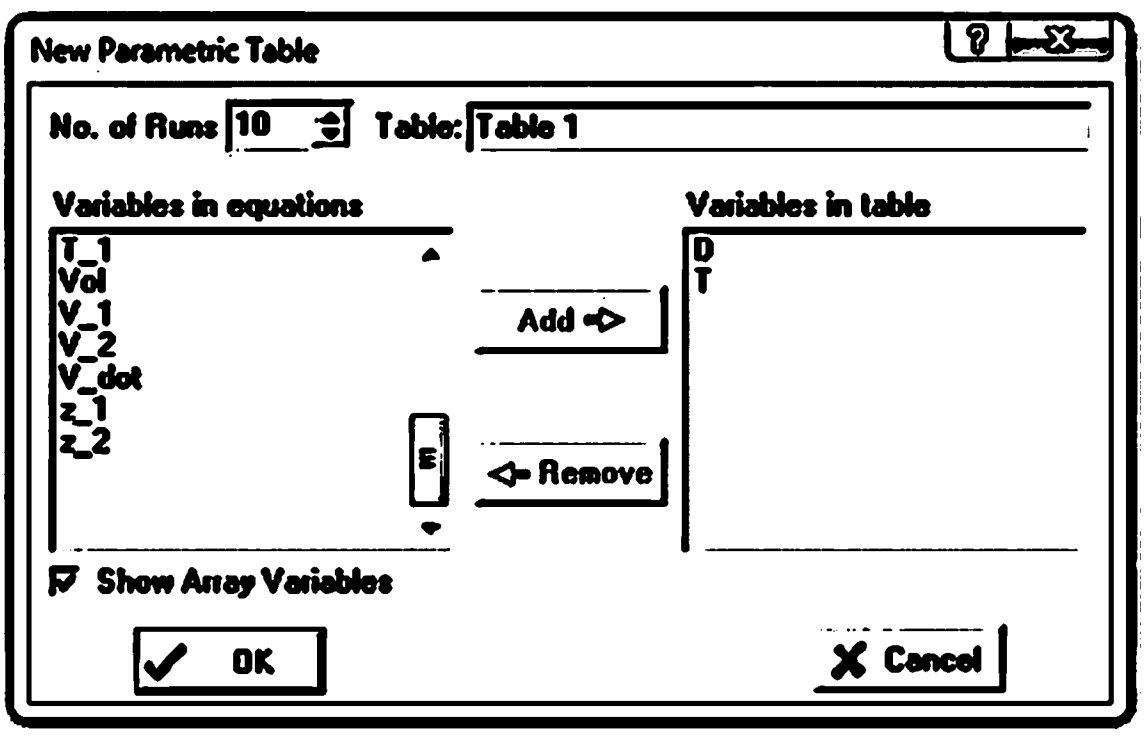
```
"Energy balance equation between free surface "
(P_1/(rho_1*g#))+(alpha_1*(V_1^2)/(2*g#))+z_1+h_pump=(P_2/(rho_1*g#))+(alpha_2
*(V_2^2)/(2*g#))+z_2+h_turbine+h_loss

P_2=14.7 [psi]         " pressure acting on the free surface of the water"
V_1=0 [ft/s]           "velocity of the water at free surface"
h_pump=0               "No involvement of pumps and turbines"
h_turbine=0
alpha_1=1
alpha_2=1
z_1=4                  "Height of free surface of water"
z_2=0                  "Datum level"
```

Step 4 of 9

```
"Head loss is given by"
h_loss=((f*L/D)+K_L)*(V_2^2/(2*g#))

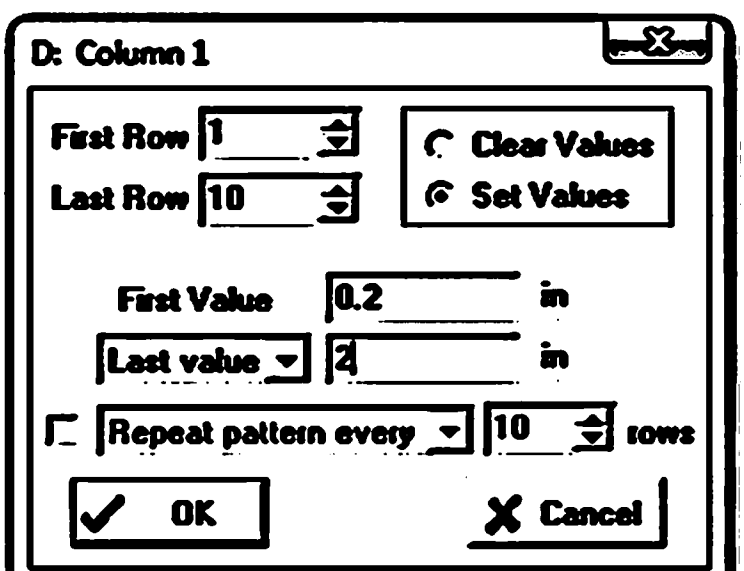
"Colebrook equation  frictional factor"
1/sqrt(f)=-2*log10(((e/D)/3.7)+(2.51/(Re*sqrt(f))))



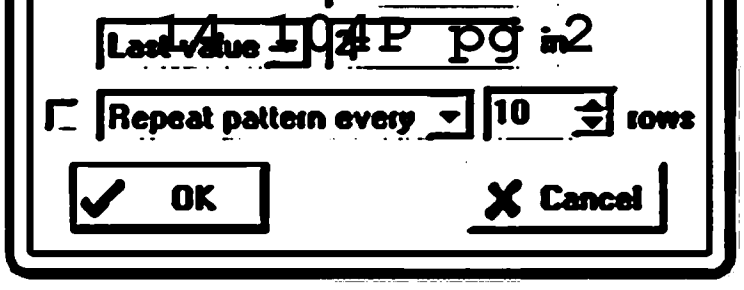
"Discharge"
V_dot=V_2*A
A=pi*D^2/4

"Reynolds number"
Re=rho_1*V_2*D*(3600/mu_1)

"Time taken for filling the glass"
T=Vol/V_dot
```



Step 5 of 9



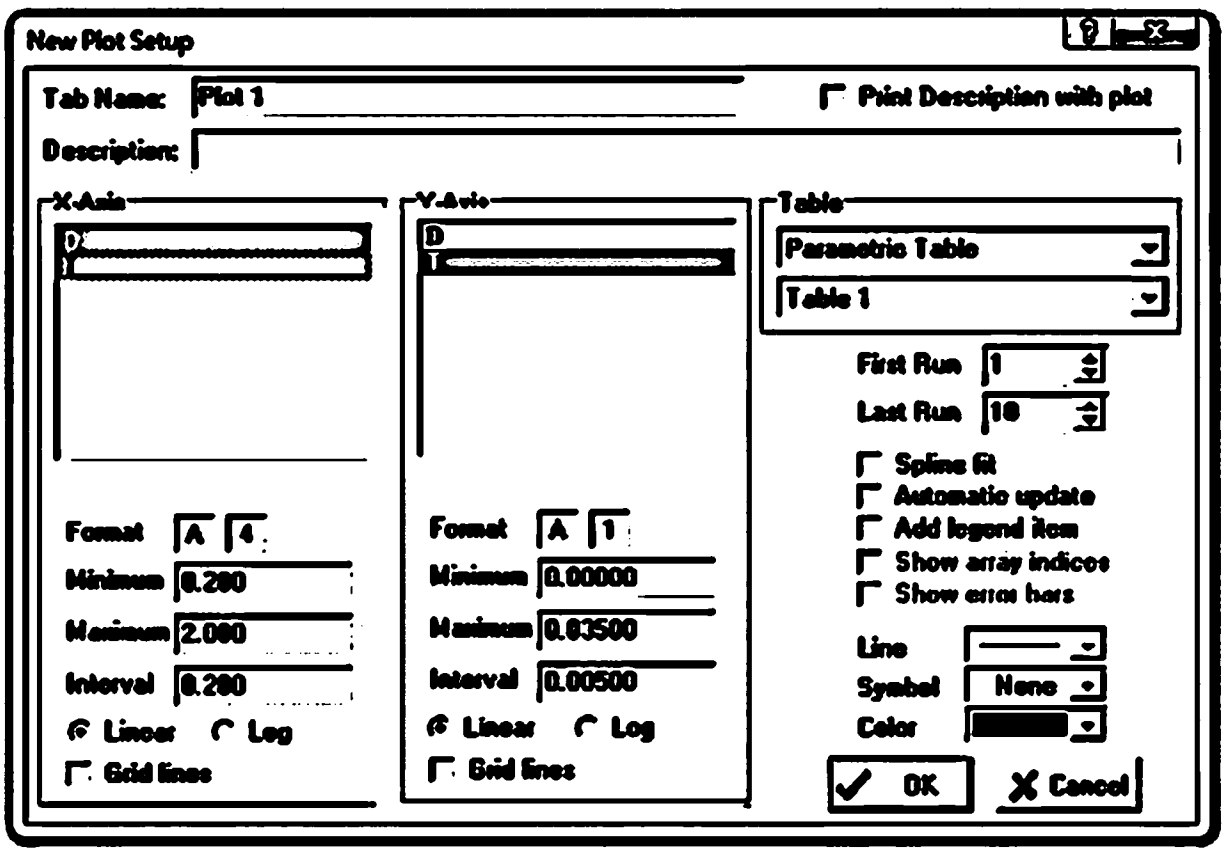
Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

Step 6 of 9

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Step 7 of 9

Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,



Parametric Table

Table 1

1..10	D [in]	T [s]

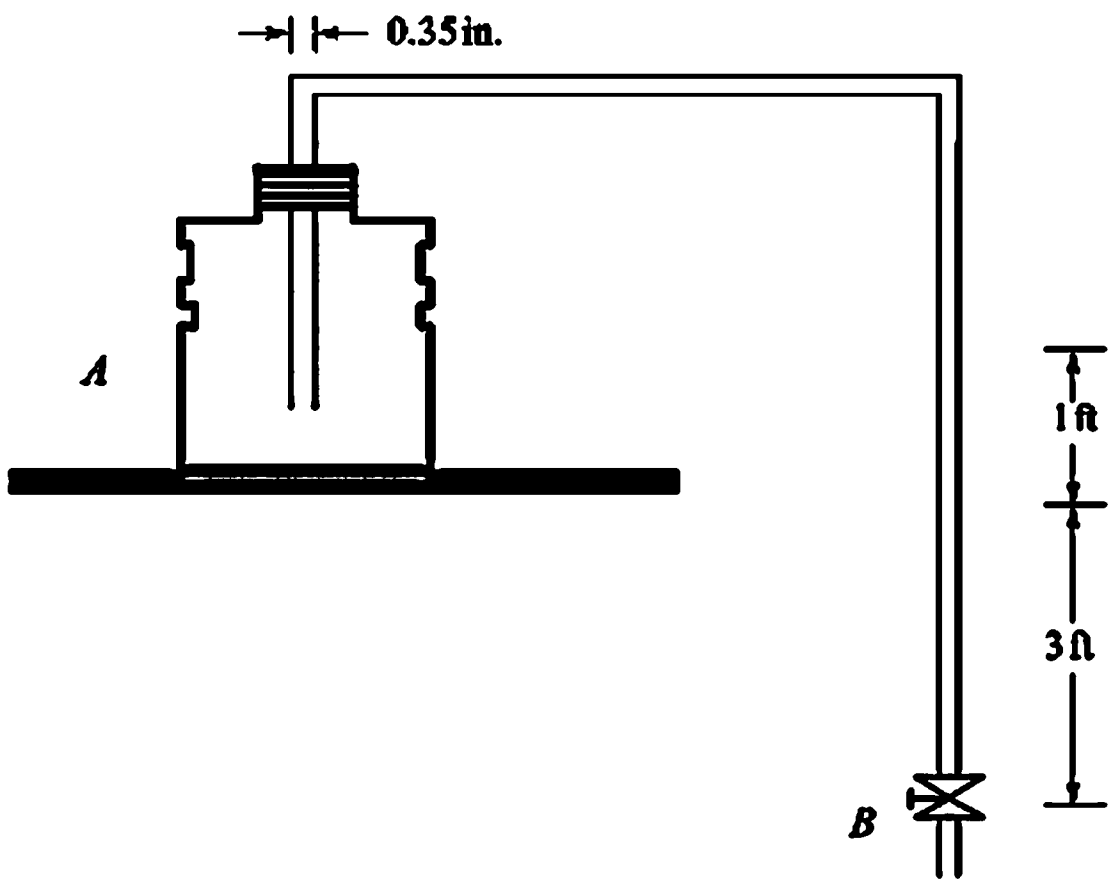
Step 8 of 9

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 9 of 9

By clicking on OK the graph will be generated as shown,

Question: 14.105P pg 1



Reconsider Prob. 14-103E. The office worker who set up the siphoning system purchased a 12-ft-long reel of the plastic tube and wanted to use the whole thing to avoid cutting it in pieces, thinking that it is the elevation difference that makes siphoning work, and the length of the tube is not important. So he used the entire 12-ft-long tube. Assuming the turns or constrictions in the tube are not significant (being very optimistic) and the same elevation is maintained, determine the time it takes to fill a glass of water for both cases (bottle nearly full and bottle nearly empty).

Step 1 of 12

Loading solution. Please wait ...

Step 2 of 12

Figure showing dinking water arrangement,

Step 3 of 12

The energy balance equation between free surface of water A and valve B is given by,

$$\frac{P_1}{\rho g}+\alpha_1\frac{V_1^2}{2g}+z_1+h_{pump}=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+z_2+h_{turbine}+h_{loss} \qquad \text{..... (1)}$$

The pressure acting on the free surface of the water and at the end of the pipe is atmospheric pressure only, $P_1=P_2$

The velocity of the water at free surface is, $V_1=0$

We know that there is no involvement of pumps and turbines therefore,

$h_{pump}=0$, $h_{turbine}=0$

We know that total head losses is given by,

$$h_{loss}=\left(f\frac{L}{D}+\sum K_1\right)\frac{V_2^2}{2g}$$

$$=\left(f\frac{12}{0.029}+2.8\right)\frac{V_2^2}{2\times 32.2}$$

$$=(6.42f+0.0434)V_2^2$$

Step 4 of 12

The equation (1) reduces to,

$$\frac{P_1}{\rho g}+\alpha_1\frac{0}{2g}+z_1+0=\frac{P_2}{\rho g}+\alpha_2\frac{V_2^2}{2g}+0+0+h_{loss}$$

$$z_1=\alpha_2\frac{V_2^2}{2g}+h_{loss}$$

$$=1\times\frac{V_2^2}{2\times 32.2}+\left[(6.42f+0.0434)V_2^2\right]$$

$$z_1=(6.42f+0.0584)V_2^2 \qquad \text{..... (2)}$$

Step 5 of 12

Discharge by the hose is fully open is given by,

$$\dot{V}=V_2\times A$$

$$=V_2\times\frac{\pi}{4}D^2$$

$$=V_2\times\frac{\pi}{4}\times(0.029)^2$$

$$\dot{V}=6.6\times10^{-4}(V_2) \qquad \text{..... (3)}$$

Reynolds number is given by,

$$\text{Re}=\frac{V_2D}{\nu}$$

$$=\frac{V_2\times 0.029}{1.052\times10^{-5}}$$

$$\text{Re}=2756.65(V_2) \qquad \text{..... (4)}$$

Time taken for filing the glass,

$$t=\frac{Vol}{\dot{V}}$$

$$=\frac{0.00835}{6.6\times10^{-4}(V_2)}$$

$$t=\frac{12.64}{V_2} \qquad \text{..... (5)}$$

Step 6 of 12

Frictional factor is given by,

$$\frac{1}{\sqrt{f}}=-2.0\log\left(\frac{\varepsilon/D}{3.7}+\frac{2.51}{\text{Re}\sqrt{f}}\right)$$

$$=-2.0\log\left(0+\frac{2.51}{\text{Re}\sqrt{f}}\right) \qquad \text{(Since roughness factor, } \varepsilon=0\text{)}$$

$$\frac{1}{\sqrt{f}}=-2.0\log\left(\frac{2.51}{\text{Re}\sqrt{f}}\right) \qquad \text{..... (6)}$$

$$= -2.0\log\left(0+\frac{2.51}{\mathrm{Re}\sqrt{f}}\right) \quad \text{(Since roughness factor, } \varepsilon = 0\text{)}$$

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{2.51}{\mathrm{Re}\sqrt{f}}\right) \qquad \ldots\ldots (6)$$

Step 7 of 12

a) When the bottle is fist opened,

The height of the frees surface of water,

z_1 = Height from glass to bottle + Height of water free surface

$= 3+1$

$= 4\,\mathrm{ft}$

Equation (2) simplifies as,

$$4 = (6.42f + 0.0584)V_2^2$$

$$f = \frac{1}{6.42}\left(\frac{4}{V_2^2} - 0.0584\right) \qquad \ldots\ldots (7)$$

$$= \left[\frac{0.623}{V_2^2} - \left(9.09\times10^{-3}\right)\right]$$

Step 8 of 12

Substituting in equations (4) and (7) in (6) the equation modifies as follows,

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{\frac{0.623}{V_2^2} - \left(9.09\times10^{-3}\right)}} = -2.0\log\left(\frac{2.51}{2756.65\times V_2\times\sqrt{\frac{0.623}{V_2^2} - \left(9.09\times10^{-3}\right)}}\right)$$

$$V_2 = 3.986\,\mathrm{ft/s}$$

Reynolds number form equation (4),

$$\mathrm{Re} = 2756.65(V_2)$$

$$= 2756.65(3.986)$$

$$= 10988$$

Since the obtained Reynolds number is grater than 4000 flow is in turbulent nature.

Step 9 of 12

Time taken to fill the glass can be found form equation (5) as,

$$t = \frac{12.64}{V_2}$$

$$= \frac{12.64}{3.986}$$

$$= 3.171\,\mathrm{s}$$

Therefore the time taken to fill the glass is $\boxed{3.171\,\text{seconds}}$ when the bottle is full.

Step 10 of 12

b) When the bottle is almost empty,

The height of the frees surface of water,

z_1 = Height from glass to bottle + Height of water free surface

$= 3+0$

$= 3\,\mathrm{ft}$

Equation (2) simplifies as,

$$3 = (6.42f + 0.0584)V_2^2$$

$$f = \frac{1}{6.42}\left(\frac{3}{V_2^2} - 0.0584\right) \qquad \ldots\ldots (8)$$

$$= \left[\frac{0.467}{V_2^2} - \left(9.09\times10^{-3}\right)\right]$$

Step 11 of 12

Substituting in equations (4) and (7) in (6) the equation modifies as follows,

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{2.51}{\mathrm{Re}\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{\frac{0.467}{V_2^2} - \left(9.09\times10^{-3}\right)}} = -2.0\log\left(\frac{2.51}{2756.65\times V_2\times\sqrt{\frac{0.467}{V_2^2} - \left(9.09\times10^{-3}\right)}}\right)$$

$$V_2 = 3.395\,\mathrm{ft/s}$$

Reynolds number form equation (4),

$$\mathrm{Re} = 2756.65(V_2)$$

$$= 2756.65(3.395)$$

$$= 9358.82$$

Since the obtained Reynolds number is grater than 4000 flow is in turbulent nature.

Step 12 of 12

Time taken to fill the glass can be found form equation (5) as,

$$t = \frac{12.64}{V_2}$$

$$= \frac{12.64}{3.395}$$

$$= 3.72\,\mathrm{s}$$

Therefore the time taken to fill the glass is $\boxed{t = 3.72\,\text{seconds}}$ when the bottle is almost empty.

$= 3.72s$

Therefore the time taken to fill the glass is $\boxed{t = 3.72 \text{ seconds}}$ when the bottle is almost empty.

Question: 14.106P pg 1

A circular water pipe has an abrupt expansion from diameter $D1$ = 15 cm to $D2$ = 20 cm. The pressure and the average water velocity in the smaller pipe are $P1$ = 120 kPa and 10 m/s, respectively, and the flow is turbulent. By applying the continuity, momentum, and energy equations and disregarding the effects of the kinetic energy and momentum- flux correction factors, show that the loss coefficient for sudden expansion is $KL = (1 - D_1^2/D_2^2)2$, and calculate KL and $P2$for the given case.

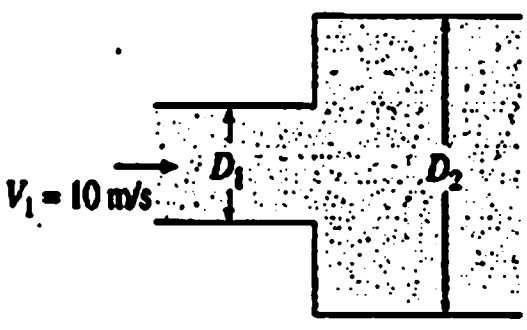


FIGURE P14–106

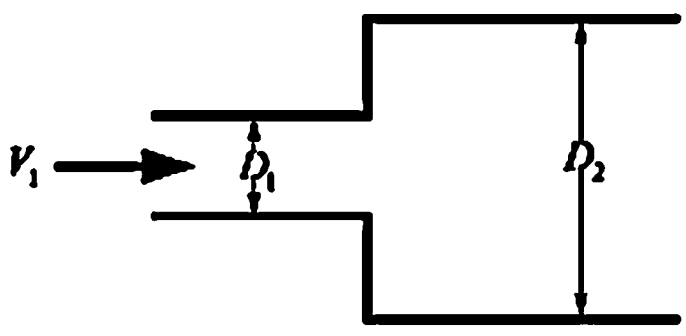
Step 1 of 9

Given data:

The diameter of the pipe 1, $D_1 = 15$ cm

The diameter of the pipe 2, $D_2 = 20$ cm



The pressure in pipe 1, $P_1 = 120$ kPa

The average velocity in pipe 1, $V_1 = 10$ m/s

The flow is turbulent.

Step 2 of 9

Given diagram:

Step 3 of 9

From the continuity equation,

$$\rho V_1 A_1 = \rho V_2 A_2$$

$$V_2 = V_1 \frac{A_1}{A_2}$$

The momentum equation for the control volume is given by

$$\sum \vec{F} = \sum_{\text{out}} \beta \dot{m} V - \sum_{\text{in}} \beta \dot{m} V$$

$$P_1 A_1 - P_2 A_2 = \dot{m}(V_2 - V_1)$$

$$P_1 A_1 - P_2 A_2 = (\rho A_2 V_2)(V_2 - V_1)$$

$$P_1 A_1 - P_2 A_2 = \left(\rho A_2 V_1 \frac{A_1}{A_2}\right)\left(V_1 \frac{A_1}{A_2} - V_1\right)$$

$$P_1 A_2 - P_2 A_2 = \rho A_2 V_1^2 \frac{A_1}{A_2}\left(\frac{A_1}{A_2} - 1\right)$$

On simplifying and rearranging,

$$\frac{P_1 - P_2}{\rho} = V_1^2 \frac{A_1}{A_2}\left(\frac{A_1}{A_2} - 1\right) \quad \text{..... (1)}$$

Step 4 of 9

The energy equation is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},s} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L$$

Here, both are placed at same elevation. So, $z_1 = z_2$.

Here, there is no turbine and pump. So, $h_{\text{pump},s} = h_{\text{turbine},e} = 0$.

The head loss,

$$h_L = K_L \frac{V_1^2}{2g}$$

Step 5 of 9

Then, the energy equation becomes

$$\frac{P_1}{\rho g} + (1)\frac{V_1^2}{2g} + z_1 + (0) = \frac{P_2}{\rho g} + (1)\frac{V_2^2}{2g} + z_1 + (0) + K_L \frac{V_1^2}{2g}$$

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + K_L \frac{V_1^2}{2g}$$

$$\frac{P_1 - P_2}{\rho} + \frac{V_1^2 - V_2^2}{2} = K_L \frac{V_1^2}{2}$$

Substituting the equation (1) in above expression

$$V_1^2 \frac{A_1}{A_2}\left(\frac{A_1}{A_2} - 1\right) + \frac{V_1^2 - \left(V_1 \frac{A_1}{A_2}\right)^2}{2} = K_L \frac{V_1^2}{2}$$

$$2V_1^2 \frac{A_1}{A_2}\left(\frac{A_1}{A_2} - 1\right) + V_1^2 - \left(V_1 \frac{A_1}{A_2}\right)^2 = K_L V_1^2$$

Step 6 of 9

Simplifying and rearranging:

$$K_L = 2\frac{A_1}{A_2}\left(\frac{A_1}{A_2} - 1\right) + 1 - \left(\frac{A_1}{A_2}\right)^2$$

$$= 2\left(\frac{A_1}{A_2}\right)^2 - 2\frac{A_1}{A_2} + 1 - \left(\frac{A_1}{A_2}\right)^2$$

$$= \left(\frac{A_1}{A_2}\right)^2 - 2\frac{A_1}{A_2} + 1$$

$$= 2\left(\frac{A_1}{A_2}\right) - 2\frac{A_1}{A_2} + 1 - \left(\frac{A_1}{A_2}\right)$$ 4.106P pg 2

$$= \left(\frac{A_1}{A_2}\right)^2 - 2\frac{A_1}{A_2} + 1$$

$$= \left(\frac{\frac{\pi}{4}D_1^2}{\frac{\pi}{4}D_2^2}\right)^2 - 2\frac{\frac{\pi}{4}D_1^2}{\frac{\pi}{4}D_2^2} + 1$$

$$= \left(\frac{D_1^2}{D_2^2}\right)^2 - 2\frac{D_1^2}{D_2^2} + 1$$

$$= \left(1 - \frac{D_1^2}{D_2^2}\right)^2$$

Thus the expression for loss coefficient for sudden expansion is $\boxed{K_L = \left(1 - \frac{D_1^2}{D_2^2}\right)^2}$

Step 7 of 9

Substituting the known values:

$$K_L = \left(1 - \frac{0.15^2}{0.2^2}\right)^2$$

$$= 0.1914$$

Therefore, the coefficient for sudden expansion is $\boxed{K_L = 0.1914}$

Step 8 of 9

Now, the velocity at exit

$$V_2 = V_1\frac{A_1}{A_2}$$

$$= V_1\frac{\frac{\pi}{4}D_1^2}{\frac{\pi}{4}D_2^2}$$

$$= V_1\frac{D_1^2}{D_2^2}$$

$$= 10\times\frac{0.15^2}{0.2^2}$$

$$= 5.625 \text{ m/s}$$

Step 9 of 9

Substituting the known values in equation (1)

$$\frac{P_1 - P_2}{\rho} = V_1^2\frac{A_1}{A_2}\left(\frac{A_1}{A_2} - 1\right)$$

$$= V_1^2\frac{D_1^2}{D_2^2}\left(\frac{D_1^2}{D_2^2} - 1\right)$$

$$\frac{\left(120\times10^3\right) - P_2}{1000} = (10)^2\times\frac{0.15^2}{0.2^2}\left(\frac{0.15^2}{0.2^2} - 1\right)$$

$$P_2 = 144.61\times10^3 \text{ Pa}$$

Therefore, the pressure, $\boxed{P_2 = 144.61\times10^3 \text{ Pa}}$

Question:

The water at 20°C in a 10-m-diameter. 2-m-high aboveground swimming pool is to be emptied by unplugging a 5-cm-diameter, 25-m-long horizontal plastic pipe attached to the bottom of the pool. Determine the initial rate of discharge of water through the pipe and the time (hours) it would take to empty the swimming pool completely assuming the entrance to the pipe is well-rounded with negligible loss. Take the friction factor of the pipe to be 0.022. Using the initial discharge velocity, check if this is a reasonable value for the friction factor.

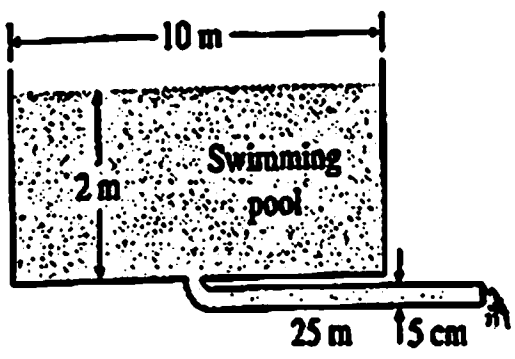


FIGURE P14–107

Step 1 of 12

Given data:

Temperature of the water $T = 20°C$

The diameter of the swimming pool, $D_1 = 10$ m

The height of the swimming pool, $H = 2$ m

The diameter of the pipe, $D = 5$cm

The length of the pipe, $L = 25$ m

The friction factor, $f = 0.022$

The pipe is made of plastic.

Step 2 of 12

From the table of properties of saturated water, corresponding to 20°C,

The density of water, $\rho = 998\ \text{kg/m}^3$

The dynamic viscosity, $\mu = 1.002 \times 10^{-3}\ \text{kg/m} \cdot \text{s}$

The roughness of plastic, $\varepsilon = 0$

Step 3 of 12

Let point 1 is at the entrance of the pipe

point 2 is at the exit of the pipe.

The velocity at point 1 is low and the velocity at point 2 is the discharge velocity.

Let the point 1 be the reference point.

The energy equation for a control volume between two points is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},e} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L \qquad \text{..... (1)}$$

Here, there is no pump or turbine in the pipe system. So, $h_{\text{pump},e} = h_{\text{turbine},e} = 0$.

The effect of kinetic energy correction factor is assumed to be negligible.

So, $\alpha_1 = \alpha_2 = 1$

The pressures, $P_1 = P_2 = P_{\text{atm}}$

Step 4 of 12

The elevations, when time $t = 0$

$z_1 = 2$ m

$z_2 = 0$

The velocities at time $t = 0$,

$$V_1 \approx 0$$

$$V_{2,t=0} = \frac{\dot{V}}{A_c} = \frac{\dot{V}}{\frac{\pi}{4}D^2} = \frac{\dot{V}}{\frac{\pi}{4}(0.05\ \text{m})^2} = 509.3\dot{V} \qquad \text{..... (2)}$$

Step 5 of 12

The head loss,

$$h_L = f\frac{L}{D}\frac{V_{2,t=0}^2}{2g} = 0.022\left(\frac{25\ \text{m}}{0.05\ \text{m}}\right)\frac{(509.3\dot{V})^2}{2(9.81\ \text{m/s}^2)} = 145.426 \times 10^3\ \dot{V}^2$$

Step 6 of 12

Substitute the known values in equation (1) for time $t = 0$.

$$\frac{P_{\text{atm}}}{\rho g} + 0 + z_1 + 0 = \frac{P_{\text{atm}}}{\rho g} + (1)\frac{V_{2,t=0}^2}{2g} + 0 + 0 + h_L$$

$$z_1 = \frac{V_{2,t=0}^2}{2g} + h_L$$

$$2\ \text{m} = \frac{(509.3\dot{V})^2}{2(9.81\ \text{m/s}^2)} + 145.426 \times 10^3\ \dot{V}^2$$

$$= 13.22 \times 10^3\ \dot{V}^2 + 145.426 \times 10^3\ \dot{V}^2$$

$$\dot{V} = \sqrt{\frac{2}{158.646 \times 10^3}}$$

$$= 3.55 \times 10^{-3}\ \text{m}^3/\text{s}$$

$$= 3.55\ \text{L/s}$$

Therefore, the initial rate of discharge, $\boxed{\dot{V} = 3.55\ \text{L/s}}$

$= \sqrt{158.646 \times 10^{-6}}$

$= 3.55 \times 10^{-3}\ \text{m}^3/\text{s}$

$= 3.55\ \text{L/s}$

Therefore, the initial rate of discharge, $\boxed{\dot{V} = 3.55\ \text{L/s}}$

Step 7 of 12

The elevation at any given time,

$$z = \frac{V_2^2}{2g} + h_L$$

$$= \frac{V_2^2}{2g} + f\frac{L}{D}\frac{V_2^2}{2g}$$

$$= \frac{V_2^2}{2g}\left(1 + f\frac{L}{D}\right)$$

$$V_2 = \sqrt{\frac{2gz}{1 + f\frac{L}{D}}}$$

The rate of flow at any given time,

$$\dot{V} = V_2 A_t$$

$$= \sqrt{\frac{2gz}{1 + f\frac{L}{D}}}\left(\frac{\pi}{4}D^2\right)$$

$$= \frac{\pi}{4}D^2\sqrt{\frac{2gz}{1 + f\frac{L}{D}}}$$

Step 8 of 12

Then, the amount of water that flows through the pipe during a differential time interval dt,

$$dV = \dot{V}dt$$

$$= \frac{\pi}{4}D^2\sqrt{\frac{2gz}{1 + f\frac{L}{D}}}\cdot dt \qquad \text{..... (3)}$$

The decrease in the volume of water in the pool,

$$dV = A_{t,\text{tank}}(-dz)$$

$$= \frac{\pi}{4}D_1^2(-dz) \qquad \text{..... (4)}$$

The height $(-dz)$ is negative because the volume is decreasing.

Step 9 of 12

Now, from equations (3) and (4),

$$\frac{\pi}{4}D^2\sqrt{\frac{2gz}{1 + f\frac{L}{D}}}\cdot dt = \frac{\pi}{4}D_1^2(-dz)$$

$$dt = -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D}}{2g}}\left(z^{-\frac{1}{2}}\right)\cdot dz$$

Step 10 of 12

On integrating,

$$\int_0^t dt = \int_{z_1}^0 -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D}}{2g}}\left(z^{-\frac{1}{2}}\right)\cdot dz$$

$$[t]_0^t = -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D}}{2g}}\left[\frac{z^{\frac{1}{2}}}{\frac{1}{2}}\right]_{z_1}^0$$

$$t - 0 = -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D}}{2g}}\left[\frac{0^{\frac{1}{2}}}{\frac{1}{2}} - \frac{z_1^{\frac{1}{2}}}{\frac{1}{2}}\right]$$

$$= -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D}}{2g}}\left(-2z_1^{\frac{1}{2}}\right)$$

$$t = 2\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D}}{2g}}\left(z_1^{\frac{1}{2}}\right)$$

Step 11 of 12

Now substituting the known values:

$$t = 2\frac{(10\ \text{m})^2}{(0.05\ \text{m})^2}\sqrt{\frac{1 + 0.022\frac{25\ \text{m}}{0.05\ \text{m}}}{2(9.81\ \text{m/s}^2)}}\left((2\ \text{m})^{1/2}\right)$$

$$= 88480.20\ \text{s}$$

$$= 24.57\ \text{h}$$

Therefore, the time for emptying the tank is $\boxed{t = 24.57\ \text{h}}$

Step 12 of 12

The Reynolds number,

$$\text{Re} = \frac{\rho V_{2,t=0} D}{\mu}$$

$$= \frac{(998\ \text{kg/m}^3)(509.3 \times 3.55 \times 10^{-3}\ \text{m/s})(0.05\ \text{m})}{1.002 \times 10^{-3}\ \text{kg/m}\cdot\text{s}}$$

$$= 90.04 \times 10^3$$

For turbulent flow, the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

$$= \frac{(\quad)(\quad)(\quad)}{1.002 \times 10^{-3}\ \text{kg/m}\cdot\text{s}} \quad \text{14 107P pg 3}$$

$$= 90.04 \times 10^3$$

For turbulent flow, the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$$

where, f is the friction factor. Now by substituting the known values:

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{0/0.05\ \text{m}}{3.7} + \frac{2.51}{90.04 \times 10^3 \sqrt{f}}\right)$$

$$= -2.0 \log\left(0 + \frac{2.787 \times 10^{-5}}{\sqrt{f}}\right)$$

$$= -2.0 \log\left(\frac{2.787 \times 10^{-5}}{\sqrt{f}}\right)$$

By solving the above equation, the friction factor, $f = 0.0184$

So, the given value of friction factor is not an accurate one.

Question:

Reconsider Prob. 14-107. Using EES (or other) software, investigate the effect of the discharge pipe diameter on the time required to empty the pool completely. Let the diameter vary from 1 to 10 cm, in increments of 1 cm. Tabulate and plot the results.

Step 1 of 6

Given data:

Temperature of the water $T = 20°C$

The diameter of the swimming pool, $D_1 = 10$ m

The height of the swimming pool, $H = 2$ m

The diameter of the pipe, $D = 5$cm

The length of the pipe, $L = 25$ m

The friction factor, $f = 0.022$

Step 2 of 6

From the table of properties of saturated water, corresponding to 20°C,

The density of water, $\rho = 998\ kg/m^3$

The dynamic viscosity, $\mu = 1.002 \times 10^{-3}\ kg/m \cdot s$

Acceleration due to gravity is considered as, $g = 9.81 m/s$

The roughness of plastic, $\varepsilon = 0$

Step 3 of 6

This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below,

```
"Given data"
D_1=10 [m]
H=2 [m]
"D=0.01 [m]"
L=25 [m]
f=0.022
rho=998 [kg/m^3]
mu=0.001002 [kg/m-s]
g=9.81 [m/s]

"Energy equation for a control volume between two points"

(P_1/(rho*g))+(alpha_1*(V_1^2)/2*g)+z_1+h_pump=(P_2/(rho*g))+(alpha_2*(V_2^2)/2*g)+z_2+h_turbine+h_l

P_1=P_2                    "Since both are open to atmosphere"

h_pump=0                   "There is no pump or turbine in the pipe system."

z_2=0                      "This level is considered as datum"

h_l=f*(L*V_2^2)/(D*2*g)    "Head loss"

"Discharge of the pipe"

V_2=Vdot/A_c

A_c=pi*D^2/4

V_2=(2*g*H)/((1+f*L/D))^0.5

"Time required to empty the pool completely"

Time=(D_1/D)^2*(2*H/(1+f*L/D)/g)^0.5*convert(s,h)
```

Step 4 of 6

To check weather the program typed is in correct mathematical format or not go to "Options > Function info" a window opens as show below ,

Given data

$D_1 = 10$ [m]

$H = 2$ [m]

$D = 0.01$ [m]

$L = 25$ [m]

$f = 0.022$

$\rho = 998$ [kg/m^3]

$\mu = 0.001002$ [kg/m-s]

$g = 9.81$ [m/s]

Energy equation for a control volume between two points

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{pump} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{turbine} + h_l$$

$P_1 = P_2$ Given both are open to atmosphere

$h_{pump} = 0$ There is no pump or turbine in the pipe system

$h_{turbine} = 0$

$\alpha_1 = 1$ The effect of kinetic energy correction factor is assumed to be negligible

$\alpha_2 = 1$

$V_1 = 0$ Water is considered to be stationary in side the pool

$z_1 = H$ Free surface of pool

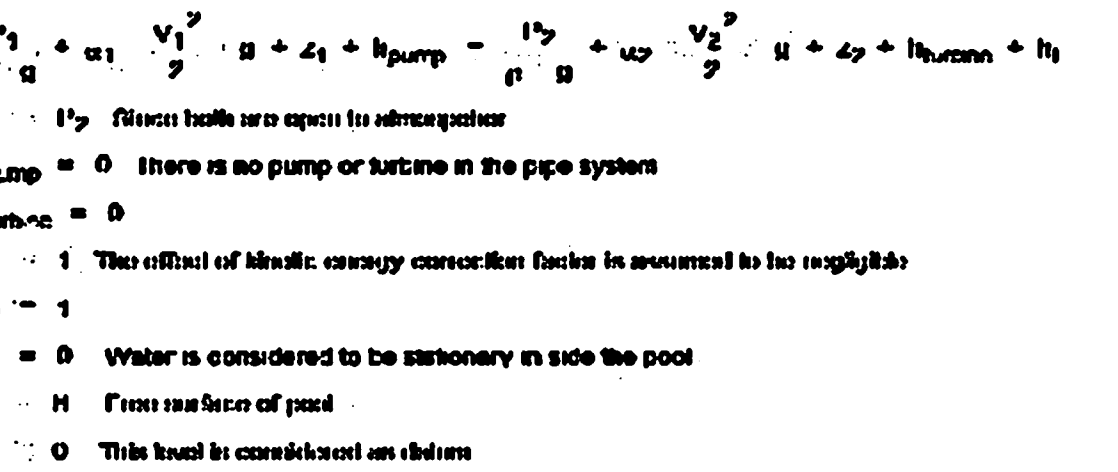
$z_2 = 0$ This level is considered as datum

$h_l = f \cdot \frac{L \cdot V_2^2}{D \cdot 2 \cdot g}$ Head loss

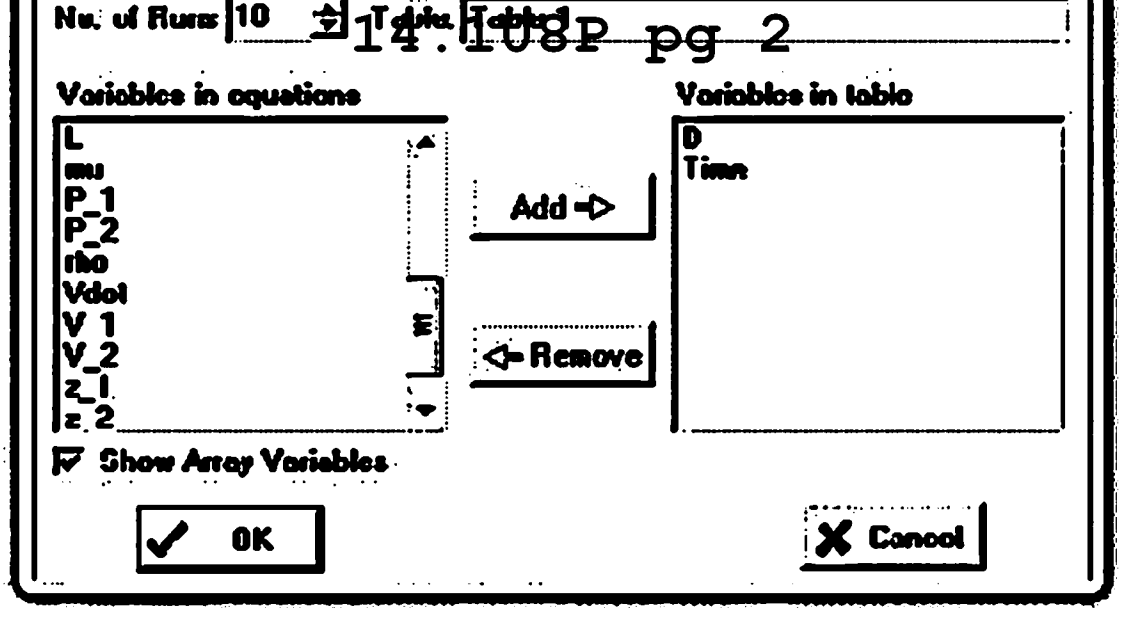
Discharge of the pipe

$$V_2 = \frac{Vdot}{A_c}$$

$$A_c = \pi \cdot \frac{D^2}{4}$$

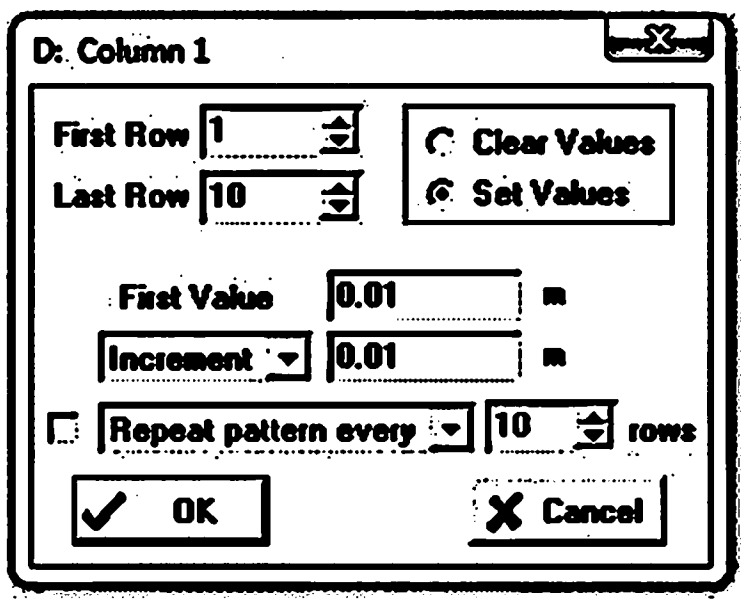


$$V_2 = \left[2 \cdot g \cdot \left[\frac{H}{1 + f \cdot \frac{L}{D}}\right]\right]^{0.5}$$



Time required to empty the pool completely

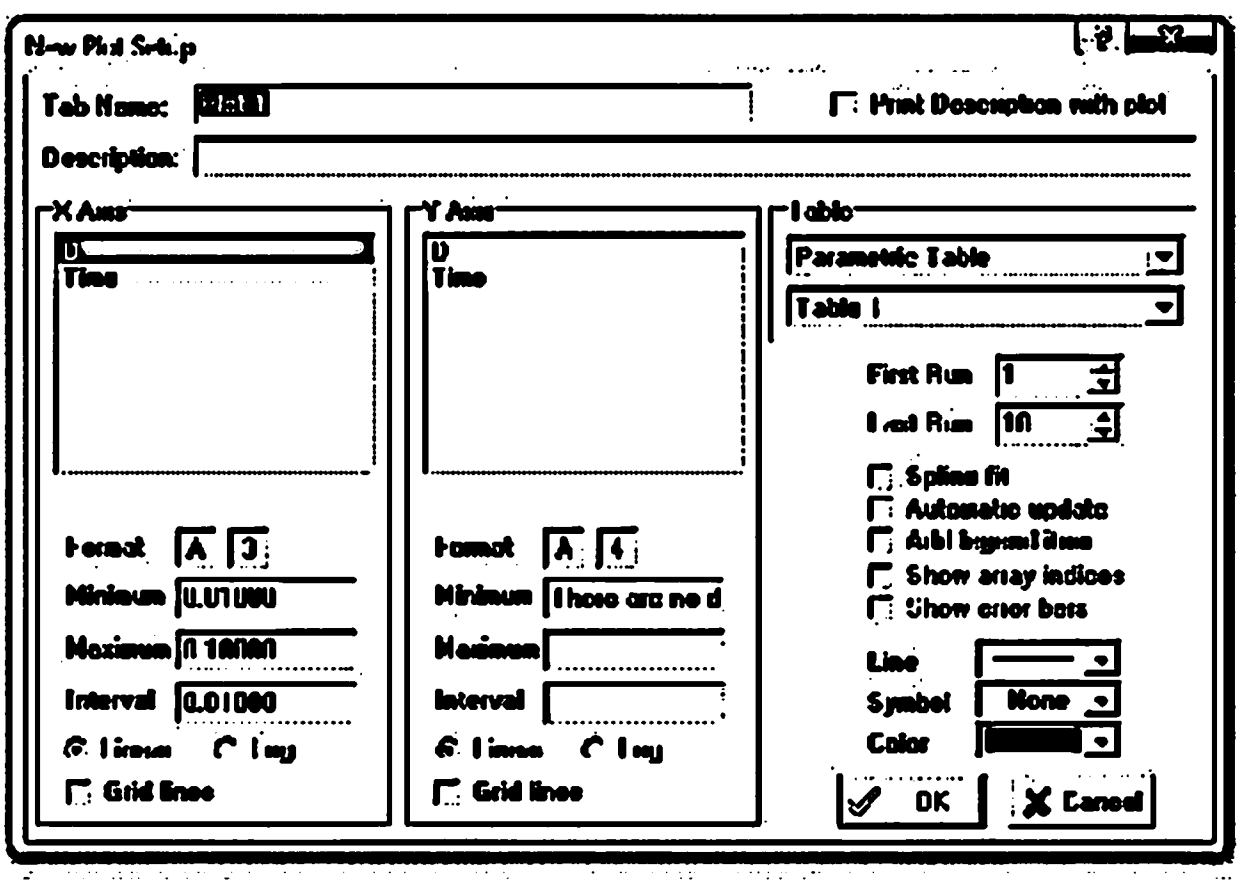
$$time = \left[\frac{D_1}{D}\right]^2 \cdot \left[2 \cdot H \cdot \left[\frac{1 + f \cdot \frac{L}{D}}{g}\right]\right]^{0.5} \cdot \left[0.000277778 \cdot \frac{hr}{s}\right]$$



Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

Step 5 of 6

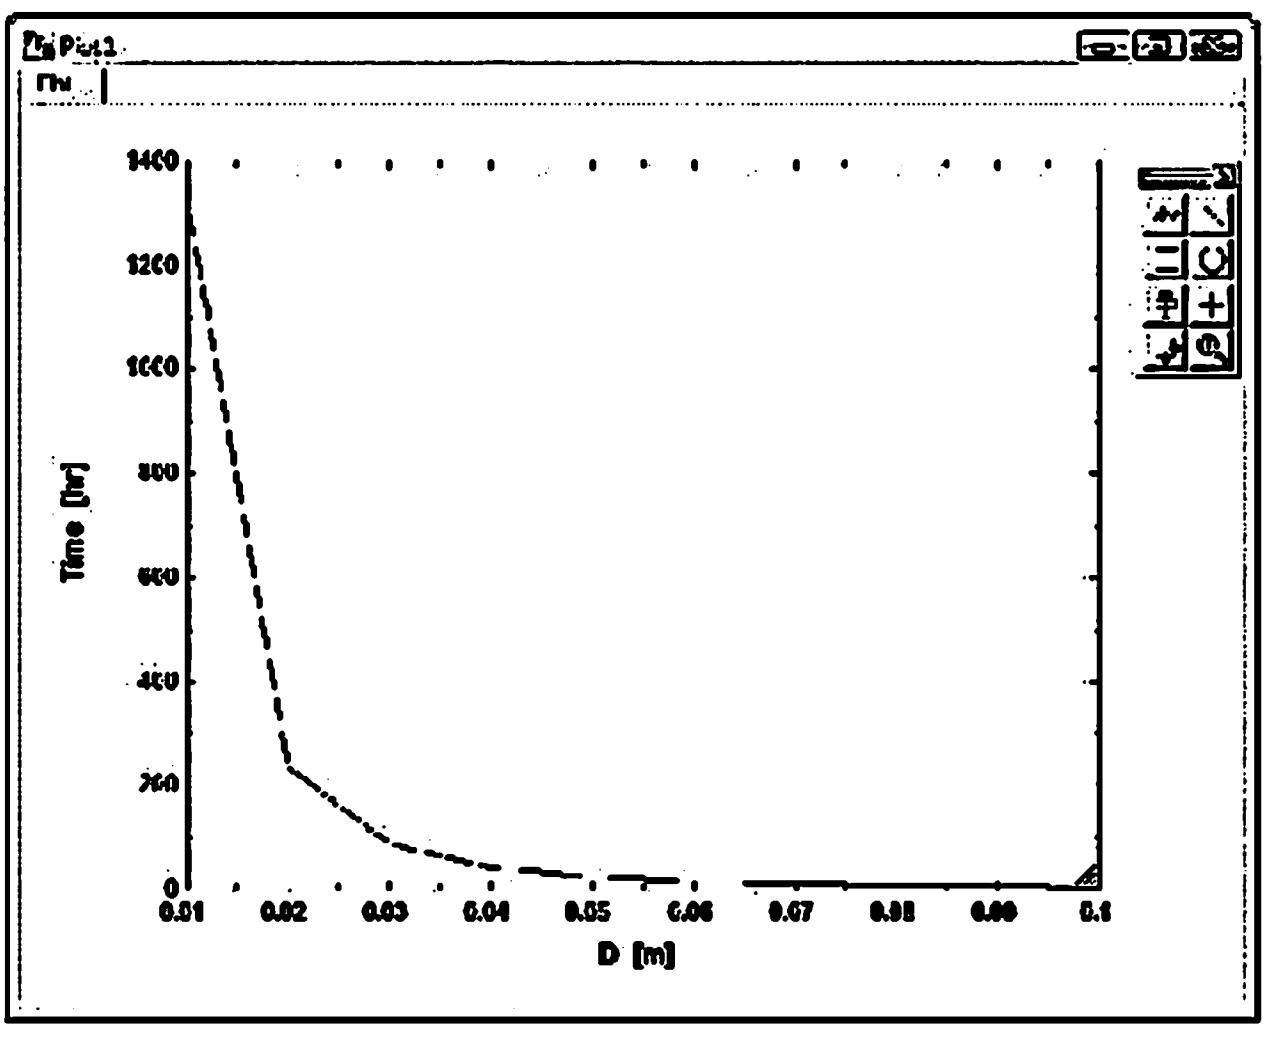
To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,



Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Parametric Table

Table 1



1..10	D [m]	Time [hr]
Run 1	0.01	1327
Run 2	0.02	236.7
Run 3	0.03	86.66
Run 4	0.04	42.58
Run 5	0.05	24.58
Run 6	0.06	15.71
Run 7	0.07	10.77
Run 8	0.08	7.777
Run 9	0.09	5.84
Run 10	0.1	4.522

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 6 of 6

By clicking on OK the graph will be generated as shown,

14.1081 pg 3

Question: 14.109P pg 1

Repeat Prob. 14-107 for a sharp-edged entrance to the pipe with $KL = 0.5$. Is this "minor loss" truly "minor" or not?

Step 1 of 12

Given data:

Temperature of the water, $T = 20°C$

The diameter of the swimming pool, $D_1 = 10$ m

The height of the swimming pool, $H = 2$ m

The diameter of the pipe, $D = 5$ cm $= 0.05$ m

The length of the pipe, $L = 25$ m

The pipe is having sharp edged entrance

The loss coefficient of sharp edged entrance, $K_{L,\text{entrance}} = 0.5$

The pipe is made of plastic.

The friction factor, $f = 0.022$

Step 2 of 12

The flow is assumed to be turbulent, fully developed and incompressible. The elevation deference between the pipe and the fountain is negligible.

From the table of properties of saturated water, corresponding to $20°C$,

The density of water, $\rho = 998\ \text{kg/m}^3$.

The dynamic viscosity, $\mu = 1.002 \times 10^{-3}\ \text{kg/m·s}$

The roughness of plastic, $\varepsilon = 0$

Step 3 of 12

Let point 1 be at the entrance of the pipe and point 2 be at the exit of the pipe. The velocity at point 1 is low and the velocity at point 2 is the discharge velocity.
Let the point 1 be the reference point.

The energy equation for a control volume between two points is given by

$$\frac{P_1}{\rho g} + \alpha_1 \frac{V_1^2}{2g} + z_1 + h_{\text{pump},u} = \frac{P_2}{\rho g} + \alpha_2 \frac{V_2^2}{2g} + z_2 + h_{\text{turbine},e} + h_L \qquad \text{..... (1)}$$

Here, there is no pump or turbine in the pipe system. So, $h_{\text{pump},u} = h_{\text{turbine},e} = 0$.

The pressures, $P_1 = P_2 = P_{\text{atm}}$

Step 4 of 12

The elevations, when time $t = 0$

$z_1 = 2$ m

$z_2 = 0$

The velocities at time $t = 0$,

$$V_1 \approx 0$$

$$V_{2,t=0} = \frac{\dot{V}}{A_c} = \frac{\dot{V}}{\frac{\pi}{4}D^2} = \frac{\dot{V}}{\frac{\pi}{4}(0.05\ \text{m})^2} = 509.3\dot{V} \qquad \text{..... (2)}$$

Step 5 of 12

The head loss,

$$h_L = \left(f\frac{L}{D} + K_L\right)\frac{V_{2,t=0}^2}{2g} = \left[0.022\left(\frac{25\ \text{m}}{0.05\ \text{m}}\right) + 0.5\right]\frac{(509.3\dot{V})^2}{2(9.81\ \text{m/s}^2)} = 152.036 \times 10^3\,\dot{V}^2$$

Step 6 of 12

Substituting the known values in equation (1).for time $t = 0$:

$$\frac{P_{\text{atm}}}{\rho g} + 0 + z_1 + 0 = \frac{P_{\text{atm}}}{\rho g} + (1)\frac{V_{2,t=0}^2}{2g} + 0 + 0 + h_L$$

$$z_1 = \frac{V_{2,t=0}^2}{2g} + h_L$$

$$2\ \text{m} = \frac{(509.3\dot{V})^2}{2(9.81\ \text{m/s}^2)} + 152.036 \times 10^3\,\dot{V}^2 = 13.22 \times 10^3\,\dot{V}^2 + 152.036 \times 10^3\,\dot{V}^2$$

$$\dot{V} = \sqrt{\frac{2}{162.256 \times 10^3}} = 3.51 \times 10^{-3}\ \text{m}^3/\text{s} = 3.51\ \text{L/s}$$

Therefore, the initial rate of discharge is $\boxed{\dot{V} = 3.51\ \text{L/s}}$

Step 7 of 12

The elevation at any given time,

$$z = \frac{V_2^2}{2g} + h_L = \frac{V_2^2}{2g} + \left(f\frac{L}{D} + K_L\right)\frac{V_2^2}{2g} = \frac{V_2^2}{2g}\left(1 + f\frac{L}{D} + K_L\right)$$

$$= \sqrt{\frac{2}{\left(1 + f\frac{L}{D} + K_L\right)}}$$

$$= \frac{V_2^2}{2g} + \left(f\frac{L}{D} + K_L\right)\frac{V_2^2}{2g}$$

$$= \frac{V_2^2}{2g}\left(1 + f\frac{L}{D} + K_L\right)$$

$$V_2 = \sqrt{\frac{2gz}{1 + f\frac{L}{D} + K_L}}$$

Step 8 of 12

The rate of flow at any given time,

$$\dot{V} = V_2 A_c$$

$$= \sqrt{\frac{2gz}{1 + f\frac{L}{D} + K_L}}\left(\frac{\pi}{4}D^2\right)$$

$$= \frac{\pi}{4}D^2\sqrt{\frac{2gz}{1 + f\frac{L}{D} + K_L}}$$

Step 9 of 12

Then, the amount of water that flows through the pipe during a differential time interval dt,

$$dV = \dot{V}dt$$

$$= \frac{\pi}{4}D^2\sqrt{\frac{2gz}{1 + f\frac{L}{D} + K_L}}\cdot dt \qquad \text{..... (3)}$$

The decrease in the volume of water in the pool,

$$dV = A_{c,\text{tank}}(-dz)$$

$$= \frac{\pi}{4}D_1^2(-dz) \qquad \text{..... (4)}$$

The height $(-dz)$ is negative because the volume is decreasing.

Step 10 of 12

Now, from the equations (3) and (4),

$$\frac{\pi}{4}D^2\sqrt{\frac{2gz}{1 + f\frac{L}{D} + K_L}}\cdot dt = \frac{\pi}{4}D_1^2(-dz)$$

$$dt = -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D} + K_L}{2g}}\left(z^{-\frac{1}{2}}\right)\cdot dz$$

On integrating,

$$\int_0^t dt = \int_{z_1}^0 -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D} + K_L}{2g}}\left(z^{-\frac{1}{2}}\right)\cdot dz$$

$$[t]_0^t = -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D} + K_L}{2g}}\left[\frac{z^{\frac{1}{2}}}{\frac{1}{2}}\right]_{z_1}^0$$

$$t - 0 = -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D} + K_L}{2g}}\left[\frac{0^{\frac{1}{2}}}{\frac{1}{2}} - \frac{z_1^{\frac{1}{2}}}{\frac{1}{2}}\right]$$

$$= -\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D} + K_L}{2g}}\left(-2z_1^{\frac{1}{2}}\right)$$

$$t = 2\frac{D_1^2}{D^2}\sqrt{\frac{1 + f\frac{L}{D} + K_L}{2g}}\left(z_1^{\frac{1}{2}}\right)$$

Step 11 of 12

Now substitute the known values.

$$t = 2\frac{(10\text{ m})^2}{(0.05\text{ m})^2}\sqrt{\frac{1 + 0.022\frac{25\text{ m}}{0.05\text{ m}} + 0.5}{2(9.81\text{ m/s}^2)}}\left((2\text{ m})^{1/2}\right)$$

$$= 90304.7\text{ s}$$

$$= 25.08\text{ hr}$$

Therefore, the time for emptying the tank is $\boxed{t = 25.08\text{ hr}}$

The Reynolds number,

$$\text{Re} = \frac{\rho V_{2,t-0}D}{\mu}$$

$$= \frac{(998\text{ kg/m}^3)(509.3 \times 3.51 \times 10^{-3}\text{ m/s})(0.05\text{ m})}{1.002 \times 10^{-3}\text{ kg/m}\cdot\text{s}}$$

$$= 89.02 \times 10^3$$

For turbulent flow, the Colebrook equation is $\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right)$, where, f is the friction factor.

Step 12 of 12

Substitute the known values.

$$\frac{1}{\sqrt{f}} = -2.0\log\left(\frac{0/0.05\text{ m}}{3.7} + \frac{2.51}{89.02 \times 10^3\sqrt{f}}\right)$$

$$= -2.0\log\left(0 + \frac{2.82 \times 10^{-5}}{\sqrt{f}}\right)$$

$$= -2.0\log\left(\frac{2.82 \times 10^{-5}}{\sqrt{f}}\right)$$

$$= -2.0 \log\left(0 + \frac{2.82 \times 10^{-5}}{\sqrt{f}}\right)$$

14.109P pg 3

$$= -2.0 \log\left(\frac{2.82 \times 10^{-5}}{\sqrt{f}}\right)$$

$$\frac{1}{\sqrt{f}} = -2.0 \log\left(\frac{2.82 \times 10^{-5}}{\sqrt{f}}\right)$$

By solving,

$f = 0.0041763$

So, the given value of friction factor is not an accurate one.

CHAPTER 15
SOLUTIONS

Question: 15.001P

Which car is more likely to be more fuel-efficient: one with sharp corners or one that is contoured to resemble an ellipse? Why?

Step 1 of 1

The car that is contoured to resemble an ellipse has more fuel efficient than the car with sharp corners, because the car that is contoured to resemble an ellipse has smaller drag coefficient and thus has smaller air resistance.

The sharp corners promote a fixed flow separation location, whereas roundness corners can lead to unsteadiness in the flow. Therefore, rounding is usually, but not always the best solution.

Question: 15.002P

Consider laminar flow over a flat plate. How does the local friction coefficient change with position?

Step 1 of 1

In a laminar flow the local friction coefficient varies with position. The local friction coefficient variations are based on the changes in the velocity boundary layer along the surface of the plate in the flow direction.

The local friction coefficient at a location x can be determined by the formula

$$C_{f,x} = \frac{0.664}{\mathrm{Re}_x^{0.5}}$$

Where, $C_{f,x}$ is the local friction coefficient at a location x.

x is the distance from the leading edge of the plate.

Re_x is the Reynolds number at the location x.

Here, Reynolds number,

$$\mathrm{Re}_x = \frac{Vx}{\nu}$$

Where, V is the upstream velocity.

x is the distance from the leading edge of the plate.

ν is the Kinematic viscosity.

Question: 15.003P

Explain when an external flow is two-dimensional, three-dimensional, and axisymmetric. What type of flow is the flow of air over a car?

Step 1 of 3

The flow over a body is classified as two-dimensional, three-dimensional, and axisymmetric based on the shape of the body through which the flow occurs.

The flow over a body is said to be two-dimensional when the body is very long and having a constant cross section and the flow is normal to the body.

Example:
Wind blowing over a long pipe perpendicular to its axis. The velocity component in axial direction is zero in this case therefore, the velocity is two-dimensional.

Step 2 of 3

When flow occurs over a body which possesses symmetry about an axis in the flow direction the flow can be considered as axisymmetric.
Example: A bullet piercing through air.

Step 3 of 3

Flow over a body that cannot be considered as two-dimensional flow or axisymmetric flow is called three-dimensional flow.
Example: Flow of air over a vehicle.

Flow of air over a car is a three-dimensional flow.

Question: 15.004P

What is the difference between the upstream velocity and the free-stream velocity? For what types of flow are these two velocities equal to each other?

Step 1 of 1

The velocity at which the fluid approaches a body is called upstream velocity. The velocity of the fluid relative to the body at which it approaches the body is called free-stream velocity. If the flow is uniform and the body is small relative to the rate of flow then upstream velocity and free stream velocity will be equal.

Question: 15.005P

What is the difference between streamlined and bluff bodies? Is a tennis ball a streamlined or bluff body?

Step 1 of 1

All the bodies subjected to fluid flow can be classified as streamlined or bluff bodies.
A body is said to be streamlined if the alignment of the body is altered to reduce the obstruction to the fluid flow. It is very easy to force a streamlined body through a fluid. Now a day's most of the vehicles ships and airplanes are streamlined to reduce the resistance caused by the fluid.

If the alignment of the body is not altered to reduce the obstruction to the fluid flow such a body is called a bluff body.
A tennis ball is a bluff body.

Question: 15.006P

Name some applications in which a large drag is desired.

Step 1 of 1

Larger drag means larger the friction, in some cases larger drag produces beneficial effect and we try to maximize it. In case of the brakes of automobiles large friction will be an advantage, larger the friction smaller will be the stopping distance. It is due to the drag that we are able to parachute, larger drag will decrease the rate of descent of the parachute, so for parachutes we try to maximize the drag.

Question: 15.007P

What is drag? What causes it? Why do we usually try to minimize it?

Step 1 of 3

While the moving of fluid over surface of a body it will cause two types of forces,

(1) Pressure force which is normal to the surface of the body and

(2) Shear force which is parallel to the surface of the body.

Consider only the resultant of these two forces. The resultant will be having two components one is perpendicular component and the other one is the parallel component.

Step 2 of 3

The component of the resultant force which acts in the direction of the flow is called the drag force or simply drag.

The component which acts perpendicular to the flow direction is called lift force.

In general a force which is exerted by the flowing body on the surface of the body in the flow direction is called drag.

Step 3 of 3

Drag will produce frictional effect on the surfaces of the body this will create undesirable effects. Reduction in drag will reduce the fuel consumption in automobiles, ships, submarines and aircrafts. It will also increase the safety and durability of structures subjected to high winds; it will also reduce the noise and vibration.

Question: 15.008P

What is lift? What causes it? Does wall shear contribute to the lift?

Step 1 of 1

The force which causes the body to move in the direction normal to the direction of fluid flow is called lift force and the motion in that direction is called lift. When a fluid moves over a body it exerts pressure force normal to the body and shear force parallel to the body surface. Both these forces have components in the direction of flow and normal to the direction of flow. The resultant components of both pressure force and shear forces in the direction normal to the fluid flow will push the body normal to the fluid flow. Therefore the sum of resultant components of pressure force and shear force will contribute to the lift. **Therefore, wall shear will contribute to the lift.**

Question: 15.009P

During flow over a given body, the drag force, the upstream velocity, and the fluid density are measured. Explain how you would determine the drag coefficient. What area would you use in the calculations?

Step 1 of 3

During flow over a given body if the drag force, upstream velocity, and the fluid density are measured the drag coefficient can be measured using the formula given below.

$$C_D = \frac{F_D}{\frac{1}{2}\rho V^2 A}$$

Where, F_D is the drag force.

ρ is the density of fluid.

V is the velocity.

A is the frontal area.

Step 2 of 3

Here the term $\frac{1}{2}\rho V^2$ is the dynamic pressure.

Now let us have a look at how the above equation can be deducted.

The drag force F_D is directly proportional to the product of dynamic pressure and frontal area.

$$F_D \propto \frac{1}{2}\rho V^2 A$$

In order to equalize RHS and LHS multiply RHS with a constant, this constant is called drag coefficient C_D

Therefore drag force $F_D = C_D \frac{1}{2}\rho V^2 A$.

Step 3 of 3

Here the area used is the frontal area of the body, which is the area projected on a plane normal to the direction of flow. It is the area seen by a person looking at the body from the direction of the approaching fluid. But for thin bodies the area A is the planform area. Planform area is the area seen by a person looking at the body from above in a direction normal to the body. Drag force F_D is the force exerted by the flowing fluid on a body in the flow direction.

Question: 15.010P

Define the frontal area of a body subjected to external flow. When is it appropriate to use the frontal area in drag and lift calculations?

Step 1 of 1

When we look at a body from the direction of fluid flow the area we see is called the frontal area. The frontal area can be used for the calculation of drag and lift if the bodies are blunt bodies like vehicles, airplanes, cylinders etc.

Question: 15.011P

Define the planform area of a body subjected to external flow. When is it appropriate to use the planform area in drag and lift calculations?

Step 1 of 1

When we look at a body from above in a direction normal to the flow, the area of the body we see is called the planform area. In drag and lift calculation of thin or slender bodies, planform area is appropriate to consider. Thus it is used for flat bodies, aero-foils and for other bodies where the frontal area is less.

Question: 15.012P

What is terminal velocity? How is it determined?

Step 1 of 1

When a body falls freely the main forces that act on the body are the drag force (the force a flowing fluid exerts on a body in the flow direction), the buoyancy force (the force which opposes the body's weight) and the weight of the body (acts downwards).

When the body is dropped from a height it first accelerates under the influence of its weight, as the body falls the motion of the body is resisted by the drag force acting opposite to the direction of the motion of the body. This drag force goes on increasing as the velocity of the body increases this continues until all the forces balance each other and the net force acting on the body is zero.

When the net force acting on the body becomes zero the velocity becomes constant and this constant velocity is the maximum velocity that the body can achieve and this velocity is called the terminal velocity.

Terminal velocity can be determined by setting the weight of the body equal to the sum of drag force and the buoyancy force.

Question: 15.013P

What is the difference between skin friction drag and pressure drag? Which is usually more significant for slender bodies such as airfoils?

Step 1 of 2

The force exerted by a fluid on a body in the flow direction is called drag. Drag force is the combined effect of wall shear and pressure forces. The part of drag that is caused by the wall shear stress is called skin friction drag because it is caused by the frictional effect. The part of drag that is caused by the pressure is called pressure drag.

Step 2 of 2

Skin friction drag or friction drag, $F_{D\text{friction}} = \frac{1}{2} C_{D\text{friction}} \rho A V^2$,

where, $C_{D\text{friction}}$ is the friction drag coefficient,

ρ is the density,

A is the frontal area and

V is the velocity.

The pressure drag, $F_{D\text{pressure}} = \frac{1}{2} C_{D\text{pressure}} \rho A V^2$,

where, $C_{D\text{pressure}}$ is the pressure drag coefficient,

ρ is the density,

A is the frontal area and

V is the velocity.

Question: 15.014P

What is the effect of surface roughness on the friction drag coefficient in laminar and turbulent flows?

Step 1 of 1

For laminar flow, the surface roughness doesn't influence the friction drag coefficient provided the roughness in not very large. But if the roughness is large, the friction drag coefficient also increases.

For turbulent flow, the increase in surface roughness increases the value of friction drag coefficient.

Question: 15.015P

In general, how does the drag coefficient vary with the Reynolds number at (*a*) low and moderate Reynolds numbers and (*b*) at high Reynolds numbers (Re > 104)?

Step 1 of 3

Drag coefficient depends on Reynolds number typically for Reynolds number below 10^4. The drag coefficient exhibit different behaviors in the low, moderate and high regions of Reynolds number.

Step 2 of 3

a)
At low and moderate Reynolds number the inertia effect is negligible therefore the drag coefficient is inversely proportional to the Reynolds number.

Step 3 of 3

b)
At higher Reynolds number the drag coefficient remains constant for almost all geometry, because at higher Reynolds number the flow becomes fully turbulent.

Question: 15.016P

What is the effect of streamlining on (*a*) friction drag and (*b*) pressure drag? Does the total drag acting on a body necessarily decrease as a result of streamlining? Explain.

Step 1 of 2

(a)

Streamlining has opposite effects on friction drag and pressure drag. It decreases pressure drag by delaying boundary layer separation and thereby reducing the pressure difference between the front and back of the body.

Step 2 of 2

(b)

Streamlining increases the friction drag by increasing the surface area. On streamlining the total drag may increase or decrease depending on the Reynolds number. Total drag will decrease if flow has high Reynolds number but will increase if the flow is with very low Reynolds number.

Question: 15.017P

What is flow separation? What causes it? What is the effect of flow separation on the drag coefficient?

Step 1 of 1

When a fluid flows over the surface of a body it will remain attached to the body surface. But with increase in flow velocity, the fluid tends to detach itself from the surface of the body. This tendency of fluid is known as Flow separation. The cause for flow separation is Velocity of the fluid. The location of separation point depends on several factors like Reynolds number, roughness of the surface, level of fluctuation in the free stream etc. Flow separation increases the drag coefficient to very high level.

Question: 15.018P

What is drafting? How does it affect the drag coefficient of the drafted body?

Step 1 of 1

Drag is the force which a flowing fluid exerts on a body in the flow direction. As the drag acts in opposite direction of motion, the body that moves in the fluid has low pressure region in its rear end. Hence by making the selected body to move behind another body, we can reduce the drag force acting on the selected body. This method of reducing drag is known as drafting. As drafting involves in making the body to move in low pressure region, the coefficient of drag of a drafted body is reduced to large extent.

Question: 15.019P

A car is moving at a constant velocity of 80 km/h. Determine the upstream velocity to be used in fluid flow analysis if (*a*) the air is calm, (*b*) wind is blowing against the direction of motion of the car at 30 km/h, and (*c*) wind is blowing in the same direction of motion of the car at 50 km/h.

Step 1 of 4

Given data:

The velocity of car, $V_{car} = 80\ \text{km/h}$

Step 2 of 4

a) Let us determine the upstream velocity when air is under calm condition.

Since, the air is calm the relative velocity will be equal to the velocity of car itself because here the velocity of air is zero.

Thus, the upstream velocity, $V = V_{car} = 80\ \text{km/h}$

Therefore, the upstream velocity, $\boxed{V = 80\ \text{km/h}}$

Step 3 of 4

b) Here we have to determine the upstream velocity when wind is blowing against the direction of motion of the car at 30 km/h .

Since wind is blowing against the direction of motion of the car, the relative velocity will be equal to the sum of velocities of car and wind.

Thus, the upstream velocity,

$$V = V_{car} + V_{wind}$$
$$= 80 + 30$$
$$= 110\ \text{km/h}$$

Therefore, upstream velocity, $\boxed{V = 110\ \text{km/h}}$

Step 4 of 4

c) Here we have to determine the upstream velocity when wind is blowing in the same direction of motion of the car at 50 Km/h .

Since wind is blowing in the same direction of motion of the car the relative velocity will be equal to the difference of velocities of car and wind.

Thus, the upstream velocity,

$$V = V_{car} - V_{wind}$$
$$= 80 - 50$$
$$= 30\ \text{km/h}$$

Therefore, the upstream velocity, $\boxed{V = 30\ \text{km/h}}$

Question: 15.020P

The resultant of the pressure and wall shear forces acting on a body is measured to be 580 N, making 35° with the direction of flow. Determine the drag and the lift forces acting on the body.

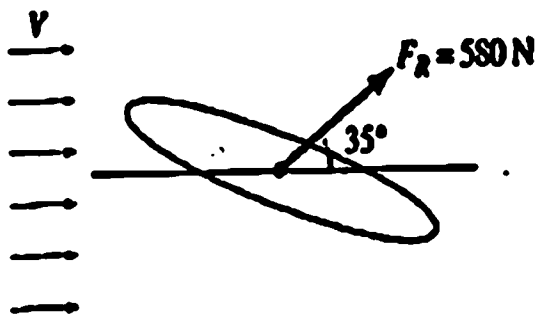


FIGURE P15–20

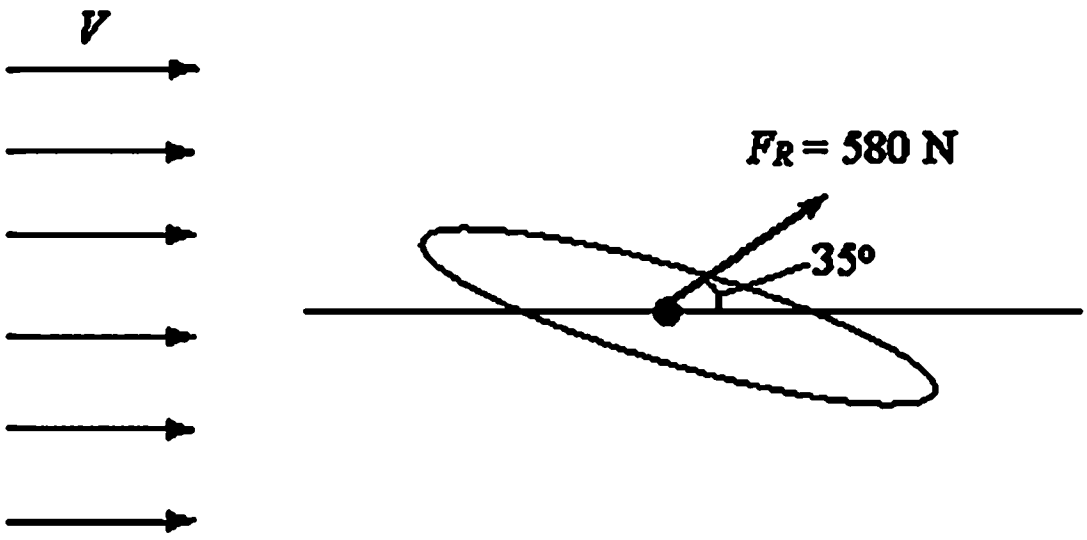
Step 1 of 3



Given data:

The resultant of pressure and wall shear forces acting on the body, $F_R = 580\,\text{N}$

Angle made by the resultant with the horizontal, $\theta = 35°$

Step 2 of 3

Force acting on the body is shown in the diagram drawn below.

Step 3 of 3

From the above figure, Component of F_R which is in the direction of flow is the drag force and normal to the flow is the lift force.

Here component of F_R which is in the direction of flow is $F_R \cos 35°$

And the component of F_R normal to the direction of flow is $F_R \sin 35°$.

Therefore,

Drag force,

$$F_D = F_R \cos 35°$$
$$= 580 \cos 35°$$
$$= 475.11\ \text{N}$$

Lift force,

$$F_L = F_R \sin 35°$$
$$= 580 \sin 35°$$
$$= 332.67\ \text{N}$$

Therefore,

Drag and lift forces are, $\boxed{F_D = 475.11\ \text{N}}$ and $\boxed{F_L = 332.67\ \text{N}}$.

Question: 15.021P

During a high Reynolds number experiment, the total drag force acting on a spherical body of diameter D =12 cm subjected to airflow at 1 atm and 5°C is measured to be 5.2 N. The pressure drag acting on the body is calculated by integrating the pressure distribution (measured by the use of pressure sensors throughout the surface) to be 4.9 N. Determine the friction drag coefficient of the sphere.

Step 1 of 4

Given data:

The diameter of the spherical body, $D = 12$ cm

The total drag force acting on the body, $F_D = 5.2$ N

Pressure drag, $F_{D(P)} = 4.9$ N

Step 2 of 4

We have, total drag force,

$$F_D = F_{D(f)} + F_{D(P)}$$

$$F_{D(f)} = F_D - F_{D(P)}$$

$$= 5.2 - 4.9$$

$$= 0.3 \text{ N}$$

From definition of total drag force, we have

$$F_D = \frac{1}{2} C_D \rho V^2 A \qquad \ldots\ldots (1)$$

From definition of friction drag force, we have

$$F_{D(f)} = \frac{1}{2} C_{D(f)} \rho V^2 A \qquad \ldots\ldots (2)$$

Step 3 of 4

By dividing equation (1) with (2), we get

$$\frac{F_D}{F_{D(f)}} = \frac{\frac{1}{2} C_D \rho V^2 A}{\frac{1}{2} C_{D(f)} \rho V^2 A}$$

$$\frac{F_D}{F_{D(f)}} = \frac{C_D}{C_{D(f)}}$$

$$C_{D(f)} = C_D \frac{F_{D(f)}}{F_D} \qquad \ldots\ldots (3)$$

Step 4 of 4

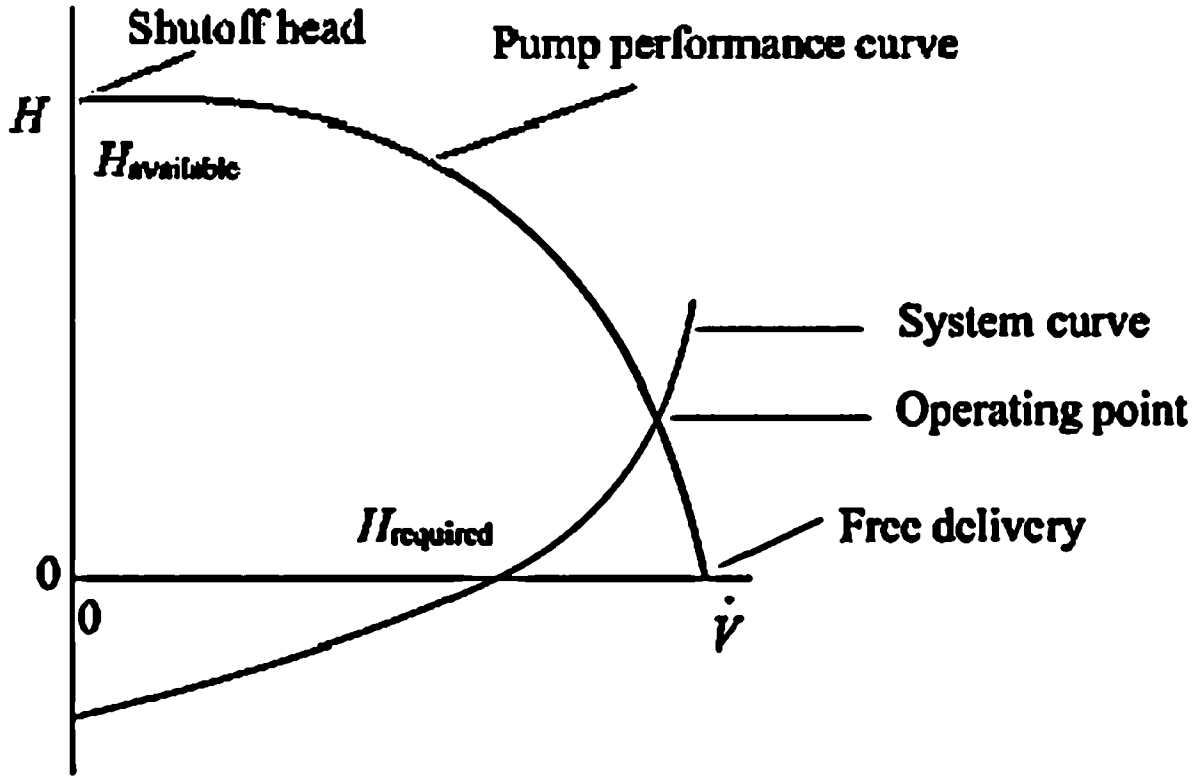
Now, assume that the flow is turbulent. For turbulent flow, $C_D = 0.2$

By substituting the values in equation (3), we get

$$C_{D(f)} = 0.2 \times \frac{0.3}{5.2}$$

$$= 0.01154$$

Therefore, the frictional drag coefficient of the sphere is $\boxed{C_{D(f)} = 0.01154}$



Question: 15.022P

The drag coefficient of a car at the design conditions of 1 atm, 25°C, and 90 km/h is to be determined experimentally in a large wind tunnel in a full-scale test. The height and width of the car are 1.40 m and 1.65 m, respectively. If the horizontal force acting on the car is measured to be 280 N, determine the total drag coefficient of this car.

Step 1 of 1

4749-15-22P AID: 1083 | 07/05/2012

In the given zero flow rate system the required head is negative as the elevation of the outlet is lower than that of the free surface of the inlet tank. The qualitative plot is generated.

Question: 15.023P

To reduce the drag coefficient and thus to improve the fuel efficiency, the frontal area of a car is to be reduced. Determine the amount of fuel and money saved per year as a result of reducing the frontal area from 18 to 15 ft2. Assume the car is driven 12,000 mi a year at an average speed of 55 mi/h. Take the density and price of gasoline to be 50 lbm/ft3 and $3.10/gal, respectively; the density of air to be 0.075 lbm/ft3, the heating value of gasoline to be 20,000 Btu/lbm; and the overall efficiency of the engine to be 30 percent.

Step 1 of 6

Given data:

Distance covered by the car in an year, $D = 12{,}000 \text{ miles} = 63.36\times10^6 \text{ ft}$

Average speed of the car $V = 55 \text{ mi/h} = 80.62 \text{ ft/s}$

Densities of air, $\rho_{air} = 0.075 \text{ lbm/ft}^3$

Densities of gasoline, $\rho_{gas} = 50 \text{ lbm/ft}^3$

Cost of gasoline, $C = \$3.10/\text{gal}$

The heating value of gasoline, $H = 20{,}000 \text{ Btu/lbm}$

Initial frontal area, $A_1 = 18 \text{ ft}^2$

Reduced frontal area, $A_2 = 15 \text{ ft}^2$

Overall efficiency of the engine, $\eta = 30\%$

Step 2 of 6

From table 15-2 for a passenger car drag coefficient is considered as $C_D = 0.3$

The drag force acting on a body is given by,

$$F_D = C_D \frac{1}{2} \rho_{air} A_1 V^2$$
$$= 0.3\times\frac{1}{2}\times0.075\times18\times80.63^2$$
$$= 1316.49 \text{ lbf}$$

Step 3 of 6

The amount of work done to overcome this drag force,

$$W_1 = F_D \times D$$
$$= 1316.49\times63.36\times10^6$$
$$= 83.41\times10^9 \text{ lbf}\cdot\text{ft/year}$$

Energy expended in doing this work,

$$E = \frac{W_1}{\eta}$$
$$= \frac{83.41\times10^9}{0.3}$$
$$= 278.03\times10^9 \text{ lbf-ft/year}$$
$$= 375.29\times10^6 \text{ Btu/year}$$

Step 4 of 6

The amount of fuel used is given by,

$$F_{amount} = \frac{m}{\rho_{gas}}$$
$$= \frac{E/H}{\rho_{gas}}$$
$$= \frac{375.29\times10^6/20000}{50}$$
$$= 357.29 \text{ ft}^3/\text{year}$$

Then the amount costs expended on fuel,

$$C_{total} = C \times F_{amount}$$
$$= 375.29\times3.10\times\frac{7.84 \text{ ft}^3}{1 \text{ gal}}$$
$$= 8683.61 \$/\text{year}$$

Step 5 of 6

The percentage of reduced area is,

$$A_p = \frac{A_1 - A_2}{A_1}$$
$$= \frac{18-15}{18}$$
$$= 16.67\%$$

The amount of fuel saved due to reduction in area,

$$F_{sav} = F_{amount} \times A_p$$
$$= 375.29\times0.1667$$
$$= 62.56 \text{ ft}^3/\text{year}$$

Step 6 of 6

Amount of money saved due to reduced area ,

$$C_{saved} = F_{sav} \times C$$
$$= 62.56\times3.1\times\frac{7.84 \text{ ft}^3}{1 \text{ gal}}$$
$$= 1520.48 \$/\text{year}$$

Therefore due to reduction of frontal area the amount of fuel saved is $\boxed{62.56 \text{ ft}^3/\text{year}}$ and the amount of money saved is $\boxed{1520.48 \$/\text{year}}$.

Question:

Reconsider Prob. 15-23E. Using EES (or other) software, investigate the effect of frontal area on the annual fuel consumption of the car. Let the frontal area vary from 10 to 30 ft2 in increments of 2 ft2. Tabulate and plot the results.

Step 1 of 5

Distance covered by the car in an year, $D = 12{,}000$ miles $= 63.36 \times 10^6$ ft

Average speed of the car $V = 55$ mi/h $= 80.62$ ft/s

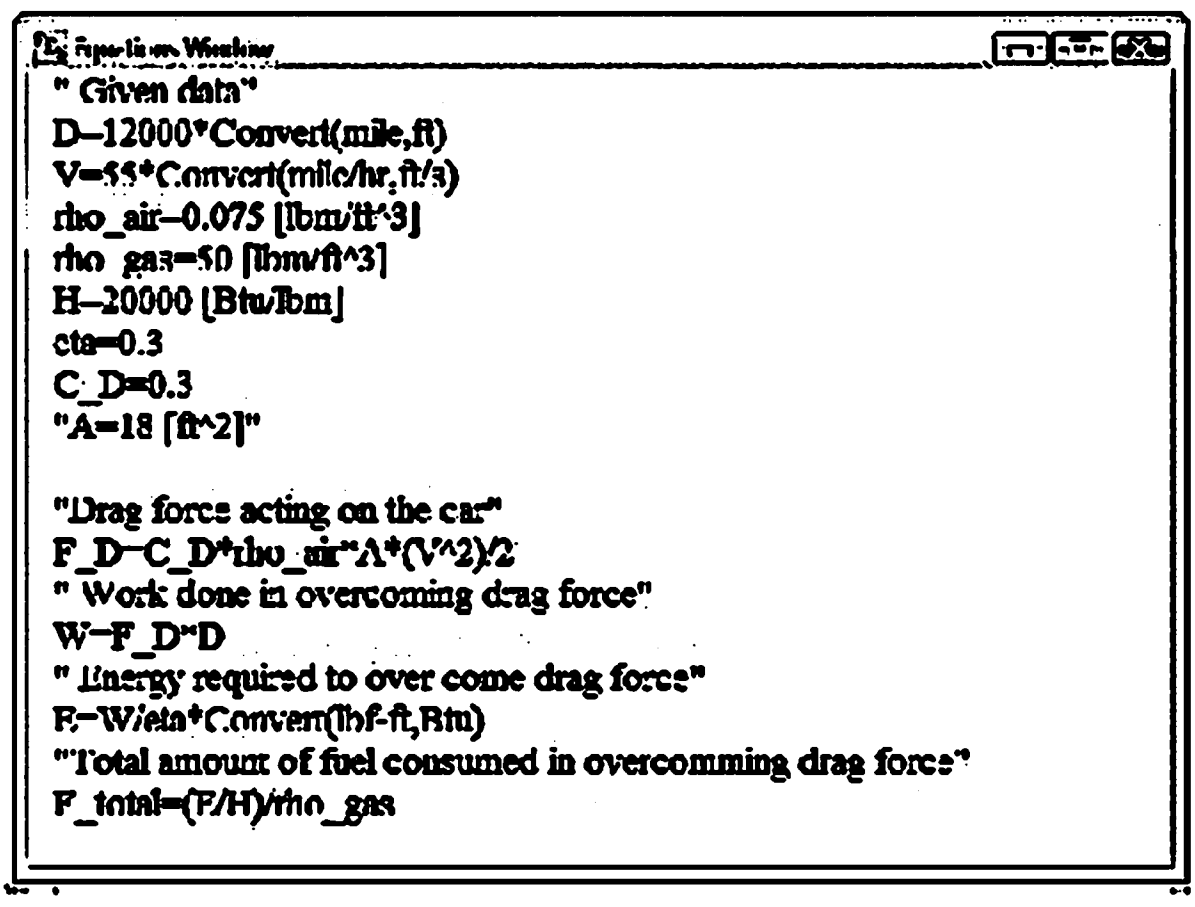
Densities of air, $\rho_{air} = 0.075$ lbm/ft^3

Densities of gasoline, $\rho_{gas} = 50$ lbm/ft^3

Cost of gasoline, $C = \$3.10$/gal

The heating value of gasoline, $H = 20{,}000$ Btu/lbm

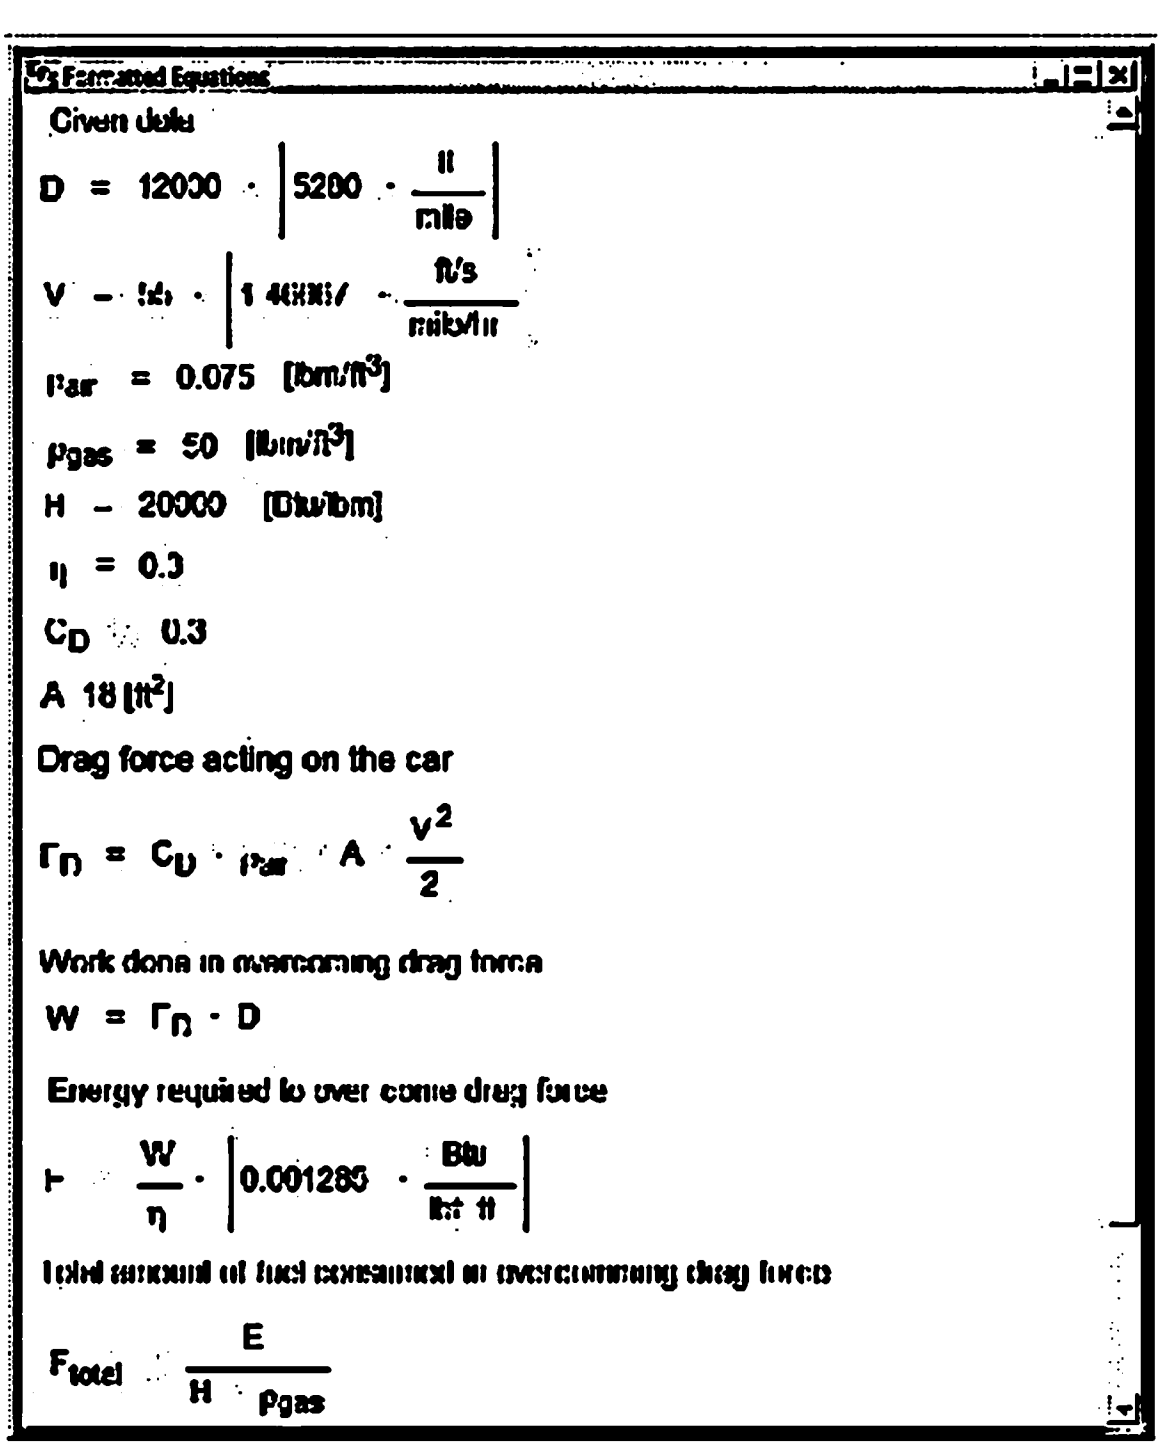
Frontal area of car, A



Overall efficiency of the engine, $\eta = 30\%$

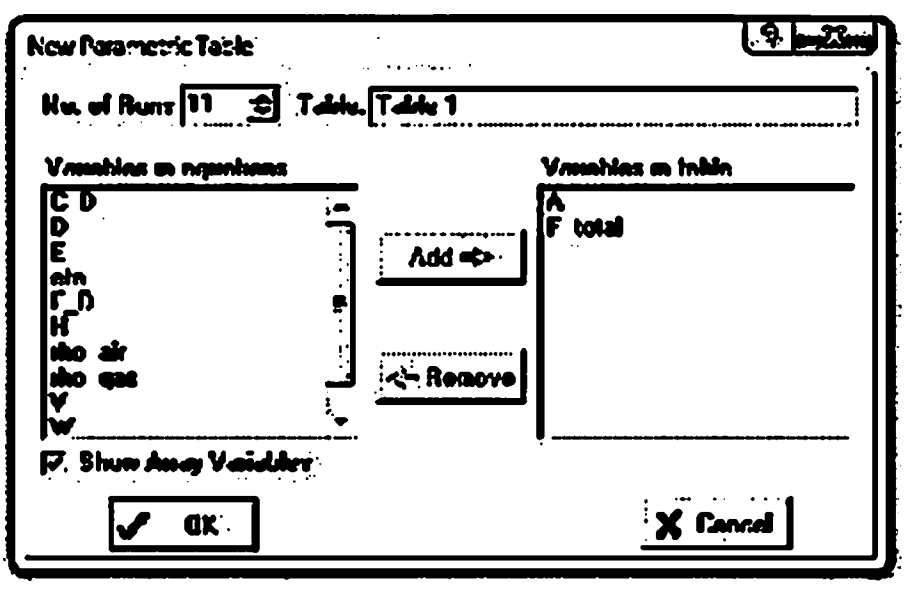
Step 2 of 5

From table 15-2 for a passenger car drag coefficient is considered as $C_D = 0.3$



This given problem is solved in EES "Engineering Equation Solver" in the following method.

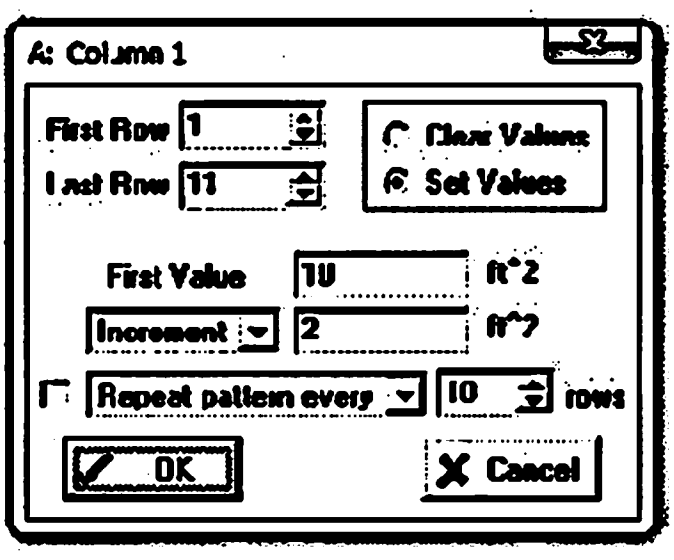
Open a new window in the EES software by ceasing " File > New " and type the program as shown below,



Step 3 of 5

To check weather the program typed is in correct mathematical format or not go to "Options > Function info" a window opens as show below ,

Step 4 of 5

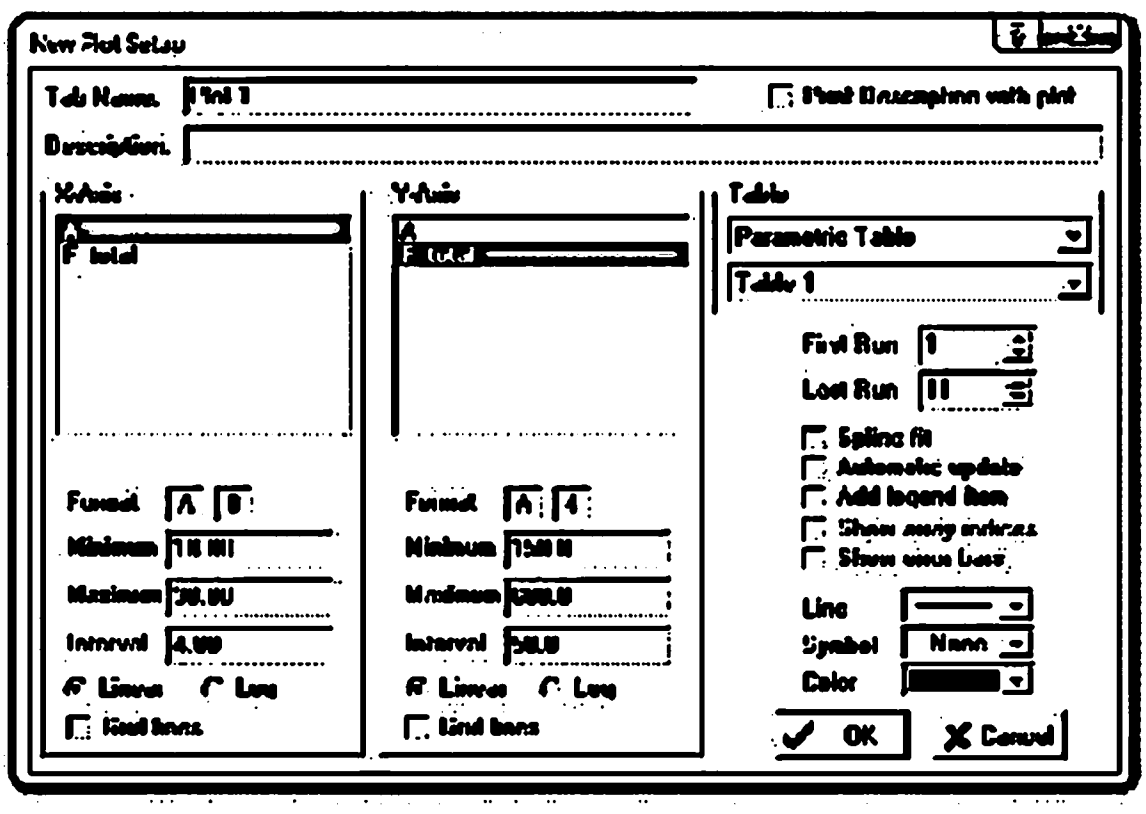


Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

Step 5 of 5

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,



Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Parametric table

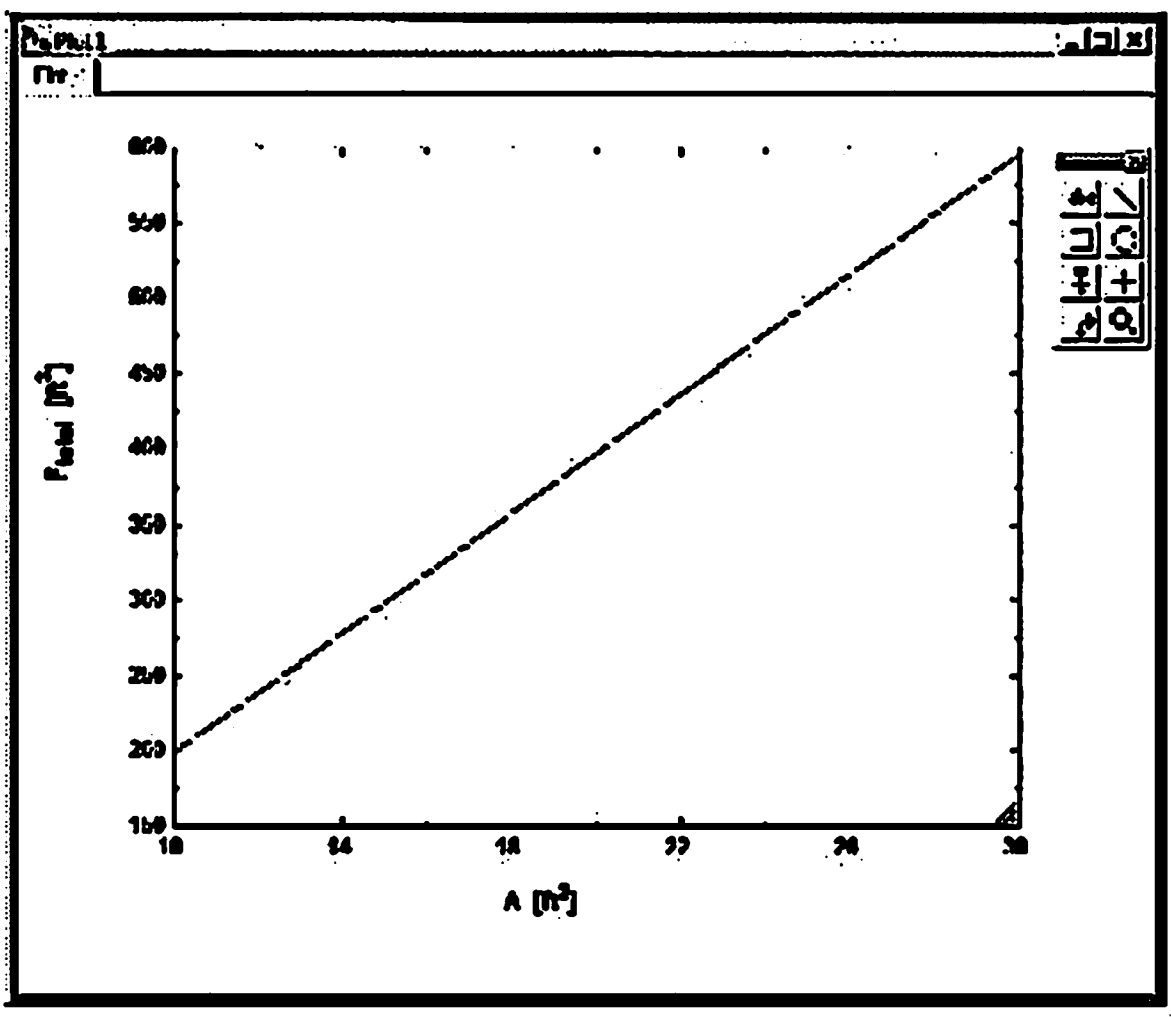


Table 1

	A [ft2]	F total [ft3]
Run 1	10	198.7
Run 2	12	238.4
Run 3	14	278.1
Run 4	16	317.9
Run 5	18	357.6
Run 6	20	397.3
Run 7	22	437.1
Run 8	24	476.8
Run 9	26	516.6
Run 10	28	556.3
Run 11	30	596

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

By clicking on OK the graph will be generated as shown,

Question: 15.025P

A circular sign has a diameter of 50 cm and is subjected to normal winds up to 150 km/h at 10°C and 100 kPa. Determine the drag force acting on the sign. Also determine the bending moment at the bottom of its pole whose height from the ground to the bottom of the sign is 1.5 m. Disregard the drag on the pole.

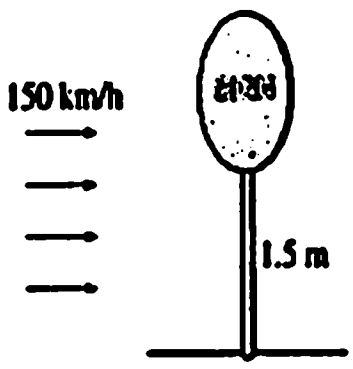

FIGURE P15–25

Step 1 of 3

Given data:

Diameter of the circular sine board, $d = 50\,\text{cm} = 0.5\,\text{m}$

Velocity of the wind, $V = 150\,\text{km/h} = 41.6\,\text{m/s}$

Length of the pole, $l = 1.5\,\text{m}$

Pressure of air, $P = 100\,\text{kPa}$

Temperature of the air, $T = 10°\text{C} = 283\,\text{K}$

Coefficient of drag, $C_D = 1.1$

Universal gas constant, $R = 0.287\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$

Step 2 of 3

Density of air at given pressure and temperature,

$$\rho = \frac{P}{RT}$$
$$= \frac{100}{0.287 \times 283}$$
$$= 1.23\,\text{kg/m}^3$$

Frontal area is given by subjected to wind flow,

$$A = \frac{\pi}{4} d^2$$
$$= \frac{\pi}{4} \times 0.5^2$$
$$= 0.1963\,\text{m}^2$$

Step 3 of 3

The drag force on the circular plate is given by,

$$F_D = C_D\left(\frac{1}{2}\rho V^2 A\right)$$
$$= 1.1\left(\frac{1}{2} \times 1.23 \times 41.66^2 \times 0.1963\right)$$
$$= 1.1 \times 209.524$$
$$= 230.47\,\text{N}$$

The bending moment on the bottom surface of the pole,

$$M = F_D \times l$$
$$= 230.47 \times 1.5$$
$$= 345.705\ \text{N}\cdot\text{m}$$

The drag force acting on the circular sine bored at given conditions obtained as $\boxed{F_D = 230.47\,\text{N}}$ and the moment at the bottom of the sine board pole is obtained as $\boxed{M = 345.705\ \text{N}\cdot\text{m}}$

Question: 15.026P

Wind loading is a primary consideration in design of the supporting mechanisms of billboards, as evidenced by many billboards being knocked down during high winds. Determine the wind force acting on an 8-ft-high, 20-ft-wide billboard due to 75-mi/h winds in the nori™ direction when the atmospheric conditions are 14.3 psia and 40°F.

Step 1 of 3

Given data:

Height of the billboard, $D = 8\,\text{ft}$

With of the billboard, $L = 20\,\text{ft}$

Velocity of the wind, $V = 75\,\text{mi/h} = 110\,\text{ft/s}$

Pressure of air, $P = 14.3\,\text{psi}$

Temperature of the air, $T = 40°\text{F} = 500\,\text{R}$

Universal gas constant, $R = 0.3704\ \text{psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$

Step 2 of 3

Coefficient of drag for rectangular plate is given by,

$$\begin{aligned} C_D &= 1.10 + 0.02\left[(L/D) + (D/L)\right] \\ &= 1.10 + 0.02\left[\left(\frac{20}{8}\right) + \left(\frac{8}{20}\right)\right] \\ &= 1.10 + 0.02\left[2.5 + 0.4\right] \\ &= 1.158 \end{aligned}$$

Density of air at given pressure and temperature,

$$\begin{aligned} \rho &= \frac{P}{RT} \\ &= \frac{14.3}{0.3704 \times 500} \\ &= \frac{14.3}{185.2} \\ &= 0.0772\ \text{lbm/ft}^3 \end{aligned}$$

Step 3 of 3

Frontal area is given by subjected to wind flow,

$$\begin{aligned} A &= L \times D \\ &= 20 \times 8 \\ &= 160\,\text{ft}^2 \end{aligned}$$

The drag force on the billboard is given by,

$$\begin{aligned} F_D &= C_D\left(\frac{1}{2}\rho V^2 A\right) \\ &= 1.158\left(\frac{1}{2} \times 0.0772 \times 110^2 \times 160\right) \\ &= 86536.87\,\text{lb} \\ &= \frac{86536.87}{32.2} \end{aligned}$$

$$= 2687.48\,\text{lbf}$$

Therefore the drag force acting on the billboard at given conditions obtained as $\boxed{F_D = 2687.48\,\text{lbf}}$

Question: 15.027P

Advertisement signs are commonly carried by taxi cabs for additional income, but they also increase the fuel cost Consider a sign that consists of a 0.30-m-high, 0.9-m-wide, and 0.9-m-long rectangular block mounted on top of a taxi cab such that the sign has a frontal area of 0.3 m by 0.9 m from all four sides. Determine the increase in the annual fuel cost of this taxicab due to this sign. Assume the taxicab is driven 60,000 km a year at an average speed of 50 km/h and the overall efficiency of the engine is 28 percent. Take the density, unit price, and heating value of gasoline to be 0.72 kg/L, \$1.10/L, and 42,000 kJ/kg, respectively, and the density of air to be 1.25 kg/m3.

FIGURE P15–27

Step 1 of 5

Given data:

Height of the billboard $D = 0.3\text{m}$

With of the billboard $W = 0.9\text{m}$

Length of the billboard $L = 0.9\text{m}$

Frontal area is given by, $A = 0.3\text{m} \times 0.9\text{m} = 0.27\,\text{m}^2$

Distance covered by the cab in a year, $d = 60,000\text{km/year}$

Average speed of the cab, $V_{cab} = 50\text{km/h} = 13.88\text{m/s}$

Velocity of the wind $V = 150\text{km/h} = 41.6\text{ m/s}$

Over all efficiency of the engine $\eta = 28\%$

Density of gasoline, $\rho_{gas} = 0.72\text{kg/L}$

Unit price of gasoline, $P_g = \$1.10/\text{L}$

Heating value of gasoline, $h = 42,000\text{kJ/kg}$

Density of air, $\rho = 1.25\text{kg/m}^3$

Step 2 of 5

Coefficient of drag for the sine board is as $C_D = 2.2$ from the table 15-1.

The drag force on the circular plate is given by,

$$F_D = C_D\left(\frac{1}{2}\rho V^2 A\right)$$
$$= 2.2\left(\frac{1}{2}\times 1.25\times 13.88^2\times 0.27\right)$$
$$= 71.523\text{N}$$

Step 3 of 5

Amount of drag force acting on the cab due to sine board for entire year can be obtained as,

$$W_{drag} = F_D \times d$$
$$= 71.523\times 60000$$
$$= 4.29\times 10^6\text{ kJ/year}$$

Energy expended on overcoming drag force due to the sine board for an entire year,

$$E_w = \frac{W_{drag}}{\eta}$$
$$= \frac{4.29\times 10^6}{0.28}$$
$$= 15.32\times 10^6\text{ kJ/year}$$

Step 4 of 5

The total amount of fuel consumed for entire year,

$$A_{fuel} = \frac{m_{gas}}{\rho_{gas}}$$
$$= \frac{E_w / h}{\rho_{gas}}$$
$$= \frac{15.32\times 10^6 / 42000}{0.72}$$
$$= 506.61\text{L/year}$$

Step 5 of 5

Annual fuel cost is given by,

$$P_{year} = P_g \times A_{fuel}$$
$$= 1.10\times 506.61$$
$$= 557.27\,\$/\text{year}$$

Increase in annual fuel cost due to the action of drag force on sign is $\boxed{557.27\,\$/\text{year}}$.

Question: 15.028P

At highway speeds, about half of the power generated by the car's engine is used to overcome aerodynamic drag, and thus the fuel consumption is nearly proportional to the drag force on a level road. Determine the percentage increase in fuel consumption of a car per unit time when a person who normally drives at 55 mi/h now starts driving at 75 mi/h.

Step 1 of 3

Given data:

Normal driving speed, $V_1 = 55\,\text{mi/h}$

New speed, $V_2 = 75\,\text{mi/h}$

Step 2 of 3

Equation for drag force,

$$F_D = \frac{1}{2} C_D \rho A V^2$$

Where F_D is the force acting on body,

A is the frontal area,

ρ is the density of air,

V is the velocity of wind,

C_D is the coefficient of drag

As all the parameters of the drag force here are constant except velocity, we get

$$F_D \propto V^2$$

$$\frac{(F_D)_2}{(F_D)_1} = \left(\frac{V_2}{V_1}\right)^2 \qquad \ldots\ldots (1)$$

Step 3 of 3

Fuel consumption is directly proportional to the drag force. Hence percentage increase in fuel consumption is equal to the percentage increase in drag force.

$$\% \Delta f = \% \Delta F_D$$

$$= \frac{(F_D)_2 - (F_D)_1}{(F_D)_1} \times 100$$

$$= \left[\frac{(F_D)_2}{(F_D)_1} - 1\right] \times 100 \qquad \ldots\ldots (2)$$

From equations (1) and (2), we get

$$\% \Delta f = \left[\frac{V_2^2}{V_1^2} - 1\right] \times 100$$

$$= \left[\frac{(75)^2}{(55)^2} - 1\right] \times 100$$

$$= 85.95\,\%$$

Hence percentage increase in fuel consumption is $\boxed{\% \Delta f = 85.95\,\%}$

Question: 15.029P

Bill gets a job delivering pizzas. The pizza company makes him mount a sign on the roof of his car. The frontal area of the sign is A = 0.612 ft2, and he estimates the drag coefficient to beCD = 0.94 at nearly all air speeds. Estimate how much additional money it costs Bill per year in fuel to drive with the sign on his roof compared to without the sign. Use the following additional information: He drives about 10,000 miles per year at an average speed of 45 mph. The overall car efficiency is 0.332, ρfuel = 50.2 lbm/ft3, and the heating value of the fuel is 1.53 × 107 ft.lbf/lbm. The fuel costs $3.50 per gallon. Use standard air properties. Be careful with unit conversions.

Step 1 of 4

Sign frontal area, $A = 0.612\,\text{ft}^2$

Sign board drag coefficient, $C_D = 0.94$

Distance covered by the car in an year, $D = 10{,}000\ \text{miles} = 52.8\times10^6\,\text{ft}$

Average speed of the car $V = 45\,\text{mi/h} = 66\,\text{ft/s}$

Overall efficiency of the engine, $\eta = 33.2\%$

Densities of gasoline, $\rho_{gas} = 50.2\ \text{lbm/ft}^3$

Cost of gasoline, $C = \$3.50/\text{gal}$

The heating value of gasoline, $H = 1.53\times10^7\ \text{ft}\cdot\text{lbf/lbm}$

Consider densities of air, $\rho_{air} = 0.075\ \text{lbm/ft}^3$

Step 2 of 4

The drag force acting on a sign board is given by,

$$F_D = C_D\frac{1}{2}\rho_{air}AV^2$$
$$= 0.94\times\frac{1}{2}\times0.075\times0.612\times66^2$$
$$= 93.97\,\text{lbf}$$

The amount of work done to overcome this drag force for an entire year,

$$W = F_D\times D$$
$$= 93.97\times52.8\times10^6$$
$$= 4961.72\times10^6\ \text{lbf}\cdot\text{ft}$$

Step 3 of 4

Energy expended in doing this work for the whole year is,

$$E = \frac{W}{\eta}$$
$$= \frac{4961.72\times10^6}{0.332}$$
$$= 14.94\times10^3\ \text{lbf}\cdot\text{ft}$$

The amount of fuel consumed in the entire given year is,

$$F_{amount} = \frac{m}{\rho_{gas}}$$
$$= \frac{E/H}{\rho_{gas}}$$
$$= \frac{14.944\times10^9/1.53\times10^7}{50.2}$$
$$= 194.57\,\text{ft}^3$$

Step 4 of 4

Then the amount costs expended on fuel,

$$C_{total} = C\times F_{amount}$$
$$= 3.5\times0.2948\times\frac{1\,\text{gal}}{7.84\,\text{ft}^3}$$
$$= 86.86\$$

Therefore the annual amount of expenditure that costs Bill due to the sine board is $\boxed{86.86\$}$

Question: 15.030P

During major windstorms, high vehicles such as RVs d semis may be thrown off the road and boxcars off their tracks, especially when they are empty and in open areas. Consider a 5000-kg semi that is 9 m long, 2.5 m high, and 2 m wide. The distance between the bottom of the truck and the road is 0.75 m. Now the truck is exposed to winds from its side surface. Determine the wind velocity that will tip the truck over to its side. Take the air density to be 1.1 kg/m3 and assume the weight to be uniformly distributed.

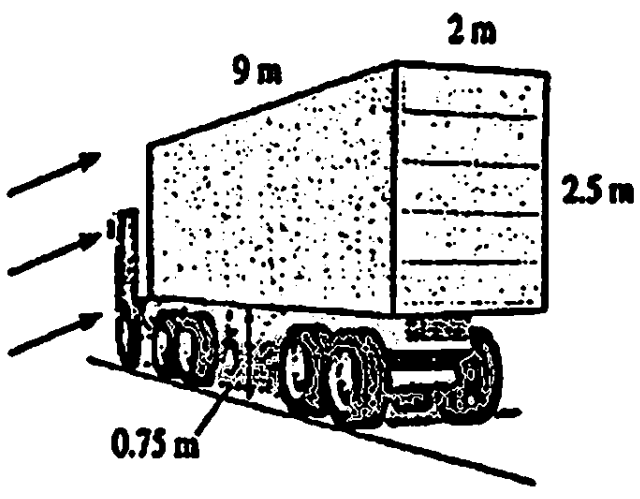

FIGURE P15–30

Step 1 of 6

Given data:

Mass of the vehicle, $m = 5000\ \text{kg}$

Length of the vehicle, $L = 9\ \text{m}$

Height of the vehicle, $h = 2.5\ \text{m}$

Width of the vehicle, $w = 2\ \text{m}$

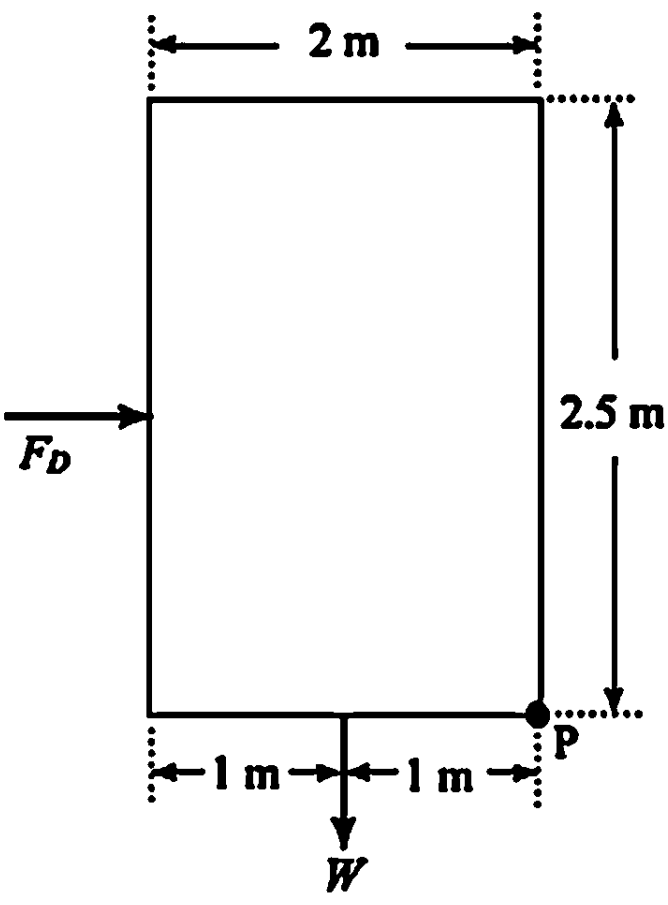
Distance between the bottom of the truck and the road, $l = 0.75\ \text{m}$

Density of air, $\rho = 1.1\ \text{kg/m}^3$

Coefficient of drag, $C_D = 2.2$

Let the frontal area be *A* and the velocity of wind be *V*

Step 2 of 6



When the truck is tipped off the wheels on wind loaded side will be off the ground first. Therefore, all the reactions will act on the wheels of other side. To find out the drag force that caused the truck to tip over. Consider an axis passing through the wheels on the non-wind loaded side of the truck and setting the moment about that point equal to zero will give the required drag force.

Weight of the truck,

$$\begin{aligned} W &= mg \\ &= 5000 \times 9.81 \\ &= 49050\ \text{N} \end{aligned}$$

Step 3 of 6

Figure showing the forces acting on truck,

Step 4 of 6

As the Drag force (F_D) on truck acts at middle, the moment about point P would be,

$$\begin{aligned} \Sigma M_P &= 0 \\ F_D\left(\frac{2.5}{2}\right) - W\left(\frac{2}{2}\right) &= 0 \\ (F_D \times 1.25) &= (49050 \times 1) \\ F_D &= \frac{49050}{1.25} \\ &= 39240\ \text{N} \end{aligned}$$

Step 5 of 6

The drag force acting on the truck,

$$F_D = \frac{1}{2} C_D \rho A V^2 \quad \text{..... (1)}$$

The frontal area is given by,

$$\begin{aligned} A &= L \times h \\ &= 9 \times 2.5 \\ &= 22.5\ \text{m}^2 \end{aligned}$$

Step 6 of 6

Now, by substituting the values in equation (1), we get

$$\begin{aligned} F_D &= \frac{1}{2} C_D \rho A V^2 \\ 39240 &= \frac{1}{2} \times 2.2 \times 1.1 \times 22.5 \times V^2 \\ V^2 &= 1441.32 \\ V &= 37.96\ \text{m/s} \end{aligned}$$

Therefore the wind velocity that will tip the truck over to its side is, $\boxed{V = 37.96\ \text{m/s}}$

Question: 15.031P

An 80-kg bicyclist is riding her 15-kg bicycle downhill on a road with a slope of 12° without pedaling or braking. The bicyclist has a frontal area of 0.45 m2 and a drag coefficient of 1.1 in the upright position, and a frontal area of 0.4 m2 and a drag coefficient of 0.9 in the racing position. Disregarding the rolling resistance and friction at the bearings, determine the terminal velocity of the bicyclist for both positions. Take the air density to be 1.25 kg/m3.

Step 1 of 6

Given data:

Mass of bicyclist is $m_1 = 80\,\text{kg}$.

Mass of bicycle is $m_2 = 15\,\text{kg}$.

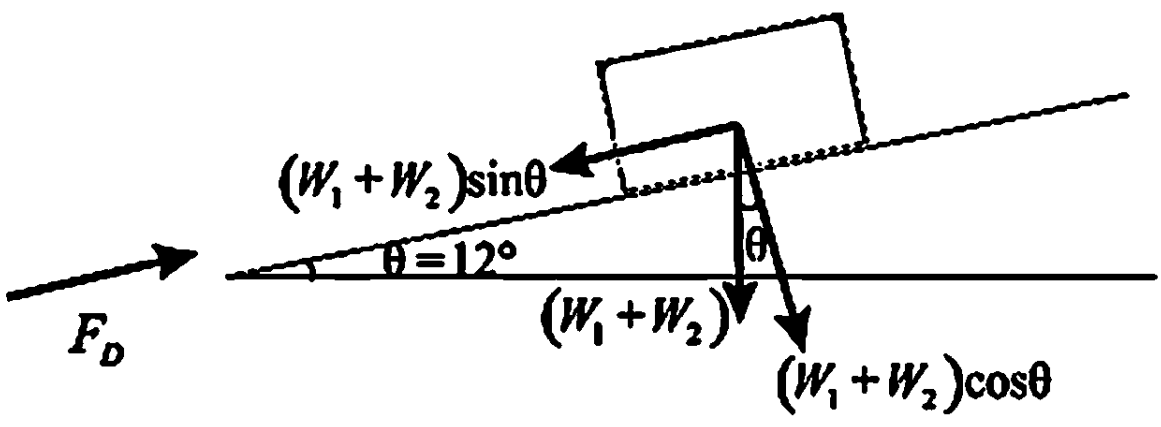
Slope of road is $\theta = 12°$.

In upright position,

Frontal area is $A_1 = 0.45\ \text{m}^2$.

Drag coefficient is $C_{D1} = 1.1$.

In racing position,



Frontal area is $A_2 = 0.4\ \text{m}^2$.

Drag coefficient is $C_{D_2} = 0.9$.

Density of air is $\rho = 1.25\,\text{kg/m}^3$.

Step 2 of 6

Diagram for the given conditions:

Step 3 of 6

Terminal velocity is attained when the sum of the weight of the bicycle and bicyclist is equal to the drag force acting opposite to it.

$$F_D = (W_1+W_2)\sin\theta \qquad \ldots\ldots (1)$$

Here W_1 is the weight of the bicyclist and W_2 is the weight of the bicycle.

$$W_1 = m_1 g$$
$$= 80 \times 9.81\ \text{kg}\cdot\text{m/s}^2$$
$$= 784.8\ \text{N}$$

Now,

$$W_2 = m_2 g$$
$$= 15 \times 9.81\ \text{kg}\cdot\text{m/s}^2$$
$$= 147.15\ \text{N}$$

Step 4 of 6

Substituting the values of W_1, W_2 and 6 in equation (1).

$$F_D = (W_1+W_2)\sin 12°$$
$$= (784.8+147.15)\sin 12°$$
$$= 193.76\ \text{N}$$

Then the drag force is $F_D = \frac{1}{2} C_D A \rho V^2$ ..... (2)

Where, V is the velocity.

A is the frontal area.

ρ is the density of air.

C_D is the drag coefficient.

Step 5 of 6

Consider upright position.

Here,

Frontal area, $A_1 = 0.45\ \text{m}^2$

Drag coefficient, $C_{D1} = 1.1$

Drag force acting for upright position,

$$F_D = \frac{1}{2} C_{D1} A_1 \rho V_1^2$$

Substituting the values of F_D, A_1, C_{D1} and ρ in the above equation.

$$193.76 = \frac{1}{2} \times 1.1 \times 0.45 \times 1.25 \times V_1^2$$
$$V_1^2 = 626.29$$
$$V_1 = 25.03\ \text{m/s}$$
$$= 25.03\left(\frac{18}{5}\right)$$
$$= 90.108\ \text{km/h}$$

Step 6 of 6

Now, consider racing position.

Here

Frontal area, $A_2 = 0.4\ \text{m}^2$

Drag coefficient, $C_{D_2} = 0.9$

Drag force acting for racing position,

$$F_D = \frac{1}{2} C_{D2} A_2 \rho V_2^2$$

Substituting the values of F_D, A_2, C_{D2} and ρ in the above equation.

$$193.76 = \frac{1}{2} \times 0.9 \times 0.4 \times 1.25 \times V_2^2$$
$$V_2^2 = 861.15$$
$$V_2 = 29.35\ \text{m/s}$$
$$= 29.35\left(\frac{18}{5}\right)$$
$$= 105.6\ \text{km/h}$$

Therefore, the terminal velocity of the bicyclist in the upright position is $\boxed{V_1 = 90.108\ \text{km/h}}$.

And the terminal velocity of the bicyclist in the racing position is $\boxed{V_2 = 105.6\ \text{km/h}}$.

Question: 15.032P

A wind turbine with two or four hollow hemispherical cups connected to a pivot is commonly used to measure wind speed. Consider a wind turbine with four 8-cm-diameter cups with a center-to-center distance of 40 cm, as shown in

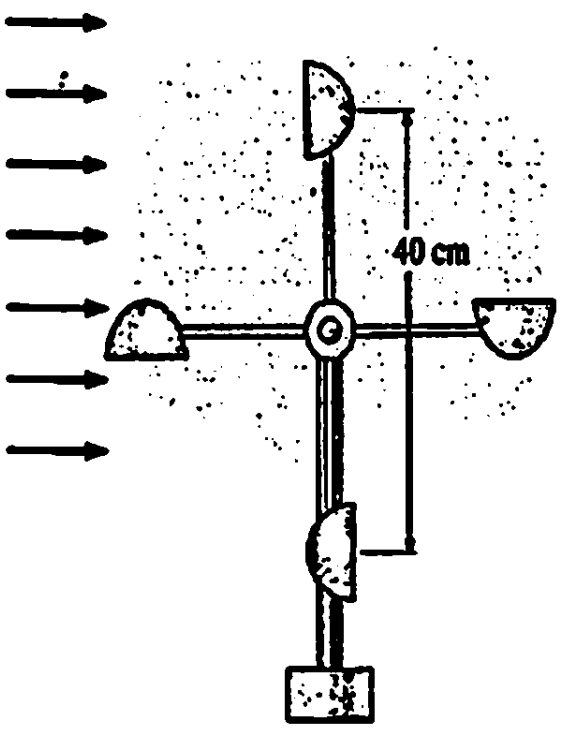


FIGURE P15–32

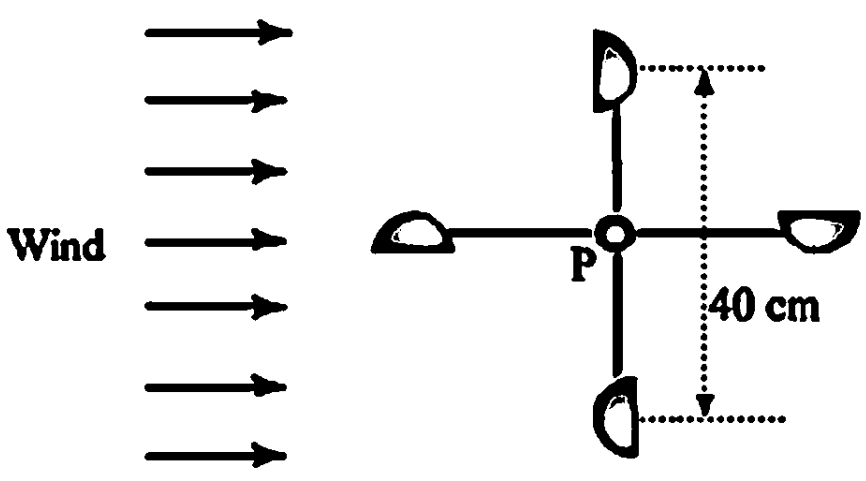
Fig. PI5-32. The pivot is stuck as a result of some malfunction, and the cups stop rotating. For a wind speed of 15 m/s and air density of 1.25 kg/m3, determine the maximum torque this turbine applies on the pivot.

Step 1 of 7

Given data:

Diameter of the cup, $D = 8$ cm

Center to center distance, $L = 40$ cm



Wind speed, $V = 15$ m/s

Density of air, $\rho = 1.25\ \text{kg/m}^3$

Let the frontal area of the hemispherical cup be A and the velocity of wind be V

Step 2 of 7

Maximum torque occurs when two cups are normal to the wind because the length of the moment arm is maximum in this case.

Step 3 of 7

Drag force acting on the convex side,

$$F_{D_1} = \frac{1}{2} C_{D_1} \rho A V^2 \qquad \ldots\ldots (1)$$

Frontal area,

$$A = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.08)^2$$

$$= 0.005\ \text{m}^2$$

Here, the drag coefficient for the hemisphere is $C_{D_1} = 0.4$ from table of drag coefficient for various three-dimensional bodies based on frontal area.

Step 4 of 7

Now, substitute the values of C_{D1}, ρ, A and V in equation (1) we have,

$$F_{D_1} = \frac{1}{2} \times 0.4 \times 1.25 \times 0.005 \times (15)^2$$

$$= 0.28\ \text{N}$$

Now, drag force acting on the concave side is given by,

$$F_{D_2} = \frac{1}{2} C_{D_2} \rho A V^2 \qquad \ldots\ldots (2)$$

Frontal area,

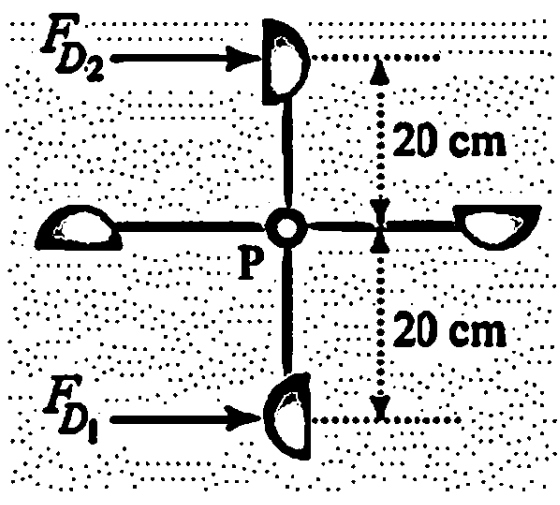
$$A = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.08)^2$$

$$= 0.005\ \text{m}^2$$

Step 5 of 7

Here, the drag coefficient for the hemisphere is $C_{D2} = 1.2$ from table of drag coefficient for various three-dimensional bodies based on frontal area



Now, substitute the values of C_{D2}, ρ, A and V in equation (2)

$$F_{D_2} = \frac{1}{2} \times 1.2 \times 1.25 \times 0.005 \times (15)^2$$

$$= 0.84\ \text{N}$$

Step 6 of 7

Free body diagram to show the forces acting on the hemispherical cups.

Step 7 of 7

To find the maximum torque acting, take moment about the pivot when two cups are normal to the direction of wind.

$+\circlearrowleft \sum M_P =$ Maximum torque

$$\text{Maximum torque} = F_{D_2}\left(\frac{L}{2}\right) - F_{D_1}\left(\frac{L}{2}\right)$$

$$= 0.84(0.02) - 0.28(0.02)$$

$$= 0.0112\ \text{N}\cdot\text{m}$$

Therefore the maximum torque the turbine applies on the pivot is $\boxed{T_{\max} = 0.0112\ \text{N}\cdot\text{m}}$

Question: 15.033P pg 1

Reconsider Prob. 15-32. Using EES (or other) Mm software, investigate the effect of wind speed on the torque applied on the pivot. Let the wind speed vary from 0 to 50 m/s in increments of 5 m/s. Tabulate and plot the results.

Step 1 of 2

4749-15-33P AID: 1083 | 14/05/2012

Given data:

Diameter of the cup, $D = 8$ cm

Center to center distance, $L = 40$ cm

Wind speed, $V = 15$ m/s

Density of air, $\rho = 1.25$ kg/m^3

Frontal area of the hemispherical cup, A

Velocity of wind, V

This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below,

Question: 15.034P

A 5-ft-diameter spherical tank completely submerged in freshwater is being towed by a ship at 12 ft/s. Assuming turbulent flow, determine the required towing power.

Step 1 of 4

Given data:

Diameter of the submerged spherical tank, $D = 5\text{ft}$

Velocity of the ship towing it, $V = 12\text{ft/s}$

Density of water is consider as, $\rho_{water} = 62.4\text{lb/ft}^3$

Step 2 of 4

From table 15-2 for a spherical body under turbulent conditions drag force coefficient is considered as $C_D = 0.2$

Frontal area of the spherical tank,

$$A = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}5^2$$

$$= 19.63\text{ft}^2$$

Step 3 of 4

The drag force acting on a body is given by,

$$F_D = C_D \frac{1}{2}\rho_{air} A V^2$$

$$= 0.2 \times \frac{1}{2} \times 62.4 \times 19.63 \times 12^2$$

$$= 17638.73\text{lbf}$$

$$= 17.63 \times 10^3\text{ lbf}$$

Step 4 of 4

The power required in towing the spherical tank,

$$P = F_d \times V$$

$$= 17.63 \times 10^3 \times 12$$

$$= 211 \times 10^3\text{ Btu/s}$$

The power required by the ship for towing a spherical tank is obtained as $\boxed{211 \times 10^3\text{ Btu/s}}$

Question: 15.035P

During steady motion of a vehicle on a level road, the power delivered to the wheels is used to overcome aerodynamic drag and rolling resistance (the product of the rolling resistance coefficient and the weight of the vehicle), assuming the friction at the bearings of the wheels is negligible. Consider a car that has a total mass of 950 kg, a drag coefficient of 0.32, a frontal area of 1.8 m2, and a rolling resistance coefficient of 0.04. The maximum power the engine can deliver to the wheels is 80 kW. Determine (*a*) the speed at which the rolling resistance is equal to the aerodynamic drag force and (*b*) the maximum speed of this car. Take the air density to be 1.20 kg/m3.

Step 1 of 6

Given data:

Mass of the car is $m = 950$ kg

Drag coefficient is $C_D = 0.32$

The rolling resistance coefficient is $C_R = 0.04$

The frontal area is $A = 1.8\ \text{m}^2$

Maximum power engine can deliver to the wheel is $P = 80$ kW

Density of air is $\rho = 1.20\ \text{kg/m}^3$

Step 2 of 6

Rolling resistance of the car,

In the question it is given that rolling resistance is the product of the rolling resistance coefficient and the weight of the vehicle.

$$R_R = C_R W \qquad \text{..... (1)}$$

Where, C_R is the rolling resistance coefficient

W is the weight of the body

Here,

$$W = mg$$
$$= 950 \times 9.81$$
$$= 9319.5\ \text{N}$$

Now, substituting the value of C_R and W in equation (1)

$$R_R = 0.04(9319.5)$$
$$= 372.78\ \text{N}$$

Step 3 of 6

Now, aerodynamic drag force acting on the car,

$$F_D = \frac{1}{2} C_D \rho A V^2 \qquad \text{..... (2)}$$

Where,

C_D is the drag coefficient,

ρ is the density,

A is the frontal area and

V is the velocity.

Substituting the values of C_D, ρ and A in equation (2)

$$F_D = \frac{1}{2} \times 0.32 \times 1.20 \times 1.8 \times V^2$$
$$= 0.3456 \times V^2$$

Step 4 of 6

To find the velocity at which rolling resistance becomes equal to the aerodynamic drag force, equate the values of rolling resistance and aerodynamic drag force.

$$R_R = F_D$$

Therefore,

$$372.78 = 0.3456 \times V^2$$
$$V^2 = \frac{372.78}{0.3456}$$
$$= 1078.65$$
$$V = 32.8\ \text{m/s}$$
$$V = 32.8\left(\frac{18}{5}\right)$$
$$= 118.08\ \text{km/h}$$

Therefore, the speed at which the rolling resistance is equal to the aerodynamic drag force is $\boxed{V = 118.08\ \text{km/h}}$

Step 5 of 6

Power required overcoming aerodynamic drag and rolling resistance, $P = (R_R + F_D)V$.

$$P = \left(372.78 + 0.3456V^2\right)V$$
$$P = 372.78V + 0.3456V^3 \qquad \text{..... (3)}$$

Maximum power is delivered at maximum speed.

So, in order to find the maximum speed, substitute the value of maximum power in equation (3).

$$80000 = 372.78V + 0.3456V^3$$
$$0.3456V^3 + 0V^2 + 372.78V - 80000 = 0$$

Step 6 of 6

On solving the above equation, we get two values for V which are, 55.5 and -27.78.

Since velocity cannot be negative we cannot take -27.78, so we take the value 55.5 as the velocity.

$$V = 55.56\left(\frac{18}{5}\right)$$
$$= 200\ \text{km/h}$$

Therefore, the maximum speed of the car is $\boxed{V = 200\ \text{km/h}}$

Question: 15.036P pg 1

Reconsider Prob. 15-35. Using EES (or other) software, investigate the effect of car speed on the required power to overcome (*a*) rolling resistance, (*b*) the aerodynamic drag, and (*c*) their combined effect. Let the car speed vary from 0 to 150 km/h in increments of 15 km/h. Tabulate and plot the results.

Step 1 of 5

Given data:

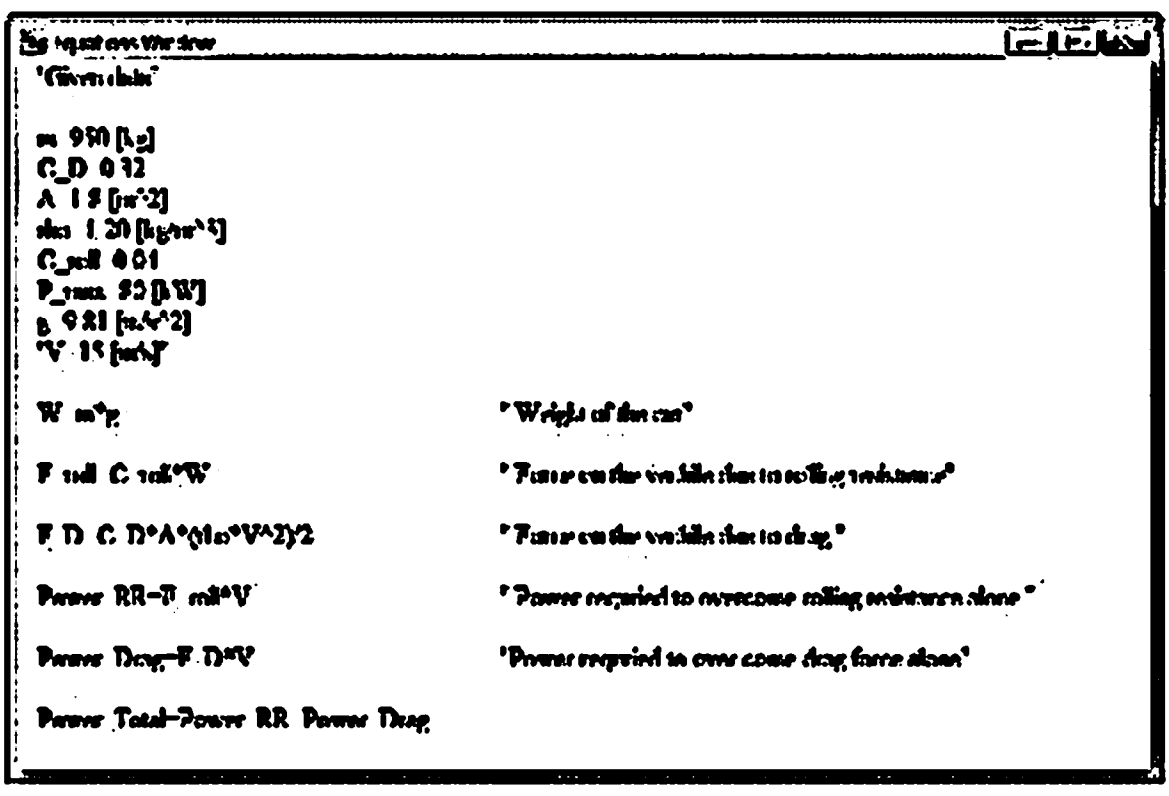
Total mass of the car, $m = 950\,\text{kg}$

Coefficient of drag of the car, $C_d = 0.32$

Frontal area of the car, $A = 1.8\,\text{m}^2$

Rolling resistance coefficient, $C_{roll} = 0.04$

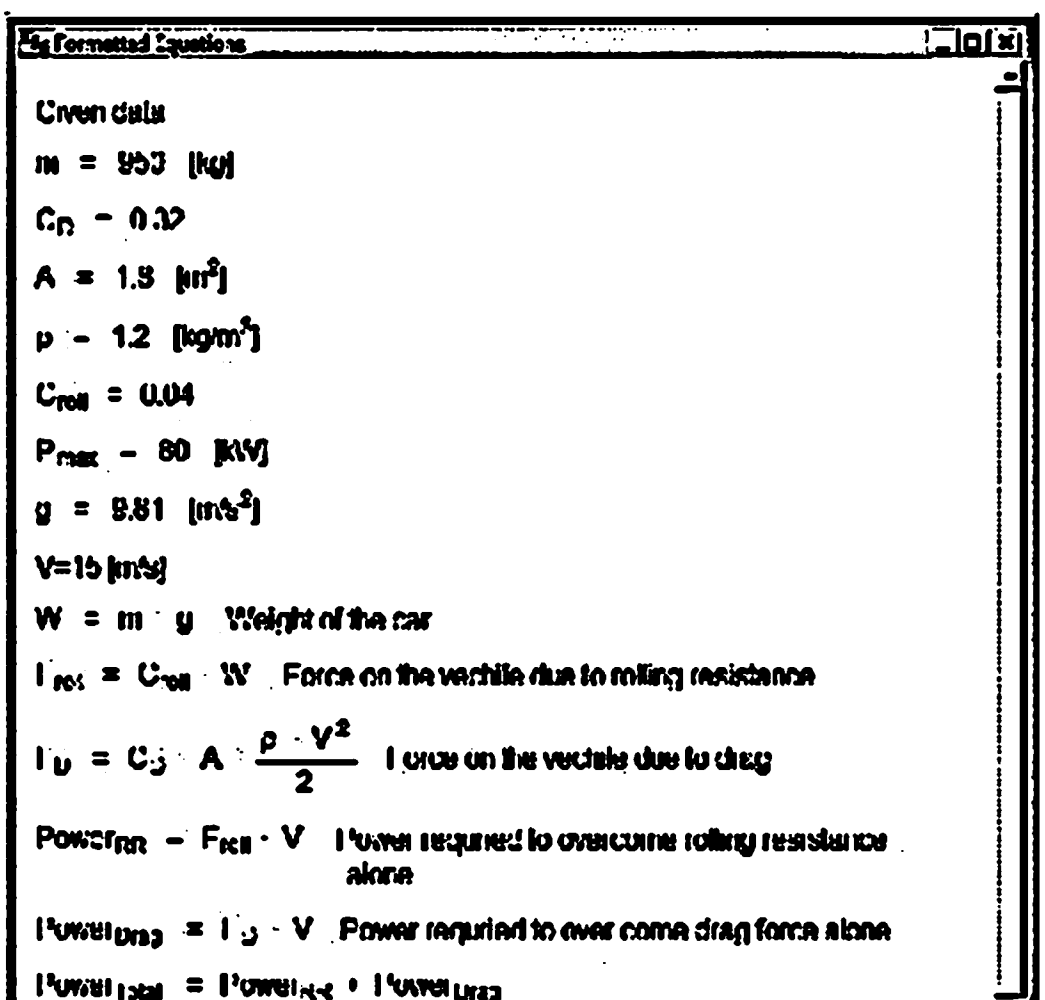
The maximum power the of engine, $P_{max} = 80\,\text{kW}$



Density of air, $\rho = 1.20\,\text{kg/m}^3$

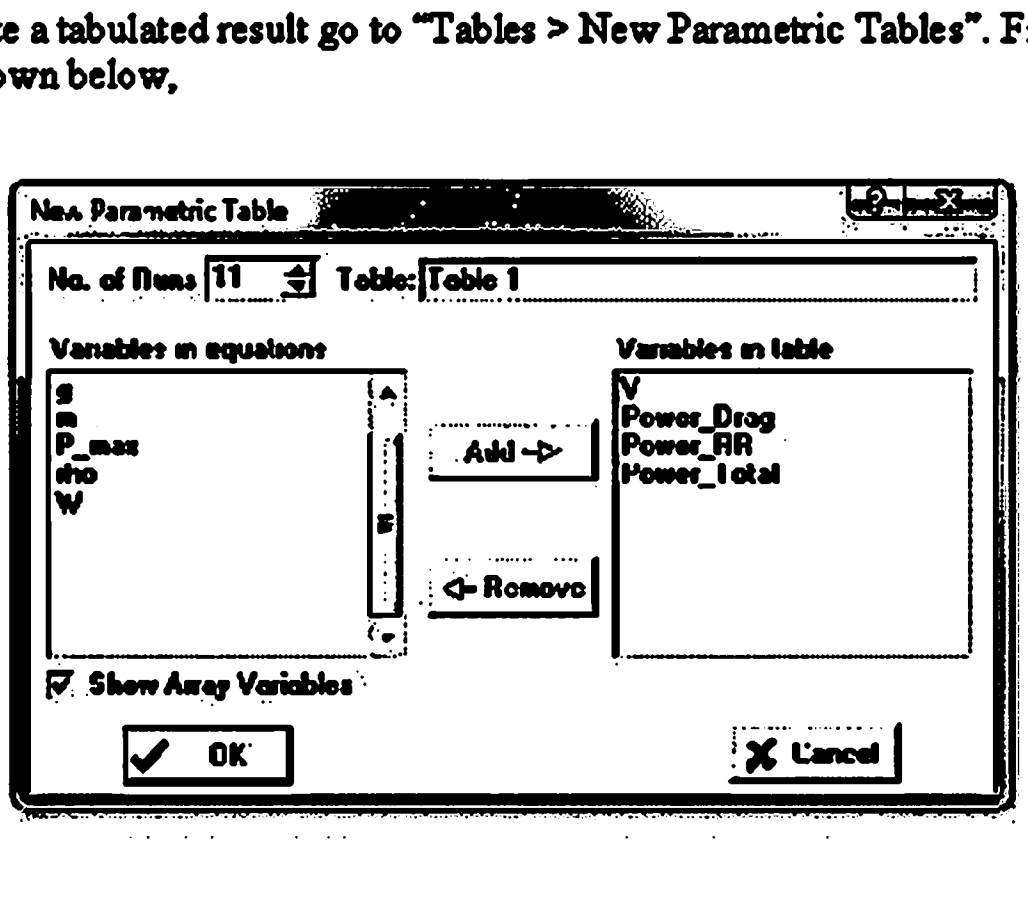
Acceleration due to gravity, $g = 9.81\,\text{m/s}^2$

Step 2 of 5



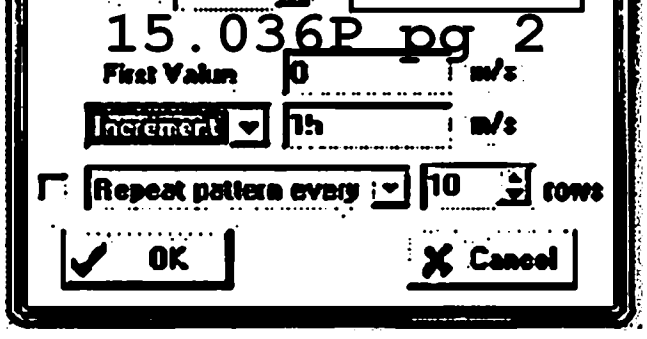
This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below,



Step 3 of 5

To check weather the program typed is in correct mathematical format or not go to "Options > Function info" a window opens as show below ,

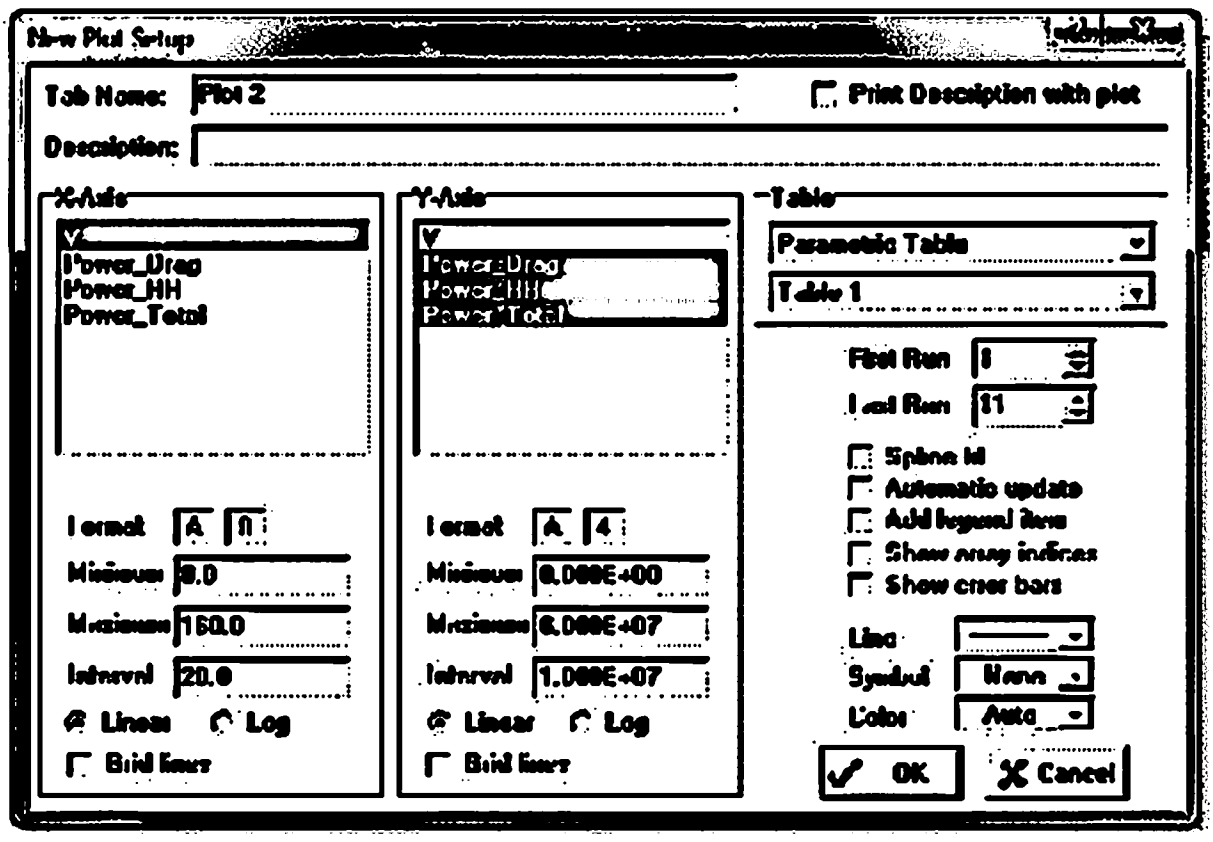


Step 4 of 5

Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Step 5 of 5



Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Question: 15.037P

A submarine can be treated as an ellipsoid with a diameter of 5 m and a length of 25 m. Determine the power required for this submarine to cruise horizontally and steadily at 65 km/h in seawater whose density is 1025 kg/m3. Also determine the power required to tow this submarine in air whose density is 1.30 kg/m3. Assume the flow is turbulent in both cases.

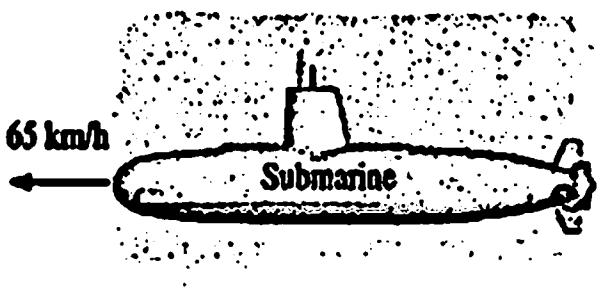

FIGURE P15–37

Step 1 of 5

Given data:

The diameter of the ellipsoid, $D = 5\ \text{m}$

The length of the submarine, $L = 25\ \text{m}$

The velocity of the submarine, $V = 65\ \text{km/h} = 18.05\ \text{m/s}$

The density of sea water, $\rho_{water} = 1025\ \text{kg/m}^3$

The density of air, $\rho_{air} = 1.30\ \text{kg/m}^3$

Drag coefficient of an ellipsoid with $\frac{L}{D} = \frac{25}{5} = 5$ is $C_D = 0.1$

Step 2 of 5

Equation for drag force,

$$F_D = \frac{1}{2} C_D \rho_{water} A V^2$$

Where F_D is the force acting on body

A is the frontal area,

ρ_{water} is the density of water,

V is the velocity of submarine,

C_D is the coefficient of drag

Frontal area of submarine,

$$A = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(5)^2$$

$$= 19.625\ \text{m}^2$$

Step 3 of 5

Substituting the values, we get

$$F_D = \frac{1}{2} \times 0.1 \times 1025 \times 19.625 \times (18.05)^2$$

$$= 327686.05\ \text{N}$$

Now, the power required to overcome this drag,

$P = F_D \times V$,

Where, F_D is the drag force and

V is the velocity.

Substituting the values,

$$P = 327686.05(18.05)$$

$$= 5914733.20\ \text{Watts}$$

$$= 5914.73\ \text{kW}$$

Therefore, the power required by the submarine to cruise horizontally and steadily at 65 km/h in sea water is $\boxed{P = 5914.73\ \text{kW}}$

Step 4 of 5

Drag force acting on the submarine when it is cruising through air,

$$F_D = \frac{1}{2} C_D A \rho_{air} V^2$$

Where C_D is the drag coefficient,

A is the frontal area of the ellipsoid,

V is the velocity of the submarine and

ρ_{air} is the density of air.

Substituting the values,

$$F_D = \frac{1}{2} \times 0.1 \times 19.625 \times 1.30 \times (18.05)^2$$

$$= 415.60\ \text{N}$$

Step 5 of 5

Now, the power required to overcome this drag,

$P = F_D \times V$

Where, F_D is the drag force and

V is the velocity.

Substituting the values,

$$P = 415.60(18.05)$$

$$= 7501.58\ \text{Watts}$$

$$= 7.5\ \text{kW}$$

Therefore, the power required by the submarine to cruise horizontally and steadily at 65 km/h through air is $\boxed{P = 7.5\ \text{kW}}$

Question: 15.038P

An 0.90-m-diameter, 1.1-m-high garbage can is found in the morning tipped over due to high winds during the night. Assuming the average density of the garbage inside to be 150 kg/m3 and taking the air density to be 1.25 kg/m3, estimate the wind velocity during the night wh.en the can was tipped over. Take the drag coefficient of the can to be 0.7.

Step 1 of 7

Given data:

The diameter of the garbage is $D = 0.90$ m

The height of the garbage is $H = 1.1$ m

The density of garbage is $\rho_g = 150\ \text{kg/m}^3$

The density of air is $\rho_{air} = 1.25\ \text{kg/m}^3$

Drag coefficient is $C_D = 0.7$

Step 2 of 7

Volume of the garbage can,

$$V = \frac{\pi}{4}D^2H$$

$$= \frac{\pi}{4}(0.90)^2(1.1)$$

$$= 0.7\ \text{m}^3$$

Now, weight of the garbage can,

$$W = mg \qquad \ldots\ldots (1)$$

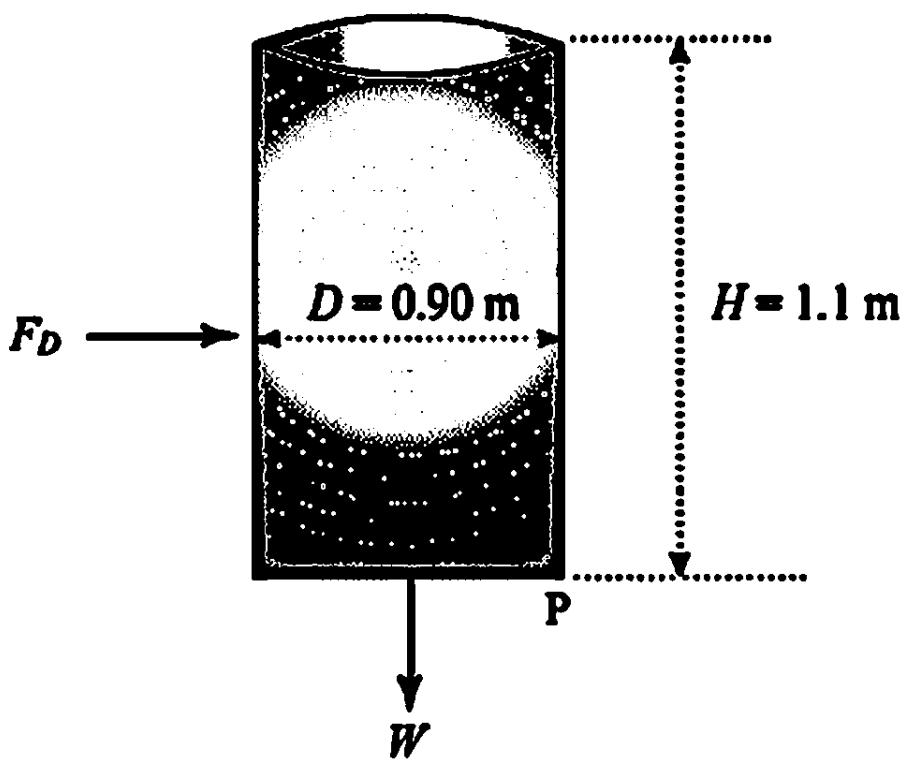
But we know that $\text{Density}(\rho) = \dfrac{\text{Mass}(m)}{\text{Volume}(V)}$

Therefore, $m = V\rho_g$

Substituting the value of mass in equation (1)

$$W = V\rho_g g$$

$$= 0.7 \times 150 \times 9.81$$



$$= 1030.05\ \text{N}$$

Step 3 of 7

When the garbage can is first tipped the wind loaded side will be off the ground first. Therefore, all the reactions will act on the other edge.
Now, we have to find out the drag force that caused the garbage to tip over.
For that consider an axis passing through the contact point and setting the moment about that point equal to zero will give the required drag force.

Step 4 of 7

Draw the garbage can to show the forces acting on the garbage can.

Step 5 of 7

Now, take moment about the contact point P

$$+\circlearrowleft \sum M_p = 0$$

$$F_D\left(\frac{H}{2}\right) - W\left(\frac{D}{2}\right) = 0$$

$$F_D\left(\frac{1.1}{2}\right) - 1030.05\left(\frac{0.9}{2}\right) = 0$$

$$F_D(0.55) = 463.52$$

$$F_D = \frac{463.52}{0.55}$$

$$= 842.76\ \text{N}$$

Step 6 of 7

Now the wind velocity that will cause this drag force can be determined by the equation given below.

$$F_D = \frac{1}{2}C_D\rho_{air}AV^2 \qquad \ldots\ldots (2)$$

Here, C_D is the drag coefficient.

ρ_{air} density of air

A is the frontal area

V is the velocity of air

Here frontal area,

$$A = DH$$

$$= 0.9 \times 1.1$$

$$= 0.99\ \text{m}^2$$

Step 7 of 7

Substituting the values of F_D C_D, ρ_{air}, and A in equation (2)

$$842.76 = \frac{1}{2} \times 0.7 \times 1.25 \times 0.99 \times V^2$$

$$V^2 = 1945.77$$

$$V = 44.11\ \text{m/s}$$

$$= 44.11\left(\frac{18}{5}\right)$$

$$= 158.8$$

$$= 159\ \text{km/h}$$

Therefore, the wind velocity during the night when the can was tipped over was,

$$\boxed{V = 159\ \text{km/h}}$$

Question: 15.039P pg 1

To reduce the drag coefficient and thus to improve the fuel efficiency of cars, the design of side rearview mirrors has changed drastically in recent decades from a simple circular plate to a streamlined shape. Determine the amount of fuel and money saved per year as a result of replacing a 13- cm-diameter flat mirror by one with a hemispherical back, as shown in the figure. Assume the car is driven 24,000 km a year at an average speed of 95 km/h. Take the density and price of gasoline to be 0.75 kg/L and $0.90/L, respectively; the heating value of gasoline to be 44,000 kJ/kg; and the overall efficiency of the engine to be 30 percent.

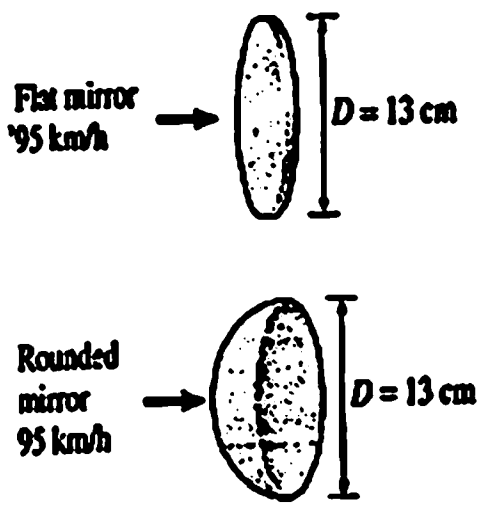


FIGURE P15–39

Step 1 of 8

Given data:

The diameter of the flat mirror, $D = 0.13\text{m}$

The diameter of the rounded mirror, $D = 0.13\ \text{m}$

Fuel costs, $0.90 per liter

Overall efficiency of the car is $\eta = 30\%$

The density of the fuel, $\rho_{fuel} = 0.75\ \text{kg/L}$

The average velocity of the car, $V = 95\ \text{km/h}$

Heating value of the fuel, $HV = 44{,}000\ \text{kJ/kg}$

The density of air can be taken as, $\rho_{air} = 1.25\ \text{kg/m}^3$

Total distance covered by the car in one year, $d = 24{,}000\ \text{km/yr}$

Step 2 of 8

The drag force acting on the flat mirror can be calculated by using the formula,

$$F_D = \frac{1}{2} C_D A \rho V^2$$

Where, C_D is the drag coefficient ($C_D = 1.1$)

ρ is the density of air

A is the frontal area

V is the velocity of wind

Now, the frontal area, is given by

$$A = \frac{\pi D^2}{4}$$

$$= \frac{\pi(0.13)^2}{4}$$

$$= 0.0133\ \text{m}^2$$

The velocity, is given by

$$V = 95\left(\frac{5}{18}\right)$$

$$= 26.4\ \text{m/s}$$

Step 3 of 8

By substituting the values in drag force, we get

$$F_D = \frac{1}{2} \times 1.1 \times 0.0133 \times 1.25 \times (26.4)^2$$

$$= 6.37\ \text{N}$$

Now, the work required to overcome this drag is

$$W = F_D \times d$$

$$= (6.37\ \text{N}) \times (24000\ \text{km/yr})$$

$$= 152880\ \text{kJ/yr}$$

Now, required energy input for a travelling 24000 km is,

$$E_{in} = \frac{W}{\eta}$$

$$= \frac{152880}{0.3}$$

$$= 509600\ \text{kJ/yr}$$

Step 4 of 8

The amount of fuel required to develop this energy,

$$f_1 = \frac{E_{in}}{HV(\rho_{fuel})}$$

$$= \frac{509600}{44000(0.75)}$$

$$= 15.44\ \text{L/yr}$$

The cost of the fuel required is

C_1 = Amount of fuel × Unit cost of fuel

$$= 15.44 \times 0.90$$

$$= \$13.9$$

Step 5 of 8

The drag force acting on the rounded mirror can be calculated by using the formula,

$$F_D = \frac{1}{2} C_D A \rho V^2$$

Where, C_D is the drag coefficient ($C_D = 0.4$)

ρ is the density of air

A is the frontal area

V is the velocity of wind

Now, the frontal area, is given by

$$A = \frac{\pi D^2}{4}$$

$$= \frac{\pi(0.13)^2}{4}$$

V is the velocity of wind

Now, the frontal area, is given by

$$A = \frac{\pi D^2}{4}$$
$$= \frac{\pi(0.13)^2}{4}$$
$$= 0.0133\ \text{m}^2$$

Step 6 of 8

By substituting the values in drag force, we get

$$F_D = \frac{1}{2} \times 0.4 \times 0.0133 \times 1.25 \times (26.4)^2$$
$$= 2.32\ \text{N}$$

Now, the work required to overcome this drag is

$$W = F_D \times d$$
$$= (2.32\ \text{N}) \times (24000\ \text{km/yr})$$
$$= 55680\ \text{kJ/yr}$$

Now, required energy input for a travelling 24000 km is,

$$E_{in} = \frac{W}{\eta}$$
$$= \frac{55680}{0.3}$$
$$= 185600\ \text{kJ/yr}$$

Step 7 of 8

The amount of fuel required to develop this energy,

$$f_2 = \frac{E_{in}}{HV(\rho_{fuel})}$$
$$= \frac{185600}{44000(0.75)}$$
$$= 5.62\ \text{L/yr}$$

The cost of the fuel required is

C_1 = Amount of fuel × Unit cost of fuel
$$= 5.62 \times 0.90$$
$$= \$5.06$$

Step 8 of 8

The amount of fuel saved,

$$f = f_1 - f_2$$
$$= 15.44 - 5.62$$
$$= 9.82\ \text{L}$$

Hence the amount of fuel saved in a year is $\boxed{f = 9.82\ \text{L}}$

The amount of money saved,

$$C = C_1 - C_2$$
$$= 13.9 - 5.06$$
$$= \$\,8.84$$

Hence the amount of money saved in a year is $\boxed{C = \$\,8.84}$

Question: 15.040P

A 5-m-diameter hot air balloon that has a total mass of 230 kg is standing still in air on a windless day. The balloon is suddenly subjected to 40 km/h winds. Determine the initial acceleration of the balloon in the horizontal direction.

Step 1 of 4

Given data:-

Diameter of the balloon, $D = 5$ m

Mass of the balloon, $m = 230$ kg

Velocity of the wind, $V = 40$ km/h

Step 2 of 4

Now, the drag force acting on the balloon can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_D \rho A V^2 \qquad \ldots\ldots (1)$$

Where, C_D is the drag coefficient

ρ is the density of air.

A is the frontal area of the balloon.

V is the velocity of the wind.

Frontal area of the parachute,

$$A = \frac{\pi}{4} D^2$$

Here, $D = 5$ m

Substituting the value in the above equation

$$A = \frac{\pi}{4}(5)^2$$

$$= 19.625 \text{ m}^2$$

Drag coefficient for the balloon is, $C_D = 0.1$

Step 3 of 4

From the table properties of air,

Density of air at 1atm pressure and 25°C is, $\rho = 1.184$ kg/m^3

Velocity of air,

$$V = 40 \text{ km/h}$$

$$= 40\left(\frac{5}{18}\right) \text{m/s}$$

$$= 11.11 \text{ m/s}$$

Now, substitute all the known values in equation (1)

$$F_D = \frac{1}{2} C_D \rho A V^2$$

$$= \frac{1}{2} \times 0.1 \times 1.184 \times 19.625 \times (11.11)^2$$

$$= 143.4 \text{ N}$$

Step 4 of 4

Now, we know that force is the product of mass and acceleration,

Therefore,

Therefore, Force,

$F = \text{mass} \times \text{acceleration}$ ..... (2)

Here mass is the mass of balloon, $m = 230$ kg

Force is the drag force acting on the balloon,

Now, substitute the known values in equation (2)

$$F = \text{mass} \times \text{acceleration}$$

$$143.4 = 230 \times a$$

$$a = \frac{143.4}{230}$$

$$= 0.62 \text{ m/s}^2$$

Therefore acceleration, $\boxed{a = 0.62 \text{ m/s}^2}$

Question: 15.041P

A 6-mm-diameter plastic sphere whose density is 1150 kg/m3 is dropped into water at 20°C. Determine the terminal velocity of the sphere in water.

Step 1 of 4

Given data:

The diameter of the plastic sphere, $D = 6$ mm

The density of the sphere, $\rho_{sphere} = 1150\ kg/m^3$

The temperature of water, $T = 20°C$

The density of water at 20°C, $\rho_{water} = 998\ kg/m^3$

The dynamic viscosity of water at 20°C, $\mu = 1.002 \times 10^{-3}$ kg/m-s

Drag coefficient of a sphere in laminar flow, $C_D = 0.5$

Step 2 of 4

The frontal area of the sphere,

$$A = \frac{\pi D^2}{4}$$

$$= \frac{\pi(0.006)^2}{4}$$

$$= 2.83 \times 10^{-5}\ m^2$$

The drag force acting on the sphere is

$$F_D = \frac{1}{2} C_D A \rho_{water} V^2$$

Where C_D is the drag coefficient

A is the frontal area of the car

V is the velocity of the car and

ρ_{water} is the density of water.

$$F_D = \frac{1}{2} C_D A \rho_{water} V^2$$

$$= \frac{1}{2} \times 0.5 \times 2.83\left(10^{-5}\right) \times 998 \times V^2$$

$$= 7.06 \times 10^{-3} \times V^2$$

Step 3 of 4

Now, weight of the body,

$$W = \rho_{sphere} g \forall$$

$$= \rho_{sphere} g \left(\frac{\pi D^3}{6}\right)$$

$$= 1150 \times 9.81 \times \frac{\pi(0.006)^3}{6}$$

$$= 0.00127\ N$$

Now, buoyant force,

$$F_B = \rho_{water} g \forall$$

$$= \rho_{water} g \left(\frac{\pi D^3}{6}\right)$$

$$= 998 \times 9.81 \times \frac{\pi(0.006)^3}{6}$$

$$= 0.0011\ N$$

Step 4 of 4

For a freely falling body terminal velocity is reached when the sum of the drag force (F_D) and buoyant force (F_B) acting on the body becomes equal to the weight of the body (W). Therefore,

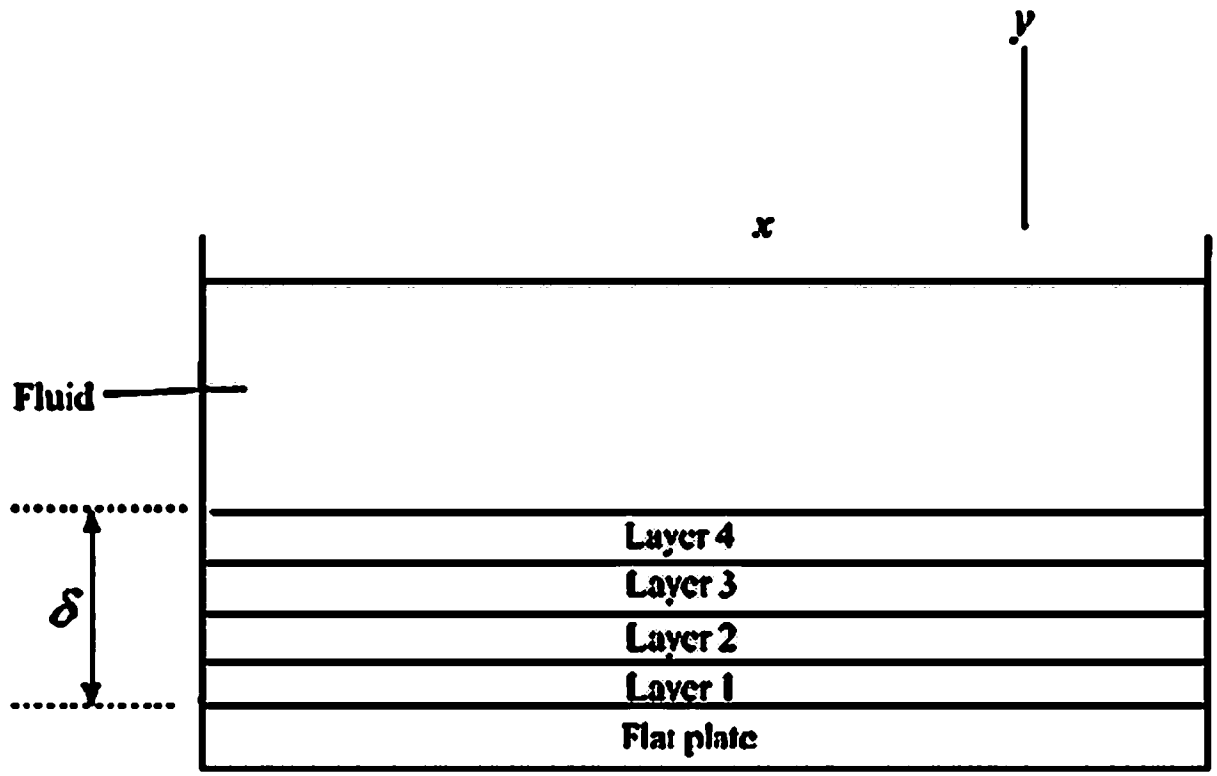
$$W = F_D + F_B$$

$$0.00127 = \left(7.06 \times 10^{-3} \times V^2\right) + 0.0011$$

$$1.7 \times 10^{-4} = 7.06 \times 10^{-3} \times V^2$$

$$V = \sqrt{\frac{1.7 \times 10^{-4}}{7.06\left(10^{-3}\right)}}$$

$$= 0.155\ m/s$$



Therefore, the terminal velocity of the sphere in water is $\boxed{V = 0.155 m/s}$

Question: 15.042P

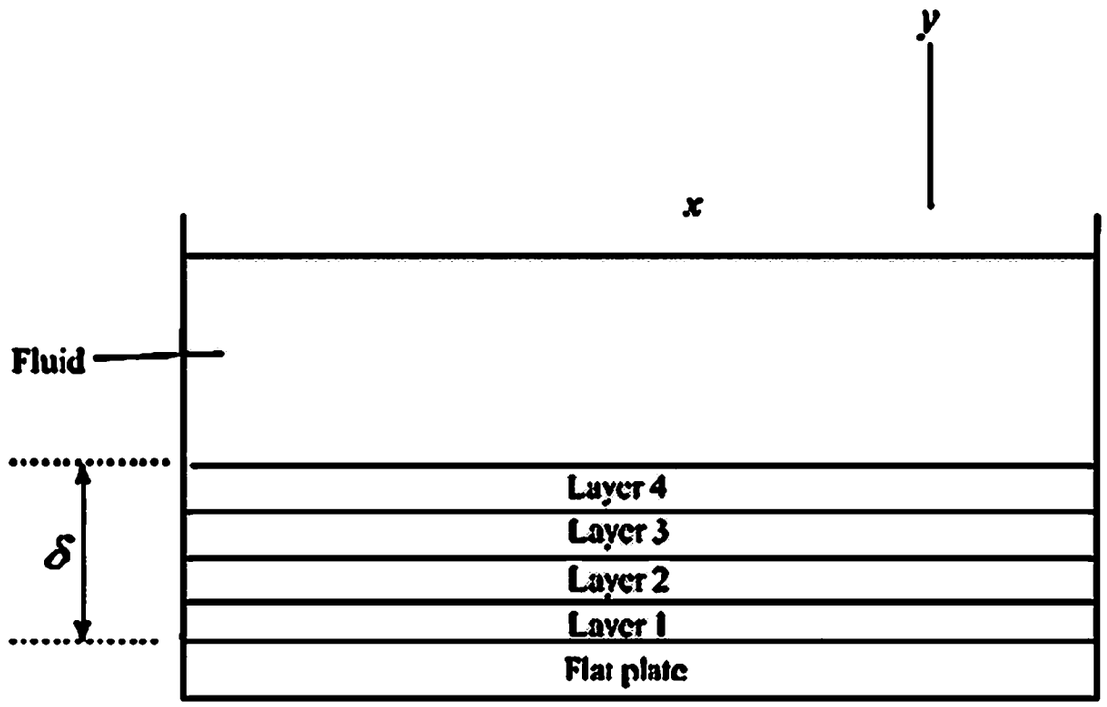
What does the friction coefficient represent in flow over a flat plate? How is it related to the drag force acting on the plate?

Step 1 of 2

Diagram for the boundary layer:

Step 2 of 2

Consider a fluid flow over a flat plate. The x coordinate is measured along the plate in the direction of flow and y coordinate is measured normal to the plate or perpendicular to the direction of flow.



The fluid approaches the plate in the x direction with a uniform velocity of V. We are assuming that the fluid consist of adjacent layers one over the other, in the figure it is layer 1, layer 2, layer 3 etc. Each layer will offer a resistance to the flow of adjacent layer; this is due to the frictional resistance between the two layers. This frictional resistance of fluid is called viscosity.

Question: 15.043P

What fluid property is responsible for the development of the velocity boundary layer? What is the effect of the velocity on the thickness of the boundary layer?

Step 1 of 3

Diagram for the boundary layer:

Step 2 of 3

Consider a fluid flow over a flat plate. The x coordinate is measured along the plate in the direction of flow and y coordinate is measured normal to the plate or perpendicular to the direction of flow.

The fluid approaches the plate in the x direction with a uniform velocity of V. We are assuming that the fluid consist of adjacent layers one over the other, in the figure it is layer 1, layer 2, layer 3 etc. Each layer will offer a resistance to the flow of adjacent layer; this is due to the frictional resistance between the two layers. This frictional resistance of fluid is called viscosity.

Step 3 of 3

The velocity of the particles in the first layer (layer 1) is zero because of the no slip condition. This motionless layer will slow down the particles of the neighboring fluid layer (layer 2) due to the frictional resistance between the two layers. Now, the layer 2 will offer frictional resistance to layer 3 and so on. This will continue up to a distance of δ from the plate surface beyond that distance the free stream velocity virtually remain unchanged, in other word beyond that distance the fluid will flow at a velocity of V (typically $0.99V$). As a result the x component (velocity) varies from zero to V (typically $0.99V$).

The region above the plate up to distance δ is called velocity boundary layer. From the above explanation we can understand that viscosity is the fluid property responsible for the development of boundary layer. Velocity brings boundary layer closer to the plate surface, so higher the velocity lower will be the thickness of the boundary layer and vise versa.

Question: 15.044P

How is the average friction coefficient determined in flow over a flat plate?

Step 1 of 2

One of he ways of determining the average friction coefficient is by dividing the drag force by dynamic pressure. For this we should first determine the drag force acting on the body experimentally and the area of the surface through which the fluid is flowing, the density of the fluid and the velocity of the fluid flow also should be known.

Coefficient of friction, $C_f = \dfrac{F_D}{\frac{1}{2}\rho A V^2}$

Where, $\frac{1}{2}\rho A V^2$ is the dynamic pressure.

Here, F_D is the drag force,

ρ is the density,

A is the area of the plate through which fluid is flowing and

V is the velocity of flow.

Step 2 of 2

Now, we can determine the average friction coefficient by another method, for this we have to know the local friction coefficient $\left(C_{f,x}\right)$ which is the local value of friction coefficient at a particular region in the plate. The local friction coefficient varies along the surface of the flat plate due to the change in velocity boundary layer in the flow direction so the values of local friction coefficient will be different in different regions of the plate.

To determine the average friction coefficient for the entire plate we should integrate the local friction coefficient for the entire length L and divide it by the length L.

$$C_f = \frac{1}{L}\int_0^L C_{f,x}\,dx$$

For laminar flow, $C_{f,x} = \dfrac{0.664}{\mathrm{Re}_x^{0.5}}$

Where, Re_x is the Reynolds number at a distance x from the leading edge of the plate.

$\mathrm{Re}_x = \dfrac{Vx}{\nu}$. Also, $\mathrm{Re}_x \le 5 \times 10^5$

V is the velocity of fluid, x is the length of the plate and ν is the kinematic viscosity of the fluid.

Question: 15.045P

Light oil at 75°F flows over a 22-ft-long flat plate with a free-stream velocity of 6 ft/s. Determine the total drag force per unit width of the plate.

Step 1 of 3

The total drag force acting per unit width can be calculated using the formula given below.

Drag force, $F_D = \frac{1}{2} C_f \rho A V^2$ ..... (1)

Where,

The density of air be ρ

The velocity of flow be V

The coefficient frictional be C_f

The area of the plate through which air is flowing be A

Step 2 of 3

Since the value of Reynolds number is unknown we have to calculate the Reynolds number.

To calculate the Reynolds number we can use the formula given below.

$$\mathrm{Re}_L = \frac{VL}{\nu} \text{ ..... (2)}$$

Here,

The velocity of flow be V

The kinematic viscosity be ν

The length of the plate be L

Substituting the values of V, L and ν in equation (2), we get

$$\mathrm{Re}_L = \frac{6(22)}{7.751 \times 10^{-3}}$$
$$= 17030.06$$

We can calculate coefficient of friction using the formula given below,

$$C_f = \frac{1.33}{\mathrm{Re}_L^{0.5}}$$
$$= \frac{1.33}{(17030.06)^{0.5}}$$
$$= 0.01019$$

Step 3 of 3

Now, we have to calculate the area of the surface of the flat plate through which oil is flowing A

Area of the surface through which oil is flowing,

$$A = L \times w$$

Here, L is the length of the plate and w is the width of the plate.

$$A = 22 \times 1$$
$$= 22 \text{ ft}^2$$

Substituting the values V, A, ρ and c_f in the equation (1), we get

$$F_D = \frac{1}{2} C_f \rho A V^2$$
$$= \frac{1}{2} \times 0.01019 \times 55.3 \times 22 \times 6^2$$
$$= 223.14 \text{ lbf}$$

Therefore, the total drag force acting per unit width of the plate is $\boxed{F_D = 223.14 \text{ lbf}}$

Question: 15.046P pg 1

The local atmospheric pressure in Denver, Colorado (elevation 1610 m) is 83.4 kPa. Air at this pressure and at 25°C flows with a velocity of 6 m/s over a 2.5-m × 8-m flat plate. Determine the drag force acting on the top surface of the plate if the air flows parallel to the (*a*) 8-m-long side and (*b*) the 2.5-m-long side.

Step 1 of 8

Given data:

Pressure of the air is $P = 83.4\ \text{kPa}$.

Temperature of air is $T = 25°\text{C}$.

Velocity of flow is $V = 6\ \text{m/s}$.

Dimensions of the flat plate is $2.5\ \text{m} \times 8\ \text{m}$.

Area of the flat plate is $A = 20\ \text{m}^2$.

Step 2 of 8

a) Air is flowing parallel to 8m long side.

Dynamic viscosity of air at $25°\text{C}$ is $\mu = 1.849 \times 10^{-5}\ \text{kg/m·s}$

Density of air at temperature, $T = 25°\text{C}$ and pressure, $P = 83.4\ \text{kPa}$

$$\rho = \frac{P}{RT} \quad \ldots\ldots (1)$$

Here, P is the pressure, T is the temperature and R is the gas constant.

$$T = 273 + 25$$
$$= 298\ \text{K}$$

$$R = 287.058\ \text{J/kg K}$$
$$= 0.287\ \text{kJ/kg K}$$

Substituting the values of P, R and T in equation (1).

$$\rho = \frac{83.4}{0.287 \times 298}$$
$$= 0.975\ \text{kg/m}^3$$

Step 3 of 8

Reynolds number is $\text{Re}_L = \frac{\rho V L}{\mu}$ ..... (2)

Where, ρ is the density of air.

V is the velocity of flow.

L is the length of the plate.

μ is the kinematic viscosity.

Here, length $L = 8\ \text{m}$

Substitute these values in equation (2).

$$\text{Re}_L = \frac{\rho V L}{\mu}$$
$$= \frac{0.975 \times 6 \times 8}{1.849 \times 10^{-5}}$$
$$= 2.531 \times 10^6$$

Step 4 of 8

We know that the critical value of Reynolds number is $\text{Re}_{cr} = 5 \times 10^5$. Since the obtained value of Reynolds number is greater then the critical value the flow will be a combined laminar and turbulent flow.

Therefore, we can now calculate the frictional coefficient by using the formula given below.

$$C_f = \frac{0.074}{\text{Re}_L^{1/5}} - \frac{1742}{\text{Re}_L}$$
$$= \frac{0.074}{\left(2.531 \times 10^6\right)^{1/5}} - \frac{1742}{2.531 \times 10^6}$$
$$= 0.0039 - 0.000688$$
$$= 0.0032$$

Step 5 of 8

Here since the pressure drag is zero the drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_f \rho A V^2 \quad \ldots\ldots (3)$$

Where, ρ is the density of air.

A is the area of the flat plate through which air is flowing.

V is the velocity of flow.

Now, substitute the value of ρ, A, V, and C_f in equation (3).

$$F_D = \frac{1}{2} \times 0.0032 \times 0.975 \times 20 \times (6)^2$$
$$= 1.12\ \text{N}$$

Therefore, the drag force acting on the flat plate when air flows parallel to 8 m long side, $\boxed{F_D = 1.12\ \text{N}}$.

Step 6 of 8

b) Air is flowing parallel to 2.5m long side.

Reynolds number, $\text{Re}_L = \frac{\rho V L}{\mu}$

Step 6 of 8

b) Air is flowing parallel to 2.5m long side.

Reynolds number, $\mathrm{Re}_L = \dfrac{\rho V L}{\mu}$

Where, ρ is the density of air.

V is the velocity of flow.

L is the length of the plate.

μ is the kinematic viscosity.

Here, length $L = 2.5\ \mathrm{m}$

Substituting these values in the above equation.

$$\begin{aligned}\mathrm{Re}_L &= \frac{\rho V L}{\mu}\\ &= \frac{0.975 \times 6 \times 2.5}{1.849 \times 10^{-5}}\\ &= 7.9 \times 10^5\end{aligned}$$

We know that the critical value of Reynolds number is $\mathrm{Re}_{cr} = 5 \times 10^5$.

Since the obtained value of Reynolds number is greater then the critical value the flow will be a combined laminar and turbulent flow.

Step 7 of 8

Therefore, we can now calculate the frictional coefficient by using the formula given below.

$$\begin{aligned}C_f &= \frac{0.074}{\mathrm{Re}_L^{1/5}} - \frac{1742}{\mathrm{Re}_L}\\ &= \frac{0.074}{\left(7.9 \times 10^5\right)^{1/5}} - \frac{1742}{7.9 \times 10^5}\\ &= 0.00489 - 0.0022\\ &= 0.00269\end{aligned}$$

Step 8 of 8

Here since the pressure drag is zero the drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_f \rho A V^2$$

Were, ρ is the density of air.

A is the area of the flat plate through which air is flowing.

V is the velocity of flow.

Substituting the value of ρ, A, V, and C_f in the above equation.

$$\begin{aligned}F_D &= \frac{1}{2} \times 0.00269 \times 0.975 \times 20 \times (6)^2\\ &= 0.944\ \mathrm{N}\end{aligned}$$

Therefore, the drag force acting on the flat plate when air flows parallel to 2.5 m long side,

$\boxed{F_D = 0.944\ \mathrm{N}}$.

Question: 15.047P pg 1

During a winter day, wind at 55 km/h, 5°C, and .1 atmis blowing parallel to a 4-m-high and 10-m-long wall of a house. Approximating the wall surfaces as smooth, determine the friction drag acting on the wall. What would your answer be if the wind velocity has doubled? How realistic is it to treat the flow over side wall surfaces as flow over a flat plat?

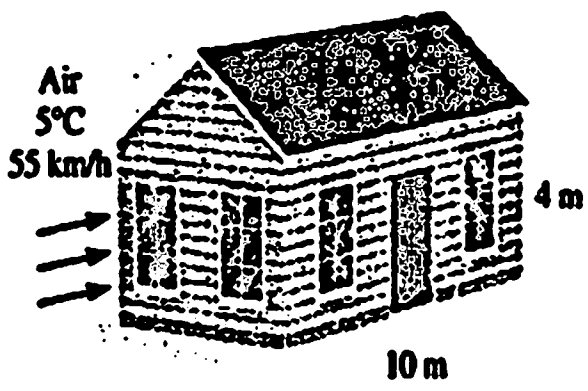


FIGURE P15–47

Step 1 of 7

Given data:

Velocity of wind is $V = 55\ \text{km/h}$.

Temperature of the air is $T = 5°\text{C}$.

Pressure of the air is $P = 1\ \text{atm}$.

Height of the wall is $h = 4\ \text{m}$.

Length of the wall is $L = 10\ \text{m}$.

Step 2 of 7

Density of air at $5°\text{C}$ and 1 atm pressure, $\rho = 1.269\ \text{kg/m}^3$

Kinematic viscosity of air at $5°\text{C}$ and 1 atm pressure, $\nu = 1.382 \times 10^{-5}\ \text{m}^2/\text{s}$

Now, the Reynolds number at the end of the wall that means at a length of 10 m of the wall,

$$\text{Re}_L = \frac{VL}{\nu} \quad \ldots\ldots (1)$$

Where, V is the velocity of flow.

L is the length of the wall.

ν is the kinematic viscosity of fluid.

Step 3 of 7

Converting velocity

$$V = 55\left(\frac{5}{18}\right)\text{m/s}$$
$$= 15.3\,\text{m/s}$$

Substituting the values of V, L and ν in equation (1).

$$\text{Re}_L = \frac{VL}{\nu}$$
$$= \frac{15.3 \times 10}{1.382 \times 10^{-5}}$$
$$= 1.1 \times 10^7$$

Step 4 of 7

We know that the critical value of Reynolds number is $\text{Re}_{cr} = 5 \times 10^5$. Since the obtained value of Reynolds number is greater then the critical value the flow will be a combined laminar and turbulent flow.

Therefore, we can now calculate the frictional coefficient by using the formula given below.

$$C_f = \frac{0.074}{\text{Re}_L^{1/5}} - \frac{1742}{\text{Re}_L}$$
$$= \frac{0.074}{\left(1.1 \times 10^7\right)^{1/5}} - \frac{1742}{1.1 \times 10^7}$$
$$= 0.0029 - 0.00016$$
$$= 0.00274$$

Step 5 of 7

Here since the pressure drag is zero the drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_f \rho A V^2 \quad \ldots\ldots (2)$$

Were, ρ is the density of air.

A is the area of the wall through which air is flowing.

V is the velocity of flow.

Here, area of the wall through which air is flowing,

$$A = L \times h$$
$$= 10 \times 4$$
$$= 40\ \text{m}^2$$

Then, substituting the value of ρ, A, V, and C_f in equation (2).

$$F_D = \frac{1}{2} \times 0.00274 \times 1.269 \times 40 \times (15.3)^2$$
$$= 16.3\ \text{N}$$

Step 6 of 7

Now, the velocity is doubled so the new velocity is, $V = 110\ \text{km/h}$

Step 6 of 7

Now, the velocity is doubled so the new velocity is, $V = 110\ \text{km/h}$

$$V = 110\left(\frac{5}{18}\right)\text{m/s}$$
$$= 30.55\,\text{m/s}$$

The new Reynolds number is,

$$\text{Re}_L = \frac{VL}{\nu}$$
$$= \frac{30.55 \times 10}{1.382 \times 10^{-5}}$$
$$= 2.21 \times 10^7$$

We know that the critical value of Reynolds number is $\text{Re}_{cr} = 5 \times 10^5$. Since the obtained value of Reynolds number is greater then the critical value the flow will be a combined laminar and turbulent flow.

Therefore, we can now calculate the frictional coefficient by using the formula given below.

$$C_f = \frac{0.074}{\text{Re}_L^{1/5}} - \frac{1742}{\text{Re}_L}$$
$$= \frac{0.074}{\left(2.21 \times 10^7\right)^{1/5}} - \frac{1742}{2.21 \times 10^7}$$
$$= 0.0025 - 0.0000788$$
$$= 0.0024$$

Step 7 of 7

Here since the pressure drag is zero the drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_f \rho A V^2$$

Were, ρ is the density of air.

A is the area of the wall through which air is flowing.

V is the velocity of flow.

Then, substituting the value of ρ, A, V, and C_f in the above equation.

$$F_D = \frac{1}{2} \times 0.0024 \times 1.269 \times 40 \times (30.55)^2$$
$$= 57\,\text{N}$$

Therefore, the drag force acting on the wall when velocity is $55\,\text{km/h}$ is $\boxed{F_D = 16.3\ \text{N}}$, and the drag force acting when the velocity is $110\,\text{km/h}$ is $\boxed{F_D = 57\ \text{N}}$.

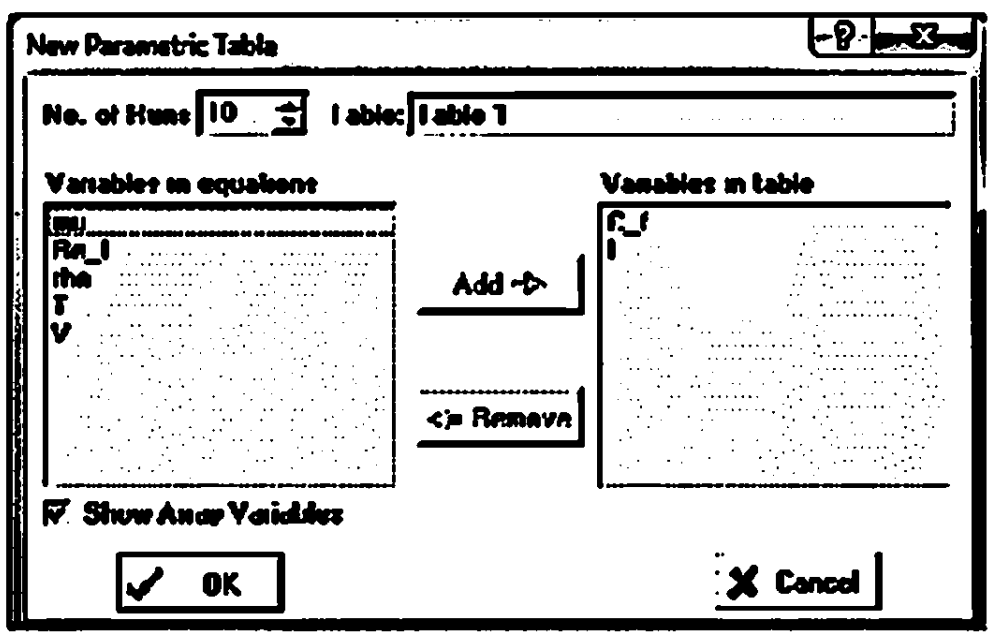
Question: 15.048P

Air at 70°F flows over a 10-ft-long flat plate ɯlɯ at 25 ft/s. Determine the local friction coefficient at intervals of 1 ft and plot the results against the distance from the leading edge.

Step 1 of 5

The given problem can be solved using EES software by following the below steps.

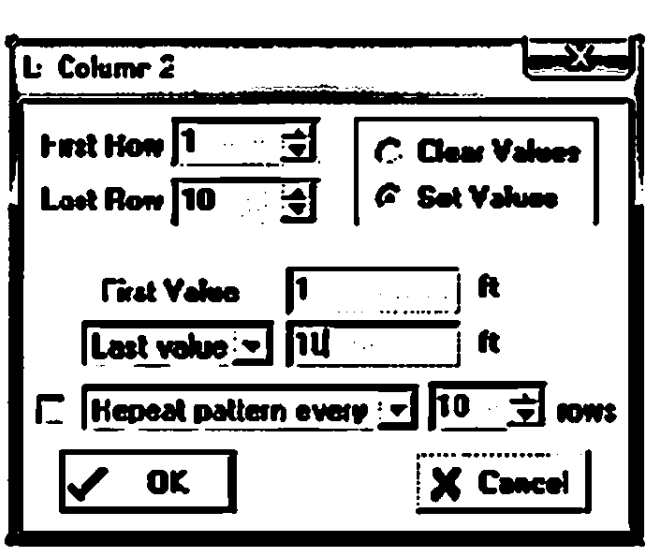
1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box



```
Function IFTEST(X, Y)
if(X<Y) Then
A:=0.664/X^(1/2)
Else
A:=0.059/(X)^(1/5)
EndIf
IFTEST:=A
End

T=70[F]                                   "Temperature of Air"
"L is varied from 0 to 10[ft]"            "Lenght of the plate"
V=25[ft/s]                                "Velocity of air"

"Properties of air"
rho=Density(Air,T=T,P=1[atm]*convert(atm,psia))
mu=Viscosity(Air,T=T)*convert(lb_m/ft hr, lb_m/ft s)
Re_L=rho*V*L/mu                           "Reynolds number"
C_f=IFTEST(Re_L,500000)                   "Friction Coefficient"
```



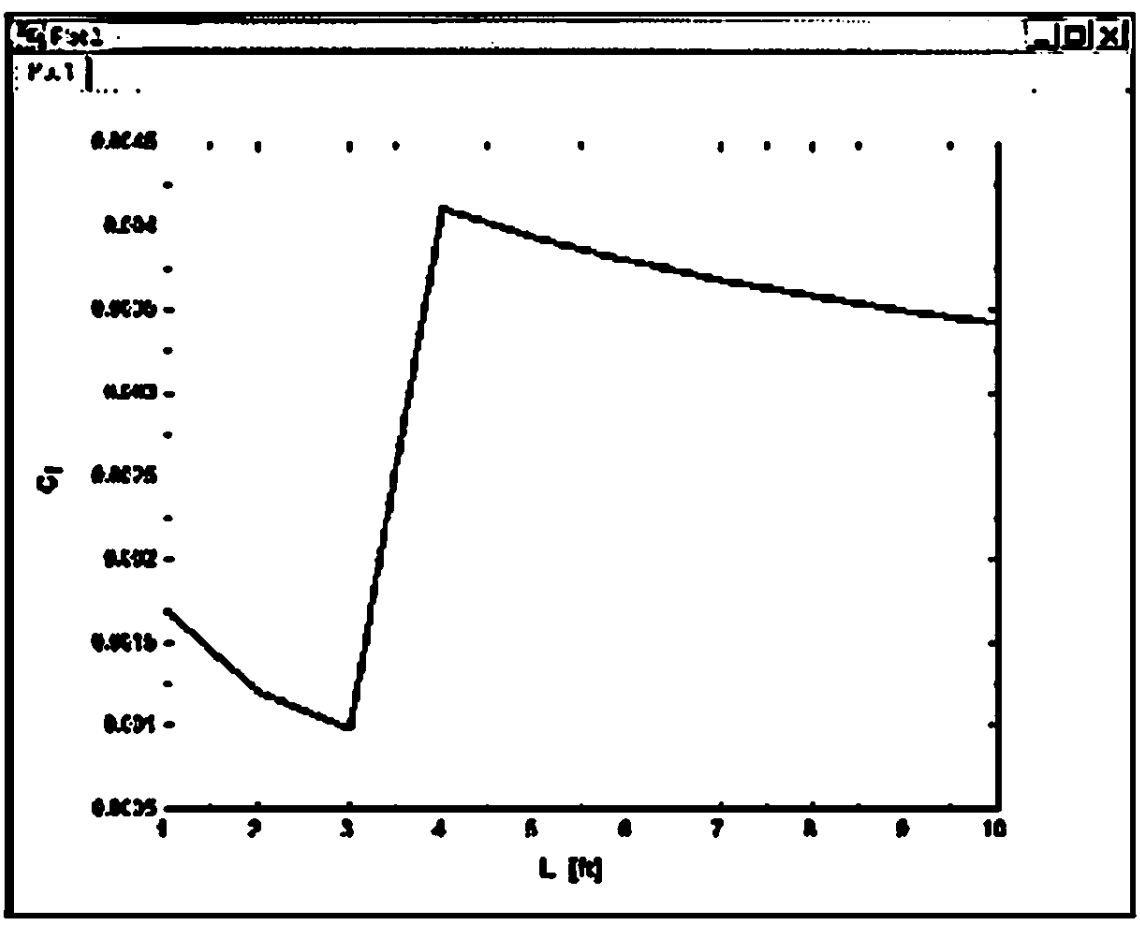
Step 2 of 5

Now to solve the equation for a range of length of the air, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 10.
Select variables in equations as "C_f", and "L" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 5

The length of the plate is varied from 0 to 10 ft
To enter the values in the "L" column, click on the drop tab in "L" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 5



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..10	C_f	L [ft]
Run 1	0.001702	1
Run 2	0.001203	2
Run 3	0.0009826	3
Run 4	0.004111	4
Run 5	0.003932	5
Run 6	0.003791	6
Run 7	0.003676	7
Run 8	0.003579	8
Run 9	0.003496	9
Run 10	0.003423	10

Step 5 of 5

To plot the coefficient of friction as a function of length of the plate, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the coefficient of friction as a function of length of the plate is shown:

Question: 15.049P

Consider laminar flow of a fluid over a flat plate. Now the free-stream velocity of the fluid is doubled. Determine the change in the drag force on the plate. Assume the flow to remain laminar.

Step 1 of 3

For a laminar fluid drag force is given by,

$$F_{D_1} = \frac{1}{2} C_f \rho A V^2 \text{ ..... (1)}$$

Where, C_f is the frictional coefficient.

ρ is the density of air.

A is the area of the plate through which air is flowing.

V is the velocity of flow.

Step 2 of 3

Then, the frictional coefficient is $C_f = \frac{1.328}{\text{Re}^{0.5}}$.

Where, Re is the Reynolds number.

Substitute the value of C_f in equation (1).

$$F_{D_1} = \frac{1}{2}\left(\frac{1.328}{\text{Re}^{0.5}}\right)\rho A V^2 \text{ ..... (2)}$$

Now, the relation for the Reynolds number is, $\text{Re} = \frac{VL}{\nu}$

Substituting the value of Re in equation (2)

$$F_{D_1} = \frac{1}{2}\left(\frac{1.328}{\left(\frac{VL}{\nu}\right)^{0.5}}\right)\rho A V^2$$

$$F_{D_1} = \frac{0.664 \rho A \nu^{0.5} V^{3/2}}{L^{0.5}} \text{ ..... (3)}$$

Step 3 of 3

When the free stream velocity is doubled,

$$V = 2V$$

Then substituting values in equation (3) drag force becomes,

$$\begin{aligned} F_{D_2} &= \frac{0.664 \rho A \nu^{0.5} (2V)^{3/2}}{L^{0.5}} \\ &= 2^{3/2}\left(\frac{0.664 \rho A \nu^{0.5} V^{3/2}}{L^{0.5}}\right) \\ &= 2.83\left(\frac{0.664 \rho A \nu^{0.5} V^{3/2}}{L^{0.5}}\right) \\ &= 2.83 F_{D_1} \end{aligned}$$

$$\boxed{F_{D_2} = 2.83 F_{D_1}}.$$

Therefore, when the free stream velocity is doubled the drag force increases by 2.83 times.

Question: 15.050P

Consider a refrigeration truck traveling at 70 mi/h at a location where the air is at 1 atm and 80°F. The refrigerated compartment of the truck can be considered to be a 9-ft- wide, 8-ft-high, and 20-ft-long rectangular box. Assuming the airflow over the entire outer surface to be turbulent and attached (no flow separation), determine the drag force acting on the top and side surfaces and the power required to overcome this drag.

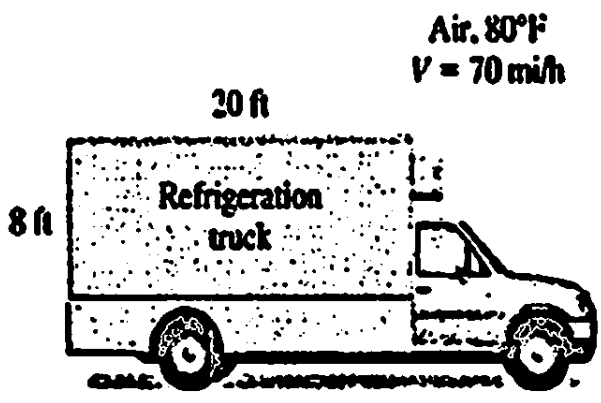


FIGURE P15–50E

Step 1 of 5

Given data:

Velocity of the truck,

$$V = 70 \text{ mi/h}$$
$$= 70 \times 1.46 \text{ ft/s}$$
$$= 102.2 \text{ ft/s}$$

Width of the refrigerated compartment is $w = 9$ ft

Length of the refrigerated compartment is $L = 20$ ft

Height of the refrigerated compartment is $h = 8$ ft

Pressure of the air, $P = 1$ atm

Temperature of the air, $T = 80°\text{F}$

Step 2 of 5

From the table properties of air,

At pressure, $P = 1$ atm

At temperature, $T = 80°\text{F}$

The density of air, $\rho = 0.0735 \text{ lbm/ft}^3$

Kinematic viscosity of air, $\nu = 1.697 \times 10^{-4} \text{ ft}^2/\text{s}$

Now, the Reynolds number at a length of 6 m of the top surface,

$$\text{Re}_L = \frac{VL}{\nu} \quad \ldots\ldots (1)$$

Where,

The velocity of flow be V

The kinematic viscosity of air be ν

The length of the refrigerated compartment be L

Step 3 of 5

Substituting the values of V, L and ν in equation (1), we get

$$\text{Re}_L = \frac{VL}{\nu}$$
$$= \frac{102.2 \times 20}{1.697 \times 10^{-4}}$$
$$= 1.204 \times 10^7$$

The air flow over the entire outer surface is assumed to be turbulent.

Therefore, we can now calculate the frictional coefficient by using the formula given below.

$$C_f = \frac{0.074}{\text{Re}_L^{1/5}}$$
$$= \frac{0.074}{\left(1.204 \times 10^7\right)^{1/5}}$$
$$= 2.83 \times 10^{-3}$$

Step 4 of 5

Here since the pressure drag is zero the drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_f \rho A V^2 \quad \ldots\ldots (2)$$

Where,

The density of air be ρ

The area of the top and side surface of the truck be A

The velocity of flow be V

Area of the top and side surface of the truck is,

$$A = \text{Area of the top surface} + 2(\text{Area of the side surface})$$
$$= (L \times w) + 2(h \times L)$$
$$= (20 \times 9) + 2(8 \times 20)$$
$$= 500 \text{ ft}^2$$

Step 5 of 5

Substituting the value of ρ, A, V, and C_f in equation (2), we get

$$F_D = \frac{1}{2} \times 2.83 \times 10^{-3} \times 0.0735 \times 500 \times (102.2)^2$$
$$= 543.14 \text{ lb}$$

Therefore, the drag force acting on the top and side surfaces is $\boxed{F_D = 543.14 \text{ lb}}$

The power required to overcome this drag is,

$$P = F_D \times V$$
$$= 543.14 \times 102.2$$
$$= 55508.9 \text{ lbf-ft/s}$$
$$= \frac{55508.9}{550} \text{ hp}$$
$$= 100.9 \text{ hp}$$

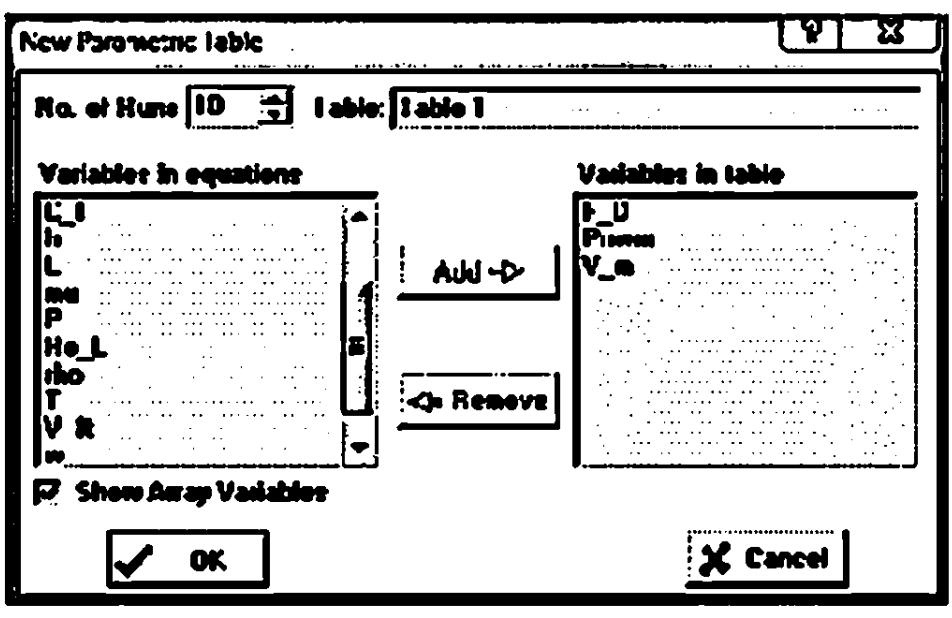
Therefore, the power required to overcome this drag is $\boxed{P = 100.9 \text{ hp}}$

Question: 15.051P

Reconsider Prob. 15-50E. Using EES (or other) software, investigate the effect of truck speed on the total drag force acting on the top and side surfaces, and the power required to overcome it. Let the truck speed vary from 0 to 100 mi/h in increments of 10 mi/h. Tabulate and plot the results.

Step 1 of 5

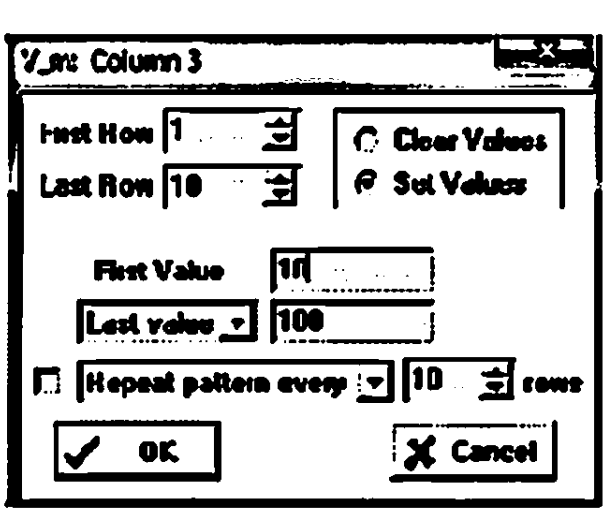
The given problem can be solved using EES software by following the below steps.



1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
"V_m is to be varied from 0 to 10 mi/hr"        "Velocity of truck"
V_ft=V_m*convert(mile/hr,ft/s)
w=9[ft]                                          "Width of refrigeration truck"
L=20[ft]                                         "Length of refrigeration truck"
h=8[ft]                                          "Height of refrigeration tuck"
P=1[atm]*convert(atm,psia)                       "Pressure of air"
T=80[F]                                          "Temperature of air"

rho=Density(Air,T=T,P=P)                         "Properties of air"
mu=Viscosity(Air,T=T)*convert(lb_m/ft hr, lb_m/ft s)
Re_L=rho*V_ft*L/mu                               "Reynolds number"
C_f=0.074/(Re_L)^(1/5)                           "Friction Coefficient"
A_t=L*W                                          "Area of the top surface"
A_s=2*L*h                                        "Area of the sides"
A=A_t+A_s                                        "Total Area"
F_D=1/2*C_f*rho*V_ft^2*A/g#                      "Drag Force"
Power=F_D*V_ft*convert(lb_f ft/s,kW)             "Power required"
```



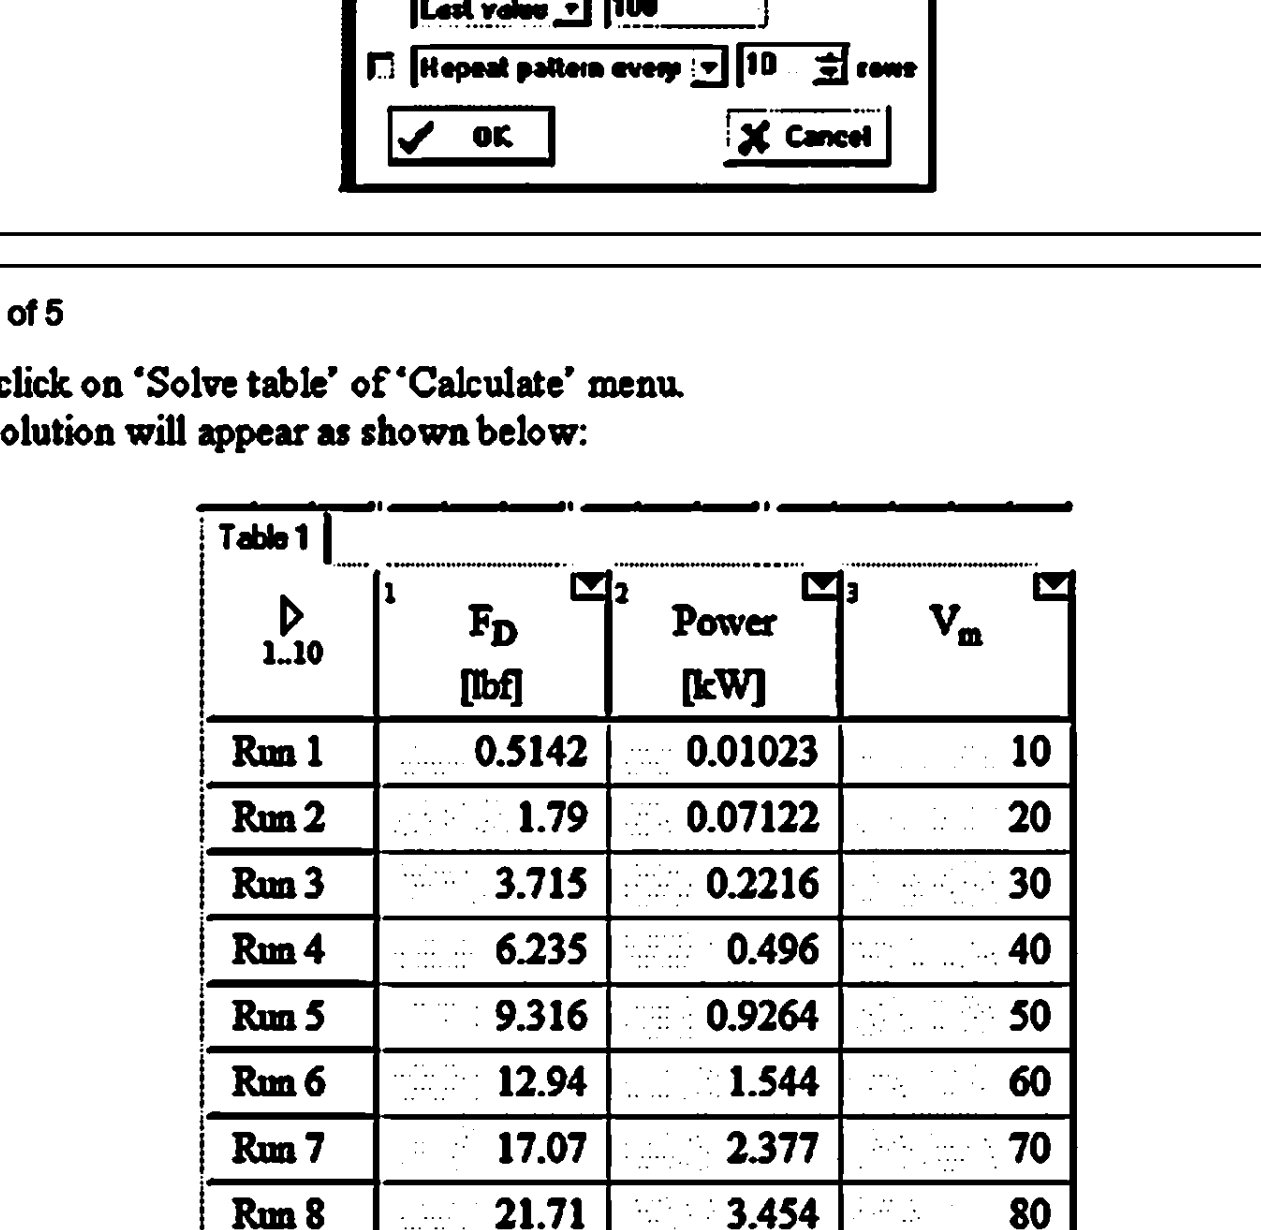
Step 2 of 5

Now to solve the equation for a range of velocity of truck, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 10.
Select variables in equations as "F_D", "Power" and "V_m" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 5

The velocity of the truck is varied from 0 to 100 mi/hr
To enter the values in the "V_m" column, click on the drop tab in "V_m" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 5



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..10	F_D [lbf]	Power [kW]	V_m
Run 1	0.5142	0.01023	10
Run 2	1.79	0.07122	20
Run 3	3.715	0.2216	30
Run 4	6.235	0.496	40
Run 5	9.316	0.9264	50
Run 6	12.94	1.544	60
Run 7	17.07	2.377	70
Run 8	21.71	3.454	80
Run 9	26.84	4.804	90
Run 10	32.44	6.452	100

Step 5 of 5

To plot the drag force and power required as a function of truck speed, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the drag force and power required as a function of truck speed is shown:

From the above plot we can interpret that as the velocity of the truck increases, the drag force and power required to overcome this drag also increases.

Question: 15.052P

Air at 25°C and 1 atm is flowing over a long flat plate with a velocity of 8 m/s. Determine the distance from the leading edge of the plate where the flow becomes turbulent, and the thickness of the boundary layer at that location.

Step 1 of 4

Given data:
Velocity of flow is $V = 8\text{m/s}$.
Atmospheric conditions,
Temperature of air is $T = 25°\text{C}$.
Atmospheric pressure is $P = 1\text{ atm}$.

Step 2 of 4

From the table properties of air at 1 atm pressure.
Density of air at 25°C and 1atm pressure is $\rho = 1.184\text{kg/m}^3$.
Kinematic viscosity of air at 25°C and 1atm pressure is $\nu = 1.562\times10^{-5}\text{ m}^2/\text{s}$.

When a fluid flows through a flat plate the transition of flow from laminar to turbulent happens when the Reynolds number becomes equal to the critical Reynolds number.
The value of critical Reynolds number is, $\text{Re}_{cr} = 5\times10^5$
The critical Reynolds number can be found out using the formula,

$$\text{Re}_{cr} = \frac{Vx_{cr}}{\nu} \qquad \ldots\ldots (1)$$

Where, V is the velocity of flow.
ν is the kinematic viscosity.
x_{cr} is the distance from the leading edge of the plate where the flow becomes turbulent.

Step 3 of 4

Substituting the value of Re_{cr}, V, and ν in equation (1).

$$\text{Re}_{cr} = \frac{Vx_{cr}}{\nu}$$

$$5\times10^5 = \frac{8(x_{cr})}{1.562\times10^{-5}}$$

$$x_{cr} = \frac{(5\times10^5)(1.562\times10^{-5})}{8}$$

$$= 0.97625\text{ m}$$

Therefore the flow becomes turbulent at a distance of $\boxed{x = 0.97625\text{ m}}$ from the leading edge of the plate.

Step 4 of 4

Now, the thickness of the boundary layer at that location can be found out using the equation given below.

$$\delta = \frac{4.91x}{\text{Re}_x^{0.5}}$$

$$= \frac{4.91x_{cr}}{\text{Re}_{cr}^{0.5}}$$

Substituting the values of x_{cr}, and Re_{cr} in the above equation.

$$\delta = \frac{4.91x_{cr}}{\text{Re}_{cr}^{0.5}}$$

$$= \frac{4.91(0.97625)}{(5\times10^5)^{0.5}}$$

$$= 0.00678\text{ m}$$

Therefore, the thickness of the boundary layer is $\boxed{\delta = 0.00678\text{ m}}$.

Question: 15.053P

Repeat Prob. 15-52 for water.

Step 1 of 4

Given data:

Velocity of flow is $V = 8\ \text{m/s}$.

Atmospheric conditions,

Temperature of air is $T = 25°\text{C}$.

Atmospheric pressure is $P = 1\ \text{atm}$.

Step 2 of 4

From the table properties of air at 1 atm pressure.

Density of water at 25°C and 1atm pressure is $\rho = 997\ \text{kg/m}^3$.

Dynamic viscosity of water at 25°C and 1atm pressure is $\mu = 0.891 \times 10^{-3}\ \text{kg/m} \cdot \text{s}$.

When a fluid flows through a flat plate the transition of flow from laminar to turbulent happens when the Reynolds number becomes equal to the critical Reynolds number.

The value of critical Reynolds number is, $\text{Re}_{cr} = 5 \times 10^5$

The critical Reynolds number can be found out using the formula,

$$\text{Re}_{cr} = \frac{\rho V x_{cr}}{\mu} \qquad \ldots\ldots (1)$$

Where, V is the velocity of flow

μ is the dynamic viscosity

x_{cr} is the distance from the leading edge of the plate where the flow becomes turbulent.

Step 3 of 4

Substituting the value of Re_{cr}, V, and μ in equation (1).

$$\text{Re}_{cr} = \frac{\rho V x_{cr}}{\mu}$$

$$5 \times 10^5 = \frac{997 \times 8 \times x_{cr}}{0.891 \times 10^{-3}}$$

$$x_{cr} = \frac{\left(5 \times 10^5\right)\left(0.891 \times 10^{-3}\right)}{997 \times 8}$$

$$= 0.056\ \text{m}$$

Therefore the flow becomes turbulent at a distance of $\boxed{x = 0.056\ \text{m}}$ from the leading edge of the plate.

Step 4 of 4

Now, the thickness of the boundary layer at that location can be found out using the equation given below.

$$\delta = \frac{4.91x}{\text{Re}_x^{0.5}}$$

$$= \frac{4.91x_{cr}}{\text{Re}_{cr}^{0.5}}$$

Substituting the values of x_{cr}, and Re_{cr} in the above equation.

$$\delta = \frac{4.91x_{cr}}{\text{Re}_{cr}^{0.5}}$$

$$= \frac{4.91(0.0559)}{\left(5 \times 10^5\right)^{0.5}}$$

$$= 0.00039\ \text{m}$$

Therefore, the thickness of the boundary layer is $\boxed{\delta = 0.00039\ \text{m}}$.

Question: 15.054P

The top surface of the passenger car of a train moving at a velocity of 70 km/h is 3.2 m wide and 8 m long. If the outdoor air is at 1 atm and 25°C, determine the drag force acting on the top surface of the car.

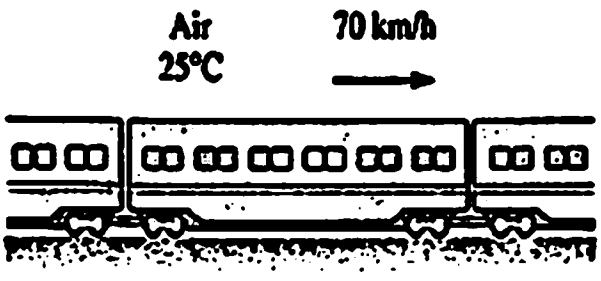


FIGURE P15–54

Step 1 of 4

Given data:

Velocity of passenger car is $V = 70$ km/h.

Width of the passenger car is $w = 3.2$ m.

Length of the passenger car is $L = 8$ m.

Atmospheric condition,

Pressure is $P = 1$ atm.

Temperature is $T = 25°C$.

Step 2 of 4

From the properties of air tables at 1 atm pressure.

The density of air at 1atm and 25°C is $\rho = 1.184$ kg/m^3.

Kinematic viscosity of air at 1atm and 25°C is $\nu = 1.562 \times 10^{-5}$ m^2/s.

Now, the Reynolds number at the end of the plate that means at a length of 10 m of the plate,

$$\mathrm{Re}_L = \frac{VL}{\nu} \qquad \ldots\ldots (1)$$

Where, V is the velocity of flow.

L is the length of the plate.

ν is the kinematic viscosity of fluid.

Converting units of velocity

$$V = 70\left(\frac{5}{18}\right) \text{m/s}$$

$$= 19.44 \text{ m/s}$$

Step 3 of 4

Substituting the values of V, L and ν in equation (1).

$$\mathrm{Re}_L = \frac{VL}{\nu}$$

$$= \frac{19.44 \times 8}{1.562 \times 10^{-5}}$$

$$= 9.956 \times 10^6$$

We know that the critical value of Reynolds number is $\mathrm{Re}_{cr} = 5 \times 10^5$ since the obtained value of Reynolds number is greater then the critical value the flow will be a combined laminar and turbulent flow.

Therefore, we can now calculate the frictional coefficient by using the formula given below.

$$C_f = \frac{0.074}{\mathrm{Re}_L^{1/5}} - \frac{1742}{\mathrm{Re}_L}$$

$$= \frac{0.074}{\left(9.956 \times 10^6\right)^{1/5}} - \frac{1742}{9.956 \times 10^6}$$

$$= 0.0029 - 0.00017$$

$$= 0.00273$$

Step 4 of 4

Since the pressure drag is zero the drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_f \rho A V^2 \qquad \ldots\ldots (2)$$

Were, ρ is the density of air.

A is the area of the top surface of the passenger car.

V is the velocity of flow.

The area of the top surface of the passenger car, through which air is flowing,

$$A = L \times w$$

$$= 8 \times 3.2$$

$$= 25.6 \text{ m}^2$$

Now, substituting the value of ρ, A, V, and C_f in equation (2).

$$F_D = \frac{1}{2} \times 0.00273 \times 1.184 \times 25.6 \times (19.44)^2$$

$$= 15.63 \text{ N}$$

Therefore, the drag force acting on the top surface of the car is $\boxed{F_D = 15.63 \text{ N}}$.

Question: 15.055P

The weight of a thin flat plate 50 cm × 50 cm in size is balanced by a counterweight that has a mass of 2 kg, as shown in Fig. P15-55. Now a fan is turned on, and air at 1 atm and 25°C flows downward over both surfaces of the plate (front and back in the sketch) with a free-stream velocity of 10 m/s. Determine the mass of the counterweight that needs to be added in order to balance the plate in this case.

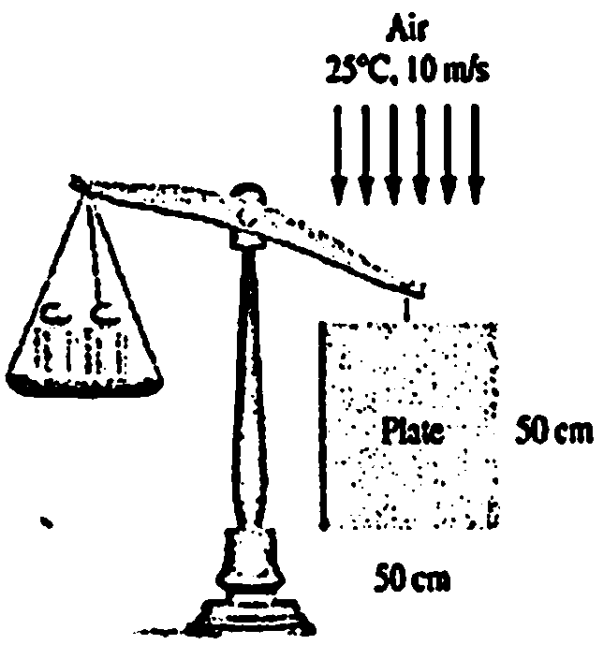

FIGURE P15–55

Step 1 of 6

Given data:

Free stream velocity of air is $V = 10\ m/s$.

Breadth of the thin flat plate is $b = 50\ cm$.

Length of the thin flat plate is $L = 50\ cm$.

Mass of the counter weight is $m = 2\ kgm$.

Atmospheric condition,

Pressure is $P = 1\ atm$.

Temperature is $T = 25°C$.

Step 2 of 6

From the table properties of air at 1 atm pressure.

The density of air at 1atm and 25°C is $\rho = 1.184\ kg/m^3$.

Kinematic viscosity of air at 1atm and 25°C is $\nu = 1.562 \times 10^{-5}\ m^2/s$.

Now, the Reynolds number for a length L is,

$$Re_L = \frac{VL}{\nu} \qquad \ldots\ldots (1)$$

Where, V is the velocity of air.

L is the length of the thin flat plate.

ν is the kinematic viscosity of fluid.

Here, length,

$L = 50\ cm$

$= 0.5\ m$

Step 3 of 6

Substituting the values of V, L and ν in equation (1).

$$Re_L = \frac{VL}{\nu}$$

$$= \frac{10 \times 0.5}{1.562 \times 10^{-5}}$$

$$= 3.2 \times 10^5$$

We know the critical Reynolds number is 5×10^5, since the obtained Reynolds number is less than the critical Reynolds number the flow is laminar.

Step 4 of 6

The friction coefficient can be found out using the formula given below.

$$C_f = \frac{1.328}{Re_L^{0.5}} \qquad \ldots\ldots (2)$$

Where Re_L is the Reynolds number.

Substituting the value of Re_L in equation (2)

$$C_f = \frac{1.328}{\left(3.2 \times 10^5\right)^{0.5}}$$

$$= 0.00235$$

Step 5 of 6

Here since the pressure drag is zero the drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_f \rho A V^2 \qquad \ldots\ldots (3)$$

Were, ρ is the density of air.

A is the area of the flat plate through which air is flowing.

V is the velocity of flow.

Here, area of the flat plate,

$A = L \times b$

We have, $b = 50\ cm = 0.5\ m$

$A = 0.5 \times 0.5$

$= 0.25\ m^2$

Here since air is flowing through both sides of the plate area should be taken as,

$A = 2 \times 0.25$

$= 0.5\ m^2$

Step 6 of 6

Now, substituting the value of ρ, A, V, and C_f in equation (3).

$$F_D = \frac{1}{2} \times 0.00235 \times 1.184 \times 0.5 \times (10)^2$$

$$= 0.06956\ N$$

Now, we have to find out the mass of the body whose weight is 0.06956 N using the formula given below.

$$m = \frac{F_D}{g}$$

Where F_D is the drag force and g is the gravitational acceleration.

Where, $g = 9.81\ m/s^2$

$$m = \frac{0.06956}{9.81}$$

$$= 0.0071\ kg$$

Therefore, a counterweight of mass $\boxed{m = 0.0071\ kg}$ is needed to balance the plate.

Question: 15.056P

In flow over cylinders, why does the drag coefficient suddenly drop when the boundary layer becomes turbulent? Isn't turbulence supposed to increase the drag coefficient instead of decreasing it?

Step 1 of 1

In flow over cylinder the drag coefficient suddenly drops when the flow in the boundary layer suddenly becomes turbulent. This is because when the flow becomes turbulent the separation point will be moved to the rear of the body, which will reduce the size of the wake and there by reduces the magnitude of pressure drag. But for stream lined bodies this turbulence will increase the drag coefficient because of friction drag.

Question: 15.057P

In flow over bluff bodies such as a cylinder, how does the pressure drag differ from the friction drag?

Step 1 of 1

Friction drag is caused due to the shear stress on the surface of the body. Pressure drag is caused due to the pressure difference between the back and front of the body. When fluid flow over a blunt body a wake is formed in the rear part of the body this wake is responsible for the pressure difference between the front and back of the body.

Question: 15.058P

Why is flow separation in flow over cylinders delayed when the boundary layer is turbulent?

Step 1 of 1

For turbulent flow the flow separation occurs at $\theta \cong 140°$. The delay in separation in turbulent flow is due to the rapid fluctuations of fluid in the transverse direction which will enable the turbulent boundary layer to travel a long distance before the separation occurs, due to this a narrow wake is formed as a result the pressure drag will be smaller.

Question: 15.059P

A 1.2-in-outer-diameter pipe is to span across a river at a 140-ft-wide section while being completely immersed in water. The average flow velocity of the water is 10 ft/s. and its temperature is 70°F. Determine the drag force exerted on the pipe by the river.

Step 1 of 3

Given data:

Outer diameter of the pipe $D = 1.2\text{in.}$

Width of the section $w = 140\text{ft}$

Average flow velocity of water $V = 10\text{ft/s}$

Temperature of water $T = 70°\text{F}$

Step 2 of 3

From properties of water table at $T = 70°\text{F}$ properties of water are

$\rho = 1.94\text{slugs/ft}^3$

$\mu = 2.04\times10^{-5}\text{lb}\cdot\text{s/ft}^2$

The Reynolds number can be found out using the formula given below.

$$\text{Re} = \frac{\rho VD}{\mu}$$

Where ρ is the density of water.

V is the velocity of flow.

D is the diameter of the pipe.

μ is the dynamic viscosity.

Substituting the values in the above formula, we get

$$\text{Re} = \frac{\rho VD}{\mu}$$

$$= \frac{1.94\times10\times\frac{1.2}{12}}{2.04\times10^{-5}}$$

$$= 9.509\times10^{4}$$

Using Reynolds number value the drag coefficient can be obtained from graph "average drag coefficient for cross flow over a smooth circular cylinder and sphere"

$C_D = 1.1$

Step 3 of 3

Now, the drag force acting on the pipe can be found out using the formula given below.

$$F_D = \frac{1}{2}C_D\rho AV^2.$$

Where C_D is the drag coefficient.

ρ is the density of water.

A is the frontal area of the pipe.

V is the velocity of flow.

The frontal area of the pipe is,

$$A = w\times D$$

$$= 140\times\frac{1.2}{12}$$

$$= 14\text{ft}^2$$

Substituting the values in the above formula, we get

$$F_D = \frac{1}{2}\times1.1\times1.94\times14\times(10)^2$$

$$= 1493.81\text{bf}$$

Therefore the drag force acting on the cylinder $\boxed{F_D = 1493.81\text{bf}}$

Question: 15.060P

A long 8-cm-diameter steam pipe passes through some area open to the wind. Determine the drag force acting on the pipe per unit of its length when the air is at 1 atm and 5°C and the wind is blowing across the pipe at a speed of 50 km/h.

Step 1 of 2

Obtain the properties of air at pressure of 1 atm and temperature of $5°C$ from the table A-9 "properties of the air at 1 atm" of the text book.

Density of air, $\rho = 1.269\ \text{kg/m}^3$.

Kinematic viscosity of air, $\nu = 1.382 \times 10^{-5}\ \text{m}^2/\text{s}$.

Convert the velocity of wind from km/h to m/s.

$$\begin{aligned} V &= 50\ \text{km/h} \\ &= 50\left(\frac{5}{18}\right)\text{m/s} \\ &= 13.88\ \text{m/s} \end{aligned}$$

Calculate the Reynolds number by using the formula.

$$\text{Re} = \frac{VD}{\nu}.$$

Here, V is the velocity of wind, D is the diameter of the pipe, and ν is the kinematic viscosity of air.

Substitute $13.88\ \text{m/s}$ for V, 0.08 m for D, and $1.382 \times 10^{-5}\ \text{m}^2/\text{s}$ for ν .

$$\begin{aligned} \text{Re} &= \frac{13.88(0.08)}{1.382 \times 10^{-5}} \\ &= 8.03 \times 10^4 \end{aligned}$$

Obtain the C_D value at Reynolds number of 8.03×10^4 from the plot of "average drag coefficient for cross flow over a smooth circular cylinder and a smooth sphere" as, $C_D = 1$

Step 2 of 2

Calculate the frontal area for flow past a cylinder.

$$A = L \times D$$

Here, A is the frontal area for flow past a cylinder, L is the length of pipe.

Calculate the drag force per unit length acting on the pipe by using the formula.

$$\begin{aligned} F_D &= \frac{\left(\frac{1}{2}C_D\rho AV^2\right)}{L} \\ &= \frac{\left(\frac{1}{2}C_D\rho(DL)V^2\right)}{L}. \\ &= \frac{1}{2}C_D\rho DV^2 \end{aligned}$$

Here, C_D is the drag coefficient, A is the frontal area, and V is the velocity of flow.

Substitute 1 for C_D , $1.269\ \text{kg/m}^3$ for ρ , 0.08 m for D, and $13.88\ \text{m/s}$ for V.

$$\begin{aligned} F_D &= \frac{1}{2} \times 1 \times 1.269 \times 0.08 \times (13.88)^2 \\ &= 9.779\ \text{N/m} \end{aligned}$$

Therefore, the drag force acting per unit length is, $\boxed{9.779\ \text{N/m}}$.

Question:

Consider 0.8-cm-diameter hail that is falling freely in atmospheric air at 1 atm and 5°C. Determine the terminal velocity of the hail. Take the density of hail to be 910 kg/m3.

Step 1 of 10

Given data:

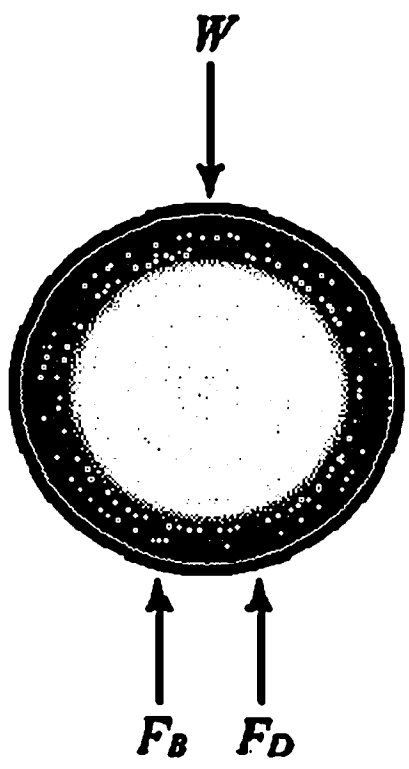
Diameter of the hail is $D = 0.8\ \text{cm}$.

Density of the hail is $\rho_{hail} = 910\ \text{kg/m}^3$.

Pressure of the air is $P = 1\ \text{atm}$.

Temperature of the air is $T = 5°\text{C}$.

Step 2 of 10



Weight of a freely falling body is equal to the sum of drag force and buoyancy force acting on the body. The drag force and buoyancy force will act opposite to the direction of motion of the body and weight of a body always acts downwards. Since the body is falling downwards the drag force and buoyancy force will act upwards.

When the body is dropped from a height it first accelerates under the influence of its weight, as the body falls the motion of the body is resisted by the drag force acting opposite to the direction of the motion of the body. This drag force goes on increasing as the velocity of the body increases, this continues until all the forces balance each other and the net force acting on the body is zero.

When the net force acting on the body becomes zero the velocity becomes constant and this constant velocity is the maximum velocity that the body can achieve and this velocity is called the terminal velocity.

Step 3 of 10

The free body diagram of the hail showing different forces acting on it.

Therefore, terminal velocity is achieved when, $F_D + F_B = W$.

Where, F_D is the drag force.

F_B is the buoyancy force.

W is the weight of the body.

Step 4 of 10

Now, we know that,

$F_D + F_B = W$

Now the drag force, $F_D = W - F_B$.

Here,

$$F_D = \frac{1}{2} C_D \rho_{air} A V^2$$

Where, C_D is the drag force.

ρ_{air} is the density of air.

A is the frontal area of the hail.

V is the velocity of the hail.

Step 5 of 10

Now, weight of the hail,,

$W = mg$ ..... (1)

We know that, $\text{Density} = \frac{\text{mass}}{\text{volume}}$

$$\rho = \frac{m}{V}$$

$$m = \rho V$$

Therefore, equation (1) becomes,

$W = \rho_{hail} V g$

Where, ρ_{hail} is the density of hail.

V is the volume of the hail.

g is the acceleration due to gravity.

Step 6 of 10

From the table properties of air at 1 atm pressure.

Density of air at 1atm and 5°C is $\rho_{air} = 1.269\ \text{kg/m}^3$.

Kinematic viscosity of air at 1atm and 5°C is $\nu = 1.382 \times 10^{-5}\ \text{m}^2/\text{s}$.

We have, $F_D = W - F_B$

Here,

$$F_D = \frac{1}{2} C_D \rho_{air} A V^2$$

$W = \rho_{hail} V g$

$F_B \cong 0$

Step 7 of 10

Substituting these expressions in the above equation.

$$\frac{1}{2} C_D \rho_{air} A V^2 = \rho_{hail} V g - 0$$

$$\frac{1}{2} C_D \rho_{air} A V^2 = \rho_{hail} V g$$ ..... (2)

Substituting these expressions in the above equation.

$$\frac{1}{2}C_D\rho_{air}AV^2 = \rho_{hail}Vg - 0$$

$$\frac{1}{2}C_D\rho_{air}AV^2 = \rho_{hail}Vg \qquad \ldots\ldots (2)$$

Here the frontal area is $A = \frac{\pi}{4}D^2$.

Volume of the hail is $V = \frac{\pi D^3}{6}$

Substituting these values in equation (2).

$$\frac{1}{2}C_D\rho_{air}\left(\frac{\pi}{4}D^2\right)V^2 = \rho_{hail}\left(\frac{\pi D^3}{6}\right)g$$

$$\frac{1}{4}C_D\rho_{air}V^2 = \frac{1}{3}\rho_{hail}gD$$

$$V^2 = \frac{4\rho_{hail}gD}{3C_D\rho_{air}}$$

$$V = \sqrt{\frac{4\rho_{hail}gD}{3C_D\rho_{air}}}$$

$$= \sqrt{\frac{4\times 910\times 9.81\times 0.008}{3\times C_D\times 1.269}}$$

$$= \frac{8.662}{\sqrt{C_D}}$$

$$V = \frac{8.662}{\sqrt{C_D}} \qquad \ldots\ldots (3)$$

Step 8 of 10

Then, calculating the Reynolds number.

$$\mathrm{Re} = \frac{VD}{\nu}.$$

Where, V is the velocity if the hail.
D is the diameter of the hail.
ν is the kinematic viscosity of air.

$$\mathrm{Re} = \frac{V\times 0.008}{1.382\times 10^{-5}}$$

$$= 578.87V$$

$$\mathrm{Re} = 578.87V \qquad \ldots\ldots (4)$$

Step 9 of 10

Now, assume a value for the velocity and substituting the assumed value in equation (4) and calculate the value of Reynolds number based on the obtained Reynolds number find out the value of C_D using the graph 'Average drag coefficient for cross flow over a smooth circular cylinder and a smooth sphere', and substitute the value of C_D in equation (3) and check whether the assumed value matches the calculated value, if not assume another value for V and repeat the process until the assumed value becomes equal to the calculated value and that velocity will be the terminal velocity of the hail.

Step 10 of 10

Here, we assume the velocity as $V = 13.7$ m/s or 49 km/h.

Substituting the value in equation (4)

$$\mathrm{Re} = 578.87\times 13.7$$

$$= 7930.5$$

Taking C_D value from the average drag coefficient for cross flow over a smooth circular cylinder and a smooth sphere.

The corresponding value of C_D is $C_D = 0.4$

Substituting the value of C_D in equation (3)

$$V = \frac{8.662}{\sqrt{0.4}}$$

$$= 13.7 \text{ m/s}$$

Since the assumed value of C_D matches the calculated value of C_D it is the terminal velocity.

Therefore, the terminal velocity of the hail is $\boxed{V = 13.7 \text{ m/s}}$.

Question: 15.062P

A 0.1-mm-diameter dust particle whose density is 2.1 g/cm3 is observed to be suspended in the air at 1 atm and 25°C at a fixed point. Estimate the updraft velocity of air motion at that location. Assume Stokes law to be applicable. Is this a valid assumption?

Step 1 of 4

Given data:

Diameter of the dust particle, $D = 0.1\,\text{mm} = 0.0001\,\text{m}$

Density of the dust particle, $\rho_d = 2.1\,\text{g/cm}^3 = 2.1\times10^3\ \text{kg/m}^3$

Pressure of air, $P = 1\,\text{atm}$

Temperature of the air, $T = 25°\text{C}$

Density of air at 1 atm pressure and 25°C, $\rho_a = 1.184\ \text{kg/m}^3$

Viscosity of air at 1 atm pressure and 25°C, $\mu = 1.849\times10^{-5}\ \text{kg/m-s}$

Step 2 of 4

The dust particle is suspended in the air so the updraft velocity of air should be equal to the terminal velocity of dust particle. Disregarding the initial transient period during which the dust particle accelerate to their terminal velocity, velocity at which the dust particle fall is equal to the terminal velocity of the particle. For a body terminal velocity is reached when the weight of the body becomes equal to the sum of drag force and buoyancy force acting on the body.

$$W = F_D + F_B \qquad \ldots\ldots (1)$$

Where W is the weight of the body $(W = \rho_d gV)$

F_B is the buoyancy force on body $(F_B = \rho_a gV)$

F_D is the drag force as per Stokes law $(F_D = 3\pi\mu VD)$

V is the velocity of the particle.

V is the Volume of the dust particle

Step 3 of 4

Volume of the dust particle (particle has a spherical shape),

$$V = \frac{\pi D^3}{6}$$

$$= \frac{\pi(0.0001)^3}{6}$$

$$= 5.23\times10^{-13}\ \text{m}^3$$

Weight of the dust particle,

$$W = \rho_d gV$$

$$= \left(2.1\times10^3\right)\times9.81\times\left(5.23\times10^{-13}\right)$$

$$= 1.077\times10^{-8}\ \text{N}$$

Step 4 of 4

Buoyancy force acting on dust particle,

$$F_B = \rho_a gV$$

$$= (1.184)\times9.81\times\left(5.23\times10^{-13}\right)$$

$$= 6.074\times10^{-12}\ \text{N}$$

The drag force on dust particle according to equation (1) is

$$F_D = W - F_B$$

$$3\pi\mu VD = \left(1.077\times10^{-8}\right) - \left(6.074\times10^{-12}\right)$$

$$V = \frac{1.0764\times10^{-8}}{3\pi\mu D}$$

$$= \frac{1.0764\times10^{-8}}{3\pi\left(1.849\times10^{-5}\right)0.0001}$$

$$= 0.6177\ \text{m/s}$$

Therefore, the velocity of the dust particle is, $\boxed{V = 0.6177\ \text{m/s}}$

Question: 15.063P

Dust particles of diameter 0.06 mm and density 1.6 g/cm3 are unsettled during high winds and rise to a height of 350 m by the time things calm down. Estimate how long it takes for the dust particles to fall back to the ground in still air at 1 atm and 15°C, and their velocity. Disregard the initial transient period during which the dust particles accelerate to their terminal velocity, and assume Stokes law to be applicable.

Step 1 of 5

Given data:

Diameter of the dust particle, $D = 0.06\ \text{mm} = 6\times10^{-5}\ \text{m}$

Density of the dust particle, $\rho_d = 1.6\ \text{g/cm}^3 = 1.6\times10^{3}\ \text{kg/m}^3$

Height through which the dust particle rises, $h = 350\ \text{m}$

Pressure of air, $P = 1\ \text{atm}$

Temperature of the air, $T = 15°\text{C}$

Density of air at 1 atm pressure and 15°C, $\rho_a = 1.225\ \text{kg/m}^3$

Viscosity of air at 1 atm pressure and 15°C, $\mu = 1.802\times10^{-5}\ \text{kg/m}\cdot\text{s}$

Step 2 of 5

Since we can disregard the initial transient period during which the dust particle accelerate to their terminal velocity, the velocity at which the dust particle fall will be equal to the terminal velocity of the particle. For a body terminal velocity is reached when the weight of the body becomes equal to the sum of drag force and buoyancy force acting on the body.

$$W = F_D + F_B \qquad \ldots\ldots (1)$$

Where W is the weight of the body $(W = \rho_d gV)$

F_B is the buoyancy force on body $(F_B = \rho_a gV)$

F_D is the drag force as per Stokes law $(F_D = 3\pi\mu VD)$

V is the velocity of the particle.

V is the Volume of the dust particle

Step 3 of 5

Volume of the dust particle (particle has a spherical shape),

$$V = \frac{\pi D^3}{6}$$

$$= \frac{\pi\left(6\times10^{-5}\right)^3}{6}$$

$$= 1.131\times10^{-13}\ \text{m}^3$$

Weight of the dust particle,

$$W = \rho_d gV$$

$$= \left(1.6\times10^{3}\right)\times9.81\times\left(1.131\times10^{-13}\right)$$

$$= 1.775\times10^{-9}\ \text{N}$$

Step 4 of 5

Buoyancy force acting on dust particle,

$$F_B = \rho_a gV$$

$$= (1.225)\times9.81\times\left(1.131\times10^{-13}\right)$$

$$= 1.36\times10^{-12}\ \text{N}$$

The drag force on dust particle according to equation (1) is

$$F_D = W - F_B$$

$$3\pi\mu VD = \left(1.775\times10^{-9}\right) - \left(1.36\times10^{-12}\right)$$

$$V = \frac{1.77\times10^{-9}}{3\pi\mu D}$$

$$= \frac{1.77\times10^{-9}}{3\pi\left(1.802\times10^{-5}\right)\left(6\times10^{-5}\right)}$$

$$= 0.1737\ \text{m/s}$$

Step 5 of 5

The time taken by the dust particle to fall back to the ground,

$$t = \frac{h}{V}$$

$$= \frac{350}{0.1737}$$

$$= 2014.97\ s$$

$$= 33.583\ \text{min}$$

Therefore time taken by the dust particle to fall back to the ground is $\boxed{t = 33.583\ \text{min}}$

Question: 15.064P pg 1

A 2-m-long, 0.2-m-diameter cylindrical pine log (density = 513 kg/m3) is suspended by a crane in the horizontal position. The log is subjected to normal winds of 40 km/h at 5°C and 88 kPa. Disregarding the weight of the cable and its drag, determine the angle θ the cable will make with the horizontal and the tension on the cable.

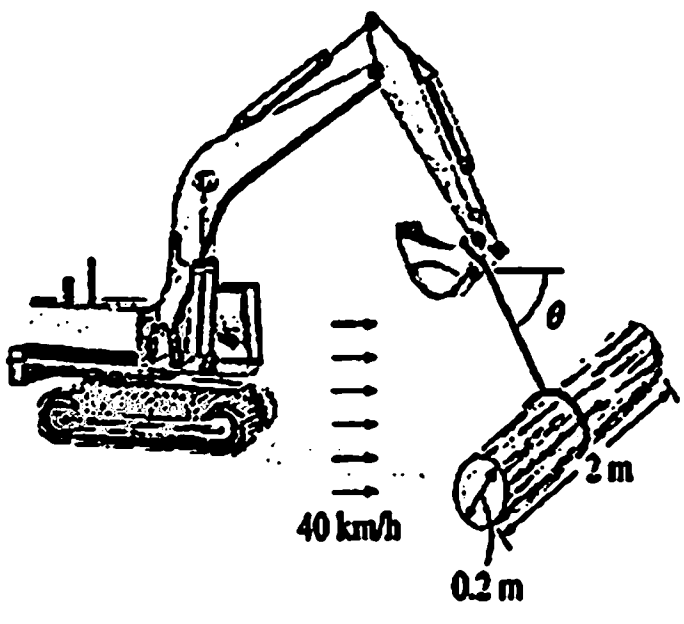


FIGURE P15–64

Step 1 of 11

Calculate the volume of the log by using the equation,

$$V_l = \frac{\pi}{4} D^2 L$$

Here, V_l is the volume of the log, D is the diameter of the cylinder and L is the length of the cylinder.

Substitute $0.2\,\text{m}$ for D and $2\,\text{m}$ for L.

$$V_l = \frac{\pi}{4} \times 0.2^2 \times 2$$
$$= 0.0628\,\text{m}^3$$

Step 2 of 11

Calculate the weight of the pine log using the equation,

$$W = \rho_l g V_l$$

Here, W is the weight of the log, ρ_l is the density of the log, g is the acceleration due to gravity and V_l is the volume of the log.

Substitute $513\,\text{kg/m}^3$ for ρ_l, $9.81\,\text{m/s}^2$ for g and $0.0628\,\text{m}^3$ for V_l.

$$W = 513 \times 9.81 \times 0.0628$$
$$= 316\,\text{N}$$

Step 3 of 11

Calculate the density of air using the relation,

$$\rho = \frac{P}{RT}$$

Here, ρ is the density of air, P is the pressure, R is the universal gas constant and T is the absolute temperature.

Substitute $88\,\text{kPa}$ for P, $0.287\,\text{kJ/kg}\cdot\text{K}$ for R and $278\,\text{K}$ for T.

$$\rho = \frac{88}{0.287 \times 278}$$
$$= 1.103\,\text{kg/m}^3$$

Step 4 of 11

Obtain the dynamic viscosity of air at $5°\text{C}$ from the properties of air.

$$\mu = 1.754 \times 10^{-5}\ \text{kg/m}\cdot\text{s}$$

Here, μ is the dynamic viscosity of air.

Calculate the kinematic viscosity of air by using the equation,

$$\nu = \frac{\mu}{\rho}$$

Here, ν is the kinematic viscosity of air.

Substitute $1.754 \times 10^{-5}\ \text{kg/m}\cdot\text{s}$ for μ, $1.103\,\text{kg/m}^3$ for ρ.

$$\nu = \frac{1.754 \times 10^{-5}}{1.103}$$
$$= 1.59 \times 10^{-5}\,\text{m}^2/\text{s}$$

Step 5 of 11

Convert the wind speed from km/h to m/s by using the following conversion factor,

$$1\,\text{km/hr} = \frac{5}{18}\,\text{m/s}$$

$$V = 40\,\text{km/h}$$
$$= 40 \times \frac{5}{18}$$
$$= 11.11\,\text{m/s}$$

Here, V is the wind speed.

Calculate the Reynold's number for the wind flow over cylindrical pine log by using the equation,

$$\text{Re} = \frac{VD}{\nu}$$

Here, Re is the Reynold's number for the wind flow, D is the diameter of the cylindrical pine log.

$$\mathrm{Re}=\frac{VD}{\nu}$$

Here, Re is the Reynold's number for the wind flow, D is the diameter of the cylindrical pine log.

Substitute $11.11\,\mathrm{m/s}$ for V , $0.2\,\mathrm{m}$ for D and $1.59\times10^{-5}\,\mathrm{m^2/s}$ for ν .

$$\begin{aligned}\mathrm{Re}&=\frac{11.11\times0.2}{1.59\times10^{-5}}\\&=1.397\times10^{5}\end{aligned}$$

Step 6 of 11

Obtain the drag coefficient corresponding to the above Reynold's number by using average drag coefficient for cross-flow over a smooth circular cylinder and a smooth sphere charts.

$$C_D=1.2$$

Here, C_D is the drag coefficient corresponding to the above Reynold's number.

Calculate the frontal area for the flow past a cylinder by using the relation,

$$A=LD$$

Here, A is the frontal area for the flow past a cylinder, L is the length of the cylinder and D is the diameter of the cylinder.

Substitute $2\,\mathrm{m}$ for L and $0.2\,\mathrm{m}$ for D .

$$\begin{aligned}A&=2\times0.2\\&=0.4\,\mathrm{m^2}\end{aligned}$$

Step 7 of 11

Calculate the drag force on the log by using the equation,

$$F_D=C_DA\frac{\rho V^2}{2}$$

Here, F_D is the drag force on the log.

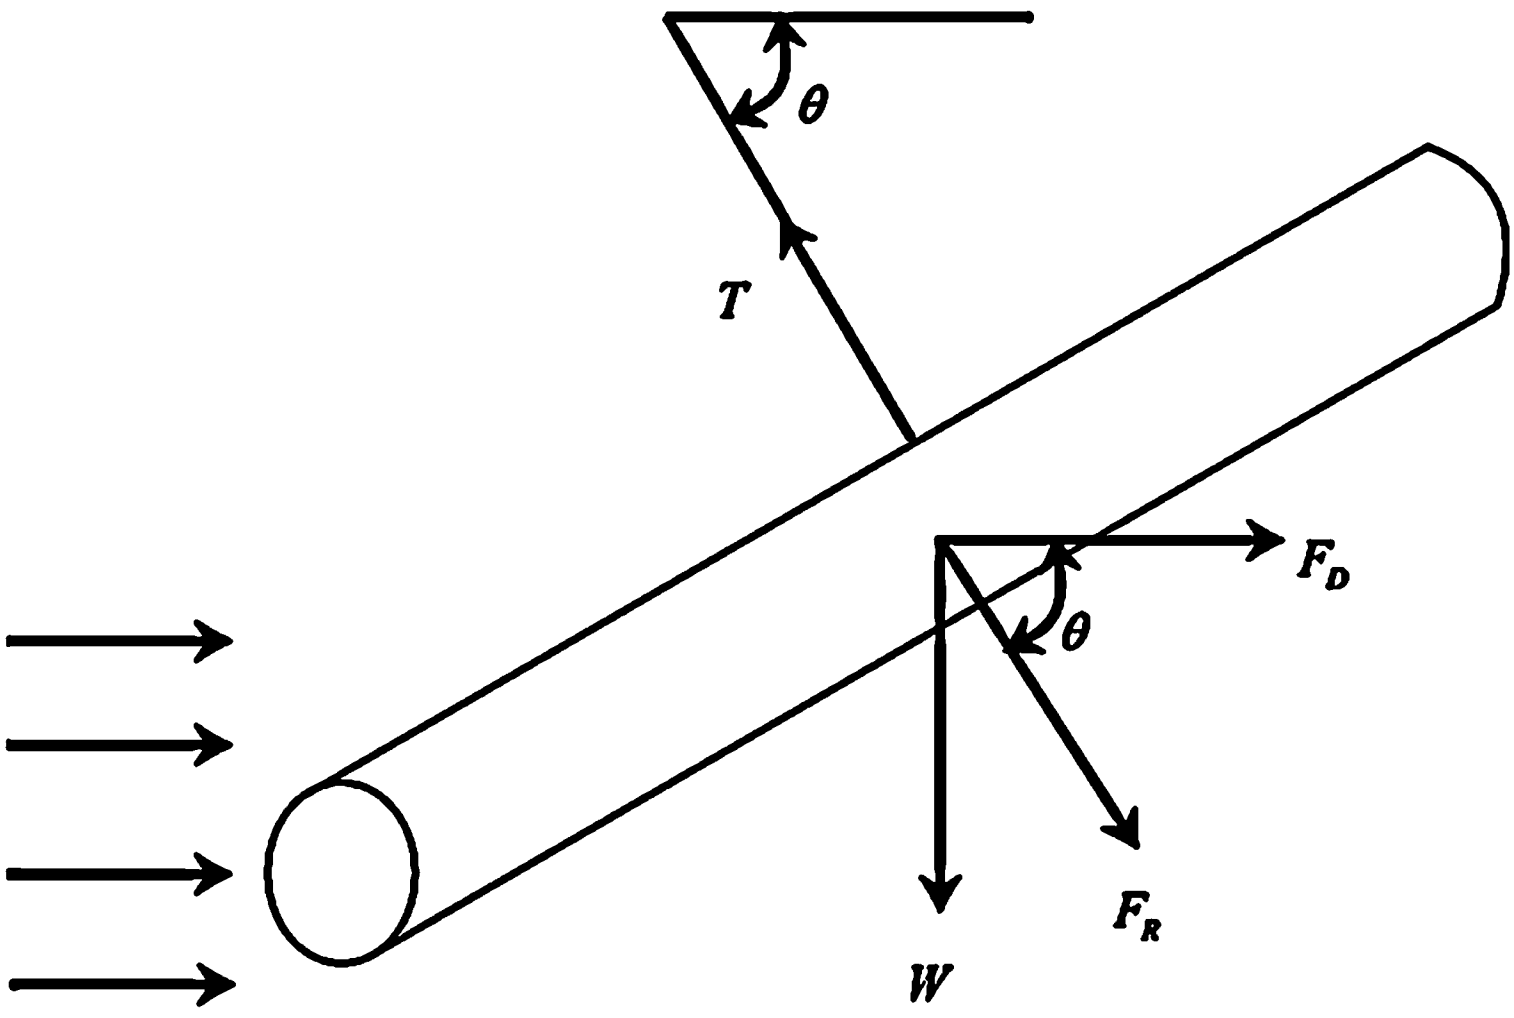
Substitute 1.2 for C_D , $0.4\,\mathrm{m^2}$ for A , $1.103\,\mathrm{kg/m^3}$ for ρ and $11.11\,\mathrm{m/s}$ for V .

$$\begin{aligned}F_D&=1.2\times0.4\times\frac{1.103\times11.11^2}{2}\\&=32.67\,\mathrm{N}\end{aligned}$$

Step 8 of 11

Calculate the resultant force acting on the log by using the equation,

$$F_R=\sqrt{F_D^2+W^2}$$



Here, F_R is the resultant force acting on the log.

Substitute $32.67\,\mathrm{N}$ for F_D and $316\,\mathrm{N}$ for W .

$$\begin{aligned}F_R&=\sqrt{F_D^2+W^2}\\&=\sqrt{32.67^2+316^2}\\&=317.68\,\mathrm{N}\end{aligned}$$

Step 9 of 11

Draw the free body diagram of the pine log.

Step 10 of 11

From the free body diagram of the pine log, calculate the angle θ the cable will make with the horizontal by using the equation,

$$\theta=\tan^{-1}\left(\frac{W}{F_D}\right)$$

Here, θ is the angle the cable will make with the horizontal.

Substitute $316\,\mathrm{N}$ for W and $32.67\,\mathrm{N}$ for F_D

$$\begin{aligned}\theta&=\tan^{-1}\left(\frac{316}{32.67}\right)\\&=84^\circ\end{aligned}$$

Therefore, the angle the cable will make with the horizontal is $\boxed{\theta=84^\circ}$.

$= 84°$

Therefore, the angle the cable will make with the horizontal is $\boxed{\theta = 84°}$.

Step 11 of 11

From the free body diagram of the pine log, use force balance to calculate the tension in the cable.

$$T = F_R$$

Here, T is the tension in the cable.

Substitute $317.68\,\text{N}$ for F_R.

$$T = 317.68\,\text{N}$$

Therefore, the tension in the cable is $\boxed{T = 317.68\,\text{N}}$.

Question: 15.065P

A person extends his uncovered arms into the windy air outside at 1 atm and 60°F and 20 mi/h in order to feel nature closely. Treating the arm as a 2-ft-long and 3-in- diameter cylinder, determine the combined drag force on both arms.

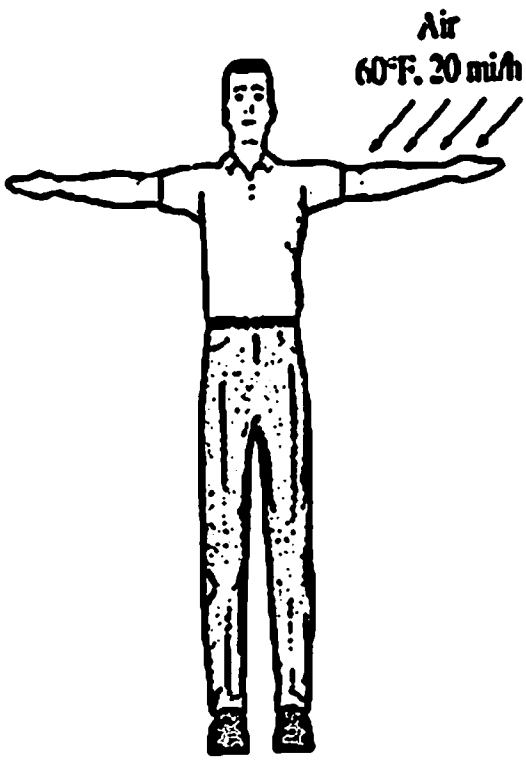


FIGURE P15–65E

Step 1 of 4

Given data:

Pressure of outside air, $P = 1\text{atm}$

Temperature of outside air, $T = 60°\text{F}$

Velocity of air, $V = 20\,\text{mi/h}$

Length of arm, $L = 2\text{ft}$

Diameter of cylinder, $D = 3\text{in.}$

Step 2 of 4

From the table of properties ideal gas of air

At $T = 60°\text{F}$

Density of air is $\rho = 0.07633\text{lbm/ft}^3$

Kinematic viscosity is

$$\nu = 0.5718\text{ft}^2/\text{h}$$

$$= \left(0.5718\text{ft}^2/\text{h}\right)\left(1\text{h}/3600\,\text{s}\right)$$

$$= 1.588\times10^{-4}\,\text{ft}^2/\text{s}$$

Reynolds number is given by

$$\text{Re} = \frac{VD}{\nu}$$

FIGURE P15–65E

Step 1 of 4

Given data:

Pressure of outside air, $P = 1\text{atm}$

Temperature of outside air, $T = 60°\text{F}$

Velocity of air, $V = 20\,\text{mi/h}$

Length of arm, $L = 2\text{ft}$

Diameter of cylinder, $D = 3\text{in.}$

Step 2 of 4

From the table of properties ideal gas of air

At $T = 60°\text{F}$

Density of air is $\rho = 0.07633\text{lbm/ft}^3$

Kinematic viscosity is

$$\nu = 0.5718\text{ft}^2/\text{h}$$

$$= \left(0.5718\text{ft}^2/\text{h}\right)\left(1\text{h}/3600\,\text{s}\right)$$

$$= 1.588\times10^{-4}\,\text{ft}^2/\text{s}$$

Reynolds number is given by

$$\text{Re} = \frac{VD}{\nu}$$

$$= \left[1\times1\times\frac{0.07633\left[20\,\text{mi/h}\times\frac{1.46\,\text{ft/s}}{1\,\text{mi/h}}\right]}{2}\right]\left(\frac{1\text{lbf}}{32.2\text{lbm}\cdot\text{ft/s}^2}\right)$$

$$= 1.020\text{lbf}$$

Therefore, drag force acting on both the arm is $\boxed{F = 1.020\text{lbf}}$.

$$= \left[1\times1\times\frac{0.07633\left[20\,\text{mi/h}\times\frac{1.46\,\text{ft/s}}{1\,\text{mi/h}}\right]}{2}\right]\left(\frac{1\text{lbf}}{32.2\text{lbm}\cdot\text{ft/s}^2}\right)$$

$$= 1.020\text{lbf}$$

Therefore, drag force acting on both the arm is $\boxed{F = 1.020\text{lbf}}$.

Question: 15.066P

A 6-mm-diameter electrical transmission line is exposed to windy air. Determine the drag force exerted on a 160-m-long section of the wire during a windy day when the air is at 1 atm and 15°C and the wind is blowing across the transmission line at 65 km/h.

Step 1 of 5

Given data:

Diameter of the electrical transmission line $D = 6\text{mm}$

Length of the wire $L = 160\text{m}$

Velocity of wind $V = 65\text{km/h}$

Pressure of the air $P = 1\text{atm}$

Temperature of the air $T = 15°\text{C}$

Step 2 of 5

The drag force can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_D \rho A V^2 \qquad \ldots\ldots (1)$$

Where, C_D is the drag force

ρ is the density of air

A is the frontal area of the transmission line

V is the velocity of the wind

Step 3 of 5

From the properties of air table at 1 atm pressure

The density of air at 1atm and 15°C $\rho = 1.225\,\text{kg/m}^3$

Kinematic viscosity of air at 1atm and 15°C $\nu = 1.470 \times 10^{-5}\,\text{m}^2/\text{s}$

Then, calculating the Reynolds number using the formula given below

$$\text{Re} = \frac{VD}{\nu} \qquad \ldots\ldots (2)$$

Where, V is the velocity of the hail.

D is the diameter of the hail.

ν is the kinematic viscosity of air.

Step 4 of 5

Here, diameter of the wire,

$D = 6\text{ mm}$

$= 0.006\text{ m}$

Now, velocity of wind,

$$V = \frac{65}{2}\,\text{km/h}$$

Where, C_D is the drag force

ρ is the density of air

A is the frontal area of the transmission line

V is the velocity of the wind

Step 3 of 5

From the properties of air table at 1 atm pressure

The density of air at 1atm and 15°C $\rho = 1.225\,\text{kg/m}^3$

Kinematic viscosity of air at 1atm and 15°C $\nu = 1.470 \times 10^{-5}\,\text{m}^2/\text{s}$

Then, calculating the Reynolds number using the formula given below

$$\text{Re} = \frac{VD}{\nu} \qquad \ldots\ldots (2)$$

Where, V is the velocity of the hail.

D is the diameter of the hail.

ν is the kinematic viscosity of air.

Step 4 of 5

Here, diameter of the wire,

$D = 6\text{ mm}$

$= 0.006\text{ m}$

Now, velocity of wind,

Question: 15.067P

Air is flowing past a nonsymmetrical airfoil at zero angle of attack. Is the (*a*) lift and (*b*) drag acting on the airfoil zero or nonzero?

Step 1 of 2

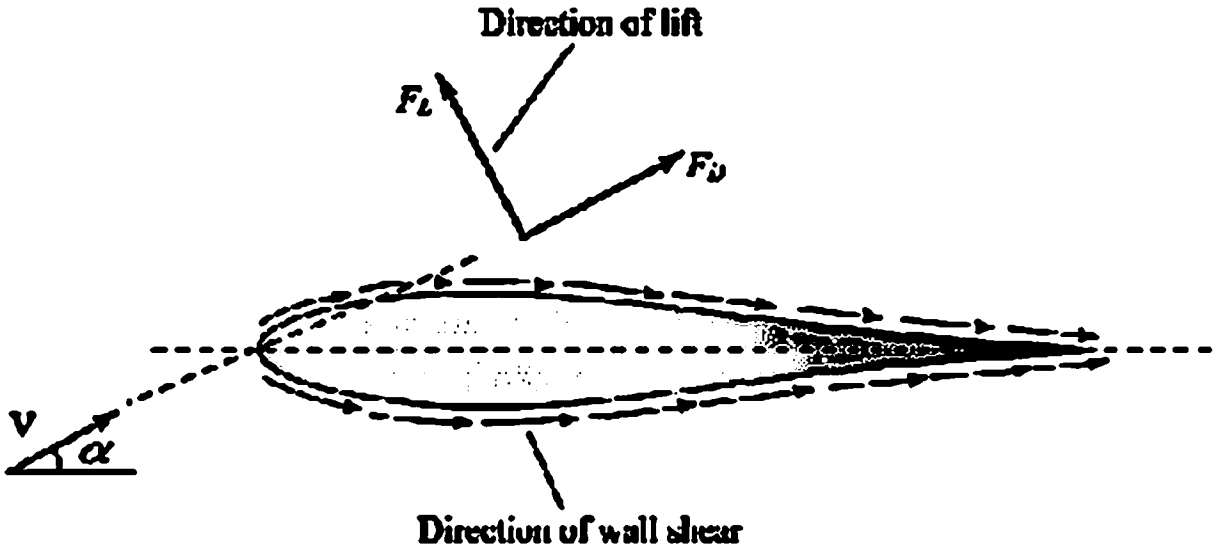
a) When air is flowing past a symmetrical airfoil at zero angle of attack ($\alpha = 0$) the lift will be zero. Because of symmetry, and the stagnation points are at the leading and trailing edges.

Step 2 of 2

b) When air is flowing past a symmetrical airfoil at zero angle of attack ($\alpha = 0$) the drag will be nonzero.

Question: 15.068P

Why is the contribution of viscous effects to lift usually negligible for airfoils?



Step 1 of 2

Contribution of viscous effects to lift is negligible because the airplane bodies are streamlined and therefore the direction of wall shear will be parallel to the surface of the body and almost normal to the direction of lift.

The lift slope is depends on the viscous effect, while the presence of viscous effects tend to decrease the lift slope therefore it seems reasonable to ignore the very thin boundary layer on the airfoil and calculate the pressure distribution around the airfoil from the relatively simple potential flow theory for which net viscous forces are zero for flow past an airfoil.

Step 2 of 2

The figure below represents an air foil, the direction of different forces are shown.

Question: 15.069P

Air is flowing past a symmetrical airfoil at an angle of attack of 5°. Is the (*a*) lift and (*b*) drag acting on the airfoil zero or nonzero?

Step 1 of 2

a) If air is flowing past a symmetrical airfoil at an angle of attack of 5° ($\alpha = 5°$) lift acting on the airfoil will be nonzero. Therefore, planes with symmetrical wing sections must fly with their wings at higher angles of attack in order to produce the same lift.

Step 2 of 2

b) If air is flowing past a symmetrical airfoil at an angle of attack of 5° ($\alpha = 5°$) drag acting on the airfoil will be nonzero.

Question: 15.070P

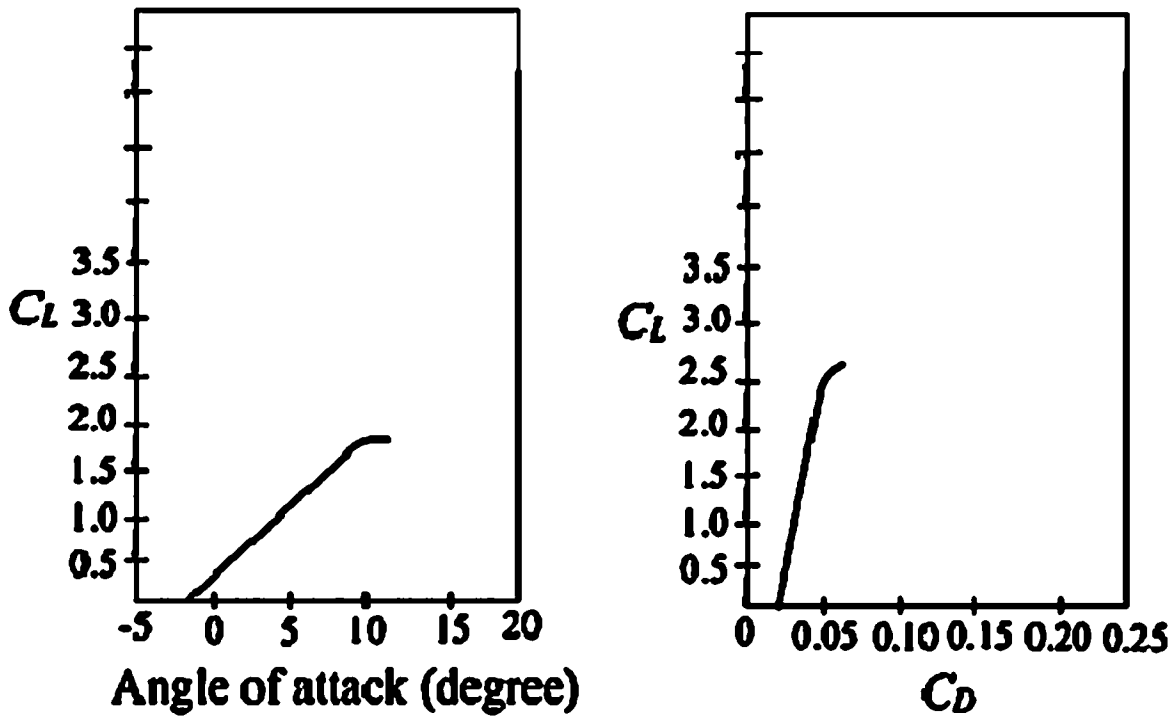
What is stall? What causes an airfoil to stall? Why are commercial aircraft not allowed to fly at conditions near stall?

Step 1 of 1

The lift coefficient (C_l) of an aircraft will increase with increase in angle of attack, but this increase is only up to a particular angle of attack, which is approximately 16° ($\alpha = 16°$) beyond that the lift coefficient will decrease drastically. This decrease in lift with increase in angle of attack beyond 16° is called stall. The stall occurs when airflow separates from the upper wing surface this happens when the plane under too higher angle of attack.

Decrease in lift of an aircraft is a serious problem with the safety of the aircraft if an aircraft losses lift it will fall down, so commercial aircrafts are not allowed to fly at a condition near stall. Stall also increases drag. It is caused due to flow separation, and due to flow separation a wide wake is formed on the top surface of the airfoil and causes stall.

Question: 15.071P



Both the lift and the drag of an airfoil increase with an increase in the angle of attack. In general, which increases at a higher rate, the lift or the drag?

Step 1 of 2

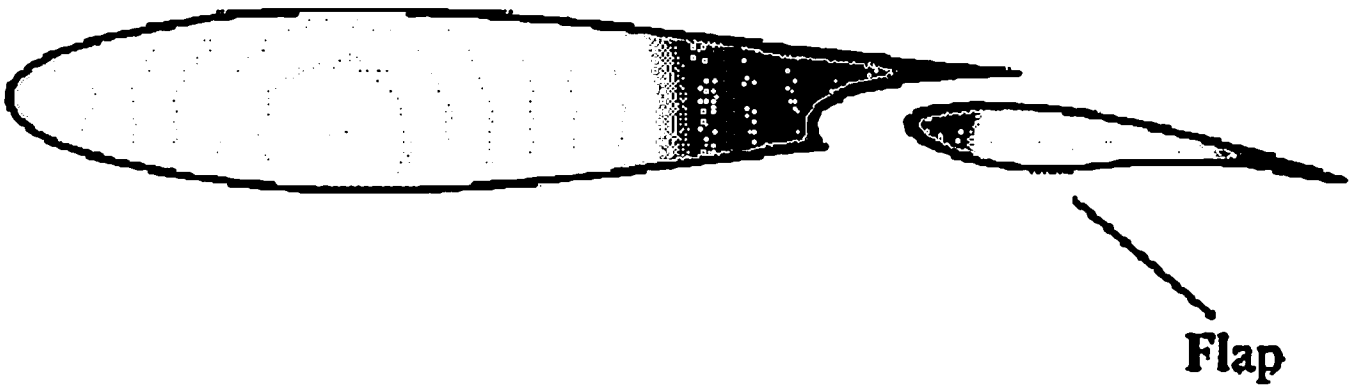
Both lift and drag will increase with an increase in angle of attack but in general lift will increase at a higher rate than drag. The lift coefficient (C_L) of an aircraft will increase with increase in angle of attack, but this increase is only up to a particular angle of attack, which is approximately 16° ($\alpha = 16°$) beyond that the lift coefficient will decrease drastically.

Step 2 of 2

The graph below represents the variations of C_L and C_D at different angle of attacks (α).

Question: 15.072P

Why are flaps used at the leading and trailing edges of the wings of large aircraft, during takeoff and landing? Can an aircraft take off or land without them?



Step 1 of 2

Flaps are used to alter the shape of the wing so that the aircraft could land and takeoff safely at low speed. These moving flaps will increase the lift and drag of the aircraft, an increase in drag will decrease the speed of the aircraft. A movable leading edge and trailing edge flap is commonly used in modern aircrafts. During cruising altitude these flaps will be retracted and come into normal shape to minimize the drag and increase the fuel efficiency.

An aircraft can land and takeoff without the flaps but only at high speed, which is not desirable.

Step 2 of 2

The figure shown below represents the wing of an aircraft with a flap attached to it.

Question: 15.073P

How do flaps affect the lift and the drag of wings?

Step 1 of 1

Flaps are used to alter the shape of the wing so that the aircraft could land and takeoff safely at low speed. These moving flaps will increase both lift and drag of the aircraft, an increase in drag will decrease the speed of the aircraft.

Question: 15.074P

What is the effect of wing tip vortices (the air circulation from the lower part of the wings to the upper part) on the drag and the lift?

Step 1 of 1

Wing tip vortices will increase the drag and decrease the lift. Since the air circulate from the lower part of the wing to the upper part of the wing it will create downdraft, this downdraft is very dangerous for small aircrafts.

Question: 15.075P

What is induced drag on wings? Can induced drag be minimized by using long and narrow wings or short and wide wings?

Step 1 of 1

When the tip vortices of the wing come into contact with the free stream some forces will be developed on the wing tip, these forces will act in all directions including the flow direction. The component of the force in the flow direction will add to the drag and this drag is called induced drag. Induced drag can be minimized by using long and narrow wings.

Question: 15.076P

Explain why endplates or winglets are added to some airplane wings.

Step 1 of 1

Endplates and winglets are attached to the tips of the wings perpendicular to the top surface to reduce the strength of the tip vortices and the induced drag. The endplates will block the leakage around the wing tips and this will result in the reduction in strength of the tip vortices and the induced drag.

Question: 15.077P

Consider an aircraft that takes off at 190 km/h when it is fully loaded. If the weight of the aircraft is increased by 20 percent as a result of overloading, determine the speed at which the overloaded aircraft will take off.

Step 1 of 6

Given data:

Mass of the aircraft when fully loaded is m_1.

Take off speed is $V_1 = 190$ km/h.

Let V_2 be the takeoff speed of the airplane when the weight of the airplane is increased.

Step 2 of 6

An aircraft can takeoff when lift is equal to the total weight of the airplane.

$F_L = W$.

Lift force,

$$F_L = \frac{1}{2} C_L \rho A V^2.$$

Where, C_L is the lift coefficient.

ρ is the density of air.

A is the wing area.

V is the take off velocity.

Therefore, the equation becomes

$$W = \frac{1}{2} C_L \rho A V^2$$

$$V^2 = \frac{2W}{C_L \rho A}$$

$$V = \sqrt{\frac{2W}{C_L \rho A}} \qquad \ldots\ldots (1)$$

Step 3 of 6

In equation (1) A C_L and ρ are constant. Therefore the takeoff velocity is directly proportional to the weight of the aircraft.

Now, the takeoff velocity of aircraft when the aircraft is fully loaded,

$$V_1 = \sqrt{\frac{2W_1}{C_L \rho A}} \qquad \ldots\ldots (2)$$

Where, W_1 is the weight of the aircraft when fully loaded.

Now, the takeoff velocity of aircraft when the weight of the aircraft is increased by 20%.

$$V_2 = \sqrt{\frac{2W_2}{C_L \rho A}} \qquad \ldots\ldots (3)$$

Where, W_2 is the weight of the aircraft when the weight of the aircraft is increased by 20%.

Step 4 of 6

Divide equation (3) by (2).

$$\frac{V_2}{V_1} = \frac{\sqrt{\frac{2W_2}{C_L \rho A}}}{\sqrt{\frac{2W_1}{C_L \rho A}}}$$

$$= \frac{\sqrt{W_2}}{\sqrt{W_1}}$$

But we know that weight is $W = mg$.

Where,

m is the mass.

g is the acceleration due to gravity.

Step 5 of 6

Therefore,

$$\frac{V_2}{V_1} = \frac{\sqrt{m_2 g}}{\sqrt{m_1 g}}$$

$$= \frac{\sqrt{m_2}}{\sqrt{m_1}}$$

$$V_2 = V_1 \frac{\sqrt{m_2}}{\sqrt{m_1}} \qquad \ldots\ldots (4)$$

Where, m_2 is the mass of airplane when the weight of the airplane is increased by 20%.

$$m_2 = m_1 + \left(\frac{20}{100}\right) m_1$$

$$= \left(\frac{120}{100}\right) m_1$$

$$= 1.2 m_1$$

Step 6 of 6

Substituting the values of m_1 and m_2 in equation (4)

$$V_2 = V_1 \left(\frac{\sqrt{1.2 m_1}}{\sqrt{m_1}}\right)$$

We know that $V_1 = 190$ km/h.

$$V_2 = 190 \left(\frac{\sqrt{1.2 m_1}}{\sqrt{m_1}}\right)$$

$$= 190 \left(\sqrt{1.2}\right)$$

$$= 208.1 \text{ km/h}$$

Therefore the takeoff speed of the airplane when the weight of the airplane is increased by 20% $\boxed{V_2 = 208 \text{ km/h}}$.

Question: 15.078P pg 1

Consider an airplane whose takeoff speed is 220 km/h and that takes 15 s to take off at sea level. For an airport at an elevation of 1600 m (such as Denver), determine (*a*) the take off speed, (*b*) the takeoff time, and (*c*) the additional runway length required for this airplane. Assume constant acceleration for both cases.

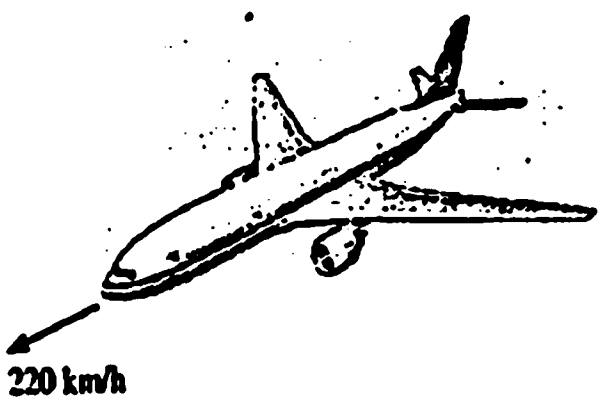


FIGURE P15–78

Step 1 of 10

Given data:

Take off speed at sea level, $V_1 = 220$ km/h

Time taken to takeoff at sea level, $t_1 = 15$ sec

Step 2 of 10

a) An aircraft can takeoff when lift is equal to the total weight of the airplane.

Means that, $F_L = W$

Lift force, $F_L = \frac{1}{2} C_L \rho A V^2$

Where, C_L is the lift coefficient

ρ is the density of air.

A is the wing area.

V is the take off velocity.

Therefore,

$$W = \frac{1}{2} C_L \rho A V^2$$

$$V^2 = \frac{2W}{C_L \rho A}$$

$$V = \sqrt{\frac{2W}{C_L \rho A}} \qquad \ldots\ldots (1)$$

Step 3 of 10

In equation (1) W, C_L and A are constants.

If the altitude is changes the density of air will also change.

Therefore, takeoff velocity is inversely proportional to the density of air.

Density of air at sea level, $\rho_1 = 1.225$ kg/m^3

Density of air at an altitude of 1600 m, $\rho_2 = 1.048$ kg/m^3.

Now, takeoff velocity of airplane at sea level,

$$V_1 = \sqrt{\frac{2W}{C_L \rho_1 A}} \qquad \ldots\ldots (2)$$

Takeoff velocity of airplane at an altitude of 1600 m,

$$V_2 = \sqrt{\frac{2W}{C_L \rho_2 A}} \qquad \ldots\ldots (3)$$

Step 4 of 10

Divide equation (3) by (2)

$$\frac{V_2}{V_1} = \frac{\sqrt{\frac{2W}{C_L \rho_2 A}}}{\sqrt{\frac{2W}{C_L \rho_1 A}}}$$

$$= \frac{\sqrt{\rho_1}}{\sqrt{\rho_2}}$$

$$V_2 = V_1 \sqrt{\frac{\rho_1}{\rho_2}}$$

We know that,

$V_1 = 220$ km/h.

$$V_2 = 220 \sqrt{\frac{1.225}{1.048}}$$

$$= 237.85$$

$$= 238 \text{ km/h}$$

Therefore takeoff velocity of aircraft at an altitude of 1600 m, $\boxed{V_2 = 238 \text{ km/h}}$

Step 5 of 10

b)

Acceleration of the aircraft at the sea level,

$$a_1 = \frac{\Delta V_1}{\Delta t_1} \qquad \ldots\ldots (4)$$

Where, a_1 is the acceleration at sea level.

ΔV_1 is the change in velocity during takeoff at sea level.

Δt_1 time for takeoff at sea level.

$$a_1 = \frac{220 - 0}{15}$$

$$= 14.67$$

$$= 14.67\left(\frac{5}{18}\right) \text{m/s}^2$$

$$= 4.075 \text{ m/s}^2$$

Step 6 of 10

Acceleration of the aircraft at an altitude of 1600 m

$$a_2 = \frac{\Delta V_2}{\Delta t_2} \qquad \ldots\ldots (5)$$

Where, a_1 is the acceleration at an altitude of 1600 m.

Acceleration of the aircraft at an altitude of 1600 m

$$a_2 = \frac{\Delta V_2}{\Delta t_2} \qquad \ldots\ldots (5)$$

Where, a_1 is the acceleration at an altitude of 1600 m.

ΔV_1 Is the change in velocity during takeoff at an altitude of 1600 m.

Δt_1 Time for takeoff at an altitude of 1600 m.

$$a_2 = \frac{238 - 0}{\Delta t_2}$$

Since the acceleration is constant in both the cases, $a_1 = a_2$.

Step 7 of 10

Therefore,

$$4.075 = \frac{238\left(\frac{5}{18}\right) - 0}{\Delta t_2}$$

$$\Delta t_2 = \frac{66.11}{4.075}$$

$$= 16.2 \text{ sec}$$

Therefore the time required to takeoff at an altitude of 1600 m, $\boxed{\Delta t_2 = 16.2 \text{ sec}}$

Step 8 of 10

c) Now we have to find out the additional runway length required for the airplane.
Runway length required for the airplane to takeoff at sea level,

$$S_1 = V_0 t_1 + \frac{1}{2} a_1 t_1^2 \qquad \ldots\ldots (6)$$

Where, S_1 is the length of the runway at sea level

V_0 is the initial velocity of the airplane at sea level.

t_1 is the time required to takeoff at sea level.

a_1 is the acceleration of the aircraft at sea level.

Here initial velocity of the airplane is zero, $V_0 = 0$.

$t_1 = 15$ sec

$a_1 = 4.075 \text{ m/s}^2$

Substitute all these values in equation (6)

$$S_1 = 0 + \frac{1}{2} \times 4.075 \times (15)^2$$

$$= 458.44 \text{ m}$$

Step 9 of 10

Runway length required for the airplane to takeoff at an altitude of 1600 m,

$$S_2 = V_0 t_2 + \frac{1}{2} a_2 t_2^2 \qquad \ldots\ldots (6)$$

Where, S_2 is the length of the runway at an altitude of 1600 m.

V_0 is the initial velocity of the airplane at an altitude of 1600 m.

t_2 is the time required to takeoff at an altitude of 1600 m.

a_2 is the acceleration of the aircraft at an altitude of 1600 m.

Here initial velocity of the airplane is zero, $V_0 = 0$.

$t_2 = 16.2$ sec

$a_2 = 4.075 \text{ m/s}^2$.

Substitute all these values in equation (6)

$$S_2 = 0 + \frac{1}{2} \times 4.075 \times (16.2)^2$$

$$= 534.72 \text{ m}$$

Step 10 of 10

Now, the additional runway length required for this airplane to takeoff at an altitude of 1600m is,

$$S_{additional} = S_2 - S_1$$

$$= 534.72 - 458.44$$

$$= 76.28 \text{ m}$$

Therefore, the additional runway length required for this airplane to takeoff at an altitude of 1600 m, $\boxed{S_{additional} = 76.28 \text{ m}}$

Question: 15.079P

An airplane is consuming fuel at a rate of 7 gal/min when cruising at a constant altitude of 10,000 ft at constant speed. Assuming the drag coefficient and the engine efficiency to remain the same, determine the rate of fuel consumption at an altitude of 30,000 ft at the same speed.

Step 1 of 5

Given data:

Consumption of fuel by the airplane at an altitude of 3000 m, $f_1 = 7\,\text{gal/min}$

Cruising Altitude $h_1 = 10000$ ft

Step 2 of 5

When an aircraft cruises at a constant altitude the acceleration will be zero as a result the net force acting on the aircraft is zero.

Therefore the thrust developed by the engine is used to overcome the drag only as a result the thrust produced will be equal to the drag force acting, (Thrust $= F_D$)

Therefore power required to overcome drag,

$P = \text{Thrust} \times V$

$= F_D \times V$

Where, V is the velocity of airplane.

F_D is the drag force.

Here, $F_D = \frac{1}{2} C_D \rho A V^2$

Substitute this value in the above equation,

Power, $P = \frac{1}{2} C_D \rho A V^2 \times V$ ..... (1)

Where, C_D is the drag coefficient.

ρ is the density of air.

A is the wing area.

V is the velocity of aircraft.

Step 3 of 5

Now, power is also the product of rate of fuel energy supplied and the propulsive efficiency.

$P = \eta f_{c1} \text{HV}$ ..... (2)

(Rate of fuel energy supplied $= f_c \text{HV}$)

Where, η is the efficiency.

f_{c1} is the rate of fuel consumption at an altitude of

HV is the heating value.

Equate equations (1) and (2).

$$\frac{1}{2} C_D \rho A V^2 \times V = \eta f_{c1} \text{HV}$$

$$f_{c1} = \frac{\frac{1}{2} C_D \rho_1 A V^2 \times V}{\eta \text{HV}} \quad \text{..... (3)}$$

ρ_1 is the density of air at $h_1 = 10000$ ft

Step 4 of 5

Rate of fuel consumption at an altitude of $h_2 = 30000$ ft

$$f_{c2} = \frac{\frac{1}{2} C_D \rho_2 A V^2 \times V}{\eta \text{HV}} \quad \text{..... (4)}$$

Where, η is the efficiency

f_{c2} is the rate of fuel consumption at an altitude of $h_2 = 30000$ ft

HV is the heating value.

ρ_2 is the density of air at $h_2 = 30000$ ft

Step 5 of 5

From equation (3) and (4) we can understand that fuel consumption is directly proportional to density of air.

Divide equation (3) by (4).

$$\frac{f_{c1}}{f_{c2}} = \frac{\frac{\frac{1}{2} C_D \rho_1 A V^2 \times V}{\eta \text{HV}}}{\frac{\frac{1}{2} C_D \rho_2 A V^2 \times V}{\eta \text{HV}}}$$

$$\frac{f_{c1}}{f_{c2}} = \frac{\rho_1}{\rho_2} \quad \text{..... (5)}$$

Now, from the table 'Properties of the atmosphere at high altitude'

Density of air at $h_1 = 10000$ ft, $\rho_1 = 0.05648\ \text{lbm/ft}^3$

Density of air at $h_2 = 30000$ ft, $\rho_2 = 0.02866\ \text{lbm/ft}^3$

Substitute all the values in equation (5)

$$\frac{7}{f_{c2}} = \frac{0.909}{0.467}$$

$$f_{c2} = \frac{0.05648 \times 7}{0.02866}$$

$= 13.79\ \text{gal/min}$

Therefore, the rate of fuel consumption at an altitude of 30000 ft is $\boxed{f_{c2} = 13.79\ \text{gal/min}}$.

Question: 15.080P

A jumbo jet airplane has a mass of about 400,000 kg when fully loaded with over 400 passengers and takes off at a speed of 250 km/h. Determine the takeoff speed when the airplane has 100 empty seats. Assume each passenger with luggage is 140 kg and the wing and flap settings are maintained the same.

Step 1 of 6

Given data:-

Mass of the aircraft when fully loaded, $m_1 = 400000$ kg.

Take off speed, $V = 250$ km/h.

Mass of each passenger with luggage, $m = 140$ kg.

Number of passengers when the aircraft is fully loaded is 400.

Step 2 of 6

An aircraft can takeoff when lift is equal to the total weight of the airplane.

$F_L = W$.

Lift force, $F_L = \frac{1}{2} C_L \rho A V^2$.

Where, C_L is the lift coefficient.

ρ is the density of air.

A is the wing area.

V is the take off velocity.

Therefore,

$$W = \frac{1}{2} C_L \rho A V^2$$

$$V^2 = \frac{2W}{C_L \rho A}$$

$$V = \sqrt{\frac{2W}{C_L \rho A}} \qquad \ldots\ldots (1)$$

Step 3 of 6

It is given that there is no change in wing and flap settings so area A remains constant in equation (1) also C_L and ρ is also constant. Therefore the takeoff velocity is directly proportional to the weight of the aircraft.

Now, the takeoff velocity of aircraft when the aircraft is fully loaded,

$$V_1 = \sqrt{\frac{2W_1}{C_L \rho A}} \qquad \ldots\ldots (2)$$

Where, W_1 is the weight of the aircraft when fully loaded.

Now, the takeoff velocity of aircraft when the aircraft has 100 empty seats.

$$V_2 = \sqrt{\frac{2W_2}{C_L \rho A}} \qquad \ldots\ldots (3)$$

Where, W_2 is the weight of the aircraft when the aircraft has 100 empty seats.

Step 4 of 6

Divide equation (3) by (2).

$$\frac{V_2}{V_1} = \frac{\sqrt{\frac{2W_2}{C_L \rho A}}}{\sqrt{\frac{2W_1}{C_L \rho A}}}$$

$$= \frac{\sqrt{W_2}}{\sqrt{W_1}}$$

But we know that weight, $W = mg$.

Where, m is the mass.

g is the gravitational acceleration.

Step 5 of 6

Therefore,

$$\frac{V_2}{V_1} = \frac{\sqrt{m_2 g}}{\sqrt{m_1 g}}$$

$$= \frac{\sqrt{m_2}}{\sqrt{m_1}}$$

$$V_2 = V_1 \frac{\sqrt{m_2}}{\sqrt{m_1}} \qquad \ldots\ldots (4)$$

Where, m_2 is the mass of airplane when 100 seats are empty.

$$m_2 = m_1 - m(100)$$

$$= 400000 - 140(100)$$

$$= 400000 - 14000$$

$$= 386000 \text{ kg}$$

Step 6 of 6

Substitute the values of m_1 and m_2 in equation (4)

$$V_2 = V_1 \left(\frac{\sqrt{386000}}{\sqrt{400000}} \right)$$

We know that

$V_1 = 250$ km/h.

$$V_2 = 250 \left(\frac{\sqrt{386000}}{\sqrt{400000}} \right)$$

$$= 245.59 \text{ km/h}$$

$$= 246 \text{ km/h}$$

Therefore the takeoff speed of the airplane when it has 100 empty seats is

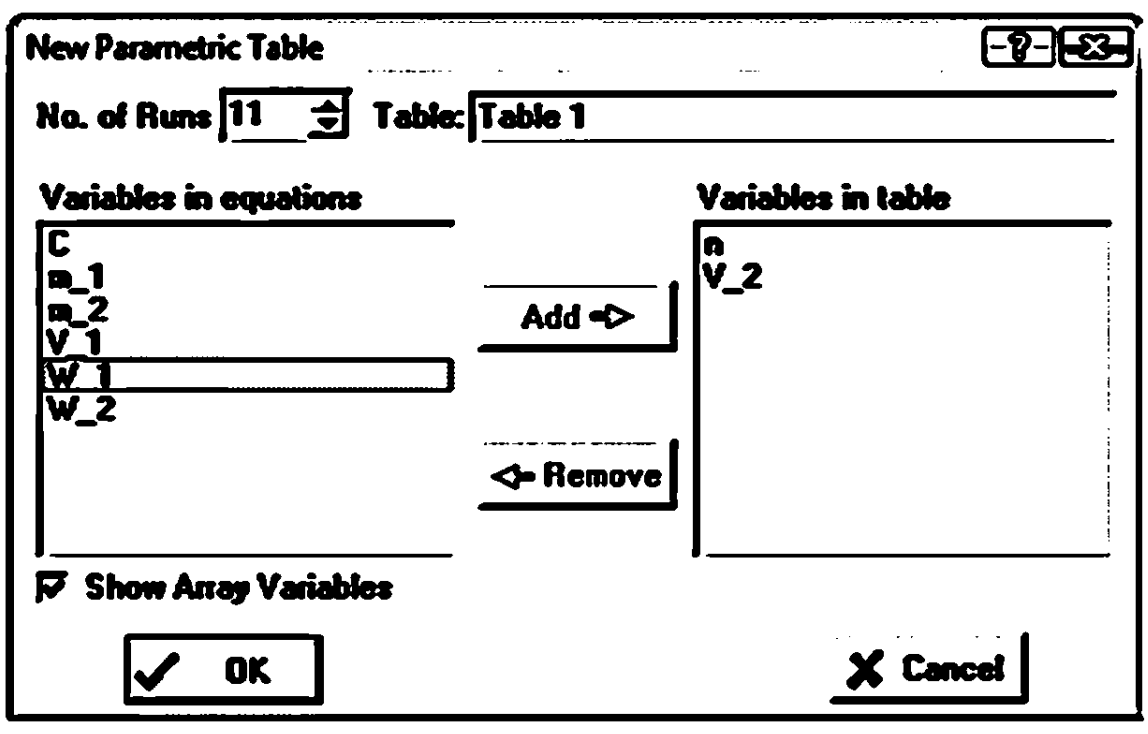
$\boxed{V_2 = 246 \text{ km/h}}$.

Question: 15.081P

Reconsider Prob. 15-80. Using EES (or other) software, investigate the effect of passenger count on the takeoff speed of the aircraft. Let the number of passengers vary from 0 to 500 in increments of 50. Tabulate and plot the results.

Step 1 of 5

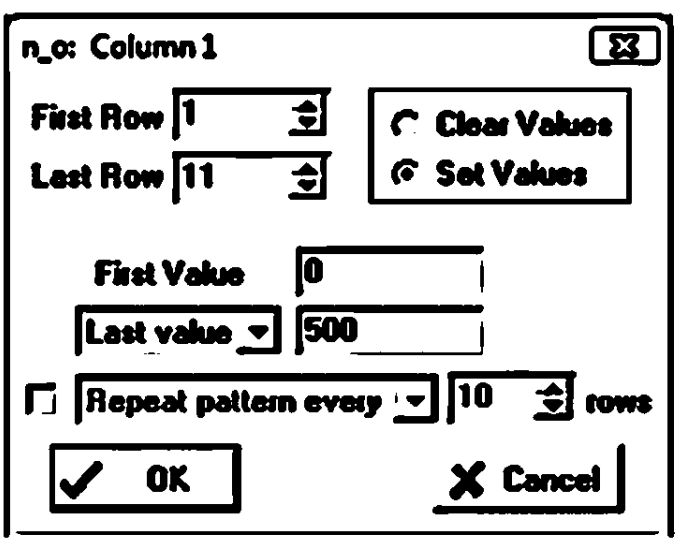
The given problem can be solved using EES software by following the below steps.



1. **Open EES software**
2. **Create a new file by clicking on the 'New' of the 'File menu'**
3. **Now type the following code in dailog box**

```
m_1=400000[kg]            "Mass of the jumbo jet airplane"
V_1=250[km/hr]            "Takeoff speed"
m_2=140[kg]               "Mass of each passenger"
"n is varied from 0 to 500"  "Number of seats empty"

W_1=m_1*g#                "Weight of the airplane loaded with 500 passengers"
W_2=W_1-m_2*g#*n          "Weight of the airplane when n seats are empty"
"Let C_L*rho*A be 'C' "
W_1=0.5*C*V_1^2           "Lift Force"
W_2=0.5*C*V_2^2
```



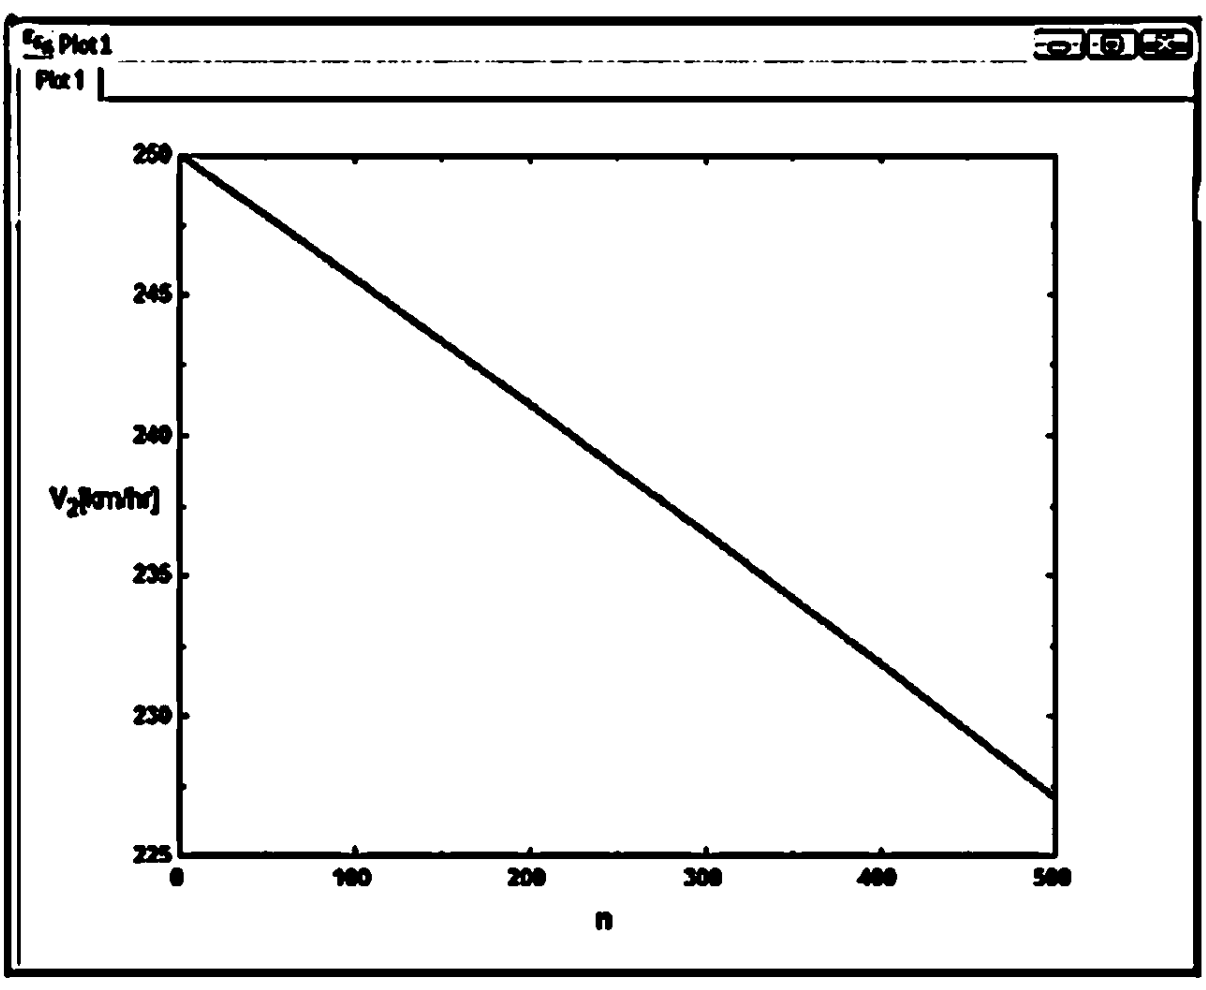
Step 2 of 5

Now to solve the equation for a range of hot surface temperature values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "n" and "V_2" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 5

To enter the values in the "n" column click on the drop tab in "n" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 5



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	n	V_2
Run 1	0	250
Run 2	50	247.8
Run 3	100	245.6
Run 4	150	243.3
Run 5	200	241.1
Run 6	250	238.8
Run 7	300	236.5
Run 8	350	234.2
Run 9	400	231.8
Run 10	450	229.5
Run 11	500	227.1

Step 5 of 5

Inorder to plot the rate of natural convection heat transfer as a function of hot surface temperature, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Select X-axis as "n" and Y-axis as "V_2" and press 'OK'
The Graph will be plotted as shown below:

From the above graph we can interpret that as the number of empty seats increases, the velocity of the plane decreases.

Question: 15.082P

A small aircraft has a wing area of 28 m2, a lift coefficient of 0.45 at takeoff settings, and a total mass of 2500 kg. Determine (*a*) the takeoff speed of this aircraft at sea level at standard atmospheric conditions, (*b*) the wing loading, and (*c*) the required power to maintain a constant cruising speed of 300 km/h for a cruising drag coefficient of 0.035.

Step 1 of 8

Mass of the aircraft, $m = 2500$ kg

Wing area, $A = 28\ \text{m}^2$

Lift coefficient, $C_L = 0.45$

Drag coefficient, $C_D = 0.035$

Step 2 of 8

a) An aircraft can takeoff when lift is equal to the total weight of the airplane.

Means that, $F_L = W$

Lift force, $F_L = \frac{1}{2} C_L \rho A V^2$

Where, C_L is the lift coefficient

ρ is the density of air.

A is the wing area.

V is the take off velocity.

Therefore,

$$W = \frac{1}{2} C_L \rho A V^2$$

$$V^2 = \frac{2W}{C_L \rho A}$$

$$V = \sqrt{\frac{2W}{C_L \rho A}} \qquad \ldots\ldots (1)$$

Step 3 of 8

Density of air at sea level, $\rho = 1.225\ \text{kg/m}^3$

Now, substitute all the known values in equation (1)

$$V = \sqrt{\frac{2mg}{C_L \rho A}}$$

$$= \sqrt{\frac{2 \times 2500 \times 9.81}{0.45 \times 1.225 \times 28}}$$

$$= \sqrt{3177.84}$$

$$= 56.37\ \text{m/s}$$

Therefore, the takeoff speed of this aircraft at sea level and at standard atmospheric condition, $\boxed{V = 56.37\ \text{m/s}}$

Step 4 of 8

b) Now, we have to find out the wing loading.

Wing loading is the lift force per unit plan form area.

Loading on the wing, $F_{\text{Wing loding}} = \frac{F_L}{A}$ ..... (2)

where, F_L is the lift force.

A is the plan form area.

Planform area is the area seen by a person when looking at the body from above the body in a direction normal to the body.

We know that $F_L = W$.

Since $W = mg$,

$$F_L = mg \qquad \ldots\ldots (3)$$

Where, m is the mass of the airplane.

g is the acceleration due to gravity.

Step 5 of 8

Substitute the value of m and g in equation (3)

$$F_L = 2500(9.81)$$

$$= 24525\ \text{N}$$

Substitute the value of F_L in equation (2)

$$F_{\text{Wing loding}} = \frac{24525}{28}$$

$$= 875.89\ \text{N/m}^2$$

Therefore the wing loading is, $\boxed{F_{\text{Wing loding}} = 875.89\ \text{N/m}^2}$.

Step 6 of 8

c)When an aircraft cruises at a constant altitude the acceleration will be zero as a result the net force acting on the aircraft is zero therefore the thrust developed by the engine is used to overcome the drag only, as a result the thrust produced will be equal to the drag force acting, (Thrust $= F_D$).

We know that the drag force acting,

$$F_D = \frac{1}{2} C_D \rho A V^2 \qquad \ldots\ldots (4)$$

Where C_D is the drag coefficient.

ρ is the density of air.

A is the wing area.

V is the velocity of airplane.

Step 7 of 8

Here,

$C_D = 0.035$.

$\rho = 1.225\ \text{kg/m}^3$.

$A = 28\ \text{m}^2$.

$V = 300$ km/h

$$= 300\left(\frac{5}{18}\right) \text{m/s}$$

$$= 83.33\ \text{m/s}$$

Substitute all these values in equation (4)

$$F_D = \frac{1}{2} C_D \rho A V^2$$

$$= \frac{1}{2} \times 0.035 \times 1.225 \times 28 \times (83.33)^2$$

$$= 4168.07\ \text{N}$$

Step 8 of 8

The power required to maintain a constant cruising speed of 300 km/h for a cruising drag coefficient of 0.035.

$P =$ Thrust $\times V$

$= F_D \times V$

Where, V is the velocity of airplane.

F_D is the drag force.

$P = 4168.07 \times 83.33$

$= 347325.27$ Watt

$= 347.3$ kW

Therefore the power required to maintain a constant cruising speed of 300 km/h for a cruising drag coefficient of 0.035 is, $\boxed{P = 347.3\ \text{kW}}$

Question: 15.083P

A small airplane has a total mass of 1800 kg and a wing area of 42 m2. Determine the lift and drag coefficients of this airplane while cruising at an altitude of 4000 m at a constant speed of 280 km/h and generating 190 kW of power.

Step 1 of 7

Given data:

Total mass of the airplane, $m = 1800$ kg

Wing area, $A = 42$ m^2

Cruising altitude, 4000 m

Speed of the aircraft, $V = 280$ km/h

Power generated by the aircraft engine, $P = 190$ kW

Step 2 of 7

An aircraft can fly when lift is equal to the total weight of the airplane.

Means that $F_L = W$

Lift force, $F_L = \frac{1}{2} C_L \rho A V^2$

Where, C_L is the lift coefficient

ρ is the density of air

A is the wing area

V is the take off velocity.

Therefore,

$$W = \frac{1}{2} C_L \rho A V^2$$

$$V^2 = \frac{2W}{C_L \rho A}$$

$$V = \sqrt{\frac{2W}{C_L \rho A}} \quad \text{..... (1)}$$

Step 3 of 7

Density of air at $h = 4000$ m, $\rho = 0.8194$ kg/m^3

Speed of the aircraft,

$V = 280$ km/h

$= 280\left(\frac{5}{18}\right)$ m/s

$= 77.8$ m/s

Weight,

$W = mg$

$= 1800 \times 9.81$

$= 17658$ N

Wing area, $A = 42$ m^2

Step 4 of 7

Substitute all these values in equation (1)

$$V = \sqrt{\frac{2W}{C_L \rho A}}$$

$$77.8 = \sqrt{\frac{2 \times 17658}{C_L \times 0.8194 \times 42}}$$

Squaring on both sides,

$$(77.8)^2 = \left(\sqrt{\frac{2 \times 17658}{C_L \times 0.8194 \times 42}}\right)^2$$

$$6052.84 = \frac{2 \times 17658}{C_L \times 0.8194 \times 42}$$

$$C_L = \frac{2 \times 17658}{6052.84 \times 0.8194 \times 42}$$

$$C_L = \frac{2 \times 17658}{6052.84 \times 0.8194 \times 42}$$

$= 0.17$

Therefore the lift coefficient, $\boxed{C_L = 0.17}$

Step 5 of 7

When an aircraft cruises at a constant altitude the acceleration will be zero as a result the net force acting on the aircraft is zero therefore the thrust developed by the engine is used to overcome the drag only, as a result the thrust produced will be equal to the drag force acting. (Thrust $= F_D$).

Power, $P = F_D \times V$ ..... (2)

Where, F_D is the drag force.

V is the velocity of the airplane.

We know that the drag force acting,

$$F_D = \frac{1}{2} C_D \rho A V^2 \quad \text{..... (3)}$$

Where C_D is the drag coefficient.

ρ is the density of air.

A is the wing area.

V is the velocity of airplane.

Step 6 of 7

Substituting the values of ρ, A and V in equation (3),

$$F_D = \frac{1}{2} C_D \left\{0.8194 \times 42 \times (77.8)^2\right\}$$

$= 104153.64\, C_D$

Power,

$P = 190$ kW

$= 190 \times 10^3$ Watt

Step 7 of 7

Now, substitute the value of P, F_D and V in equation (2),

$190 \times 10^3 = 104153.64\, C_D \times 77.8$

$$C_D = \frac{190 \times 10^3}{104153.64 \times 77.8}$$

$= 0.02345$

Therefore the drag coefficient, $\boxed{C_D = 0.02345}$

Question: 15.084P

The NACA 64(1)-412 airfoil has a lift-to-drag ratio of 50 at 0° angle of attack, as shown in Fig. 15-43.,At what angle of attack does this ratio increase to 80?

Step 1 of 1

From the graph, 'The variation of the lift-to-drag ratio with angle of attack for a two-dimensional airfoil' for an angle of attack of 3 the lift to drag ratio becomes 80.

$\boxed{\frac{C_L}{C_D} = 80}$ When $\alpha = 3°$.

Question: 15.085P

Consider a light plane that has a total weight of 15,000 N and a wing area of 46 m2 and whose wings resemble ϕe NAC A 23012 airfoil with no flaps. Using data from pig. 15-45, determine the takeoff speed at an angle of attack of 5° at sea level. Also determine the stall speed.

Step 1 of 6

Given data:
Weight of the plane is $W = 15000\ \text{N}$.
Wing area is $A = 46\ \text{m}^2$.
Angle of attack is $\alpha = 5°$.

Step 2 of 6

Taking density of air at sea level is $\rho = 1.225\ \text{kg/m}^3$.
From the graph, 'Effect of flaps on the lift and drag coefficients of an airfoil'

For an angle of attack of $\alpha = 5°$,
Lift coefficient, $C_L = 0.58$
Drag coefficient, $C_D = 0.02$

Step 3 of 6

There was a problem loading this step. We have been notified and we will fix it shortly.

Step 4 of 6

Substituting all values in equation (1)

$$V_{takeoff} = \sqrt{\frac{2 \times 15000}{0.58 \times 1.225 \times 46}}$$
$$= 30.29\ \text{m/s}$$
$$= 30.29\left(\frac{18}{5}\right)\ \text{km/h}$$
$$= 109.04\ \text{km/h}$$

Therefore the takeoff velocity is $\boxed{V_{takeoff} = 109.04\ \text{km/h}}$.

Step 5 of 6

Now, the stall speed can be determined by using the formula given below,

$$V_{stall} = \sqrt{\frac{2W}{C_{L\max}\rho A}} \qquad \ldots\ldots (2)$$

Where, $C_{L\max}$ is the maximum lift coefficient.
ρ is the density of air.
A is the wing area.
W is the weight of the airplane.

Step 6 of 6

Here, $C_{L\max} = 1.52$
Substituting all values in equation (2)

$$V_{stall} = \sqrt{\frac{2W}{C_{L\max}\rho A}}$$
$$= \sqrt{\frac{2 \times 15000}{1.52 \times 1.225 \times 46}}$$
$$= 18.72\ \text{m/s}$$
$$= 18.72\left(\frac{18}{5}\right)\ \text{km/h}$$
$$= 67.4\ \text{km/h}$$

Therefore the stall speed is $\boxed{V_{stall} = 67.4\ \text{km/h}}$.

Question: 15.086P

An airplane has a mass of 50,000 kg, a wing W area of 300 m2, a maximum lift coefficient of 3.2, and a cruising drag coefficient of 0.03 at an altitude of 12,000 m. Determine (*a*) the takeoff speed at sea level, assuming it is 20 percent over the stall speed, and (*b*) the thrust that the engines must deliver for a cruising speed of 700 km/h.

Step 1 of 3

Mass of the airplane, $m = 50000\text{kg}$

Area of the wing, $a = 300\ \text{m}^2$

Maximum lift coefficient, $C_{L,\max} = 3.2$

Drag coefficient, $C_D = 0.03$

Altitude, $h = 12000\text{m}$

Step 2 of 3

From the table of properties of the atmosphere at high altitude,

Density of standard air at sea level, $\rho_1 = 1.225\ \text{kg/m}^3$

Density of standard air at an altitude of 12,000 m, $\rho_2 = 0.312\text{kg/m}^3$

(*a*) An aircraft will takeoff when lift equals the total weight.

Therefore,

$$W = F_L$$

$$= \frac{1}{2} C_L \rho V^2 A$$

So,

$$V = \sqrt{\frac{2W}{\rho C_L A}}$$

$$= \sqrt{\frac{2mg}{\rho C_L A}}$$

The stall velocity is determined by using the maximum lift coefficient.

Hence,

$$V_{\min} = \sqrt{\frac{2mg}{\rho C_{L,\max} A}}$$

$$= \sqrt{\frac{2(50000 \times 9.81)}{1.225 \times 3.2 \times 300}}$$

$$= 28.88\,\text{m/s}$$

Then the "safe" minimum velocity to avoid the stall region,

$$V_{\min,\text{safe}} = 1.2 V_{\min}$$

$$= 1.2 \times (28.9)$$

$$= 34.7\ \text{m/s}$$

$$= 124.77\text{km/hr}$$

Therefore, the take off speed at sea level over the stall speed, $\boxed{V_{\min,\text{safe}} = 124.77\text{km/hr}}$

Step 3 of 3

(*b*) When the aircraft cruises steadily at a constant altitude, the net force acting on the aircraft is zero, and thus the thrust provided by the engines must be equal to the drag force.

Drag force,

$$F_D = C_D A \frac{\rho_2 V^2}{2}$$

$$= 0.03 \times 300\ \text{m}^2 \left(\frac{0.312\ \text{kg/m}^3 \times \left(\frac{700}{3.6}\text{m/s} \right)^2}{2} \right) \left(\frac{1\,\text{kN}}{1000\ \text{kg}\cdot\text{m/s}^2} \right)$$

$$= 53.08\ \text{kN}$$

So,

$$\text{Power} = \text{Thrust} \times \text{Velocity}$$

$$= F_D \times V$$

$$= (53.08\ \text{kN}) \left(\frac{700}{3.6}\ \text{m/s} \right) \left(\frac{1\,\text{kW}}{1\ \text{kN}\cdot\text{m/s}} \right)$$

$$= 10{,}321.11\,\text{kW}$$

Therefore, the thrust force deliver for the crushing speed is $\boxed{\text{Power} = 10{,}321.11\,\text{kW}}$

Question: 15.087P

The passenger compartment of a minivan traveling at 60 mi/h in ambient air at 1 atm and 80°F is modeled as a 3.2-ft-high, 6-ft-wide, and 11-ft-long rectangular box. The airflow over the exterior surfaces is assumed to be turbulent because of the intense vibrations involved. Determine the drag force acting on the top and the two side surfaces of the van and the power required to overcome it.

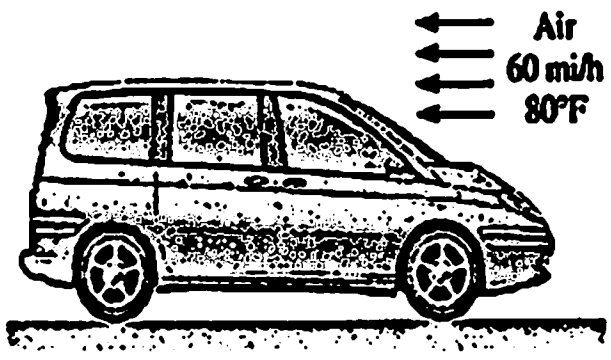


FIGURE P15–87E

Step 1 of 4

Velocity f the minivan, $V_\infty = 60\,\text{mi/h} = 86.82\,\text{ft/s}$

Ambient air pressure, $P = 1\,\text{atm}$

Ambient air temperature, $T = 80°\text{F}$

Height of the minivan, $h = 3.2\,\text{ft}$

With of the minivan, $w = 6\,\text{ft}$

Length of the minivan, $l = 11\,\text{ft}$

The air flow is assumed to be turbulent.

Step 2 of 4

At the given conditions of air the coefficient of kinematic viscosity, $\nu = 1.697\times10^{-4}\,\text{ft}^2/\text{s}$

The density of air at this ambient air conditions , $\rho = 0.074\,\text{lbm/ft}^3$

Reynold's number is given by,

$$\begin{aligned}\text{Re} &= \frac{V_\infty l}{\nu}\\ &= \frac{86.82\times11}{1.697\times10^{-4}}\\ &= 56.277\times10^5\end{aligned}$$

Since the air flow is assumed to be turbulent the coefficient of drag is calculated as,

$$\begin{aligned}C_f &= \frac{0.074}{\text{Re}^{1/5}}\\ &= \frac{0.074}{\left(56.277\times10^5\right)^{1/5}}\\ &= 3.305\times10^{-3}\end{aligned}$$

Step 3 of 4

The total are encountering drag force,

Total area= Area of top + area of sides + area of sides

$$\begin{aligned}A_{Total} &= A_{top} + 2A_{sides}\\ &= (6\times11)+2(3.2\times11)\\ &= 136.4\,\text{ft}^2\end{aligned}$$

Total drag force acting on the minivan die to this surfaces,

$$\begin{aligned}F_D &= C_f \times \frac{1}{2}\rho A_{Total} V_\infty^2\\ &= 3.305\times10^{-3}\times\frac{1}{2}\times0.074\times136.4\times86.82^2\\ &= 125.68\,\text{lbm}\\ &= 3.9\,\text{lbf}\end{aligned}$$

Step 4 of 4

The power required to over come the drag force is given by,

$$\begin{aligned}P &= F_D V_\infty\\ &= 3.9\times86.82\\ &= 338.89\,\text{lbf}\cdot\text{ft/s}\\ &= 0.459\,\text{kW}\end{aligned}$$

The over all drag force due the top and both the side surfaces is found to be $\boxed{3.9\,\text{lbf}}$ and power required by the minivan to over the drag force is obtained as $\boxed{0.459\,\text{kW}}$

Question: 15.088P

A 1.2-m-external-diameter spherical tank is located outdoors at 1 atm and 25°C and is subjected to winds at 48 km/h. Determine the drag force exerted on it by the wind.

Step 1 of 5

Given data:
External diameter of the spherical tank is $D = 1.2$ m.
Velocity of the wind is $V = 48$ km/h.

Step 2 of 5

(From the table of properties of air)
Density of air at 1 atm pressure and 25°C is $\rho = 1.184\ \text{kg/m}^3$.
Kinematic viscosity of air at 1 atm and 25°C is $\nu = 1.562 \times 10^{-5}\ \text{m}^2/\text{s}$.
Here, velocity,

$$V = 48\ \text{km/h}$$
$$= 48\left(\frac{5}{18}\right)\text{m/s}$$
$$= 13.33\ \text{m/s}$$

Step 3 of 5

Now, we have to find out the Reynolds number using the formula given below,

$$\text{Re} = \frac{VD}{\nu}$$

Where, V is the velocity of the air.
D is the diameter of the spherical tank.
ν is the kinematic viscosity.

Substituting all these values in the above equation,

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{13.33 \times 1.2}{1.562 \times 10^{-5}}$$
$$= 1.02 \times 10^{6}$$

From the graph, 'Effect of surface roughness on the drag coefficient of a sphere'
The drag coefficient (C_D) corresponding to the obtained Reynolds number is,

$$C_D = 0.14$$

Step 4 of 5

Now, the drag force acting on the sphere,

$$F_D = \frac{1}{2}C_D\rho A V^2 \qquad \ldots\ldots (1)$$

Where, C_D is the drag coefficient.
ρ is the density of air.
A is the area of the spherical tank.
V is the velocity of wind.

Here, area,

$$A = \frac{\pi}{4}D^2$$
$$= \frac{\pi}{4}(1.2)^2$$
$$= 1.13\ \text{m}^2$$

Step 5 of 5

Substituting all the values in equation (1).

$$F_D = \frac{1}{2}C_D\rho A V^2$$
$$= \frac{1}{2} \times 0.14 \times 1.184 \times 1.13 \times (13.33)^2$$
$$= 16.6\ \text{N}$$

Therefore the drag force acting on the sphere is $\boxed{F_D = 16.6\ \text{N}}$.

Question: 15.089P pg 1

A 2-m-high, 4-m-wide rectangular advertisement panel is attached to a 4-m-wide, 0.15-m-high rectangular concrete block (density = 2300 kg/m3) by two 5-cm-diameter, 4-m-high (exposed part) poles, as shown in Fig. PI5-89. If the sign is to withstand 150 km/h winds from any direction, determine (*a*) the maximum drag force on the panel, (*b*) the drag force acting on the poles, and (*c*) the minimum length *L* of the concrete block for the panel to resist the winds. Take the density of air to be 1.30 kg/m3.

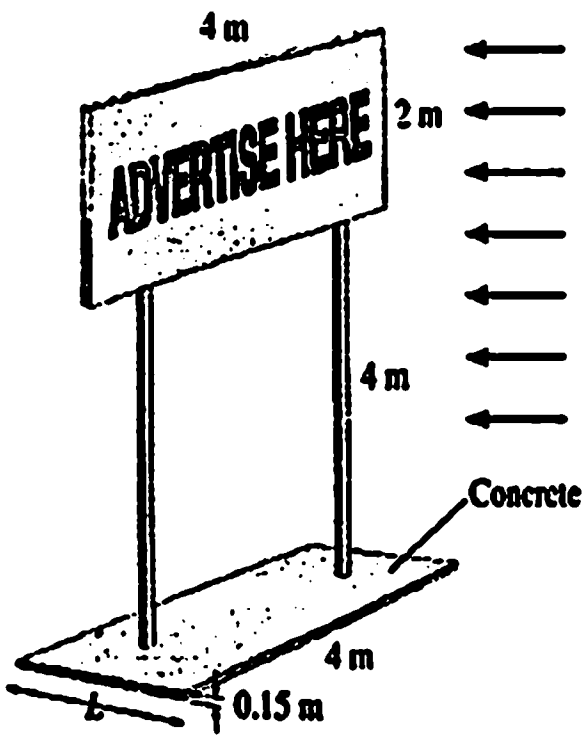

FIGURE P15–89

Step 1 of 9

Given data:

Height of rectangular advertisement panel is $h_1 = 2\ \text{m}$.

Width of rectangular advertisement panel is $w_1 = 4\ \text{m}$.

Height of rectangular concrete block is $h_2 = 0.15\ \text{m}$.

Width of rectangular concrete block is $w_2 = 4\ \text{m}$.

Diameter of the poles is $D = 5\ \text{cm}$.

Height of the poles is $h_3 = 4\ \text{m}$.

Velocity of the wind is $V = 150\ \text{km/h}$.

Density of the concrete block is $\rho_c = 2300\ \text{kg/m}^3$.

Density of the air is $\rho_{air} = 1.30\ \text{kg/m}^3$.

Assume the flow is turbulent.

Step 2 of 9

a) For calculating the maximum drag force on the panel.

Drag force, $F_D = \frac{1}{2} C_D \rho_{air} A V^2$ ..... (1)

Where,

C_D is the drag coefficient.

ρ_{air} is the density of air.

A is the frontal area of the panel.

V is the velocity of the wind.

Step 3 of 9

Here velocity,

$$V = 150\ \text{km/h}$$

$$= 150\left(\frac{5}{18}\right)\ \text{m/s}$$

$$= 41.7\ \text{m/s}$$

Frontal area of the panel,

$$A = h_1 \times w_1$$

$$= 2 \times 4$$

$$= 8\ \text{m}^2$$

In turbulent flow drag coefficient for a thin rectangular plate is, $C_D = 2$

Step 4 of 9

Substituting all these values in equation (1).

$$F_D = \frac{1}{2} C_D \rho_{air} A V^2$$

$$= \frac{1}{2} \times 2 \times 1.30 \times 8 \times (41.7)^2$$

$$= 18084.5\ \text{N}$$

Therefore the maximum drag force on the panel is $\boxed{F_{D\,\text{Panel}} = 18084.5\ \text{N}}$.

Step 5 of 9

b) Now, we have to find out the drag force acting on the pole.

It can be found out using equation (1)

In turbulent flow drag coefficient for a circular rod is, $C_D = 0.3$

Now, the frontal area of the circular rod,

$$A = D \times h_3$$

$$= 0.05 \times 4$$

$$= 0.2\ \text{m}^2$$

Substituting all the values in equation (1)

$$F_D = \frac{1}{2} C_D \rho_{air} A V^2$$

$$= \frac{1}{2} \times 0.3 \times 1.30 \times 0.2 \times (41.7)^2$$

$$= 67.8\ \text{N}$$

Therefore the drag force acting on each pole is $\boxed{F_{D\,\text{pole}} = 67.8\ \text{N}}$.

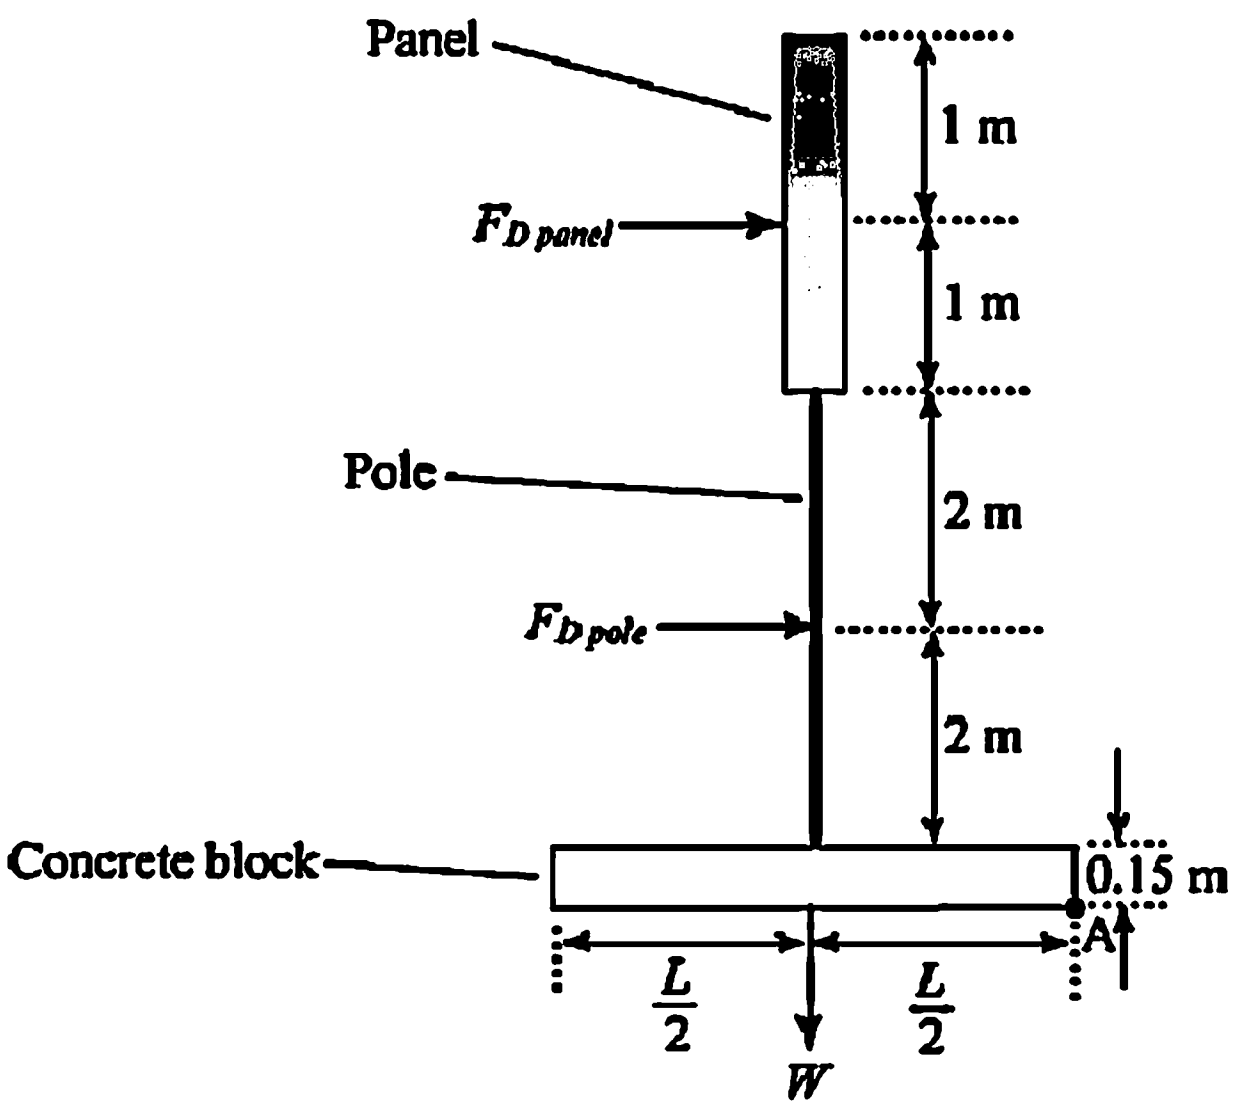
Step 6 of 9

c) Now, we have to find out the minimum length L of the concrete block for the panel to resist the winds.

The resultant drag force acting on the panel passes through the centre of the panel, the drag force acting on the pole passes through the centre of the pole, the weight of the concrete block acts through the centre of the concrete block.

Assume that the concrete block is tipped due to the wind force, when the concrete block is first tipped the wind loaded side of the panel will be lifted off the ground as

to resist the winds.



15.089P pg 2

The resultant drag force acting on the panel passes through the centre of the panel, the drag force acting on the pole passes through the centre of the pole, the weight of the concrete block acts through the centre of the concrete block.

Assume that the concrete block is tipped due to the wind force, when the concrete block is first tipped the wind loaded side of the panel will be lifted off the ground as a result all the reaction force from the ground will act on the other side of the block. Take moment about this side and equate it to zero.

Step 7 of 9

Draw the figure of the side view of the advertisement panel.

Step 8 of 9

Taking moment about point A.

$$+\circlearrowleft \sum M_A = 0$$

$$F_{D\,Panel}(5.15) + F_{D\,Pole}(2.15) - W\left(\frac{L}{2}\right) = 0 \qquad \ldots\ldots (2)$$

Now, weight of the concrete block,

$W = mg$

Since,

mass = Density × volume

$= \rho \times V$

$W = \rho_c V g$

Here, volume of the concrete block, $V = L \times h_2 \times w_2$

$V = L \times 0.15 \times 4$

$= 0.6L$

Now, mass,

$m = 2300 \times 0.6L$

$= 1380L$

Now, weight,

$W = 1380L \times 9.81$

$= 13537.8L$

Step 9 of 9

Substituting all the values in equation (2).

$$F_{D\,Panel}(5.15) + F_{D\,Pole}(2.15) - W\left(\frac{L}{2}\right) = 0$$

$$18084.5(5.15) + 67.8(2)(2.15) - 13537.8L\left(\frac{L}{2}\right) = 0$$

$$13537.8L\left(\frac{L}{2}\right) = 93426.715$$

$L^2 = 13.8$

$L = 3.7$ m

Therefore the minimum length of the concrete block for the panel to resist the wind is $\boxed{L = 3.7 \text{ m}}$.

Question: 15.090P

A plastic boat whose bottom surface can be approximated as a 1.5-m-wide, 2-m-long flat surface is to move through water at 15°C at speeds up to 45 km/h. Determine the friction drag exerted on the boat by the water and the power needed to overcome it.

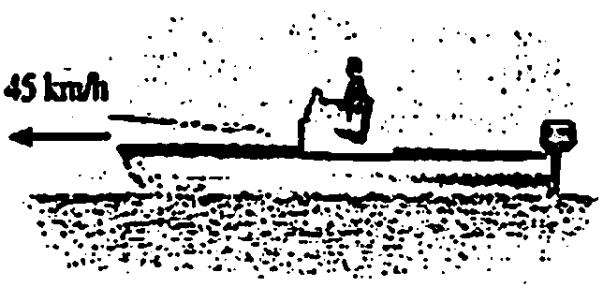


FIGURE P15–90

Step 1 of 5

Given data:-

Width of the bottom surface of the boat, $w = 1.5\ \text{m}$.

Length of the bottom surface of the boat, $L = 2\ \text{m}$.

Temperature of water, $T = 15°\text{C}$.

Speed of the boat, $V = 45\ \text{km/h}$.

Step 2 of 5

Frictional drag exerted on the boat by the water can be found out using the formula given below

$$F_D = \frac{1}{2} C_f \rho A V^2 \qquad \ldots\ldots (1)$$

Where, C_f is the friction coefficient.

ρ is the density of water.

A is the frontal area of the bottom surface of the boat.

V is the velocity of the boat.

Here the frictional coefficient C_f is unknown, to find the frictional coefficient use the formula given below,

(The flow is assumed to be turbulent)

$$C_f = \frac{0.074}{\text{Re}_L^{0.2}} \qquad \ldots\ldots (2)$$

Where, Re_L is the Reynolds number.

Here Re_L is unknown which can be found out using the formula given below,

$$\text{Re}_L = \frac{\rho V L}{\mu} \qquad \ldots\ldots (3)$$

Where, ρ is the density of water.

V is the velocity of the boat.

L is the length of the bottom surface of the boat.

μ is the dynamic viscosity of water.

Step 3 of 5

From the table 'properties of saturated water'

Density of water at 15°C, $\rho = 999.1\ \text{kg/m}^3$.

Dynamic viscosity of water at 15°C, $\mu = 1.138 \times 10^{-3}\ \text{kg/m} \cdot \text{s}$

Now, velocity of the boat,

$$V = 45\ \text{km/h}$$

$$= 45\left(\frac{5}{18}\right)\ \text{m/s}$$

$$= 12.5\ \text{m/s}$$

Substitute all the values in equation (3)

$$\text{Re}_L = \frac{\rho V L}{\mu}$$

$$= \frac{999.1 \times 12.5 \times 2}{1.138 \times 10^{-3}}$$

$$= 2.2 \times 10^7$$

Step 4 of 5

Now, substitute the value of Re_L in equation (2)

$$C_f = \frac{0.074}{\text{Re}_L^{0.2}}$$

$$= \frac{0.074}{\left(2.2 \times 10^7\right)^{0.2}}$$

$$= 0.0025$$

Now, frontal area of the bottom surface of the boat,

$$A = w \times L$$

$$= 1.5 \times 2$$

$$= 3\ \text{m}^2$$

Now, substitute the values of C_f, ρ, A, and V in equation (1)

$$F_D = \frac{1}{2} C_f \rho A V^2$$

$$= \frac{1}{2} \times 0.0025 \times 999.1 \times 3 \times (12.5)^2$$

$$= 585.41\ \text{N}$$

Therefore the frictional drag exerted on the boat by the water is, $\boxed{F_D = 585.41\ \text{N}}$.

Step 5 of 5

Now, the power required to overcome this frictional drag has to be determined.

Power required is the product of frictional drag force and velocity of the boat.

Power, $P = F_D \times V \qquad \ldots\ldots (4)$

Where, F_D frictional drag and V is the velocity of boat.

Substitute these values in equation (4)

$$P = F_D \times V$$

$$= 585.41 \times 12.5$$

$$= 7317.625\ \text{Watt}$$

Therefore the power required to overcome the frictional drag is, $\boxed{P = 7.3\ \text{kW}}$.

Question: 15.091P

Reconsider Prob. 15-90. Using EES (or other) NU software, investigate the effect of boat speed on the drag force acting on the bottom surface of the boat, and the power needed to overcome it. Let the boat speed vary from 0 to 100 km/h in increments of 10 km/h. Tabulate and plot the results.

Step 1 of 5

Wide of boat, $W = 1.5\text{m}$

Length of boat, $L = 2\text{m}$

Step 2 of 5

Drag force acting on the boat is

$$F_D = c_D \frac{\rho A V^2}{2}$$

$$= \frac{1000 \times 2 \times 1.5 V^2}{2} \times \frac{0.074}{\text{Re}}$$

$$= \frac{1000 \times 2 \times 1.5 V^2}{2} \times \frac{0.074}{\left(\frac{V \times L}{\nu}\right)}$$

$$= \frac{1000 \times 2 \times 1.5 V^2}{2} \times \frac{0.074}{\left(\frac{V \times 2}{0.001138}\right)}$$

$$= 1500 V^2 \times \frac{5}{18} \text{ m/s}$$

$$= 0.00583 V$$

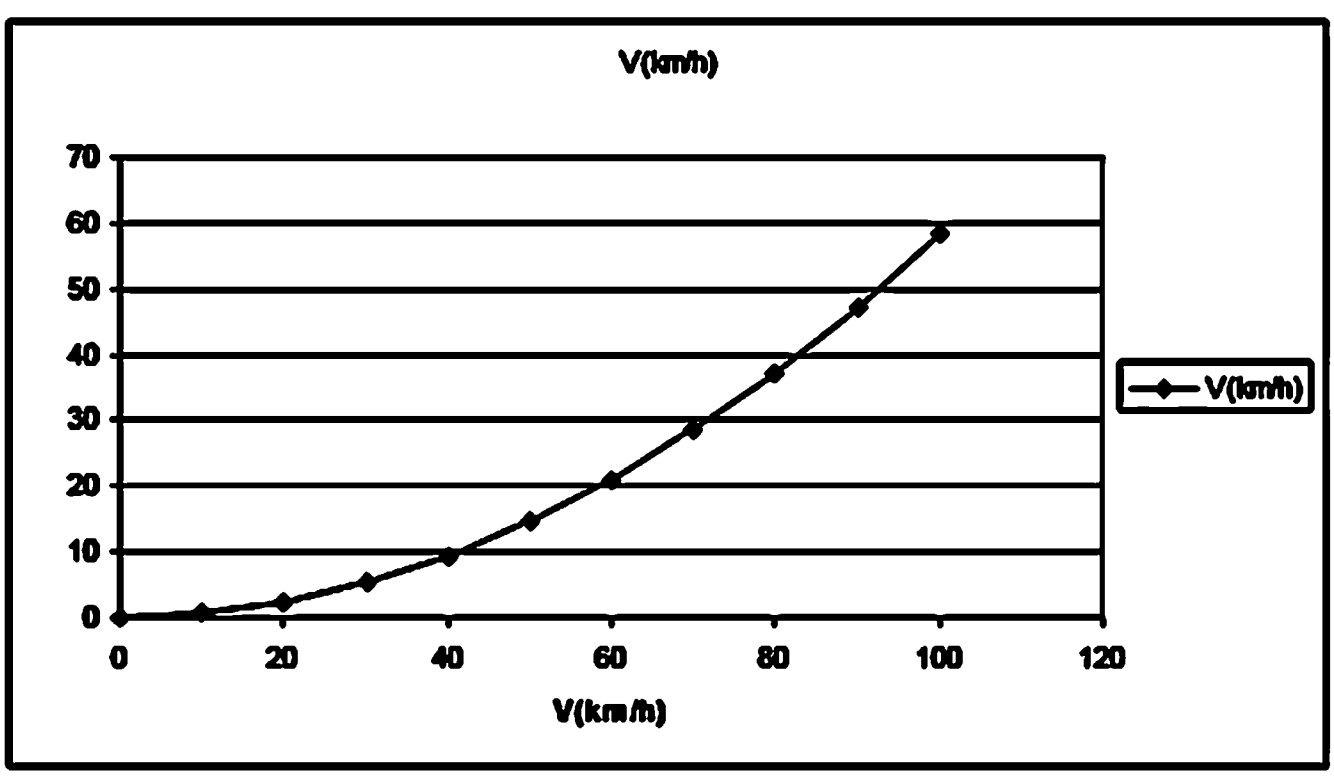
Step 3 of 5

Power required is

$$P = F_D \times V$$

$$= 0.00583 V \times V$$

$$= 0.0583 V^2$$



Step 4 of 5

Calculation of velocity and power:

V(km/h)	F(N)	P(kW)
0	0	0
10	0.0583	0.583
20	0.1166	2.332
30	0.1749	5.247
40	0.2332	9.328
50	0.2915	14.575
60	0.3498	20.988
70	0.4081	28.567
80	0.4664	37.312
90	0.5247	47.223
100	0.583	58.3

Step 5 of 5

Power vs. velocity:

Question: 15.092P

The cylindrical chimney of a factory has an external diameter of 1.6 m and is 35 m high. Determine the bending moment at the base of the chimney when winds at 110 km/h are blowing across it. Take the atmospheric conditions to be 20°C and 1 atm.

Step 1 of 8

Given data:-

External diameter of the chimney, $D = 1.6$ m.

Height of the chimney, $h = 35$ m.

Velocity of the wind, $V = 110$ km/h.

Atmospheric conditions,

Temperature of the air, $T = 20°C$.

Pressure of the air, $P = 1$ atm.

Step 2 of 8

(From the table of properties of air)

Density of air at 1 atm pressure and 20°C, $\rho = 1.204$ kg/m^3.

Kinematic viscosity of air at 1 atm and 20°C is $\nu = 1.516 \times 10^{-5}$ m^2/s.

When wind blows across the chimney a drag force will act on the chimney, this drag force will act at the centre of the chimney.

Step 3 of 8

Drag force acting on the chimney can be found out using the formula given below,

$$F_D = \frac{1}{2} C_D \rho A V^2 \quad \ldots\ldots (1)$$

Where, C_D is the drag coefficient.

ρ is the density of air.

A is the frontal area of the chimney.

V is the velocity of wind.

In the above equation drag coefficient C_D is unknown so in order to find out the drag coefficient we have to find out the Reynolds number.

Step 4 of 8

Reynolds number can be found out using the formula given below,

$$\text{Re} = \frac{VD}{\nu} \quad \ldots\ldots (2)$$

Where, V is the velocity of the air.

D is the diameter of the spherical tank.

ν is the kinematic viscosity.

Here, velocity,

$$V = 110 \text{ km/h}$$

$$= 110\left(\frac{5}{18}\right) \text{m/s}$$

$$= 30.55 \text{ m/s}$$

Step 5 of 8

Substitute all the values in equation (2)

$$\text{Re} = \frac{30.55(1.6)}{1.516 \times 10^{-5}}$$

$$= 3.22 \times 10^6$$

From the graph, 'Effect of surface roughness on the drag coefficient of a sphere'

The drag coefficient (C_D) corresponding to the obtained Reynolds number is,

$$C_D = 0.15$$

Step 6 of 8

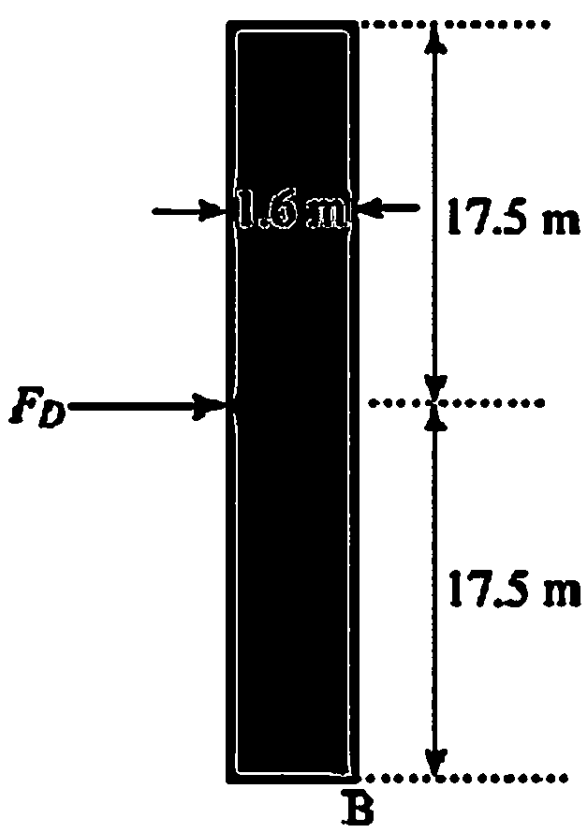
Now, frontal area of the chimney,

$$A = h \times D$$

$$= 35 \times 1.6$$

$$= 56 \text{ m}^2$$

Now, substitute all the values in equation (1)



$$F_D = \frac{1}{2} C_D \rho A V^2$$

$$= \frac{1}{2} \times 0.15 \times 1.204 \times 56 \times (30.55)^2$$

$$= 4719.5 \text{ N}$$

Step 7 of 8

Now, draw the free body diagram of the chimney to show the forces acting on it.

Step 8 of 8

Now, to find out the bending moment about the base of the chimney, take moment about B.

$$+\circlearrowleft \sum M_B$$

$$M_B = F_D(17.5)$$

$$= 4719.5(17.5)$$

$$= 82591.25 \text{ N} \cdot \text{m}$$

Therefore the bending moment at the base of the chimney, $\boxed{M_B = 82591.25 \text{ N} \cdot \text{m}}$.

Question: 15.093P

Consider a blimp that can be approximated as a 3-m diameter, 8-m long ellipsoid and is connected to the ground. On a windless day, the rope tension due to the net buoyancy effect is measured to be 120 N. Determine the rope tension when there are 50 km/h winds blowing along the blimp (parallel to the blimp axis).

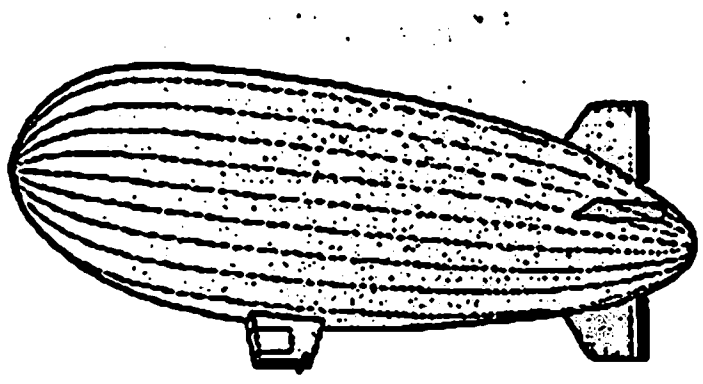


FIGURE P15–93

Step 1 of 6

Diameter of the blimp, $D = 3\,\text{m}$

Length of the blimp, $L = 8\,\text{m}$

Rope tension, $T = 120\,\text{N}$

Velocity of the wind, $V = 50\,\text{km/h}$

Step 2 of 6

The drag force acting on the blimp can be calculated using the formula given below,

$$F_D = \frac{1}{2} C_D \rho A V^2 \qquad \ldots\ldots (1)$$

Where, C_D is the drag coefficient.

ρ is the density of air.

A is the frontal area of the blimp.

V is the velocity of the wind.

Step 3 of 6

Frontal area of the parachute,

$$A = \frac{\pi}{4} D^2$$

Here, $D = 3\,\text{m}$.

Substitute the value in the above equation.

$$A = \frac{\pi}{4}(3)^2$$

$$= 7.065\,\text{m}^2$$

Drag coefficient for the balloon is, $C_D = 0.1$

Step 4 of 6

From the table properties of air,

Density of air at 1atm pressure and 25°C is, $\rho = 1.184\,\text{kg/m}^3$

Velocity of air,

$$V = 50\,\text{km/h}$$

$$= 50\left(\frac{5}{18}\right)\text{m/s}$$

$$= 13.88\,\text{m/s}$$

Step 5 of 6

Now, substitute all the known values in equation (1)

$$F_D = \frac{1}{2} C_D \rho A V^2$$

$$= \frac{1}{2} \times 0.1 \times 1.184 \times 7.065 \times (13.88)^2$$

$$= 80.577\,\text{N}$$

Step 6 of 6

Now, the rope tension is the sum of rope tension due to buoyancy effect and the force due to wind blowing.

Therefore, rope tension is,

$$T = 120 + F_D$$

$$= 120 + 80.577$$

$$= 200.577\,\text{N}$$

Therefore, the rope tension is, $\boxed{T = 200.577\,\text{N}}$

Question: 15.094P

A commercial airplane has a total mass of 150,000 lbm and a wing planform area of 1800 ft2. The plane has a cruising speed of 550 mi/h and a cruising altitude of 38,000 ft where the air density is 0.0208 lbm/ft3. The plane has double-slotted flaps for use during takeoff and landing, but it cruises with all flaps retracted. Assuming the lift and drag characteristics of the wings can be approximated by NAC A 23012, determine (*a*) the minimum safe speed for takeoff and landing with and without extending the flaps, (*b*) the angle of attack to cruise steadily at the cruising altitude, and (*c*) the power that needs to be supplied to provide enough thrust to overcome drag. Take the air density on the ground to be 0.075 lbm/ft3.

Step 1 of 5

Mass of the air plane is $m = 150000\,\text{lbm}$

Speed of the air plane, $V = 550\,\text{mi/h} = 806.7\,\text{ft/s}$

Area of the wines, $A = 1800\,\text{ft}^2$

Air density, $\rho = 0.0208\,\text{lbm/ft}^3$

Step 2 of 5

From the figure of variation of lift coefficient with angle of attack for a symmetrical section"

$C = 3.48$

$C_2 = 1.52$

Weight of air plane is

$$W = mg$$
$$= 150000 \times 32.2$$
$$= 150000\,\text{lbf}$$

Mean velocity corresponding stalling is

$$V_1 = \sqrt{\frac{2W}{\rho C A}}$$
$$= \sqrt{\frac{2 \times 150000}{0.075 \times 3.48 \times 1800}}$$
$$= 217 \frac{\text{ft}}{\text{s}}$$
$$V_2 = \sqrt{\frac{2W}{\rho C_2 A}}$$
$$= \sqrt{\frac{2 \times 150000}{0.075 \times 3.48 \times 1800}}$$
$$= 143 \frac{\text{ft}}{\text{s}}$$

Step 3 of 5

Without flaps,

$$V = 1.2(V_1)$$
$$= 1.2(217)$$
$$= 178\,\text{mph}$$
$$V_{flaps} = 1.2V_2$$
$$= 1.2(143)$$
$$V_{flaps} = 172 \frac{\text{ft}}{\text{s}}$$

Therefore, velocity of the air plane with flaps is $\boxed{V_{flaps} = 172 \frac{\text{ft}}{\text{s}}}$

Step 4 of 5

b)

Coefficient of lift is given as

$$C_L = \frac{F_L}{\frac{1}{2}\rho V^2 A}$$
$$= \frac{150000}{\frac{1}{2} \times 0.0208 \times 806.7}$$
$$= 0.400$$

From the figure of drag coefficient corresponds angle of attack is $\boxed{\alpha = 3.4^\circ}$

Step 5 of 5

c)

Power needed to run the plane is

$$P = F \times V$$
$$= \left(C_D A \frac{\rho V^2}{2} \right) V$$
$$= \left(0.0153 \times 1800 \times \frac{0.0208 \times 806.7}{2} \right) 806.7$$
$$= 6199.90\,\text{W}$$

Therefore, power needed to run the air plane is $\boxed{P = 6199.90\,\text{W}}$

Question: 15.095P

A 9-cm-diameter smooth sports ball has a velocity of 36 km/h during a typical hit. Determine the percent increase in ithe drag coefficient if the ball is given a spin of 3500 rpm in'air at 1 atm and 25°C.

Step 1 of 6

Given data:-
Diameter of the ball, $D = 9$ cm.
Velocity of the ball, $V = 36$ km/h.
Number of revolutions, $N = 3500$ rpm.
Atmospheric conditions,
Temperature of the air, $T = 25\,^{\circ}C$.
Pressure of the air, $P = 1$ atm.

Step 2 of 6

Since we have to find out the percentage increase in drag coefficient we have to determine the drag coefficient of the ball with spinning and with out spinning.
Since here the drag force acting is not given it is not possible to calculate the drag coefficient directly so in order to calculate the drag coefficient we have to first calculate the Reynolds number and nondimensional rate of rotation after calculating that we can find the drag coefficient using the graphs 'The effect of surface roughness on the drag coefficient of a sphere' for a ball without spinning and 'The variation of lift and drag coefficients of a smooth sphere with the nondimensional rate of rotation for $\mathrm{Re} = 6\times10^4$' for a ball with spinning.
First of all let us calculate the drag coefficient of the ball with out spinning.
For that first of all calculate the Reynolds number using the formula given below.

$$\mathrm{Re} = \frac{VD}{\nu} \qquad \ldots\ldots (1)$$

Where, V is the velocity of the ball.
D is the diameter of the ball.
ν is the kinematic viscosity of air.
From the table 'Properties of air at 1atm pressure',
Kinematic viscosity of air, $\nu = 1.562\times10^{-5}\,\mathrm{m^2/s}$.

Step 3 of 6

Now, the velocity of ball,

$$V = 36\ \mathrm{km/h}$$
$$= 36\left(\frac{5}{18}\right)\mathrm{m/s}$$
$$= 10\ \mathrm{m/s}$$

Diameter of the ball,

$$D = 9\ \mathrm{cm}$$
$$= 0.09\ \mathrm{m}$$

Step 4 of 6

Now, substitute all the known values in equation (1)

$$\mathrm{Re} = \frac{VD}{\nu}$$
$$= \frac{10\times0.09}{1.562\times10^{-5}}$$
$$= 5.76\times10^4$$

Now, using the graph 'The effect of surface roughness on the drag coefficient of a sphere' the drag coefficient of the ball corresponding to the obtained Reynolds number is, $\boxed{C_D = 0.49}$, this is for a ball with out spinning.

Step 5 of 6

Now, to calculate the drag coefficient of the ball with spin, calculate the nondimensional rate of rotation.

$$\text{nondimensional rate of rotation} = \frac{\varpi D}{2V} \qquad \ldots\ldots (2)$$

Where, ϖ is the angular velocity.
D is the diameter of the ball.
V is the linear velocity of the ball.
Here the angular velocity ϖ is unknown so we have to calculate it using the formula given below.

$$\varpi = \frac{2\pi N}{60}$$

Where, N is the number of revolutions.

$$\varpi = \frac{2\times3.14\times3500}{60}$$
$$= 366.33$$
$$= 367\ \mathrm{rad/sec}$$

Now, substitute all the values in equation (2)

$$\text{nondimensional rate of rotation} = \frac{367\times0.09}{2\times10}$$
$$= 1.65\ \mathrm{rad}$$

Step 6 of 6

The Reynolds number that we have obtained is $\mathrm{Re} = 5.76\times10^4$ which is close to $\mathrm{Re} = 6\times10^4$ we can use the graph 'The variation of lift and drag coefficients of a smooth sphere with the nondimensional rate of rotation for $\mathrm{Re} = 6\times10^4$'.
Now, using the graph 'The variation of lift and drag coefficients of a smooth sphere with the nondimensional rate of rotation for $\mathrm{Re} = 6\times10^4$' the drag coefficient corresponding to the obtained nondimensional rate of rotation is, $\boxed{C_D = 0.59}$.
Therefore,
Drag coefficient (without spin), $C_{D\,no\,spin} = 0.49$
Drag coefficient (with spin), $C_{D\,spin} = 0.59$
Now, the percent increase in drag coefficient,

$$C_{D\,increase} = \frac{C_{D\,spin} - C_{D\,no\,spin}}{C_{D\,no\,spin}}$$
$$= \frac{0.59 - 0.49}{0.49}$$
$$= 0.20$$

Now, percent increase in C_D

$$C_{D\,increase} = 0.20\times100$$
$$= 20\%$$

Therefore, the percent increase is $\boxed{C_{D\,increase} = 20\%}$.

Question: 15.096P

A paratrooper and his 8-m-diameter parachute weigh 950 N. Taking the average air density to be 1.2 kg/m3, determine the terminal velocity of the paratrooper.

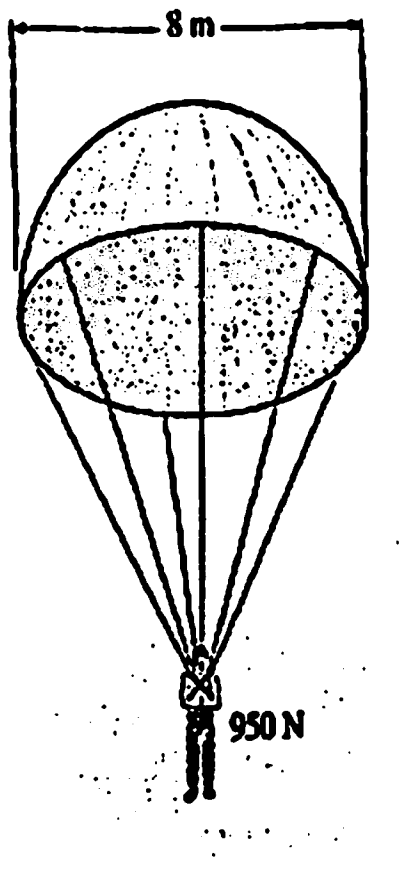

FIGURE P15–96

Step 1 of 4

Given data:-

Diameter of the parachute, $D = 8\ \text{m}$.

Weight of the paratrooper and the parachute, $W = 950\ \text{N}$.

Density of air, $\rho = 1.2\ \text{kg/m}^3$

Step 2 of 4

When a body falls freely the acceleration of the body will be equal to $9.8\ \text{m/s}^2$, the weight of the body will acts downwards and the drag force and buoyancy force will acts upwards. Terminal velocity of the body will be reached when the drag force acting will be equal to the difference of weight and buoyancy force acting on it.

$F_D = W - F_B$

Where, F_D is the drag force.

W is the weight of the body.

F_B is the buoyancy force.

Here, $F_B \cong 0$ (F_B is approximately equal to zero)

Therefore, $F_D = W$ ..... (1)

Now, drag force,

$$F_D = \frac{1}{2} C_D \rho A V^2 \quad \text{..... (2)}$$

Where, C_D is the drag coefficient.

ρ is the density of air.

A is the frontal area of the parachute.

V is the terminal velocity.

Step 3 of 4

Frontal area of the parachute,

$$A = \frac{\pi}{4} D^2$$

Here, $D = 8\ \text{m}$.

Substitute the value in the above equation.

$$A = \frac{\pi}{4}(8)^2$$

$$= 50.24\ \text{m}^2$$

Drag coefficient for a parachute is, $C_D = 1.3$

Step 4 of 4

Substitute all the known values in equation (2)

$$F_D = \frac{1}{2} \times 1.3 \times 1.2 \times 50.24 \times V^2$$

$$= 39.2\, V^2$$

Substitute the value of F_D in equation (1)

$$39.2\, V^2 = 950$$

$$V^2 = \frac{950}{39.2}$$

$$V^2 = 24.23$$

$$V = 4.9\ \text{m/s}$$

Therefore the terminal velocity of the paratrooper, $\boxed{V = 4.9\ \text{m/s}}$.

Question: 15.097P

It is proposed to meet the water needs of a recreational vehicle (RV) by installing a 2-m-long, 0.5-m-diameter cylindrical tank on top of the vehicle. Determine the additional power requirement of the RV at a speed of 95 km/h when the tank is installed such that its circular surfaces face (*a*) the front and back (as sketched) and (*b*) the sides of the RV. Assume atmospheric conditions are 87 kPa and 20°C.

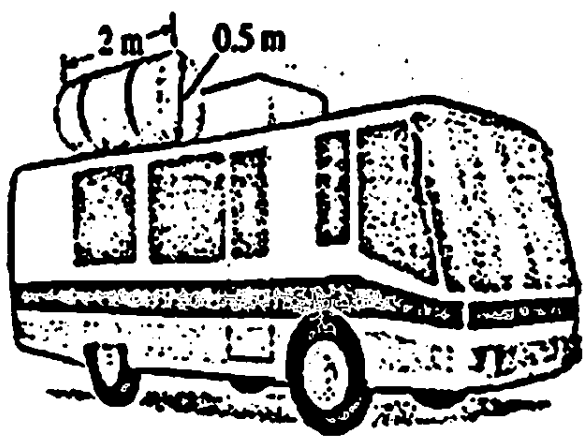

FIGURE P15–97

Step 1 of 5

Given data:

Length of the cylindrical tank, $L = 2$ m

Diameter of the cylindrical tank, $D = 0.5$ m

Speed of the vehicle, $V = 95$ km/h

Atmospheric conditions,

Pressure of the air, $P = 87$ kPa

Temperature of the air, $T = 20°C$

Step 2 of 5

a) Circular surfaces face the front and back of the vehicle.

Drag force acting on the tank is found out using the formula given below,

$$F_D = \frac{1}{2} C_D \rho A V^2 \qquad \ldots\ldots (1)$$

Where, C_D is the drag coefficient

ρ is the density of air.

A is the frontal area of the tank.

V is the velocity of the vehicle.

Velocity of the vehicle,

$$V = 95 \text{ km/h}$$

$$= 95\left(\frac{5}{18}\right) \text{m/s}$$

$$= 26.4 \text{ m/s}$$

Since for horizontal cylinder with ratio $L/D = 4$, drag coefficient, $C_D = 0.9$

Step 3 of 5

Here, frontal area,

$$A = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.5)^2$$

$$= 0.19625 \text{ m}^2$$

From the table 'properties of air'

Density of air, $\rho = 1.027 \text{ kg/m}^3$

Substitute all the values in equation (1)

$$F_D = \frac{1}{2} \times 0.9 \times 1.027 \times 0.19625 \times (26.4)^2$$

$$= 63.21 \text{ N}$$

Power required for overcoming drag force,

$$P = F_D \times V$$

$$= 63.21 \times 26.4$$

$$= 1668.74 \text{ Watt}$$

Therefore the additional power required is, $\boxed{P = 1.67 \text{ kW}}$

Step 4 of 5

b) Circular surfaces face the sides of the vehicle.

Drag force acting on the tank is found out using the formula given below,

$$F_D = \frac{1}{2} C_D \rho A V^2 \qquad \ldots\ldots (1)$$

Where, C_D is the drag coefficient.

ρ is the density of air.

A is the frontal area of the tank.

V is the velocity of the vehicle.

Velocity of the vehicle,

$$V = 95 \text{ km/h}$$

$$= 95\left(\frac{5}{18}\right) \text{m/s}$$

$$= 26.4 \text{ m/s}$$

Here, drag coefficient, $C_D = 0.8$

Here, frontal area,

$$A = L \times D$$

$$= 2 \times 0.5$$

$$= 1 \text{ m}^2$$

Step 5 of 5

From the table 'properties of air'

Density of air, $\rho = 1.027 \text{ kg/m}^3$

Substitute all the values in equation (1)

$$F_D = \frac{1}{2} \times 0.8 \times 1.027 \times 1 \times (26.4)^2$$

$$= 286.3 \text{ N}$$

Power required for overcoming this drag,

$$P = F_D \times V$$

$$= 286.3 \times 26.4$$

$$= 7558.6 \text{ Watt}$$

Therefore the additional power required is, $\boxed{P = 7.55 \text{ kW}}$

Question: 15.098P

A 17,000-kg tractor-trailer rig has a frontal area of 92 m2, a drag coefficient of 0.96, a rolling resistance coefficient of 0.05 (multiplying the weight of a vehicle by the rolling resistance coefficient gives the rolling resistance), a bearing friction resistance of 350 N, and a maximum speed of 110 km/h on a level road during steady cruising in calm weather with an air density of 1.25 kg/m3. Now a fairing is installed to the front of the rig to suppress separation and to streamline the flow to the top surface, and the drag coefficient is reduced to 0.76. Determine the maximum speed of the rig with the fairing.

Step 1 of 7

Loading solution. Please wait ...

Step 2 of 7

In order to calculate the maximum speed of the rig with the fairing, let us calculate the maximum power of the vehicle

Power developed can be found out using the equation given below.

P = Force × Velocity

Here,

Force is the sum of all the resistive forces acting on the tractor-trailer rig which are bearing friction, drag force and rolling resistance.

Velocity is the maximum velocity of the tractor-trailer rig, maximum power occurs at maximum velocity.

Therefore, we have maximum power,

$$P = \left(F_{D1} + F_{\text{Bearing}} + F_{RR}\right) V_1 \qquad \text{..... (1)}$$

Where, F_{D1} is the drag force acting on the tractor-trailer rig with out fairing.

F_{Bearing} is the bearing resistance

F_{RR} is the rolling resistance

V_1 is the maximum velocity of the tractor-trailer rig

Step 3 of 7

Here, F_{D1} and F_{RR} are unknown so we have to calculate it as follows,

Now, the drag force acting on the tractor-trailer rig with out fairing,

$$F_{D1} = \frac{1}{2} C_{D_1} \rho A V_1^2 \qquad \text{..... (2)}$$

Where, C_{D1} drag coefficient.

ρ is the density of air.

A is the frontal area.

V_1 is the maximum speed

Here, maximum speed,

$$V_1 = 110 \text{ km/h}$$

$$= 110\left(\frac{5}{18}\right)$$

$$= 30.55 \text{ m/s}$$

Substitute all the known values in equation (2), we get

$$F_{D1} = \frac{1}{2} C_{D_1} \rho A V_1^2$$

$$= \frac{1}{2} \times 0.96 \times 1.25 \times 9.2 \times (30.55)^2$$

$$= 5151.83 \text{ N}$$

Step 4 of 7

It has given that rolling resistance is the product of weight of the vehicle and rolling resistance coefficient.

Therefore, rolling resistance $F_{RR} = W \times C_{RR}$ ..... (3)

Weight of the vehicle, $W = mg$

Where, m is the mass.

g is the acceleration due to gravity

Therefore, $W = 17000 \times 9.81$

Substitute all the values in equation (3), we get

$$F_{RR} = 17000 \times 9.81 \times 0.05$$

$$= 8339 \text{ N}$$

Now, substitute all the calculated values in equation (1).

$$P = \left(F_{D1} + F_{\text{Bearing}} + F_{RR}\right) V_1$$

$$= (5151.83 + 350 + 8339)\, 30.55$$

$$= 422837.36 \text{ Watt}$$

$$= \frac{422837.36}{1000} \text{ kW}$$

$$= 423 \text{ kW}$$

Therefore, the maximum power the vehicle can developed is, $P = 423$ kW

Step 5 of 7

Now, a fairing is installed and the drag coefficient reduces to 0.76.

Therefore, $C_{D2} = 0.76$

Let us calculate the maximum speed of the rig in this condition.

It can be calculated using the equation given below.

$$P = \left(F_{D2} + F_{\text{Bearing}} + F_{RR}\right) V_2 \qquad \text{..... (4)}$$

Where, F_{D2} is the drag force acting on the tractor-trailer rig with fairing.

F_{Bearing} is the bearing resistance

F_{RR} is the rolling resistance

V_2 is the maximum velocity of the tractor-trailer rig

Step 6 of 7

$$F_{D2} = \frac{1}{2} C_{D_2} \rho A V_2^2$$

Where, C_{D2} drag coefficient

ρ is the density of air

A is the frontal area

V_2 is the maximum speed

Step 7 of 7

Substitute all the values in the above equation, we get,

$$F_{D2} = \frac{1}{2} C_{D_2} \rho A V_2^2$$

$$= \frac{1}{2} \times 0.76 \times 1.25 \times 9.2 \times V_2^2$$

$$= 4.37\, V_2^2$$

Substitute all the values in equation (4)

$$P = \left(F_{D2} + F_{\text{Bearing}} + F_{RR}\right) V_2$$

$$423000 = \left(4.37\, V_2^2 + 350 + 8339\right) V_2$$

$$423000 = \left(4.37\, V_2^2 + 8689\right) V_2$$

$$423000 = 4.37\, V_2^3 + 8689\, V_2$$

$$4.37\, V_2^3 + 8689\, V_2 - 423000 = 0$$

Solving the above equation we get V_2 as 32.08 m/s

$$V_2 = \frac{32.08 \times 3600}{10^3}$$

$$= 115.5 \text{ km/h}$$

Therefore, the maximum speed of the rig with the fairing is, $\boxed{V_2 = 115.5 \text{ km/h}}$

Question: 15.099P

Stokes law can be used to determine the viscosity of a fluid by dropping a spherical object in it and measuring the terminal velocity of the object in that fluid. This can be done by plotting the distance traveled against time and observing when the curve becomes linear. During such an experiment a 3-inm-diameter glass ball (ρ = 2500 kg/m3) is dropped into a fluid whose density is 875 kg/m3, and the terminal velocity is measured to be 0.16 m/s. Disregarding the wall effects, determine the viscosity of the fluid.

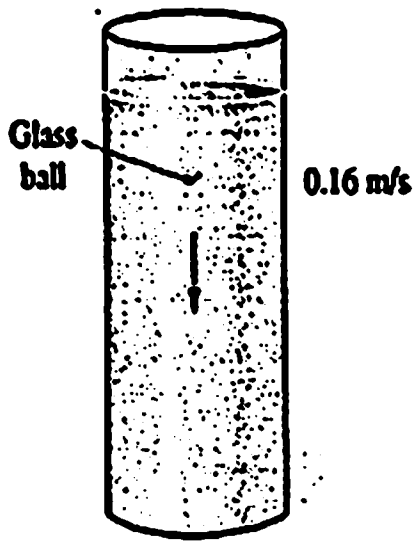

FIGURE P15–99

Step 1 of 4

Given data:

Diameter of the glass ball, $D = 3$ mm

Density of the glass ball, $\rho_s = 2500\ \text{kg/m}^3$

Density of the fluid, $\rho_f = 875\ \text{kg/m}^3$

Terminal velocity of the ball, $V = 0.16$ m/s

Step 2 of 4

The terminal velocity of freely falling body is reached when the drag force becomes equal to the difference of weight of the body and buoyancy force acting on it.

$F_D = W - F_B$ ..... (1)

Where, F_D drag force.

W is the weight of the body.

F_B is the buoyancy force.

According to Stokes law,

$F_D = 3\pi\mu VD$

Where, μ is the dynamic viscosity of fluid.

V is the terminal velocity.

D is the diameter of the glass ball.

Step 3 of 4

Now, weight of the body,

$W = \rho_s gV$

Where, ρ_s is the density of the glass ball.

g is the acceleration due to gravity.

V is the volume of the glass.

The buoyancy force applied by the fluid,

$F_B = \rho_f gV$

Where, ρ_f is the density of the fluid.

g is the acceleration due to gravity.

V is the volume of the glass.

Step 4 of 4

By substituting all the values in equation (1), we get,

$3\pi\mu VD = \rho_s gV - \rho_f gV$

$$3\pi\mu VD = g\frac{\pi D^3}{6}(\rho_s - \rho_f)$$

$$\mu = \frac{gD^2}{18}(\rho_s - \rho_f)$$

$$= \frac{9.81 \times .003^2}{18}(2500 - 875)$$

$$= 0.05\ \text{kg/m} \cdot \text{s}$$

Therefore, the viscosity of the fluid is, $\boxed{\mu = 0.05\ \text{kg/m} \cdot \text{s}}$

Question: 15.100P

During an experiment, three aluminum balls (ρs =2600 kg/m3) having diameters 2, 4, and 10 mm, respectively, are dropped into a tank filled with glycerin at 22°C (ρf = 1274 kg/m3 and μ = 1 kg/m-s). The terminal settling velocities of the balls are measured to be 3.2, 12.8, and 60.4 mm/s, respectively. Compare these values with the velocities predicted by Stokes law for drag force $FD = 3\pi\mu DV$, which is valid for very low Reynolds numbers (Re $\ll$ 1). Determine the error involved for each case and assess the accuracy of Stokes law.

Step 1 of 9

Loading solution. Please wait ...

Step 2 of 9

The terminal velocity of freely falling body is reached when the drag force becomes equal to the difference of weight of the body and buoyancy force acting on it.

$$F_D = W - F_B \qquad \ldots\ldots (1)$$

Where, F_D drag force.

W is the weight of the ball.

F_B is the buoyancy force

According to Stokes law,

$$F_D = 3\pi\mu VD$$

Where, μ is the dynamic viscosity of fluid.

V is the terminal velocity.

D is the diameter of the ball.

Step 3 of 9

Now, weight of the body,

$$W = \rho_s gV$$

Where, ρ_s is the density of the ball.

g is the acceleration due to gravity.

V is the volume of the ball.

Now, the buoyancy force applied by the fluid,

$$F_B = \rho_f gV$$

Where, ρ_f is the density of the fluid.

g is the acceleration due to gravity.

V is the volume of the ball, $V = \frac{\pi}{6}D^3$

Step 4 of 9

Now, substitute all the values in equation (1), we get,

$$3\pi\mu VD = \rho_s gV - \rho_f gV$$

$$V = \frac{gV(\rho_s - \rho_f)}{3\pi\mu D}$$

$$= \frac{g\pi D^3(\rho_s - \rho_f)}{18\pi\mu D}$$

$$= \frac{9.81(0.002)^2(2600-1274)}{18\times 1}$$

$$= 0.0029 \text{ m/s}$$

Terminal setting velocity of the first ball,

$$V_1 = 3.2 \text{ mm/s}$$

$$= 0.0032 \text{ m/s}$$

Therefore the velocity of the first ball according to Stokes law is, $V = 0.0029$ m/s and experimental velocity is, $V_1 = 0.0032$ m/s

Step 5 of 9

Therefore the error is,

$$\text{Error} = \frac{V_1 - V}{V_1}\times 100$$

$$= \frac{0.0032 - 0.0029}{0.0032}\times 100$$

$$= 9.37\ \%$$

Therefore, the error involved in first ball is, $\boxed{\text{Error} = 9.37\ \%}$

Step 6 of 9

The velocity of second ball,

$$V = \frac{gV(\rho_s - \rho_f)}{3\pi\mu D}$$

$$= \frac{g\pi D^3(\rho_s - \rho_f)}{18\pi\mu D}$$

$$= \frac{9.81(0.004)^2(2600-1274)}{18\times 1}$$

$$= 0.012 \text{ m/s}$$

Terminal setting velocity of the second ball,

$$V_2 = 12.8 \text{ mm/s}$$

$$= 0.0128 \text{ m/s}$$

Therefore, the velocity of second ball according to Stokes law is, $V = 0.012$ m and experimental velocity is, $V_2 = 0.0128$ m/s

Step 7 of 9

Now, the error involved for the second ball,

$$\text{Error} = \frac{V_2 - V}{V_2}\times 100$$

$$= \frac{0.0128 - 0.012}{0.0128}\times 100$$

$$= 6.25\ \%$$

Therefore, the error involved in second ball is, $\boxed{\text{Error} = 6.25\ \%}$

Step 8 of 9

The velocity of third ball,

$$V = \frac{gV(\rho_s - \rho_f)}{3\pi\mu D}$$

$$= \frac{g\pi D^3(\rho_s - \rho_f)}{18\pi\mu D}$$

$$= \frac{9.81(0.01)^2(2600-1274)}{18\times 1}$$

$$= 0.072 \text{ m/s}$$

Terminal setting velocity of the second ball,

$$V_3 = 60.4 \text{ mm/s}$$

$$= 0.0604 \text{ m/s}$$

Therefore the velocity according to Stokes law is, $V = 0.072$ m and experimental velocity is, $V_3 = 0.0604$ m/s.

Step 9 of 9

Now, the error involved for the third ball,

$$\text{Error} = \frac{V_3 - V}{V_3}$$

$$= \frac{0.0604 - 0.072}{0.0604}$$

$$= -0.192$$

$$= -19.2\ \%$$

Therefore, the error involved in the third ball is, $\boxed{\text{Error} = -19.2\ \%}$

Question: 15.101P pg 1

Repeat Prob. 15-100 by considering the more general form of Stokes law expressed as$F_D = 3\pi\mu DV + (9\pi/16)\rho V^2D^2$ whereρ is the fluid density.

Step 1 of 11

Given data:

Density of aluminum balls, $\rho_s = 2600\ \text{kg/m}^3$

Diameter of the first aluminum ball, $D_1 = 2\ \text{mm}$

Diameter of the second aluminum ball, $D_2 = 4\ \text{mm}$

Diameter of the third aluminum ball, $D_3 = 10\ \text{mm}$

Temperature of glycerin, $T = 22°\text{C}$

Density of glycerin, $\rho_f = 1274\ \text{kg/m}^3$

Dynamic viscosity of glycerin, $\mu = 1\ \text{kg/m}\cdot\text{s}$

Terminal setting velocity of the first ball, $V_1 = 3.2\ \text{mm/s}$

Terminal setting velocity of the second ball, $V_2 = 12.8\ \text{mm/s}$

Terminal setting velocity of the third ball, $V_3 = 60.4\ \text{mm/s}$

Step 2 of 11

The terminal velocity of freely falling body is reached when the drag force becomes equal to the difference of weight of the body and buoyancy force acting on it.

$$F_D = W - F_B \qquad \ldots\ldots (1)$$

Where, F_D drag force.

W is the weight of the ball.

F_B is the buoyancy force

According to Stokes law,

$$F_D = 3\pi\mu VD + \left(\frac{9\pi}{16}\right)\rho V^2D^2$$

Where, μ is the dynamic viscosity of fluid.

V is the terminal velocity.

D is the diameter of the ball.

ρ is the density of fluid.

Step 3 of 11

Now, weight of the body,

$$W = \rho_s gV$$

Where, ρ_s is the density of the ball

g is the acceleration due to gravity.

V is the volume of the ball.

Now, the buoyancy force applied by the fluid,

$$F_B = \rho_f gV$$

Where, ρ_f is the density of the fluid.

g is the acceleration due to gravity.

V is the volume of the ball.

Step 4 of 11

Now, by substituting all the values in equation (1), we get

$$3\pi\mu VD + \left(\frac{9\pi}{16}\right)\rho V^2D^2 = \rho_s gV - \rho_f gV$$

$$3\pi\mu VD + \left(\frac{9\pi}{16}\right)\rho V^2D^2 = gV\left(\rho_s - \rho_f\right)$$

Now, to find the velocity of ball solve the above quadratic for V.

$$V = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \qquad \ldots\ldots (2)$$

Where,

$$a = \left(\frac{9\pi}{16}\right)\rho D^2$$

$$b = 3\pi\mu D$$

$$c = -gV\left(\rho_s - \rho_f\right)$$

Step 5 of 11

Diameter of the first ball,

$$D_1 = 2\ \text{mm}$$
$$= 0.002\ \text{m}$$

Terminal setting velocity of the first ball,

$$V_1 = 3.2\ \text{mm/s}$$
$$= 0.0032\ \text{m/s}$$

For first ball,

$$a = \left(\frac{9\pi}{16}\right)\rho D^2$$
$$= \left(\frac{9\pi}{16}\right) \times 1274 \times (0.002)^2$$
$$= 0.009$$
$$b = 3\pi\mu D$$
$$= 3 \times 3.14 \times 1 \times 0.002$$
$$= 0.01884$$
$$c = -gV\left(\rho_s - \rho_f\right)$$
$$= -g\frac{\pi D^3}{6}\left(\rho_s - \rho_f\right)$$
$$= -9.81 \times \frac{3.14 \times (0.002)^3}{6}(2600 - 1274)$$
$$= -0.0000545$$

Step 6 of 11

Substitute all known values in equation (2), we get,

$$V = \frac{-b + \sqrt{b^2 - 4ac}}{2a}$$
$$= \frac{-0.01884 + \sqrt{0.01884^2 - 4(0.009 \times -0.0000545)}}{2 \times 0.009}$$
$$= 0.0029\ \text{m/s}$$

$$V = \frac{-b + \sqrt{b^2 - 4ac}}{2a}$$

$$= \frac{-0.01884 + \sqrt{0.01884^2 - 4(0.009 \times -0.0000545)}}{2 \times 0.009}$$

$$= 0.0029 \text{ m/s}$$

Therefore, the velocity of first ball according to Stokes law is, $V = 0.0029$ m/s and experimental velocity is, $V_1 = 0.0032$ m/s

Therefore the error is,

$$\text{Error} = \frac{V_1 - V}{V_1} \times 100$$

$$= \frac{0.0032 - 0.0029}{0.0032} \times 100$$

$$= 9.375\ \%$$

Therefore, here the error involved is, $\boxed{\text{Error} = 9.375\ \%}$

Step 7 of 11

Diameter of the second ball,

$D_2 = 4$ mm

$= 0.004$ m

Terminal setting velocity of the second ball,

$V_2 = 12.8$ mm/s

$= 0.0128$ m/s

For second ball

$$a = \left(\frac{9\pi}{16}\right)\rho D^2$$

$$= \left(\frac{9\pi}{16}\right) \times 1274 \times (0.004)^2$$

$$= 0.036$$

$$b = 3\pi\mu D$$

$$= 3 \times 3.14 \times 1 \times 0.004$$

$$= 0.03768$$

$$c = -gV(\rho_s - \rho_f)$$

$$= -g\frac{\pi D^3}{6}(\rho_s - \rho_f)$$

$$= -9.81 \times \frac{3.14 \times (0.004)^3}{6}(2600 - 1274)$$

$$= -0.00044$$

Step 8 of 11

Substitute all known values in equation (2), we get,

$$V = \frac{-b + \sqrt{b^2 - 4ac}}{2a}$$

$$= \frac{-0.03768 + \sqrt{0.03768^2 - 4(0.036 \times -0.00044)}}{2 \times 0.036}$$

$$= 0.0115 \text{ m/s}$$

Therefore the velocity of second ball according to Stokes law is, $V = 0.0115$ m/s and experimental velocity is, $V_2 = 0.0128$ m/s

Now, the error involved for the second ball,

$$\text{Error} = \frac{V_2 - V}{V_2} \times 100$$

$$= \frac{0.0128 - 0.0115}{0.0128} \times 100$$

$$= 10.16\ \%$$

Therefore, here the error involved is, $\boxed{\text{Error} = 10.16\ \%}$

Step 9 of 11

Diameter of the third ball,

$D_3 = 10$ mm

$= 0.01$ m

Terminal setting velocity of the second ball,

$V_3 = 60.4$ mm/s

$= 0.0604$ m/s

For the third ball,

$$a = \left(\frac{9\pi}{16}\right)\rho D^2$$

$$= \left(\frac{9\pi}{16}\right) \times 1274 \times (0.01)^2$$

$$= 0.225$$

Step 10 of 11

$$b = 3\pi\mu D$$

$$= 3 \times 3.14 \times 1 \times 0.01$$

$$= 0.0942$$

$$c = -gV(\rho_s - \rho_f)$$

$$= -g\frac{\pi D^3}{6}(\rho_s - \rho_f)$$

$$= -9.81 \times \frac{3.14 \times (0.01)^3}{6}(2600 - 1274)$$

$$= -0.0068$$

Step 11 of 11

Substitute all known values in equation (2)

$$V = \frac{-b + \sqrt{b^2 - 4ac}}{2a}$$

$$= \frac{-0.0942 + \sqrt{0.0942^2 - 4(0.225 \times -0.0068)}}{2 \times 0.225}$$

$$= 0.063 \text{ m/s}$$

$V = \dfrac{}{2a}$ 15.101P pg 3

$$= \frac{-0.0942 + \sqrt{0.0942^2 - 4(0.225 \times -0.0068)}}{2 \times 0.225}$$

$$= 0.063 \text{ m/s}$$

Therefore the velocity of third ball according to Stokes law is, $V = 0.063$ m/s and experimental velocity is, $V_3 = 0.0604$ m/s

Now, the error involved for the third ball,

$$\text{Error} = \frac{V_3 - V}{V_3} \times 100$$

$$= \frac{0.0604 - 0.063}{0.0604} \times 100$$

$$= -4.3\%$$

Therefore, here the error involved is, $\boxed{\text{Error} = -4.3\%}$

Question:

Engine oil at 40°C is flowing over a long flat plate with a velocity of 6 m/s. Determine the distance xcr from the leading edge of the plate where the flow becomes turbulent, and calculate and plot the thickness of the boundary layer over a length of 2xCr.

Step 1 of 6

From the table A-19 "Properties of liquid" in the text book, take the value of kinematic viscosity for engine oil at temperature, $T = 40°C$.

$$\nu = \left(2.485\times10^{-4}\right)\ \text{m}^2/\text{s}$$

Calculate the distance x_{cr} from the leading edge of the plate where the flow becomes turbulent.

$$\text{Re}_{cr} = \frac{Vx_{cr}}{\nu}$$

Here, Re_{cr} is the critical Reynolds number and V is the velocity.

Substitute 5×10^5 for Re_{cr}, $\left(2.485\times10^{-4}\right)\ \text{m}^2/\text{s}$ for ν, and $6\ \text{m/s}$ for V .

$$5\times10^5 = \frac{6\times x_{cr}}{\left(2.485\times10^{-4}\right)}$$

$$\left(6\times x_{cr}\right) = 124.25$$

$$x_{cr} = 20.7\ \text{m}$$

Therefore, the distance x_{cr} from the leading edge of the plate where the flow becomes turbulent is $\boxed{20.7\ \text{m}}$.

Step 2 of 6

Use laminar flow relation to calculate the boundary layer thickness for first half of the flow, $x = 0$ to $20.7\ \text{m}$:

Assume $x = 4\ \text{m}$:

Calculate the Reynolds number.

$$\text{Re}_x = \frac{Vx}{\nu}$$

Substitute $4\ \text{m}$ for x, $\left(2.485\times10^{-4}\right)\ \text{m}^2/\text{s}$ for ν, and $6\ \text{m/s}$ for V .

$$\text{Re}_x = \frac{6\times4}{\left(2.485\times10^{-4}\right)}$$

$$= 96579.4768$$

Calculate the thickness of the boundary layer for laminar flow.

$$\left(\delta_x\right)_{\text{laminar}} = \frac{4.91x}{\text{Re}_x^{1/2}}$$

Substitute $4\ \text{m}$ for x, and 96579.4768 for Re_x.

$$\left(\delta_x\right)_{\text{laminar}} = \frac{4.91\times4}{\left(96579.4768\right)^{1/2}}$$

$$= 0.0632\ \text{m}$$

Step 3 of 6

Use turbulent flow relation to calculate the boundary layer thickness for second half of the flow.

$x = 20.7\ \text{m}$ to $2x_{cr}$

Substitute $20.7\ \text{m}$ to x_{cr}.

$$x = 20.7\ \text{m to}\ \left(2\times20.7\right)$$

$$= 20.7\ \text{m to}\ 41.4\ \text{m}$$

Assume $x = 24\ \text{m}$:

Calculate the Reynolds number.

$$\text{Re}_x = \frac{Vx}{\nu}$$

Substitute $24\ \text{m}$ for x, $\left(2.485\times10^{-4}\right)\ \text{m}^2/\text{s}$ for ν, and $6\ \text{m/s}$ for V .

$$\text{Re}_x = \frac{6\times24}{\left(2.485\times10^{-4}\right)}$$

$$= 579476.86116$$

Step 4 of 6

Calculate the thickness of the boundary layer for turbulent flow.

$$\left(\delta_x\right)_{\text{turbulent}} = \frac{0.38x}{\text{Re}_x^{1/5}}$$

Substitute $24\ \text{m}$ for x, and 579476.86116 for Re_x.

$$\left(\delta_x\right)_{\text{turbulent}} = \frac{0.38\times24}{\left(579476.86116\right)^{1/5}}$$

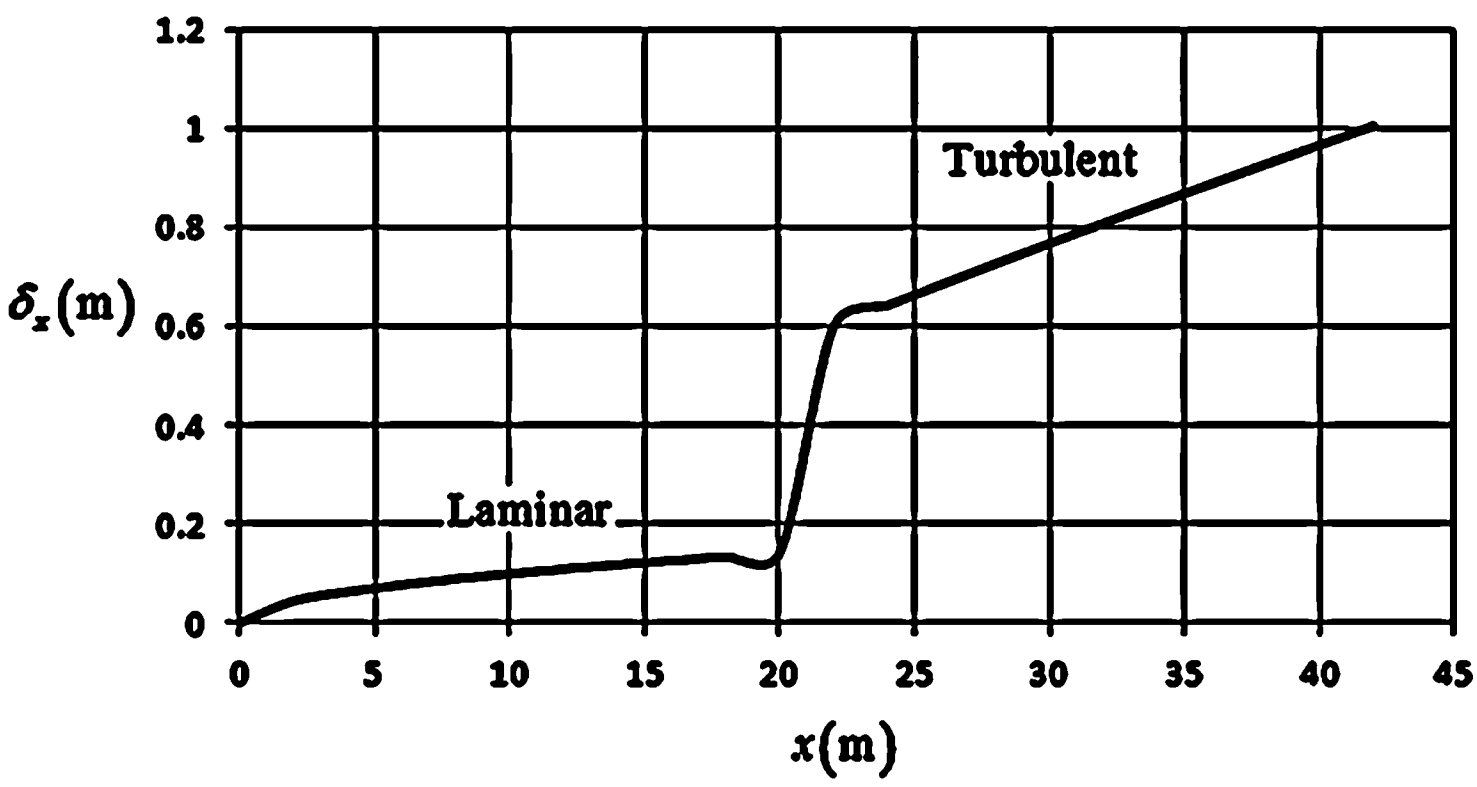
$$= \frac{9.12}{14.21043}$$

$$= 0.64178\ \text{m}$$

Step 5 of 6

Tabulate the values of thickness of the boundary layer for laminar and turbulent flows over a length of $41.4\ \text{m}$.

$x\ (\text{m})$	Re_x	$\left(\delta_x\right)_{\text{laminar}}$	$\left(\delta_x\right)_{\text{turbulent}}$
0	0	0	



Tabulate the values of thickness of the boundary layer for laminar and turbulent flows over a length of 41.4 m .

15.102P pg 2

x (m)	Re_x	$(\delta_x)_{\text{laminar}}$	$(\delta_x)_{\text{turbulent}}$

Step 6 of 6

Plot the thickness of the boundary layer over a length of $2x_{cr}\,(41.4\text{ m})$.

Question: 15.103P

Janie likes to drive with a tennis ball on her car antenna. The ball diameter is D = 2.62 in and its equivalent roughness factor is ε/D - 1.5 × 10–3. Her friends tell her she is wasting gas because of the additional drag on the ball. Estimate how much money (in dollars) she wastes per year by driving around with this tennis ball on her antenna. Use the following additional information: She drives mostly on the highway, about 12,000 miles per year at an average speed of 55 mph. The overall car efficiency is 0.308, ρfuel, = 50.2 lbm/ft3, and the heating value of the fuel is 1.47 × 107ft.lbf/lbm. The fuel costs $4.00 per gallon. Use standard air properties. Be careful with unit conversions. Should Janie remove the tennis ball?

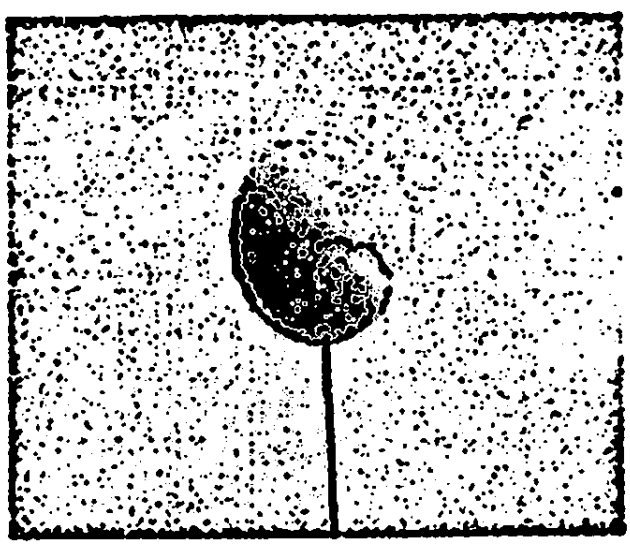

FIGURE P15–103E

Step 1 of 6

Loading solution. Please wait ...

Step 2 of 6

Now, the drag force acting on the ball can be calculated by using the formula given as

$$F_D = \frac{1}{2} C_D A \rho_{air} V^2 \qquad \text{..... (1)}$$

Where C_D is the drag coefficient

A is the frontal area of the ball.

V is the velocity of the car.

ρ_{air} is the density of air.

Now, velocity of car,

$$V = 55 \text{ mph}$$

$$= \frac{55 \times 5280}{3600} \text{ ft/s}$$

$$= 80.666 \text{ ft/s}$$

Now, frontal area of the ball,

$$A = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4} (0.2183)^2$$

$$= 0.03742 \text{ ft}^2$$

Step 3 of 6

The value C_D is unknown, but roughness factor is given in the question, so by calculating the Reynolds number we can find out the drag coefficient from the graph,

Reynolds number,

$$\text{Re} = \frac{VD}{\nu} \qquad \text{..... (2)}$$

Where, V is the velocity of car.

D is the diameter of the ball.

ν is the kinematic viscosity of air.

At standard air condition kinematic viscosity of air,

$$\nu = 1.535 \times 10^{-4} \text{ ft}^2/\text{s}$$

Step 4 of 6

Now, substitute all the known values in equation (2)

$$\text{Re} = \frac{VD}{\nu}$$

$$= \frac{80.666 \times 0.218}{1.535 \times 10^{-4}}$$

$$= 1.145 \times 10^5$$

Based on the obtained Reynolds number, from the graph "The effect of surface roughness

$$= \frac{\pi}{4} (0.2183)^2$$

$$= 0.03742 \text{ ft}^2$$

Step 3 of 6

The value C_D is unknown, but roughness factor is given in the question, so by calculating the Reynolds number we can find out the drag coefficient from the graph,

Reynolds number,

$$\text{Re} = \frac{VD}{\nu} \qquad \text{..... (2)}$$

Where, V is the velocity of car.

D is the diameter of the ball.

ν is the kinematic viscosity of air.

At standard air condition kinematic viscosity of air,

$$\nu = 1.535 \times 10^{-4} \text{ ft}^2/\text{s}$$

Step 4 of 6

Now, substitute all the known values in equation (2)

$$\text{Re} = \frac{VD}{\nu}$$

$$= \frac{80.666 \times 0.218}{1.535 \times 10^{-4}}$$

$$= 1.145 \times 10^5$$

Based on the obtained Reynolds number, from the graph "The effect of surface roughness

The amount of fuel required to develop this much energy for one year,

$$f = \frac{E_{in}}{\text{HV}(\rho_{fuel})}$$

$$= \frac{984662.33}{1.47 \times 10^7 (6.711)}$$

$$= 0.01 \text{ gallons/year}$$

Cost of fuel = Amount of fuel × Unit cost of fuel.

$$= 0.01 \times 4.00$$

$$= \$0.04$$

Therefore, the amount wasted per year to overcome the drag produced by tennis ball is $\boxed{\$0.04}$.

CHAPTER 16
SOLUTIONS

Question: 16.001P

Which is a better heat conductor, diamond or silver?

Step 1 of 1

Diamond is a better heat conductor than silver. Because of thermal conductivity of the Diamond is $K = 2000 \frac{\mathrm{W}}{\mathrm{m} \cdot \mathrm{K}}$ and silver is $K_s = 430 \frac{\mathrm{W}}{\mathrm{m} \cdot \mathrm{K}}$.

Then we know that heat transfer rate can calculate by

$$\dot{Q}_{cond} = kA\frac{\Delta T}{L}$$

From the above Value we know that rate of heat transfer directly proportional to thermal conductivity. so that it is better conductivity than the silver.

Question: 16.002P

Define thermal conductivity and explain its significance in heat transfer.

Step 1 of 2

Thermal conductivity: It is a property of a material by which the rate of heat transfer is measure through a unit thickness of the material per unit area and per unit temperature difference. It is a measure of the ability of material to conduct heat.

Step 2 of 2

By the help of thermal conductivity of a material we can measure how fast heat will be conducted in that material. A high value of thermal conductivity signifies that material is highly conductor of heat and low value how that material is less conductor of heat that mean insulator.

Question: 16.003P

What are the mechanisms of heat transfer? How are they distinguished from each other?

Step 1 of 3

There are three mechanisms of heat transfer which are conduction, convection and radiation.

Conduction is the transfer of energy from the more energetic particles of a substance to the adjacent less energetic ones as a result of interactions between the particles. So in this method heat can be transfer from solid to solid. Conduction is expressed by Fourier's law of conduction as

$$Q = kA\frac{dt}{dx}$$

Where

$\frac{dt}{dx}$ is the temperature gradient,

K is the thermal conductivity, and

A is the area which is normal to the direction of heat transfer.

Step 2 of 3

Convection is the mode of energy transfer between a solid surface and the adjacent liquid or gas which is in motion, and it involves combined effects of conduction and fluid motion. So when heat is transfer between solid to fluid or vice versa Convection is expressed by Newton's law of cooling as

$$Q_{conv} = hA(T_0 - T_\infty)$$

Where

h is the convection heat transfer coefficient,

A Is the surface area through which convection heat transfer takes place,

T_0 Is the surface temperature and

T_∞ Is the temperature of the fluid sufficiently far from the surface.

Step 3 of 3

Radiation is energy emitted by matter in the form of electromagnetic waves (or photons) as a result of the changes in the electronic configurations of the atoms or molecules. So in radiation no medium is required. Radiation is expressed by Stefan-Boltzman law as

$$\dot{Q}_{rad} = \varepsilon\sigma A_s(T_s^4 - T_{surr}^4)$$

Where

ε Is the emissivity of surface,

A_s Is the surface area,

T_s Is the surface temperature

T_{surr} is average surrounding surface temperature and

$\sigma = 5.67 \times 10^{-8}\frac{W}{m^2 \cdot K^4}$ Is the Stefan-Boltzman constant.

Question: 16.004P

What is the physical mechanism of heat conduction in a solid, a liquid, and a gas?

Step 1 of 1

Physical mechanism of heat conduction in solid is due to the combination of the vibrations of the molecules in a lattice and the energy transport by free electrons. In gases and liquids, it is due to the collisions of the molecules during their random motion.

Question: 16.005P

Consider heat transfer through a windowless wall of a house on a winter day. Discuss the parameters that affect the rate of heat conduction through the wall.

Step 1 of 3

Conduction is the transfer of energy from the more energetic particles of a substance to the adjacent less energetic ones as a result of interactions between the particles. So in this method heat can be transfer from solid to solid. Conduction is expressed by Fourier's law of conduction as

$$Q = kA\frac{dt}{dx}$$

Where

$\frac{dt}{dx}$ is the temperature gradient,

K is the thermal conductivity, and

A is the area which is normal to the direction of heat transfer.

From the above expression we know that rate of heat transfer directly proportional to thermal conductivity and inversely proportional to the wall thickness

Step 2 of 3

Thermal conductivity: It is a property of a material by which the rate of heat transfer is measure through a unit thickness of the material per unit area and per unit temperature difference. It is a measure of the ability of material to conduct heat'

A high value of thermal conductivity signifies that material is highly conductor of heat and low value how that material is less conductor of heat that mean insulator.

Step 3 of 3

The parameters that affect the rate of heat conduction through a windowless wall are

- The geometry and
- Surface area of wall,
- Its thickness,
- The material of the wall,
- And the temperature difference across the wall.

Question: 16.006P

Write down the expressions for the physical laws that govern each mode of heat transfer, and identify the variables involved in each relation.

Step 1 of 3

There are three mechanisms of heat transfer which are conduction, convection and radiation.

Conduction is the transfer of energy from the more energetic particles of a substance to the adjacent less energetic ones as a result of interactions between the particles. So in this method heat can be transfer from solid to solid. Conduction is expressed by Fourier's law of conduction as

$$Q = kA\frac{dt}{dx}$$

Where

$\frac{dt}{dx}$ is the temperature gradient,

K is the thermal conductivity, and

A is the area which is normal to the direction of heat transfer.

Step 2 of 3

Convection is the mode of energy transfer between a solid surface and the adjacent liquid or gas which is in motion, and it involves combined effects of conduction and fluid motion. So when heat is transfer between solid to fluid or vice versa Convection is expressed by Newton's law of cooling as

$$Q_{conv} = hA(T_0 - T_\infty)$$

Where

h is the convection heat transfer coefficient,

A Is the surface area through which convection heat transfer takes place,

T_0 Is the surface temperature and

T_∞ Is the temperature of the fluid sufficiently far from the surface.

Step 3 of 3

Radiation is energy emitted by matter in the form of electromagnetic waves (or photons) as a result of the changes in the electronic configurations of the atoms or molecules. So in radiation no medium is required. Radiation is expressed by Stefan-Boltzman law as

$\dot{Q}_{rad} = \varepsilon\sigma A_s(T_s^4 - T_{surr}^4)$

Where

ε Is the Emissivity of surface,

A_s Is the surface area,

T_s Is the surface temperature

T_{surr} is average surrounding surface temperature and

$\sigma = 5.67\times10^{-8}\frac{W}{m^2\cdot K^4}$ Is the Stefan-Boltzman constant.

Question: 16.007P

How does heat conduction differ from convection?

Step 1 of 2

Convection is the mode of energy transfer between a solid surface and the adjacent liquid or gas which is in motion, and it involves combined effects of conduction and fluid motion. So when heat is transfer between solid to fluid or vice versa Convection is expressed by Newton's law of cooling as

$$Q_{conv} = hA(T_0 - T_\infty)$$

Where

h is the convection heat transfer coefficient,

A Is the surface area through which convection heat transfer takes place,

T_0 Is the surface temperature and

T_∞ Is the temperature of the fluid sufficiently far from the surface.

Step 2 of 2

In the case of solids we can only conduction. Because of there is no fluid motion in the solids so amount of heat transfer is only due to conduction only .

Question: 16.008P

Does any of the energy of the sun reach the earth by conduction or convection?

Step 1 of 1

Conduction and convection requires the presence of material medium and heat transfer through a vacuum is by radiation only. Since space is almost completely empty so the heat energy of the sun reaches the earth by radiation only. Therefore there is no energy of the sun reach the earth by conduction and convection.

Question: 16.009P

How does forced convection differ from natural convection?

Step 1 of 1

If the fluid is forced to flow over the surface by external means such as fan, pump or blower then the convection is called Forced convection.
And if the fluid motion is caused by buoyancy forces that are induced by density differences due to variation of temperature in the fluid then the convection is called Natural convection.

Question: 16.010P

Define emissivity and absorptivity. What is Kirch-hoff's law of radiation?

Step 1 of 3

Emissivity:
It is the ratio of the radiation emitted by a surface to the radiation emitted by a blackbody at the same temperature. Emissivity is denoted by ε.
and its Value of Emissivity is $0 \leq \varepsilon \leq 1$
So Emissivity is a property of a material which shows how closely a surface approximates a black body whose emissivity is 1.

Step 2 of 3

Absorptivity:
It is the fraction of radiation incident on a surface that is absorbed by the surface. It is denoted by α.
And its value is $0 \leq \alpha \leq 1$.
A black body can absorb entire radiation incident on it. So for black body the value of α is 1.

Step 3 of 3

Kirchoffs Law of radiation: -
The Kirchhoff's law of radiation states that the emissivity and the absorptivity of a surface are equal at the same temperature and wavelength.

Question: 16.011P

What is a blackbody? How do real bodies differ from blackbodies?

Step 1 of 1

A blackbody is an idealized body which emits the maximum amount of radiation at a given temperature and which absorbs the entire radiation incident on it. Real bodies emit and absorb less radiation than a blackbody at the same temperature.

Question: 16.012P

Judging from its unit W/m·K, can we define thermal conductivity of a material as the rate of heat transfer through the material per unit thickness per unit temperature difference? Explain.

Step 1 of 1

No, such a definition will imply that doubling the thickness would double the heat transfer rate. The equivalent but "more correct" unit of thermal conductivity is $\frac{W \cdot m}{m^2 \cdot {}^\circ C}$

That indicates product of heat transfer rate and thickness per unit surface area per unit temperature difference.

Question:

16.013P

Consider heat loss through the two walls of a house on a winter night. The walls are identical, except that one of them has a tightly fit glass window. Through which wall will the house lose more heat? Explain.

Step 1 of 2

Then we know that heat transfer rate can calculate by

$$\dot{Q}_{cond} = kA\frac{\Delta T}{L}.$$

From the above expression we know that rate of heat transfer directly proportional to thermal conductivity and inversely proportional to the wall thickness.

Step 2 of 2

In this house, heat loss through the wall with glass window will be larger since the glass is much thinner than a wall, and its thermal conductivity is higher than the average conductivity of a wall.

Question: 16.014P

Consider two houses that are identical, except that the walls are built using bricks in one house, and wood in the other. If the walls of the brick house are twice as thick, which house do you think will be more energy efficient?

Step 1 of 2

Thermal conductivity (K) of brick $K_b = 0.72 \frac{W}{m \cdot K}$

And for wood it is $K_W = 0.17 \frac{W}{m \cdot K}$

So if the brick wall thickness is twice than the wood wall thickness.
Then we know that heat transfer rate can calculate by

$$\dot{Q}_{cond} = kA\frac{\Delta T}{L} .$$

From the above expression we know that rate of heat transfer directly proportional to thermal conductivity and inversely proportional to the wall thickness.

Step 2 of 2

So if the brick wall thickness is twice than the wood wall thickness.
For brick wall value of thermal conductivity

$$k = \frac{0.72 \frac{W}{m \cdot K}}{2}$$

$$k = 0.36 \frac{W}{m \cdot K}$$

And for wood $0.17 \frac{W}{m^2 \cdot K}$ rest parameter are same.

The house with the lower rate of heat transfer through the walls will be the more efficient. so from clearly shows that wood wall is more efficient then the brick wall because of it has lower thermal conductivity than the brick.

Question: 16.015P

Consider two walls of a house that are identical except that one is made of 10-cm-thick wood, while the other is made of 25-cm-thick brick. Through which wall will the house lose more heat in winter?

Step 1 of 4

Given:

Thickness of the wood $L_{thick} = 10\,\text{cm}$
$= 0.1\,\text{m}$

Thickness of the Brick $L_{Brick} = 25\,\text{cm}$
$= 0.25\,\text{m}$

Step 2 of 4

From the Data book we get the

Thermal conductivity of the Wood is $k = 0.16\dfrac{\text{W}}{\text{m}\cdot\text{K}}$

Thermal conductivity of the Brick is $k_b = 0.72\dfrac{\text{W}}{\text{m}\cdot\text{K}}$

Step 3 of 4

The rate of heat transfer through both walls can be expressed as

$$\dot{Q}_{\text{wood}} = k_{\text{wood}} A\frac{T_1 - T_2}{L_{\text{wood}}}$$
$$= (0.16\ \text{W/m.°C})A\frac{T_1 - T_2}{0.1\,\text{m}}$$
$$= 1.6A(T_1 - T_2)$$

Step 4 of 4

$$\dot{Q}_{\text{brick}} = k_{\text{brick}} A\frac{T_1 - T_2}{L_{\text{brick}}}$$
$$= (0.72\ \text{W/m}\cdot\text{°C})A\frac{(T_1 - T_2)}{0.25\,\text{m}}$$
$$= 2.88A(T_1 - T_2)$$

Therefore, heat transfer through the brick wall will be larger despite its higher thickness.

Question: 16.016P

How do the thermal conductivity of gases and liquids vary with temperature?

Step 1 of 1

For gases, the molecules are in continues random motion. as the temperature increases, velocities of molecules become higher than in a lower temperature region. the molecules move from a high temperature region to a region of low temperature and gives up their energy through collisions to lower energy molecules. thus the thermal conductivity of gas increases with an increases in temperature and is proportional to the square root of the absolute temperature

The thermal conductivity of most liquids, however, decreases with increasing temperature, with water being a notable exception.

Question: 16.017P

Why is the thermal conductivity of superinsulation orders of magnitude lower than the thermal conductivity of ordinary insulation?

Step 1 of 1

Super insulations are obtained by using layers of highly reflective sheets separated by glass fibers in an evacuated space. Radiation heat transfer between two surfaces is inversely proportional to the number of sheets used and thus heat loss by radiation will be very low by using these highly reflective sheets.

At the same time, evacuating the space between the layers forms a vacuum under 0.000001 atm pressure which minimizes conduction or convection through the air space between the layers. Thermal conductivity of super-insulation is very low.

Question: 16.018P

Why do we characterize the heat conduction ability of insulators in terms of their apparent thermal conductivity instead of the ordinary thermal conductivity?

Step 1 of 1

Generally insulations are obtained by mixing fibers, powders, or flakes of insulating materials with air. Heat transfer through such insulations is by three modes of heat transfer namely, conduction, convection or radiation.
Such systems are characterized by apparent thermal conductivity instead of the ordinary thermal conductivity in order to incorporate these convection and radiation effects.

Question: 16.019P

Consider an alloy of two metals whose thermal conductivities are *k*1 and *k*2. Will the thermal conductivity of the alloy be less than *k*1 greater than *k*2, or between *k*1 and *k*2?

Step 1 of 1

Suppose an alloy made of two metals of thermal conductivities k_1 and k_2, then thermal conductivity of alloy k is in between k_1 and k_2. But this turns out not to be the case. The thermal conductivity of an alloy of two metals is usually much lower than that of either metal.

For example,

At 300 K

Thermal conductivity of Copper, $k_{Cu} = 401\,W/m \cdot °C$

Thermal conductivity of Aluminum, $k_{Al} = 237\,W/m \cdot °C$

Thermal conductivity of commercial bronze $(90\%Cu + 10Al)$, $k_{bronze} = 52\,W/m \cdot °C$

Question: 16.020P

Two surfaces of a 2-cm-thick plate are maintained at 0°C and 80°C, respectively. If it is determined that heat is transferred through the plate at a rate of 500 W/m2, determine its thermal conductivity.

Step 1 of 2

Given

Thickness of plate, $L = 2\,\text{cm}$

Temperatures both surfaces, $T_1 = 0°\text{C}$

$T_2 = 80°\text{C}$

Heat transfer rate through the plate, $\dot{Q} = 500\,\text{W/m}^2$

Step 2 of 2

Loading solution. Please wait ...

Question: 16.021P

Four power transistors, each dissipating 12 W, are mounted on a thin vertical aluminum plate 22 cm × 22 cm in size. The heat generated by the transistors is to be dissipated by both surfaces of the plate to the surrounding air at 25°C, which is blown over the plate by a fan. The entire plate can be assumed to be nearly isothermal, and the exposed surface area of the transistor can be taken to be equal to its base area. If the average convection heat transfer coefficient is 25 W/m2·K, determine the temperature of the aluminum plate. Disregard any radiation effects.

Step 1 of 2

Calculate the area of cross section.

$$A_s = 2(l \times b)$$

Here, l is the length, and b is the breadth.

Substitute $22\ \text{cm}$ for l and $22\ \text{cm}$ for b .

$$\begin{aligned} A_s &= 2\times(22\times22)\text{cm}^2 \times \frac{10^{-4}\ \text{m}^2}{1\ \text{cm}^2} \\ &= 2\times(22\times22\times10^{-4}) \\ &= 0.0968\,\text{m}^2 \end{aligned}$$

Calculate the heat balance equation to the aluminum plate and surrounding air.

$$Q = hA_s\Delta T$$

Here, h is the heat transfer coefficient, A_s is the area of cross section, and ΔT is the temperature difference.

Substitute $25\ \text{W/m}^2\cdot\text{K}$ for h , $(T - T_{air})$ for ΔT , $25°\text{C}$ for T_{air} , and $0.0968\,\text{m}^2$ for A_s .

$$\begin{aligned} Q &= 25(0.0968)(T - T_{air}) \\ &= 25(0.0968)(T - 25) \quad \text{..... (1)} \\ &= 2.42(T - 25) \end{aligned}$$

Step 2 of 2

The heat dissipation from each transistor,

$$Q_T = 12\ \text{W}$$

Then total heat transfer is,

$$\begin{aligned} Q &= 4Q_T \\ &= 4\times12 \\ &= 48\ \text{W} \end{aligned}$$

Substitute $48\ \text{W}$ for Q_T in equation (1).

$$\begin{aligned} Q_T &= 2.42(T - 25) \\ 48 &= 2.42(T - 25) \\ (T - 25) &= 19.835 \\ T &= 44.835°\text{C} \end{aligned}$$

Therefore, the temperature of aluminum plate is approximately $\boxed{45°\text{C}}$.

Question: 16.022P

In a power plant, pipes transporting superheated vapor are very common. Superheated vapor is flowing at a rate of 0.3 kg/s inside a pipe with 5 cm in diameter and 10 m in Length. The pipe is located in a power plant at 20°C, and has a uniform pipe surface temperature of 100°C. If the temperature drop between the inlet and exit of the pipe is 30°C, and the specific heat of the vapor is 2190 J/kg·K, determine the heat transfer coefficient as a result of convection between the pipe surface and the surrounding.

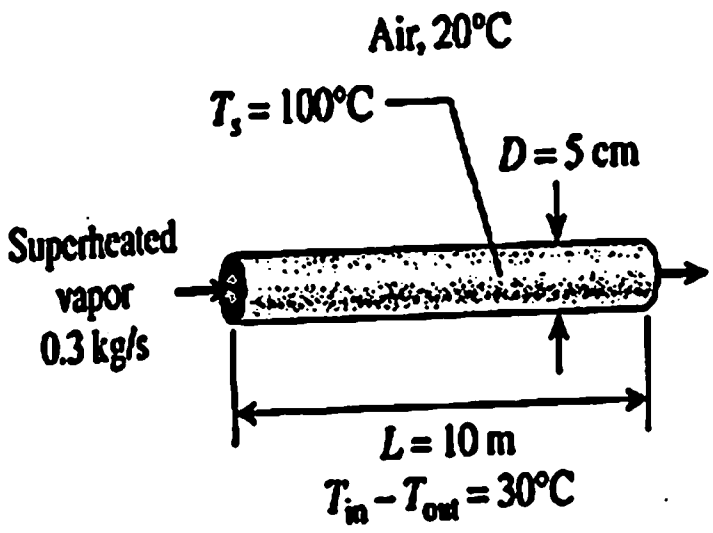

FIGURE P16–22

Step 1 of 3

Given data:

Heat is dissipated through the pipes of a power plant transporting superheated vapor

Superheated vapor mass flow rate, $\dot{m} = 0.3 kg/s$

Inside diameter of the pipe, $D = 5 cm$

Length of the pipe, $L = 10 m$

Temperature drop between inlet and exit of the pipe, $\Delta T_D = 30 °C$

Surface temperature of the pipe, $T_s = 100 °C$

Surrounding temperature of the air, $T_\infty = 20 °C$

Potential energy and kinetic energy changes are negligible

Step 2 of 3

The heat balance equation to the pipes,

$P_p \times \Delta t = \Delta U$

Taking the specific heat of vapor, $S = 2190 J/kg \cdot K$

Assume the convection heat transfer takes place from steam to pipe and then to the surrounding air respectively.

The rate of change in internal energy in the steam can be written as

$$\frac{\Delta U}{\Delta t} = \dot{m} S \Delta T_D$$
$$= 0.3 \times 2190 \times 30$$
$$= 19710 \text{ W}$$

Step 3 of 3

The power loss through the pipe to the ambient air by convection process so that from balance equation of heat, the heat transfer coefficient can be

$P_p \times \Delta t = \Delta U$

$$hA_s \Delta T = \frac{\Delta U}{\Delta t}$$

$$h \times (\pi \times d \times l) \times (100 - 20) = 19710$$

$$h \times (\pi \times 0.05 \times 10) \times (100 - 20) = 19710$$

$$h = 156.847 \text{ W/m}^2 \cdot \text{K}$$

Therefore, the convective heat transfer coefficient between pipe and air is

$$\boxed{h = 157 \text{ W/m}^2 \cdot \text{K}}$$

Question: 16.023P

An electric current of 5 A passing through a resistor has a measured voltage of 6 V across the resistor. The resistor is cylindrical with a diameter of 2.5 cm and length of 15 cm. The resistor has a uniform temperature of 90°C and the room air temperature is 20°C. Assuming that heat transfer by radiation is negligible, determine the heat transfer coefficient by convection.

Step 1 of 3

Given data:

An electric current passing through the resistor, $I = 5\text{A}$

Voltage across the resistor, $V = 6\text{V}$

Diameter of the cylindrical resistor, $D = 2.5\text{cm}$

Length of the cylindrical resistor, $L = 15\text{cm}$

The resistor has uniform temperature, $T = 90^\circ\text{C}$

The room air temperature, $T_{air} = 20^\circ\text{C}$

Step 2 of 3

Let h be the convective heat transfer coefficient,

The heat balance equation to the room and resistor can be

$$Q = hA_s\Delta T$$

For cylindrical resistor, surface area of heat dissipation to the air should be

$$A_s = \left(2\times\frac{\pi D^2}{4}\right)+\pi DL$$

$$= 2\times\frac{\pi\times(0.025)^2}{4}+\pi\times 0.025\times 0.15$$

$$= 0.0128\ \text{m}^2$$

Step 3 of 3

The rate of heat dissipation due to current passing through the resistor from the heat balance equation

$$Q = hA_s\Delta T$$

$$VI = h\times 0.0128\times(90-20)$$

$$h = \frac{5\times 6}{0.0128\times(90-20)}$$

$$= 33.48\ \text{W/m}^2\cdot\text{K}$$

Therefore, the convective heat transfer coefficient between resistor and air is

$$\boxed{h = 33.6\ \text{W/m}^2\cdot\text{K}}$$

Question: 16.024P

The inner and outer surfaces of a 4-m × 7-m brick wall of thickness 30 cm and thermal conductivity 0.69 W/m-K are maintained at temperatures of 26°C and 8°C, respectively. Determine the rate of heat transfer through the wall, in W.

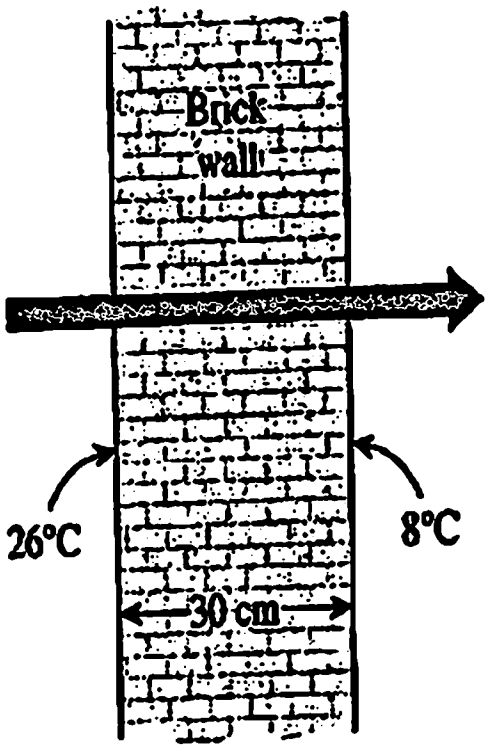

FIGURE P16–24

Step 1 of 2

Given data:

The dimensions of brick wall, $4\,\text{m} \times 7\,\text{m}$

Thickness of the wall, $L = 30\text{cm} = 0.3\text{m}$

Thermal conductivity, $k = 0.69\ \text{W/m} \cdot \text{K}$

Temperature of inner surface of the wall,

$T_1 = 26°\text{C}$

$= 26 + 273$

$= 299\ \text{K}$

Temperature of inner surface of the wall,

$T_2 = 8°\text{C}$

$= 8 + 273$

$= 281\ \text{K}$

Step 2 of 2

Heat transfer area of the wall,

$A = 4 \times 7$

$= 28\,\text{m}^2$

Under steady conditions,

The rate of heat transfer through the wall by conduction is given by

$$\dot{Q} = -kA\frac{T_2 - T_1}{L}$$

$$= -0.69 \times 28 \times \frac{(281 - 299)}{0.3}$$

$$= 1159.2\ \text{W}$$

Therefore, the rate of heat transfer through the wall by conduction is $\boxed{\dot{Q} = 1159.2\ \text{W}}$.

Question: 16.025P

The inner and outer surfaces of a 0.5-cm thick 2-m × 2-m window glass in winter are 10°C and 3°C, respectively If the thermal conductivity of the glass is 0.78 W/m·K, determine the amount of heat loss through the glass over a period of 5 h. What would your answer be if the glass were 1 cm thick?

Step 1 of 4

Given

Inner temperature of window glass, $T_1 = 10°C$

Outer surface temperature of window glass, $T_1 = 3°C$

Thickness of window glass $L = 0.5$ cm

Thermal conductivity of the glass, $k = 0.78\ W/m \cdot C$

Time period, $t = 5h$

Step 2 of 4

Area of window glass, $A = 2 \times 2$

$= 4\ m^2$

The rate of heat transfer through the glass by conduction is given by

$$\dot{Q}_{cond} = kA\frac{\Delta T}{L}$$

$$= 0.78 \times 4 \times \frac{(10-3)}{0.005}$$

$$= \frac{21.84}{0.005}$$

$$= 4368\ W$$

Step 3 of 4

Then the amount of heat transfer over a period of $t = 5h$ becomes

$$Q = \dot{Q}_{cond} t$$

$$= 4368 \times (5 \times 3600)$$

$$= 78624000\ J$$

$$= 78.624\ MJ$$

The amount of heat transfer over a period of $t = 5h$, $\boxed{Q = 78.624\ MJ}$

Step 4 of 4

If the thickness of the glass doubled to $L = 1$ cm

Then the amount of heat transfer will go down by half.

So, amount of heat transfer, $Q_{L=1cm} = \frac{Q_{L=0.5cm}}{2}$

$$= \frac{78.6}{2}$$

$$= 39.3MJ$$

The amount of heat transfer over a period of $t = 5h$, $\boxed{Q = 39.3MJ}$

Question: 16.026P

Reconsider Prob. 16–25. Using EES (or other) software, plot the amount of heat loss through the glass as a function of the window glass thickness in the range of 0.1 cm to 1.0 cm. Discuss the results.

Step 1 of 7

Given

Inner temperature of window glass, $T_1 = 10°C$

Outer surface temperature of window glass, $T_1 = 3°C$

Thickness range of window glass, $0.1\text{cm} \le L \le 1.0\text{ cm}$

Thermal conductivity of the glass, $k = 0.78\ \text{W/m} \cdot \text{C}$

Time period, $t = 5\text{h}$

Step 2 of 7

To solve this question using EES software open EES software

Then FILE->New

A dailogbox will open type the following in dailog box

```
"GIVEN"
A=2*2 "[m^2]"
T_1=10 "[C]"
T_2=3 "[C]"
k=0.78 "[W/m-C]"
time=5*3600 "[s]"

"ANALYSIS"
Q_dot_cond=k*A*(T_1-T_2)/L
Q_cond=Q_dot_cond*time*Convert(J, kJ)
```

Step 3 of 7

Then from Tables -> New parametric table

A dailog box will open

Select no of runs = 10

Select variables in equations as L and Q_{cond} press ADD and then press ok

A table will appear put values of L as 0.001,0.002,0.003....0.01 in run 1to 10

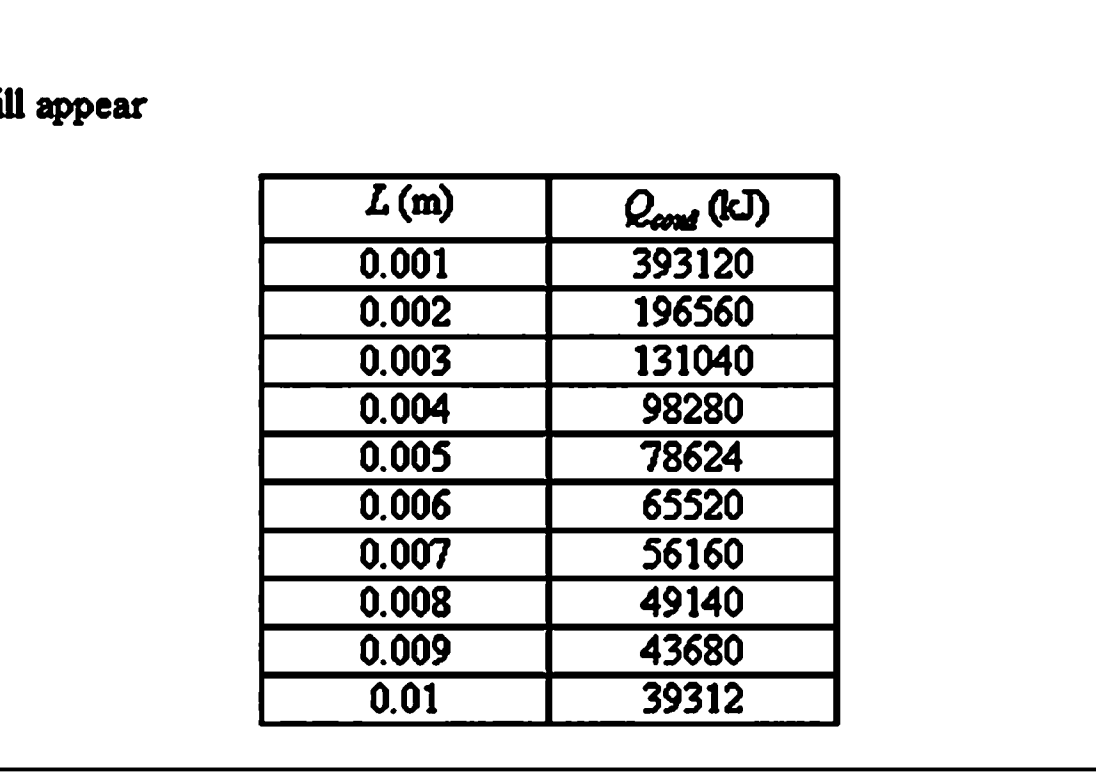
Then from Calculate -> Solve table

Step 4 of 7

Solution will appear

L (m)	Q_{cond} (kJ)
0.001	393120
0.002	196560
0.003	131040
0.004	98280
0.005	78624
0.006	65520
0.007	56160
0.008	49140
0.009	43680
0.01	39312

Step 5 of 7



Then from Plot -> New plot window -> X-Y Plot

Select X-axis L and Y-axis Q_{cond}

Press OK

Step 6 of 7

Graph will be plotted.

Step 7 of 7

Result:

Heat conduction through the glass is decreased with increasing thickness of glass.

Question: 16.027P

An aluminum pan whose thermal conductivity 237 W/m·K has a flat bottom with diameter 15 cm and thickness 0.4 cm. Heat is transferred steadily to boiling water in the pan through its bottom at a rate of 1400 W. If the inner surface of the bottom of the pan is at 105°C, determine the temperature of the outer surface of the bottom of the pan.

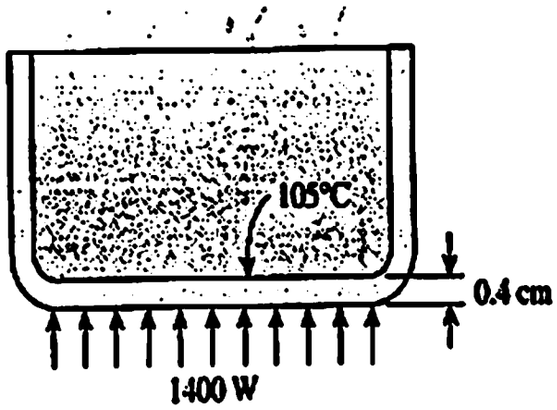


FIGURE P16–27

Step 1 of 2

Given data:

Thermal conductivity of the aluminum, $k = 237\ \text{W/m}\cdot\text{K}$

Diameter of the pan, $d = 15\,\text{cm} = 0.15\,\text{m}$

Thickness, $L = 0.4\,\text{cm} = 4\times10^{-3}\ \text{m}$

Total heat transfer rate through bottom, $Q = 1400\,\text{W}$

Temperature of inner surface of bottom of pan,

$T_1 = 105°\text{C}$

$= 105 + 273$

$= 378\,\text{K}$

Step 2 of 2

Area of the pan,

$$A = \frac{\pi d^2}{4}$$

$$= \frac{\pi \times 0.15^2}{4}$$

$$= 0.0177\ \text{m}^2$$

Under steady state condition,

The rate of heat transfer through the bottom of the pan by conduction is given by

$$\dot{Q} = kA\frac{T_2 - T_1}{L}$$

$$1400 = 237 \times 0.0177 \times \frac{(T_2 - 378)}{0.004}$$

$$T_2 - 378 = 1.334$$

$$T_2 = 379.334\ \text{K}$$

Therefore, the temperature of outer surface of bottom of pan is $\boxed{T_2 = 379.334\ \text{K}}$.

Question: 16.028P

The north wall of an electrically heated home is 20 ft long. 10 ft high, and 1 fl thick, and is made of brick whose thermal conductivity is $k = 0.42$ Btu/h·ft·°F. On certain winter night, the temperatures of the inner and the outer surfaces of the wall are measured to be at about 62°F and 25°F, respectively, for a period of 8 h. Determine (*a*) the rate of heat loss through the wall that night and (*b*) the cost of that heat loss to the home owner if the cost of electricity is $0.07/kWh.

Step 1 of 3

Given

Length of the wall, $L = 20\,\text{ft}$

Height of the wall, $h = 10\,\text{ft}$

Thickness of the wall, $t = 1\text{ft}$

Thermal conductivity of brick, $k = 0.42\,\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$

Temperature of inner surface of the wall, $T_1 = 62^\circ\text{F}$

Temperature of outer surface of the wall, $T_2 = 25^\circ\text{F}$

Time period, $\Delta t = 8\text{h}$

Cost of electricity, $0.07/kWh

Step 2 of 3

(a) Surface area of wall, $A = L \times h$

$= 20 \times 10$

$= 200\,\text{ft}^2$

Rate of heat transfer through the wall in the night is given by

$$\dot{Q} = kA\frac{T_1 - T_2}{L}$$

$$= 0.42 \times 200 \times \frac{(62-25)}{1}$$

$$= 3108\,\text{Btu/h}$$

Rate of heat transfer through the wall, $\boxed{\dot{Q} = 3108\,\text{Btu/h}}$

Step 3 of 3

(b) Rate of heat transfer through the wall, $\dot{Q} = 3108\,\text{Btu/h}$

$= 0.911\,\text{kW}$ $(\because 1\text{kW} = 3412\ \text{Btu/h})$

The amount of heat lost during an 8 hour period

$$Q = \dot{Q}\Delta t$$

$$= 0.911 \times 10^3 \times 8$$

$$= 7.288\,\text{kWh}$$

Cost = (Amount of energy)(Unit cost of energy)

$= 7.288 \times 0.07$

$= \$0.51$

The cost of the heat loss through the wall, $\boxed{\$0.51}$

Question: 16.029P

In a certain experiment, cylindrical samples of diameter 4 cm and length 7 cm are used (see Fig. 16–9). The two thermocouples in each sample are placed 3 cm apart. After initial transients, the electric heater is observed to draw 0.6 A at 110 V, and both differential thermometers read a temperature difference of 8°C. Determine the thermal conductivity of the sample.

Step 1 of 4

Given data:

Diameter of the cylinder, $d = 4\,\text{cm} = 0.04\,\text{m}$

Length of the cylinder, $L = 7\,\text{cm} = 0.07\,\text{m}$

Distance between two thermocouples, $a = 3\,\text{cm} = 0.03\,\text{m}$

Temperature difference reading,

$\Delta T = 8^\circ\text{C} = 8\,\text{K}$

Specifications of electric heater

Current, $I = 0.6\,\text{A}$

Voltage, $V = 110\,\text{V}$

Step 2 of 4

Area of the surface,

$$A = \frac{\pi d^2}{4}$$

$$= \frac{\pi \times 0.04^2}{4}$$

$$= 0.00125\,\text{m}^2$$

Step 3 of 4

The electrical power consumed by the heater is given by

$$\dot{W}_e = VI$$

$$= 110 \times 0.6$$

$$= 66\,\text{W}$$

The rate of heat flow through each sample is

$$\dot{Q} = \dot{W}_e / 2$$

$$= 66/2$$

$$= 33\,\text{W}$$

Step 4 of 4

Thermal conductivity of the sample can be calculating as

$$\dot{Q} = kA\frac{\Delta T}{L}$$

$$k = \frac{\dot{Q}L}{A\Delta T}$$

$$= \frac{33 \times 0.03}{0.00125 \times 8}$$

$$= \frac{0.99}{0.01}$$

$$= 99\,\text{W/m} \cdot \text{K}$$

Therefore, the thermal conductivity of the sample is $\boxed{k = 99\,\text{W/m} \cdot \text{K}}$

Question: 16.030P

One way of measuring the thermal conductivity of a material is to sandwich an electric thermofoil heater between two identical rectangular samples of the material and to heavily insulate the four outer edges, as shown in the figure. Thermocouples attached to the inner and outer surfaces of the samples record the temperatures.

During an experiment, two 0.5-cm thick samples 10 cm × 10 cm in size arc used. When steady operation is reached, the heater is observed to draw 25 W of electric power, and the temperature of each sample is observed to drop from 82°C at the inner surface to 74°C at the outer surface. Determine the thermal conductivity of the material at the average temperature.

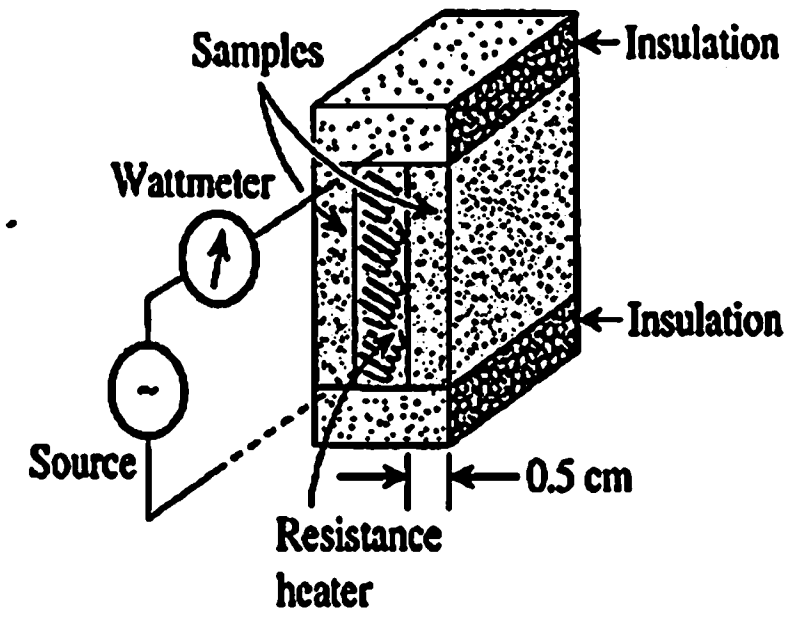

FIGURE P16–30

Step 1 of 2

Calculate the area of each sample as follows:

$$A=\left(10\,\text{cm}\times\frac{1\,\text{m}}{100\,\text{cm}}\right)\times\left(10\,\text{cm}\times\frac{1\,\text{m}}{100\,\text{cm}}\right)$$
$$=0.01\,\text{m}^2$$

Find the rate of heat transfer for each sample using the following equation.

$$\dot{Q}=\frac{W_{\text{elec}}}{2}$$

Substitute $25\,\text{W}$ for W_{elec}.

$$\dot{Q}=\frac{25}{2}$$
$$=12.5\,\text{W}$$

Step 2 of 2

Calculate the thermal conductivity using the following equation.

$$\dot{Q}=kA\frac{(T_2-T_1)}{L}$$
$$k=\frac{\dot{Q}L}{A(T_2-T_1)}$$

Here, k is the thermal conductivity of the material, L is the thickness of the insulation, A is the cross sectional area, T_1 and T_2 are the temperatures at inside and outside respectively.

Substitute $12.5\,\text{W}$ for $\dot{Q}$, $0.005\,\text{m}$ for L, $0.01\,\text{m}^2$ for A, $82°\text{C}$ for T_2 and $74°\text{C}$ for T_1.

$$k=\frac{12.5\times0.005}{0.01(82-74)}$$
$$=\frac{0.0625}{0.08}$$
$$=0.781\,\text{W/m}\cdot°\text{C}$$

Therefore, the thermal conductivity of the material is $\boxed{0.781\,\text{W/m}\cdot°\text{C}}$

Question: 16.031P

Repeat Prob. 16–30 for an electric power consumption of 20W.

Step 1 of 2

Given

Thickness of sample, $L = 0.5$ cm

Area of sample, $A = 10\,\text{cm} \times 10\,\text{cm}$

Temperature of outer surface, $T_2 = 82°\text{C}$

Temperature of inner surface, $T_1 = 74°\text{C}$

Power consumed by heater, $P = 20\,\text{W}$

Step 2 of 2

Area of each sample, $A = 0.1 \times 0.1$

$= 0.01\,\text{m}^2$

Rate of heat transfer for each sample

$\dot{Q} = 20/2$

$= 10\,\text{W}$

And we have

$$\therefore \dot{Q} = kA\frac{(T_2 - T_1)}{L}$$

$$\Rightarrow k = \frac{\dot{Q}L}{A(T_2 - T_1)}$$

$$= \frac{10 \times 0.005}{0.01(82-74)}$$

$$= \frac{0.05}{0.08}$$

$$= 0.625\,\text{W/m} \cdot °\text{C}$$

The thermal conductivity of the material, $\boxed{k = 0.625\,\text{W/m} \cdot °\text{C}}$

Question: 16.032P

A heat flux meter attached to the inner surface of a 3-cm-thick refrigerator door indicates a heat flux of 32 W/m2 through the door. Also, the temperatures of the inner and the outer surfaces of the door are measured to be 7°C and 15°C. respectively. Determine the average thermal conductivity of the refrigerator door.

Step 1 of 2

Given data:

Thickness of refrigerator door, $L = 3\text{cm} = 0.03\text{ m}$

Heat flux through the door, $\dot{q} = 32\ \text{W/m}^2$

Temperature of inner surface,

$T_1 = 7°\text{C}$

$= 7 + 273$

$= 280\ \text{K}$

Temperature of outer surface,

$T_2 = 15°\text{C}$

$= 15 + 273$

$= 288\ \text{K}$

Step 2 of 2

Heat flux through the slab is given by

$$\dot{q} = k\frac{(T_2 - T_1)}{L}$$

$$k = \frac{\dot{q}L}{(T_2 - T_1)}$$

$$= \frac{32 \times 0.03}{(288 - 280)}$$

$$= \frac{0.96}{8}$$

$$= 0.12\ \text{W/m} \cdot \text{K}$$

Therefore, the average thermal conductivity of the door material is $\boxed{k = 0.12\ \text{W/m} \cdot \text{K}}$

Question: 16.033P

Consider a person standing in a room maintained at 20°C at all times. The inner surfaces of the walls, floors, and ceiling of the house are observed to be at an average temperature of 12°C in winter and 23°C in summer. Determine the rates of radiation heat transfer between this person and the surrounding surfaces in both summer and winter if the exposed surface area, emissivity, and the average outer surface temperature of the person are 1.6 m2. 0.95, and 32°C, respectively.

Step 1 of 3

Given

Temperature of inner surface in winter, $T_{winter} = 12°C$

Temperature of inner surface in summer, $T_{summer} = 23°C$

Emissivity of person, $\varepsilon = 0.95$

Surface area, $A = 1.6\,m^2$

Temperature of outer surface, $T_s = 32°C$

Step 2 of 3

In summer:

Rate of radiation heat transfer is given by

$$\dot{Q}_{rad} = \varepsilon\sigma A\left(T_s^4 - T_{summer}^4\right)$$

$$= 0.95\times\left(5.67\times10^{-8}\right)\times1.6\times\left[(32+273)^4 - (23+273)^4\right]$$

$$= 8.62\times10^{-8}\times\left[305^4 - 296^4\right]$$

$$= 84.2\,W$$

Rate of radiation heat transfer in summer, $\boxed{\dot{Q}_{rad} = 84.2\,W}$

Step 3 of 3

In winter:

Rate of radiation heat transfer is given by

$$\dot{Q}_{rad} = \varepsilon\sigma A\left(T_s^4 - T_{winter}^4\right)$$

$$= 0.95\times\left(5.67\times10^{-8}\right)\times1.6\times\left[(32+273)^4 - (12+273)^4\right]$$

$$= 8.62\times10^{-8}\times\left[305^4 - 285^4\right]$$

$$= 177.2\,W$$

Rate of radiation heat transfer in winter, $\boxed{\dot{Q}_{rad} = 177.2\,W}$

Question: 16.034P

Reconsider Prob. 16–33. Using EES (or other) software, plot the rate of radiation heat transfer in winter as a function of the temperature of the inner surface of the room in the range of 8°C to 18°C. Discuss the results.

Step 1 of 7

Given

Temperature range of inner surface in winter, $8°C \le T_{sur,winter} \le 18°C$

$281K \le T_{sur,winter} \le 291K$

Temperature of inner surface in summer, $T_{sur,sum} = 23°C$

Emissivity of person, $\varepsilon = 0.95$

Surface area, $A = 1.6 m^2$

Temperature of outer surface, $T_s = 32°C$

Step 2 of 7

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
T_infinity=20+273 "[K]"
"T_surr_winter=12+273 [K], parameter to be varied"
T_surr_summer=23+273 "[K]"
A=1.6 "[m^2]"
epsilon=0.95
T_s=32+273 "[K]"

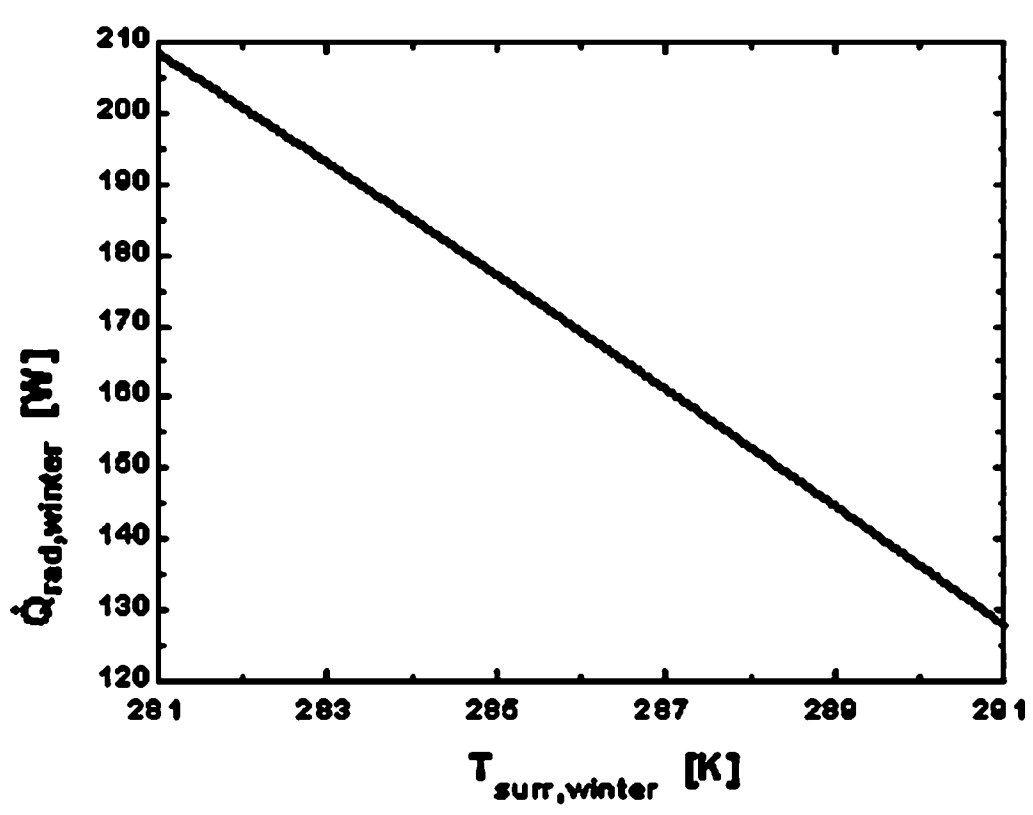
"ANALYSIS"
sigma=5.67E-8 "[W/m^2-K^4], Stefan-Boltzman constant"
"(a)"
Q_dot_rad_summer=epsilon*sigma*A*(T_s^4-T_surr_summer^4)
"(b)"
Q_dot_rad_winter=epsilon*sigma*A*(T_s^4-T_surr_winter^4)
```

Step 3 of 7

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 11
Select variables in equations as $T_{sur,winter}$ and $Q_{rad,winter}$ press ADD and then press ok
A table will appear put values of L as 281,282,283....291 in run 1to 11
Then from Calculate -> Solve table

Step 4 of 7

Solution will appear



$T_{sur,winter}$ (T)	$Q_{rad,winter}$ (W)
281	208.5
282	200.8
283	193
284	185.1
285	177.2
286	169.2
287	161.1
288	152.9
289	144.6
290	136.2
291	127.8

Step 5 of 7

Then from Plot -> New plot window -> X-Y Plot
Select X-axis $T_{sur,winter}$ and Y-axis $Q_{rad,winter}$
Press OK

Step 6 of 7

Graph will be plotted

Step 7 of 7

Result:
Rate of radiation heat transfer is decreased with increasing temperature of surroundings in winter. It varies linearly.

Question: 16.035P

For heat transfer purposes, a standing man can be modeled as a 30-cm-diameter, 170-cm-long vertical cylinder with both the top and bottom surfaces insulated and with the side surface at an average temperature of 34°C. For a convection heat transfer coefficient of 8 W/m2·K, determine the rate of heat loss from this man by convection in an environment at l8°C.

Step 1 of 2

Given data:

A standing man can be modeled as a vertical cylinder.

Diameter of the cylinder, $d = 30\text{cm} = 0.03\text{m}$

Length of the cylinder, $L = 170\,\text{cm} = 1.7\,\text{m}$

Top and bottom surfaces are insulated

Temperature of side surface,

$T_2 = 34°\text{C}$

$= 34 + 273$

$= 307\,\text{K}$

Temperature of environment,

$T_1 = 18°\text{C}$

$= 18 + 273$

$= 291\text{K}$

Coefficient of convection heat transfer, $h = 8\,\text{W/m}^2\cdot\text{K}$

Step 2 of 2

Surface area of the person,

$A = \pi dL$

$= \pi \times 0.03 \times 1.7$

$= 0.1602\,\text{m}^2$

The rate of heat transfer by convection is given by

$\dot{Q}_{conv} = hA(T_2 - T_1)$

$= 8 \times 1.602 \times (307 - 291)$

$= 205.056\,\text{W}$

Therefore, the rate of heat loss from man by convection, $\boxed{\dot{Q}_{conv} = 205.056\,\text{W}}$

Question: 16.036P

Hot air at 80°C is blown over a 2-m × 4-m flat surface at 30°C. If the average convection heat transfer coefficient is 55 W/m2·K, determine the rate of heat transfer from the air to the plate, in kW.

Step 1 of 2

Given

Temperature of hot air, $T_2 = 80°C$

Dimensions of flat surface, $2\,m \times 4\,m$

Temperature of flat surface, $T_1 = 30°C$

Coefficient of heat transfer, $h = 55\,W/m^2 \cdot °C$

Step 2 of 2

Area of flat surface, $A = 2 \times 4$

$= 8\,m^2$

Rate of heat transfer by convection is given by

$$\dot{Q}_{conv} = hA(T_2 - T_1)$$

$$= 55 \times 8 \times (80 - 30)$$

$$= 22000\,W$$

$$= 22\,kW$$

Rate of heat transfer from air to the plate, $\boxed{\dot{Q}_{conv} = 22\,kW}$

Question: 16.037P

Reconsider Prob. 16–36. Using EES (or other) software, plot the rate of heat transfer as a function of the heat transfer coefficient in the range of 20 W/m2·K to 100 W/m2·K. Discuss the results.

Step 1 of 7

Given

Temperature of hot air, $T_\infty = 80°C$

Dimensions of flat surface, $2\,m \times 4\,m$

Temperature of flat surface, $T_s = 30°C$

Range of coefficient of heat transfer, $20\ W/m^2 \cdot °C \le h \le 55\ W/m^2 \cdot °C$

Step 2 of 7

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
T_infinity=80 "[C]"
A=2*4 "[m^2]"
T_s=30 "[C]"
"h=55 [W/m^2-C], parameter to be varied"

"ANALYSIS"
Q_dot_conv=h*A*(T_infinity-T_s)
```

Step 3 of 7

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 10
Select variables in equations as h and $\dot{Q}_{conv}$ press ADD and then press ok
A table will appear put values of h as 20,30,40....,100 in run 1to 10
Then from Calculate -> Solve table

Step 4 of 7

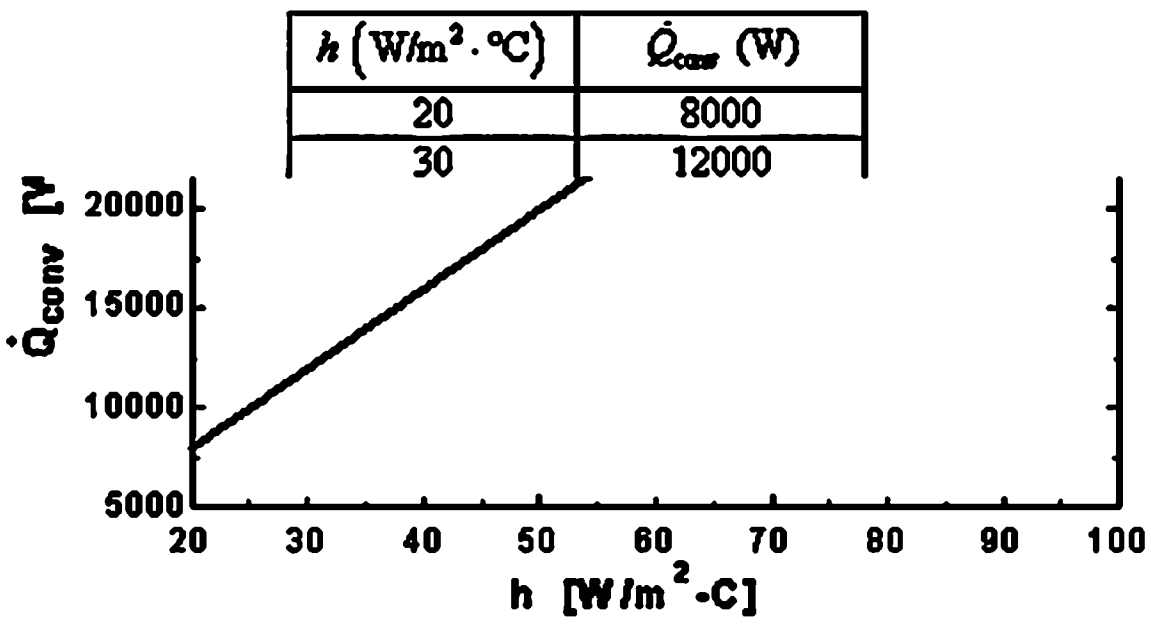
Solution will appear

$h\ (W/m^2 \cdot °C)$	$\dot{Q}_{conv}$ (W)
20	8000
30	12000

A dailogbox will open type the following in dailog box

```
"GIVEN"
T_infinity=80 "[C]"
A=2*4 "[m^2]"
T_s=30 "[C]"
"h=55 [W/m^2-C], parameter to be varied"

"ANALYSIS"
Q_dot_conv=h*A*(T_infinity-T_s)
```



Step 3 of 7

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 10
Select variables in equations as h and $\dot{Q}_{conv}$ press ADD and then press ok
A table will appear put values of h as 20,30,40....,100 in run 1to 10
Then from Calculate -> Solve table

Step 4 of 7

Solution will appear

$h\ (W/m^2 \cdot °C)$	$\dot{Q}_{conv}$ (W)
20	8000
30	12000

Step 7 of 7

From graph, rate of heat transfer increases with coefficient of heat transfer increases linearly.

Question: 16.038P

The outer surface of a spacecraft in space has an emissivity of 0.8 and a solar absorptivity of 0.3. If solar radiation is incident on the spacecraft at a rate of 950 W/m2, determine the surface temperature of the spacecraft when the radiation emitted equals the solar energy absorbed.

Step 1 of 3

Given data:

The outer surface of a spacecraft has emissivity, $\varepsilon = 0.8$

The outer surface of a spacecraft has absorptivity, $\alpha = 0.3$

The rate of solar radiation is incident on the spacecraft, $q_{rad} = 950\ W/m^2$

Step 2 of 3

Assume the radiation emitted is equal to the solar energy absorbed.

Heat absorbed by the spacecraft due to solar radiation,

$$\begin{aligned} Q_{abs} &= \alpha A_s q_{rad} \\ &= 0.3 \times A_s \times 950 \\ &= 258 A_s \end{aligned}$$

Heat transferred from the spacecraft due to solar radiation,

$$\begin{aligned} Q_{rad} &= \varepsilon \sigma A_s T^4 \\ &= 0.8 \times \left(5.67 \times 10^{-8}\right) \times A_s \times T^4 \\ &= 4.536 \times 10^{-8} A_s \times T^4 \end{aligned}$$

Step 3 of 3

From the given condition of equality between the radiation emitted and the solar energy absorbed the temperature,

$$Q_{abs} = Q_{rad}$$

$$285 A_s = 4.536 \times 10^{-8} A_s \times T^4$$

$$\begin{aligned} T^4 &= \frac{285}{4.536 \times 10^{-8}} \\ &= \sqrt[4]{6.283 \times 10^9} \\ &= 281.5\text{K} \end{aligned}$$

Therefore, the surface temperature of spacecraft, $\boxed{T = 282\ \text{K}}$

$= 258 A_s$

Heat transferred from the spacecraft due to solar radiation,

$$\begin{aligned} Q_{rad} &= \varepsilon \sigma A_s T^4 \\ &= 0.8 \times \left(5.67 \times 10^{-8}\right) \times A_s \times T^4 \\ &= 4.536 \times 10^{-8} A_s \times T^4 \end{aligned}$$

Step 3 of 3

From the given condition of equality between the radiation emitted and the solar energy absorbed the temperature,

$$Q_{abs} = Q_{rad}$$

$$285 A_s = 4.536 \times 10^{-8} A_s \times T^4$$

Question: 16.039P

The heat generated in the circuitry on the surface of a silicon chip (k= 130 W/m·K) is conducted to the ceramic substrate to which it is attached. The chip is 6 mm × 6 mm in size and 0.5 mm thick and dissipates 5 W of power. Disregarding any heat transfer through the 0.5-mm high side surfaces, determine the temperature difference between the front and back surfaces of the chip in steady operation.

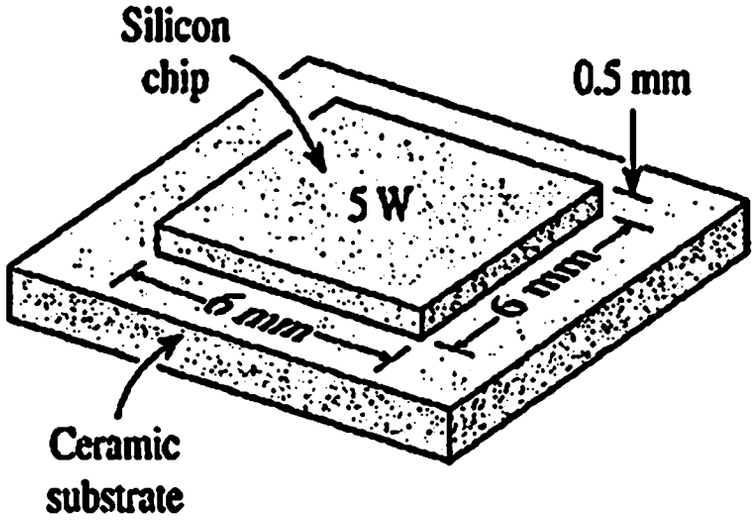


FIGURE P16–39

Step 1 of 2

Loading solution. Please wait ...

Step 2 of 2

Let the temperature difference between the front and back surfaces of the chip be ΔT
Heat transfer area of the chip,

$$A = 0.006 \times 0.006$$

$$= 3.6 \times 10^{-5}\ \text{m}^2$$

Heat transfer by conduction is given by

$$Q = kA\frac{\Delta T}{L}$$

$$\Delta T = \frac{QL}{kA}$$

$$= \frac{5 \times 0.0005}{130 \times 3.6 \times 10^{-5}}$$

$$= \frac{2.5 \times 10^{-3}}{4.68 \times 10^{-3}}$$

$$= 0.534\,\text{K}$$

Therefore, the temperature difference between the front and back surfaces of the chip,

$$\boxed{\Delta T = 0.534\,\text{K}}$$

Question: 16.040P

A 40-cm-long, 800-W electric resistance heating element with diameter 0.5 cm and surface temperature 120°C is immersed in 75 kg of water initially at 20°C. Determine how long it will take for this heater to raise the water temperature to 80°C. Also, determine the convection heat transfer coefficients at the beginning and at the end of the heating process.

Step 1 of 5

Given

Length of heating element, $L = 40\,\text{cm}$

Diameter of heating element, $d = 0.5\text{cm}$

Surface temperature of heating element, $T_s = 120°\text{C}$

Amount of water, $m = 75\text{kg}$

Initial temperature of water, $T_1 = 20°\text{C}$

Final temperature of water, $T_2 = 80°\text{C}$

Generated heat of heating element, $\dot{Q} = 800W$

Step 2 of 5

From table, properties of common liquids, solids and foods

Specific heat of water at room temperature, $C_p = 4.18\text{kJ/kg}\cdot\text{K}$

Here generated heat is equal to the rate of heat gain by water.

Noting that this is the only mechanism of energy transfer, the time it takes to raise the water temperature from 20°C to 80°C is determined to be

$$Q = mC_p(T_2 - T_1)$$

$$\Rightarrow \dot{Q}\Delta t = mC_p(T_2 - T_1)$$

$$\Rightarrow \Delta t = \frac{mC_p(T_2 - T_1)}{\dot{Q}}$$

$$= \frac{75\times 4.18\times 10^3 \times (80-20)}{800}$$

$$= \frac{18810000}{800}$$

$$= 23512s$$

$$= 6.53\text{h}$$

Time taken for heater to raise the water temperature to 80°C, $\boxed{\Delta t = 6.53\text{h}}$

Step 3 of 5

The surface area of the wire,

$$A = \pi dL$$

$$= \pi\times 0.005\times 0.4$$

$$= 0.00628\,\text{m}^2$$

The Newton's law of cooling for convection heat transfer is given by

$$\dot{Q} = hA(T_s - T_\infty)$$

Disregarding any heat transfer by radiation and thus assuming all the heat loss from the wire to occur by convection.

Step 4 of 5

The convection heat transfer coefficient at the beginning process is calculated as

$$h_1 = \frac{\dot{Q}}{A(T_s - T_{\infty 1})}$$

$$= \frac{800}{0.00628\times(120-20)}$$

$$= \frac{800}{0.628}$$

$$= 1273.8\,\text{W/m}^2\cdot°\text{C}$$

The convection heat transfer coefficient at the beginning process, $\boxed{h_1 = 1273.8\,\text{W/m}^2\cdot°\text{C}}$

Step 5 of 5

The convection heat transfer coefficient at the end of the process is determined as

$$h_2 = \frac{\dot{Q}}{A(T_s - T_{\infty 2})}$$

$$= \frac{800}{0.00628\times(120-80)}$$

$$= \frac{800}{0.2512}$$

$$= 3184.7\,\text{W/m}^2\cdot°\text{C}$$

The convection heat transfer coefficient at the end of the process, $\boxed{h_2 = 3184.7\,\text{W/m}^2\cdot°\text{C}}$

Question: 16.041P

A 5-cm-external-diameter, 10-m-long hot-water pipe at 80°C is losing heat to the surrounding air at 5°C by natural convection with a heat transfer coefficient of 25 W/m2·K. Determine the rate of heat loss from the pipe by natural convection.

Step 1 of 2

Given

Diameter of hot water pipe, $d = 5\text{cm}$

Length of hot water pipe, $L = 10\text{m}$

Temperature of pipe, $T_2 = 80°\text{C}$

Temperature of surroundings, $T_2 = 5°\text{C}$

Coefficient convection heat transfer, $h = 25\,\text{W/m}^2 \cdot °\text{C}$

Step 2 of 2

The heat transfer surface area

$$\begin{aligned} A &= \pi dL \\ &= \pi \times 0.05 \times 10 \\ &= 1.571\text{m}^2 \end{aligned}$$

Under steady conditions,

The rate of heat transfer by convection is given by

$$\begin{aligned} \dot{Q}_{conv} &= hA(T_2 - T_1) \\ &= 25 \times 1.571 \times (80 - 5) \\ &= 2945.6\,\text{W} \end{aligned}$$

The rate of heat transfer by convection, $\boxed{\dot{Q}_{conv} = 2945.6\,\text{W}}$

Question: 16.042P

A hollow spherical iron container with outer diameter 20 cm and thickness 0.2 cm is filled with iced water at 0°C.

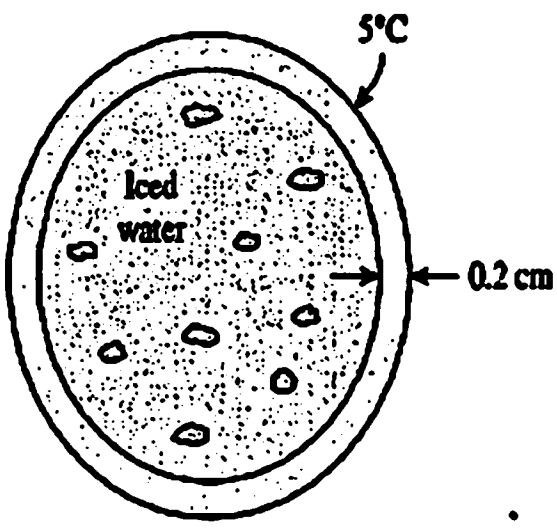

FIGURE P16–42

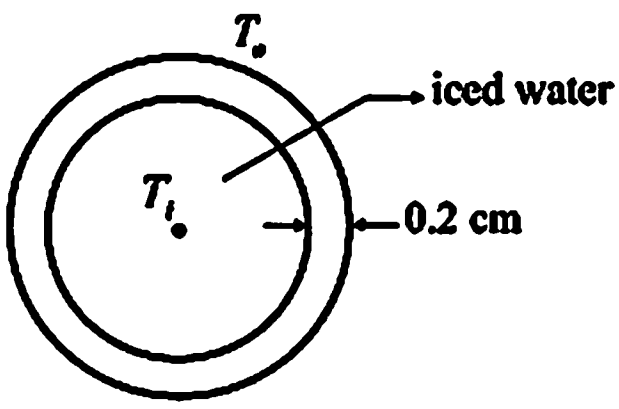
If the outer surface temperature is 5°C, determine the approximate rate of heat loss from the sphere in kW, and the rate at which ice melts in the container. The heat of fusion of water is 333.7 kJ/kg.

Step 1 of 4

Given data:

Outer diameter of the spherical container, $d_o = 20$ cm

Thickness of the container, $t = 0.2$ cm



Temperature of iced water, $T_i = 0°C$

Outer surface temperature, $T_o = 5°C$

Heat of fusion of water, $h_{if} = 333.7$ kJ/kg

Step 2 of 4

A schematic of the given iron container is shown below.

Step 3 of 4

The conduction heat transfer through the iron container is given by,

$$Q_{cond} = kA\frac{\Delta T}{dx}$$

where, A is the outer surface area of the container.

k is the thermal conductivity of the container, i.e., $k_{Fe} = 80.2$ W/m·K

dx is the length of the container.

$$Q_{cond} = (80.2 \text{ W/m}\cdot\text{K})\left(4\pi\times(0.1 \text{ m})^2\right)\times\frac{(5-0) \text{ K}}{0.002 \text{ m}}$$

$$= 80.2\times0.125\times2500$$

$$= 25{,}195.57 \text{ W}$$

Therefore, the total heat transferred through the spherical container is $\boxed{Q_{cond} = 25.195 \text{ kW}}$.

Step 4 of 4

Rate at which ice melts is given by,

$$\dot{m} = \frac{Q}{h_{if}}$$

$$= \frac{25.195 \text{ kW}}{333.7 \text{ kJ/s}}$$

$$= 0.075 \text{ kg/s}$$

Hence, the rate at which the ice melts due to the conduction heat transfer is $\boxed{\dot{m} = 0.075 \text{ kg/s}}$.

Question: 16.043P

Reconsider Prob. 16–12. Using EES (or other) software, plot the rate at which ice melts as a function of the container thickness in the range of 0.1 cm to 1.0 cm. Discuss the results.

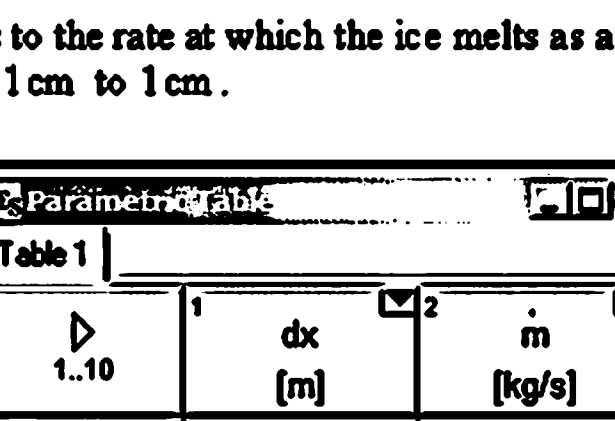
Step 1 of 5

Given data:

Outer diameter of the spherical container, $d_o = 20$ cm

Thickness of the container, $t = 0.2$ cm

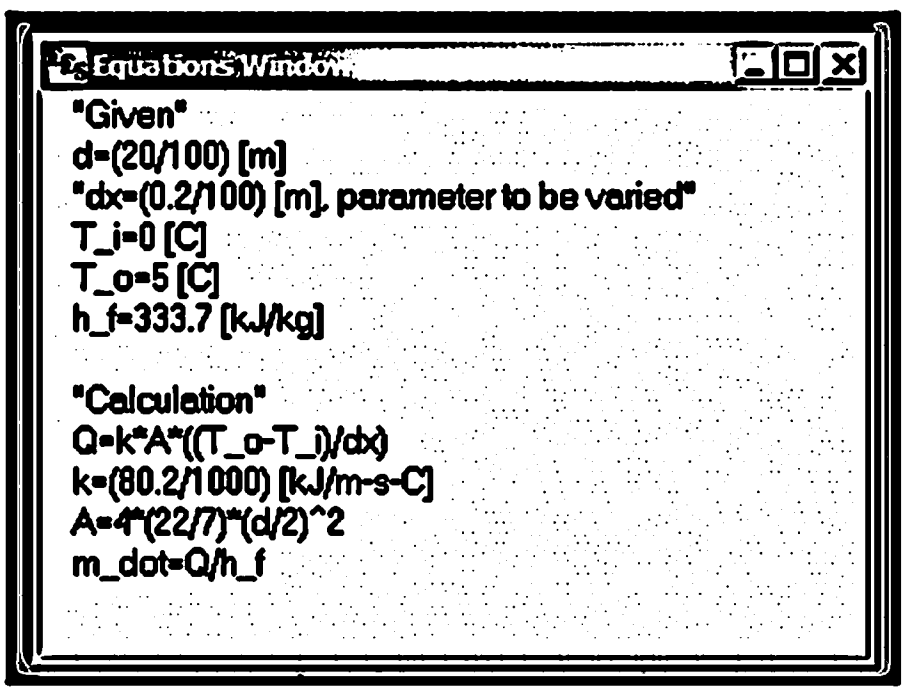
Temperature of iced water, $T_i = 0°C$



Outer surface temperature, $T_o = 5°C$

Heat of fusion of water, $h_{if} = 333.7$ kJ/kg

The thickness of the shell ranges from 0.1 cm to 1 cm.



Step 2 of 5

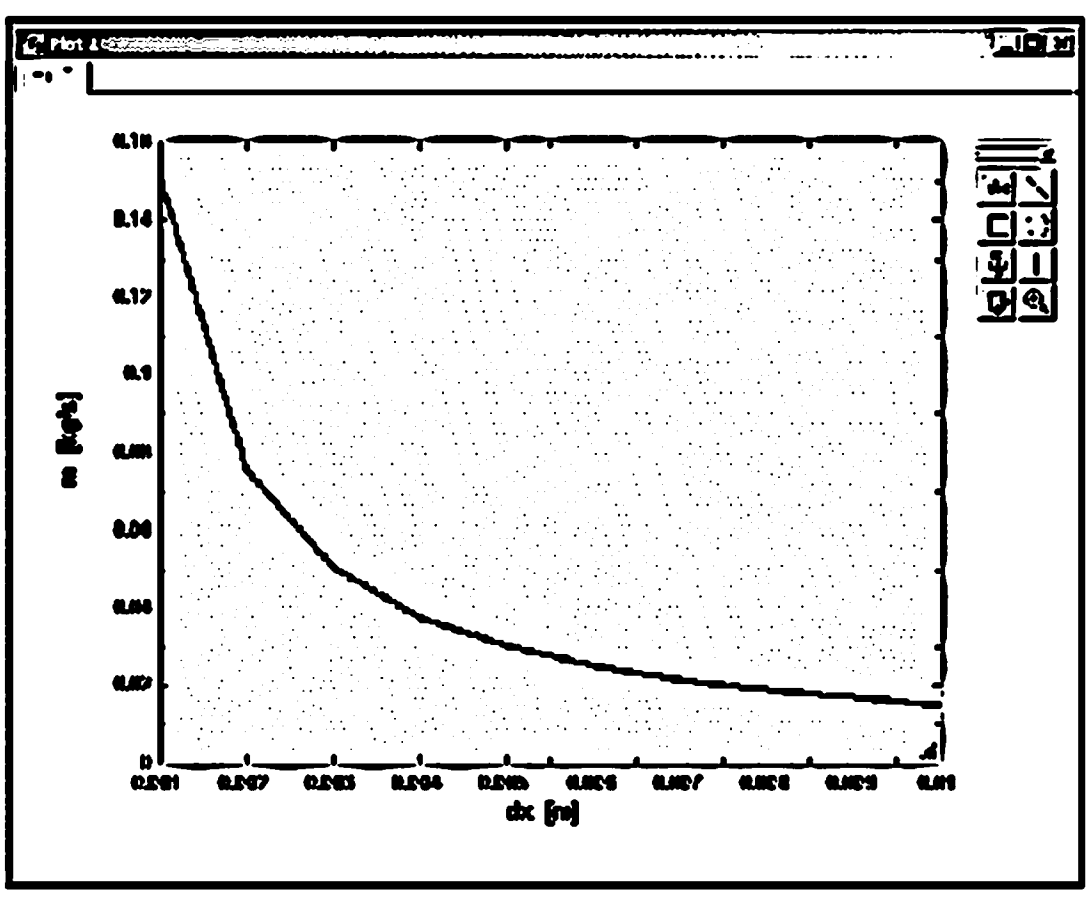
A schematic of the given iron container is shown below.

Step 3 of 5

The following program represents the given parameters followed by the calculation of the rate of ice melt for the thickness of the shell varied.

Step 4 of 5

The following table refers to the rate at which the ice melts as a function of container thickness ranging from 0.1 cm to 1 cm.



Parametric Table

Table 1

1..10	1 dx [m]	2 $\dot{m}$ [kg/s]
Run 1	0.001	0.1511
Run 2	0.002	0.07553
Run 3	0.003	0.05036
Run 4	0.004	0.03777
Run 5	0.005	0.03021
Run 6	0.006	0.02518
Run 7	0.007	0.02158
Run 8	0.008	0.01888
Run 9	0.009	0.01679
Run 10	0.01	0.01511

Step 5 of 5

Following is the graph showing the variation in the rate of ice melt as the thickness of the shell varies from 0.1 cm to 1 cm.

Question:

16.044P

The inner and outer glasses of a 4-ft × 4-ft double-pane window are at 60°F and 48°F, respectively. If the 0.25-in space between the two glasses is filled with still air, determine the rate of heat transfer through the window.

Step 1 of 3

Given

Dimensions of glass, $4\text{ft}\times 4\text{ft}$

Temperature of inner glass, $T_1 = 60°\text{F}$

Temperature of outer glass, $T_2 = 48°\text{F}$

Space between two glasses, $L = 0.25\text{in}$

Step 2 of 3

Surface area of glass, $A = 4\times 4$

$$= 16\text{ft}^2$$

The average temperature of glass,

$$T_{avg} = \frac{T_1+T_2}{2}$$

$$= \frac{60+48}{2}$$

$$= 54°\text{F}$$

Step 3 of 3

From table, properties of air at 1atm pressure,

The thermal conductivity of air at $54°\text{F}$, $k = 0.01419\text{Btu/h}\cdot\text{ft}\cdot°\text{F}$

The rate of heat loss through window

$$\dot{Q} = kA\frac{(T_1-T_2)}{L}$$

$$= 0.01419\times 16\times\frac{(60-48)}{(0.25/12)}$$

$$= \frac{32.694}{0.25}$$

$$= 130.8\text{Btu/h}$$

The rate of heat loss through window, $\boxed{\dot{Q} = 130.8\text{Btu/h}}$

Question: 16.045P

A transistor with a height of 0.4 cm and a diameter of 0 6 cm is mounted on a circuit board. The transistor is cooled by air flowing over it with an average heat transfer coefficient of 30 W/m2·K.If the air temperature is 55°C and the transistor case temperature is not to exceed 70°C, determine the amount of power this transistor can dissipate safely. Disregard any heat transfer from the transistor base.

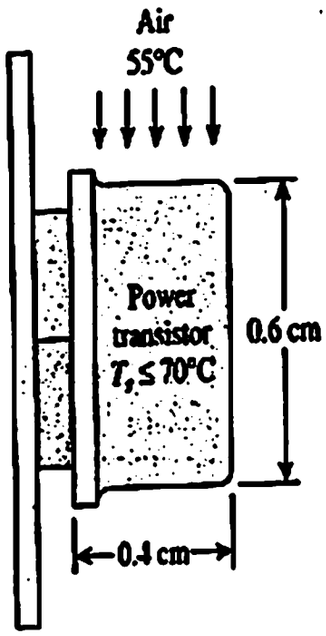


FIGURE P16–45

Step 1 of 3

Given

Height of transistor, $h = 0.4\,\text{cm}$

Diameter of transistor, $d = 0.6\,\text{cm}$

Coefficient of heat transfer, $h = 30\,\text{W/m}\cdot{}^\circ\text{C}$

Temperature of air, $T_1 = 55°\text{C}$

Temperature of transistor case, $T_2 = 70°\text{C}$

Neglect heat transfer from transistor base

Step 2 of 3

Total heat transfer area of the transistor is

$$\begin{aligned} A &= \pi dh + \pi d^2/4 \\ &= \pi \times 0.6 \times 0.4 + \pi \times 0.6^2/4 \\ &= 0.754 + 0.283 \\ &= 1.037\ \text{cm}^2 \\ &= 1.037 \times 10^{-4}\ \text{m}^2 \end{aligned}$$

Step 3 of 3

Amount of power dissipated by transistor is given by rate of heat transfer from the power transistor

$$\begin{aligned} \dot{Q} &= hA(T_2 - T_1) \\ &= 30 \times \left(1.037 \times 10^{-4}\right) \times (70 - 55) \\ &= 0.047\,\text{W} \end{aligned}$$

Amount of power dissipated by transistor, $\boxed{\dot{Q} = 0.047\,\text{W}}$

Question: 16.046P

Reconsider Prob. 16–45. Using EES (or other) software, plot the amount of power the transistor can dissipate safely as a function of the maximum case temperature in the range of 60°C to 90°C. Discuss the results.

Step 1 of 7

Given

Height of transistor, $h = 0.4\,\text{cm}$

Diameter of transistor, $d = 0.6\,\text{cm}$

Coefficient of heat transfer, $h = 30\,\text{W/m}\cdot{}^\circ\text{C}$

Temperature of air, $T_\infty = 55^\circ\text{C}$

Range of temperature of transistor case, $60^\circ\text{C} \le T_2 \le 90^\circ\text{C}$

Neglect heat transfer from transistor base

Step 2 of 7

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
L=0.004 "[m]"
D=0.006 "[m]"
h=30 "[W/m^2-C]"
T_infinity=55 "[C]"
"T_case_max=70 [C], parameter to be varied"

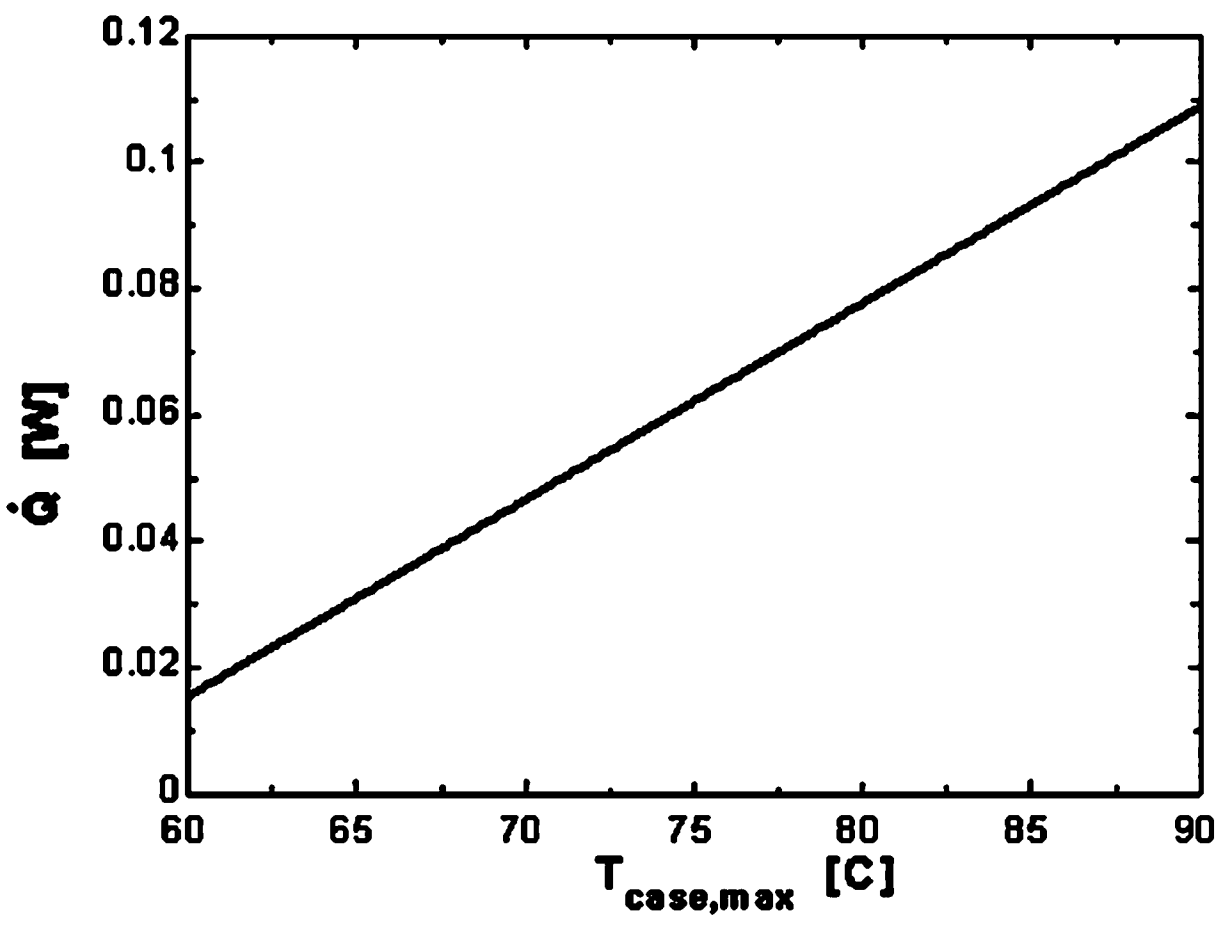
"ANALYSIS"
A=pi*D*L+pi*D^2/4
Q_dot=h*A*(T_case_max-T_infinity)
```

Step 3 of 7

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 13
Select variables in equations as T_{max} and Q press ADD and then press ok
A table will appear put values of T_{max} as 60,62.5,65.....90 upto 0.01 in run 1to 13
Then from Calculate -> Solve table

Step 4 of 7

Solution will appear



T_{max} (°C)	Q (W)
60	0.01555
62.5	0.02333
65	0.0311
67.5	0.03888
70	0.04665
72.5	0.05443
75	0.0622
77.5	0.06998
80	0.07775
82.5	0.08553
85	0.09331
87.5	0.1011
90	0.1089

Step 5 of 7

Then from Plot -> New plot window -> X-Y Plot
Select X-axis T_{max} and Y-axis Q
Press OK

Step 6 of 7

Graph will be plotted.

Step 7 of 7

From graph, amount of power increases with increasing maximum case temperature linearly.

Question: 16.047P

A 300-ft-long section of a steam pipe whose outer diameter is 4 in passes through an open space at 50°F. The average temperature of the outer surface of the pipe is measured be 280°F, and the average heat transfer coefficient on that surface is determined to be 6 Btu/h-ft2-°F. Determine (*a*) the rate of heat loss from the steam pipe and (*b*) the annual cost of this energy loss if steam is generated in a natural as furnace having an efficiency of 86 percent, and the priced natural gas is $ 1.10/therm (1 therm = 100,000 Btu).

Step 1 of 3

Use the conversion factor to convert the outer diameter of the pipe from in. to ft.

$$1\,\text{ft} = 12\,\text{in.}$$

$$\begin{aligned} d &= 4\,\text{in} \\ &= \frac{4\,\text{in.} \times 1\,\text{ft}}{12\,\text{in.}} \\ &= 0.33333\,\text{ft} \end{aligned}$$

Calculate the total area through which heat transfer.

$$A = \pi dL$$

Here, d is the outer diameter of the steam pipe, and L is the length of the steam pipe.

Substitute $0.333\,\text{ft}$ for d, and $300\,\text{ft}$ for L.

$$\begin{aligned} A &= \pi dL \\ &= \pi \times 0.33333 \times 300 \\ &= 314.156\,\text{ft}^2 \end{aligned}$$

Step 2 of 3

Calculate the Rate of heat loss from pipe.

$$\dot{Q}_{pipe} = hA\left(T_s - T_{air}\right)$$

Here, h is the heat transfer coefficient, T_s is surface temperature, and T_{air} is ambient air temperature.

Substitute $6\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ for h, $50°\text{F}$ for T_{air}, $280°\text{F}$ for T_s, and $314.156\,\text{ft}^2$ for A.

$$\begin{aligned} \dot{Q}_{pipe} &= 6 \times 314.156 \times (280 - 50) \\ &= 433535.45\,\text{Btu/h} \end{aligned}$$

Therefore, the rate of heat loss from pipe is $\boxed{433535.45\,\text{Btu/h}}$.

Step 3 of 3

(b)

Calculate the amount of heat loss per year.

$$Q = \dot{Q}t$$

Substitute $433535.45\,\text{Btu/h}$ for $\dot{Q}$.

$$\begin{aligned} Q &= 433535.45\,\text{Btu/h} \times \left(\frac{365\,\text{days}}{1\,\text{year}} \times \frac{24\,\text{h}}{1\,\text{days}}\right) \\ &= 3.79 \times 10^9\ \text{Btu/yr} \end{aligned}$$

Calculate the Amount of gas consumed per year in the furnace with efficiency of 86%.

$$\begin{aligned} \text{Annual Energy loss} &= \frac{3.79 \times 10^9}{0.86 \times 100000} \\ &= 44160.122\ \text{therms/yr} \end{aligned}$$

Calculate the total annual cost for energy loss.

$$\text{Energy cost} = \left[(\text{Annual energy loss}) \times (\text{Unit cost of energy})\right]$$

Substitute $44160.122\ \text{therms/yr}$ for for annual energy loss and 1.10 for Unit cost of energy.

$$\begin{aligned} \text{Energy cost} &= 44160.122 \times 1.10 \\ &= 48576.134/\text{yr} \end{aligned}$$

Therefore, the total annual cost for energy loss is $\boxed{48576.134/\text{yr}}$.

Question: 16.048P

The boiling temperature of nitrogen at atmospheric pressure at sea level (1 atm) is - 196°C. Therefore, nitrogen is commonly used in low temperature scientific studies since the temperature of liquid nitrogen in a tank open to the atmosphere remains constant at –196°C until the liquid nitrogen in the tank is depleted. Any heat transfer to the tank results in the evaporation of some liquid nitrogen, which has a heat of vaporaization of 198 kJ/kg and a density of 810 kg/m3- at 1 atm.

Consider a 4-m-diameter spherical tank initially filled with liquid nitrogen at 1 atm and –196°C. The tank is exposed to 20°C ambient air with a heat transfer coefficient of 25 W/m2·K. The temperature of the thin-shelled spherical tank is observed to be almost the same as the temperature of the nitrogen inside. Disregarding any radiation heat exchange, determine the rate of evaporation of the liquid nitrogen in the tank as a result ofthe heat transfer from the ambient air.

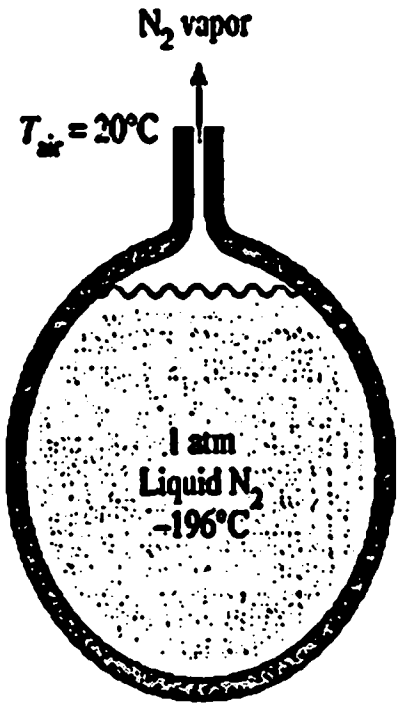


FIGURE P16–48

Step 1 of 2

Calculate the heat transfer area.

$$A = \pi d^2$$

Here, d is the diameter of the spherical tank.

Substitute $4\,\text{m}$ for d .

$$A = \pi \times 4^2$$
$$= 50.27\,\text{m}^2$$

Calculate the rate of heat transfer for nitrogen tank.

$$\dot{Q} = hA(T_{air} - T_s)$$

Here, h is the convective heat transfer coefficient, T_{air} is the ambient temperature, and T_s is the temperature of the liquid nitrogen.

Substitute $25\,\text{W/m}^2$ for h , $50.27\,\text{m}^2$ for A , $20°\text{C}$ for T_{air} , and $-196°\text{C}$ for T_s .

$$\dot{Q} = 25 \times 50.27\left[20 - (-196)\right]$$
$$= 271458\,\text{W}$$

Step 2 of 2

Calculate the rate of evaporation of liquid nitrogen.

$$\dot{Q} = \dot{m} h_{fg}$$

Here, h_{fg} is the heat of vaporization of liquid nitrogen.

Substitute $271458\,\text{W}$ for $\dot{Q}$ and $198 \times 10^3\,\text{J/kg}$ for h_{fg} .

$$271485 = \dot{m}\left(198 \times 10^3\right)$$
$$\dot{m} = 1.371\,\text{kg/s}$$

Therefore, the rate of evaporation of liquid nitrogen is $\boxed{1.371\,\text{kg/s}}$.

Question: 16.049P

Repeat Prob. 16–18 for liquid oxygen, which has a boiling temperature of −183°C. a heat of vaporization of 213 kJ/kg. and a density of 1140 kg/m3 at 1atm pressure.

Step 1 of 3

Given

Boiling temperature of nitrogen at 1atm , $T_s = -183°C$

Diameter of spherical tank, $d = 4\,m$

Temperature of ambient air, $T_{air} = 20°C$

Heat transfer coefficient, $h = 25\,W/m^2 \cdot °C$

Heat of vaporization for nitrogen, $h_{fg} = 213 kJ/kg$

Neglect any radiation heat exchange

Step 2 of 3

Heat transfer area,

$$A = \pi d^2$$
$$= \pi \times 4^2$$
$$= 50.27\,m^2$$

Rate of heat transfer for nitrogen tank is given by

$$\dot{Q} = hA(T_{air} - T_s)$$
$$= 25 \times 50.27\left[20 - (-183)\right]$$
$$= 255120\,W$$

Step 3 of 3

Rate of evaporation of liquid nitrogen is calculated as

$$\dot{Q} = \dot{m} h_{fg}$$
$$\Rightarrow \dot{m} = \frac{\dot{Q}}{h_{fg}}$$
$$= \frac{255120}{213 \times 10^3}$$
$$= 1.2 kg/s$$

Rate of evaporation of liquid nitrogen, $\boxed{\dot{m} = 1.2 kg/s}$

Question: 16.050P

Reconsider Prob. 16–48. Using EES (or other) software, plot the rate of evaporation of liquid nitrogen as a function of the ambient air temperature in the range of 0°C to 40°C. Discuss the results.

Step 1 of 4

Given data:

Boiling temperature of nitrogen at 1 atm is $T_s = -196°C$

Diameter of spherical tank, $D = 4$ m

Temperature of ambient air, $T_{air} = 20°C$

Heat transfer coefficient, $h = 25\ W/m^2 \cdot K$

Heat of vaporizations for nitrogen, $h_{fg} = 198$ kJ/kg

Step 2 of 4

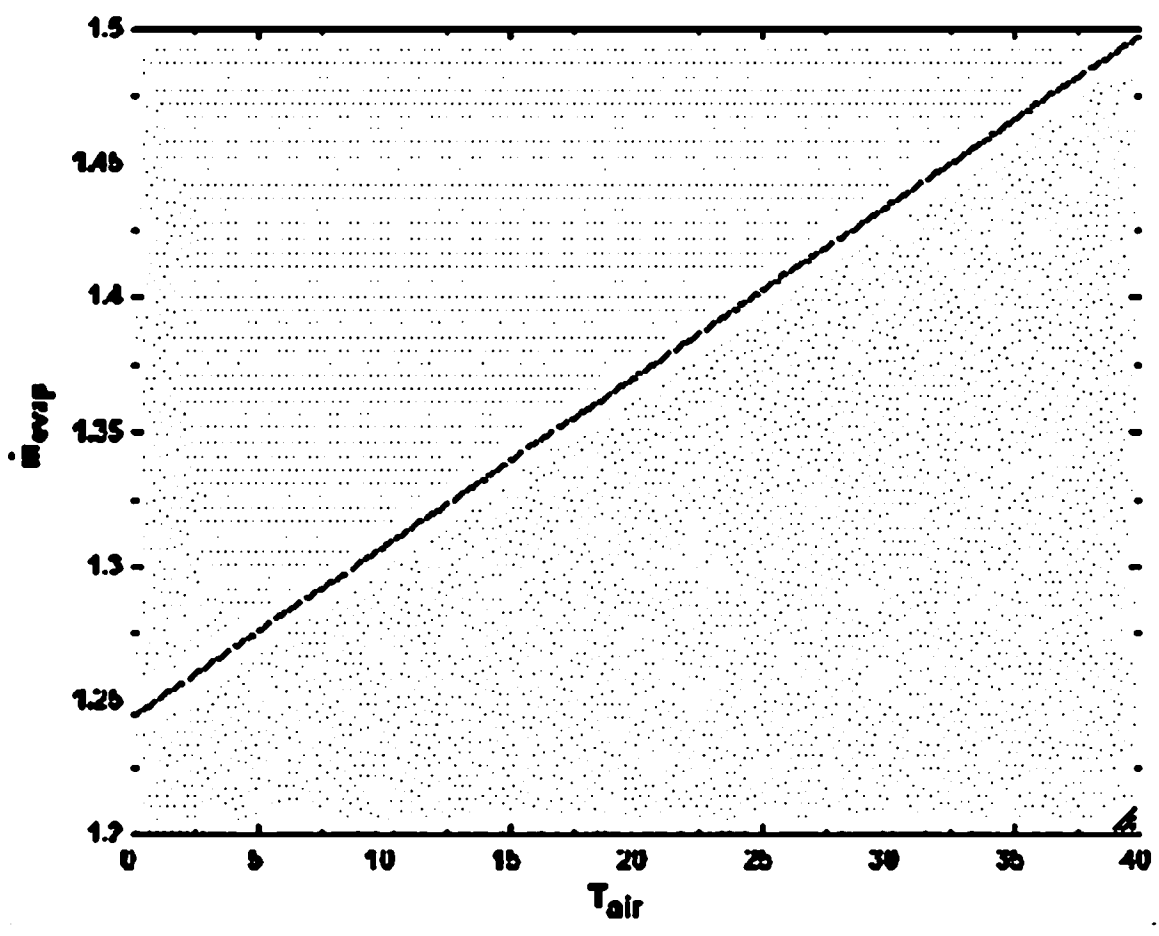
To solve this question using EES software, open EES software
Then open a new file from 'FILE' menu by cliking on 'New'
A dailogbox will open type the following in dailog box

```
"GIVEN"
D=4 [m]
T_s=-196 [C]
"T_air=20 [C], parameter to be varied"
h=25 [W/m^2-C]

"PROPERTIES"
h_fg=198 [kJ/kg]

"ANALYSIS"
A=pi*D^2
Q_dot=h*A*(T_air-T_s)
m_dot_evap=(Q_dot*Convert(J/s, kJ/s))/h_fg
```

Step 3 of 4



Then from 'Tables' menu, select 'New parametric table'. A dailog box will open
Select no of runs = 21
Select variables in equations as T_{air} and $\dot{m}_{evap}$ press 'ADD' and then press 'OK'
A table will appear, assign the values of T_{air} as 0,2,4.....40 in run 1 to 21 for that table
Then from 'Calculate' menu click 'Solve table'

Solution will be displayed as below:

1 21	1 $\dot{m}_{evap}$	2 T_{air}
Run 1	1.244	0
Run 2	1.257	2
Run 3	1.269	4
Run 4	1.282	6
Run 5	1.295	8
Run 6	1.307	10
Run 7	1.32	12
Run 8	1.333	14
Run 9	1.345	16
Run 10	1.358	18
Run 11	1.371	20
Run 12	1.384	22
Run 13	1.396	24
Run 14	1.409	26
Run 15	1.422	28
Run 16	1.434	30
Run 17	1.447	32
Run 18	1.46	34
Run 19	1.472	36
Run 20	1.485	38
Run 21	1.498	40

Step 4 of 4

Then from 'Plot' menu, click on 'New plot window' and then select 'X-Y Plot'.
Select X-axis as T_{air} and Y-axis as m_{evap}
Press 'OK' the Graph will be plotted as shown.

Question: 16.051P

Consider a person whose exposed surface area is 1.7 m2, emissivity is 0.5, and surface temperature is 32°C. Determine the rate of heat loss from that person by radiation in a large room having walls at a temperature of (*a*) 300 K and (*b*) 280 K.

Step 1 of 3

Given: -

Exposed surface area of person $A_s = 1.7\ m^2$

Emissivity $\varepsilon = 0.5$

Surface temperature $T_s = 32°C$

Step 2 of 3

(a) Net rate of heat transfer is given by

$T_{sur} = 300\ K$

$\dot{Q}_{rad} = \varepsilon\sigma A_s(T_s^4 - T_{sur}^4)$

Where

Stefan Boltzmann constant $\sigma = 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}$

$\dot{Q}_{rad} = (0.5)(5.67 \times 10^{-8}\ (\frac{W}{m^2 \cdot K^4}))(1.7\ m^2)[(32+273)^4 - (300\ K)^4]K^4$

$\dot{Q}_{rad} = 26.7\ W$

$\boxed{Q_{rad} = 26.7\ W}$

Step 3 of 3

(b) Net rate of heat transfer is given by

$T_{sur} = 280\ K$

$\dot{Q}_{rad} = \varepsilon\sigma A_s(T_s^4 - T_{sur}^4)$

Where

Stefan Boltzmann constant $\sigma = 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}$

$\dot{Q}_{rad} = (0.5)(5.67 \times 10^{-8}\ (\frac{W}{m^2 \cdot K^4}))(1.7\ m^2)[(32+273)^4 - (280\ K)^4]K^4$

$\dot{Q}_{rad} = 121\ W$

$\boxed{Q_{rad} = 121\ W}$

Question: 16.052P

A 0.3-cm-thick. 12-cm-high, and 18-cm-long circuit board houses 80 closely spaced logic chips on one side, each dissipating 0.06 W. The board is impregnated with copper fillings and has an effective thermal conductivity of 16 W/m·K. All the heat generated in the chips is conducted across the circuit board and is dissipated from the back side of the board to the ambient air. Determine the temperature difference between the two sides of the circuit board.

Step 1 of 4

Given:

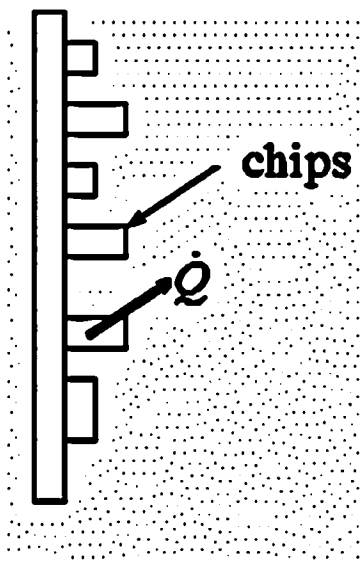
Thickness of circuit board $L = 0.3\text{cm}$

$= 0.003\text{ m}$

Height of circuit board $H = 12\text{ cm}$

$= 0.12\text{ m}$

Length of circuit board $W = 18\text{ cm}$



$= 0.18\text{ m}$

No of chips $n = = 80$

Power dissipated by each chip $Q = 0.06\text{ W}$

Effective thermal conductivity of board $k = 16\ \frac{\text{W}}{\text{m}\cdot^\circ\text{C}}$

Step 2 of 4

Step 3 of 4

Total rate of heat dissipated by the chips

$Q_{Total} = n \times Q$

$\dot{Q}_{Total} = 80 \times (0.06\text{ W})$

$= 4.8\text{ W}$

Step 4 of 4

Temperature difference between two sides of the board is

$A = (0.12\text{ m})(0.18\text{ m})$

$= 0.0216\text{ m}^2$

Heat transfer due to conduction is

$$\dot{Q} = kA\frac{\Delta T}{L}$$

$$\Delta T = \frac{\dot{Q}L}{kA}$$

$$= \frac{(4.8\text{ W})(0.003\text{ m})}{(16\text{ W/m}\cdot^\circ\text{C})(0.0216\text{ m}^2)}$$

$=0.042^\circ\text{C}$

$\boxed{\Delta T = 0.042^\circ\text{C}}$

Question: 16.053P

Consider a sealed 20-cm-high electronic box whose base dimensions are 50 cm × 50 cm placed in a vacuum chamber. The emissivity of the outer surface of the box is 0.95. If the electronic components in the box dissipate a total of 120 W of power and the outer surface temperature of the box is not to exceed 55°C, determine the temperature at which the surrounding surfaces must be kept if this box is to be cooled by radiation alone. Assume the heat transfer from the bottom surface of the box to the stand to be negligible.

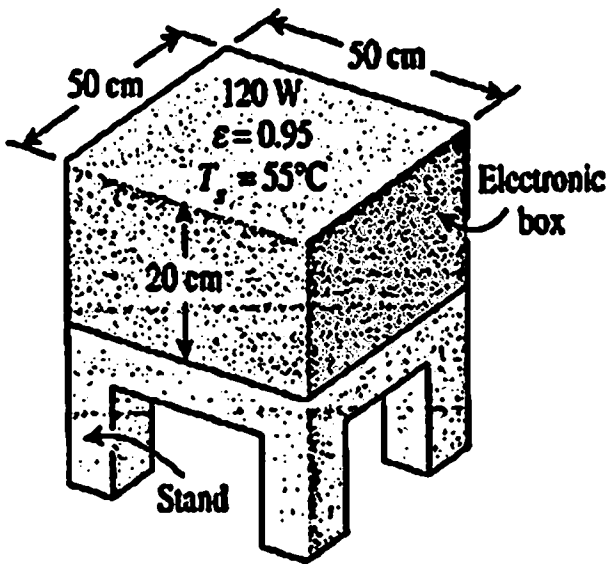


FIGURE P16–53

Step 1 of 3

Given data:

The emissivity, $\varepsilon = 0.95$.

Area of the box, $A = 50 \times 50\ \text{cm}^2$.

Height of the box, $l = 20\ \text{cm}$.

Total amount of heat dissipated by the electronic box, $Q_{rad} = 120\ \text{W}$.

Outer surface temperature of the electronic box, $T_s = 55°\text{C} = 328\ \text{K}$.

Step 2 of 3

The heat transferred by the radiation is given by,

$$Q_{rad} = \varepsilon \sigma A_s \left(T_s^4 - T_\infty^4\right)$$

The surface radiation of the electronic box from which heat is dissipates can be

A_s = Area of Top surface + Area of four side surfaces

Here, the bottom surface area is negligible.

$$A_s = (50 \times 50) + 4 \times (20 \times 50)$$
$$= 2500 + 4000$$
$$= 6500\ \text{cm}^2$$
$$= 0.65\ \text{m}^2$$

Step 3 of 3

Let T_∞ be the temperature of the surrounding at which the surfaces must be kept if box is to cooled by radiation alone.

$$Q_{rad} = \varepsilon \sigma A_s \left(T_s^4 - T_\infty^4\right)$$

$$120 = 0.95 \times \left(5.67 \times 10^{-8}\right) \times 0.65 \times \left(328^4 - T_\infty^4\right)$$

$$\left(328^4 - T_\infty^4\right) = \frac{120}{0.95 \times \left(5.67 \times 10^{-8}\right) \times 0.65}$$

$$T_\infty = \sqrt[4]{328^4 - \left(3.427 \times 10^9\right)}$$
$$= \sqrt[4]{8.146 \times 10^9}$$
$$= 300.43\ \text{K}$$
$$= 27.28\ °\text{C}$$

Hence, the surrounding air temperature should be less than $\boxed{T_\infty = 27.28°\text{C}}$.

Question: 16.054P

Using the conversion factors between W and Btu/h, m and ft, and K and R, express the Stefan-Boltz-mann constant σ= 5.67 × 10−8 W/m2·K4 in the English unit Btu/h-ft2·R4.

Step 1 of 3

Given:

Stefan-Boltzmann constant $\sigma = 5.67 \times 10^{-8}\ \mathrm{W/m^2.K^4}$

Step 2 of 3

The conversion factors for W, m, and K are taken from conversion tables

$1\ \mathrm{W} = 3.41214\ \mathrm{Btu/h}$

$1\ \mathrm{m} = 3.2808\ \mathrm{ft}$

$1\ \mathrm{K} = 1.8\ \mathrm{R}$

Step 3 of 3

Substituting gives the Stefan-Boltzmann constant in the desired units,

$$\sigma = 5.67 \times 10^{-8}\ \frac{\mathrm{W}}{\mathrm{m^2 \cdot K^4}}$$

$$= (5.67)\ \frac{(3.41214\ \mathrm{Btu/h})}{(3.2808\ \mathrm{ft})^2 (1.8\ \mathrm{R})^4}$$

$$= 0.171\ \frac{\mathrm{Btu}}{\mathrm{h \cdot ft^2 \cdot R^4}}$$

$$\boxed{0.171\ \frac{\mathrm{Btu}}{\mathrm{h \cdot ft^2 \cdot R^4}}}$$

Question: 16.055P

An engineer who is working on the heat transfer analysis of a house in English units needs the convection heat transfer coefficient on the outer surface of the house, But the only value he can find from his handbooks is 22 W/m2·K. which is in SI units. The engineer does not have a direct conversion factor between the two unit systems for the convection heat transfer coefficient. Using the conversion factors between W and Btu/h, m and ft, and °C and °F, express the given convection heat transfer coefficient in Btu/h·ft2·°F.

Step 1 of 2

Given data:

Convective heat transfer coefficient on the outer surface of the house, $h = 22\ \text{W/m}^2\cdot\text{K}$

By using some known conversion factors, we have,

$1\text{m} = 3.28084\ \text{ft}$

$1\text{W} = 3.412\ \text{Btu/h}$

$1\ ^\circ\text{C} = \frac{9}{5} + 32^\circ\text{F}$

Step 2 of 2

Now converting the heat transfer coefficient into the English units:

$$h = 22\ \text{W/m}^2\cdot\text{K}$$

$$= 22 \times \frac{3.412}{(3.28084)^2 \times \left(\frac{9}{5} + 32 - 32\right)}$$

$$= 22 \times \frac{3.412}{19.375}$$

$$= 3.874\ \text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

Hence, the convective heat transfer coefficient in English units is $\boxed{h = 3.87\ \text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}}$.

Question: 16.056P

Water at 0°C releases 333.7 kJ/kg of heat as it freezes to ice (ρ = 920 kg/m3) at 0°C. An aircraft flying under icing conditions maintains a heat transfer coefficient of 150 W/m2·K between the air and wing surfaces. What temperature must the wings be maintained at to prevent ice from forming on them during icing conditions at a rate of 1 mm/min or less?

Step 1 of 2

Given: -

Wings initial temperature $T_1 = 0°C$

Latent heat of water $L = 333.7 \text{kJ/kg}$

Density of ice $\rho = 920 \frac{\text{kg}}{\text{m}^3}$

Heat transfer coefficient $h = 150 \frac{\text{W}}{\text{m}^2 \cdot °\text{C}}$

Rate of ice formation on wings $V = 1 \frac{\text{mm}}{\text{min}}$

$$= \frac{0.001}{60} \frac{\text{m}}{\text{sec}}$$

Step 2 of 2

Assume steady state condition we can write

Heat transfer by wing = heat taken by ice

$hA(T_{wing} - T_{ice}) = \rho A V h_{if}$

Cancelling area on both sides we get

$$\left(150 \frac{\text{W}}{\text{m}^2 \cdot °\text{C}}\right)(T_{wing} - 0°\text{C}) = \left(920 \frac{\text{kg}}{\text{m}^3}\right)\left(\frac{0.001\text{m}}{60s}\right)\left(333{,}700 \frac{\text{J}}{\text{kg}}\right)$$

$T_{wing} = 34.11°\text{C}$

$\boxed{T_{wing} = 34.11°\text{C}}$

Question: 16.057P

A 2.1-m-long, 0.2-cm-diameter electrical wire extends across a room that is maintained at 20°C. Heat is generated in the wire as a result of resistance heating, and the surface temperature of the wire is measured to be 180°C in steady operation. Also, the voltage drop and electric current through the wire are measured to be 110 V and 3 A, respectively. Disregarding any heat transfer by radiation, determine the convection heat transfer coefficient for heat transfer between the outer surface of the wire and the air in the room.

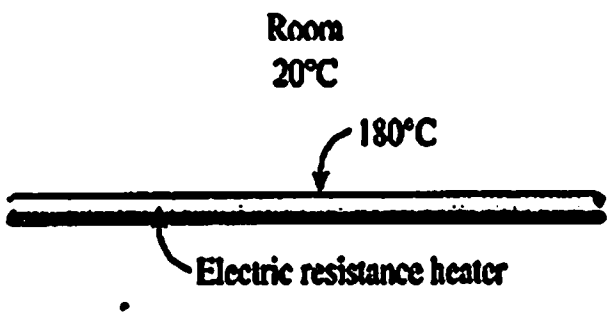

FIGURE P16–57

Step 1 of 4

Given data:

Diameter of the wire, $d = 0.2$ cm

Length of the wire, $l = 2.1$ m

Ambient temperature, $T_A = 20°C$

Surface temperature of the wire, $T_s = 180°C$

Voltage drop across the wire, $V = 110$ V

Current across the wire, $I = 3$ A

Step 2 of 4

Given figure:

Step 3 of 4

For an electrical wire, the surface area is determined using the formula,

$$A_s = \pi dl$$

$$= \pi \times \frac{0.2}{100} \times 2.1$$

$$= \pi \times 0.002 \times 2.1$$

Diameter of the wire, $d = 0.2$ cm

Length of the wire, $l = 2.1$ m

Ambient temperature, $T_A = 20°C$

Surface temperature of the wire, $T_s = 180°C$

Voltage drop across the wire, $V = 110$ V

Current across the wire, $I = 3$ A

Step 2 of 4

Given figure:

Step 3 of 4

For an electrical wire, the surface area is determined using the formula,

Question: 16.058P

Reconsider Prob. 16–57. Using EES (or other) software, plot the convection heat transfer coefficient as a function of the wire surface temperature in the range of 100°C to 300°C. Discuss the results.

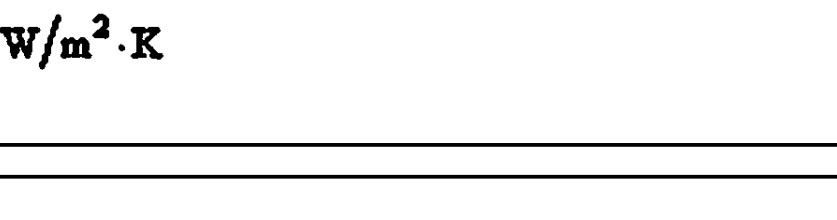
Step 1 of 7

Given data:

Diameter of the wire, $d = 0.2\,\text{cm}$

Length of the wire, $l = 2.1\,\text{m}$

Room temperature, $T_A = 20°\text{C}$



Surface temperature of the wire varies from, $T_s = 100\,°\text{C}$ to $300\,°\text{C}$

Voltage drop in the wire, $V = 110\,\text{V}$

Current across the wire, $I = 3\,\text{A}$

Step 2 of 7

Given figure:

Step 3 of 7

For an electrical wire, the surface area is given by,

$$A_s = \pi dl$$

$$= \pi \times \frac{0.2}{100} \times 2.1$$

$$= \pi \times 0.002 \times 2.1$$

$$= 0.0132\,\text{m}^2$$

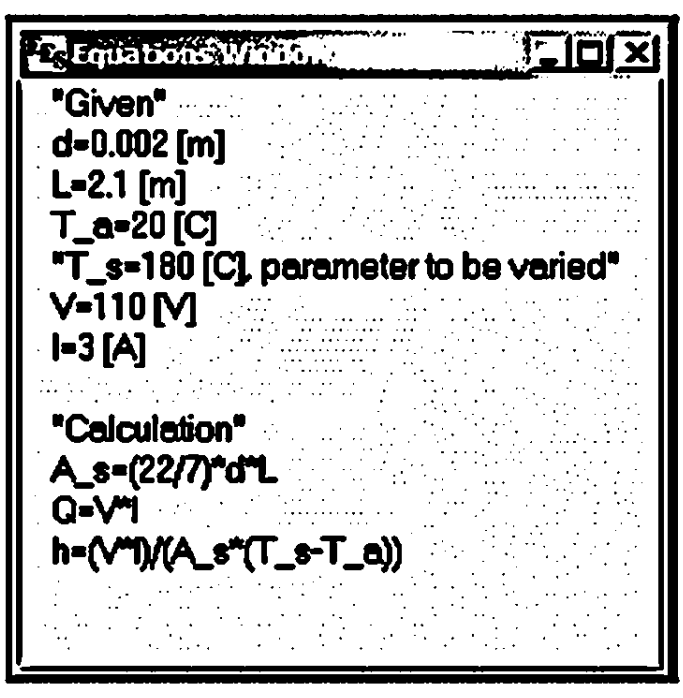
Step 4 of 7

Let h be the heat transfer coefficient between the ambient air and the wire.

Rate of heat dissipation due to the current passing through the electrical wire is given by

$$Q = hA_s\Delta T$$

$$I \times V = h \times 0.0132 \times (T_S - 20)$$



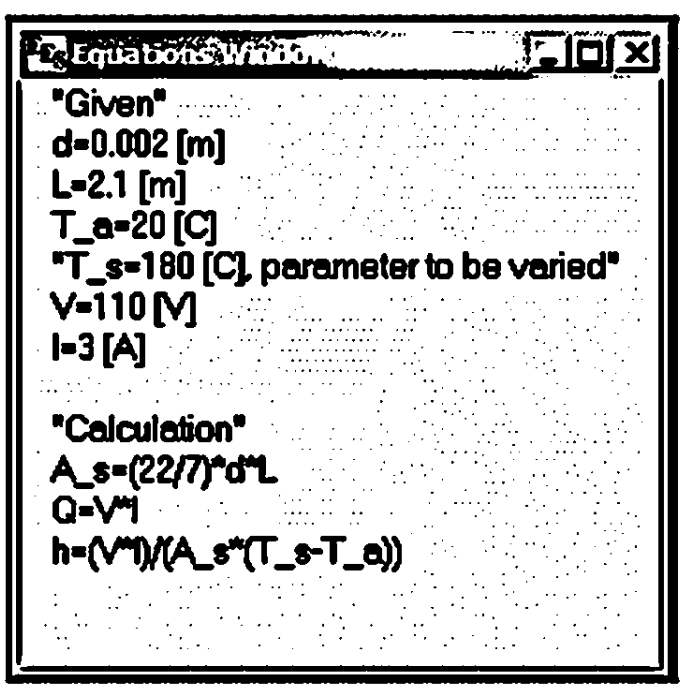
$$110 \times 3 = h \times 0.0132 \times (T_S - 20)$$

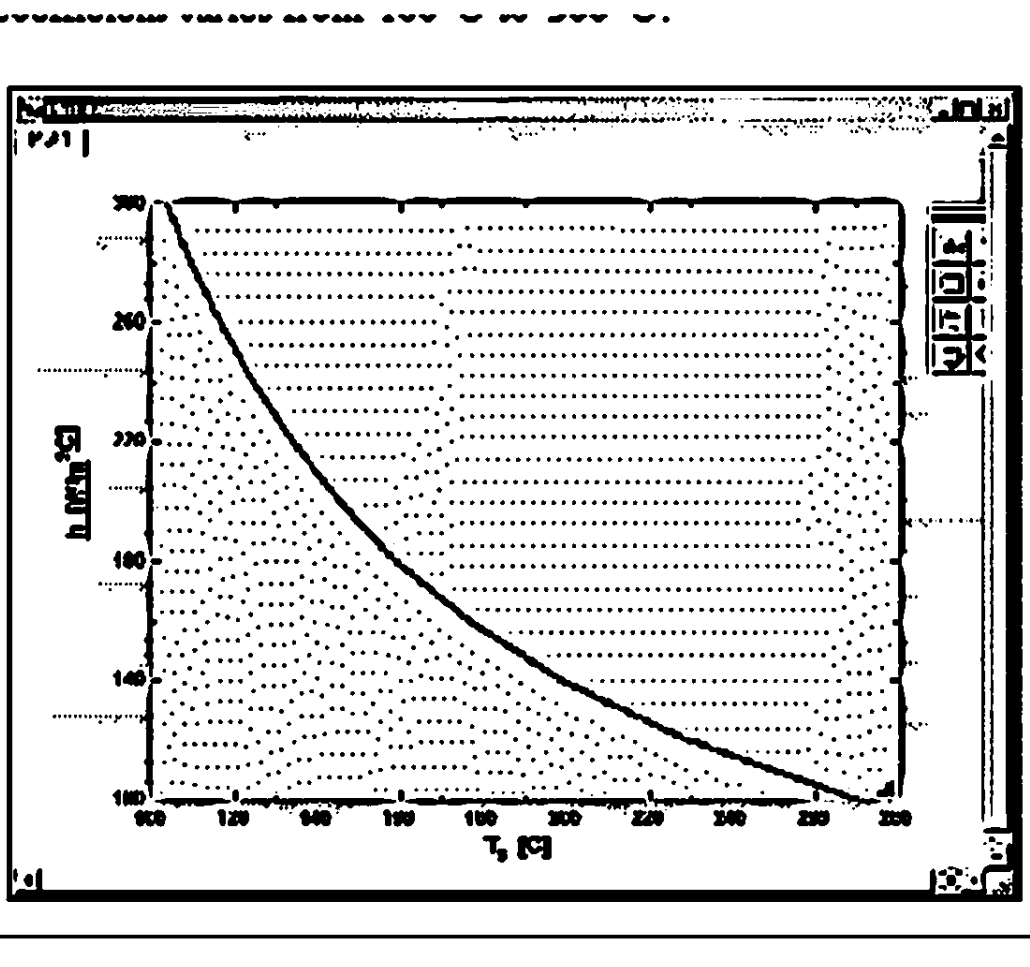
$$h = \frac{110 \times 3}{0.0132 \times (T_S - 20)}$$

$$= \frac{25000}{(T_S - 20)}\,\text{W/m}^2 \cdot \text{K}$$

Step 5 of 7

The following program represents the given parameters followed by the calculation of the heat transfer coefficient.





$$h = \frac{110 \times 3}{0.0132 \times (T_S - 20)}$$

$$= \frac{25000}{(T_S - 20)}\,\text{W/m}^2 \cdot \text{K}$$

Step 5 of 7

The following program represents the given parameters followed by the calculation of the heat transfer coefficient.

Question: 16.059P

Can all three modes of heat transfer occur simultaneously (in parallel) in a medium?

Step 1 of 1

All three modes of heat transfer cannot occur simultaneously in a medium.
Because of medium required only for conduction and convention. But not required for radiation. A medium may involve two of them simultaneously.

Question: 16.060P

Can a medium involve (*a*) conduction and convection, (*b*) conduction and radiation, or (*c*) convection and radiation simultaneously? Give examples for the "yes" answers.

Step 1 of 3

(a)
Heat transfer through fluid is either by conduction or convention, depending upon the presence of any bulk fluid motion. So that Conduction and convection not occurs simultaneously.

Step 2 of 3

(b)
The combined mode of Conduction and radiation occurs simultaneously.
Example: A roof heating of a house in winter. Where the heat from hot air the outside roof is transferred to the colder ambient environmental inside the room. Another example hot cup tea to the surrounding air thought the side walls of the cup contains in the tea.

Step 3 of 3

(c)
The combined mode of Convection and radiation occurs simultaneously.
The combined mode of Conduction and radiation occurs simultaneously where the solid surface either the loses the heat or gain the heat from the surrounding medium. This modes are occurs simultaneously in order to determine the total heat transfer.
Example: Heat transferred from the hot furnace wall to the surrounding air
And the outer surface of the cold piece of rock will warm up in a warmer environmental as a result by heat gain by convention (from the air) and radiation from the sun or warmer surrounding surface.

Step 3 of 3

(c)
The combined mode of Convection and radiation occurs simultaneously.
The combined mode of Conduction and radiation occurs simultaneously where the solid surface either the loses the heat or gain the heat from the surrounding medium. This modes are occurs simultaneously in order to determine the total heat transfer.
Example: Heat transferred from the hot furnace wall to the surrounding air
And the outer surface of the cold piece of rock will warm up in a warmer environmental as a result by heat gain by convention (from the air) and radiation from the sun or warmer surrounding surface.

Question: 16.061P

The deep human body temperature of a healthy person remains constant at 37°C while the temperature and the humidity of the environment change with time. Discuss the heat transfer mechanisms between the human body and the environment both in summer and winter, and explain how a person can keep cooler in summer and warmer in winter.

Step 1 of 2

The human body loses heat by convection, radiation, and evaporation in both summer and winter.

In summer season our body temperature is more than that of the surrounding .so in order to maintain the body temperature there is formation of boundary layer on the body due to wet on the surface or evaporation process. In summer, we can keep cool by dressing lightly, staying in cooler environments, turning a fan on, avoiding humid places and direct exposure to the sun.

Step 2 of 2

In winter season our body contains fat which is the high calorific value which generates more heat in body to maintain the temperature constant in winter season by means of melting of the fat. In winter, we can keep warm by dressing heavily, staying in a warmer environment, and avoiding drafts.

Question: 16.062P

We often turn the fan on in summer to help us cool. Explain how a fan makes us feel cooler in the summer. Also explain why some people use ceiling fans also in winter.

Step 1 of 2

The fan increases the air motion around the body and thus the convection heat transfer coefficient, which increases the rate of heat transfer from the body by convection and evaporation

When using the ceiling fans in a summer day, make certain to let the blades rotate ins the counter clockwise in order that to blow the air downward towards to you as well as in your space. The gust of wind from the fan evaporates perspiration on human skin faster which in effect leaves our body felling cooler.

Step 2 of 2

In rooms with high ceilings, ceiling fans are used in winter to force the warm air at the top downward to increase the air temperature at the body level. This is usually done by forcing the air up which hits the ceiling and moves downward in a gently manner to avoid drafts.

Question: 16.063P

Consider a person standing in a room at 18°C. Determine the total rate of heat transfer from this person if the exposed surface area and the skin temperature of the person are 1.7 m2 and 32°C. respectively, and the convection heat transfer coefficient is 5 W/m2·K. Take the emissivity of the skin and the clothes to be 0.9, and assume the temperature of the inner surfaces of the room to be the same as the air temperature.

Step 1 of 3

Given data:

Temperature of the ambience, $T_A = 18°C = 291\ K$

Surface area of the person, $A_s = 1.7\ m^2$

Surface temperature of the person, $T_s = 32°C = 305\ K$

Convective heat transfer coefficient, $h = 5\ W/m^2 \cdot K$

Emissivity between man and air, $\varepsilon = 0.9$.

Step 2 of 3

The total heat transfer from the person is given by,

$$Q = Q_{rad} + Q_{conv}$$
$$= \varepsilon\sigma A_s \left(T_s^4 - T_\infty^4\right) + hA_s\Delta T$$

where, $\sigma = 5.67\times10^{-8}\ W/m^2 \cdot K^4$

Heat transfer from the person to the surroundings due to radiation is given by

$$Q_{rad} = \varepsilon\sigma A_s \left(T_s^4 - T_\infty^4\right)$$
$$= \varepsilon\sigma A_s \left(T_s^4 - T_A^4\right)$$
$$= 0.9\times5.67\times10^{-8}\times1.7\times\left((32+273)^4 - (18+273)^4\right)$$
$$= 0.9\times\left(5.67\times10^{-8}\right)\times1.7\times\left(305^4 - 291^4\right)$$
$$= 128.63\ W$$

Step 3 of 3

Heat transfer from the person to the surroundings due to convection:

$$Q_{conv} = hA_s\Delta T$$
$$= hA_s\left(T_s - T_A\right)$$
$$= 5\times1.7\times(32-18)$$
$$= 119\ W$$

Now, the total heat transfer from the person due to convection and radiation together is given by,

$$Q = Q_{rad} + Q_{conv}$$
$$= 128.63 + 119$$
$$= 247.63\ W$$

Hence, the rate of total heat transfer from the person to the surroundings is $\boxed{Q = 248\ W}$.

Question: 16.064P

Consider steady heat transfer between two large parallel plates at constant temperatures of $T1$ = 290 K and $T2$=150 K that are L=2 cm apart. Assuming the surfaces to be black (emissivity ε = 1). determine the rate of heal transfer between the plates per unit surface area assuming the gap between the plates is (*a*) filled with atmospheric air, (*b*) evacuated, (*c*) filled with fiberglass insulation, and (*d*) filled with superinsulation having an apparent thermal conductivity of 0.00015 W/m·K.

Step 1 of 10

Given: -

Temperature of plate 1 $(T_1) = 290\ K$

Temperature of plate 2 $(T_2) = 150\ K$

Distance between two plates $(L) = 2\ cm$

$= 0.02\ m$

Emissivity $\varepsilon = 1$

Thermal conductivities for super insulation $(k) = 0.00015\ \frac{W}{m.^\circ C}$

Step 2 of 10

Mean film temperature

$$T_{mean} = \frac{T_1 + T_2}{2}$$

$$T_{mean} = \frac{290 + 150}{2}$$

$$T_{mean} = 220\,K$$

$$T_{mean} = -53^\circ C$$

Step 3 of 10

From the Properties of air

At -53°C

By using the interpolation we get

$$k_{air} = 0.01582 + \frac{(0.01979 - 0.01582)(-53 - (-50))}{-50 - (-100)}$$

$$k_{air} = 0.0195519\ \frac{W}{m.^\circ C}$$

From the Properties of glass

For fiberglass insulation at -53°C

$$k = 0.036\ \frac{W}{m.^\circ C}$$

Step 4 of 10

(a) Rates of heat transfer by conduction

$$\dot{Q}_{cond} = kA\frac{T_1 - T_2}{L}$$

$$= (0.0195519\ \frac{W}{m^2.^\circ C})(1\ m^2)\frac{(290 - 150)\ K}{0.02\ m}$$

$$= 136.863\ W$$

Step 5 of 10

Rates of heat transfer by radiation

$$\dot{Q}_{rad} = \varepsilon\sigma A_s(T_1^4 - T_2^4)$$

$$= 1(5.67 \times 10^{-8}\ W/m^2.K^4)(1m^2)\left[(290\ K)^4 - (150\ K)^4\right]$$

$$= 372\ W$$

Step 6 of 10

Total heat transfer is

$$\dot{Q}_{total} = \dot{Q}_{cond} + \dot{Q}_{rad}$$

$$= 136.833 + 372$$

$$= 508.86\ W$$

$\boxed{Q_{Total} = 508.86\ W}$

Step 7 of 10

(b) In case of vacuum there will no heat transfer through conduction and all heat Transfer will be through radiation so

Rates of heat transfer by radiation

$$\dot{Q}_{rad} = \varepsilon\sigma A_s(T_1^4 - T_2^4)$$

$$= 1(5.67 \times 10^{-8}\ W/m^2.K^4)(1m^2)\left[(290\ K)^4 - (150\ K)^4\right]$$

$$= 372\ W$$

$$\dot{Q}_{total} = \dot{Q}_{rad} = 372\ W$$

$\boxed{\dot{Q}_{total} = 372\ W}$

Step 8 of 10

C) In case of fiberglass entire heat transfer will be through conduction

Rates of heat transfer by conduction

$$\dot{Q}_{total} = \dot{Q}_{cond}$$

$$= kA\frac{(T_1 - T)_2}{L}$$

$$= (0.036\ \frac{W}{m.^\circ C})(1\ m^2)\frac{(290 - 150)\ K}{0.02\ m}$$

$$= 252\ W$$

$\boxed{Q_{Total} = 252\ W}$

Step 9 of 10

e) The rate of heat transfer in case of super-insulation will be

Rates of heat transfer by conduction

$$\dot{Q}_{total} = \dot{Q}_{cond}$$

$$= kA\frac{(T_1 - T_2)}{L}$$

Step 10 of 10

$$= (0.00015\ W/m.^\circ C)(1\ m^2)\frac{(290 - 150)\ K}{0.02\ m}$$

$$= 1.05\ W$$

$\boxed{Q_{Total} = 1.05\ W}$

Question: 16.065P

The inner and outer surfaces of a 25-cm-thiek wall in summer are at 27?C and 44?C, respectively. The outer surface of the wall exchanges heat by radiation with surrounding surfaces at 40?C, and convection with ambient air also at 40?C with a convection heat transfer coefficient of 8 W/m2?K. Solar radiation is incident on the surface at a rate of 150 W/m2. If both the emissivity and the solar absorptivity of the outer surface are 0.8, determine the effective thermal conductivity of the wall.

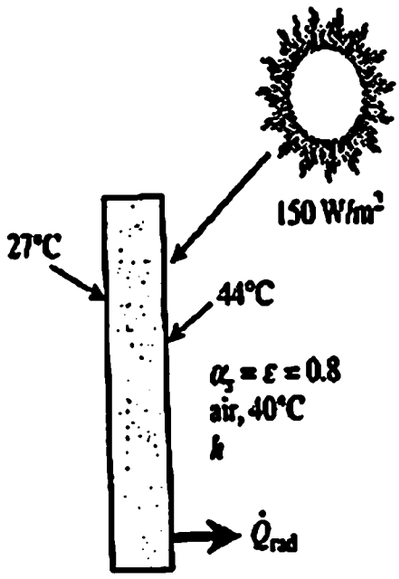


FIGURE P16–65

Step 1 of 1

Apply steady state condition on the surface to calculate the required effective thermal conductivity.

$$\dot{q}_{cond} = \dot{q}_{conv} + \dot{q}_{rad} + \dot{q}_{solar}$$

Here, $\dot{q}_{conv}$ is the convection heat transfer, $\dot{q}_{cond}$ is the conduction heat transfer, $\dot{q}_{solar}$ is the solar heat transfer and $\dot{q}_{rad}$ is the radiation heat transfer.

Substitute $k\left(\frac{T_2 - T_1}{L}\right)$ for $\dot{q}_{cond}$, $h(T_0 - T_2)$ for $\dot{q}_{conv}$, $\varepsilon\sigma\left(T_{surr}^4 - T_2^4\right)$ for $\dot{q}_{rad}$, and $\alpha_s I$ for $\dot{q}_{solar}$.

$$k\left(\frac{T_2 - T_1}{L}\right) = h(T_0 - T_2) + \varepsilon\sigma\left(T_{surr}^4 - T_2^4\right) + \alpha_s I$$

Here, T_1 is the inner temperature of the wall, T_2 is outer temperature of the wall, L is the thickness of the wall, k is the thermal conductivity, h is the heat transfer co efficient, T_0 is the ambient air temperature, ε is the emissivity of the surface, σ is the Stefan Boltzmann constant, T_{surr} is surrounding temperature, α_s is the solar absorptivity of the outer surface, and I is the solar radiation incident on surface.

Substitute 0.25 m for L, $27°C$ for T_1, $44°C$ for T_2, $40°C$ for T_{surr}, $8\,W/m^2 \cdot °C$ for h, $40°C$ for T_0, $150\,W/m^2$ for I, $\left(5.67\times10^{-8}\right)$ for σ, 0.8 for ε, and 0.8 for α_s.

$$k\times\left(\frac{44-27}{0.25}\right) = 8\times(40-44) + (0.8)\left(5.67\times10^{-8}\right)\left[313^4 - 317^4\right] + (0.8)(150)$$

$$k = 0.960\,W/m \cdot °C$$

Therefore, the required effective thermal conductivity of the wall is $\boxed{0.960\,W/m \cdot °C}$.

Question: 16.066P

A 2-in-diameter spherical ball whose surface is maintained at a temperature of 170°F is suspended in the middle of a room at 70°F. If the convection heat transfer coefficient is 15 Btu/h·ft2·°F and the emissivity of the surface is 0.8, determine the total rate of heat transfer from the ball.

Step 1 of 5

Given:

Diameter of the spherical ball $D = 2\text{in}$

A spherical ball surface temperature $T_s = 170°\text{F}$

Room temperature $T_0 = 70°\text{F}$

The Emissivity of the ball surface is given to be $\varepsilon = 0.8$.

Convection heat coefficient $h = 15\dfrac{\text{Btu}}{\text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F}}$

Step 2 of 5

The heat transfer surface area is

$$A_s = \pi D^2$$
$$= \pi\left(\frac{2}{12}\text{ ft}\right)^2$$
$$= 0.08727\text{ ft}^2$$

Step 3 of 5

Under steady conditions, the rates of convection and radiation heat transfer are

$$\dot{Q}_{conv} = hA_s\Delta T$$
$$= \left(15\frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F}}\right)(0.08727\text{ ft}^2)(170-70)^\circ\text{F}$$
$$= 130.905\frac{\text{Btu}}{\text{h}}$$

Step 4 of 5

$$\dot{Q}_{rad} = \varepsilon\sigma A_s(T_s^4 - T_\infty^4)$$
$$= 0.8(0.08727\text{ ft}^2)\left(0.1714\times10^{-8}\frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\cdot\text{R}^4}\right)[(170+460\text{ R})^4 - (70+460\text{ R})^4]$$
$$= 9.4\ \frac{\text{Btu}}{\text{h}}$$

Step 5 of 5

Therefore, Total Heat transfer is

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$= 130.9 + 9.4$$
$$= 140.3\frac{\text{Btu}}{\text{h}}$$

$$\boxed{Q_{Total} = 140.3\frac{\text{Btu}}{\text{h}}}$$

Question: 16.067P

An 800-W iron is left on the iron board with its base exposed to the air at 20°C. The convection heat transfer coefficient between the base surface and the surrounding air is 35 W/m2·K. If the base has an emissivity of 0.6 and a surface area of 0.02 m2, determine the temperature of the base of the iron.

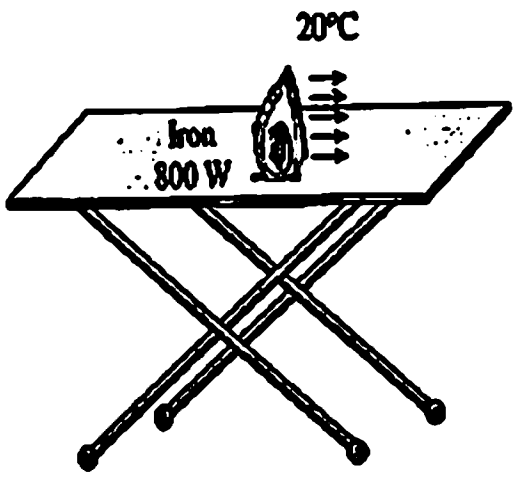

FIGURE P16–67

Step 1 of 3

Given data:

Capacity of the an iron box, $Q = 800\ \text{W}$

The ambient temperature, $T_\infty = 20°\text{C} = 293\ \text{K}$

Convective heat transfer coefficient, $h = 35\ \text{W/m}^2\cdot\text{K}$

The emissivity of the base, $\varepsilon = 0.6$

The surface area of the base, $A_s = 0.02\ \text{m}^2$

Step 2 of 3

Thermal properties of man are assumed to be constant and the heat transfer takes place due to both convective and radiation.

$$Q = Q_{rad} + Q_{conv}$$
$$= \varepsilon\sigma A_s\left(T^4 - T_\infty^4\right) + hA_s\Delta T$$

Heat transfer from the person to the surroundings due to radiation is given by

$$Q_{rad} = \varepsilon\sigma A_s\left(T^4 - T_\infty^4\right)$$
$$= 0.6\times\left(5.67\times10^{-8}\right)\times0.02\times\left(T^4 - 293^4\right)$$

Step 3 of 3

Heat transfer from the iron to the surroundings due to convection:

$$Q_{conv} = hA_s\Delta T$$
$$= 35\times0.02\times(T - 293)$$

Now the total heat transfer can be obtained by,

$$Q = Q_{rad} + Q_{conv}$$
$$800 = \left(0.6\times\left(5.67\times10^{-8}\right)\times0.02\times\left(T^4 - 293^4\right)\right) + \left(35\times0.02\times(T - 293)\right)$$
$$800 = \left(0.06804\times10^{-8}T^4 - 5.0145\right) + (0.7T - 205.1)$$
$$0.06804\times10^{-8}T^4 + 0.7T - 210.11 = 800$$
$$0.06804\times10^{-8}T^4 + 0.7T = 1{,}010.11\ \text{W}$$

By trial and error method, we have,

$T = 601°\text{C}$

Hence, the base temperature of iron is $\boxed{T = 601°\text{C}}$.

Question: 16.068P

A 3-m-internal-diameter spherical tank made of 1-cm-thick stainless steel is used to store iced water at 0°qC.The lank is located outdoors at 25°C. Assuming the entire steel lank to be at 0°C and thus the thermal resistance of the tank to be negligible, determine (*a*) the rate of heat transfer to the iced water in the lank and (*b*) the amount of ice at 0°C that melts during a 24-hour period. The heat of fusion of water at atmospheric pressure is *hif* =333.7 kJ/kg. Theemissivity of the outer surface of the tank is 0.75. and the convection heat transfer coefficient on the outer surface can be taken to be 30 W/m2·K. Assume the average surrounding surface temperature for radiation exchange to be 15°C.

Step 1 of 4

Given

Internal diameter of spherical tank, $d = 3\text{m}$

Thickness, $t = 1\text{cm}$

Average surrounding surface temperature for radiation exchange, $T_{sur} = 15°\text{C}$

Temperature of entire steel tank, $T_s = 0°\text{C}$

Outdoor temperature, $T_\infty = 25°\text{C}$

The heat of fusion of water at atmospheric pressure, $h_{if} = 333.7\,\text{kJ/kg}$.

The emissivity of the outer surface of the tank, $\varepsilon = 0.75$

Heat transfer coefficient, $h = 30\,\text{W/m}^2\cdot°\text{C}$

Step 2 of 4

(a) The outer surface area of the spherical tank,

$$A = \pi d_2^2$$
$$= \pi \times 3.02^2$$
$$= 28.65\,\text{m}^2$$

The rate of heat transfer to the tank by convection is given by

$$\dot{Q}_{conv} = hA(T_\infty - T_s)$$
$$= 30 \times 28.65 \times (25-0)$$
$$= 21487.5\,\text{W}$$
$$= 21.5\text{kW}$$

Step 3 of 4

The rate of heat transfer to the tank by radiation is given by

$$\dot{Q}_{rad} = \varepsilon A\sigma\left(T_{sur}^4 - T_s^4\right)$$
$$= 0.75 \times 28.65 \times \left(5.67\times10^{-8}\right) \times \left(288^4 - 273^4\right)$$
$$= 1614.5\,\text{W}$$
$$= 1.61\text{kW}$$

The total rate of heat transfer,

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$= 21.5 + 1.61$$
$$= 23.11\text{kW}$$

Total rate of heat transfer, $\boxed{\dot{Q}_{total} = 23.11\text{kW}}$

Step 4 of 4

(b) The amount of heat transfer during a 24-hour period is

$$Q = \dot{Q}t$$
$$= 23.1 \times (24 \times 3600)$$
$$= 1996704\,\text{kJ}$$

Then the amount of ice that melts during this period becomes

$$Q = mh_{if}$$
$$\Rightarrow m = \frac{Q}{h_{if}}$$
$$= \frac{1996704}{333.7}$$
$$= 5983.5\text{kg}$$

The amount of ice that melts during 24 h period, $\boxed{m = 5983.5\text{kg}}$

Question: 16.069P

The roof of a house consists of a 22-cm-thick concrete slab (k = 2 W/m·K) that is 15 m wide and 20 m long. The emissivity of the outer surface of the 1roof is 0.9, and the convection heat transfer coefficient on that surface is estimated to be 15 W/m2·K. The inner surface of the roof is maintained at 15°C. On a clear winter night, the ambient air is reported to be at 10°C while the night sky temperature for radiation heat transfer is 255 K. Considering both radiation and convection heat transfer, determine the outer surface temperature and the rate of heat transfer through the roof.

If the house is heated by a furnace burning natural gas with an efficiency of 85 percent, and the unit cost of natural gas is $1.20/therm (1 therm = 105.500 kJ of energy content), determine the money lost through the roof that night during a 14-hour period.

Step 1 of 3

Consider the outer surface temperature of the roof be T_{out} .

Since, the total heat conducted is equal to the sum of the heat transferred through convection and the rest by radiation.

$$Q_{cond} = Q_{rad} + Q_{conv}$$

Re-write the equation as follows:

$$kA_s\frac{\Delta T}{L} = \varepsilon\sigma A_s\left(T_s^4 - T_\infty^4\right) + hA_s\Delta T$$

$$k\frac{\Delta T}{L} = \varepsilon\sigma\left(T_s^4 - T_\infty^4\right) + h\Delta T$$

$$k\frac{T_{in} - T_{out}}{L} = \varepsilon\sigma\left(T_{out}^4 - T_{rad}^4\right) + h\left(T_{out} - T_\infty\right)$$

Here, k is the thermal conductivity of the roof, L is the thickness, T_{in} the inner temperature, T_{out} is the outer temperature, ε is the emissivity, σ is the Stephen-Boltzmann Constant, T_{rad} is the sky temperature for radiation heat transfer, h is the heat transfer coefficient, and T_∞ is the ambient temperature.

Substitute $2\ \text{W/m}\cdot\text{K}$ for k, $15°\text{C}$ for T_{in} , 0.22 m for L, 0.9 for ε , $5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4$ for σ , 255 K for T_{rad} , $15\ \text{W/m}^2\cdot\text{K}$ for h, and $10°\text{C}$ for T_∞ .

$$2\times\frac{15 - T_{out}}{0.22} = \left[0.9\times\left(5.67\times10^{-8}\right)\times\left(\left(T_{out}+273\right)^4 - 255^4\right)\right] + \left[15\times\left(T_{out} - 10\right)\right]$$

$$T_{out} = 7.7°\text{C}$$

Hence, the temperature of outer surface of the roof is $\boxed{T_{out} = 7.7°\text{C}}$.

Step 2 of 3

Calculate the surface area of the roof.

$$A_s = b\times l$$

Here, b is the width, and l is the length.

Substitute 15 m for b and 20 m for l.

$$A_s = 15\times20$$
$$= 300\ \text{m}^2$$

Write the equation for conduction.

$$Q_{cond} = kA_s\frac{\Delta T}{L}$$

Substitute $2\ \text{W/m}\cdot\text{K}$ for k, $300\ \text{m}^2$ for A_s , $(15-7.7)°\text{C}$ for ΔT , and 0.22 m for L.

$$Q_{cond} = 2\times300\times\frac{15 - 7.7}{0.22}$$
$$= 19{,}909\ \text{W}$$

Therefore, the total heat transferred through conduction is $\boxed{Q_{cond} = 19{,}909\ \text{W}}$.

Step 3 of 3

Consider the amount of natural gas required be R and the cost incurred in running the furnace through the night be M.

$$R = \frac{Q_{cond}}{0.85}\times T$$

Duration of time, $T = 14\times3600\ \text{s}$

$$R = \frac{19.909\times\left(14\times3600\right)}{0.85}\ \text{kJ}$$
$$= \frac{19.909\times\left(14\times3600\right)}{0.85\times105{,}500}\ \text{therm}$$
$$= 11.2\ \text{therm}$$

And the required money for this gas,

$$M = 11.2\times\$1.2$$
$$= \$13.44$$

Therefore, the money lost through the roof due to the heat transfer, $\boxed{M = \$13.44}$.

Question: 16.070P

Consider a flat-plate solar collector placed horizontally on the flat roof of a house. The collector is 5 ft wide and 15 ft long, and the average temperature of the exposed surface of the collector is 100°F. The emissivity of the exposed surface of the collector is 0.9. Determine the rate of heat loss from the collector by convection and radiation during a calm day when the ambient air temperature is 70°F and the effective sky temperature for radiation exchange is 50°F. Take the convection heat transfer coefficient on the exposed surface to be 2.5 Btu/h·ft2·°F.

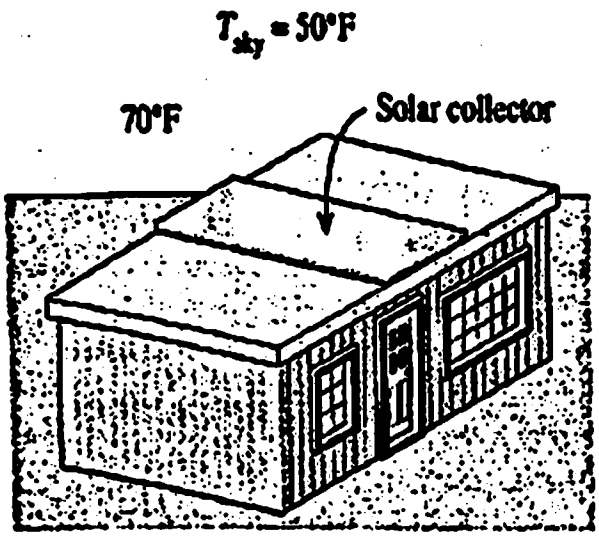

FIGURE P16–70E

Step 1 of 2

Given

Width of the collector, $w = 5\text{ft}$

Length of the collector, $L = 15\text{ft}$

Temperature of exposed surface of collector, $T_w = 100°\text{F}$

The emissivity of the outer surface of the collector, $\varepsilon = 0.9$

Ambient temperature of air, $T_\infty = 70°\text{F}$

Sky temperature for radiation, $T_{sky} = 50°\text{F}$

Convection heat transfer coefficient, $h = 2.5\,\text{Btu/h}\cdot\text{ft}^2\cdot°\text{F}$

Step 2 of 2

Heat transfer area, $A = 5\times15$

$= 75\text{ ft}^2$

The total rate of heat loss from the collector to the environment by convection and radiation.

Rate of heat loss by convection is given by

$$\dot{Q}_{conv} = hA(T_w - T_\infty)$$

$$= 2.5\times75\times(100-70)$$

$$= 5625\text{ Btu/h}$$

Rate of heat loss by radiation is given by

$$\dot{Q}_{rad} = \varepsilon A\sigma\left(T_w^4 - T_{sky}^4\right)$$

$$= 0.9\times75\times\left(0.1714\times10^{-8}\right)\times\left[(100+460)^4 - (50+460)^4\right]$$

$$= 3551\text{ Btu/h}$$

The total rate of heat loss is given by

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$

$$= 5625+3551$$

$$= 9176\,\text{Btu/h}$$

The total rate of heat loss from the collector to the environment, $\boxed{\dot{Q}_{total} = 9176\,\text{Btu/h}}$

Question: 16.071P

A soldering iron has a cylindrical tip of 2.5 mm in diameter and 20 mm in length. With age and usage, the tip has oxidized and has an emissivity of 0.80. Assuming that the average convection heat transfer coefficient over the soldering iron tip is 25 W/m2·K, and the surrounding air temperature is 20°C, determine the power required to maintain the tip at 400°C.

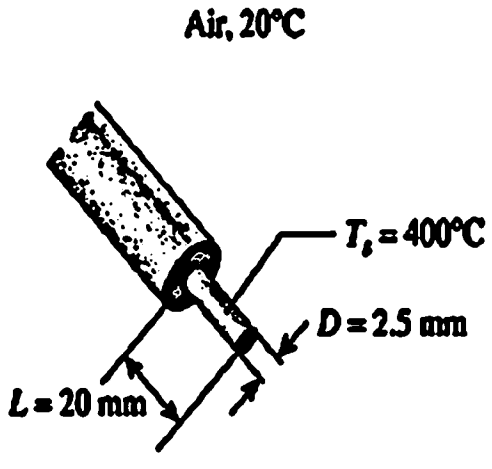

FIGURE P16–71

Step 1 of 4

Given data:

Diameter of the cylindrical tip, $D = 2.5\text{mm}$

Length of the tip, $L = 20\text{mm}$

Emissivity between tip and air, $\varepsilon = 0.8$.

Convective heat transfer coefficient between tip and air, $h = 25\ \text{W/m}^2\cdot\text{K}$

Ambient temperature, $T_\infty = 20\,°\text{C}$

Temperature of the tip, $T = 400\,°\text{C}$

Step 2 of 4

The total heat transfer is due to convection followed by radiation.

$$Q = Q_{rad} + Q_{conv}$$
$$= \varepsilon\sigma A_s\left(T^4 - T_\infty^4\right) + hA_s\Delta T$$

The surface area of the cylindrical tip is given by

$$A_s = \pi DL$$
$$= \pi\times\left(\frac{2.5}{1,000}\right)\times\left(\frac{20}{1,000}\right)$$
$$= 1.57\times10^{-4}\ \text{m}^2$$

Step 3 of 4

Heat transfer due to radiation:

$$Q_{rad} = \varepsilon\sigma A_s\left(T^4 - T_\infty^4\right)$$
$$= 0.8\times\left(5.67\times10^{-8}\right)\times1.57\times10^{-4}\times\left[(400+273)^4 - (20+273)^4\right]$$
$$= 1.41\ \text{W}$$

Heat transfer due to convection:

$$Q_{conv} = hA_s\Delta T$$
$$= 25\times\left(1.57\times10^{-4}\right)\times(400-20)$$
$$= 1.49\ \text{W}$$

Step 4 of 4

Total heat transfer between tip and the air,

$$Q = Q_{rad} + Q_{conv}$$
$$= 1.41+1.49$$
$$= 2.9\ \text{W}$$

Therefore, the power required to maintain a tip temperature of 400 °C is $\boxed{Q = 2.9\ \text{W}}$

Question: 16.072P

It is well known that wind makes the cold air feel much colder as a result of the *wind chill effect*that is due to the increase in the convection heat transfer coefficient with increasing air velocity. The wind chill effect is usually expressed in terms of the *wind chill temperature*(WCT), which is the apparent temperature felt by exposed skin. For outdoor air temperature of 0°C, for example, the wind chill temperature is −5°C at 20 km/h winds and −9°C at 60 km/h winds. That is. a person exposed to 0°C windy air at 20 km/h will feel as cold as a person exposed to −5°C calm air (air motion under 5 km/h).

For heat transfer purposes, a standing man can be modeled as a 30-cm-diameter, 170-cm-long vertical cylinder with both the top and bottom surfaces insulated and with the side surface at an average temperature of 34°C. For a convection heat transfer coefficient of 15 W/m2·K, determine the rate of heat loss from this man by convection in still air at 20°C. What would your answer be if the convection heat transfer coefficient is increased to 30 W/m2·K as a result of winds? What is the wind chill temperature in this case?

Step 1 of 3

Given data:

Diameter of the standing man, $D = 30$ cm

Length of the standing man, $L = 170$ cm

Average temperature of side surface, $T_s = 34°C$

Convective heat transfer coefficient between man and air is $h = 15\ \text{W/m}^2\cdot\text{K}$

Still air temperature, $T_{air} = 20°C$

For wind chill effect, convective heat transfer coefficient between man and air is $h = 30\ \text{W/m}^2\cdot\text{K}$

Step 2 of 3

Rate of heat loss from the man by convection in still air is given by,

$$Q = hA_s\Delta T$$

Surface area of the man is given by

$$\begin{aligned} A_s &= \pi dl \\ &= \pi\times 0.3\times 1.7 \\ &= 1.6\ \text{m}^2 \end{aligned}$$

$$\begin{aligned} Q &= hA_s\Delta T \\ &= 15\times 1.6\times(34-20) \\ &= 336\ \text{W} \end{aligned}$$

Thus, rate of heat loss from the man is $\boxed{Q = 336\ \text{W}}$

Step 3 of 3

For windy air, if Q is the rate of heat dissipation due to generation of heat, we have,

$$\begin{aligned} Q &= hA_s\Delta T \\ &= 30\times 1.6\times(34-20) \\ &= 672\ \text{W} \end{aligned}$$

For an effective balance of heat to cause wind-chill effect,

$$Q = hA_s\Delta T$$

$$672 = 15\times 1.6\times(34-T)$$

$$(34-T) = \frac{672}{15\times 1.6}$$

$$T = 6°C$$

Thus, rate of heat loss due to windy air, $\boxed{Q = 672\ \text{W}}$

Therefore, the wind chill temperature turns out to be $\boxed{T = 6°C}$.

Question: 16.073P

A thin metal plate is insulated on the back and exposed to solar radiation on the front surface. The exposed surface of the plate has an absorptivity of 0.7 for solar radiation. If solar radiation is incident on the plate at a rate of 550 W/m2and the surrounding air temperature is 10°C. determine the surface temperature of the plate when the heat loss by convection equals the solar energy absorbed by the plate. Take the convection heat transfer coefficient to be 25 W/m2·K, and disregard any heat loss by radiation.

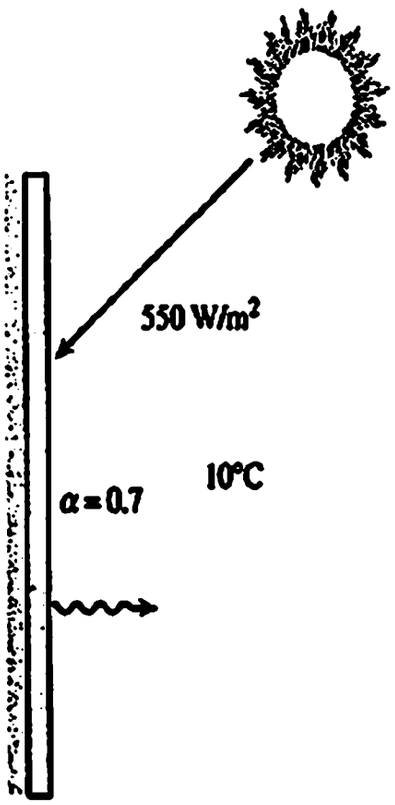

FIGURE P16–73

Step 1 of 2

Given

Surrounding temperature, $T_{surr} = 10°C$

Heat absorb by the surface, $\dot{Q}_{abs} = 550\,W/m^2$

The solar absorptivity of the plate, $\alpha = 0.7$

Heat transfer coefficient, $h = 25\,W/m^2 \cdot °C$

Step 2 of 2

Let heat transfer area is A.

And surface temperature of the plate is $T_{surface}$

When the heat loss from the plate by convection equals the solar radiation absorbed,

The surface temperature of the plate can be determined from

$$\dot{Q}_{solar,abs} = \dot{Q}_{conv}$$

$$\Rightarrow \alpha A \dot{Q}_{solar} = hA\left(T_{surface} - T_{surr}\right)$$

$$\Rightarrow 0.7 \times A \times 550 = 25 \times A \times \left(T_{surface} - 10\right)$$

$$\Rightarrow \left(T_{surface} - 10\right) = 15.4$$

$$\Rightarrow T_{surface} = 25.4°C$$

The surface temperature of the plate, $\boxed{T_{surface} = 25.4°C}$

Question: 16.074P

Consider a 3-m × 3-m × 3-m cubical furnace whose top and side surfaces closely approximate black surfaces at a temperature of 1200 K. The base surface has an emissivity of ε = 0.4, and is maintained at 800 K. Determine the net rate of radiation heat transfer to the base surface from the top and side surfaces.

Step 1 of 3

Given data:

The length of the side of the cube is $3\ \text{m}$

Emissivity between furnace and air, $\varepsilon = 0.4$

Temperature of the black body surfaces, $T_\infty = 1200\ \text{K}$

Base surface temperature, $T = 800\ \text{K}$

Step 2 of 3

The heat emitted from the top and side wall surfaces through radiation is equal to the heat absorbed by the base surface. Hence, the total heat transfer to the base surface,

$$Q = Q_{rad}$$

$$= \varepsilon \sigma A_s \left(T^4 - T_\infty^4\right)$$

where, surface area of heat transferring face,

$$A_s = 3 \times 3$$

$$= 9\ \text{m}^2$$

Step 3 of 3

Heat transfer due to radiation,

$$Q_{rad} = \varepsilon \sigma A_s \left(T^4 - T_\infty^4\right)$$

$$= 0.4 \times \left(5.67 \times 10^{-8}\right) \times 9 \times \left(1200^4 - 800^4\right)$$

$$= 339{,}655\ \text{W}$$

$$= 340\ \text{kW}$$

Therefore, heat transfer due to radiation is $\boxed{Q_{rad} = 340\ \text{kW}}$

Question: 16.075P

Engine valves (cp= 440 J/kg·K and ρ= 7840 kg/m3) are to be heated from 40°C to 800° in 5 min in the heat treatment section of a valve manufacturing facility. The valves have a cylindrical stem with a diameter of 8 mm and a length of 10 cm. The valve head and the stem may be assumed to be of equal surface area, with a total mass of 0.0788 kg. For a single valve, determine (*a*) the amount of heat transfer, (*b*) the average rate of heat transfer, (*c*) the average heat flux, and (*d*) the number of valves that can be heat treated per day if the heating section can hold 25 valves and it is used 10 h per day.

Step 1 of 5

Given

Specific heat of valve material, $c_p = 440\,\text{J/kg}\cdot^\circ\text{C}$

Density of valve material, $\rho = 7840\,\text{kg/m}^3$

Initial temperature, $T_1 = 40^\circ\text{C}$

Final temperature, $T_2 = 800^\circ\text{C}$

Time taken, $\Delta t = 5\,\text{min}$

Diameter of cylinder stem, $d = 8\,\text{mm}$

Length of cylinder stem, $L = 10\,\text{cm}$

Total mass of valve, $m = 0.0788\,\text{kg}$

Step 2 of 5

(a) The amount of heat transferred for a single valve is given by change in its internal energy.

So, $Q = \Delta U$

$$= mc_p(T_2 - T_1)$$
$$= 0.0788\times 440\times(800-40)$$
$$= 26350.7\,\text{J}$$
$$= 26.35\,\text{kJ}$$

Amount of heat transferred for a single valve, $\boxed{Q = 26.35\,\text{kJ}}$

Step 3 of 5

(b) The average rate of heat transfer is calculated as Amount of heat transfer divided by total time taken.

$$\dot{Q}_{ave} = \frac{Q}{\Delta t}$$
$$= \frac{26.35}{5\times 60}$$
$$= 0.0878\,\text{kW}$$

Average rate of heat transfer, $\boxed{\dot{Q}_{ave} = 0.0878\,\text{kW}}$

Step 4 of 5

(c) The average heat flux is determined from

$$\dot{q}_{ave} = \frac{\dot{Q}_{ave}}{A}$$
$$= \frac{\dot{Q}_{ave}}{2\pi dL}$$
$$= \frac{0.0878\times 10^3}{2\pi\times 0.008\times 0.1}$$
$$= \frac{87.8}{5.026\times 10^{-3}}$$
$$= 17467.2\,\text{W/m}^2$$

Average heat flux, $\boxed{\dot{q}_{ave} = 17467.2\,\text{W/m}^2}$

Step 5 of 5

(d) The heating section can hold 25 valves and it is used 10 h per day.

The total number of valves that can be heat treated daily is

Number of valves,

$$n = \frac{(10\times 60)\times 25}{5}$$
$$= 3000\,\text{valves}$$

Number of valves, $\boxed{n = 3000\,\text{valves}}$

Question: 16.076P

Consider a flat-plate solar collector placed on the roof of a house. The temperatures at the inner and outer surfaces of the glass cover are measured to be 33°C and 31°C, respectively. The glass cover has a surface area of 2.5 m2, a thickness of 0.6 cm, and a thermal conductivity of 0.7 W/m·K. Heat is lost from the outer surface of the cover by convection and radiation with a convection heat transfer coefficient of 10 W/m2·K and an ambient temperature of 15°C. Determine the fraction of heat lost from the glass cover by radiation.

Step 1 of 3

Given data:

The surface area of the glass cover, $A_s = 2.5\ \text{m}^2$

Thickness of the cover, $L = 0.6\ \text{cm}$

Thermal conductivity of the cover, $k = 0.7\ \text{W/m}\cdot\text{K}$

Convective heat transfer coefficient between plate and air, $h = 10\ \text{W/m}^2\cdot\text{K}$

Inner surface temperature of the glass cover, $T_{in} = 31°\text{C}$

Outer surface temperature of the glass cover, $T_{out} = 33°\text{C}$

Ambient temperature, $T_\infty = 15°\text{C}$

Step 2 of 3

The total heat conducted across the cover is transferred by convection, followed by radiation.

$$Q_{cond} = Q_{rad} + Q_{conv}$$

$$kA_s \frac{\Delta T}{L} = Q_{rad} + hA_s\Delta T$$

Substituting the known values in the above equation, we have,

$$\begin{aligned} Q_{rad} &= Q_{cond} - Q_{conv} \\ &= \left(0.7\times 2.5\times \frac{33-31}{0.006}\right) - \left(10\times 2.5\times (31-15)\right) \\ &= 583.334 - 400 \\ &= 183.334\ \text{W} \end{aligned}$$

Step 3 of 3

The fraction of heat lost through radiation is the ratio of the heat lost by radiation to the total heat conducted. Let this fraction be x.

$$\begin{aligned} x &= \frac{Q_{rad}}{Q_{cond}} \\ &= \frac{Q_{rad}}{kA_s \frac{\Delta T}{L}} \\ &= \frac{183.334}{0.7\times 2.5\times \frac{33-31}{0.006}} \\ &= 0.314 \end{aligned}$$

The fraction of heat lost by radiation of the total heat loss is $\boxed{x = 0.314}$

Question: 16.077P

The rate of heat loss through a unit surface area of a window per unit temperature difference between the indoors and the outdoors is called the *U*-factor. The value of the *U*-factor ranges from about 1.25 W/m2·K (or 0.22 Btu/h·ft2·°F) for low-ecoated, argon-filled, quadruple-pane windows to 6.25 W/m2·K (or 1.1 Btu/h·ft2·°F) for a singlc: pane window with aluminum frames. Determine the range for the rate of heat loss through a 1.2-m × 1.8-m window of a house that is maintained at 20°C when the outdoor air temperature is –8°C.

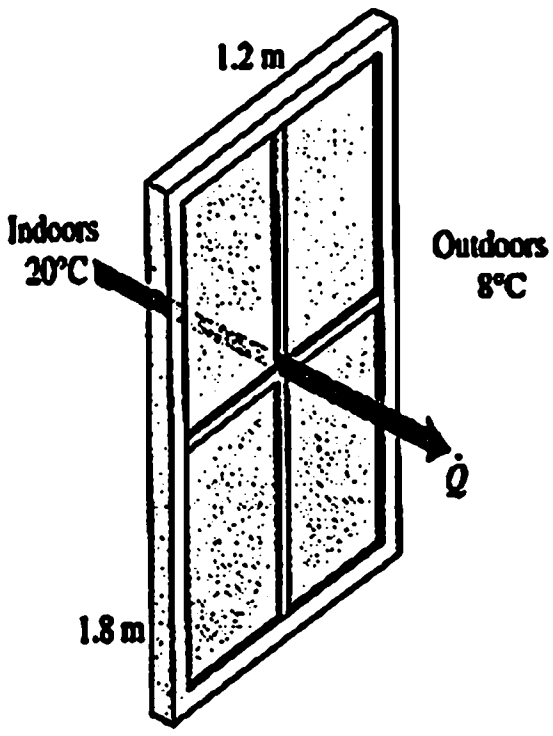

FIGURE P16–77

Step 1 of 4

Given:

U- Factor ranges from $1.25\ \frac{W}{m^2 \cdot °C}$ to $6.25\ \frac{W}{m^2 \cdot °C}$

Area of window $A = 1.2m \times 1.8m$

Inside temperature of house $T_{inside} = 20°C$

Outside temperature $T_{outside} = -8°C$

Step 2 of 4

The rate of heat loss $\dot{Q}_{window}$ through the window is given by

$\dot{Q}_{window} = U_{overall} A_{window} (T_{in} - T_{out})$

$U_{overall}$ Is the U-factor (the overall heat transfer coefficient) of the window,

A_{window} Is the window area.

Step 3 of 4

Substituting,

Maximum heat loss:

$$\dot{Q}_{window,max} = \left(6.25\ \frac{W}{m^2 \cdot °C}\right)(1.2 \times 1.8\ m^2)[20 - (-8)]°C$$

$Q_{window\,max} = 378\ W$

$\boxed{Q_{window\,max} = 378\ W}$

Step 4 of 4

Minimum heat loss:

$$\dot{Q}_{window,min} = \left(1.25\ \frac{W}{m^2 \cdot °C}\right)(1.2 \times 1.8\ m^2)[20 - (-8)]°C$$

$\dot{Q}_{window,min} = 75.6\ W$

$\boxed{\dot{Q}_{window,min} = 75.6\ W}$

Range of rate of heat loss through the window for low e-coated, argon filled, quadruple-pane windows to single-pane with aluminum frames is from 75.6 W to 378 W.

Question: 16.078P

Reconsider Prob. 16–77. Using EES (or other)software, plot the rate of heat loss through the window as a function of the *U*-factor. Discuss the results.

Step 1 of 6

Given:

U- Factor ranges from $1.25\ \frac{W}{m^2 \cdot C}$ to $6.25\ \frac{W}{m^2 \cdot C}$

Area of window $A = 1.2m \times 1.8m$

Inside temperature of house $T_{inside} = 20°C$

Outside temperature $T_{outside} = -8°C$

Step 2 of 6

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box
"GIVEN"
A=1.2*1.8 "[m^2]"
T_1=20 "[C]"
T_2=-8 "[C]"
"U=1.25 [W/m^2-C], parameter to be varied"

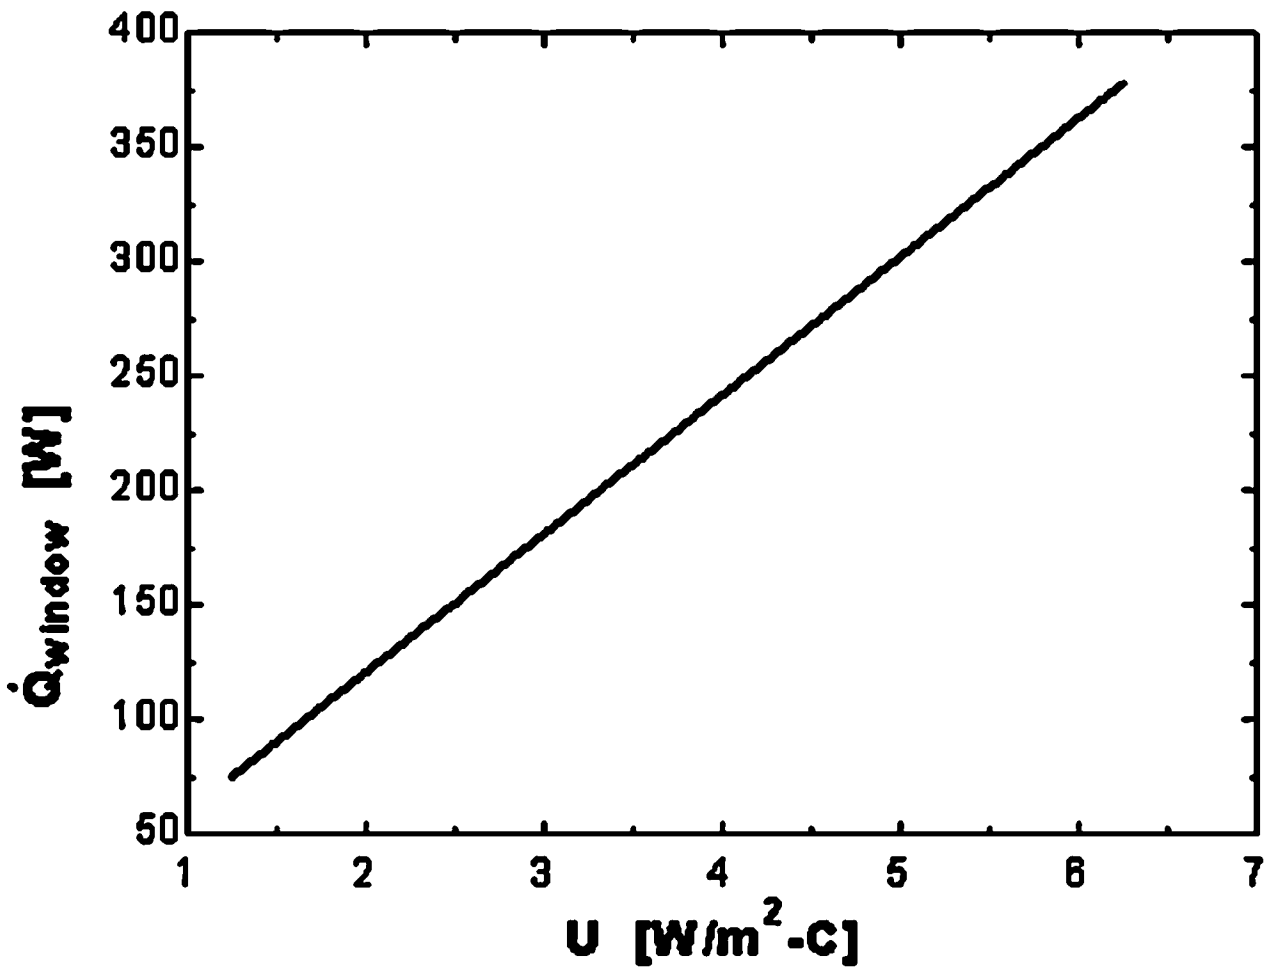
"ANALYSIS"
Q_dot_window=U*A*(T_1-T_2)

Step 3 of 6

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 11
Select variables in equations as U and Q_{window} press ADD and then press ok
A table will appear put values of U as 1.25,1.75,2.25....6.25 in run 1to 11
Then from Calculate -> Solve table

Step 4 of 6

Solution will appear



$U\ [W/m^2.C]$	$Q_{window}\ [W]$
1.25	75.6
1.75	105.8
2.25	136.1
2.75	166.3
3.25	196.6
3.75	226.8
4.25	257
4.75	287.3
5.25	317.5
5.75	347.8
6.25	378

Step 5 of 6

Then from Plot -> New plot window -> X-Y Plot
Select X-axis U and Y-axis Q_{window}
Press OK

Step 6 of 6

Graph will be plotted

Question: 16.079P

An electric heater with the total surface area of 0.25 m2 and emissivity 0.75 is in a room where the air has a temperature of 20°C and the walls are at 10°C. When the heater consumes 500 W of electric power, its surface has a steady temperature of 120°C. Determine the temperature of the heater surface when it consumes 700 W, Solve the problem (*a*) assuming negligible radiation and (*b*) taking radiation into consideration. Based on your results, comment on the assumption made in part (*a*).

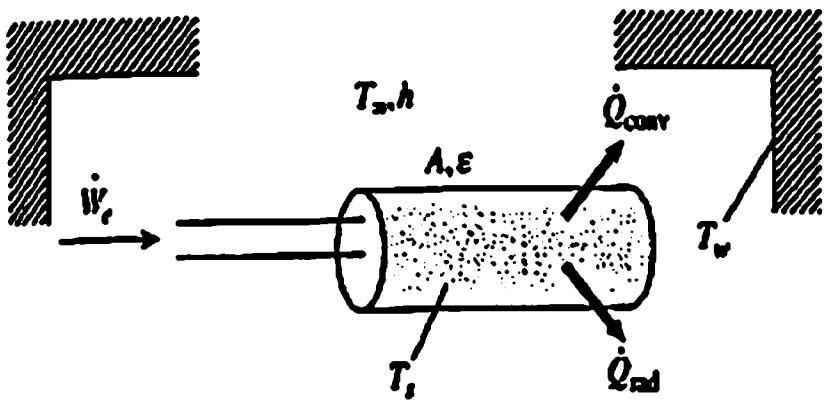


FIGURE P16–79

Step 1 of 4

Given: -

Surface area of heater $(A) = 0.25\text{m}^2$

Emissivity of heater surface $(\varepsilon) = 0.75$

Temperature of surrounding air $T_\infty = 20^\circ\text{C}$

Temperature of walls $T_w = 10^\circ\text{C}$

Power consumed by heater $Q = 500\text{ W}$

Surface temperature of temperature $T_s = 120^\circ\text{C}$

Step 2 of 4

(a) For steady flow condition

Heat developed in heater = heat flow by convection + heat flow by radiation

Neglecting Radiation

So Heat developed in heater = Heat flow by convection

$$(500\text{W}) = h \times (0.25\text{m}^2) \times (120 - 20)^\circ\text{C}$$

$$h = 20 \frac{\text{W}}{\text{m}^2 \cdot {}^\circ\text{C}}$$

Step 3 of 4

Surface temperature of heater when heater consumes 700 W

$$(700\text{W}) = \left(20 \frac{\text{W}}{\text{m}^2 \cdot {}^\circ\text{C}}\right) \times (0.25\text{m}^2) \times (T - 20)^\circ\text{C}$$

$$(T - 20)^\circ\text{C} = 140^\circ\text{C}$$

$$T = 160^\circ\text{C}$$

Step 4 of 4

(b) Taking radiation into consideration

$$Q = hA(\Delta T) + \varepsilon\sigma A(T^4 - T_2^4)$$

$$(500\text{W}) = h \times (0.25\text{m}^2) \times (120 - 20)^\circ\text{C} + 0.75 \times (5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}) \times (0.25\text{m}^2) \times \left[(393\text{K})^4 - (283\text{K})^4\right]$$

$$h = 12.58 \frac{\text{W}}{\text{m}^2 \cdot {}^\circ\text{C}}$$

When Q = 700W then surface temperature of heater will be

$$700 = 12.58 \times 0.25 \times (T - 293) + 0.75 \times 5.67 \times 10^{-8} \times 0.25 \times (T^4 - 283^4)$$

$$T_s = 425.9\text{K}$$

$$\boxed{T_s = 152.9^0\text{C}}$$

So comparing the two answers we can say that we cannot affect of radiation in this case as temperature difference in two case is up to 7°C

CHAPTER 17
SOLUTIONS

Question: 17.001P

Consider heat conduction through a wall of thickness L and area A. Under what conditions will the temperature distributions in the wall be a straight line?

Step 1 of 2

The thermal resistance of a medium represents the resistance of that medium against heat transfer. Heat flow through any medium can be compared with the electrical circuit

For electrical circuits, $dV = IR$

Here, dV is voltage difference in the resistance of the circuit, and I is the current flow.

This equation can be rearranged as $I = dV/R$ .....(1)

Step 2 of 2

Write the equation of Fourier's as follows:

$$Q = \frac{dT}{\left(\frac{dx}{KA}\right)} \quad \text{.....(2)}$$

Here, Q is the heat flow through medium, dx is the change of thickness, K is the thermal conductivity, and A is the cross-sectional area.

Compare the equations (1) and (2), resistance (R) of the electrical circuit can be compared with the terms $\frac{dx}{KA}$ and it is called thermal resistance.

Question: 17.002P

Consider heat conduction through a plane wall. Does the energy content of the wall change during steady heat conduction? How about during transient conduction? Explain.

Step 1 of 1

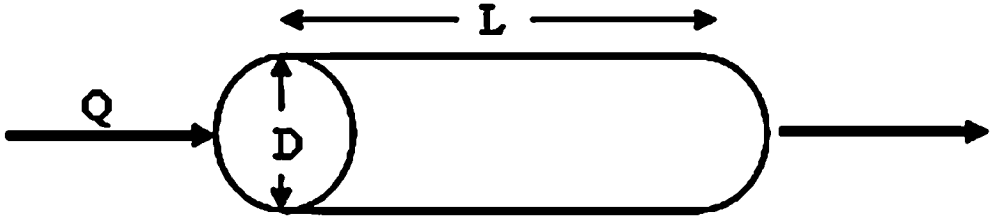
During the steady heat conduction, the rate of heat transfer into the wall is equal to the rate of heat transfer out of it. Also, the temperature at any point in the wall remains constant. Therefore, the energy content of the wall does not change.

During transient conduction the temperature along the wall will change with time, thus the energy content of the wall will change.

Question: 17.003P

Consider steady heat transfer through the wall of a room in winter. The convection heat transfer coefficient at the outer surface of the wall is three times that of the inner surface as a result of the winds. On which surface of the wall do you think the temperature will be closer to the surrounding air temperature? Explain.

Step 1 of 1



We know that convection heat transfer through the wall is expressed as $\dot{Q} = hA_s(T_s - T_\infty)$. In steady heat transfer, heat transfer rate to the wall and from the wall are equal. Therefore at the outer surface which has convection heat transfer coefficient three times that of the inner surface will experience three times smaller temperature drop compared to the inner surface. Therefore, at the outer surface, the temperature will be closer to the surrounding air temperature.

Question: 17.004P

Consider one-dimensional heat conduction through a cylindrical rod of diameter *D* and length *L*. What is the heat transfer area of the rod if (*a*) the lateral surfaces of the rod are insulated and (*b*) the top and bottom surfaces of the rod are insulated?

Step 1 of 3

Consider a one – dimensional heat conduction through a cylindrical rod of diameter D and length L.

Step 2 of 3

(a)

If the lateral surfaces of the rod is insulated, the heat transfer surface area of the cylindrical rod is the bottom or the top surface area of the rod, $A_s = \pi D^2/4$.

Step 3 of 3

(b)

When the top and the bottom surfaces of the rod are insulated, the heat transfer area of the rod is the lateral surface area of the rod, $A = \pi DL$.

Question: 17.005P

What does the thermal resistance of a medium represent?

Step 1 of 2

The thermal resistance of a medium represents the resistance of that medium against heat transfer. Heat flow through any medium can be compared with the electrical circuit

For electrical circuits, $dV = IR$

Here, dV is voltage difference in the resistance of the circuit, and I is the current flow.

This equation can be rearranged as $I = dV/R$ .....(1)

Step 2 of 2

Write the equation of Fourier's as follows:

$$Q = \frac{dT}{\left(\frac{dx}{KA}\right)} \quad \text{.....(2)}$$

Here, Q is the heat flow through medium, dx is the change of thickness, K is the thermal conductivity, and A is the cross-sectional area.

Compare the equations (1) and (2), resistance (R) of the electrical circuit can be compared with the terms $\frac{dx}{KA}$ and it is called thermal resistance.

Question: 17.006P

How is the combined heat transfer coefficient defined? What convenience does it offer in heat transfer calculations?

Step 1 of 1

The combined heat transfer coefficient represents the combined effects of radiation and convection heat transfers on a surface, and is defined as $h_{combined} = h_{convection} + h_{radiation}$.
It offers the convenience of incorporating the effects of radiation in the convection heat transfer coefficient, and to ignore radiation in heat transfer calculations.

Question: 17.007P

Can we define the convection resistance for a unit surface area as the inverse of the convection heat transfer coefficient?

Step 1 of 1

Yes, from Newton's law of cooling heat flow (Q) = hAdT where A is the surface area and dT is the change of temperature.This equation can compare with electrical analogy equation dV is voltage difference, R is the restence of the circuit and I is the current flow I = dV/R This R after compare with thermal resistence it is the inverse of the convection heat transfer coefficient per unit surface area since it is defined as $R_{conv} = \frac{1}{hA}$

Question: 17.008P

Why are the convection and the radiation resistances at a surface in parallel instead of being in series?

Step 1 of 1

A surface exposed to the surrounding air involves convection and radiation simultaneously, and the total heat transfer at the surface is determined by adding the radiation and convection components. The convection and radiation are parallel to each other. When $T_{surr} \approx T_{\infty}$

Convection can occurs when heat is transferred between two different medium and radiation can occurs with out medium. So both the convection and radiation heat transfers occur simultaneously and they are parallel.

Question: 17.009P

Consider a surface of area A at which the convection and radiation heat transfer coefficients are $h$conv and $h$rad, respectively. Explain how you would determine (*a*) the single equivalent heat transfer coefficient, and (*b*) the equivalent thermal resistance. Assume the medium and the surrounding surfaces are at the same temperature.

Step 1 of 2

(a) For a surface of A at which the convection and radiation heat transfer coefficients are h_{conv} and h_{rad}. When a surface exposed to the surroundings air involves convection and radiation simultaneously, the convection and radiation resistances are parallel to each other, the single equivalent heat transfer coefficient is $h_{eqv} = h_{conv} + h_{rad}$ when the medium and the surrounding surfaces are at the same temperature.

Step 2 of 2

(b) The equivalent thermal resistance will be $R_{eqv} = 1/(h_{eqv}A)$ where A is the surface area.

Question: 17.010P

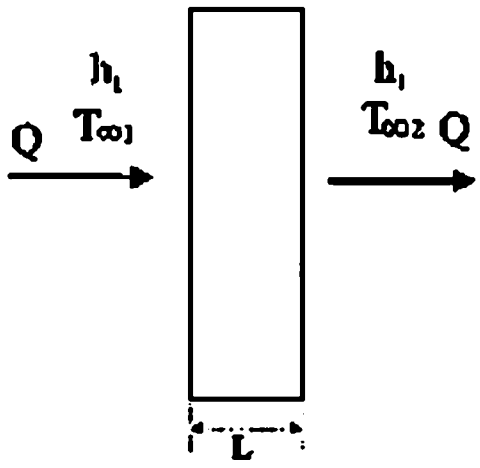
How does the thermal resistance network associated with a single-layer plane wall differ from the one associated with a five-layer composite wall?

Step 1 of 1

The thermal resistance network associated with a five-layer composite wall involves five single-layer resistances connected in series. If thermal resistance of any single all is R_{th} then for five layer it will be $R_{th1} + R_{th2} + R_{th3} + R_{th4} + R_{th5}$

Question: 17.011P

Consider steady one-dimensional heat transfer through a multilayer medium. If the rate of heat transfer Q is known, explain how you would determine the temperature drop across each layer.



Step 1 of 1

Once the rate of heat transfer $\dot{Q}$ is known, the temperature drop across any layer can be determined by multiplying heat transfer rate by the thermal resistance across that layer, $\Delta T_{layer} = \dot{Q} R_{layer}$

Question: 17.012P

Consider steady one-dimensional heat transfer through a plane wall exposed to convection from both sides to environments at known temperatures $T_{\infty 1}$ and $T_{\infty 2}$ with known heat transfer coefficients h_1, and h_2. Once the rate of heat transfer Q has been evaluated, explain how you would determine the temperature of each surface.

Step 1 of 6

Step 2 of 6

Let the thickness of the body is L
Surface area is A
Convective heat transfer coefficient is h_1 for inside and h_2 for outside
Inside surface temperature, T_1
Inside surrounding temperature, $T_{\infty 1}$
And outside surface temperature is T_2
Outside surrounding temperature, $T_{\infty 2}$
Thermal conductivity of material is K

Step 3 of 6

Then heat transfer from surface to wall due to inside convection is

$$Q = h_1 A(T_{\infty 1} - T_1)$$

$$(T_{\infty 1} - T_1) = \frac{Q}{h_1 A} \quad \text{----------(1)}$$

Step 4 of 6

Heat transfer through wall to wall due to conduction is

$$Q = KA(T_1 - T_2)$$

$$(T_1 - T_2) = \frac{Q}{KA} \quad \text{----------(2)}$$

Step 5 of 6

Heat transfer from wall to surface due to outside convection is

$$Q = h_2 A(T_2 - T_{\infty 2})$$

$$(T_2 - T_{\infty 2}) = \frac{Q}{h_2 A} \quad \text{----------(3)}$$

Step 6 of 6

So after addition equation (1), (2), and (3)

$$T_{\infty 1} - T_{\infty 2} = Q\left(\frac{1}{h_1 A} + \frac{1}{KA} + \frac{1}{h_2 A}\right)$$

$$\boxed{T_1 = T_{\infty 1} - \frac{Q}{h_1 A}}$$

$$\boxed{T_2 = \frac{Q}{h_2 A} + T_{\infty 2}}$$

Question: 17.013P

Someone comments that a microwave oven can be viewed as a conventional oven with zero convection resistance at the surface of the food. Is this an accurate statement?

Step 1 of 1

Yes, it is. Because when zero convection resistance there is no convective heat transfer so it is treated as a conventional oven

Question: 17.014P

Consider a window glass consisting of two 4-mm-thick glass sheets pressed tightly against each other. Compare the heat transfer rate through this window with that of one consisting of a single 8-mm-thick glass sheet under identical conditions.

Step 1 of 1

The window glass which consists of two 4 mm thick glass sheets pressed tightly against each other will probably have thermal contact resistance which serves as an additional thermal resistance to heat transfer through window, and thus the heat transfer rate will be smaller relative to the one which consists of a single 8 mm thick glass sheet.

Question: 17.015P

Consider two cold canned drinks, one wrapped in a blanket and the other placed on a table in the same room. Which drink will warm up faster?

Step 1 of 1

The blanket will introduce additional resistance due to conduction and convection so the heat transfer from the wrapped blanket surface is less. Where as the heat transfer from the drink which is placed on a table is more because in this resistance due to convection only. Therefore, the drink left on a table will warm up faster.

Question: 17.016P

Consider a 3-m-high, 6-m-wide, and 0.25-m-thick brick wall whose thermal conductivity is k =0.8 W/m·K. On a certain day, the temperatures of the inner and the outer surfaces of the wall are measured to be 14°C and 5°C, respectively. Determine the rate of heat loss through the wall on that day.

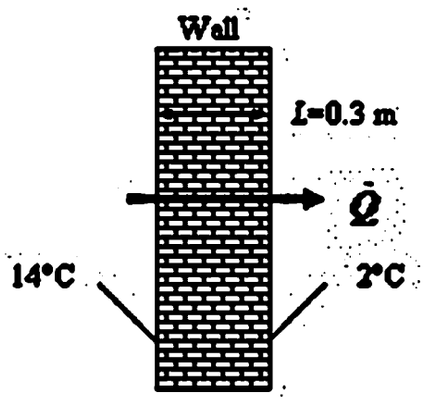
Step 1 of 4

Given data:

Height of the wall $h = 3\,\text{m}$

Wide of the wall $b = 6\,\text{m}$

Thickness of the wall, $L = 0.25\text{m}$



The thermal conductivity $k = 0.8\,\text{W/m}\cdot\text{K}$

Inner surface temperature $T_1 = 14°\text{C}$

Outer surface temperature $T_2 = 5°\text{C}$

Step 2 of 4

Diagram:

Step 3 of 4

If the heat transfer through the wall is steady since the surface temperatures remain constant at the specified values and the heat transfer is one-dimensional since any significant temperature gradients will exist in the direction from the indoors to the outdoors

Step 4 of 4

The surface area of the wall and the rate of heat loss through the wall are

$A = bh$

$A = (3\,\text{m}) \times (6\,\text{m})$

$A = 18\,\text{m}^2$

Rate of heat transfer,

$$\dot{Q} = kA\frac{T_1 - T_2}{L}$$

$$= (0.8)(18) \times \frac{(14-5)}{0.25}$$

$$= 518.4\,\text{W}$$

Hence, the rate of heat transfer is $\boxed{\dot{Q} = 518.4\,\text{W}}$

Question: 17.017P

Consider a 1.5-m-high and 2.4-m-wide glass window. whose thickness is 6 mm and thermal conductivity is k = 0.78 W/m·K. Determine the steady rate of heat transfer through this glass window and the temperature of its inner surface for a day during which the room is maintained at 24°C while the temperature of the outdoors is −5°C. Take the convection heat transfer coefficients on the inner and outer surfaces of the window to be $h1$, = 10 W/m2·K and $h2$ = 25 W/m2·K, and disregard any heat transfer by radiation.

Step 1 of 6

Given data:

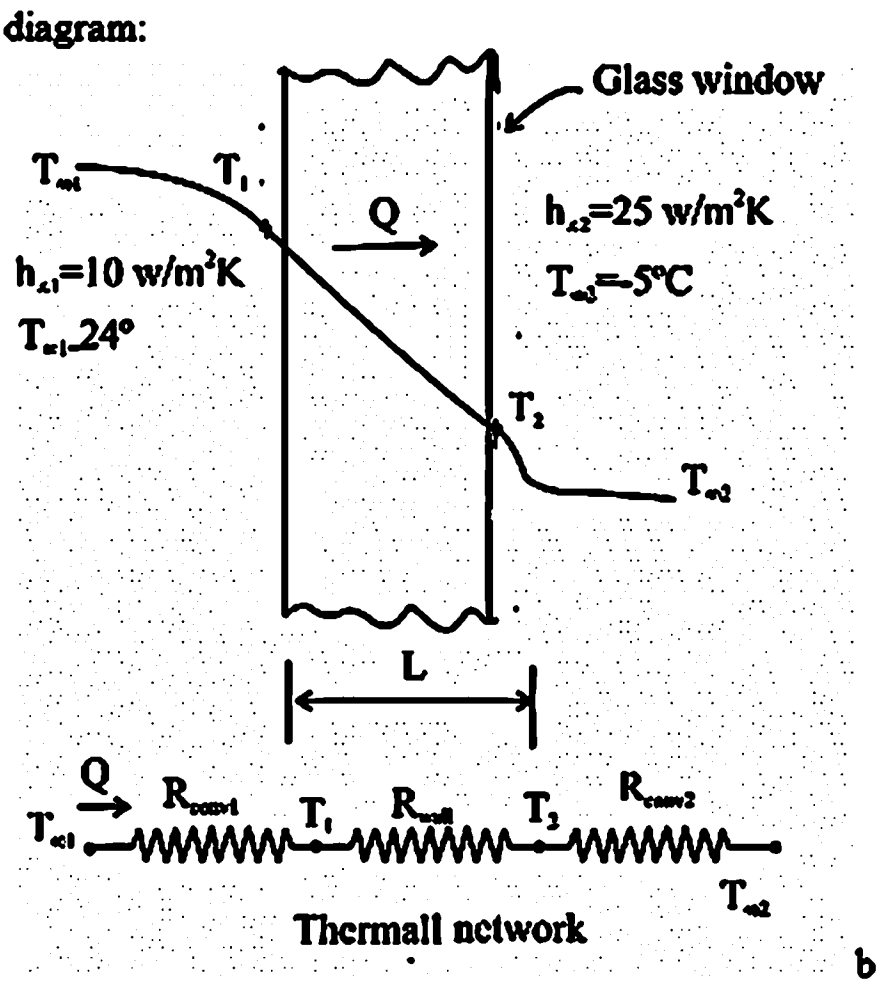
Height of the glass window, $H = 1.5\,\text{m}$.

Width of the glass window, $W = 2.4\text{m}$.

Thickness of the glass, $L = 0.006\,\text{m}$.

Thermal conductivity of the glass, $k = 0.78\,\text{W/m-K}$.

Temperature of the room, $T_{\infty 1} = 24°\text{C}$.



Temperature of the outdoors, $T_{\infty 2} = -5°\text{C}$.

Heat transfer coefficient on the inner surface of the window, $h_1 = 10\,\text{W/m}^2\text{-K}$.

Heat transfer coefficient on the outer surface of the window, $h_2 = 25\,\text{W/m}^2\text{-K}$.

Step 2 of 6

Thermal network diagram:

Step 3 of 6

The heat transfer through the glass window can be determined using the thermal resistance network concept as follows,

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{conv,1} + R_{glass} + R_{conv,2}}$$

The cross sectional area of the glass window can be calculated as

$$A = H \times W$$
$$= 1.5(\text{m}) \times 2.4(\text{m})$$
$$= 3.6\,\text{m}^2$$

Step 4 of 6

The individual resistances are calculated as follows

$$R_{conv,1} = \frac{1}{h_1 A}$$
$$= \frac{1}{10(\text{W/m}^2\text{-K}) \times 3.6(\text{m}^2)}$$
$$= 0.02778\,\text{K/W}$$
$$R_{glass} = \frac{L}{kA}$$
$$= \frac{0.006(\text{m})}{0.78(\text{W/m-K}) \times 3.6(\text{m}^2)}$$
$$= 0.002137\,\text{K/W}$$
$$R_{conv,2} = \frac{1}{h_2 A}$$
$$= \frac{1}{25(\text{W/m}^2\text{-K}) \times 3.6(\text{m}^2)}$$
$$= 0.0111\,\text{K/W}$$

Step 5 of 6

Therefore, the heat transfer through glass window is

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{conv,1} + R_{glass} + R_{conv,2}}$$
$$= \frac{297.15(\text{K}) - 268.15(\text{K})}{0.02778(\text{K/W}) + 0.002137(\text{K/W}) + 0.0111(\text{K/W})}$$
$$= 707.024\,\text{W}$$

Therefore, the heat transfer through glass window is $\boxed{\dot{Q} = 707.024\,\text{W}}$.

Step 6 of 6

The inner surface temperature of the glass window can be expressed as

$$\dot{Q} = \frac{T_{\infty 1} - T_1}{R_{conv,1}}$$
$$707.024(\text{W}) = \frac{297.15(\text{K}) - (T_1)(\text{K})}{0.02778(\text{K/W})}$$
$$\Rightarrow T_1 = 277.51\,\text{K}$$
$$\Rightarrow T_1 = 4.36\,°\text{C}$$

$\boxed{T_1 = 4.36\,°\text{C}}$

Question: 17.018P pg 1

Consider a 1.5-m-high and 2.4-m-wide double-pane window consisting of two 3-mm-thick layers of glass (k = 0.78 W/m·K) separated by a 12-mm-wide stagnant air space (k = 0.026 W/m·K). Determine the steady rate of heat transfer through this double-pane window and the temperature of its inner surface for a day during which the room is maintained at 21°C while the temperature of the outdoors is −5°C. Take the convection heat transfer coefficients on the inner and outer surfaces of the window to be $h1$, = 10 W/m2·K and $h2$ = 25 W/m2·K, and disregard any heat transfer by radiation.

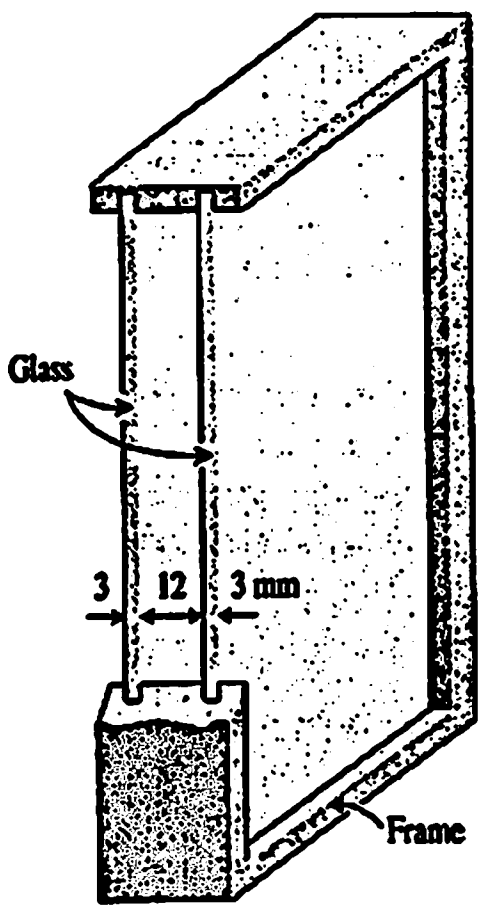


FIGURE P17–18

Step 1 of 8

Given data:

Height of the glass window, $H = 1.5\,\text{m}$.

Width of the glass window, $W = 2.4\,\text{m}$.

Thickness of the glass,

$$L_1 = 3\,\text{mm}$$
$$= \frac{3}{1000}\,\text{m}$$
$$= 0.003\,\text{m}$$

Distance between two glasses,

$$L_2 = 12\,\text{mm}$$
$$= \frac{12}{1000}\,\text{m}$$
$$= 0.012\,\text{m}$$

Thermal conductivity of the glass, $k = 0.78\ \text{W/m}\cdot\text{K}$

Thermal conductivity of the air, $k_2 = 0.026\ \text{W/m}\cdot\text{K}$

Temperature of the room,

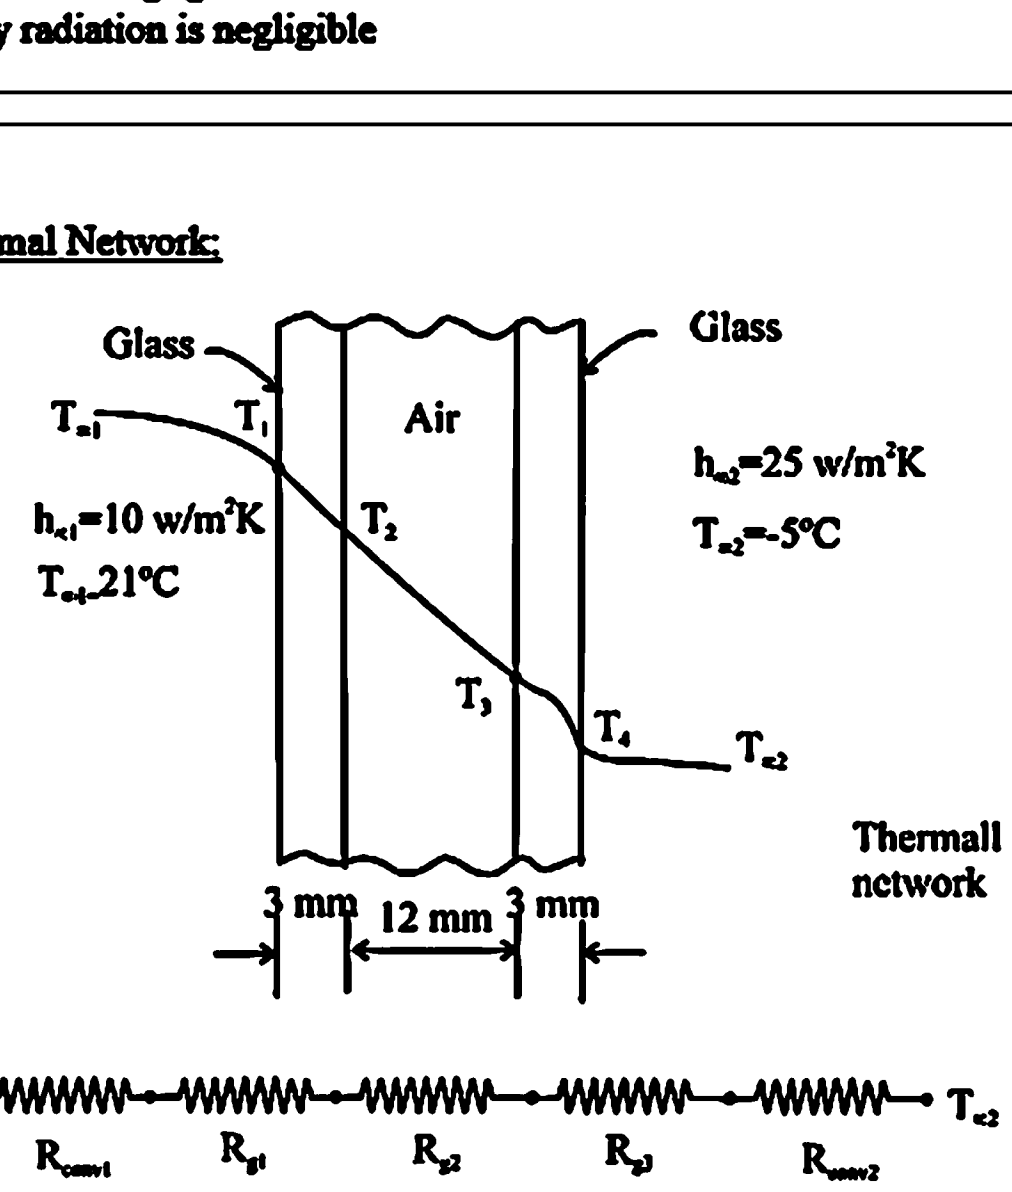
$$T_{\infty 1} = 21°\text{C}$$
$$= 21 + 273.15\ \text{K}$$
$$= 294.15\ \text{K}$$

Temperature of the outdoors,

$$T_{\infty 2} = -5°\text{C}$$
$$= -5 + 273.15\ \text{K}$$
$$= 2268.15\ \text{K}$$

Heat transfer coefficient on the inner surface of the window, $h_1 = 10\ \text{W/m}^2\cdot\text{K}$

Heat transfer coefficient on the outer surface of the window, $h_2 = 25\ \text{W/m}^2\cdot\text{K}$



Step 2 of 8

Assumptions:

1. Heat transfer through the glass window is under steady state.
2. Thermal conductivity of the glass window is constant.
3. Heat transfer through the glass window is one dimensional and the gradients in Width and height direction are negligible.
4. Heat transfer by radiation is negligible

Step 3 of 8

Diagram for Thermal Network:

Step 4 of 8

The individual resistances are calculated as follows

$$R_{conv,1} = \frac{1}{h_1 A}$$
$$= \frac{1}{10 \times 3.6}$$
$$= 0.02778\,\text{K/W}$$

$$R_{glass,1} = \frac{L_1}{k_1 A}$$
$$= \frac{0.003}{0.78 \times 3.6}$$
$$= 0.0010684\,\text{K/W}$$

$$R_{glass,1}=\frac{L_1}{k_1A}$$
$$=\frac{0.003}{0.78\times3.6}$$
$$=0.0010684\,\text{K/W}$$

Step 5 of 8

$$R_{air,2}=\frac{L_2}{k_2A}$$
$$=\frac{0.012}{0.026\times3.6}$$
$$=0.1282\,\text{K/W}$$
$$R_{glass,3}=\frac{L_3}{k_3A}$$
$$=\frac{0.003}{0.78\times3.6}$$
$$=0.0010684\,\text{K/W}$$

Step 6 of 8

$$R_{conv,2}=\frac{1}{h_2A}$$
$$=\frac{1}{25\times3.6}$$
$$=0.0111\,\text{K/W}$$

The cross sectional area of the glass window can be calculated as

$$A=H\times W$$
$$=1.5(\text{m})\times2.4(\text{m})$$
$$=3.6\,\text{m}^2$$

Step 7 of 8

The heat transfer through the glass window can be determined using the thermal resistance network concept as follows,

$$\dot{Q}=\frac{T_{\infty1}-T_{\infty2}}{R_{conv,1}+R_{glass,1}+R_{air,2}+R_{glass,3}+R_{conv,2}}$$
$$=\frac{21-(-5)}{0.02778+0.001068+0.1282+0.001068+0.0111}$$
$$=153.65\,\text{W}$$

Hence, heat transfer through glass window is $\boxed{\dot{Q}=153.65\,\text{W}}$

Step 8 of 8

The inner surface temperature of the glass window can be expressed as,

$$\dot{Q}=\frac{T_{\infty1}-T_1}{R_{conv,1}}$$
$$153.65=\frac{294.15-(T_1)}{0.02778}$$
$$T_1=289.8812\,\text{K}$$
$$=16.73^\circ\text{C}$$

Hence, inner surface temperature of the glass window is $\boxed{T_1=16.73^\circ\text{C}}$

Question: 17.019P pg 1

Repeat Prob. 17–18, assuming the space between the two glass layers is evacuated.

Step 1 of 12

Given data:

Height of the glass window, $H = 1.5\,\text{m}$

Width of the glass window, $W = 2.4\,\text{m}$

Thickness of the glass,

$L_1 = 3\,\text{mm}$

$= \frac{3}{1000}\,\text{m}$

$= 0.003\,\text{m}$

Distance between two glasses,

$L_2 = 12\,\text{mm}$

$= \frac{12}{1000}\,\text{m}$

$= 0.012\,\text{m}$

Thermal conductivity of the glass, $k_1 = 0.78\ \text{W/m}\cdot\text{K}$

Temperature of the room,

$T_{\infty 1} = 21°\text{C}$

$= 21 + 273.15\ \text{K}$

$= 294.15\ \text{K}$

Temperature of the outdoors,

$T_{\infty 2} = -5°\text{C}$

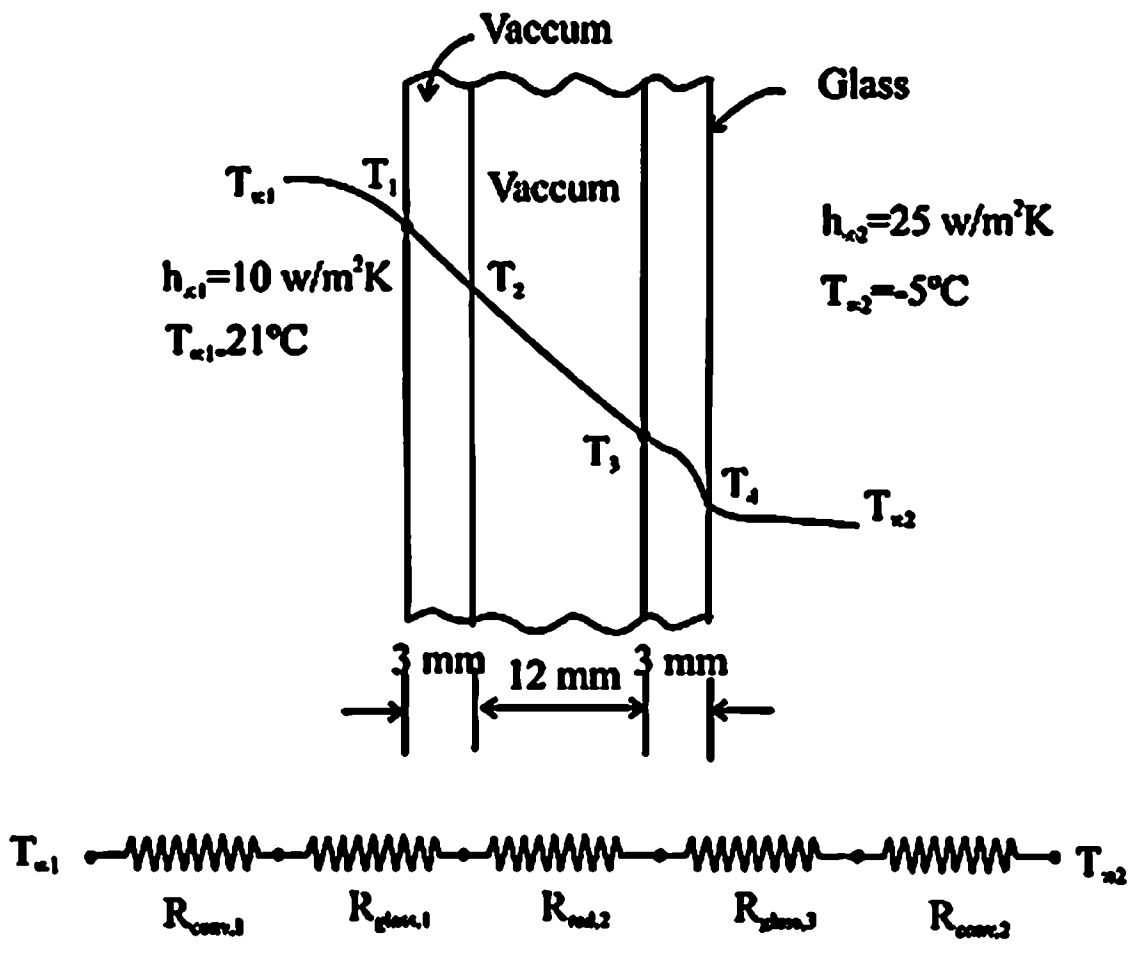
$= -5 + 273.15\ \text{K}$

$= 2268.15\ \text{K}$

Heat transfer coefficient on the inner surface of the window, $h_1 = 10\ \text{W/m}^2\cdot\text{K}$

Heat transfer coefficient on the outer surface of the window, $h_2 = 25\ \text{W/m}^2\cdot\text{K}$

Stefan Boltzmann constant, $\sigma = 5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4$



Step 2 of 12

Assumptions:

1. Heat transfer through the glass window is under steady state.
2. Thermal conductivity of the glass window is constant.
3. Heat transfer through the glass window is one dimensional and the gradients in width and height direction are negligible.

Step 3 of 12

Diagram for thermal network:

Step 4 of 12

The space between the two glass plates is evacuated and hence it can be considered that pure vacuum in the evacuated space. The mode of heat transfer between the glasses is radiation. In order to calculate the heat resistance with in the vacuum space, we need to know the inner surface temperature of the glasses. But we don't know the inner surface temperature of the glasses.

Therefore, assume the inner surface temperature of the glasses to be $T_2 = 18°\text{C}$ and $T_3 = 3°\text{C}$, and the emissivity of the glass is to be 1.

Therefore, the heat transfer through glasses can be determined as

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{conv,1} + R_{glass,1} + R_{vac,2} + R_{glass,3} + R_{conv,2}} \qquad \ldots\ldots (1)$$

Step 5 of 12

The cross sectional area of the glass window can be calculated as

$A = H \times W$

$= 1.5(\text{m}) \times 2.4(\text{m})$

$= 3.6\ \text{m}^2$

The individual resistances are calculated as follows,

$R_{conv,1} = \frac{1}{h_1 A}$

$= \frac{1}{10 \times 3.6}$

$= 0.02778\,\text{K/W}$

Step 6 of 12

$R_{glass,1} = \frac{L_1}{k_1 A}$

$= \frac{0.003}{0.78 \times 3.6}$

$= 0.0010684\,\text{K/W}$

$$R_{glass,1}=\frac{L_1}{k_1A}$$
$$=\frac{0.003}{0.78\times3.6}$$
$$=0.0010684\,\text{K/W}$$

$$R_{rad,2}=\frac{1}{\varepsilon\sigma A(T_2^2+T_3^2)(T_2+T_3)}$$
$$=\frac{1}{1\times5.67\times10^{-8}\times3.6\times(291.15^2+276.15^2)\times(291.15+276.15)}$$
$$=0.0536\,\text{K/W}$$

$$R_{glass,3}=\frac{L_3}{k_3A}$$
$$=\frac{0.003}{0.78\times3.6}$$
$$=0.0010684\,\text{K/W}$$

Step 7 of 12

$$R_{conv,2}=\frac{1}{h_2A}$$
$$=\frac{1}{25\times3.6}$$
$$=0.0111\,\text{K/W}$$

Substituting $R_{conv,1}$, $R_{glass,1}$, $R_{rad,2}$, $R_{glass,3}$ and $R_{conv,2}$ in equation (1), we get

$$\dot{Q}=\frac{T_{\infty1}-T_{\infty2}}{R_{conv,1}+R_{glass,1}+R_{rad,2}+R_{glass,3}+R_{conv,2}}$$
$$=\frac{21-(-5)}{0.02778+0.001068+0.0536+0.001068+0.0111}$$
$$=274.8\text{ W}$$

Hence, heat transfer through glass window is $\boxed{\dot{Q}=274.8\text{ W}}$

Step 8 of 12

The inner surface temperature of the glass window can be expressed as

$$\dot{Q}=\frac{T_{\infty1}-T_1}{R_{conv,1}}$$
$$274.8=\frac{294.15-T_1}{0.02778}$$
$$T_1=286.515\text{ K}$$
$$=13.36^\circ\text{C}$$

So, the $T_1=13.6^\circ\text{C}<T_2=18^\circ\text{C}$, it is impossible and in reality $T_1>T_2$. Therefore, the assumption of T_2 and T_3 are wrong. Hence the calculation needs to be repeated by re assuming inner surface temperatures of glasses are 12 and 1°C .

The resistance in the vacuum space can be determined as,

$$R_{rad,2}=\frac{1}{\varepsilon\sigma A(T_2^2+T_3^2)(T_2+T_3)}$$
$$=\frac{1}{1\times5.67\times10^{-8}\times3.6\times(285.15^2+274.15^2)\times(285.15+274.15)}$$
$$=0.056\text{ K/W}$$

Step 9 of 12

Therefore, the heat transfer through glass can be calculated as

$$\dot{Q}=\frac{T_{\infty1}-T_{\infty2}}{R_{conv,1}+R_{glass,1}+R_{rad,2}+R_{glass,3}+R_{conv,2}}$$
$$=\frac{21-(-5)}{0.02778+0.001068+0.056+0.001068+0.0111}$$
$$=268\text{ W}$$

Hence, the heat transfer through glass is $\boxed{\dot{Q}=268\,\text{W}}$

Step 10 of 12

The inner surface temperature of the glass window can be expressed as

$$\dot{Q}=\frac{T_{\infty1}-T_1}{R_{conv,1}}$$
$$268=\frac{294.15-T_1}{0.02778}$$
$$T_1=286.7\text{K}$$
$$=13.55^\circ\text{C}$$

Hence, the inner surface temperature of the glass window is $\boxed{T_1=13.55^\circ\text{C}}$

Step 11 of 12

Similarly the inner surface temperatures of glasses calculated as

$$\dot{Q}=\frac{T_1-T_2}{R_{glass,1}}$$
$$268=\frac{286.7-T_2}{0.001068}$$
$$T_2=286.4\text{K}$$
$$=13.26^\circ\text{C}$$

Hence, the inner surface temperature of the glass window and vacuum is $\boxed{T_2=13.26^\circ\text{C}}$

Step 12 of 12

$$\dot{Q}=\frac{T_2-T_3}{R_{glass,1}}$$
$$268=\frac{286.4-T_3}{0.056}$$
$$T_3=271.4\text{K}$$

$$\dot{Q} = \frac{T_3 - T_2}{R_{glass,1}}$$

$$268 = \frac{286.4 - T_3}{0.056}$$

$$T_3 = 271.4\text{K}$$

$$= -1.76°\text{C}$$

Hence, the outer surface temperature of the glass window and vacuum is $\boxed{T_2 = -1.76°\text{C}}$

Therefore the assumed values are very close to the calculated results.

Question: 17.020P

Reconsider Prob. 17–18. Using EES (or other) software, plot the rate of heat transfer through the window as a function of the width of air space in the range of 2 mm to 20 mm, assuming pure conduction through the air. Discuss the results.

Step 1 of 7

Given data:

Height of the glass window, $H = 1.5\,\text{m}$.

Width of the glass window, $W = 2.4\,\text{m}$.

Thickness of the glass, $L_1 = 0.003\,\text{m}$.

Distance between two glasses, $L_2 = 0.002\,\text{to}\,0.012\,\text{m}$.

Thermal conductivity of the glass, $k_1 = 0.78\,\text{W/m-K}$.

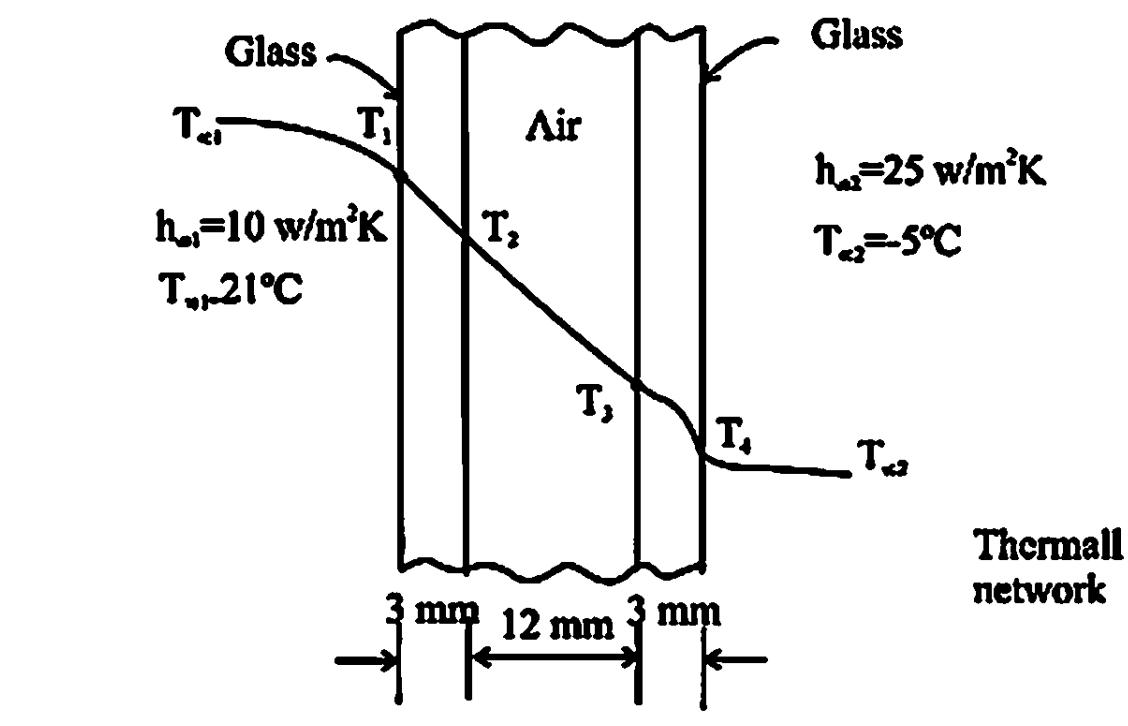
Thermal conductivity of the air, $k_2 = 0.026\,\text{W/m-K}$.

Temperature of the room, $T_{\infty 1} = 21^\circ\text{C}$.

Temperature of the outdoors, $T_{\infty 2} = -5^\circ\text{C}$.

Heat transfer coefficient on the inner surface of the window, $h_1 = 10\,\text{W/m}^2\text{-K}$.

Heat transfer coefficient on the outer surface of the window, $h_2 = 25\,\text{W/m}^2\text{-K}$.



Step 2 of 7

Assumptions:

1. Heat transfer through the glass window is under steady state.
2. Thermal conductivity of the glass window is constant.
3. Heat transfer through the glass window is one dimensional and the gradients in width and height direction are negligible.
4. Heat transfer by radiation is negligible

Step 3 of 7

Diagram for thermal network:

Step 4 of 7

The heat transfer through the glass window can be determined using the thermal resistance network concept as follows,

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{conv,1} + R_{glass,1} + R_{air,2} + R_{glass,3} + R_{conv,2}}$$

The cross sectional area of the glass window can be calculated as

$$A = H \times W$$
$$= 1.5(\text{m}) \times 2.4(\text{m})$$
$$= 3.6\,\text{m}^2$$

Step 5 of 7

The individual resistances are calculated as follows

$$R_{conv,1} = \frac{1}{h_1 A}$$
$$= \frac{1}{10(\text{W/m}^2\text{-K}) \times 3.6(\text{m}^2)}$$
$$= 0.02778\,\text{K/W}$$

$$R_{glass,1} = \frac{L_1}{k_1 A}$$
$$= \frac{0.003(\text{m})}{0.78(\text{W/m-K}) \times 3.6(\text{m}^2)}$$
$$= 0.0010684\,\text{K/W}$$

$$R_{air,2} = \frac{L_2}{k_2 A}$$
$$= \frac{L_2(\text{m})}{0.026(\text{W/m-K}) \times 3.6(\text{m}^2)}$$
$$= 10.684 L_2\,\text{K/W}$$

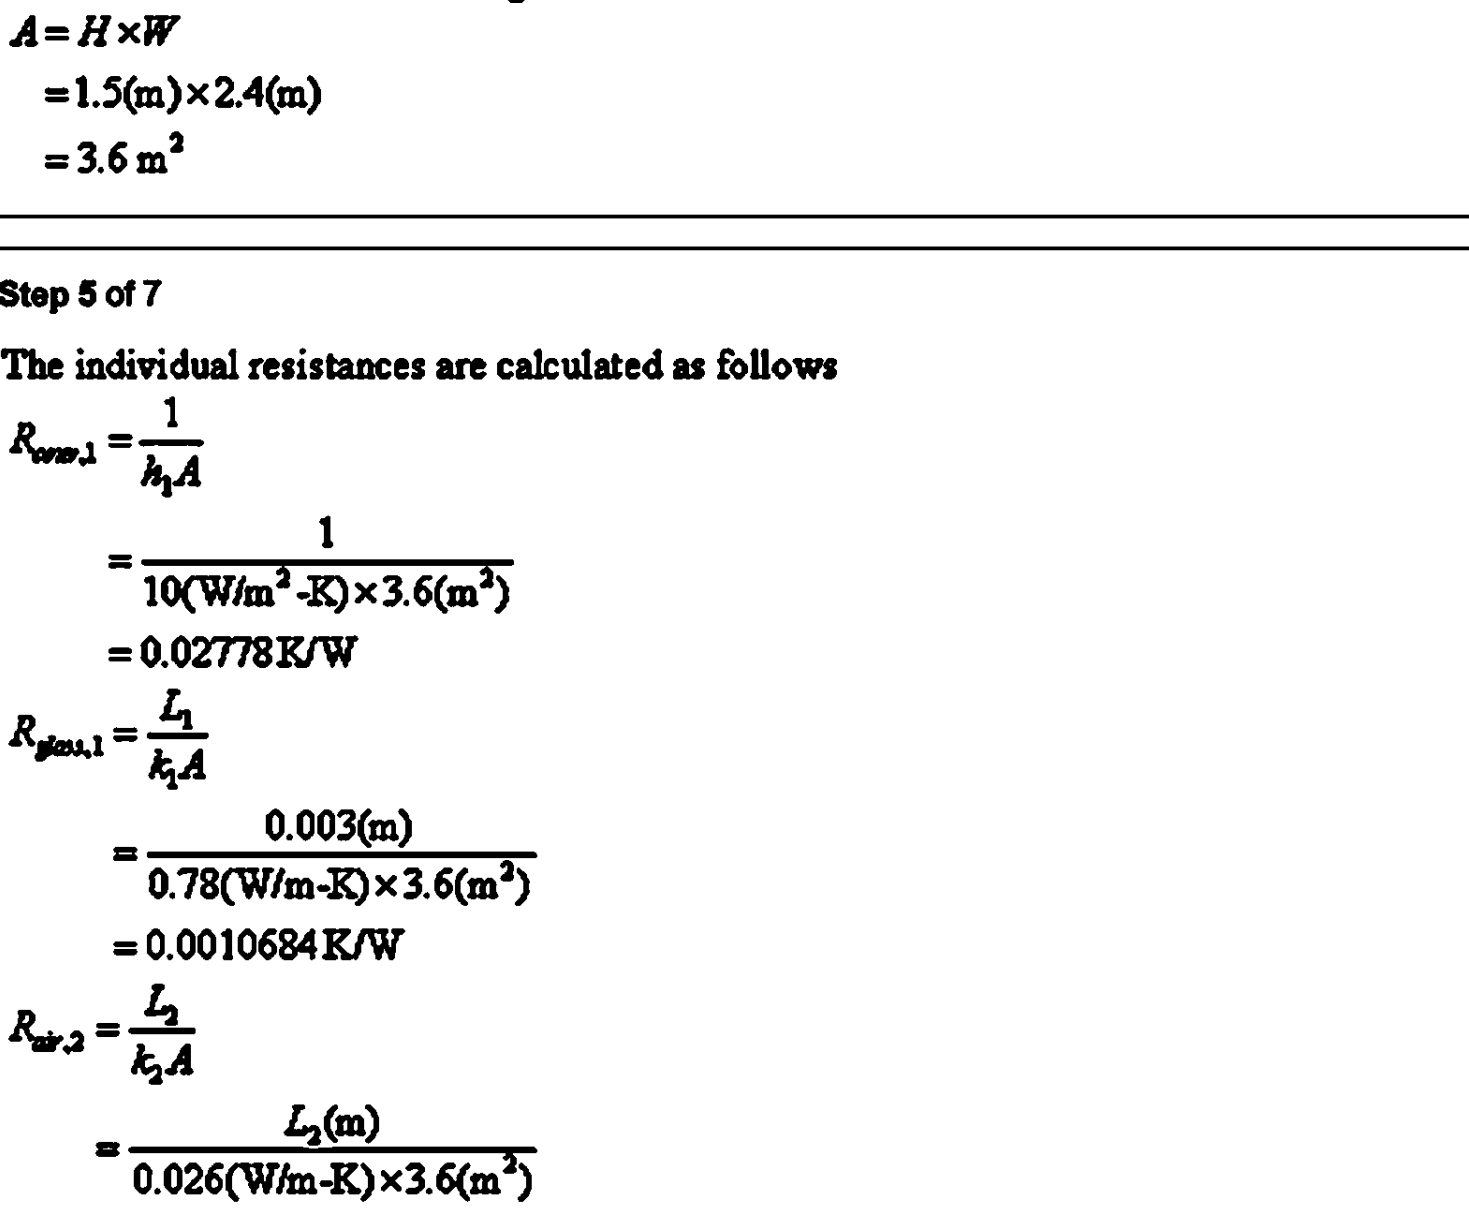
$$R_{glass,3} = \frac{L_3}{k_3 A}$$
$$= \frac{0.003(\text{m})}{0.78(\text{W/m-K}) \times 3.6(\text{m}^2)}$$
$$= 0.0010684\,\text{K/W}$$

$$R_{conv,2} = \frac{1}{h_2 A}$$
$$= \frac{1}{25(\text{W/m}^2\text{-K}) \times 3.6(\text{m}^2)}$$
$$= 0.0111\,\text{K/W}$$

Step 6 of 7

Therefore, the heat transfer through glass window is

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{conv,1} + R_{glass,1} + R_{air,2} + R_{glass,3} + R_{conv,2}}$$
$$= \frac{294.15(\text{K}) - 268.15(\text{K})}{0.02778(\text{K/W}) + 0.001068(\text{K/W}) + 10.684 L_2(\text{K/W}) + 0.001068(\text{K/W}) + 0.0111(\text{K/W})}$$



By varying the Length values from 0.002 to 0.02 by using the excel or EES software .

The problem is solved using the Microsoft Excel and the solution is given below

Lair(m)	Q(W)
0.002	416.7735
0.004	310.4403
0.006	247.3364
0.008	205.5531
0.01	175.8468
0.012	153.6425
0.014	136.4171
0.016	122.6647
0.018	111.4311
0.02	102.0825

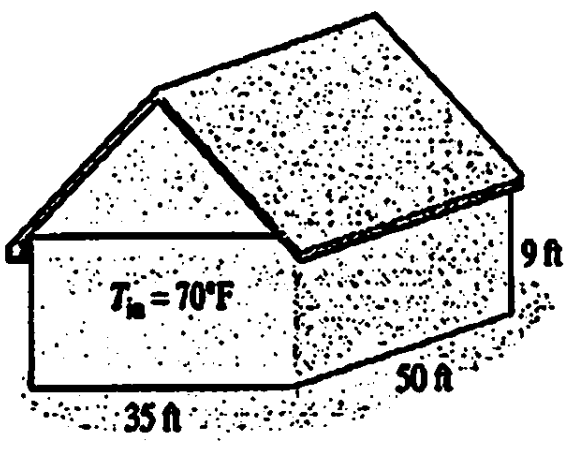
Step 7 of 7

Grapgh between the heatvtrasfer rate and Width of the space :

Therefore, from the graphical plot we can infer that by increasing the width of the air space the net heat transfer rate through window glasses decreasing parabolically.

Question: 17.021P

Consider an electrically heated brick house (k = 0.40 Btu/h·ft·°F) whose walls are 9 ft high and 1 ft thick. Two of the walls of the house are 50 ft long and the others are 35 ft long. The house is maintained at 70°F at all times while the temperature of the outdoors varies. On a certain day, the temperature of the inner surface of the walls is measured to be at 55°F while the average temperature of the outer surface is observed to remain at 45°F during the day for 10 h and at 35°F at night for 14 h. Determine the amount of heat lost from the house that day. Also determine the cost of that heat loss to the home owner for an electricity price of $0.09/kWh.



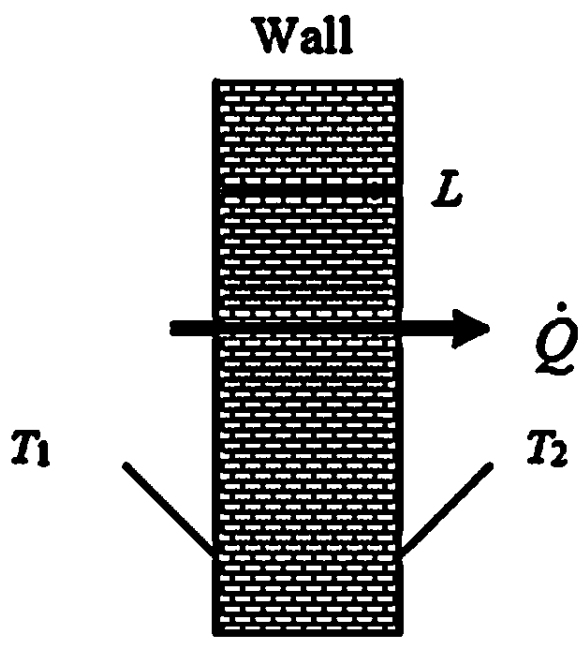


FIGURE P17–21E

Step 1 of 6

Draw a schematic diagram for steady state heat conduction through a wall.

Step 2 of 6

If heat transfer through the walls is steady since the surface temperatures of the walls remain constant at the specified values during the time period considered and heat transfer is one-dimensional since any significant temperature gradients will exist in the direction from the indoors to the outdoors considering heat loss through the walls only.

Calculate the total heat transfer area.

$$A = 2(50\times9 + 35\times9)$$
$$= 1530\ \text{ft}^2$$

Step 3 of 6

Calculate the rate of heat loss during the day time using the following equation:

$$\dot{Q}_{day} = kA\frac{T_1 - T_2}{L}$$

Here, k is the thermal conductivity, A is the heat transfer area, T_1 and T_2 are temperatures at inner and outer wall surfaces and L is thickness of the wall.

Substitute 0.40 Btu/h·ft·°F for k, 1530 ft² for A, 55°F for T_1, 45°F for T_2 and 1 ft for L.

$$\dot{Q}_{day} = (0.40\ \text{Btu/h}\cdot\text{ft}\cdot\text{°F})(1530\ \text{ft}^2)\frac{(55-45)\text{°F}}{1\ \text{ft}}$$
$$= 6120\ \text{Btu/h}$$

Step 4 of 6

Calculate the rate of heat loss during night time as follows:

$$\dot{Q}_{night} = kA\frac{T_1 - T_2}{L}$$

Substitute 0.40 Btu/h·ft·°F for k, 1530 ft² for A, 55°F for T_1, 45°F for T_2 and 1 ft for L.

$$\dot{Q}_{night} = (0.40\ \text{Btu/h}\cdot\text{ft}\cdot\text{°F})(1530\ \text{ft}^2)\frac{(55-35)\text{°F}}{1\ \text{ft}}$$
$$= 12240\ \text{Btu/h}$$

Step 5 of 6

Calculate the total amount of heat loss from the house that day.

$$\dot{Q} = \frac{Q}{\Delta t}$$
$$Q = \dot{Q}\Delta t$$
$$= 10\dot{Q}_{day} + 14\dot{Q}_{night}$$

Substitute 6120 Btu/h for $\dot{Q}_{day}$ and 12240 Btu/h for $\dot{Q}_{night}$.

$$Q = (10\ \text{h})(6120\ \text{Btu/h}) + (14\ \text{h})(12240\ \text{Btu/h})$$
$$= 232560\ \text{Btu}$$

Therefore, The total amount of heat loss from the house that day is **232560 Btu**.

Step 6 of 6

Calculate the cost of this heat loss for that day as follows:

$$\text{Cost} = \left(232560\ \text{Btu}\times\frac{0.000293071\ \text{kWh}}{1\ \text{Btu}}\right)\times\left(\frac{\$0.09}{\text{kWh}}\right)$$
$$= \$6.134$$

Therefore, the electricity cost of that heat loss is **$6.134**.

Question: 17.022P

A cylindrical resistor element on a circuit board dissipates 0.15 W of power in an environment at 35°C. The resistor is 1.2 cm long, and has a diameter of 0.3 cm. Assuming heat to be transferred uniformly from all surfaces, determine (*a*) the amount of heat this resistor dissipates during a 24-h period; (*b*) the heat flux on the surface of the resistor, in W/m2; and (*c*) the surface temperature of the resistor for a combined convection and radiation heat transfer coefficient of 9 W/m2·K.

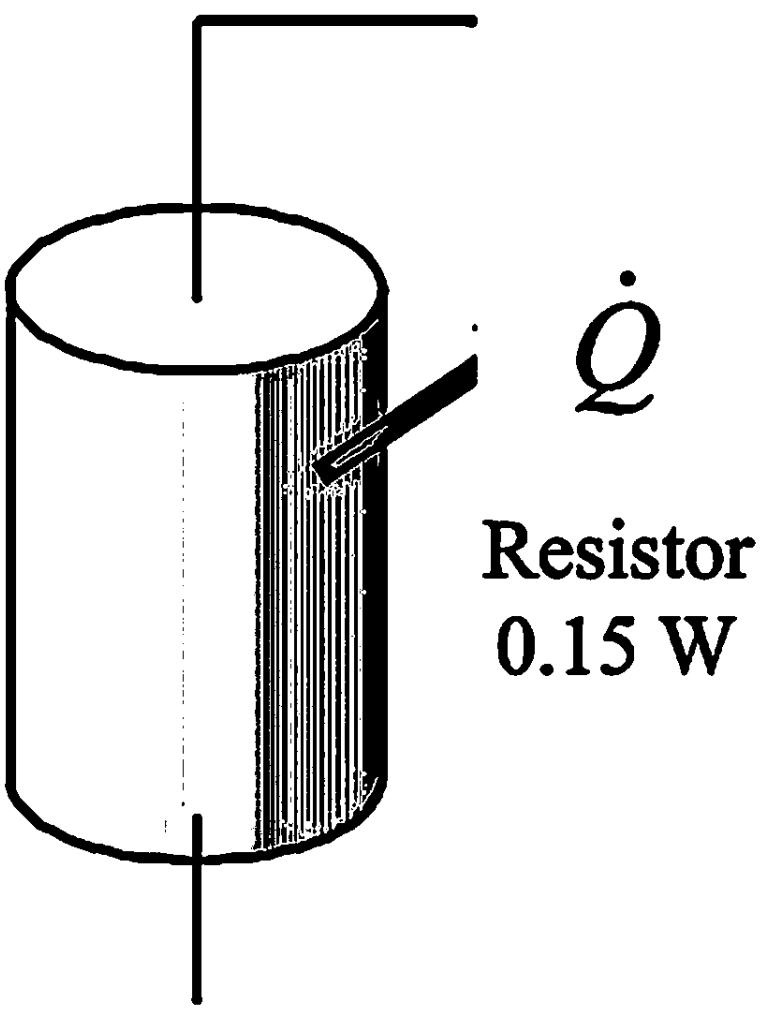
Step 1 of 5

Given data:

Power dissipates $\dot{Q} = 0.15\text{W}$

Environment temperature $T = 35°\text{C}$

Resistor length,



$$\begin{aligned} L &= 1.2\text{ cm} \\ &= \frac{1.2}{100}\text{ m} \\ &= 0.012\text{ m} \end{aligned}$$

Resistor diameter,

$$\begin{aligned} D &= 0.3\text{ cm} \\ &= \frac{0.3}{100}\text{ m} \\ &= 0.003\text{ m} \end{aligned}$$

Step 2 of 5

Diagram:

Step 3 of 5

If steady operating conditions exist and heat is transferred uniformly from all surfaces of the resistor then

(*a*)

Time period, $\Delta t = 24\text{ hr}$

The amount of heat this resistor dissipates during a 24-hour period is

$$\begin{aligned} Q &= \dot{Q}\Delta t \\ &= (0.15 \times 24) \\ &= 3.6\text{ Wh} \end{aligned}$$

Hence, the amount of heat this resistor dissipates during a 24-hour period is $\boxed{Q = 3.6\text{ Wh}}$

(*b*)

The heat flux on the surface of the resistor is

$$\begin{aligned} A_s &= 2\frac{\pi D^2}{4} + \pi DL \\ &= 2\frac{\pi(0.003\text{ m})^2}{4} + \pi(0.003\text{ m})(0.012\text{ m}) \\ &= 0.000127\text{ m}^2 \end{aligned}$$

Step 4 of 5

Heat flux on the surface of the transistor,

$$\begin{aligned} \dot{q} &= \frac{\dot{Q}}{A_s} \\ &= \frac{0.15\text{ W}}{0.000127\text{ m}^2} \\ &= 1179\text{ W/m}^2 \end{aligned}$$

Hence, Heat flux on the surface of the transistor is $\boxed{\dot{q} = 1181\text{ W/m}^2}$

Step 5 of 5

(*c*)

The surface temperature of the resistor can be determined from

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$\begin{aligned} T_s &= T_\infty + \frac{\dot{Q}}{hA_s} \\ &= 35 + \frac{0.15}{(9)(0.000127)} \\ &= 166°\text{C} \end{aligned}$$

Hence, the surface temperature of the resistor is $\boxed{T_s = 166°\text{C}}$

Question: 17.023P

To defog the rear window of an automobile, a very thin transparent heating element is attached to the inner surface of the window. A uniform heat flux of 1300 W/m2 is providedto the heating element for defogging a rear window with thickness of 5 mm. The interior temperature of the automobile is22°C and the convection heat transfer coefficient is 15 W/m2·K The outside ambient temperature is −5°C and the convection heat transfer coefficient is 100 W/m2·K. If the thermal conductivity of the window is 1.2 W/m·K, determine the inner surface temperature of the window.

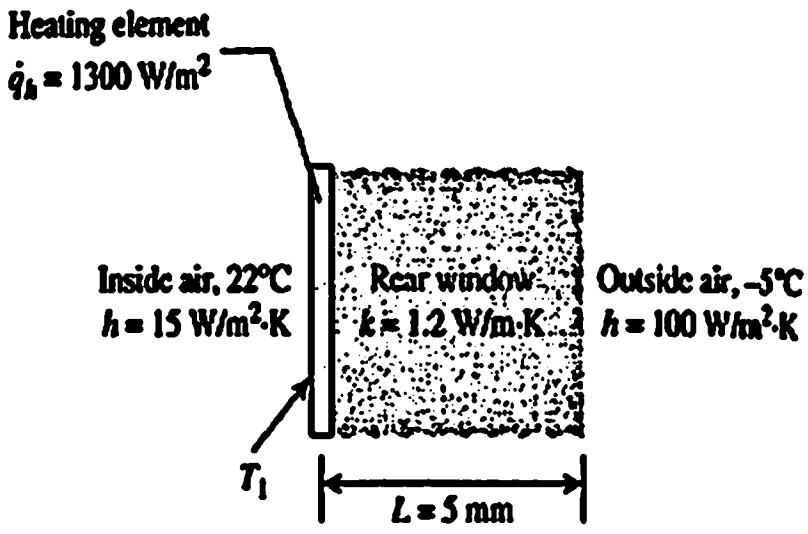


FIGURE P17–23

Step 1 of 3

Apply equilibrium equation to the system under steady state condition. The amount of internal heat generation in the heating element is equal to the amount of heat convection either of the heating element.

$$q'' = q_{conv,i} + q_{conv,o}$$
$$q'' = h_{conv,i}\left(T_1 - T_{\infty,i}\right) + h_{conv,o}\left(T_2 - T_{\infty,o}\right)$$

Here, $h_{conv,i}$ is the heat transfer coefficient of inside air, $h_{conv,o}$ is the heat transfer coefficient of outside air, $T_{\infty,i}$ is the temperature of inside air, $T_{\infty,o}$ is the temperature of outside air, T_1 is inner surface of the window, and T_2 is outer surface of the window.

Substitute $15\ W/m^2.K$ for $h_{conv,i}$, $100\ W/m^2.K$ for $h_{conv,o}$, $22°C$ for $T_{\infty,i}$, $5°C$ for $T_{\infty,o}$, and

$1300\ W/m^2$ for q''

$$1300 = 15\left(T_1 - 22\right) + 100\left(T_2 - (-5)\right)$$
$$1300 = 15\left(T_1 - 22\right) + 100\left(T_2 + 5\right)$$

$$15T_1 + 100T_2 = 1130 \quad \text{..... (1)}$$

Step 2 of 3

The heat transfer due to conduction through the glass is equal to the heat transfer due to convection out of the glass.

$$q_{cond} = q_{conv}$$
$$\frac{k\left(T_1 - T_2\right)}{L} = h_{conv,o}\left(T_2 - T_{\infty}\right)$$

Here, k is thermal conductivity of the rear window and L is thickness of the window.

Substitute $1.2\ W/m.K$ for k, 0.005 m for L, $100\ W/m^2.K$ for $h_{conv,o}$, and $5°C$ for $T_{\infty,o}$

$$\frac{1.2\left(T_1 - T_2\right)}{0.005} = 100\left(T_2 + 5\right)$$
$$T_1 - T_2 = 0.4167\left(T_2 + 5\right)$$

$$T_1 = T_2 + 0.4167\left(T_2 + 5\right) \quad \text{..... (2)}$$

Step 3 of 3

Solve equations (1) and (2)

Substitute $T_2 + 0.4167\left(T_2 + 5\right)$ for T_1 in equation (1)

$$15T_1 + 100T_2 = 1130$$
$$15\left(T_2 + 0.4167\left(T_2 + 5\right)\right) + 100T_2 = 1130$$
$$15T_2 + 6.2505T_2 + 31.252 + 100T_2 = 1130$$
$$T_2 = 9.0618°C$$

Substitute $9.0618°C$ for T_2 in equation (1).

$$15T_1 + 100T_2 = 1130$$
$$15T_1 + 100 \times 9.0618 = 1130$$
$$T_1 = 14.9213°C$$

Therefore, the temperature of the inner surface of the window is $\boxed{14.9213°C}$

Question: 17.024P

Consider a power transistor that dissipates 0.15 W of power in an environment at 30°C. The transistor is 0.4 cm long and has a diameter of 0.5 cm. Assuming heat to be transferred uniformly from all surfaces, determine (*a*) the amount of heat this resistor dissipates during a 24-h period, in kWh; (*b*) the heat flux on the surface of the transistor, in W/m2; and (*c*) the surface temperature of the resistor for a combined convection and radiation heat transfer coefficient of 18 W/m2·K.

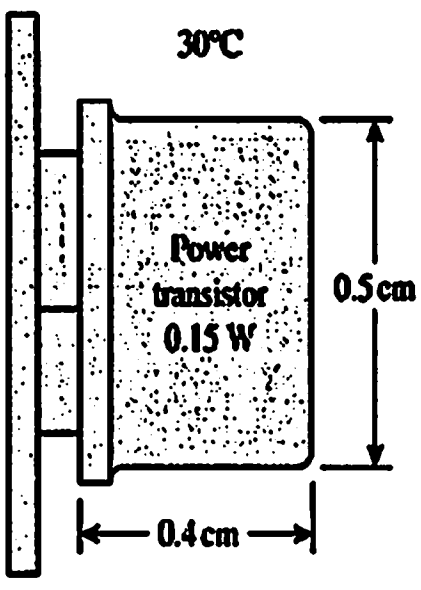

FIGURE P17–24

Step 1 of 5

Loading solution. Please wait ...

Step 2 of 5

Loading solution. Please wait ...

Step 3 of 5

a) The amount of heat dissipated by transistor during 24-h period can be determined as

$$Q = \dot{Q} \times t$$
$$= 0.15(\text{W}) \times 24(\text{h})$$
$$= 3.6\,\text{Wh}$$

Therefore amount of heat transferred is $\boxed{Q = 3.6\,\text{Wh}}$

Step 4 of 5

b) The heat flux on the surface of the transistor can be determined as follows,

$$\dot{q} = \frac{\dot{Q}}{A_s}$$

Where A_s is the surface area of the transistor from which heat is dissipating to the ambient air and it is calculated as

$$A_s = 2\frac{\pi D^2}{4} + \pi DL$$
$$= 2 \times \frac{\pi \times 0.005^2(\text{m}^2)}{4} + \pi \times 0.005(\text{m}) \times 0.004(\text{m})$$
$$= 0.0001021\text{m}^2$$

Therefore, the heat flux calculated as,

$$\dot{q} = \frac{0.15(\text{W})}{0.0001021(\text{m}^2)}$$
$$= 1469.12\,\text{W/m}^2$$

$\boxed{\dot{q} = 1469.12\,\text{W/m}^2}$

Step 5 of 5

The surface temperature of the transistor can be determined by applying the energy balance as follows,

$$\dot{E}_{in} + \dot{Q}_{gen} - \dot{E}_{out} = 0$$

$$0 + \dot{Q}_{gen} - h_{conv}A_s(T_s - T_\infty) - h_{rad}A_s(T_s - T_\infty) = 0$$

$$\dot{Q}_{gen} = (h_{conv} + h_{rad})A_s(T_s - T_\infty)$$
$$0.15(\text{W}) = 18(\text{W/m}^2\text{-K}) \times 0.0001021(\text{m}^2) \times (T_s - 303.15)$$
$$T_s = 384.77\,\text{K}$$
$$= 111.62°\text{C}$$

Hence, The surface temperature of the transistor is $\boxed{T_s = 111.62°\text{C}}$.

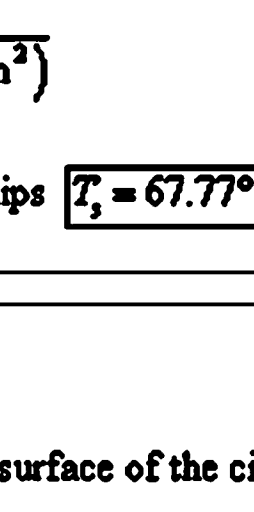
Question: 17.025P

A 12-cm × 18-cm circuit board houses on its surface 100 closely spaced logic chips, each dissipating 0.06 W in an environment at 40°C. The heat transfer from the back surface of the board is negligible. If the heat transfer coefficient on the surface of the board is 10 W/m2·K, determine (*a*) the heat flux on the surface of the circuit board, in W/m2; (*b*) the surface temperature of the chips; and (*c*) the thermal resistance between the surface of the circuit board and the cooling medium, in °C/W.

Step 1 of 5

Given data:

Area of circuit board $A_s = 12\text{cm} \times 18\text{cm}$



Dissipated heat $Q = 0.06\ \text{W}$

No of chips $n = 100$

Environment temperature $T_\infty = 40°\text{C}$

Surface heat transfer coefficient of the board $h = 10\text{W/m}^2 \cdot °\text{C}$

Step 2 of 5

Step 3 of 5

(*a*)

If steady operating conditions exist and heat transfer from the back surface of the board is negligible then

The heat flux on the surface of the circuit board is calculated by

$$A_s = 0.12\text{m} \times 0.18\text{m}$$

$$A_s = 0.0216\text{m}^2$$

$$\dot{q} = \frac{\dot{Q}}{A_s}$$

$$= \frac{(100 \times 0.06)\ \text{W}}{0.0216\ \text{m}^2}$$

$$= 277.77\ \text{W/m}^2$$

∴ The heat flux $\boxed{\dot{q} = 277.77\ \text{W/m}^2}$

Step 4 of 5

(*b*)

The surface temperature of the chips is

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$T_s = T_\infty + \frac{\dot{Q}}{hA_s}$$

$$= 40°\text{C} + \frac{(100 \times 0.06)\text{W}}{(10\ \text{W/m}^2.°\text{C})(0.0216\ \text{m}^2)}$$

$$= 67.77°\text{C}$$

∴ The surface temperature of the chips $\boxed{T_s = 67.77°\text{C}}$

Step 5 of 5

(*c*)

The thermal resistance between the surface of the circuit board and the cooling medium is calculated by

$$R_{conv} = \frac{1}{hA_s}$$

$$= \frac{1}{(10\ \text{W/m}^2 \cdot °\text{C})(0.0216\ \text{m}^2)}$$

$$= 4.629°\text{C/W}$$

∴ The thermal resistance $\boxed{R_{conv} = 4.629°\text{C/W}}$

Question: 17.026P

Consider a person standing in a room at 20°C with an exposed surface area of 1.7 m2. The deep body temperature of the human body is 37°C, and the thermal conductivity of the human tissue near the skin is about 0.3 W/m·K. The body is losing heat at a rate of 150 W by natural convection and radiation to the surroundings. Taking the body temperature 0.5 cm beneath the skin to be 37°C, determine the skin temperature of the person.

Question: 17.027P

A 1.0 m × 1.5 m double-pane window consists of two 4-mm-thick layers of glass (k= 0.78 W/m·K) that are the separated by a 5-mm air gap ($k$air = 0.025 W/m·K). The heat flow through the air gap is assumed to be by conduction. The inside and outside air temperatures are 20°C and −20°C, respectively, and the inside and outside heat transfer coefficients are 40 and 20 W/m2·K. Determine (*a*) the daily rate of heat loss through the window in steady operation and (*b*) the temperature difference across the largest thermal resistence.

Step 1 of 8

Given that:

Area of the window, $A = 1.0\text{m} \times 1.5\text{m}$

Thickness of glass layers, $L_1 = L_2 = 4\text{mm}$

Thickness of air gap, $L_3 = 5\text{mm}$

The thermal conductivity of the glass, $k_{glass} = 0.78\ \text{W/m} \cdot ^\circ\text{C}$

The thermal conductivity of the air, $k_{air} = 0.025\ \text{W/m} \cdot ^\circ\text{C}$

Inside temperature of the room, $T_{\infty 1} = 20^\circ\text{C}$

Outside temperature of the room, $T_{\infty 2} = 20^\circ\text{C}$

Step 2 of 8

(a) Consider heat transfer through the window is steady since the surface temperatures remain constant at the specified values and heat transfer by radiation is negligible.

The area of the window

$A = 1.0\ \text{m} \times 1.5\ \text{m}$

$A = 1.5\ \text{m}^2$

Step 3 of 8

The individual resistances are

$R_1 = R_{conv,1}$

$$R_{conv,1} = \frac{1}{h_1 A}$$

$$R_1 = \frac{1}{(40\ \text{W/m}^2 \cdot ^\circ\text{C})(1.5\ \text{m}^2)}$$

$R_1 = 0.01667^\circ\text{C/W}$

Step 4 of 8

$$R_{glass1} = \frac{L_1}{k_{glass} A}$$

$$R_{glass1} = \frac{0.004\ \text{m}}{0.78\ \text{W/m} \cdot ^\circ\text{C} \times 1.5}$$

$R_{glass1} = 0.00342\ ^\circ\text{C/W}$

$$R_{glass2} = \frac{L_2}{k_{glass} A}$$

$$R_{glass2} = \frac{0.004\ \text{m}}{0.78\ \text{W/m} \cdot ^\circ\text{C} \times 1.5\ \text{m}^2}$$

$R_{glass2} = 0.00342\ ^\circ\text{C/W}$

Step 5 of 8

$$R_{air} = \frac{L_{air}}{k_{air} A}$$

$$R_{air} = \frac{0.005\ \text{m}}{0.025\text{W/m} \cdot ^\circ\text{C} \times 1.5\ \text{m}^2}$$

$R_{air} = 0.133\ ^\circ\text{C/W}$

$R_2 = R_{conv,2}$

$$R_2 = \frac{1}{h_2 A}$$

$$R_2 = \frac{1}{20\text{W/m}^2 \cdot ^\circ\text{C} \times 1.5\ \text{m}^2}$$

$R_2 = 0.0333\ ^\circ\text{C/W}$

Step 6 of 8

$R_{total} = R_{conv,1} + R_{glass} + R_{air} + R_{glass} + R_{conv,2}$

$R_{total} = 0.01667 + 0.00342 + 0.00342 + 0.133 + 0.0333$

$R_{total} = 0.18981^\circ\text{C/W}$

Step 7 of 8

The steady rate of heat transfer through window glass is then

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{total}}$$

$$\dot{Q} = \frac{[20 - (-20)]^\circ\text{C}}{0.18981^\circ\text{C/W}}$$

$\dot{Q} = 210W$

∴ The heat transfer is $\boxed{\dot{Q} = 210W}$

Step 8 of 8

(b) Temperature difference across greatest thermal resistance can be determined by using thermal resistance of air which is maximum

$$\dot{Q} = \frac{\Delta t}{R_{air}}$$

$\Delta t = \dot{Q} R_{conv,1}$

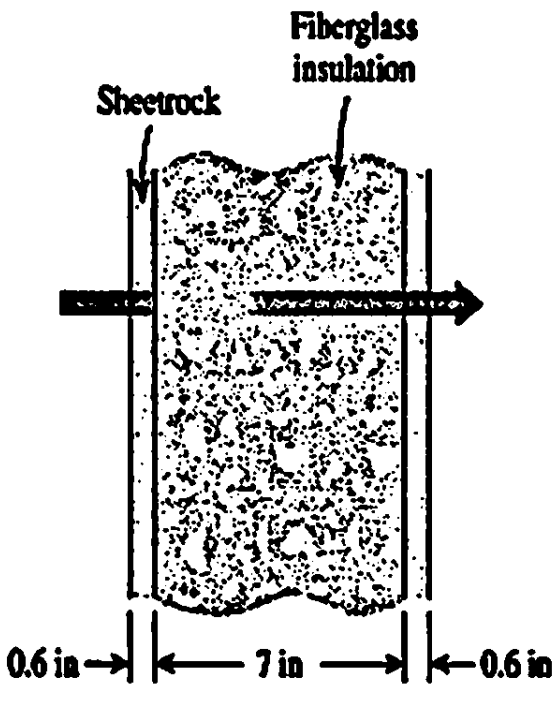
$\Delta t = (210\ \text{W})(0.133\ ^\circ\text{C/W})$

$\Delta t = 28^\circ\text{C}$

∴ Temperature difference across greatest thermal resistance is $\boxed{\Delta t = 28^\circ\text{C}}$

Question: 17.028P

A wall is constructed of two layers of 0.6-in-thick sheetrock (k= 0.10 Btu/h·ft·°F), which is a plasterboard made of two layers of heavy paper separated by a layer of gypsum, placed 7 in apart. The space between the sheetrocks is filled with fiberglass insulation (k = 0.020 Btu/h·ft·°F), Determine (*a*) the thermal resistance of the wall and (*b*) its *R*-value of insulation in English units.



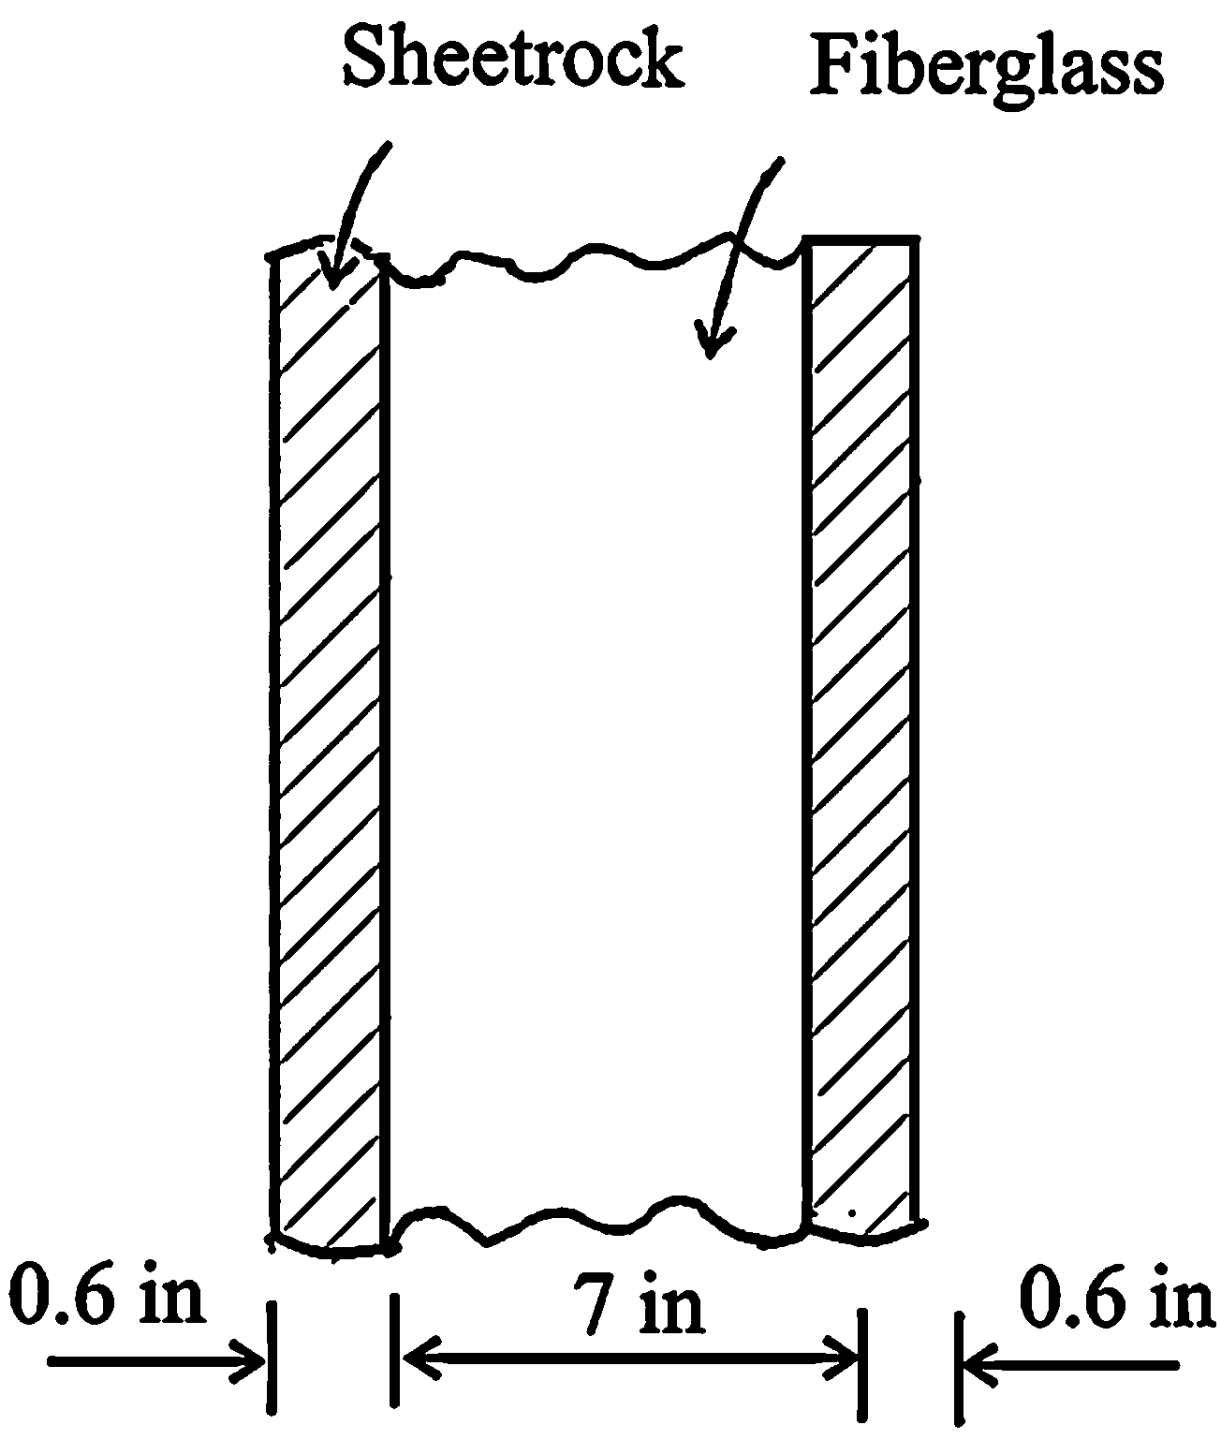


FIGURE P17–28E

Step 1 of 3

Schematic Diagram of construction of wall thickness:

Step 2 of 3

(a)

Calculate the thermal resistance of the wall

$$R_1 = \frac{L_1}{k_1}$$

Here,

Wall thickness is L_1 and L_3 respectively.

Thermal conductivity of the wall is k_1

Use the conversion factor to convert $1\,\text{in.}\,\text{to}\,\text{ft}$ of

$$1\,\text{ft} = 12\,\text{in}$$

Substitute $0.6\,\text{in.}\,\text{for}\,L_1, 0.10\,\text{Btu/h-ft}\cdot{}^\circ\text{F}\,\text{for}\,k_1$

$$R_1 = \frac{L_1}{k_1}$$
$$= \frac{0.6\,\text{in.}\times 1\,\text{ft}}{0.1\,\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}\times 12\,\text{in.}}$$
$$= 0.5{}^\circ\text{F}\cdot\text{h/Btu}$$

Therefore, the thermal resistance of the wall is $\boxed{0.5{}^\circ\text{F}\cdot\text{h/Btu}}$

Step 3 of 3

(b)

Calculate the *R*-value of the insulation is

$$R_2 = \frac{L_2}{k_2}$$

Here,

Thermal conductivity of the insulation is k_2

Thickness of the fiber glass Insulation is L_2

Use the conversion factor to convert $1\,\text{in.}\,\text{to}\,\text{ft}$ of

$$1\,\text{ft} = 12\,\text{in}$$

Substitute $7\,\text{in.}\,\text{for}\,L_2, 0.020\,\text{Btu/h-ft}\cdot{}^\circ\text{F}\,\text{for}\,k_2$

$$R_2 = \frac{L_2}{k_2}$$
$$= \frac{7\,\text{in.}\times 1\,\text{ft}}{0.020\,\text{Btu/hft}\cdot{}^\circ\text{F}\times 12\,\text{in.}}$$
$$= 29.167{}^\circ\text{F}\cdot\text{h/Btu}$$

Therefore, the insulation is *R*- value wall in English units is $\boxed{29.167{}^\circ\text{F}\cdot\text{h/Btu}}$

Question: 17.029P

The roof of a house consists of a 15-cm-thick concrete slab (k =2 W/m·K) that is 15 m wide and 20 m long. The convection heat transfer coefficients on the inner and outersurfaces of the roof are 5 and 12 W/m2·K, respectively. On a clear winter night, the ambient air is reported to be at 10°C, while the night sky temperature is 100 K. The house and the interior surfaces of the wall are maintained at a constant temperature of 20°C. The emissivity of both surfaces of the concrete roof is 0.9. Considering both radiation and convection heat transfers, determine the rate of heat transfer through the roof, and the inner surface temperature of the roof.

If the house is heated by a furnace burning natural gas with an efficiency of 80 percent, and the price of natural gas is $1.20/therm (1 therm = 105,500 kJ of energy content), determine the money lost through the roof that night during a 14-h period.

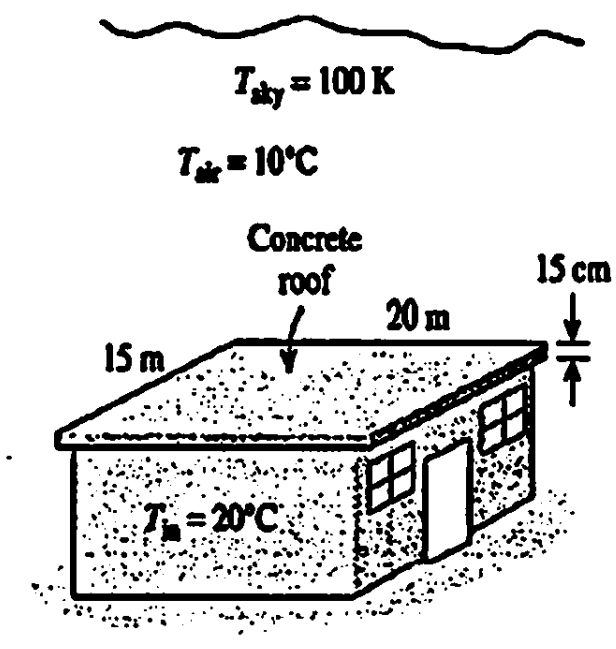

FIGURE P17–29

Step 1 of 9

Draw the schematic diagram of the house.

Step 2 of 9

Step 3 of 9

If steady operating conditions exist and the emissivity, thermal conductivity of the roof are constant and in steady operation, heat transfer from the room to the roof (by convection and radiation) must be equal to the heat transfer from the roof to the surroundings (by convection and radiation), that must be equal to the heat transfer through the roof by conduction that is,

$$\dot{Q}_{\text{roof, cond}} = \dot{Q}_{\text{room to roof, conv}} + \dot{Q}_{\text{rad}} = \dot{Q}_{\text{roof to surroundings, conv}} + \dot{Q}_{\text{rad}}$$

Step 4 of 9

Taking the inner and outer surface temperatures of the roof to be $T_{s,in}$ and $T_{s,out}$, respectively, the quantities above can be expressed as

$$\dot{Q}_{\text{room to roof, conv}} + \dot{Q}_{\text{rad}}$$
$$= h_i A\left(T_{room} - T_{s,in}\right) + \varepsilon A\sigma\left(T_{room}^4 - T_{s,in}^4\right)$$

Substitute $5\,\text{W/m}^2\cdot{}^\circ\text{C}$ for h_i , $300\,\text{m}^2$ for A , 20°C for T_{room} , $5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4$ for σ , 0.9 for ε , $293\,\text{K}$ for T_{room} in the terms containing fourth power of temperature and $\left(T_{s,in} + 273\,\text{K}\right)$ for $T_{s,in}$ in the terms containing fourth power of temperature.

$$= \left(5\ \text{W/m}^2\cdot{}^\circ\text{C}\right)\left(300\ \text{m}^2\right)\left(20 - T_{s,in}\right)^\circ\text{C}$$
$$+ (0.9)\left(300\ \text{m}^2\right)\left(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4\right)\left[(293\,\text{K})^4 - \left(T_{s,in} + 273\,\text{K}\right)^4\right]$$

$$\dot{Q}_{\text{room to roof, conv}} + \dot{Q}_{\text{rad}} = \left[1500\times\left(20 - T_{s,in}\right)\right]$$
$$+ \left(1.5309\times10^{-5}\left[(20+273\,\text{K})^4 - \left(T_{s,in} + 273\,\text{K}\right)^4\right]\right) \quad \text{..... (1)}$$

$$\dot{Q}_{\text{roof, cond}} = kA\frac{T_{s,in} - T_{s,out}}{L}$$

$$= \left(2\ \text{W/m}\cdot{}^\circ\text{C}\right)\left(300\ \text{m}^2\right)\frac{T_{s,in} - T_{s,out}}{0.15\ \text{m}}$$

$$= 4000\left(T_{s,in} - T_{s,out}\right)\ \text{W} \quad \text{..... (2)}$$

Step 5 of 9

Calculate the rate of heat transfer from room to surroundings by using the equation,

$$\dot{Q}_{\text{roof to surr, conv+rad}} = h_o A\left(T_{s,out} - T_{surr}\right) + \varepsilon A\sigma\left(T_{s,out}^4 - T_{sky}^4\right)$$

Substitute $12\ \text{W/m}^2\cdot{}^\circ\text{C}$ for h_0 , $300\,\text{m}^2$ for A , 0.9 for ε , $5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4$ for σ ,

10°C for T_{surr} , $\left(T_{s,out} + 273\,\text{K}\right)$ for $T_{s,out}$ in the terms containing fourth power of temperature and $100\,\text{K}$ for T_{sky} .

$$\dot{Q}_{\text{roof to surr, conv+rad}} = \left(12\ \text{W/m}^2\cdot{}^\circ\text{C}\right)\left(300\ \text{m}^2\right)\left(T_{s,out} - 10\right)^\circ\text{C}$$
$$+ 0.9\left(300\ \text{m}^2\right)\left(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4\right)\left[\left(T_{s,out} + 273\,\text{K}\right)^4 - (100\,\text{K})^4\right]$$

$$\dot{Q}_{\text{roof to surr, conv+rad}} = 3600\left(T_{s,out} - 10\right)^\circ\text{C} + 1.5309\times10^{-5}\left[\left(T_{s,out} + 273\,\text{K}\right)^4 - (100\,\text{K})^4\right] \quad \text{..... (3)}$$

Step 6 of 9

Equating equations (1) and (2)

$$4000\left(T_{s,in} - T_{s,out}\right) = 1500\left(20 - T_{s,in}\right)^\circ\text{C} + 1.5309\times10^{-5}\left[7.37\times10^9 - \left(T_{s,in} + 273\,\text{K}\right)^4\right]$$

$$4000\left(T_{s,in} - T_{s,out}\right) = 30000 - 1500T_{s,in} + 112827.33 - 1.5309\times10^{-5}\left(T_{s,in} + 273\,\text{K}\right)^4 \quad \text{..... (4)}$$

Equating equations (2) and (3)

$$4000\left(T_{s,in} - T_{s,out}\right) = 3600\left(T_{s,out} - 10\right)^\circ\text{C} + 1.5309\times10^{-5}\left[\left(T_{s,out} + 273\,\text{K}\right)^4 - (100\,\text{K})^4\right] \quad \text{..... (5)}$$

Step 7 of 9

Solving the equations (4) and (5) we get

$$T_{s,in} = 7.3^\circ\text{C}$$

$$T_{s,out} = -2.1^\circ\text{C}$$

Substituting values in the equation (2) we get

$$\dot{Q} = 37600\text{W}$$

Step 8 of 9

Calculate the total amount of natural gas consumption during a period by using the equation,

$$Q_{gas} = \frac{Q_{input}}{0.80}$$

$$= \frac{\dot{Q}\Delta t}{0.80}$$

Substitute $37.6\,\text{kW}$ for $\dot{Q}$ and $(14\times3600)\text{sec}$ for Δt .

$$Q_{gas} = \frac{(37.600\ \text{kJ/s})(14\times3600\ \text{s})}{0.80}\left(\frac{1\ \text{therm}}{105{,}500\ \text{kJ}}\right)$$
$$= 22.453\ \text{therms}$$

Step 9 of 9

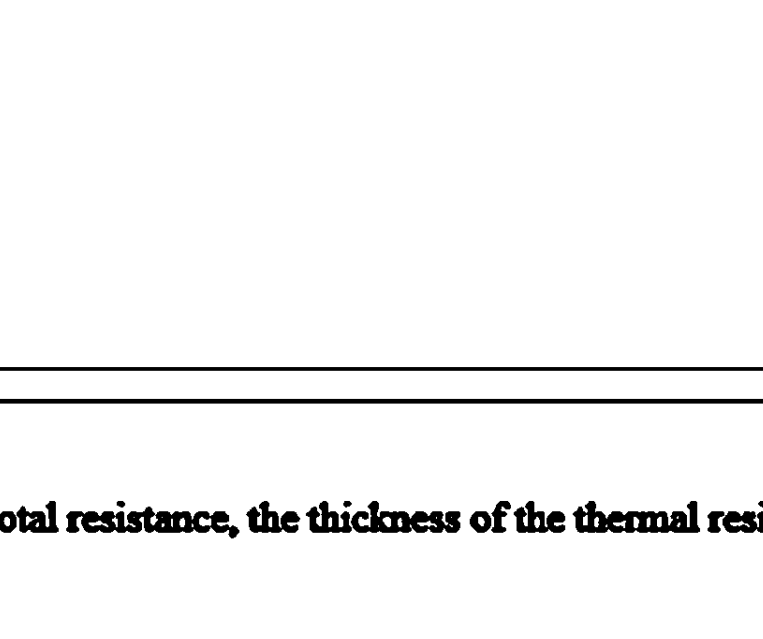
Calculate the money lost through the roof during that period is

$$\text{Money lost} = (22.453\ \text{therms})(\$1.20/\text{therm})$$
$$= 26.943$$

Therefore the money lost through the roof during that period is $\boxed{\$26.943}$.

Question: 17.030P

A 2-m × 1.5-m section of wall of an industrial furnace burning natural gas is not insulated, and the temperature at the outer surface of this section is measured to be 110°C. The temperature of the furnace room is 32°C, and the combined convection and radiation heat transfer coefficient at the surface of the outer furnace is 10 W/m2·K. It is proposed to insulate this section of the furnace wall with glass wool insulation (k = 0.038 W/m·K) in order to reduce the heat loss by 90 percent, Assuming the outer surface temperature of the metal section still remains at about 110°C, determine the thickness of the insulation that needs to be used.



The furnace operates continuously and has an efficiency of 78 percent. The price of the natural gas is $1.10/therm (1 therm = 105,500 kJ of energy content). If the installation of the insulation will cost $250 for materials and labor, determine how long it will take for the insulation to pay for itself from the energy it saves.

Step 1 of 8

Loading solution. Please wait ...

Step 2 of 8

Diagram for thermal network:

Step 3 of 8

Without having any insulation the rate of heat transfer can be determined as

$$\dot{Q} = hA(T_s - T_\infty)$$
$$= 10 \times 3 \times (110 - 32)$$
$$= 2340\,\text{W}$$

Step 4 of 8

In order to reduce heat loss by 90%, the new heat transfer rate calculated as

$$\dot{Q} = 0.1 \times 2340\,(\text{W})$$
$$= 234\,\text{W}$$

The thermal resistance calculated as

$$\dot{Q} = \frac{\Delta T}{R_{total}}$$
$$R_{total} = \frac{\Delta T}{\dot{Q}}$$
$$= \frac{(110 - 32)}{234}$$
$$= 0.3333\,\text{K/W}$$

Step 5 of 8

In order to have this total resistance, the thickness of the thermal resistance must be,

$$R_{total} = \frac{1}{hA} + \frac{L}{kA}$$
$$L = kA\left(R_{total} - \frac{1}{hA}\right)$$
$$L = 0.038 \times 3 \times \left(0.3333 - \frac{1}{10 \times 3}\right)$$
$$= 0.0342\,\text{m}$$

Therefore, thickness of the insulation is $\boxed{L = 0.0342\,\text{m}}$

Step 6 of 8

The amount of heat transfer rate saved by the insulation is 90% of the total heat transfer rate, therefore

$$\dot{Q} = 0.9 \times 2340\,(\text{W})$$
$$= 2106\,\text{W}$$
$$= 2.106\,\text{kJ/s}$$
$$= 2.106 \times 3600\,\text{kJ/h}$$
$$= 7851.6\,\text{kJ/h}$$

Therefore, the rate of heat transfer is $\boxed{\dot{Q} = 7851.6\,\text{kJ/h}}$

Step 7 of 8

Since the furnace operates continuously, the number of hours per year is $365 \times 24 = 8760\,\text{h/year}$ and the efficiency if the furnace is 78%, the amount of energy saved per year can be determined as

$$\text{Energy saved per year} = 7851.6\,(\text{kJ/h}) \times 8760\,(\text{h})$$
$$= 68780016\,\text{kJ}$$

Amount of energy saved in terms of therms can be calculated as

$$1\,\text{therm} = 105500\,\text{kJ}$$
$$\text{Energy saved per year} = 68780016\,(\text{kJ}) \times \frac{1\,\text{therm}}{105500\,(\text{kJ})}$$
$$= 652\,\text{therms}$$

Therefore, the money saved can be determined as

$$\text{money saved} = \text{Energy saved} \times \text{cost of energy}$$
$$= 652\,(\text{therms}) \times 1.1\,(\$/\text{therm})$$
$$= \$717.2\,\text{per year}$$

Therefore, amount of money saved is $\boxed{\text{money saved} = \$717.2\,\text{per year}}$

Step 8 of 8

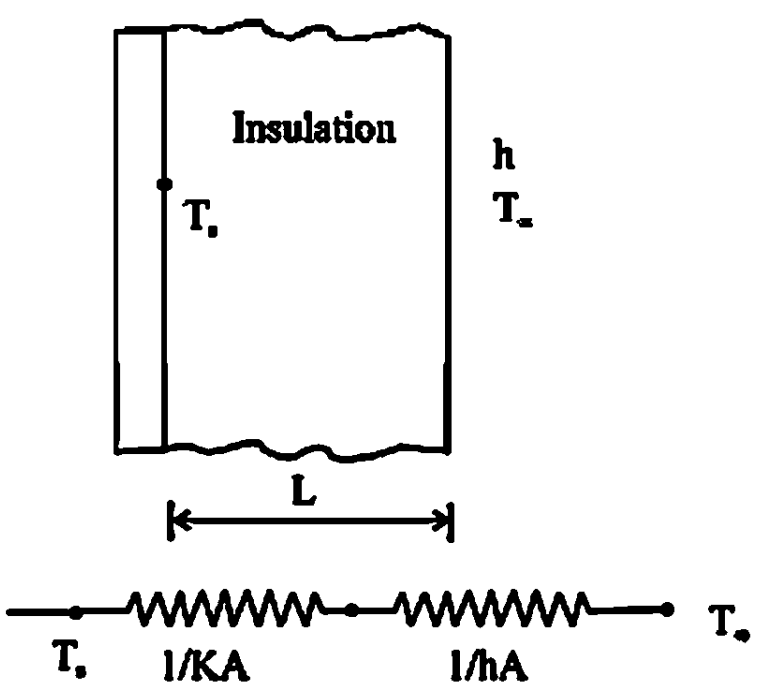
cost of the insulation = $250

The payback period can be calculated as,

$$\text{Payback period}\,(t) = \frac{\text{insulation cost}}{\text{Money saved}}$$
$$= \frac{\$250}{\$717.2\,(\text{per year})}$$
$$= 0.35\,\text{years}$$
$$= 4.2\,\text{months}$$

Therefore, payback period is $\boxed{t = 4.2\,\text{months}}$

Question: 17.031P



Repeat Prob. 17–30 for expanded perlite insulation assuming conductivity is $k = 0.052$ W/m·K.

Step 1 of 9

Loading solution. Please wait ...

Step 2 of 9

Diagram for thermal network:

Step 3 of 9

Without having any insulation the rate of heat transfer can be determined as

$$\dot{Q} = hA(T_s - T_\infty)$$
$$= 10 \times 3 \times (110 - 32)$$
$$= 2340\,\text{W}$$

Step 4 of 9

In order to reduce heat loss by 90%, the new heat transfer rate calculated as

$$\dot{Q} = 0.1 \times 2340$$
$$= 234\,\text{W}$$

The thermal resistance calculated as

$$\dot{Q} = \frac{\Delta T}{R_{total}}$$
$$R_{total} = \frac{\Delta T}{\dot{Q}}$$
$$= \frac{(110 - 32)}{234}$$
$$= 0.3333\,\text{K/W}$$

Step 5 of 9

In order to have this total resistance, the thickness of the thermal resistance must be,

$$R_{total} = \frac{1}{hA} + \frac{L}{kA}$$
$$L = kA\left(R_{total} - \frac{1}{hA}\right)$$
$$L = 0.052 \times 3 \times \left(0.3333 - \frac{1}{10 \times 3}\right)$$
$$= 0.0468\,\text{m}$$

Therefore, thickness of the insulation, $\boxed{L = 0.0468\,\text{m}}$

Step 6 of 9

The amount of heat transfer rate saved by the insulation is 90% of the total heat transfer rate, therefore

$$\dot{Q} = 0.9 \times 2340$$
$$= 2106\,\text{W}$$
$$= 2.106\,\text{kJ/s}$$
$$= 2.106 \times 3600\,\text{kJ/h}$$
$$= 7851.6\,\text{kJ/h}$$

Step 7 of 9

Since the furnace operates continuously, the number of hours per year is $365 \times 24 = 8760\,\text{h/year}$ and the efficiency if the furnace is 78%, the amount of energy saved per year can be determined as,

Energy saved per year $= 7851.6\,(\text{kJ/h}) \times 8760\,(\text{h})$
$= 68780016\,\text{kJ}$

Amount of energy saved in terms of therms can be calculated as,

$1\,\text{therm} = 105500\,\text{kJ}$

$$\text{Energy saved per year} = 68780016\,(\text{kJ}) \times \frac{1\,\text{therm}}{105500\,(\text{kJ})}$$
$$= 652\,\text{therms}$$

Step 8 of 9

Therefore, the money saved can be determined as,

money saved = Energy saved × cost of energy
$= 652\,(\text{therms}) \times 1.1\,(\$/\text{therm})$
$= \$717.2\,\text{per year}$

Therefore, amount of money saved is $\boxed{\text{money saved} = \$717.2\,\text{per year}}$

Step 9 of 9

cost of the insulation $= \$250$

The payback period can be calculated as,

$$\text{Payback period}(t) = \frac{\text{insulation cost}}{\text{Money saved}}$$
$$= \frac{\$250}{\$717.2\,(\text{per year})}$$
$$= 0.35\,\text{years}$$
$$= 4.2\,\text{months}$$

Therefore, payback period is $\boxed{t = 4.2\,\text{months}}$

Question:

Reconsider Prob. 17–30. Using EES (or other) software, investigate the effect of thermal conductivity on the required insulation thickness. Plot the thickness of insulation as a function of the thermal conductivity of the insulation in the range of 0.02 W/m·K to 0.08 W/m·K, and discuss the results.

Step 1 of 11

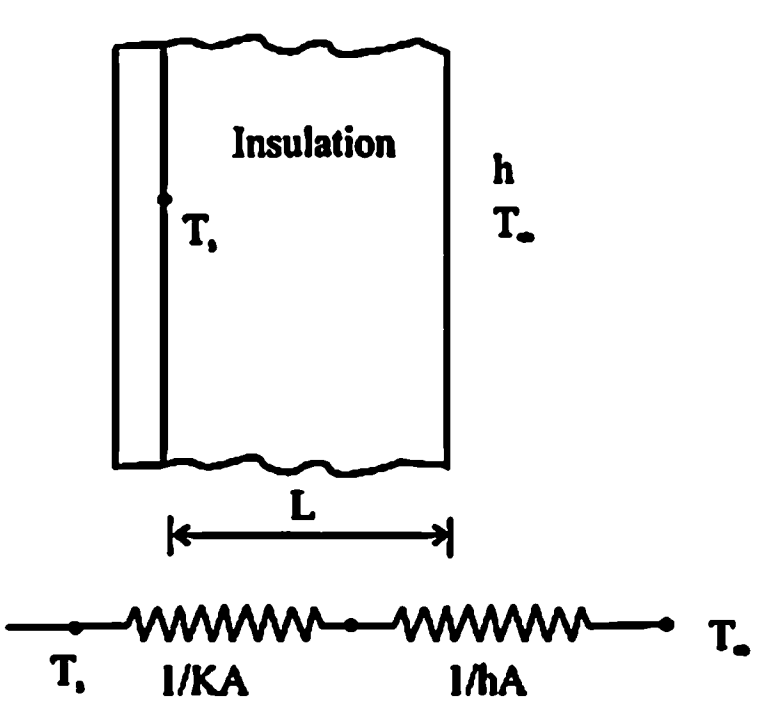
Given data:

Area of the wall,

$A = 2 \times 1.5$

$= 3\text{m}^2$

Temperature of the outer surface of the furnace wall, $T_s = 110°\text{C}$



Temperature inside the furnace room, $T_\infty = 32°\text{C}$

Thermal conductivity of the glass insulation range, $k = 0.02 - 0.08\ \text{W/m-K}$

Combined Convection and radiation heat transfer coefficient, $h = 10\,\text{W/m}^2 \cdot \text{K}$

Step 2 of 11

Diagram for thermal network:

Step 3 of 11

Without having any insulation the rate of heat transfer can be determined as,

$\dot{Q} = hA(T_s - T_\infty)$

$= 10 \times 3 \times (110 - 32)$

$= 2340\,\text{W}$

Step 4 of 11

In order to reduce heat loss by 90%, the new heat transfer rate calculated as

$Q = 0.1 \times 2340(\text{W})$

$= 234\,\text{W}$

The thermal resistance calculated as,

$$\dot{Q} = \frac{\Delta T}{R_{total}}$$

$$R_{total} = \frac{\Delta T}{\dot{Q}}$$

$$= \frac{(110 - 32)}{234}$$

$$= 0.3333\ \text{K/W}$$

Step 5 of 11

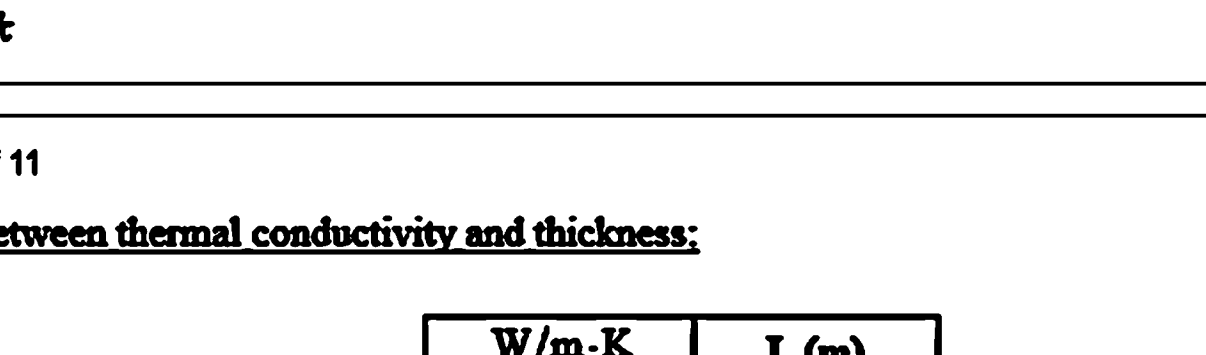
In order to have this total resistance, the thickness of the thermal resistance calculated and tabulated using Excel,

$$R_{total} = \frac{1}{hA} + \frac{L}{kA}$$

$$L = kA\left(R_{total} - \frac{1}{hA}\right)$$

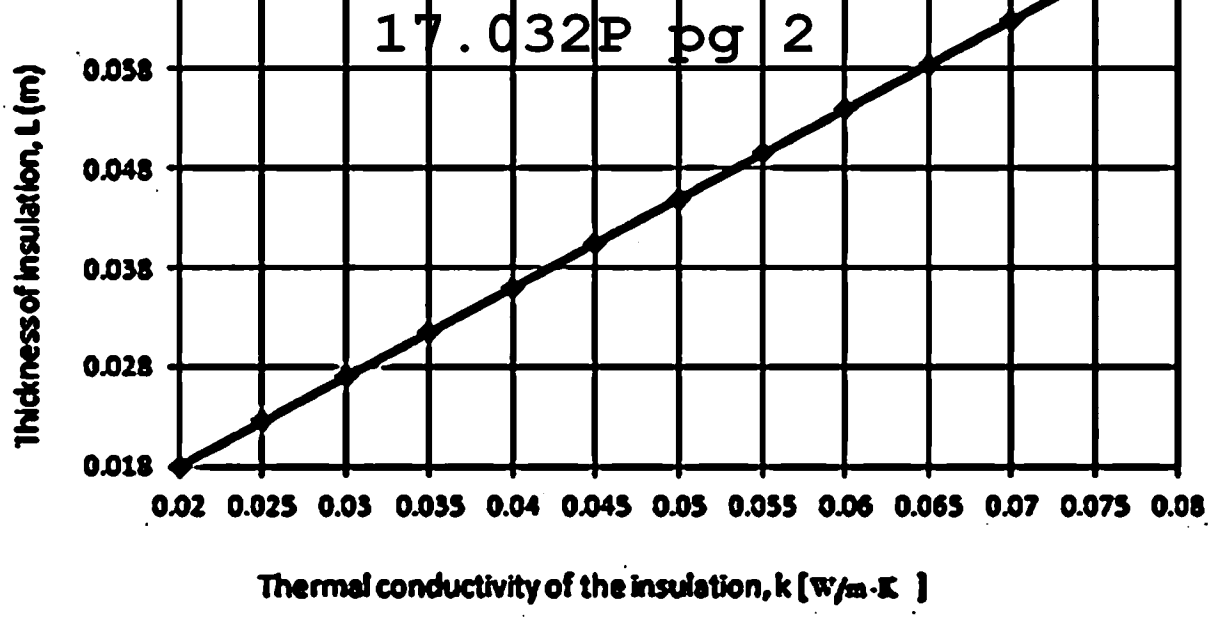
$$L = k \times 3 \times \left(0.3333 - \frac{1}{10 \times 3}\right)$$

$$= 0.9k$$



Step 6 of 11

Table between thermal conductivity and thickness:



W/m-K	L (m)
0.02	0.018
0.025	0.0225
0.03	0.027
0.035	0.0315
0.04	0.036
0.045	0.0405
0.05	0.045
0.055	0.0495
0.06	0.054
0.065	0.0585
0.07	0.063
0.075	0.0675
0.08	0.072

Step 7 of 11

Plot between thermal conductivity and thickness:

17.032P pg 2

Step 8 of 11

From the above graph shows that thickness of the insulation is directly proportionally to the thermal conductivity. So amount of insulation added which will reduce the amount heat losses.

The amount of heat transfer rate saved by the insulation is 90% of the total heat transfer rate, therefore

$$\dot{Q} = 0.9 \times 2340\,(\text{W})$$
$$= 2106\,\text{W}$$
$$= 2.106\,\text{kJ/s}$$
$$= 2.106 \times 3600\,\text{kJ/h}$$
$$= 7851.6\,\text{kJ/h}$$

Step 9 of 11

Since the furnace operates continuously, the number of hours per year is $365 \times 24 = 8760\,\text{h/year}$ and the efficiency if the furnace is 78%, the amount of energy saved per year can be determined as

$$\text{Energy saved per year} = 7851.6\,(\text{kJ/h}) \times 8760\,(\text{h})$$
$$= 68780016\,\text{kJ}$$

Amount of energy saved in terms of therms can be calculated as

$$1\,\text{therm} = 105500\,\text{kJ}$$

$$\text{Energy saved per year} = 68780016\,(\text{kJ}) \times \frac{1\,\text{therm}}{105500\,(\text{kJ})}$$
$$= 652\,\text{therms}$$

Step 10 of 11

Therefore, the money saved can be determined as,

$$\text{money saved} = \text{Energy saved} \times \text{cost of energy}$$
$$= 652\,(\text{therms}) \times 1.1\,(\$/\text{therm})$$
$$= \$717.2\,\text{per year}$$

Therefore, amount of money saved is $\boxed{\text{money saved} = \$717.2\,\text{per year}}$

Step 11 of 11

$$\text{cost of the insulation} = \$250$$

The payback period can be calculated as,

$$\text{Payback period}\,(t) = \frac{\text{insulation cost}}{\text{Money saved}}$$
$$= \frac{\$250}{\$717.2\,(\text{per year})}$$
$$= 0.35\,\text{years}$$
$$= 4.2\,\text{months}$$

Therefore, payback period is $\boxed{t = 4.2\,\text{months}}$

Question: 17.033P

The wall of a refrigerator is constructed of fiberglass insulation (k = 0.035 W/m·K) sandwiched between two layers of 1-mm-thick sheet metal (k = 15.1 W/m·K). The refrigerated space is maintained at 2°C, and the average heat transfer coefficients at the inner and outer surfaces of the wall are 4 W/m2·K and 9 W/m2·K, respectively. The kitchen temperature averages 24°C. It is observed that condensation occurs on the outer surfaces of the refrigerator when the temperature of the outer surface drops to 20°C. Determine the minimum thickness of fiberglass insulation that needs to be used in the wall in order to avoid condensation on the outer surfaces.

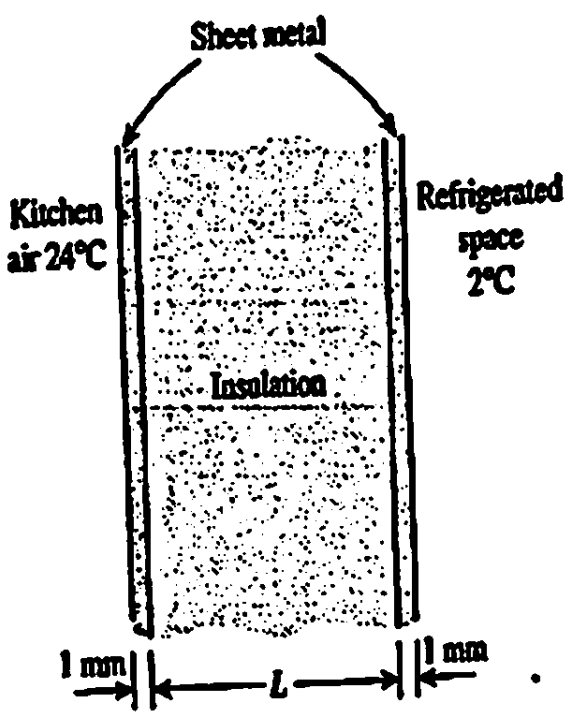


FIGURE P17-33

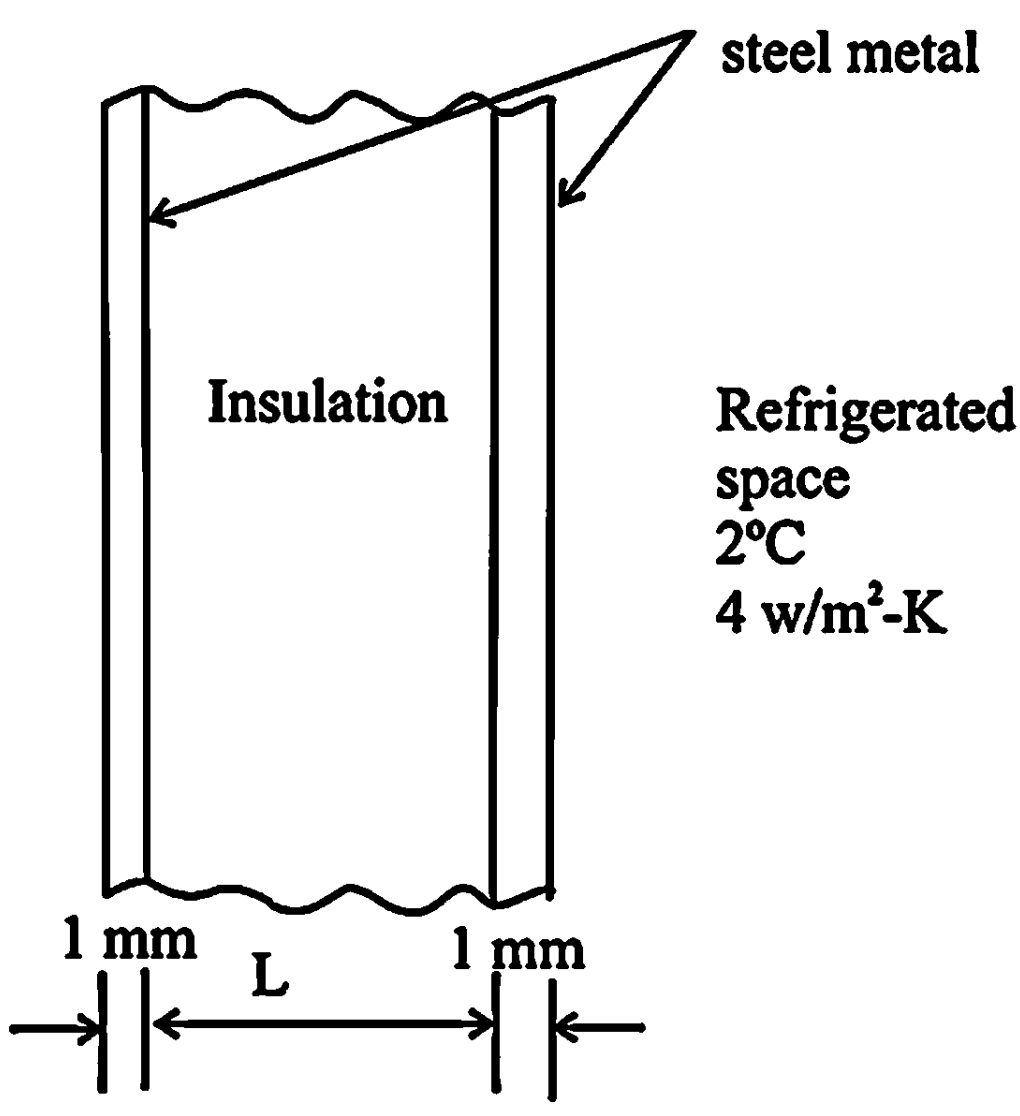
Step 1 of 5

Calculate the heat flux of the system is

$$\dot{q} = h(T_{room} - T_{s,out})$$

Here,

Temperature inside the kitchen room T_{room}



Temperature of the surface is $T_{s,out}$

Substitute $9\,\mathrm{W/m^2 \cdot K}$ for h_o, 24°C for T_{room}, 20°C for $T_{s,out}$

$$\begin{aligned}\dot{q} &= h(T_{room} - T_{s,out}) \\ &= 9(24-20) \\ &= 36\,\mathrm{W/m^2}\end{aligned}$$

Step 2 of 5

Schematic diagram of the wall of refrigerator system:

Step 3 of 5

Calculate the thermal resistance of the wall,

$$\dot{q} = \frac{\Delta T}{R_{total}}$$

$$R_{total} = \frac{\Delta T}{\dot{q}}$$

$$R_{total} = \frac{T_{room} - T_{refrig}}{\dot{q}}$$

Here,

Total thermal resistance is R_{total}

Temperature of the room is T_{room}

Temperature of the refrigeration is T_{refrig}

Substitute 25°C for T_{room}, 2°C for T_{refri}, $36\,\mathrm{W/m^2}$ for $\dot{q}$

$$\begin{aligned}R_{total} &= \frac{T_{room} - T_{refrig}}{\dot{q}} \\ &= \frac{(24-2)}{36} \\ &= 0.611\,\mathrm{m^2 \cdot K/W}\end{aligned}$$

Step 4 of 5

Write the thermal resistance expression in terms of heat transfer coefficient and wall coefficient

$$R_{total} = \frac{1}{h_o} + \frac{L_1}{k_1} + \frac{L_2}{k_2} + \frac{L_3}{k_3} + \frac{1}{h_i}$$

By rewrite the above equation, the thickness of the insulation

$$L_2 = k_2\left(R_{total} - \frac{1}{h_o} - 2\frac{L_1}{k_1} - \frac{1}{h_i}\right)$$

Here,

Thermal conductivity of the fiberglass insulation, k_2

Thermal conductivity of the sheet metal wall, k_1

Thicknesses of the sheet metal are L_1 and L_3

Heat transfer coefficient at the inner surface of the wall, h_i

Heat transfer coefficient at the outer surface of the wall, h_o

Step 5 of 5

Substitute $0.611\,\mathrm{m^2 \cdot K/W}$ for R_{total}, $9\,\mathrm{W/m^2 \cdot K}$ for h_o, $= 4\,\mathrm{W/m^2 \cdot K}$ for h_i, $15.1\,\mathrm{W/m \cdot K}$ for k_1, $0.035\,\mathrm{W/m \cdot K}$ for k_2,

$$\begin{aligned}L_2 &= k_2\left(R_{total} - \frac{1}{h_o} - 2\frac{L_1}{k_1} - \frac{1}{h_i}\right) \\ &= 0.035\left(0.611 - \frac{1}{9} - \frac{2\times 0.001}{15.1} - \frac{1}{4}\right) \\ &= 0.00874\,\mathrm{m}\end{aligned}$$

Therefore, thickness of insulation is $\boxed{0.00874\,\mathrm{m}}$

Question: 17.034P

Reconsider Prob. 17-33. Using EES(or other) software, investigate the effects of the thermal conductivities of the insulation material and the sheet metal on the thickness of the insulation. Let the thermal conductivity vary from 0.02 W/m·K to 0.08 W/m·K for insulation and 10W/m·K to 400 W/m·K for sheet metal. Plot the thickness of the insulation as the functions of the thermal conductivities of the insulation and the sheet metal, and discuss the results.

Step 1 of 5

Given data:

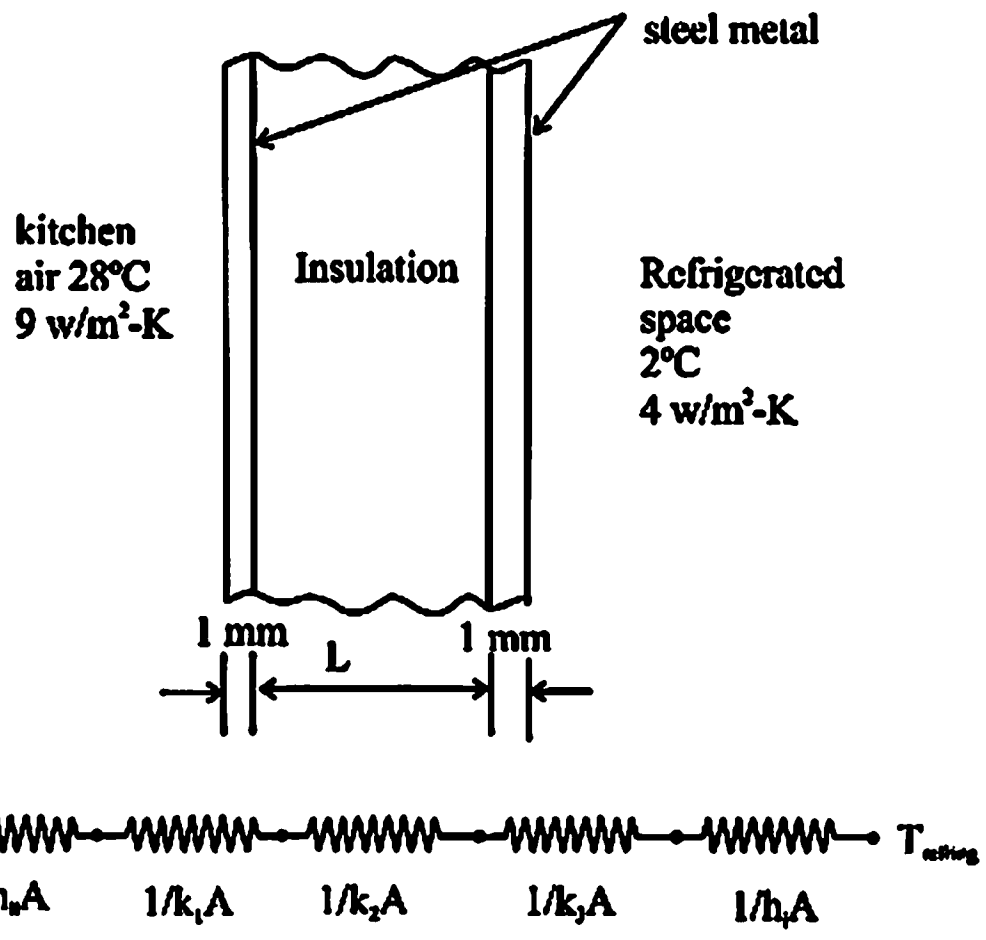
Thermal conductivity of the fiberglass insulation, $k_2 = 0.02 - 0.08 \text{W/m-K}$

Thermal conductivity of the sheet metal wall, $k_1 = k_3 = 10 - 400 \text{W/m-K}$

Thickness of the sheet metal, $L_1 = L_3 = 1\text{mm} = 0.001\text{m}$

Temperature inside the refrigerator, $T_{refrig} = 2^\circ\text{C}$

Temperature inside the kitchen room, $T_{room} = 28^\circ\text{C}$



Heat transfer coefficient at the inner surface of the wall, $h_i = 4 \text{W/m}^2\text{-K}$

Heat transfer coefficient at the outer surface of the wall, $h_o = 9 \text{W/m}^2\text{-K}$

Temperature of the outer surface the refrigerator, $T_{s,out} = 20^\circ\text{C}$

Step 2 of 5

Network diagram:

Step 3 of 5

The minimum thickness of insulation can be determined by assuming the outer surface temperature of the refrigerator to be 20°C. In steady operation, the rate of heat transfer through the refrigerator wall is constant, and thus heat transfer/heat flux between the room and the refrigerated space is equal to the heat transfer/heat flux between the room and the outer surface of the refrigerator.

Therefore, the heat flux can be calculated as

$$\dot{q} = h(T_{room} - T_{s,out})$$
$$= 9(\text{W/m}^2\text{-K}) \times (25 - 20)$$
$$= 45 \text{W/m}^2$$

Step 4 of 5

By using the thermal resistance network approach, the total thermal resistance can be calculated as

$$\dot{q} = \frac{\Delta T}{R_{total}} \rightarrow R_{total} = \frac{\Delta T}{\dot{q}}$$

$$R_{total} = \frac{T_{room} - T_{refrig}}{\dot{q}}$$
$$= \frac{(25-2)}{45(\text{W/m}^2)}$$
$$= 0.511 \text{m}^2\text{-K/W}$$

The total thermal resistance can be expressed as

$$R_{total} = \frac{1}{h_o} + \frac{L_1}{k_1} + \frac{L_2}{k_2} + \frac{L_3}{k_3} + \frac{1}{h_i}$$

By rewriting the above equation for the insulation thickness

$$L_2 = k_2 \left(R_{total} - \frac{1}{h_o} - 2\frac{L_1}{k_1} - \frac{1}{h_i} \right)$$

Using the Microsoft Excel sheet the above equation solved by varying the thermal conductivities of insulation and sheet metal as follows

Step 5 of 5

The Variation of insulation thickness by varying the thermal conductivity of the insulation tabulated and plotted as follows,

$$L_2 = k_2 \left(R_{total} - \frac{1}{h_o} - 2\frac{L_1}{k_1} - \frac{1}{h_i} \right)$$
$$= k_2 \left(0.511(\text{m}^2\text{-K/W}) - \frac{1}{9(\text{W/m}^2\text{-K})} - 2 \times \frac{0.001(\text{m})}{15.1(\text{W/m-K})} - \frac{1}{4(\text{W/m}^2\text{-K})} \right)$$
$$= k_2 0.15\text{m}$$

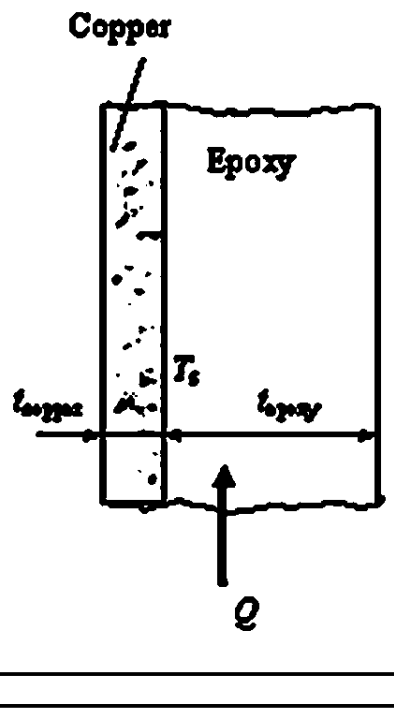
Question: 17.035P

Heat is to be conducted along a circuit board that has a copper layer on one side. The circuit board is 15 cm long and 15 cm wide, and the thicknesses of the copper and epoxy layers are 0.1 mm and 1.2 mm, respectively. Disregarding heat transfer from side surfaces, determine the percentages of heat conduction along the copper (k = 386 W/m·K) and epoxy (k = 0.26 W/m·K) layers. Also determine the effective thermal conductivity of the board.

Step 1 of 8

Given data:

Area of circuit board $A = 15\text{cm} \times 15\text{cm}$



Thickness of copper layer $t_{copper} = 0.1\text{mm}$

Thickness of epoxy layer $t_{epoxy} = 1.2\text{mm}$

Thermal conductivity of copper $k_{Cu} = 386\text{W/m°C}$

Thermal conductivity of epoxy $k_{epoxy} = 0.26\text{W/m°C}$

Step 2 of 8

Step 3 of 8

If steady operating condition exists and heat transfer is one-dimensional since heat transfer from the side surfaces is disregarded then take the length in the direction of heat transfer to be L and the width of the board to be w. Then heat conduction along this two-layer board can be expressed as

$$\dot{Q} = \dot{Q}_{copper} + \dot{Q}_{epoxy}$$
$$= \left(kA\frac{\Delta T}{L}\right)_{copper} + \left(kA\frac{\Delta T}{L}\right)_{epoxy}$$
$$= \left[(kt)_{copper} + (kt)_{epoxy}\right] w\frac{\Delta T}{L}$$

Step 4 of 8

Heat conduction along an "equivalent" board of thickness $t = t_{copper} + t_{epoxy}$ and thermal conductivity k_{eff} can be expressed as

$$\dot{Q} = \left(kA\frac{\Delta T}{L}\right)_{board}$$
$$= k_{eff}\,(t_{copper} + t_{epoxy}) w\frac{\Delta T}{L}$$

Setting the two relations above equal to each other and solving for the effective conductivity gives

$$k_{eff}\left(t_{copper} + t_{epoxy}\right) = (kt)_{copper} + (kt)_{epoxy}$$
$$k_{eff} = \frac{(kt)_{copper} + (kt)_{epoxy}}{t_{copper} + t_{epoxy}}$$

Step 5 of 8

Note that heat conduction is proportional to kt.

Substituting, the fractions of heat conducted along the copper and epoxy layers as well as the effective thermal conductivity of the board are determined to be

$$(kt)_{copper} = (386\ \text{W/m°C})(0.0001\ \text{m})$$
$$= 0.0386\ \text{W/°C}$$
$$(kt)_{epoxy} = (0.26\ \text{W/m°C})(0.0012\ \text{m})$$
$$= 0.000312\ \text{W/°C}$$
$$(kt)_{total} = (kt)_{copper} + (kt)_{epoxy}$$
$$= 0.0386 + 0.000312$$
$$= 0.038912\ \text{W/°C}$$

Step 6 of 8

The percentage of heat conduction along the epoxy

$$f_{epoxy} = \frac{(kt)_{epoxy}}{(kt)_{total}}$$
$$= \frac{0.000312}{0.038912}$$
$$= 0.008$$
$$= 0.8\%$$

∴ The percentage of heat conduction $\boxed{f_{epoxy} = 0.8\%}$

Step 7 of 8

The percentage of heat conduction along the copper

$$f_{copper} = \frac{(kt)_{copper}}{(kt)_{total}}$$
$$= \frac{0.0386}{0.038912}$$
$$= 0.992$$
$$= 99.2\%$$

∴ The percentage of heat conduction $\boxed{f_{copper} = 99.2\%}$

Step 8 of 8

The effective thermal conductivity of the board

$$k_{eff} = \frac{(kt)_{copper} + (kt)_{epoxy}}{t_{copper} + t_{epoxy}}$$
$$k_{eff} = \frac{(386 \times 0.0001 + 0.26 \times 0.0012)\ \text{W/°C}}{(0.0001 + 0.0012)\ \text{m}}$$
$$k_{eff} = 29.9\text{W/m°C}$$

∴ The effective thermal conductivity $\boxed{k_{eff} = 29.9\text{W/m°C}}$

Question: 17.036P

A 0.05-in-thick copper plate (k = 223 Btu/h·ft·°F) is sandwiched between two 0.15-in-thick epoxy boards (k = 0.15 Btu/h·ft·°F) that are 7 in ×9 in in size. Determine the effective thermal conductivity of the board along its 9-in-long side. What fraction of the heat conducted along that side is, conducted through copper?

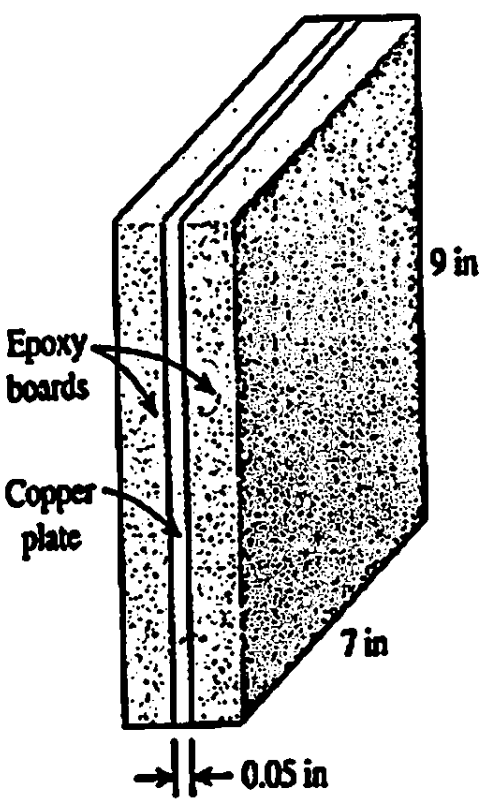


FIGURE P17–36E

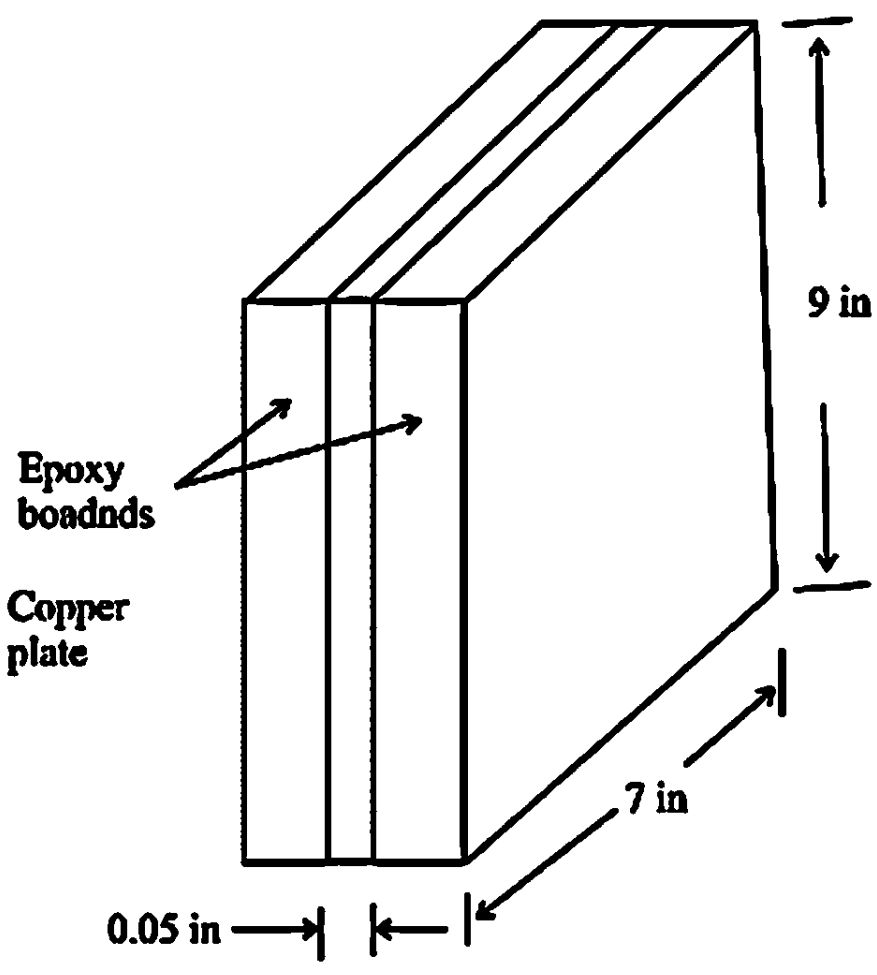
Step 1 of 7

Given data:



Thermal conductivity of the copper plate, $k = 223\text{Btu/h-ft-°F}$.

Thermal conductivity of the epoxy boards, $k = 0.15\text{Btu/h-ft-°F}$.

Thickness of the copper plate, $L = 0.05\text{in}$.

Thickness of the epoxy boards, $L = 0.15\text{in}$.

Step 2 of 7

Step 3 of 7

Take the length in the direction of heat transfer to be L, the width of the board to be w. and treat the two layers of epoxy as a single layer that is twice as thick. Then heat conduction along this two-layer plate can be expressed as

$$\begin{aligned}\dot{Q} &= \dot{Q}_{copper} + \dot{Q}_{epoxy} \\ &= \left(kA\frac{\Delta T}{L}\right)_{copper} + \left(kA\frac{\Delta T}{L}\right)_{epoxy} \\ &= \left(kwt\frac{\Delta T}{L}\right)_{copper} + \left(kwt\frac{\Delta T}{L}\right)_{epoxy} \\ &= \left[(kt)_{copper} + (kt)_{epoxy}\right]w\frac{\Delta T}{L}\end{aligned}$$

Step 4 of 7

The heat conduction happening along an equivalent plate thickness $t = t_{copper} + t_{epoxy}$ and the effective thermal conductivity k_{eff} can be expressed as

$$\begin{aligned}\dot{Q} &= \left(kA\frac{\Delta T}{L}\right)_{total} \\ &= \left(kwt\frac{\Delta T}{L}\right)_{total} \\ &= k_{eff}(t_{copper} + t_{epoxy})w\frac{\Delta T}{L}\end{aligned}$$

By equating the two equations the effective thermal conductivity can be expressed as

$$\dot{Q} = \left[(kt)_{copper} + (kt)_{epoxy}\right]w\frac{\Delta T}{L} = k_{eff}(t_{copper} + t_{epoxy})w\frac{\Delta T}{L}$$

$$k_{eff} = \frac{(kt)_{copper} + (kt)_{epoxy}}{(t_{copper} + t_{epoxy})}$$

Step 5 of 7

Heat conduction is proportional to kt, therefore the kt can be calculated for copper and epoxy as follows,

$$\begin{aligned}(kt)_{copper} &= 223(\text{Btu/h-ft-°F}) \times \frac{0.05}{12}(\text{ft}) \\ &= 0.93\text{Btu/h-°F}\end{aligned}$$

$$\begin{aligned}(kt)_{epoxy} &= 2 \times 0.15(\text{Btu/h-ft-°F}) \times \frac{0.15}{12}(\text{ft}) \\ &= 0.00375\text{Btu/h-°F}\end{aligned}$$

$$\begin{aligned}(kt)_{total} &= (kt)_{copper} + (kt)_{epoxy} \\ &= 0.93\text{Btu/h-°F} + 0.00375\text{Btu/h-°F} \\ &= 0.93375\text{Btu/h-°F}\end{aligned}$$

Step 6 of 7

The effective thermal conductivity can be calculated as

$$\begin{aligned}k_{eff} &= \frac{(kt)_{copper} + (kt)_{epoxy}}{(t_{copper} + t_{epoxy})} \\ &= \frac{0.93375(\text{Btu/h-°F})}{(0.05/12)(\text{ft}) + (2 \times 0.15/12)(\text{ft})} \\ &= 32.0143\text{Btu/h-ft-°F}\end{aligned}$$

Step 7 of 7

Fraction of the heat conducted along the length direction conducted through copper plate can be determined as

$$\begin{aligned}f_{copper} &= \frac{(kt)_{copper}}{(kt)_{total}} \\ &= \frac{0.93(\text{Btu/h-°F})}{0.93375(\text{Btu/h-°F})} \\ &= 0.996\end{aligned}$$

Therefore, Fraction of the heat conducted along the length direction conducted through copper plate is $\boxed{f_{copper} = 99.6\%}$.

Question: 17.037P

To defrost ice accumulated on the outer surface of an automobile windshield, warm air is blown over the inner surface of the windshield. Consider an automobile windshield with thickness of 5 mm and thermal conductivity of 1.4 W/m·K. The outside ambient temperature is −10°C and the convection heat transfer coefficient is 200 W/m2·K, while the ambient temperature inside the automobile is 25°C. Determine the value of the convection heat transfer coefficient for the warm air blowing over the inner surface of the windshield necessary to cause the accumulated ice to begin melting.

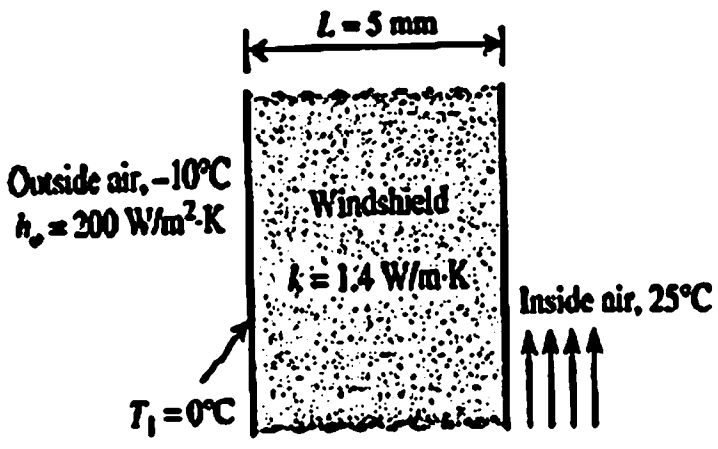


FIGURE P17–37

Step 1 of 5

Given data:

Thermal conductivity of the wind shield, $k = 1.4\text{W/m-K}$.

Thickness of the wind shield, $L = 5\text{mm} = 0.005\text{m}$.

Temperature of outside air, $T_{\infty,o} = -10\,^{\circ}\text{C}$.

Temperature of inside air, $T_{\infty,i} = 25\,^{\circ}\text{C}$.

Heat transfer coefficient at the outer surface of the wind shield, $h_o = 200\,\text{W/m}^2\text{-K}$.

Temperature of the outer surface the wind shield, $T_1 = 0\,^{\circ}\text{C}$.

Step 2 of 5

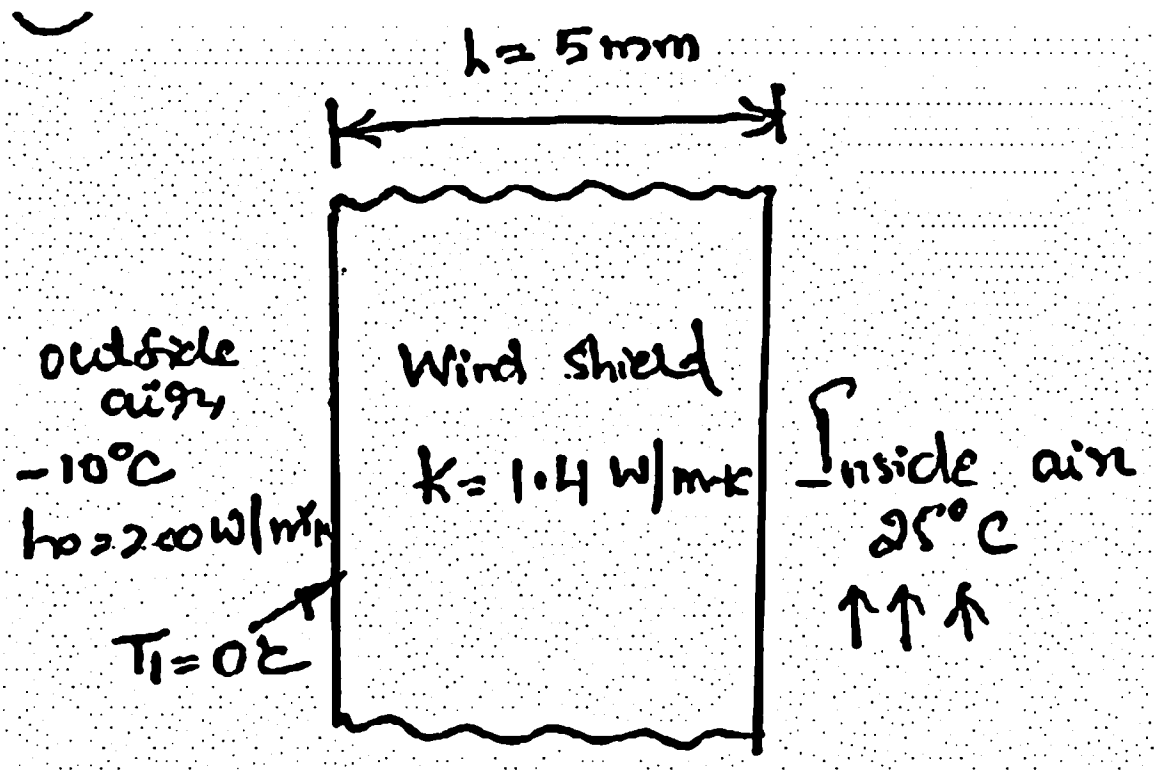

Figure 1 Schematic

Step 3 of 5

The temperature of the outer surface of the wind shield assumed to be $T_1 = 0\,^{\circ}\text{C}$, since the accumulated ice to begin melting. In order to determine the convective heat transfer coefficient for the warm air blowing over inner surface of the wind shield, the heat flux through the wind shield to be determined. Therefore, the heat flux through the wind shield can be calculated as

$$\dot{q} = h_o(T_1 - T_{\infty,o})$$
$$= 200\,(\text{W/m}^2\text{-K}) \times (0 - (-10))$$
$$= 2000\,\text{W/m}^2$$

Step 4 of 5

By using the thermal resistance network approach, the total thermal resistance can be calculated as

$$\dot{q} = \frac{\Delta T}{R_{total}}$$
$$\rightarrow R_{total} = \frac{\Delta T}{\dot{q}}$$
$$R_{total} = \frac{T_{\infty,i} - T_{\infty,o}}{\dot{q}}$$
$$= \frac{(25 - (-10))}{2000(\text{W/m}^2)}$$
$$= 0.0175\,\text{m}^2\text{-K/W}$$

Step 5 of 5

The total thermal resistance per unit area can be expressed as

$$R_{total} = \frac{1}{h_o} + \frac{L}{k} + \frac{1}{h_i}$$

By re writing the above equation, the convective heat transfer coefficient for the warm air blowing over inner surface of the wind shield can be expressed as

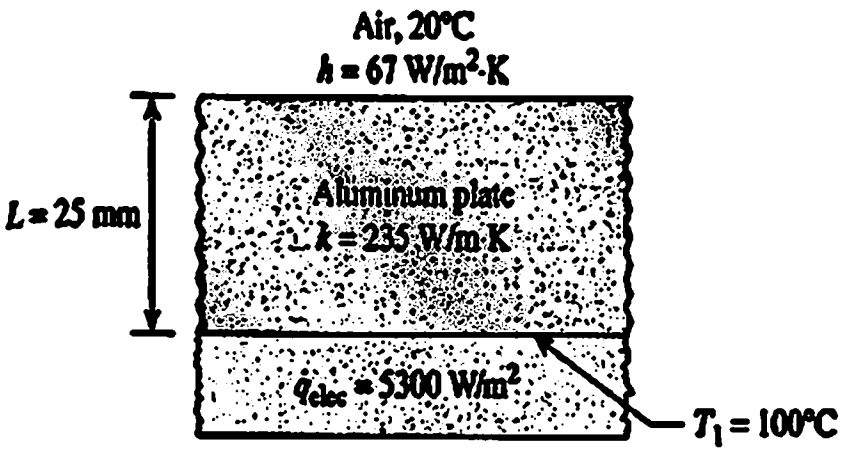
$$h_i = \frac{1}{\left(R_{total} - \left(\frac{1}{h_o} + \frac{L}{k}\right)\right)}$$
$$= \frac{1}{\left(0.0175(\text{m}^2\text{-K/W}) - \left(\frac{1}{200(\text{W/m}^2\text{-K})} + \frac{0.005(\text{K})}{1.4(\text{W/m-K})}\right)\right)}$$
$$= 112\,\text{W/m}^2\text{-K}$$

Therefore, convective heat transfer coefficient is

$$\boxed{h_i = 112\,\text{W/m}^2\text{-K}}$$

Question: 17.038P

An aluminum plate of 25 mm thick (k =235 W/m·K) is attached on a copper plate with thickness of 10 mm. The copper plate is heated electrically to dissipate a uniform heat flux of 5300 W/ m2.The upper surface of the aluminum plate is exposed to convection heat transfer in a condition such that the convection heat transfer coefficient is 67 W/m2·K and the surrounding room temperature is 20°C. Other surfaces of the two attached plates are insulated such that heat only dissipates through the upper surface of the aluminum plate. If the surface of the copper plate that is attached to the aluminum plate has a temperature of 100°C, determine the thermal contact conductance of the aluminum/copper interface.



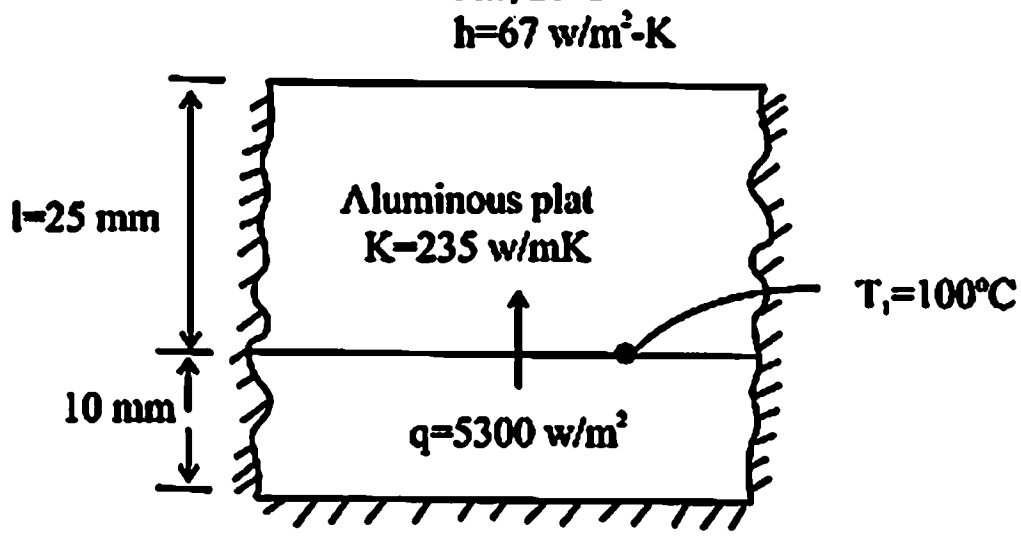


FIGURE P17–38

Step 1 of 5

Loading solution. Please wait ...

Step 2 of 5

Let us draw the diagram:

Step 3 of 5

By using the thermal resistance network approach, the total thermal resistance per unit area can be calculated as

$$\dot{q} = \frac{\Delta T}{R_{total}}$$

$$\rightarrow R_{total} = \frac{\Delta T}{\dot{q}}$$

$$R_{total} = \frac{T_i - T_\infty}{\dot{q}}$$

$$= \frac{(100-20)}{5300(\mathrm{W/m^2})}$$

$$= 0.0151 \mathrm{m^2\text{-}K/W}$$

Step 4 of 5

The total thermal resistance per unit area can be expressed as

$$R_{total} = R_{interface} + R_{plate} + R_{sub}$$

$$= R_{interface} + \frac{L}{k} + \frac{1}{h_\infty}$$

By re writing the above equation, the thermal resistance at the interface of the aluminum/copper plates can be expressed as

$$R_{interface} = R_{total} - \left(\frac{L}{k} + \frac{1}{h_i}\right)$$

$$= 0.0151(\mathrm{m^2\text{-}K/W}) - \left(\frac{0.025(\mathrm{m})}{235(\mathrm{W/m\text{-}K})} + \frac{1}{67(\mathrm{W/m^2\text{-}K})}\right)$$

$$= 6.8244 \times 10^{-5} \mathrm{m^2\text{-}K/W}$$

Step 5 of 5

Therefore, the thermal contact conductance of the aluminum/copper interface can be calculated as

$$\text{Thermal contact conductance} = \frac{1}{R_{interface}}$$

$$= \frac{1}{6.8244 \times 10^{-5}(\mathrm{m^2\text{-}K/W})}$$

$$= 14653.30 \mathrm{W/m^2\text{-}K}$$

Thermal contact conductance of the aluminum and copper interface is

$$\boxed{R_{cont} = 14.653 \mathrm{kW/m^2\text{-}K}}$$

Question: 17.039P

What is thermal contact resistance? How is it related to thermal contact conductance?

Step 1 of 2

When tow surfaces are pressed against each other the peaks form good material contact but the valleys form voids filled with air. As a result an interface contains numerous air gaps of varying sizes that act as insulation because of the low thermal conductivity of air. Thus an interface offers some resistance to heat transfer, and this resistance per unit interface area is called thermal contact resistance and it is denoted by R_c

$$R_c = \frac{1}{h_c} = \frac{\Delta T_{\text{interface}}}{\dot{Q}/A}$$

Step 2 of 2

Loading solution. Please wait ...

Question: 17.040P

Will the thermal contact resistance be greater for smooth or rough plain surfaces?

Step 1 of 1

The thermal contact resistance depends on the surface roughness and the material properties as well as the temperature and pressure at the interface and the type of fluid trapped at the interface

The thermal contact resistance will be greater for rough surfaces because an interface with rough surfaces will contain more air gaps whose thermal conductivity is low.

Question: 17.041P

A wall consists of two layers of insulation pressed against each other. Do we need to be concerned about the thermal contact resistance at the interface in a heat transfer analysis or can we just ignore it?

Step 1 of 1

The thermal contact resistance depends on the surface roughness and the material properties as well as the temperature and pressure at the interface and the type of fluid trapped at the interface. The thermal contact resistance is significant and can even dominate the heat transfer for good heat conductors such as metals, but can be disregarded for poor heat conductors such as insulators

An interface acts like a very thin layer of insulation, and thus the thermal contact resistance has significance only for highly conducting materials like metals. Therefore, the thermal contact resistance can be ignored for two layers of insulation pressed against each other.

Question: 17.042P

A plate consists of two thin metal layers pressed against each other. Do we need to be concerned about the thermal contact resistance at the interface in a heat transfer analysis or can we just ignore it?

Step 1 of 1

The thermal contact resistance depends on the surface roughness and the material properties as well as the temperature and pressure at the interface and the type of fluid trapped at the interface. The thermal contact resistance is significant and can even dominate the heat transfer for good heat conductors such as metals, but can be disregarded for poor heat conductors such as insulators. Therefore, the thermal contact resistance must be considered for two layers of metals pressed against each other.

Question: 17.043P

Consider two surfaces pressed against each other. Now the air at the interface is evacuated. Will the thermal contact resistance at the interface increase or decrease as a result?

Step 1 of 1

The thermal contact resistance is decrease with decreasing the roughness and increasing interface pressure. Heat transfer through the voids at an interface is by conduction and radiation. Evacuating the interface eliminates heat transfer by conduction, and thus increases the thermal contact resistance.

Question: 17.044P

Explain how the thermal contact resistance can be minimized.

Step 1 of 1

Thermal contact resistance can be minimized by
1) The thermal contact resistance is decrease with decreasing the roughness and increasing interface pressure.
2) Applying a thermally conducting liquid on the surfaces before they are pressed against each other,
3) By replacing the air at the interface by a better conducting gas such as helium or hydrogen,
5) By inserting a soft metallic foil such as tin, silver, copper, nickel, or aluminum between the two surfaces.

Question: 17.045P

The thermal contact conductance at the interface of two 1-cm-thick copper plates is measured to be 14,000 W/m2·K. Determine the thickness of the copper plate whose thermal resistance is equal to the thermal resistance of the interface between the plates.

Step 1 of 2

Obtain the thermal conductivity of the copper material from the table "properties of solid metal"

$$k = 401\,\mathrm{W/m \cdot K}$$

The thermal contact conductance, h_c is the inverse of thermal contact resistance, R_c and then the thermal contact resistance is,

$$R_c = \frac{1}{h_c}$$

Substitute $14,000\,\mathrm{W/m^2 \cdot K}$ for h_c

$$R_c = \frac{1}{14,000}$$
$$= 7.143 \times 10^{-5}\,\mathrm{m^2 \cdot K/W}$$

Step 2 of 2

The thermal resistance of the copper plates per unit area is,

$$R = \frac{L}{k}$$

Here L is the equivalent thickness of the copper plate and it can be determined by equating the thermal resistance of the copper plates and the thermal resistance of the interface between plates.

$$R = \frac{L}{k} = R_c$$

By rewriting the above equation for determining the equivalent thickness,

$$L = R_c k$$
$$= 7.143 \times 10^{-5} \times 401$$
$$= 0.02864\,\mathrm{m}$$
$$= 2.864\,\mathrm{cm}$$

Therefore, the thickness of the copper plate is $\boxed{L = 2.86\,\mathrm{cm}}$

Question: 17.046P

A 1-mm-thick copper plate (k = 386 W/m·K) is sandwiched between two 7-mm-thick epoxy boards (k = 0.26 W/m·K) that are 15 cm × 20 cm in size. If the thermal contact conductance on both sides of the copper plate is estimated to be 6000 W/m·K, determine the error involved in the total thermal resistance of the plate if the thermal contact conductances are ignored.

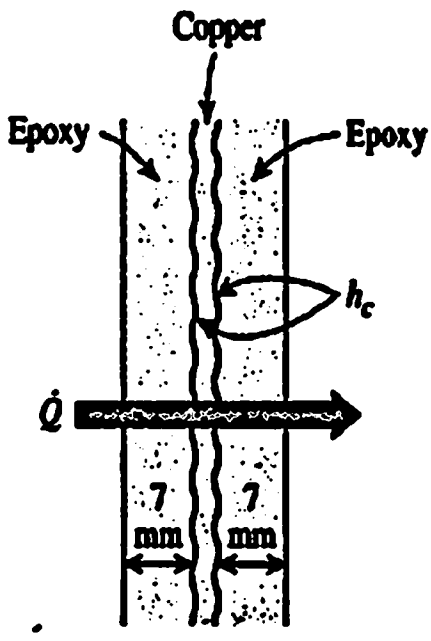

FIGURE P17–46

Step 1 of 5

Given data:

Thickness of the Epoxy plates, $L_1 = 7\text{mm} = 0.007\text{m}$.

Thickness of the copper plate, $L_2 = 1\text{mm} = 0.001\text{m}$.

Thermal conductivity of the copper plate, $k_c = 386\,\text{W/m-K}$.

Thermal conductivity of the epoxy boards, $k_e = 0.26\,\text{W/m-K}$.

Cross sectional area of the plates, $A = 0.15 \times 0.20\,\text{m}^2 = 0.03\text{m}^2$.

Thermal contact conductance of the copper plate, $h_c = 6000\,\text{W/m-K}$.

Step 2 of 5

Loading solution. Please wait ...

Step 3 of 5

Without considering the contact resistance:

By using the thermal network approach the total resistance of the network can be determined as

$$\begin{aligned} R_{total} &= R_{epoxy} + R_{copper} + R_{epoxy} \\ &= 2R_{epoxy} + R_{copper} \\ &= 2\frac{L_1}{k_e A} + \frac{L_2}{k_c A} \\ &= 2 \times \frac{0.007(\text{m})}{0.26(\text{W/m-K}) \times 0.03(\text{m}^2)} + \frac{0.001(\text{m})}{386(\text{W/m-K}) \times 0.03(\text{m}^2)} \\ &= 1.795\text{m-K/W} \end{aligned}$$

Step 4 of 5

With considering the contact resistance:

By using the thermal network approach the total resistance of the network can be determined as

$$\begin{aligned} R_{total} &= R_{epoxy} + R_c + R_{copper} + R_c + R_{epoxy} \\ &= 2R_{epoxy} + R_{copper} + 2R_c \\ &= 2\frac{L_1}{k_e A} + \frac{L_2}{k_c A} + 2\frac{1}{h_c A} \\ &= \left[2 \times \frac{0.007(\text{m})}{0.26(\text{W/m-K}) \times 0.03(\text{m}^2)} + \frac{0.001(\text{m})}{386(\text{W/m-K}) \times 0.03(\text{m}^2)} + 2 \times \frac{1}{6000(\text{W/m}^2\text{-K}) \times 0.03(\text{m}^2)} \right] \\ &= 1.806\text{m-K/W} \end{aligned}$$

Step 5 of 5

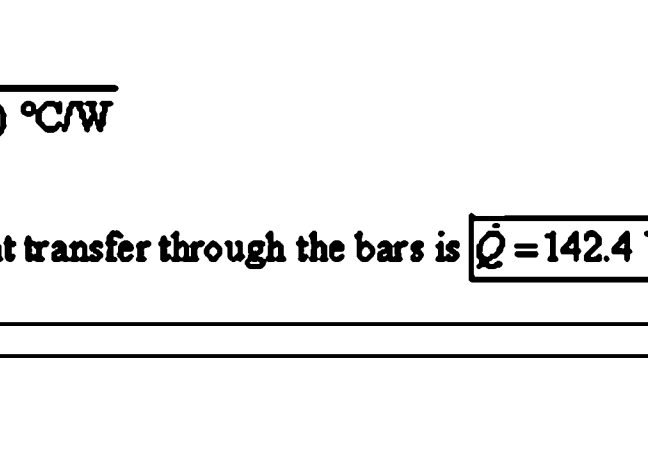
Therefore, the error associated in the total thermal resistance of the plate if the contact conductances are ignored can be calculated as

$$\begin{aligned} \text{Error} &= 1.806(\text{m-K/W}) - 1.795(\text{m-K/W}) \\ &= 0.011\,\text{m-K/W} \end{aligned}$$

% Error can be expressed as

$$\begin{aligned} \%\text{Error} &= \frac{Error}{R_{total}} \times 100 \\ &= \frac{0.011(\text{m-K/W})}{1.806\,(\text{m-K/W})} \times 100 \\ &= 0.61\% \end{aligned}$$

Therefore, Percentage of error involved is $\boxed{\%\text{Error} = 0.61\%}$



Question: 17.047P

Two 5-cm-diameter, 15-cm-long aluminum bars (k = 176 W/m·K) with ground surfaces are pressed against each other with a pressure of 20 atm. The bars are enclosed in an insulation sleeve and, thus, heat transfer from the lateral surfaces is negligible. If the top and bottom surfaces of the two-bar system are maintained at temperatures of 150°C and 20°C, respectively, determine (*a*) the rate of heat transfer along the cylinders under steady conditions and (*b*) the temperature drop at the interface.

Step 1 of 4

Given:
Diameter of aluminum bar = 5cm
Length of aluminum bar = 15cm
Thermal conductivity of aluminum k = 176 W/m·°C
The contact conductance at the interface of aluminum-aluminum plates for the case of ground surfaces and of 20 atm ≈ 2 MPa pressure is $h_c = 11{,}400\ \text{W/m}^2\cdot^\circ\text{C}$

Step 2 of 4

Step 3 of 4

(a)
The thermal resistance network in this case consists of two resistances.
Contact resistance

$$R_{contact} = \frac{1}{h_c A_c}$$

$$R_{contact} = \frac{1}{(11{,}400\ \text{W/m}^2\cdot^\circ\text{C})[\pi(0.05\ \text{m})^2/4]}$$

$$R_{contact} = 0.0447\ ^\circ\text{C/W}$$

Conduction resistance

$$R_{plate} = \frac{L}{kA}$$

$$R_{plate} = \frac{0.15\ \text{m}}{(176\ \text{W/m}\cdot^\circ\text{C})[\pi(0.05\ \text{m})^2/4]}$$

$$R_{plate} = 0.4341\ ^\circ\text{C/W}$$

Then the rate of heat transfer is determined to be

$$\dot{Q} = \frac{\Delta T}{R_{total}}$$

$$\dot{Q} = \frac{\Delta T}{R_{contact} + 2R_{bar}}$$

$$\dot{Q} = \frac{(150-20)^\circ\text{C}}{(0.0447 + 2\times 0.4341)\ ^\circ\text{C/W}}$$

$$\dot{Q} = 142.4\ \text{W}$$

Therefore, the rate of heat transfer through the bars is $\boxed{\dot{Q} = 142.4\ \text{W}}$.

Step 4 of 4

(b)
The temperature drop at the interface is determined to be

$$\Delta T_{interface} = \dot{Q} R_{contact}$$

$$\Delta T_{interface} = (142.4\ \text{W})(0.0447\ ^\circ\text{C/W})$$

$$\boxed{\Delta T_{interface} = 6.4^0\text{C}}$$

Question: 17.048P

What are the two approaches used in the development of the thermal resistance network for two-dimensional problems?

Step 1 of 1

The two approaches used in development of the thermal resistance network in the x-direction for multi-dimensional problems are

(1) to assume any plane wall normal to the x-axis to be isothermal and

(2) to assume any plane parallel to the x-axis to be adiabatic.

Question: 17.049P

The thermal resistance networks can also be used approximately for multidimensional problems. For what kind of multidimensional problems will the thermal resistance approach give adequate results?

Step 1 of 1

Loading solution. Please wait ...

Question: 17.050P

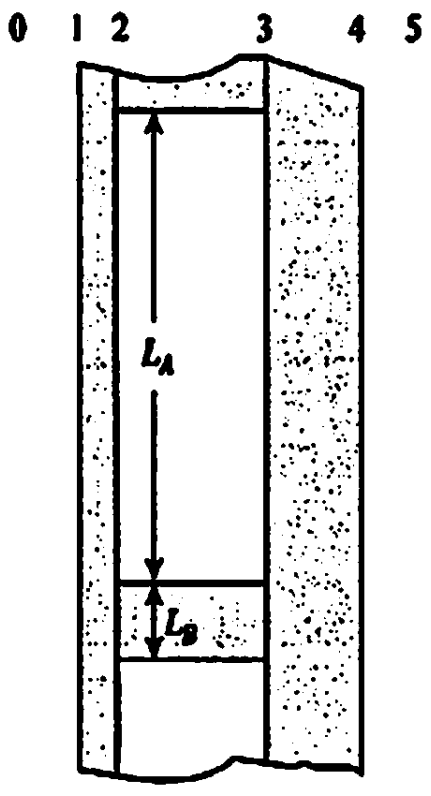
When plotting the thermal resistance network associated with a heat transfer problem, explain when two resistances are in series and when they are in parallel.

Step 1 of 1

Parallel resistances indicate simultaneous heat transfer (such as convection and radiation on a surface). Series resistances indicate sequential heat transfer (such as two homogeneous layers of a wall).

Question: 17.051P

A typical section of a building wall is shown in Fig. P17-51. This section extends in and out of the page and is



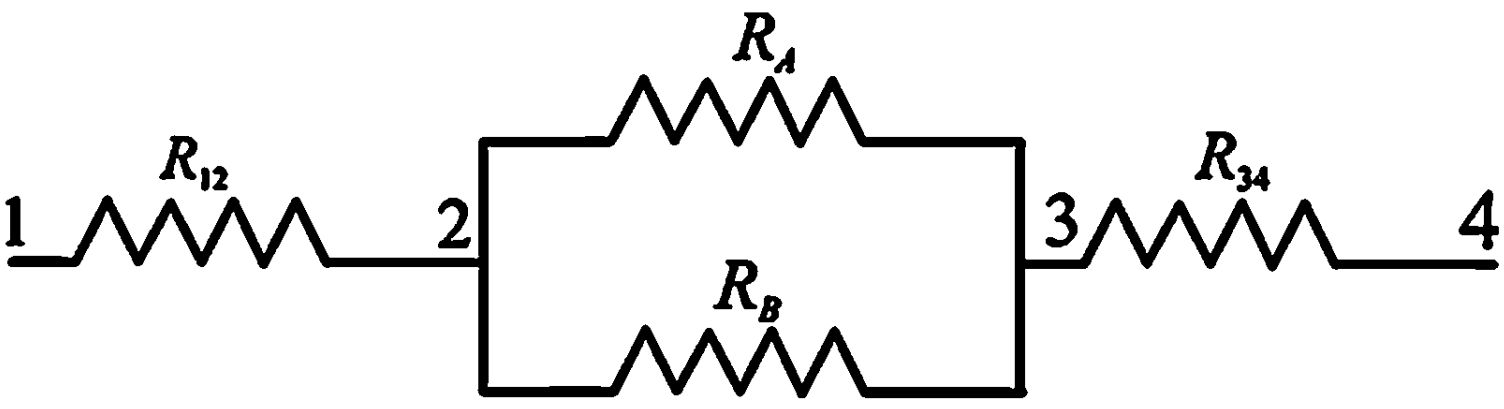


FIGURE P17–51

repeated in the vertical direction. The wall support members are made of steel (k = 50 W/m·K). The support members are 8 cm ($t23$) × 0.5 cm (LB). The remainder of the inner wall space is filled with insulation (k = 0.03 W/m·K) and measures 8 cm ($t23$) × 60 cm (LB). The inner wall is made of gypsum board (k= 0.5 W/m·K) that is 1 cm thick ($t12$) and the outer wall is made of brick (k = 1.0 W/m·K) that is 10 cm thick ($t34$). What is the average heat flux through this wall when $T1$ = 20°C and $T4$ = 35°C?

Step 1 of 4

The thermal network of the building wall is as shown in the diagram:

Step 2 of 4

By using the thermal network approach, the total resistance can be determined as follows:

$$R_{total} = R_{12} + R_{23} + R_{34}$$

$$= R_{12} + \frac{R_A R_B}{R_A + R_B} + R_{34}$$

$$= \frac{t_{12}}{k_i A_i} + \frac{\left(\frac{t_A}{k_A A_A}\right)\left(\frac{t_B}{k_B A_B}\right)}{\frac{t_A}{k_A A_A} + \frac{t_B}{k_B A_B}} + \frac{t_{34}}{k_o A_o}$$

The cross sectional area of the inner or outer side of the building wall is as follows:

$$A_i = A_o = (L_A + L_B)w$$

$$A_A = L_A w$$

$$A_B = L_B w$$

Here, w is the width of the wall.

Step 3 of 4

The total resistance multiplies with $A_i = A_o = (L_A + L_B)w$ and it can be expressed as follows:

$$R_{total} A_i = \frac{t_{12}}{k_i} + A_i \left[\frac{\left(\frac{t_A}{k_A A_A}\right)\left(\frac{t_B}{k_B A_B}\right)}{\frac{t_A}{k_A A_A} + \frac{t_B}{k_B A_B}}\right] + \frac{t_{34}}{k_o}$$

$$= \frac{t_{12}}{k_i} + (L_A + L_B)w \left(\frac{\left(\frac{t_A}{k_A L_A w}\right)\left(\frac{t_B}{k_B L_B w}\right)}{\frac{t_A}{k_A L_A w} + \frac{t_B}{k_B L_B w}}\right) + \frac{t_{34}}{k_o}$$

Assume, $w = 1\,\text{m}$, then the above equation is modified as follows:

$$R_{total} A_i = \frac{t_{12}}{k_i} + (L_A + L_B)\left(\frac{\left(\frac{t_A}{k_A L_A}\right)\left(\frac{t_B}{k_B L_B}\right)}{\frac{t_A}{k_A L_A} + \frac{t_B}{k_B L_B}}\right) + \frac{t_{34}}{k_o}$$

Substitute 0.01 m for t_{12} , $0.5\,\text{W/m}\cdot\text{K}$ for k_i , 0.005 m for L_B , 0.6 m for L_A , 0.08 m for t_A, t_B , $0.03\,\text{W/m}\cdot\text{K}$ for k_A , $50\,\text{W/m}\cdot\text{K}$ for k_B , 0.1 m for t_{34} and $1\,\text{W/m}\cdot\text{K}$ for k_o

$$R_{total} A_i = \frac{0.01}{0.5} + (0.6 + 0.005)\left(\frac{\left[\frac{0.08}{(0.03\times 0.6)}\right] \times \left[\frac{0.08}{(50\times 0.005)}\right]}{\left[\frac{0.08}{(0.03\times 0.6)}\right] + \left[\frac{0.08}{(50\times 0.005)}\right]}\right) + \frac{0.1}{1}$$

$$= 0.3006\,\text{m}^2\cdot\text{K/W}$$

Step 4 of 4

Calculate the average heat flux through the wall by using the following equation:

$$\frac{\dot{Q}}{A_i} = \frac{(T_4 - T_1)}{R_{total} A_i}$$

Here, T_1, T_4 are the extreme wall temperatures.

Substitute $35°\text{C}$ for T_4 and $20°\text{C}$ for T_1 .

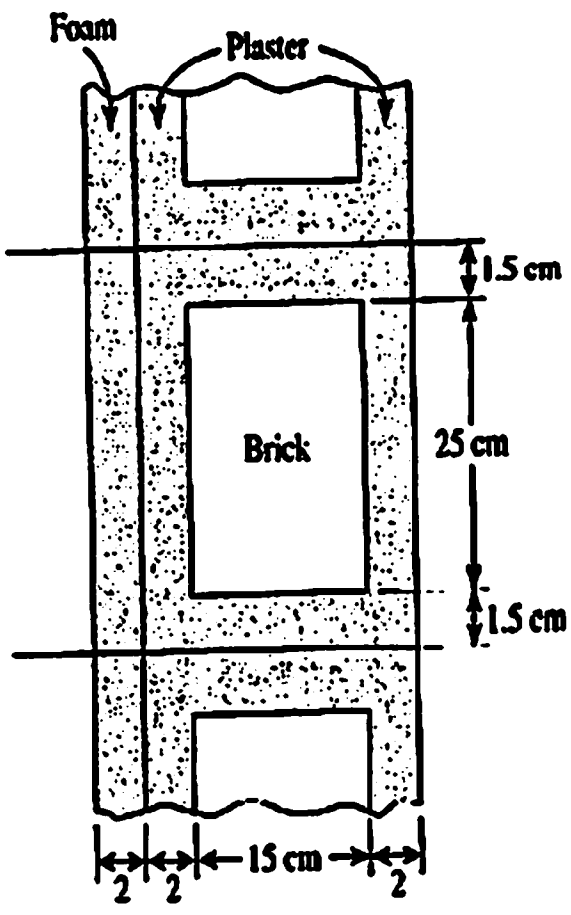
$$\frac{\dot{Q}}{A_i} = \frac{35 - 20}{0.3006}$$

$$= 49.9\,\text{W/m}^2$$

Thus, the average heat flux through the wall is $\boxed{49.9\,\text{W/m}^2}$.

Question: 17.052P pg 1

A 4-m-high and 6-m-wide wall consists of a long 15-cm × 25-cm cross section of horizontal bricks (k = 0.72 W/m·K) separated by 3-cm-thick plaster layers (k = 0.22 W/m·K). There are also 2-cm-thick plaster layers on each side of the wall, and a 2-cm-thick rigid foam (k = 0.026 W/m·K) on the inner side of the wall. The indoor and the outdoor temperatures are 22°C and −4°C, and the convection heat transfer coefficients on the inner and the outer sides are $h1$ = 10 W/m2·K and $h2$ = 20 W/m2·K, respectively. Assuming one-dimensional heat transfer and disregarding radiation, determine the rate of heal transfer through the wall.



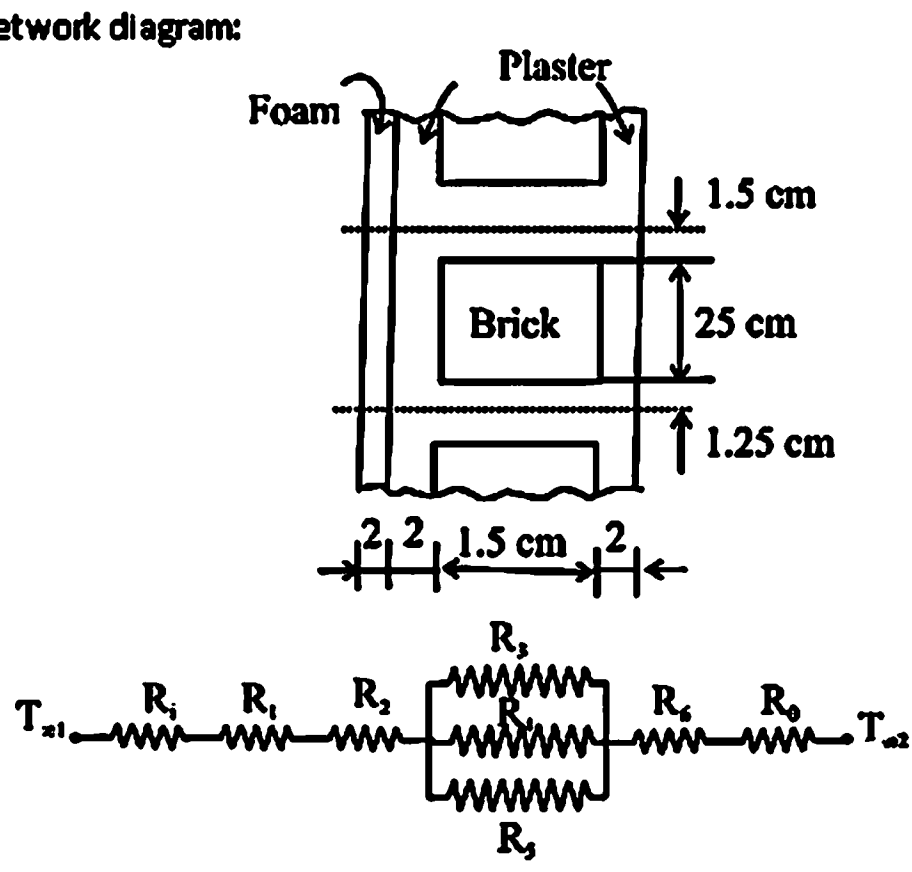


FIGURE P17–52

Step 1 of 7

Loading solution. Please wait ...

Step 2 of 7

Let us draw the network diagram:

Step 3 of 7

There is a pattern in the construction of the wall that repeats itself every 28-cm distance in the vertical direction. There is no variation in the horizontal direction. Therefore, consider a 1-m deep and 0.28 m high portion of the wall, since it is representative of the entire wall.

Assuming any cross section of the wall normal to the X-direction to be isothermal, the thermal resistance network for the representative section of the wall becomes as shown in the Fig above.

The individual resistances are evaluated as:

$$R_1 = R_{conv,1} = \frac{1}{h_1 A_1} = \frac{1}{10(\text{W/m}^2\text{-K}) \times (0.28 \times 1\text{m}^2)} = 0.357\text{K/W}$$

$$R_1 = R_{foam} = \frac{t_1}{k_1 A_1} = \frac{0.02(\text{m})}{0.026(\text{W/m-K}) \times (0.28 \times 1\text{m}^2)} = 2.75\text{K/W}$$

Step 4 of 7

$$R_2 = R_6 = R_{plaster,side} = \frac{t_2}{k_2 A_2} = \frac{0.02(\text{m})}{0.22(\text{W/m-K}) \times (0.28 \times 1\text{m}^2)} = 0.325\text{K/W}$$

$$R_3 = R_5 = R_{plaster,center} = \frac{t_3}{k_3 A_3} = \frac{0.15(\text{m})}{0.22(\text{W/m-K}) \times (0.015 \times 1\text{m}^2)} = 45.455\text{K/W}$$

Step 5 of 7

$$R_4 = R_{brick} = \frac{t_4}{k_4 A_4}$$

Step 5 of 7

$$R_4 = R_{brick}$$
$$= \frac{t_4}{k_4 A_4}$$
$$= \frac{0.15(\text{m})}{0.72(\text{W/m-K}) \times (0.25 \times 1\text{m}^2)}$$
$$= 0.8333\text{K/W}$$
$$R_o = R_{conv,2}$$
$$= \frac{1}{h_2 A_2}$$
$$= \frac{1}{20(\text{W/m}^2\text{-K}) \times (0.28 \times 1\text{m}^2)}$$
$$= 0.1786\text{K/W}$$

Step 6 of 7

The three resistances R_3, R_4 and R_5 in the middle are parallel, and their equivalent resistance is determined from

$$\frac{1}{R_{mid}} = \frac{1}{R_3} + \frac{1}{R_4} + \frac{1}{R_5}$$
$$= \frac{1}{45.455(\text{K/W})} + \frac{1}{0.8333(\text{K/W})} + \frac{1}{45.455(\text{K/W})}$$
$$= 1.244\text{W/K}$$

This gives

$$R_{mid} = \frac{1}{1.244(\text{W/K})}$$
$$= 0.804\text{K/W}$$

Now all the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_1 + R_2 + R_{mid} + R_6 + R_o$$
$$= 0.357(\text{K/W}) + 2.75(\text{K/W}) + 0.325(\text{K/W}) + 0.804(\text{K/W}) + 0.325(\text{K/W}) + 0.1786(\text{K/W})$$
$$= 4.7396\text{K/W}$$

Step 7 of 7

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{22 - (-4)}{4.7396(\text{K/W})}$$
$$= 5.5\text{W}$$

5.5 W Of heat is transferring through per 0.28m^2 surface area

And the total heat flux through the wall can be computed as

$$\dot{q} = \frac{\dot{Q}}{A}$$
$$= \frac{5.5(\text{W})}{0.28(\text{m}^2)}$$
$$= 19.6\text{W/m}^2$$

The total area of the wall is $A = 4 \times 6 = 24\text{m}^2$. Then the rate of heat transfer through the entire wall becomes

$$\dot{Q}_{total} = 19.6(\text{W/m}^2) \times 24(\text{m}^2)$$
$$= 470.4\text{ W}$$

Therefore maximum heat transfer is $\boxed{\dot{Q}_{total} = 470.4\text{ W}}$.

Question: 17.053P pg 1

Reconsider Prob. 17-52. Using EES (or other) software, plot the rate of heat transfer through the wall as a function of the thickness of the rigid foam in the range of 1 cm to 10 cm. Discuss the results.

Step 1 of 9

Given data:

Cross sectional are of the wall, $A = 4 \times 6 = 24\text{m}^2$

Thickness of the foam, $t_1 = 1-10\text{cm} = 0.01-0.1\text{m}$

Thickness of the plaster, $t_2 = t_6 = 2\text{cm} = 0.02\text{m}$

Thickness of the plaster between two bricks, $t_3 = t_5 = 15\text{cm} = 0.15\text{m}$

Thickness of the brick, $t_4 = 15\text{cm} = 0.15\text{m}$

Length of the foam, $L_1 = 28\text{cm}=0.28\text{m}$

Length of the plaster, $L_2 = L_6 = 28\text{cm}=0.28\text{m}$

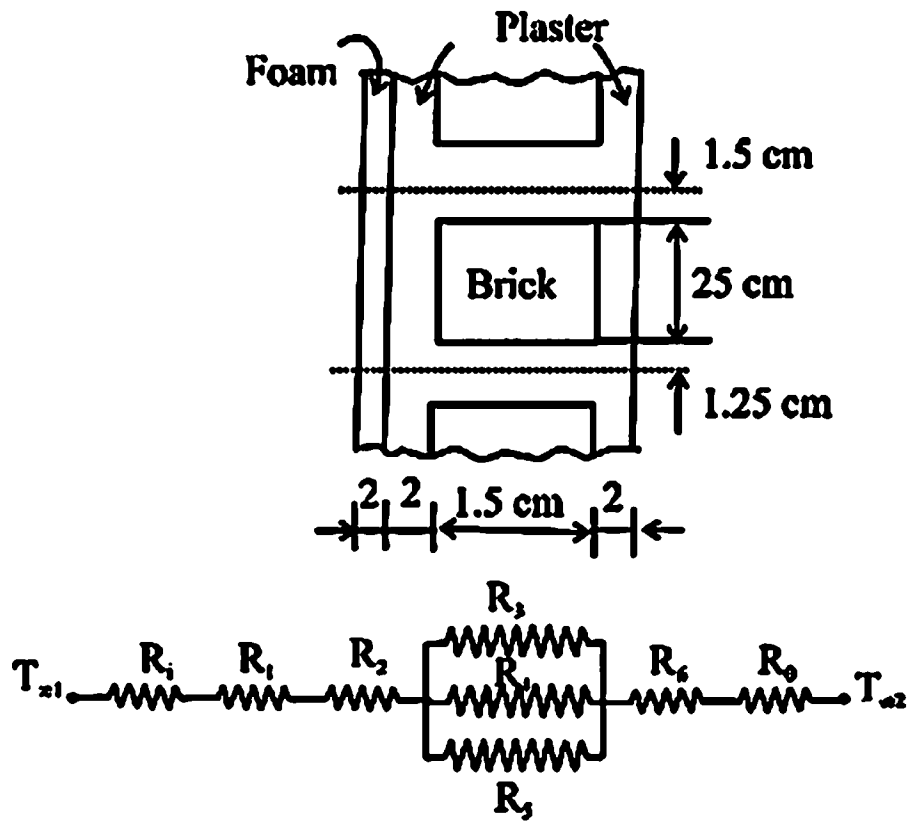
Length of the plaster between two bricks, $L_3 = L_5 = 1.5\text{cm}=0.015\text{m}$

Length of the bricks, $L_4 = 25\text{cm}=0.25\text{m}$

Thermal conductivity of the foam, $k_1 = 0.026\ \text{W/m-K}$

Thermal conductivity of the plaster, $k_2 = k_3 = k_5 = k_6 = 0.22\ \text{W/m-K}$

Thermal conductivity of the brick, $k_4 = 0.72\ \text{W/m-K}$



Indoor temperature, $T_{\infty,1} = 22^\circ\text{C}$

Outdoor temperature, $T_{\infty,2} = -4^\circ\text{C}$

Heat transfer coefficient on the inner wall, y

Heat transfer coefficient on the outer wall, $h_2 = 20\ \text{W/m}^2\text{-K}$

Step 2 of 9

Step 3 of 9

There is a pattern in the construction of the wall that repeats itself every 28-cm distance in the vertical direction. There is no variation in the horizontal direction. Therefore, consider a 1-m deep and 0.28 m high portion of the wall, since it is representative of the entire wall.

Assuming any cross section of the wall normal to the X-direction to be isothermal, the thermal resistance network for the representative section of the wall becomes as shown in the Fig above.

The individual resistances are evaluated as:

$$R_1 = R_{conv,1}$$

$$= \frac{1}{h_1 A_1}$$

$$= \frac{1}{10\,(\text{W/m}^2\text{-K}) \times (0.28 \times 1\text{m}^2)}$$

$$= 0.357\,\text{K/W}$$

$$R_1 = R_{foam}$$

$$= \frac{t_1}{k_1 A_1}$$

$$= \frac{t_1}{0.026\,(\text{W/m-K}) \times (0.28 \times 1\text{m}^2)}$$

$$= 137.4 t_1\,\text{K/W}$$

Step 4 of 9

$$R_2 = R_6$$

$$= R_{plaster,side}$$

$$= \frac{t_2}{k_2 A_2}$$

$$= \frac{0.02(\text{m})}{0.22\,(\text{W/m-K}) \times (0.28 \times 1\text{m}^2)}$$

$$= 0.325\,\text{K/W}$$

$$R_3 = R_5$$

$$= R_{plaster,center}$$

$$= \frac{t_3}{k_3 A_3}$$

$$= \frac{0.15(\text{m})}{0.22\,(\text{W/m-K}) \times (0.015 \times 1\text{m}^2)}$$

$$= 45.455\,\text{K/W}$$

Step 5 of 9

$$R_4 = R_{brick}$$

$$= \frac{t_4}{k_4 A_4}$$

$$= \frac{0.15(\text{m})}{0.72\,(\text{W/m-K}) \times (0.25 \times 1\text{m}^2)}$$

$$= 0.8333\,\text{K/W}$$

$$R_y = R_{conv,2}$$

$$= \frac{1}{h_2 A_2}$$

$$= 0.8333\,\text{K/W}$$

$$R_o = R_{conv,2}$$

$$= \frac{1}{h_2 A_2}$$

$$= \frac{1}{20\,(\text{W/m}^2\text{-K}) \times (0.28 \times 1\text{m}^2)}$$

$$= 0.1786\,\text{K/W}$$

Step 6 of 9

The three resistances R_3, R_4 and R_5 in the middle are parallel, and their equivalent resistance is determined from

$$\frac{1}{R_{mid}} = \frac{1}{R_3} + \frac{1}{R_4} + \frac{1}{R_5}$$

$$= \frac{1}{45.455(\text{K/W})} + \frac{1}{0.8333(\text{K/W})} + \frac{1}{45.455(\text{K/W})}$$

$$= 1.244\,\text{W/K}$$

This gives

$$R_{mid} = \frac{1}{1.244(\text{W/K})}$$

$$= 0.804\,\text{K/W}$$

Now all the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_1 + R_2 + R_{mid} + R_6 + R_o$$

$$= 0.357(\text{K/W}) + 137.4t_1(\text{K/W}) + 0.325(\text{K/W}) + 0.804(\text{K/W}) + 0.325(\text{K/W}) + 0.1786(\text{K/W})$$

$$= 2 + 137.4t_1\,\text{K/W}$$

Step 7 of 9

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$

$$= \frac{22 - (-4)}{2 + 137.4t_1(\text{K/W})}$$

$$= \frac{26}{2 + 137.4t_1(\text{K/W})}$$

This amount heat is transferring through per 0.28m^2 surface area

And the total heat flux through the wall can be computed as

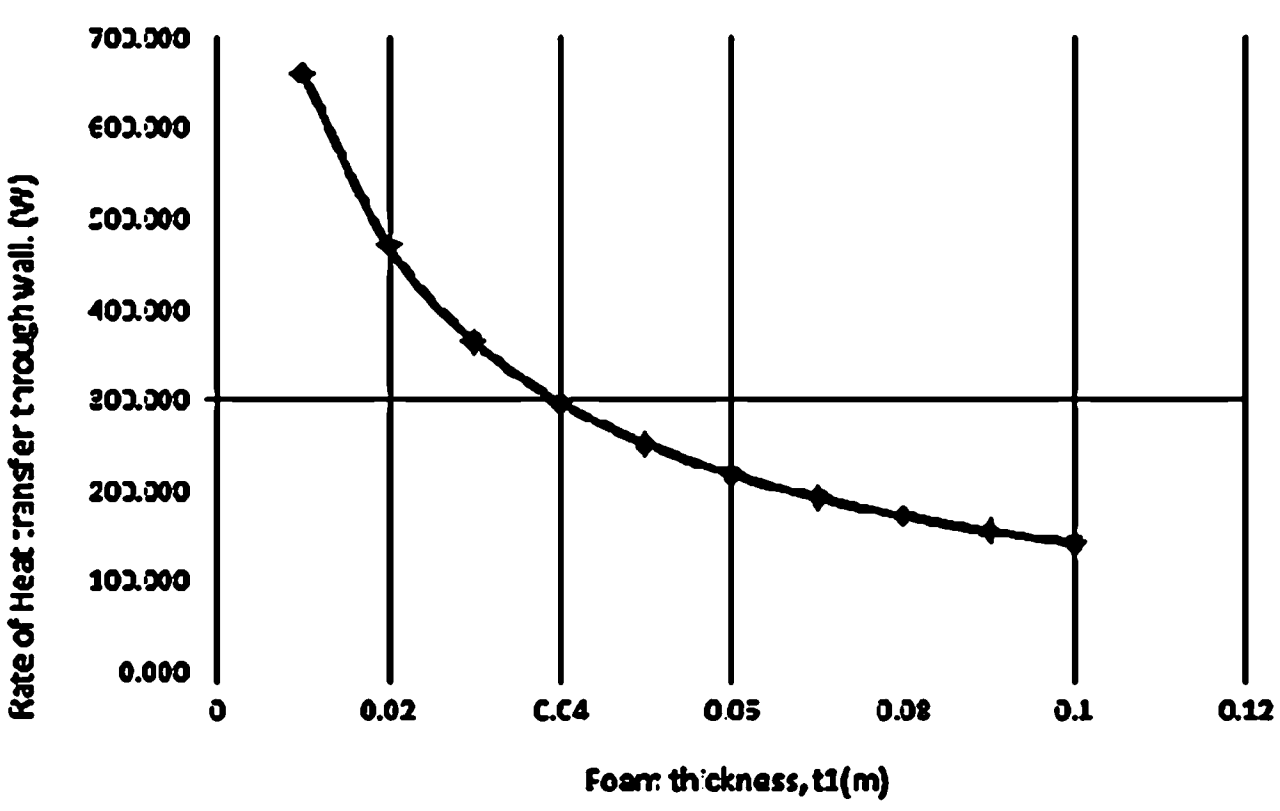
$$\dot{q} = \frac{\dot{Q}}{A}$$

$$= \frac{26/[2 + 137.4t_1(\text{K/W})]}{0.28(\text{m}^2)}$$

$$= \frac{92.86}{[2 + 137.4t_1(\text{K/W})]}\,\text{W/m}^2$$

Step 8 of 9

The total area of the wall is $A = 4 \times 6 = 24\text{m}^2$. Then the rate of heat transfer through the entire wall becomes



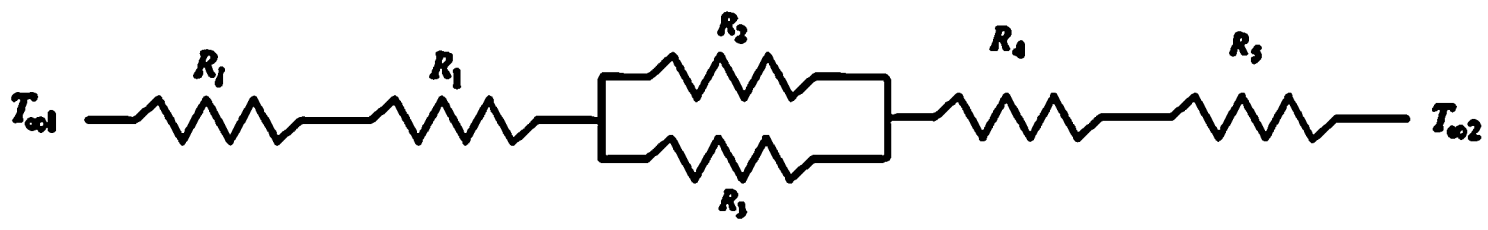
$$\dot{Q}_{total} = \frac{92.86}{[2 + 137.4t_1(\text{K/W})]}(\text{W/m}^2) \times 24(\text{m}^2)$$

$$= \frac{2228.57}{[2 + 137.4t_1(\text{K/W})]}\,\text{W}$$

The rate heat transfer through the wall computed by varying the foam thickness from 1 cm to 10 cm and this calculation performed using the Excel spread sheet; the computed values are tabulated and plotted as shown in below

foam thickness (m)	Rate of Heat transfer (W)
0.01	660.513
0.02	469.371
0.03	364.027
0.04	297.301
0.05	251.248
0.06	217.549
0.07	191.821
0.08	171.534
0.09	155.128
0.1	141.586

Step 9 of 9



Question:

A 12-m-long and 5-m-high wall is constructed of two layers of 1-cm-thick sheetrock (k =0.17 W/m·K) spaced 16 cm by wood studs (k = 0.11 W/m·K) whose cross section is 16 cm × 5 cm. The studs are placed vertically 60 cm apart, and the space between them is filled with fiberglass insulation (k =0.034 W/m·K). The house is maintained at 20°C and the ambient temperature outside is−9°C. Taking the heat transfer coefficients at the inner andouter surfaces ofthe house to be 8.3 and 34 W/m2·K. respectively, determine (*a*) the thermal resistance of the wall considering a representative section of it and (*b*) the rate of heat transfer through the wall

Step 1 of 7

Draw the thermal resistance network for the representative section of the wall:

Step 2 of 7

(a)

Consider the home is $1\ \text{m}$ deep.

Find the individual resistances as shown.

Calculate the convectional thermal resistance at inner surface of house by using the following relation.

$$R_i = \frac{1}{h_i A}$$
$$= \frac{1}{h_i \times (d \times l)}$$

Here, h_i is the heat transfer coefficient at inner surface of home and A is surface area.

Substitute $8.3\ \text{W/m}^2\cdot^\circ\text{C}$ for h_i, 1m for d and $65\ \text{cm} = 0.65\ \text{m}$ for l

$$R_i = \frac{1}{8.3 \times (1 \times 0.65)}$$
$$= 0.1854\ ^\circ\text{C/W}$$

Calculate the conductive thermal resistance of sheetrock by using the following relation.

$$R_1 = R_4$$
$$= \frac{L}{k_{\text{sheetrock}} A}$$
$$= \frac{L}{k_{\text{sheetrock}} \times A}$$

Here, k is coefficient of thermal conductivity and L is length of the room.

Substitute $0.01\ \text{m}$ for L, $0.17\ \text{W/m}^\circ\text{C}$ for $k_{\text{sheetrock}}$ and $0.65\,\text{m}^2$ for A.

$$R_1 = R_4$$
$$= \frac{0.01}{0.17 \times 0.65}$$
$$= 0.0905\ ^\circ\text{C/W}$$

Step 3 of 7

Calculate the conductive thermal resistance of studs by using the following relation.

$$R_2 = \frac{L}{k_{stud} A_{stud}}$$
$$= \frac{L}{k \times A_{stud}}$$

Here, k_{stud} is coefficient of thermal conductivity of stud and A_{stud} is area of the stud.

Substitute $12\ \text{m}$ for L, $0.11\ \text{W/m}^\circ\text{C}$ for k_{stud} and $0.12\,\text{m} \times 0.05\,\text{m} = 0.60\ \text{m}^2$ for A_{stud}.

$$R_2 = \frac{0.12}{0.11 \times 0.05}$$
$$= 21.82\ ^\circ\text{C/W}$$

Calculate the conductive thermal resistance of fiber glass by using the following relation.

$$R_3 = \frac{L}{k_{\text{fiber glass}} A}$$
$$= \frac{L}{k_{\text{fiber glass}} \times A}$$

Here, $k_{\text{fiber glass}}$ is coefficient of thermal conductivity of fiber glass.

Substitute $0.12\ \text{m}$ for L, $0.034\,\text{W/m}^\circ\text{C}$ for $k_{\text{fiber glass}}$ and $0.65\ \text{m}^2$ for A.

$$R_3 = \frac{0.12}{0.037 \times 0.65}$$
$$= 5.882\ ^\circ\text{C/W}$$

Step 4 of 7

Calculate the convectional thermal resistance at outer surface of house by using the following relation.

$$R_o = \frac{1}{h_o A}$$
$$= \frac{1}{h_o \times (d \times l)}$$

Here, h_o is the heat transfer coefficient at outer surface of home.

Substitute $34\ \text{W/m}^2\cdot^\circ\text{C}$ for h_o, $0.65\ \text{m}^2$ for A.

$$R_o = \frac{1}{34 \times 0.65}$$

Substitute $34\ \text{W/m}^2\cdot^\circ\text{C}$ for h_o , $0.65\ \text{m}^2$ for A.

$$R_o = \frac{1}{34\times 0.65}$$
$$= 0.0452\ ^\circ\text{C/W}$$

Step 5 of 7

Calculate the resultant thermal resistance of stud and fiber glass.

$$\frac{1}{R_{sheetrock}} = \frac{1}{R_2} + \frac{1}{R_3}$$

Substitute $21.82\ ^\circ\text{C/W}$ for R_2 and $5.882\ ^\circ\text{C/W}$ for R_3.

$$\frac{1}{R_{sheetrock}} = \frac{1}{21.82} + \frac{1}{5.882}$$
$$R_{sheetrock} = 4.633\ ^\circ\text{C/W}$$

Step 6 of 7

Find the total thermal resistance by sung the following relation.

$$R_{total} = R_i + R_1 + R_{sheetrock} + R_4 + R_o$$

Substitute $0.1854\ ^\circ\text{C/W}$ for R_i , $0.0905\ ^\circ\text{C/W}$ for R_1, $4.633\ ^\circ\text{C/W}$ for $R_{sheetrock}$, $0.0905\ ^\circ\text{C/W}$ for R_4 , and $0.0452\ ^\circ\text{C/W}$ for R_o .

$$R_{total} = 0.1854 + 0.0905 + 4.633 + 0.0905 + 0.0452$$
$$= 5.0446\ ^\circ\text{C/W}$$

Therefore, thermal resistance of wall is $\boxed{5.0446\ ^\circ\text{C/W}}$.

Calculate the rate of heat transfer through the wall section.

$$\dot{Q} = \frac{T_1 - T_{\infty 2}}{R_{total}}$$

Here, T_1 is the temperature of house and $T_{\infty 2}$ is the temperature of outer surface.

Substitute 20°C for T_1 , -9°C for $T_{\infty 2}$, and $5.0446\ ^\circ\text{C/W}$ for R_{total} .

$$\dot{Q} = \frac{20-(-9)}{5.0446}$$
$$= \frac{29}{5.0446}$$
$$= 5.748\ \text{W}$$

Step 7 of 7

(b)

Calculate the heat transfer through entire wall.

$$Q_{total} = \dot{Q}\times\left(\frac{L\times D}{d\times l}\right)$$

Here, D is height of the wall.

Substitute $5.748\ \text{W}$ for $\dot{Q}$, $12\ \text{m}$ for L , 5m for D , 1m for d , and $0.65\ \text{m}$ for l .

$$Q_{total} = 5.748\times\left(\frac{12\times 5}{1\times 0.65}\right)$$
$$= 530.65\ \text{W}$$

Therefore, the rate of heat transfer through the wall is $\boxed{530.65\ \text{W}}$.

Question: 17.055P

A 10-cm-thick wall is to be constructed with2.5 long wood studs (k =0.11 W/m·K) that have a crosssection of 10 cm × 10 cm. At some point the builder ran out ofthose studs and started using pairs of 2.5-m-long wood studsthat have a cross section of 5 cm × 10 cm nailed to eachother in stead. The manganese steel nails (k =50 W/m·K) are 10 cm long and have a diameter of 0.4 cm. A total of 50 nailsare used to connect the two studs, which are mounted to the wall such that the nails cross the wall. The temperature difference between the inner and outer surfaces of the wall is 8°C. Assuming the thermal contact resistance between the two layers tobenegligible, determine the rate of heat transfer (*a*) through a solid stud and (*b*) through a stud pair of equal length andwidth nailed toeach other. (*c*) Also determine the effective conductivity of the nailed stud pair.

Step 1 of 5

Given:
Thickness of wall = 10cm
Length of studs = 2.5m
Thermal conductivity for wood studs = 0.11 W/m·°C
Thermal conductivity for manganese steel nails = 50 W/m·°C
Cross section of studs=5cmX 10cm
Length of manganeses steel = 10cm
Diameter of manganeses steel = 0.4cm

Step 2 of 5

If the heat transfer is steady since there is no indication of change with time and heat transfer can be approximated as being one-dimensional since it is predominantly in the x direction

Step 3 of 5

(a) The thermal resistance and heat transfer rate through the solid stud are

$$R_{stud} = \frac{L}{kA} = \frac{0.1\text{ m}}{(0.11\text{ W/m.°C})(0.25\text{ m}^2)} = 3.636\text{ °C/W}$$

$$\dot{Q} = \frac{\Delta T}{R_{stud}} = \frac{8°C}{3.636\text{ °C/W}}$$

$$\boxed{\dot{Q} = 2.2\text{ W}}$$

Step 4 of 5

(b) The thermal resistances of stud pair and nails are in parallel

$$A_{nails} = 50\frac{\pi D^2}{4} = 50\left[\frac{\pi(0.004\text{ m})^2}{4}\right] = 0.000628\text{ m}^2$$

$$R_{nails} = \frac{L}{kA} = \frac{0.1\text{ m}}{(50\text{ W/m.°C})(0.000628\text{ m}^2)} = 3.18\text{ °C/W}$$

$$R_{stud} = \frac{L}{kA} = \frac{0.1\text{ m}}{(0.11\text{ W/m.°C})(0.25 - 0.000628\text{ m}^2)} = 3.65\text{ °C/W}$$

$$\frac{1}{R_{total}} = \frac{1}{R_{stud}} + \frac{1}{R_{nails}} = \frac{1}{3.65} + \frac{1}{3.18} \longrightarrow R_{total} = 1.70\text{ °C/W}$$

$$\dot{Q} = \frac{\Delta T}{R_{stud}} = \frac{8°C}{1.70\text{ °C/W}}$$

$$= 4.7\text{ W}$$

$$\boxed{\dot{Q} = 4.7\text{ W}}$$

Step 5 of 5

(c) The effective conductivity of the nailed stud pair can be determined from

$$\dot{Q} = k_{eff} A\frac{\Delta T}{L}$$

$$k_{eff} = \frac{\dot{Q}L}{\Delta TA} = \frac{(4.7\text{ W})(0.1\text{ m})}{(8°C)(0.25\text{ m}^2)}$$

$$k_{eff} = 0.235\text{ W/m°C}$$

$$\boxed{k_{eff} = 0.235\text{ W/m°C}}$$

Question: 17.056P pg 1

A 10-in-thick., 30-ft-long, and 10-ft-high wall is to be constructed using 9-in-long solid bricks (k = 0.40 Btu/h·ft·°F) of cross section 7 in × 7 in, or identical size bricks withnine square air holes (k = 0.015 Btu/h·ft·°F) that are 9 inlong and have a cross section of 1.5 in× 1.5 in . There isa 0.5- in-thick plaster layer (k = 0.10 Btu/h·ft·°F) between twoadjacent bricks on all four sides and on both sides of the wall. The house is maintained at 80°F and the ambient temperature outside is35°F. Taking the heat transfer coefficients at the inner andouter surfaces of the wall to be 1.5 and 6 Btu/h·ft2·°F. respectively, determine the rate of heat transfer through the wall constructed of(*a*) solid bricks and (*b*) bricks with air holes.

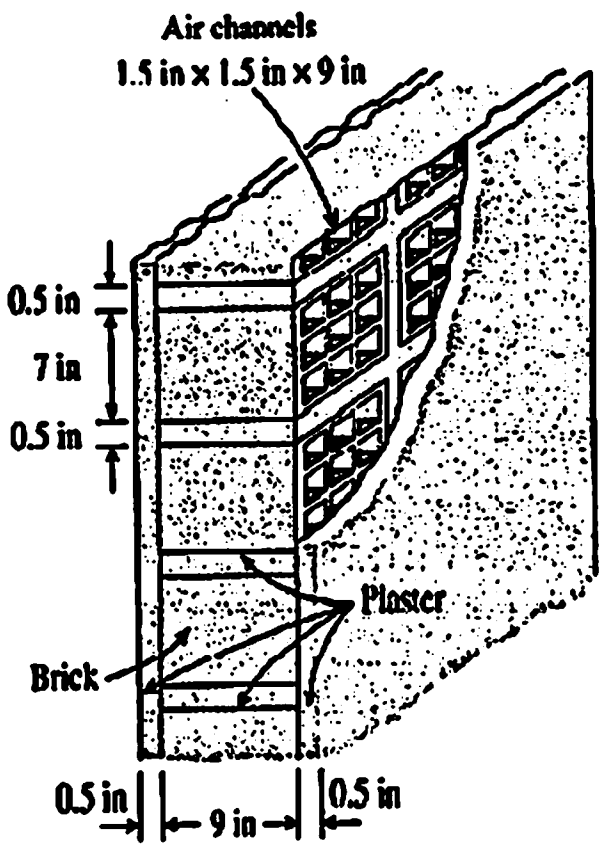


FIGURE P17–56E

Step 1 of 12

Given data:

Cross sectional are of the wall, $A = 30 \times 10\,\text{ft}^2 = 300\,\text{ft}^2$

Thickness of the plaster, $t_1 = t_5 = 0.5\text{in}$

Thickness of the plaster between two bricks, $t_2 = t_4 = 9\text{in}$

Thickness of the brick, $t_3 = 9\text{in}$

Length of the plaster, $L_1 = L_5 = 7.5\text{in}$

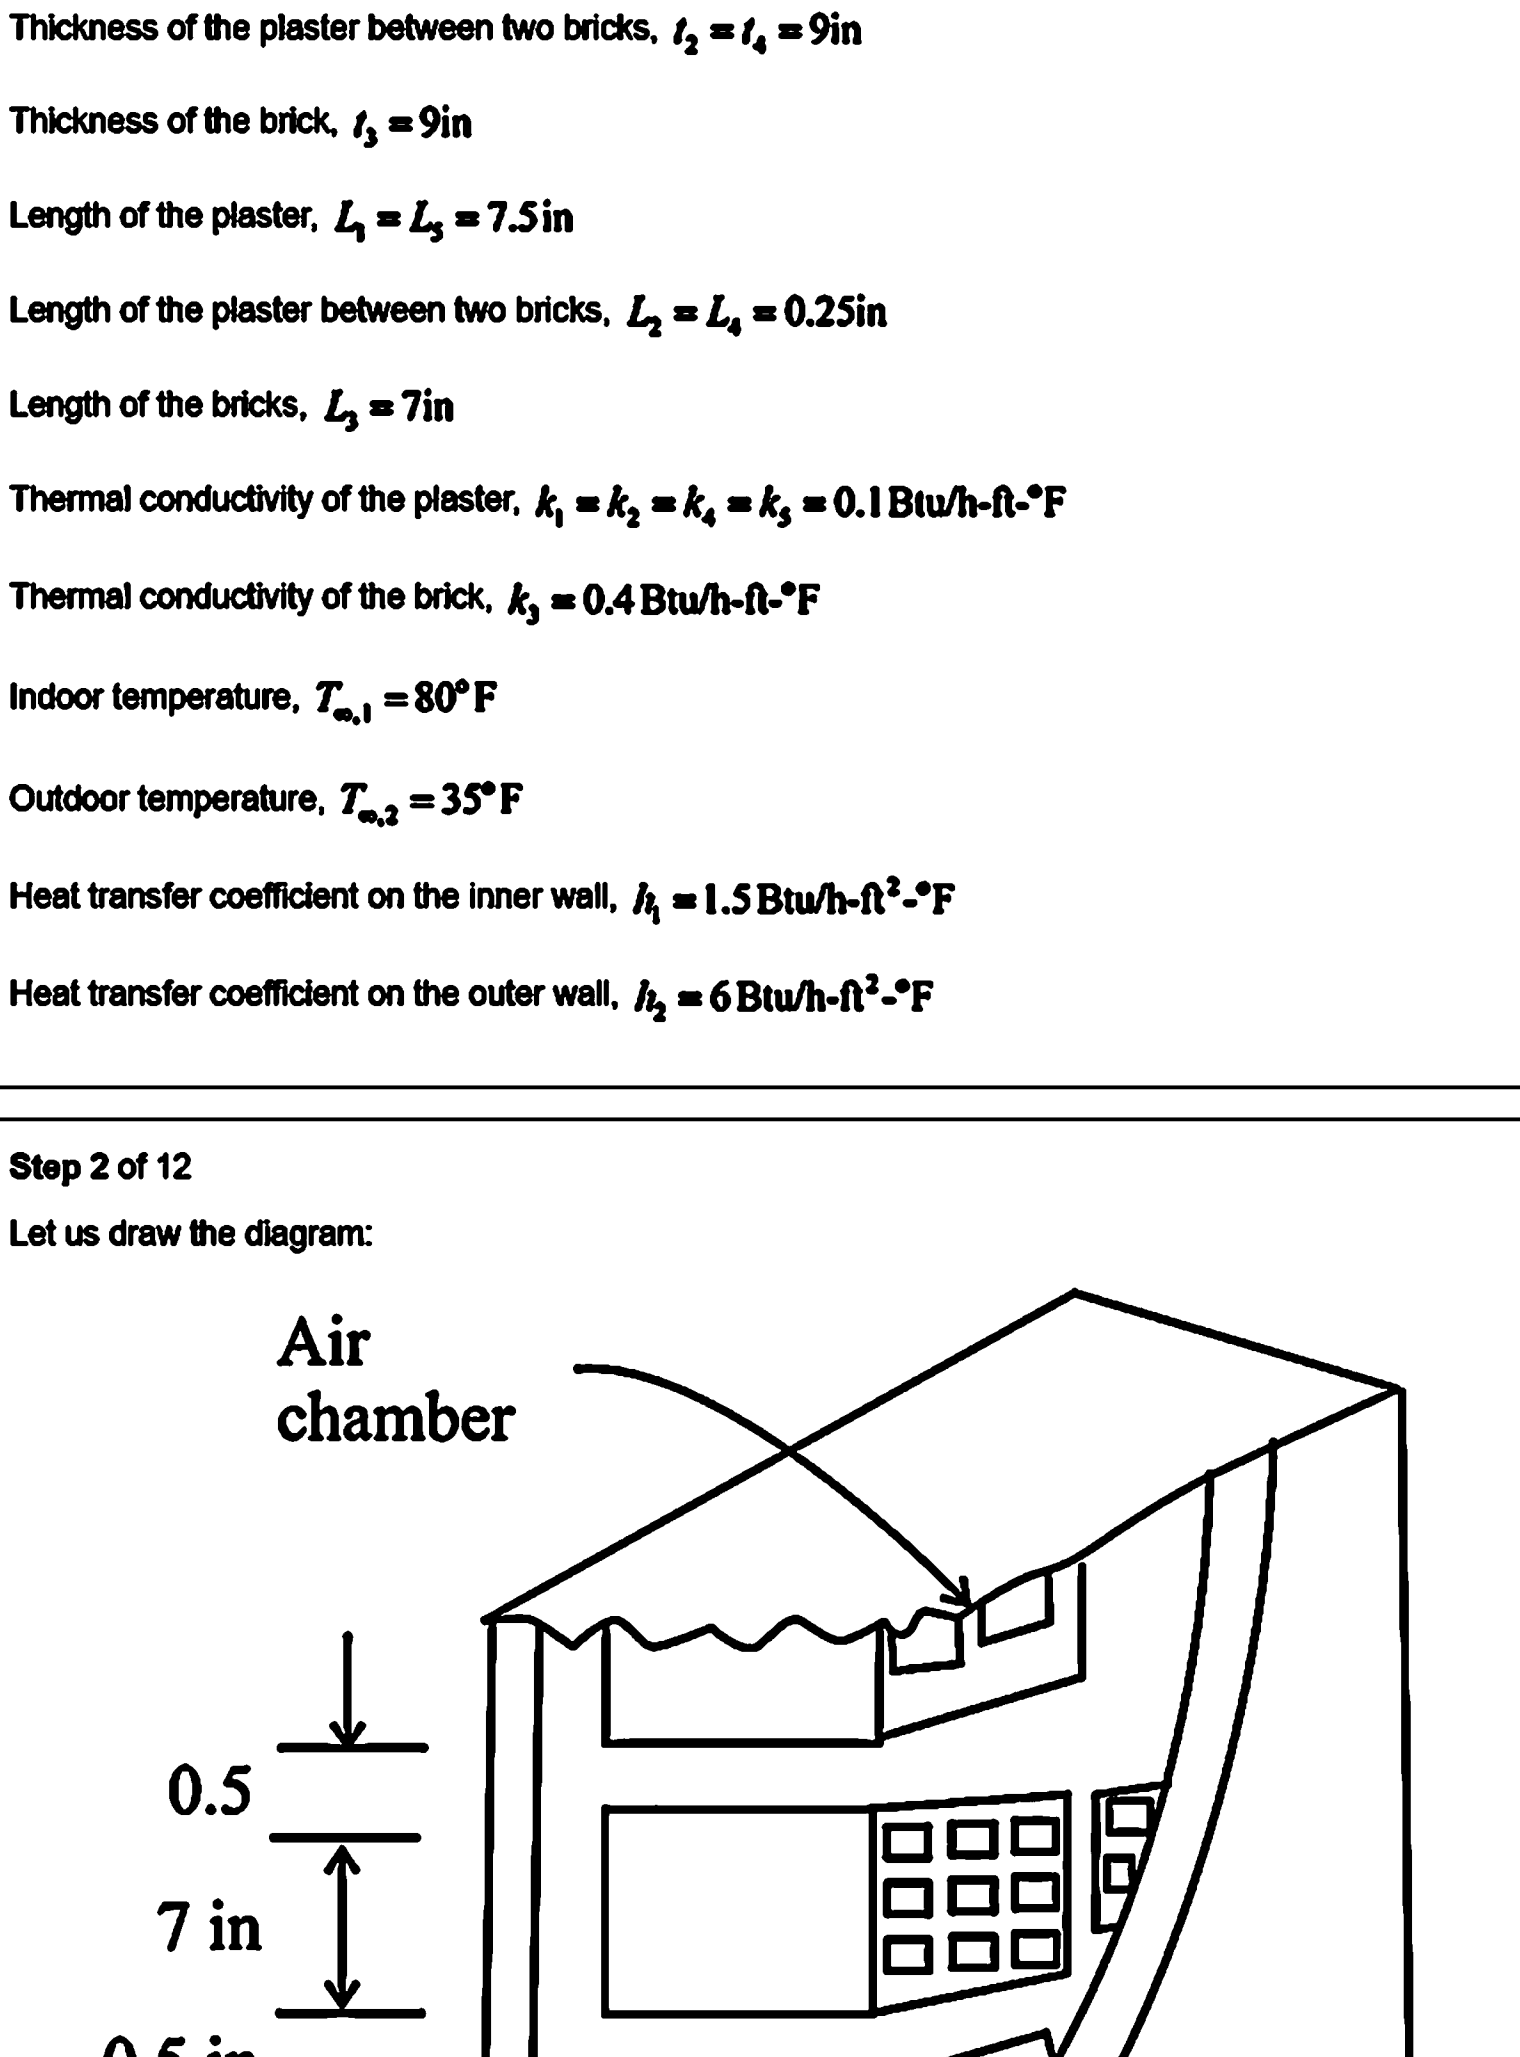
Length of the plaster between two bricks, $L_2 = L_4 = 0.25\text{in}$

Length of the bricks, $L_3 = 7\text{in}$

Thermal conductivity of the plaster, $k_1 = k_2 = k_4 = k_5 = 0.1\,\text{Btu/h-ft-°F}$

Thermal conductivity of the brick, $k_3 = 0.4\,\text{Btu/h-ft-°F}$

Indoor temperature, $T_{\infty,1} = 80°\text{F}$



Outdoor temperature, $T_{\infty,2} = 35°\text{F}$

Heat transfer coefficient on the inner wall, $h_1 = 1.5\,\text{Btu/h-ft}^2\text{-°F}$

Heat transfer coefficient on the outer wall, $h_2 = 6\,\text{Btu/h-ft}^2\text{-°F}$

Step 2 of 12

Let us draw the diagram:

Step 3 of 12

Step 3 of 12

Step 4 of 12

With Solid Bricks:

There is a pattern in the construction of the wall that repeats itself every 7.5-in distance in the vertical direction. The representative surface area of the wall is $A = \frac{7.5}{12} \times \frac{7.5}{12} \text{ft}^2 = 0.3906 \text{ft}^2$

Assuming any cross section of the wall normal to the X-direction to be isothermal, the thermal resistance network for the representative section of the wall becomes as shown in the Fig above.

The individual resistances are evaluated as:

$$R_i = R_{conv,1}$$
$$= \frac{1}{h_1 A_1}$$
$$= \frac{1}{1.5(\text{Btu/h-ft}^2\text{-}^\circ\text{F}) \times 0.3906(\text{ft}^2)}$$
$$= 1.7067 \text{ h-}^\circ\text{F/Btu}$$

Step 5 of 12

$$R_1 = R_5$$
$$= R_{plaster,side}$$
$$= \frac{t_1}{k_1 A_1}$$
$$= \frac{0.5/12(\text{ft})}{0.1(\text{Btu/h-ft-}^\circ\text{F}) \times 0.3906(\text{ft}^2)}$$
$$= 1.0667 \text{ h-}^\circ\text{F/Btu}$$

$$R_2 = R_4$$
$$= R_{plaster,center}$$
$$= \frac{t_2}{k_2 A_2}$$
$$= \frac{9/12(\text{ft})}{0.1(\text{Btu/h-ft-}^\circ\text{F}) \times (7.5/12 \times 0.25/12 \text{ft}^2)}$$
$$= 576 \text{ h-}^\circ\text{F/Btu}$$

$$R_3 = R_{brick}$$
$$= \frac{t_3}{k_3 A_3}$$
$$= \frac{9/12(\text{ft})}{0.4(\text{Btu/h-ft-}^\circ\text{F}) \times (7/12 \times 7/12 \text{ft}^2)}$$
$$= 5.51 \text{ h-}^\circ\text{F/Btu}$$

$$R_o = R_{conv,2}$$
$$= \frac{1}{h_2 A_2}$$
$$= \frac{1}{6(\text{Btu/h-ft}^2\text{-}^\circ\text{F}) \times 0.3906(\text{ft}^2)}$$
$$= 0.4267 \text{ h-}^\circ\text{F/Btu}$$

Step 6 of 12

The three resistances R_2, R_3 and R_4 in the middle are parallel, and their equivalent resistance is determined from

$$\frac{1}{R_{mid}} = \frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4}$$
$$= \frac{1}{576(\text{h-}^\circ\text{F/Btu})} + \frac{1}{5.51(\text{h-}^\circ\text{F/Btu})} + \frac{1}{576(\text{h-}^\circ\text{F/Btu})}$$
$$= 0.185 \text{ Btu/h-}^\circ\text{F}$$

This gives

$$R_{mid} = \frac{1}{0.185(\text{Btu/h-}^\circ\text{F})}$$
$$= 5.406 \text{ h-}^\circ\text{F/Btu}$$

Now all the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_1 + R_{mid} + R_5 + R_o$$
$$= \left\{ \begin{array}{l} 1.7067(\text{h-}^\circ\text{F/Btu}) + 1.0667(\text{h-}^\circ\text{F/Btu}) + 5.406(\text{h-}^\circ\text{F/Btu}) \\ \qquad + 1.0667(\text{h-}^\circ\text{F/Btu}) + 0.4267(\text{h-}^\circ\text{F/Btu}) \end{array} \right\}$$
$$= 9.674 \text{ h-}^\circ\text{F/Btu}$$

Step 7 of 12

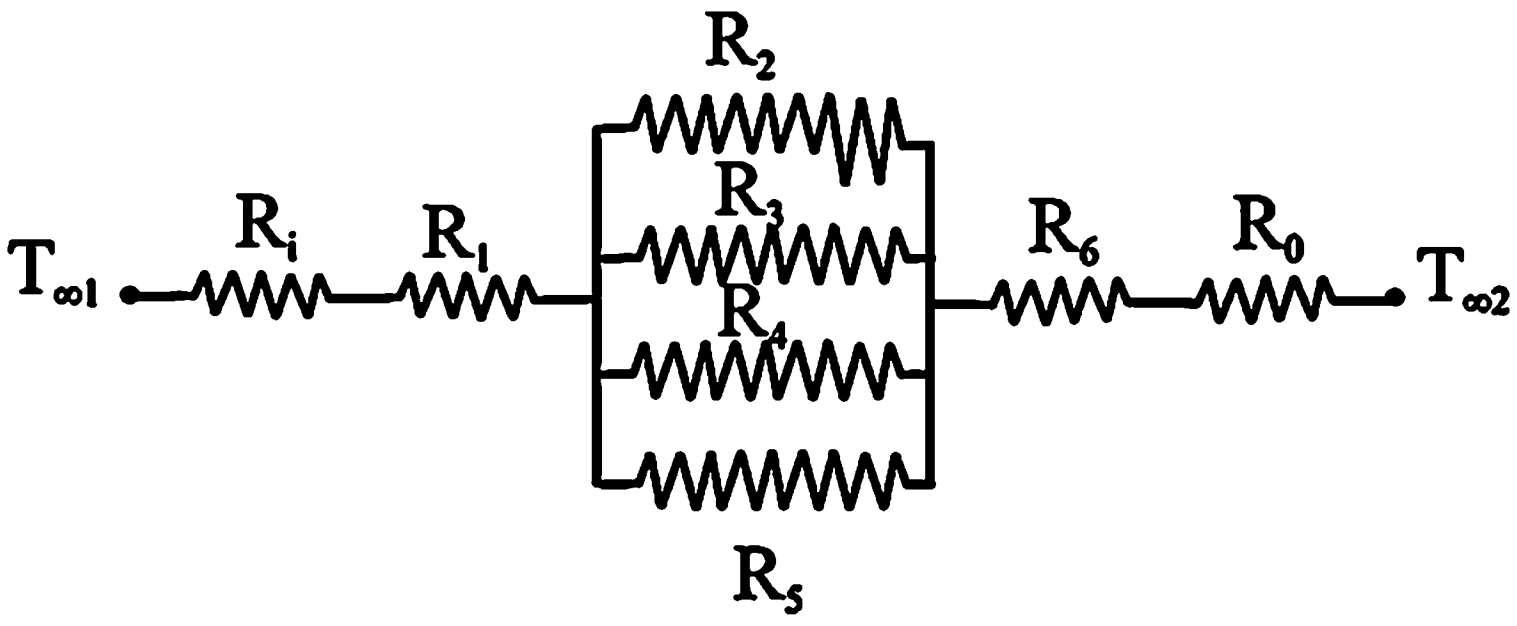
Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{(80 - 35)^\circ\text{F}}{9.674(\text{h-}^\circ\text{F/Btu})}$$
$$= 4.652 \text{ Btu/h}$$

4.652 Btu/h Of heat is transferring through per 0.3906ft^2 surface area

And the total heat flux through the wall can be computed as

$$\dot{q} = \frac{\dot{Q}}{A}$$
$$= \frac{4.652(\text{Btu/h})}{0.3906(\text{ft}^2)}$$



$$\dot{q} = \frac{\dot{Q}}{A}$$
$$= \frac{4.652(\text{Btu/h})}{0.3906(\text{ft}^2)}$$
$$= 12\,\text{Btu/ft}^2\text{-h}$$

The total area of the wall is $A = 30 \times 10 = 300\text{ft}^2$. Then the rate of heat transfer through the entire wall becomes

$$\dot{Q}_{total} = 12(\text{Btu/ft}^2\text{-h}) \times 300(\text{ft}^2)$$
$$= 3600\,\text{Btu/h}$$

$$\boxed{\dot{Q}_{total} = 3600\,\text{Btu/h}}$$

Step 8 of 12

Step 9 of 12

Bricks with square air holes:

Area occupied by Air holes in each brick can be calculated as

$$A_{airholes} = 9 \times (1.5/12 \times 1.5/12)\text{ft}^2$$
$$= 0.140625\text{ft}^2$$

The area occupied by the brick can be calculated as

$$A_{brick} = (7/12 \times 7/12)\text{ft}^2 - 0.140625\text{ft}^2$$
$$= 0.19965\text{ft}^2$$

The individual resistances are evaluated as

$$R_i = R_{conv,1}$$
$$= \frac{1}{h_1 A_1}$$
$$= \frac{1}{1.5(\text{Btu/h-ft}^2\text{-°F}) \times 0.3906(\text{ft}^2)}$$
$$= 1.7067\,\text{h-°F/Btu}$$

$$R_1 = R_6$$
$$= R_{plaster,side}$$
$$= \frac{l_1}{k_1 A_1}$$
$$= \frac{0.5/12(\text{ft})}{0.1(\text{Btu/h-ft-°F}) \times 0.3906(\text{ft}^2)}$$
$$= 1.0667\,\text{h-°F/Btu}$$

$$R_2 = R_5$$
$$= R_{plaster,center}$$
$$= \frac{l_2}{k_2 A_2}$$
$$= \frac{9/12(\text{ft})}{0.1(\text{Btu/h-ft-°F}) \times (7.5/12 \times 0.25/12\text{ft}^2)}$$
$$= 576\,\text{h-°F/Btu}$$

Step 10 of 12

$$R_3 = R_{brick}$$
$$= \frac{l_3}{k_3 A_3}$$
$$= \frac{9/12(\text{ft})}{0.4(\text{Btu/h-ft-°F}) \times (0.19965\text{ft}^2)}$$
$$= 9.391\,\text{h-°F/Btu}$$

$$R_4 = R_{airholes}$$
$$= \frac{l_4}{k_4 A_4}$$
$$= \frac{9/12(\text{ft})}{0.015(\text{Btu/h-ft-°F}) \times (0.140625\text{ft}^2)}$$
$$= 355.55\,\text{h-°F/Btu}$$

$$R_o = R_{conv,2}$$
$$= \frac{1}{h_2 A_2}$$
$$= \frac{1}{6(\text{Btu/h-ft}^2\text{-°F}) \times 0.3906(\text{ft}^2)}$$
$$= 0.4267\,\text{h-°F/Btu}$$

Step 11 of 12

The four resistances R_2, R_3, R_4 and R_5 in the middle are parallel, and their equivalent resistance is determined from

$$\frac{1}{R} = \frac{1}{R} + \frac{1}{R} + \frac{1}{R} + \frac{1}{R}$$

The four resistances R_2, R_3, R_4 and R_5 in the middle are parallel, and their equivalent resistance is determined from

$$\begin{aligned}\frac{1}{R_{mid}} &= \frac{1}{R_2}+\frac{1}{R_3}+\frac{1}{R_4}+\frac{1}{R_5}\\ &= \frac{1}{576(\text{h-°F/Btu})}+\frac{1}{9.391(\text{h-°F/Btu})}+\frac{1}{355.55(\text{h-°F/Btu})}+\frac{1}{576(\text{h-°F/Btu})}\\ &= 0.1065\,\text{Btu/h-°F}\end{aligned}$$

This gives

$$\begin{aligned}R_{mid} &= \frac{1}{0.1065(\text{Btu/h-°F})}\\ &= 9.4\,\text{h-°F/Btu}\end{aligned}$$

Now all the resistances are in series, and the total resistance is

$$\begin{aligned}R_{total} &= R_i + R_1 + R_{mid} + R_6 + R_o\\ &= \left[\begin{array}{l}1.7067(\text{h-°F/Btu})+1.0667(\text{h-°F/Btu})+9.4(\text{h-°F/Btu})\\ \qquad\qquad +1.0667(\text{h-°F/Btu})+0.4267(\text{h-°F/Btu})\end{array}\right]\\ &= 13.657\,\text{h-°F/Btu}\end{aligned}$$

Step 12 of 12

Then the steady rate of heat transfer through the wall becomes

$$\begin{aligned}\dot{Q} &= \frac{(T_{\infty,1}-T_{\infty,2})}{R_{total}}\\ &= \frac{(80-35)°\text{F}}{13.657(\text{h-°F/Btu})}\\ &= 3.3\,\text{Btu/h}\end{aligned}$$

$3.3\,\text{Btu/h}$ Of heat is transferring through per 0.3906ft^2 surface area

And the total heat flux through the wall can be computed as

$$\begin{aligned}\dot{q} &= \frac{\dot{Q}}{A}\\ &= \frac{3.3(\text{Btu/h})}{0.3906(\text{ft}^2)}\\ &= 8.436\,\text{Btu/ft}^2\text{-h}\end{aligned}$$

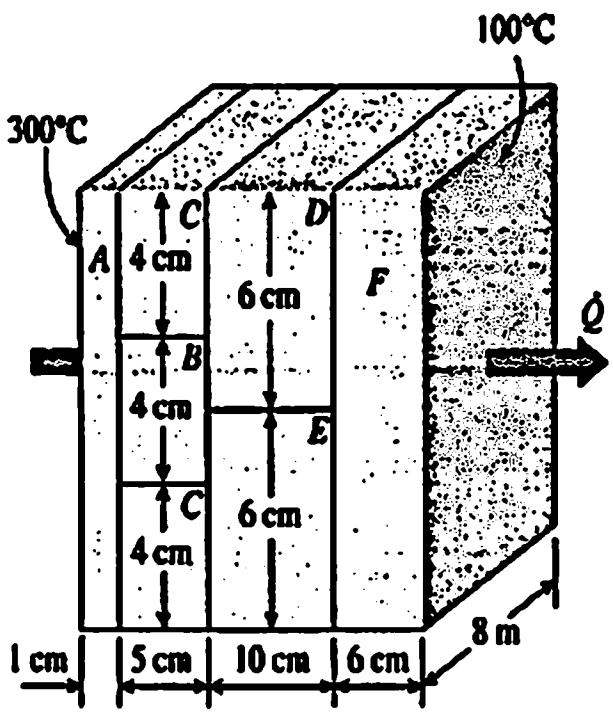
The total area of the wall is $A = 30\times 10 = 300\text{ft}^2$. Then the rate of heat transfer through the entire wall becomes

$$\begin{aligned}\dot{Q}_{total} &= 8.436(\text{Btu/ft}^2\text{-h})\times 300(\text{ft}^2)\\ &= 2530.8\,\text{Btu/h}\end{aligned}$$

$$\boxed{\dot{Q}_{total} = 2530.8\,\text{Btu/h}}$$

Question: 17.057P pg 1

Consider a 5-m-high, 8-m-long, and 0.22-m-thick wall whose representative cross section is as given in the figure. The thermal conductivities of various materials used, in W/m·K, are $kA = kF = 2, kB = 8$, $kc = 20$, $kD = 15$, and $kE = 35$. The left and right surfaces of the wall are maintained at uniform temperatures of 300°C and 100°C, respectively. Assuming heat transfer through the wall to be one-dimensional, determine (*a*) the rate of heat transfer through the wall; (*b*) the temperature at the point where the sections *B*, *D*, and *E* meet; and (*c*) the temperature drop across the section *F*. Disregard any contact resistances at the interfaces.



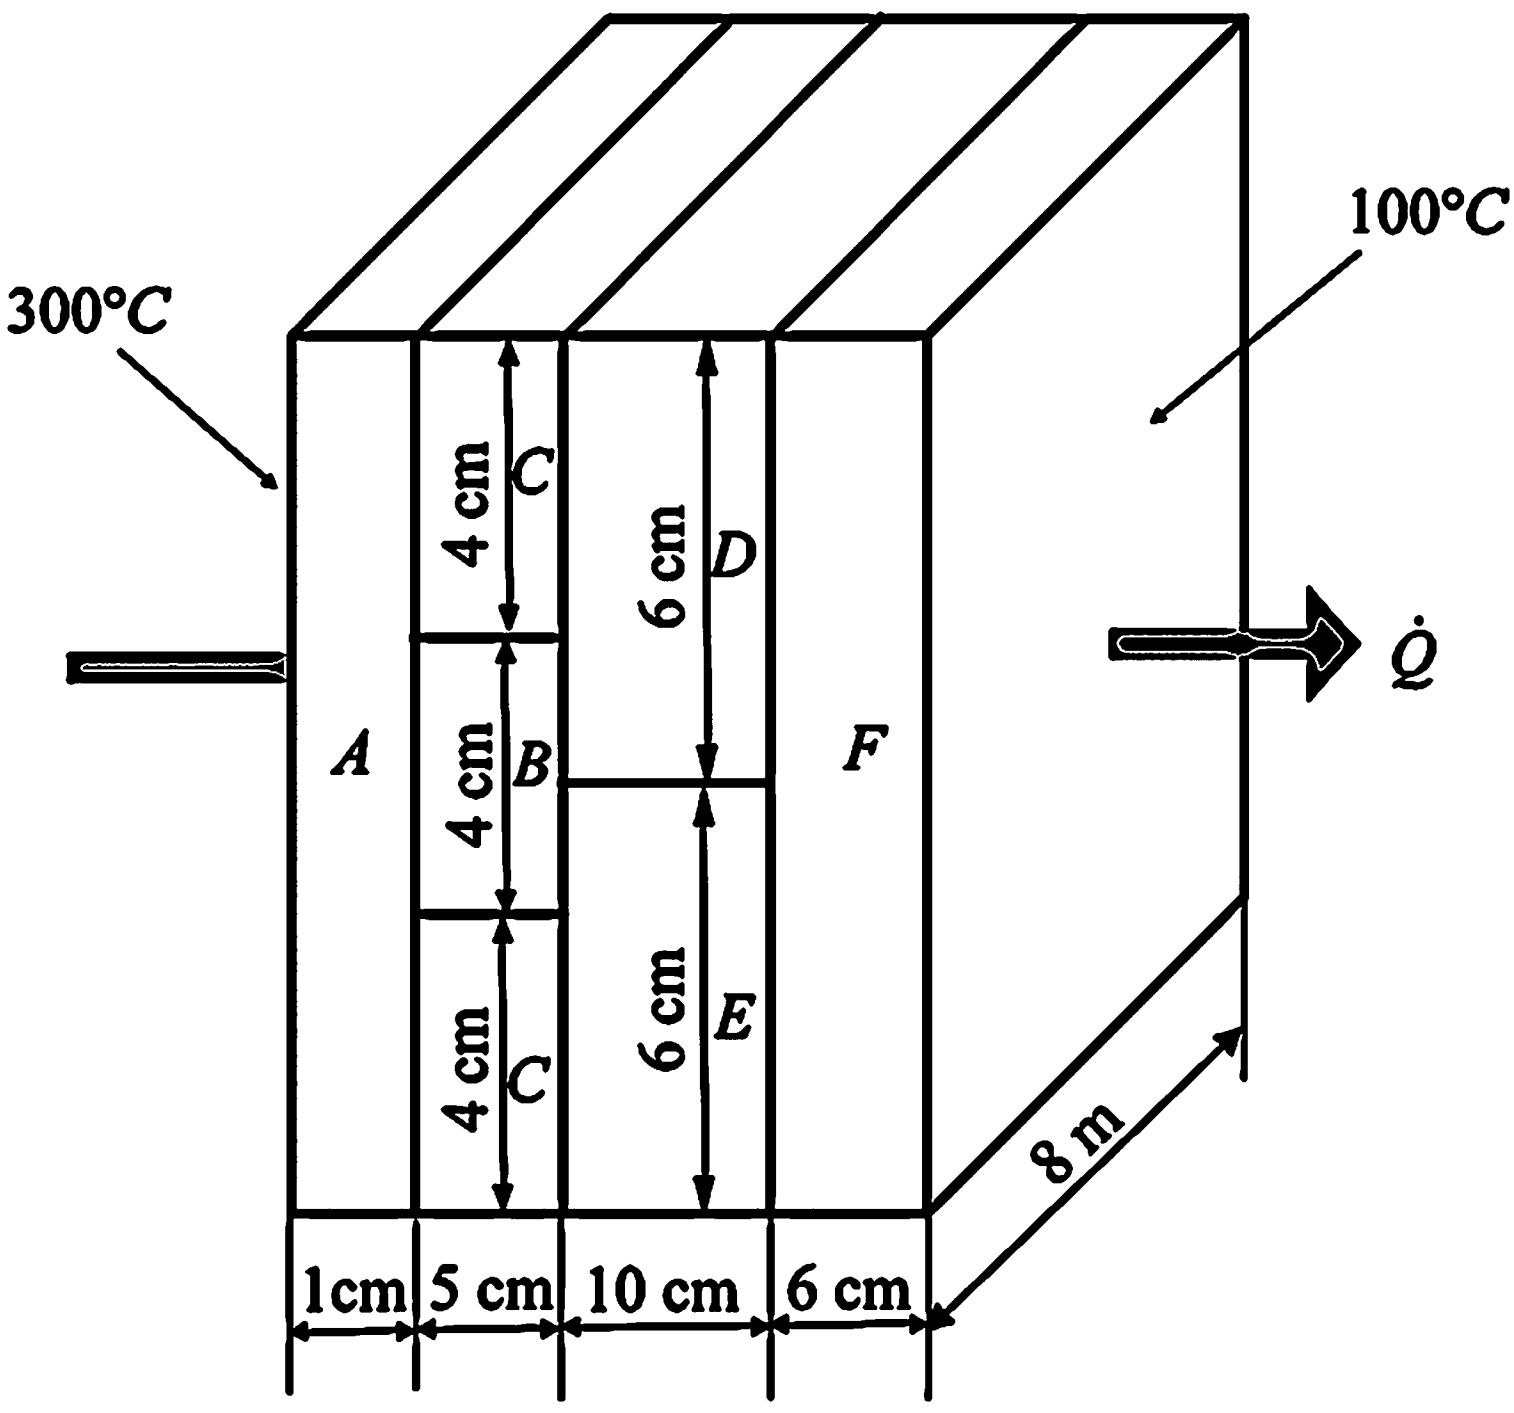


FIGURE P17–57

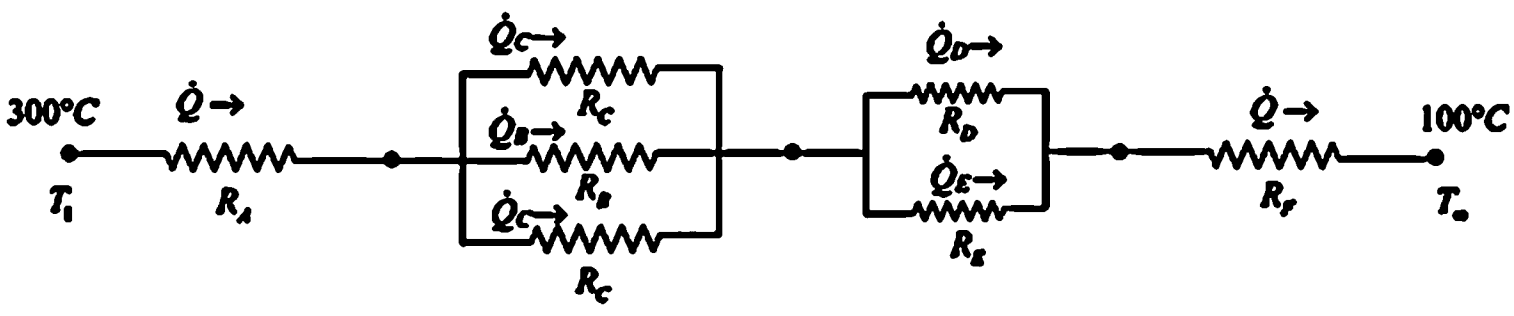
Step 1 of 13



a)

Draw the cross section of $0.22\ \text{m}$ thick plane wall shown as follows:

Step 2 of 13

Draw the thermal resistance network due to conduction as shown below.

Step 3 of 13

Calculate the thermal resistance in wall A due to conduction, by using the equation as shown below.

$$R_A = \left(\frac{L_A}{k_A A_A}\right)$$

Here, the thickness of the wall A is L_A, thermal conductivity of wall A is k_A and the area normal to the direction of heat flow through A is A_A.

Substitute $0.01\ \text{m}$ for L_A, $(0.12\times 8)\ \text{m}^2$ for A_A and $2\ \text{W/m.°C}$ for k_A.

$$R_A = \frac{0.01\ \text{m}}{(2\ \text{W/m.°C})(0.12\times 8\ \text{m}^2)}$$
$$= 0.0052\ \text{°C/W}$$

Step 4 of 13

Calculate the thermal resistance in wall B due to conduction, by using the equation as shown below.

$$R_B = \left(\frac{L_B}{k_B A_B}\right)$$

Here, the thickness of the wall B is L_B, thermal conductivity of wall B is k_B and the area normal to the direction of heat flow through B is A_B.

Substitute $0.05\ \text{m}$ for L_B, $(0.04\times 8)\ \text{m}^2$ for A_B and $8\ \text{W/m.°C}$ for k_B.

$$R_B = \frac{0.05\ \text{m}}{(8\ \text{W/m.°C})(0.04\times 8\ \text{m}^2)}$$
$$= 0.01953\ \text{°C/W}$$

$$R_B = \frac{0.05\ \text{m}}{(8\ \text{W/m.°C})(0.04\times 8\ \text{m}^2)}$$

17.057P pg 2

$$= 0.01953\ \text{°C/W}$$

Step 5 of 13

Calculate the thermal resistance in wall C due to conduction, by using the equation as shown below.

$$R_C = \left(\frac{L_C}{k_C A_C}\right)$$

Here, the thickness of the wall C is L_C, thermal conductivity of wall C is k_C and the area normal to the direction of heat flow through C is A_C.

Substitute $0.05\ \text{m}$ for L_C, $(0.04\times 8)\ \text{m}^2$ for A_C and $20\ \text{W/m.°C}$ for k_C.

$$R_C = \frac{0.05\ \text{m}}{(20\ \text{W/m.°C})(0.04\times 8\ \text{m}^2)}$$

$$= 0.00781\ \text{°C/W}$$

Step 6 of 13

Calculate the thermal resistance in wall D due to conduction, by using the equation as follows:

$$R_D = \left(\frac{L_D}{k_D A_D}\right)$$

Here, the thickness of the wall D is L_D, thermal conductivity of wall D is k_D and the area normal to the direction of heat flow through D is A_D.

Substitute $0.1\ \text{m}$ for L_D, $(0.06\times 8)\ \text{m}^2$ for A_D and $15\ \text{W/m.°C}$ for k_D.

$$R_D = \frac{0.1\ \text{m}}{(15\ \text{W/m.°C})(0.06\times 8\ \text{m}^2)}$$

$$= 0.01388\ \text{°C/W}$$

Calculate the thermal resistance in wall E due to conduction, by using the equation as follows:

$$R_E = \left(\frac{L_E}{k_E A_E}\right)$$

Here, the thickness of the wall E is L_E, thermal conductivity of wall E is k_E and the area normal to the direction of heat flow through E is A_E.

Substitute $0.1\ \text{m}$ for L_E, $(0.06\times 8)\ \text{m}^2$ for A_E and $35\ \text{W/m.°C}$ for k_E.

$$R_E = \frac{0.1\ \text{m}}{(35\ \text{W/m.°C})(0.06\times 8\ \text{m}^2)}$$

$$= 0.00595\ \text{°C/W}$$

Step 7 of 13

Calculate the thermal resistance in wall F due to conduction, by using the equation as shown below.

$$R_F = \left(\frac{L_F}{k_F A_F}\right)$$

Here, the thickness of the wall F is L_F, thermal conductivity of the wall F is k_F and the area normal to the direction of heat flow through F is A_F.

Substitute $0.06\ \text{m}$ for L_F, $(0.12\times 8)\ \text{m}^2$ for A_F and $2\ \text{W/m.°C}$ for k_F.

$$R_F = \frac{0.06\ \text{m}}{(2\ \text{W/m.°C})(0.12\times 8\ \text{m}^2)}$$

$$= 0.03125\ \text{°C/W}$$

Step 8 of 13

The three resistances R_C, R_B and R_C in the middle are parallel.

Calculate the equivalent resistance of R_C, R_B and R_C, by using the equation as shown below.

$$\frac{1}{R_{mid,1}} = \frac{1}{R_C} + \frac{1}{R_B} + \frac{1}{R_C}$$

Substitute the known values in the above equation.

$$\frac{1}{R_{mid,1}} = \frac{1}{0.00781} + \frac{1}{0.01953} + \frac{1}{0.00781}$$

$$\frac{1}{R_{mid,1}} = 307.2852$$

$$R_{mid,1} = 0.003254\ \text{°C/W}$$

Step 9 of 13

The two resistances R_D and R_E in the middle are parallel.

Calculate the equivalent resistance of R_D and R_E by using the equation as shown below.

$$\frac{1}{R_{mid,2}} = \frac{1}{R_D} + \frac{1}{R_E}$$

Substitute the known values in the above equation.

$$\frac{1}{R_{mid,2}} = \frac{1}{0.01388} + \frac{1}{0.00595}$$

$$\frac{1}{R_{mid,2}} = 240.1133$$

$$R_{mid,2} = 0.004164$$

$$\frac{1}{R_{mid,2}} = 240.1133$$

$$R_{mid,2} = 0.004164$$

Step 10 of 13

Calculate the total thermal resistance.

$$R_{total} = R_A + R_{mid,1} + R_{mid,2} + R_F$$

Substitute the known values in the above equation.

$$R_{total} = 0.0052 + 0.003254 + 0.004164 + 0.03125$$
$$= 0.0438\ ^\circ\text{C/W}$$

Step 11 of 13

Calculate the rate of heat transfer by using the equation as shown below.

$$\dot{Q} = \frac{T_1 - T_\infty}{R_{total}}$$

Here, the temperature of the left surface is T_1 and the temperature of the right surface is T_∞.

Substitute $300\ ^\circ\text{C}$ for T_1, $100\ ^\circ\text{C}$ for T_∞ and $0.0438\ ^\circ\text{C/W}$ for R_{total}.

$$\dot{Q} = \frac{(300 - 100)^\circ\text{C}}{0.0438\ ^\circ\text{C/W}}$$
$$= 4566.21\ \text{W}$$
$$= 4.56\ \text{kW}\ (\text{for a } 0.12\ \text{m} \times 8\ \text{m section})$$

Calculate the rate of heat transfer through entire wall $(\text{for } 5\ \text{m} \times 8\ \text{m section})$.

$$\dot{Q}_{total} = 4.56\ \text{kW} \times \frac{5\ \text{m}}{0.12\ \text{m}}$$
$$= 190\ \text{kW}$$
$$= 1.9 \times 10^5\ \text{W}$$

Therefore, the rate of heat transfer through the wall is $\boxed{1.9 \times 10^5\ \text{W}}$.

b)

Calculate the total thermal resistance between left surface and the point where the sections *B*, *D*, and *E* meet.

$$R_{total} = R_A + R_{mid,3}$$

Substitute the known values in the above equation.

$$R_{total} = 0.0052 + 0.003254$$
$$= 0.008454\ ^\circ\text{C/W}$$

Step 12 of 13

Calculate the temperature at the point where the sections *B*, *D*, and *E* meet.

$$\dot{Q} = \frac{T_1 - T}{R_{total}}$$
$$T_1 - T = \dot{Q} R_{total}$$
$$T = T_1 - \dot{Q} R_{total}$$

Substitute $300\ ^\circ\text{C}$ for T_1, $4566.21\ \text{W}$ for $\dot{Q}$ and $0.008454\ ^\circ\text{C/W}$ for R_{total}.

$$T = 300^\circ\text{C} - (4566.21\ \text{W} \times 0.008454\ ^\circ\text{C/W})$$
$$= 300 - 38.60$$
$$= 261.40^\circ C$$

Therefore, the temperature at *B*, *D*, and *E* interface is $\boxed{261.40^\circ\text{C}}$.

Step 13 of 13

c)

Calculate the temperature drop across the section *F* by using the equation as shown below.

$$\dot{Q} = \frac{\Delta T}{R_F}$$
$$\Delta T = \dot{Q} R_F$$

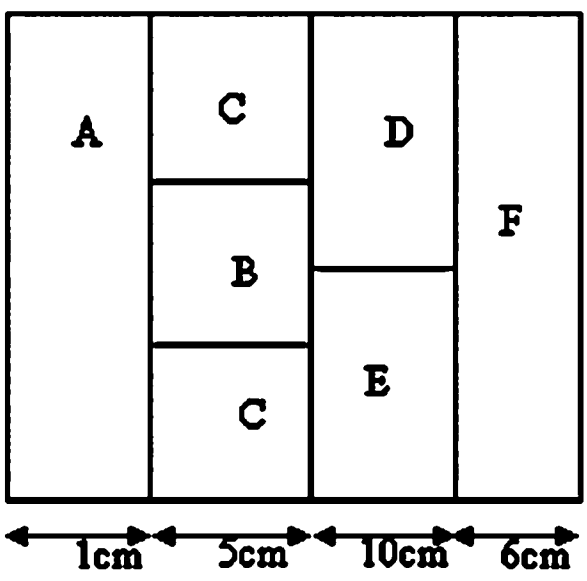
Substitute $4566.21\ \text{W}$ for $\dot{Q}$ and $0.03125\ ^\circ\text{C/W}$ for R_F.

$$\Delta T = \dot{Q} R_F$$
$$= (4566.21\ \text{W}) \times (0.03125\ ^\circ\text{C/W})$$
$$= 142.70^\circ\text{C}$$

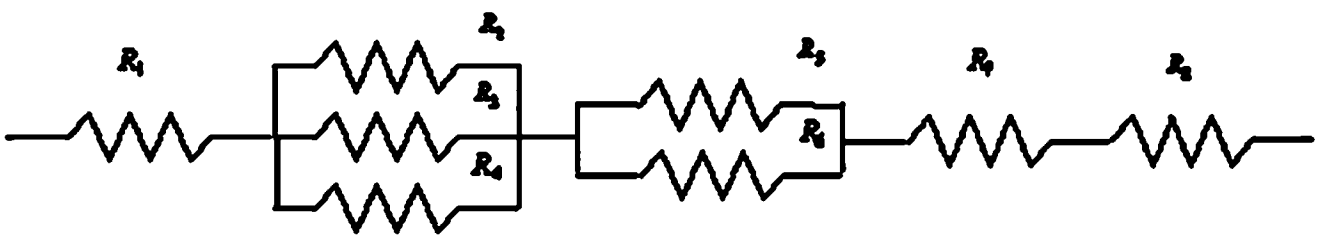
Therefore, the temperature drop across the section *F* is $\boxed{142.70^\circ\text{C}}$.

Question: 17.058P pg 1

Repeat Prob. 17-57 assuming that the thermal contact resistance at the interfaces *D-F* and *E-F* is 0.00012 m2·°C/W.



Step 1 of 9



Given:
Length of the wall =8m
Thickness of the wall = .22m
Height of the wall = 5m
Bricks length = 9in
Thermal conductivity for A = 2 W/m·°C.
Thermal conductivity for B = 8 W/m·°C.
Thermal conductivity for C = 20 W/m·°C.
Thermal conductivity for D = 15 W/m·°C.
Thermal conductivity for E = 35 W/m·°C.
Thermal conductivity for F = 2 W/m·°C.
The thermal contact resistence at the interfaces D-F and E-F is $0.00012 m^2$
Left surface temperature = $300^0 C$
Right surface temperature = $100^0 C$

Step 2 of 9

If the heat transfer is steady since there is no indication of change with time and heat transfer through the wall is one-dimensionalthe then the thermal resistance network and the individual thermal resistances are

Step 3 of 9

Step 4 of 9

(a) The thermal resistance network and the individual thermal resistances are

$$R_1 = R_A = \left(\frac{L}{kA}\right)_A$$
$$= \frac{0.01\,\text{m}}{(2\ \text{W/m.°C})(0.12\ \text{m}^2)}$$
$$= 0.04\ \text{°C/W}$$
$$R_2 = R_4 = R_C = \left(\frac{L}{kA}\right)_C$$
$$= \frac{0.05\,\text{m}}{(20\ \text{W/m.°C})(0.04\ \text{m}^2)}$$
$$= 0.06\ \text{°C/W}$$
$$R_3 = R_B = \left(\frac{L}{kA}\right)_B$$
$$= \frac{0.05\,\text{m}}{(8\ \text{W/m.°C})(0.04\ \text{m}^2)}$$
$$= 0.16\ \text{°C/W}$$

Step 5 of 9

$$R_5 = R_D = \left(\frac{L}{kA}\right)_D$$
$$= \frac{0.1\,\text{m}}{(15\ \text{W/m.°C})(0.06\ \text{m}^2)}$$
$$= 0.11\ \text{°C/W}$$
$$R_6 = R_E = \left(\frac{L}{kA}\right)_E$$
$$= \frac{0.1\,\text{m}}{(35\ \text{W/m.°C})(0.06\ \text{m}^2)}$$
$$= 0.05\ \text{°C/W}$$
$$R_7 = R_F = \left(\frac{L}{kA}\right)_F$$
$$= \frac{0.06\,\text{m}}{(2\ \text{W/m.°C})(0.12\ \text{m}^2)}$$
$$= 0.25\ \text{°C/W}$$
$$R_8 = \frac{0.00012\ \text{m}^2\text{°C/W}}{0.12\ \text{m}^2}$$
$$= 0.001\ \text{°C/W}$$
$$\frac{1}{R_{mid,1}} = \frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4}$$
$$= \frac{1}{0.06} + \frac{1}{0.16} + \frac{1}{0.06}$$
$$R_{mid,1} = 0.025\ \text{°C/W}$$

Step 6 of 9

$$\frac{1}{R_{mid,2}} = \frac{1}{R_5} + \frac{1}{R_6}$$
$$= \frac{1}{0.11} + \frac{1}{0.05}$$
$$R_{mid,2} = 0.034\ \text{°C/W}$$
$$R_{total} = R_1 + R_{mid,1} + R_{mid,2} + R_7 + R_8$$

$$= \frac{1}{0.11} + \frac{1}{0.05}$$

$$R_{mid,2} = 0.034\ ^\circ\text{C/W}$$

$$R_{total} = R_1 + R_{mid,1} + R_{mid,2} + R_7 + R_8$$
$$= 0.04 + 0.025 + 0.034 + 0.25 + 0.001$$
$$= 0.350\ ^\circ\text{C/W}$$

Step 7 of 9

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{total}}$$
$$= \frac{(300 - 100)^\circ\text{C}}{0.350\ ^\circ\text{C/W}}$$
$$= 571\ \text{W (for a 0.12 m} \times \text{1 m section)}$$

Then steady rate of heat transfer through entire wall becomes

$$\dot{Q}_{total} = (571\ \text{W})\frac{(5\ \text{m})(8\ \text{m})}{0.12\ \text{m}^2}$$
$$\dot{Q}_{total} = 1.90 \times 10^5\ \text{W}$$
$$\boxed{\dot{Q}_{total} = 1.90 \times 10^5\ \text{W}}$$

Step 8 of 9

(b) The total thermal resistance between left surface and the point where the sections B, D, and E meet is

$$R_{total} = R_1 + R_{mid,1}$$
$$= 0.04 + 0.025$$
$$= 0.065\ ^\circ\text{C/W}$$

Then the temperature at the point where The sections B, D, and E meet becomes

$$\dot{Q} = \frac{T_1 - T}{R_{total}}$$
$$T = T_1 - \dot{Q}R_{total}$$
$$= 300^\circ\text{C} - (571\ \text{W})(0.065\ ^\circ\text{C/W})$$
$$= 263^\circ C$$
$$\boxed{T = 263^\circ C}$$

Step 9 of 9

(c) The temperature drop across the section F can be determined from

$$\dot{Q} = \frac{\Delta T}{R_7}$$
$$\Delta T = \dot{Q}R_7$$
$$= (571\ \text{W})(0.25\ ^\circ\text{C/W})$$
$$= 143^\circ\text{C}$$
$$\boxed{\Delta T = 143^\circ\text{C}}$$

Question: 17.059P pg 1

Clothing made of several thin layers of fabric with trapped air in between, often called ski clothing, is commonly used in cold climates because it is light, fashionable, and a very effective thermal insulator. So it is no surprise that such clothing has largely replaced thick and heavy old-fashioned coats.

Consider a jacket made of five layers of 0.15-mm-thick synthetic fabric (k = 0.13 W/m·K) with 1.5-mm-thick air space (k = 0.026 W/m·K) between the layers. Assuming the inner surface temperature of the jacket to be 25°C and the surface area to be 1.25 m2, determine the rate of heat loss through the jacket when the temperature of the outdoors is 0°C and the heat transfer coefficient at the outer surface is 25 W/m2. K.

What would your response be if the jacket is made of a single layer of 0.75-mm-thick synthetic fabric? What should be the thickness of a wool fabric (k = 0.035 W/m·K) if the person is to achieve the same level of thermal comfort wearing a thick wool coat instead of a five-layer ski jacket?

FIGURE P17–59

Step 1 of 8

Given data:

Thickness of the jacket, $t_1 = 0.15\text{mm} = 0.00015\text{m}$

Thickness of the airspace, $t_2 = 1.5\text{mm} = 0.0015\text{m}$

Thermal conductivity of the jacket, $k_1 = k_3 = k_5 = k_7 = k_9 = 0.13\,\text{W/m-K}$

Thermal conductivity of the air, $k_2 = k_4 = k_6 = 0.026\,\text{W/m-K}$

Inner surface temperature of the jacket, $T_1 = 25^\circ\text{C}$

Outdoor temperature, $T_{\infty,2} = 0^\circ\text{C}$

Heat transfer coefficient on the outer surface, $h_2 = 25\,\text{W/m}^2\text{-K}$

Surface area of the Jacket, $A = 1.25\text{m}^2$

Step 2 of 8

Step 3 of 8

With five layered synthetic fabric:

The individual resistances are evaluated as:

$$R_{fabric} = R_1 = R_3 = R_5 = R_7 = R_9$$

$$= \frac{t_1}{k_1 A_1}$$

$$= \frac{0.00015(\text{m})}{0.13(\text{W/m-K}) \times 1.25(\text{m}^2)}$$

$$= 0.0009231\text{K/W}$$

$$R_{air} = R_2 = R_4 = R_6 = R_8$$

$$= \frac{t_2}{k_2 A_2}$$

$$= \frac{0.0015(\text{m})}{0.026(\text{W/m-K}) \times 1.25(\text{m}^2)}$$

$$= 0.04615\text{K/W}$$

$$R_o = R_{conv,2}$$

$$= \frac{1}{h_2 A_2}$$

$$= \frac{1}{25(\text{W/m}^2\text{-K}) \times 1.25(\text{m}^2)}$$

$$= 0.032\text{K/W}$$

Step 4 of 8

All the resistances are in series, and the total resistance is

$$R_{total} = 5R_{fabric} + 4R_{air} + R_o$$

$$= 5 \times 0.0009231(\text{K/W}) + 4 \times 0.04615(\text{K/W}) + 0.032(\text{K/W})$$

$$= 0.2212\text{K/W}$$

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{(T_1 - T_{\infty,2})}{R_{total}}$$

$$= \frac{(25-0)}{0.2212(\text{K/W})}$$

$$= 113\text{W}$$

$$\boxed{\dot{Q}_{total} = 113\text{W}}$$

Step 5 of 8

Step 6 of 8

If the jacket is made of a single layer of 0.75 mm thick synthetic fabric, the rate of heat transfer would be calculated as

$$R_{fabric} = \frac{t_1}{k_1 A_1}$$

$$= \frac{0.00075(\text{m})}{0.13(\text{W/m-K}) \times 1.25(\text{m}^2)}$$

$$= 0.0004615\text{K/W}$$

$$R_o = R_{conv,2}$$

$$= \frac{1}{h_2 A_2}$$

$$0.13(\text{W/m-K})\times 1.25(\text{m}^2)$$

$$= 0.0004615\text{K/W}$$

$$R_o = R_{conv,2}$$

$$= \frac{1}{h_2 A_2}$$

$$= \frac{1}{25(\text{W/m}^2\text{-K})\times 1.25(\text{m}^2)}$$

$$= 0.032\text{K/W}$$

Step 7 of 8

All the resistances are in series, and the total resistance is

$$R_{total} = R_{fabric} + R_o$$

$$= 0.0004615\,(\text{K/W}) + 0.032\,(\text{K/W})$$

$$= 0.0366\text{K/W}$$

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{(T_1 - T_{\infty,2})}{R_{total}}$$

$$= \frac{(25-0)}{0.0366\,(\text{K/W})}$$

$$= 682.77\text{W}$$

Since the Jacket is made with single layer, the heat transfer rate increased by 6 times, this is due to the fact that the jacket with air space having high resistance or low conductance to conduct heat across the jacket.

$$\boxed{\dot{Q}_{total} = 682.77\text{W}}$$

Step 8 of 8

In order to have the same level of thermal comfort with wool coat, the thickness of the jacket can be calculated as follows,

$$R_{total} = R_{wool} + R_o = 0.2212\text{K/W}$$

$$R_{wool} = \frac{t}{kA}$$

$$= \frac{t}{0.035(\text{W/m-K})\times 1.25(\text{m}^2)}$$

$$R_o = R_{conv,2}$$

$$= \frac{1}{h_2 A_2}$$

$$= \frac{1}{25(\text{W/m}^2\text{-K})\times 1.25(\text{m}^2)}$$

$$= 0.032\text{K/W}$$

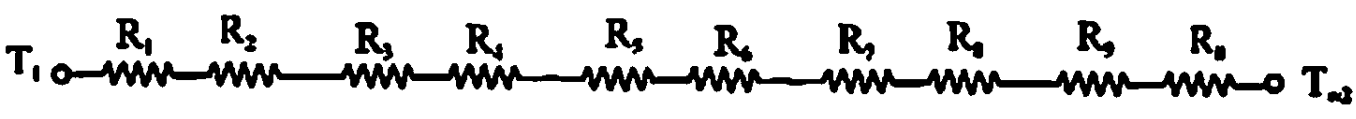
$$R_{wool} + R_o = 0.2212\text{K/W}$$

$$\frac{t}{0.035\,(\text{W/m-K})\times 1.25(\text{m}^2)} + 0.032\,(\text{K/W}) = 0.2212\text{K/W}$$

$$t = 0.0082775\text{m}$$

Therefore, the thickness of the wool coat, $t = 0.0082775\text{m}$

$$\boxed{t = 8.2775\text{mm}}$$



Question: 17.060P

Repeat Prob. 17-59 assuming the layers of the jacket are made of cotton fabric (k = 0.06 W/m·K).

Step 1 of 8

Loading solution. Please wait ...

Step 2 of 8

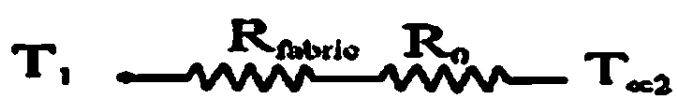
Step 3 of 8

With five layered synthetic fabric:
The individual resistances are evaluated as:

$$R_{fabric} = R_1 = R_3 = R_5 = R_7 = R_9$$

Step 4 of 8

All the resistances are in series, and the total resistance is



$$R_{total} = 5R_{fabric} + 4R_{air} + R_o$$
$$= 5\times 0.002(\text{K/W}) + 4\times 0.04615(\text{K/W}) + 0.032(\text{K/W})$$
$$= 0.2266\,\text{K/W}$$

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{(T_1 - T_{\infty,2})}{R_{total}}$$
$$= \frac{(25-0)}{0.2266\,(\text{K/W})}$$
$$= 110.33\,\text{W}$$

$$\boxed{\dot{Q}_{total} = 113\,\text{W}}$$

Step 5 of 8

Step 6 of 8

If the jacket is made of a single layer of 0.75 mm thick synthetic fabric, the rate of heat transfer would be calculated as

$$R_{fabric} = \frac{t_1}{k_1 A_1}$$
$$= \frac{0.00075(\text{m})}{0.06\,(\text{W/m-K})\times 1.25(\text{m}^2)}$$
$$= 0.01\,\text{K/W}$$

$$R_o = R_{conv,2}$$
$$= \frac{1}{h_2 A_2}$$
$$= \frac{1}{25(\text{W/m}^2\text{-K})\times 1.25(\text{m}^2)}$$
$$= 0.032\,\text{K/W}$$

Step 7 of 8

All the resistances are in series, and the total resistance is

$$R_{total} = R_{fabric} + R_o$$
$$= 0.01(\text{K/W}) + 0.032(\text{K/W})$$
$$= 0.042\,\text{K/W}$$

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{(T_1 - T_{\infty,2})}{R_{total}}$$
$$= \frac{(25-0)}{0.042\,(\text{K/W})}$$
$$= 595.24\,\text{W}$$

Since the Jacket is made with single layer, the heat transfer rate increased by 6 times, this is due to the fact that the jacket with air space having high resistance or low conductance to conduct heat across the jacket.

$$\boxed{\dot{Q}_{total} = 595.24\,\text{W}}$$

Step 8 of 8

In order to have the same level of thermal comfort with wool coat, the thickness of the jacket can be calculated as follows,

$$R_{total} = R_{wool} + R_o = 0.2266\,\text{K/W}$$

$$R_{wool} = \frac{t}{kA}$$
$$= \frac{t}{0.035(\text{W/m-K})\times 1.25(\text{m}^2)}$$

$$R_o = R_{conv,2}$$
$$= \frac{1}{h_2 A_2}$$
$$= \frac{1}{25(\text{W/m}^2\text{-K})\times 1.25(\text{m}^2)}$$
$$= 0.032\,\text{K/W}$$

$$R_{wool} + R_o = 0.2266\,\text{K/W}$$

$$\frac{t}{0.035\,(\text{W/m-K})\times 1.25(\text{m}^2)} + 0.032\,(\text{K/W}) = 0.2266\,\text{K/W}$$

$$t = 0.00851375\,\text{m}$$

Therefore, the thickness of the wool coat, $t = 0.00851375\,\text{m}$

$$\boxed{t = 8.51375\,\text{mm}}$$

Question: 17.061P

In an experiment to measure convection heat transfer coefficients, a very thin metal foil of very low emissivity (e.g., highly polished copper) is attached on the surface of a slab of material with very low thermal conductivity. The other surface of the metal foil is exposed to convection heat transfer by flowing fluid over the foil surface. This setup diminishes heat conduction through the slab and radiation on the metal foil surface, while heat convection plays the prominent role. The slab on which the metal foil is attached to has a thickness of 25 mm and a thermal conductivity of 0.023 W/m·K. In a condition where the surrounding room temperature is 20°C, the metal foil is heated electrically with a uniform heat flux of 5000 W/m2. If the bottom surface of the slab is 20°C and the metal foil has an emissivity of 0.02, determine.

(a) The convection heat transfer coefficient if air is flowing over the metal foil and the surface temperature of the foil is 150°C.

(b) The convection heat transfer coefficient if water is flowing over the metal foil and the surface temperature of the foil is 30°C.

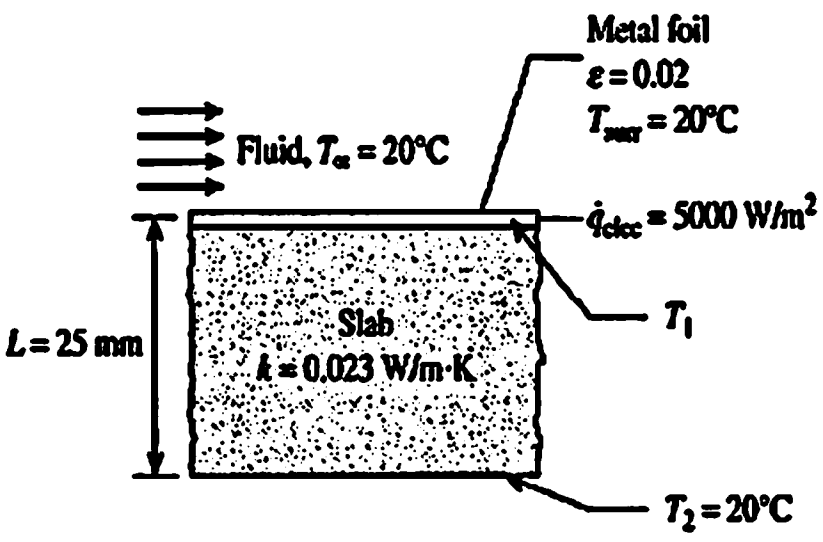


FIGURE P17–61

Step 1 of 3

The foil is heated electrically with a uniform flux of $5000\ W/m^2$. The electrical energy supplied is lost in three ways. They are conduction through the slab, convection from the foil and radiation from the foil.

Foil setup results in diminishing of heat conduction through the slab and radiation from the metal foil. Thus, only convection from the foil helps in conservation of energy.

$\dot{q}_{elec} = \dot{Q}_{conv}$ ..... (1)

Write the formula for rate of heat transferred by convection from metal foil.

$\dot{Q}_{conv} = h(T_s - T_\infty)$

Here, convection heat transfer coefficient is h.

Substitute $h(T_s - T_\infty)$ for $\dot{Q}_{conv}$ in equation (1).

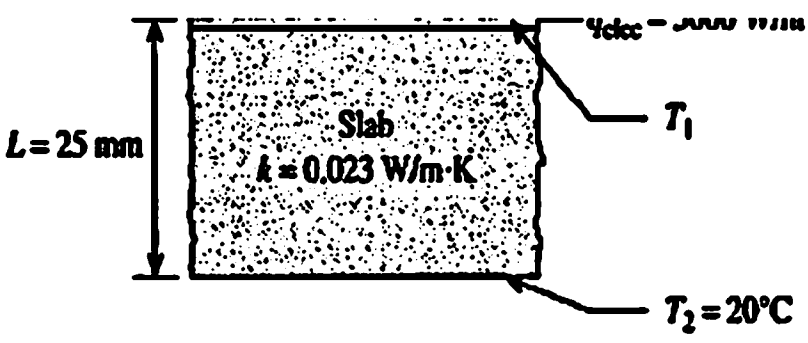

FIGURE P17–61

Step 1 of 3

The foil is heated electrically with a uniform flux of $5000\ W/m^2$. The electrical energy supplied is lost in three ways. They are conduction through the slab, convection from the foil and radiation from the foil.

Foil setup results in diminishing of heat conduction through the slab and radiation from the metal foil. Thus, only convection from the foil helps in conservation of energy.

$\dot{q}_{elec} = \dot{Q}_{conv}$ ..... (1)

Write the formula for rate of heat transferred by convection from metal foil.

$\dot{Q}_{conv} = h(T_s - T_\infty)$

Here, convection heat transfer coefficient is h.

Substitute $h(T_s - T_\infty)$ for $\dot{Q}_{conv}$ in equation (1).

Calculate the convection heat transfer coefficient when water is flowing over the surface of the metal foil at $30\ °C$ by using the relation in equation (2) as shown.

$\dot{q}_{elec} = h(T_s - T_\infty)$

Substitute $5000\ W/m^2$ for $\dot{q}_{elec}$, $(30+273)\ K$ for T_s , and $(20+273)\ K$ for T_∞ in equation (2).

$$5000 = h[(30+273)-(20+273)]$$
$$5000 = h(30-20)$$
$$h = \frac{5000}{10}$$
$$= 500\ W/m^2 \cdot K$$

Therefore, the convection heat transfer coefficient when water is flowing over the surface of the metal foil at $30\ °C$ is $\boxed{500\ W/m^2 \cdot K}$.

Question: 17.062P

Consider a 10-in × 12-in epoxy glass laminate (k = 0.10 Btu/h·ft·°F) whose thickness is 0.05 in. In order to reduce the thermal resistance across its thickness, cylindrical copper fillings (k = 223 Btu/h·ft·°F) of 0.02 in diameter are to be planted throughout the board, with a center-to-center distance of 0.06 in. Determine the new value of the thermal resistance of the epoxy board for heat conduction across its thickness as a result of this modification.

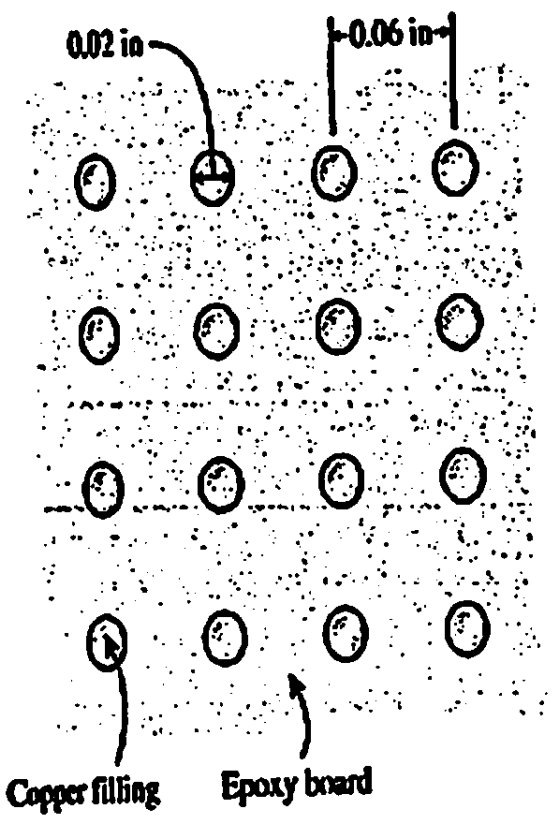

FIGURE P17–62E

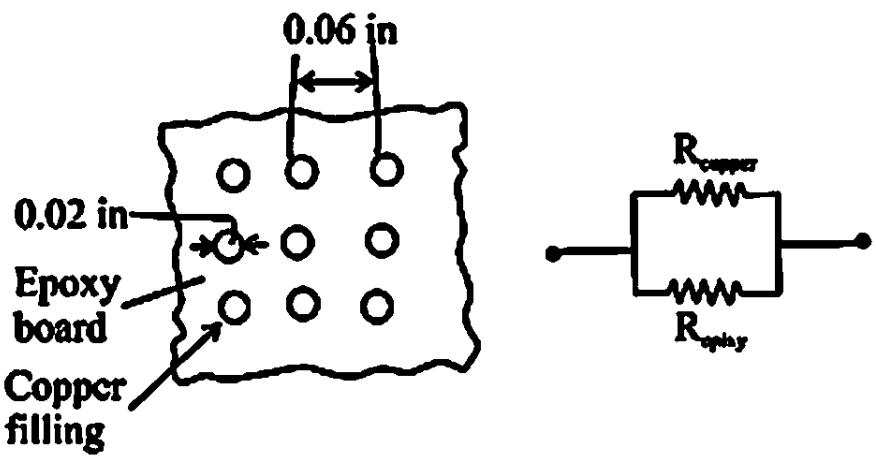
Step 1 of 5

Given data:

Cross sectional are of the laminate, $A = 10 \times 12 \text{in}^2 = 120 \text{in}^2$



Thickness of the epoxy board, $t_1 = 0.05 \text{in}$

Thermal conductivity of the epoxy, $k_1 = 0.1 \text{Btu/h-ft-}^\circ\text{F}$

Thermal conductivity of the copper, $k_2 = 223 \text{Btu/h-ft-}^\circ\text{F}$

Diameter of the copper fillings, $d = 0.02 \text{in}$

Step 2 of 5

Step 3 of 5

The thermal resistances of copper fillings and the epoxy board are in parallel. The number of copper fillings in the board and the area they comprise are

$$A_{total} = \frac{10}{12} \times \frac{12}{12} \text{ft}^2$$
$$= 0.8333 \text{ft}^2$$

Number of copper fillings can be determined as

$$n_{copper} = \frac{0.8333(\text{ft}^2)}{0.06/12 \times 0.06/12(\text{ft}^2)}$$
$$= 33333$$

Area of the copper fillings can be determined as

$$A_{copper} = n\frac{\pi}{4} \times d^2 \text{ft}^2$$
$$= 33333 \times \frac{\pi}{4} \times \left(\frac{0.02}{12}\right)^2 \text{ft}^2$$
$$= 0.07272 \text{ ft}^2$$

Area of the epoxy can be calculated as

$$A_{epoxy} = A_{total} - A_{copper}$$
$$= (0.8333 - 0.07272)\text{ft}^2$$
$$= 0.7605 \text{ft}^2$$

Step 4 of 5

The Thermal resistances are evaluated to be

$$R_{copper} = \frac{t_2}{k_2 A_{copper}}$$
$$= \frac{0.05/12\,(\text{ft})}{223(\text{Btu/h-ft-}^\circ\text{F}) \times 0.07272(\text{ft}^2)}$$
$$= 0.000257 \text{h-}^\circ\text{F/Btu}$$

$$R_{epoxy} = \frac{t_1}{k_1 A_{epoxy}}$$
$$= \frac{0.05/12(\text{ft})}{0.1(\text{Btu/h-ft-}^\circ\text{F}) \times 0.7605(\text{ft}^2)}$$
$$= 0.0548 \text{h-}^\circ\text{F/Btu}$$

Step 5 of 5

Then the thermal resistance of the entire epoxy board becomes

$$\frac{1}{R_{board}} = \frac{1}{R_{copper}} + \frac{1}{R_{epoxy}}$$
$$= \frac{1}{0.000257(\text{h-}^\circ\text{F/Btu})} + \frac{1}{0.0548(\text{h-}^\circ\text{F/Btu})}$$
$$= 3909.3 \text{Btu/h-}^\circ\text{F}$$

Therefore the epoxy board resistance is

$$R_{board} = \frac{1}{3909.3(\text{Btu/h-}^\circ\text{F})}$$
$$= 0.000256 \text{h-}^\circ\text{F/Btu}$$

$$\boxed{R_{board} = 0.000256 \text{h-}^\circ\text{F/Btu}}$$

Question: 17.063P

What is an infinitely long cylinder? When is it proper to treat an actual cylinder as being infinitely long , and when is it not?

Step 1 of 1

When the diameter of cylinder is very small compared to its length, it can be treated as an indefinitely long cylinder.
Cylindrical rods can also be treated as being infinitely long when dealing with heat transfer at locations far from the top or bottom surfaces. However, it is not proper to use this model when finding temperatures near the bottom and the top of the cylinder.

Question: 17.064P

Can the thermal resistance concept be used for a solid cylinder or sphere in steady operation? Explain.

Step 1 of 1

No. In steady-operation the temperature of a solid cylinder or sphere does not change in radial direction (unless there is heat generation).

Question: 17.065P

Consider a short cylinder whose top and bottom surfaces are insulated. The cylinder is initially at a uniform temperature *Ti* and is subjected to convection from its side surface to a medium at temperature T_∞, with a heat transfer coefficient of *h*. Is the heat transfer in this short cylinder one- or two-dimensional? Explain.

Step 1 of 1

Heat transfer in this short cylinder is one-dimensional since there will be no heat transfer in the axial and tangential directions.

Question: 17.066P pg 1

An 8-m-internal-diameter spherical tank made of 1.5-cm-thick stainless steel (k =15 W/m·K) is used to store iced water at 0°C. The tank is located in a room whose temperature is 25°C. The walls of the room are also at 25° C. The outer surface of the tank is black (emissivity ε = 1), and heat transfer between the outer surface of the tank and the surroundings is by natural convection and radiation. The convection heat transfer coefficients at the inner and the outer surfaces of the tank are 80 W/m2·K and 10 W/m2·K, respectively. Determine (*a*) the rate of heat transfer to the iced water in the tank and (*b*) the amount of ice at 0°C that melts during a 24-h period. The heat of fusion of water at atmospheric sure is *hif*=333.7 kJ/kg.

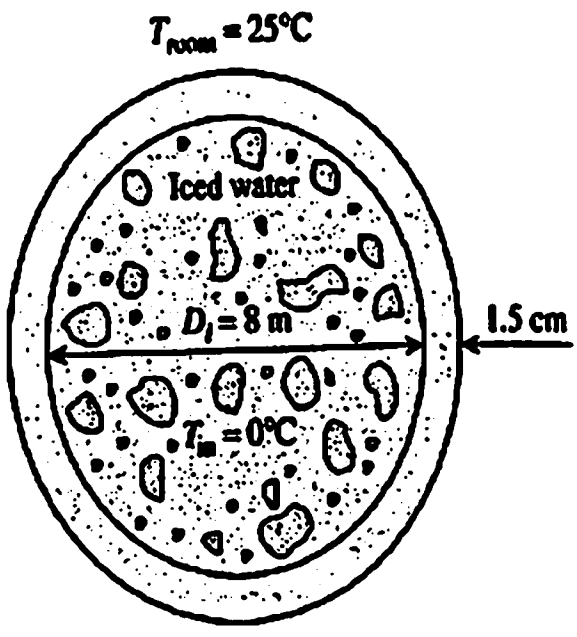


FIGURE P17–66

Step 1 of 8

Calculate the outer diameter of the spherical tank

$$D_o = D_i + 2t$$

Here, D_o is the outer diameter of the spherical tank, D_i is the inner diameter of the spherical tank and t is the thickness of the spherical tank.

Substitute $8\,\text{m}$ for D_i, $0.015\,\text{m}$ for t

$$\begin{aligned} D_o &= D_i + 2t \\ &= 8 + (2 \times 0.015) \\ &= 8.03\,\text{m} \end{aligned}$$

Step 2 of 8

Calculate the inside area of the spherical tank

$$\begin{aligned} A_i &= \pi D_i^2 \\ &= \pi (8\,\text{m})^2 \\ &= 201.06\,\text{m}^2 \end{aligned}$$

Calculate the outside area of the spherical tank

$$\begin{aligned} A_o &= \pi D_o^2 \\ &= \pi (8.03\,\text{m})^2 \\ &= 202.57\,\text{m}^2 \end{aligned}$$

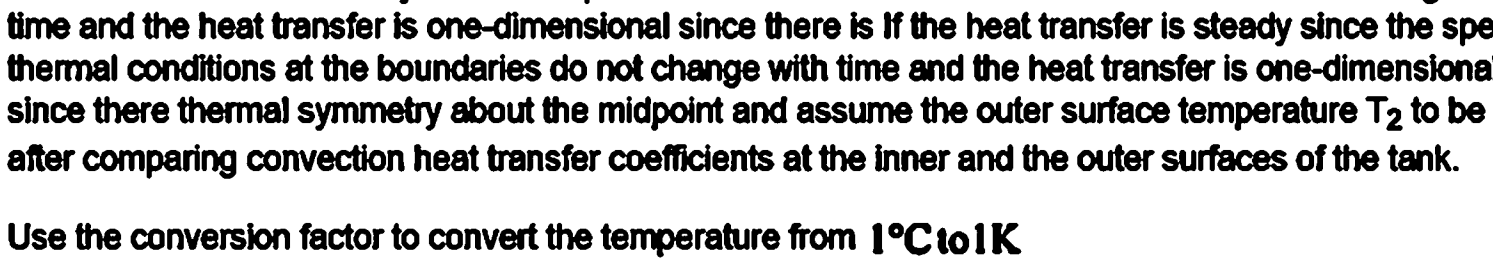
Step 3 of 8

If the heat transfer is steady since the specified thermal conditions at the boundaries do not change with time and the heat transfer is one-dimensional since there is If the heat transfer is steady since the specified thermal conditions at the boundaries do not change with time and the heat transfer is one-dimensional since there thermal symmetry about the midpoint and assume the outer surface temperature T_2 to be 4°C after comparing convection heat transfer coefficients at the inner and the outer surfaces of the tank.

Use the conversion factor to convert the temperature from $1°\text{C to } 1\text{K}$

$$1\text{K} = 1°\text{C} + 273$$

Calculate the radiation heat transfer coefficient



$$h_{rad} = \varepsilon\sigma\left(T_2^2 + T_{surr}^2\right)\left(T_2 + T_{surr}\right)$$

Here, σ is the Stefan Boltzmann constant, ε is the emissivity of the spherical tank, T_2 is the outer surface temperature of the tank and T_{surr} is the surrounding temperature

$$\begin{aligned} h_{rad} &= \varepsilon\sigma\left(T_2^2 + T_{surr}^2\right)\left(T_2 + T_{surr}\right) \\ &= 1\left(5.67 \times 10^{-8}\right)\left[(273+4)^2 + (273+25)^2\right]\left[(273+25) + (273+4)\right] \\ &= 1\left(5.67 \times 10^{-8}\right)(165533)(575) \\ &= 5.39 \end{aligned}$$

Step 4 of 8

Circuit diagram of spherical tank as shown below:

Step 5 of 8

Calculate the inner resistance of the spherical tank

$$R_{conv,1} = R_i = \frac{1}{h_i A_i}$$

Here, h_i is the inside heat transfer coefficient,

Substitute $201.06\,\text{m}^2$ for A_i, $80\,\text{W/m}^2 \cdot °\text{C}$

$$\begin{aligned} R_{conv,1} = R_i &= \frac{1}{h_i A_i} \\ &= \frac{1}{80(201.06)} \end{aligned}$$

$$R_{conv,i} = R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{80(201.06)}$$
$$= 0.0000622\ ^\circ C/W$$

Step 6 of 8

Calculate the resistance of the sphere

$$R_1 = R_{sphere}$$
$$= \frac{r_2 - r_1}{4\pi k r_1 r_2}$$

Substitute $4.015\,m$ for r_2, $4\,m$ for r_1, $15\,W/m\cdot^\circ C$ for k

$$R_1 = R_{sphere}$$
$$= \frac{r_2 - r_1}{4\pi k r_1 r_2}$$
$$= \frac{(4.015-4)\ m}{4\pi(15\ W/m.^\circ C)(4.015\ m)(4\ m)}$$
$$= 0.00000496\ ^\circ C/W$$

Calculate the outer convection resistance

$$R_{conv,o} = \frac{1}{h_o A_0}$$

Here, h_o is the outer heat transfer coefficient

Substitute $202.57\ m^2$ for A_o, $10\ W/m^2\cdot^\circ C$ for h_o

$$R_{conv,o} = \frac{1}{h_o A_0}$$
$$= \frac{1}{(10\ W/m^2.^\circ C)(202.57\ m^2)}$$
$$= 0.00049\ ^\circ C/W$$

Step 7 of 8

Calculate the radiation resistance

$$R_{rad} = \frac{1}{h_{rad} A_0}$$

Here, h_{rad} is the radiation heat transfer coefficient

Substitute $5.39\ W/m^2\cdot^\circ C$ for h_{rad},

$$R_{rad} = \frac{1}{h_{rad} A_0}$$
$$= \frac{1}{(5.57\ W/m^2\cdot^\circ C)(202.57\ m^2)}$$
$$= 0.000886\ ^\circ C/W$$

Calculate the equivalent resistance

$$\frac{1}{R_{eqv}} = \frac{1}{R_{conv,o}} + \frac{1}{R_{rad}}$$
$$= \frac{1}{0.00049} + \frac{1}{0.000886}$$
$$= 0.000316\ ^\circ C/W$$

Calculate the total resistance

$$R_{total} = R_{conv,i} + R_1 + R_{eqv}$$
$$= 0.0000622 + 0.00000496 + 0.000316$$
$$= 0.00038316\ ^\circ C/W$$

(a)

Calculate the steady rate of heat transfer to the iced water

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{total}}$$

Substitute $0.00038316\ ^\circ C/W$ for R_{total}

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{total}}$$
$$= \frac{25-0}{0.00038316}$$
$$= 65246.894\,W$$
$$= 65.246894\,kW$$

Therefore, Steady rate of heat transfer to the iced water is $\boxed{65246.894\,W}$

Step 8 of 8

(b)

Calculate the total amount of heat transfer during a 24-hour period and the amount of ice that will melt during this period

$$Q = \dot{Q}\Delta t$$
$$= 65.246894(24\times 3600)$$
$$= 5.637\times 10^6\ kJ$$

Calculate the amount of ice melted

$$m_{ice} = \frac{Q}{h_{if}}$$
$$= \frac{5.637\times 10^6\ kJ}{333.7\ kJ/kg}$$
$$= 16892.41kg$$

$$m_{ice} = \frac{Q}{h_{if}}$$

$$= \frac{5.637 \times 10^6 \text{ kJ}}{333.7 \text{ kJ/kg}}$$

$$= 16892.41 \text{kg}$$

Therefore, the amount of ice melted is **16892.41kg**

Question: 17.067P

Steam at 280°C flows in a stainless steel pipe (k=15 W/m·K) whose inner and outer diameters are 5 cm and; 5.5 cm, respectively. The pipe is covered with 3-cm-thick glass wool insulation (k= 0.038 W/m· K). Heat is lost to the surroundings at 5°C by natural convection and radiation, with a combined natural convection and radiation heat transfer coefficient of 22 W/m2. K. Taking the heat transfer coefficient inside the pipe to be 80 W/m2. K, determine the rate of heat loss from the steam per unit length of the pipe. Also determine the temperature drops across the pipe shell and the insulation.

Step 1 of 8

Given data:

Inner diameter of the steel pipe, $d = 5\,\text{cm} = 0.05\,\text{m}$

Outer diameter of the steel pipe, $D = 5.5\,\text{cm} = 0.055\,\text{m}$

Thickness of the insulation, $t = 3\,\text{cm} = 0.03\,\text{m}$

Thermal conductivity of the steel pipe, $k_1 = 15\,\text{W/m-K}$

Thermal conductivity of the insulation, $k_2 = 0.038\,\text{W/m-K}$

Inside steam temperature of the pipe, $T_{\infty,1} = 280°\text{C}$

Surroundings temperature, $T_{\infty,2} = 5°\text{C}$

Combined heat transfer coefficient on the outer surface, $h_o = 22\,\text{W/m}^2\text{-K}$

Heat transfer coefficient on the inner surface, $h_i = 80\,\text{W/m}^2\text{-K}$

Step 2 of 8

Let us draw the net work diagram:

Step 3 of 8

The inner and outer surface areas of the insulate pipe per unit length are

$$A_i = \pi dL$$
$$= \pi \times 0.05 \times 1$$
$$= 0.1571\,\text{m}^2$$
$$A_o = \pi D_o L$$
$$= \pi \times (0.055 + 0.06) \times 1$$
$$= 0.3613\,\text{m}^2$$

Step 4 of 8

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{80 \times 0.1571}$$
$$= 0.08\,\text{K/W}$$

$$R_1 = R_{pipe}$$
$$= \frac{\ln(r_2/r_1)}{2\pi k_1 L}$$
$$= \frac{\ln(2.75/2.5)}{2\pi \times 15 \times 1}$$
$$= 0.00101\,\text{K/W}$$

Step 5 of 8

$$R_2 = R_{insulation}$$
$$= \frac{\ln(r_3/r_2)}{2\pi k_2 L}$$
$$= \frac{\ln(5.75/2.75)}{2\pi \times 0.038 \times 1}$$
$$= 3.09\,\text{K/W}$$

$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{22 \times 0.3613}$$
$$= 0.1258\,\text{K/W}$$

Step 6 of 8

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_1 + R_2 + R_o$$
$$= 0.08 + 0.00101 + 3.09 + 0.1256$$
$$= 3.2968\,\text{K/W}$$

Then the steady rate of heat loss from the steam per unit length becomes

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{(280° - 5°)}{3.2968}$$
$$= 83.413\,\text{W}$$

Step 7 of 8

The temperature drop across the steel pipe can be determined as

$$\dot{Q} = \frac{\Delta T_{pipe}}{R_{pipe}}$$

By rewriting the above equation we would get

$$\Delta T_{pipe} = \dot{Q} R_{pipe}$$
$$= 83.413 \times 0.00101$$
$$= 0.08425\,\text{K}$$

Step 8 of 8

The temperature drop across the insulation can be determined as

$$\dot{Q} = \frac{\Delta T_{insulation}}{R_{insulation}}$$

By rewriting the above equation we would get

$$\Delta T_{insulation} = \dot{Q} R_{insulation}$$
$$= 83.413 \times 3.09$$
$$= 257.75\,\text{K}$$

Therefore the temperature drop is $\boxed{\Delta T_{insulation} = 257.75\,\text{K}}$

Question: 17.068P

Reconsider Prob. 17-67. Using EES (or other) software, investigate the effect of the thickness of the insulation on the rate of heat loss from the steam and the temperature drop across the insulation layer. Let the insulation thickness vary from 1 cm to 10 cm. Plot the rate of heat loss and the temperature drop as a function of insulation thickness, and discuss the results.

Step 1 of 9

Given data:

Inner diameter of the steel pipe, $d = 5\,\text{cm} = 0.05\,\text{m}$

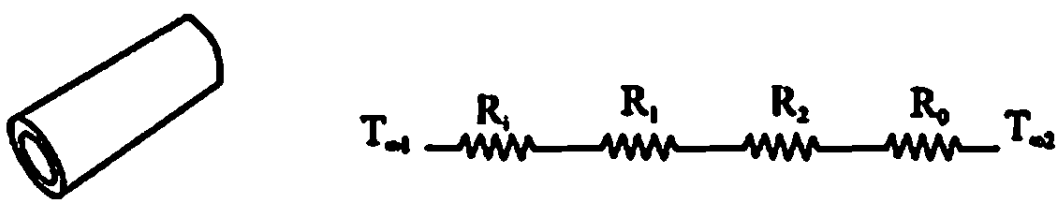
Outer diameter of the steel pipe, $D = 5.5\,\text{cm} = 0.055\,\text{m}$

Thickness of the insulation, $t = (1-10)\,\text{cm}$

Thermal conductivity of the steel pipe, $k_1 = 15\,\text{W/m-K}$

Thermal conductivity of the insulation, $k_2 = 0.038\,\text{W/m-K}$

Inside steam temperature of the pipe, $T_{\infty,1} = 280°\text{C}$



Surroundings temperature, $T_{\infty,2} = 5°\text{C}$

Combined heat transfer coefficient on the outer surface, $h_o = 22\,\text{W/m}^2\text{-K}$

Heat transfer coefficient on the inner surface, $h_i = 80\,\text{W/m}^2\text{-K}$

Step 2 of 9

Thermal network diagram:

Step 3 of 9

The inner and outer surface areas of the insulate pipe per unit length are

$$A_i = \pi dL$$
$$= \pi \times 0.05 \times 1$$
$$= 0.1571\,\text{m}^2$$
$$A_o = \pi D_o L$$
$$= \pi \times (0.055 + 2t) \times 1$$
$$= \pi \times (0.055 + 2t)\,\text{m}^2$$

Step 4 of 9

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{80 \times 0.1571}$$
$$= 0.08\,\text{K/W}$$
$$R_1 = R_{pipe}$$
$$= \frac{\ln(r_2/r_1)}{2\pi k_1 L}$$
$$= \frac{\ln(2.75/2.5)}{2\pi \times 15 \times 1}$$
$$= 0.00101\,\text{K/W}$$

Step 5 of 9

$$R_2 = R_{insulation}$$
$$= \frac{\ln(r_3/r_2)}{2\pi k_2 L}$$
$$= \frac{\ln[(2.75+t)/2.75]}{2\pi \times 0.038 \times 1}$$
$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{22 \times \pi \times (0.055 + 2t)}$$

Step 6 of 9

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_1 + R_2 + R_o$$
$$= 0.08 + 0.00101 + \frac{\ln[(2.75+t)/2.75]}{2\pi \times 0.038 \times 1} + \frac{1}{22 \times \pi \times (0.055 + 2t)}$$

Therefore the heat loss from the steam can be computed by varying the insulation thickness from 1-10 cm using the Excel spread sheet. The heat lost and the temperature drop across the insulation tabulated and plotted as a function of insulation thickness as shown in the below figures.

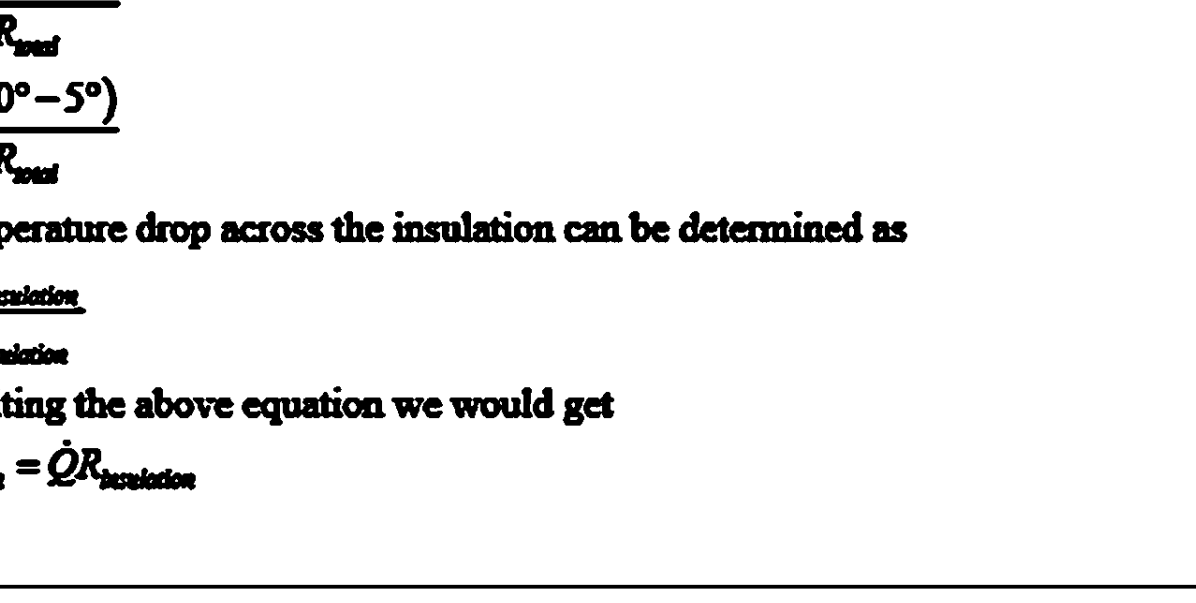
Step 7 of 9

Heat lost from the steam calculated as

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{(280° - 5°)}{R_{total}}$$

The temperature drop across the insulation can be determined as

$$\dot{Q} = \frac{\Delta T_{insulation}}{R_{insulation}}$$



By rewriting the above equation we would get

$$\Delta T_{insulation} = \dot{Q} R_{insulation}$$

Step 8 of 9

Thickness (m)	A_o (m2)	$R_{insulation}$(K/W)	R_o(K/W)	R_{total}(K/W)	Heat loss(W)	ΔT_{ins} (K)
0.01	0.236	1.299	0.193	1.573	174.831	227.109
0.02	0.298	2.289	0.152	2.522	109.023	249.564
0.03	0.361	3.089	0.126	3.296	83.432	257.744
0.04	0.424	3.761	0.107	3.949	69.637	261.895
0.05	0.487	4.339	0.093	4.514	60.924	264.378

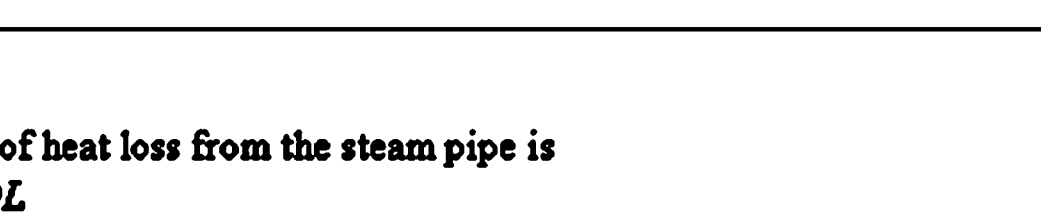
0.07	0.613	5.301	0.074	5.456	50.402	267.177
0.08	0.675	5.710	0.067	5.858	46.943	268.038
0.09	0.738	6.082	0.062	6.225	44.176	268.701
0.1	0.801	6.425	0.057	6.562	41.906	269.227

Step 9 of 9

Question: 17.069P

A 50-m-long section of a steam pipe whose outer diameter is 10 cm passes through an open space at 15°C. The average temperature of the outer surface of the pipe is measured to be 150°C. If the combined heal transfer coefficient on the outer surface of the pipe is 20 W/m2. K, determine (*a*) the rate of heat loss from the steam pipe; (*b*) the annual cost of this energy lost if steam is generated in a natural gas furnace that has an efficiency of 75 percent and the price of natural gas is $0.52/therm (1 therm = 105,500 kJ); and (*c*) the thickness of fiberglass insulation (*k*= 0.035 W/m·K) needed in order to save 90 percent of the heat lost. Assume the pipe temperature to remain constant at 150°C.



Step 1 of 6

Given: -
Length of steam pipe = 50m
Outer diameter of pipe = 10cm
Combined heat transfer coefficient = $20 W/m^{2o} C$
Pipe temperature = 150°C
Thermal conductivity of fiberglass insulation = 0.035 W/m °C

Step 2 of 6

If the heat transfer is steady since there is no indication of any change with time and the heat transfer is one-dimensional since there is thermal symmetry about the center line and no variation in the axial direction

Step 3 of 6

Step 4 of 6

(*a*) The rate of heat loss from the steam pipe is

$$A_s = \pi DL$$
$$= \pi(0.1\text{ m})(50\text{ m})$$
$$= 15.71\text{ m}^2$$
$$\dot{Q}_{conv} = h_o A(T_s - T_{air})$$
$$= (20\text{ W/m}^2.^\circ\text{C})(15.71\text{ m}^2)(150-15)^\circ\text{C}$$
$$= 42412\text{ W}$$

The rate of heat loss from the steam pipe is **42412 W**

Step 5 of 6

(*b*) The amount of heat loss per year is

$$Q = \dot{Q}\Delta t$$
$$= (42.412\text{ kJ/s})(365\times24\times3600\text{ s/yr})$$
$$= 1.337\times10^9\text{ kJ/yr}$$

The amount of gas consumption from the natural gas furnace that has an efficiency of 75% is

$$Q_{gas} = \frac{1.337\times10^9\text{ kJ/yr}}{0.75}\left(\frac{1\text{ therm}}{105{,}500\text{ kJ}}\right)$$
$$= 16{,}903\text{ therms/yr}$$

The annual cost of this energy lost is
Energy cost = (Energy used)(Unit cost of energy)
=(16,903 therms/yr)($0.52/therm)
= $8790/yr

The annual cost of this energy lost is **$8790/yr**

Step 6 of 6

(*c*) In order to save 90% of the heat loss and thus to reduce it to 0.1×42,412 = 4241 W, the thickness of insulation needed is determined from

$$\dot{Q}_{insulated} = \frac{T_s - T_{air}}{R_o + R_{insulation}}$$
$$= \frac{T_s - T_{air}}{\frac{1}{h_o A_o} + \frac{\ln(r_2/r_1)}{2\pi kL}}$$

Substituting and solving for r_2, we get

$$4241\text{ W} = \frac{(150-15)^\circ\text{C}}{\frac{1}{(20\text{ W/m}^2.^\circ\text{C})[(2\pi r_2(50\text{ m})]} + \frac{\ln(r_2/0.05)}{2\pi(0.035\text{ W/m.}^\circ\text{C})(50\text{ m})}}$$

$$r_2 = 0.0692\text{ m}$$

Then the thickness of insulation becomes

$$t_{insulation} = r_2 - r_1$$
$$= 6.92-5$$
$$= 1.92\text{cm}$$

The thickness of insulation is **1.92cm**

Question: 17.070P pg 1

Consider a 1.5-m-high electric hot-water heater that has a diameter of 40 cm and maintains the hot water at 60°C. The tank is located in a small room whose average temperature is 27°C, and the heat transfer coefficients on the inner and outer surfaces of the heater are 50 and 12 W/m2 · K, respectively. The tank is placed in another 46-cm-diameter sheet metal tank of negligible thickness, and the space between the two tanks is filled with foam insulation (k= 0.03 W/m · K). The thermal resistances of the water tank and the outer thin sheet metal shell are very small and can be neglected. The price of electricity is $0.08/kWh, and the home owner pays $280 a year for water heating. Determine the fraction of the hot-water energy cost of this household that is due to the heat loss from the tank.

Hot-water tank insulation kits consisting of 3-cm-thick fiberglass insulation (k =0.035 W/m · K) large enough to wrap the entire tank are available in the market for about $30. If such an insulation is installed on this water tank by the home owner himself, how long will it take for this additional insulation to pay for itself? *Answers;*15.2 percent, 21 months

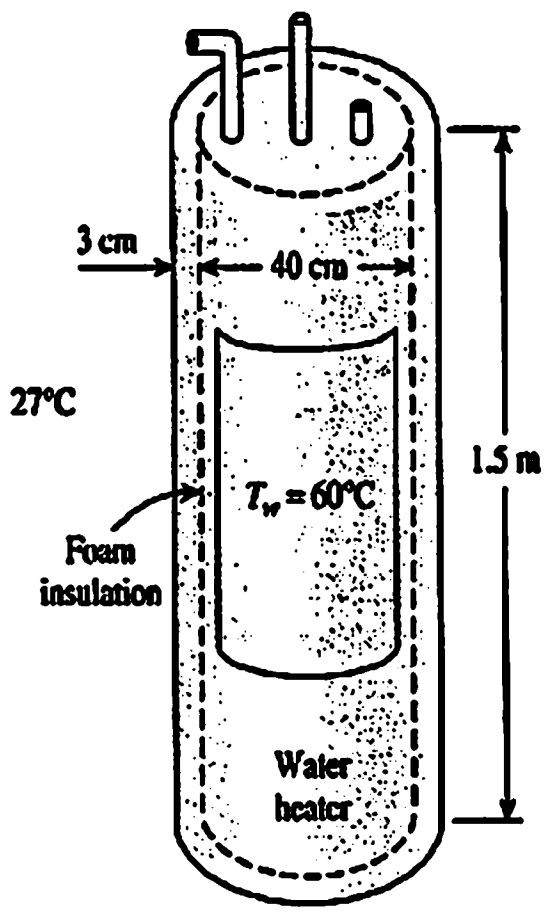


FIGURE P17–70

Step 1 of 13

Given data:

Height of the tank, $L = 1.5\text{m}$

Diameter of the heater, $d_1 = 40\text{cm} = 0.4\text{m}$

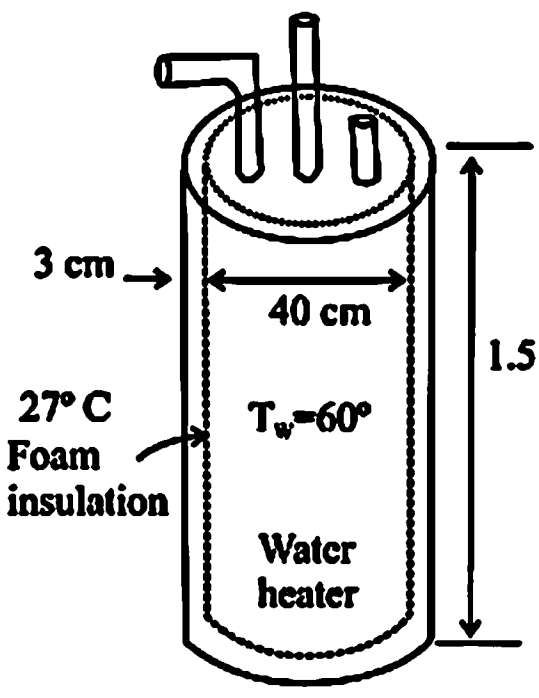
Diameter of the sheet metal tank, $d_2 = 46\text{cm} = 0.46\text{m}$

Heat transfer coefficient on the inner surface of the heater, $h_i = 50\,\text{W/m}^2\cdot\text{K}$

Heat transfer coefficient on the outer surface of the heater, $h_0 = 12\,\text{W/m}^2\cdot\text{K}$

Thermal conductivity of the foam insulation, $k_{foam} = 0.03\,\text{W/m}\cdot\text{K}$

Inside water temperature, $T_w = 60°\text{C}$



Surroundings temperature, $T_{\infty,2} = 27°\text{C}$

Price of electricity = $0.08/kWh

Amount of money paid by house owner = $280/year

Step 2 of 13

Figure representing the water heater

Step 3 of 13

The inner and outer surface areas of the insulate pipe per unit length are

$$A_i = \pi d_1 L$$
$$= \pi \times 0.4 \times 1.5$$
$$= 1.885\ \text{m}^2$$
$$A_0 = \pi d_2 L$$
$$= \pi \times 0.46 \times 1.5$$
$$= 2.1677\ \text{m}^2$$

Step 4 of 13

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{50 \times 1.885}$$
$$= 0.01061\text{K/W}$$
$$R_{foam} = \frac{\ln(r_2/r_1)}{2\pi k_{foam} L}$$
$$= \frac{\ln(0.23/0.2)}{2\pi \times 0.03 \times 1.5}$$
$$= 0.4943\text{K/W}$$
$$R_0 = \frac{1}{h_0 A_0}$$
$$= \frac{1}{12 \times 2.1677}$$
$$= 0.038443\text{K/W}$$

Step 5 of 13

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_{foam} + R_0$$

Step 5 of 13

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_{foam} + R_o$$
$$= 0.01061 + 0.4943 + 0.038443$$
$$= 0.54335\,K/W$$

Then the steady rate of heat loss from the steam per unit length becomes

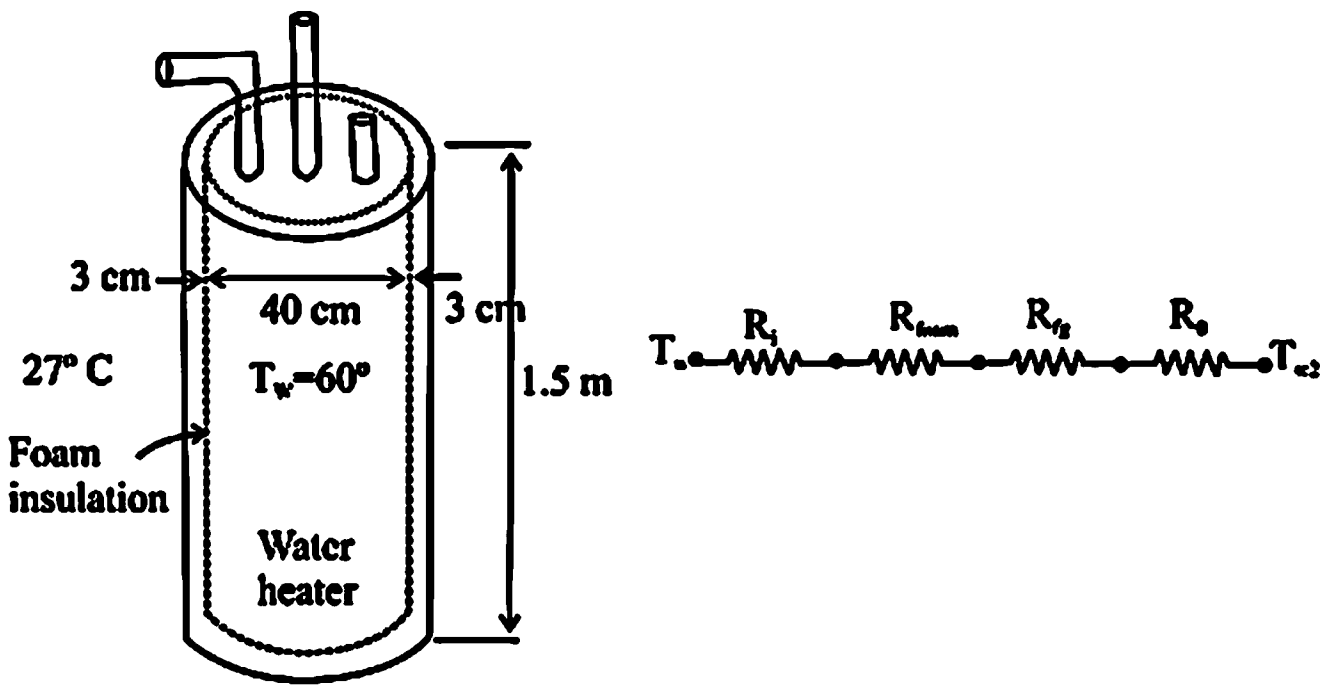
$$\dot{Q} = \frac{(T_w - T_{\infty,2})}{R_{total}}$$
$$= \frac{(60° - 27°)}{0.54335}$$
$$= 60.734\,W$$

$$\boxed{\dot{Q} = 60.734\,W}$$

Step 6 of 13

The amount and cost of heat loss per year are

$$Q = \dot{Q}\Delta t$$
$$= \frac{60.734}{1000} \times (365 \times 24\,h/year)$$
$$= 532.03\,kW\,h/year$$



$$\text{Cost of Energy} = \text{Amount of Energy} \times \text{Unit cost}$$
$$= 532.03\,(kW\,h/year) \times (\$0.08/kWh)$$
$$= \$42.562/year$$

Step 7 of 13

Therefore, the fraction of the hot water energy cost of this household that is due to the heat loss from the tank calculated as

$$f = \frac{\text{cost of energy due to heat loss}}{\text{Amount paid annuallyfor water heating}}$$
$$= \frac{\$42.562/year}{\$280/year}$$
$$= 0.152$$
$$= 15.2\%$$

Step 8 of 13

Step 9 of 13

If 3 cm thick fiber glass insulation is used to wrap the entire tank, the individual resistances becomes

The inner and outer surface areas of the insulate pipe per unit length are

$$A_i = \pi d_1 L$$
$$= \pi \times 0.4 \times 1.5$$
$$= 1.885\,m^2$$
$$A_o = \pi d_3 L$$
$$= \pi \times 0.52 \times 1.5$$
$$= 2.4504\,m^2$$

Step 10 of 13

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{50 \times 1.885}$$
$$= 0.01061 K/W$$
$$R_{foam} = \frac{\ln(r_2/r_1)}{2\pi k_{foam} L}$$
$$= \frac{\ln(0.23/0.2)}{2\pi \times 0.03 \times 1.5}$$
$$= 0.4943 K/W$$

Step 11 of 13

$$R_{fiberglass} = \frac{\ln(r_3/r_2)}{2\pi k_{fiberglass} L}$$
$$= \frac{\ln(0.26/0.23)}{2\pi \times 0.035 \times 1.5}$$
$$= 0.3716 K/W$$
$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{12 \times 2.4504}$$
$$= 0.034 K/W$$

Step 12 of 13

All the resistances are in series, and the total resistance is

$= 0.034\,\text{K/W}$

Step 12 of 13

All the resistances are in series, and the total resistance is

$$\begin{aligned} R_{total} &= R_i + R_{foam} + R_{fiberglass} + R_o \\ &= 0.01061 + 0.4943 + 0.3716 + 0.034 \\ &= 0.91052\,\text{K/W} \end{aligned}$$

Then the steady rate of heat loss from the steam per unit length becomes

$$\begin{aligned} \dot{Q} &= \frac{(T_w - T_{\infty,2})}{R_{total}} \\ &= \frac{(60° - 37°)}{0.91052} \\ &= 36.2431\,\text{W} \end{aligned}$$

The energy saving is

$$\begin{aligned} \text{saving} &= 60.734 - 36.2431 \\ &= 24.5\,\text{W} \end{aligned}$$

Step 13 of 13

The time necessary for this additional insulation to pay for its cost of \$30 is then determined to be

$$\text{cost of extra insulation} = \text{saving} \times \text{time period} \times \text{unit cost}$$

$$\$30 = \frac{24.5}{1000} \times \text{time period} \times (\$0.08/\text{kWh})$$

$$\begin{aligned} \text{time period} &= 15306.12245\,\text{h} \\ &= 15306.12245(\text{h}) \times \left(\frac{1\,\text{year}}{24(\text{h}) \times 365} \right) \\ &= 1.7472\,\text{years} \\ &= 21\,\text{months} \end{aligned}$$

Therefore the payback period is $\boxed{\text{payback period} = 21\,\text{months}}$

Question: 17.071P

Reconsider Prob. 17-70. Using EES (or other) software, plot the fraction of energy cost of hot water due to the heat loss from the tank as a function of the hot-water temperature in the range of 40°C to 90°C. Discuss the results.

Step 1 of 8

Given data:

Height of the tank, $L = 1.5\,\text{m}$

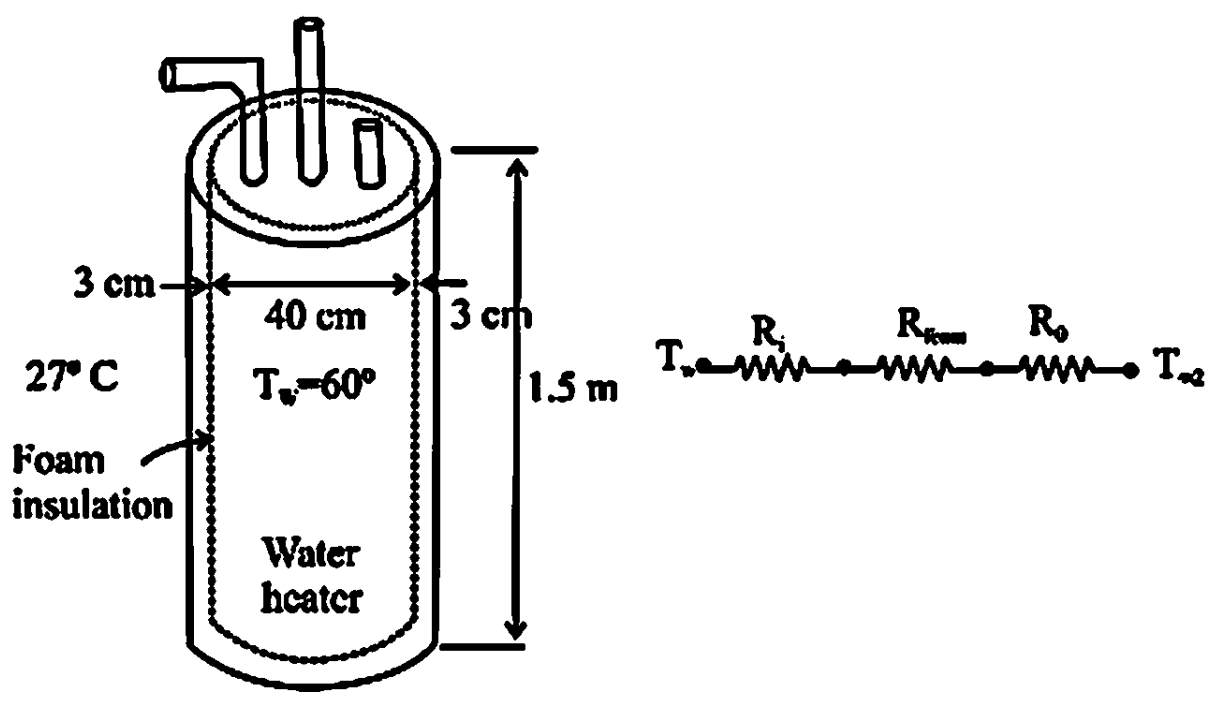
Diameter of the heater, $d_1 = 40\text{cm} = 0.4\text{m}$

Diameter of the sheet metal tank, $d_2 = 46\text{cm} = 0.46\text{m}$

Heat transfer coefficient on the inner surface of the heater, $h_i = 50\,\text{W/m}^2\text{-K}$

Heat transfer coefficient on the outer surface of the heater, $h_0 = 12\,\text{W/m}^2\text{-K}$

Thermal conductivity of the foam insulation, $k_{foam} = 0.03\text{W/m-K}$



Inside water temperature, $T_w = 40 - 90^\circ\text{C}$

Surroundings temperature, $T_{\infty,2} = 27^\circ\text{C}$

Price of electricity = \$0.08/kWh

Amount of money paid by house owner = \$280/year

Step 2 of 8

Step 3 of 8

The inner and outer surface areas of the insulate pipe per unit length are

$$A_i = \pi d_1 L$$
$$= \pi \times (0.4\text{m}) \times (1.5\text{m})$$
$$= 1.885\,\text{m}^2$$
$$A_0 = \pi d_2 L$$
$$= \pi \times (0.46\text{m}) \times (1.5\text{m})$$
$$= 2.1677\,\text{m}^2$$

Step 4 of 8

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{50(\text{W/m}^2\text{-K}) \times 1.885(\text{m}^2)}$$
$$= 0.01061\text{K/W}$$
$$R_{foam} = \frac{\ln(r_2/r_1)}{2\pi k_{foam} L}$$
$$= \frac{\ln(0.23/0.2)}{2\pi \times 0.03(\text{W/m-K}) \times 1.5(m)}$$
$$= 0.4943\text{K/W}$$
$$R_0 = \frac{1}{h_0 A_0}$$
$$= \frac{1}{12(\text{W/m}^2\text{-K}) \times 2.1677(\text{m}^2)}$$
$$= 0.038443\text{K/W}$$

Step 5 of 8

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_{foam} + R_0$$
$$= 0.01061(\text{K/W}) + 0.4943(\text{K/W}) + 0.038443(\text{K/W})$$
$$= 0.54335\text{K/W}$$

Then the steady rate of heat loss from the steam per unit length becomes

$$\dot{Q} = \frac{(T_w - T_{\infty,2})}{R_{total}}$$
$$= \frac{(T_w - 37)}{0.54335(\text{K/W})}$$

Step 6 of 8

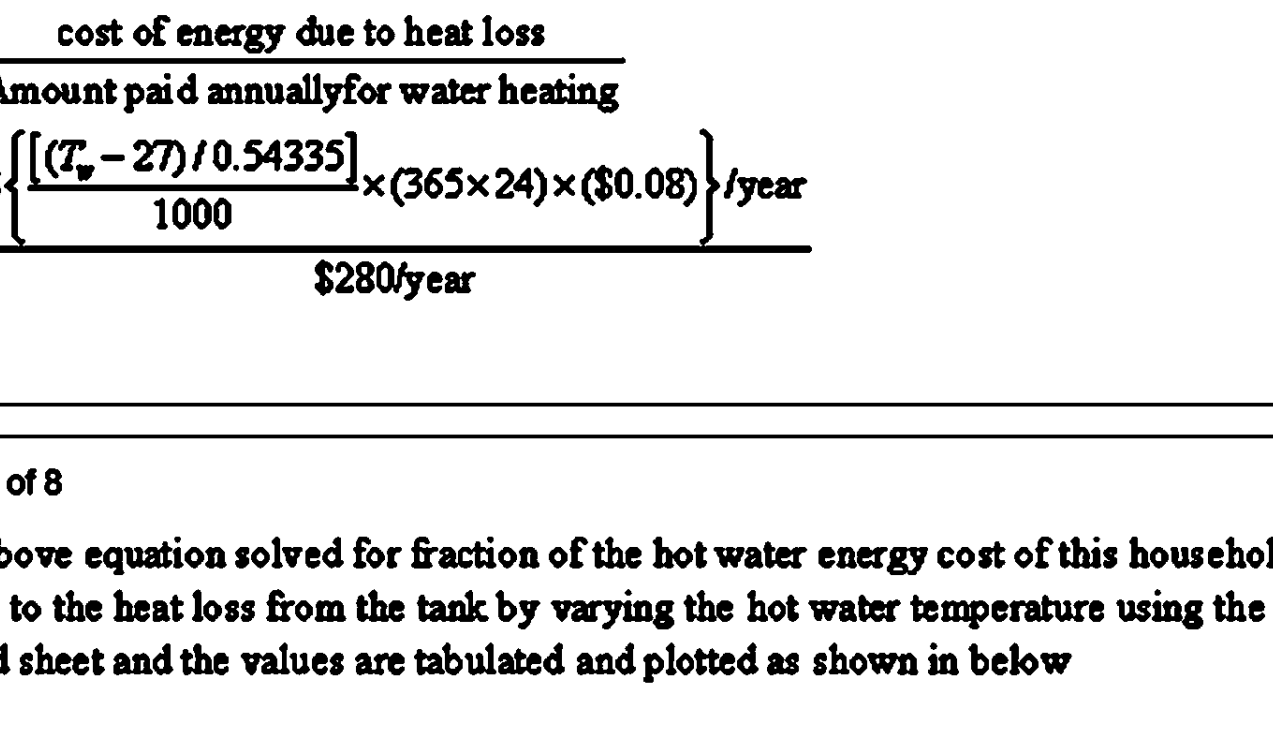
The amount and cost of heat loss per year are

$$Q = \dot{Q}\Delta t$$
$$= \frac{[(T_w - 37)/0.54335]}{1000}(\text{kW}) \times (365 \times 24\text{h/year})$$

Cost of Energy = Amount of Energy × Unit cost

$$= \frac{[(T_w - 37)/0.54335]}{1000} \times (365 \times 24)(\text{kWh/year}) \times (\$0.08/\text{kWh})$$

Therefore, the fraction of the hot water energy cost of this household that is due to the heat loss from the tank calculated as



$$f = \frac{\text{cost of energy due to heat loss}}{\text{Amount paid annuallyfor water heating}}$$
$$= \frac{\$\left\{\frac{[(T_w - 27)/0.54335]}{1000} \times (365 \times 24) \times (\$0.08)\right\}/\text{year}}{\$280/\text{year}}$$

Step 7 of 8

The above equation solved for fraction of the hot water energy cost of this household that is due to the heat loss from the tank by varying the hot water temperature using the Excel spread sheet and the values are tabulated and plotted as shown in below

Hot water Temperature, T_w(°C)	f (%)
40	5.988
45	8.292
50	10.595
55	12.898
60	15.201
65	17.504
70	19.808
75	22.111
80	24.414
85	26.717
90	29.021

Step 8 of 8

Question: 17.072P

Chilled water enters a thin-shelled. 4-cm-diameter, 200-m-long pipe at 7°C at a rate of 0.98 kg/s and leaves at 8°C. The pipe is exposed to ambient air at 30°C with a heat transfer coefficient of 9 W/m2· K. If the pipe is to be insulated with glass wool insulation (k= 0.05 W/m · K) in order to decrease the temperature rise of water to 0.25°C, determine the required thickness of the insulation.

Step 1 of 6

Mean temperature of the pipe,

$$T_w = \frac{T_i + T_e}{2}$$

Substitute 7°C for T_i and 8°C for T_e,

$$T_w = \frac{T_i + T_e}{2} = \frac{8+7}{2} = 7.5°C$$

Heat transfer from the pipe without any insulation,

$$Q_{old} = \dot{m} c_p (T_e - T_i)$$

Here,

Flow rate of chilled water is $\dot{m}$

Substitute 0.98kg/s for $\dot{m}$, $T_\infty = 30°C$ and 4.18 for c_p,

$$Q_{old} = \dot{m} c_p (T_e - T_i) = 0.98 \times 4.18(8-7) = 4.0964 kW = 4096.4 W$$

Step 2 of 6

Heat transfer from the pipe can also be calculated as,

$$Q_{old} = \frac{T_\infty - T_w}{R_{total}}$$

Substitute 4096.4 W for Q_{old}, 30°C for T_∞ and 7.5°C for T_w,

$$Q_{old} = \frac{T_\infty - T_w}{R_{total}}$$

$$4096.4 = \frac{30 - 7.5}{R_{total}}$$

$$R_{total} = 0.00549 K/W$$

The convection resistance from the outer surface of the pipe,

$$R_o = \frac{1}{h_o A_o} = \frac{1}{h_o \times \pi DL} = \frac{1}{9 \times \pi \times 0.04 \times 200} = 0.00442 K/W$$

Step 3 of 6

The inside convective resistance and conduction resistance due to pipe thickness,

$$R_1 = R_{total} - R_o$$

Substitute 0.00549 K/W for R_{total} and 0.00442 K/W for R_o,

$$R_1 = R_{total} - R_o = 0.00549 - 0.00442 = 0.00107 K/W$$

If temperature rise of water is $\Delta T = 0.25°C$ then the rate of heat transfer with new insulation is,

$$Q_{new} = \dot{m} c_p \Delta T = 0.98 \times 4.18 \times 0.25 = 1.0241 kW = 1024.1 W$$

Step 4 of 6

The total thermal resistance with insulation can be calculated as,

$$Q_{new} = \frac{T_\infty - T_w}{R_{total,new}}$$

Substitute 1024.1 W for Q_{new}, 30°C for T_∞ and 7.125°C for T_w,

$$Q_{new} = \frac{T_\infty - T_w}{R_{total,new}}$$

$$1024.1 = \frac{30 - \left(\frac{7+7.25}{2}\right)}{R_{total,new}}$$

$$R_{total,new} = 0.0223 K/W$$

Step 5 of 6

The total thermal resistance with insulation can be written as

$$R_{total,new} = R_1 + R_{o,new} + R_{ins}$$

$$R_{total,new} = R_1 + \frac{1}{h_o A_{o,new}} + \frac{\ln\left(\frac{D_2}{D_1}\right)}{2\pi kL}$$

$$0.0223 = 0.00107 + \frac{1}{9 \times \pi D_2 \times 200} + \frac{\ln \frac{D_2}{0.04}}{2\pi \times 0.05 \times 200}$$

$$0.02123 = \frac{1}{5654.866 D_2} + \frac{\ln \frac{D_2}{0.04}}{62.83}$$

By solving the above equation using any equation solver we get $D_2 = 0.140267 m$

Step 6 of 6

Then the thickness of the insulation can be calculated as,

$$t = \frac{D_2 - D_1}{2} = \frac{0.140267 - 0.04}{2} = 0.0501 m$$

$$\boxed{t = 5.01 cm}$$

Therefore, the thickness of the insulation is 5.01cm

Question: 17.073P

Superheated steam at an average temperature 200°C is transported through a steel pipe (k= 50 W/m · K, $D0$ = 8.0 cm, Di =6.0 cm, and L= 20.0 m). The pipe is insulated with a 4-cm thick layer of gypsum plaster (k =0.5 W/m · K). The insulated pipe is placed horizontally inside a warehouse where the average air temperature is 10°C. The steam and the air heat transfer coefficients are estimated to be 800 and 200 W/m2· K, respectively. Calculate (*a*) the daily rate of heat transfer from the superheated steam, and (*b*) the temperature on the outside surface of the gypsum plaster insulation.

Step 1 of 5

Temperature of superheated steam $T_s = 200°C$

Thermal conductivity of the steel pipe $k_{steel} = 50\,W/m \cdot K$

Outer diameter of the steel pipe $D_o = 8.0\,cm = 0.08\,m$

Inner diameter of the steel pipe $D_i = 6.0\,cm = 0.06\,m$

Length of the steel pipe $L = 20.0\,m$

Thickness of the gypsum plaster $t_{gyp} = 4\,cm = 0.04\,m$

Thermal conductivity of the gypsum plaster $k_{gyp} = 0.5\,W/m \cdot K$

Average air temperature $T_{air} = 10°C$

Heat transfer coefficient of the steam $h_i = 800\,W/m^2.K$

Heat transfer coefficient of the air $h_o = 200\,W/m^2.K$

Step 2 of 5

The thermal resistance network from superheated steam to ambient air can be represented as,

Step 3 of 5

Step 4 of 5

The individual resistances can be calculated as;

Convection resistance due to superheated steam,

$$R_i = \frac{1}{h_i A}$$
$$= \frac{1}{h_i \times \pi D_i L}$$
$$= \frac{1}{800 \times \pi \times 0.06 \times 20}$$
$$= 0.00033\,K/W$$

Conduction resistance due to thickness of the steel pipe is

$$R_{steel} = \frac{\ln\left(\frac{D_o}{D_i}\right)}{2\pi k_{steel} L}$$
$$= \frac{\ln\left(\frac{0.08}{0.06}\right)}{2 \times \pi \times 50 \times 20}$$
$$= 0.0000457\,K/W$$

Conduction resistance due to thickness of the insulation

$$R_{ins} = \frac{\ln\left(\frac{D_o + 2t}{D_o}\right)}{2\pi k_{gyp} L}$$
$$= \frac{\ln\left(\frac{0.08 + 2 \times 0.04}{0.08}\right)}{2 \times \pi \times 0.5 \times 20}$$
$$= 0.01103\,K/W$$

Convection resistance due to air,

$$R_o = \frac{1}{h_o A}$$
$$= \frac{1}{h_o \times \pi (D_o + 2t) L}$$
$$= \frac{1}{200 \times \pi \times (0.08 + 2 \times 0.04) \times 20}$$
$$= 0.000497\,K/W$$

Step 5 of 5

Therefore, the total thermal resistance can be determined as

$$R_{total} = R_i + R_{steel} + R_{ins} + R_o$$
$$= 0.00033 + 0.0000457 + 0.01103 + 0.000497$$
$$= 0.0119027\,K/W$$

Rate of heat transfer from the superheated steam can be calculated as

$$\dot{Q} = \frac{T_s - T_{air}}{R_{total}}$$
$$= \frac{200 - 10}{0.0119027}$$
$$= 15962.76\,W$$

$$\boxed{\dot{Q} = 15.962\,kW}$$

(b)Assume temperature on the outside surface of the gypsum plaster insulation is T_{ins}

The rate of heat transfer on the outer surface of the pipe is

$$\dot{Q} = \frac{T_{ins} - T_{air}}{R_o}$$
$$15962.76 = \frac{T_{ins} - 10}{0.000497}$$
$$T_{ins} = 17.933°C$$

Therefore, temperature of the outside surface of the gypsum plaster insulation is $\boxed{T_{ins} = 17.933°C}$

Question: 17.074P

Steam at 450°F is flowing through a steel pipe (k = 8.7 Btu/h · ft·°F) whose inner and outer diameters are 3.5 in and 4.0 in, respectively, in an environment at 55°F. The pipe is insulated with 2-in-thick fiberglass insulation (k = 0.020 Btu/h · ft · °F). If the heat transfer coefficients on the inside and the outside of the pipe are 30 and 5 Btu/h·ft2·°F, respectively, determine the rate of heat loss from the steam per foot length of the pipe. What is the error involved in neglecting the thermal resistance of the steel pipe in calculations?

Step 1 of 11

Given: -

Inner diameter of pipe $D_i = 3.5\text{in}$

Outer diameter of pipe $D_o = 4.0\text{in}$

Thickness of the insulation $t = 2\text{in}$

Thermal conductivity of fiberglass $k_{fiber\ glass} = 0.020\ \text{Btu/h·ft·°F}$

Thermal conductivity of steel $k_{steel} = 8.7\ \text{Btu/h·ft·°F}$

Heat transfer coefficient on inside of the pipe $h_i = 30\ \text{Btu/h.ft}^2$

Convection heat transfer coefficient outside pipe $h_o = 5\ \text{Btu/h.ft}^2$

Ambient temperature $T_\infty = 55^0\text{F}$

Steam temperature $T = 450^0\text{F}$

Step 2 of 11

If the heat transfer is steady since there is no indication of any change with time and the heat transfer is one-dimensional since there is thermal symmetry about the center line and no variation in the axial direction

The inner and outer surface areas of the insulated pipe per foot length of the pipe are

$$A_i = \pi D_i L$$
$$= \pi(3.5/12)(1)$$
$$A_i = 0.916\ \text{ft}^2$$

$$A_o = \pi(D_o + 2t)L$$
$$= \pi(8/12)(1)$$
$$A_o = 2.094\ \text{ft}^2$$

Step 3 of 11

Thermal resistance circuit of this present system is

Step 4 of 11

The convection resistances on inside of the pipe is

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{(30)\times(0.916)}$$
$$R_i = 0.0363\ \text{h}\cdot{}^\circ\text{F/Btu}$$

Step 5 of 11

Conduction resistance from inner surface to outer surface of the pipe

$$R_1 = R_{pipe} = \frac{\ln(r_o/r_i)}{2\pi k_{steel} L}$$
$$= \frac{\ln(2/1.75)}{2\pi(8.7)\times(1)}$$
$$R_1 = R_{pipe} = 0.00244\ \text{h}\cdot{}^\circ\text{F/Btu}$$

Step 6 of 11

Conduction resistance from outer surface to insulation of the pipe

$$R_2 = R_{insulation}$$
$$= \frac{\ln(r_3/r_o)}{2\pi k_2 L}$$
$$= \frac{\ln((r_o+t)/r_o)}{2\pi k_2 L}$$
$$= \frac{\ln(4/2)}{2\pi(0.020)\times(1)}$$
$$R_2 = R_{insulation} = 5.516\ \text{h}\cdot{}^\circ\text{F/Btu}$$

Step 7 of 11

Convection resistance from outer surface of the pipe to environment

$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{(5)\times(2.094)}$$
$$R_o = 0.096\ \text{h}\cdot{}^\circ\text{F/Btu}$$

Step 8 of 11

Total resistance is

$$R_{total} = R_i + R_1 + R_2 + R_o$$
$$= 0.0363 + 0.00244 + 5.516 + 0.096$$
$$R_{total} = 5.6507\ \text{h}\cdot{}^\circ\text{F/Btu}$$

Step 9 of 11

Then the steady rate of heat loss from the steam per ft. pipe length becomes

$$\dot{Q} = \frac{T - T_\infty}{R_{total}}$$
$$= \frac{(450-55)}{5.6507}$$
$$\dot{Q} = 69.9028\ \text{Btu/h}$$

Step 10 of 11

If the thermal resistance of the steel pipe is neglected, the new value of total thermal resistance will be

$$R_{total,1} = R_i + R_2 + R_o$$
$$= 0.0363 + 5.516 + 0.096$$
$$R_{total,1} = 5.648\ \text{h°F/Btu}$$

Step 11 of 11

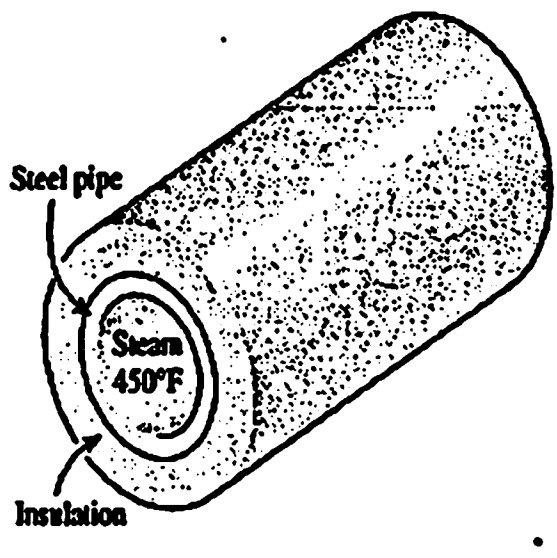
Then the percentage error involved in neglecting the thermal resistance of the steel pipe is

$$\%error = \frac{R_{total} - R_{total,1}}{R_{total}}$$
$$\%error = \frac{(5.6507 - 5.648)}{5.6507}\times 100$$
$$\boxed{\%error = 0.0477\%}$$

Error percentage is not significant

Question: 17.075P pg 1

Hot water at an average temperature of 90°C is flowing through a 15-m section of a cast iron pipe (k = 52 W/m · K) whose inner and outer diameters are 4 cm and 4.6 cm, respectively. The outer surface of the pipe, whose emissivity is 0.7, is exposed to the cold air at 10°C in the basement, with a heat transfer coefficient of 15 W/m2 · K. The heat transfer coefficient at the inner surface of the pipe is 120 W/ m2 · K. Taking the walls of the basement to be at 10°C also, determine the rate of heat loss from the hot water. Also, determine the average velocity of the water in the pipe if the temperature of the water drops by 3°C as it passes through the basement.



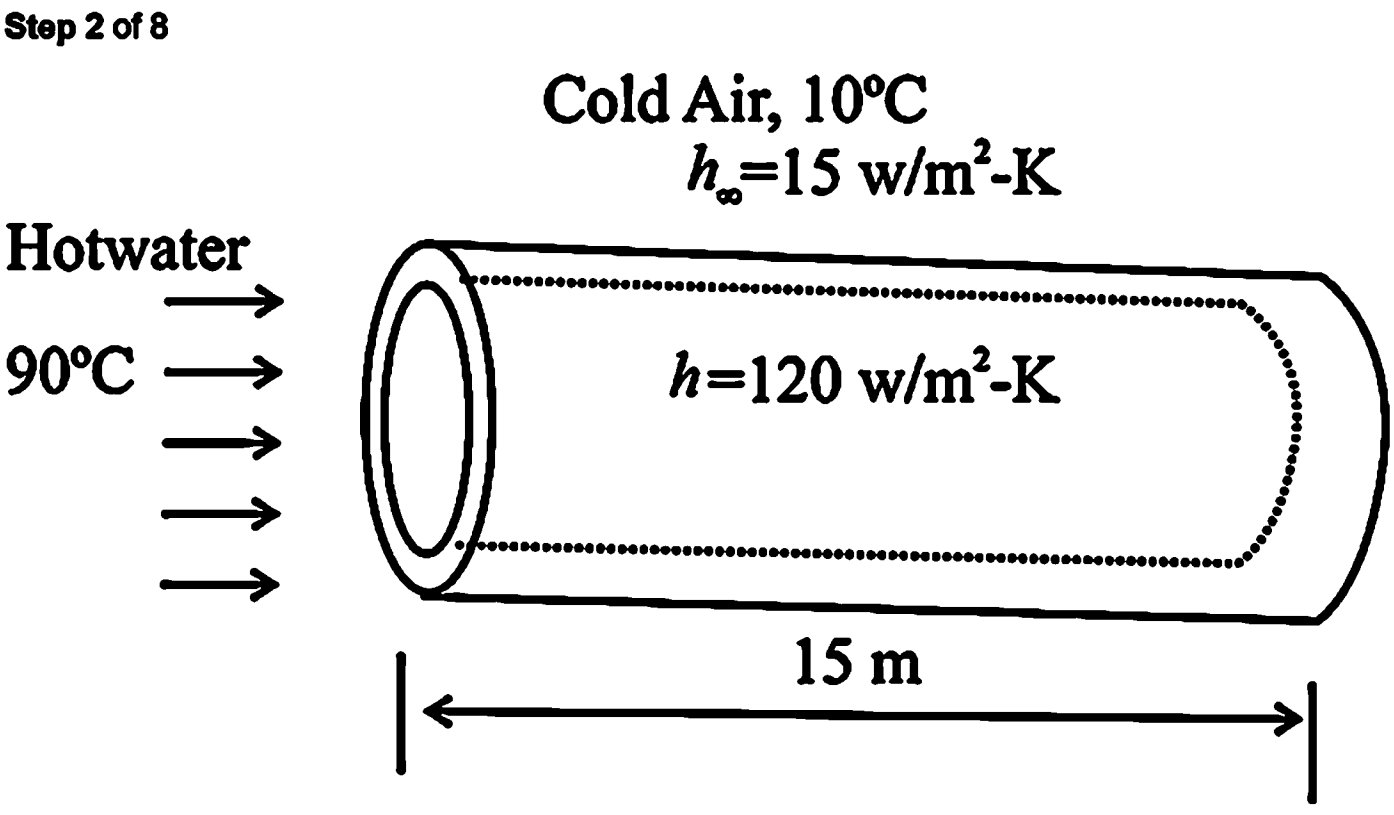


FIGURE P17–75

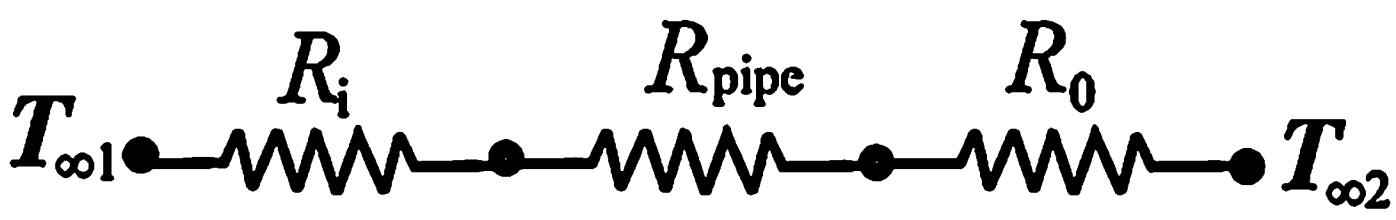


Step 1 of 8

Draw the schematic representation of the given system as shown below:

Step 2 of 8

Draw the thermal resistance circuit from inner surface to outer surface of the pipe as shown below:

Step 3 of 8

Find the inner surface area of the insulated pipe per unit length,

$$A_i = \pi d_1 L$$

Here, d_1 is inner diameter of the pipe, L is length of the pipe.

Substitute $0.04\,\text{m}$ for d_1 and 15 m for L

$$A_i = \pi \times 0.04 \times 15$$
$$= 1.885\,\text{m}^2$$

Find the outer surface area of the insulate pipe per unit length,

$$A_o = \pi d_2 L$$

Here, d_2 is outer diameter of the pipe.

Substitute $0.046\,\text{m}$ for d_2

$$A_o = \pi \times 0.046 \times 15$$
$$= 2.1677\,\text{m}^2$$

Step 4 of 8

Find convective thermal resistance due to hot water flowing through the pipe,

$$R_i = \frac{1}{h_i A_i}$$

Here, h_i is heat transfer coefficient at the inner surface of the pipe

Substitute $120\,\text{W/m}^2 \cdot \text{K}$ for h_i

$$R_i = \frac{1}{120 \times 1.885}$$
$$= 0.004421\,\text{K/W}$$

Find conductive resistance of the pipe by using the equation,

$$R_{pipe} = \frac{\ln(r_2 / r_1)}{2\pi k_{pipe} L}$$

Here, k_{pipe} is thermal conductivity of the pipe.

Substitute $52\,\text{W/m} \cdot \text{K}$ for k

$$R_{pipe} = \frac{\ln(0.023/0.02)}{2\pi \times 52 \times 15}$$
$$= 0.00002852\,\text{K/W}$$

Step 5 of 8

The outer surface temperature of the pipe will be little below the water temperature. Assume the outer surface temperature of the pipe to be 70°C (we will check this assumption later),

Find the radiation heat transfer coefficient by using the equation,

Step 5 of 8

The outer surface temperature of the pipe will be little below the water temperature. Assume the outer surface temperature of the pipe to be 70°C (we will check this assumption later),

Find the radiation heat transfer coefficient by using the equation,

$$h_{rad} = \varepsilon\sigma(T_2^2 + T_{surr}^2)(T_2 + T_{surr})$$

Here, ε is emissivity, σ is Stefan Boltzmann constant, T_2 is outer surface temperature and T_{surr} is surrounding temperature.

Substitute 0.7 for ε, $5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}$ for σ, $70+273=343\,\mathrm{K}$ for T_2 and $10°\mathrm{C}=283\,\mathrm{K}$ for T_{surr}

$$\begin{aligned} h_{rad} &= 0.7\times5.67\times10^{-8}\times\left[343.15^2+283.15^2\right]\times\left[343.15+283.15\right] \\ &= 4.92\,\mathrm{W/m^2\cdot K} \end{aligned}$$

Since the surrounding medium and surfaces are at the same temperature, the radiation and convection heat transfer coefficients can be added and the result can be taken as the combined heat transfer coefficient. Then,

$$h_{combined} = h_{rad} + h_{conv}$$

Here, h_{conv} is convection heat transfer coefficient

Substitute $15\,\mathrm{W/m^2\cdot K}$ for h_{conv}

$$\begin{aligned} h_{combined} &= 4.92+15 \\ &= 19.92\,\mathrm{W/m^2\cdot K} \end{aligned}$$

Find convective thermal resistance from outer surface of the pipe due to cold air,

$$\begin{aligned} R_o &= \frac{1}{h_{combined}A_o} \\ &= \frac{1}{19.92\times2.1677} \\ &= 0.02315\,\mathrm{K/W} \end{aligned}$$

All the resistances are in series, and the total resistance becomes,

$$\begin{aligned} R_{total} &= R_i + R_{pipe} + R_o \\ &= 0.004421+0.00002852+0.02315 \\ &= 0.0276\,\mathrm{K/W} \end{aligned}$$

Find the steady rate of heat loss from the hot water by using the equation,

$$\dot{Q} = \frac{(T_{\infty,1}-T_{\infty,2})}{R_{total}}$$

Here, $T_{\infty,1}$ is hot water temperature and $T_{\infty,2}$ is cold air temperature

Substitute $90°\mathrm{C}$ for $T_{\infty,1}$ and $10°\mathrm{C}$ for $T_{\infty,2}$

$$\begin{aligned} \dot{Q} &= \frac{90-10}{0.0276} \\ &= 2898.5\,\mathrm{W} \end{aligned}$$

Therefore, the steady rate of heat loss from the hot water pipe is, $\boxed{2898.5\,\mathrm{W}}$

Step 6 of 8

Find the mass flow rate of water for a temperature drop of $3°\mathrm{C}$ by using the equation,

$$\dot{Q} = \dot{m}c_p\Delta T$$

Here, c_p is specific heat of water

Substitute $4180\,\mathrm{J/kg\cdot K}$ for c_p

$$\begin{aligned} \dot{m} &= \frac{\dot{Q}}{c_p\Delta T} \\ &= \frac{2898.5}{4180\times3} \\ &= 0.2311\,\mathrm{kg/s} \end{aligned}$$

Step 7 of 8

Find the velocity of water in the pipe by using the equation,

$$\dot{m} = \rho AV$$

Here, ρ is density of water

Substitute $1000\,\mathrm{kg/m^3}$ for ρ

$$\begin{aligned} V &= \frac{\dot{m}}{\rho A} \\ &= \frac{\dot{m}}{\rho\times\frac{\pi}{4}d_1^2} \\ &= \frac{0.2311}{1000\times\frac{\pi}{4}\times0.04^2} \\ &= 0.184\,\mathrm{m/s} \end{aligned}$$

Therefore, the velocity of water in the pipe, $\boxed{0.184\,\mathrm{m/s}}$

Step 8 of 8

Verify the outer surface temperature is correct or not

The outer surface temperature of the pipe by using the equation,

$$\dot{Q} = \frac{(T_{\infty,1}-T_s)}{R_i + R_{pipe}}$$

$$2898.5 = \frac{(90-T_s)}{0.004421+0.00002852}$$

$T_s = 77.18°\mathrm{C}$

$$\dot{Q} = \frac{(T_{\infty,1} - T_s)}{R_1 + R_{pipe}}$$

$$2898.5 = \frac{(90 - T_s)}{0.004421 + 0.00002852}$$

$$T_s = 77.1°C$$

This is very close to the value assumed for the surface temperature in the evaluation of the radiation resistance. Therefore, there is no need to repeat the calculations.

Question: 17.076P

Repeat Prob. 17-75 for a pipe made of copper (k = 386 W/m · K) instead of cast iron.

Step 1 of 8

Given data:

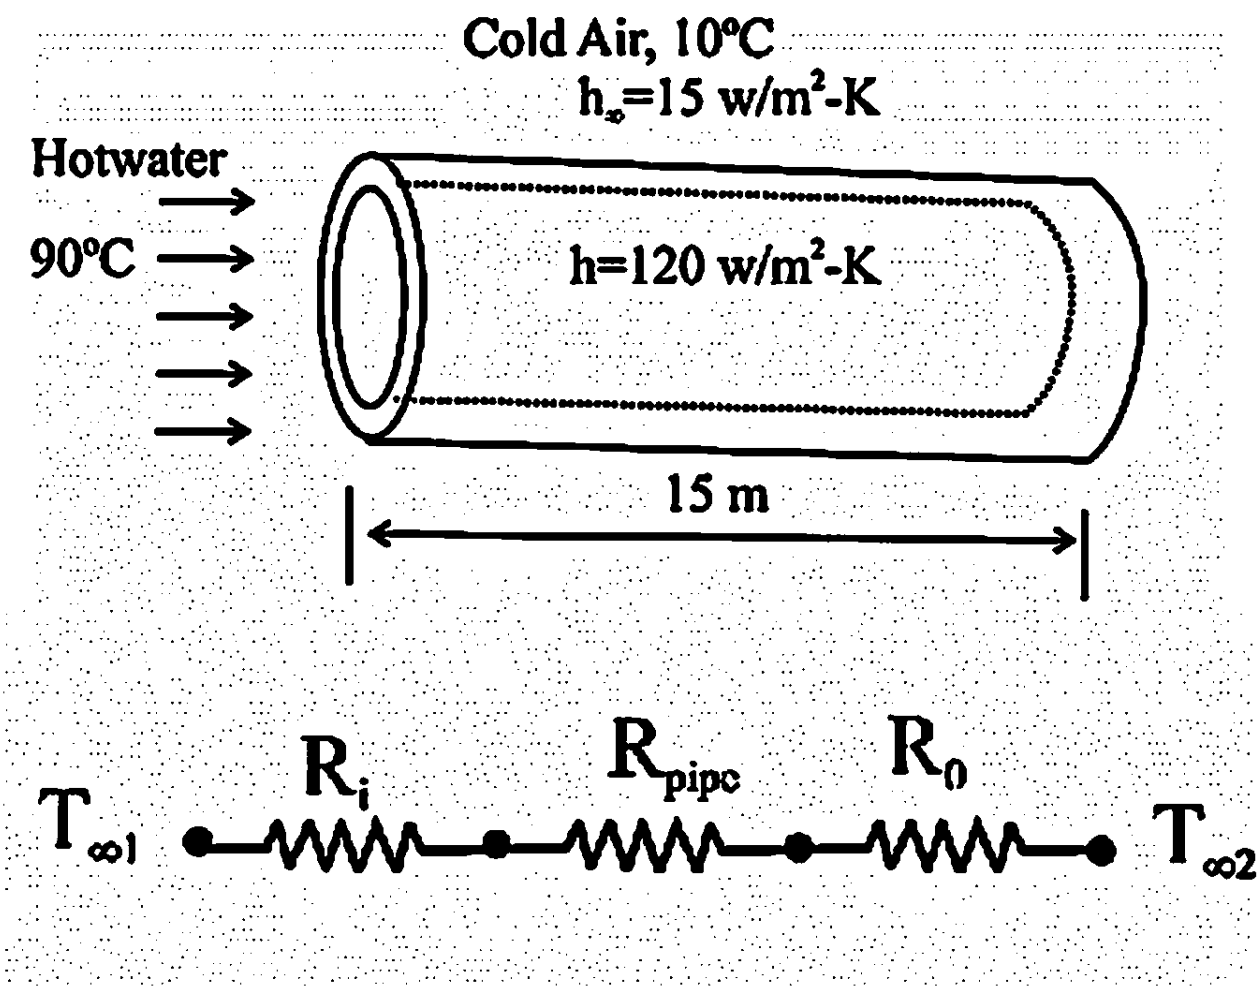
Average temperature of hot water, $T_w = 90°C$

Length of the pipe, $L = 15m$

Thermal conductivity of the copper, $k_{copper} = 386 W/m\text{-}K$

Inner diameter of the pipe, $d_1 = 4cm = 0.04m$

Outer diameter of the pipe, $d_2 = 4.6cm = 0.046m$



Emissivity of the outer surface, $\varepsilon = 0.7$

Cold air temperature in the basement, $T_\infty = 10°C$

Heat transfer coefficient on the outer surface of the pipe, $h_0 = 15 W/m^2\text{-}K$

Heat transfer coefficient on the inner surface of the heater, $h_i = 120 W/m^2\text{-}K$

Step 2 of 8

Step 3 of 8

The inner and outer surface areas of the insulate pipe per unit length are

$$A_i = \pi d_1 L$$
$$= \pi \times (0.4m) \times (1.5m)$$
$$= 1.885\ m^2$$
$$A_o = \pi d_2 L$$
$$= \pi \times (0.46m) \times (1.5m)$$
$$= 2.1677\ m^2$$

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{120(W/m^2\text{-}K) \times 1.885(m^2)}$$
$$= 0.004421 K/W$$
$$R_{pipe} = \frac{\ln(r_2/r_1)}{2\pi k_{pipe} L}$$
$$= \frac{\ln(0.23/0.2)}{2\pi \times 386(W/m\text{-}K) \times 15(m)}$$
$$= 0.000003842 K/W$$

Step 4 of 8

The outer surface temperature of the pipe will be somewhat below the water temperature. Assuming the outer surface temperature of the pipe to be 70°C (we will check this assumption later), the radiation heat transfer coefficient is determined to be

$$h_{rad} = \varepsilon\sigma(T_2^2 + T_{surr}^2)(T_2 + T_{surr})$$
$$= 0.7 \times 5.67 \times 10^{-8}(W/m^2\text{-}K^4) \times \left[(343.15K)^2 + (283.15K)^2\right] \times \left[(343.15K) + (283.15K)\right]$$
$$= 4.92\ W/m^2\text{-}K$$

Since the surrounding medium and surfaces are at the same temperature, the radiation and convection heat transfer coefficients can be added and the result can be taken as the combined heat transfer coefficient. Then,

$$h_{combined} = h_{rad} + h_{conv}$$
$$= (4.92 + 15)\ W/m^2\text{-}K$$
$$= 19.92\ W/m^2\text{-}K$$
$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{19.92(W/m^2\text{-}K) \times 2.1677(m^2)}$$
$$= 0.02315 K/W$$

Step 5 of 8

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_{pipe} + R_o$$
$$= 0.0044221(K/W) + 0.000003842(K/W) + 0.02315(K/W)$$
$$= 0.0275 K/W$$

The steady rate of heat loss from the hot water pipe becomes

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{(90 - 10)}{0.0275(K/W)}$$
$$= 2901.2 W$$

$$\boxed{\dot{Q} = 2901.2 W}$$

Step 6 of 8

For a temperature drop of 3°C, the mass flow rate of water and the average velocity of water must be

$$\dot{Q} = \dot{m} C_p \Delta T$$

Therefore, the mass flow rate of the water can be expressed as

$$\dot{m} = \frac{\dot{Q}}{C_p \Delta T}$$
$$= \frac{2901.2(W)}{4180(J/kg\text{-}K) \times (3K)}$$
$$= 0.2313 kg/s$$

$$\boxed{\dot{m} = 0.2311 kg/s}$$

Step 7 of 8

Velocity if the water in the pipe can be expressed as

$$V = \frac{\dot{m}}{\rho A}$$
$$= \frac{0.23113(kg/s)}{1000(kg/m^3) \times \frac{\pi}{4} \times 0.04^2(m^2)}$$
$$= 0.1841 m/s$$

$$\boxed{V = 0.1841 m/s}$$

Step 8 of 8

Discussion:

The outer surface temperature of the pipe calculated as

$$\dot{Q} = \frac{(T_{\infty,1} - T_s)}{R_i + R_{pipe}}$$
$$2901.2 W = \frac{(90 - T_s)}{0.004421(K/W) + 0.000003842(K/W)}$$
$$T_s = 77.16°C$$

this is very close to the value assumed for the surface temperature in the evaluation of the radiation resistance. Therefore, there is no need to repeat the calculations.

Question: 17.077P

Steam exiting the turbine of a steam power plant at 100°F is to be condensed in a large condenser by cooling water flowing through copper pipes (k = 223 Btu/h · ft · °F) of inner diameter 0.4 in and outer diameter 0.6 in at an average temperature of 70°F. The heat of vaporization of water at 100°F is 1037 Btu/lbm. The heat transfer coefficients are 2400 Btu/h · ft · °F on the steam side and 35 Btu/h·ft2·°F on the water side. Determine the length of the tube required to condense steam at a rate of 250 lbm/h. tower.- 2380 ft

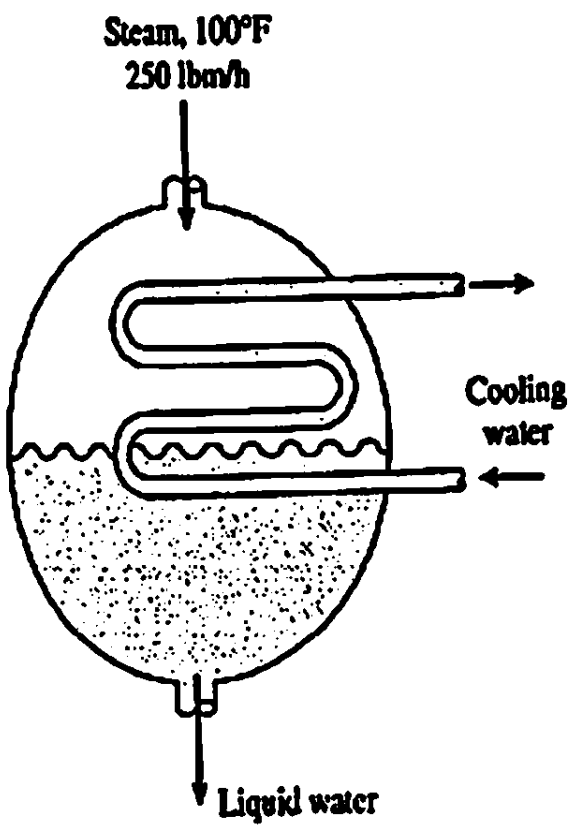


FIGURE P17–77E

Step 1 of 6

Given data:

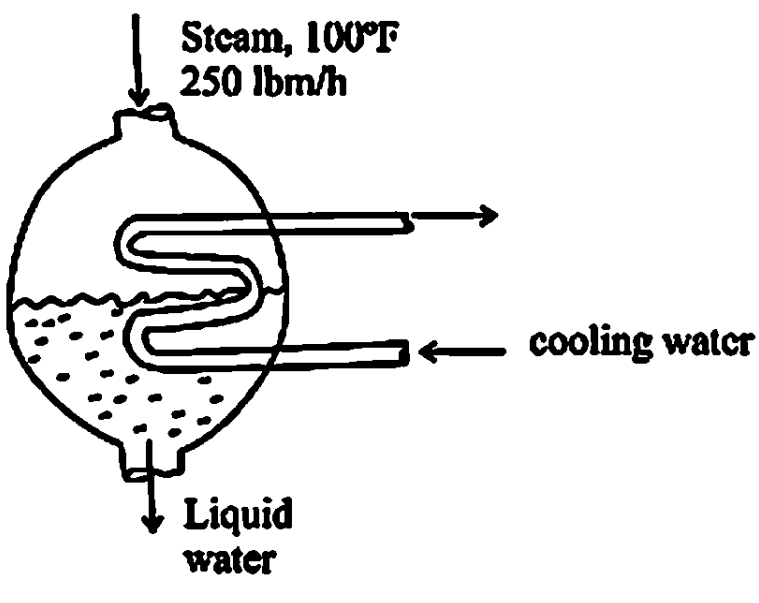
Turbine exit temperature, $T_{\infty 1} = 100^{\circ}\text{F}$

Cooling water temperature, $T_{\infty 2} = 70^{\circ}\text{F}$

Mass flow rate of the steam, $\dot{m}_s = 250\text{lbs/h}$

Thermal conductivity of the copper pipe, $k_{copper} = 223\text{Btu/h-ft-}^{\circ}\text{F}$

Heat of vaporization of water, $h_{fg} = 1037\text{ Btu/lbm @}100^{\circ}\text{F}$



Inner diameter of the pipe, $d_1 = 0.4\text{in}$

Outer diameter of the pipe, $d_2 = 0.6\text{in}$

Heat transfer coefficient on the steam side, $h_o = 2400\text{Btu/h-ft}^2\text{-}^{\circ}\text{F}$

Heat transfer coefficient on the water side, $h_i = 35\text{Btu/h-ft}^2\text{-}^{\circ}\text{F}$

Step 2 of 6

Step 3 of 6

The inner and outer surface areas of the cooling pipe per unit length are calculated as

$$A_i = \pi d_1 L$$
$$= \pi \times (\frac{0.4}{12}\text{ft}) \times (1\text{ft})$$
$$= 0.10472\text{ ft}^2$$
$$A_o = \pi d_2 L$$
$$= \pi \times (\frac{0.6}{12}\text{ft}) \times (1\text{ft})$$
$$= 0.15708\text{ ft}^2$$

Step 4 of 6

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{35(\text{Btu/h-ft}^2\text{-}^{\circ}\text{F}) \times 0.10472\ (\text{ft}^2)}$$
$$= 0.2728\text{h-}^{\circ}\text{F/Btu}$$
$$R_{pipe} = \frac{\ln(r_2/r_1)}{2\pi k_{copper} L}$$
$$= \frac{\ln(0.6/0.4)}{2\pi \times 223(\text{Btu/h-ft-}^{\circ}\text{F}) \times 1(\text{ft})}$$
$$= 0.00028\text{h-}^{\circ}\text{F/Btu}$$
$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{2400(\text{Btu/h-ft}^2\text{-}^{\circ}\text{F}) \times 0.15708\ (\text{ft}^2)}$$
$$= 0.0026\text{h-}^{\circ}\text{F/Btu}$$

Step 5 of 6

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_{pipe} + R_o$$
$$= 0.2728\,(\text{h-}^{\circ}\text{F/Btu}) + 0.000289\,(\text{h-}^{\circ}\text{F/Btu}) + 0.0026\,(\text{h-}^{\circ}\text{F/Btu})$$
$$= 0.27541\text{h-}^{\circ}\text{F/Btu}$$

The steady rate of heat rate per unit length of the tube can be determined as

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{(100-70)^{\circ}\text{F}}{0.27541(\text{h-}^{\circ}\text{F/Btu})}$$
$$= 108.9285\text{Btu/h}$$

Step 6 of 6

The total rate of heat transfer required for condensing the steam at a rate of 250 lbm/h and the length of the tube required is determined to be

$$\dot{Q}_{total} = \dot{m}_s h_{fg}$$
$$= 250\,(\text{lbm/h}) \times 1037(\text{Btu/lbm})$$
$$= 259250\text{Btu/h}$$

$$\text{Tube length (L)} = \frac{\dot{Q}_{total}}{\dot{Q}}$$
$$= \frac{259250(\text{Btu/h})}{108.9285(\text{Btu/h})}$$
$$= 2380\text{ft}$$

Therefore, tube length is $\boxed{L = 2380\text{ft}}$

Question: 17.078P

Repeat Prob. 17-77E, assuming that a 0.01-in-thick layer of mineral deposit (k = 0.5 Btu/h·ft·°F) has formed on the inner surface of the pipe.

Step 1 of 6

Given data:

Turbine exit temperature, $T_{\infty 1} = 100^\circ F$

Cooling water temperature, $T_{\infty 2} = 70^\circ F$

Mass flow rate of the steam, $\dot{m}_s = 250 lbs/h$

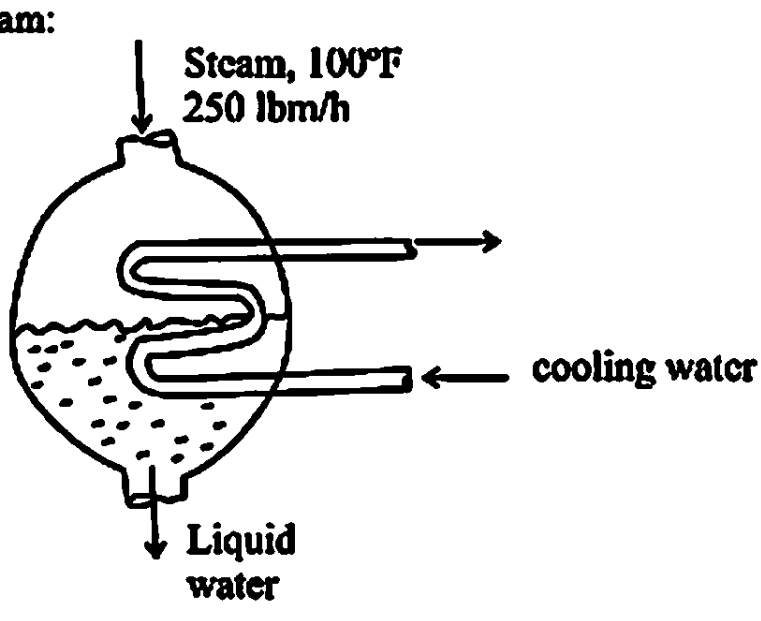
Thickness of mineral deposit, $L = 0.01 in$

Thermal conductivity of the mineral deposit, $k_{deposit} = 0.5 Btu/h\text{-}ft\text{-}^\circ F$

Thermal conductivity of the copper pipe, $k_{copper} = 223 Btu/h\text{-}ft\text{-}^\circ F$

Heat of vaporization of water, $h_{fg} = 1037\ Btu/lbm\ @100^\circ F$

Inner diameter of the pipe, $d_1 = 0.4 in$



Outer diameter of the pipe, $d_2 = 0.6 in$

Heat transfer coefficient on the steam side, $h_o = 2400 Btu/h\text{-}ft^2\text{-}^\circ F$

Heat transfer coefficient on the water side, $h_i = 35 Btu/h\text{-}ft^2\text{-}^\circ F$

Step 2 of 6

Let us draw the diagram:

Step 3 of 6

The inner and outer surface areas of the cooling pipe per unit length are calculated as

$$A_i = \pi d_1 L$$

$$= \pi \times \left(\frac{0.4 - 0.02}{12} ft\right) \times (1 ft)$$

$$= 0.0995\ ft^2$$

$$A_o = \pi d_2 L$$

$$= \pi \times \left(\frac{0.6}{12} ft\right) \times (1 ft)$$

$$= 0.157\ ft^2$$

Step 4 of 6

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$

$$= \frac{1}{35\,(Btu/h\text{-}ft^2\text{-}^\circ F) \times 0.0995\ (ft^2)}$$

$$= 0.287\ h\text{-}^\circ F/Btu$$

$$R_{pipe} = \frac{\ln(r_2 / r_1)}{2\pi k_{copper} L}$$

$$= \frac{\ln(0.3/0.2)}{2\pi \times 223 (Btu/h\text{-}ft\text{-}^\circ F) \times 1 (ft)}$$

$$= 0.00028\ h\text{-}^\circ F/Btu$$

$$R_{deposit} = \frac{\ln(r_1 / r_0)}{2\pi k_{deposit} L}$$

$$= \frac{\ln(0.2/0.19)}{2\pi \times 0.5 (Btu/h\text{-}ft\text{-}^\circ F) \times 1 (ft)}$$

$$= 0.01632\ h\text{-}^\circ F/Btu$$

$$R_o = \frac{1}{h_o A_o}$$

$$= \frac{1}{2400\,(Btu/h\text{-}ft^2\text{-}^\circ F) \times 0.15708\ (ft^2)}$$

$$= 0.0026\ h\text{-}^\circ F/Btu$$

Step 5 of 6

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_{pipe} + R_{deposit} + R_o$$

$$= 0.287\,(h\text{-}^\circ F/Btu) + 0.00028 (h\text{-}^\circ F/Btu) + 0.01632 + 0.0026 (h\text{-}^\circ F/Btu)$$

$$= 0.3062\ h\text{-}^\circ F/Btu$$

The steady rate of heat rate per unit length of the tube can be determined as

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$

$$= \frac{(100 - 70)^\circ F}{0.3062\,(h\text{-}^\circ F/Btu)}$$

$$= 97.975 Btu/h$$

Step 6 of 6

The total rate of heat transfer required for condensing the steam at a rate of 250 lbm/h and the length of the tube required is determined to be

$$\dot{Q}_{total} = \dot{m}_s h_{fg}$$

$$= 250\,(lbm/h) \times 1037 (Btu/lbm)$$

$$= 259250\ Btu/h$$

$$\text{Tube length}\,(L) = \frac{\dot{Q}_{total}}{\dot{Q}}$$

$$= \frac{259250 (Btu/h)}{97.975 (Btu/h)}$$

$$= 2646\ ft$$

Therefore, tube length is $\boxed{L = 2646 ft}$

Question: 17.079P pg 1

Reconsider Prob. 17-77E. Using EES (or other) software, investigate the effects of the thermal conductivity of the pipe material and the outer diameter of the pipe on the length of the tube required. Let the thermal conductivity vary from 10 Btu/h·ft·°F to 400 Btu/h·ft·°F and the outer diameter from 0.5 in to 1.0 in. Plot the length of the tube as functions of pipe conductivity and the outer pipe diameter, and discuss the results.

Step 1 of 10

Given data:

Turbine exit temperature, $T_{w1} = 100°F$

Cooling water temperature, $T_{w2} = 70°F$

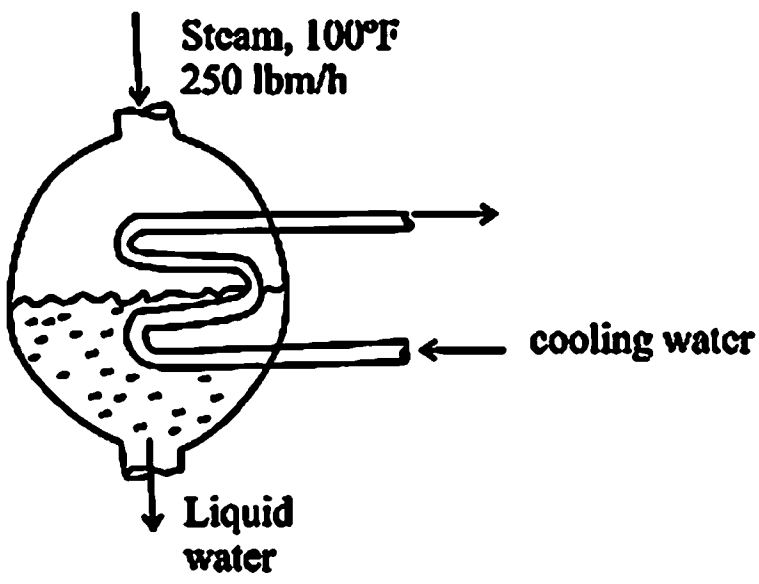
Mass flow rate of the steam, $\dot{m}_s = 250 lbs/h$

Thickness of mineral deposit, $L = 0.01 in$

Thermal conductivity of the copper pipe, $k_{copper} = 10 - 400 Btu/h\text{-}ft\text{-}°F$

Heat of vaporization of water, $h_{fg} = 1037 Btu/lbm \ @100°F$

Inner diameter of the pipe, $d_1 = 0.4 in$



Outer diameter of the pipe, $d_2 = 0.5 - 1 in$

Heat transfer coefficient on the steam side, $h_o = 2400 Btu/h\text{-}ft^2\text{-}°F$

Heat transfer coefficient on the water side, $h_i = 35 Btu/h\text{-}ft^2\text{-}°F$

Step 2 of 10

Let us draw the diagram:

Step 3 of 10

The inner and outer surface areas of the cooling pipe per unit length are calculated as

$$A_i = \pi d_1 L$$

$$= \pi \times \left(\frac{0.4 - 0.02}{12} ft \right) \times (1 ft)$$

$$= 0.0995 \ ft^2$$

$$A_o = \pi d_2 L$$

$$= \pi \times d_2 \times (1 ft)$$

Step 4 of 10

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$

$$= \frac{1}{35 (Btu/h\text{-}ft^2\text{-}°F) \times 0.0995 \ (ft^2)}$$

$$= 0.287 \ h\text{-}°F/Btu$$

$$R_{pipe} = \frac{\ln(r_2 / r_1)}{2\pi k_{copper} L}$$

$$= \frac{\ln\left(\frac{d_2 / 2}{0.2} \right)}{2\pi \times k_{copper} (Btu/h\text{-}ft\text{-}°F) \times 1 (ft)}$$

$$R_o = \frac{1}{h_o A_o}$$

$$= \frac{1}{2400 (Btu/h\text{-}ft^2\text{-}°F) \times \pi \times d_2 \times 1 \ (ft^2)}$$

Step 5 of 10

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_{pipe} + R_{deposit} + R_o$$

$$= 0.287 \ (h\text{-}°F/Btu) + \frac{\ln\left(\frac{d_2 / 2}{0.2} \right)}{2\pi \times k_{copper} \times 1} (h\text{-}°F/Btu) + \frac{1}{2400 \times \pi \times d_2 \times 1} (h\text{-}°F/Btu)$$

The steady rate of heat rate per unit length of the tube can be determined as

$$\dot{Q} = \frac{(T_{w,1} - T_{w,2})}{R_{total}}$$

$$= \frac{(100 - 70)°F}{R_{total} \ (h\text{-}°F/Btu)}$$

Step 6 of 10

The total rate of heat transfer required for condensing the steam at a rate of 250 lbm/h and the length of the tube required is determined to be

$$\dot{Q}_{total} = \dot{m}_s h_{fg}$$

$$= 250 \ (lbm/h) \times 1037 (Btu/lbm)$$

$$= 259250 \ Btu/h$$

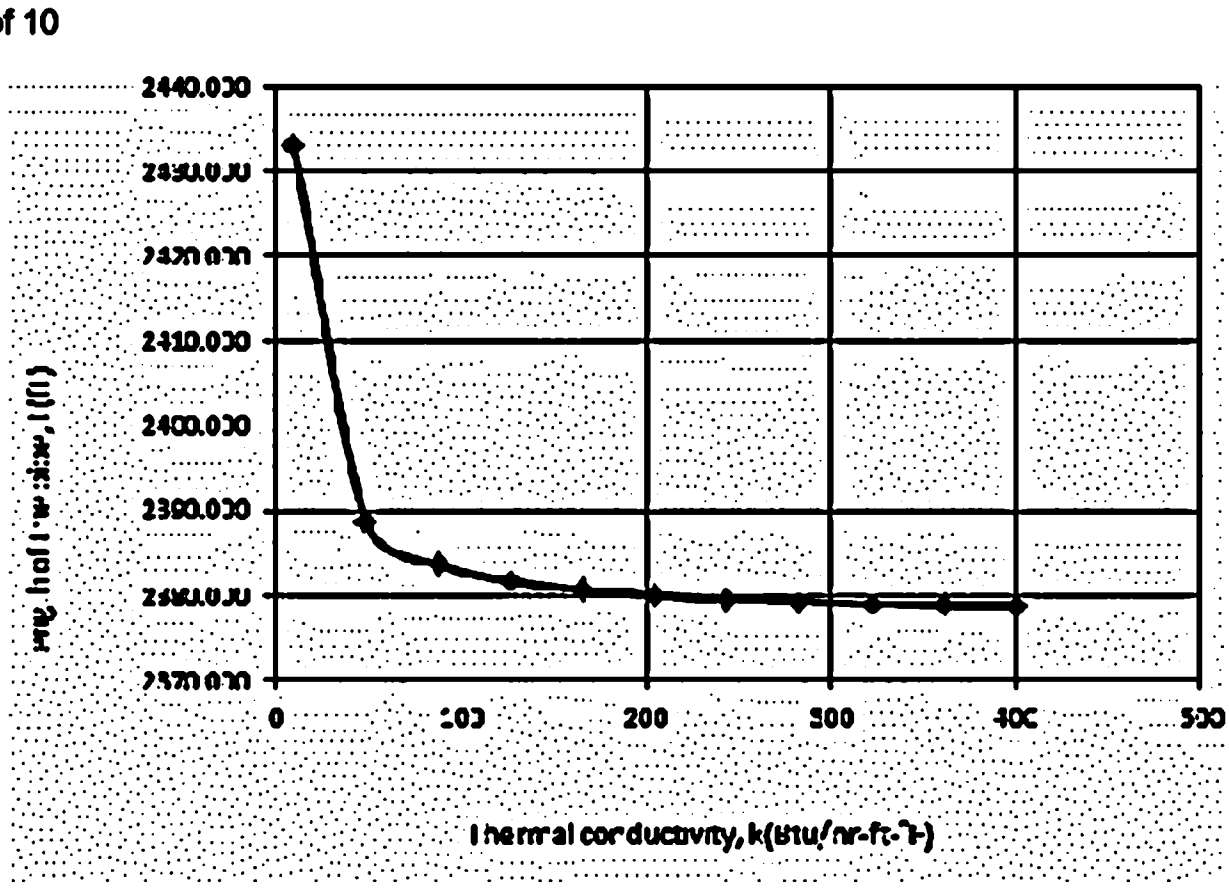
Step 7 of 10

$$\text{Tube length} = \frac{\dot{Q}_{total}}{\dot{Q}}$$

Step 7 of 10

$$\text{Tube length} = \frac{\dot{Q}_{total}}{\dot{Q}}$$

$$= \frac{259250(\text{Btu/h})}{\dot{Q}(\text{Btu/h})}$$



The length of the pipe calculated by solving the above equations using the Excel spread sheet by varying the thermal conductivity of the pipe material form $10-400$Btu/h-ft-°F and the pipe outer diameter from $0.5-1$in .

Step 8 of 10

Length of pipe required by Variation of Pipe thermal conductivity:

k (Btu/hr-ft-°F)	L (ft)
10	2558.4
49	2514
88	2509
127	2507
166	2506
205	2505.3
244	2504.9
283	2504.6
322	2504.4
361	2504.2
400	2504

Step 9 of 10

Step 10 of 10

Length of pipe required by Variation of Pipe outer diameter:

Outer Diameter (in)	L (ft)
0.5	2383.7
0.55	2381.8
0.6	2380.3
0.65	2379
0.7	2378
0.75	2377.1
0.8	2376.3
0.85	2375.7
0.9	2375.1
0.95	2374.7
1	2374.3

Question: 17.080P

A 2.2-mm-diameter and 14-m-long electric wire is tightly wrapped with a 1-mm-thick plastic cover whose thermal conductivity is k = 0.15 W/m·K. Electrical measurements indicate that a current of 13 A passes through the wire and there is a voltage drop of 8 V along the wire. If the insulated wire is exposed to a medium at T_∞ = 30°C with a heat transfer coefficient of h = 24 W/m2·K, determine the temperature at the interface of the wire and the plastic cover in steady operation. Also determine if doubling the thickness of the plastic cover will increase or decrease this interface temperature.

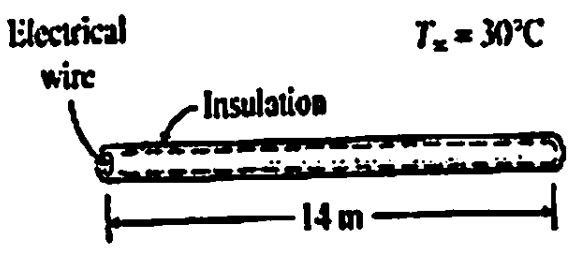


FIGURE P17–80

Step 1 of 8

Given data:

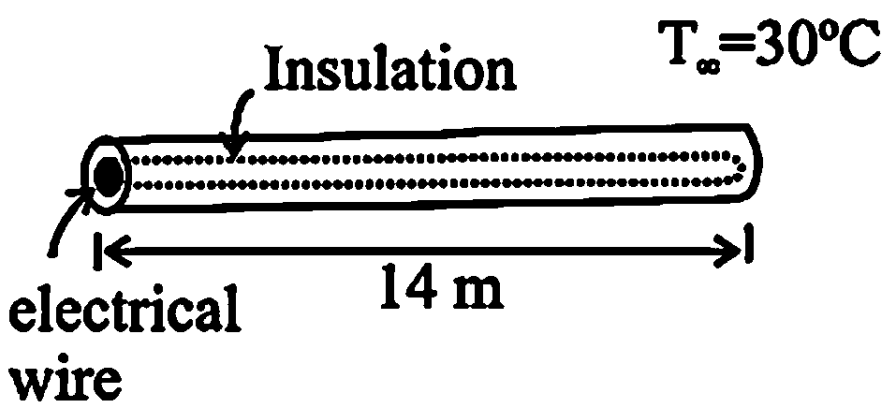
Length of the wire, $L = 14\,\text{m}$

Thermal conductivity of the plastic, $k_{plastic} = 0.15\,\text{W/m-K}$

Diameter of the wire, $d_1 = 2.2\,\text{mm}$

Thickness of the insulation, $t = 1\,\text{mm}$

Electrical current, $I = 13\,\text{A}$



Voltage drop, $V = 8\,\text{V}$

Temperature of the environment, $T_\infty = 30°\text{C}$

Heat transfer coefficient of the exposed medium, $h_0 = 24\,\text{W/m}^2\text{-K}$

Step 2 of 8

Schematic representation of the given system,

Step 3 of 8

Using the Ohms Law, the heat generated inside the pipe,

$$\dot{Q} = IV$$
$$= 13 \times 8$$
$$= 104\,\text{W}$$

Outer surface area of the insulate pipe,

$$A_o = \pi d_2 L$$
$$= \pi \times 0.0042 \times 14$$
$$= 0.1847\,\text{m}^2$$

Step 4 of 8

The individual thermal resistances,

$$R_{plastic} = \frac{\ln(r_2/r_1)}{2\pi k_{plastic} L}$$
$$= \frac{\ln(2.1/1.1)}{2\pi \times 0.15 \times 14}$$
$$= 0.049\,\text{K/W}$$

$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{24 \times 0.1847}$$
$$= 0.22559\,\text{K/W}$$

Step 5 of 8

All the resistances are in series, and the total resistance,

$$R_{total} = R_{plastic} + R_o$$
$$= 0.049 + 0.22559$$
$$= 0.2746\,\text{K/W}$$

The steady rate of heat loss from the hot water pipe,

$$\dot{Q} = \frac{(T_{int} - T_\infty)}{R_{total}}$$
$$= \frac{T_{int} - 30}{0.2746}$$

The temperature at the interface of the wire,

$$T_{int} = \dot{Q} R_{total} + T_\infty$$
$$= 104 \times 0.2746 + 30$$
$$= 58.56\,°\text{C}$$

Therefore the interface temperature of the wire, $\boxed{T_{int} = 58.56\,°\text{C}}$

Step 6 of 8

By doubling the thickness of the plastic cover the interface temperature:

Since outer diameter changed, the outer surface area,

$$A_o = \pi d_2 L$$
$$= \pi \times 0.0062 \times 14$$
$$= 0.27269\,\text{m}^2$$

The individual thermal resistances,

$$R_{plastic} = \frac{\ln(r_2/r_1)}{2\pi k_{plastic} L}$$
$$= \frac{\ln(3.1/1.1)}{2\pi \times 0.15 \times 14}$$
$$= 0.078523\,\text{K/W}$$

$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{24 \times 0.27269}$$
$$= 0.152798\,\text{K/W}$$

Step 7 of 8

All the resistances are in series, and the total resistance,

$$R_{total} = R_{plastic} + R_o$$
$$= 0.078523 + 0.152798$$
$$= 0.23132\,\text{K/W}$$

The steady rate of heat loss from the hot water pipe,

$$\dot{Q} = \frac{(T_{int} - T_\infty)}{R_{total}}$$
$$= \frac{T_{int} - 30}{0.23132}$$

Step 8 of 8

The temperature at the interface of the wire,

$$T_{int} = \dot{Q} R_{total} + T_\infty$$
$$= 104 \times 0.2313 + 30$$
$$= 54\,°\text{C}$$

Therefore the interface temperature of the wire, $\boxed{T_{int} = 54\,°\text{C}}$

Hence, the interface temperature is decreased due to increase in thickness of the plastic cover.

Question: 17.081P

Ina pharmaceutical plant, a copper pipe (*kc*= 400 W/m · K) with inner diameter of 20 mm and wall thicknessof 2.5 mmis used for carrying liquid oxygen to a storage tank. The liquid oxygen flowing in the pipe has an average temperature of-200°C and a convection heat transfer coefficient of 120 W/m2·K.The condition surrounding the pipe has an ambient air temperature of 20°C and a combined heat transfer coefficient of 20 W/m2-K. Ifthe dew point is 10° C, determine the thickness of the insulation (*ki* -0.05 W/ m·K)around the copper pipe to avoid condensation on the outer surface. Assumethermal contact resistance is negligible.

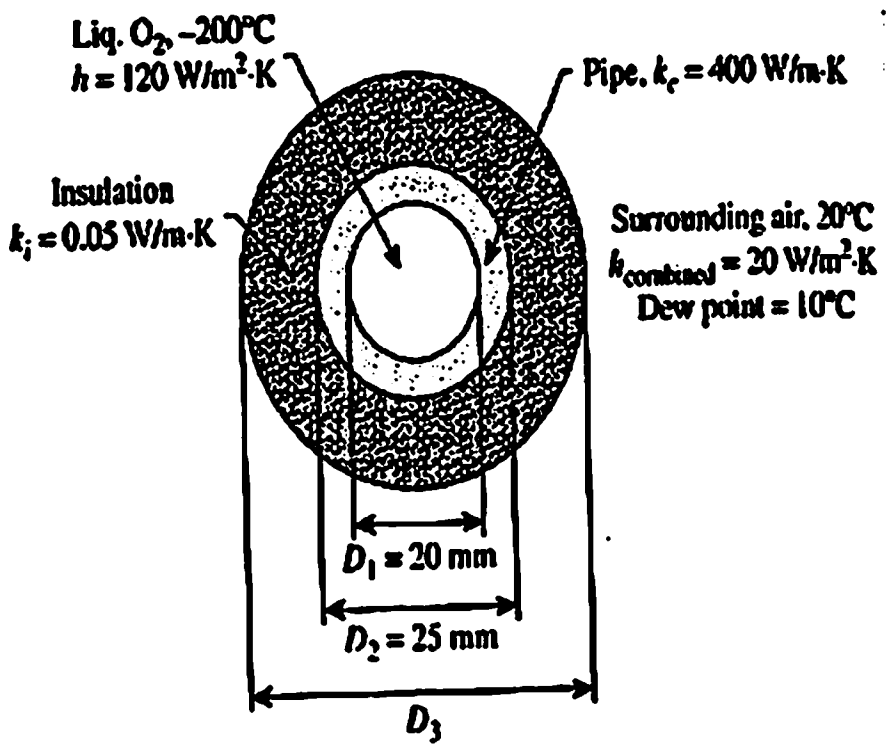


FIGURE P17-81

Step 1 of 3

Neglect the thermal contact resistance.

Calculate the overall rate of heat transfer through the pipe per unit length and insulation using the relation,

$$\begin{aligned}\dot{Q}_r &= U\Delta T \\ &= UA(T_\infty - T_i)\end{aligned}$$

Here, combined heat transfer coefficient is U , total area is A , surrounding temperature is T_∞ , and inside temperature is T_i .

Write the formula for total surface area per unit length of the system as shown.

$$A = \pi D_3 L$$

Substitute $20\ W/m^2 \cdot K$ for U , πD_3 for A , $(20+273)\ K$ for T_∞ , $(-200+273)\ K$ for T_i .

$$\begin{aligned}\dot{Q}_r &= 20 \times \pi D_3 \times [(20+273)-(-200+273)] \\ &= 20 \times 220 \times \pi D_3 \\ &= 4400\pi D_3\ W\end{aligned}$$

Step 2 of 3

Mode of heat transfer takes place as convection from surroundings to insulation, conduction through insulation, conduction through pipe and convection from fluid.

Overall heat transfer rate is equal to heat transfer due to convection from surroundings to insulation, conduction through insulation, conduction through pipe and convection from fluid.

Calculate the thickness of insulation to avoid condensation as shown.

$$\dot{Q}_r = \frac{T_\infty - T_i}{\frac{1}{h(\pi D_1)} + \frac{\ln(D_2/D_1)}{\pi L_1 k_1} + \frac{\ln(D_3/D_2)}{\pi L_2 k_2}} \quad \text{..... (1)}$$

Here, conduction through insulation is R_{cond2} , and conduction through pipe is R_{cond3} , and convection from fluid is R_{conv1} , thickness of pipe is L_1 , insulation thickness is L_2 , conduction coefficient of pipe is $k1$, conduction coefficient of insulation is k_2 , overall diameter is D_3 , diameter of pipe is D_1 , and outer diameter of the pipe is D_2 .

Step 3 of 3

Calculate the thickness of insulation to avoid condensation as shown.

Substitute $4400\pi D_3\ W$ for $\dot{Q}_r$, $120\ W/m^2 \cdot K$ for h , $(10+273)\ K$ for T_∞ , $(-200+273)\ K$ for T_i , $400\ W/m \cdot K$ for k_1 , $0.05\ W/m \cdot K$ for k_2 , $20\times10^{-3}\ m$ for D_1 , $(25\times10^{-3}+L_2)$ for D_3 , and $2.5\times10^{-3}\ m$ for L_1 in equation (1).

$$4400\pi(25\times10^{-3}+L_2)^2 = \frac{(10+273)-(-200+273)}{\left[\frac{1}{120(\pi\times20\times10^{-3}\times2.5\times10^{-3})} + \frac{\ln(25\times10^{-3}/20\times10^{-3})}{\pi\times2.5\times10^{-3}\times400} + \frac{\ln(25\times10^{-3}+L_2/25\times10^{-3})}{\pi L_2\times0.05}\right]}$$

Solve the equation and obtain the value of L_2 .

$$L_2 = 28.73\ mm$$

Therefore, thickness of insulation to prevent condensation is $\boxed{28.73\ mm}$.

Question: 17.082P

What is the critical radius of insulation? Howis it defined for a cylindrical layer?

Step 1 of 1

In a cylindrical pipe or a spherical shell, the additional insulation increases the conduction resistance of insulation, but decreases the convection resistance of the surface because of the increase in the outer surface area. Due to these opposite effects, a critical radius of insulation is defined as the outer radius that provides maximum rate of heat transfer.

For a cylindrical layer, it is defined as

$r_{cr} = k/h$

Where k is the thermal conductivity of insulation and

h is the external convection heat transfer coefficient.

Question: 17.083P

Consider an insulated pipe exposed to the atmosphere. Will the critical radius of insulation be greater on calm days or on windy days? Why?

Step 1 of 1

For a cylindrical pipe, the critical radius of insulation is defined as

$r_{cr} = k/h$.

On windy days, the external convection heat transfer coefficient is greater compared to calm days. Therefore critical radius of insulation will be greater on calm days.

Question: 17.084P

A pipe is insulated to reduce the heat loss fromit. However, measurements indicate that the rate of heat loss has increased instead of decreasing. Can the measurements be right?

Step 1 of 1

Yes, the measurements can be right. If the radius of insulation is less than critical radius of insulation of the pipe, then the rate of heat loss has increased instead of decreasing

Question: 17.085P

Consider a pipe at a constant temperature whose radius is greater than the critical radius of insulation. Someone claims that the rate of heat loss from the pipe has increased when someinsulation is added to the pipe. Is this claim valid?

Step 1 of 1

The rate of heat transfer from the cylinder increases with the addition of insulation and reaches a maximum when radius of the cylinder reaches to critical radius. The rate of heat transfer decreases when radius of the cylinder is greater than critical radius.
So the claim is wrong.

Question: 17.086P

A pipe is insulated such that the outer radius of the insulation is less than the critical radius. Now the insulation is taken off. Will the rate of heat transfer from the pipe increase or decrease for the same pipe surface temperature?

Step 1 of 1

When the outer radius is less than critical radius then rate of heat transfer from the cylinder increases

In the given problem the outer radius is less than critical radius then if the insulation is removed the rate of heat transfer from the pipe decreases

Question: 17.087P

A 0.083-in-diameter electrical wire at 90°F is covered by 0.02-in-thick plastic insulation (k = 0.075 Btu/h·ft·°F). The wire is exposed to a medium at 50°F, with a combined convection and radiation heat transfer coefficient of 2.5 Btu/h·ft2·°F. Determine if the plastic insulation on the wire will increase or decrease heat transfer from the wire.

Step 1 of 3

Given: -

Diameter of electric wire D = 0.083in

Thickness of plastic cover t= 0.02in

Thermal conductivity of plastic insulation $k = 0.075$ Btu/h·ft·°F.

Combined convection and radiation heat transfer coefficient h= 2.5 Btu/h.ft^2.°F

Ambient temperature $T_\infty = 50^0$F

Step 2 of 3

Outer diameter of the electric wire with plastic insulation

$D_0 = D + 2t$

$D_0 = 0.083 + 2\times 0.02$

$D_0 = 0.123$in

$$r_0 = \frac{0.123}{2}$$

$r_0 = 0.0615$in

Step 3 of 3

Critical radius of plastic insulation for a cylindrical body is

$$r_{cr} = \frac{k}{h}$$

$$= \frac{0.075}{2.5}$$

$= 0.03$ ft

$= 0.03\times 12$

$r_{cr} = 0.36$ in

$r_0 < r_{cr}$

Since the outer radius of the wire with insulation is smaller than critical radius of insulation, plastic insulation will increase heat transfer from the wire.

$D_0 = 0.083 + 2\times 0.02$

$D_0 = 0.123$in

0.123

Question: 17.088P

Repeat Prob. 17–87E, assuming a thermal contact resistance of 0.001 h·ft2·°F/Btu at the interface of the wire and the insulation.

Step 1 of 8

Given: -

Diameter of electric wire D = 0.083in

Thickness of plastic cover t= 0.02in

Thermal conductivity of plastic insulation $k = 0.075$ Btu/h·ft·°F.

Combined convection and radiation heat transfer coefficient h= 2.5 Btu/h.ft^2.°F

Ambient temperature $T_\infty = 50^0$F

Diameter of electric wire = 0.083in

Thermal contact resistance $h_c = 0.001$h.ft^2.^{0}F/Btu

Step 2 of 8

Outer diameter of the electric wire with plastic insulation

$D_0 = D + 2t$

$D_0 = 0.083 + 2\times 0.02$

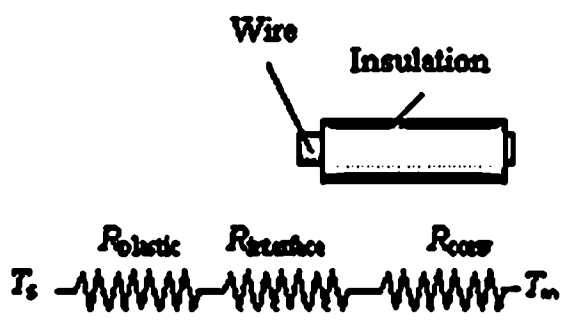
$D_0 = 0.123$in

$$r_0 = \frac{0.123}{2}$$

$r_0 = 0.0615$in

Step 3 of 8

If the heat transfer from the wire is steady since there is no indication of any change with time and the heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction then for without insulation, the total thermal resistance is (per ft length of the wire)



$$R_{tot} = R_{conv} = \frac{1}{h_o A_o}$$

$$= \frac{1}{h_0 \times \pi D \times L}$$

$$= \frac{1}{(2.5)[\pi(0.083/12)(1)]}$$

$R_{tot} = R_{conv} = 18.4$ h.°F/Btu

Step 4 of 8

Step 5 of 8

Thermal resistance due to convection from outer surface

$$R_{conv} = \frac{1}{h_o A_o}$$

$$= \frac{1}{h_o \times \pi D_0 L}$$

$$= \frac{1}{(2.5)[\pi(0.123/12)(1)]}$$

$R_{conv} = 12.42$ h.°F/Btu

Step 6 of 8

Thermal resistance due to conduction in electric wire and the insulation

$$R_{plastic} = \frac{\ln(r_2/r_1)}{2\pi k L}$$

$$= \frac{\ln(0.123/0.083)}{2\pi(0.075)(1)}$$

$R_{plastic} = 0.835$ h.°F/Btu

Step 7 of 8

Thermal resistance at the interface of the wire and insulation

$$R_{interface} = \frac{h_c}{A_c}$$

$$= \frac{h_c}{\pi D L}$$

$$= \frac{0.001}{[\pi(0.083/12)(1)]}$$

$R_{interface} = 0.046$ h.°F/Btu

Step 8 of 8

Total thermal resistance due to insulation

$R_{total} = R_{conv} + R_{plastic} + R_{interface}$

$= 12.42 + 0.835 + 0.046$

$R_{total} = 13.30$ h.°F/Btu

Since the total thermal resistance decreases with insulation, plastic insulation will increase heat transfer from the wire. The thermal contact resistance appears to have negligible effect in this case.

Question: 17.089P

A 4-mm-diameter spherical ball at 50°C is covered by a 1-mm-thick plastic insulation (k = 0.13 W/m·K). The ball is exposed to a medium at 15°C. with a combined convection and radiation heat transfer coefficient of 20 W/m2·K. Determine if the plastic insulation on the ball will help or hurt heat transfer from the ball.

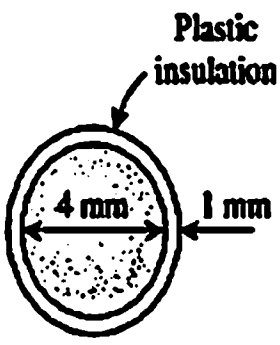


FIGURE P17–89

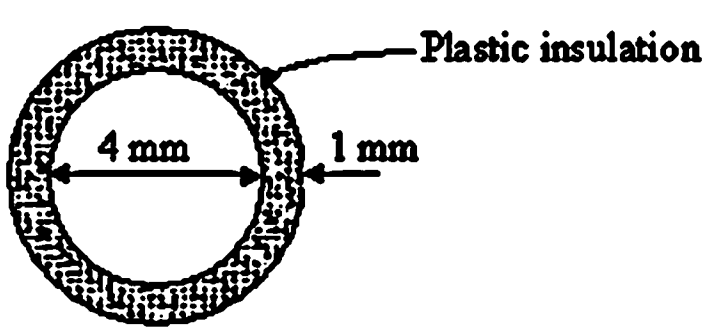
Step 1 of 4

Given data:

Diameter of the spherical ball, $d = 4\,\text{mm}$

Thermal conductivity of the plastic insulation, $k_{insulation} = 0.13\,\text{W/m-K}$



Thickness of the insulation, $t = 1\text{mm}$

Temperature of the ball, $T_{ball} = 50°\text{C}$

Temperature of the environment, $T_\infty = 15°\text{C}$

Combined convection and radiation heat transfer coefficient $h_0 = 20\,\text{W/m}^2\text{-K}$

Step 2 of 4

Step 3 of 4

Outer diameter of the spherical shell is

$$D_o = D_i + 2t$$
$$D_o = 4 + 2\times 1$$
$$D_o = 6\,\text{mm}$$

$$r_0 = \frac{D_0}{2}$$
$$r_0 = \frac{6}{2}$$
$$r_0 = 3\text{mm}$$

The critical radius of insulation for a sphere can be determined as

$$r_{cr,sphere} = \frac{2k}{h}$$
$$= \frac{2\times 0.13(\text{W/m-K})}{20(\text{W/m}^2\text{-K})}$$
$$= 0.013\text{m}$$
$$= 13\text{mm}$$

Step 4 of 4

Since the critical radius of insulation depends on the thermal conductivity of the insulation $k_{insulation}$ and the external convection heat transfer coefficient h. The rate of heat transfer from the sphere increases with the addition of insulation for $r_2 < r_{cr,sphere}$, reaches maximum when $r_2 = r_{cr,sphere}$, and starts to decrease for $r_2 > r_{cr,sphere}$. Since in the current problem the outer radius of the insulation $r_2(3\text{mm}) < r_{cr,sphere}(13\text{mm})$. Hence the rate of heat transfer from the sphere increases with the addition of insulation.

Question: 17.090P

Reconsider Prob. 17-89. Using EES (or other) software, plot the rate of heat transfer from the ball as a function of the plastic insulation thickness in the range of 0.5 mm to 20 mm. Discuss the results.

Step 1 of 7

Given data:

Diameter of the spherical ball, $d_1 = 4\,\text{mm}$

Thermal conductivity of the plastic insulation, $k_{insulation} = 0.13\,\text{W/m}\cdot\text{K}$

Thickness of the insulation, $t = 0.5\,\text{to}\,20\,\text{mm}$

Temperature of the ball, $T_{ball} = 50°\text{C}$

Temperature of the environment, $T_\infty = 15°\text{C}$

Combined convection and radiation heat transfer coefficient medium, $h_0 = 20\,\text{W/m}^2\text{-K}$

Step 2 of 7

Schematic representation of the given system,

Step 3 of 7

The outer surface area of the sphere,

$$A_2 = \pi d_2^2$$
$$= \pi \times (0.004 + 2t)^2$$

The individual resistance of the given system:

Conduction resistance,

$$R_{sphere} = \frac{r_2 - r_1}{4\pi k r_1 r_2}$$
$$= \frac{(0.002 + t) - 0.002}{4\pi \times 0.13 \times 0.002 \times (0.002 + t)}$$
$$= \frac{t}{0.00326 \times (0.002 + t)}$$

Convection resistance from the surface to the environment,

$$R_{conv} = \frac{1}{h_0 A_2}$$
$$= \frac{1}{20 \times \pi \times (0.004 + 2t)^2}$$

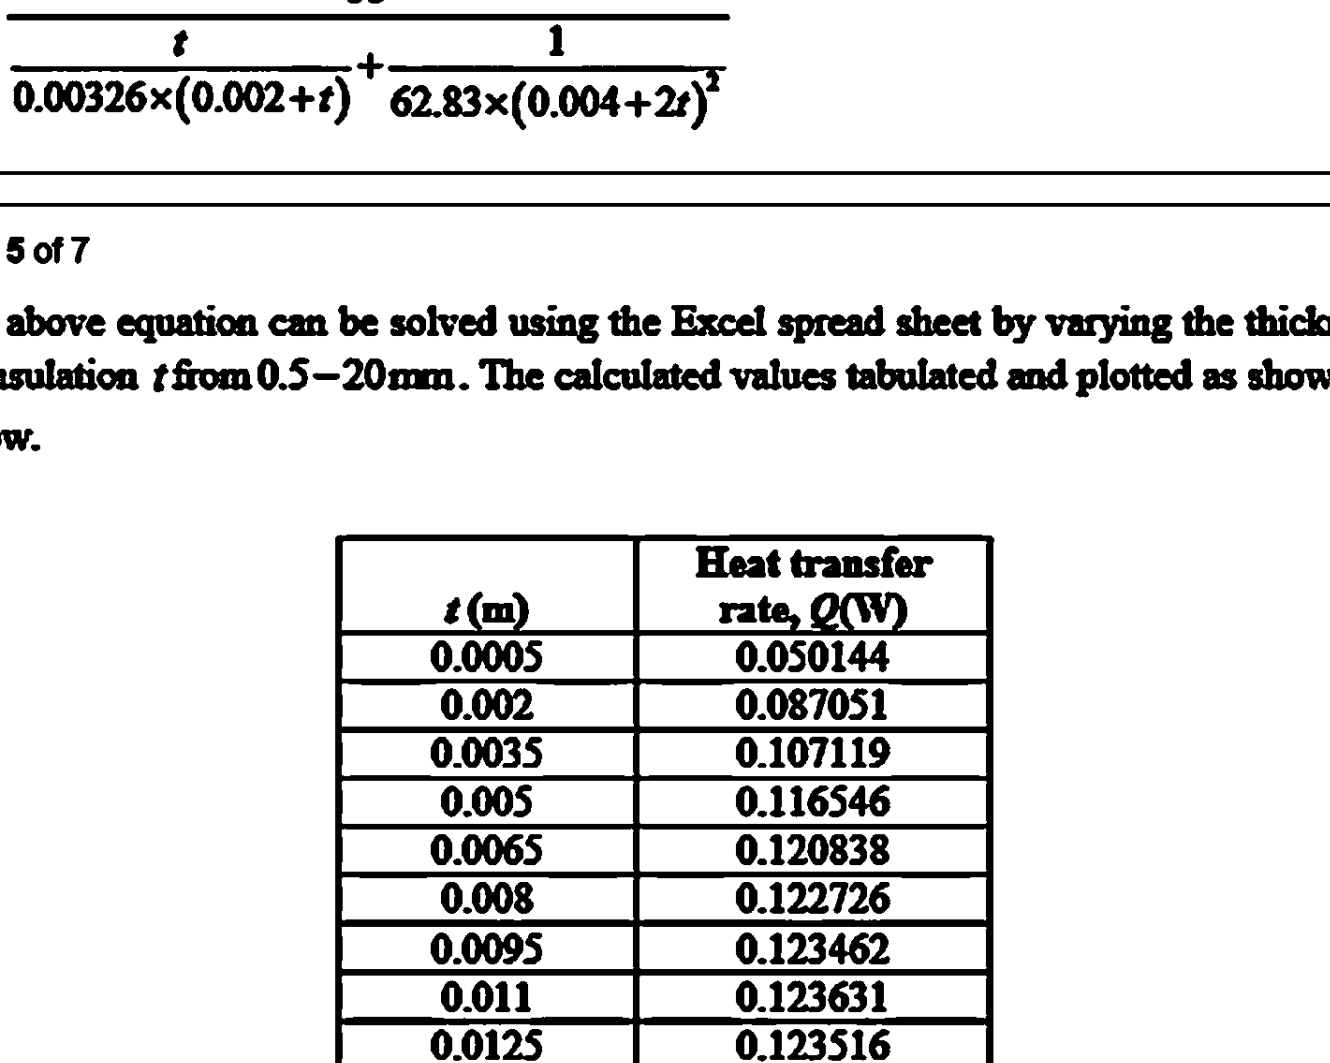
Step 4 of 7

The total thermal resistance of the given system,

$$R_{total} = R_{sphere} + R_{conv}$$
$$= \frac{t}{0.00326 \times (0.002 + t)} + \frac{1}{20 \times \pi \times (0.004 + 2t)^2}$$

Therefore, the rate of heat transfer from the sphere

$$\dot{Q} = \frac{T_{ball} - T_\infty}{R_{total}}$$
$$= \frac{(50 - 15)}{\frac{t}{0.00326 \times (0.002 + t)} + \frac{1}{20 \times \pi \times (0.004 + 2t)^2}}$$
$$= \frac{35}{\frac{t}{0.00326 \times (0.002 + t)} + \frac{1}{62.83 \times (0.004 + 2t)^2}}$$



Step 5 of 7

The above equation can be solved using the Excel spread sheet by varying the thickness of insulation t from $0.5 - 20\,\text{mm}$. The calculated values tabulated and plotted as shown in below.

t (m)	Heat transfer rate, Q(W)
0.0005	0.050144
0.002	0.087051
0.0035	0.107119
0.005	0.116546
0.0065	0.120838
0.008	0.122726
0.0095	0.123462
0.011	0.123631
0.0125	0.123516
0.014	0.123262
0.0155	0.122943
0.017	0.1226
0.0185	0.122254
0.02	0.121916

Step 6 of 7

Graphical representation for heat transfer versus the thickness of the insulation,

Step 7 of 7

The critical radius of insulation for a sphere,

$$r_{cr,sphere} = \frac{2k}{h}$$
$$= \frac{2 \times 0.13}{20}$$
$$= 0.013\,\text{m}$$
$$= 13\,\text{mm}$$

Note that the critical radius of insulation depends on the thermal conductivity of the insulation $k_{insulation}$ and the external convection heat transfer coefficient h. From the plot it can be observed that the rate of heat transfer from the sphere increases with the addition of insulation for $r_2 < r_{cr,sphere}$, reaches maximum when $r_2 = r_{cr,sphere} = 13\,\text{mm}$, and starts to decrease for $r_2 > r_{cr,sphere}$. Thus, insulating the pipe may actually increasing the rate of heat transfer from the pipe instead of decreasing it when $r_2 < r_{cr,sphere}$.

Question: 17.091P

Hot air is to be cooled as it is forced to flow through the tubes exposed to atmospheric air. Fins are to be added in order to enhance heat transfer. Would you recommend attaching the fins inside or outside the tubes? Why? When would you recommend attaching fins both inside and outside the tubes?

Step 1 of 1

Fins should be attached to the outside since the heat transfer coefficient inside the tube will be higher due to forced convection. Fins should be added to both sides of the tubes when the convection coefficients at the inner and outer surfaces are comparable in magnitude.

Question: 17.092P

What is the reason for the widespread use of fins on surfaces?

Step 1 of 1

Fins increase the rate of heat transfer from the surface by increasing the heat transfer surface area.

Question: 17.093P

What is the difference between the fin effectiveness and the fin efficiency?

Step 1 of 1

The fin efficiency is defined as the ratio of actual heat transfer rate from the fin to the ideal heat transfer rate from the fin if the entire fin were at base temperature, and its value is between 0 and 1. Fin effectiveness is defined as the ratio of heat transfer rate from a finned surface to the heat transfer rate from the same surface if there were no fins, and its value is expected to be greater than 1.

Question: 17.094P

The fins attached to a surface are determined to have an effectiveness of 0.9. Do you think the rate of heat transfer from the surface has increased or decreased as a result of the addition of these fins?

Step 1 of 1

Fin effectiveness value is 0.9 (smaller than 1) this indicates that the heat transferred from the surface is decreased and hence the fins here were acting as thermal insulation.

Question: 17.095P

Explain how the fins enhance heat transfer from a surface. Also, explain how the addition of fins may actually decrease heat transfer from a surface.

Step 1 of 1

Fins enhance heat transfer from a surface by increasing heat transfer surface area for convection heat transfer. However, adding too many fins on a surface can suffocate the fluid and retard convection, and thus it may cause the overall heat transfer coefficient and heat transfer to decrease.

Question: 17.096P

How does the overall effectiveness of a finned surface differ from the effectiveness of a single fin?

Step 1 of 1

Effectiveness of a single fin is the ratio of the heat transfer rate from the entire exposed surface of the fin to the heat transfer rate from the fin base area. The overall effectiveness of a finned surface is defined as the ratio of the total heat transfer from the finned surface to the heat transfer from the same surface if there were no fins.

Question: 17.097P

Hot water is to be cooled as it flows through the tubes exposed to atmospheric air. Fins are to be attached in order to enhance heat transfer. Would you recommend attaching the fins inside or outside the tubes? Why?

Step 1 of 1

Fins should be attached on the outside (surface exposed to air) since the convection heat transfer coefficient is lower on the air side than it is on the water side.

Question: 17.098P

Consider two finned surfaces that are identical except that the fins on the first surface are formed by casting or extrusion, whereas they are attached to the second surface afterwards by welding or tight fitting. For which case do you think the fins will provide greater enhancement in heat transfer? Explain.

Step 1 of 1

Welding or tight fitting introduces thermal contact resistance at the interface, and thus retards heat transfer. Therefore, the fins formed by casting or extrusion will provide greater enhancement in heat transfer.

Question: 17.099P

The heat transfer surface area of a fin is equal to the sum of all surfaces of the fin exposed to the surrounding medium, including the surface area of the fin tip. Under what conditions can we neglect heat transfer from the fin tip?

Step 1 of 1

If the fin is too long, the temperature of the fin tip will approach the surrounding temperature and we can neglect heat transfer from the fin tip. Also, if the surface area of the fin tip is very small compared to the total surface area of the fin, heat transfer from the tip can again be neglected.

Question: 17.100P

Does the (*a*) efficiency and (*b*) effectiveness of a fin increase or decrease as the fin length is increased?

Step 1 of 2

(a)
Increasing the length of a fin decreases its efficiency because for longer fins it is difficult to maintain entire surface at base temperature.

Step 2 of 2

(b)
Increasing the length of a fin increases its effectiveness because it enhances heat transfer by increasing the surface area.

Question: 17.101P

Two pin fins are identical, except that the diameter of one of them is twice the diameter of the other. For which fin is the (*a*) fin effectiveness and (*b*) fin efficiency higher? Explain.

Step 1 of 2

(a)

Fin with large diameter has more efficiency because more heat can reach the fin tip of a large diameter fin when compared to that of a fin with small diameter.

Step 2 of 2

(b)

Fin with smaller diameter is of higher effectiveness. This is due to the reason that for small diameter fins the surface area available per unit volume is relatively larger than that of the fins of large diameter.

Question: 17.102P

Two plate fins of constant rectangular cross section are identical, except that the thickness of one of them is twice the thickness of the other. For which fin is the (*a*) fin effectiveness and (*b*) fin efficiency higher? Explain.

Step 1 of 2

(a)

The thicker fin will have higher efficiency, because for thicker fin the tendency to maintain base temperature is more when compared to that of the thinner fin.

Step 2 of 2

(b)

The thinner fin will have higher effectiveness, because the thinner fin has relatively more surface area per unit volume when compared to that of the thicker fin.

Question: 17.103P

Two finned surfaces are identical, except that the convection heat transfer coefficient of one of them is twice that of the other. For which finned surface is the (*a*) fin effectiveness and (*b*) fin efficiency higher? Explain.

Step 1 of 2

(a)

The fin with the lower convective heat transfer coefficient will have the higher effectiveness because the effectiveness of fin is inversely proportional to the convective heat transfer coefficient.

Step 2 of 2

(b)

The fin with the lower convective heat transfer coefficient will also have the higher efficiency because the fin efficiency is directly proportional to the effectiveness of fin

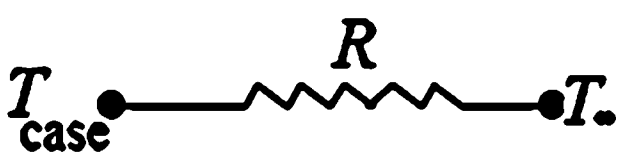
Question: 17.104P

The case-to-ambient thermal resistance of a power transistor that has a maximum power rating of 15 W is given to be 25°C/W. If the case temperature of the transistor is not to exceed 80°C, determine the power at which this transistor can be operated safely in an environment at 35°C.

Step 1 of 3

Given data:

Maximum power rating of the transistor, $P = 15\text{W}$



Case-to-ambient thermal resistance of a power transistor, $R = 25°\text{C/W}$

Case temperature of the transistor, $T_{case} = 80°\text{C}$

Ambient temperature, $T_\infty = 35°\text{C}$

Step 2 of 3

Assume temperature of the transistor is uniform throughout the surface and steady state conditions exist.

Step 3 of 3

The power at which this transistor can be operated safely can be determined as

$$\dot{Q} = \frac{(T_{case} - T_\infty)}{R}$$

$$= \frac{(80-35)(°\text{C})}{25(°\text{C/W})}$$

$$= 1.8\,\text{W}$$

$$\boxed{\dot{Q} = 1.8\,\text{W}}$$

Question: 17.105P

A 4-mm-diameter and (0-cm-long aluminum fin (k =237 W/m·K) is attached to a surface. If the heat transfer coefficient is 12 W/m2·K, determine the percent error in the rate of heat transfer from the fin when the infinitely long fin assumption is used instead of the adiabatic fin tip assumption.

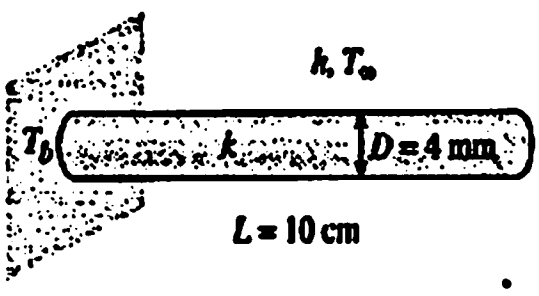


FIGURE P17–105

Step 1 of 2

The rate of heat transfer for a fin with insulated tip is as shown below:

$$\dot{Q}_{long} = \sqrt{hpkA_C}(T_b - T_\infty)$$

Here, h is heat transfer coefficient; k is thermal conductivity of the fin, p is perimeter of the fin, A_c is cross sectional area of the fin, T_b is base temperature of the fin and T_∞ is ambient air temperature.

The rate of heat transfer for a fin of infinitely long fin is as shown below:

$$\dot{Q}_{adiabatic} = \sqrt{hpkA_C}(T_b - T_\infty)\tanh(mL)$$

Calculate the value of m is as shown below,

$$m = \sqrt{\frac{hp}{kA_c}}$$
$$= \sqrt{\frac{h\pi D}{k\frac{\pi D^2}{4}}}$$
$$= \sqrt{\frac{4h}{kD}}$$

Substitute $12\,\mathrm{W/m^2 \cdot K}$ for h, $237\,\mathrm{W/m \cdot K}$ for k and $0.004\,\mathrm{m}$ for D

$$m = \sqrt{\frac{4\times 12}{237\times 0.004}}$$
$$= 7.1156\,\mathrm{m^{-1}}$$

Step 2 of 2

Find the percent error of the heat transfer as shown below,

$$\%error = \frac{\dot{Q}_{long} - \dot{Q}_{adiabatic}}{\dot{Q}_{adiabatic}} \times 100$$
$$= \frac{\sqrt{hpkA_C}(T_b - T_\infty) - \sqrt{hpkA_C}(T_b - T_\infty)\tanh(mL)}{\sqrt{hpkA_C}(T_b - T_\infty)\tanh(mL)} \times 100$$
$$= \left[\frac{1}{\tanh(mL)} - 1\right] \times 100$$

Here, L is length of the fin

Substitute $10\,\mathrm{cm} = 0.1\,\mathrm{m}$ for L

$$\%error = \left[\frac{1}{\tanh(7.116\times 0.1)} - 1\right] \times 100$$
$$= 0.6348 \times 100$$
$$= 63.48\%$$

Therefore, the percent error in the rate of heat transfers when the infinitely long fin assumption is used instead of the adiabatic fin tip assumption **63.48%**

Question: 17.106P

Consider a very long rectangular fin attached to a flat surface such that the temperature at the end of the fin is essentially that of the surrounding air, i.e. 20°C Its width is 5.0 cm; thickness is 1.0 mm; thermal conductivity is 200 W/m· K; and base temperature is 40°C The heat transfer coefficient is 20 W/m2·K. Estimate the fin temperature at a distance of 5.0 cm from the base and the rate of heat loss from the entire fin.

Step 1 of 3

The temperature distribution equation for long rectangular fin is

$$\frac{T-T_\infty}{T_b-T_\infty}=e^{-mx}$$

Here, T is the temperature of fin at any point, T_b is base temperature, T_∞ is ambient temperature and x is length of the fin.

Calculate the value of m by using the formula

$$m=\sqrt{\frac{hp}{kA_C}}$$
$$=\sqrt{\frac{h\times(2w+2t)}{k\times wt}}$$

Here, h is heat transfer coefficient, p is perimeter of the rectangular fin, k is thermal conductivity of aluminum fin, A_c is cross sectional area of the fin, w is width of the fin and t is thickness of the fin.

Substitute $20\,\mathrm{W/m^2\cdot K}$ for h, $0.05\,\mathrm{m}$ for w, $0.001\,\mathrm{m}$ for t

$$m=\sqrt{\frac{20\times(2\times0.05+2\times0.001)}{200\times(0.05\times0.001)}}$$
$$=\sqrt{\frac{20\times0.102}{200\times0.00005}}$$
$$=14.28\,\mathrm{m^{-1}}$$

Step 2 of 3

Now find the temperature at a distance x from the base by using equation (1)

$$\frac{T-T_\infty}{T_b-T_\infty}=e^{-mx}$$

Substitute $20°\mathrm{C}$ for T_∞, $40°\mathrm{C}$ for T_b and $0.05\,\mathrm{m}$ for x

$$\frac{T-20}{40-20}=e^{-(14.3)(0.05)}$$
$$=\sqrt{\frac{h\times(2w+2t)}{k\times wt}}$$

Here, h is heat transfer coefficient, p is perimeter of the rectangular fin, k is thermal conductivity of aluminum fin, A_c is cross sectional area of the fin, w is width of the fin and t is thickness of the fin.

Substitute $20\,\mathrm{W/m^2\cdot K}$ for h, $0.05\,\mathrm{m}$ for w, $0.001\,\mathrm{m}$ for t

$$m=\sqrt{\frac{20\times(2\times0.05+2\times0.001)}{200\times(0.05\times0.001)}}$$
$$=\sqrt{\frac{20\times0.102}{200\times0.00005}}$$
$$=14.28\,\mathrm{m^{-1}}$$

Step 2 of 3

Now find the temperature at a distance x from the base by using equation (1)

Question: 17.107P

A DC motor delivers mechanical power to a rotating stainless steel shaft (k = 15.1 W/m·K) with a length of 25 cm and a diameter of 25 mm. In a surrounding with ambient air temperature of 20°C and convection heat transfer coefficient of 25 W/m2·K, the surface area of the motor housing that is exposed to the ambient air is 0.075 m2. The motor uses 300 W of electrical power and delivers 55% of it as mechanical power to rotate the stainless steel shaft. If the tip of the stainless steel shaft has a temperature of 22°C, determine the surface temperature of the motor housing. Assume the base temperature of the shaft is equal to the surface temperature of the motor housing. *Answer:*87.7°C.

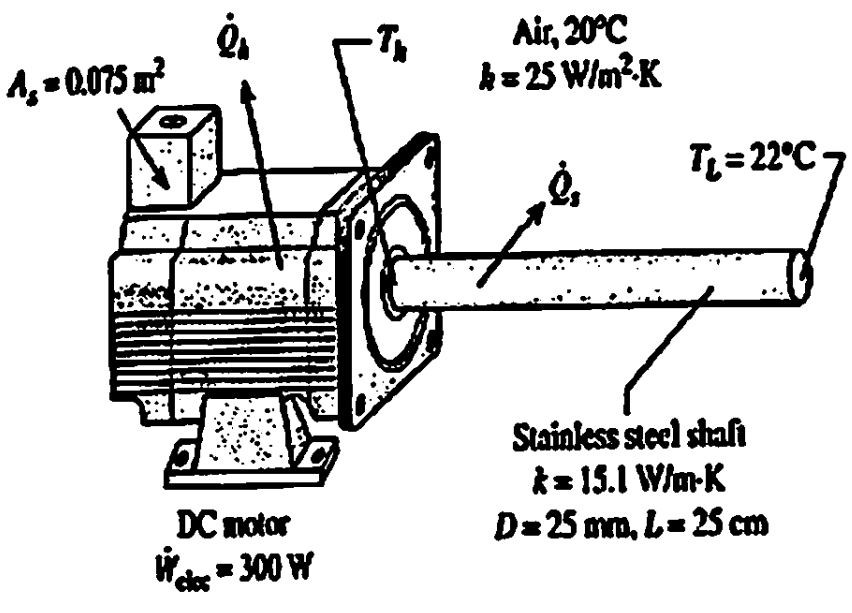

FIGURE P17–107

Step 1 of 5

Given data:

Diameter of the shaft, $D = 25\,\text{mm}$

Length of the shaft, $L = 25\,\text{cm}$

Thermal conductivity of the stainless steel shaft, $k = 15.1\,\text{W/m.K}$

Ambient air temperature, $T_\infty = 20\,^\circ\text{C}$

Convection heat transfer coefficient of ambient air, $h = 25\,\text{W/m}^2\text{.K}$

Surface area of the motor, $A_s = 0.075\,\text{m}^2$

Electrical power of the motor, $P = 300\,\text{W}$

Percentage of mechanical power delivered by the motor, $\eta = 55\%$

Temperature at the tip of the stainless shaft, $T_L = 22\,^\circ\text{C}$

Step 2 of 5

Since the motor transmitting 55 % of the power to rotate the shaft, remaining 45 % power will be converted into heat energy and that will be lost through the motor surface and the shaft.

Therefore the heat generated during transmission can be expressed as

$$\dot{Q}_{gen} = (1-\eta)P$$
$$= (1-0.55)\times 300(\text{W})$$
$$= 135\,\text{W}$$

The total heat generated in the motor will be lost to the surroundings can be expressed as

$$\dot{Q}_{gen} = \dot{Q}_b + \dot{Q}_s \qquad \ldots\ldots (1)$$

Where the heat transfer from the motor surface is $\dot{Q}_b$ with the constant surface temperature of T_b and it can be expressed as

$$\dot{Q}_b = hA_s(T_b - T_\infty)$$
$$= 25(\text{W/m}^2\text{-K})\times 0.075(\text{m}^2)\times(T_b - T_\infty)$$
$$= 1.875(T_b - T_\infty)$$

Step 3 of 5

The heat transfer from the shaft $\dot{Q}_s$ with base temperature same as the motor surface temperature and considering the shaft as an extended fin by fixing the fin tip temperature at $T_L = 22\,^\circ\text{C}$ can be expressed as

$$\dot{Q}_s = \sqrt{hpkA_c}(T_b - T_\infty)\frac{\cosh mL - \left[(T_L - T_\infty)/(T_b - T_\infty)\right]}{\sinh mL}$$

Where

$$\sqrt{hpkA_c} = \sqrt{h\times\pi D\times k\times\frac{\pi}{4}D^2}$$
$$= \sqrt{25(\text{W/m}^2\text{-K})\times\pi\times 0.025(\text{m})\times 15.1(\text{W/m-K})\times\frac{\pi}{4}\times 0.025^2(\text{m}^2)}$$
$$= 0.12064$$

$$mL = \sqrt{\frac{hp}{kA_c}}L$$
$$= \sqrt{\frac{h\times\pi D}{k\times\frac{\pi}{4}D^2}}L$$
$$= \sqrt{\frac{25(\text{W/m}^2\text{-K})\times\pi\times 0.025(\text{m})}{15.1(\text{W/m-K})\times\frac{\pi}{4}\times 0.025^2(\text{m}^2)}}0.25(\text{m})$$
$$= 4.06894$$

Step 4 of 5

Then substituting the known values in heat transfer from the shaft

$$\dot{Q}_s = \sqrt{hpkA_c}(T_b - T_\infty)\frac{\cosh mL - \left[(T_L - T_\infty)/(T_b - T_\infty)\right]}{\sinh mL}$$
$$= 0.12064\times(T_b - T_\infty)\frac{\cosh(4.06894) - \left[(22-20)/(T_b - T_\infty)\right]}{\sinh(4.06894)}$$
$$= 0.12071\times(T_b - T_\infty) - 0.008252$$

Step 5 of 5

Therefore, the surface temperature of the motor can be determined from equation (1)

$$\dot{Q}_{gen} = \dot{Q}_b + \dot{Q}_s$$
$$135 = \dot{Q}_b + \dot{Q}_s$$
$$= 1.875(T_b - T_\infty) + 0.12071\times(T_b - T_\infty) - 0.008252$$
$$= 1.875\times(T_b - 20) + 0.12071\times(T_b - 20) - 0.008252$$
$$135 = (T_b - 20)\times 1.9957 - 0.008252$$
$$(T_b - 20) = 67.649$$
$$\boxed{T_b = 87.65\,^\circ\text{C}}$$

Therefore the surface temperature of the motor housing is $T_b = 87.65\,^\circ\text{C}$

Question: 17.108P pg 1

Two 4-m-long and 0.4-cm-thick cast iron (k = 52 W/m·K) steam pipes of outer diameter 10 cm are connected to each other through two 1-cm-thick flanges of outer diameter 18cm. The steam flows inside the pipe at an average temperature of 200°C with a heat transfer coefficient of 180 W/m2·K. The outer surface of the pipe is exposed to an ambient at I2°C, with a heat transfer coefficient of 25 W/m2·K. (*a*) Disregarding the flanges, determine the average outer surface temperature of the pipe, (*b*) Using this temperature for the base of the flange and treating the flanges as the fins, determine the fin efficiency and the rate of heat transfer from the flanges, (*c*) What length of pipe is the flange section equivalent to for heat transfer purposes?

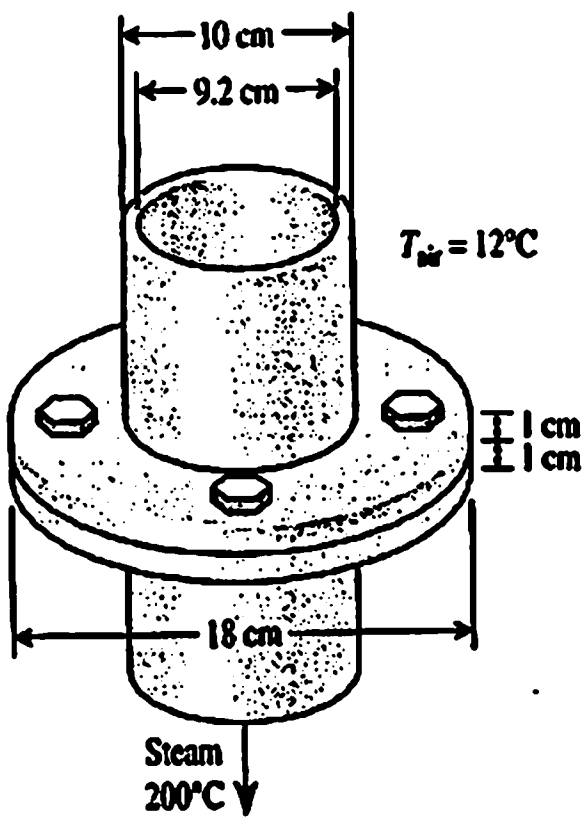

FIGURE P17–108

Step 1 of 10

Given data:

Outer diameter of the pipe, $d_2 = 10\,\text{cm}$

Inner diameter of the pipe, $d_1 = 9.2\,\text{cm}$

Length of the two pipes, $L = 4\,\text{m}$

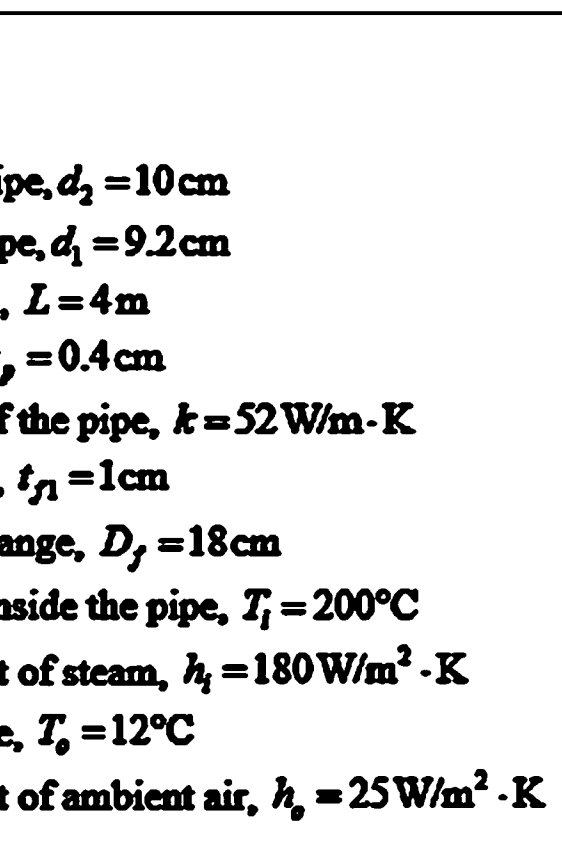
Thickness of the pipe, $t_p = 0.4\,\text{cm}$

Thermal conductivity of the pipe, $k = 52\,\text{W/m-K}$

Thickness of the flange, $t_{f1} = 1\,\text{cm}$

Outer diameter of the flange, $D_f = 18\,\text{cm}$

Temperature of steam inside the pipe, $T_i = 200°\text{C}$



Heat transfer coefficient of steam, $h_i = 180\,\text{W/m}^2\text{-K}$

Ambient air temperature, $T_o = 12°\text{C}$

Heat transfer coefficient of ambient air, $h_o = 25\,\text{W/m}^2\text{-K}$

Step 2 of 10

Given diagram:

Step 3 of 10

a)

The inner and outer surface areas of the pipe are

$$A_i = \pi d_1 L$$
$$= \pi \times (0.092\text{m}) \times (8\text{m})$$
$$= 2.3122\,\text{m}^2$$
$$A_o = \pi d_2 L$$
$$= \pi \times (0.1\text{m}) \times (8\text{m})$$
$$= 2.5132\,\text{m}^2$$

The individual thermal resistances are evaluated as:

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{180(\text{W/m}^2\cdot\text{K}) \times 2.3122(\text{m}^2)}$$
$$= 0.002403\,\text{K/W}$$
$$R_1 = \frac{\ln(r_2/r_1)}{2\pi kL}$$
$$= \frac{\ln(0.05/0.046)}{2\pi \times 52(\text{W/m-K}) \times 8(\text{m})}$$
$$= 0.0000319\,\text{K/W}$$
$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{25(\text{W/m}^2\cdot\text{K}) \times 2.5132(\text{m}^2)}$$
$$= 0.015916\,\text{K/W}$$

Step 4 of 10

All the resistances are in series, and the total resistance will be

$$R_{total} = R_i + R_1 + R_o$$
$$= 0.002403(\text{K/W}) + 0.0000319(\text{K/W}) + 0.015916(\text{K/W})$$
$$= 0.018351\,\text{K/W}$$

Step 4 of 10

All the resistances are in series, and the total resistance will be

$$R_{total} = R_i + R_1 + R_o$$
$$= 0.002403(\text{K/W}) + 0.0000319(\text{K/W}) + 0.015916(\text{K/W})$$
$$= 0.018351\text{K/W}$$

The steady rate of heat loss from the hot water pipe becomes

$$\dot{Q} = \frac{(T_i - T_o)}{R_{total}}$$
$$= \frac{(200-12)}{0.018351(\text{K/W})}$$
$$= 10244.67331\text{W}$$

Step 5 of 10

The surface temperature of the pipe can be determined as

$$\dot{Q} = \frac{(T_s - T_o)}{R_o}$$

Therefore, the surface temperature can be expressed as

$$T_s = T_o + \dot{Q} R_o$$
$$= 12 + 10244.67331 \times 0.015916$$
$$= 175.05°\text{C}$$

$$\boxed{T_s = 175.05°\text{C}}$$

Step 6 of 10

b)

Since convection heat transfer only occurs from one surface of a flange, the connected flanges may be modeled as a single annular fin of thickness $t_f = 2t_{f1} = 2\,\text{cm}$

Hence,

$$r_{2c} = \frac{d_f}{2} + \frac{t_f}{2}$$
$$= \frac{0.18}{2} + \frac{0.02}{2}$$
$$= 0.1\text{m}$$

$$A_{fin} = 2\pi\left(r_{2c}^2 - r_1^2\right)$$
$$= 2\pi \times (0.1^2 - 0.05^2)$$
$$= 0.047123\text{m}^2$$

$$L_c = L + \frac{t_f}{2}$$
$$= \frac{d_f - d_o}{2} + \frac{t_f}{2}$$
$$= \frac{0.18-0.10}{2} + \frac{0.02}{2}$$
$$= 0.05\text{m}$$

Step 7 of 10

And

$$A_p = L_c t_f$$
$$= 0.05(\text{m}) \times 0.02(\text{m})$$
$$= 0.001\text{m}^2$$

$$\xi = L_c^{3/2}\left(h/kA_p\right)^{1/2}$$
$$= (0.05\text{m})^{3/2} \times \left(\frac{25(\text{W/m}^2\text{-K})}{52(\text{W/m-K}) \times 0.001(\text{m}^2)}\right)^{1/2}$$
$$= 0.2451$$

$$\frac{r_{2c}}{r_1} = \frac{r_{2c}}{d_o/2}$$
$$= \frac{0.1}{0.05}$$
$$= 2$$

From the diagram efficiency of annular fins of constant thickness the efficiency of the fin at $\xi = 0.2451$ and $\frac{r_{2c}}{r_1} = 2$ is

$$\eta_{fin} = 0.945$$

$$\boxed{\eta_{fin} = 94.5\%}$$

Step 8 of 10

Heat transfer from the flanges can be expressed as

$$\dot{Q}_{flanges} = \eta_{fin} h A_{fin} (T_s - T_\infty)$$
$$= 0.945 \times 25(\text{W/m}^2\text{-K}) \times 0.047123(\text{m}^2) \times (175.05 - 12)$$
$$= 181.52\,\text{W}$$

$$\boxed{\dot{Q}_{flanges} = 181.52\,\text{W}}$$

Therefore the fin efficiency is $\eta_{fin} = 94.5\%$ and rate of heat transfer from the flange is

$$\dot{Q}_{flanges} = 181.52\,\text{W}$$

Step 9 of 10

c)

The equivalent length of pipe at the flange section for heat transfer can be calculated by assuming that the heat lost from the flanges is same as the heat lost from the pipe for the equivalent length

$$\dot{Q} = \frac{(T_i - T_o)}{R_{total}}$$

$$181.52\,\text{W} = \frac{(200-12)}{R_{total}}$$

$$R_{total} = 1.0357\text{K/W}$$

$$R_{total} = R_i + R_1 + R_o$$

$$R_1 = R_{total} - (R_i + R_o)$$
$$= 1.0357 - [0.002403(\text{K/W}) + 0.015916(\text{K/W})]$$
$$= 1.01738\text{K/W}$$

$R_{total} = R_i + R_1 + R_o$

$R_1 = R_{total} - (R_i + R_o)$

$= 1.0357 - [0.002403(\text{K/W}) + 0.015916(\text{K/W})]$

$= 1.01738\text{K/W}$

$$R_1 = \frac{\ln(r_2/r_1)}{2\pi k L_{eq}}$$

Step 10 of 10

The equivalent pipe length can be expressed as

$$L_{eq} = \frac{\ln(r_2/r_1)}{2\pi k R_1}$$

$$L_{eq} = \frac{\ln(0.05/0.046)}{2\pi \times 52(\text{W/m-K}) \times 1.01738(\text{K/W})}$$

$= 0.000251\text{m}$

$= 0.251\text{mm}$

$\boxed{L_{eq} = 0.251\text{mm}}$

Therefore the equivalent length of the pipe for heat transfer purposes is $L_{eq} = 0.251\text{mm}$

Question: 17.109P

A 40-W power transistor is to be cooled by attaching it to one of the commercially available heat sinks shown in Table 17-6. Select a heat sink that will allow the case temperature of the transistor not to exceed 90°C in the ambient air at 20°C.

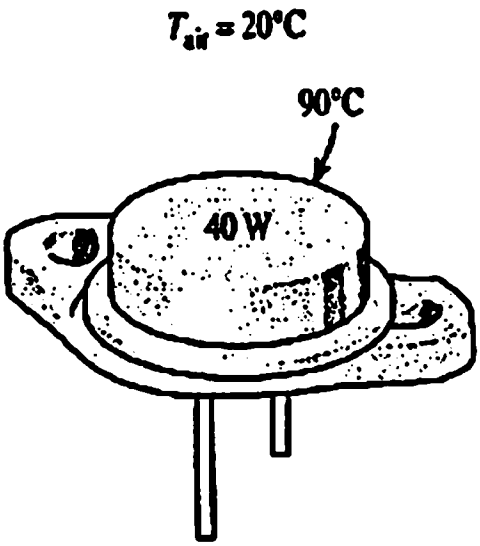


FIGURE P17–109

Step 1 of 2

Given
Power of transistor $(Q) = 40W$
Maximum allowable temperature of transistor $= 90°C$
Ambient air temperature $= 20°C$
Let thermal resistance of heat sink be R

Step 2 of 2

Rate of heat transfer is given by

$$\dot{Q} = \frac{\Delta T}{R}$$

$$R = \frac{T_{transistor} - T_{\infty}}{\dot{Q}}$$

$$R = \frac{(90 - 20)°C}{40\ W}$$

$$R = 1.75\,°C/W$$

Hence the thermal resistance for the heat sink which is selected for this purpose should be below 1.75 °C/W. From table of heat sinks for electronic devices (Table 10-6) HS5030 and HS6115 can be selected in both horizontal and vertical position and HS6071 can be selected in vertical position.

Question: 17.110P

A 25-W power transistor is to be cooled by attaching it to one of the commercially available heat sinks shown in Table 17-6. Select a heat sink that will allow the case temperature of the transistor not to exceed 55°C in the ambient air at 18°C

Step 1 of 3

Given data:

Power transistor $Q = 25\ \text{W}$

Transistor temperature, $T_{\text{transistor}} = 55°\text{C}$

Ambient temperature, $T_{\infty} = 18°\text{C}$

Step 2 of 3

Thermal resistance of heat sink be R

Rate of heat transfer is given by

$$\dot{Q} = \frac{\Delta T}{R}$$

$$R = \frac{T_{\text{transistor}} - T_{\infty}}{\dot{Q}}$$

$$R = \frac{(55-18)°\text{C}}{25\ \text{W}}$$

$$R = 1.48\ °\text{C/W}$$

∴ The thermal resistance $\boxed{R = 1.48°\text{C/W}}$

Step 3 of 3

To select a heat sink from the combined natural convection and radiation thermal resistance of various heat sink table such that temperature of case not to exceed 55°C when ambient air at 18°C

The thermal resistance for the heat sink which is selected for the purpose should be below 1.48 °C/W. From above mentioned table HS6115 can be selected in both horizontal and vertical position and HS6071 can be selected in vertical position.

Question: 17.111P pg 1

A plane wall with surface temperature of 350°C is attached with straight rectangular fins (k= 235 W/m·K). The fins are exposed to an ambient air condition of 25°C and the convection heat transfer coefficient is 154 W/m2·K. Each fin has a length of 50 mm, a base of 5 mm thick and a width of 100 mm. Determine the efficiency, heat transfer rate, and effectiveness of each fin. using (*a*) Table 17–3 and (*b*) Figure 17-43.

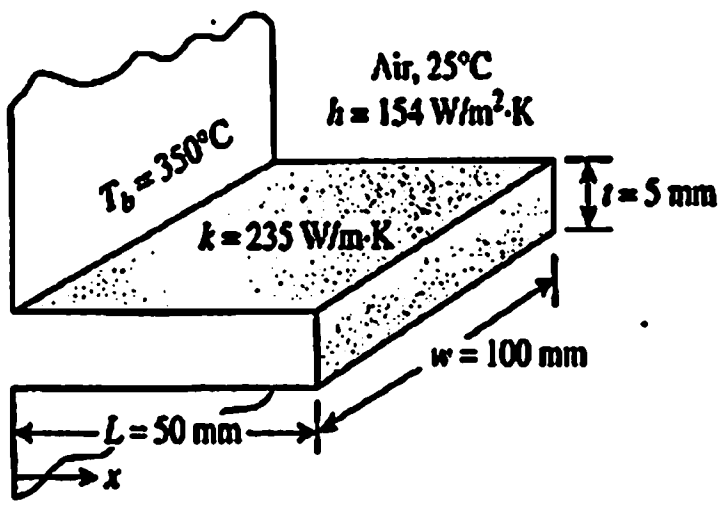

FIGURE P17–111

Step 1 of 7

Length of the fin, $L = 50\,\text{mm}$

Thickness of the fin, $t = 5\text{mm}$

Width of the fin, $w = 100\text{mm}$

Thermal conductivity of the fin, $k = 235\,\text{W/m·K}$

Surface temperature of the wall, $T_b = 350°\text{C}$

Ambient air temperature, $T_\infty = 25°\text{C}$

Convection heat transfer coefficient of ambient air, $h_\infty = 154\,\text{W/m}^2\text{·K}$

Step 2 of 7

a)

From efficiency and surface areas of common fin configuration table

For a straight rectangular fins the efficiency of the fin can be determined as

$$\eta_{fin} = \frac{\tanh mL_c}{mL_c}$$

Where m and L_c can be calculated as

$$m = \sqrt{\frac{2h}{kt}}$$

$$= \sqrt{\frac{2\times154}{235\times0.005}}$$

$$= 16.19035\,(1/\text{m})$$

$$L_c = L + \frac{t}{2}$$

$$= 0.05 + \frac{0.005}{2}$$

$$= 0.0525\,(\text{m})$$

Therefore, the efficiency of the fin can be calculated as

$$\eta_{fin} = \frac{\tanh(16.19035\times0.0525)}{16.19035\times0.0525}$$

$$= 0.813$$

$$= 81.3\%$$

The efficiency of the fin is $\boxed{81.3\%}$

Step 3 of 7

The fin surface area can be expressed as

$$A_{fin} = 2wL_c$$

$$= 2\times0.1\times0.0525$$

$$= 0.0105\,\text{m}^2$$

The rate of heat transfer from the fin can be expressed as

$$\dot{Q}_{fin} = \eta_{fin} h_\infty A_{fin}(T_b - T_\infty)$$

$$= 0.813\times154\times0.0105\times(350-25)$$

$$= 427.252\,\text{W}$$

The rate of heat transfer from the fin is $\boxed{427.252\text{W}}$

Step 4 of 7

The effectiveness of the fin can be expressed as

$$\varepsilon_{fin} = \frac{\dot{Q}_{fin}}{\dot{Q}_{without\ fin}}$$

$$= \frac{\dot{Q}_{fin}}{h_\infty A_b(T_b - T_\infty)}$$

$$= \frac{\text{Heat tarnsfer from the fin of surface area } A_{fin}}{\text{Heat transfer from the fin base area } A_b}$$

Where A_b represents the cross sectional area of the fin at the base and

And $\dot{Q}_{without\ fin}$ represents the rate of heat transfer from the base area if no fins are attached to the surface

Base area A_b can be expressed as

$$A_b = wt$$

$$= 0.1\times0.005$$

$$= 0.0005\,\text{m}^2$$

Therefore, the effectiveness of the fin can be calculated as

$$\varepsilon_{fin} = \frac{\dot{Q}_{fin}}{\dot{Q}_{without\ fin}}$$

$$= \frac{\dot{Q}_{fin}}{h_\infty A_b(T_b - T_\infty)}$$

$$= \frac{427.252}{154\times0.0005\times(350-25)}$$

$$= 17.073$$

$$= \frac{Q_{fin}}{h_w A_b (T_b - T_\infty)}$$

$$= \frac{427.252}{154 \times 0.0005 \times (350 - 25)}$$

$$= 17.073$$

The effectiveness of the fin is $\boxed{17.073}$

Step 5 of 7

b)

Efficiency of straight fins of rectangular profile

$$L_c = L + \frac{t}{2}$$

$$= 0.05 + \frac{0.005}{2}$$

$$= 0.0525\,\text{m}$$

$$A_p = L_c t$$

$$= 0.0525 \times 0.005$$

$$= 0.0002625\,\text{m}^2$$

$$\xi = L_c^{3/2} \left(h / k A_p \right)^{1/2}$$

$$= (0.0525\text{m})^{3/2} \times \left(\frac{154}{235 \times 0.0002625} \right)^{1/2}$$

$$= 0.601$$

Efficiency of straight fins of rectangular profile, the efficiency of the fin at $\xi = 0.601$ is

$\eta_{fin} = 0.81$

$\boxed{\eta_{fin} = 81\%}$

Step 6 of 7

The rate of heat transfer from the fin can be expressed as

$$\dot{Q}_{fin} = \eta_{fin} h_w A_{fin} (T_b - T_\infty)$$

$$= 0.81 \times 154 \times 0.0105 \times (350 - 25)$$

$$= 425.675\,\text{W}$$

$\boxed{\dot{Q}_{fin} = 425.675\text{W}}$

Step 7 of 7

The effectiveness of the fin can be expressed as

$$\varepsilon_{fin} = \frac{\dot{Q}_{fin}}{\dot{Q}_{without\,fin}}$$

$$= \frac{\dot{Q}_{fin}}{h_w A_b (T_b - T_\infty)}$$

$$= \frac{\text{Heat tarnsfer from the fin of surface area } A_{fin}}{\text{Heat transfer from the fin base area } A_b}$$

Where A_b represents the cross sectional area of the fin at the base

And $\dot{Q}_{without\,fin}$ represents the rate of heat transfer from the base area if no fins are attached to the surface

Therefore, the effectiveness of the fin can be calculated as

$$\varepsilon_{fin} = \frac{\dot{Q}_{fin}}{\dot{Q}_{without\,fin}}$$

$$= \frac{\dot{Q}_{fin}}{h_w A_b (T_b - T_\infty)}$$

$$= \frac{425.675}{154 \times 0.0005 \times (350 - 25)}$$

$$= 17.0099$$

$\boxed{\varepsilon_{fin} = 17.0099}$

Question: 17.112P pg 1

Steam in a heating system flows through tubes whose outer diameter is 5 cm and whose walls are maintained at a temperature of 130°C. Circular aluminum alloy 2024-T6 fins (k =186 W/m·K) of outer diameter 6 cm and constant thickness 1 mm are attached to the tube. The space between the fins is 3 mm, and thus there are 250 fins per meter length of the tube. Heat is transferred to the surrounding air at $T\infty$ =25°C, with a heat transfer coefficient of 40 W/m2·K. Determine the increase in heat transfer from the tube per meter of its length as a result of adding fins.

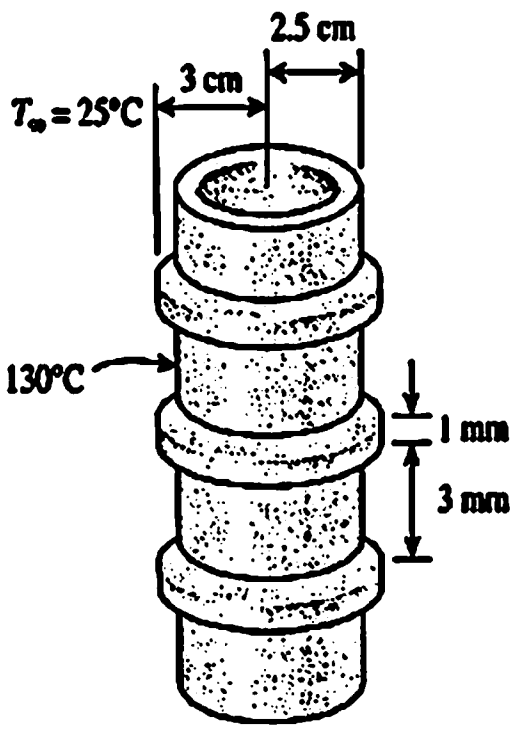

FIGURE P17–112

Step 1 of 7

Given data:

Outer diameter of tubes $D_1 = 5$ cm

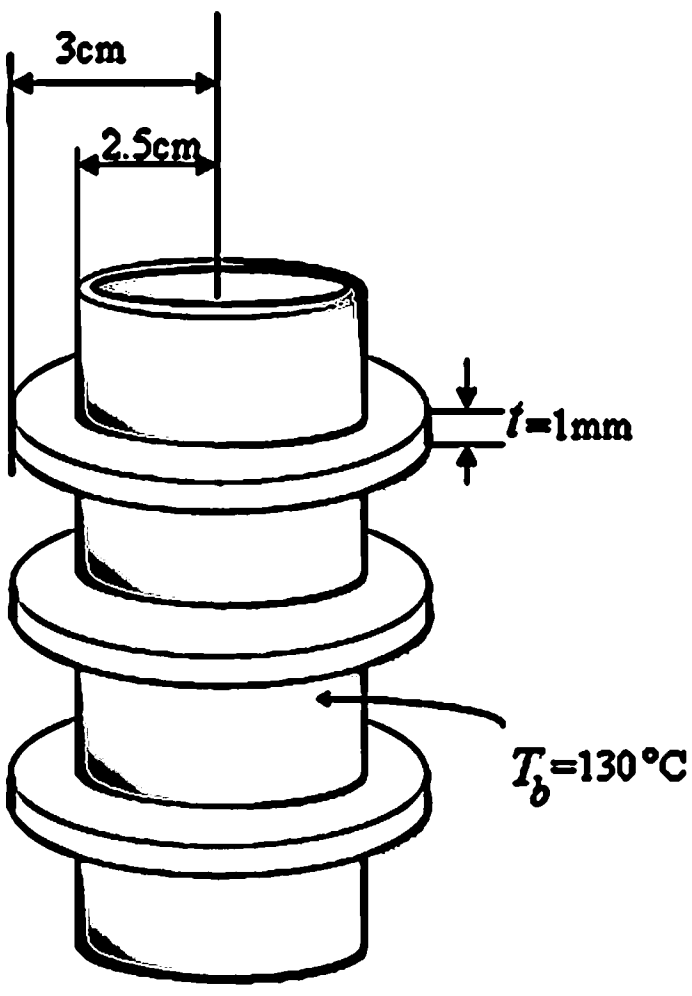
Temperature of walls $T_b = 130°C$

Thermal conductivity of 2024-T6 fins $k = 186$ W/m·°C

Outer diameter of fins $D_f = 6$ cm

Thickness of fins $t = 1$ mm

Space between fins $s = 3$mm



Ambient air temperature, $T_\infty = 25°C$

Heat transfer coefficient of ambient air, $h_\infty = 40 W/m^2 \cdot K$

Number of fins per meter length, $n = 250$

Step 2 of 7

Given diagram:

Step 3 of 7

The efficiency of the fin can be calculated by calculating these parameters

$$r_{2c} = \frac{D_f}{2} + \frac{t_f}{2}$$
$$= \frac{0.06}{2} + \frac{0.001}{2}$$
$$= 0.0305\,\text{m}$$
$$A_{fin} = 2\pi\left(r_{2c}^2 - r_1^2\right)$$
$$= 2\pi \times (0.0305^2 - 0.025^2)$$
$$= 0.00191794\,\text{m}^2$$
$$L_c = L + \frac{t_f}{2}$$
$$= \frac{D_f - D_1}{2} + \frac{t_f}{2}$$
$$= \frac{0.06 - 0.05}{2} + \frac{0.001}{2}$$
$$= 0.0055\,\text{m}$$

Step 4 of 7

And

$$A_p = L_c t_f$$
$$= 0.0055 \times 0.001$$
$$= 0.0000055\,\text{m}^2$$
$$\xi = L_c^{3/2}\left(h/kA_p\right)^{1/2}$$
$$= (0.0055\text{m})^{3/2} \times \left(\frac{40}{186 \times 0.0000055}\right)^{1/2}$$
$$= 0.0806559$$
$$\frac{r_{2c}}{r_1} = \frac{r_{2c}}{D_1/2}$$
$$= \frac{0.0305}{0.025}$$
$$= 1.22$$

From the graph efficiency of annular fins at $\xi = 0.0806559$ and $\frac{r_{2c}}{r_1} = 1.22$

$$= \frac{0.0305}{0.025}$$
$$= 1.22$$

From the graph efficiency of annular fins at $\xi = 0.0806559$ and $\frac{r_{2c}}{r_1} = 1.22$

$$\eta_{fin} = 0.97$$

Step 5 of 7

The rate of heat transfer from the fin can be expressed as

$$\dot{Q}_{fin} = \eta_{fin} h A_{fin} (T_s - T_\infty)$$
$$= 0.97 \times 40 \times 0.00191794 \times (130 - 25)$$
$$= 7.8136\,\text{W}$$

Step 6 of 7

For 250 fins the total heat transfer rate from the fins can be expressed as

$$\dot{Q}_{fins} = n \times \dot{Q}_{fin}$$
$$= 250 \times 7.81368$$
$$= 1953.42\,\text{W}$$

The heat transfer from the base area if no fins are attached to the surface can be calculated as

$$\dot{Q}_{no\,fin} = h_\infty A_b (T_b - T_\infty)$$
$$A_b = 2\pi r_1 t$$
$$= 2 \times \pi \times 0.025 \times 0.001$$
$$= 0.0001571\,\text{m}^2$$

$$\dot{Q}_{no\,fin} = h_\infty A_b (T_b - T_\infty)$$
$$= 40 \times 0.0001571 \times (130 - 25)$$
$$= 0.65982\,\text{W}$$

Step 7 of 7

For 250 fins, the total heat transfer rate from the fins base area becomes

$$\dot{Q}_{no\,fins} = n \times \dot{Q}_{no\,fin}$$
$$= 250 \times 0.65982$$
$$= 164.955\,\text{W}$$

Therefore, the increase in heat transfer due to addition of fins can be calculated as

$$\Delta\dot{Q}_{increase} = \dot{Q}_{fins} - \dot{Q}_{no\,fins}$$
$$= 1953.42 - 164.955$$
$$= 1788.465\,\text{W}$$

$$\boxed{\Delta\dot{Q}_{increase} = 1788.5\,\text{W}}$$

Question: 17.113P

Consider a stainless steel spoon (k =8.7Btu/h·ft·°F) partially immersed in boiling water at 200°F in a kitchen at 75°F. The handle of the spoon has a cross section of 0.08 in × 0.5 in, and extends 7 in in the air from the free surface of the water. If the heat transfer coefficient at the exposed surfaces of the spoon handle is 3 Btu/h·ft2·°F, determine the temperature difference across the exposed surface of the spoon handle. State your assumptions.

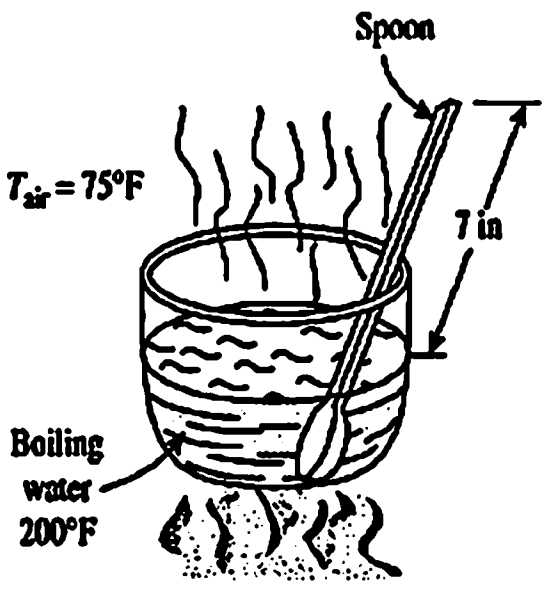


FIGURE P17–113E

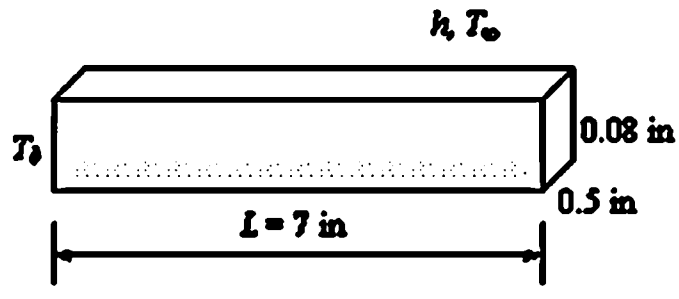
Step 1 of 6

Given data:

Cross section area of spoon $A = 0.008\text{ in} \times 0.5\text{ in}$

Temperature of boiling water $T_b = 200°F$



Temperature of kitchen $T_\infty = 75°F$

Heat transfer coefficient $h = 3\text{ Btu/h}\cdot\text{ft}^2\cdot°F$

Thermal conductivity of spoon $k = 8.7\text{ Btu/h/ft}\cdot°F$

Spoon extends 7 in from the surface of water

Step 2 of 6

Step 3 of 6

The temperature variation of spoon can be given by

$$\frac{T(x)-T_\infty}{T_b-T_\infty}=\frac{\cosh m(L-x)}{\cosh mL}$$

p = perimeter

$$= 2\left(\frac{0.5}{12}\text{ft}+\frac{0.08}{12}\text{ft}\right)$$

$$= 0.0967\text{ ft}$$

$$A_c = \left(\frac{0.5}{12}\text{ft}\right)\left(\frac{0.08}{12}\text{ft}\right)$$

$$= 0.000278\text{ft}^2$$

Step 4 of 6

Therefore the fin parameter

$$m = \sqrt{\frac{hp}{kA_c}}$$

$$= \sqrt{\frac{(3\text{ Btu/h.ft}^2.°F)(0.0967\text{ ft})}{(8.7\text{ Btu/h.ft.°F})(0.000278\text{ ft}^2)}}$$

$$= 10.95\text{ ft}^{-1}$$

Step 5 of 6

Now $x = L$

$L = 7/12$

$L = 0.583$ ft

$$T(L) = T_\infty + (T_b - T_\infty)\frac{\cosh m(L-L)}{\cosh mL}$$

$$= 75°F + (200-75)\frac{\cosh 0}{\cosh(10.95\times 0.583)}$$

$$= 75°F + (200-75)\frac{1}{296}$$

$$= 75.4°F$$

Step 6 of 6

Therefore, the temperature difference across the exposed surface of the spoon handle is

$$\Delta T = T_b - T_{tip}$$

$$= (200-75.4)°F$$

$$= 124.6°F$$

∴ The temperature difference $\boxed{\Delta T = 124.6°F}$

Question: 17.114P

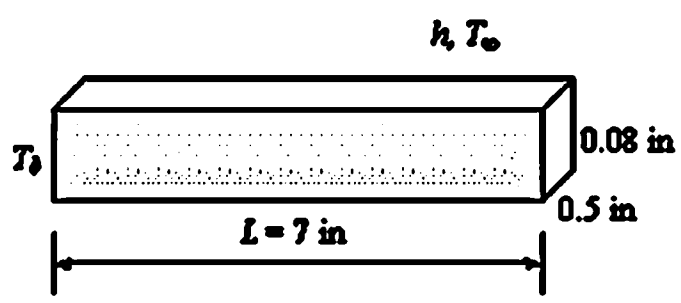
Repeat Prob. 17-113E for a silver spoon (k =247 Btu/h·ft·°F).

Step 1 of 6

Given data:

Cross section area of spoon $A = 0.08\text{ in} \times 0.5\text{ in}$

Temperature of boiling water $T_b = 200°\text{F}$



Temperature of kitchen $T_\infty = 75°\text{F}$

Heat transfer coefficient $h = 3\text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$

Thermal conductivity of spoon $k = 247\text{ Btu/h/ft}\cdot°\text{F}$

Spoon extends 7 in from the surface of water

Step 2 of 6

Step 3 of 6

Assuming the spoon handle is acts as a fin

The temperature variation of spoon is be given by the equation

$$\frac{T(x)-T_\infty}{T_b-T_\infty}=\frac{\cosh m(L-x)}{\cosh mL}$$

p = perimeter

$$=2\left(\frac{0.5}{12}\text{ft}+\frac{0.08}{12}\text{ft}\right)$$

$$=0.0967\text{ ft}$$

$$A_c=\left(\frac{0.5}{12}\text{ft}\right)\left(\frac{0.08}{12}\text{ft}\right)$$

$$=0.000278\text{ft}^2$$

Step 4 of 6

Therefore the fin parameter

$$m=\sqrt{\frac{hp}{kA_c}}$$

$$=\sqrt{\frac{(3\text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F})(0.0967\text{ft})}{(247\text{ Btu/h}\cdot\text{ft}\cdot°\text{F})(0.000278\text{ ft}^2)}}$$

$$=2.055\text{ ft}^{-1}$$

Step 5 of 6

Now $x = L$

$L = 7/12$

$L = 0.583$ ft

$$T(L)=T_\infty+(T_b-T_\infty)\frac{\cosh m(L-L)}{\cosh mL}$$

$$=75°\text{F}+(200-75)\frac{\cosh 0}{\cosh(2.055\times0.583)}$$

$$=75°\text{F}+(200-75)\frac{1}{1.81}$$

$$=144.1°\text{F}$$

Step 6 of 6

Therefore, the temperature difference across the exposed surface of the spoon handle is

$\Delta T = T_b - T_{tip}$

$$=(200-144.1)°\text{F}$$

$$=55.9°\text{F}$$

∴ The temperature difference $\boxed{\Delta T = 55.9°\text{F}}$

Question: 17.115P pg 1

Reconsider Prob. 17 −113E. Using EES (or other) software, investigate the effects of the thermal conductivity of the spoon material and the length of its extension in the air on the temperature difference across the exposed surface of the spoon handle. Let the thermal conductivity vary from 5 Btu/h·ft·°F to 225 Btu/h·ft·°F and the length from 5 in to 12 in. Plot the temperature difference as the functions of thermal conductivity and length, and discuss the results.

Step 1 of 5

To solve this question using EES software open EES software

Then FILE->New

A dailogbox will open type the following in dailog box

"GIVEN"

"k_spoon=8.7 [Btu/h-ft-F], parameter to be varied"

T_w=200 "[F]"

T_infinity=75 "[F]"

A_c=0.08/12*0.5/12 "[ft^2]"

L=7 "[in], parameter to be varied"

h=3 "[Btu/h-ft^2-F]"

Step 2 of 5

"ANALYSIS"

p=2*(0.08/12+0.5/12)

a=sqrt((h*p)/(k_spoon*A_c))

(T_tip-T_infinity)/(T_w-T_infinity)=cosh(a*(L-x)*Convert(in, ft))/cosh(a*L*Convert(in, ft))

x=L "for tip temperature"

DELTAT=T_w-T_tip

Then from Tables -> New parametric table

A dailog box will open

Select no of runs = 20

Select variables in equations as k_{spoon} and T press ADD and then press ok

A table will appear put values of k_{spoon} as 5,16.58,28.16....225 in run 1to 20

Then from Calculate -> Solve table

Solution will appear

k_{spoon} [Btu/h.ft.F]	T [F]
5	124.9

Question: 17.116P pg 1

A 0.4-cm-thick, 12-cm-high, and 18-cm-long circuit board houses 80 closely spaced logic chips on one side, each dissipating 0.04 W. The board is impregnated with copper fillings and has an effective thermal conductivity of 30 W/m·K. All the heat generated in the chips is conducted across the circuit board and is dissipated from the back side of the board to a medium at 40°C, with a heat transfer coefficient of 52 W/m2·K. (*a*) Determine the temperatures on the two sides of the circuit board, (*b*) Now a 0.2-cm-thick, 12-cm-high, and 18- cm-long aluminum plate (k =237 W/m·K) with 864 2-cm- long aluminum pin fins of diameter 0.25 cm is attached to the back side of the circuit board with a 0.02-cm-thick epoxy adhesive (k = 1.8 W/m·K). Determine the new temperatures on the two sides of the circuit board.

Step 1 of 11

Given data:

Height of the circuit board, $H = 0.12\,\text{cm}$

Length of the circuit board, $L = 18\text{cm}$

Thickness of the board, $t = 0.4\,\text{cm}$

Thermal conductivity of the circuit board, $k = 30\,\text{W/m}\cdot\text{K}$

Heat generated by each chip, $\dot{Q} = 0.04\,\text{W}$

Ambient temperature, $T_\infty = 40°\text{C}$

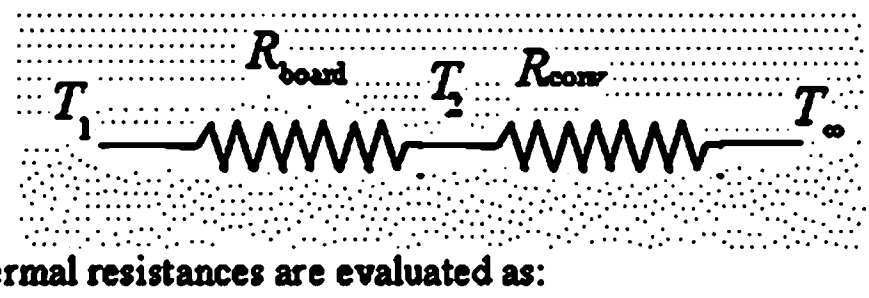
Heat transfer coefficient of ambient medium, $h_\infty = 52\,\text{W/m}^2\cdot\text{K}$

Number of logic chips, $n = 80$

Step 2 of 11

a)

Total heat dissipated by chips



$$\dot{Q} = n \times Q$$
$$= 80 \times 0.04$$
$$= 3.2\ \text{W}$$

The surface area of the circuit board can be calculated as

$$A = HL$$
$$= 0.12 \times 0.18$$
$$= 0.0216\ \text{m}^2$$

Step 3 of 11

The thermal resistance of the circuit board is

The individual thermal resistances are evaluated as:

The thermal resistance due to conduction

$$R_{board} = \frac{t}{kA}$$
$$= \frac{0.004}{30 \times 0.0216}$$
$$= 0.00617284\,\text{K/W}$$

The thermal resistance due to convection

$$R_{conv} = \frac{1}{h_\infty A}$$
$$= \frac{1}{52 \times 0.0216}$$
$$= 0.8903134\,\text{K/W}$$

Since all the resistances are in series, and the total resistance is

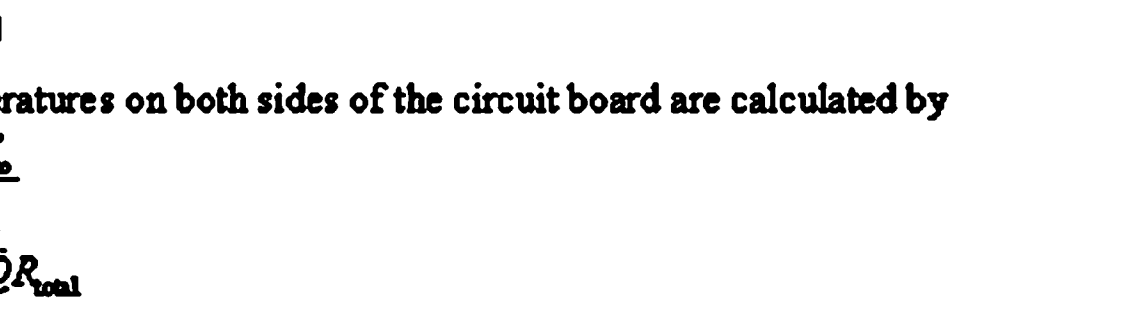
$$R_{total} = R_{board} + R_{conv}$$
$$= 0.00617284 + 0.8903134$$
$$= 0.8964862\,\text{K/W}$$

Step 4 of 11

The temperatures on both sides of the circuit board are calculated by

$$\dot{Q} = \frac{T_1 - T_\infty}{R_{total}}$$
$$T_1 = T_\infty + \dot{Q}R_{total}$$
$$= 40 + (3.2)(0.8964862)$$
$$= 42.868°\text{C}$$

The temperature on one side of the board $\boxed{T_1 = 42.868°\text{C}}$



Step 5 of 11

$$\dot{Q} = \frac{T_1 - T_2}{R_{board}}$$
$$T_2 = T_1 - \dot{Q}R_{board}$$
$$= 42.868 - (3.2)(0.00617284)$$
$$= 42.848°\text{C}$$

The temperature on the other side of the board $\boxed{T_2 = 42.848°\text{C}}$

Step 6 of 11

b) The thermal resistance of the circuit board with new resistances becomes

Step 7 of 11

The cross sectional areas of the fins are constant, the efficiency of the circular fins for tip condition assumed to be adiabatic, can be determined as

$$\eta_{fin} = \frac{\tanh mL}{mL}$$

Step 7 of 11

The cross sectional areas of the fins are constant, the efficiency of the circular fins for tip condition assumed to be adiabatic, can be determined as

$$\eta_{fin} = \frac{\tanh mL}{mL}$$

Where

$$m = \sqrt{\frac{hp}{kA_c}}$$

$$= \sqrt{\frac{52 \times \pi \times 0.0025}{237 \times \frac{\pi}{4} \times (0.0025)^2}}$$

$$= 18.7365$$

$$mL = 18.7365 \times 0.02$$

$$= 0.37473$$

Therefore, the efficiency of the fin becomes

$$\eta_{fin} = \frac{\tanh mL}{mL}$$

$$= \frac{\tanh (0.37473)}{0.37473}$$

$$= 0.9557$$

$$= 95.57\%$$

Step 8 of 11

Thermal resistance due to circuit board

$$R_{board} = \frac{t}{kA}$$

$$= \frac{0.004}{30 \times 0.0216}$$

$$= 0.00617284 \text{ K/W}$$

Thermal resistance due to thick epoxy adhesive

$$R_{epoxy} = \frac{t}{kA}$$

$$= \frac{0.0002}{1.8 \times 0.0216}$$

$$= 0.005144 \text{ K/W}$$

Thermal resistance due to aluminum plate

$$R_{alu} = \frac{t}{kA}$$

$$= \frac{0.002}{237 \times 0.0216}$$

$$= 0.00039 \text{ K/W}$$

Step 9 of 11

Area of the finned surface

$$A_{finned} = \eta_{fin} n \pi D L$$

$$= 0.9557 \times 864 \pi (0.0025)(0.02)$$

$$= 0.1297 \text{ m}^2$$

Area of the unfinned surface

$$A_{unfinned} = 0.0216 - 864 \frac{\pi D^2}{4}$$

$$= 0.0216 - 864 \times \frac{\pi (0.0025)^2}{4}$$

$$= 0.0174 \text{ m}^2$$

$$A_{total,with fins} = A_{finned} + A_{unfinned}$$

$$= 0.1297 + 0.0174$$

$$= 0.1471 \text{m}^2$$

Step 10 of 11

$$R_{conv} = \frac{1}{hA_{total,with fins}}$$

$$= \frac{1}{(52)(0.1471)}$$

$$= 0.13073 \text{K/W}$$

$$R_{total} = R_{board} + R_{epoxy} + R_{aluminum} + R_{conv}$$

$$= 0.00617284 + 0.005144 + 0.00039 + 0.13073$$

$$= 0.14243 \text{K/W}$$

Step 11 of 11

Temperatures on both sides of the circuit board is

$$\dot{Q} = \frac{T_1 - T_{\infty 2}}{R_{total}}$$

$$T_1 = T_{\infty 2} + \dot{Q} R_{total}$$

$$= 40 + (3.2)(0.14243)$$

$$= 40.45^\circ\text{C}$$

The temperature on one side of the board $\boxed{T_1 = 40.45^\circ\text{C}}$

Question: 17.117P pg 1

Repeat Prob. 17-116 using a copper plate with copper fins (ft= 386 W/m·K) instead of aluminum ones.

Step 1 of 11

Given data:

Height of the circuit board, $H = 0.12\,\text{cm}$

Length of the circuit board, $L = 18\text{cm}$

Thickness of the board, $t = 0.4\,\text{cm}$

Thermal conductivity of the circuit board, $k = 30\,\text{W/m}\cdot\text{K}$

Heat generated by each chip, $\dot{Q} = 0.04\,\text{W}$

Ambient temperature, $T_\infty = 40°\text{C}$

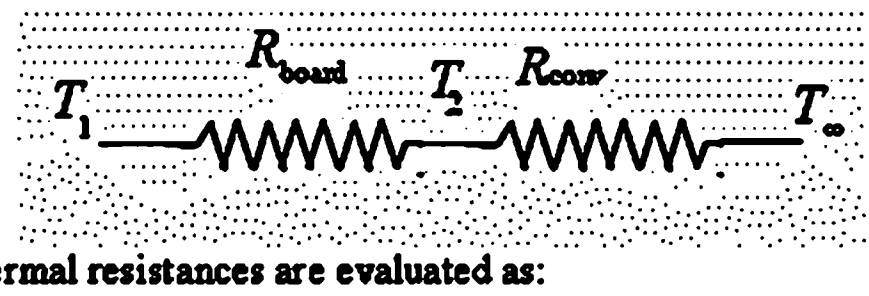
Heat transfer coefficient of ambient medium, $h_\infty = 52\,\text{W/m}^2\cdot\text{K}$

Number of logic chips, $n = 80$

Step 2 of 11

a)

Total heat dissipated by chips



$$\dot{Q} = n \times Q$$
$$= 80 \times 0.04$$
$$= 3.2\ \text{W}$$

The surface area of the circuit board can be calculated as

$$A = HL$$
$$= 0.12 \times 0.18$$
$$= 0.0216\,\text{m}^2$$

Step 3 of 11

The thermal resistance of the circuit board is

The individual thermal resistances are evaluated as:

The thermal resistance due to conduction

$$R_{board} = \frac{t}{kA}$$
$$= \frac{0.004}{30 \times 0.0216}$$
$$= 0.00617284\,\text{K/W}$$

The thermal resistance due to convection

$$R_{conv} = \frac{1}{h_\infty A}$$
$$= \frac{1}{52 \times 0.0216}$$
$$= 0.8903134\,\text{K/W}$$

Since all the resistances are in series, and the total resistance is

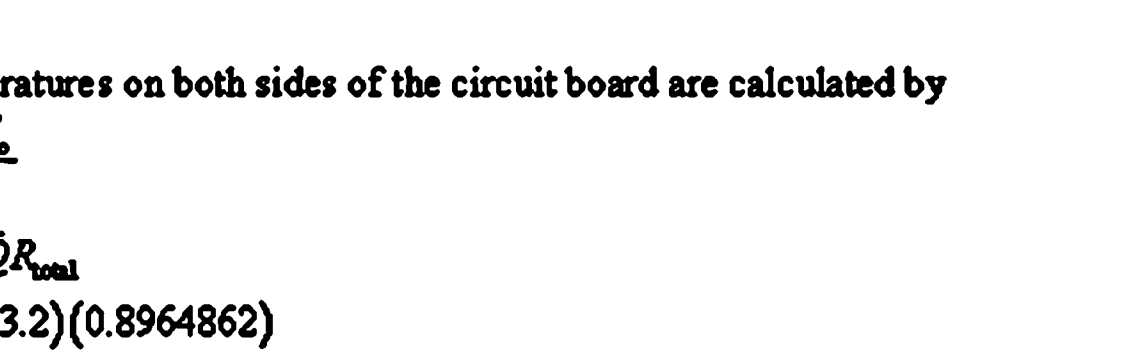
$$R_{total} = R_{board} + R_{conv}$$
$$= 0.00617284 + 0.8903134$$
$$= 0.8964862\,\text{K/W}$$

Step 4 of 11

The temperatures on both sides of the circuit board are calculated by

$$\dot{Q} = \frac{T_1 - T_\infty}{R_{total}}$$
$$T_1 = T_\infty + \dot{Q}R_{total}$$
$$= 40 + (3.2)(0.8964862)$$
$$= 42.868°\text{C}$$

The temperature on one side of the board $\boxed{T_1 = 42.868°\text{C}}$



Step 5 of 11

$$\dot{Q} = \frac{T_1 - T_2}{R_{board}}$$
$$T_2 = T_1 - \dot{Q}R_{board}$$
$$= 42.868 - (3.2)(0.00617284)$$
$$= 42.848°\text{C}$$

The temperature on the other side of the board $\boxed{T_2 = 42.848°\text{C}}$

Step 6 of 11

b) The thermal resistance of the circuit board with new resistances becomes

Step 7 of 11

The cross sectional areas of the fins are constant, the efficiency of the circular fins for tip condition assumed to be adiabatic, can be determined as

$$\eta_{fin} = \frac{\tanh mL}{mL}$$

Where

$$m = \sqrt{\frac{hp}{kA_c}}$$
$$= \sqrt{\frac{52 \times \pi \times 0.0025}{}}$$

Where

$$m = \sqrt{\frac{hp}{kA_c}}$$

$$= \sqrt{\frac{52 \times \pi \times 0.0025}{386 \times \frac{\pi}{4} \times (0.0025)^2}}$$

$$= 14.681$$

$$mL = 14.681 \times 0.02$$

$$= 0.29362$$

Therefore, the efficiency of the fin becomes

$$\eta_{fin} = \frac{\tanh mL}{mL}$$

$$= \frac{\tanh (0.29362)}{0.29362}$$

$$= 0.9722$$

$$= 97.22\%$$

Step 8 of 11

Thermal resistance due to circuit board

$$R_{board} = \frac{t}{kA}$$

$$= \frac{0.004}{30 \times 0.0216}$$

$$= 0.00617284\,K/W$$

Thermal resistance due to thick epoxy adhesive

$$R_{epoxy} = \frac{t}{kA}$$

$$= \frac{0.0002}{1.8 \times 0.0216}$$

$$= 0.005144\,K/W$$

Thermal resistance due to copper plate

$$R_{cu} = \frac{t}{kA}$$

$$= \frac{0.002}{386 \times 0.0216}$$

$$= 0.000239\,K/W$$

Step 9 of 11

Area of the finned surface

$$A_{finned} = \eta_{fin} n \pi D L$$

$$= 0.9722 \times 864 \pi (0.0025)(0.02)$$

$$= 0.13194\ m^2$$

Area of the unfinned surface

$$A_{unfinned} = 0.0216 - 864 \frac{\pi D^2}{4}$$

$$= 0.0216 - 864 \times \frac{\pi (0.0025)^2}{4}$$

$$= 0.0174\ m^2$$

$$A_{total with fins} = A_{finned} + A_{unfinned}$$

$$= 0.13194 + 0.0174$$

$$= 0.1493 m^2$$

Step 10 of 11

$$R_{conv} = \frac{1}{hA_{total with fins}}$$

$$= \frac{1}{(52)(0.1493)}$$

$$= 0.1288 k/W$$

$$R_{total} = R_{board} + R_{epoxy} + R_{cu} + R_{conv}$$

$$= 0.00617284 + 0.005144 + 0.000239 + 0.1288$$

$$= 0.140355 K/W$$

Step 11 of 11

Temperatures on both sides of the circuit board is

$$\dot{Q} = \frac{T_1 - T_{\infty 2}}{R_{total}}$$

$$T_1 = T_{\infty 2} + \dot{Q} R_{total}$$

$$= 40 + (3.2)(0.140355)$$

$$= 40.449°C$$

The temperature on one side of the board $\boxed{T_1 = 40.449°C}$

Question: 17.118P

A hot surface at 100°C is to be cooled by attaching 3-cm-long, 0.25-cm-diameter aluminum pin fins (k = 237 W/m·K) to it, with a center-to-center distance of 0.6 cm. The temperature of the surrounding medium is 30°C, and the heat transfer coefficient on the surfaces is 35 W/m2· K. Determine the rate of heat transfer from the surface for a 1 -m × 1 -m section of the plate. Also determine the overall effectiveness of the fins.

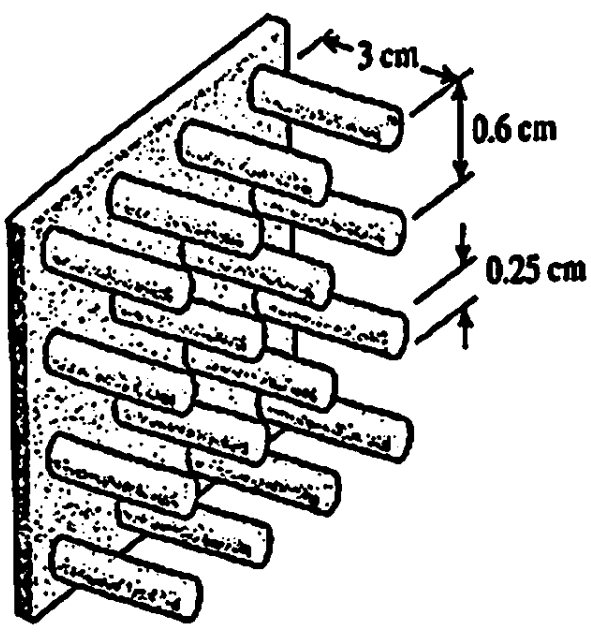


FIGURE P17–118

Step 1 of 10

Given data:

Temperature of surface $= 100°C$

Length of fins $L = 3\text{cm}$

Diameter of fins $D = 0.25\text{cm}$

Thermal conductivity of fins $k = 237\ \text{W/m} \cdot °C$

Centre to centre distance $= 0.6\ \text{cm}$

Temperature of the hot surface $T_s = 100°C$

Temperature of surrounding medium $T_\infty = 30°C$

Heat transfer coefficient $h = 35\ \text{W/m}^2 \cdot °C$

Step 2 of 10

Efficiency of the fins can be calculated by

Fin parameter

$$m = \sqrt{\frac{hp}{kA_c}}$$

$$= \sqrt{\frac{h\pi D}{k\pi D^2/4}}$$

$$= \sqrt{\frac{4h}{kD}}$$

$$= \sqrt{\frac{4(35\ \text{W/m}^2 \cdot °C)}{(237\ \text{W/m} \cdot °C)(0.0025\ \text{m})}}$$

$$= 15.37\ \text{m}^{-1}$$

Step 3 of 10

The fin efficiency is given by

$$\eta_{\text{fin}} = \frac{\tanh mL}{mL}$$

$$= \frac{\tanh(15.37\ \text{m}^{-1} \times 0.03\ \text{m})}{15.37\ \text{m}^{-1} \times 0.03\ \text{m}}$$

$$= 0.935$$

Total number of fins

$$n = \frac{1\ \text{m}^2}{(0.006\ \text{m})(0.006\ \text{m})}$$

$$= 27,777$$

Step 4 of 10

Surface area of fins

$$A_{\text{fin}} = 27777\left[\pi DL + \frac{\pi D^2}{4}\right]$$

$$= 27777\left[\pi(0.0025)(0.03) + \frac{\pi(0.0025)^2}{4}\right]$$

$$= 6.68\ \text{m}^2$$

Step 5 of 10

Un finned surface area

$$A_{\text{unfinned}} = 1 - 27777\left(\frac{\pi D^2}{4}\right)$$

$$= 1 - 27777\left[\frac{\pi(0.0025)^2}{4}\right]$$

$$= 0.86\ \text{m}^2$$

Step 6 of 10

Heat transfer through finned surface

$$\dot{Q}_{\text{finned}} = \eta_{\text{fin}} \dot{Q}_{\text{finmax}}$$

$$= \eta_{\text{fin}} h A_{\text{fin}} (T_s - T_\infty)$$

$$= 0.935\left(35\ \text{W/m}^2 \cdot °C\right)\left(6.68\ \text{m}^2\right)(100-30)°C$$

$$= 15,302.2\ \text{W}$$

Step 7 of 10

Heat transfer through un finned surface

$$\dot{Q}_{\text{unfinned}} = hA_{\text{unfinned}} (T_s - T_\infty)$$

$$= \left(35\ \text{W/m}^2 \cdot °C\right)\left(0.86\ \text{m}^2\right)(100-30)°C$$

$$= 2107\ \text{W}$$

Step 8 of 10

Total heat transfer from the plate with fins

$$\dot{Q}_{\text{total fin}} = \dot{Q}_{\text{finned}} + \dot{Q}_{\text{unfinned}}$$

$$= 15,300 + 2107$$

$$= 1.74 \times 10^4\ \text{W}$$

$$= 17.4\ \text{kW}$$

Step 9 of 10

Rate of heat transfer when there are no fins

$$A_{\text{without fin}} = (1\ \text{m})(1\ \text{m})$$

$$= 1\ \text{m}^2$$

$$\dot{Q}_{\text{without fin}} = hA_{\text{no fin}} (T_s - T_\infty)$$

$$= \left(35\ \text{W/m}^2.°C\right)\left(1\ \text{m}^2\right)(100-30)°C$$

$$= 2450\ \text{W}$$

∴ The rate of heat transfer $\boxed{\dot{Q} = 2450\ \text{W}}$

Step 10 of 10

Then the fin effectiveness becomes

$$\varepsilon_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{without fin}}}$$

$$= \frac{17,400}{2450}$$

$$= 7.10$$

∴ The overall effectiveness of the fin $\boxed{\varepsilon_{\text{fin}} = 7.10}$

Question: 17.119P

Repeat Prob. 17-118 using copper fins (k =386 W/m·K) instead of aluminum ones.

Step 1 of 10

Given data:
Temperature of surface $= 100°C$
Length of fins $L = 3\text{cm}$
Diameter of fins $D = 0.25\text{cm}$
Thermal conductivity of fins $k = 386\ \text{W/m} \cdot °C$
Centre to centre distance $= 0.6\ \text{cm}$
Temperature of the hot surface $T_s = 100°C$
Temperature of surrounding medium $T_\infty = 30°C$
Heat transfer coefficient $h = 35\ \text{W/m}^2 \cdot °C$

Step 2 of 10

Efficiency of the fins can be calculated by
Fin parameter

$$m = \sqrt{\frac{hp}{kA_c}}$$
$$= \sqrt{\frac{h\pi D}{k\pi D^2/4}}$$
$$= \sqrt{\frac{4h}{kD}}$$
$$= \sqrt{\frac{4(35\ \text{W/m}^2 \cdot °C)}{(386\ \text{W/m} \cdot °C)(0.0025\ \text{m})}}$$
$$= 12.04\ \text{m}^{-1}$$

Step 3 of 10

The fin efficiency is given by

$$\eta_{\text{fin}} = \frac{\tanh mL}{mL}$$
$$= \frac{\tanh(12.04\ \text{m}^{-1} \times 0.03\ \text{m})}{12.04\ \text{m}^{-1} \times 0.03\ \text{m}}$$
$$= 0.959$$

Step 4 of 10

Total number of fins

$$n = \frac{1\ \text{m}^2}{(0.006\ \text{m})(0.006\ \text{m})}$$
$$= 27777$$

Surface area of fins

$$A_{\text{fin}} = 27777\left[\pi DL + \frac{\pi D^2}{4}\right]$$
$$= 27777\left[\pi(0.0025)(0.03) + \frac{\pi(0.0025)^2}{4}\right]$$
$$= 6.68\ \text{m}^2$$

Step 5 of 10

Un finned surface area

$$A_{\text{unfinned}} = 1 - 27777\left(\frac{\pi D^2}{4}\right)$$
$$= 1 - 27777\left[\frac{\pi(0.0025)^2}{4}\right]$$
$$= 0.86\ \text{m}^2$$

Step 6 of 10

Heat transfer through finned surface

$$\dot{Q}_{\text{finned}} = \eta_{\text{fin}} \dot{Q}_{\text{finmax}}$$
$$= \eta_{\text{fin}} h A_{\text{fin}} (T_s - T_\infty)$$
$$= 0.959(35\ \text{W/m}^2 \cdot °C)(6.68\ \text{m}^2)(100 - 30)°C$$
$$= 15{,}700\ \text{W}$$

Step 7 of 10

$$\dot{Q}_{\text{unfinned}} = hA_{\text{unfinned}} (T_s - T_\infty)$$
$$= (35\ \text{W/m}^2 °C)(0.86\ \text{m}^2)(100 - 30)°C$$
$$= 2107\ \text{W}$$

Step 8 of 10

Total heat transfer from the plate with fins

$$\dot{Q}_{\text{total fin}} = \dot{Q}_{\text{finned}} + \dot{Q}_{\text{unfinned}}$$
$$= 15{,}700 + 2107$$
$$= 1.78 \times 10^4\ \text{W}$$
$$= 17.8\text{kW}$$

Step 9 of 10

Rate of heat transfer when there are no fins

$$A_{\text{no fin}} = 1 \times 1$$
$$= 1\ \text{m}^2$$
$$\dot{Q}_{\text{no fin}} = hA_{\text{no fin}} (T_s - T_\infty)$$
$$= 35\ \text{W/m}^2 \cdot °C \times 1\ \text{m}^2 \times (100 - 30)°C$$
$$= 2450\ \text{W}$$

∴ The rate of heat transfer $\boxed{\dot{Q} = 2450\ \text{W}}$

Step 10 of 10

Then the fin effectiveness becomes

$$\varepsilon_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{without fin}}}$$
$$= \frac{17800}{2450}$$
$$= 7.27$$

∴ The overall effectiveness of the fin $\boxed{\varepsilon_{\text{fin}} = 7.27}$

Question: 17.120P pg 1

Reconsider Prob. 17-118. Using EES (or other) software, investigate the effect of the center-to-center distance of the fins on the rate of heat transfer from the surface and the overall effectiveness of the fins. Let the center-to-center distance vary from 0.4 cm to 2.0 cm. Plot the rate of heat transfer and the overall effectiveness as a function of the center-to-center distance, and discuss the results.

Step 1 of 5

To solve this question using EES software open EES software

Then FILE->New

A dailogbox will open type the following in dailog box

"GIVEN"

"k_spoon=8.7 [Btu/h-ft-F], parameter to be varied"

T_w=200 "[F]"

T_infinity=75 "[F]"

A_c=0.08/12*0.5/12 "[ft^2]"

L=7" [in], parameter to be varied"

h=3 "[Btu/h-ft^2-F]"

Step 2 of 5

"ANALYSIS"

p=2*(0.08/12+0.5/12)

a=sqrt((h*p)/(k_spoon*A_c))

(T_tip-T_infinity)/(T_w-T_infinity)=cosh(a*(L-x)*Convert(in, ft))/cosh(a*L*Convert(in, ft))

x=L "for tip temperature"

DELTAT=T_w-T_tip

Then from Tables -> New parametric table

A dailog box will open

Select no of runs = 20

Select variables in equations as k_{spoon} and T press ADD and then press ok

A table will appear put values of k_{spoon} as 5,16.58,28.16....225 in run 1to 20

Then from Calculate -> Solve table

Solution will appear

k_{spoon} [Btu/h.ft.F]	T [F]

17.120P pg 3

Question: 17.121P pg 1

Circular cooling fins of diameter D = 1 mm and length L= 30 mm, made of copper (k = 380 W/m·K), are used to enhance heat transfer from a surface that is maintained at temperature $T\infty$ = 132°C. Each rod has one end attached to this surface (x = 0), while the opposite end (x = L) is joined to a second surface, which is maintained at $Ts2$ =0°C. The air flowing between the surfaces and the rods is also at $T\infty$ = 0°C, and the convection coefficient is h = 100 W/m2·K.

(*a*) Express the function $\theta(x) = T(x) - T\infty$ along a fin, and calculate the temperature at $x = L/2$.

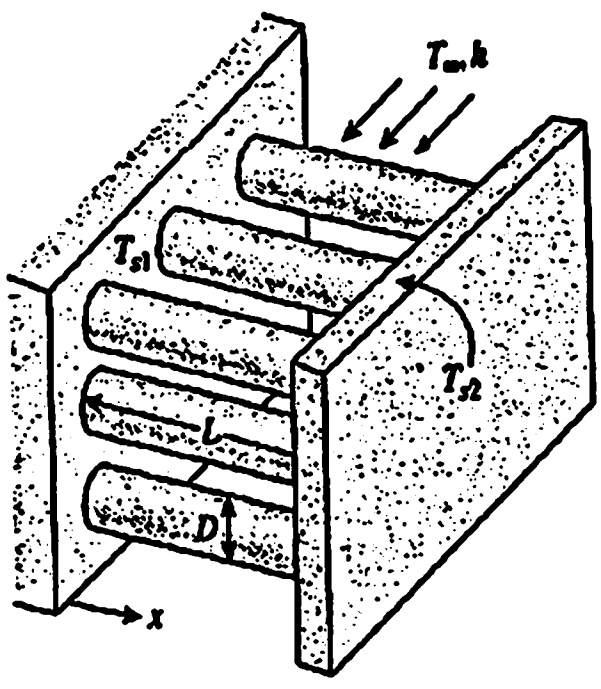

FIGURE P17–121

(*b*) Determine the rate of heal transferred from the hot surface through each fin and the fin effectiveness. Is the use of fins justified? Why?

(*c*) What is the total rate of heat transfer from a 10-cm by 10-cm section of the wall, which has 625uniformly distributed fins? Assume the same convection coefficient for the fin and for the unfinned wall surface.

Step 1 of 14

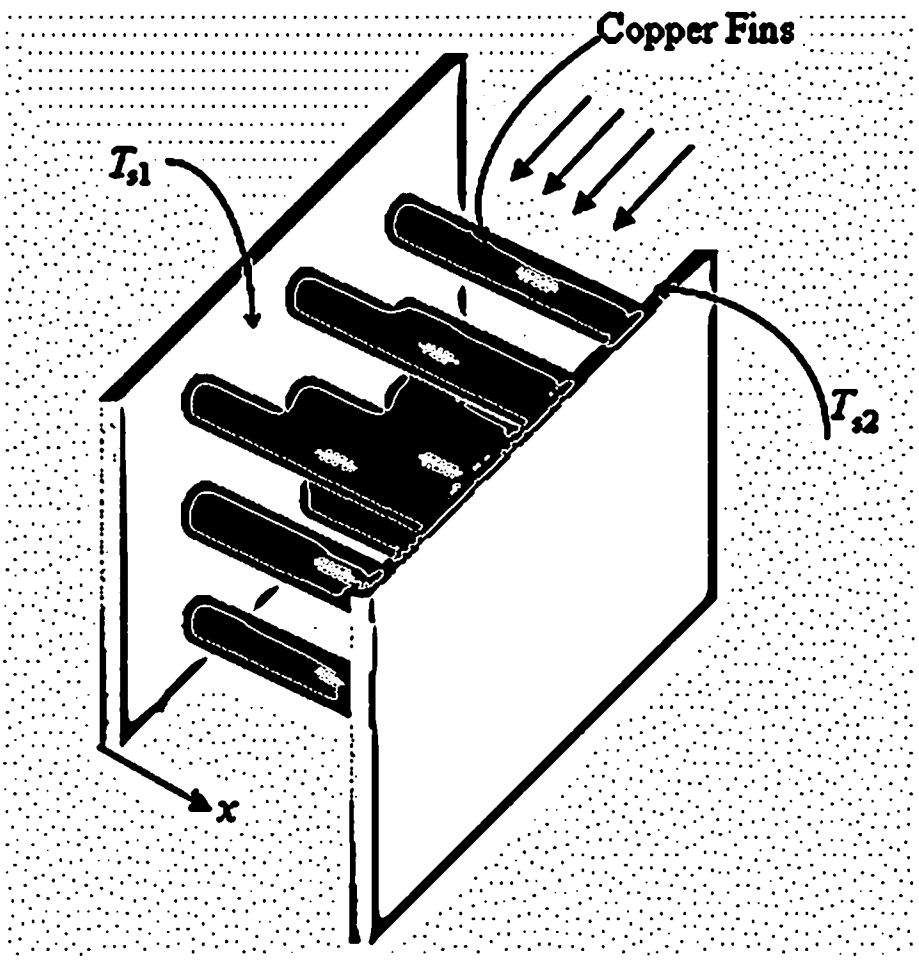
Given data:

Diameter of the fin, $D = 1\,\text{mm}$

Length of the fin, $L = 30\,\text{mm}$

Thermal conductivity of the copper plate, $k = 380\,\text{W/m}\cdot\text{K}$

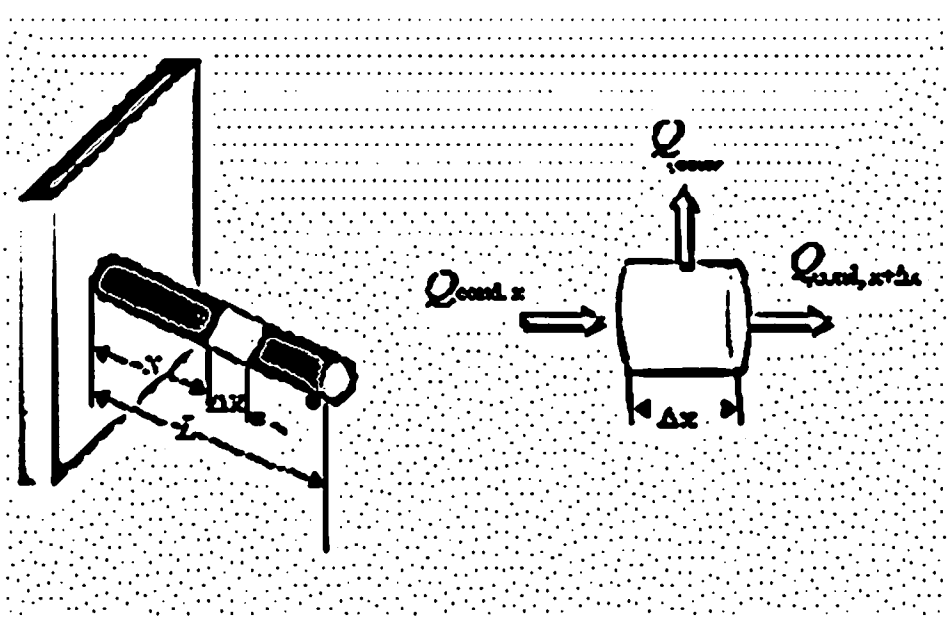
Surface temperature of the copper plate, $T_{s1} = 132°\text{C}$



Surface temperature of the other plate, $T_{s2} = 0°\text{C}$

Ambient temperature, $T_\infty = 0°\text{C}$

Heat transfer coefficient of ambient medium, $h_\infty = 100\,\text{W/m}^2\cdot\text{K}$



Number of fins, $n = 625$

Step 2 of 14

Step 3 of 14

a) Consider elemental volume of fin

Step 4 of 14

The fin equation can be derived by considering an elemental volume of a fin at a location x having a length of Δx, cross sectional area of A_c and a perimeter p.

Under steady conditions, the energy balance for the elemental volume can be expressed as

$$\begin{pmatrix}\text{Rate of heat}\\ \text{conduction into the}\\ \text{element at } x\end{pmatrix} = \begin{pmatrix}\text{Rate of heat}\\ \text{conduction from the}\\ \text{element at } x+\Delta x\end{pmatrix} + \begin{pmatrix}\text{Rate of heat}\\ \text{convection from the}\\ \text{element}\end{pmatrix}$$

$$\dot{Q}_{cond,x} = \dot{Q}_{cond,x+\Delta x} + \dot{Q}_{conv}$$

Where heat transfer due to convection is

$$\dot{Q}_{conv} = hp\Delta x(T - T_\infty)$$

Substituting the above expression and dividing by Δx, we will get

$$\frac{\dot{Q}_{cond,x+\Delta x} - \dot{Q}_{cond,x}}{\Delta x} + hp(T - T_\infty) = 0$$

Taking the limit as $\Delta x \to 0$ gives

$$\frac{d\dot{Q}}{}$$

Substituting the above expression and dividing by Δx, we will get

$$\frac{\dot{Q}_{cond,x+\Delta x}-\dot{Q}_{cond,x}}{\Delta x}+hp(T-T_\infty)=0$$

Taking the limit as $\Delta x \to 0$ gives

$$\frac{d\dot{Q}_{cond}}{dx}+hp(T-T_\infty)=0$$

From Fourier law of heat conduction we have

$$\dot{Q}_{cond}=-kA_c\frac{dT}{dx}$$

Substituting this relation gives the differential equation governing heat transfer in fins,

$$\frac{d}{dx}\left(kA_c\frac{dT}{dx}\right)-hp(T-T_\infty)=0$$

Step 5 of 14

For the constant cross sectional area and the constant thermal conductivity, the differential equation reduces to

$$\frac{d^2T}{dx^2}-\frac{hp}{kA_c}(T-T_\infty)=0$$

Let

$$\theta=T-T_\infty$$

$$\frac{d\theta}{dx}=\frac{dT}{dx}$$

$$\frac{d^2\theta}{dx^2}=\frac{d^2T}{dx^2}$$

And

$$m^2=\frac{hp}{kA_c}$$

Then the differential equation reduces to

$$\frac{d^2\theta}{dx^2}-m^2\theta=0$$

The general solution of the differential equation is

$$\theta(x)=C_1e^{mx}+C_2e^{-mx}$$

Step 6 of 14

In sufficiently long fin, the temperature of the fin at the tip approaches the environment temperature T_∞

At $x=L\to\infty$

$$\theta=T_\infty-T_\infty=0$$

Then

$$\theta(x)=C_1e^{mx}+C_2e^{-mx}$$

$$0=C_1e^{m\times\infty}+C_2e^{-m\times\infty}$$

$$C_1=0$$

At fin base $x=0$

Temperature at the base is T_b

$$\theta_b=T_b-T_\infty$$

Then

$$\theta_b=C_1+C_2$$

$$\theta_b=0+C_2$$

$$C_2=\theta_b$$

Then substituting the constants the general solution of the differential equation is

$$\theta(x)=C_1e^{mx}+C_2e^{-mx}$$

$$\theta(x)=\theta_be^{-mx}$$

Step 7 of 14

Therefore, for a very long fin the temperature distribution can be expressed as

$$\frac{T(x)-T_\infty}{T_b-T_\infty}=e^{-mx}$$

$$\frac{T(x)-T_\infty}{T_b-T_\infty}=e^{-x\sqrt{hp/kA_c}}$$

Therefore,

$$T(x)-T_\infty=(T_b-T_\infty)e^{-x\sqrt{hp/kA_c}}$$

$$\theta(x)=\theta_be^{-x\sqrt{hp/kA_c}}$$

$$\boxed{\theta(x)=\theta_be^{-x\sqrt{hp/kA_c}}}$$

Step 8 of 14

The temperature at $x=L/2$ can be determined as

$$m=\sqrt{\frac{hp}{kA_c}}$$

$$=\sqrt{\frac{h\pi D}{k\frac{\pi}{4}D^2}}$$

$$=\sqrt{\frac{4h}{kD}}$$

$$=\sqrt{\frac{100\times4}{380\times0.001}}$$

$$=32.44(1/\text{m})$$

The temperature on the fin at $x=L/2$ can be determined as

$$T(x)-T_\infty=(T_b-T_\infty)e^{-x\sqrt{hp/kA_c}}$$

$$T(L/2)=T_\infty+(T_b-T_\infty)e^{-\frac{L}{2}\sqrt{hp/kA_c}}$$

$$=0+(132-0)\times e^{-\frac{0.08}{2}\times32.44}$$

$$=81.142^\circ\text{C}$$

$$\boxed{T(L/2)=81.142^\circ\text{C}}$$

Therefore the temperature at $x=L/2$ is $T(L/2)=81.142^\circ\text{C}$

Step 9 of 14

$\boxed{T(L/2)=81.142^{\circ}C}$

Therefore the temperature at $x=L/2$ is $T(L/2)=81.142^{\circ}C$

Step 9 of 14

b) The rate of heat transfer from the entire fin can be determined using the Fourier's law of heat conduction

$$\dot{Q}_{long\,fin}=-kA_c\frac{dT}{dx}$$

$$=\sqrt{hpkA_c}(T_b-T_\infty)$$

$$=\sqrt{100\times\pi\times0.001\times380\times\frac{\pi}{4}\times(0.001)^2}\times(132-0)$$

$$=1.2782\,W$$

$\boxed{\dot{Q}_{long\,fin}=1.2782\,W}$

Step 10 of 14

The effectiveness of the fin can be expressed as

$$\varepsilon_{fin}=\frac{\dot{Q}_{fin}}{\dot{Q}_{no\,fin}}$$

$$=\frac{\dot{Q}_{fin}}{h_\infty A_b(T_b-T_\infty)}$$

Where A_b represents the cross sectional area of the fin at the base

And $\dot{Q}_{no\,fin}$ represents the rate of heat transfer from the base area if no fins are attached to the surface

Base area A_b can be expressed as

$$A_b=\frac{\pi}{4}D^2$$

$$=\frac{\pi}{4}\times(0.001)^2$$

$$=7.854\times10^{-7}\,m^2$$

Step 11 of 14

Therefore, the effectiveness of the fin can be calculated as

$$\varepsilon_{fin}=\frac{\dot{Q}_{fin}}{\dot{Q}_{no\,fin}}$$

$$=\frac{\dot{Q}_{fin}}{h_\infty A_b(T_b-T_\infty)}$$

$$=\frac{1.2782}{100\times7.854\times10^{-7}\times(132-0)}$$

$$=123.292$$

$\boxed{\varepsilon_{fin}=123.292}$

Since $\varepsilon_{fin}>1$ it indicates that fins are enhancing the heat transfer from the surface and it is justifiable.

The rate of heat transfer from the hot surface through each fin is $\dot{Q}_{long\,fin}=1.2782\,W$ and fin effectiveness is $\varepsilon_{fin}=123.292$

Step 12 of 14

c)

The total fin area can be determined as

$$A_{finned}=n\pi DL$$

$$=625\times\pi\times0.001\times0.03$$

$$=0.0589\,m^2$$

The unfinned area can be calculated as

$$A_{unfinned}=A-864\frac{\pi}{4}D^2$$

$$=(0.1\times0.1)-625\times\frac{\pi}{4}\times0.001^2$$

$$=0.0095091\,m^2$$

The total area exposed to the ambient medium can be calculated as

$$A_{total}=A_{finned}+A_{unfinned}$$

$$=0.0589+0.0095091$$

$$=0.0684\,m^2$$

Step 13 of 14

Thermal resistance due to convection

$$R_{conv}=\frac{1}{h_\infty A}$$

$$=\frac{1}{100\times0.0684}$$

$$=0.1462\,K/W$$

Step 14 of 14

The steady total rate of heat transfer from the wall can be expressed as

$$\dot{Q}_{total}=\frac{(T_{s1}-T_\infty)}{R_{total}}$$

$$=\frac{(132-0)}{0.1462}$$

$$=902.87\,W$$

$\boxed{\dot{Q}_{total}=902.87\,W}$

Therefore the total rate of heat transfer from a 10-cm by 10-cm section of the wall is

$\dot{Q}_{total}=902.87\,W$

$\boxed{\dot{Q}_{total} = 902.87\,\text{W}}$

Therefore the total rate of heat transfer from a 10-cm by 10-cm section of the wall is

$\dot{Q}_{total} = 902.87\,\text{W}$

Question: 17.122P

Steam in a heating system flows through tubes whoseouter diameter is 3 cm and whose walls are maintained at a temperature of 120T. Circular aluminum alloy fins (k = 180 W/m·K) of outer diameter 6 cm and constant thickness t = 2 mm are attached to the tube, as shown in Fig. P17–i22. The space between the fins is 3 mm, and thus there are 200 fins per meter length of the tube. Heat is transferred to the surrounding air at 25°C, with a combined heat transfer coefficient of60 W/m2·K. Determine the increase in heat transfer from the tube per meter of its length as a result of adding fins.

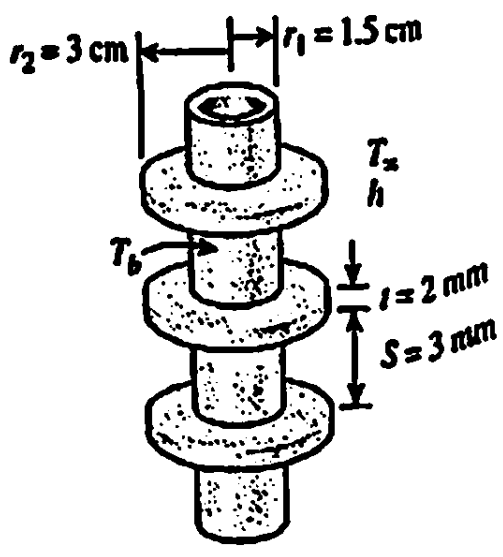


FIGURE P17–122

Step 1 of 6

Given data:

Outer radius of the pipe, $r_1 = 1.5\,\text{cm}$

Thickness of the fin, $t = 2\,\text{mm}$

Thermal conductivity of the fin material, $k = 180\,\text{W/m·K}$

Outer radius of the fin, $r_f = 3\,\text{cm}$

Temperature of the pipe at the outer surface, $T_b = 120°\text{C}$

Ambient air temperature, $T_\infty = 25°\text{C}$

Heat transfer coefficient of ambient air, $h_\infty = 60\,\text{W/m}^2\cdot\text{K}$

Number of fins per meter length of the tube, $n = 200$

Step 2 of 6

Efficiency of annular fins can be calculated by finding these parameters

$$r_{2c} = r_f + \frac{t_f}{2}$$
$$= 0.03 + \frac{0.002}{2}$$
$$= 0.031\,\text{m}$$
$$A_{fin} = 2\pi\left(r_{2c}^2 - r_1^2\right)$$
$$= 2\pi \times (0.031^2 - 0.015^2)$$
$$= 0.0046244\,\text{m}^2$$
$$L_c = L + \frac{t_f}{2}$$
$$= r_f - r_1 + \frac{t_f}{2}$$
$$= 0.03 - 0.015 + \frac{0.002}{2}$$
$$= 0.016\,\text{m}$$

Step 3 of 6

Hence,

$$A_p = L_c t_f$$
$$= 0.016 \times 0.002$$
$$= 0.000032\,\text{m}^2$$
$$\xi = L_c^{3/2}\left(h/kA_p\right)^{1/2}$$
$$= (0.016)^{3/2} \times \left(\frac{60}{180 \times 0.000032}\right)^{1/2}$$
$$= 0.20656$$
$$\frac{r_{2c}}{r_1} = \frac{0.031}{0.015}$$
$$= 2.0667$$

Step 4 of 6

From the graph efficiency of annular fins of constant thickness t at $\xi = 0.20656$ and $\frac{r_{2c}}{r_1} = 2.0667$ the efficiency are

$$\eta_{fin} = 0.955$$

The rate of heat transfer from the fin can be expressed as

$$\dot{Q}_{fin} = \eta_{fin} h A_{fin} (T_s - T_\infty)$$
$$= 0.955 \times 60 \times 0.0046244 \times (120 - 25)$$
$$= 25.173\,\text{W}$$

Since there are 200 fins per meter length of the tube then the total heat transfer rate from the fins can be expressed as

$$\dot{Q}_{fins} = n \times \dot{Q}_{fins}$$
$$= 200 \times 25.173$$
$$= 5034.6\,\text{W}$$

Step 5 of 6

The heat transfer from the base area if no fins are attached to the surface can be calculated as

$$\dot{Q}_{no\,fin} = h_\infty A_b (T_b - T_\infty)$$
$$A_b = 2\pi r_1 t$$
$$= 2 \times \pi \times 0.015 \times 0.002$$
$$= 0.0001885\,\text{m}^2$$
$$\dot{Q}_{no\,fin} = h_\infty A_b (T_b - T_\infty)$$
$$= 60 \times 0.0001885 \times (120 - 25)$$
$$= 1.0744\,\text{W}$$

For 200 fins, the total heat transfer rate from the fins base area becomes

$$\dot{Q}_{no\,fins} = n \times \dot{Q}_{no\,fin}$$
$$= 200 \times 1.0744$$
$$= 214.885\,\text{W}$$

Step 6 of 6

Therefore, the increase in heat transfer due to addition of fins per meter length of the tube can be calculated as

$$\Delta\dot{Q}_{increase} = \dot{Q}_{fins} - \dot{Q}_{no\,fins}$$
$$= 5034.6 - 214.885$$
$$= 4819.715\,\text{W}$$

$$\boxed{\Delta\dot{Q}_{increase} = 4819.715\,\text{W}}$$

Question: 17.123P

Steam is produced in the copper tubes (k = 223 Btu/h·ft·°F) of a heat exchanger at a temperature of 280°F by another fluid condensing on the outside surfaces of the tubes at 350°F. The inner and outer diameters of the tube are 1 in and 1.3 in, respectively. When the heat exchanger was new, the rate of heat transfer per foot length of the tube was 2 × 104 Btu/h. Determine the rate of heat transfer per foot length of the tube when a 0.01-in-thick layer of limestone (k = 1.7 Btu/h·°F) has formed on the inner surface of the tube after extended use.

Step 1 of 4

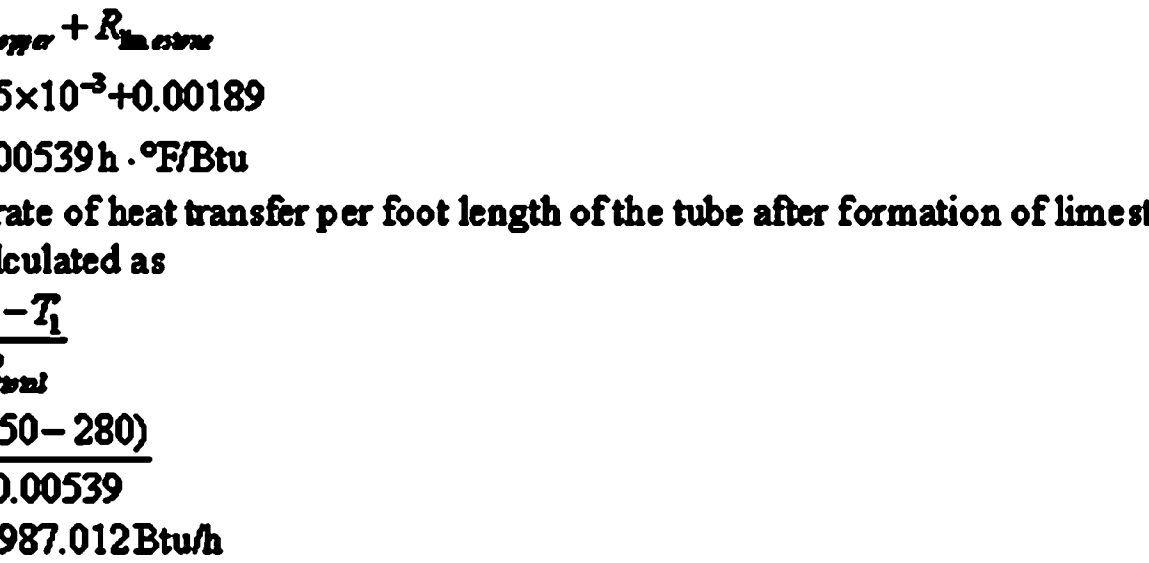
Given data:

Outer diameter of the pipe, $d_1 = 1.3\text{in}$

Inner diameter of the pipe, $d_2 = 1\text{in}$

Thickness of the limestone layer, $t = 0.01\text{in}$

Thermal conductivity of the copper tubes, $k = 223\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$



Thermal conductivity of the limestone, $k = 1.7\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$

Temperature of the steam in copper tubes, $T_1 = 280^\circ\text{F}$

Condensing fluid temperature, $T_2 = 350^\circ\text{F}$

The rate of heat transfer per foot length of the tube, $\dot{Q} = 2\times10^4\ \text{Btu/h}$

Step 2 of 4

Step 3 of 4

The total thermal resistance of the new heat exchanger can be determined using the Fourier law of heat conduction equation, which is given by

$$\dot{Q}_{copper} = \frac{T_2 - T_1}{R_{copper}}$$

Therefore, the total new resistance can be calculated as

$$\begin{aligned} R_{copper} &= \frac{T_2 - T_1}{\dot{Q}_{new}} \\ &= \frac{(350-280)}{2\times10^4} \\ &= 3.5\times10^{-3}\ \text{h}\cdot{}^\circ\text{F/Btu} \end{aligned}$$

Step 4 of 4

If there is 0.01 in thick layer of limestone forms on the inner surface of the copper pipes, the total value of thermal resistance and heat transfer rate are determined to be

$$\begin{aligned} R_{limestone} &= \frac{\ln(r_2/r_3)}{2\pi kL} \\ &= \frac{\ln[0.5/(0.5-0.01)]}{2\times\pi\times1.7\times1} \\ &= 0.00189\ \text{h}\cdot{}^\circ\text{F/Btu} \end{aligned}$$

Therefore, the total resistance becomes

$$\begin{aligned} R_{total} &= R_{copper} + R_{limestone} \\ &= 3.5\times10^{-3} + 0.00189 \\ &= 0.00539\ \text{h}\cdot{}^\circ\text{F/Btu} \end{aligned}$$

The new rate of heat transfer per foot length of the tube after formation of limestone layer can be calculated as

$$\begin{aligned} \dot{Q}_{new} &= \frac{T_2 - T_1}{R_{total}} \\ &= \frac{(350-280)}{0.00539} \\ &= 12987.012\ \text{Btu/h} \end{aligned}$$

$$\boxed{\dot{Q}_{new} = 12987.012\ \text{Btu/h}}$$

Since the limestone layer forming on the inner surface of the copper pipes it will change the inner surface area of the pipe and thus the internal convection resistance slightly and hence reduced heat transfer to the steam formation.

Question: 17.124P

Repeat Prob. 17-123E, assuming that a 0.01-in-thick limestone layer has formed on both the inner and outer surfaces of the tube.

Step 1 of 5

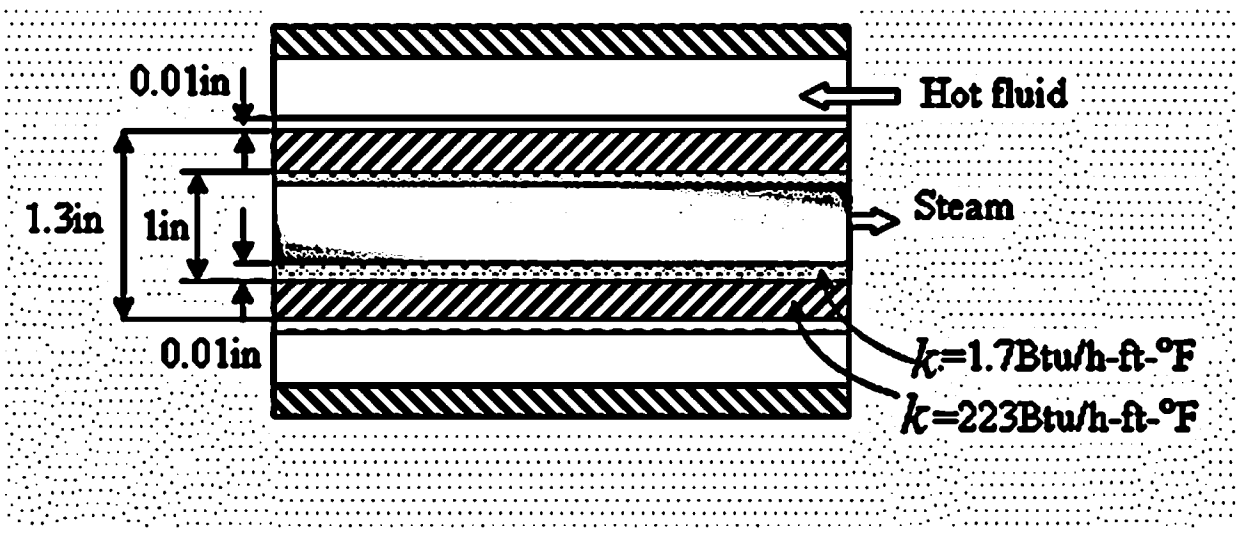
Given data:

Outer diameter of the pipe, $d_1 = 1.3\text{in}$

Inner diameter of the pipe, $d_2 = 1\text{in}$

Thickness of the limestone layer on both sides of the pipe, $t = 0.01\text{in}$

Thermal conductivity of the copper tubes, $k = 223\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$



Thermal conductivity of the limestone, $k = 1.7\,\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$

Temperature of the steam in copper tubes, $T_1 = 280^\circ\text{F}$

Condensing fluid temperature, $T_2 = 350^\circ\text{F}$

The rate of heat transfer per foot length of the tube, $\dot{Q} = 2\times10^4\ \text{Btu/h}$

Step 2 of 5

Step 3 of 5

The total thermal resistance of the new heat exchanger can be determined using the Fourier law of heat conduction equation, which is given by

$$\dot{Q}_{copper} = \frac{T_2 - T_1}{R_{copper}}$$

Therefore, the total new resistance can be calculated as

$$\begin{aligned} R_{copper} &= \frac{T_2 - T_1}{\dot{Q}_{new}} \\ &= \frac{(350-280)}{2\times10^4} \\ &= 3.5\times10^{-3}\ \text{h}\cdot{}^\circ\text{F/Btu} \end{aligned}$$

Step 4 of 5

After 0.01 in thick layer of limestone forms on the inner and outer surfaces of the copper pipes, the total value of thermal resistance and heat transfer rate are determined to be

$$\begin{aligned} R_{limestone,i} &= \frac{\ln(r_2/r_i)}{2\pi kL} \\ &= \frac{\ln\left[0.5/(0.5-0.01)\right]}{2\times\pi\times1.7\times1} \\ &= 0.00189\,\text{h}\cdot{}^\circ\text{F/Btu} \end{aligned}$$

$$\begin{aligned} R_{limestone,o} &= \frac{\ln(r_o/r_1)}{2\pi kL} \\ &= \frac{\ln\left[(0.65+0.01)/0.65)\right]}{2\times\pi\times1.7\times1} \\ &= 1.42935\times10^{-3}\,\text{h-}^\circ\text{F/Btu} \end{aligned}$$

Therefore, the total resistance becomes

$$\begin{aligned} R_{total} &= R_{limestone,i} + R_{copper} + R_{limestone,o} \\ &= 0.00189 + 3.5\times10^{-3} + 1.42935\times10^{-3} \\ &= 0.00681\,\text{h}\cdot{}^\circ\text{F/Btu} \end{aligned}$$

Step 5 of 5

The new rate of heat transfer per foot length of the tube after formation of limestone layer can be calculated as

$$\begin{aligned} \dot{Q}_{new} &= \frac{T_2 - T_1}{R_{total}} \\ &= \frac{(350-280)}{0.00681} \\ &= 10279.0014\,\text{Btu/h} \end{aligned}$$

$$\boxed{\dot{Q}_{new} = 10279.0014\,\text{Btu/h}}$$

Since the limestone layer forming on the inner and outer surfaces of the copper pipes it will change the inner and outer surface areas of the pipe and thus the internal and external convection resistance slightly and hence reduced heat transfer to the steam formation.

Question: 17.125P

Hot water is flowing at an average velocity of 1.5 m/s through a cast iron pipe (k = 52 W/m·K) whose inner and outer diameters are 3 cm and 3.5 cm. respectively. The pipe passes through a 15-m-long section of a basement whose temperature is 15°C. If the temperature of the water drops from 70°C to 67°C as it passes through the basement and the heat transfer coefficient on the inner surface of the pipe is 400 W/m2-K. determine the combined convection and radiation heat transfer coefficient at the outer surface of the pipe.

Step 1 of 5

Given: -

Average velocity of water = 1.5 m/s

Thermal conductivity of cast iron pipe (k) = 52 W/m.°C

Inner diameter of pipe = 3 cm

Outer diameter of pipe = 3.5 cm

Pipe passes through section of basement 15 m long at temperature of T_2 =15°C

Temperature drop of water from 70°C to 67°C

Heat transfer coefficient h= 400 W/m^2°C

Step 2 of 5

Mass flow rate of water

$$\dot{m} = \rho V A_c$$
$$= (1000)(1.5)\left[\pi(0.03)^2/4\right]$$
$$\dot{m} = 1.06028 \text{ kg/s}$$

Heat transfer rate from the water can be calculated as

$$\dot{Q} = \dot{m} C_p \Delta T$$
$$= (1.06028)(4180)(70-67)$$
$$\dot{Q} = 13295.91 \text{ W}$$

Step 3 of 5

Thermal resistance of pipe and for convection through pipe is

$$R_p = \frac{\ln(r_2/r_1)}{2\pi kL}$$
$$= \frac{\ln(1.75/1.5)}{2\pi(52)\times(15)}$$
$$R_p = 0.000031 \text{ °C/W}$$

$$R_c = \frac{1}{h_i A_i}$$
$$= \frac{1}{(400)[\pi(0.03)(15)]}$$
$$R_c = 0.001768 \text{ °C/W}$$

$$R_{combine} = \frac{1}{h_{combine} A_o}$$
$$= \frac{1}{h_{combine}[\pi(0.035)(15)]}$$
$$= \frac{1}{h_{combine}[1.649]} \text{°C/W}$$

Step 4 of 5

Total thermal resistance can be calculated as

$$R_{total} = R_p + R_c + R_{combine}$$
$$= 0.000031 + 0.001768 + \frac{1}{h_{combine}[1.649]}$$
$$R_{total} = 0.001799 + \frac{1}{h_{combine}[1.649]} \text{°C/W}$$

Step 5 of 5

Mean temperature difference of water is

$$T_{AMTD} = \frac{70+67}{2}$$
$$T_{AMTD} = 68.5^0\text{C}$$

Rate of heat transfer can be expressed as

$$\dot{Q} = \frac{T_{AMTD} - T_2}{R_{total}}$$
$$13295.91 = \frac{(68.5-15)}{\left(0.001799 + \frac{1}{h_{combine}[1.649]}\right)}$$
$$\left(0.001799 + \frac{1}{h_{combine}[1.649]}\right) = 0.004023$$
$$\frac{1}{h_{combine}[1.649]} = 0.002224$$
$$\boxed{h_{combine} = 272.67 \text{ W/m}^2.^0\text{C}}$$

Question: 17.126P

Newly formed concrete pipes are usually cured first overnight by steam in a curing kiln maintained at a temperature of 45°C before the pipes are cured for several days outside. The heat and moisture to the kiln is provided by steam (lowing in a pipe whose outer diameter is 12 cm. During a plant inspection, it was noticed that the pipe passes through a g-m section that is completely exposed to the ambient air before it reaches the kiln. The temperature measurements indicate that the average temperature of the outer surface of the steam pipe is 90°C when the ambient temperature is 8°C. The combined convection and radiation heat transfer coefficient at the outer surface of the pipe is estimated to be 35 W/m2-K. Determine the amount of heat lost from the steam during a 10-h curing process that night.

Steam is supplied by a gas-fired steam generator that has an efficiency of 85 percent, and the plant pays $ 1.20/therm of natural gas (1 therm = 105,500 kJ). If the pipe is insulated and 90 percent of the heat loss is saved as a result, determine the amount of money this facility will save a year as a result of insulating the steam pipes. Assume that the concrete pipes are cured 110 nights a year. State your assumptions.

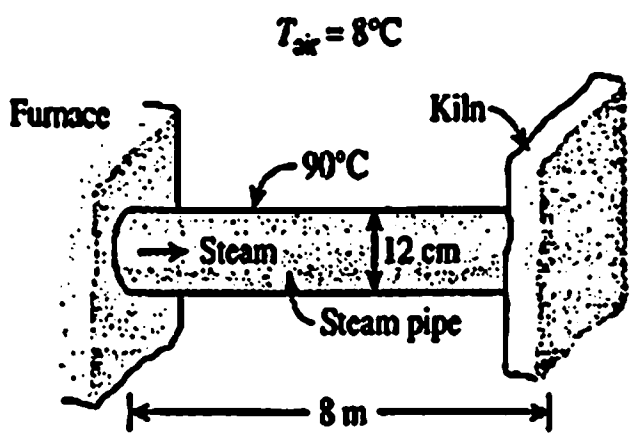


FIGURE P17–126

Step 1 of 3

Given data:

Diameter of the pipe, $D = 12\,\text{cm}$

Temperature of the kiln, $T_i = 45°C$

Length of the pipe, $L = 8\,\text{m}$

Temperature of the pipe at the outer surface, $T_s = 90°C$

Ambient air temperature, $T_\infty = 8°C$

Combined convection and radiation Heat transfer coefficient of air, $h_\infty = 35\,\text{W/m}^2\cdot\text{K}$

Efficiency of the steam generator, $\eta = 85\%$

Unit cost of fuel \$1.20/ therm

1therm = 105,500kJ

Step 2 of 3

Assumptions:

1. Heat transfer through the pipe is steady and one-dimensional.
2. Thermal conductivities are constant.
3. The furnace operates continuously.
4. The given heat transfer coefficients accounts for the radiation effects.
5. The temperatures of the pipe surface and the surroundings are representative of annual average during operating hours.
6. The plant operates 110 days a year.

Step 3 of 3

The surface area of the steam pipe can be determined as

$$\begin{aligned} A_s &= \pi DL \\ &= \pi \times 0.12 \times 8 \\ &= 3.016\,\text{m}^2 \end{aligned}$$

The rate of heat transfer from the pipe can be determined as

$$\begin{aligned} \dot{Q} &= hA_s(T_s - T_\infty) \\ &= 35 \times 3.016 \times (90 - 8) \\ &= 8655.92\,\text{W} \end{aligned}$$

The amount of heat loss during a 10-hour period can be calculated as

$$\begin{aligned} Q &= \dot{Q}\Delta t \\ &= 8655.92 \times 10 \times 3600 \\ &= 3.116 \times 10^5\,\text{kJ (per day)} \end{aligned}$$

Question: 17.127P

Consider an 18-cm × 18-cm multilayer circuit board dissipating 27 W of heat. The board consists of four layers of 0.2-mm-thick copper (k =386 W/m·K) and three layers of 1.5-mm-thick epoxy glass (k = 0.26 W/m·K) sandwiched together, as shown in the figure. The circuit board is attached to a heat sink from both ends, and the temperature of the board at those ends is 35°C. Heat is considered to be uniformly generated in the epoxy layers of the board at a rate of 0.5 W per 1 -cm × 18-cm epoxy laminate strip (or 3.5 W per 1-cm × 18-cm strip of the board). Considering only a portion of the board because of symmetry, determine the magnitude and location of the maximum temperature that occurs in the board. Assume heat transfer from the top and bottom faces of the board to be negligible.

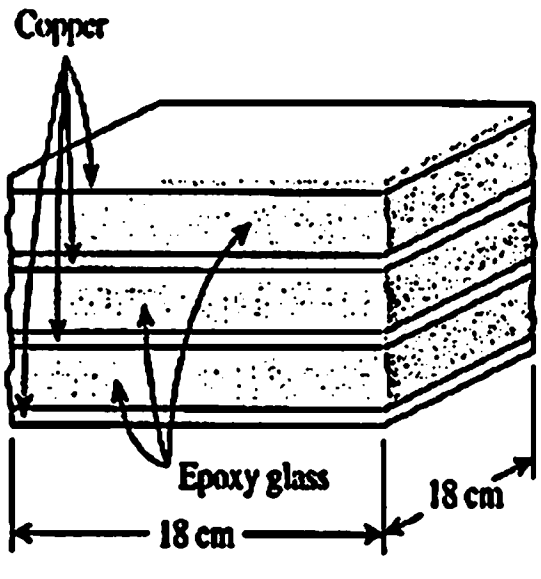

FIGURE P17–127

Step 1 of 3

Given: -

Area of circuit board = 18 cm × 18 cm

Heat dissipated by board Q= 27 W

Number of layers of copper = 4

Number of layers of epoxy glass = 3

Temperature of heat sink T_2= 35C.

Thickness of copper layer = 0.2 mm

Thickness of epoxy layer = 1.5 mm

Thermal conductivity of copper (k_{copper}) = 386 W/m°C

Thermal conductivity (k_{epoxy}) = 0.26 W/m°C

Step 2 of 3

Effective thermal conductivity of circuit board can be calculated as

$$(kt)_{copper} = 4[(386)(0.0002)]$$

$$(kt)_{copper} = 0.3088 \text{ W/°C}$$

$$(kt)_{epoxy} = 3[(0.26)(0.0015)]$$

$$(kt)_{epoxy} = 0.00117 \text{ W/°C}$$

$$k_{eff} = \frac{(kt)_{copper} + (kt)_{epoxy}}{t_{copper} + t_{epoxy}}$$

$$= \frac{(0.3088 + 0.00117)}{[4(0.0002) + 3(0.0015)]}$$

$$k_{eff} = 58.48 \text{ W/m.°C}$$

Step 3 of 3

Maximum temperature can be calculated as

$$A = 0.18[4(0.0002) + 3(0.0015)]$$

$$A = 0.000954 \text{ m}^2$$

$$\dot{Q} = \frac{k_{eff} A}{L}(T_{max} - T_2)$$

Because of the symmetry of the plane taking $\dot{Q} = \dot{Q}/2$ and $L = L/2$

$$T_{max} = T_2 + \frac{\dot{Q}L}{k_{eff} A}$$

$$T_{max} = 35 + \frac{(27/2)(0.18/2)}{(58.48)(0.000954)}$$

$$\boxed{T_{max} = 56.8^0\text{C}}$$

Question: 17.128P

The surface temperature of a 3-in-diameter baked potato is observed to drop from 300°F to 200°F in 5 min in an environment at 70°F. Determine the average heat transfer coefficient between the potato and its surroundings. Using this heat transfer coefficient and the same surface temperature, determine how long it will take for the potato to experience the same temperature drop if it is wrapped completely in a 0.12-in-thick towel (k =0.035 Btu/h·ft·°F), You may use the properties of water for potato.

Step 1 of 11

Given: -

Diameter of potato $d = 3\text{in}$

Radius of potato $r = 1.5\text{in}$

Temperature drop of baked potato from 300°F to 200°F

Time taken for temperature drop of potato is t = 5 minutes

Temperature of surrounding $T_\infty = 70°\text{F}$

Thermal conductivity of towel (k) = 0.035 Btu/h·ft·°F

Thickness of towel $t = 0.12\text{in}$

Step 2 of 11

Taking properties of water for potato

Density (ρ) = 62.2 lbm/ft^3

Specific heat at constant pressure (C_p) = 0.998 Btu/lbm·°F

Step 3 of 11

Assuming constant average temperature of potato

Mass of potato will be

$$m = \rho V$$

$$= \rho \frac{4}{3}\pi r^3$$

$$= (62.2)\frac{4}{3}\pi(1.5/12)^3$$

$$m = 0.5089\ \text{lbm}$$

Step 4 of 11

Heat lost from potato

$$Q = mC_p\Delta T$$

$$= (0.5089)(0.998)(300\text{-}200)$$

$$Q = 50.8\ \text{Btu}$$

Step 5 of 11

Heat transfer rate

$$\dot{Q} = \frac{Q}{\Delta t}$$

$$= \frac{50.8\ \text{Btu}}{(5/60\ \text{h})}$$

$$\dot{Q} = 609.6\ \text{Btu/h}$$

Step 6 of 11

Coefficient of heat transfer between surrounding and potato is

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$h = \frac{\dot{Q}}{A_s(T_s - T_\infty)}$$

$$= \frac{609.6}{\pi(3/12)^2(250-70)}$$

$$\boxed{h = 17.248\ \text{Btu/h.ft}^2.°\text{F}}$$

Step 7 of 11

If the potato is wrapped completely by 0.12 in thick towel then

Outer diameter will be $d_2 = 3+0.12+0.12 = 3.24\text{in}$

Or outer radius will be $r_2 = (1.5+0.12)\text{in}$

Thermal resistance due to conduction is

$$R_t = \frac{r_2 - r_1}{4\pi k r_1 r_2}$$

$$= \frac{[(1.5+0.12)/12]-(1.5/12)}{4\pi(0.035)[(1.5+0.12)/12](1.5/12)}$$

$$= \frac{[0.135]-(0.125)}{4\pi(0.035)[0.135](0.125)}$$

$$R_t = 1.3473\ \text{h°F/Btu}$$

Step 8 of 11

Thermal resistance due to convection from outer surface

$$R_c = \frac{1}{hA}$$

$$= \frac{1}{(17.248)\pi\left[(3+0.24)/12\right]^2}$$

$$R_c = 0.2531\ \text{h.°F/Btu}$$

Step 9 of 11

Total thermal resistance due to conduction and convection

$$R_{total} = R_t + R_c$$

$$= 1.3473+0.2531$$

$$R_{total} = 1.6004\ \text{h°F/Btu}$$

Step 10 of 11

Rate of heat transfer

$$\dot{Q} = \frac{T_s - T_\infty}{R_{total}}$$

Where average surface temperature of potato will be

$$T_s = \left(\frac{300+200}{2}\right)$$

$$T_s = 250^0\text{F}$$

Step 11 of 11

Then

$$\dot{Q} = \frac{(250-70)}{1.6004}$$

$$= 112.47\ \text{Btu/h}$$

Time taken for the potato to experience same temperature drop when wrapped in 0.12-in thick towel

$$\Delta t = \frac{Q}{\dot{Q}}$$

$$= \frac{50.8}{112.47}$$

$$= 0.452\ \text{h}$$

$$\boxed{\Delta t = 27.12\ \text{min}}$$

Question: 17.129P

Repeat Prob. 17-128E assuming there is a 0.02-in-thick air space (k = 0.015 Btu/h·ft·°F) between the potato and the towel.

Step 1 of 12

Given: -

Diameter of potato $d = 3\text{in}$

Radius of potato $r = 1.5\text{in}$

Temperature drop of baked potato from 300°F to 200°F

Time taken for temperature drop of potato is t = 5 minutes

Temperature of surrounding $T_\infty = 70°\text{F}$

Thermal conductivity of towel (k_{towel}) = 0.035 Btu/h·ft·°F

Thickness of towel $t = 0.12\text{in}$

Thermal conductivity of air $k_{air} = 0.015\text{Btu/h.ft.}^0\text{F}$

Thickness of air space $t_{air} = 0.02\text{in}$

Step 2 of 12

Taking properties of water for potato

Density (ρ) = 62.2 lbm/ft^3

Specific heat at constant pressure (C_p) = 0.998 Btu/lbm·°F

Step 3 of 12

Assuming constant average temperature of potato

Mass of potato will be

$$m = \rho V$$
$$= \rho\frac{4}{3}\pi r^3$$
$$= (62.2)\frac{4}{3}\pi(1.5/12)^3$$
$$m = 0.5089\text{ lbm}$$

Step 4 of 12

Heat lost from potato

$$Q = mC_p\Delta T$$
$$= (0.5089)(0.998)(300\text{-}200)$$
$$Q = 50.8\text{ Btu}$$

Step 5 of 12

Heat transfer rate

$$\dot{Q} = \frac{Q}{\Delta t}$$
$$= \frac{50.8\text{ Btu}}{(5/60\text{ h})}$$
$$\dot{Q} = 609.6\text{ Btu/h}$$

Step 6 of 12

Coefficient of heat transfer between surrounding and potato is

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$h = \frac{\dot{Q}}{A_s(T_s - T_\infty)}$$
$$= \frac{609.6}{\pi(3/12)^2(250-70)}$$
$$h = 17.248\text{Btu/h.ft}^2\text{.°F}$$

Step 7 of 12

Total thermal resistance for the system is

Outer radius of the air gap is $r_2 = (1.5+0.02)\text{in}$

Thermal resistance due to air gap will be

$$R_{air} = \frac{r_2 - r_1}{4\pi k r_1 r_2}$$
$$= \frac{[(1.50+0.02)/12] - (1.50/12)}{4\pi(0.015)[(1.50+0.02)/12](1.50/12)}$$
$$= \frac{0.001666}{0.00298}$$
$$R_{air} = 0.55906\text{ h.°F/Btu}$$

Step 8 of 12

Outer radius of the towel is $r_3 = (1.5+0.02+0.12)\text{in}$

Then thermal resistance between air gap and towel will be

$$R_t = \frac{r_3 - r_2}{4\pi k r_2 r_3}$$
$$= \frac{[(1.52+0.12)/12] - (1.52/12)}{4\pi(0.035)[(1.52+0.12)/12](1.52/12)}$$
$$= \frac{0.01}{0.007613}$$
$$R_t = 1.31354\text{ h°F/Btu}$$

Step 9 of 12

Convection resistance from the outer surface of the towel

$$R_c = \frac{1}{hA}$$
$$= \frac{1}{(17.248)\pi\left[(3+0.02+0.02+0.12+0.12)/12\right]^2}$$
$$R_c = 0.247\text{ h.°F/Btu}$$

Step 10 of 12

Then total thermal resistance will be

$$R_{total} = R_{air} + R_t + R_c$$
$$= 0.55906 + 1.31354 + 0.247$$
$$R_{total} = 2.1196\text{ h°F/Btu}$$

Step 11 of 12

Rate of heat transfer

$$\dot{Q} = \frac{T_s - T_\infty}{R_{total}}$$

Where average surface temperature of potato will be

$$T_s = \left(\frac{300+200}{2}\right)$$
$$T_s = 250^0\text{F}$$

Then

$$\dot{Q} = \frac{T_s - T_\infty}{R_{total}}$$
$$= \frac{(250-70)}{2.1196}$$
$$\dot{Q} = 84.92\text{ Btu/h}$$

Step 12 of 12

Time taken for the potato to experience same temperature drop when wrapped in 0.12-in thick towel and there is a 0.02 in thick air space

$$\Delta t = \frac{Q}{\dot{Q}}$$
$$= \frac{50.8}{84.92}$$
$$= 0.598\text{ h}$$
$$\boxed{\Delta t = 35.88\text{min}}$$

Question: 17.130P

A 6-m-wide, 2.8-m-high wall is constructed of one layer of common brick (k = 0.72 W/m·K) of thickness 20 cm, one inside layer of light-weight plaster (k = 0.36 W/m·K) of thickness 1 cm. and one outside layer of cement based covering (k = 1.40 W/m·K) of thickness 2 cm. The inner surface of the wall is maintained at 23°C while the outer surface is exposed to outdoors at 8°C with a combined convection and radiation heat transfer coefficient of 17 W/m2 ·K. Determine the rate of heat transfer through the wall and temperature drops across the plaster, brick, covering, and surface-ambient air.

Step 1 of 12

Given: -

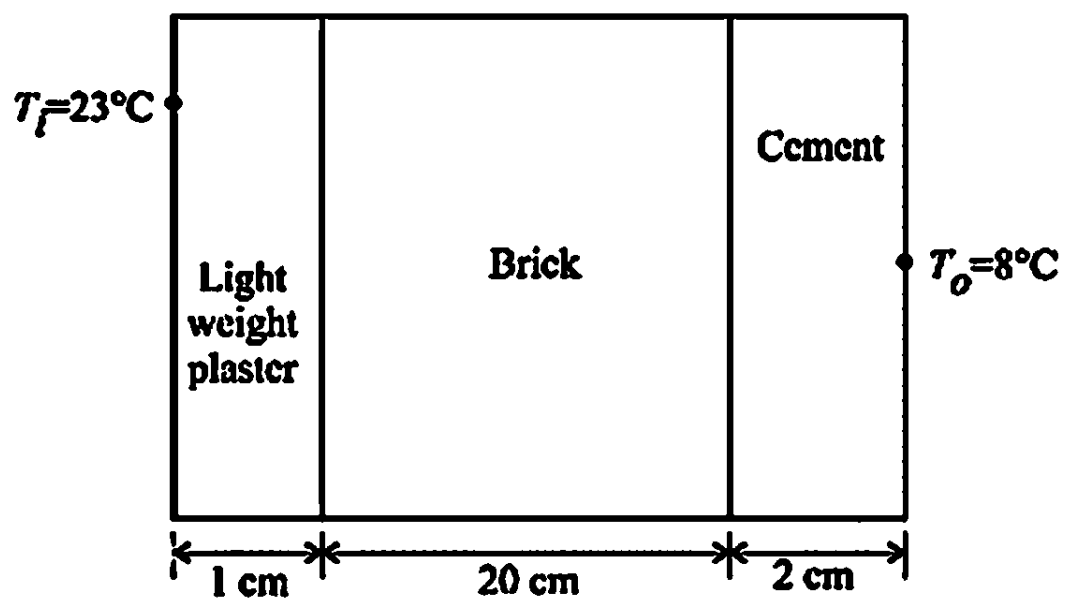
Thickness of brick layer is $L_2 = 20\,\text{cm}$

Thickness of plaster layer $L_1 = 1\text{cm}$

Thickness of cement based covering $L_3 = 2\,\text{cm}$

Thermal conductivity of plaster $k_1 = 0.36\ \text{W/m}\cdot{}^\circ\text{C}$

Thermal conductivity of brick $k_2 = 0.72\ \text{W/m}\cdot{}^\circ\text{C}$



Thermal conductivity of cement covering $k_3 = 1.40\ \text{W/m}\cdot{}^\circ\text{C}$

Inner surface temperature of the wall $T_i = 23^0\,\text{C}$

Outer surface temperature of the wall $T_o = 8^0\,\text{C}$

Combined convection and radiation heat transfer coefficient $h = 17\,\text{W/m}^2.{}^0\text{C}$

Step 2 of 12

Step 3 of 12

Area of heat transfer

$A = (6)\times(2.8)$

$A = 16.8\ \text{m}^2$

Thermal resistance in case of plaster layer

$$R_1 = \frac{L_1}{k_1 A}$$

$$= \frac{0.01}{(0.36)(16.8)}$$

$R_1 = 0.00165\ ^\circ\text{C/W}$

Step 4 of 12

Thermal resistance in case of brick

$$R_2 = \frac{L_2}{k_2 A}$$

$$= \frac{0.20}{(0.72)(16.8)}$$

$R_2 = 0.01653\ ^\circ\text{C/W}$

Step 5 of 12

Thermal resistance in case of cement based coating

$$R_3 = \frac{L_3}{k_3 A}$$

$$= \frac{0.02}{(1.4)(16.8)}$$

$R_3 = 0.00085\ ^\circ\text{C/W}$

Step 6 of 12

Thermal resistance due to convection

$$R_{conv} = \frac{1}{hA}$$

$$= \frac{1}{(17)(16.8)}$$

$R_{conv} = 0.00350^\circ\text{C/W}$

Step 7 of 12

Then total thermal resistance will be

$R_t = R_1 + R_2 + R_3 + R_{conv}$

$= 0.00165 + 0.01653 + 0.00085 + 0.00350$

$R_t = 0.02253\ ^\circ\text{C/W}$

Step 8 of 12

Heat transfer rate for the entire wall can be calculated as

$$\dot{Q} = \frac{T_i - T_o}{R_t}$$

$$= \frac{(23-8)}{0.02253}$$

$$\boxed{\dot{Q} = 665.778\,\text{W}}$$

Step 9 of 12

Temperature drop across the plaster is

$\Delta T_1 = \dot{Q} R_1$

$= (665.778)(0.00165)$

$$\boxed{\Delta T_1 = 1.098^0\,\text{C}}$$

Step 10 of 12

Temperature drop across the brick is

$\Delta T_2 = \dot{Q} R_2$

$= (665.778)(0.01653)$

$$\boxed{\Delta T_2 = 11.0053^0\,\text{C}}$$

Step 11 of 12

Temperature drop across the cement covering

$\Delta T_3 = \dot{Q} R_3$

$= (665.778)(0.00085)$

$$\boxed{\Delta T_3 = 0.565^0\,\text{C}}$$

Step 12 of 12

Temperature drop across surface ambient air

$\Delta T_{conv} = \dot{Q} R_{conv}$

$= (665.778)(0.00350)$

$$\boxed{\Delta T_{conv} = 2.33^0\,\text{C}}$$

Question: 17.131P pg 1

Reconsider Prob. 17-130. It is desired to insulate the wall in order to decrease the heat loss by 90 percent. For the same inner surface temperature, determine the thickness of insulation and the outer surface temperature if the wall is insulated with (*a*) polyurethane foam (k = 0.025 W/m·K) and (*b*) glass fiber (k = 0.036 W/m·K).

Step 1 of 11

Given data:

Cross sectional area of the wall, $A = 6 \times 2.8 = 16.8 \text{ m}^2$

Thickness of the light weight plaster, $t_1 = 1\text{cm} = 0.01\text{m}$

Thickness of the common brick, $t_2 = 20\text{ cm} = 0.2\text{m}$

Thickness of the cement covering, $t_3 = 2\text{cm} = 0.02\text{m}$

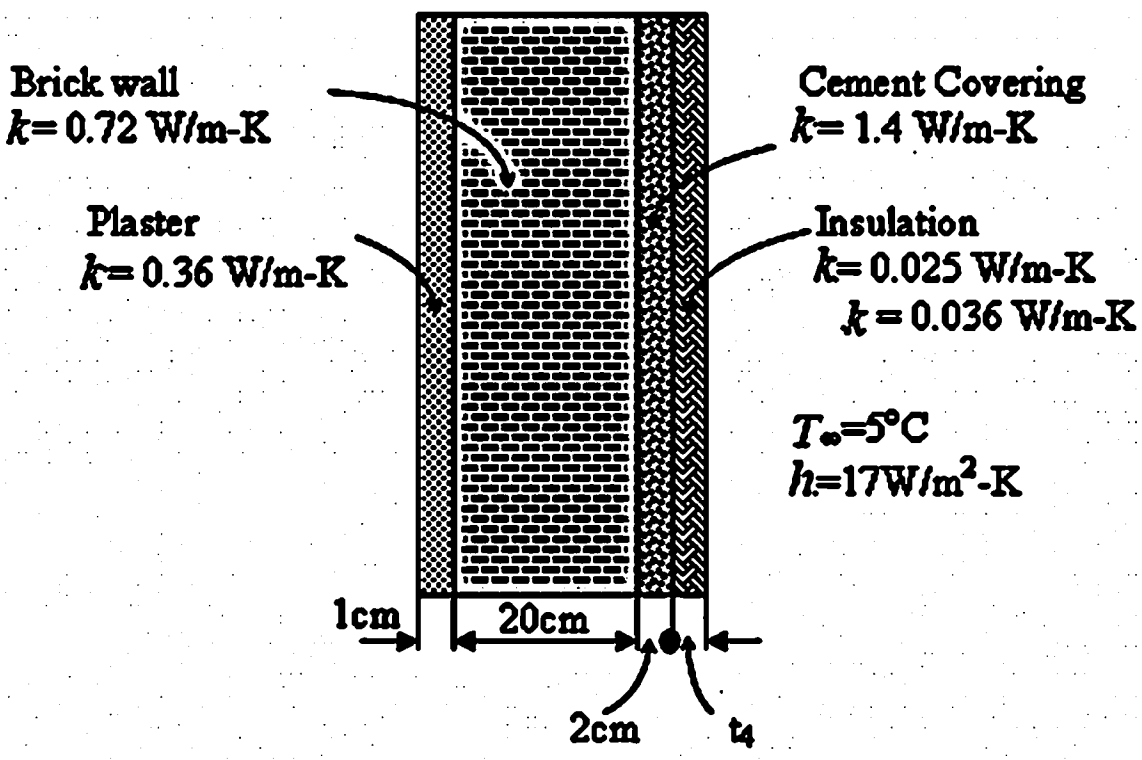
Thermal conductivity of the light weight plaster, $k_1 = 0.36 \text{ W/m} \cdot \text{K}$

Thermal conductivity of the common brick, $k_2 = 0.72 \text{ W/m} \cdot \text{K}$

Thermal conductivity of the cement covering, $k_3 = 1.4 \text{ W/m} \cdot \text{K}$

Thermal conductivity of the polyurethane foam, $k_4 = 0.025 \text{ W/m} \cdot \text{K}$

Thermal conductivity of the glass fiber, $k_4 = 0.036 \text{ W/m} \cdot \text{K}$



Inner surface temperature of the wall, $T_1 = 23°\text{C}$

Outdoor temperature, $T_{\infty,2} = 8°\text{C}$

Heat transfer coefficient on the outer wall, $h_o = 17 \text{ W/m}^2 \cdot \text{K}$

Step 2 of 11

The schematic diagram of the concrete wall and the thermal resistances can be represented as follows.

Step 3 of 11

Without any insulation, the heat lost by the wall to the ambient air can be determined as follows.

The individual resistances are evaluated in order to find out the thicknesses and surface temperatures of different layers of the wall.

Thermal resistance due to light weight plaster:

$$R_1 = R_{plaster} = \frac{t_1}{k_1 A_1} = \frac{0.01}{0.36 \times 16.8} = 0.0016534 \text{ K/W}$$

Thermal resistance due to common brick:

$$R_2 = R_{brick} = \frac{t_2}{k_2 A_2} = \frac{0.2}{0.72 \times 16.8} = 0.016534 \text{ K/W}$$

Step 4 of 11

Thermal resistance due to the cement based covering:

$$R_3 = R_{cement} = \frac{t_3}{k_3 A_3} = \frac{0.02}{1.4 \times 16.8} = 0.00085034 \text{ K/W}$$

Convection resistance from the outer surface of the wall:

$$R_o = R_{conv,o} = \frac{1}{h_o A} = \frac{1}{17 \times 16.8} = 0.0035014 \text{ K/W}$$

Step 5 of 11

As all the resistances are in series, the total resistance is given by,

$$R_{total} = R_1 + R_2 + R_3 + R_o = 0.0016534 + 0.016534 + 0.00085034 + 0.0035014 = 0.02254 \text{ K/W}$$

Step 6 of 11

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q}_t = \frac{(T_1 - T_{\infty,2})}{R_{total}}$$

Step 6 of 11

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q}_t = \frac{(T_1 - T_{\infty,2})}{R_{total}}$$
$$= \frac{23-8}{0.02254}$$
$$= 665.483\,\text{W}$$

Step 7 of 11

It is desired to insulate the wall in order to decrease the heat loss by 90%. Hence only 10% of total heat allowed.

Therefore, the allowable heat transfer through the wall with insulation can be calculated as

$$\dot{Q} = 0.1 \times \dot{Q}_t$$
$$= 0.1 \times 665.483$$
$$= 66.5483\,\text{W}$$

The total resistance can be determined as

$$R_{total} = \frac{(T_1 - T_{\infty,2})}{\dot{Q}}$$
$$= \frac{23-8}{66.5483}$$
$$= 0.2254\ \text{K/W}$$

Step 8 of 11

a) Using the polyurethane foam as an insulation material, the thickness of the insulation can be determined as,

$$R_4 = R_{total} - (R_1 + R_2 + R_3 + R_o)$$
$$= 0.2254 - 0.02254$$
$$= 0.20286\ \text{K/W}$$

where R_4 represents the thermal resistance across the insulation and the thickness of insulation can be determined as,

$$R_4 = \frac{t_4}{Ak_4}$$
$$t_4 = R_4 k_4 A_4$$
$$= 0.20286 \times 0.025 \times 16.8$$
$$= 0.0852\,\text{m}$$
$$= 8.52\,\text{cm}$$

$\boxed{t_4 = 8.52\,\text{cm}}$

Step 9 of 11

The outer surface temperature can be calculated using the heat rate equation.

$$\dot{Q} = \frac{(T_2 - T_\infty)}{R_o}$$

By rewriting the heat rate equation, we have,

$$T_2 = T_\infty + R_o \dot{Q}$$
$$= 8 + 0.0035014 \times 66.5483$$
$$= 8.233^\circ\text{C}$$

$\boxed{T_2 = 8.233^\circ\text{C}}$

Therefore if the insulation is polyurethane foam, then the thickness of insulation and the outer surface temperature are $t_4 = 8.52\,\text{cm}$ and $T_2 = 8.233^\circ\text{C}$ respectively.

Step 10 of 11

b)

Using glass fiber as an insulation material, the thickness of the insulation can be determined as follows.

$$R_4 = R_{total} - (R_1 + R_2 + R_3 + R_o)$$
$$= 0.2254 - 0.02254$$
$$= 0.20286\ \text{K/W}$$

where R_4 represents the thermal resistance across the insulation.

The thickness of insulation is given by,

$$t_4 = R_4 k_4 A_4$$
$$= 0.20286 \times 0.036 \times 16.8$$
$$= 0.1226\,\text{m}$$
$$= 12.26\,\text{cm}$$

$\boxed{t_4 = 12.26\,\text{cm}}$

Step 11 of 11

The outer surface temperature can be calculated using the heat rate equation

$$\dot{Q} = \frac{(T_2 - T_\infty)}{R_o}$$

By rewriting the heat rate equation, we have,

$$T_2 = T_\infty + R_o \dot{Q}$$
$$= 8 + 0.0035014 \times 66.5483$$
$$= 8.233^\circ\text{C}$$

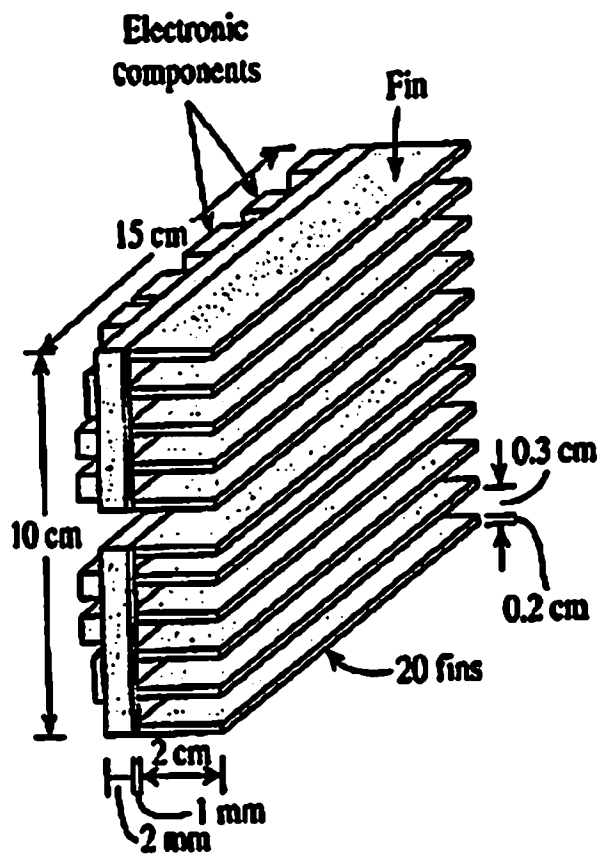
$\boxed{T_2 = 8.233^\circ\text{C}}$

Therefore if the insulation is Glass fiber then the thickness of insulation and the outer surface temperature are $t_4 = 12.26\,\text{cm}$ and $T_2 = 8.233^\circ\text{C}$.

Question: 17.132P pg 1

A 0.2-cm-thick, 10-cm-high, and 15-cm-long circuit board houses electronic components on one side that dissipate a total of 15 W of heat uniformly. The board is impregnated with conducting metal fillings and has an effective thermal conductivity of 12 W/m·K. All the heat generated in the components is conducted across the circuit board and is dissipated from the back side of the board to a medium at 37°C, with a heat transfer coefficient of 45 W/m2·K. (*a*) Determine the surface temperatures on the two sides of the circuit board. (*b*) Now a 0.1-cm-thick, 10-cm-high, and 15-cm-long aluminum plate (k= 237 W/m·K) with 20 0.2-cm-thick. 2-cm-long, and 15-cm-wide aluminum fins of rectangular profile are

attached to the back side of the circuit board with a 0.03-cm.-thick epoxy adhesive (k = 1.8 W/m·K). Determine the new temperatures on the two sides of the circuit board.



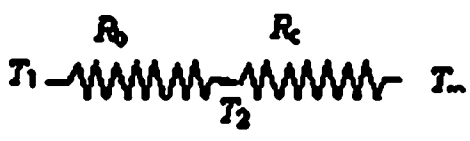


FIGURE P17–132

Step 1 of 12

Given: -
Dimensions of circuit board 0.2 cm-thick 10cm-high 15 cm-long
Heat dissipated Q= 15 W
Effective thermal conductivity of board k= 12 W/m.°C
Heat transfer coefficient h= 45 W/m^2.°C
Temperature of the medium $T_\infty = 37\,^\circ C$

Step 2 of 12

(*a*)
Total thermal resistance for the board can be calculated as follows:

Thermal resistance due to conduction in the board

$$R_b = \frac{L}{kA}$$
$$= \frac{0.002}{(12)(0.1)(0.15)}$$
$$R_b = 0.011\ ^\circ C/W$$

Thermal resistance due to convection from surface of the board to medium

$$R_t = \frac{1}{hA}$$
$$= \frac{1}{(45)\times(0.1)\times(0.15)}$$
$$R_t = 1.481\ ^\circ C/W$$

Total thermal resistance
$$R_t = R_b + R_t$$
$$= 0.011+1.481$$
$$R_t = 1.492\ ^\circ C/W$$

Step 3 of 12

The rate of heat transfer from the board is

$$\dot{Q} = \frac{T_1 - T_\infty}{R_t}$$
$$T_1 = T_\infty + \dot{Q}R_t$$
$$= 37 + (15)(1.492)$$
$$\boxed{T_1 = 59.38^0\,C}$$

Temperature on other surface of the board can be calculated as follows

$$\dot{Q} = \frac{T_1 - T_2}{R_b}$$
$$T_2 = T_1 - \dot{Q}R_b$$
$$= 59.38 - (15)(0.011)$$
$$\boxed{T_2 = 59.215^0\,C}$$

Step 4 of 12

(*b*)
Given: -
Dimensions of aluminum plate 0.1 cm-thick, 10 cm-high and 15 cm-long
Total number of fins N= 20
Dimensions of fins 0.2 cm-thick, 2 cm-long and 15 cm-wide
Thermal conductivity of aluminum $k_{al} = 237$ W/m. °C
Thermal conductivity of epoxy adhesive $k_{epoxy} = 1.8$ W/m. °C

Step 5 of 12

Efficiency of rectangular fins can be calculated as follows

$$m = \sqrt{\frac{hp}{kA_c}} \cong \sqrt{\frac{h(2w)}{k(tw)}}$$
$$\sqrt{\frac{2h}{}}$$

Efficiency of rectangular fins can be calculated as follows

$$m = \sqrt{\frac{hp}{kA_c}} \cong \sqrt{\frac{h(2w)}{k(tw)}}$$

$$= \sqrt{\frac{2h}{kt}}$$

$$= \sqrt{\frac{2(45)}{(237)(0.002)}}$$

$$m = 13.78 \text{ m}^{-1}$$

$$\eta_{fin} = \frac{\tanh mL}{mL}$$

$$= \frac{\tanh(13.78 \times 0.02)}{13.78 \times 0.02}$$

$$\eta_{fin} = 0.975$$

Step 6 of 12

Area of finned surface can be calculated as

$$A_f = N \times 2w \times L_c$$

Where L_c the characteristic length and characteristic length for rectangular fins is

$$L_c = L + \frac{t}{2}$$

Step 7 of 12

Then area of finned surfaces will be

$$A_f = (20)2w\left(L + \frac{t}{2}\right)$$

$$= (20)2(0.15)\left(0.02 + \frac{0.002}{2}\right)$$

$$A_f = 0.126 \text{ m}^2$$

Surface area of unfinned surface

$$A_{uf} = (0.1)(0.15) - 20(0.002)(0.15)$$

$$A_{uf} = 0.009 \text{ m}^2$$

Step 8 of 12

Efficiency of the fin is defined as the ratio of actual heat transfer rate from the fin to the ideal heat transfer rate from the fin if the entire fin were at base temperature

Then

$$\eta_{fin} = \frac{\dot{Q}_{fin}}{\dot{Q}_{fin\,max}}$$

$$\dot{Q}_{fin} = \eta_{fin}\dot{Q}_{fin\,max}$$

$$= \eta_{fin}hA_f(T_b - T_\infty)$$

Heat transfer rate from the unfinned surface is

$$\dot{Q}_{uf} = hA_{uf}(T_b - T_\infty)$$

Then total heat transfer rate is

$$\dot{Q}_t = \dot{Q}_{uf} + \dot{Q}_{fin}$$

$$= hA_{uf}(T_b - T_\infty) + \eta_{fin}hA_f(T_b - T_\infty)$$

$$= h(T_b - T_\infty)(\eta_{fin}A_f + A_{uf})$$

Step 9 of 12

Temperature of base for finned surface can be calculated as

$$T_b = T_\infty + \frac{\dot{Q}_t}{h(\eta_{fin}A_f + A_{uf})}$$

$$= 37 + \frac{15}{(45)[(0.975)(0.126) + (0.0090)]}$$

$$T_b = 39.528^0\text{C}$$

Step 10 of 12

Temperature of surface on two side of the board can be calculated as follows:

$$R_{al} = \frac{L}{kA}$$

$$= \frac{0.001}{(237)(0.1)(0.15)}$$

$$R_{Al} = 0.00028 \text{ °C/W}$$

$$R_{ep} = \frac{L}{kA}$$

Since thickness of the epoxy layer is $L = 0.03\text{cm} = 0.0003\text{m}$

$$R_{ep} = \frac{0.0003}{(1.8)(0.1)(0.15)}$$

$$R_{ep} = 0.0111 \text{ °C/W}$$

Step 11 of 12

Heat transfer rate is

$$\dot{Q} = \frac{T_1 - T_{base}}{R_{aluminum} + R_{epoxy} + R_{board}}$$

$$15 = \frac{(T_1 - 39.5)}{(0.00028 + 0.0111 + 0.011)}$$

$$T_1 = 39.5 + (15)(0.02238)$$

$$\boxed{T_1 = 39.8357^0\text{C}}$$

Step 12 of 12

$$\dot{Q} = \frac{T_1 - T_2}{R_{board}}$$

$$T_2 = T_1 - \dot{Q}R_{board}$$

$$= 39.8357 - (15)(0.011)$$

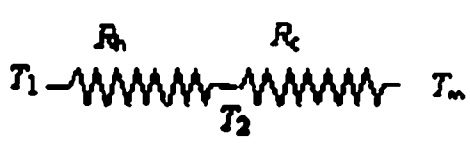
$$\boxed{T_2 = 39.67^0\text{C}}$$

17.132P pg 3

$$T_2 = T_1 - \dot{Q}R_{board}$$
$$= 39.8357 - (15)(0.011)$$

$$\boxed{T_2 = 39.67^0\text{C}}$$

Question: 17.133P pg 1



Repeat Prob, 17-132 using a copper plate with copper fins (k = 386 W/m·K) instead of aluminum ones.

Step 1 of 12

Given: -
Dimensions of circuit board 0.2 cm-thick 10cm-high 15 cm-long
Heat dissipated Q= 15 W
Effective thermal conductivity of board k= 12 W/m.°C
Heat transfer coefficient h= 45 W/m^2.°C
Temperature of the medium = 37 °C

Step 2 of 12

(*a*)
Total thermal resistance for the board can be calculated as follows:

Thermal resistance due to conduction in the board

$$R_b = \frac{L}{kA}$$
$$= \frac{0.002}{(12)(0.1)(0.15)}$$
$$R_b = 0.011\ ^\circ C/W$$

Thermal resistance due to convection from surface of the board to medium

$$R_c = \frac{1}{hA}$$
$$= \frac{1}{(45)\times(0.1)\times(0.15)}$$
$$R_c = 1.481\ ^\circ C/W$$

Total thermal resistance

$$R_t = R_b + R_c$$
$$= 0.011+1.481$$
$$R_t = 1.492\ ^\circ C/W$$

Step 3 of 12

The rate of heat transfer from the board is

$$\dot{Q} = \frac{T_1 - T_\infty}{R_t}$$
$$T_1 = T_\infty + \dot{Q}R_t$$
$$= 37 + (15)(1.492)$$
$$\boxed{T_1 = 59.38^0\,C}$$

Step 4 of 12

Temperature on other surface of the board can be calculated as follows

$$\dot{Q} = \frac{T_1 - T_2}{R_b}$$
$$T_2 = T_1 - \dot{Q}R_b$$
$$= 59.38 - (15)(0.011)$$
$$\boxed{T_2 = 59.215^0\,C}$$

Step 5 of 12

(*b*)
Given: -
Dimensions of aluminum plate 0.1 cm-thick, 10 cm-high and 15 cm-long
Total number of fins N= 20
Dimensions of fins 0.2 cm-thick, 2 cm-long and 15 cm-wide
Thermal conductivity of copper k_{Cu} = 386 W/m. °C
Thermal conductivity of epoxy adhesive k_{epoxy} = 1.8 W/m. °C

Step 6 of 12

Efficiency of rectangular fins can be calculated as follows

$$m = \sqrt{\frac{hp}{kA_c}} \cong \sqrt{\frac{h(2w)}{k(tw)}}$$
$$= \sqrt{\frac{2h}{kt}}$$
$$= \sqrt{\frac{2(45)}{(386)(0.002)}}$$
$$m = 10.79\ m^{-1}$$

$$\eta_{fin} = \frac{\tanh mL}{mL}$$
$$= \frac{\tanh(10.79\times 0.02)}{10.79\times 0.02}$$
$$\eta_{fin} = 0.9847$$

Step 7 of 12

Area of finned surface can be calculated as
$$A_f = N\times 2w\times L_c$$
Where L_c the characteristic length and characteristic length for rectangular fins is

$$L_c = L + \frac{t}{2}$$

Then area of finned surfaces will be

$$A_f = (20)2w\left(L + \frac{t}{2}\right)$$
$$= (20)2(0.15)\left(0.02 + \frac{0.002}{2}\right)$$
$$A_f = 0.1290\ m^2$$

Then area of finned surfaces will be

$$A_f = (20)2w\left(L+\frac{t}{2}\right)$$

$$= (20)2(0.15)\left(0.02+\frac{0.002}{2}\right)$$

$$A_f = 0.126\ \text{m}^2$$

Surface area of unfinned surface

$$A_{uf} = (0.1)(0.15) - 20(0.002)(0.15)$$

$$A_{uf} = 0.009\ \text{m}^2$$

Step 8 of 12

Efficiency of the fin is defined as the ratio of actual heat transfer rate from the fin to the ideal heat transfer rate from the fin if the entire fin were at base temperature

Then

$$\eta_{fin} = \frac{\dot{Q}_{fin}}{\dot{Q}_{finmax}}$$

$$\dot{Q}_{fin} = \eta_{fin}\dot{Q}_{finmax}$$

$$= \eta_{fin}hA_f(T_b - T_\infty)$$

Heat transfer rate from the unfinned surface is

$$\dot{Q}_{uf} = hA_{uf}(T_b - T_\infty)$$

Then total heat transfer rate is

$$\dot{Q}_t = \dot{Q}_{uf} + \dot{Q}_{fin}$$

$$= hA_{uf}(T_b - T_\infty) + \eta_{fin}hA_f(T_b - T_\infty)$$

$$= h(T_b - T_\infty)(\eta_{fin}A_f + A_{uf})$$

Step 9 of 12

Temperature of base for finned surface can be calculated as

$$T_b = T_\infty + \frac{\dot{Q}_t}{h(\eta_{fin}A_f + A_{uf})}$$

$$= 37 + \frac{15}{(45)[(0.9847)(0.126)+(0.0090)]}$$

$$T_b = 39.505^0\text{C}$$

Step 10 of 12

Temperature of surface on two side of the board can be calculated as follows:

$$R_{Cu} = \frac{L}{kA}$$

$$= \frac{0.001}{(386)(0.1)(0.15)}$$

$$R_{Cu} = 0.000172\ ^\circ\text{C/W}$$

$$R_{ep} = \frac{L}{kA}$$

Since thickness of the epoxy layer is $L = 0.03\text{cm} = 0.0003\text{m}$

$$R_{ep} = \frac{0.0003}{(1.8)(0.1)(0.15)}$$

$$R_{ep} = 0.0111\ ^\circ\text{C/W}$$

Step 11 of 12

Heat transfer rate is

$$\dot{Q} = \frac{T_1 - T_{base}}{R_{Cu} + R_{epoxy} + R_{board}}$$

$$15 = \frac{(T_1 - 39.505)}{(0.000172 + 0.0111 + 0.011)}$$

$$T_1 = 39.505 + (15)(0.02227)$$

$$\boxed{T_1 = 39.839^0\text{C}}$$

Step 12 of 12

$$\dot{Q} = \frac{T_1 - T_2}{R_{board}}$$

$$T_2 = T_1 - \dot{Q}R_{board}$$

$$= 39.839 - (15)(0.011)$$

$$\boxed{T_2 = 39.674^0\text{C}}$$

Question: 17.134P

Consider two identical people each generating 60 w of metabolic heat steadily while doing sedentary work, and dissipating it by convection and perspiration. The first person is wearing clothes made of 1-mm-thick leather (k = 0.159 W/m·K) that covers half of the body while the second one is wearing clothes made of 1-mm-thick synthetic fabric (k = 0.13 W/m·K) that covers the body completely. The ambient air is at 30°C, the heat transfer coefficient at the outer surface is 15 W/m2·K, and the inner surface temperature of the clothes can be taken to be 32°C. Treating the body of each person as a 25-cm-diameter, 1.7-m-long cylinder, determine the fractions of heat lost from each person by perspiration.

Step 1 of 4

Given: - Heat generated by both people = 60 W

Thickness of cloth of person one = 1mm

Thermal conductivity of leather = 0.159 W/m°C

Thickness of cloth of second person = 1mm

Thermal conductivity of synthetic fibre = 0.13 W/m°C

Temperature of ambient air = 30°C

Heat transfer coefficient = 15 W/m^2.°C

Area of heat transfer for both persons

$$A_1 = \pi DL/2$$
$$= \pi(0.25\text{ m})(1.7\text{ m})/2 = 0.6675\text{ m}^2$$
$$A_2 = 2A_1$$
$$= 2\times 0.6675 = 1.335\text{ m}^2$$

Step 2 of 4

Calculating thermal resistance from first person body

$$R_1 = \frac{L}{kA}$$
$$= \frac{0.001\text{ m}}{(0.159\text{ W/m.°C})(0.6675\text{ m}^2)} = 0.00942\text{ °C/W}$$
$$R_c = \frac{1}{hA}$$
$$= \frac{1}{(15\text{ W/m}^2\text{.°C})(0.6675\text{ m}^2)} = 0.09988\text{ °C/W}$$
$$R_t = R_1 + R_c$$
$$= 0.00942 + 0.09988 = 0.10930\text{ °C/W}$$

Step 3 of 4

Rate of sensible heat transfer through the first person

$$\dot{Q}_c = \frac{T_i - T_o}{R_t}$$
$$= \frac{(32-30)°\text{C}}{0.10930°\text{C/W}} = 18.3\text{ W}$$
$$\dot{Q}_s = \frac{T_i - T_o}{R_c}$$
$$= \frac{(32-30)°\text{C}}{0.09988°\text{C/W}} = 20.0\text{ W}$$
$$\dot{Q}_{sensible} = \dot{Q}_c + \dot{Q}_s$$
$$= 18.3 + 20 = 38.3\text{ W}$$

Fraction of heat lost by respiration can be calculated as

$$f = \frac{\dot{Q}_r}{\dot{Q}_t}$$
$$= \frac{\dot{Q}_t - \dot{Q}_{sensible}}{\dot{Q}_t}$$
$$= \frac{60-38.3}{60} = 0.362$$

Step 4 of 4

Now calculating fraction of heat lost by respiration for second person

T_2

$$R_s = \frac{L}{kA}$$
$$= \frac{0.001\text{ m}}{(0.13\text{ W/m.°C})(1.335\text{ m}^2)} = 0.00576\text{ °C/W}$$
$$R_c = \frac{1}{hA}$$
$$= \frac{1}{(15\text{ W/m}^2\text{.°C})(1.335\text{ m}^2)} = 0.04994\text{ °C/W}$$
$$R_t = R_s + R_c$$
$$= 0.00576 + 0.04994 = 0.05570\text{ °C/W}$$
$$\dot{Q}_{sensible} = \frac{T_i - T_o}{R_t}$$
$$= \frac{(32-30)°\text{C}}{0.05570°\text{C/W}} = 35.9\text{ W}$$

$$f = \frac{\dot{Q}_r}{\dot{Q}_t}$$
$$= \frac{\dot{Q}_t - \dot{Q}_{sensible}}{\dot{Q}_t} = \frac{60-35.9}{60}$$
$$= 0.402$$

Question: 17.135P pg 1

A 4-m-high and 6-m-long wall is constructed of two large 0.8-cm-thick steel plates (k = 15 W/m·K) separated by 1-cm-thick and 22-cm wide steel bars placed 99 cm apart. The remaining space between the steel plates is filled with fiberglass insulation (k = 0.035 W/m·K). If the temperature difference between the inner and the outer surfaces of the walls is 22°C, determine the rate of heat transfer through the wall. Can we ignore the steel bars between the plates in heat transfer analysis since they occupy only 1 percent of the heat transfer surface area?

Step 1 of 10

Given data:

Area of the steel wall, $A_1 = 6 \times 4 = 24 \text{ m}^2$

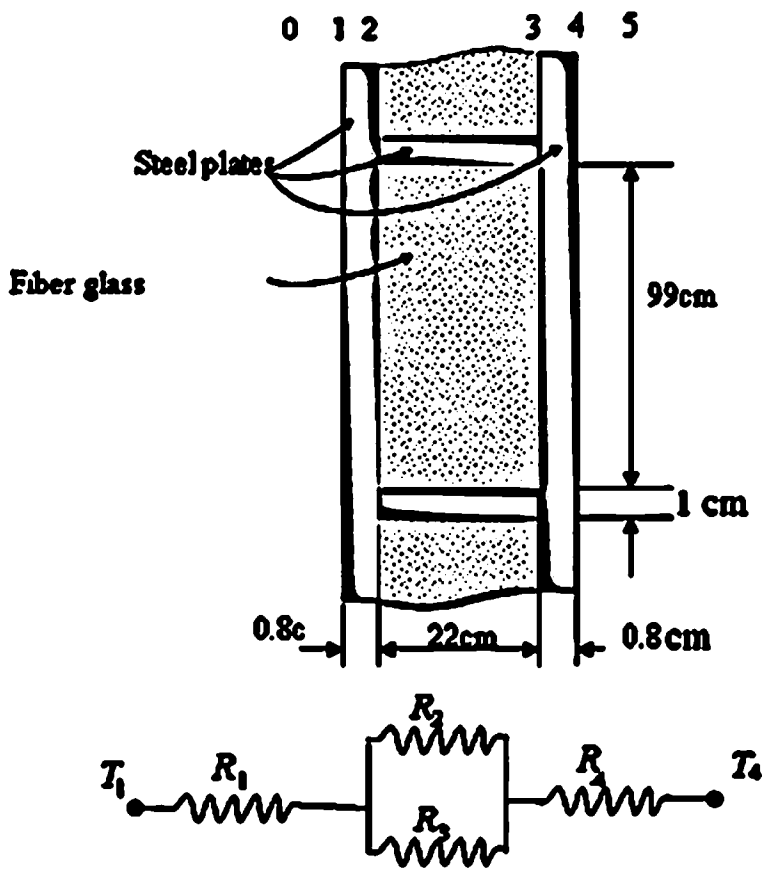
Thickness of the steel plates, $t_{12} = t_{34} = 0.8 \text{ cm} = 0.008 \text{ m}$

Thickness of the steel bar, $t_{23} = 22\text{cm} = 0.22\text{m}$

Thickness of the fiber glass insulation, $t_{23} = 22\text{cm} = 0.22\text{m}$

Length of the fiber glass insulation, $L_A = 99 \text{ cm} = 0.99 \text{ m}$

Length of the steel plate, $L_B = 1\text{cm} = 0.01\text{m}$



Thermal conductivity of the steel plates, $k_{steel} = 15\,\text{W/m}\cdot\text{K}$

Thermal conductivity of the insulation, $k_{insulation} = 0.035\,\text{W/m}\cdot\text{K}$

Temperature difference between inner and outer surfaces of the wall, $\Delta T = 22°\text{C}$

Step 2 of 10

The schematic diagram of the steel plates and thermal network is as shown below:

Step 3 of 10

By using the thermal network approach the total resistance of the network can be determined as

$$R_{total} = R_1 + R_{23} + R_4$$

$$= R_1 + \frac{R_2 R_3}{R_2 + R_3} + R_4$$

The individual thermal resistance formulae are as follows,

$$R_1 = \frac{t_{12}}{k_{steel} A_i}$$

$$R_2 = \frac{t_{23}}{k_{insulation} A_A}$$

$$R_3 = \frac{t_{23}}{k_{steel} A_B}$$

$$R_{23} = \frac{R_2 R_3}{R_2 + R_3}$$

$$= \frac{\left(\frac{t_{23}}{k_{insulation} A_A}\right)\left(\frac{t_{23}}{k_{steel} A_B}\right)}{\frac{t_{23}}{k_{insulation} A_A} + \frac{t_{23}}{k_{steel} A_B}}$$

$$R_4 = \frac{t_{34}}{k_{steel} A_o}$$

Step 4 of 10

Then total thermal resistance becomes,

$$R_{total} = \frac{t_{12}}{k_{steel} A_i} + \frac{\left(\frac{t_{23}}{k_{insulation} A_A}\right)\left(\frac{t_{23}}{k_{steel} A_B}\right)}{\frac{t_{23}}{k_{insulation} A_A} + \frac{t_{23}}{k_{steel} A_B}} + \frac{t_{34}}{k_{steel} A_o}$$

Where cross sectional areas are

$$A_i = A_o = (L_A + L_B) w$$

$$A_A = L_A w$$

$$A_B = L_B w$$

Where, w represents the width of all walls

Step 5 of 10

The total resistance multiplies with $A_i = A_o = (L_A + L_B) w$ and it can be expressed as

$$R_{total} A_i = \frac{t_{12}}{k_{steel}} + A_i \left[\frac{\left(\frac{t_{23}}{k_{insulation} A_A}\right)\left(\frac{t_{23}}{k_{steel} A_B}\right)}{\frac{t_{23}}{k_{insulation} A_A} + \frac{t_{23}}{k_{steel} A_B}} \right] + \frac{t_{34}}{k_{steel}}$$

$$= \frac{t_{12}}{k_{steel}} + (L_A + L_B) w \left[\frac{\left(\frac{t_{23}}{k_{insulation} A_A}\right)\left(\frac{t_{23}}{k_{steel} A_B}\right)}{\frac{t_{23}}{k_{insulation} A_A} + \frac{t_{23}}{k_{steel} A_B}} \right] + \frac{t_{34}}{k_{steel}}$$

$$= \frac{t_{12}}{k_{steel}} + (L_A + L_B) \left[\frac{\left(\frac{t_{23}}{k_{insulation} L_A}\right)\left(\frac{t_{23}}{k_{steel} L_B}\right)}{\frac{t_{23}}{k_{insulation} L_A} + \frac{t_{23}}{k_{steel} L_B}} \right] + \frac{t_{34}}{k_{steel}}$$

$$= \frac{t_{12}}{k_{steel}} + (L_A + L_B)w\left[\frac{1}{\frac{t_{23}}{k_{insulation}A_A} + \frac{t_{23}}{k_{steel}A_B}}\right] + \frac{t_{34}}{k_{steel}}$$

$$= \frac{t_{12}}{k_{steel}} + (L_A + L_B)\left(\frac{\left(\frac{t_{23}}{k_{insulation}L_A}\right)\left(\frac{t_{23}}{k_{steel}L_B}\right)}{\frac{t_{23}}{k_{insulation}L_A} + \frac{t_{23}}{k_{steel}L_B}}\right) + \frac{t_{34}}{k_{steel}}$$

Step 6 of 10

Then substituting the known values in the above equation,

$$R_{total}A_i = \frac{0.008}{15} + 1\times\left(\frac{\left[\frac{0.22}{(0.035\times0.99)}\right]\times\left[\frac{0.22}{(15\times0.01)}\right]}{\left[\frac{0.22}{(0.035\times0.99)}\right]+\left[\frac{0.22}{(15\times0.01)}\right]}\right) + \frac{0.008}{15}$$

$$= 0.00053 + \frac{9.712}{7.0158} + 0.000533$$

$$= 1.3853\,\text{m}^2\cdot\text{K/W}$$

Step 7 of 10

The average heat flux through the wall can be determined as

$$q = \frac{\dot{Q}}{A_i}$$

$$= \frac{(T_4 - T_1)}{R_{total}A_i}$$

$$= \frac{22}{1.3853}$$

$$= 15.88\,\text{W/m}^2$$

The total heat transfer through the composite wall can be determined as

$$\dot{Q} = Aq$$

$$= 24\times15.88$$

$$= 381.12\,\text{W}$$

Therefore, the total heat transfer through the composite wall is $\boxed{\dot{Q} = 381.12\,\text{W}}$

Step 8 of 10

Let us calculate the total heat transfer through the wall by neglecting the steel bars between the plates,

Cross sectional areas are

$$A_i = A_o = L_A w$$

$$A_A = L_A w$$

Then total thermal resistance becomes,

$$R_{total}A_i = \frac{t_{12}}{k_{steel}} + \frac{t_{23}}{k_{insulation}} + \frac{t_{34}}{k_{steel}}$$

$$= \frac{0.008}{15} + \frac{0.22}{0.035} + \frac{0.008}{15}$$

$$= 6.286\,\text{m}^2\cdot\text{K/W}$$

Step 9 of 10

The average heat flux through the wall can be determined as

$$q = \frac{\dot{Q}}{A_i}$$

$$= \frac{(T_4 - T_1)}{R_{total}A_i}$$

$$= \frac{22}{6.286}$$

$$= 3.499\,\text{W/m}^2$$

The total heat transfer through the composite wall can be determined as

$$\dot{Q} = Aq$$

$$= 24\times3.499$$

$$= 83.976\ \text{W}$$

Therefore, the total heat transfer through the composite wall is $\boxed{\dot{Q} = 83.976\ \text{W}}$

Step 10 of 10

Since we neglected the steel bars in between two steel plates, the total heat transfer rate drastically reduced and the error is to be

$$\%\text{Error} = \frac{(381.12 - 83.976)}{381.12}\times100$$

$$= 77.96\%$$

Therefore, though we ignored 1% of the total area, the error is significant and hence we cannot ignore the steel bars for calculation. 77% of total heat transfer occurs through the steel bars across the wall despite the negligible space that they occupy. The connecting bars are served as "thermal bridges".

Question: 17.136P

Cold conditioned air at 12°C is flowing inside a l·5-cm-thick square aluminum (k = 237 W/m·K) duct ofinner cross section 22 cm × 22 cm at a mass flow rate of 0.8 kg/s. The duct is exposed to air at 33°C with a combined convection-radiation heal transfer coefficient of 13 W/nr-K. The convection heat transfer coefficient at the inner surface is 75 W/m2-K. If thc air temperature in the duct should not increase by more than l°C determine the maximum length of the duct.

Step 1 of 8

Given: -

Temperature of cold conditioned air $T_i = 12°C$

Thickness of square aluminum duct $L_{Al} = 15$ cm

Thermal conductivity of aluminum $k_{Al} = 237\ W/m^0C$

Inner cross-section of aluminum duct is 22 cm × 22 cm

Mass flow rate of cold conditioned air $\dot{m} = 0.8$ kg/s

Temperature of air surrounding duct $T_\infty = 33°C$

Combined convection and radiation heat transfer coefficient on outer surface $h_o = 13\ W/m^2.°C$

Convection heat transfer coefficient for inner surface $h_i = 75\ W/m^2.°C$

Step 2 of 8

The thermal resistance circuit is

Step 3 of 8

Inner and outer surface area for unit length of the duct can be calculated as follows

$$A_i = 4a_1$$
$$= 4(0.22)$$
$$A_i = 0.88\ m^2$$
$$A_o = 4a_2$$
$$= 4(0.22+0.03)$$
$$A_o = 1.0\ m^2$$

Step 4 of 8

Thermal resistances for the system can be calculated as follows

$$R_{inner} = \frac{1}{h_1 A_i}$$
$$= \frac{1}{(75)(0.88)}$$
$$R_{inner} = 0.01515°C/W$$

$$R_{Al} = \frac{L_{Al}}{kA}$$
$$R_{Al} = \frac{L_{Al}}{k(A_i + A_o)/2}$$
$$= \frac{0.015}{(237)[(0.88+1)/2]}$$
$$R_{Al} = 0.0000673\ °C/W$$

$$R_{outer} = \frac{1}{h_2 A_o}$$
$$= \frac{1}{(13)(1.0)}$$
$$R_{outer} = 0.07692°C/W$$

Step 5 of 8

Total thermal resistance will be

$$R_t = R_{inner} + R_{Alm} + R_{outer}$$
$$= 0.01515+0.0000673+0.07692$$
$$R_t = 0.09213\ °C/W$$

Step 6 of 8

Rate of heat loss per length of duct

$$\dot{Q} = \frac{T_\infty - T_i}{R_t}$$
$$= \frac{(33-12)}{0.09213}$$
$$\dot{Q} = 227.938\ W/m$$

Step 7 of 8

If inside temperature of air in the duct increases by 1°C, rate of heat gained by inside air can be calculated as follows

$$\dot{Q}_t = \dot{m} C_p \Delta T$$
$$= (0.8)(1006)(1)$$
$$\dot{Q}_t = 804\ W$$

Step 8 of 8

Maximum length of duct can be calculated as

$$L = \frac{\dot{Q}_{total}}{\dot{Q}}$$
$$= \frac{804}{227.938}$$
$$\boxed{L = 3.527\ m}$$

Question: 17.137P pg 1

When analyzing heat transfer through windows, it is important to consider the frame as well as the glass area. Consider a 2-m-wide, 1.5-m-high wood-framed window with 85 percent of the area covered by 3-mm-thick single-pane glass (k = 0.7 W/m·K). The frame is 5 cm thick, and is made of pine wood (k = 0.12 W/m·K). The heat transfer coefficient is 7 W/m2·K inside and 13 W/m2·K outside. Thc room is maintained at 24°C, and the outdoor temperature is 40°C. Determine the percent error involved in heat transfer when the window is assumed to consist of glass only.

Step 1 of 14

Given: -

Width of window = 2-m

Height of window =1.5 m

Inside heat transfer coefficient $h_i = 7\ \text{W/m}^2\cdot^\circ\text{C}$

Outer heat transfer coefficient $h_o = 13\ \text{W/m}^2\cdot^\circ\text{C}$

Thermal conductivity of glass $k_{glass} = 0.7\ \text{W/m}\cdot^\circ\text{C}$

Thermal conductivity of pine wood $k_{pinewood} = 0.12\ \text{W/m}\cdot^\circ\text{C}$

Thickness of the glass $L_g = 3\text{mm}$

Room air temperature $T_{\infty 1} = 24^0\text{C}$

Outside air temperature $T_{\infty 2} = 40^0\text{C}$

Step 2 of 14

Only 85% of the area covered by thick single pane glass

Heat transfer area of glass and wood

$A_g = 0.85(1.5)(2)$

$A_g = 2.55\ \text{m}^2$

$A_w = 0.15(1.5)(2)$

$A_w = 0.45\ \text{m}^2$

Step 3 of 14

Thermal resistance due to convection from inside air and inner surface of the glass

$$R_{ig} = \frac{1}{h_i A_g}$$

$$= \frac{1}{(7)(2.55)}$$

$R_{ig} = 0.05602^\circ\text{C/W}$

Thermal resistance due to conduction inside the glass

$$R_g = \frac{L_g}{k_g A_g}$$

$$= \frac{0.003}{(0.7)(2.55)}$$

$R_g = 0.00168\ ^\circ\text{C/W}$

Thermal resistance due to convection from outside air and outer surface of the glass

$$R_{og} = \frac{1}{h_0 A_g}$$

$$= \frac{1}{(13)(2.55)}$$

$R_{og} = 0.03017^\circ\text{C/W}$

Step 4 of 14

Total resistance in the glass

$R_{tg} = R_{ig} + R_g + R_{og}$

$= 0.05602 + 0.00168 + 0.03017$

$R_{tg} = 0.08787\ ^\circ\text{C/W}$

Step 5 of 14

Thermal resistance due to convection from inside air and inner surface of the pine wood

$$R_{iw} = \frac{1}{h_i A_w}$$

$$= \frac{1}{(7)(0.45)}$$

$R_{iw} = 0.31746^\circ\text{C/W}$

Thermal resistance due to conduction inside the pine wood

$$R_w = \frac{L_w}{k_w A_w}$$

$$= \frac{0.05}{(0.12)(0.45)}$$

$R_w = 0.92593\ ^\circ\text{C/W}$

Thermal resistance due to convection from outside air and outer surface of the pine wood

$$R_{ow} = \frac{1}{h_o A_w}$$

$$= \frac{1}{(13)(0.45)}$$

$R_{ow} = 0.17094^\circ\text{C/W}$

Step 6 of 14

Total resistance in the pine wood

$R_{tw} = R_{iw} + R_w + R_{ow}$

$= 0.31746 + 0.92593 + 0.17094$

$R_{tw} = 1.41433\ ^\circ\text{C/W}$

Step 7 of 14

Heat transfer rate through glass

$$\dot{Q}_g = \frac{T_{\infty 2} - T_{\infty 1}}{R_{tg}}$$

$$= \frac{(40-24)}{0.08787}$$

Heat transfer rate through glass

$$\dot{Q}_g = \frac{T_{\infty 2} - T_{\infty 1}}{R_{tg}}$$
$$= \frac{(40-24)}{0.08787}$$
$$\dot{Q}_g = 182.1\ \text{W}$$

Step 8 of 14

Heat transfer rate through pine wood

$$\dot{Q}_w = \frac{T_{\infty 2} - T_{\infty 1}}{R_{tw}}$$
$$= \frac{(40-24)}{1.41433}$$
$$\dot{Q}_w = 11.3\ \text{W}$$

Step 9 of 14

Total heat transfer rate through glass and pine wood

$$\dot{Q}_t = \dot{Q}_g + \dot{Q}_w$$
$$= 182.1 + 11.3$$
$$\dot{Q}_t = 193.4\ \text{W}$$

Step 10 of 14

Heat transfer area when there is only glass

$$A_g = (1.5)(2)$$
$$A_g = 3.0\ \text{m}^2$$

Step 11 of 14

Thermal resistance for the system can be calculated as follows
Thermal resistance due to convection from inside air and inner surface of the glass

$$R_{ig} = \frac{1}{h_i A_g}$$
$$= \frac{1}{(7)(3.0)}$$
$$R_{ig} = 0.04762°\text{C/W}$$

Thermal resistance due to conduction inside the glass

$$R_g = \frac{L_g}{k_g A_g}$$
$$= \frac{0.003}{(0.7)(3.0)}$$
$$R_g = 0.001428\ °\text{C/W}$$

Thermal resistance due to convection from outside air and outer surface of the glass

$$R_{og} = \frac{1}{h_0 A_g}$$
$$= \frac{1}{(13)(3.0)}$$
$$R_{og} = 0.02564°\text{C/W}$$

Step 12 of 14

Total thermal resistance if there is only glass

$$R_{tg} = R_{ig} + R_g + R_{og}$$
$$= 0.04762 + 0.001428 + 0.02564$$
$$R_{tg} = 0.07468\ °\text{C/W}$$

Step 13 of 14

Heat transfer rate

$$\dot{Q}_g = \frac{T_{\infty 2} - T_{\infty 1}}{R_{tg}}$$
$$= \frac{(40-24)}{0.07468}$$
$$\dot{Q}_g = 214.247\ \text{W}$$

Step 14 of 14

Percentage change for heat transfer rate with glass and wood and with only glass can be calculated as follows

$$\%\ \text{Error} = \frac{\dot{Q}_g - \dot{Q}_t}{\dot{Q}_t}$$
$$= \frac{214.247 - 193.4}{193.4} \times 100$$
$$\boxed{\%\text{Error} = 10.779\%}$$

Question: 17.138P pg 1

Steam at 260°C is flowing inside a steel pipe (k = 61 W/m·K) whose inner and outer diameters are 10 cm and 12 cm, respectively, in an environment at 20°C. Thc heal transfer coefficients inside and outside the pipe are 120 W/m2·K and 14 W/m2·K. respectively. Determine (*a*) the thickness of the insulation (k = 0.038 W/m·K) needed to reduce the heat loss by 95 percent and (*b*) the thickness of the insulation needed to reduce the exposed surface temperature of insulated pipe to 40°C for safety reasons.

Step 1 of 10

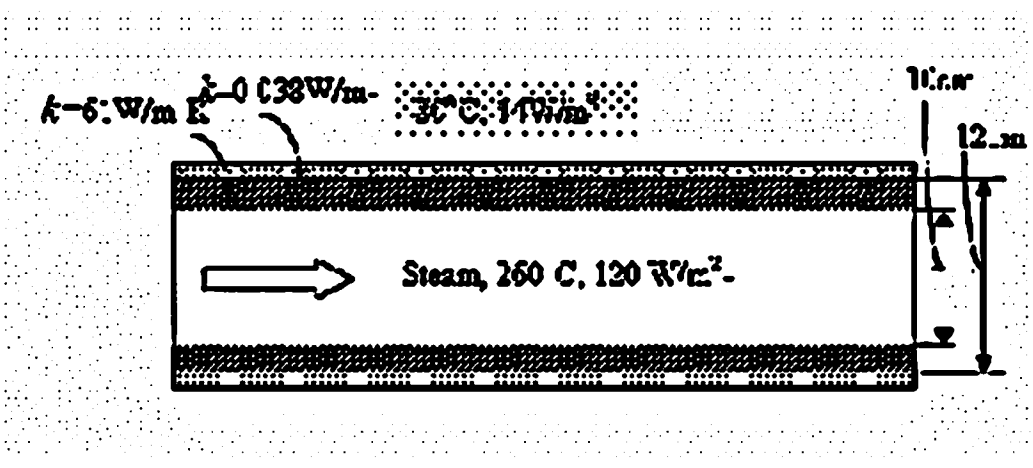
Given data:

Inner diameter of the steel pipe, $d_1 = 10\text{cm} = 0.1\text{m}$

Outer diameter of the steel pipe, $d_2 = 12\text{cm} = 0.12\text{m}$

Thermal conductivity of the steel pipe, $k_1 = 61\,\text{W/m}\cdot\text{K}$

Thermal conductivity of the insulation, $k_2 = 0.038\,\text{W/m}\cdot\text{K}$



Inside steam temperature of the pipe, $T_{\infty,1} = 260°\text{C}$

Surroundings temperature, $T_{\infty,2} = 20°\text{C}$

Heat transfer coefficient on the outer surface, $h_o = 14\,\text{W/m}^2\cdot\text{K}$

Heat transfer coefficient on the inner surface, $h_i = 120\,\text{W/m}^2\cdot\text{K}$

Step 2 of 10

Step 3 of 10

The inner and outer surface areas of the insulate pipe per unit length are

$$A_i = \pi d_1 L$$
$$= \pi\times(0.1)\times(1)$$
$$= 0.31416\,\text{m}^2$$
$$A_o = \pi d_2 L$$
$$= \pi\times 0.12\times(1)$$
$$= 0.377\,\text{m}^2$$

The individual thermal resistances are evaluated as:

Convection resistance from steam to inner surface of the pipe

$$R_i = \frac{1}{h_i A_i}$$
$$= \frac{1}{120\times 0.31416}$$
$$= 0.0265\,\text{K/W}$$

Conduction resistance in the steel pipe

$$R_1 = R_{pipe}$$
$$= \frac{\ln(r_2/r_1)}{2\pi kL}$$
$$= \frac{\ln(0.06/0.05)}{2\pi\times 61\times 1}$$
$$= 0.0004757\,\text{K/W}$$

Convection resistance from the outer surface of the pipe

$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{14\times 0.377}$$
$$= 0.189466\,\text{K/W}$$

Step 4 of 10

All the resistances are in series, and the total resistance is

$$R_{total} = R_i + R_1 + R_o$$
$$= 0.0265 + 0.0004757 + 0.189466$$
$$= 0.21644\,\text{K/W}$$

Then the steady rate of heat loss from the steam per unit length becomes

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{260-20}{0.21644}$$
$$= 1108.852\,\text{W}$$

$$\boxed{\dot{Q} = 1108.852\ \text{W}}$$

Step 5 of 10

a) The thickness of insulation needed to reduce the heat loss by 95% can be determined as follows

The amount of heat lost with insulation can be calculated as

$$\dot{Q} = 1108.852\times(1-0.95)$$
$$= 55.4426\,\text{W}$$

Step 6 of 10

The total resistance can be determined as

$$R_{total} = \frac{(T_{\infty,1} - T_{\infty,2})}{\dot{Q}}$$
$$= \frac{260-20}{55.4426}$$
$$= 4.328\,\text{K/W}$$

Then the total thermal resistance with insulation becomes

$$= \frac{260-20}{55.4426}$$
$$= 4.328\,\text{K/W}$$

Then the total thermal resistance with insulation becomes

$$R_{total} = R_i + R_1 + R_{insulation} + R_o$$
$$R_{insulation} = R_{total} - (R_i + R_1 + R_o)$$
$$= 4.328 - 0.21644$$
$$= 4.11156\,\text{K/W}$$

Step 7 of 10

We know thermal resistance of the insulation can be written as

$$R_2 = R_{insulation}$$
$$4.11156 = \frac{\ln(r_3/r_2)}{2\pi k_2 L}$$
$$= \frac{\ln(r_3/0.06)}{2\pi \times 0.038 \times 1}$$
$$\ln(r_3/0.06) = 0.9816$$
$$r_3 = 0.16012\,\text{m}$$

Therefore the thickness of insulation can be calculated as

$$t_{insulation} = r_3 - r_2$$
$$= 0.16012 - 0.06$$
$$= 0.10012\,\text{m}$$
$$= 10.012\,\text{cm}$$

$$\boxed{t_{insulation} = 10.012\,\text{cm}}$$

Step 8 of 10

b) The thickness of insulation needed to reduce the exposed surface temperature of insulated pipe to 40°C, can be determined as

The amount of heat lost with insulation can be calculated as

$$\dot{Q} = \frac{(T_{\infty,1} - T_{\infty,2})}{R_{total}}$$
$$= \frac{(T_2 - T_{\infty,2})}{R_o}$$
$$\frac{(260-20)}{R_{total}(\text{K/W})} = \frac{(40-20)}{R_o(\text{K/W})}$$
$$R_{total} = R_o \times \frac{240}{20}$$
$$R_{total} = 12R_o$$

Where R_{total} and R_o can be represented as

$$R_o = \frac{1}{h_o A_o}$$
$$= \frac{1}{14 \times \pi \times d_3 \times 1}$$
$$= \frac{0.02274}{d_3}\,\text{K/W}$$
$$R_{total} = R_i + R_1 + R_{insulation} + R_o$$
$$= 0.0265 + 0.0004757 + \frac{\ln(d_3/0.12)}{2\pi \times 0.038 \times 1} + \frac{0.02274}{d_3}$$
$$R_{total} = 0.0269 + \frac{\ln(d_3/0.12)}{2\pi \times 0.038 \times 1} + \frac{0.02274}{d_3}$$

Step 9 of 10

Substituting $R_{total} = 12R_o$ in the above equation

$$R_{total} = 0.0269 + \frac{\ln(d_3/0.12)}{2\pi \times 0.038 \times 1} + \frac{0.02274}{d_3}$$
$$12R_o = 0.0269 + \frac{\ln(d_3/0.12)}{2\pi \times 0.038 \times 1} + \frac{0.02274}{d_3}$$
$$12 \times \frac{0.02274}{d_3} = 0.0269 + \frac{\ln(d_3/0.12)}{2\pi \times 0.038 \times 1} + \frac{0.02274}{d_3}$$
$$\frac{0.25014}{d_3} = 0.0269 + \frac{\ln(d_3/0.12)}{2\pi \times 0.038 \times 1}$$
$$\frac{0.25014}{d_3} = 0.0269 + \frac{\ln(d_3/0.12)}{0.2387}$$

By solving the above equation we can obtain the outer diameter of the insulated pipe, which is given by

$$d_3 = 0.1695\,\text{m}$$

Step 10 of 10

Therefore, the thickness of insulation becomes

$$t_{insulation} = r_3 - r_2$$
$$= \frac{d_3}{2} - \frac{d_2}{2}$$
$$= \frac{0.1695}{2} - \frac{0.12}{2}$$
$$= 0.08475 - 0.06$$
$$= 0.02475\,\text{m}$$
$$= 2.475\,\text{cm}$$

$$\boxed{t_{insulation} = 2.475\,\text{cm}}$$

Question: 17.139P

When the transportation of natural gas in a pipeline is not feasible for economic or other reasons, if is first liquefied at about -160°C, and then transported in specially insulated tanks placed in marine ships. Consider a 4-m-diameter spherical tank that is filled with liquefied natural gas (LNG) at - 160°C. The tank is exposed to ambient air at 24°C with a heat transfer coefficient of 22 W/m2·K. The tank is thin-shelled and its temperature can be taken to be the same as the LNG temperature. The tank is insulated with 5-cm-thick super insulation that has an effective thermal conductivity of 0.00008 W/m·K. Taking the density and the specific heat of LNG to be 425 kg/m3 and 3.475 kJ/kg·°C, respectively, estimate how long it will take for the LNG temperature to rise to -150°C

Step 1 of 10

Given:

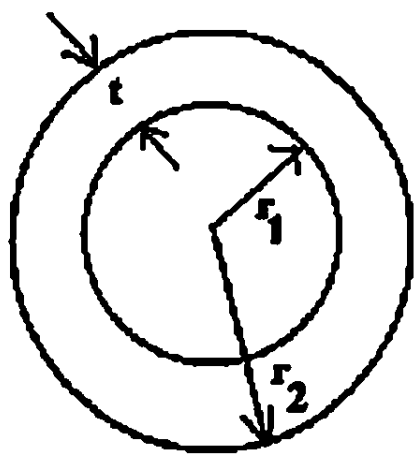
Diameter of spherical tank $D_1 = 4$ m

Temperature of LNG $T_1 = -160°C$

Temperature of ambient air $T_\infty = 24°C$

Heat transfer coefficient of ambient air $h_o = 22\ W/m^{2.0}C$

Thickness of the insulation is $t = 5$ cm



Density of LNG $\rho = 425\ kg/m^3$

Specific heat of LNG $C = 3.475\ kJ/kg.°C$

Thermal conductivity of super insulation $k = 0.00008\ W/m.°C$

Temperature rise of LNG is $T_2 = -150^0C$

Step 2 of 10

Step 3 of 10

Outer and inner surface areas of the spherical tank are

$$A_1 = \pi D_1^2$$
$$= \pi(4)^2$$
$$A_1 = 50.265\ m^2$$
$$A_2 = \pi D_2^2$$
$$= \pi(D_1 + 2t)^2$$
$$= \pi(4 + 2\times 0.05)^2$$
$$= \pi(4.1)^2$$
$$A_2 = 52.81\ m^2$$

Step 4 of 10

Volume of LNG tank is

$$V_1 = \frac{4}{3}\pi r_1^3$$
$$V_1 = \pi D_1^3 / 6$$
$$= \pi(4)^3 / 6$$
$$V_1 = 33.51\ m^3$$

Mass of LNG is

$$m = \rho V_1$$
$$= (425)(33.51)$$
$$m = 14241.75\ kg$$

Step 5 of 10

Thermal resistance for this spherical system due to conduction is

$$R_1 = \frac{r_2 - r_1}{4\pi k r_1 r_2}$$
$$= \frac{(2.05 - 2)}{4\pi(0.00008)(2)(2.05)}$$
$$R_1 = 12.13°C/W$$

Step 6 of 10

Thermal resistance due to convection from the outer surface to the atmospheric air

$$R_o = \frac{1}{h_o A_2}$$
$$= \frac{1}{(22)(52.81)}$$
$$R_o = 0.00086\ °C/W$$

Step 7 of 10

Total resistance becomes

$$R_t = R_o + R_1$$
$$= 0.00086 + 12.13$$
$$R_t = 12.13086°C/W$$

Step 8 of 10

Heat transfer rate for the LNG can be calculated as

$$\dot{Q} = \frac{T_\infty - T_1}{R_t}$$
$$= \frac{[24 - (-160)]}{12.13086}$$
$$\dot{Q} = 15.1679\ W$$

Step 9 of 10

Total amount of heat added to increase the temperature of LNG from -160°C to -150°C is

$$Q = mC\Delta T$$
$$= (14241.75)(3.475)[(-150) - (-160)]$$
$$Q = 494900.812\ kJ$$

Step 10 of 10

Time taken for LNG to rise from -160°C to -150°C is

$$\Delta t = \frac{Q}{\dot{Q}}$$
$$= \frac{494900.812}{0.0151679}$$
$$= 32628169.49\ s$$
$$= 32628169.49 \times \frac{1}{3600} \times \frac{1}{24}$$

$$\boxed{\Delta t = 377.6408\ days}$$

Question: 17.140P

A 15-cm × 20-cm hot surface at 85°C is to be cooled by attaching 4-cm-long aluminum (k = 237 W/m·K) fins of 2-mm × 2-mm square cross section. The temperature of surrounding medium is 25°C and the heat transfer coefficient on the surfaces can be taken to be 20 W/m2·K. If it is desired to triple the rate of heat transfer from the bare hot surface, determine the number of fins that needs to be attached.

Step 1 of 8

Given: -

Temperature of hot surface T_s = 85°C

Dimensions of hot surface is $15\,\text{cm} \times 20\,\text{cm}$

Length of fin L = 4 cm =0.04m

Area of cross-section of fin is 2 mm × 2 mm

Temperature of surrounding medium T_∞ = 25°C

Heat transfer coefficient on the surfaces h = 20 W/m^2.°C

Thermal conductivity of the aluminum fins k = 237 W/m°C

Effectiveness of the fin is 3

Step 2 of 8

As cross-section area of fins remains constant

We know

$$m = \sqrt{\frac{hp}{kA_c}}$$

$$= \sqrt{\frac{h \times 4a}{ka^2}}$$

Where a side of the fin

$$= \sqrt{\frac{4(20) \times (0.002)}{(237)(0.002)^2}}$$

$$m = 12.99\ \text{m}^{-1}$$

Step 3 of 8

Efficiency of the fin is

$$\eta_f = \frac{\tanh mL}{mL}$$

$$= \frac{\tanh(12.99\ \text{m}^{-1} \times 0.04\ \text{m})}{12.99\ \text{m}^{-1} \times 0.04\ \text{m}}$$

$$\eta_f = 0.9187$$

Step 4 of 8

Let number of fins will be n_f

Heat transfer area for finned surface is

$$A_f = n_f \times 4 \times (0.002)(0.04)$$

$$A_f = 0.00032 n_f\ \text{m}^2$$

Heat transfer area of unfinned surface is

$$A_{uf} = (0.15)(0.20) - n_f(0.002)(0.002)$$

$$A_{uf} = 0.03 - 0.000004 n_f\ \text{m}^2$$

Step 5 of 8

We know efficiency of the fin is ratio of actual heat transfer rate from the fin to the ideal heat transfer rate from the fin if the entire fin were at base temperature

$$\eta_f = \frac{\dot{Q}_f}{hA_f(T_s - T_\infty)}$$

$$\dot{Q}_f = \eta_f h A_f (T_s - T_\infty)$$

$$= 0.9187 \times (20) \times (0.00032 n_{fin})(85 - 25)$$

$$\dot{Q}_f = 0.35278 n_{fin}\ \text{W}$$

Step 6 of 8

The amount of heat transfer rate from unfinned fin is

$$\dot{Q}_{uf} = hA_{uf}(T_s - T_\infty)$$

$$= (20)(0.03 - 0.000004 n_f)(85 - 25)$$

$$\dot{Q}_{uf} = 36 - 0.0048 n_f\ \text{W}$$

Total rate of heat transfer

$$\dot{Q}_{total} = \dot{Q}_f + \dot{Q}_{uf}$$

$$\dot{Q}_{total} = 0.35278 n_{fin} + 36 - 0.0048 n_{fin}$$

$$\dot{Q}_{total} = (0.34798 n_{fin} + 36)\ \text{W}$$

Step 7 of 8

Area of the base surface without fin

$$A_{nf} = (0.15)(0.20)$$

$$A_{nf} = 0.03\ \text{m}^2$$

Heat transfer rate without fins

$$\dot{Q}_{nf} = hA_{nf}(T_b - T_s)$$

$$= (20)(0.03)(85 - 25)$$

$$\dot{Q}_{nf} = 36\ \text{W}$$

Step 8 of 8

Overall effectiveness of fins can be used to calculate total number of fins

We know effectiveness of fin is ratio rate of heat transfer with fin to rate of heat transfer without fin

$$\varepsilon_{fin} = \frac{\dot{Q}_f}{\dot{Q}_{nf}}$$

$$3 = \frac{0.34798 n_f + 36}{36}$$

$$n_f = 206.908$$

The total number of fins attached should be

$$\boxed{n_f = 207}$$

Question: 17.141P

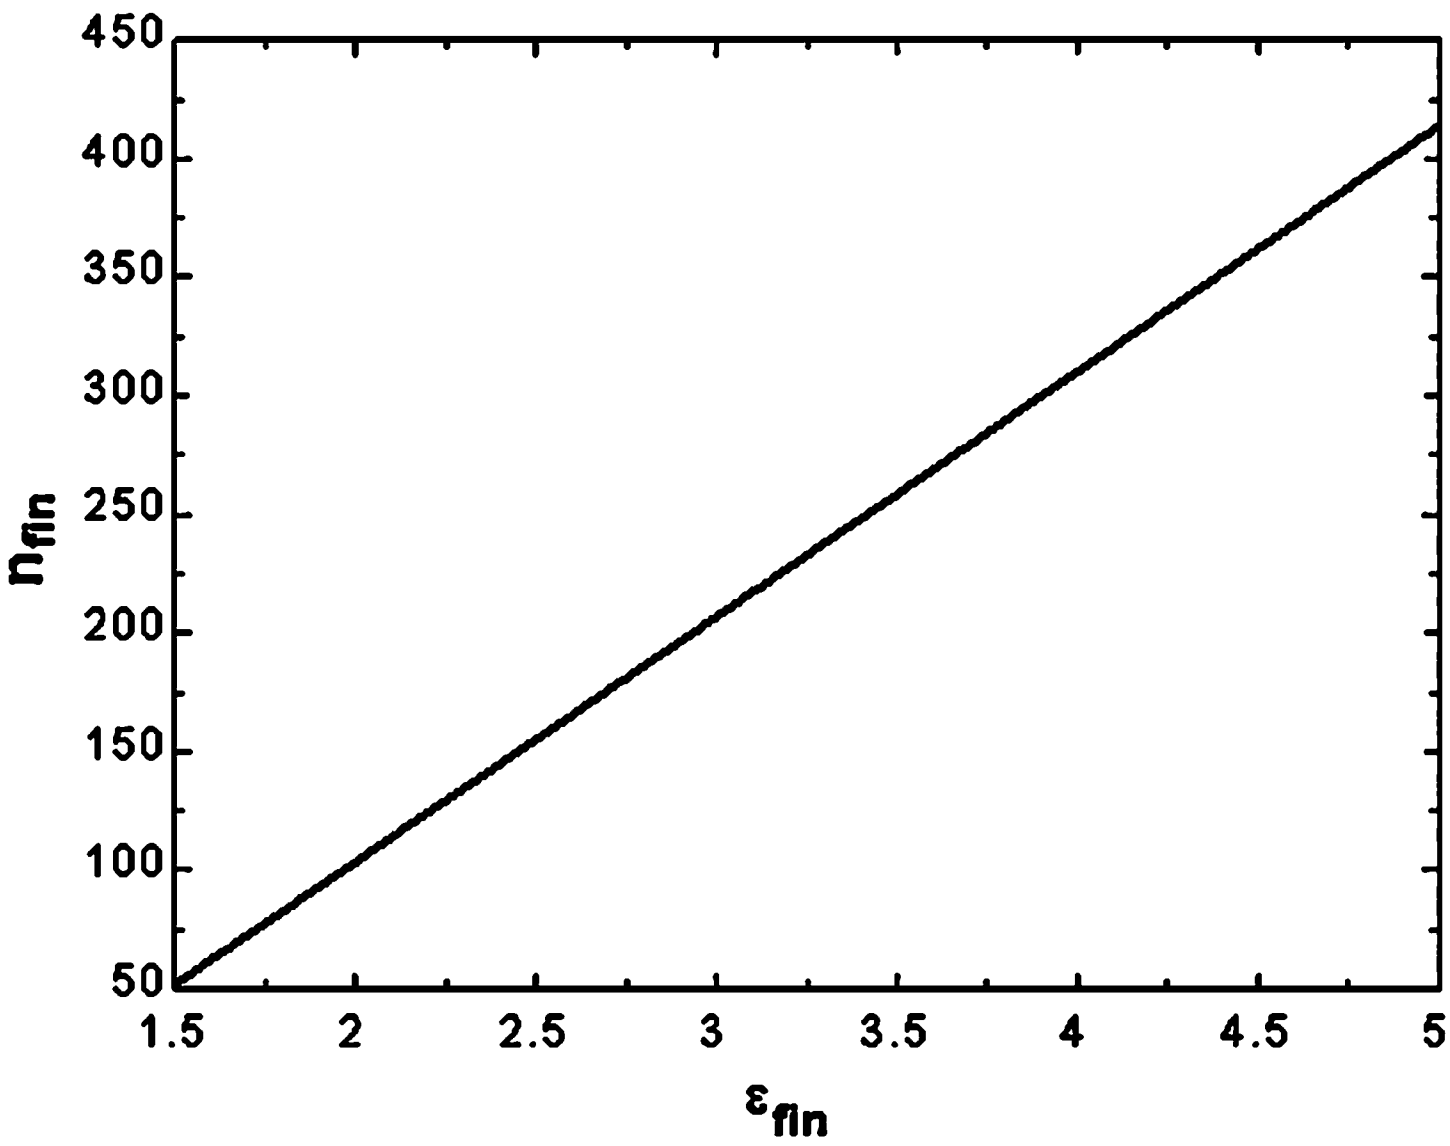
Reconsider Prob. 17-140. Using EES (or other) software, plot the number of fins as a function of the increase in the heat loss by fins relative to no fin case (i.e., overall effectiveness of the fins) in the range of 1.5 to 5. Discuss the results. Is it realistic to assume the heal transfer coefficient to remain constant?

Step 1 of 3

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
A_surface=0.15*0.20 "[m^2]"
T_b=85 "[C]"
k=237 "[W/m-C]"
side=0.002  "[m]"
L=0.04 "[m]"
T_infinity=25 "[C]"
h=20 "[W/m^2-C]"
"epsilon_fin=3 parameter to be varied"

"ANALYSIS"
A_c=side^2
p=4*side
a=sqrt((h*p)/(k*A_c))
eta_fin=tanh(a*L)/(a*L)
A_fin=n_fin*4*side*L
A_unfinned=A_surface-n_fin*side^2
Q_dot_finned=eta_fin*h*A_fin*(T_b-T_infinity)
Q_dot_unfinned=h*A_unfinned*(T_b-T_infinity)
Q_dot_total_fin=Q_dot_finned+Q_dot_unfinned
Q_dot_nofin=h*A_surface*(T_b-T_infinity)
epsilon_fin=Q_dot_total_fin/Q_dot_nofin
```



Step 2 of 3

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 15
Select variables in equations as ε_{fin} and n_{fin} press ADD and then press ok
A table will appear put values of ε_{fin} as 1.5,1.75,2....5 in run 1to 15
Then from Calculate -> Solve table
Solution will appear

ε_{fin}	n_{fin}
1.5	51.72
1.75	77.59
2	103.4
2.25	129.3
2.5	155.2
2.75	181
3	206.9
3.25	232.8
3.5	258.6
3.75	284.5
4	310.3
4.25	336.2
4.5	362.1
4.75	387.9
5	413.8

Step 3 of 3

Then from Plot -> New plot window -> X-Y Plot
Select X-axis ε_{fin} and Y-axis n_{fin}
Press OK
Graph will be plotted.

Question: 17.142P

An agitated vessel is used for heating 500 kg/min of an aqueous solution at 15°C by saturated steam condensing in the jacket outside the vessel. The vessel can hold 6200 kg of the aqueous solution. It is fabricated from 15-mm-thick sheet of 1.0 percent carbon steel (k = 43 W/m·K). and it provides a heat transfer area of 12.0 m. The heat transfer coefficient due to agitation is 5.5 kW/m2·K. while the steam condensation at 115°C in the jacket gives a heal transfer coefficient of 10.0 k W/m2·K. All properties of the aqueous solution are comparable to those of pure water. Calculate the temperature of the outlet stream in steady operation.

Step 1 of 4

Given data:

Mass flow rate of aqueous solution, $\dot{m} = 500\ \text{kg/min}$

Mass capacity of aqueous solution, $m = 6200\,\text{kg}$

Thickness of the steel sheet, $t = 15\,\text{mm}$

Heat transfer area of steel sheet, $A = 12\,\text{m}^2$

Thermal conductivity of the steel sheet, $k = 43\,\text{W/m-K}$

Temperature of aqueous solution, $T_{in} = 15°\text{C}$

Temperature of the steam, $T_{steam} = 115°\text{C}$

Heat transfer coefficient due to the agitation, $h_i = 5.5\,\text{kW/m}^2\text{-K}$

Heat transfer coefficient of jacket, $h_i = 10\,\text{kW/m}^2\text{-K}$

Step 2 of 4

The heat balance applied for the system under steady operation gives

$$\dot{m}c_p(T - T_{in}) = UA(T_{steam} - T)$$

We know specific heat of water is $C_p = 4180\,\text{J/kg-K}$

The thermal resistance due to convection from inside of the vessel is

$$R_i = \frac{1}{h_i}$$
$$= \frac{1}{5.5\times10^3}$$
$$= \frac{1}{5500}$$

The thermal resistance due to conduction because of thickness of vessel

$$R_1 = \frac{t}{k}$$
$$= \frac{0.015}{43}$$
$$= \frac{0.015}{43}$$

Step 3 of 4

Thermal resistance due to convection from outside of the vessel

$$R_o = \frac{1}{h_o}$$
$$= \frac{1}{10\times10^3}$$
$$= \frac{1}{10000}$$

Overall heat transfer coefficient, U can be calculated as

$$U = \frac{1}{\Sigma R}$$
$$= \frac{1}{R_i + R_1 + R_o}$$
$$= \frac{1}{\frac{1}{5500} + \frac{0.015}{43} + \frac{1}{10000}}$$
$$= 1585.652\,\text{W/m}^2\text{-K}$$

Step 4 of 4

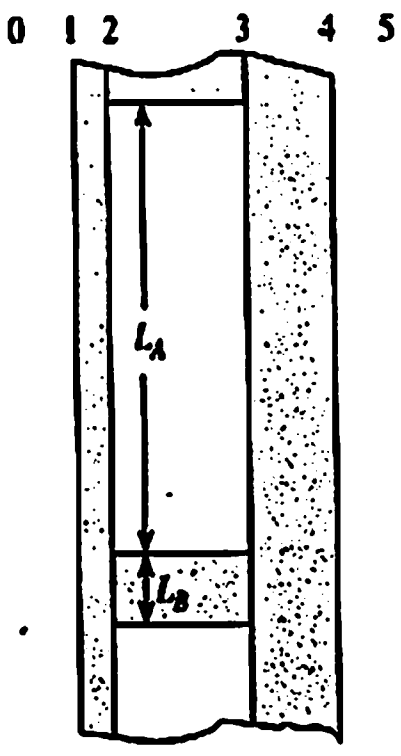
Substituting the known values in heat balance equation, gives

$$\dot{m}c_p(T - T_{in}) = UA(T_{steam} - T)$$
$$\frac{500}{60}\times4180\times(T-15) = 1585.652\times12(115-T)$$
$$1.8306\times(T-15) = (115-T)$$
$$2.8306T = 142.459$$
$$T = 50.328°\text{C}$$

Therefore, the temperature of the outlet stream T in steady operation is $\boxed{T = 50.328°\text{C}}$

Question: 17.143P pg 1

A typical section of a building wall is shown in Fig. P17-143. This section extends in and out of the page and is repeated in the vertical direction. The wall support members are made of steel (k = 50 W/m·K).The support members are 8 cm ($t23$) × 0.5 cm (LB). The remainder of the inner wall space is filled with insulation (k = 0.03 W/m·K) and measures 8 cm ($t23$) × 60 cm (LB). The inner wall is made of gypsum board (k = 0.5 W/m·K) that is 1 cm thick ($t12$) and the outer wall is made of brick (K = 1.0W/m·K)that is 10 cm thick ($t34$). What is the temperature on the interior brick surface. 3, when $T1$ = 20°C and $T4$ = 35°C?



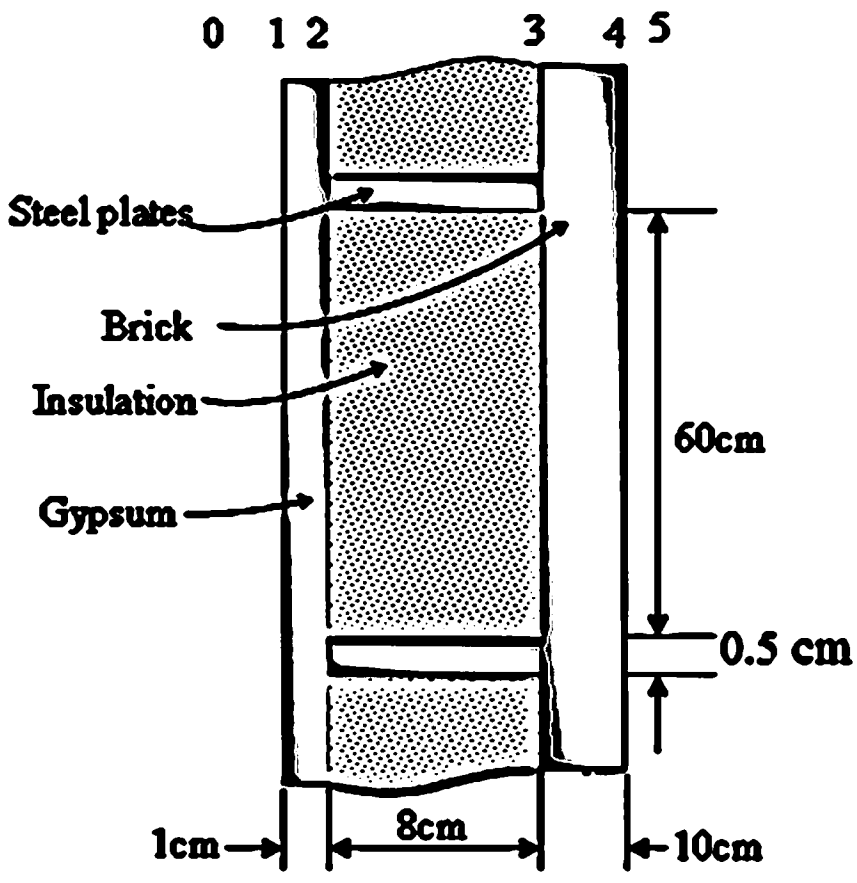


FIGURE P17–143

Step 1 of 10

Draw the schematic layout of building wall:

Step 2 of 10

Find the thermal resistance from 1 to 2:

$$R_{12} = \frac{t_{12}}{k_t A}$$

Here, R_{12} is the thermal resistance, t_{12} is the thickness of the portion, k_t is the thermal conductivity of gypsum board, A is the cross-sectional area of wall.

Find the thermal resistance of the insulation:

$$R_A = \frac{t_A}{k_A A_A}$$

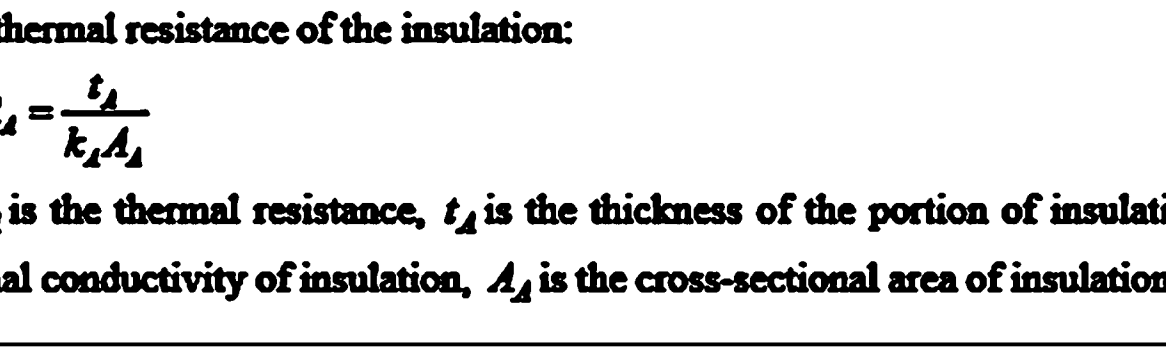
Here, R_A is the thermal resistance, t_A is the thickness of the portion of insulation, k_A is the thermal conductivity of insulation, A_A is the cross-sectional area of insulation.

Step 3 of 10

Find the thermal resistance of steel:

$$R_B = \frac{t_B}{k_B A_B}$$

Here, R_B is the thermal resistance, t_B is the thickness of the portion of steel, k_B is the thermal conductivity of insulation, A_B is the cross-sectional area of steel.



Find the thermal resistance from 3 to 4:

$$R_{34} = \frac{t_{34}}{k_o A}$$

Here, R_{34} is the thermal resistance, t_{34} is the thickness of the portion of brick, k_o is the thermal conductivity of brick, A is the cross-sectional area of wall.

Step 4 of 10

Draw the thermal network circuit of the building wall:

Step 5 of 10

By using the thermal network approach, find the total resistance:

$$R_{total} = R_{12} + \frac{R_A R_B}{R_A + R_B} + R_{34}$$

Substitute, $\frac{t_{12}}{k_t A}$ for R_{12}, $\frac{t_A}{k_A A_A}$ for R_A, $\frac{t_B}{k_B A_B}$ for R_B and $\frac{t_{34}}{k_o A}$ for R_{34}

$$R_{total} = \frac{t_{12}}{k_t A} + \frac{\left(\frac{t_A}{k_A A_A}\right)\left(\frac{t_B}{k_B A_B}\right)}{\frac{t_A}{k_A A_A} + \frac{t_B}{k_B A_B}} + \frac{t_{34}}{k_o A}$$

17 143P pg 2

$$R_{total}=\frac{t_{12}}{k_i A}+\frac{\left(\frac{t_A}{k_A A_A}\right)\left(\frac{t_B}{k_B A_B}\right)}{\frac{t_A}{k_A A_A}+\frac{t_B}{k_B A_B}}+\frac{t_{34}}{k_o A}$$

$$R_{total}\times A=\frac{t_{12}}{k_i}+A\left(\frac{\left(\frac{t_A}{k_A A_A}\right)\left(\frac{t_B}{k_B A_B}\right)}{\frac{t_A}{k_A A_A}+\frac{t_B}{k_B A_B}}\right)+\frac{t_{34}}{k_o} \quad \text{..... (1)}$$

Step 6 of 10

Find the cross-sectional area of wall:

$$A=(L_A+L_B)w$$

Here, L_A is the length of the insulation filled, L_B is the length of steel and w is the width of the wall.

Find the cross-sectional area of insulation:

$$A_A=L_A w$$

Here, L_A is the length of the insulation filled and w is the width of the wall.

Find the cross-sectional area of steel:

$$A_B=L_B w$$

Here, L_B is the length of steel and w is the width of the wall.

Step 7 of 10

Substitute, $(L_A+L_B)w$ for A, $L_A w$ for A_A and $L_B w$ for A_B in equation (1)

$$R_{total}A=\frac{t_{12}}{k_i}+A\left[\frac{\left(\frac{t_A}{k_A A_A}\right)\left(\frac{t_B}{k_B A_B}\right)}{\frac{t_A}{k_A A_A}+\frac{t_B}{k_B A_B}}\right]+\frac{t_{34}}{k_o}$$

$$=\frac{t_{12}}{k_i}+(L_A+L_B)w\left(\frac{\left(\frac{t_A}{k_A L_A w}\right)\left(\frac{t_B}{k_B L_B w}\right)}{\frac{t_A}{k_A L_A w}+\frac{t_B}{k_B L_B w}}\right)+\frac{t_{34}}{k_o}$$

$$=\frac{t_{12}}{k_i}+(L_A+L_B)\left(\frac{\left(\frac{t_A}{k_A L_A}\right)\left(\frac{t_B}{k_B L_B}\right)}{\frac{t_A}{k_A L_A}+\frac{t_B}{k_B L_B}}\right)+\frac{t_{34}}{k_o}$$

Step 8 of 10

Substitute, $1\,\text{cm}=0.01\,\text{m}$ for t_{12}, $0.5\,\text{W/m-K}$ for k_i, $60\,\text{cm}=0.6\,\text{m}$ for L_A, $0.5\,\text{cm}=0.005\,\text{m}$ for L_B, $8\,\text{cm}=0.08\,\text{m}$ for t_A, $8\,\text{cm}=0.08\,\text{m}$ for t_B, $0.03\,\text{W/m-K}$ for k_A, $50\,\text{W/m-K}$ for k_B, $10\,\text{cm}=0.1\,\text{m}$ for t_{34} and $1\,\text{W/m-K}$ for k_o

$$R_{total}A=\frac{0.01}{0.5}+(0.6+0.005)\times\left(\frac{\left[\frac{0.08}{(0.03\times 0.6)}\right]\times\left[\frac{0.08}{(50\times 0.005)}\right]}{\left[\frac{0.08}{(0.03\times 0.6)}\right]+\left[\frac{0.08}{(50\times 0.005)}\right]}\right)+\frac{0.1}{1}$$

$$=0.3006\,\text{m}^2\text{-K/W}$$

Step 9 of 10

Find the average heat flux through the wall using the equation:

$$\frac{\dot{Q}}{A}=\frac{(T_4-T_1)}{R_{total}A}$$

Here, $\frac{\dot{Q}}{A}$ is the average heat flux, T_4 is the temperature of the wall at point 4, T_1 is the temperature of the wall at point 1.

Substitute, $35°\text{C}$ for T_4, $20°\text{C}$ for T_1 and $0.3006\,\text{m}^2\text{-K/W}$ for $R_{total}A$.

$$\frac{\dot{Q}}{A}=\frac{35-20}{0.3006}$$
$$=49.9\,\text{W/m}^2$$

Step 10 of 10

Find the temperature on the interior brick surface, 3, from the equation:

$$\dot{Q}=\frac{(T_4-T_3)}{R_{34}}$$

$$\dot{Q}=\frac{(T_4-T_3)}{\left(\frac{t_{34}}{k_o A}\right)}$$

$$\frac{\dot{Q}}{A}=\frac{(T_4-T_3)k_o}{t_{34}}$$

Substitute, $49.9\,\text{W/m}^2$ for $\frac{\dot{Q}}{A}$, $35°\text{C}$ for T_4, $10\,\text{cm}=0.1\,\text{m}$ for t_{34} and $1\,\text{W/m-K}$ for k_o

$$49.9=\frac{(35-T_3)1}{0.1}$$
$$T_3=30.01°\text{C}$$

Therefore, the temperature on the interior brick surface is $\boxed{30.01°\text{C}}$

Question: 17.144P

A total of 10 rectangular aluminum fins (k = 203 W/m·K) are placed on the outside flat surface of an electronic device. Each fin is 100 mm wide, 20 mm high and 4 mm thick. The fins are located parallel to each other at a center-to-center distance of 8 mm. The temperature at the outside surface of the electronic device is 72°C. The air is at 20°C, and the heat transfer coefficient is 80 W/m2·K. Determine *(a)* the rate of heat loss from the electronic device to the surrounding air and *(b)* the fin effectiveness.

Step 1 of 7

Given data:

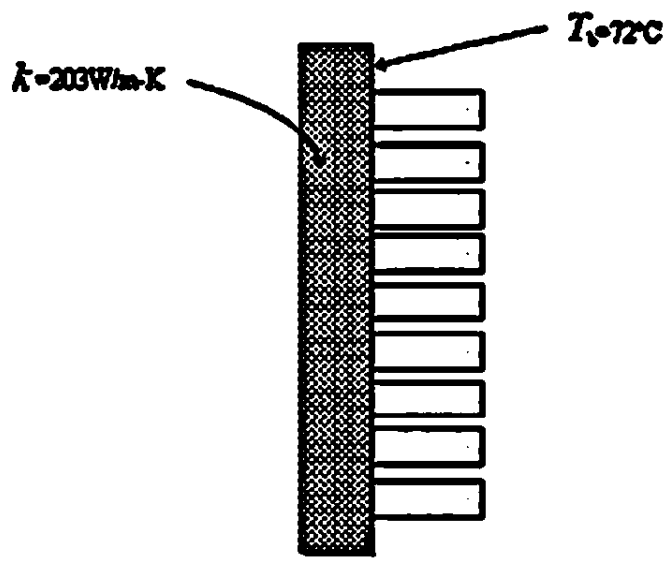
Number of fins, $n=10$

Width of the fin, $w=100\,\text{mm}$

Height of the fin, $L=20\,\text{mm}$

Thickness of the fin, $t=4\,\text{mm}$

Thermal conductivity of the aluminum fin, $k=203\,\text{W/m}\cdot\text{K}$



Outer surface temperature of the circuit board, $T_b=72°\text{C}$

Surroundings air temperature, $T_\infty=20°\text{C}$

Heat transfer coefficient on the outer surface, $h=80\,\text{W/m}^2\cdot\text{K}$

Step 2 of 7

The figure representing flat surface having 10 rectangular Aluminum fins,

Step 3 of 7

(a)

The fin efficiency can be determined by finding these parameters

$$\xi = L_c^{3/2}\sqrt{h/kA_p}$$
$$= L_c^{3/2}\sqrt{h/kL_ct}$$
$$= L_cL_c^{1/2}\sqrt{h/kL_ct}$$
$$= L_c\sqrt{h/kt}$$
$$= (L+t/2)\sqrt{h/kt}$$

By substituting the known values in the above expression

$$\xi = (0.02+0.004/2)\times\sqrt{\frac{80}{203\times0.004}}$$
$$= 0.2184$$

Step 4 of 7

From the graph efficiency of straight fins of rectangular profiles at $\xi=0.2184$, the efficiency of the fin is obtained as

$$\eta_{fin}=0.97$$

The surface area of the fin can be determined as

$$A_{fin}=2n(Lt+Lw)$$
$$=2\times10\times(0.02\times0.004+0.02\times0.1)$$
$$=0.0416\,\text{m}^2$$

Area at the base of the fin,

$$A_b=n(wt)$$
$$=10\times(0.1\times0.004)$$
$$=0.004\,\text{m}^2$$

Step 5 of 7

The rate of heat loss from the fin tip can be determined as

$$\dot{Q}_{fin}=\eta_{fin}hA_{fin}(T_b-T_\infty)$$
$$=0.97\times80\times0.0416\times(72-20)$$
$$=167.864\,\text{W}$$

The rate of heat loss from the base surface of the fin can be determined as

$$\dot{Q}_{base}=hA_b(T_b-T_\infty)$$
$$=80\times0.004\times(72-20)$$
$$=16.64\,\text{W}$$

Step 6 of 7

Total heat loss becomes,

$$\dot{Q}_{total}=\dot{Q}_{fin}+\dot{Q}_{base}$$
$$=167.864+16.64$$
$$=184.504\,\text{W}$$

Therefore, the total heat loss from the electronic device to the surrounding air is

$$\boxed{\dot{Q}_{total}=184.504\,\text{W}}$$

Step 7 of 7

(b)

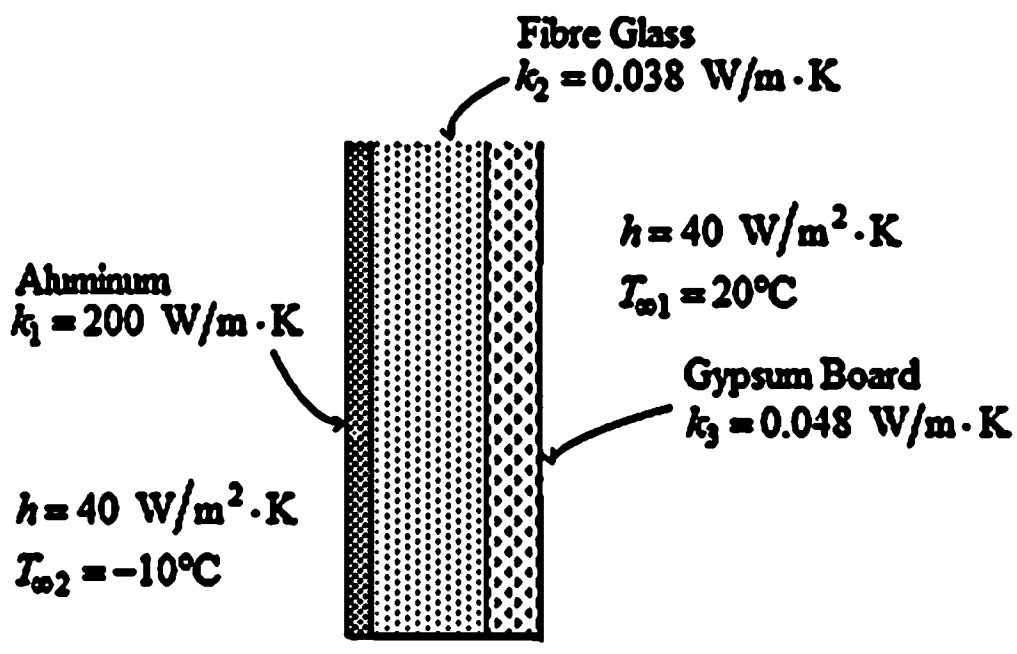
The fin effectiveness can be determined as the ratio of the heat transfer rate with fin to the heat transfer rate without fin

$$\varepsilon_{fin}=\frac{\dot{Q}_{total}}{\dot{Q}_{base}}$$
$$=\frac{184.504}{16.64}$$
$$=11.088$$

Therefore, the fin effectiveness is $\boxed{\varepsilon_{fin}=11.088}$.

Question: 17.145P pg 1

One wall of a refrigerated warehouse is 10.0-m-high and 5.0-m-wide. The wall is made of three layers: 1.0-cm-thick aluminum (k = 200 W/m·K), 8.0-cm-thick fibreglass (k = 0.038 W/m·K), and 3.0-cm thick gypsum board (k = 0.48 W/m-K). The warehouse inside and outside temperatures are -10°C and 20°C, respectively, and (he average value of both inside and outside heat transfer coefficients is 40 W/m2·K.



(a) Calculate the rate of heat transfer across the warehouse wall in steady operation.

(*b*) Suppose that 400 metal bolts (k = 43 W/m·K), each 2.0 cm in diameter and 12.0 cm long, are used to fasten (i.e., hold together) the three wall layers. Calculate the rate of heat transfer for the "bolted"wall,

(*c*) What is the percent change in the rate of heat transfer across the wall due to metal bolts?

Step 1 of 16

Draw the schematic diagram of the refrigerated warehouse:

Step 2 of 16

(a)

Find the cross-sectional area for the wall of a refrigerated warehouse:

$$A = L \times w$$

Here, A is the cross-sectional area, L is the length of the wall and w is the width of the wall.

Substitute, 10 m for L and 5 m for w.

$$A = 10 \times 5$$
$$= 50 \text{ m}^2$$

Step 3 of 16

Calculate the thermal resistances at entrance and exit:

$$R = \frac{1}{hA}$$

Here, R is the thermal resistance at entrance and exit, h is the heat transfer coefficient.

Substitute, 50 m^2 for A and 40 W/m^2·K for h.

$$R = \frac{1}{40 \times 50}$$
$$= 0.0005 \text{ K/W}$$

Step 4 of 16

Find the resistance due to the aluminum layer:

$$R_1 = \frac{t_1}{k_1 A}$$

Here, t_1 is the thickness of the aluminum layer, k_1 is the thermal conductivity of aluminum.

Substitute, 1cm = 0.01 m for t_1, 200 W/m·K for k_1 and 50 m^2 for A.

$$R_1 = \frac{0.01}{200 \times 50}$$
$$= 0.000001 \text{K/W}$$

Step 5 of 16

Find the resistance due to fiberglass:

$$R_2 = \frac{t_2}{k_2 A}$$

Here, t_2 is the thickness of the fiberglass layer, k_2 is the thermal conductivity of fiberglass.

Substitute, 8cm = 0.08 m for t_2, 0.038 W/m·K for k_2 and 50 m^2 for A.

$$R_2 = \frac{0.08}{0.038 \times 50}$$
$$= 0.042105 \text{K/W}$$

Step 6 of 16

Find the resistance due to gypsum board:

$$R_3 = \frac{t_3}{k_3 A}$$

Here, t_3 is the thickness of the gypsum board, k_3 is the thermal conductivity of gypsum.

Substitute, 3cm = 0.03 m for t_3, 0.48 W/m·K for k_3 and 50 m^2 for A.

$$R_3 = \frac{0.03}{0.48 \times 50}$$
$$= 0.00125 \text{K/W}$$

Step 7 of 16

Find the total resistance of the refrigerated warehouse wall:

$$R_{total} = R + R_1 + R_2 + R_3 + R$$

Substitute, 0.0005 K/W for R, 0.000001K/W for R_1, 0.042105K/W for R_2 and 0.00125K/W for R_3.

$$R_{total} = 0.0005 + 0.000001 + 0.042105 + 0.00125 + 0.0005$$
$$= 0.044356 \text{K/W}$$

Step 8 of 16

Find the total rate of heat transfer:

$$\dot{Q} = \frac{(T_{\infty 1} - T_{\infty 2})}{R_{total}}$$

Here, $T_{\infty 2}$ is the temperature inside the refrigerated warehouse and $T_{\infty 1}$ is the temperature

Step 8 of 16

Find the total rate of heat transfer:

$$\dot{Q}=\frac{(T_{\infty 1}-T_{\infty 2})}{R_{total}}$$

Here, $T_{\infty 2}$ is the temperature inside the refrigerated warehouse and $T_{\infty 1}$ is the temperature outside the refrigerated warehouse.

Substitute, $-10°C$ for $T_{\infty 2}$, $20°C$ for $T_{\infty 1}$ and $0.044356 K/W$ for R_{total}.

$$\dot{Q}=\frac{(20-(-10))}{0.044356}$$
$$=676.342\,W$$

Therefore, the total rate of heat transfer is $\boxed{676.342\,W}$

Step 9 of 16

(b)

To fasten the three layers, 400 metal bolts are used.

The rate of heat transfer through the wall with the consideration of bolts can be determine as follows,

Calculate the total cross-sectional area of the 400 bolts:

$$A_{bolt}=n\frac{\pi}{4}d^2$$

Here, n is the number of bolts and d is the diameter of the bolt.

Substitute, 400 for n and 2.0 cm = 0.02 m for d.

$$A_{bolt}=400\times\frac{\pi}{4}\times 0.02^2$$
$$=0.125664\,m^2$$

Step 10 of 16

Calculate the area of the wall without the bolts:

$$A_{wall}=A-A_{bolt}$$

Here, A is the area of the original area of the wall.

Substitute, $50\,m^2$ for A and $0.125664\,m^2$ for A_{bolt}

$$A_{wall}=50-\left(400\times\frac{\pi}{4}\times 0.02^2\right)$$
$$=49.87434\,m^2$$

Step 11 of 16

Calculate the total resistance of the wall:

$$R_{wall}=R+R_1+R_2+R_3+R$$
$$=\frac{1}{hA_{wall}}+\frac{t_1}{k_1A_{wall}}+\frac{t_2}{k_2A_{wall}}+\frac{t_3}{k_3A_{wall}}+\frac{1}{hA_{wall}}$$
$$=\frac{1}{A_{wall}}\left[\frac{1}{h}+\frac{t_1}{k_1}+\frac{t_2}{k_2}+\frac{t_3}{k_3}+\frac{1}{h}\right]$$

Substitute, $49.87434\,m^2$ for A_{wall}, $40\,W/m^2\cdot K$ for h, $1cm=0.01\,m$ for t_1, $200\,W/m\cdot K$ for k_1, $8cm=0.08\,m$ for t_2, $0.038\,W/m\cdot K$ for k_2, $3cm=0.03\,m$ for t_3, $0.48\,W/m\cdot K$ for k_3

$$R_{wall}=\frac{1}{49.87434}\left[\frac{1}{40}+\frac{0.01}{200}+\frac{0.08}{0.038}+\frac{0.03}{0.48}+\frac{1}{40}\right]$$
$$=0.044468\,K/W$$

Step 12 of 16

Find the heat transfer through the wall by using the equation:

$$\dot{Q}_1=\frac{(T_{\infty 1}-T_{\infty 2})}{R_{wall}}$$

Substitute, $0.044468\,K/W$ for R_{wall}, $20°C$ for $T_{\infty 1}$ and $-10°C$ for $T_{\infty 2}$

$$\dot{Q}_1=\frac{(20+10)}{0.044468(K/W)}$$
$$=674.642\,W$$

Step 13 of 16

Find the total resistance of the bolts:

$$R_{bolt}=\frac{t}{kA_{bolt}}+\left(2\times\frac{1}{hA_{bolt}}\right)$$

Substitute, $0.125664\,m^2$ for A_{bolt}, $40\,W/m^2\cdot K$ for h, $43\,W/m\cdot K$ for k.

$$R_{bolt}=\frac{0.12}{43\times 0.125664}+\left(2\times\frac{1}{40\times 0.125664}\right)$$
$$=0.0222+0.3978$$
$$=0.4201K/W$$

Step 14 of 16

Find the heat transfer through the bolts:

$$\dot{Q}_2=\frac{(T_{\infty 1}-T_{\infty 2})}{R_{bolt}}$$

Substitute, $0.4201\,K/W$ for R_{bolt}, $20°C$ for $T_{\infty 1}$ and $-10°C$ for $T_{\infty 2}$

$$\dot{Q}_2=\frac{(20+10)}{0.4201(K/W)}$$
$$=71.4126\,W$$

Step 15 of 16

Find the total heat transfer rate through wall with bolts:

$$\dot{Q}_{total}=\dot{Q}_1+\dot{Q}_2$$

Substitute, $674.642\,W$ for $\dot{Q}_1$ and $71.4126\,W$ for $\dot{Q}_2$

$$\dot{Q}_{total}=674.642+71.4126$$
$$=746.055\,W$$

Therefore, the total rate of heat transfer for the bolted wall is $\boxed{746.055\,W}$

It can be observed that, the heat transfer rate increased due to fixing of bolts in wall.

Step 16 of 16

It can be observed that, the heat transfer rate increased due to fixing of bolts in wall.

Step 16 of 16

(c)

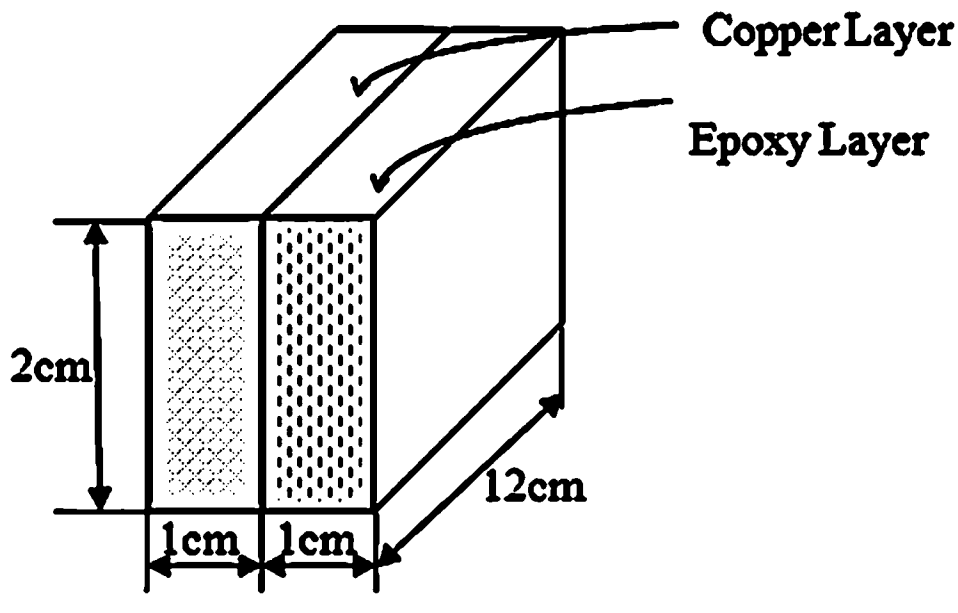
Calculate the percentage change in the rate of heat transfer across the wall due to metal bolts:

$$\%\text{change} = \frac{\dot{Q}_{total} - \dot{Q}}{\dot{Q}} \times 100$$

Substitute, 746.055 W for $\dot{Q}_{total}$ and 676.342 W for $\dot{Q}$

$$\%\text{change} = \frac{746.055 - 676.342}{676.342} \times 100$$

$$= 10.31\%$$



Therefore, by the addition of bolts, the heat transfer rate increases by $\boxed{10.31\%}$

Question: 17.146P pg 1

A 12-cm-long bar with a square cross-section, as shown in Fig. P17-146, consists of a 1-cm-thick copper layer (k = 380 W/m·K) and a 1-cm-thick epoxy composite layer (k = 0.4 W/m·K). Calculate the rate of heat transfer under a thermal driving force of 50°C, when thc direction of steady one-dimensional heat transfer is *(a)* from front to back (i.e., along its length), *(b)* from left to right, and *(c)* from top to bottom.

Step 1 of 7

Draw the figure as follows:

Step 2 of 7

(a)

Along the length direction, determine the rate of heat transfer as follows:

Write the equation for thermal resistance of copper bar as follows:

$$R_1 = \frac{L}{k_c A}$$

Here, L is the length of the bar, k_c is the thermal conductivity of the copper, and A is the area of the surface normal to the heat transfer.

Substitute 0.12 m for L, $380\ \text{W/m}\cdot\text{K}$ for k_c, and $(0.02\times0.01)\ \text{m}^2$ for A.

$$R_1 = \frac{0.12}{380\times0.02\times0.01}$$
$$= 1.57895\ \text{K/W}$$

Write the equation for epoxy layer bar as follows:

$$R_2 = \frac{L}{k_e A}$$

Here, k_e is the thermal conductivity of the epoxy layer bar.

$$R_2 = \frac{0.12}{0.4\times0.02\times0.01}$$
$$= 1500\ \text{K/W}$$

Step 3 of 7

Since the two resistances are in parallel, calculate the total resistance as follows:

$$R_{total} = \frac{R_1 R_2}{R_1 + R_2}$$

Substitute $1.57895\ \text{K/W}$ for R_1 and $1500\ \text{K/W}$ for R_2.

$$R_{total} = \frac{1.57895\times1500}{1.57895+1500}$$
$$= 1.5773\ \text{K/W}$$

Calculate the rate of heat transfer as follows:

$$\dot{Q} = \frac{\Delta T}{R_{total}}$$

Here, ΔT is the temperature difference.

Substitute $50°\text{C}$ for ΔT and $1.5773\ \text{K/W}$ for R_{total}.

$$\dot{Q} = \frac{50}{1.5773(\text{K/W})}$$
$$= 31.7\ \text{W}$$

Therefore, the heat transfer from front to back is $\boxed{31.7\ \text{W}}$.

Step 4 of 7

(b)

From left to the right, calculate the rate of heat transfer as follows:

Calculate the thermal resistance of copper bar as follows:

$$R_1 = \frac{L}{k_c A}$$

Substitute 0.01 m for L, $380\ \text{W/m}\cdot\text{K}$ for k_c, and $(0.02\times0.12)\ \text{m}^2$ for A.

$$R_1 = \frac{0.01}{380\times0.02\times0.12}$$
$$= 0.011\ \text{K/W}$$

Calculate the thermal resistance of epoxy layer bar as follows:

$$R_2 = \frac{L}{k_e A}$$

Substitute 0.01 m for L, $0.4\ \text{W/m}\cdot\text{K}$ for k_e, and $(0.02\times0.12)\ \text{m}^2$ for A.

$$R_2 = \frac{0.01}{0.4\times0.02\times0.12}$$
$$= 10.4167\ \text{K/W}$$

Substitute 0.01 m for L, $0.4\ \text{W/m}\cdot\text{K}$ for k_1, and $(0.02\times0.12)\ \text{m}^2$ for A.

$$R_2 = \frac{0.01}{0.4\times0.02\times0.12}$$
$$= 10.4167\,\text{K/W}$$

Step 5 of 7

Since the two resistances are in series, calculate the total resistance as follows:

$$R_{total} = R_1 + R_2$$

Substitute $0.011\,\text{K/W}$ for R_1 and $10.4167\,\text{K/W}$ for R_2.

$$R_{total} = 0.011(\text{K/W}) + 10.4167(\text{K/W})$$
$$= 10.4276\,\text{K/W}$$

Calculate the rate of heat transfer as follows:

$$\dot{Q} = \frac{\Delta T}{R_{total}}$$

Substitute $10.4276\,\text{K/W}$ for R_{total} and $50°\text{C}$ for ΔT.

$$\dot{Q} = \frac{50}{10.4276(\text{K/W})}$$
$$= 4.8\,\text{W}$$

Therefore, the rate of heat transfer is $\boxed{4.8\,\text{W}}$.

Step 6 of 7

From the top to bottom direction, calculate the rate of heat transfer as follows:

Calculate the thermal resistance of copper wire as follows:

$$R_1 = \frac{L}{k_c A}$$

Substitute 0.02 m for L, $380\ \text{W/m}\cdot\text{K}$ for k_c, and $(0.01\times0.12)\ \text{m}^2$ for A.

$$R_1 = \frac{0.02(\text{m})}{380(\text{W/m-K})\times0.01(\text{m})\times0.12(\text{m})}$$
$$= 0.04386\,\text{K/W}$$

Calculate the thermal resistance of epoxy layer as follows:

$$R_2 = \frac{L}{kA}$$

Substitute 0.02 m for L, $0.4\ \text{W/m}\cdot\text{K}$ for k_e, and $(0.01\times0.12)\ \text{m}^2$ for A.

$$R_2 = \frac{0.02(\text{m})}{0.4(\text{W/m-K})\times0.01(\text{m})\times0.12(\text{m})}$$
$$= 41.667\,\text{K/W}$$

Step 7 of 7

Since the two resistances are in parallel, calculate the total resistance as follows:

$$R_{total} = \frac{R_1 R_2}{R_1 + R_2}$$

Substitute $0.04386\,\text{K/W}$ for R_1 and $41.667\,\text{K/W}$ for R_2.

$$R_{total} = \frac{0.04386(\text{K/W})\times41.667(\text{K/W})}{0.04386(\text{K/W}) + 41.667(\text{K/W})}$$
$$= 0.04381\,\text{K/W}$$

Calculate the heat transfer rate as follows:

$$\dot{Q} = \frac{\Delta T}{R_{total}}$$

Substitute $50°\text{C}$ for ΔT and $0.04381\,\text{K/W}$ for R_{total}.

$$\dot{Q} = \frac{50}{0.04381(\text{K/W})}$$
$$= 1141.2\,\text{W}$$

Therefore, the heat transfer rate is $\boxed{1141.2\,\text{W}}$.

CHAPTER 18
SOLUTIONS

Question: 18.001P

What is lumped system analysis? When is it applicable?

Step 1 of 1

The bodies in which the internal temperature will be uniform throughout the heat transfer process are treated as "Lump". The temperature of the lump is expressed as the function of time and the calculation of the heat transfer with respect to this temperature is defined as "Lumped System analysis".

It is applicable when the Biot number (the ratio of conduction resistance within the body to convection resistance at the surface of the body) is less than or equal to 0.1.

$$Bi = \frac{hL_c}{K}$$

Therefore, lumped system analysis is applicable when Biot number is less than 0.1.

Question: 18.002P

For which solid is the lumped system analysis more likely to be applicable: an actual apple or a golden apple of the same size? Why?

Step 1 of 1

The lumped system analysis is more likely to be applicable for a golden apple than for an actual apple since the thermal conductivity is much larger and thus the Biot number is much smaller for gold.

Question: 18.003P

For which kind of bodies made of the same material is the lumped system analysis more likely to be applicable: slender ones or well-rounded ones of the same volume? Why?

Step 1 of 1

The lumped system analysis is more likely to be applicable to slender bodies than the well-rounded bodies since the characteristic length (ratio of volume to surface area) and thus the Biot number is much smaller for slender bodies.

Question: 18.004P

Consider heat transfer between two identical hot solid bodies and the air surrounding them. The first solid is being cooled by a fan while the second one is allowed to cool naturally. For which solid is the lumped system analysis more likely to be applicable? Why?

Step 1 of 1

The lumped system analysis is more likely to be applicable for the body cooled naturally.

As we know the Biot number is proportional to the convection heat transfer coefficient, and it is proportional to the air velocity. Therefore, the Biot number is more likely to be less than 0.1 for the case of natural convection. When Biot no is less than 0.1 then only we can apply lumped analysis.

Question: 18.005P

Consider heat transfer between two identical hot solid bodies and their environments. The first solid is dropped in a large container filled with water, while the second one is allowed to cool naturally in the air. For which solid is the lumped system analysis more likely to be applicable? Why?

Step 1 of 1

The lumped system analysis is more likely to be applicable for the body allowed to cool in the air since the Biot number is proportional to the convection heat transfer coefficient, which is larger in water than it is in air because of the larger thermal conductivity of water. Therefore, the Biot number is more likely to be less than 0.1 for the case of the solid cooled in the air. So solid which is cooled in natural air is more likely to be applicable.

Question: 18.006P

Consider a hot baked potato on a plate. The temperature of the potato is observed to drop by 4°C during the first minute. Will the temperature drop during the second minute be less than, equal to, or more than 4°C? Why?

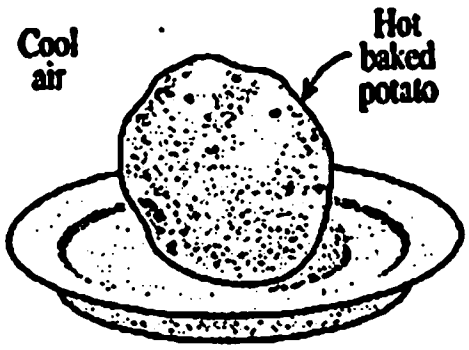


FIGURE P18-6C

Step 1 of 1

The temperature drop of the potato during the second minute will be less than 4°C, since the temperature of a body approaches the temperature of the surrounding

Question:

Consider a hot baked potato on a plate. The temperature of the potato is observed to drop by 4°C during

Question: 18.007P

Consider a potato being baked in an oven that is maintained at a constant temperature. The temperature of the potato is observed to rise by 5°C during the first minute. Will the temperature rise during the second minute be less than, equal to, or more than 5°C? Why?

Step 1 of 1

The temperature rise of the potato during the second minute will be less than 5°C since the temperature of a body approaches the temperature of the surrounding medium asymptotically, and thus it changes rapidly at the beginning, but slowly later on

Question: 18.008P

What is the physical significance of the Biot number? Is the Biot number more likely to be larger for highly conducting solids or poorly conducting ones?

Step 1 of 1

Biot number represents the ratio of conduction resistance within the body to convection resistance at the surface of the body.

The Biot number is more likely to be larger for poorly conducting solids since such bodies have larger resistances against heat conduction.

Question: 18.009P

Consider two identical 4-kg pieces of roast beef. The first piece is baked as a whole, while the second is baked after being cut into two equal pieces in the same oven. Will there be any difference between the cooking limes of the whole and cut roasts? Why?

Step 1 of 1

The heat transfer is proportional to the surface area. Two half pieces of the roast have a much larger surface area than the single piece and thus a higher rate of heat transfer. As a result, the two half pieces will cook much faster than the single large piece

Question: 18.010P

Consider a sphere and a cylinder of equal volume made of copper. Both the sphere and the cylinder are initially at the same temperature and are exposed to convection in the same environment. Which do you think will cool faster, the cylinder or the sphere? Why?

Step 1 of 2

The lumped parameter analysis yields the following equation:

$$\frac{(T-T_0)}{(T_\infty-T_0)}=\exp\left[-\frac{hA}{\rho Vc}t\right]$$

Here, T_0 is the initial temperature, T_∞ is the temperature of the ambient, T is the temperature at a prescribed time, h is the heat transfer coefficient, A is the surface area, ρ is the density of the material, V is the volume of the material, c is the specific heat and t is the time taken for heat transfer.

Differentiate the equation with respect to time.

$$\frac{dT}{dt}=(T_\infty-T_0)\left(-\frac{hA}{\rho Vc}\right)\exp\left[-\frac{hA}{\rho Vc}t\right]$$

$$\frac{dT}{dt}\propto\frac{A}{V}$$

Step 2 of 2

For a sphere:

$$\left(\frac{A}{V}\right)_{sphere}=\frac{4\pi r^2}{\frac{4}{3}\pi r^3}$$

$$\left(\frac{A}{V}\right)_{sphere}=\frac{3}{r}$$

For a cylinder:

$$\left(\frac{A}{V}\right)_{cylinder}=\frac{2\pi rh}{\pi r^2 h}$$

$$\left(\frac{A}{V}\right)_{cylinder}=\frac{2}{r}$$

It is obvious that:

$$\left(\frac{A}{V}\right)_{sphere}>\left(\frac{A}{V}\right)_{cylinder}$$

$$\left(\frac{dT}{dt}\right)_{sphere}>\left(\frac{dT}{dt}\right)_{cylinder}$$

Therefore, **the sphere will cool faster than the cylinder**.

Question: 18.011P

In what medium is the lumped system analysis more likely to be applicable: in water or in air? Why?

Step 1 of 1

Write the expression for Biot number.

$$Bi = \frac{\text{Conduction resistance}}{\text{Convection resistance}}$$

$$= \frac{\frac{L}{Ak}}{\frac{1}{hA}}$$

$$= \frac{hL}{k}$$

Here, h is convection heat transfer coefficient and k is thermal conductivity.

The lumped system analysis is applicable when Biot number is less than 0.1.

From the above expression, Biot number is proportional to convection heat transfer coefficient and inversely proportional to thermal conductivity. The convection coefficient is more in water than in air because of larger thermal conductivity of water.

Hence, the Biot number is less in case of solid cooled in the air when compared to solid cooled in the water.

Therefore, **the Biot number is much smaller in air.**

Question: 18.012P

To warm up some milk for a baby, a mother pours milk into a thin-walled glass whose diameter is 6 cm. The height of the milk in the glass is 7 cm. She then places the glass into a large pan filled with hot water at 70°C. The milk is stirred constantly, so that its temperature is uniform at all times. If the heat transfer coefficient between the water and the glass is 120 W/m2 -K, determine how long it will take for the milk to warm up from 3°C to 38°C. Take the properties of the milk to be the same as those of water. Can the milk in this case be treated as a lumped system? Why?

Step 1 of 5

Given data:

Diameter of the thin glass is $D = 6\text{cm}$.

Radius of the thin glass is $r = 3\text{cm}$.

Heat transfer coefficient between water and glass is $h = 120\ \text{W/m}^2 \cdot \text{K}$.

Temperature of the hot water is $T_\alpha = 70^\circ\text{C}$.

Initial temperature of the milk is $T_i = 3^\circ\text{C}$.

Final temperature of the milk is $T(t) = 38^\circ\text{C}$.

Step 2 of 5

Assumption:

We use lumped analysis for this problem as temperature of milk is assumed to remain constant always.

Thermal properties of milk are assumed to be as close as that of water and properties are constant.

Characteristic length is:

$$L_c = \frac{V}{A}$$

$$= \frac{\pi r^2 h}{(2\pi r h) + (2\pi r^2)}$$

$$= \frac{\pi \times 0.03^2 \times 0.07}{(2\pi \times 0.03 \times 0.07) + (2\pi \times 0.03^2)}$$

$$= 0.0105\text{m}$$

Step 3 of 5

Then, Biot number is

$$Bi = \frac{hL_c}{K}$$

$$= \frac{120 \times 0.0105}{0.607}$$

$$= 2.076$$

Hence Biot number is greater than 0.1, so lumped system analysis not applicable. But in this problem we are using the lumped system analysis because of temperature remains uniform due to constant stirring.

Step 4 of 5

Then,

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = e^{-bt}$$

Where

't' is the time taken for warming up.

Here:

$$b = \frac{h}{\rho C_p L_c}$$

$$= \frac{120}{998 \times 4182 \times 0.0105}$$

$$= 0.00274\ s^{-1}$$

Step 5 of 5

Substituting the values we get,

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = e^{-bt}$$

$$\frac{38 - 70}{3 - 70} = e^{-0.00274t}$$

$$\ln\left(\frac{38 - 70}{3 - 70}\right) = -0.00274t$$

$$t = 4.5\ \text{min}$$

Therefore, time taken for warming up milk is $\boxed{t = 4.5\ \text{min}}$

As milk is stirred constantly, the temperature of the milk remains constant almost all the time even if the Biot number is much larger. So lumped system analysis is quite appropriate for this problem.

Question: 18.013P

Repeat Prob. 18-12 for the case of water also being stirred, so that the heat transfer coefficient is doubled to 240W/m2 ·K.

Step 1 of 5

Given data:

Diameter of the glass, $D = 6\text{cm}$

Radius of the glass, $r = 3\text{cm}$

Heat transfer coefficient between water and glass, $h = 240\ \text{W/m}^2\cdot\text{K}$

Height of the milk in glass, $H = 7\text{cm}$

Temperature of hot water, $T_a = 70°\text{C}$

Initially temperature of the milk, $T_i = 3°\text{C}$

Final temperature of the milk, $T(t) = 38°\text{C}$

Step 2 of 5

Let us assume the temperature of the milk is $T = 25°\text{C}$

Characteristic length of the thin walled glass is given as

$$L_c = \frac{V}{A}$$

$$= \frac{\left(\pi r^2 H\right)}{\left(2\pi rH\right)+\left(2\pi r^2\right)}$$

$$= \frac{\pi\times 0.03^2\times 0.07}{\left(2\pi\times 0.03\times 0.07\right)+\left(2\pi\times 0.03^2\right)}$$

$$= 0.0105\text{m}$$

Step 3 of 5

From the table of "Properties of saturated water"

At $T = 25°\text{C}$

Specific heat of water is $c_p = 4182\text{kJ/kg}\cdot\text{K}$

Density of the water is $\rho = 998\text{kg/m}^3$

Thermal conductivity is $k = 0.607\ \text{W/m}\cdot\text{K}$

Then, Biot number of the process is

$$Bi = \frac{hL_c}{k}$$

$$= \frac{240\times L_c}{0.607}$$

$$= \frac{240\times 0.0105}{0.607}$$

$$= 4.15$$

In this problem lumped analysis can't be used because of Biot number is greater than 0.1 But as temperature remains uniform due to constant stirring process. We use the lumped system analysis.

Step 4 of 5

Then, lumped system analysis expression is given as

$$\frac{T(t)-T_a}{T_i-T_a} = e^{-bt}$$

Where

't' is the time taken for warming up.

Here:

$$b = \frac{h}{\rho c_p L_c}$$

$$= \frac{240}{998\times 4182\times 0.0105}$$

$$= 0.00548\text{s}^{-1}$$

Step 5 of 5

Substitute the known values in above expression, we get

$$\frac{T(t)-T_a}{T_i-T_a} = e^{-bt}$$

$$\frac{38-70}{3-70} = e^{-0.00548t}$$

$$\ln\left(\frac{38-70}{3-70}\right) = -0.00548t$$

$$t = 134.846\text{sec}$$

$$= 2.25\text{min}$$

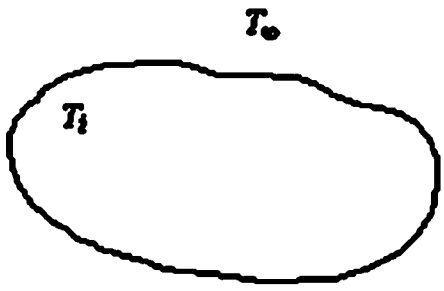
Therefore, time taken for warming up is $\boxed{t = 2.25\ \text{min}}$.

As milk is stirred constantly, the temperature of the milk remains constant almost all the time even if the Biot number is much larger. So lumped system analysis is quite appropriate for this problem.

Question: 18.014P

Obtain a relation for the time required for a lumped system to reach the average temperature $\frac{1}{2}(Ti + T\infty)$ where Ti is the initial temperature and $T\infty$ is the temperature of the environment.

Step 1 of 3



Initial temperature of lumped system $= T_i$

Environment temperature $= T_\infty$

Average temperature of lumped system $= \frac{(T_i + T_\infty)}{2}$

The relation for time period for a lumped system to reach the average temperature $\frac{(T_i + T_\infty)}{2}$ can be determined as

Step 2 of 3

Step 3 of 3

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

$$\frac{\frac{T_i + T_\infty}{2} - T_\infty}{T_i - T_\infty} = e^{-bt}$$

$$\frac{T_i - T_\infty}{2(T_i - T_\infty)} = e^{-bt}$$

$$\frac{1}{2} = e^{-bt}$$

$$-bt = -\ln 2$$

$$t = \frac{\ln 2}{b}$$

the time $\boxed{t = \frac{0.693}{b}}$

Question: 18.015P

The temperature of a gas stream is to be measured by a thermocouple whose junction can be approximated as a 1.2-mm-diameter sphere. The properties of the junction are k = 35 W/m·K, ρ = 8500 kg/m3 and cp = 320 J/kg·K, the heat transfer coefficient between the junction and the gas is h = 110 W/m2 ·K. Determine how long it will take for the thermocouple to read 99 percent of the initial temperature difference.

Step 1 of 5

Given data:

Diameter of the sphere, $D = 1.2\text{mm} = 0.0012\text{m}$

Heat transfer coefficient between junction and gas, $h = 110\ \text{W/m}^2\cdot\text{K}$

Reading of the thermocouple to initially temperature, 99%

Properties of junction are:

Thermal conductivity, $k = 35\ \text{W/m}\cdot\text{K}$

Density, $\rho = 8500\ \text{kg/m}^3$

Specific heat, $c_p = 320\ \text{J/kg}\cdot\text{K}$

Step 2 of 5

Characteristic length is of the thermocouple is given as

$$L_c = \frac{V}{A}$$
$$= \frac{\left(\frac{\pi D^3}{6}\right)}{\pi D^2}$$
$$= \frac{\pi \times \frac{0.0012^3}{6}}{\pi \times 0.0012^2}$$
$$= 0.0002\text{m}$$

Step 3 of 5

Then, Biot number of the process given as

$$Bi = \frac{hL_c}{K}$$
$$= \frac{110 \times L_c}{35}$$
$$= \frac{110 \times 0.0002}{35}$$
$$= 3.7 \times 10^{-3}$$

Here Biot number is less than the 0.1, therefore lumped system analysis is applicable.

Step 4 of 5

From the expression of lumped system analysis, we have

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = e^{-bt}$$

As the thermocouple reads 99 percent of the initial temperature difference, we put

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = 0.01$$

Here:

$$b = \frac{h}{\rho C_p L_c}$$
$$= \frac{110}{8500 \times 320 \times 0.0002}$$
$$= 0.2022\ s^{-1}$$

Step 5 of 5

Substituting the known values, we get

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = e^{-bt}$$
$$0.01 = e^{-0.2022t}$$
$$\ln(0.01) = -0.2022t$$
$$t = 22.8\ \text{sec}$$

Therefore, time taken to read the temperature is $\boxed{t = 22.8\ \text{sec}}$.

Question: 18.016P

In a manufacturing facility, 2-in-diameter brass balls (k = 64.1 Btu/h· ft·°F, ρ = 532 lbm/ft3 , and cp = 0.092 Btu/lbm·°F) initially at 250°F are quenched in a water bath at 120°F for a period of 2 min at a rate of 120 balls per minute . If the convection heat transfer coefficient is 42 Btu/h·ft2 ·F, determine (*a*) the temperature of the balls after quenching and (*b*) the rate at which heat needs to be removed from the water in order to keep its temperature constant at 120°F.

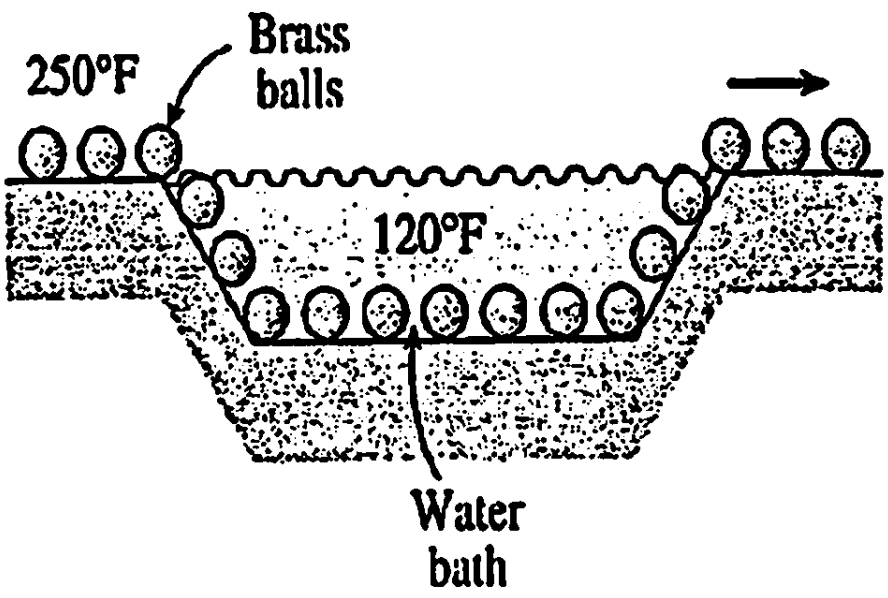


FIGURE PI8-16E

Step 1 of 5

Given:

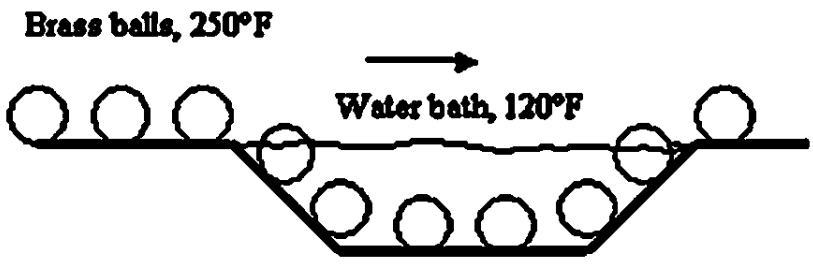
Diameter of brass ball $D = 2\ in$

Thermal conductivity of brass $K = 64.1\ \frac{\text{Btu}}{\text{h.ft.°F}}$

Density of brass $\rho = 532\ \frac{\text{lbm}}{\text{ft}^3}$

Specific heat of brass $C_p = 0.092\ \frac{\text{Btu}}{\text{lbm.°F}}$

The balls are spherical in shape with a radius $r_o = 1\ \text{in}$



The initial temperature $T_i = 250°\text{F}$

The water bath temperature $T_\infty = 120°\text{F}$

Time $t = 120\ S$

Step 2 of 5

The thermal properties of the balls are constant. If the heat transfer coefficient is constant and uniform over the entire surface. Then the characteristic length and the Biot number for the brass balls are

Step 3 of 5

The characteristic length $L_c = \frac{V}{A_s}$

$$L_c = \frac{\pi D^3/6}{\pi D^2}$$

$$L_c = \frac{D}{6}$$

$$L_c = \frac{2/12\ \text{ft}}{6}$$

$$L_c = 0.02778\ \text{ft}$$

The Biot number $Bi = \frac{hL_c}{k}$

$$Bi = \frac{(42\ \text{Btu/h.ft}^2\text{.°F})(0.02778\ \text{ft})}{(64.1\ \text{Btu/h.ft.°F})}$$

$$Bi = 0.01820 < 0.1$$

Step 4 of 5

The lumped system analysis is applicable since Bi < 0.1. Then the temperature of the balls after quenching becomes

The value of exponent $b = \frac{hA_s}{\rho C_p V}$

$$b = \frac{h}{\rho C_p L_c}$$

$$b = \frac{42\ \text{Btu/h.ft}^2\text{.°F}}{(532\ \text{lbm/ft}^3)(0.092\ \text{Btu/lbm.°F})(0.02778\ \text{ft})}$$

$$b = 30.9\ \text{h}^{-1}$$

$$b = 0.00858\ s^{-1}$$

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

$$\frac{T(t)-120}{250-120} = e^{-(0.00858\ s^{-1})(120\ s)}$$

$$T(t) = 166\ °\text{F}$$

Step 5 of 5

(*b*) The total amount of heat transfer from a ball during a 2-minute period is

The mass $m = \rho V$

$$m = \rho\frac{\pi D^3}{6}$$

$$m = (532\ \text{lbm/ft}^3)\frac{\pi(2/12\ \text{ft})^3}{6}$$

$$m = 1.290\ \text{lbm}$$

The heat transfer from a ball $Q = mC_p[T_i - T(t)]$

$$Q = (1.29\ \text{lbm})(0.092\ \text{Btu/lbm.°F})[250-166]°\text{F}$$

$$Q = 9.97\ \text{Btu}$$

Then the rate of heat transfer from the balls to the water becomes

$$\dot{Q}_{total} = \dot{n}_{ball} Q_{ball}$$

$$\dot{Q}_{total} = (120\ \text{balls/min}) \times (9.97\ \text{Btu})$$

$$\boxed{\dot{Q}_{total} = 1196\ \text{Btu/min}}$$

Therefore, heat must be removed from the water at a rate of 1196 Btu/min in order to keep its temperature constant at 120°F.

Question: 18.017P

Repeat Prob. 18-16E for aluminum balls.

Step 1 of 5

Calculate the characteristic length of the ball.

$$L_c = \frac{D}{6}$$

Here, D is the diameter of the ball.

Substitute 2 in. for D.

$$L_c = \frac{(2/12)\text{ ft}}{6}$$
$$= 0.02778\text{ ft}$$

Calculate the Biot number.

$$\text{Bi} = \frac{hL_c}{k}$$

Here, h is the heat transfer coefficient, k is the coefficient of thermal conductivity of brass, and L_c is the characteristic length of the ball.

Substitute $42\text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ for h, 0.02778 ft for L_c, and $64.1\text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ for k.

$$\text{Bi} = \frac{(42)(0.02778)}{(64.1)}$$
$$= 0.0182$$

As $\text{Bi} < 0.1$, lumped system analysis is applicable.

Step 2 of 5

Calculate the value of exponent (b).

$$b = \frac{h}{\rho c_p L_c}$$

Here, ρ is the density of the brass ball, c_p is the specific heat at constant pressure.

Substitute 532 lbm/ft^3 for ρ, $0.092\text{ Btu/lbm}\cdot^\circ\text{F}$ for c_p, 0.02778 ft for L_c, and $42\text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ for h.

$$b = \frac{42}{(532)(0.092)(0.02778)}$$
$$= 30.889\text{ h}^{-1}$$
$$= 0.00858\text{ s}^{-1}$$

Step 3 of 5

Calculate the temperature of the balls after quenching using the following relation.

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

Here, T_i is the initial temperature of ball and T_∞ is the water bath temperature.

Substitute 0.00858 s^{-1} for b and 250°F for T_i, and 120°F for T_∞.

$$\frac{T(t)-120}{250-120} = e^{-(0.00858)(120)}$$
$$\frac{T(t)-120}{250-120} = 0.3571$$
$$T(t) = 166.43^\circ\text{F}$$

Therefore, the temperature of the balls after quenching is $\boxed{166.43^\circ\text{F}}$.

Step 4 of 5

(*b*)

Calculate the mass of each ball.

$$m = \rho V$$
$$= \rho\frac{\pi D^3}{6}$$

Substitute $532\frac{\text{lbm}}{\text{ft}^3}$ for ρ and 2 in. for D.

$$m = \left(532\text{ lbm/ft}^3\right)\frac{\pi(2/12\text{ ft})^3}{6}$$
$$= 1.2896\text{ lbm}$$

Step 5 of 5

Calculate the heat transfer from each ball.

$$Q_{\text{ball}} = mC_p\left[T_i - T(t)\right]$$

Substitute 1.2896 lbm for m, 250°F for T_i and 166.43°F for $T(t)$.

$$Q_{\text{ball}} = (1.2896)(0.092)(250-166.43)$$
$$= 9.915\text{ Btu}$$

Calculate the total rate of heat transfer from the balls to the water.

$$\dot{Q}_{\text{total}} = \dot{n}_{\text{ball}}Q_{\text{ball}}$$

Substitute 120 balls/min for $\dot{n}_{\text{ball}}$ and 9.915 Btu for Q_{ball}.

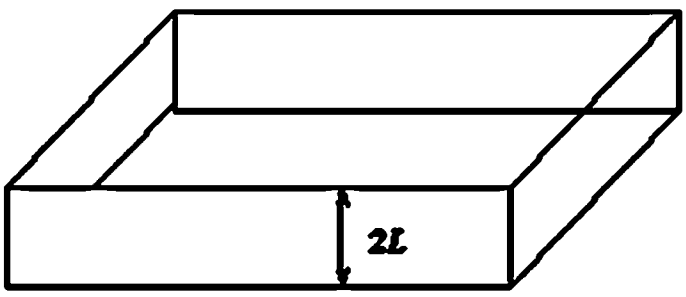
$$\dot{Q}_{\text{total}} = (120)\times(9.915)$$
$$= 1189.80\text{ Btu/min}$$

Therefore, the rate of heat needs to be removed from the water in order to keep its temperature constant is $\boxed{1189.80\text{ Btu/min}}$.

Question: 18.018P

Obtain relations for the characteristic lengths of a large plane wall of thickness 2L, a very long cylinder of radius *r0* , and a sphere of radius *r0* .

Step 1 of 4



Thickness of large plane wall $= 2L$

Radius of long cylinder $= r$

Radius of sphere $= r_o$

Relations for the characteristic lengths of a large plane wall of thickness 2L, a very long cylinder of radius r_o and a sphere of radius r_o are

Step 2 of 4

The characteristic lengths of a large plane wall $L_{c,wall} = \dfrac{V}{A_{surface}}$

$$L_{c,wall} = \frac{2LA}{2A}$$

$$L_{c,wall} = L$$

Step 3 of 4

The characteristic lengths of a cylinder $L_{c,cylinder} = \dfrac{V}{A_{surface}}$

$$L_{c,cylinder} = \frac{\pi r_o^2 h}{2\pi r_o h}$$

$$L_{c,cylinder} = \frac{r_o}{2}$$

Step 4 of 4

The characteristic lengths of a sphere $L_{c,sphere} = \dfrac{V}{A_{surface}}$

$$L_{c,sphere} = \frac{\frac{4\pi r_o^3}{3}}{4\pi r_o^2}$$

$$L_{c,sphere} = \frac{r_o}{3}$$

Question: 18.019P

A long copper rod of diameter 2.0 cm is initially at a uniform temperature of 100°C. It is now exposed to an air stream at 20°C with a heat transfer coefficient of 200 W/m2 ·K. How long would it take for the copper road to cool to an average temperature of 25°C?

Step 1 of 4

Given:

Diameter of copper rod $D = 2\ \text{cm}$

Initial temperature of rod $T_i = 100°\text{C}$

Temperature of air stream $T_\infty = 20°\text{C}$

The average temperature $T(t) = 25°\text{C}$

Heat transfer coefficient $h = 200\ \dfrac{\text{W}}{\text{m}^2.°\text{C}}$

Step 2 of 4

From properties of solid metals take values

The thermal conductivity of copper $k = 401\ \text{W/m.°C}$

The density of copper $\rho = 8933\ \text{kg/m}^3$

The specific heat of the copper $C_p = 385\text{J/kg.°C}$

The thermal properties of the rod are constant. If the heat transfer coefficient is constant and uniform over the entire surface. Then the characteristic length and the Biot number for the copper rod are

Step 3 of 4

The characteristic length $L_c = \dfrac{V}{A_s}$

$$L_c = \frac{(\pi D^2/4)L}{\pi DL}$$

$$L_c = \frac{D}{4}$$

$$L_c = \frac{0.02m}{6}$$

$$L_c = 0.005m$$

The Biot number $Bi = \dfrac{hL_c}{k}$

$$Bi = \frac{(200W/\text{m}^2.°\text{C})(0.005m)}{(401\ \text{W/m.°C})}$$

$$Bi = 0.0025 < 0.1$$

Step 4 of 4

The lumped system analysis is applicable since Bi < 0.1. Then the temperature of the rod becomes

The value of exponent $b = \dfrac{hA}{\rho C_p V}$

$$b = \frac{h}{\rho C_p L_c}$$

$$b = \frac{200\ \text{W/m}^2.°\text{C}}{(8933\ \text{kg/m}^3)(385\ \text{J/kg.°C})(0.005\text{m})}$$

$$b = 0.01163\ s^{-1}$$

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

$$\frac{25-20}{100-20} = e^{-(0.01163s^{-1})t}$$

$t = 238s$

$\boxed{t = 4.0\text{min}}$

Question:

Consider a sphere of diameter 5 cm, a cube of side length 5 cm, and a rectangular prism of dimension 4 cm × 5 cm × 6 cm, all initially at 0°C and all made of silver (k = 429 W/m2·K, ρ = 10,500 kg/m3 , Cp = 0.235 kJ/kg·K). Now all three of these geometries are exposed to ambient air at 33°C on all of their surfaces with a heat transfer coefficient of 12 W/m2 ·K. Determine how long it will take for the temperature of each geometry to rise to 25°C.

Step 1 of 12

For sphere:

Find the characteristic length for sphere using the equation:

$$L_c = \frac{V}{A}$$

$$= \frac{\left(\frac{\pi D^3}{6}\right)}{\pi D^2}$$

Here, V is the volume of the sphere, A is the area of the sphere and D is the diameter of the sphere.

Substitute, 5 cm = 0.05 m for D.

$$L_c = \frac{\left(\frac{\pi \times 0.05^3}{6}\right)}{\left(\pi \times 0.05^2\right)}$$

$$= 0.00833 \text{ m}$$

Step 2 of 12

Find the Biot number for sphere using the equation,

$$\text{Bi} = \frac{hL_c}{k}$$

Here, Bi is the Biot number, h is the convection heat transfer coefficient, L_c is the characteristic length and k is conduction heat transfer coefficient.

Substitute, 12 $\text{W/m}^2\cdot^\circ\text{C}$ for h, 0.00833 m for L_c and 429 $\text{W/m}\cdot^\circ\text{C}$ for k.

$$\text{Bi} = \frac{12 \times 0.00833}{429}$$

$$= 0.0002330$$

Here Biot number is less than 0.1, therefore lumped system analysis is applicable.

Step 3 of 12

Find the time period required to reach the temperature of 25 °C by using the equation,

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

Here, t is the time in second taken for heating, T_∞ is the temperature of the surroundings, T_i is the initial temperature, $T(t)$ is the temperature after t seconds and b is constant.

Find the constant b using the equation,

$$b = \frac{h}{\rho c_p L_c}$$

Here, ρ is the density of the sphere, c_p is the specific heat of the sphere at constant pressure.

Substitute, 12 $\text{W/m}^2\cdot^\circ\text{C}$ for h, 10500 kg/m^3 for ρ, 235 J/kg for c_p and 0.00833 m for L_c

$$b = \frac{12}{10500 \times 235 \times 0.00833}$$

$$= 0.00058 \text{ s}^{-1}$$

Step 4 of 12

Find the time period required to reach the temperature of 25 °C by,

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

Substitute, 25 °C for $T(t)$, 33°C for T_∞, 0°C for T_i and 0.00058 s^{-1} for b.

$$\frac{25 - 33}{0 - 33} = e^{-(0.00058)(t)}$$

$$t = 2443.22 \text{ s}\left|\frac{1 \text{ min}}{60 \text{ s}}\right|$$

$$= 40.72 \text{ min}$$

Therefore, in order to reach the temperature of 25°C, the sphere will take a time of

$\boxed{40.72 \text{ min.}}$

Step 5 of 12

For cube:

Find the characteristic length for cube by using the equation,

$$L_c = \frac{V}{A}$$

$$= \frac{L^3}{6L^2}$$

Here, V is the volume of cube, A is the surface area of cube and L is the length of the cube.

Substitute, 5 cm = 0.05 m for L.

$$L_c = \frac{0.05^3}{6 \times 0.05^2}$$

$$= 0.00833 \text{ m}$$

Step 6 of 12

Find the Biot number for cube using the equation,

$$\text{Bi} = \frac{hL_c}{k}$$

Substitute, 12 $\text{W/m}^2\cdot^\circ\text{C}$ for h, 0.00833 m for L_c and 429 $\text{W/m}\cdot^\circ\text{C}$ for k.

$$\text{Bi} = \frac{12 \times 0.00833}{429}$$

$$= 0.0002330$$

Here Biot number is less than 0.1, therefore lumped system analysis is applicable.

$$=\frac{429}{}$$
$$=0.0002330$$

Here Biot number is less than 0.1, therefore lumped system analysis is applicable.

Step 7 of 12

Find the time period required to reach the temperature of 25 °C by,

$$\frac{T(t)-T_\infty}{T_i-T_\infty}=e^{-bt}$$

Here, t is the time in second taken for heating, T_∞ is the temperature of the surroundings, T_i is the initial temperature, $T(t)$ is the temperature after t seconds and b is constant.

Find the value of the constant b:

$$b=\frac{h}{\rho c_p L_c}$$

Substitute, 12 $W/m^2\cdot°C$ for h, 10500 kg/m^3 for ρ, 235 J/kg for c_p and 0.00833 m for L_c

$$b=\frac{12}{10500\times235\times0.00833}$$
$$=0.00058\,s^{-1}$$

Step 8 of 12

Find the time period required to reach the temperature of 25 °C by,

$$\frac{T(t)-T_\infty}{T_i-T_\infty}=e^{-bt}$$

Substitute, 25 °C for $T(t)$, 33°C for T_∞, 0°C for T_i and 0.00058 s^{-1} for b.

$$\frac{25-33}{0-33}=e^{-(0.00058)\times(t)}$$
$$t=2443.22\text{ s}\left|\frac{1\text{ min}}{60\text{ s}}\right|$$
$$=40.72\text{ min}$$

Therefore, in order to reach the temperature of 25°C, the cube will take a time of $\boxed{40.72\,\text{min.}}$

Step 9 of 12

For rectangular prism:

Find the characteristic for rectangular prism by using the equation,

$$L_c=\frac{V}{A}$$
$$=\frac{L\times B\times H}{2(L\times B)+2(B\times H)+2(H\times L)}$$

Here, Here, V is the volume of rectangular prism, A is the surface area of rectangular prism, L is the length of rectangular prism, B is the breadth of the rectangular prism and H is the height of the rectangular prism.

Substitute, 4 cm = 0.04 m for L, 5 cm = 0.05 m for B, 6 cm = 0.06 m for H.

$$L_c=\frac{0.04\times0.05\times0.06}{2\times(0.04\times0.05)+2\times(0.04\times0.06)+2\times(0.05\times0.06)}$$
$$=0.0081\text{ m}$$

Step 10 of 12

Find the Biot number for rectangular prism by using the equation,

$$\text{Bi}=\frac{hL_c}{k}$$

Substitute, 12 $W/m^2\cdot°C$ for h, 0.0081 m for L_c and 429 $W/m\cdot°C$ for k.

$$\text{Bi}=\frac{12\times0.0081}{429}$$
$$=0.0002266$$

Here Biot number is less than 0.1, therefore lumped system analysis is applicable.

Step 11 of 12

Find the time period required to reach the temperature of 25 °C by using the equation,

$$\frac{T(t)-T_\infty}{T_i-T_\infty}=e^{-bt}$$

Here, t is the time in second taken for heating, T_∞ is the temperature of the surroundings, T_i is the initial temperature, $T(t)$ is the temperature after t seconds and b is constant.

Find the constant b by using the equation,

$$b=\frac{h}{\rho c_p L_c}$$

Substitute, 12 $W/m^2\cdot°C$ for h, 10500 kg/m^3 for ρ, 235 J/kg for c_p and 0.0081 m for L_c

$$b=\frac{12}{10500\times235\times0.0081}$$
$$=0.0006\,s^{-1}$$

Step 12 of 12

Find the time period required to reach the temperature of 25 °C by using the equation,

$$\frac{T(t)-T_\infty}{T_i-T_\infty}=e^{-bt}$$

Substitute, 25 °C for $T(t)$, 33°C for T_∞, 0°C for T_i and 0.0006 s^{-1} for b.

$$\frac{25-33}{0-33}=e^{-(0.0006)\times(t)}$$
$$t=39.36$$

Therefore, in order to reach the temperature of 25°C, the rectangular prism will take a time of $\boxed{39.36\,\text{min.}}$

Question: 18.021P

Consider a 800-W iron whose base plate is made of 0.5-cm-thick aluminum alloy 20218-T6 (p = 2770 kg/m3 , *cp* = 875 J/kg·K, α = 7.3 × 10-5 m2 /s). The base plate has a surface area of 0,03 m2 . Initially, the iron is in thermal equilibrium with the ambient air at 22°C. Taking the heat transfer coefficient at the surface of the base plate to be 12 W/m2 ·K and assuming 85 percent of the heat generated in the resistance wires is transferred to the plate, determine how long it will take for the plate temperature to reach 140°C. Is it realistic to assume the plate temperature to be uniform at all times?

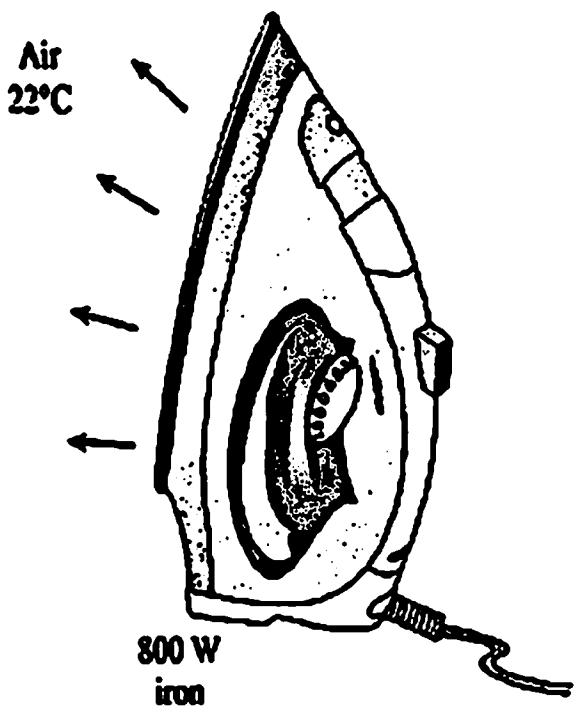


FIGURE P18-21

Step 1 of 5

Given data:

Capacity of the iron, $P = 800\,\text{W}$

Thickness of the aluminum, $t = 0.5\,\text{cm} = 0.005\,\text{m}$

Temperature of ambient air, $T = 22°\text{C}$

Heat transfer coefficient of the base plate, $h = 12\,\text{W/m}^2\cdot\text{K}$

Percentage of heat transferred to the plate, $\eta_t = 85\% = 0.85$

Center temperature of the plate is $T(t) = 140°\text{C}$

Area of the plate, $A = 0.03\,\text{m}^2$

Step 2 of 5

Properties of the iron:

Density, $\rho = 2770\,\text{kg/m}^3$

Specific heat, $c_p = 875\,\text{J/kg}\cdot\text{K}$

Thermal diffusivity, $\alpha = 7.3\times10^{-5}\,\text{m}^2/\text{s}$

Amount of heat going to iron,

$$P_{iron} = \eta \times P$$
$$= 0.85\times800$$
$$= 680\ \text{W}$$

Average temperature of the plate,

$$T_{avg} = \frac{140+22}{2}$$
$$= 81°\text{C}$$

Step 3 of 5

The rate of heat loss from plate,

$$Q_{loss} = hA\left(T_{avg} - T\right)$$
$$= 12\times0.03\times(81-22)$$
$$= 21.24\ \text{W}$$

Mass of the plate is

$$m = \rho A t$$
$$= 2770\times0.005\times0.03$$
$$= 0.4155\ \text{Kg}$$

Therefore, amount of heat available is

$$Q = P - Q_{loss}$$
$$= 680-21.24$$
$$= 658.76\,\text{W}$$

Step 4 of 5

Now if this temperature difference occurs over the span of time is equal to't', then an energy balance gives:

$$658.76t = mc_p(140-22)$$

Putting this data:

$$658.76t = mc_p(140-22)$$

$$658.76t = 0.4155\times875\times(140-22)$$

$$t = 65.12\ \text{sec}$$

Therefore, the required time is $\boxed{t = 65.12\ \text{sec}}$

Step 5 of 5

For this problem Biot Number becomes

$$Bi = \frac{hL_c}{K}$$
$$= \frac{12\times L_c}{177}$$

Now, characteristic length is:

$$L_c = t = 0.005\ \text{m}$$

Putting this into Biot number expression, we get:

$$Bi = \frac{hL_c}{K}$$
$$= \frac{12\times L_c}{117}$$
$$= \frac{12\times0.005}{117}$$
$$= 3.4\times10^{-4}$$

In this problem lumped analysis and as well as uniform base plate temperature can be used as Biot no is much smaller than 0.1.

Question: 18.022P

Reconsider Prob. 18-21. Using EES (or other) software, investigate the effects of the heat transfer coefficient and the final plate temperature on the time it will take for the plate to reach this temperature. Let the heat transfer coefficient vary from 5 W/m2 ·K to 25 W/m·K and the temperature from 30°C to 200°C. Plot the time as functions of the heat transfer coefficient and the temperature, and discuss the results.

Step 1 of 7

Given data:

Capacity of the iron, $Q = 800\,\text{W}$

Thickness of the base plate, $t = 0.5\,\text{cm}$

Cross sectional area of the base plate, $A = 0.03\,\text{m}^2$

Heat transfer coefficient between base plate and air, $h = 12\ \text{W/m}^2\cdot\text{K}$

Temperature of the ambient air, $T_a = 22°\text{C}$

Final temperature of the air, $T_f = 140°\text{C}$

Efficiency of the iron, $\eta = 0.85$

Step 2 of 7

Properties of the aluminum alloy 2024-T6:

$\rho = 2770\ \text{kg/m}^3$.

$c_p = 875\,\text{J/kg}\cdot\text{K}$.

$\alpha = 7.3\times10^{-5}\ \text{m}^2/\text{s}$.

Heat transfer coefficient between base plate and air is $h\ \text{W/m}^2\cdot\text{K}$.

Actual heat transferred at the base plate is

$$Q = 0.85\times800$$
$$= 680\ \text{W}$$

Mean film temperature is $T_{avg} = \dfrac{T_f+22}{2}$.

Step 3 of 7

The rate of heat loss from plate is $h\times0.03\times\left(\dfrac{T_f+22}{2}-22\right)$

So difference in heat transfer is $680-h\times0.03\times\left(\dfrac{T_f+22}{2}-22\right)$

Now if this temperature difference occurs over the span of time is equal to't', then an energy balance gives:

$$\left\{680-h\times0.03\times\left(\frac{T_f+22}{2}-22\right)\right\}t = mC_p\left(T_f-22\right)$$

$$\boxed{\left\{680-h\times0.03\times\left(\frac{T_f+22}{2}-22\right)\right\}t = 0.4155\times875\times\left(T_f-22\right)}$$

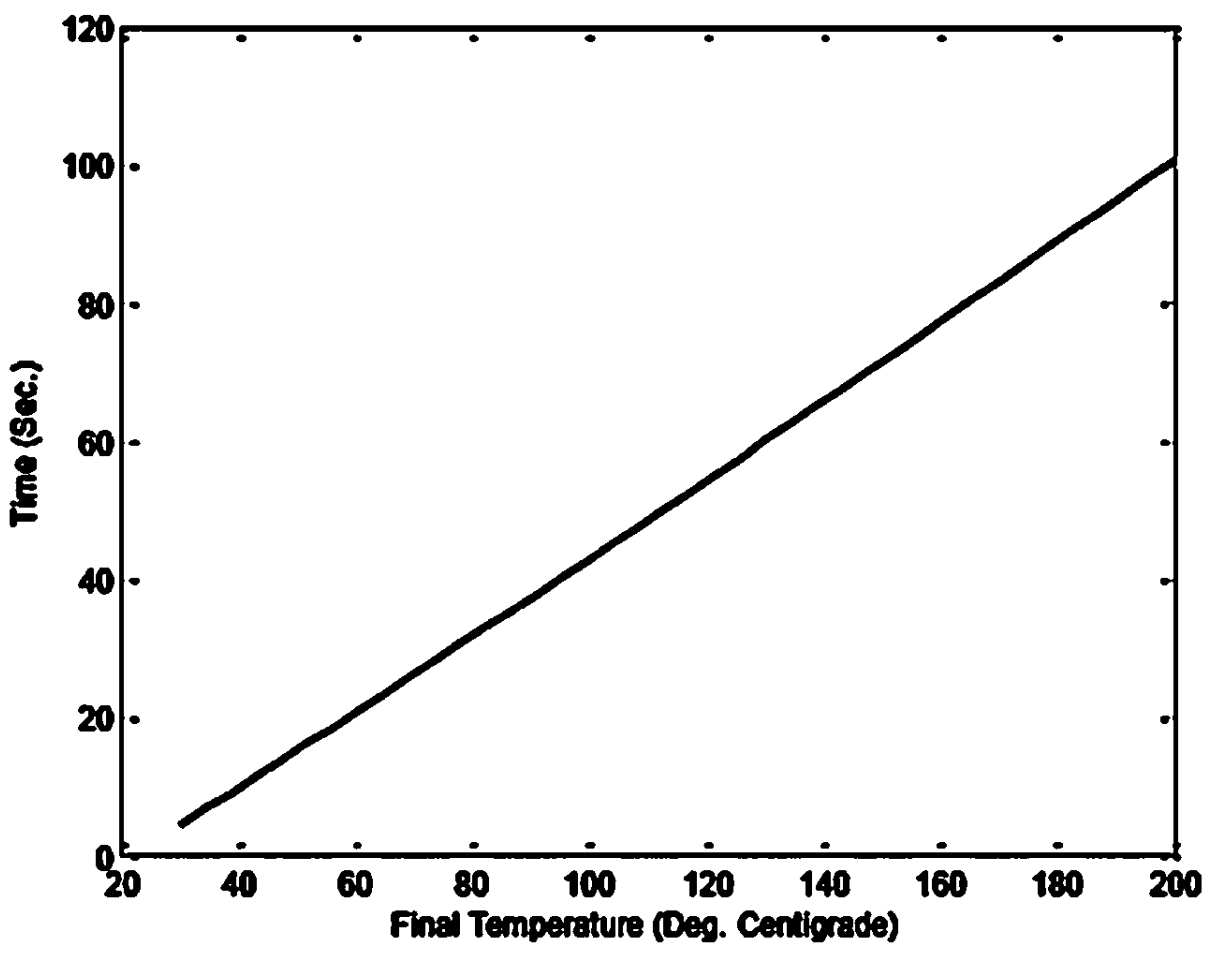
Step 4 of 7

Let us first consider $h = 12\ \text{W/m}^2\cdot\text{K}$.

So, it implies:

$$\left\{680-h\times0.03\times\left(\frac{T_f+22}{2}-22\right)\right\}t = 0.4155\times875\times\left(T_f-22\right)$$

$$\Rightarrow\left\{680-12\times0.03\times\left(\frac{T_f+22}{2}-22\right)\right\}t = 0.4155\times875\times\left(T_f-22\right)$$



$$\Rightarrow\boxed{t = \frac{0.4155\times875\times\left(T_f-22\right)}{\left\{680-12\times0.03\times\left(\dfrac{T_f+22}{2}-22\right)\right\}}}$$

Step 5 of 7

This expression is used to plot variation of time as function of final temperature.

MATLAB Program:

```
clear all
clc
x=linspace(30,200,40);
y=0.4185*875*(x-22);
z=680-((((x+22)/2)-22)*12*0.03);
t=y./z;
plot(x,t)
```

Step 6 of 7

Again in the expression:

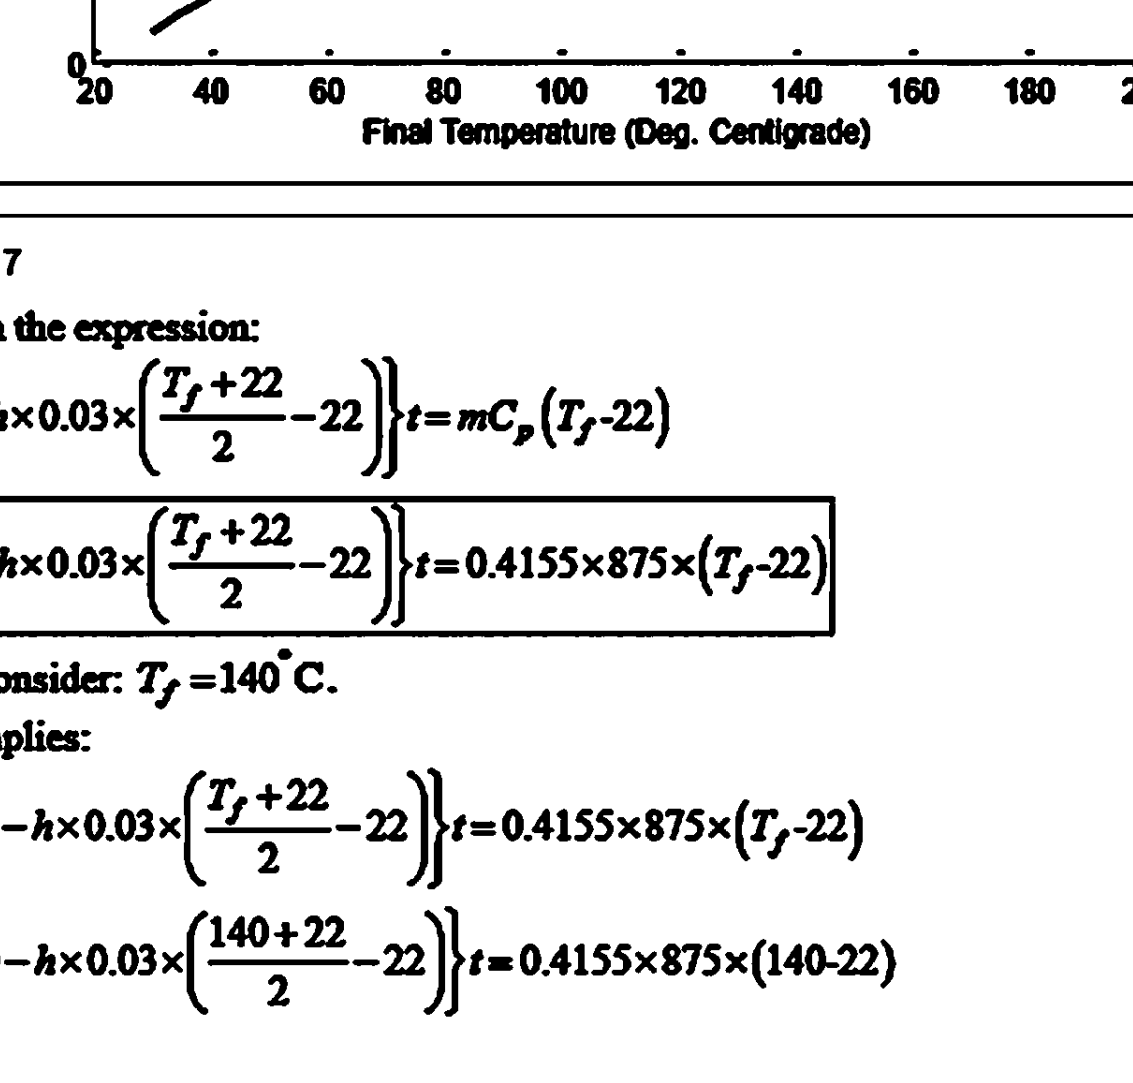
$$\left\{680-h\times0.03\times\left(\frac{T_f+22}{2}-22\right)\right\}t = mC_p\left(T_f-22\right)$$

$$\boxed{\left\{680-h\times0.03\times\left(\frac{T_f+22}{2}-22\right)\right\}t = 0.4155\times875\times\left(T_f-22\right)}$$

Let us consider: $T_f = 140^{\circ}\text{C}$.

So, it implies:

$$\left\{680-h\times0.03\times\left(\frac{T_f+22}{2}-22\right)\right\}t = 0.4155\times875\times\left(T_f-22\right)$$



$$\Rightarrow\left\{680-h\times0.03\times\left(\frac{140+22}{2}-22\right)\right\}t = 0.4155\times875\times(140-22)$$

Step 7 of 7

This expression is used to plot variation of time as function of heat transfer coefficient.

MATLAB Program:

```
clear all
clc
x=linspace(5,25,40);
y=0.4185*875*(140-22);
z=680-((((140+22)/2)-22)*x*0.03);
t=y./z;
plot(x,t)
```

Question: 18.023P

A people is found dead at 5pm in a room whose temperature is 20°C. The temperature of the body is measured to be 25°C when found, and the heat transfer coefficient is estimated to be 8 W/m2 ·K. Modeling the body as a 30-cm-diameter, 1.70-m-long cylinder and using the lumped system analysis as a rough approximation, estimate the time of death of that person.

Step 1 of 5

Calculate the radius of the cylinder.

$$r = \frac{D}{2}$$

Here, D is the diameter of the cylinder.

Substitute 30 cm for D.

$$\begin{aligned} r &= \frac{30}{2} \\ &= 15\ \text{cm} \\ &= 15\times10^{-2}\ \text{m} \end{aligned}$$

Step 2 of 5

Calculate the characteristics length of the person as follows:

$$\begin{aligned} L_c &= \frac{V}{A} \\ &= \frac{\left(\frac{\pi}{4}D^2L\right)}{\left(2\pi rL+2\pi r^2\right)} \end{aligned}$$

Here, L is the length of the cylinder (Body assumed as cylinder), r is the radius of the cylinder, D is the diameter of the cylinder.

Substitute $15\times10^{-2}\ \text{m}$ for r, 30 cm for D, 1.70 m for L.

$$\begin{aligned} L_c &= \frac{\left(\frac{\pi\times\left(30\times10^{-2}\right)^2}{4}\right)(1.7)}{\left(2\pi\times15\times10^{-2}\ \text{m}\times1.7\right)+\left(2\pi\times\left(15\times10^{-2}\ \text{m}\right)^2\right)} \\ &= 0.0689\ \text{m} \end{aligned}$$

Step 3 of 5

Consider the average temperature of human body is to be $(37°\text{C})$.

The average human body is 72 percent water by mass, and thus assume the body to have the properties of water at the average temperature of $\left(\frac{37+25}{2}\right)=31°\text{C}$.

Obtain the properties of water from table A-9 "Saturated properties of water" at $T_{av}=31°\text{C}$

$$k = 0.617\ \text{W/m}$$
$$\rho = 996\ \text{kg/m}^3$$
$$c_p = 4718\ \text{J/kg}\cdot\text{K}$$

Calculate the Biot number.

$$\text{Bi} = \frac{hL_c}{k}$$

Here, h is the heat transfer coefficient, k is the thermal conductivity.

Substitute $0.617\ \text{W/m}$ for k, $0.0689\ \text{m}$ for L_c and $8\ \text{W/m}^2$ for h.

$$\begin{aligned} \text{Bi} &= \frac{hL_c}{k} \\ &= \frac{8\times0.0689}{0.617} \\ &= 0.89>1 \end{aligned}$$

Thus, lumped system analysis is not applicable.

Step 4 of 5

Calculate the time constant as follows:

$$b = \frac{h}{\rho c_p L_c}$$

Here, h is the heat transfer coefficient, ρ is the density, and c_p is the specific heat capacity at constant pressure.

Substitute $8\ \text{W/m}^2$ for h, $996\ \text{kg/m}^3$ for ρ, $4718\ \text{J/kg}\cdot\text{K}$ for c_p, $0.0689\ \text{m}$ for L_c.

$$\begin{aligned} b &= \frac{8}{996\times4178\times0.0689} \\ &= 2.79\times10^{-5}\ \text{s}^{-1} \end{aligned}$$

Calculate the time required to reach the temperature of $25°\text{C}$ as follows:

$$\frac{T(t)-T_a}{T_i-T_a} = e^{-bt}$$

Here, time taken for cooling is t, b is Biot constant, T_a is the ambient temperature, T_i is the initial temperature of the body of that person, $T(t)$ is the final temperature of the body after death.

Step 5 of 5

Substituting $25°\text{C}$ for $T(t)$, $20°\text{C}$ for T_a, $\left(2.79\times10^{-5}\ \text{s}^{-1}\right)$ for b, $37°\text{C}$ for T_i.

$$\begin{aligned} \frac{T(t)-T_a}{T_i-T_a} &= e^{-bt} \\ \frac{25-20}{37-20} &= e^{-\left(2.79\times10^{-5}\right)(t)} \\ 0.294 &= e^{-\left(2.79\times10^{-5}t\right)} \\ \ln 0.294 &= -\left(2.79\times10^{-5}t\right) \\ -1.224 &= -\left(2.79\times10^{-5}t\right) \\ t &= \frac{2.79\times10^{-5}}{1.224} \\ &= 43870 \\ &= 12.2\ \text{hours} \end{aligned}$$

Therefore, the time of death of the person is $\boxed{12.2\,\text{hour}}$.

Question: 18.024P

Springs in a suspension system of automobiles are made of steel rods heated and wound into coils while ductile. Consider steel rods (ρ = 7832 kg/m3 , cp = 434 J/kg·K. and k = 63.9 W/m·K) with diameter of 2.5 cm and length of 1.27 m. The steel rods are heated in an oven with a uniform convection heat transfer coefficient of 20 W/m2 ·K. The steel rods were heated from an initial temperature of 20°C to the desired temperature of 450°C before being wound into coils. Determine the ambient temperature in the oven, if the steel rods were to be heated to the desired temperature within 10 minutes.

Step 1 of 3

Characteristic length of the steel rod is given by,

$$L_C = \frac{V}{A}$$

Here,
Volume of the steel rod is V
Area of the steel rod is A

$$L_C = \frac{V}{A}$$
$$= \frac{\left(\frac{\pi}{4}D^2L\right)}{(\pi DL)}$$
$$= \frac{D}{4}$$

Now substitute 0.025 m for D,

$$L_C = \frac{0.025}{4}$$
$$= 6.25\times10^{-3}\ \text{m}$$

Step 2 of 3

Then, Biot number is

$$Bi = \frac{hL_c}{k}$$

Here,
Heat transfer coefficient is h
Thermal conductivity of the steel rod is k

$$Bi = \frac{hL_c}{k}$$
$$= \frac{20\times6.25\times10^{-3}}{63.9}$$
$$= 0.001956$$

Since Biot number is less than the 0.1, therefore lumped system analysis is applicable.

Step 3 of 3

From the equation of lumped system analysis

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{\frac{-hA\tau}{\rho c_p V}}$$

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{\frac{-h\tau}{\rho c_p L_C}}$$

Substitute 450°C for $T(t)$, 20°C for T_i, 20 W/m^2·K for h, 600 s for τ and 7832 kg/m^3 for ρ

$$\frac{450-T_\infty}{20-T_\infty} = e^{-\left(\frac{20\times600}{7832\times434\times6.25\times10^{-3}}\right)}$$
$$\frac{450-T_\infty}{20-T_\infty} = 0.568$$
$$\boxed{T_\infty = 1016°C}$$

Therefore, temperature of the fluid is 1016°C.

Question: 18.025P

Steel rods (ρ = 7832 kg/m3 , cp = 434 J/kg·K. and k = 63.9 W/m2 ·K) are heated in a furnace to 850°C and then quenched in a water bath at 50°C for a period of 40 seconds as part of a hardening process. The convection heat transfer coefficient is 650 W/m2 ·K. If the steel rods have diameter of 40 mm and length of 2 m, determine their average temperature when they are taken out of the water bath.

Step 1 of 3

Calculate the characteristic length of the steel rod using the relation below

$$\begin{aligned} L_c &= \frac{V}{A} \\ &= \frac{\left(\frac{\pi}{4}D^2L\right)}{(\pi DL)} \\ &= \frac{D}{4} \end{aligned}$$

Here, volume of the steel rod is V , Area of the steel rod is A and diameter of the steel rod is D

Substitute $0.04\,\text{m}$ for D in the above equation

$$\begin{aligned} L_c &= \frac{0.04}{4} \\ &= 0.01\,\text{m} \end{aligned}$$

Step 2 of 3

The relation for the Biot number is as follows

$$Bi = \frac{hL_c}{k}$$

Here, heat transfer coefficient is h and thermal conductivity of the steel rod is k

Substitute $650\,\text{W/m}^2\cdot\text{K}$ for h, $63.9\,\text{W/m}\cdot\text{K}$ for k and 0.01

$$\begin{aligned} Bi &= \frac{hL_c}{k} \\ &= \frac{650\times 0.01}{63.9} \\ &= 0.1 \end{aligned}$$

Since the Biot number, $Bi \le 0.1$, the lumped system analysis is applicable.

Substitute $0.04\,\text{m}$ for D in the above equation

$$\begin{aligned} L_c &= \frac{0.04}{4} \\ &= 0.01\,\text{m} \end{aligned}$$

Step 2 of 3

The relation for the Biot number is as follows

$$Bi = \frac{hL_c}{k}$$

Here, heat transfer coefficient is h and thermal conductivity of the steel rod is k

Substitute $650\,\text{W/m}^2\cdot\text{K}$ for h, $63.9\,\text{W/m}\cdot\text{K}$ for k and 0.01

$$\begin{aligned} Bi &= \frac{hL_c}{k} \\ &= \frac{650\times 0.01}{63.9} \\ &= 0.1 \end{aligned}$$

Since the Biot number, $Bi \le 0.1$, the lumped system analysis is applicable.

Question: 18.026P

A brick of 203 × 102 × 57 mm in dimension is being burned in a kiln to 1100°C, and then allowed to cool in a room with ambient air temperature of 30°C and convection heat transfer coefficient of 5 W/m2 ·K. If the brick has properties of ρ = 1920 kg/m3 , cp = 790 J/kg·K, and k = 0.90 W/m2 ·K, determine the time required to cool the brick to a temperature difference of 5°C from the ambient air temperature.

Step 1 of 3

Find the volume of the brick.

$$V = 203 \times 102 \times 57$$
$$= 1180242 \text{ mm}^3$$

Find the surface area of the brick.

$$A = 2\left[(203 \times 102) + (203 \times 57) + (102 \times 57)\right]$$
$$= 76182 \text{ mm}^2$$

Find the characteristic length of the steel rod.

$$L_C = \frac{V}{A}$$

Substitute 1180242 mm^3 for V and 76182 mm^2 for A .

$$L_C = \frac{1180242}{76182}$$
$$= 15.49 \text{ mm}$$
$$= 0.01549 \text{ m}$$

Step 2 of 3

Find the Biot number using the equation.

$$Bi = \frac{hL_c}{k}$$

Here, h is the heat transfer coefficient and k is the thermal conductivity.

Substitute $5 \text{ W/m}^2 \cdot \text{K}$ for h , $0.90 \text{ W/m} \cdot \text{K}$ for k and 0.01549 m for L_c .

$$Bi = \frac{5 \times 0.01549}{0.90}$$
$$= 0.0860$$

Since, the Biot number is less than or equal to 0.1, therefore lumped system analysis is applicable.

Step 3 of 3

Use the equation of lumped system analysis and find the time taken to brick reach the temperature.

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{\frac{-hA\tau}{\rho c_p V}}$$
$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{\frac{-h\tau}{\rho c_p L_c}}$$

Here, ρ is the density of the steel rod, c_p is the specific heat at constant pressure, T_∞ is the ambient temperature, $T(t)$ is center temperature of the steel rod and τ is the time.

Substitute 1920 kg/m^3 for ρ , 30°C for T_∞ , 5°C for $(T(t) - T_\infty)$, 1100°C for $T(t)$, $790 \text{ J/kg} \cdot \text{K}$ for c_p and 0.01549 m for L_C .

$$\left(\frac{5}{1100 - 30}\right) = e^{-\left(\frac{5 \times \tau}{1920 \times 790 \times 0.01549}\right)}$$
$$\ln\left(\frac{5}{1100 - 30}\right) = \ln\left(e^{-\left(\frac{5 \times \tau}{1920 \times 790 \times 0.01549}\right)}\right)$$
$$-5.365976 = -\left(\frac{5 \times \tau}{1920 \times 790 \times 0.01549}\right)$$
$$\tau = 25214.97 \text{ sec}$$
$$\tau = 7 \text{ h}$$

Therefore, the time taken to brick reach the temperature of 1100°C is $\boxed{7 \text{ h}}$.

Question:

18.027P

Carbon steel balls (ρ = 7833 kg/m3 , k = 54 W/m·K. cp = 0.465 kJ/kg·°C, and α = 1.474 × 10-6 m/s) 8 mm in diameter are annealed by heating them first to 900°C in a furnace and then allowing them to cool slowly to 100°C in ambient air at 35°C. If the average heat transfer coefficient is 75 W/m2 ·K, determine how long the annealing process will take. If 2500 balls are to be annealed per hour, determine the total rate of heat transfer from the balls to the ambient air.

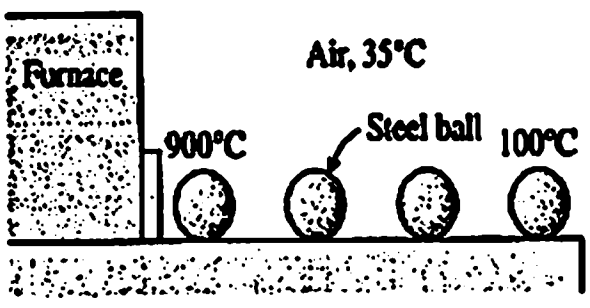


FIGURE P18-27

Step 1 of 5

Given:

Diameter of carbon ball, D_c = 1.2 cm

Question:

Carbon steel balls (ρ = 7833 kg/m3 , k = 54 W/m·K. cp = 0.465 kJ/kg·°C, and α = 1.474 × 10-6 m/s) 8 mm in diameter are annealed by heating them first to 900°C in a furnace and then allowing them to cool slowly to 100°C in ambient air at 35°C. If the average heat transfer coefficient is 75 W/m2 ·K, determine how long the annealing process will take. If 2500 balls are to be annealed per hour, determine the total rate of heat transfer from the balls to the ambient air.

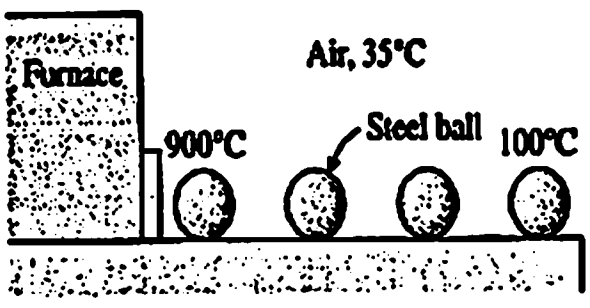

FIGURE P18-27

Step 1 of 5

Given:

Diameter of carbon ball, D_c = 1.2 cm

$$\frac{A_s}{}$$

$$L_c = \frac{\pi D^3/6}{\pi D^2}$$

$$L_c = \frac{D}{6}$$

$$L_c = \frac{0.008\ \text{m}}{6}$$

$$L_c = 0.0013\ \text{m}$$

The Biot number $Bi = \frac{hL_c}{k}$

$$Bi = \frac{(75\ \text{W/m}^2.^\circ\text{C})(0.0013\ \text{m})}{(54\ \text{W/m.}^\circ\text{C})}$$

$$Bi = 0.0018 < 0.1$$

Step 4 of 5

Therefore, the lumped system analysis is applicable. Then the time for the annealing process is determined to be

The value of exponent $b = \frac{hA_s}{\rho C_p V}$

$$b = \frac{h}{\rho C_p L_c}$$

$$b = \frac{75\ \text{W/m}^2.^\circ\text{C}}{(7833\ \text{kg/m}^3)(465\ \text{J/kg.}^\circ\text{C})(0.0013\ \text{m})}$$

$$b = 0.01584\ s^{-1}$$

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

$$\frac{100-35}{900-35} = e^{-(0.01584\ s^{-1})t}$$

t=163 s

t=2.7 min

Step 5 of 5

The amount of heat transfer from a single ball is

The mass $m = \rho V$

$$m = \rho\frac{\pi D^3}{6}$$

$$m = (7833\ \text{kg/m}^3)\frac{\pi(0.008\ \text{m})^3}{6}$$

$$m = 0.0021\ \text{kg}$$

The heat transfer from a ball

$Q = mC_p[T_f - T_i]$

$Q = (0.0021\ \text{kg})(465\ \text{J/kg.}^\circ\text{C})(900-100)^\circ\text{C}$

$Q = 781\ \text{J}$

$Q = 0.781\ \text{kJ}$ (per ball)

Then the total rate of heat transfer from the balls to the ambient air becomes

$\dot{Q} = \dot{n}_{ball} Q$

$\dot{Q} = (2500\ \text{balls/h}) \times (0.781\ \text{kJ/ball})$

$\dot{Q} = 1{,}953\ \text{kJ/h}$

$\dot{Q}$=543 W

Question: 18.028P

Reconsider Prob. 18-27. Using EES (or other) software, investigate the effect of the initial temperature of the balls on the annealing time and the total rate of heat transfer. Let the temperature vary from 500°C to 1000°C. Plot the time and the total rate of heat transfer as a function of the initial temperature, and discuss the results.

Step 1 of 3

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box
"GIVEN"
D=0.008 "[m]"
"T_i=900 [C], parameter to be varied"
T_f=100 "[C]"
T_infinity=35 "[C]"
h=75 "[W/m^2-C]"
n_dot_ball=2500 "[1/h]"
"PROPERTIES"

Question: 18.029P

An electronic device dissipating 18 W has a mass of 20 g, a specific heat of 850 J/kg·K, and a surface area of 4 cm2 . The device is lightly used, and it is on for 5 min and then off for several hours, during which it cools to the ambient temperature of 25°C. Taking the heat transfer coefficient to be 12 W/m2 -K, determine the temperature of the device at the end of the 5-min operating period. What would your answer be if the device were attached to an aluminum heat sink having a mass of 200 g and a surface area of 80 cm2 ? Assume the device and the heat sink to be nearly isothermal.

Step 1 of 3

Calculate the rate of heat loss from the electronic device.

$$Q = hA_s\left(\frac{T+T_\infty}{2}\right)\Delta t$$

Here, heat transfer coefficient is h, surface area of the device is A_s and time is t.

Substitute $12\ \mathrm{W/m^2\cdot K}$ for h, $4\times10^{-4}\ \mathrm{m^2}$ for A_s, $25°\mathrm{C}$ for T_∞ and $5\times60\ \mathrm{sec}$ for Δt.

$$Q = 12\times4\times10^{-4}\times\left(\frac{T+25}{2}\right)\times300$$
$$= 0.72(T+25)\ \mathrm{J}$$

Step 2 of 3

Write the energy balance on the device.

$$\Delta E_{device} = E_{in} - E_{out} + E_{generation}$$
$$mC_p\Delta T_{device} = -\dot{Q}_{out}\Delta t + \dot{E}_{generation}\Delta t \quad \text{..... (1)}$$
$$mC_p(T-T_\infty) = \dot{E}_{generation}\Delta t - hA_s\left(\frac{T+T_\infty}{2}\right)\Delta t$$

Here, mass of the electronic device is m and specific heat of the electronic device is c_p.

Substitute $0.72(T+25)$ for Q, $0.02\ \mathrm{kg}$ for m, $850\ \mathrm{J/kg\cdot K}$ for c_p, $300\ \mathrm{sec}$ for Δt and $18\ \mathrm{W}$ for E_g in equation (1).

$$18\times300 - 0.72(T+25) = 0.02\times850\times(T-25)$$
$$5400 - 0.72T - 18 = 17T - 425$$
$$17.72T = 5807$$
$$T = 327.7°\mathrm{C}$$

Therefore, the temperature of the electronic device after 5 min time is $\boxed{327.7°\mathrm{C}}$.

Step 3 of 3

Calculate the temperature of the electronic device when it is attached to an aluminum heat sink having mass $0.2\ \mathrm{kg}$.

$$\dot{E}_{generation}\Delta t - hA_s\left(\frac{T+T_\infty}{2}\right)\Delta t = (m+m_a)c_p(T-T_\infty) \quad \text{..... (2)}$$

Here, mass of the electronic device is m, mass of aluminum heat sink is m_a and specific heat of the electronic device is c_p.

Substitute $0.72(T+25)$ for Q, $0.02\ \mathrm{kg}$ for m, $0.2\ \mathrm{kg}$ for m_a, $850\ \mathrm{J/kg\cdot K}$ for c_p, $300\ \mathrm{sec}$ for Δt and $18\ \mathrm{W}$ for E_g in equation (2).

$$18\times300 - 0.72(T+25) = (0.02+0.2)\times850\times(T-25)$$
$$5400 - 0.72T - 18 = 187T - 4675$$
$$187.72T = 10057$$
$$T = 53.57°\mathrm{C}$$

Therefore, the temperature of electronic device with an aluminum heat sink attachment is $\boxed{53.57°\mathrm{C}}$.

Question: 18.030P

An egg is to be cooked to a certain level of doneness by being dropped into boiling water. Can the cooking time be shortened by turning up the heat and bringing water to a more rapid boiling?

Step 1 of 2

Assume the temperature of the egg at room temperature $(T_R = 30°C)$ is cooked in boiling water which is at $T_f = 80°C$, the rate of heat transfer from the boiling water to the egg is more when compared to the egg boiling in the water at room temperature. Now calculate the heat transfer rate of the egg boiling hot water at temperature

Consider the mass of the egg as m and the specific heat of water as c_p. The quantity of heat transfer rate for the egg boiling in the water at 100°C is given by

$$\begin{aligned} Q_{boil} &= mc_p(\Delta T) \\ &= mc_p(T_f - T_R) \\ &= mc_p(80-30) \\ &= 50mc_p \end{aligned}$$

Step 2 of 2

Now consider the egg is at temperature $(T_{egg} = 24°C)$ and water is at room temperature $T_R = 30°C$ then the rate of heat transfer from water to the egg on boiling is given by

$$\begin{aligned} Q_{room} &= mc_p(\Delta T) \\ &= mc_p(T_R - T_{egg}) \\ &= mc_p(30-24) \\ &= 6mc_p \end{aligned}$$

From the above obtained heat transfer rate on comparing $Q_{boil} > Q_{room}$
The time required for cooking the egg in boiled water is less when compared to the water at room temperature.

The cooking of the egg depends on the following parameters

1. size of the egg
2. temperature of the egg before cooking
3. heat transfer coefficient

Question: 18.031P

What is an infinitely long cylinder? When is it proper to treat an actual cylinder as being infinitely long, and when is it not? For example, is it proper to use this model when finding the temperatures near the bottom or top surfaces of a cylinder? Explain.

Step 1 of 1

A cylinder whose diameter is small relative to its length is called infinitely long cylinder. When the diameter and length of the cylinder are comparable, it is not proper to treat the cylinder as being infinitely long. It is also not proper to use this model when finding the temperatures near the bottom or top surfaces of a cylinder since heat transfer at those locations can be two-dimensional.

Question: 18.032P

Can the transient temperature charts in Fig. 18-15 for a plane wall exposed to convection on both sides be used for a plane wall with one side exposed to convection while the other side is insulated? Explain.

Step 1 of 1

Yes. A plane wall whose one side is insulated is equivalent to a plane wall that is twice as thick and is exposed to convection from both sides. The midplane in the latter case will behave like an insulated surface because of thermal symmetry.

Question: 18.033P

Why are the transient temperature charts prepared using nondimensionalized quantities such as the Biot and Fourier numbers instead of the actual variables such as thermal conductivity and time?

Step 1 of 1

The solution for determination of the one-dimensional transient temperature distribution involves many variables that make the graphical representation of the results impractical. In order to reduce the number of parameters, some variables are grouped into dimensionless quantities.

Question: 18.034P

What is the physical significance of the Fourier number? Will the Fourier number for a specified heat transfer problem double when the time is doubled?

Step 1 of 1

The Fourier number is a measure of heat conducted through a body relative to the heat stored. Thus a large value of Fourier number indicates faster propagation of heat through body. Since Fourier number is proportional to time, doubling the time will also double the Fourier number.

Question: 18.035P

How can we use the transient temperature charts when the surface temperature of the geometry is specified instead of the temperature of the surrounding medium and the convection heat transfer coefficient?

Step 1 of 1

This case can be handled by setting the heat transfer coefficient h to infinity ∞ since the temperature of the surrounding medium in this case becomes equivalent to the surface temperature.

Question: 18.036P

A body at an initial temperature of T_i is brought into a medium at a constant temperature of T_∞ . How can you determine the maximum possible amount of heat transfer between the body and the surrounding medium?

Step 1 of 1

Loading solution. Please wait ...

Question: 18.037P

The Biot number during a heat transfer process between a sphere and its surroundings is determined to be 0.02. Would you use lumped system analysis or the transient temperature charts when determining the midpoint temperature of the sphere? Why?

Step 1 of 1

When the Biot number is less than 0.1, the temperature of the sphere will be nearly uniform at all times. Therefore, it is more convenient to use the lumped system analysis in this case.

Question: 18.038P

A long cylindrical wood log (k = 0.17 W/m2·K and α = 1.28 × 10-7 m2 /s) is 10 cm in diameter and is initially at a uniform temperature of 25°C. It is exposed to hot gases at 600°C in a fireplace with a heat transfer coefficient of 13.6 W/m2 ·K on the surface. If the ignition temperature of the wood is 420°C, determine how long it will be before the log ignites.

Step 1 of 2

Obtain the constants λ_1 and A_1 corresponding to the Biot number, $\mathrm{Bi}=4$ from the table "coefficient used for in dimensional approximation of transient one dimensional heat conduction in cylinder",

$$\lambda_1 = 1.9081$$

$$A_1 = 1.4698$$

Calculate the Fourier number by using the equation,

$$\frac{T(r_o,t)-T_\infty}{T_i-T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

Here,

Temperature of hot gases T_∞

Wooden log temperature T_i

Ignition temperature of wood, $T(r_o,t)$

Substitute $420°C$ for $T(r_o,t)$, $600°C$ for T_∞, $25°C$ for T_i . 1.4698 for A_1. 1.9081 for λ_1

$$\frac{T(r_o,t)-T_\infty}{T_i-T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{420-600}{25-600} = (1.4698)e^{-(1.9081)^2 \tau}$$

$$0.313 = 1.4698e^{-(1.9081)^2 \tau}$$

$$0.21295 = e^{-(1.9081)^2 \tau}$$

$$\tau = 0.424$$

Step 2 of 2

Calculate the length of time before the log ignites, by using the dimensionless number, Fourier number,

$$\tau = \frac{\alpha t}{r_o^2}$$

$$t = \frac{\tau r_o^2}{\alpha}$$

Here,

Time taken to reach the log final temperature is t and Thermal diffusivity is α

Substitute 0.424 for τ, $1.28\times10^{-7}\ \mathrm{m^2/s}$ for α, $0.05\,\mathrm{m}$ for r_0

$$t = \frac{\tau r_o^2}{\alpha}$$

$$= \frac{0.424\times0.05^{\,2}}{1.28\times10^{-7}}$$

$$= 8281.25\ \mathrm{s}$$

$$= \frac{8281.25}{3600}$$

$$= 2.3003\,\mathrm{hr}$$

Therefore, the length of time before the log ignites is $\boxed{2.300\,\mathrm{hr}}$

Question: 18.039P

An experiment is to be conducted to determine heat transfer coefficient on the surfaces of tomatoes that are placed in cold water at 7°C. The tomatoes (k = 0.59 W/m-K, α= 0.141 × 10-6 m2 /s, ρ = 999 kg/m3 , cp = 3.99 kJ/kg-K) with an initial uniform temperature of 30°C are spherical in shape with a diameter of 8 cm. After a period of 2 hours, the temperatures at the center and the surface of the tomatoes are measured to be 10.0°C and 7.1°C, respectively. Using analytical one-term approximation method (not the Heisler charts), determine the heat transfer coefficient and the amount of heat transfer during this period if there are eight such tomatoes in water.

Step 1 of 5

Calculate the radius of the tomato.

$$r_o = \frac{D}{2}$$

Here, D is the diameter of the tomato.

Substitute 0.08 m for D.

$$r_o = \frac{0.08\ \text{m}}{2}$$
$$= 0.04\ \text{m}$$

Calculate the Fourier number by using the relation,

$$\tau = \frac{\alpha t}{r_o^2}$$

Here, τ is the Fourier number, α is the thermal diffusivity of the material, and t is the time.

Substitute $0.141\times10^{-6}\ \text{m}^2/\text{s}$ for α , $2\times3600\ \text{s}$ for t, and $0.04\ \text{m}$ for r_o .

$$\tau = \frac{0.141\times10^{-6}\ \text{m}^2/\text{s}(2\times3600\ \text{s})}{(0.04\ \text{m})^2}$$
$$= 0.6345$$

As the Fourier number is more than 0.2, the one term solution is applicable.

Step 2 of 5

Calculate the value of λ_1 from the ratio of dimensionless temperatures at the surface and the center of the tomatoes.

$$\frac{\theta_{s,sph}}{\theta_{o,sph}} = \frac{\left(\frac{T_s - T_\infty}{T_i - T_\infty}\right)}{\left(\frac{T_o - T_\infty}{T_i - T_\infty}\right)}$$
$$= \frac{T_s - T_\infty}{T_o - T_\infty}$$
$$= \frac{A_1 e^{-\lambda_1^2\tau}\frac{\sin(\lambda_1)}{\lambda_1}}{A_1 e^{-\lambda_1^2\tau}}$$
$$= \frac{\sin(\lambda_1)}{\lambda_1}$$

Here, $\theta_{s,sph}$ is the dimensionless temperature at the surface, $\theta_{o,sph}$ is the dimensionless temperature at the center of the surface, T_s is the surface temperature of the tomato, T_∞ is the temperature of the cold water, T_i is the initial temperature of the tomato, T_o is the temperature at the center of the tomato, A_1 and λ_1 are the constants.

Substitute $7.1°\text{C}$ for T_s , $7°\text{C}$ for T_∞ , and $10°\text{C}$ for T_o .

$$\frac{T_s - T_\infty}{T_o - T_\infty} = \frac{\sin(\lambda_1)}{\lambda_1}$$
$$\frac{7.1°\text{C} - 7°\text{C}}{10°\text{C} - 7°\text{C}} = \frac{\sin(\lambda_1)}{\lambda_1}$$
$$\frac{0.1}{3} = \frac{\sin(\lambda_1)}{\lambda_1}$$
$$0.03334 = \frac{\sin\left(\lambda_1 \times \frac{180}{\pi}\right)}{\lambda_1}$$

From the calculation,

$$\lambda_1 = 3.0401.$$

Step 3 of 5

Obtain the Biot number from the table 4-2 corresponding to the value of λ_1 (3.0401) for sphere by interpolation.

$$\text{Bi} = 30 + \frac{40-30}{3.0632-3.0372}(3.0401-3.0372)$$
$$= 30 + 1.11$$
$$= 31.11$$

Calculate the convective heat transfer coefficient by using the relation,

$$\text{Bi} = \frac{hr_o}{k}$$
$$h = \frac{\text{Bi}\times k}{r_o}$$

Here, h is the convective heat transfer coefficient, and k is the thermal conductivity of the tomato.

Substitute 31.11 for Bi , 0.04 m for r_o , and $0.59\ \text{W/m}\cdot\text{K}$ for k.

$$h = \frac{31.1\times0.59\ \text{W/m}\cdot\text{K}}{0.04\ \text{m}}$$
$$= 458.95\ \text{W/m}^2\cdot\text{K}$$

Therefore, the heat transfer coefficient is $\boxed{458.95\ \text{W/m}^2\cdot\text{K}}$.

Step 4 of 5

Calculate the mass of eight tomatoes by using the relation,

$$m = 8\rho V$$
$$= 8\rho\frac{\pi D^3}{6}$$

Here, ρ is the density of the tomato, and D is the diameter of the tomato.

Substitute $999\ \text{kg/m}^3$ for ρ , and $0.08\ \text{m}$ for D.

$$m = (8\times999)\frac{\pi\times0.08^3}{6}$$
$$= 2.1425\ \text{kg}$$

Calculate the maximum heat transfer rate by using the relation,

$$Q_{max} = mc_p(T_i - T_\infty)$$

Substitute $2.1425\ \text{kg}$ for m, $3.99\ \text{kJ/kg}\cdot\text{K}$ for c_p , $30+273\ \text{K}$ for T_i , and $7+273\ \text{K}$ for T_∞ .

$$Q_{max} = 2.1425\times3.99[(30+273)-(7+273)]$$
$$= 196.62\ \text{kJ}$$

Step 5 of 5

Calculate the actual amount of heat transferred by using the relation,

$$\left(\frac{Q}{Q_{max}}\right)_{sph} = 1 - 3\theta_{o,sph}\frac{\sin\lambda_1 - \lambda_1\cos\lambda_1}{\lambda_1^3}$$
$$= 1 - 3\left(\frac{T_o - T_\infty}{T_i - T_\infty}\right)\frac{\sin\lambda_1 - \lambda_1\cos\lambda_1}{\lambda_1^3}$$

Here, Q is the actual amount of heat transferred.

Substitute $196.62\ \text{kJ}$ for Q_{max} , $7°\text{C}$ for T_∞ , $10°\text{C}$ for T_o , $30°\text{C}$ for T_i , and 3.0401 for λ_1 .

$$\left(\frac{Q}{196.62\ \text{kJ}}\right)_{sph} = 1 - 3\left(\frac{10°\text{C} - 7°\text{C}}{30°\text{C} - 7°\text{C}}\right)\frac{\sin3.0401 - 3.0401\cos3.0401}{3.0401^3}$$
$$\frac{Q}{196.62\ \text{kJ}} = 0.9564$$
$$Q = 188.04\ \text{kJ}$$

Therefore, the amount of heat transferred during the period of 2 hours is $\boxed{188.04\ \text{kJ}}$.

Question: 18.040P

In an annealing process, a 50-mm-thick stainless steel plate (p = 8238 kg/m3 , cp = 468 J/kg·K, k = 13.4 W/m·K, and α = 3.48 × 10-6 m2 /s) was reheated in a furnace from an initial uniform temperature of 230°C. The ambient temperature inside the furnace is at a uniform temperature of 1000°C and has a convection heat transfer coefficient of 215 W/m2 ·K. If the entire stainless steel plate is to be heated to at least 600°C, determine the time that the plate should be heated in the furnace using (*a*) Table 18-2 (*b*) the Heisler chart (Figure 18-15).

Step 1 of 5

Calculate the Biot number by using the relation,

$$\mathrm{Bi} = \frac{hL}{k}$$

Here, h is the convection heat transfer coefficient, and k is the thermal conductivity of the brass plate.

Substitute $215\ \mathrm{W/m^2 \cdot K}$ for h, $0.025\ \mathrm{m}$ for L . $13.4\ \mathrm{W/m \cdot K}$ for k.

$$\mathrm{Bi} = \frac{(215\ \mathrm{W/m^2 \cdot K})(0.025\ \mathrm{m})}{13.4\ \mathrm{W/m \cdot K}}$$
$$= 0.4$$

Obtain the constant λ_1 and A_1 from table 4-2 at $\mathrm{Bi} = 0.4$ (For plane wall).

$$\lambda_1 = 0.5932$$

$$A_1 = 1.0580$$

Step 2 of 5

Calculate the Fourier number by using the dimensionless temperature relation,

$$\theta_{0,\mathrm{wall}} = \frac{T_o - T_\infty}{T_i - T_\infty}$$
$$= A_1 e^{-\lambda_1^2 \tau}$$

Here, T_o is the center plane temperature of the plate after heating, T_∞ is the ambient temperature of the furnace, T_i is the initial temperature of the plate, A_1 and λ_1 are the constants, and τ is the Fourier number.

Substitute $600°\mathrm{C}$ for T_o . $1000°\mathrm{C}$ for T_∞ . $230°\mathrm{C}$ for T_i . 0.5932 for λ_1 , and 1.0580 for A_1 .

$$\frac{T_o - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$
$$\frac{600°\mathrm{C} - 1000°\mathrm{C}}{230°\mathrm{C} - 1000°\mathrm{C}} = (1.0580) e^{-(0.5932)^2 \tau}$$
$$0.52 = (1.0580) e^{-(0.5932)^2 \tau}$$
$$0.491 = e^{-(0.5932)^2 \tau}$$
$$\tau = 2.021$$

Step 3 of 5

Calculate the time that the plate should be heated in the furnace by using the relation,

$$\tau = \frac{\alpha t}{L^2}$$
$$t = \frac{\tau L^2}{\alpha}$$

Here, t is the time that plate should be heated, α is the thermal diffusivity, and L is the critical length.

Substitute 2.021 for τ , $0.025\ \mathrm{m}$ for L , and $3.48 \times 10^{-6}\ \mathrm{m^2/s}$ for α .

$$t = \frac{2.021 \times (0.025\ \mathrm{m})^2}{3.48 \times 10^{-6}\ \mathrm{m^2/s}}$$
$$= 362.97\ \mathrm{s}$$

Therefore, the time that the plate should be heated in the furnace is $\boxed{362.97\ \mathrm{s}}$.

Step 4 of 5

b)

Calculate the inverse of the Biot number.

$$\frac{1}{\mathrm{Bi}} = \frac{1}{0.4}$$
$$= 2.5$$

Calculate the dimensionless temperature of the plate by using the relation,

$$\theta_{0,\mathrm{wall}} = \frac{T_o - T_\infty}{T_i - T_\infty}$$

Substitute $600°\mathrm{C}$ for T_o , and $1000°\mathrm{C}$ for T_∞ . $230°\mathrm{C}$ for T_i .

$$\theta_{0,\mathrm{wall}} = \frac{600°\mathrm{C} - 1000°\mathrm{C}}{230°\mathrm{C} - 1000°\mathrm{C}}$$
$$= 0.52$$

Step 5 of 5

Obtain the Fourier number from the Heisler chart (Figure 4-16 (*a*)) corresponding to the value of 2.5 for $\frac{1}{\mathrm{Bi}}$ and 0.52 for $\theta_{0,\mathrm{wall}}$.

$$\tau = 2.1$$

Calculate the time that the plate should be heated in the furnace by using the relation,

$$t = \frac{\tau L^2}{\alpha}$$

Substitute 2.1 for τ , $0.025\ \mathrm{m}$ for L , and $3.48 \times 10^{-6}\ \mathrm{m^2/s}$ for α .

$$t = \frac{2.1 \times (0.025\ \mathrm{m})^2}{3.48 \times 10^{-6}\ \mathrm{m^2/s}}$$
$$= 377.15\ \mathrm{s}$$

Therefore, the time that the plate should be heated in the furnace is $\boxed{377.15\ \mathrm{s}}$.

Question: 18.041P

An ordinary egg can be approximated as a 5.5- cm diameter sphere whose properties are roughly k = 0.6 W/m·k and α = 0.14 × 10-6 m2 /s. The egg is initially at a uniform temperature of 4°C and is dropped into boiling water at 97°C. Taking the convection heat transfer coefficient to be h = 1400 W/m2 ·K, determine how long it will take for center of the egg to reach 70°C.

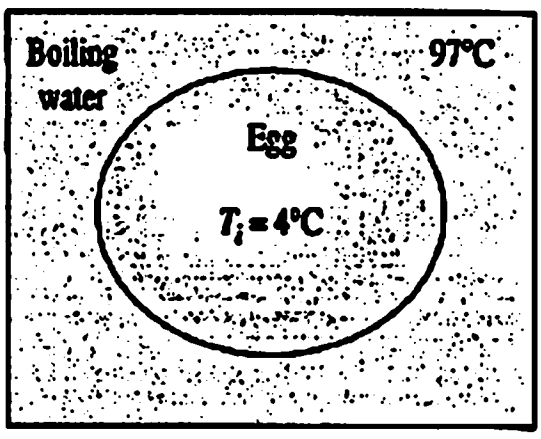

FIGURE P 18-41

Step 1 of 4

Given data:

Diameter of egg $D = 5.5$ cm.

Thermal conductivity of egg $k = 0.6\ W/m^2 \cdot K$.

Thermal diffusivity of egg $\alpha = 0.14 \times 10^{-6}\ m^2/s$.

Initial temperature of egg $T_i = 4°C$.

Temperature of boiling water $T_\infty = 97°C$.

Final temperature of egg $T(t) = 70°C$.

Heat transfer coefficient $h = 1400\ W/m^2 \cdot K$.

Egg is spherical in shape with a radius of $r_0 = 2.75$ cm.

Step 2 of 4

If the heat conduction in the egg is one-dimensional because of symmetry about the midpoint and the thermal properties of the egg are constant

The Biot number for this process is

$$Bi = \frac{hr_o}{k}$$

$$= \frac{(1400\ W/m^2.°C)(0.0275\ m)}{(0.6\ W/m.°C)}$$

$$= 64.2$$

Since Biot number is greater than 0.1, and thus lumped system analysis is not applicable.

The coefficient λ_1 and A_1 for a cylinder corresponding to the Bi number are

From the coefficient used for in dimensional approximation of transient one dimensional heat conduction in cylinder is

For this Biot number, we get $\lambda = 3.0877$, $A = 1.9969$

Step 3 of 4

Then one term approximation is

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = Ae^{-\lambda^2 \tau}$$

$$\frac{70 - 97}{4 - 97} = 1.9969e^{-3.0877^2 \tau}$$

$$\tau = 0.202$$

This is above the value of 0.2. Therefore, the one-term approximate solution be used.

Step 4 of 4

Then the length of time will take for center of the egg to reach 70°C is determined from the Fourier number to be

$$t = \frac{\tau r_o^2}{\alpha}$$

$$= \frac{0.2 \times 0.0275^2}{0.14 \times 10^{-6}}$$

$$= 18\ min$$

Therefore, the time needed for the centre of egg to reach 70° C is $\boxed{18\ min}$.

Question: 18.042P

Reconsider Prob. 18-41. Using EES (or other) software, investigate the effect of the final center temperature of the egg on the time it will take for the center to reach this temperature. Let the temperature vary from 50°C to 95°C. Plot the time versus the temperature, and discuss the results.

Step 1 of 4

Given data:

Diameter of egg, $D = 5.5$ cm

Thermal conductivity of egg, $k = 0.6\,W/m \cdot K$

Thermal diffusivity of egg, $\alpha = 0.14 \times 10^{-6}\ m^2/s$

Initial temperature of egg, $T_i = 8°C$

Temperature of boiling water, $T_\infty = 97°C$

Final temperature of egg, $T_o = 70°C$

Heat transfer coefficient, $h = 1400\ W/m^2 \cdot K$

Egg is spherical in shape with a radius, $r_0 = 2.75$ cm

Step 2 of 4

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"

Question: 18.043P

In a production facility, 3-cm-thick large brass plates (k - 110 W/m2 ·K, ρ - 8530 kg/m3 , $c\rho$ = 380 J/kg-K. and α = 33.9 × 10-6 m2 /s) that are initially at a uniform temperature of 25°C are heated by passing them through an oven maintained at 700°C. The plates remain in the oven for a period of 10 min. Taking the convection heat transfer coefficient to be h = 80 W/m2 ·K, determine the surface temperature of the plates when they come out of the oven.

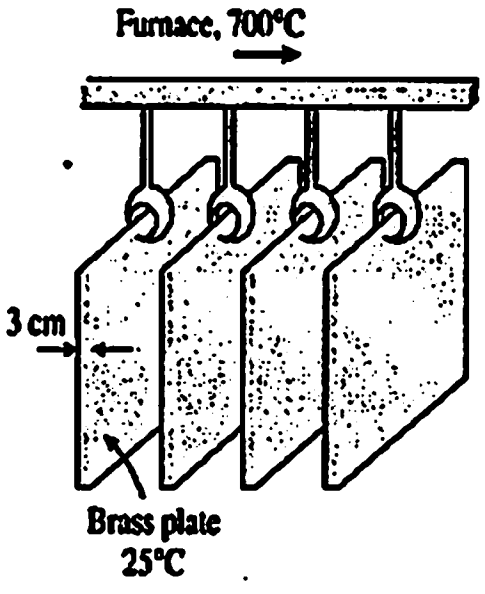

FIGURE P 18-43

Step 1 of 3

Given:

Thickness of brass plate $t = 3$ cm

Thermal conductivity of brass $k = 110$ W/m.°C

Density of brass $\rho = 8530$ kg/m^3

Specific heat of brass $C_p = 380$ J/kg.°C

Thermal diffusivity of brass $\alpha = 33.9\times10^{-6}$ m^2/s

Temperature of oven $T_\infty = 700$°C

The initial temperature $T_i = 25$°C

Plate remain in the oven $t = 10$ min

Step 2 of 3

Heat conduction in the plate is one-dimensional since the plate is large relative to its thickness and there is thermal symmetry about the center plane.

The thermal properties of the plate are constant.

The heat transfer coefficient is constant and uniform over the entire surface.

The Fourier number is $\tau > 0.2$ so that the one-term approximate solutions (or the transient temperature charts) are applicable (this assumption will be verified).

The Biot number for this process $Bi = \dfrac{hL}{k}$

$$Bi = \frac{(80\ \text{W/m}^2.^\circ\text{C})(0.015\ \text{m})}{(110\ \text{W/m.}^\circ\text{C})}$$

$$Bi = 0.0109$$

The constants λ_1 and A_1 corresponding to this Biot number are, from 11-2 tables

The interpolation method used to find the

$$\lambda_1 = 0.1039 \quad \text{and} \quad A_1 = 1.0018$$

The Fourier number $\tau = \dfrac{\alpha t}{L^2}$

$$\tau = \frac{(33.9\times10^{-6}\ \text{m}^2/\text{s})(10\ \text{min}\times60\ \text{s/min})}{(0.015\ \text{m})^2}$$

$$\tau = 90.4 > 0.2$$

Step 3 of 3

Therefore, the one-term approximate solution (or the transient temperature charts) is applicable. Then the temperature at the surface of the plates becomes

$$\theta(L,t)_{wall} = \frac{T(x,t)-T_\infty}{T_i-T_\infty}$$

$$\theta(L,t)_{wall} = A_1 e^{-\lambda_1^2\tau}\cos(\lambda_1 L/L)$$

$$\theta(L,t)_{wall} = (1.0018)e^{-(0.1039)^2(90.4)}\cos(0.1039)$$

$$\theta(L,t)_{wall} = 0.378$$

$$\frac{T(L,t)-700}{25-700} = 0.378$$

$$\boxed{T(L,t) = 445\ ^\circ\text{C}}$$

Question:

Reconsider Prob. 18-43. Using EES (or other) software, investigate the effects of the temperature of the oven and the heating time on the final surface temperature of the plates. Let the oven temperature vary from 500°C to 900°C and the time from 2 min to 30 min. Plot the surface temperature as the functions of the oven temperature and the time, and discuss the results.

Step 12 of 12

Question: 18.045P

A long 35-cm-diameter cylindrical shaft made of stainless steel 304 (k = 14.9 W/m2·K, ρ = 7900 kg/m3 , cp = 477 J/kg·K, and α = 3.95 × 10-6 m2 /s) comes out of an oven at a uniform temperature of 500°C. The shaft is then allowed to cool slowly in a chamber at 150°C with an average convection heat transfer coefficient of h = 60 W/m2 ·K. Determine the temperature at the center of the shaft 20 min after the start of the cooling process. Also, determine the heat transfer per unit length of the shaft during this time period.

Step 1 of 7

Calculate the Biot number by using the equation as shown below.

$$\text{Bi} = \frac{hr_o}{k}$$

Here, the heat transfer coefficient is h, the radius is r_o and the thermal conductivity is k.

Substitute $60\ \text{W/m}^2\cdot\text{K}$ for h, $0.175\ \text{m}$ for r_o and $14.9\ \text{W/m}\cdot\text{K}$ for k.

$$\text{Bi} = \frac{(60\ \text{W/m}^2\cdot\text{K})(0.175\ \text{m})}{(14.9\ \text{W/m}\cdot\text{K})}$$
$$= 0.705$$

Since $Bi > 0.1$, and thus lumped system analysis is not applicable.

Step 2 of 7

From the coefficient used for in dimensional approximation of transient one dimensional heat conduction in cylinder,

Obtain the values of the coefficients λ and A for a cylinder corresponding to this Biot number.

$$\lambda = 1.0935\ ,\ A = 1.1558$$

Calculate the Fourier number by using the equation as shown below.

$$t = \frac{\tau r_o^2}{\alpha}$$

Here, the thermal diffusivity is α.

Step 3 of 7

Substitute $(20\times 60)\text{sec}$ for t and $3.95\times10^{-6}\ \text{m}^2/\text{s}$ for α.

$$20\times 60 = \frac{\tau\times 0.175^2}{3.95\times10^{-6}}$$
$$\tau = 0.155$$

This is very close to the value of 0.2.

Therefore, the one-term approximate solution (or the transient temperature charts) is applicable with an error of more than 2 percent.

Step 4 of 7

Calculate the temperature at the center of the shaft by using the equation as shown below.

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = Ae^{-\lambda^2\tau}$$

Substitute the known values in the above equation.

$$\frac{T(t)-150}{500-150} = 1.1558e^{-(1.0935)^2\times0.155}$$
$$T(t) = 486°\text{C}$$

Step 5 of 7

Therefore, the temperature at the center of the shaft is $\boxed{486°\text{C}}$.

Determine the maximum heat can be transferred from the cylinder per meter of its length.

Calculate the mass of the stainless steel cylinder per meter of its length.

$$m = \rho V$$

Step 4 of 7

Calculate the temperature at the center of the shaft by using the equation as shown below.

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = Ae^{-\lambda^2\tau}$$

Substitute the known values in the above equation.

$$\frac{T(t)-150}{500-150} = 1.1558e^{-(1.0935)^2\times0.155}$$
$$T(t) = 486°\text{C}$$

Step 5 of 7

Therefore, the temperature at the center of the shaft is $\boxed{486°\text{C}}$.

Determine the maximum heat can be transferred from the cylinder per meter of its length.

Calculate the mass of the stainless steel cylinder per meter of its length.

$$m = \rho V$$

1	0.440
1.1	0.4709
1.0935	x

$$\frac{1.0935-1}{1.1-1} = \frac{x-0.440}{0.4709-0.440}$$
$$\frac{0.0935}{0.1} = \frac{x-0.440}{0.0309}$$
$$x = 0.4689$$

Step 7 of 7

Calculate the actual heat transfer by using the equation as shown below.

$$\left(\frac{Q}{Q_{max}}\right)_{cyl} = 1-2\left(\frac{T_0-T_\infty}{T_i-T_\infty}\right)\frac{J_1(\lambda_1)}{\lambda_1}$$

Substitute the known values in the above equation.

$$\frac{Q}{126882} = 1-2\left(\frac{486-150}{500-150}\right)\times\frac{0.4689}{1.0935}$$
$$Q = 22420\ \text{kJ}$$

Therefore, heat transfer per unit length is $\boxed{Q = 22420\ \text{kJ}}$

Question: 18.046P

Reconsider Prob. 18-45. Using EES (or other) software, investigate the effect of the cooling time on the final center temperature of the shaft and the amount of heat transfer. Let the time vary from 5 min to 60 min. Plot the center temperature and the heat transfer as a function of the time, and discuss the results.

Step 1 of 6

Given data:

Diameter of cylindrical shaft, $D = 35$ cm

Thermal conductivity of stainless steel at room temperature, $k = 14.9\ \text{W/m} \cdot \text{K}$

Density of stainless steel at room temperature, $\rho = 7900\ \text{kg/m}^3$

Specific heat of stainless steel at room temperature, $c_p = 477\ \text{J/kg} \cdot \text{K}$

Thermal diffusivity of stainless steel at room temperature, $\alpha = 3.95 \times 10^{-6}\ \text{m}^2/\text{s}$

Temperature of cylindrical shaft, $T_i = 500°\text{C}$

Heat transfer coefficient, $h = 60\ \text{W/m}^2.\text{K}$

Cooling Temperature, $T_\infty = 150°\text{C}$

Step 2 of 6

The procedure for developing solution by using EES software:

Open the new equations window EES software and type all the information which is used to solve the problem

For developing table:

1) Click on table followed by new parametric table and add the variables, which are varying variable and required answer variable, then one table will form with that variables

2) Click on the variable which is varying and enter initial value and final value.

3) For getting the required answer variable values corresponding to the varying variable values click on the green color button and then the table will form with required answers

For developing graph:

1) Click on plot followed by new plot window followed by x-y plot.

2) Select the x-axis variable and y-axis variable and then press ok, then the graph will form with the given values.

Step 3 of 6

The equations which are using in EES software for developing the solution are given in equations window is as shown below

Run 12	54394	60	382.2

Step 6 of 6

The EES software is developing the graph between T_0 and time is as shown below,

Question: 18.047P

Long cylindrical AISI stainless steel rods (k = 7.74 Btu/h·ft·°F and α = 0.135 ft2 /h) of 4-in-diameter are heat treated by drawing them at a velocity of 7 ft/min through a 21-ft-long oven maintained at 1700°F. The heat transfer coefficient in the oven is 20 Btu/h·ft2 ·°F. If the rods enter the oven at 70°F, determine their centerline temperature when they leave.

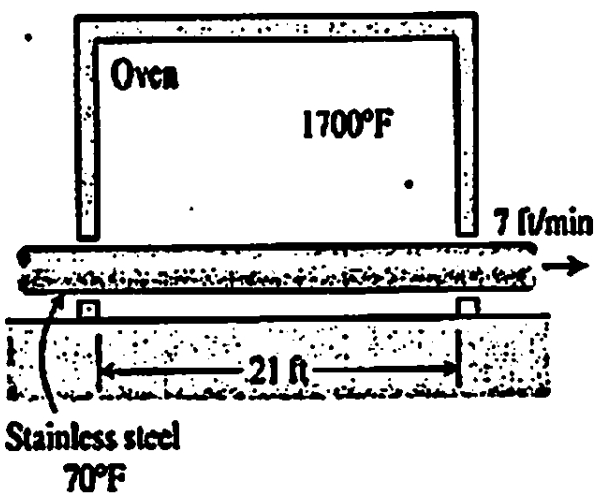

FIGURE P18-47E

Step 1 of 6

Assumptions:

Long cylindrical steel rods are heat-treated in an oven.

Heat conduction in the rods is one-dimensional since the rods are long and they have thermal symmetry about the center line.

The heat transfer coefficient is constant and uniform over the entire surface.

The Fourier number is > 0.2 so that the one-term approximate solutions are applicable.

Step 2 of 6

Find the time the steel rod stays in the oven by using the equation,

$$t = \frac{L}{V}$$

Here, L is length of the steel rod in an oven; V is velocity of steel rod drawing from the oven.

Substitute 21 ft for L, $7\,\text{ft/min}$ for V

$$t = \frac{21\,\text{ft}}{7\,\text{ft/min}}$$
$$= 3\,\text{min}$$
$$= \frac{3}{60}\,\text{h}$$

Step 3 of 6

Find the Fourier number by using the expression,

$$\tau = \frac{\alpha t}{r_o^2}$$

Here, α is thermal diffusivity of the rod, r_o is radius of the rod.

Substitute $0.135\,\text{ft}^2/\text{h}$ for α and $(2/12)\,\text{ft}$ for r_o

$$\tau = \frac{(0.135\ \text{ft}^2/\text{h})(3/60\ \text{h})}{(2/12\ \text{ft})^2}$$
$$= 0.243$$

Here the Fourier is greater than 0.2, the one-term approximate solutions are applicable.

Step 4 of 6

Find the Biot number by using the expression,

$$\text{Bi} = \frac{hr_o}{k}$$

Here, h is heat transfer coefficient; k is thermal conductivity of the rod.

Substitute $20\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ for h, $7.74\,\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$ for k

$$\text{Bi} = \frac{(20\ \text{Btu/h.ft}^2.{}^\circ\text{F})(2/12\ \text{ft})}{(7.74\ \text{Btu/h.ft.}{}^\circ\text{F})}$$
$$= 0.4306$$

Step 5 of 6

Obtain the constants λ_1 and A_1 corresponding to this Biot number from table "Coefficients used in the one term approximate solution of transient one dimensional heat conduction in cylinders" by using interpolation,

$$\lambda_1 = 0.8516 + (0.9408 - 0.8516)\left(\frac{0.4306 - 0.4}{0.5 - 0.4}\right)$$
$$= 0.8788$$

$$A_1 = 1.0931 + (1.1143 - 1.0931)\left(\frac{0.4306 - 0.4}{0.5 - 0.4}\right)$$
$$= 1.0995$$

Step 6 of 6

Find the temperature at the center of the rod, T_0 by using the equation,

$$\frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

Here, T_∞ is temperature of the oven, T_i is initial temperature of the steel rod that enters in to the oven

Substitute $1700°\text{F}$ for T_∞ and $70°\text{F}$ for T_i

$$\frac{x - 1700}{70 - 1700} = (1.0995)e^{-(0.8788)^2(0.243)}$$
$$T_0 = 214.474°\text{F}$$

Therefore, the center line temperature of the rod when it leaves from the oven is $\boxed{214.474°\text{F}}$

Question: 18.048P

In a meat processing plant, 2-cm-thick steaks (k = 0.45 W/m·K and α = 0.91 × 10-7 m2 /s) that are initially at 25°C are to be cooled by passing them through a refrigeration room at -11°C. The heat transfer coefficient on both sides of the steaks is 9 W/m2 ·K. If both surfaces of the steaks are to be cooled to 2°C, determine how long the steaks should be kept in the refrigeration room.

Step 1 of 4

Given:

Thickness of steaks $t = 2$ cm

Thermal conductivity of stainless steel at room temperature $k = 0.45$ W/m.°C

Thermal diffusivity of stainless steel at room temperature $\alpha = 0.91\times10^{-7}$ m^2/s

Initial temperature of meat $T_i = 25°C$

Temperature of refrigeration room $T_\infty = -11°C$

Heat transfer coefficient on both side of steak $h = 9$ W/m^2.°C

Step 2 of 4

Steaks are cooled by passing them through a refrigeration room.

Heat conduction in the steaks is one-dimensional since the steaks are large relative to their thickness and there is thermal symmetry about the center plane. The thermal properties of the steaks are constant. The heat transfer coefficient is constant and uniform over the entire surface.

The Fourier number is $\tau > 0.2$ so that the one-term approximate solutions (or the transient temperature charts) are applicable (this assumption will be verified).

Step 3 of 4

The Biot number $Bi = \dfrac{hL}{k}$

$$Bi = \frac{(9\ \text{W/m}^2.°\text{C})(0.01\ \text{m})}{(0.45\ \text{W/m.°C})}$$

$$Bi = 0.200$$

The constants λ_1 and A_1 corresponding to this Biot number are, from 11-2 tables

$$\lambda_1 = 0.4328 \quad \text{and} \quad A_1 = 1.0311$$

The Fourier number

$$\frac{T(L,t)-T_\infty}{T_i-T_\infty} = A_1 e^{-\lambda_1^2 \tau} \cos(\lambda_1 L/L)$$

$$\frac{2-(-11)}{25-(-11)} = (1.0311)e^{-(0.4328)^2 \tau} \cos(0.4328)$$

$$\tau = 5.601 > 0.2$$

Step 4 of 4

Therefore, the one-term approximate solution (or the transient temperature charts) is applicable. Then the length of time for the steaks to be kept in the refrigerator is determined to be

$$t = \frac{\tau L^2}{\alpha}$$

$$t = \frac{(5.601)(0.01\ \text{m})^2}{(0.91\times10^{-7}\ \text{m}^2/\text{s})}$$

$$t = 6155\ \text{s}$$

$$\boxed{\text{t=102.6 min}}$$

Question: 18.049P

A student calculates that the total heat transfer from a spherical copper ball of diameter 18 cm initially at 200°C and its environment at a constant temperature of 25°C during the first 20 min of cooling is 3150 kJ. Is this result reasonable? Why?

Step 1 of 3

Given data:

Diameter of the spherical ball is $D = 18\text{cm} = 0.18\text{ m}$

Initially temperature of the ball is $T_i = 200°\text{C}$

Ambient temperature is $T_\infty = 25°\text{C}$

Step 2 of 3

From the properties of solid metal

For copper,

Density, $\rho = 8933\ \text{kg/m}^3$

Specific heat, $c_p = 0.385\ \text{KJ/kg-K}$

Mass of cylinder is given by

$$m = \rho V$$

$$= 8933 \times \frac{\pi \times 0.18^3}{8}$$

$$= 20.45\ \text{Kg}$$

Step 3 of 3

Maximum heat transfer from copper ball is

$$Q = mc_p(T_i - T_\infty)$$

$$= mc_p(200 - 25)$$

$$= 20.45 \times 0.385 \times (200 - 25)$$

$$= 1378.39\ \text{kJ}$$

Therefore, the student's result is not reasonable as 3150 KJ is much greater than maximum heat transfer data i.e. 1378.39 kJ .

Question: 18.050P pg 1

In *Betty Crocker's Cookbook*, it is stated that it takes 2 h 45 min to roast a 3.2-kg rib initially at 4.5°C "rare" in an oven maintained at 163°C. It is recommended that a meat thermometer be used to monitor the cooking, "and the rib is considered rare done when the thermometer inserted into the center of the thickest part of the meat registers 60°C. The rib can be treated as a homogeneous spherical object with the properties ρ = 1200 kg/m3 , cp = 4.1 kJ/kg·K, k = 0.45 W/m2·K, and α = 0.91× 10 -7 m2 /s. Determine (*a*) the heat transfer coefficient at the surface of the rib; (*b*) the temperature of the outer surface of the rib when it is done; and (*c*) the amount of heat transferred to the rib. (*d*) Using the values obtained, predict how long it will take to roast this rib to "medium" level, which occurs when the innermost temperature of the rib reaches 71°C. Compare your result to the listed value of 3 h 20 min.

If the roast rib is to be set on the counter for about 15 min before it is sliced, it is recommended that the rib be taken out of the oven when the thermometer registers about 4°C below the indicated value because the rib will continue cooking even after it is taken out of the oven. Do you agree with this recommendation?

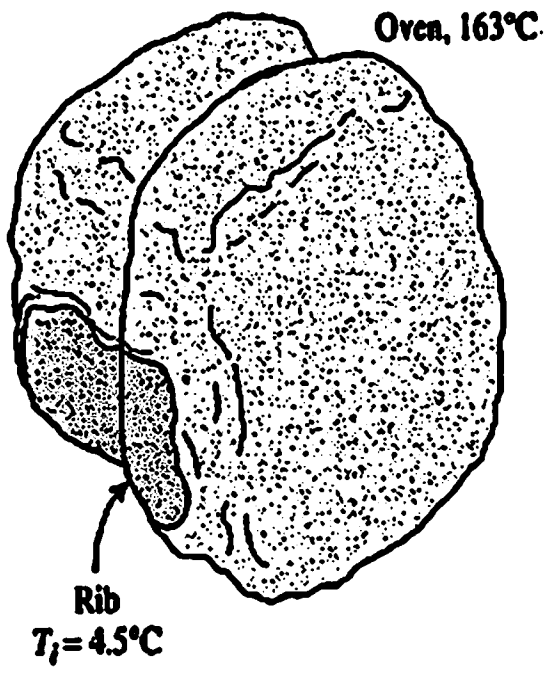

FIGURE P 18-50

Step 1 of 10

(a)

Calculate the volume of the roast.

$$V = \frac{m}{\rho}$$

Here, V is the volume of the roast, m is the mass of the roast, and ρ is the density of the roast.

Substitute 3.2 kg for m and 1200kg/m^3 for ρ .

$$V = \frac{3.2}{1200}$$
$$= 0.002667 \text{m}^3$$

Step 2 of 10

Calculate the radius of the roast.

$$V = \frac{4}{3}\pi r_o^3$$

$$r_o = \left(\frac{3V}{4\pi}\right)^{\frac{1}{3}}$$

Here, r_o is the radius of the roast.

Substitute 0.002667m^3 for V.

$$r_o = \left(\frac{3 \times 0.002667}{4\pi}\right)^{\frac{1}{3}}$$
$$= 0.08603 \text{m}$$

Step 3 of 10

Convert the time from hours to seconds.

$$t = 2\text{hr}45\text{min}$$

Calculate the Fourier number.

$$\tau = \frac{\alpha t}{r_o^2}$$

Here, τ is the Fourier number, α is the thermal expansion coefficient, and t is the time.

Substitute $0.91 \times 10^{-7} \text{m}^2/\text{s}$ for α , 2 hr 45 min for t, 0.08603 m for r_o .

$$\tau = \frac{0.91 \times 10^{-7} \text{m}^2/\text{s} \times 2\text{hr}45\text{min}}{(0.08603\text{m})^2}$$

$$\tau = \frac{(0.91 \times 10^{-7}\ \text{m}^2/\text{s})(2 \times 3600 + 45 \times 60)\text{s}}{(0.08603\ \text{m})^2}$$
$$= 0.1217$$

Which is somewhat below the value of 0.2, therefore, the one-term approximate solution (or the transient temperature charts) can still be used, with the understanding that the error involved will be a little more than 2 percent.

Step 4 of 10

Write the one-term solution for sphere.

$$\theta_{0,\text{sph}} = A_1 e^{-\lambda_1^2 \tau}$$
$$\frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

Here, T_0 is the temperature of the roast at the center, T_i is the initial temperature, and T_∞ is the temperature in oven, A_1 and λ_1 are the constants.

Substitute $60°\text{C}$ for T_0 , $4.5°\text{C}$ for T_i , $163°\text{C}$ for T_∞ , and 0.1217 for τ .

$$\frac{60 - 163}{4.5 - 163} = A_1 e^{-\lambda_1^2 (0.1217)} \quad \text{..... (1)}$$
$$0.65 = A_1 e^{-\lambda_1^2 (0.1217)}$$

$$\frac{60-163}{4.5-163} = A_1 e^{-\lambda_1^2(0.1217)} \quad \text{..... (1)}$$

$$0.65 = A_1 e^{-\lambda_1^2(0.1217)}$$

Step 5 of 10

Use trial and error method to obtain the values of A_1 and λ_1 .

Trail-1: Assume $\lambda_1 = 3.0372$ and $A_1 = 1.9898$.

Substitute 1.9898 for A_1 , 3.0372 for λ_1 in equation (1).

$$0.65 = A_1 e^{-\lambda_1^2(0.1217)}$$

$$0.65 = 1.9898 \times e^{-(3.0372)^2(0.1217)}$$

$$0.65 = 0.65$$

Here, $\text{LHS} = \text{RHS}$, therefore, take $\lambda_1 = 3.0372$ and $A_1 = 1.9898$.

Obtain the Biot number at $\lambda_1 = 3.0372$ and $A_1 = 1.9898$ from the table 11-2 "coefficients used in the one-term approximate solution of transient one dimensional heat conduction in plane walls, cylinders, and spheres" of the text book.

Biot number, $Bi = 30$.

Step 6 of 10

Calculate the heat transfer coefficient by using the following relation.

$$Bi = \frac{hr_o}{k}$$

$$h = \frac{kBi}{r_o}$$

Substitute $0.45\ \text{W/m.°C}$ for *k*, 30 for *Bi*, and 0.08603 m for r_o .

$$h = \frac{(0.45\ \text{W/m.°C})(30)}{(0.08603\ \text{m})}$$

$$= 156.922\ \text{W/m}^2\text{.°C}$$

Therefore, the heat transfer coefficient is, $\boxed{156.9\ \text{W/m}^2\text{.°C}}$.

Step 7 of 10

(b)

Calculate the temperature at the surface of the rib by using the following relation.

$$\theta(r_o,t)_{sph} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r_o / r_o)}{\lambda_1 r_o / r_o}$$

$$\frac{T(r_o,t)-T_\infty}{T_i-T_\infty} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1)}{\lambda_1}$$

Here, $T(r_o,t)$ is the temperature at the surface of the rib.

Substitute $4.5°\text{C}$ for T_i , $163°\text{C}$ for T_∞ , 0.1217 for τ , 1.9898 for A_1 , 3.0372 for λ_1 , and 0.08603 m for r_o .

$$\frac{T(r_o,t)-163}{4.5-163} = (1.9898) e^{-(3.0372)^2(0.1217)} \frac{\sin(3.0372\ \text{rad})}{3.0372}$$

$$\frac{T(r_o,t)-163}{4.5-163} = 0.0222$$

$$T(r_o,t) = 159.5°\text{C}$$

Therefore, the temperature of the outer surface of the rib is, $\boxed{159.5\ °\text{C}}$.

Step 8 of 10

(c)

Calculate the maximum possible heat transfer.

$$Q_{max} = mC_p(T_\infty - T_i)$$

Here, Q_{max} is the maximum possible heat transfer and C_p is the constant pressure specific heat capacity.

Substitute 3.2 kg for *m*, $4.1\ \text{kJ/kg.°C}$ for C_p , $4.5°\text{C}$ for T_i , and $163°\text{C}$ for T_∞

$$Q_{max} = (3.2\ \text{kg})(4.1\ \text{kJ/kg.°C})(163-4.5)°\text{C}$$

$$= 2080\ \text{kJ}$$

Calculate the actual amount of heat transfer.

$$\frac{Q}{Q_{max}} = 1 - 3\theta_{o,sph} \frac{\sin(\lambda_1) - \lambda_1 \cos(\lambda_1)}{\lambda_1^3}$$

Here, Q is the actual heat transfer.

Substitute 2080 kJ for Q_{max} , 0.65 for $\theta_{o,sph}$, and 3.0372 for λ_1 .

$$\frac{Q}{2080} = 1 - 3(0.65) \frac{\sin(3.0372) - (3.0372)\cos(3.0372)}{(3.0372)^3}$$

$$\frac{Q}{2080} = 0.783$$

$$Q = 1629\ \text{kJ}$$

Therefore, the actual amount of heat transfer is, $\boxed{1629\ \text{kJ}}$.

Step 9 of 10

(d)

Calculate the Fourier number at innermost temperature of rib is $71°\text{C}$.

$$\theta_{o,sph} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{T_o - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

Calculate the Fourier number at innermost temperature of rib is 71°C .

18.0302 pg 3

$$\theta_{0,rib} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

Substitute $71°C$ for T_0 , $4.5°C$ for T_i , $163°C$ for T_∞ , 1.9898 for A_1 , and 3.0372 for λ_1 .

$$\frac{71-163}{4.5-163} = (1.9898)e^{-(3.0372)^2 \tau}$$

$$\tau = 0.1336$$

Step 10 of 10

Calculate the cooking time for medium-done rib.

$$t = \frac{\tau r_o^2}{\alpha}$$

Here, t is the cooking time for medium-done rib.

Substitute 0.1336 for τ , 0.08603 m for r_o , and $0.91 \times 10^{-7}\ m^2/s$ for α .

$$t = \frac{(0.1336)(0.08603\ m)^2}{(0.91 \times 10^{-7}\ m^2/s)}$$

$$\approx 10866\ s$$

$$\approx 181\ min$$

$$\approx 3hr$$

Therefore, the cooking time for medium-done rib is, $\boxed{3hr}$.

Question: 18.051P

Repeat Prob. 18-50 for a roast rib that is to be "well-done" instead of "rare." A rib is considered to be well-done when its center temperature reaches 77°C, and the roasting in this case takes about 4 h 15 min.

Step 1 of 6

Loading solution. Please wait ...

Step 2 of 6

The rib is a homogeneous spherical object.
Heat conduction in the rib is one-dimensional because of symmetry about the midpoint.
The thermal properties of the rib are constant.
The heat transfer coefficient is constant and uniform over the entire surface.
The Fourier number is $\tau > 0.2$ so that the one-term approximate solutions (or the transient temperature charts) are applicable (this assumption will be verified).
(a) The heat transfer coefficient can be determined from
First the radius of the rib is determined to be
The mass $m = \rho V$

$$V = \frac{m}{\rho}$$

$$V = \frac{3.2\ \text{kg}}{1200\ \text{kg/m}^3}$$

$$V = 0.00267\ \text{m}^3$$

$$V = \frac{4}{3}\pi r_o^3$$

Step 3 of 6

The radius $r_o = \sqrt[3]{\frac{3V}{4\pi}}$

$$r_o = \sqrt[3]{\frac{3(0.00267\ \text{m}^3)}{4\pi}}$$

$$r_o = 0.08603\ \text{m}$$

The Fourier number $\tau = \frac{\alpha t}{r_o^2}$

$$\tau = \frac{(0.91\times10^{-7}\ \text{m}^2/\text{s})(4\times3600+15\times60)\text{s}}{(0.08603\ \text{m})^2}$$

$$\tau = 0.1881$$

Which is somewhat below the value of 0.2. Therefore, the one-term approximate solution (or the transient temperature charts) can still be used, with the understanding that the error involved will be a little more than 2 percent. Then the one-term solution formulation can be written in the form

$$\theta_{0,\text{spl}} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$\theta_{0,\text{spl}} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{77-163}{4.5-163} = 0.54$$

$$0.54 = A_1 e^{-\lambda_1^2 (0.1881)}$$

It is determined from Biot number table by trial and error that this equation is satisfied when $Bi = 4.3$, which corresponds to $\lambda_1 = 2.4900$ and $A_1 = 1.7402$. Then the heat transfer coefficient can be determined from.

$$Bi = \frac{hr_o}{k}$$

$$h = \frac{kBi}{r_o}$$

$$h = \frac{(0.45\ \text{W/m.°C})(4.3)}{(0.08603\ \text{m})}$$

$$\boxed{h = 22.5\ \text{W/m}^2.\text{°C}}$$

Step 4 of 6

(b) The temperature at the surface of the rib is

$$\theta(r_o,t)_{\text{spl}} = \frac{T(r_o,t) - T_\infty}{T_i - T_\infty}$$

$$\theta(r_o,t)_{\text{spl}} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r_o / r_o)}{\lambda_1 r_o / r_o}$$

$$\theta(r_o,t)_{\text{spl}} = (1.7402) e^{-(2.49)^2 (0.1881)} \frac{\sin(2.49)}{2.49}$$

$$\frac{T(r_o,t) - 163}{4.5-163} = 0.132$$

$$\boxed{T(r_o,t) = 142.1\ \text{°C}}$$

Step 5 of 6

(c) The maximum possible heat transfer is

$$Q_{\max} = mC_p(T_\infty - T_i)$$

$$Q_{\max} = (3.2\ \text{kg})(4.1\ \text{kJ/kg.°C})(163-4.5)\text{°C}$$

$$Q_{\max} = 2080\ \text{kJ}$$

Then the actual amount of heat transfer becomes

$$\frac{Q}{Q_{\max}} = 1 - 3\theta_{o,\text{spl}} \frac{\sin(\lambda_1) - \lambda_1 \cos(\lambda_1)}{\lambda_1^3}$$

$$\frac{Q}{Q_{\max}} = 1 - 3(0.543) \frac{\sin(2.49) - (2.49)\cos(2.49)}{(2.49)^3}$$

$$\frac{Q}{Q_{\max}} = 0.727$$

$$Q = 0.727 Q_{\max}$$

$$Q = (0.727)(2080\ \text{kJ})$$

$$\boxed{Q = 1512\ \text{kJ}}$$

Step 6 of 6

(d) The cooking time for medium-done rib is determined to be

$$\theta_{0,\text{spl}} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$\theta_{0,\text{spl}} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{71-163}{4.5-163} = (1.7402) e^{-(2.49)^2 \tau}$$

$$\tau = 0.177$$

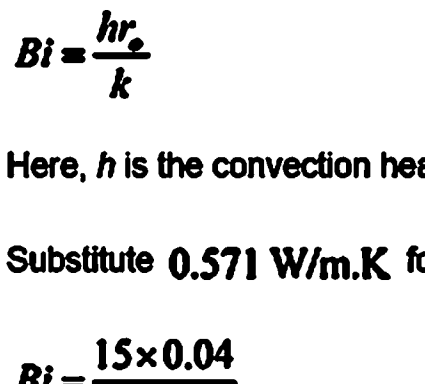
$$t = \frac{\tau r_o^2}{\alpha}$$

$$t = \frac{(0.177)(0.08603\ \text{m})^2}{(0.91\times10^{-7}\ \text{m}^2/\text{s})}$$

$$t = 14{,}403\ \text{s}$$

$$t = 240.0\ \text{min}$$

$$\boxed{t = 4\ \text{hr}}$$



Question: 18.052P

Citrus fruits are very susceptible to cold weather, and extended exposure to subfreezing temperatures can destroy them. Consider an 8-cm-diameter orange that is initially at 15°C. A cold front moves in one night, and the ambient temperature suddenly drops to -6°C, with a heat transfer coefficient of 15 W/m2 ·K. Using the properties of water for the orange and assuming the ambient conditions to remain constant for 4 h before the cold front moves out, determine if any part of the orange will freeze that night.

Step 1 of 6

Draw the schematic diagram of the orange.

Step 2 of 6

Step 3 of 6

Obtain the properties of orange which are approximated by those of water at the average temperature of $5°C$ from the Table A-9, "Properties of saturated water" from the text book.

Thermal conductivity, $k = 0.571\ \text{W/m.K}$

Specific heat $C_p = 4205\ \text{J/kg.k}$

Calculate the thermal diffusivity if the orange by using the following relation:

$$\alpha = \frac{k}{\rho C_p}$$

Here, ρ is the density.

Substitute $0.571\ \text{W/m.K}$ for k, $1000\ \text{kg/m}^3$ for ρ, and $4205\ \text{J/kg.k}$ for C_p.

$$\alpha = \frac{0.571}{1000 \times 4205}$$
$$= 0.136 \times 10^{-6}\ \text{m}^2/\text{s}$$

Step 4 of 6

Calculate the Biot number.

$$Bi = \frac{hr_o}{k}$$

Here, h is the convection heat transfer coefficient, and r_o is the radius of the sphere.

Substitute $0.571\ \text{W/m.K}$ for k, $15\ \text{W/m}^2\text{.K}$ for h, and $0.04\ \text{m}$ for r_o.

$$Bi = \frac{15 \times 0.04}{0.571}$$
$$= 1.05$$
$$\approx 1$$

Obtain the constants λ_1 and A_1 corresponding to this Biot number:

$$\lambda_1 = 1.5708$$
$$A_1 = 1.2732$$

Step 5 of 6

Calculate the Fourier number.

$$\tau = \frac{\alpha t}{r_o^2}$$

Here, t is the time.

Substitute $0.136 \times 10^{-6}\ \text{m}^2/\text{s}$ for α, $4\ \text{h}$ for t, and $0.04\ \text{m}$ for r_o.

$$\tau = \frac{(0.136 \times 10^{-6}\ \text{m}^2/\text{s})(4\ \text{h} \times \frac{3600\ \text{s}}{\text{h}})}{(0.04\ \text{m})^2}$$
$$= 1.224 > 0.2$$

Therefore the one-term approximate solution is applicable.

Step 6 of 6

Calculate the surface temperature of the oranges from the following relation:

$$\theta(r_o, t)_{sph} = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty}$$
$$= A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r_o / r_o)}{\lambda_1 r_o / r_o}$$

Substitute 1.5708 for λ_1, 1.2732 for A_1, and 1.224 for τ.

$$\theta(r_o, t)_{sph} = (1.2732) e^{-(1.5708)^2 (1.224)} \frac{\sin(1.5708\ \text{rad})}{1.5708}$$
$$\theta(r_o, t)_{sph} = 0.0396$$
$$\frac{T(r_o, t) - (-6)}{15 - (-6)} = 0.0396$$
$$T(r_o, t) = -5.2°C < 0°C$$

Therefore, the oranges will freeze.

Question: 18.053P

In a chicken processing plant, whole chickens averaging 5 lbm each and initially at 65°F are to be cooled in the racks of a large refrigerator that is maintained at 5°F. The entire chicken is to be cooled below 45°F, but the temperature of the chicken is not to drop below 35°F at any point during refrigeration. The convection heat transfer coefficient and thus the rate of heat transfer from the chicken can be controlled by varying the speed of a circulating fan inside, Determine the heat transfer-coefficient that will enable us to meet both temperature constraints while keeping the refrigeration time to a minimum. The chicken can be treated as a homogeneous spherical object having the properties ρ= 74.9 lbm/ft3 , *cp* = 0.98 Btu/lbm-°F, *k* - 0.26 BtuM· °F, and α = 0.0035 ft2 /h.

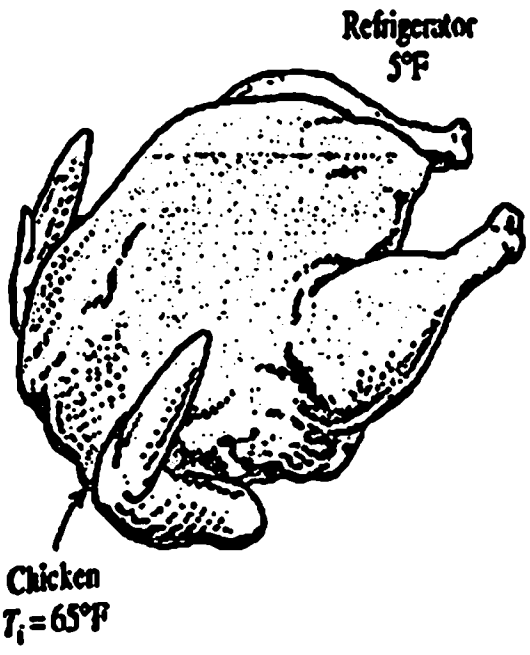


FIGURE P18-53E

Step 1 of 3

Given:

Initial temperature of chicken $T_i = 65°F$

Refrigerators racks temperature $T_\infty = 5°F$

Chicken cooled temperature $T_o = 45°F$

The chicken not to drop below temperature $T = 35°F$

The chicken is a homogeneous spherical object. Heat conduction in the chicken is one-dimensional because of symmetry about the midpoint. The thermal properties of the chicken are constant. The heat transfer coefficient is constant and uniform over the entire surface.

The thermal conductivity of the chicken $k = 0.26 \frac{\text{Btu}}{\text{h.ft.°F}}$

The density of the chicken $\rho = 74.9 \frac{\text{lbm}}{\text{ft}^3}$,

The sp.heat of the chicken $C_p = 0.98 \frac{\text{Btu}}{\text{lbm.°F}}$

The thermal diffusivity of the chicken $\alpha = 0.003598 \frac{\text{ft}^2}{\text{h}}$

Step 2 of 3

The radius of the chicken is determined to be

The Fourier number is $\tau > 0.2$ so that the one-term approximate solutions (or the transient temperature charts) are applicable (this assumption will be verified).

The mass $m = \rho V$

$$V = \frac{m}{\rho}$$

$$V = \frac{5\ \text{lbm}}{74.9\ \text{lbm/ft}^3}$$

$$V = 0.06676\ \text{ft}^3$$

$$V = \frac{4}{3}\pi r_o^3$$

The radius $r_o = \sqrt[3]{\frac{3V}{4\pi}}$

$$r_o = \sqrt[3]{\frac{3(0.06676\ \text{ft}^3)}{4\pi}}$$

$$r_o = 0.2517\ \text{ft}$$

Step 3 of 3

we have

$$\frac{T - T_\infty}{T_o - T_\infty} = \frac{35 - 5}{45 - 5}$$

$$\frac{T - T_\infty}{T_o - T_\infty} = 0.75$$

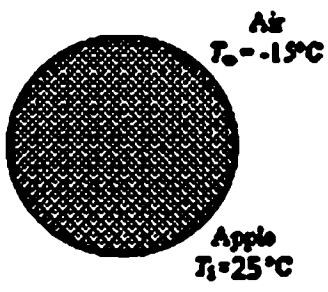
$$\frac{r}{r_o} = \frac{r_o}{r_o} = 1$$

$$\frac{1}{Bi} = \frac{k}{hr_o} = 1.75$$

Then the heat transfer coefficients becomes

$$h = \frac{k}{1.75 r_o}$$

$$h = \frac{(0.26\ \text{Btu/h.ft.°F})}{1.75(0.2517\ \text{ft})}$$



$$\boxed{h = 0.590 \frac{\text{Btu}}{\text{h.ft}^2\text{.°F}}}$$

Question: 18.054P

A person puts a few apples into the freezer at -15°C to cool them quickly for guests who are about to arrive. Initially, the apples are at a uniform temperature of 25°C, and the heat transfer coefficient on the surfaces is 8 W/m2 K. Treating the apples as 9-cm-diameter spheres and taking their properties to be ρ = 840 kg/m3 , cp = 3.81 kJ/kg·K. k = 0.418 W/m·K, and α = 1.3 × 10 7 m2 /s. determine the center and surface temperatures of the apples in 1 h. Also, determine the amount of heat transfer from each apple.

Step 1 of 5

Let us draw the diagram:

Step 2 of 5

A person puts apples into the freezer to cool them quickly. Heat conduction in the apples is one-dimensional because of symmetry about the midpoint. The thermal properties of the apples are constant. The Fourier number is > 0.2 so that the one-term approximate solutions (or the transient temperature charts) are applicable.

Characteristic c length of the s[here is

$$r_0 = \frac{9}{2}$$
$$= 4.5\text{cm}$$
$$= 0.045\text{m}$$

Then Biot number is

$$Bi = \frac{hL_c}{K}$$
$$= \frac{8 \times 0.045}{0.418}$$
$$= 0.861$$

Since Biot number is greater than 0.1, and thus lumped system analysis is not applicable. The coefficient λ_1 and A_1 for a cylinder corresponding to the Bi number are

From the coefficient used for in dimensional approximation of transient one dimensional heat conduction in sphere is

For this Biot number, we get: $\lambda = 1.476, A = 1.2390$

Step 3 of 5

Therefore, Fourier number is obtained to be:

$$t = \frac{\tau r^2}{\alpha}$$
$$3600 = \frac{\tau \times 0.045^2}{1.3 \times 10^{-7}}$$
$$\tau = 0.231$$

Then the temperature at the center of the apples is determined from the dimensional approximation

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$
$$\frac{T(t) + 15}{25 + 15} = 1.2392e^{-1.476^2 \times 0.231}$$
$$T(t) = 14.96^\circ\text{C}$$

So, the temperature at the centre of apple is $\boxed{T(t) = 14.96^\circ\text{C}}$.

Step 4 of 5

Now for temperature at the surface of apple we use the expression:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau} \frac{\sin(\lambda)}{\lambda}$$
$$\frac{T(t) + 15}{25 + 15} = 1.2392e^{-1.476^2 \times 0.231} \times \frac{\sin(1.476)}{1.476}$$
$$T(t) = 5.21^\circ\text{C}$$

Therefore, the temperature at the surface of apple is: $\boxed{T(t) = 5.21^\circ\text{C}}$.

Step 5 of 5

The maximum possible heat transfer is

$$m = \rho V$$
$$= \rho \frac{4}{3} \pi r_o^3$$
$$= (840\ \text{kg/m}^3)\left[\frac{4}{3}\pi(0.045\ \text{m})^3\right]$$
$$= 0.3206\ \text{kg}$$

Maximum heat transfer from apple is

Then the actual amount of heat transfer is determined from the fraction of heat transfer for sphere is

Therefore, heat transfer per unit length is 1.

Question: 18.055P

Reconsider Prob. 18-54. Using EES (or other) software, investigate the effect of the initial temperature of the apples on the final center and surface temperatures and the amount of heat transfer. Let the initial temperature vary from 2°C to 30°C. Plot the center temperature, the surface temperature, and the amount of heat transfer as a function of the initial temperature, and discuss the results.

Step 1 of 6

Loading solution. Please wait ...

Step 2 of 6

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
T_infinity=-15 "[C]"
"T_i=25 [C], parameter to be varied"
h=8 "[W/m^2-C]"
r_o=0.09/2 "[m]"
time=1*3600 "[s]"

"PROPERTIES"
k=0.418 "[W/m-C]"
rho=840 "[kg/m^3]"
C_p=3.81 "[kJ/kg-C]"
alpha=1.3E-7 "[m^2/s]"
```

Step 3 of 6

```
"ANALYSIS"
Bi=(h*r_o)/k
"From biot number Table corresponding to this Bi number, we read"
lambda_1=1.476
A_1=1.239
tau=(alpha*time)/r_o^2
(T_o-T_infinity)/(T_i-T_infinity)=A_1*exp(-lambda_1^2*tau)

(T_r-T_infinity)/(T_i-T_infinity)=A_1*exp(-
lambda_1^2*tau)*(Sin((lambda_1*r_o/r_o)*180/3.14))/(lambda_1*r_o/r_o)

V=4/3*pi*r_o^3
m=rho*V
Q_max=m*C_p*(T_i-T_infinity)
Q/Q_max=1-3*(T_o-T_infinity)/(T_i-T_infinity)*(Sin(lambda_1*180/3.14)-
lambda_1*Cos(lambda_1*180/3.14))/lambda_1^3
```

Step 4 of 6

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 15
Select variables in equations as T_i and T_o press ADD and then press ok
A table will appear put values of T_i as 2,4,6....30 in run 1 to 15
Repeat procedure for T_i and T_r and T_i and Q
Then from Calculate -> Solve table

Step 5 of 6

Loading solution. Please wait ...

Step 6 of 6

Then from Plot -> New plot window -> X-Y Plot
Select X-axis T_i and Y-axis T_r, T_o and Q
Press OK
Graph will be plotted.

Question: 18.056P

A 9-cm-diameter potato (ρ = 1100 kg/m3 , cp = 3900 J/kg·K, k = 0.6 W/m·K, and α = 1.4 × 10-7 m2 /s) that is initially at a uniform temperature of 25°C is baked in an oven at 170°C until a temperature sensor inserted to the center of the potato indicates a reading of 70°C. The potato is then taken out of the oven and wrapped in thick J that almost no heat is lost from the baked potato. Assuming the heat transfer coefficient in the oven to be 40 W/m2 ·K determine (*a*) how long the potato is baked in the (*b*) the final equilibrium temperature of the potato after it is Wrapped.

Step 1 of 6

Given:

Diameter of potato $D = 8\text{cm}$

Thermal conductivity of the potato $k = 0.6\ \text{W/m.°C}$

Density of the potato $\rho = 1000\,\frac{\text{kg}}{\text{m}^3}$,

Specific heat of potato $C_p = 3.9\,\frac{\text{kJ}}{\text{kg.°C}}$

Thermal diffusivity of potato $\alpha = 1.4\times10^{-7}\,\frac{\text{m}^2}{S}$.

Initial temperature of potato $T_i = 25°\text{C}$

Temperature at the center of potato $T_o = 70°\text{C}$

Oven temperature of potato $T_\infty = 170°\text{C}$

Step 2 of 6

Heat conduction in the potato is one-dimensional because of symmetry about the midpoint.

The thermal properties of the potato are constant.

The Biot number $Bi = \frac{hr_o}{k}$

$$Bi = \frac{(25\ \text{W/m}^2.°\text{C})(0.04\ \text{m})}{(0.6\ \text{W/m.°C})}$$

$$Bi = 1.67$$

The constants λ_1 and A_1 corresponding to this Biot number are from 11-2 tables

Using interpolation method to find

$$\lambda_1 = 1.8777 \quad \text{and} \quad A_1 = 1.4113$$

Step 3 of 6

Then the Fourier number and the time period become

$$\theta_{0,sph} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$\theta_{0,sph} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{70-170}{25-170} = 0.69$$

$$\frac{70-170}{25-170} = (1.4113)e^{-(1.8777)^2 \tau}$$

$$\tau = 0.203 > 0.2$$

The baking time of the potatoes is determined to be

$$t = \frac{\tau r_o^2}{\alpha}$$

$$t = \frac{(0.203)(0.04\ \text{m})^2}{(1.4\times10^{-7}\ \text{m}^2/s)}$$

$$t = 2320\ s$$

$$\boxed{t=38.7\ \text{min}}$$

Step 4 of 6

(*b*)**The maximum amount of heat transfer is**

The mass $m = \rho V$

$$m = \rho\frac{4}{3}\pi r_o^3$$

$$m = (1100\ \text{kg/m}^3)\left[\frac{4}{3}\pi(0.04\ \text{m})^3\cdot\right]$$

$$m = 0.295\ \text{kg}$$

$$Q_{max} = mC_p(T_\infty - T_i)$$

$$Q_{max} = (0.295\ \text{kg})(3.900\ \text{kJ/kg.°C})(170-25)°\text{C}$$

$$Q_{max} = 166.76\ \text{kJ}$$

Step 5 of 6

Then the actual amount of heat transfer becomes

$$\frac{Q}{Q_{max}} = 1 - 3\theta_{0,sph}\frac{\sin(\lambda_1) - \lambda_1\cos(\lambda_1)}{\lambda_1^3}$$

$$\frac{Q}{Q_{max}} = 1 - 3(0.69)\frac{\sin(1.8777) - (1.8777)\cos(1.8777)}{(1.8777)^3}$$

$$\frac{Q}{Q_{max}} = 0.525$$

$$Q = 0.525Q_{max}$$

$$Q = (0.525)(166.76\ \text{kJ})$$

$$\boxed{Q=87.5\ \text{kJ}}$$

Step 6 of 6

The final equilibrium temperature of the potato after it is wrapped is

$$Q = mC_p(T_{eqv} - T_i)$$

$$T_{eqv} = T_i + \frac{Q}{mC_p}$$

$$T_{eqv} = 25°\text{C} + \frac{87.5\ \text{kJ}}{(0.295\ \text{kg})(3.9\ \text{kJ/kg.°C})}$$

$$\boxed{T_{eqv}=101°\text{C}}$$

Question: 18.057P

White potatoes (k = 0.50 W/m·K and α = 0.13×10-6 m2 /s) that are initially at a uniform temperature of 20°C and have an average diameter of 6 cm are to be cooled by refrigerated air at 2°C flowing at a velocity of 3 m/s. The average heat transfer coefficient between the potatoes and the air is experimentally determined to be 19 W/m2 · K. Determine how long it will take for the center temperature of the potatoes to drop to 6°C. Also, determine if any part of the potatoes will experience chilling injury during this process.

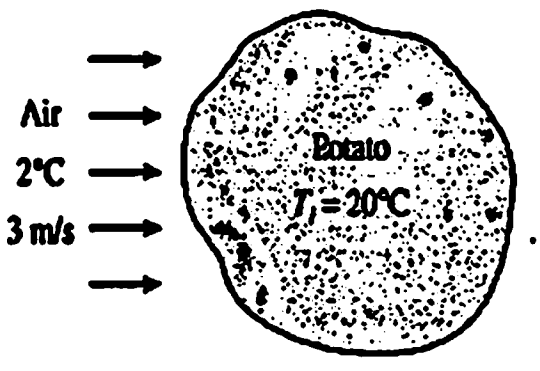

FIGURE P18-57

Step 1 of 4

Given data:

Thermal conductivity of potatoes, $k = 0.50\ \text{W/m}\cdot\text{K}$

Thermal diffusivity of potatoes, $\alpha = 0.13\times10^{-6}\ \text{m}^2/\text{s}$

Initial temperature of potatoes, $T_i = 20^\circ\text{C}$

Average heat transfer coefficient between the potato and air, $h = 19\ \text{W/m}^2\cdot\text{K}$

Center temperature of the potato, $T(t) = 6^\circ\text{C}$

Velocity of the air, $V = 3\ \text{m/s}$

Radius of the spherical potato, $r_o = 3\ \text{cm}$

Step 2 of 4

Heat conduction in the potato is one-dimensional in the radial direction because of the symmetry about the midpoint. The thermal properties of the potato are constant.
First we shall find the Biot number:

$$\text{Bi} = \frac{hr_0}{k}$$
$$= \frac{(19\ \text{W/m}^2.^\circ\text{C})(0.03\ \text{m})}{0.5\ \text{W/m.}^\circ\text{C}}$$
$$= \frac{0.57}{0.5}$$
$$= 1.14$$

Since Biot number is greater than 0.1, and thus lumped system analysis is not applicable. The coefficients λ_1 and A_1 for a cylinder corresponding to the Bi number are determined from the coefficient table used for in dimensional approximation of transient one dimensional heat conduction in sphere is $\lambda_1 = 1.635$ and $A_1 = 1.302$.

Step 3 of 4

The one dimensional approximation is

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = Ae^{-\lambda^2\tau}$$
$$\frac{6-2}{20-2} = 1.302e^{-1.635^2\tau}$$
$$\tau = 0.661$$

This is above the value of 0.2. Therefore, the one-term approximate solution must be used.

Then the length of time will take for center of the potato to reach 6°C is determined from the Fourier number to be

$$t = \frac{\tau r^2}{\alpha}$$
$$= \frac{0.661(0.03)^2}{0.13\times10^{-6}}$$
$$= 1.27\ \text{hour}$$

Therefore, the required time for cooling is $\boxed{1.27\ \text{hour}}$

Step 4 of 4

The lowest temperature during cooling will occur on the surface ($r/r_0 = 1$), and is determined to be

$$\frac{T(r)-T_\infty}{T_i-T_\infty} = A_1e^{-\lambda_1^2\tau}\frac{\sin(\lambda_1 r/r_0)}{\lambda_1 r/r_0}$$
$$\frac{T(r_0)-T_\infty}{T_i-T_\infty} = \theta_0\frac{\sin(\lambda_1 r_0/r_0)}{\lambda_1 r_0/r_0}$$
$$= \frac{T_0-T_\infty}{T_i-T_\infty}\frac{\sin(\lambda_1 r_0/r_0)}{\lambda_1 r_0/r_0}$$
$$\frac{T(r)-T_\infty}{T_i-T_\infty} = Ae^{-\lambda^2\tau}\frac{\sin(\lambda)}{\lambda}$$
$$\frac{T(r)-2}{20-2} = 1.302e^{-1.635^2\times0.661}\times\frac{\sin(1.635\text{rad})}{1.635}$$
$$T(r) = 6^\circ\text{C}$$

For potato chilling injury occurs at 6° C. As the obtained temperature is more than the threshold value, there will be no chilling injury.

Question: 18.058P

Layers of 23-cm-thick meat slabs (k = 0.47 W/m·K and $\alpha = 0.13 \times 10\text{-}6$ m2 /s) initially at a uniform temperature of 7° C are to be frozen by refrigerated air at -30°C flowing at a velocity of 1.4 m/s. The average heat transfer coefficient between the meat and the air is 20 W/m2 ·K. Assuming the size of the meat slabs to be large relative to their thickness, determine how long it will take for the center temperature ofthe slabs to drop to -18° C . Also, determine the surface temperature of the meat slab at that time.

Step 1 of 5

Consider the meat slabs as very large plane wall of half-thickness, L = 11.5cm.

Calculate the Biot number

$$\text{Bi} = \frac{hL}{k}$$

Here, Bi is the Biot number, h is the convection coefficient, k is the thermal conductivity, L is the half thickness of the slab.

Substitute $20\ \text{W/m}^2\text{.K}$ for h, $0.47\ \text{W/m.K}$ for k, and $0.115\ \text{m}$ for L.

$$\text{Bi} = \frac{(20\ \text{W/m}^2\text{.K})(0.115\ \text{m})}{0.47\ \text{W/m.K}}$$
$$= 4.89$$

Step 2 of 5

Consider the one term approximate of transient one dimensional heat conduction.

Determine the coefficient for one term approximate of transient one dimensional heat conduction for a plane wall with Biot number 4.89 using interpolation formula.

Linear interpolate the Coefficient values between 4 and 5 to get value at 4.89.

Calculate the coefficient, λ_1 .

$$\lambda_1 = 1{\cdot}2646 + [1{\cdot}3138 - 1{\cdot}2646]\left[\frac{4{\cdot}89 - 4}{5 - 4}\right]$$
$$\lambda_1 = 1.308388$$

Linear interpolate the Coefficient values between 4 and 5 to get value at 4.89.

Calculate the coefficient, A_1 .

$$A_1 = 1{\cdot}2287 + [1{\cdot}2403 - 1{\cdot}2287]\left[\frac{4{\cdot}89 - 4}{5 - 4}\right]$$
$$A_1 = 1.239024$$

Step 3 of 5

Calculate the Fourier number.

$$\frac{T_o - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

Here, T_o is the temperature at the center of the slab after time t, T_i is the initial temperature of the slab, T_∞ is the ambient temperature, and τ is the Fourier number.

Substitute $-18°\text{C}$ for T_o , $-30°\text{C}$ for T_∞ , $7°\text{C}$ for T_i , 1.239024 for A_1 , and 1.308388 for λ_1 .

$$\frac{-18 - (-30)}{7 - (-30)} = 1.239024 e^{-(1.308388)^2 \tau}$$
$$\tau = 0.783$$

Since $\tau(0.783) > 0.2$ one term approximation method is valid.

Step 4 of 5

Calculate the time required to bring the temperature of the meat slab to $-18°\text{C}$.

$$\tau = \frac{\alpha t}{L^2}$$

Here, α is the thermal diffusivity of the meat.

Rearrange the formula to find time , t.

$$t = \frac{\tau L^2}{\alpha}$$

Substitute 0.783 for τ , $0.115\ \text{m}$ for L, and $0.13 \times 10^{-6}\ \text{m}^2/\text{s}$ for τ .

$$t = \frac{(0.783)(0.115\ \text{m})^2}{0.13 \times 10^{-6}\ \text{m}^2/\text{s}}$$
$$t = 796555.19\ \text{s}$$
$$t = 22.126\ \text{hrs}$$

Time taken to reach the center temperature $-18°\text{C}$ for the meat slab is $\boxed{22.126\ \text{h}}$.

Step 5 of 5

Calculate the surface temperature of the slab after time, $22.126\ \text{hrs}$.

Write the formula to find the temperature at a distance from center.

$$\frac{T(x) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \cos(\lambda_1 x / L)$$

Substitute L for x and $\left(\frac{T_o - T_\infty}{T_i - T_\infty}\right)$ for $A_1 e^{-\lambda_1^2 \tau}$.

$$\frac{T(L) - T_\infty}{T_i - T_\infty} = \left(\frac{T_o - T_\infty}{T_i - T_\infty}\right)\cos(\lambda_1 L / L)$$

$$(T(L) - T_\infty) = (T_0 - T_\infty)\cos(\lambda_1)$$
$$T(L) = T_\infty + (T_0 - T_\infty)\cos(\lambda_1)$$

Substitute $-18°\text{C}$ for T_o , $-30°\text{C}$ for T_∞ , and 1.308388 for λ_1 .

$$T(L) = -30 + (-18 - (-30))\cos(1.308388\text{rad}) \in$$
$$T(L) = -26.88°\text{C}$$

Thus, the temperature at the surface of the meat slab is $\boxed{-26.88°\text{C}}$.

Question: 18.059P

Layers of 6-in-thick meat slabs (k = 0.26 Btu/h·ft·° C and α = 1.4×10-6 ft2 /s) initially at a uniform temperature of 50° F arc cooled by refrigerated air at 23°F to a temperature of 36°F at their center in 12 h. Estimate the average heat transfer coefficient during this cooling process.

Step 1 of 4

Given:

Thickness of metal slab = 6in

Thermal conductivity of meat slabs are given to be $k = 0.26\ \text{Btu/h} \cdot \text{ft} \cdot {}^{\circ}\text{F}$

Thermal diffusivity of metal slab $\alpha = 1.4 \times 10^{-6}\ \text{ft}^2/\text{s}.$

Step 2 of 4

Center temperature of meat slabs is to be lowered to 36°F during 12-h of cooling.

The meat slabs can be approximated as very large plane walls of half-thickness L = 3-in.

Heat conduction in the meat slabs is one-dimensional because of symmetry about the centerplane.

Step 3 of 4

The Fourier number is τ > 0.2 so that the one-term approximate solutions (or the transient temperature charts) are applicable (this assumption will be verified).

The average heat transfer coefficient during this cooling process is determined from the transient temperature charts for a flat plate as follows:

$$\tau = \frac{\alpha t}{L^2}$$

$$= \frac{(1.4\times10^{-6}\text{ft}^2/\text{s})(12\times3600\ \text{s})}{(3/12\ \text{ft})^2}$$

$$= 0.968$$

$$\frac{T_o - T_\infty}{T_i - T_\infty} = \frac{36-23}{50-23}$$

$$= 0.481$$

From the transient temperature charts for a flat plate above two values gives the

$$\frac{1}{Bi} = 0.7$$

Step 4 of 4

Therefore,

$$h = \frac{kBi}{L}$$

$$= \frac{(0.26\text{Btu/h.ft.}^{\circ}\text{F})(1/0.7)}{(3/12)\ \text{ft}}$$

$$= 1.5\ \text{Btu/h.ft}^2.^{\circ}\text{F}$$

Average heat transfer coefficient is $\boxed{1.5\ \text{Btu/h.ft}^2.^{\circ}\text{F}}$

Question: 18.060P

Oranges of 2.5-in-diameter (k = 0 26 Btu/h·ft·°F and α = 1.4 × 10-6 ft2 /s) initially at a uniform temperature of 78°F are to be cooled by refrigerated air at 25°F flowingat a velocity of 1ft/s. The average heat transfer coefficient between the oranges and the air is experimentally determined to be 4.6 Btu/h·ft2 ·°F. Determine how long it will take for the center temperature of the oranges to drop to 40°F. Also, determine if any pan of the oranges will freeze during this process.

Step 1 of 6

Given:

Diameter of orange $D = 2.5\ \text{in}$

Thermal conductivity of oranges $k = 0.26\ \text{Btu/h}\cdot\text{ft}\cdot{}^{\circ}\text{F}$

Thermal diffusivity of oranges $\alpha = 1.4\ 10^{-6}\ \text{ft}^2/\text{s}$

Initial temperature of orange $T_i = 78^0\text{F}$

Refrigerated air temperature $T_\infty = 25^0\text{F}$

Refrigerated air velocity $v = 1\text{ft/sec}$

Final temperature of orange $T_o = 40^0\text{F}$

Step 2 of 6

The oranges are spherical in shape with a radius of

$r_o = 1.25\ \text{in}$

$r_o = 0.1042\ \text{ft}$

The Fourier number is $\tau > 0.2$ so that the one-term approximate solutions (or the transient temperature charts) are applicable (this assumption will be verified).

First we find the Biot number:

$$\text{Bi} = \frac{hr_0}{k}$$

$$= \frac{(4.6\ \text{Btu/h.ft}^2.^{\circ}\text{F})(1.25/12\ \text{ft})}{0.26\ \text{Btu/h.ft.}^{\circ}\text{C}}$$

$$= 1.843$$

Step 3 of 6

From the transient one dimensional heat conduction for a sphere,

$\lambda_1 = 1.9569$ And $A_1 = 1.447$

Substituting these values into the one-term solution gives

$$\theta_0 = \frac{T_o - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{40-25}{78-25} = 1.447 e^{-(1.9569)^2 \tau}$$

$\tau = 0.426$

Step 4 of 6

Which is greater than 0.2 and thus the one-term solution is applicable. Then the cooling time becomes

$$\tau = \frac{\alpha t}{r_0^2}$$

$$t = \frac{\tau r_0^2}{\alpha}$$

$$= \frac{(0.426)(1.25/12\ \text{ft})^2}{1.4\times10^{-6}\ \text{ft}^2/\text{s}}$$

$$= 3302\ \text{s}$$

Time required dropping temperature is $\boxed{55.0\ \text{min}}$

Step 5 of 6

The lowest temperature during cooling will occur on the surface ($r/r_0 = 1$), and is determined to be

$$\frac{T(r) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r / r_0)}{\lambda_1 r / r_0}$$

$$\frac{T(r_0) - T_\infty}{T_i - T_\infty} = \theta_0 \frac{\sin(\lambda_1 r_0 / r_0)}{\lambda_1 r_0 / r_0}$$

$$= \frac{T_0 - T_\infty}{T_i - T_\infty} \frac{\sin(\lambda_1 r_0 / r_0)}{\lambda_1 r_0 / r_0}$$

Step 6 of 6

Substituting,

$$\frac{T(r_0) - 25}{78 - 25} = \left(\frac{40-25}{78-25}\right) \frac{\sin(1.9569\ \text{rad})}{1.9569}$$

$T(r_0) = 32.1^{\circ}\text{F}$

Which is above the freezing temperature of 31 °C for oranges. Therefore, no part of the oranges will freeze during this cooling process.

Question: 18.061P

A heated 6-mm-thick Pyroceram plate (ρ= 2600 kg/m3 , cp = 808 J/kg · K, k = 3.98 W/m2 · K, and α = 1.89 × 10-6 m2 /s) is being cooled in a room with air temperature of 25°C and convection heat transfer coefficient of 13.3 W/m2 ·K. The heated Pyroceram plate had an initial temperature of 500°C. and is allowed to cool for 286 seconds. If the mass of the Pyroceram plate is 10 kg, determine the heat transfer from the Pyroceram plate during the cooling process using (*a*) Table 18-2 and (*b*) Figure 18-15.

Step 1 of 6

Calculate the Biot number by using the relation,

$$\mathrm{Bi} = \frac{hL}{k}$$

Here, h is the convection heat transfer coefficient, and k is the thermal conductivity of the brass plate.

Substitute $13.3\ \mathrm{W/m^2 \cdot K}$ for h, $0.003\ \mathrm{m}$ for L . $3.98\ \mathrm{W/m \cdot K}$ k.

$$\mathrm{Bi} = \frac{(13.3\ \mathrm{W/m^2 \cdot K})(0.003\ \mathrm{m})}{3.98\ \mathrm{W/m \cdot K}}$$
$$= 0.01$$

Obtain the constant λ_1 and A_1 from table 4-2 at $\mathrm{Bi} = 0.01$ (For plane wall).

$$\lambda_1 = 0.0998$$

$$A_1 = 1.0017$$

Step 2 of 6

Calculate the Fourier number by using the relation,

$$\tau = \frac{\alpha t}{L^2}$$

Here, τ is the Fourier number, α is the thermal diffusivity of the material, t is the time, and L is the critical length of the plate.

Substitute $1.89\times10^{-6}\ \mathrm{m^2/s}$ for α , $286\ \mathrm{s}$ for t, and $0.003\ \mathrm{m}$ for L .

$$\tau = \frac{(1.89\times10^{-6}\ \mathrm{m^2/s})(286\ \mathrm{s})}{(0.003\ \mathrm{m})^2}$$
$$= 60.06$$

Step 3 of 6

Calculate the dimensionless temperature at the center of the plate by using the relation,

$$\theta_{0,\mathrm{wall}} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$
$$= A_1 e^{-\lambda_1^2 \tau}$$

Here, T_0 is the upper surface temperature of the plate, T_∞ is the temperature of the surrounding air, and T_i is the initial temperature of the plate.

Substitute 1.0017 for A_1 , 0.0998 for λ_1 , and 60.06 for τ .

$$\theta_{0,\mathrm{wall}} = 1.007 e^{-(0.0998)^2 60.06}$$
$$= 0.5507$$

Step 4 of 6

Calculate the maximum amount of heat transferred from the plate by using the relation,

$$Q_{\max} = mc_p(T_i - T_\infty)$$

Substitute 10 kg for m, $808\ \mathrm{J/kg \cdot K}$ for c_p , $(25+273)\mathrm{K}$ for T_∞ , and $(500+273)\mathrm{K}$ for T_i .

$$Q_{\max} = (10\ \mathrm{kg})(808\ \mathrm{J/kg \cdot K})((500+273)\mathrm{K} - (25+273)\mathrm{K})$$
$$= 3.838\times10^6\ \mathrm{J}$$

Step 5 of 6

Calculate the heat transfer from the Pyroceram plate during the cooling process by using the relation,

$$\left(\frac{Q}{Q_{\max}}\right)_{\mathrm{wall}} = 1 - \theta_{0,\mathrm{wall}} \frac{\sin(\lambda_1)}{\lambda_1}$$

Substitute $3.838\times10^6\ \mathrm{J}$ for $Q_{\max}$, 0.5507 for $\theta_{0,\mathrm{wall}}$, and 0.0998 for λ_1 .

$$\frac{Q}{3.838\times10^6\ \mathrm{J}} = 1 - (0.5507)\frac{\sin(0.0998^{\mathrm{rad}})}{0.0998}$$
$$= 1 - (0.5507)\frac{\sin\left(0.0998\times\frac{180^\circ}{\pi}\right)}{0.0998}$$
$$= 0.4502$$

$$Q = 0.4502(3.838\times10^6\ \mathrm{J})$$
$$= 1.728\times10^6\ \mathrm{J}$$

Therefore, the heat transferred from the Pyroceram plate during the cooling process is $\boxed{1.728\times10^6\ \mathrm{J}}$.

Step 6 of 6

b)
Calculate the value of the $\mathrm{Bi}^2\tau$.

Substitute 0.01 for Bi, and 60.06 for τ .

$$\mathrm{Bi}^2\tau = 0.01^2 \times 60.06$$
$$= 0.006$$

Obtain the ratio of heat transferred from the plate to the maximum amount of heat transferred from the plate $\left(\frac{Q}{Q_{\max}}\right)$ from figure 4-18 (*c*) corresponding to 0.01 of Bi and 0.006 of $\mathrm{Bi}^2\tau$.

$$\frac{Q}{Q_{\max}} = 0.45$$

Substitute $3.838\times10^6\ \mathrm{J}$ for $Q_{\max}$.

$$\frac{Q}{3.838\times10^6\ \mathrm{J}} = 0.45$$
$$Q = 1.7271\times10^6\ \mathrm{J}$$

Therefore, the heat transferred from the Pyroceram plate during the cooling process is $\boxed{1.7271\times10^6\ \mathrm{J}}$.

Question: 18.062P

A 10-cm thick aluminum plate ($\rho = 2702$ kg/m3 , $cp = 903$ J/kg · K, $k = 237$ W/m · K, and $\alpha = 97.1 \times 10\text{-}6$ m2 /s) is being heated in liquid with temperature of 500°C. The aluminum plate has a uniform initial temperature of 25°C. If the surface temperature of the aluminum plate is approximately the liquid temperature, determine the temperature at the center plane of the aluminum plate after 15 seconds of heating.

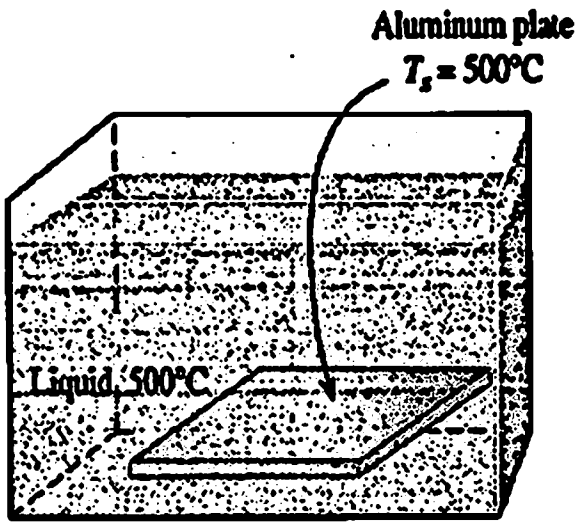

FIGURE P18-62

Step 1 of 3

As the surface temperature of the plate is equal to the liquid temperature, the convective heat transfer coefficient is infinitive.

$$h = \infty$$

Calculate the Biot number by using the relation,

$$\text{Bi} = \frac{hL}{k}$$

Here, L is the characteristic length, and k is the thermal conductivity of the plate material.

Substitute ∞ for h.

$$\text{Bi} = \frac{\infty L}{k}$$
$$= \infty$$

Obtain the constants for the plate from table 4-2 corresponding to the Biot number of ∞ for plane wall.

$$\lambda_1 = 1.5708$$

And, $A_1 = 1.2732$

Step 2 of 3

Calculate the Fourier number by using the relation,

$$\tau = \frac{\alpha t}{L^2}$$

Here, τ is the Fourier number, α is the thermal diffusivity of the material, t is the time, and L is the critical length of the plate.

Substitute $97.1\times10^{-6}\ \text{m}^2/\text{s}$ for α , $15\ \text{s}$ for t, and $0.05\ \text{m}$ for L .

$$\tau = \frac{97.1\times10^{-6}\ \text{m}^2/\text{s}(15\ \text{s})}{(0.05\ \text{m})^2}$$
$$= 0.5826 > 0.2$$

As the Fourier number is more than 0.2, the one term approximation method is used to solve the problem.

Step 3 of 3

Calculate the temperature of the plate at the center plane of the aluminum plate by using the relation,

$$\theta_{\text{o,sph}} = \left(\frac{T_o - T_\infty}{T_i - T_\infty}\right)$$
$$= A_1 e^{-\lambda_1^2 \tau}$$

Further solve the equation as follows,

$$T_o - T_\infty = (T_i - T_\infty) A_1 e^{-\lambda_1^2 \tau}$$
$$T_o = T_\infty + (T_i - T_\infty) A_1 e^{-\lambda_1^2 \tau}$$

Here, T_o is the center plane temperature, T_∞ is the fluid temperature, and T_i is the initial temperature of the plate.

Substitute $25°C$ for T_i , $550°C$ for T_∞ , 1.2732 for A_1 , 1.5708 for λ_1 , and 0.5826 for τ .

$$T_o = 500°C + (25°C - 500°C)(1.2732) e^{-(1.5708)^2(0.5826)}$$
$$= 500°C + (25°C - 500°C)(1.2732) e^{-1.4375}$$
$$= 500°C + (25°C - 500°C)(1.2732) \times 0.2375$$
$$= 500°C - 143.64°C$$

$$T_o = 356.36°C$$

Therefore, the center plane temperature of the aluminum plate after 15 seconds of heating is **356.36°C** .

Question: 18.063P

A long iron rod (ρ = 7870 kg/m3 , cp = 447 J/kg · K, k = 80.2 W/m · K, and α = 23.1 × 10-6 m2 /s) with diameter of 25 mm is initially heated to a uniform temperature of 700°C. The iron rod is then quenched in a large water bath that is maintained at constant temperature of 50°C and convection heat transfer coefficient of 128 W/m2 ·K. Determine the time required for the iron rod surface temperature to cool to 200°C.

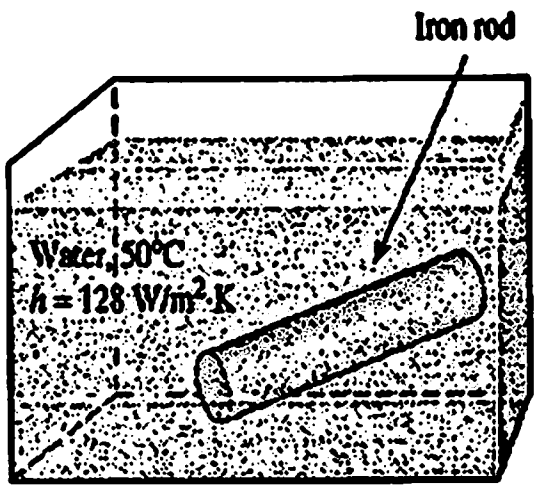

FIGURE P 18-63

Step 1 of 3

Determine the characteristic length of the long cylinder rod.

$$r_o = \frac{d}{2}$$

Here, diameter of the rod is d and characteristic length of the rod is r_o .

Substitute 25×10^{-3} m for d.

$$r_o = \frac{25\times10^{-3}}{2}$$
$$= 12.5\times10^{-3} \text{ m}$$

Calculate the Biot number of the rod and water system.

$$\text{Bi} = \frac{hr_o}{k}$$

Here, convective heat transfer coefficient is h , Biot number of the rod is Bi, and conduction coefficient of the rod is k .

Substitute $128 \text{ W/m}^2\cdot\text{K}$ for h, $80.2 \text{ W/m}\cdot\text{K}$ for k, and 12.5×10^{-3} m for r_o .

$$\text{Bi} = \frac{128\times12.5\times10^{-3}}{80.2}$$
$$= 0.02$$

Step 2 of 3

Consider the one term approximate of transient one dimensional heat conduction.

Take values of one term approximate coefficient for a cylinder from the table "Coefficients used in one term approximate solution of one dimensional transient heat conduction" recorded at Biot number 0.02.

$$\lambda_1 = 0.1995$$
$$A_1 = 1.005$$

Calculate the Fourier number.

$$\frac{T_o - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

Here, T_o is the temperature at the centre of the cylinder after time t, T_i is the initial temperature of the cylinder, T_∞ is the ambient temperature, and τ is the Fourier number.

Substitute $200°\text{C}$ for T_o , $50°\text{C}$ for T_∞ , $700°\text{C}$ for T_i , 1.005 for A_1 , and 0.1995 for λ_1 .

$$\frac{200-50}{700-50} = 1.005e^{-(0.1995)^2\tau}$$
$$\tau = 36.96$$

Since $\tau(36.96) > 0.2$ one term approximation method is valid.

Step 3 of 3

Calculate the time required to bring the temperature of the cylinder to $200°\text{C}$.

$$\tau = \frac{\alpha t}{L^2}$$

Here, α is the thermal diffusivity of the cylinder.

Rearrange the formula to find time , t.

$$t = \frac{\tau L^2}{\alpha}$$

Substitute 36.96 for τ , 12.5×10^{-3} m for r_o , and 23.1×10^{-6} m^2/s for τ .

$$t = \frac{(36.96)(12.5\times10^{-3}\text{ m})^2}{23.1\times10^{-6}\ \text{m}^2/\text{s}}$$
$$t = 250 \text{ s}$$

Thus, the time required to bring the temperature of the cylinder to $200°\text{C}$ is $\boxed{250 \text{ s}}$.

Question: 18.064P

A long Pyroceram rod (ρ = 2600 kg/m3 , cp = 808 J/kg · K, k = 3.98 W/m · K, and α = 1.89 × 10-6 m2 /s) with diameter of 10 mm has an initial uniform temperature of 1000°C. The Pyroceram rod is allowed to cool in ambient temperature of 25°C and convection heat transfer coefficient of 80 W/m2 ·K. If the Pyroceram rod is allowed to cool for 3 minutes, determine the temperature at the center of the rod using (a) Tabic 18-2 and (b) the Heisler chart (Figure 18-16).

Step 1 of 6

Calculate the Biot number for the heating process of pyroceram rod by using the relation,

$$\mathrm{Bi} = \frac{hL_c}{k} \quad \text{..... (1)}$$

Here, convective heat transfer coefficient is h , characteristic length of the rod is L_c , and conduction coefficient of the rod is k .

Calculate the characteristic length of the pyroceram rod by using the relation,

$$L_c = r_o$$

Here, radius of the rod is r_o .

Substitute $0.005\ \mathrm{m}$ for r_o .

$$L_c = 0.005\ \mathrm{m}$$

Step 2 of 6

Calculate the Biot number for this process as shown.

Substitute $0.005\ \mathrm{m}$ for L_c . $80\ \mathrm{W/m^2 \cdot K}$ for h , and $3.98\ \mathrm{W/m \cdot K}$ for k in equation (1).

$$\mathrm{Bi} = \frac{80 \times 0.005}{3.98}$$
$$= 0.10$$

Calculate the Fourier number for this process by using the formula,

$$\tau = \frac{\alpha t}{r_o^2}$$

Here, diffusivity of pyroceram rod is α , and time for which the rod is heated is t .

Substitute $1.89 \times 10^{-6}\ \mathrm{m^2/s}$ for α . $(3 \times 60)\ \mathrm{s}$ for t , and $0.005\ \mathrm{m}$ for r_o .

$$\tau = \frac{1.89 \times 10^{-6} \times 3 \times 60}{(0.005)^2}$$
$$= 13.61$$

Step 3 of 6

(a).

Calculate the dimensionless temperature of the cylindrical rod by using the relation,

$$\theta_{0,cyl} = A_1 e^{-\lambda_1^2 \tau} \quad \text{..... (2)}$$

Obtain the values of λ_1 and A_1 for $\mathrm{Bi} = 0.10$ from table 4.2 as shown.

$$\lambda_1 = 0.4417$$
$$A_1 = 1.0246$$

Substitute 13.61 for τ . 1.0246 for A_1 , and 0.4417 for λ_1 in equation (2).

$$\theta_{0,cyl} = (1.0246) e^{-\left[(0.4417)^2 \times 13.61\right]}$$
$$= 0.072$$

Step 4 of 6

Calculate the temperature at the centre of the rod by using the relation,

$$\frac{T_0 - T_\infty}{T_i - T_\infty} = \theta_{0,cyl}$$

Here, the temperature at the centre of the rod is T_0 , surroundings temperature is T_∞ , and initial temperature of the rod is T_i .

Substitute 0.072 for $\theta_{0,cyl}$. $25\ ^\circ\mathrm{C}$ for T_∞ , and $1000\ ^\circ\mathrm{C}$ for T_i .

$$\frac{T_0 - 25}{1000 - 25} = 0.072$$
$$T_0 - 25 = 975 \times 0.072$$
$$T_0 = 25 + 70.2$$
$$= 95.2\ ^\circ\mathrm{C}$$

Therefore, the temperature at the centre of the rod is $\boxed{95.2\ ^\circ\mathrm{C}}$.

Step 5 of 6

(b).

Calculate the value $\frac{1}{\mathrm{Bi}}$ as shown.

$$\frac{1}{\mathrm{Bi}} = \frac{1}{0.10}$$
$$= 10$$

Obtain the value of dimensionless temperature at the centre, θ_0 corresponding to values $\frac{1}{\mathrm{Bi}} = 10$ and $\tau = 13.61$ from figure 4-17 as shown.

$$\theta_0 = 0.075$$

Step 6 of 6

Calculate the temperature at the centre of the rod as shown.

$$\frac{T_0 - T_\infty}{T_i - T_\infty} = \theta_{0,cyl}$$

Substitute 0.075 for $\theta_{0,cyl}$. $25\ ^\circ\mathrm{C}$ for T_∞ , and $1000\ ^\circ\mathrm{C}$ for T_i .

$$\frac{T_0 - 25}{1000 - 25} = 0.075$$
$$T_0 - 25 = 975 \times 0.075$$
$$T_0 = 25 + 73.125$$
$$= 98.125\ ^\circ\mathrm{C}$$

Therefore, the temperature at the centre of the rod is $\boxed{98.125\ ^\circ\mathrm{C}}$.

Question: 18.065P

A 2-cm-diameter plastic rod has a thermocouple inserted to measure temperature at the center of the rod. The plastic (ρ = 1190 kg/m3 , cp = 1465 J/kg · K, k = 0.19 W/m · K) was initially heated to a uniform temperature of 70°C, and allowed to be cooled in ambient air temperature of 25°C. After 1388 s of cooling, the thermocouple measured the temperature at the center of the rod to be 30°C. Determine the convection heat transfer coefficient for this process.

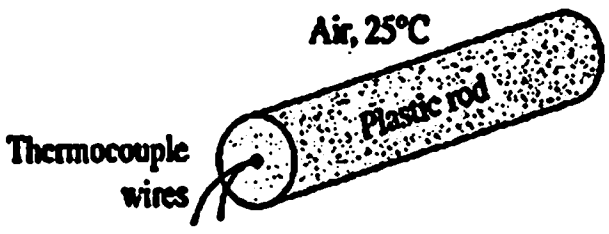

FIGURE P 18-65

Step 1 of 4

Diameter of the rod is, $D=2$ cm

Density is, $\rho=1190$ kg/m^3

Specific heat, $c_p=1465$ kJ/kg·K

Center temperature, $T=30$ °C

Initially temperature is, $T_i=70$ °C

Ambient temperature is, $T_\infty=25$ °C

Time taken for cooling, $t=1388$s

Step 2 of 4

Calculation of the convective heat transfer coefficient:

In order to calculate the convective heat transfer coefficient, let us calculate Biot number, Proper choice of characteristic length is important for this problem. At outer surface, $r=r_o$

Since $r=1$cm, $\frac{r}{r_o}=1$ and non-dimensional temperature as:

$$\frac{T-T_\infty}{T_i-T_\infty}=\frac{30-25}{70-25}$$

$$\frac{T-T_\infty}{T_i-T_\infty}=0.111$$

Step 3 of 4

And we know that,

$$\tau=\frac{\alpha t}{L^2} \qquad \text{..... (1)}$$

Where,

$$\alpha=\frac{k}{\rho c_p}$$

$$=\frac{(0.19)}{(1190\times1465)}$$

$$=1.08\times10^{-7}\ \text{m}^2/\text{s}$$

By substituting the above value in equation (1), we get,

$$\tau=\frac{\alpha t}{r^2}$$

$$=\frac{\left(1.08\times10^{-7}\right)(1388)}{(0.01)^2}$$

$$=1.51$$

From the transient temperature and heat transfer charts for long cylinder,

At $\frac{T-T_\alpha}{T_i-T_\alpha}=0.11$ and $\frac{r}{r_o}=1$, we have,

$$\frac{1}{\text{Bi}}=0.18$$

Step 4 of 4

We know that,

$$\text{Bi}=\frac{hr_o}{k}$$

$$\frac{1}{\text{Bi}}=\frac{k}{hr_o}$$

$$0.18=\frac{0.19}{h\times0.01}$$

$$\boxed{h=105.55\ \text{W/m}^2\cdot\text{K}}$$

Therefore, the convective heat transfer coefficient is obtained as, $\boxed{h=105.55\ \text{W/m}^2\cdot\text{K}}$

Question: 18.066P

Steel rods, 2 m in length and 60 mm in diameter, are being drawn through an oven that maintains a temperature of 800°C and convection heat transfer coefficient of 128 W/m2 ·K. The steel rods (ρ = 7832 kg/m3 , *cp* = 434 J/kg · K, *k* = 63.9 W/m · K, and α = 1.88 × 10-6 m2 /s) were initially in uniform temperature of 30°C. Using (*a*) Table 18-2 and (*b*) Figure 18-16, determine the amount of heat is transferred to the steel rod after 133 s of heating.

Step 1 of 5

Calculate the maximum heat transferred to the steel rod by using the relation,

..... (1)

Here, density of steel rod is , volume of the steel rod is , and specific heat at constant pressure is C_p , surrounding temperature is T_∞ , and initial temperature of the rod is T_i .

Calculate the volume of the steel rod by using the formula,

$$V = \pi r_o^2 L$$

Here, radius of the rod is r_o , and length of the rod is L .

Calculate the maximum heat transferred to the steel rod as shown.

Substitute $\pi r_o^2 L$ for V in equation (1).

$$Q_{max} = \rho \times \pi r_o^2 L \times C_p (T_\infty - T_i)$$

Substitute 2 m for L , 0.03 m for r_o , 7832 kg/m^3 for ρ , $434\text{ J/kg}\cdot\text{K}$ for C_p , 800 °C for T_∞ , and 30 °C for T_i .

$$\begin{aligned} Q_{max} &= 7832 \times \pi \times (0.03)^2 \times 2 \times 434 \times (800 - 30) \\ &= 1.48 \times 10^7\text{ J} \end{aligned}$$

Step 2 of 5

Calculate the Biot number of the steel rod by using the relation,

$$\text{Bi} = \frac{hL_c}{k} \quad \text{..... (2)}$$

Here, convective heat transfer coefficient is h , characteristic length of the rod is L_c , and conduction coefficient of the rod is k .

Calculate the characteristic length of the steel rod by using the relation,

$$L_c = r_o$$

Here, radius of the rod is r_o .

Substitute 0.03 m for r_o .

$$L_c = 0.03\text{ m}$$

Step 3 of 5

Calculate the Biot number for this process as shown.

Substitute 0.03 m for L_c , $128\text{ W/m}^2\cdot\text{K}$ for h , and $63.9\text{ W/m}\cdot\text{K}$ for k in equation (2).

$$\begin{aligned} \text{Bi} &= \frac{128 \times 0.03}{63.9} \\ &= 0.06 \end{aligned}$$

Calculate the Fourier number for this process by using the formula,

$$\tau = \frac{\alpha t}{r_o^2}$$

Here, diffusivity of steel rod is α , and time for which the rod is heated is t .

Substitute $18.8 \times 10^{-6}\text{ m}^2/\text{s}$ for α , 133 s for t , and 0.03 m for r_o .

$$\begin{aligned} \tau &= \frac{18.8 \times 10^{-6} \times 133}{(0.03)^2} \\ &= 2.778 \end{aligned}$$

Step 4 of 5

(a).

Calculate the dimensionless temperature of the cylindrical rod by using the relation,

$$\theta_{0,cyl} = A_1 e^{-\lambda_1^2 \tau} \quad \text{..... (3)}$$

Obtain the values of λ_1 and A_1 for $\text{Bi} = 0.06$ from table 4.2 as shown.

$$\lambda_1 = 0.3438$$
$$A_1 = 1.0148$$

Substitute 2.778 for τ , 1.0148 for A_1 , and 0.3438 for λ_1 in equation (3).

$$\begin{aligned} \theta_{0,cyl} &= (1.0148) e^{-\left[(0.3438)^2 \times 2.778\right]} \\ &= 0.7308 \end{aligned}$$

Obtain the value of $J(0.3438)$ from table 4.3 as shown.

$$J(0.3438) = 0.1694$$

Step 5 of 5

Calculate the heat transfer to a steel rod after 133 s by using the relation,

$$Q = Q_{max}\left[1 - 2\theta_{0,cyl}\frac{J_1(\lambda_1)}{\lambda_1}\right]$$

Substitute 0.1694 for $J(0.3438)$, 0.3438 for λ_1 , 0.7308 for $2\theta_{0,cyl}$, and $1.48 \times 10^7\text{ J}$ for Q_{max} .

$$\begin{aligned} Q &= 1.48 \times 10^7\left[1 - 2(0.7308)\left(\frac{0.1694}{0.3438}\right)\right] \\ &= 1.48 \times 10^7\left[1 - 0.72\right] \\ &= 4.14 \times 10^6\text{ J} \\ &= 4140\text{ kJ} \end{aligned}$$

Therefore, the heat transfer to a steel rod after 133 s is $\boxed{4140\text{ kJ}}$.

(b).

Calculate the value $\text{Bi}^2\tau$ as shown.

$$\begin{aligned} \text{Bi}^2\tau &= (0.06)^2 \times 2.778 \\ &= 0.0036 \times 2.778 \\ &= 0.01 \end{aligned}$$

Obtain the value of $\frac{Q}{Q_{max}}$ corresponding to value $\text{Bi}^2\tau = 0.01$ from figure 4-17 as shown.

$$\frac{Q}{Q_{max}} = 0.3 \quad \text{..... (4)}$$

Calculate the heat transfer to a steel rod after 133 s as shown.

Rearrange equation (4) as shown.

$$Q = 0.3Q_{max}$$

Substitute $1.48 \times 10^7\text{ J}$ for Q_{max} .

$$\begin{aligned} Q &= 0.3 \times 1.48 \times 10^7 \\ &= 4.44 \times 10^6\text{ J} \\ &= 4440\text{ kJ} \end{aligned}$$

Therefore, the heat transfer to a steel rod after 133 s is $\boxed{4440\text{ kJ}}$.

Question: 18.067P

What is a semi-infinite medium? Give examples of solid bodies that can be treated as semi-infinite mediums for heat transfer purposes.

Step 1 of 1

A semi-infinite medium is an idealized body which has a single exposed plane surface and extends to infinity in all directions. The earth and thick walls can be considered to be semi-infinite media.

Question: 18.068P

Under what conditions can a plane wall be treated as a semi-infinite medium?

Step 1 of 1

A thick plane wall can be treated as a semi-infinite medium if all we are interested in is the variation of temperature in a region near one of the surfaces for a time period during which the temperature in the mid section of the wall does not experience any change.

Question: 18.069P

Consider a hot semi-infinite solid at an initial temperature of Ti that is exposed to convection to a cooler medium at a constant temperature of $T\infty$ with a heat transfer coefficient of h. Explain how you can determine the total amount of heat transfer from the solid up to a specified time t 0

Step 1 of 1

The total amount of heat transfer from a semi-infinite solid up to a specified time t_0 can be determined by integration from

$$Q = \int_0^{t_0} Ah[T(0,t) - T_\infty]dt$$

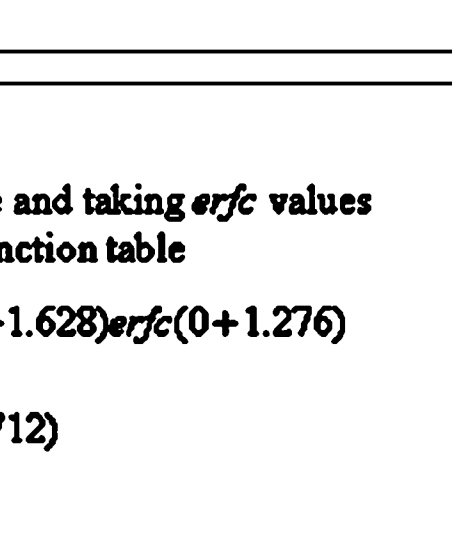
Where the surface temperature T(0,t) is obtained from above equation by substituting $x = 0$.

Question: 18.070P

A thick wood slab (k = 0.17 W/m·K and α = 1.28 × 10-7 m2 /s) that is initially at a uniform temperature of 25°C is exposed to hot gases at 550°C for a period of 5 min. The heat transfer coefficient between the gases and the wood slab is 35 W/m2 ·K. If the ignition temperature of the wood is 450°C, determine if the wood will ignite.

Step 1 of 4

Given:



Initial temperature of wood slab $T_i = 25°C$

Temperature of hot gases $T_\infty = 550°C$

Thermal conductivity of the wood slab $k = 0.17 \dfrac{W}{m.°C}$

Thermal diffusivity of the wood slab $\alpha = 1.28 \times 10^{-7} \dfrac{m^2}{S}$

Step 2 of 4

Step 3 of 4

The wood slab is treated as a semi-infinite medium subjected to convection at the exposed surface. The thermal properties of the wood slab are constant. The heat transfer coefficient is constant and uniform over the entire surface.

The one-dimensional transient temperature distribution in the wood can be determined from

$$\frac{T(x,t)-T_i}{T_\infty-T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\left[erfc\left(\frac{x}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right)\right]$$

Where

$$\frac{h\sqrt{\alpha t}}{k} = \frac{(35\ W/m^2.°C)\sqrt{(1.28\times10^{-7}\ m^2/s)(5\times60\ s)}}{0.17\ W/m.°C}$$

$$\frac{h\sqrt{\alpha t}}{k} = 1.276$$

$$\frac{h^2\alpha t}{k^2} = \left(\frac{h\sqrt{\alpha t}}{k}\right)^2$$

$$\frac{h^2\alpha t}{k^2} = 1.276^2$$

$$\frac{h^2\alpha t}{k^2} = 1.628$$

Step 4 of 4

Noting that $x = 0$ at the surface and taking $erfc$ values

From complementary error function table

$$\frac{T(x,t)-25}{550-25} = erfc(0) - \exp(0+1.628)erfc(0+1.276)$$

$$\frac{T(x,t)-25}{550-25} = 1-(5.0937)(0.0712)$$

$$\frac{T(x,t)-25}{550-25} = 0.630$$

Solving for $T(x, t)$ gives

$\boxed{T(x,t)=360°C}$

Which is less than the ignition temperature of 450°C. Therefore, the wood will not ignite.

Question: 18.071P

The soil temperature in the upper layers of the earth varies with the variations in the atmospheric conditions. Before a cold front moves in, the earth at a location is initially at a uniform temperature of 15°C. Then the area is subjected to a temperature of -8°C and high winds that resulted in a convection heat transfer coefficient of 40 W/m2 ·K on the earth's surface for a period of 10 h. Taking the properties of the soil at that location to be k = 0.9 W/m·K and α = 1.6 × 10- 5 m2 /s, determine the soil temperature at distances 0, 10, 20, and 50 cm from the earth's surface at the end of this 10-h period.

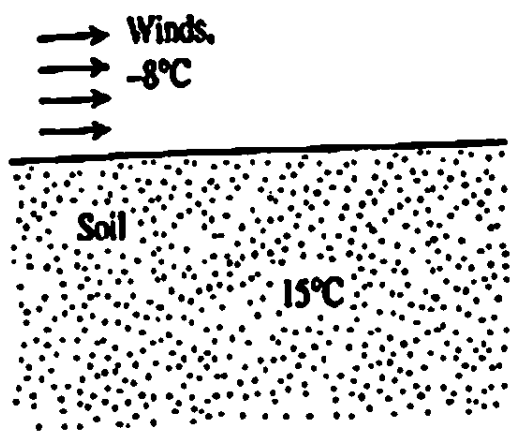


FIGURE P 18-71

Step 1 of 7

Given data:

Temperature of earth, $T_\infty = 15°C$

Temperature of operating area, $T_i = -8°C$

Convection heat transfer coefficient, $h = 40\ W/m^2 \cdot K$

Thermal conductivities of the soil, $k = 0.9\ W/m \cdot K$

Thermal diffusivity, $\alpha = 1.6 \times 10^{-5}\ m^2/s$

Step 2 of 7

An area is subjected to cold air for a 10-h period. The soil temperatures at distances 0, 10, 20, and 50 cm from the earth's surface are to be determined. The one-dimensional transient temperature distribution in the ground can be determined from

$$\frac{T(x,t)-T_i}{T_\infty - T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\left[erfc\left(\frac{x}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right)\right]$$

Where

$$\frac{h\sqrt{\alpha t}}{k} = \frac{(40\ W/m^2.°C)\sqrt{(1.6\times10^{-5}\ m^2/s)(10\times3600\ s)}}{0.9\ W/m.°C}$$

$$\frac{h^2\alpha t}{k^2} = \left(\frac{h\sqrt{\alpha t}}{k}\right)^2$$

$$\frac{h^2\alpha t}{k^2} = 33.7^2$$

$$\frac{h^2\alpha t}{k^2} = 1138$$

Step 3 of 7

Then we conclude that the last term in the temperature distribution relation above must be zero regardless of x despite the exponential term tending to infinity since $erfc(\xi) \to 0$ for $\xi > 4$ and the term has to remain less than 1 to have physically meaningful solutions. That is,

$$= \exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\left[erfc\left(\frac{x}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right)\right]$$

$$= \exp\left(\frac{hx}{k}+1138\right)\left[erfc\left(\frac{x}{2\sqrt{\alpha t}}+33.3\right)\right]$$

$$\cong 0$$

Therefore, the temperature distribution relation simplifies to

$$\frac{T(x,t)-T_i}{T_\infty - T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

Step 4 of 7

Then the temperature of the soil at distance of 0m is

At $x = 0$

$$\frac{T(x,t)-T_i}{T_\alpha - T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{T(x,t)-15}{-8-15} = erfc(0)$$

From the complementary error function table

At $erfc(0)$ is 1

Then,

$$\frac{T(x,t)-15}{-8-15} = erfc(0)$$

$$\frac{T(x,t)-15}{-8-15} = 1$$

$$T(x,t) = -8°C$$

Therefore, the temperature of the soil at distance of 0 m is $\boxed{T(x,t) = -8°C}$

Step 5 of 7

The temperature of the soil at distance of x=10m is

At $x = 10\ cm$

$$\frac{T(x,t)-T_i}{T_\alpha - T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{T(x,t)-15}{-8-15} = erfc\left(\frac{0.1}{2\sqrt{1.6\times10^{-5}\times3600\times10}}\right)$$

From the complementary error function table

At $erfc(0.066)$ is 0.9257

$$\frac{T(x,t)-15}{-8-15} = 0.9257$$

$$T(x,t) = -6.3°C$$

Therefore, the temperature of the soil at distance of 10m is $\boxed{T(x,t) = -6.3°C}$

Step 6 of 7

The temperature of the soil at distance of $x = 20\ cm$ is

At $x = 20\ cm$

$$\frac{T(x,t)-T_i}{T_\alpha - T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{T(x,t)-15}{-8-15} = erfc\left(\frac{0.2}{2\sqrt{1.6\times10^{-5}\times3600\times10}}\right)$$

From the complementary error functions table

At $erfc(0.131)$ is 0.8519

$$\frac{T(x,t)-15}{-8-15} = 0.8519$$

$$T(x,t) = -4.6°C$$

Therefore, the temperature of the soil at distance of 10m is $\boxed{T(x,t) = -4.6°C}$

Step 7 of 7

The temperature of the soil at distance of x=20m is

At $x = 50\ cm$

$$\frac{T(x,t)-T_i}{T_\alpha - T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{T(x,t)-15}{-8-15} = erfc\left(\frac{0.5}{2\sqrt{1.6\times10^{-5}\times3600\times10}}\right)$$

From the complementary error functions table

At $erfc(0.329)$ is 0.6418

$$\frac{T(x,t)-15}{-8-15} = 0.6418$$

$$T(x,t) = 0.24°C$$

Therefore, the temperature of the soil at distance of 10m is $\boxed{T(x,t) = 0.24°C}$

Question: 18.072P

Reconsider Prob. 18-71. Using EES (or other) software, plot the soil temperature as a function of the distance from the earth's surface as the distance varies from 0 m to 1m, and discuss the results.

Step 1 of 4

Given data:

Temperature of earth $T_\infty = 15°C$.

Temperature of operating area $T_i = -8°C$.

Convection heat transfer coefficient $h = 40\ W/m^2 \cdot K$.

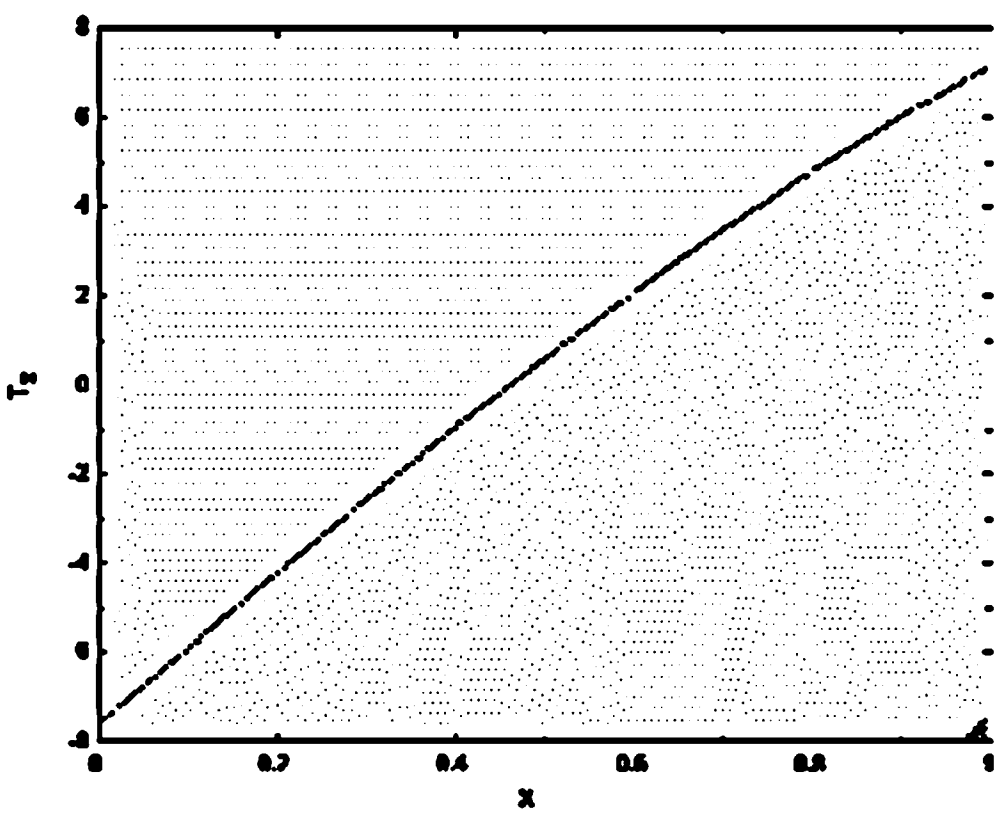
Thermal conductivities of the soil $k = 0.9\ W/m \cdot K$.

Thermal diffusivity $\alpha = 1.6 \times 10^{-5}\ m^2/s$.

Step 2 of 4

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
T_i=15 "[C]"
T_infinity=-8 "[C]"
h=40 "[W/m^2-C]"
time=10*3600 "[s]"
"x=0.1 [m], parameter to be varied"
"PROPERTIES"
k=0.9 "[W/m-C]"
alpha=1.6E-5 "[m^2/s]"
"ANALYSIS"
(T_x-T_i)/(T_infinity-T_i)=erfc(x/(2*sqrt(alpha*time)))-
exp((h*x)/k+(h^2*alpha*time)/k^2)*erfc(x/(2*sqrt(alpha*time))+(h*sqrt(alpha*time)/
k))
```



Step 3 of 4

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 21
Select variables in equations as x and T_x press ADD and then press ok
A table will appear put values of x as 0,0.05,0.1....1 in run 1 to 21
Then from Calculate -> Solve table
Solution will appear

1_21	x	T_x
Run 1	0	-7.611
Run 2	0.05	-6.762
Run 3	0.1	-5.911
Run 4	0.15	-5.064
Run 5	0.2	-4.224
Run 6	0.25	-3.391
Run 7	0.3	-2.569
Run 8	0.35	-1.758
Run 9	0.4	-0.96
Run 10	0.45	-0.1764
Run 11	0.5	0.5912
Run 12	0.55	1.342
Run 13	0.6	2.074
Run 14	0.65	2.786
Run 15	0.7	3.478
Run 16	0.75	4.149
Run 17	0.8	4.797
Run 18	0.85	5.423
Run 19	0.9	6.026

Step 4 of 4

Plot for Variation of Soil Temperature with Distance from Earth's Surface:

Question: 18.073P

A thick aluminum block initially at 20°C is subjected to constant heat flux of 4000 W/m2 by an electric resistance heater whose top surface is insulated. Determine how much the surface temperature of the block will rise after 30 minutes.

Step 1 of 2

Given:

Temperature of aluminum block $T_i = 20°C$

Heat flux $\dot{q}_s = 4000 \ \frac{W}{m^2}$

Time $t = 30 \text{ min}$

Step 2 of 2

This is conduction in transient mode where constant surface heat flux is applied to semi infinite medium, so surface temperature can be calculated as

$$T_s = T_i + \frac{\dot{q}_s}{k}\sqrt{\frac{4\alpha t}{\pi}}$$

$$T_s = 20°C + \frac{4000 W/m^2}{237 W/m.°C}\sqrt{\frac{4(9.71\times10^{-5} m^2/s)(30\times60s)}{\pi}}$$

$$T_s = 28.0°C$$

Rise in temperature for the surface will be

$$\Delta T_s = 28 - 20$$

$$\boxed{\Delta T_s = 8°C}$$

Question: 18.074P

A bare-footed person whose feet are at 32°C steps on a large aluminum block at 20°C. Treating both the feet and the aluminum block as semi-infinite solids, determine the contact surface temperature. What would your answer be if the person stepped on a wood block instead? At room temperature, the $\sqrt{k\rho c_p}$ value is 218 kJ/m2 ·°C for aluminum, 0.38 kJ/m2 ·°C for wood, and 1.1 kJ/m2 ·°C for human flesh.

Step 1 of 3

Given:

Temperature of feet at $T = 32°C$

Aluminium block at temperature $T_{Al} = 20°C$

The value of $\sqrt{(k\rho c_p)}$ for human flesh is $1.1 kJ/m^2 \cdot °C$

The value of $\sqrt{(k\rho c_p)}$ for Aluminium is $218 kJ/m^2 \cdot °C$

The value of $\sqrt{(k\rho c_p)}$ for wood is $0.38 kJ/m^2 \cdot °C$

Step 2 of 3

Contact of two semi infinite solids of different initial temperatures, the contact surface temperature can be determined as

$$T_s = \frac{\sqrt{(k\rho c_p)_A}T_{Ai} + \sqrt{(k\rho c_p)_B}T_{Bi}}{\sqrt{(k\rho c_p)_A} + \sqrt{(k\rho c_p)_B}}$$

Consider the surface A is human feet and surface B is Aluminium block and substituting the known values in the above equation,

$$T_s = \frac{1.1\times(32+273)+218\times(20+273)}{1.1+218}$$

$$= 293.06 K$$

$$= 20.06°C$$

Therefore, contact surface temperature, T_s between human feet and aluminium block is

$\boxed{20.06°C}$

Step 3 of 3

Consider the surface A is human feet and surface B is wood and substituting the known values in the surface temperature.

$$T_s = \frac{\sqrt{(k\rho c_p)_A}T_{Ai} + \sqrt{(k\rho c_p)_B}T_{Bi}}{\sqrt{(k\rho c_p)_A} + \sqrt{(k\rho c_p)_B}}$$

$$= \frac{1.1\times(32+273)+0.38\times(20+273)}{1.1+0.38}$$

Step 2 of 3

Contact of two semi infinite solids of different initial temperatures, the contact surface temperature can be determined as

$$T_s = \frac{\sqrt{(k\rho c_p)_A}T_{Ai} + \sqrt{(k\rho c_p)_B}T_{Bi}}{\sqrt{(k\rho c_p)_A} + \sqrt{(k\rho c_p)_B}}$$

Consider the surface A is human feet and surface B is Aluminium block and substituting the known values in the above equation,

$$T_s = \frac{1.1\times(32+273)+218\times(20+273)}{1.1+218}$$

Question: 18.075P

The walls of a furnace are made of 1.5-ft-thick concrete (k = 0.64 Btu/h·ft·°F and α = 0.023 ft2 /h). Initially, the furnace and the surrounding air are in thermal equilibrium at 70°F. The furnace is then fired, and the inner surfaces of the furnace are subjected to hot gases at 1800°F with a very large heat transfer coefficient. Determine how long it will take for the temperature of the outer surface of the furnace walls to rise to 70.1 °F.

Step 1 of 3

Given data:

Thickness of the wall, $x = 1.5$ ft.

Thermal conductivity of the concrete, $k = 0.64\ \text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$

Thermal diffusivity, $\alpha = 0.023\ \text{ft}^2/\text{h}$

Temperature of outer furnace wall and air $T_i = 70\,^\circ\text{F}$

Inner temperature of furnace, $T_s = 1800\,^\circ\text{F}$

Final temperature of outer furnace temperature $T(x,t) = 70.1\,^\circ\text{F}$

Step 2 of 3

The temperature in the wall is affected by the thermal conditions at inner surfaces only and the convection heat transfer coefficient inside is given to be very large. Therefore, the wall can be considered to be a semi-infinite medium with a specified surface temperature of 1800°F.

The one-dimensional transient temperature distribution in the wall for that time period can be determined from

$$\frac{T(x,t)-T_i}{T_s-T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

By substituting the known values in the above equation, we get:

$$\frac{T(x,t)-T_i}{T_\alpha-T_i} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{70.1-70}{1800-70} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$5.78\times10^{-5} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

Step 3 of 3

From the complementary error function table,

By interpolating the values at $\text{erfc}(0.00008)$ and $\text{erfc}(0.00004)$, we get the error function at 5.78×10^{-5} as,

$$\text{erfc}(2.85) = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{x}{2\sqrt{\alpha t}} = 2.85$$

$$1.5 = 2.85\times2\times\sqrt{0.023t}$$

$$\sqrt{0.023t} = 0.26315$$

$$0.023t = 0.0692$$

$$t = 3\ \text{hour}$$

Therefore, the required time to reach the temperature, $\boxed{t = 3\ \text{hour}}$

$$\frac{x}{2\sqrt{\alpha t}} = 2.85$$

$$1.5 = 2.85\times2\times\sqrt{0.023t}$$

$$\sqrt{0.023t} = 0.26315$$

$$0.023t = 0.0692$$

$$t = 3\ \text{hour}$$

Therefore, the required time to reach the temperature, $\boxed{t = 3\ \text{hour}}$

Question: 18.076P

In areas where the air temperature remains below 0°C for prolonged periods of time, the freezing of water in underground pipes is a major concern. Fortunately, the soil remains relatively warm during those periods, and it takes weeks for the subfreezing temperatures to reach the water mains in the ground. Thus, the soil effectively serves as an insulation to protect the water from the freezing atmospheric temperatures in winter.

The ground at a particular location is covered with snow pack at -8°C for a continuous period of 60 days, and the average soil properties at that location are k = 0.35 W/m·K and α = 0.15 × 10-6 m2 /s. Assuming an initial uniform temperature of 8°C for the ground, determine the minimum burial depth to prevent the water pipes from freezing.

Step 1 of 3

The length of time the snow pack stays on the ground t is 60 days. Convert the length of time from days to seconds by using the conversion formula.

$$t = (60 \text{ days})(24 \text{ hr/days})(3600 \text{ s/hr})$$
$$= 5.184 \times 10^6 \text{ s}$$

Find the depth at which freezing occurs at 0C by using analytical solution,

Question:

In areas where the air temperature remains below 0°C for prolonged periods of time, the freezing of water in underground pipes is a major concern. Fortunately, the soil remains relatively warm during those periods, and it takes weeks for the subfreezing temperatures to reach the water mains in the ground. Thus, the soil effectively serves as an insulation to protect the water from the freezing atmospheric temperatures in winter.

The ground at a particular location is covered with snow pack at -8°C for a continuous period of 60 days, and the average soil properties at that location are k = 0.35 W/m·K and α = 0.15 × 10-6 m2 /s. Assuming an initial uniform temperature of 8°C for the ground, determine the minimum burial depth to prevent the water pipes from freezing.

Step 1 of 3

The length of time the snow pack stays on the ground t is 60 days. Convert the length of time from days to seconds by using the conversion formula.

$$t = (60 \text{ days})(24 \text{ hr/days})(3600 \text{ s/hr})$$
$$= 5.184 \times 10^6 \text{ s}$$

Find the depth at which freezing occurs at 0C by using analytical solution,

0.02

$$\eta = 0.477$$

$$\frac{x}{1.7636} = 0.477$$

Step 3 of 3

The complementary error function of $\left(\frac{x}{1.7636}\right)$ is 0.477. Use the value to find x.

$$\frac{x}{1.7636} = 0.477$$
$$x = 0.8412 \text{ m}$$

Therefore, the minimum burial depth x required to prevent the water pipes from freezing is, **0.8412 m** .

Question: 18.077P

A highway made of asphalt is initially at a uniform temperature of 55°C. Suddenly the highway surfacetemperature is reduced to 25°C by rain. Determine the temperature at the depth of 3 cm from the highway surface andthe heat flux transferred from the highway after 60 minutes. Assume the highway surface temperature is maintained at 25°C.

Step 1 of 3

Obtain the values for properties of asphalt from Appendix table A-8 as shown.

$$k = 0.062 \text{ W/m} \cdot \text{K}$$
$$\rho = 2115 \text{ kg/m}^3$$
$$C_p = 920 \text{ J/kg} \cdot \text{K}$$

Calculate the thermal diffusivity of asphalt by using the relation,

$$\alpha = \frac{k}{\rho C_p}$$

Here, thermal conductivity of the asphalt material is k, density of the asphalt material is ρ, and specific heat of the material is C_p.

Substitute $0.062 \text{ W/m} \cdot \text{K}$ for k, 2115 kg/m^3 for ρ, and $920 \text{ J/kg} \cdot \text{K}$ for ρ.

$$\alpha = \frac{0.062}{2115 \times 920}$$
$$= 3.186 \times 10^{-8} \text{ m}^2/\text{s}$$

Step 2 of 3

Calculate the temperature at a depth of 3 cm from the highway surface after 60 min as shown.

$$\frac{T(x,i) - T_i}{T_s - T_i} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

Here, initial temperature is T_i, surface temperature is T_s, depth from the highway surface is x, and time required for heat flux transfer is t.

Substitute 55 °C for T_i, 25 °C for T_s, 0.03 m for x, $3.186 \times 10^{-8} \text{ m}^2/\text{s}$ for α, and 3600 s for t.

$$\frac{T(0.03 \text{ m}, 3600 \text{ s}) - 55}{25 - 55} = \text{erfc}\left(\frac{0.03}{2\sqrt{3.186 \times 10^{-8} \times 3600}}\right) \quad \text{..... (1)}$$
$$T(0.03 \text{ m}, 3600 \text{ s}) - 55 = (-30)\text{erfc}(1.40)$$
$$T = 55 - 30[\text{erfc}(1.40)]$$

Obtain the value of $\text{erfc}(1.40)$ from table 4-4 as shown.

$$\text{erfc}(1.40) = 0.04772$$

Step 3 of 3

Calculate the temperature at a depth of 3 cm from the highway surface after 60 min as shown.

Substitute 0.04772 for $\text{erfc}(1.40)$ in equation (1).

$$T = 55 - 30[0.04772]$$
$$= 53.57 \text{ °C}$$

Therefore, the temperature at a depth of 3 cm from the highway surface after 60 min is $\boxed{53.57 \text{ °C}}$.

Calculate the heat flux transferred from the highway surface by using the relation,

$$\dot{q}_s = \frac{k(T_i - T_s)}{\sqrt{\pi \alpha t}}$$

Substitute 55 °C for T_i, 25 °C for T_s, $0.062 \text{ W/m} \cdot \text{K}$ for k, $3.186 \times 10^{-8} \text{ m}^2/\text{s}$ for α, and 3600 s for t.

$$\dot{q}_s = \frac{0.062(55 - 25)}{\sqrt{\pi \times 3.186 \times 10^{-8} \times 3600}}$$
$$= \frac{1.86}{18.98 \times 10^{-5}}$$
$$= 98 \text{ W/m}^2$$

Therefore, the heat flux transferred from the highway surface is $\boxed{98 \text{ W/m}^2}$.

Question: 18.078P

In a vacuum chamber, a thick slab is placed under an array of laser diodes with an output constant pulse *M* thermocouple is inserted inside the slab at 25 mm from the surface and the slab has an initial uniform temperature of20°C. The known properties of the slab are $k = 63.9$ W/m·K and $\alpha = 18.8 \times 10\text{-}6$ m2 /s. If the thermocouple measured temperature of 130°C after 30 s the slab surface has been exposed to the laser pulse, determine (*a*) the amount of J energy per unit surface area directed on the slab surface and (*b*) the thermocouple reading after 60 s has elapsed

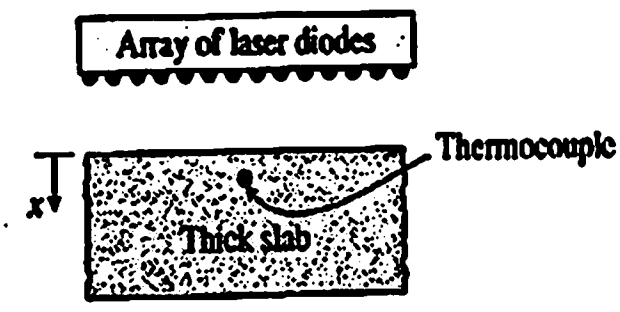


FIGURE P 18-78

Step 1 of 3

(a).

Calculate the energy pulse directed on the surface of slab per unit surface area by using the relation,

$$T(x,t)-T_i=\frac{e_s}{k\sqrt{\frac{\pi t}{\alpha}}}\exp\left(-\frac{x^2}{4\alpha t}\right) \quad \text{..... (1)}$$

Rearrange the equation as shown.

$$T(x,t)-T_i=\frac{e_s}{k\sqrt{\frac{\pi t}{\alpha}}}\exp\left(-\frac{x^2}{4\alpha t}\right)$$

$$e_s=\frac{k\sqrt{\frac{\pi t}{\alpha}}\left[T(x,t)-T_i\right]}{\exp\left(-\frac{x^2}{4\alpha t}\right)} \quad \text{..... (2)}$$

Here, thermal conductivity of the slab is k , thermal diffusivity of the slab is α , time taken by the slab to reach temperature $T(x,t)$ is t , depth to which thermocouple is inserted is x .

Step 2 of 3

Calculate the energy pulse directed on the surface of slab per unit surface area as shown.

Substitute $63.9\ \text{W/m}\cdot\text{K}$ for k , $30\ \text{s}$ for t , $18.8\times10^{-6}\ \text{m}^2/\text{s}$ for α , $130\ ^\circ\text{C}$ for $T(x,t)$, $20\ ^\circ\text{C}$ for T_i , and $0.025\ \text{m}$ for x in equation (2).

$$e_s=\frac{(63.9)\sqrt{\frac{\pi\times30}{18.8\times10^{-6}}}\left[130-20\right]}{\exp\left(-\frac{(0.025)^2}{4\times18.8\times10^{-6}\times30}\right)}$$

$$=\frac{7029\times2.24\times10^{-3}}{\exp(-0.277)}$$

$$=2.076\times10^7\ \text{J/m}^2$$

Therefore, the energy pulse directed on the surface of slab per unit surface area is $\boxed{2.076\times10^7\ \text{J/m}^2}$.

Step 3 of 3

(b).

Calculate the thermocouple reading after $60\ \text{s}$ using the relation in equation (1) as shown.

$$T(x,t)-T_i=\frac{e_s}{k\sqrt{\frac{\pi t}{\alpha}}}\exp\left(-\frac{x^2}{4\alpha t}\right)$$

Substitute $2.076\times10^7\ \text{J/m}^2$ for e_s , $63.9\ \text{W/m}\cdot\text{K}$ for k , $60\ \text{s}$ for t , $18.8\times10^{-6}\ \text{m}^2/\text{s}$ for α , $20\ ^\circ\text{C}$ for T_i , and $0.025\ \text{m}$ for x in equation (1).

$$T-20=\frac{2.076\times10^7}{(63.9)\sqrt{\frac{\pi\times60}{18.8\times10^{-6}}}}\exp\left(-\frac{(0.025)^2}{4\times18.8\times10^{-6}\times60}\right)$$

$$=20+10.26\exp(-0.1385)$$

$$=20+89.33$$

$$=109.33\ ^\circ\text{C}$$

Therefore, the thermocouple reading after $60\ \text{s}$ is $\boxed{109.33\ ^\circ\text{C}}$.

Question: 18.079P

What is the product solution method? How is it used to determine the transient temperature distribution in a two-dimensional system?

Step 1 of 1

The product solution enables us to determine the dimensionless temperature of two- or three-dimensional heat transfer problems as the product of dimensionless temperatures of one-dimensional heat transfer problems. The dimensionless temperature for a two-dimensional problem is determined by determining the dimensionless temperatures in both directions, and taking their product.

Question: 18.080P

How is the product solution used to determine the variation of temperature with time and position in three-dimensional systems?

Step 1 of 1

The dimensionless temperature for a three-dimensional heat transfer is determined by determining the dimensionless temperatures of one-dimensional geometries whose intersection is the three dimensional geometry, and taking their product.

Question: 18.081P

A short cylinder initially at a uniform temperature Ti is subjected to convection from all of its surfaces to a medium at temperature $T\infty$. Explain how you can determine the temperature of the midpoint of the cylinder at a specified time t.

Step 1 of 1

This short cylinder is physically formed by the intersection of a long cylinder and a plane wall. The dimensionless temperatures at the center of plane wall and at the center of the cylinder are determined first. Their product yields the dimensionless temperature at the center of the short cylinder.

Question: 18.082P

Consider a short cylinder whose top and bottom surfaces are insulated. The cylinder is initially at a uniform temperature *Ti* and is subjected to convection from its side surface to a medium at temperature T_∞ with a heat transfer coefficient of *h*. Is the heat transfer in this short cylinder one-or two-dimensional? Explain.

Step 1 of 1

The heat transfer in this short cylinder is one-dimensional since there is no heat transfer in the axial direction. The temperature will vary in the radial direction only.

Question: 18.083P pg 1

Consider a cubic block whose sides are 5 cm long and a cylindrical block whose height and diameter are also 5 cm. Both blocks are initially at 20°C and are made of granite (k = 2.5 W/m·K and α = 1.15 × 10-6 m2 /s). Now both blocks are exposed to hot gases at 500°C in a furnace on all of their surfaces with a heat transfer coefficient of 40 W/m2 K. Determine the center temperature of each geometry after 10, 20. and 60 min.

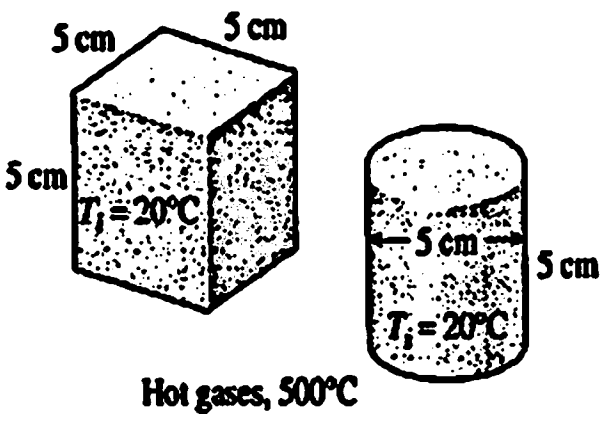

FIGURE P 18-83

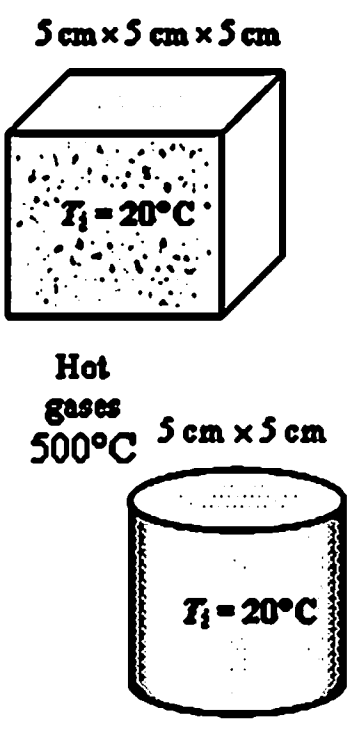
Step 1 of 11

Given:

Length of the cubic block $L = 5$ cm

Height of the cylindrical block $H = 5$ cm

Diameter of the cylindrical block $D = 5$ cm



Initial temperature of the blocks $T_i = 20°C$

Thermal Conductivity, $k = 2.5\ W/m \cdot °C$

Thermal Diffusivity, $\alpha = 1.15 \times 10^{-6}\ m^2/s$

Heat transfer coefficient $h = 40\ \frac{W}{m^2 \cdot °C}$

Step 2 of 11

Step 3 of 11

Calculation after 10 minutes: The Biot number, the corresponding constants, and the Fourier number are

$$Bi = \frac{hL}{k}$$

$$Bi = \frac{(40\ W/m^2.°C)(0.025\ m)}{(2.5\ W/m.°C)}$$

$$Bi = 0.400$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$\lambda_1 = 0.5932$ and $A_1 = 1.0580$

Step 4 of 11

$$\tau = \frac{\alpha t}{L^2}$$

$$\tau = \frac{(1.15 \times 10^{-6}\ m^2/s)(10\ min \times 60\ s/min)}{(0.025\ m)^2}$$

$$\tau = 1.104 > 0.2$$

To determine the center temperature, the product solution can be written as

$$\theta(0,0,0,t)_{block} = [\theta(0,t)_{wall}]^3$$

$$\frac{T(0,0,0,t) - T_\infty}{T_i - T_\infty} = \left(A_1 e^{-\lambda_1^2 \tau}\right)^3$$

$$\frac{T(0,0,0,t) - 500}{20 - 500} = \left\{(1.0580) e^{-(0.5932)^2 (1.104)}\right\}^3$$

$$\frac{T(0,0,0,t) - 500}{20 - 500} = 0.369$$

$$\boxed{T(0,0,0,t) = 323°C}$$

Step 5 of 11

After 20 minutes

$$\tau = \frac{\alpha t}{L^2}$$

$$\tau = \frac{(1.15 \times 10^{-6}\ m^2/s)(20\ min \times 60\ s/min)}{(0.025\ m)^2}$$

$$\tau = 2.208 > 0.2$$

$$\frac{T(0,0,0,t) - 500}{20 - 500} = \left\{(1.0580) e^{-(0.5932)^2 (2.208)}\right\}^3$$

$$\frac{T(0,0,0,t) - 500}{20 - 500} = 0.115$$

$$\boxed{T(0,0,0,t) = 445°C}$$

Step 6 of 11

After 60 minutes

$$\frac{\alpha t}{}$$

Step 6 of 11

After 60 minutes

$$\tau = \frac{\alpha t}{L^2}$$

$$\tau = \frac{(1.15\times10^{-6}\ \text{m}^2/\text{s})(60\ \text{min}\times 60\ \text{s/min})}{(0.025\ \text{m})^2}$$

$$\tau = 6.624 > 0.2$$

$$\frac{T(0,0,0,t)-500}{20-500} = \left\{(1.0580)e^{-(0.5932)^2(6.624)}\right\}^3$$

Step 7 of 11

$$\frac{T(0,0,0,t)-500}{20-500} = 0.00109$$

$$\boxed{T(0,0,0,t)=500^\circ C}$$

Note that $\tau > 0.2$ in all dimensions and thus the one-term approximate solution for transient heat conduction is applicable.

Step 8 of 11

Cylinder: This cylindrical block can physically be formed by the intersection of a long cylinder of radius $r_o = D/2 = 2.5$ cm and a plane wall of thickness $2L = 5$ cm.

After 10 minutes: The Biot number and the corresponding constants for the long cylinder are

$$Bi = \frac{hr_o}{k}$$

$$Bi = \frac{(40\ \text{W/m}^2.^\circ\text{C})(0.025\ \text{m})}{(2.5\ \text{W/m}.^\circ\text{C})}$$

$$Bi = 0.400$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$$\lambda_1 = 0.8516 \quad \text{and} \quad A_1 = 1.0931$$

Step 9 of 11

To determine the center temperature, the product solution can be written as

$$\theta(0,0,t)_{brick} = [\theta(0,t)_{wall}][\theta(0,t)_{cyl}]$$

$$\frac{T(0,0,t)-T_\infty}{T_i-T_\infty} = \left(A_1 e^{-\lambda_1^2\tau}\right)_{wall}\left(A_1 e^{-\lambda_1^2\tau}\right)_{cyl}$$

$$\frac{T(0,0,t)-500}{20-500} = \left\{(1.0580)e^{-(0.5932)^2(1.104)}\right\}\left\{(1.0931)e^{-(0.8516)^2(1.104)}\right\}$$

$$\frac{T(0,0,t)-500}{20-500} = 0.352$$

$$\boxed{T(0,0,t)=331^\circ C}$$

Step 10 of 11

After 20 minutes

$$\frac{T(0,0,t)-500}{20-500} = \left\{(1.0580)e^{-(0.5932)^2(2.208)}\right\}\left\{(1.0931)e^{-(0.8516)^2(2.208)}\right\}$$

$$\frac{T(0,0,t)-500}{20-500} = 0.107$$

$$\boxed{T(0,0,t)=449^\circ C}$$

Step 11 of 11

After 60 minutes

$$\frac{T(0,0,t)-500}{20-500} = \left\{(1.0580)e^{-(0.5932)^2(6.624)}\right\}\left\{(1.0931)e^{-(0.8516)^2(6.624)}\right\}$$

$$\frac{T(0,0,t)-500}{20-500} = 0.00092$$

$$\boxed{T(0,0,t)=500^\circ C}$$

Note that $\tau > 0.2$ in all dimensions and thus the one-term approximate solution for transient heat conduction is applicable.

Question:

Repeat Prob. 18-83 with the heat transfer coefficient at the top and the bottom surfaces of each block being doubled to 80 W/m2 ·K.

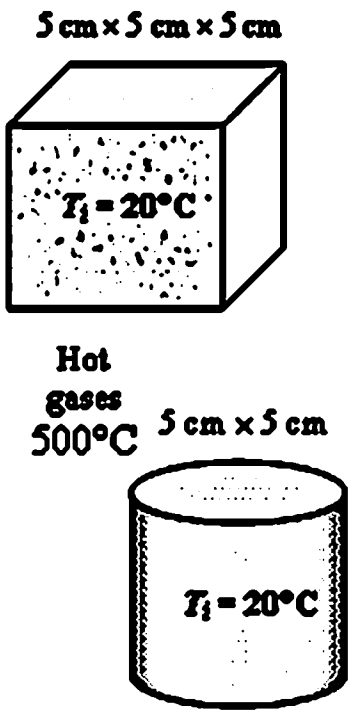
Step 1 of 11

Given:

Length of the cubic block $L = 5$ cm

Height of the cylindrical block $H = 5$ cm

Diameter of the cylindrical block $D = 5$ cm



Initial temperature of the blocks $T_i = 20°C$

Thermal Conductivity, $k = 2.5$ W/m · °C

Thermal Diffusivity, $\alpha = 1.15\times10^{-6}$ m^2/s

Heat transfer coefficient $h = 40 \dfrac{\text{W}}{\text{m}^2 \cdot °\text{C}}$

Step 2 of 11

Step 3 of 11

Calculation after 10 minutes: The Biot number, the corresponding constants, and the Fourier number are

$$Bi = \frac{hL}{k}$$

$$Bi = \frac{(40\ \text{W/m}^2.°\text{C})(0.025\ \text{m})}{(2.5\ \text{W/m.°C})}$$

$$Bi = 0.400$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$\lambda_1 = 0.5932$ and $A_1 = 1.0580$

Step 4 of 11

$$\tau = \frac{\alpha t}{L^2}$$

$$\tau = \frac{(1.15\times10^{-6}\ \text{m}^2/\text{s})(10\ \text{min}\times60\ \text{s/min})}{(0.025\ \text{m})^2}$$

$$\tau = 1.104 > 0.2$$

To determine the center temperature, the product solution can be written as

$$\theta(0,0,0,t)_{\text{block}} = [\theta(0,t)_{\text{wall}}]^2[\theta(0,t)_{\text{wall}}]$$

$$\frac{T(0,0,0,t)-T_\infty}{T_i-T_\infty} = \left(A_1 e^{-\lambda_1^2\tau}\right)^2\left(A_1 e^{-\lambda_1^2\tau}\right)$$

$$\frac{T(0,0,0,t)-500}{20-500} = \left\{(1.0580)e^{-(0.5932)^2(1.104)}\right\}^2\left\{(1.1016)e^{-(0.7910)^2(1.104)}\right\}$$

$$\boxed{T(0,0,0,t) = 364°\text{C}}$$

Step 5 of 11

<u>After 20 minutes</u>

$$\tau = \frac{\alpha t}{L^2}$$

$$\tau = \frac{(1.15\times10^{-6}\ \text{m}^2/\text{s})(20\ \text{min}\times60\ \text{s/min})}{(0.025\ \text{m})^2}$$

$$\tau = 2.208 > 0.2$$

$$\frac{T(0,0,0,t)-500}{20-500} = \left\{(1.0580)e^{-(0.5932)^2(2.208)}\right\}^2\left\{(1.1016)e^{-(0.7910)^2(2.208)}\right\}$$

$$\frac{T(0,0,0,t)-500}{20-500} = 0.0654$$

$$\boxed{T(0,0,0,t) = 469°\text{C}}$$

Step 6 of 11

After 60 minutes

$$\tau = \frac{\alpha t}{L^2}$$

$$\tau = \frac{(1.15\times10^{-6}\ \text{m}^2/\text{s})(60\ \text{min}\times60\ \text{s/min})}{(0.025\ \text{m})^2}$$

$$\tau = 6.624 > 0.2$$

Step 7 of 11

$$\frac{T(0,0,0,t)-500}{20-500} = \left\{(1.0580)e^{-(0.5932)^2(6.624)}\right\}^2\left\{(1.1016)e^{-(0.7910)^2(6.624)}\right\}$$

$$\frac{T(0,0,0,t)-500}{20-500} = 0.000186$$

$$\boxed{T(0,0,0,t)=500°\text{C}}$$

Note that $\tau > 0.2$ in all dimensions and thus the one-term approximate solution for transient heat conduction is applicable

$$\frac{T(0,0,t)-500}{20-500}=0.000186$$

$\boxed{T(0,0,t)=500°C}$

Note that $\tau > 0.2$ in all dimensions and thus the one-term approximate solution for transient heat conduction is applicable

Step 8 of 11

Cylinder: This cylindrical block can physically be formed by the intersection of a long cylinder of radius $r_o = D/2 = 2.5$ cm and a plane wall of thickness $2L = 5$ cm.

<u>After 10 minutes</u>: The Biot number and the corresponding constants for the long cylinder are

$$Bi = \frac{hr_o}{k}$$

$$Bi = \frac{(40\ \text{W/m}^2.°\text{C})(0.025\ \text{m})}{(2.5\ \text{W/m}.°\text{C})}$$

$$Bi = 0.400$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$$\lambda_1 = 0.8516 \quad \text{and} \quad A_1 = 1.0931$$

Step 9 of 11

To determine the center temperature, the product solution can be written as

$$\theta(0,0,t)_{block} = [\theta(0,t)_{wall}][\theta(0,t)_{cyl}]$$

$$\frac{T(0,0,t)-T_\infty}{T_i-T_\infty} = \left(A_1 e^{-\lambda_1^2 \tau}\right)_{wall}\left(A_1 e^{-\lambda_1^2 \tau}\right)_{cyl}$$

$$\frac{T(0,0,t)-500}{20-500} = \left\{(1.1061)e^{-(0.7910)^2(1.104)}\right\}\left\{(1.0931)e^{-(0.8516)^2(1.104)}\right\}$$

$$\frac{T(0,0,t)-500}{20-500} = 0.271$$

$\boxed{T(0,0,t)=370°C}$

Step 10 of 11

After 20 minutes

$$\frac{T(0,0,t)-500}{20-500} = \left\{(1.1016)e^{-(0.7910)^2(2.208)}\right\}\left\{(1.0931)e^{-(0.8516)^2(2.208)}\right\}$$

$$\frac{T(0,0,t)-500}{20-500} = 0.06094$$

$\boxed{T(0,0,t)=471°C}$

Step 11 of 11

After 60 minutes

$$\frac{T(0,0,t)-500}{20-500} = \left\{(1.1016)e^{-(0.7910)^2(6.624)}\right\}\left\{(1.0931)e^{-(0.8516)^2(6.624)}\right\}$$

$$\frac{T(0,0,t)-500}{20-500} = 0.0001568$$

$\boxed{T(0,0,t)=500°C}$

Note that $\tau > 0.2$ in all dimensions and thus the one-term approximate solution for transient heat conduction is applicable.

Question: 18.085P pg 1

A short brass cylinder (ρ = 8530 kg/m3 , cp = 0.389 kJ/kg-K, k = 110 W/m2·K, and α = 3.39 × 10–5 m2 /s) of diameter 4 cm and height 20 cm is initially at a uniform temperature of 150°C. The cylinder is now placed in atmospheric air at 20°C, where heat transfer takes place by convection with a heat transfer coefficient of 40 W/m2 -K. Calculate (*a*) the center temperature of the cylinder; (*b*) the center temperature of the top surface of the cylinder; and (*c*) the total heat transfer from the cylinder 15 min after the start of the cooling.

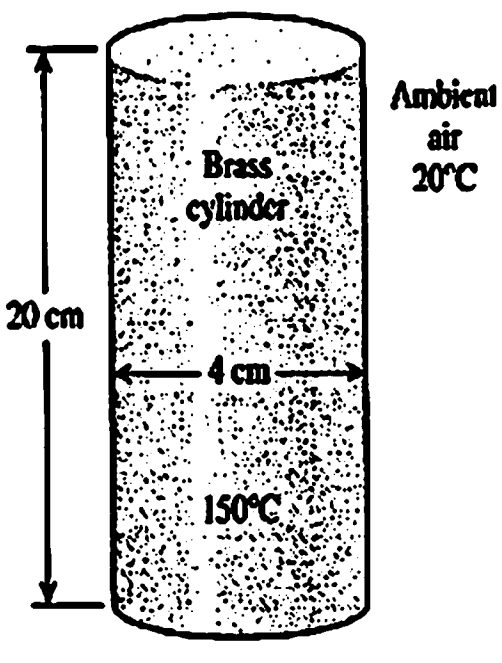


FIGURE P18–85

Step 1 of 8

Calculate Biot number,

$$Bi = \frac{hL_c}{k}$$

$$Bi = \frac{40 \times L_c}{110}$$

Now, characteristic length can be obtained by approximating a plane wall having thickness: $2L_c = 20$ cm

Putting this into Biot number expression, we get:

$$Bi = \frac{hL_c}{K}$$

$$= \frac{40 \times L_c}{110}$$

$$= \frac{40 \times \left(\frac{10}{100}\right)}{110}$$

$$Bi = 0.036$$

Step 2 of 8

For this Biot number, using table 4-2, we get: $\lambda = 0.187, A = 1.0059$

Again, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L^2}$$

$$= \frac{\left(3.39 \times 10^{-5}\right)(15 \times 60)}{\left(\frac{10}{100}\right)^2}$$

$$= 3.051$$

So, to determine the dimensionless temperature at the centre of approximated plane wall, we can use:

$$\left(\frac{T - T_\alpha}{T_i - T_\alpha}\right) = Ae^{-\lambda^2 \tau}$$

$$\left(\frac{T - T_\alpha}{T_i - T_\alpha}\right) = 1.0059 \times e^{-0.187^2 \times 3.051}$$

$$\left(\frac{T - T_\alpha}{T_i - T_\alpha}\right) = 0.904$$

Step 3 of 8

For long cylinder:

$$Bi = \frac{hL_c}{K}$$

$$= \frac{40 \times L_c}{110}$$

$$= \frac{40 \times \left(\frac{2}{100}\right)}{110}$$

$$Bi = 7.27 \times 10^{-3}$$

For this Biot number, using table 4-2, we get: $\lambda = 0.08, A = 1.0006$

And, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L^2}$$

$$= \frac{\left(3.39 \times 10^{-5}\right)(15 \times 60)}{\left(\frac{2}{100}\right)^2}$$

$$\tau = 76.275$$

Step 4 of 8

So, the dimensionless temperature is determined to be:

$$\left(\frac{T - T_\alpha}{T_i - T_\alpha}\right) = Ae^{-\lambda^2 \tau}$$

$$\left(\frac{T - T_\alpha}{T_i - T_\alpha}\right) = 1.0006 \times e^{-0.08^2 \times 76.275}$$

$$\left(\frac{T - T_\alpha}{T_i - T_\alpha}\right) = 0.614$$

Finally, temperature of the short cylinder at the centre is obtained as:

$$\frac{T - T_\alpha}{T_i - T_\alpha} = 0.904 \times 0.614$$

$$\Rightarrow \frac{T - T_\alpha}{T_i - T_\alpha} = 0.55$$

$$\Rightarrow \frac{T - 20}{(150 - 20)} = 0.55$$

$$\Rightarrow \frac{T-T_\alpha}{T_i-T_\alpha}=0.55$$

$$\Rightarrow \frac{T-20}{(150-20)}=0.55$$

$$\Rightarrow \boxed{T=91.5^\circ \text{ C}}$$

So the temperature of the short cylinder at centre is obtained to be $\boxed{91.5°C}$.

Step 5 of 8

For the determination of the centre temperature of the top surface of the cylinder, first the dimensionless temperature at the surface of the chosen approximated plane wall is to be obtained. This is:

$$\left(\frac{T-T_\alpha}{T_i-T_\alpha}\right)=Ae^{-\lambda^2\tau}\cos(\lambda)$$

$$=1.0059\times e^{-0.187^2\times 3.051}\times\cos(0.187)$$

$$=0.904\times\cos(0.187)$$

$$\left(\frac{T-T_\alpha}{T_i-T_\alpha}\right)=0.888$$

For long cylinder:

$$Bi=\frac{hL_c}{K}$$

$$=\frac{40\times L_c}{110}$$

$$=\frac{40\times\left(\frac{2}{100}\right)}{110}$$

$$Bi=7.27\times10^{-3}$$

Step 6 of 8

So, the dimensionless temperature is determined to be:

$$\left(\frac{T-T_\alpha}{T_i-T_\alpha}\right)=Ae^{-\lambda^2\tau}$$

$$=1.0006\times e^{-0.08^2\times 76.275}$$

$$\left(\frac{T-T_\alpha}{T_i-T_\alpha}\right)=0.614$$

Finally, temperature of the short cylinder at the top surface is obtained as:

$$\frac{T-T_\alpha}{T_i-T_\alpha}=0.888\times0.614$$

$$\frac{T-T_\alpha}{T_i-T_\alpha}=0.54$$

$$\frac{T-20}{(150-20)}=0.54$$

$$\boxed{T=90.2^\circ \text{ C}}$$

Step 7 of 8

So the temperature of the short cylinder at top surface is obtained 90.2° C.

Maximum heat transfer from the cylinder is obtained as: $Q=mC_p(150\text{-}20)$

Where mass (m) of cylinder is: $8530\times\pi\times0.02^2\times\frac{20}{100}=2.14$ Kg

Putting this data:

$$Q=mC_p(150\text{-}20)$$

$$=2.14\times0.389\times(150\text{-}20)$$

$$Q=108 \text{ KJ}$$

And, for dimensionless heat transfer we get for plane wall:

$$\left(\frac{Q}{108}\right)_W=1-0.904\times\frac{\sin(\lambda)}{\lambda}$$

$$\left(\frac{Q}{108}\right)_W=1-0.904\times\frac{\sin(0.187)}{0.187}$$

$$\left(\frac{Q}{108}\right)_W=0.1$$

Step 8 of 8

And for cylinder:

$$\left(\frac{Q}{108}\right)_C=1-2\times0.614\times\frac{J_1(\lambda)}{\lambda}$$

$$=1-2\times0.614\times\frac{J_1(0.187)}{0.187}$$

$$=1-2\times0.614\times\frac{0.093}{0.187}$$

$$\left(\frac{Q}{108}\right)_C=0.389$$

So total heat transfer for short cylinder is:

$$\left(\frac{Q}{108}\right)=\left(\frac{Q}{108}\right)_W+\left(\frac{Q}{108}\right)_C\times\left[1-\left(\frac{Q}{108}\right)_W\right]$$

$$\left(Q/108\right)=0.1+0.389\times[1-0.1]$$

$$\left(Q/108\right)=0.45$$

$$\boxed{Q=48.60 \text{ KJ}}$$

Finally, total heat transfer for short cylinder is obtained as $\boxed{48.60 \text{ KJ}}$

Question:

Reconsider Prob. 18-85. Using EES (or other) b & software, investigate the effect of the cooling time on the center temperature of the cylinder, the center temperature of the top surface of the cylinder, and the total heat transfer. Let the time vary from 5 min to 60 min. Plot the center temperature of the cylinder, the center temperature of the top surface, and the total heat transfer as a function of the time, and discuss the results.

Step 1 of 17

Given data:

Diameter of cylinder $D = 4$ cm

Height of cylinder $L = 20$ cm

Initial temperature of cylinder $T_i = 150°C$

Atmospheric temperature $T_\infty = 20°C$

The density of brass $\rho = 8530$ kg/m^3

The specific heat of brass are given to be $C_p = 0.389$ kJ/kg·°C,

The thermal conductivities of brass are given to be $k = 110$ W/m·°C,

The thermal diffusivity of brass are given to be $\alpha = 3.39\times10^{-5}$ m^2/s.

Step 2 of 17

For this problem:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{40\times L_c}{110}$$

Now, characteristic length can be obtained by approximating a plane wall having thickness: $2L_c = 20$ cm

Step 3 of 17

Putting this into Biot number expression, we get:

$$Bi = \frac{hL_c}{K}$$

$$= \frac{40\times L_c}{110}$$

$$= \frac{40\times\left(10/100\right)}{110}$$

$$= 0.036$$

Step 4 of 17

From the coefficient used in one term approximation solution of transient one dimensional heat conduction,

At Bi=0.036

$\lambda = 0.187, A = 1.0059$

Again, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L^2}$$

So, to determine the dimensionless temperature at the centre of approximated plane wall, we can use:

$$\frac{T - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2\tau}$$

$$\frac{T - T_\alpha}{T_i - T_\alpha} = 1.0059\times e^{-0.187^2\times\tau}$$

Step 5 of 17

For long cylinder:

$$Bi = \frac{hL_c}{K}$$

$$= \frac{40\times L_c}{110}$$

$$= \frac{40\times\left(2/100\right)}{110}$$

$$= 7.27\times10^{-3}$$

Step 6 of 17

From the coefficient used in one term approximation solution of transient one dimensional heat conduction,

At $Bi = 7.27\times10^{-3}$

$\lambda = 0.08, A = 1.0006$

And, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L^2}$$

So, the dimensionless temperature is determined to be:

$$\frac{T - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2\tau}$$

$$\frac{T - T_\alpha}{T_i - T_\alpha} = 1.0006\times e^{-0.08^2\times\tau}$$

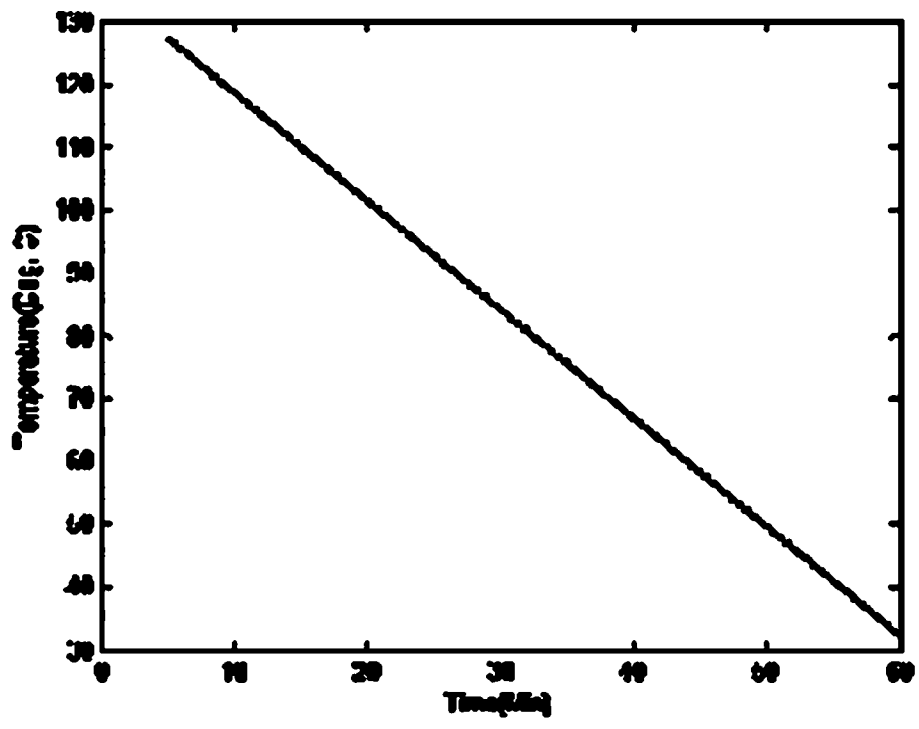
Step 7 of 17

Finally, temperature of the short cylinder at the centre is obtained as:

$$\frac{T - T_\alpha}{T_i - T_\alpha} = 1.0059\times e^{-0.187^2\times\tau}\times 1.0006\times e^{-0.08^2\times\tau}$$

$$\frac{T - 20}{(150 - 20)} = 1.0059\times e^{-0.187^2\times\tau}\times 1.0006\times e^{-0.08^2\times\tau}$$

Step 8 of 17



The MATLAB code for this plot is:

```
clear all
clc
x=linspace(5,60,2);
y=((3.39*(10^-5))*x*60)/(0.1*0.1);
z=(1.0059*exp(-0.187*0.187*y));
```

```
clear all
clc
x=linspace(5,60,2);
y=((3.39*(10^-5))*x*60)/(0.1*0.1);
z=(1.0059*exp(-0.187*0.187*y));
y1=((3.39*(10^-5))*x*60)/(0.02*0.02);
z1=(1.0006*exp(-0.08*0.08*y1));
zz=z.*z1.*(150-20)+20;
plot(x,zz);
```

Step 9 of 17

Below is shown the variation of the temperature of the short cylinder at centre versus time:

Step 10 of 17

For the determination of the centre temperature of the top surface of the cylinder, first the dimensionless temperature at the surface of the chosen approximated plane wall is to be obtained. This is:

$$\frac{T-T_\alpha}{T_i-T_\alpha}=Ae^{-\lambda^2\tau}\cos(\lambda)$$

$$\frac{T-T_\alpha}{T_i-T_\alpha}=1.0059\times e^{-0.187^2\times\tau}\times\cos(0.187)$$

For long cylinder:

$$Bi=\frac{hL_o}{K}$$

$$=\frac{40\times L_o}{110}$$

$$=\frac{40\times\left(2/100\right)}{110}$$

$$=7.27\times10^{-3}$$

Step 11 of 17

So, the dimensionless temperature is determined to be:

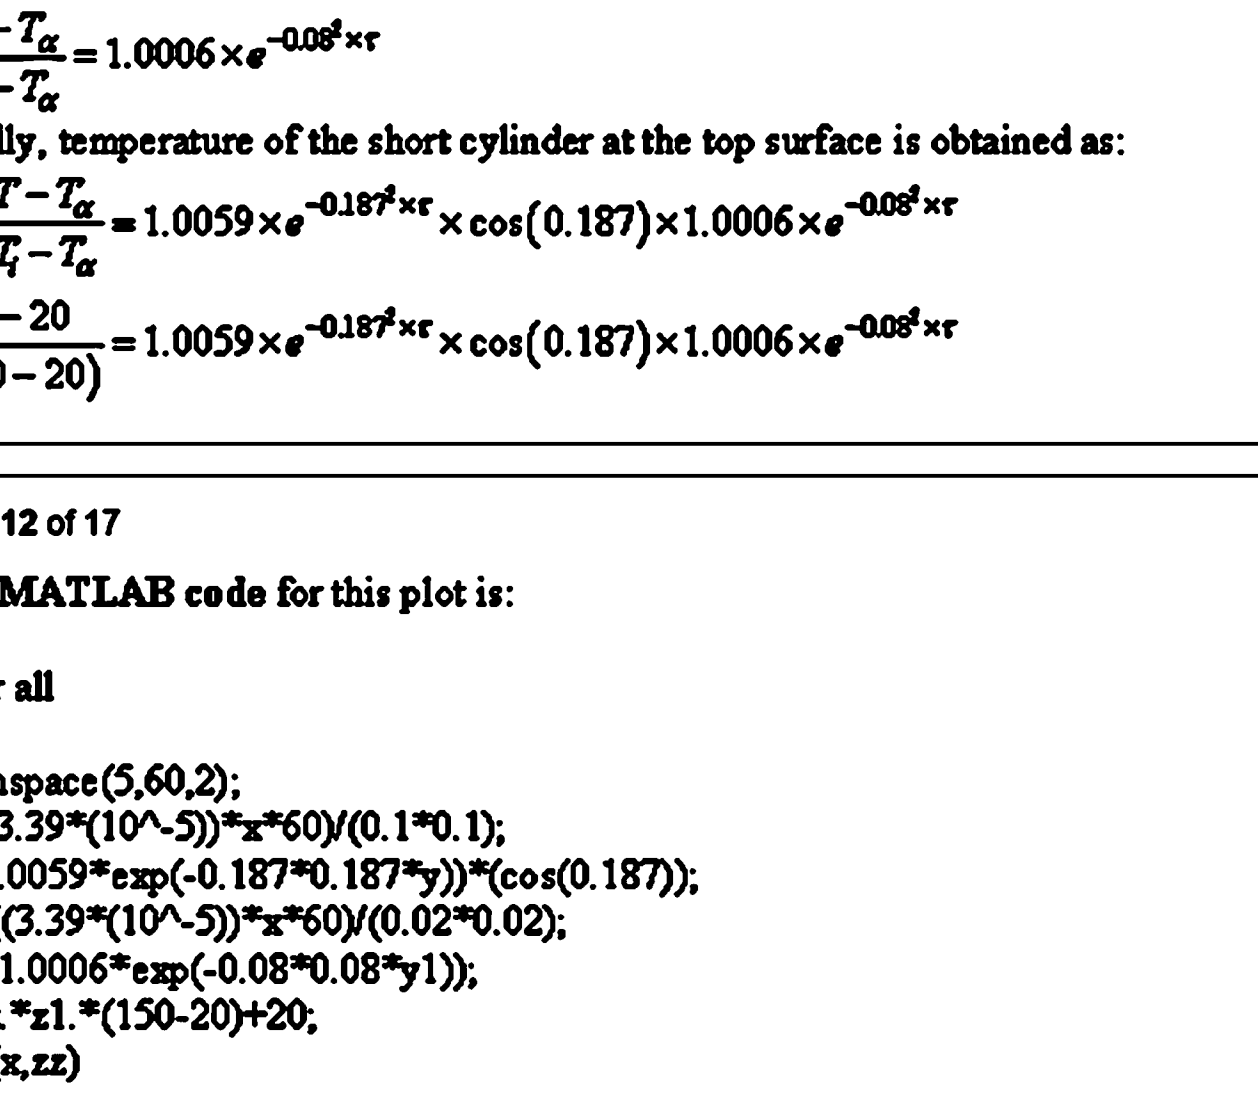
$$\frac{T-T_\alpha}{T_i-T_\alpha}=Ae^{-\lambda^2\tau}$$

$$\frac{T-T_\alpha}{T_i-T_\alpha}=1.0006\times e^{-0.08^2\times\tau}$$

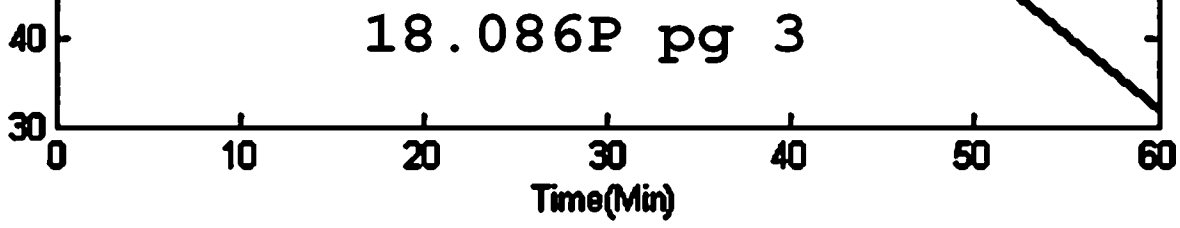
Finally, temperature of the short cylinder at the top surface is obtained as:

$$\frac{T-T_\alpha}{T_i-T_\alpha}=1.0059\times e^{-0.187^2\times\tau}\times\cos(0.187)\times1.0006\times e^{-0.08^2\times\tau}$$

$$\frac{T-20}{(150-20)}=1.0059\times e^{-0.187^2\times\tau}\times\cos(0.187)\times1.0006\times e^{-0.08^2\times\tau}$$



Step 12 of 17



The MATLAB code for this plot is:

```
clear all
clc
x=linspace(5,60,2);
y=((3.39*(10^-5))*x*60)/(0.1*0.1);
z=(1.0059*exp(-0.187*0.187*y))*(cos(0.187));
y1=((3.39*(10^-5))*x*60)/(0.02*0.02);
z1=(1.0006*exp(-0.08*0.08*y1));
zz=z.*z1.*(150-20)+20;
plot(x,zz)
```

Step 13 of 17

Below is shown the variation of the temperature of the short cylinder at top surface versus time:

Step 14 of 17

Maximum heat transfer from the cylinder is obtained as: $Q = mC_p(150\text{-}20)$

Where mass (m) of cylinder is: $8530 \times \pi \times 0.02^2 \times \frac{20}{100} = 2.14 \text{ Kg}$

Putting this data:

$$Q = mC_p(150\text{-}20)$$
$$= 2.14 \times 0.389 \times (150\text{-}20)$$
$$= 108 \text{ KJ}$$

Step 15 of 17

And, for dimensionless heat transfer we get for plane wall:

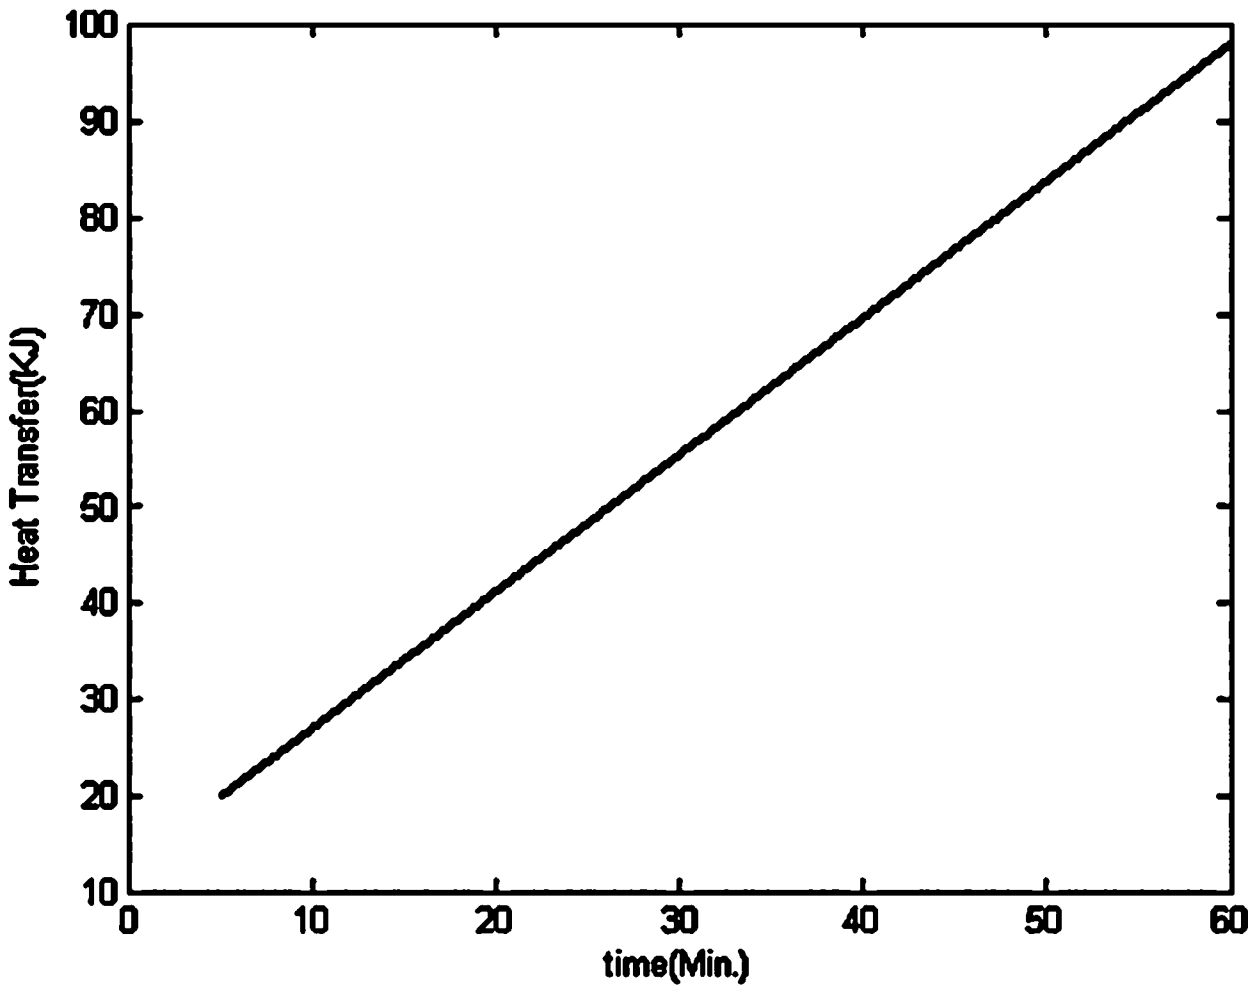
$$\left(Q/108\right)_w = 1 - 1.0059 \times e^{-0.187^2 \times \tau} \times \frac{\sin(0.187)}{0.187}$$

And for cylinder:

$$\left(Q/108\right)_c = 1 - 2 \times 1.0006 \times e^{-0.08^2 \times \tau} \times \frac{J_1(0.08)}{0.08}$$

So total heat transfer for short cylinder is:

$$\left(Q/108\right) = \left(Q/108\right)_w + \left(Q/108\right)_c \times \left[1 - \left(Q/108\right)_w\right]$$



Step 16 of 17

The MATLAB code for this plot is:

```
clear all
clc
x=linspace(5,60,2);
y=((3.39*(10^-5))*x*60)/(0.1*0.1);
z=1-(((1.0059/0.187)*exp(-0.187*0.187*y))*(sin(0.187)));
y1=((3.39*(10^-5))*x*60)/(0.02*0.02);
z1=1-((2*1.0006*exp(-0.08*0.08*y1))*(0.093/0.187));
zz=108*(z+z1.*(1-z));
plot(x,zz)
```

Step 17 of 17

Below is shown the variation of the heat transfer of the short cylinder versus time:

Question: 18.087P

A semi-infinite aluminum cylinder (k = 237 W/m·K, α = 9.71 × 10–5 m2 /s) of diameter D = 15 cm is initially at a uniform temperature of Ti = 115°C. The cylinder is now placed in water at 10°C, where heat transfer lakes place by convection with a heat transfer coefficient of h = 140 W/m2 ·K. Determine the temperature at the center of the cylinder 5 cm from the end surface 8 min after the start of cooling.

Step 1 of 6

Given:

Diameter of cylinder $D = 15\text{cm}$

Initial temperature $T_i = 115^0\text{C}$

Temperature of water $T_\infty = 10^0\text{C}$

Convection heat transfer coefficient $h = 140\,\text{W/m}^2.^0\text{C}$

Thermal conductivity of aluminum $k = 237\,\text{W/m.°C}$

Thermal diffusivity of aluminum $\alpha = 9.71\times10^{-5}\text{m}^2/s$

Step 2 of 6

The semi-infinite cylinder can physically be formed by the intersection of a long cylinder of radius $r_o = D/2 = 7.5$ cm and a semi-infinite medium.

The dimensionless temperature 5 cm from the surface of a semi-infinite medium is first determined from

$$\frac{T(x,t)-T_i}{T_\infty-T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\left[erfc\left(\frac{x}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right)\right]$$

$$= erfc\left(\frac{0.05}{2\sqrt{(9.71\times10^{-5})(8\times60)}}\right) - \exp\left(\frac{(140)(0.05)}{237}+\frac{(140)^2(9.71\times10^{-5})(8\times60)}{(237)^2}\right)$$

$$\times\left[erfc\left(\frac{0.05}{2\sqrt{(9.71\times10^{-5})(8\times60)}}+\frac{(140)\sqrt{(9.71\times10^{-5})(8\times60)}}{237}\right)\right]$$

$$= erfc(0.1158) - \exp(0.0458)erfc(0.2433)$$

$$\frac{T(x,t)-T_i}{T_\infty-T_i} = 0.8699 - (1.0468)(0.7308)$$

$$\frac{T(x,t)-T_i}{T_\infty-T_i} = 0.1049$$

$$\theta_{semi-inf} = \frac{T(x,t)-T_\infty+T_\infty-T_i}{T_i-T_\infty} = 0.1049$$

$$\theta_{semi-inf} = \frac{T(x,t)-T_\infty}{T_i-T_\infty} - \frac{T_i-T_\infty}{T_i-T_\infty} = 0.1049$$

$$\frac{T(x,t)-T_\infty}{T_i-T_\infty} - 1 = 0.1049$$

$$\frac{T(x,t)-T_\infty}{T_i-T_\infty} = 1.1049$$

Step 3 of 6

The Biot number is calculated for the long cylinder to be

$$Bi = \frac{hr_o}{k}$$

$$= \frac{(140)\times(0.075)}{(237)}$$

$$Bi = 0.0443$$

The constants λ_1 and A_1 corresponding to this Biot number from Table transient heat conduction in cylinders

$\lambda_1 = 0.2948$ and

$A_1 = 1.0110$

Step 4 of 6

The Fourier number is

$$\tau = \frac{\alpha t}{r_o^2}$$

$$= \frac{(9.71\times10^{-5})(8\times60)}{(0.075)^2}$$

$$\tau = 8.286 > 0.2$$

Therefore, the one-term approximate solution (or the transient temperature charts) is applicable.

Step 5 of 6

Then the dimensionless temperature at the center of the plane wall is determined from

$$\theta_{o,cyl} = \frac{T_0-T_\infty}{T_i-T_\infty}$$

$$= A_1 e^{-\lambda_1^2\tau}$$

$$= (1.0110)e^{-(0.2948)^2(8.286)}$$

$$\theta_{o,cyl} = 0.4921$$

Step 6 of 6

The center temperature of the semi-infinite cylinder then becomes

$$\left[\frac{T(x,0,t)-T_\infty}{T_i-T_\infty}\right]_{\substack{\text{semi-infinite}\\\text{cylinder}}} = \theta_{semi-inf}(x,t)\times\theta_{o,cyl}$$

$$= 1.1049\times0.4921$$

$$\left[\frac{T(x,0,t)-T_\infty}{T_i-T_\infty}\right]_{\substack{\text{semi-infinite}\\\text{cylinder}}} = 0.5437$$

$$\left[\frac{T(x,0,t)-10}{115-10}\right]_{\substack{\text{semi-infinite}\\\text{cylinder}}} = 0.5437$$

$$\boxed{T(x,0,t) = 67.0885^0\text{C}}$$

Question: 18.088P pg 1

A hot dog can be considered to be a cylinder 5 in long and 0.8 in in diameter whose properties are ρ = 61.2 lbm/ft3 , *cp* = 0.93 Btu/lbm-°F, *k* = 0.44 Btu/h·ft·°F, and α = 0.0077 ft2 /h. A hot dog initially at 40°F is dropped into boiling water at 212°F. If the heat transfer coefficient at the surface of the hot dog is estimated to be 120 Btu/h·ft2 ·°F, determine the center temperature of the hot dog after 5, 10, and 15 min by treating the hot dog as (*a*) a finite cylinder and (*b*) an infinitely long cylinder.

Step 1 of 10

Given:

Length of cylinder $L = 5$ in

Diameter of cylinder $D = 0.8$ in

The thermal conductivity of the hot dog $k = 0.44 \frac{\text{Btu}}{\text{h ft °F}}$,

The density of the hot dog $\rho = 61.2 \frac{\text{lbm}}{\text{ft}^3}$

The specific heat of hotdog $C_p = 0.93 \frac{\text{Btu}}{\text{lbm.°F}}$

The thermal diffusivity of hot dog $\alpha = 0.0077\ \text{ft}^2/\text{h}$

Step 2 of 10

Hot dog is dropped into boiling water.

The center temperature of the hot dog is do be determined by treating hot dog as a finite cylinder and also as an infinitely long cylinder.

When treating hot dog as a finite cylinder, heat conduction in the hot dog is two-dimensional, and thus the temperature varies in both the axial *x*- and the radial *r*-directions.

When treating hot dog as an infinitely long cylinder, heat conduction is one-dimensional in the radial *r*- direction.

The thermal properties of the hot dog are constant.

This hot dog can physically be formed by the intersection of a long cylinder of radius r_o $D/2 = (0.4/12)$ ft and a plane wall of thickness $2L = (5/12)$ ft. The distance *x* is measured from the midplane.

Step 3 of 10

<u>After 5 minutes</u>

First the Biot number is calculated for the plane wall to be

$$Bi = \frac{hL}{k}$$

$$Bi = \frac{(120\ \text{Btu/h.ft}^2\text{.°F})(2.5/12\ \text{ft})}{(0.44\ \text{Btu/h.ft.°F})}$$

$$Bi = 56.8$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$\lambda_1 = 1.5421$ and $A_1 = 1.2728$

Step 4 of 10

The Fourier number $\tau = \frac{\alpha t}{L^2}$

$$\tau = \frac{(0.0077\ \text{ft}^2/\text{h})(5/60\ \text{h})}{(2.5/12\ \text{ft})^2}$$

$\tau = 0.015 < 0.2$ (Be cautious!)

Then the dimensionless temperature at the center of the plane wall is determined from

$$\theta_{o,wall} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$\theta_{o,wall} = A_1 e^{-\lambda_1^2 \tau}$$

$$\theta_{o,wall} = (1.2728) e^{-(1.5421)^2 (0.015)}$$

$$\theta_{o,wall} \cong 1$$

We repeat the same calculations for the long cylinder,

$$Bi = \frac{hr_o}{k}$$

$$Bi = \frac{(120\ \text{Btu/h.ft}^2\text{.°F})(0.4/12\ \text{ft})}{(0.44\ \text{Btu/h.ft.°F})}$$

$$Bi = 9.1$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$\lambda_1 = 2.1589$ and $A_1 = 1.5618$

Step 5 of 10

$$\tau = \frac{\alpha t}{r_o^2}$$

$$\tau = \frac{(0.0077\ \text{ft}^2/\text{h})(5/60\ \text{h})}{(0.4/12\ \text{ft})^2}$$

$$\tau = 0.578 > 0.2$$

$$\theta_{o,cyl} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$\theta_{o,cyl} = A_1 e^{-\lambda_1^2 \tau}$$

$$\theta_{o,cyl} = (1.5618) e^{-(2.1589)^2 (0.578)}$$

$$\theta_{o,cyl} = 0.106$$

Then the center temperature of the short cylinder becomes

$$\left[\frac{T(0,0,t) - T_\infty}{T_i - T_\infty}\right]_{\substack{\text{short} \\ \text{cylinder}}} = \theta_{o,wall} \times \theta_{o,cyl}$$

$$\left[\frac{T(0,0,t) - T_\infty}{T_i - T_\infty}\right]_{\substack{\text{short} \\ \text{cylinder}}} = 1 \times 0.106$$

$$\left[\frac{T(0,0,t) - T_\infty}{T_i - T_\infty}\right]_{\substack{\text{short} \\ \text{cylinder}}} = 0.106$$

$$\frac{T(0,0,t) - 212}{40 - 212} = 0.106$$

$$\boxed{T(0,0,t) = 194\text{°F}}$$

Step 6 of 10

$$\frac{T(0,0,t)-212}{40-212}=0.100$$

$\boxed{T(0,0,t)=194°F}$

Step 6 of 10

After 10 minutes

$$\tau=\frac{\alpha t}{L^2}$$

$$\tau=\frac{(0.0077\ \text{ft}^2/\text{h})(10/60\ \text{h})}{(2.5/12\ \text{ft})^2}$$

$$\tau=0.03<0.2 \quad \text{(Be cautious!)}$$

$$\theta_{o,wall}=\frac{T_0-T_\infty}{T_i-T_\infty}$$

$$\theta_{o,wall}=A_1e^{-\lambda_1^2\tau}$$

$$\theta_{o,wall}=(1.2728)e^{-(1.5421)^2(0.03)}$$

$$\theta_{o,wall}\cong 1$$

Step 7 of 10

$$\tau=\frac{\alpha t}{r_o^2}$$

$$\tau=\frac{(0.0077\ \text{ft}^2/\text{h})(10/60\ \text{h})}{(0.4/12\ \text{ft})^2}$$

$$\tau=1.156>0.2$$

$$\theta_{o,cyl}=\frac{T_0-T_\infty}{T_i-T_\infty}$$

$$\theta_{o,cyl}=A_1e^{-\lambda_1^2\tau}$$

$$\theta_{o,cyl}=(1.5618)e^{-(2.1589)^2(1.156)}$$

$$\theta_{o,cyl}=0.007$$

$$\left[\frac{T(0,0,t)-T_\infty}{T_i-T_\infty}\right]_{\substack{\text{short}\\\text{cylinder}}}=\theta_{o,wall}\times\theta_{o,cyl}$$

$$\left[\frac{T(0,0,t)-T_\infty}{T_i-T_\infty}\right]_{\substack{\text{short}\\\text{cylinder}}}=1\times 0.007$$

$$\left[\frac{T(0,0,t)-T_\infty}{T_i-T_\infty}\right]_{\substack{\text{short}\\\text{cylinder}}}=0.007$$

$$\frac{T(0,0,t)-212}{40-212}=0.007$$

$\boxed{T(0,0,t)=211°F}$

Step 8 of 10

After 15 minutes

$$\tau=\frac{\alpha t}{L^2}$$

$$\tau=\frac{(0.0077\ \text{ft}^2/\text{h})(15/60\ \text{h})}{(2.5/12\ \text{ft})^2}$$

$$\tau=0.045<0.2 \quad \text{(Be cautious!)}$$

$$\theta_{o,wall}=\frac{T_0-T_\infty}{T_i-T_\infty}$$

$$\theta_{o,wall}=A_1e^{-\lambda_1^2\tau}$$

$$\theta_{o,wall}=(1.2728)e^{-(1.5421)^2(0.045)}$$

$$\theta_{o,wall}\cong 1$$

Step 9 of 10

$$\tau=\frac{\alpha t}{r_o^2}$$

$$\tau=\frac{(0.0077\ \text{ft}^2/\text{h})(15/60\ \text{h})}{(0.4/12\ \text{ft})^2}$$

$$\tau=1.734>0.2$$

$$\theta_{o,cyl}=\frac{T_0-T_\infty}{T_i-T_\infty}$$

$$\theta_{o,cyl}=A_1e^{-\lambda_1^2\tau}$$

$$\theta_{o,cyl}=(1.5618)e^{-(2.1589)^2(1.734)}$$

$$\theta_{o,cyl}=0.0005$$

$$\left[\frac{T(0,0,t)-T_\infty}{T_i-T_\infty}\right]_{\substack{\text{short}\\\text{cylinder}}}=\theta_{o,wall}\times\theta_{o,cyl}$$

$$\left[\frac{T(0,0,t)-T_\infty}{T_i-T_\infty}\right]_{\substack{\text{short}\\\text{cylinder}}}=1\times 0.0005=0.0005$$

$$\frac{T(0,0,t)-212}{40-212}=0.0005$$

$\boxed{T(0,0,t)=212\ °F}$

Step 10 of 10

b) Treating the hot dog as an infinitely long cylinder will not change the results obtained in the part (a) since dimensionless temperatures for the plane wall is 1 for all cases.

Question: 18.089P

A 2-cm-high cylindrical ice block (k = 2.22 W/m·K and α = 0.124 × 10–7 m2 /s) is placed on a table on its base of diameter 2 cm in a room at 24°C. The heat transfer coefficient on the exposed surfaces of the ice block is 13 W/m2 ·K, and heat transfer from the base of the ice block to the table is negligible. If the ice block is not to start melting at any point for at least 3 h, determine what the initial temperature of the ice block should be.

Step 1 of 4

Given:

Height of cylinder $L = 2$ cm

Thermal conductivity of the ice $k = 2.22\ \text{W/m}\cdot{}^\circ\text{C}$

Thermal diffusivity of the ice $\alpha = 0.124\times10^{-7}\ \text{m}^2/\text{s}$

Base diameter of table $D = 2$ cm

Room temperature $T_\infty = 24^\circ\text{C}$

Heat transfer coefficient $h = 13\ \dfrac{\text{W}}{\text{m}^2\cdot{}^\circ\text{C}}$

Step 2 of 4

A cylindrical ice block is placed on a table. This cylindrical ice block can be treated as a short cylinder that can physically be formed by the intersection of a long cylinder of diameter $D = 2$ cm and an infinite plane wall of thickness $2L = 4$ cm. We measure x from the bottom surface of the block since this surface represents the adiabatic center surface of the plane wall of thickness $2L = 4$ cm. The melting starts at the outer surfaces of the top surface when the temperature drops below 0°C at this location. The Biot numbers, the corresponding constants, and the Fourier numbers are

$$Bi_{wall} = \frac{hL}{k}$$

$$Bi_{wall} = \frac{(13\ \text{W/m}^2.^\circ\text{C})(0.02\ \text{m})}{(2.22\ \text{W/m.}^\circ\text{C})}$$

$$Bi_{wall} = 0.1171$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$$\lambda_1 = 0.3318 \quad \text{and} \quad A_1 = 1.0187$$

Step 3 of 4

$$Bi_{cyl} = \frac{hr_o}{k}$$

$$Bi_{cyl} = \frac{(13\ \text{W/m}^2.^\circ\text{C})(0.01\ \text{m})}{(2.22\ \text{W/m.}^\circ\text{C})}$$

$$Bi_{cyl} = 0.05856$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$$\lambda_1 = 0.3407 \quad \text{and} \quad A_1 = 1.0146$$

$$\tau_{wall} = \frac{\alpha t}{L^2}$$

$$\tau_{wall} = \frac{(0.124\times10^{-7}\ \text{m}^2/\text{s})(2\ \text{h}\times3600\ \text{s/h})}{(0.02\ \text{m})^2}$$

$$\tau_{wall} = 0.2232 > 0.2$$

$$\tau_{cyl} = \frac{\alpha t}{r_o^2}$$

$$\tau_{cyl} = \frac{(0.124\times10^{-7}\ \text{m}^2/\text{s})(2\ \text{h}\times3600\ \text{s/h})}{(0.01\ \text{m})^2}$$

$$\tau_{cyl} = 0.8928 > 0.2$$

Step 4 of 4

Note that $\tau > 0.2$ in all dimensions and thus the one-term approximate solution for transient heat conduction is applicable. The product solution for this problem can be written as

$$\theta(L, r_o, t)_{block} = \theta(L, t)_{wall}\,\theta(r_o, t)_{cyl}$$

$$\frac{0-20}{T_i-20} = \left[A_1 e^{-\lambda_1^2\tau}\cos(\lambda_1 L/L)\right]\left[A_1 e^{-\lambda_1^2\tau} J_0(\lambda_1 r_o/r_o)\right]$$

$$\frac{0-20}{T_i-20} = \left[(1.0187)e^{-(0.3318)^2(0.2232)}\cos(0.3318)\right]\left[(1.0146)e^{-(0.3407)^2(0.8928)}(0.9707)\right]$$

which gives $\boxed{T_i = -4^\circ\text{C}}$

Therefore, the ice will not start melting for at least 2 hours if its initial temperature is -4°C or below.

Question: 18.090P pg 1

A 30-cm-long cylindrical aluminum block (ρ = 2702 kg/m3 , cp = 0.896 kJ/kg·K. k = 236 W/m·K, and α = 9.75 × 10–5 m2 /s), 15 cm in diameter, is initially at a uniform temperature of 20°C. The block is to be heated in a furnace at 1200o C until its center temperature rises to 300°C. If the heat transfer coefficient on all surfaces of the block is 80 W/m2 ·K. determine how long the block should be kept in the furnace. Also, determine the amount of heat transfer from the aluminum block if it is allowed to cool in the room until its temperature drops to 20°C throughout.

Step 1 of 9

Given data:

Length of the cylindrical aluminum block, $2L = 30$ cm

Diameter of the cylindrical block, $D = 15$ cm

The density of the block, $\rho = 2702\ \text{kg/m}^3$

Thermal Conductivity of the block, $k = 236\ \text{W/m·K}$

Thermal Diffusivity, $\alpha = 9.75\times10^{-5}\ \text{m}^2/\text{s}$

Specific heat $c_p = 0.896\ \text{kJ/kg-K}$

Heat transfer coefficient, $h = 80\ \text{W/m}^2\text{·K}$

Initial temperature of the block $T_i = 20\ ^\circ\text{C}$

Furnace temperature, $T_\infty = 1200^\circ\text{C}$

Centre temperature, $T = 300^\circ\text{C}$

Step 2 of 9

This cylindrical block can physically be formed by the intersection of a long cylinder of radius

$r_o = D/2 = 7.5\text{cm}$

Calculation of Biot number, for the plain wall

And a plane wall of thickness

$2L = 30$ cm

$L = 15$ cm

The Biot number and the corresponding constants for the plane wall along the length is

$$\text{Bi} = \frac{hL}{k}$$

$$\text{Bi} = \frac{(80)(0.15)}{236}$$

$$\text{Bi} = 0.0508$$

Step 3 of 9

From the table transient one dimensional heat conduction in cylinders, the constants corresponding to this Biot number are determined as follow ,
By interpolating the values of at $\text{Bi} = 0.04$ **and** $\text{Bi} = 0.06$ **we get,**

$$\lambda_1 = \lambda_{0.0508} = \lambda_{0.04} + (\lambda_{0.06} - \lambda_{0.04})\left(\frac{0.0508-0.04}{0.06-0.04}\right)$$
$$= 0.1987 + [(0.2425-0.1987)\times 0.54]$$
$$= 0.1987 + 0.023652$$
$$= 0.222$$

$$A_1 = A_{0.0508} = A_{0.04} + (A_{0.06} - A_{0.04})\left(\frac{0.0508-0.04}{0.06-0.04}\right)$$
$$= 1.0066 + [(1.0098-1.0066)\times 0.54]$$
$$= 1.0066 + 0.00172$$
$$= 1.00832$$

So, the dimensionless temperature for approximated plane wall is obtained as:

$$\theta_{0,wall} = \frac{T-T_\infty}{T_i-T_\infty} = Ae^{-\lambda^2\tau}$$

$$\frac{T-T_\infty}{T_i-T_\infty} = 1.00832\times e^{-0.222^2\times\tau}$$

Step 4 of 9

The Biot number and the corresponding constants for the long cylinder along the radial direction is

$$\text{Bi} = \frac{hr_0}{k}$$

$$\text{Bi} = \frac{(80\ \text{W/m}^2.^\circ\text{C})(0.075\ \text{m})}{236\ \text{W/m.}^\circ\text{C}}$$

$$\text{Bi} = 0.0254$$

From the table transient one dimensional heat conduction in cylinders, the constants corresponding to this Biot number are determined as follow ,
By interpolating the values of at $\text{Bi} = 0.02$ **and** $\text{Bi} = 0.04$ **we get,**

$$\lambda_1 = \lambda_{0.0254} = \lambda_{0.02} + (\lambda_{0.04} - \lambda_{0.02})\left(\frac{0.0254-0.02}{0.04-0.02}\right)$$
$$= 0.1995 + [(0.2814-0.1995)\times 0.27]$$
$$= 0.1995 + 0.022113$$
$$= 0.222$$

$$A_1 = A_{0.0254} = A_{0.02} + (A_{0.04} - A_{0.02})\left(\frac{0.0254-0.02}{0.04-0.02}\right)$$
$$= 1.005 + [(1.0099-1.005)\times 0.27]$$
$$= 1.005 + 0.001323$$
$$= 1.006323$$

Step 5 of 9

So, the dimensionless temperature is determined to be:

$$\theta_{0,cyl} = \frac{T-T_\infty}{T_i-T_\infty} = Ae^{-\lambda^2\tau}$$

$$\frac{T-T_\infty}{T_i-T_\infty} = 1.0063\times e^{-0.222^2\times\tau}$$

Finally, combined non-dimensional temperature is:

$$\frac{T-T_\infty}{T_i-T_\infty}=1.0063\times e^{-0.222^2\times\tau}$$ 18.090P pg 2

Finally, combined non-dimensional temperature is:

$$\frac{T-T_\infty}{T_i-T_\infty}=\left[1.0084\times e^{-0.222^2\times\tau}\right]\times\left[1.0063\times e^{-0.222^2\times\tau}\right]$$

$$\frac{300-1200}{20-1200}=\left[1.0084\times e^{-0.222^2\times\tau}\right]\times\left[1.0041\times e^{-0.156^2\times\tau}\right]$$

$$0.763=\left[1.0147\times e^{-0.0985\times\tau}\right]$$

$$e^{-0.0985\times\tau}=0.752$$

$$0.0985\tau=0.285$$

$$\tau=2.893$$

Step 6 of 9

Now, Fourier number is obtained to be:

$$\tau=\frac{\alpha t}{L^2}$$

$$2.89=\frac{\left(9.75\times10^{-5}\right)t}{\left(\frac{15}{100}\right)^2}$$

$$t=666.923\text{ sec}$$

$$\boxed{t=11.11\text{ min.}}$$

So the required time for heating is 11.11 min.

Now, Maximum heat transfer from the block is obtained as:

$$Q=mc_p(20-1200)$$

Where mass of cylinder is:

$$m=\rho\times V$$

$$=\rho\times\pi r^2L$$

$$=2702\times\pi\times0.075^2\times\frac{30}{100}$$

$$m=14.32\text{ kg}$$

Step 7 of 9

Substituting known values in heat transfer

$$Q=mc_p(1200-20)$$

$$Q=14.32\times0.896\times(1200-20)$$

$$Q=15140.24\text{kJ}$$

Using the one term solutions the fractional heat transfer in plane wall is

$$\left(\frac{Q}{Q_{max}}\right)_{wall}=1-\theta_{0,wall}\frac{\sin\lambda_1}{\lambda_1}$$

$$\left(\frac{Q}{15140.24}\right)_W=1-\left[\left(1.00832\times e^{-0.222^2\times3.843}\right)\times\frac{\sin(0.222)}{0.222}\right]$$

$$\left(\frac{Q}{15140.24}\right)_W=1-0.01456$$

$$\left(\frac{Q}{15140.24}\right)_W=0.9854$$

Step 8 of 9

And for cylinder:

$$\left(\frac{Q}{Q_{max}}\right)_{cyl}=1-2\theta_{0,cyl}\frac{J_1(\lambda_1)}{\lambda_1}$$

$$\left(\frac{Q}{15140.24}\right)_{cyl}=1-\left(2\times1.0063\times e^{-0.222^2\times\tau}\times\frac{J_1(0.222)}{0.222}\right)$$

From first order Bessel functions table, by interpolating the values of $J_1(\lambda_1)$ at $\lambda_1=0.2$ and $\lambda_1=0.3$ we get the value at $\lambda_1=0.222$

$$J_1=J_{0.222}=J_{0.2}+(J_{0.3}-J_{0.2})\left(\frac{0.222-0.2}{0.3-0.2}\right)$$

$$=0.0995+\left[(0.1483-0.0995)\times0.22\right]$$

$$=0.0995+0.010736$$

$$=0.11$$

Step 9 of 9

Now, the fractional heat transfer in cylinder is,

$$\left(\frac{Q}{15140.24}\right)_{cyl}=1-2\times1.0063\times e^{-0.222^2\times2.893}\times\frac{0.11}{0.222}$$

$$\left(\frac{Q}{15140.24}\right)_{cyl}=0.135$$

So total heat transfer for block is:

$$\left(\frac{Q}{15140.24}\right)=\left(\frac{Q}{15140.24}\right)_{wall}+\left(\frac{Q}{15140.24}\right)_{cyl}\times\left[1-\left(\frac{Q}{15140.24}\right)_{wall}\right]$$

$$\left(\frac{Q}{15140.24}\right)=0.9847+0.135\times\left[1-0.9847\right]$$

$$\boxed{Q=14939.86\text{kJ}}$$

Finally, total heat transfer for block is obtained as, 14939.86 kJ

Question: 18.091P pg 1

Repeal Prob. 18-90 for the case where the aluminum block is inserted into the furnace on a low-conductivity material so that the heat transfer to or from the bottom surface of the block is negligible.

Step 1 of 10

Given data:

Length of the cylindrical aluminum block $L=30$ cm

Diameter of the cylindrical block, $D=15$ cm

The density of the block, $\rho=2702\ \text{kg/m}^3$

Thermal Conductivity of the block, $k=236\ \text{W/m}\cdot\text{K}$

Thermal Diffusivity, $\alpha=9.75\times10^{-5}\ \text{m}^2/\text{s}$

Specific heat $c_p=0.896\ \text{kJ/kg-K}$

Heat transfer coefficient, $h=80\ \text{W/m}^2\cdot\text{K}$

Initial temperature of the block $T_i=20\ ^\circ\text{C}$

Furnace temperature, $T_\infty=1200^\circ\text{C}$

Centre temperature, $T=300^\circ\text{C}$

Step 2 of 10

For this problem Biot number

$$\text{Bi}=\frac{hL_c}{k}$$

$$\text{Bi}=\frac{80\times L_c}{236}$$

Now, characteristic length can be obtained by approximating a plane wall having semi thickness: $L_c=30$ cm

Putting this into Biot number expression, we get:

$$\text{Bi}=\frac{hL_c}{K}$$

$$\text{Bi}=\frac{80\times L_c}{236}$$

$$\text{Bi}=\frac{80\times\left(\frac{30}{100}\right)}{236}$$

$$\text{Bi}=0.101$$

From the table transient one dimensional heat conduction in cylinders, the constants corresponding to this Biot number are determined as follow ,

$\lambda=0.3111, A=1.0161$

So, the dimensionless temperature for approximated plane wall is obtained as:

$$\frac{T-T_\infty}{T_i-T_\infty}=Ae^{-\lambda^2\tau}$$

$$\frac{T-T_\infty}{T_i-T_\infty}=1.0161\times e^{-0.3111^2\times\tau}$$

Step 3 of 10

Biot number for long cylinder:

$$\text{Bi}=\frac{hL_c}{K}$$

$$\text{Bi}=\frac{80\times L_c}{236}$$

$$\text{Bi}=\frac{80\times\left(\frac{7.5}{100}\right)}{236}$$

$$\text{Bi}=0.0254$$

Step 4 of 10

From the table transient one dimensional heat conduction in cylinders, the constants corresponding to this Biot number are determined as follow ,

By interpolating the values of at $\text{Bi}=0.02$ and $\text{Bi}=0.04$ we get,

$$\lambda_1=\lambda_{0.0254}=\lambda_{0.02}+(\lambda_{0.04}-\lambda_{0.02})\left(\frac{0.0254-0.02}{0.04-0.02}\right)$$

$$=0.1995+\left[(0.2814-0.1995)\times0.27\right]$$

$$=0.1995+0.022113$$

$$=0.222$$

$$A_1=A_{0.0254}=A_{0.02}+(A_{0.04}-A_{0.02})\left(\frac{0.0254-0.02}{0.04-0.02}\right)$$

$$=1.005+\left[(1.0099-1.005)\times0.27\right]$$

$$=1.005+0.001323$$

$$=1.006323$$

So, the dimensionless temperature is determined to be:

$$\theta_{0,cyl}=\frac{T-T_\alpha}{T_i-T_\alpha}=Ae^{-\lambda^2\tau}$$

$$\frac{T-T_\alpha}{T_i-T_\alpha}=1.0063\times e^{-0.222^2\times\tau}$$

Step 5 of 10

Finally, combined non-dimensional temperature is:

$$\frac{T-T_\alpha}{T_i-T_\alpha}=\left[1.0161\times e^{-0.3111^2\times\tau}\right]\times\left[1.0063\times e^{-0.222^2\times\tau}\right]$$

$$\frac{300-1200}{20-1200}=\left[1.0161\times e^{-0.3111^2\times\tau}\right]\times\left[1.0063\times e^{-0.222^2\times\tau}\right]$$

$$0.763=\left[1.0225\times e^{-0.146\times\tau}\right]$$

$$e^{-0.146\times\tau}=0.75$$

$$\tau=1.97$$

Step 6 of 10

Fourier number is obtained to be:

$$\tau=\frac{\alpha t}{L^2}$$

$$=\frac{\left(0.75\times10^{-5}\right)t}{}$$

Step 6 of 10

Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L^2}$$

$$1.97 = \frac{\left(9.75\times10^{-5}\right)t}{\left(\frac{30}{100}\right)^2}$$

$$t = 1818.46 \text{ sec}$$

$$\boxed{t = 30.30 \text{ min.}}$$

So the required time for heating is 30.30 min.

Step 7 of 10

Now, Maximum heat transfer from the block is obtained as:

$$Q = mc_p(20-1200)$$

Where mass of cylinder is:

$$m = \rho \times V$$

$$= \rho \times \pi r^2 L$$

$$= 2702 \times \pi \times 0.075^2 \times \frac{30}{100}$$

$$m = 14.32 \text{ kg}$$

Step 8 of 10

Substituting known values in heat transfer

$$Q = mc_p(1200-20)$$

$$Q = 14.32\times0.896\times(1200-20)$$

$$Q = 15140.24 \text{kJ}$$

Using the one term solutions the fractional heat transfer in plane wall is

$$\left(\frac{Q}{15140.24}\right)_W = 1-1.0161\times e^{-0.3111^2\times1.97}\times\frac{\sin(0.3111)}{0.3111}$$

$$\left(\frac{Q}{15140.24}\right)_W = 1-0.0146$$

$$\left(\frac{Q}{15140.24}\right)_W = 0.985$$

Step 9 of 10

And for cylinder:

$$\left(\frac{Q}{Q_{max}}\right)_{cyl} = 1-2\theta_{0,cyl}\frac{J_1(\lambda_1)}{\lambda_1}$$

$$\left(\frac{Q}{15140.24}\right)_{cyl} = 1-2\times1.0063\times e^{-0.222^2\times\tau}\times\frac{J_1(0.222)}{0.222}$$

From first order Bessel functions table, by interpolating the values of $J_1(\lambda_1)$ at $\lambda_1 = 0.2$ and $\lambda_1 = 0.3$ we get the value at $\lambda_1 = 0.222$ as,

$$J_1 = J_{0.222} = J_{0.2} + (J_{0.3} - J_{0.2})\left(\frac{0.222-0.2}{0.3-0.2}\right)$$

$$= 0.0995 + \left[(0.1483-0.0995)\times0.22\right]$$

$$= 0.0995 + 0.010736$$

$$= 0.11$$

Then the fractional heat transfer in cylinder is

$$\left(\frac{Q}{15140.24}\right)_{cyl} = 1-2\times1.0063\times e^{-0.222^2\times30.30}\times\frac{0.11}{0.222}$$

$$\left(\frac{Q}{15140.24}\right)_{cyl} = 0.775$$

Step 10 of 10

So total heat transfer for block is:

$$\left(\frac{Q}{15140.24}\right) = \left(\frac{Q}{15140.24}\right)_W + \left(\frac{Q}{15140.24}\right)_C \times \left[1-\left(\frac{Q}{15140.24}\right)_W\right]$$

$$\left(\frac{Q}{15140}\right) = 0.999 + 0.775\times[1-0.999]$$

$$\boxed{Q = 15136.83 \text{kJ}}$$

Finally, total heat transfer for block is obtained as 15136.83kJ

Question: 18.092P pg 1

Reconsider Prob. 18-90. Using EES (or other) MM software, investigate the effect of the final center temperature of the block on the heating time and the amount of heat transfer. Let the final center temperature vary from 50°C to 1000°C. Plot the time and the heat transfer as a function of the final center temperature, and discuss the results.

Step 1 of 9

Given:
Length of the cylindrical aluminum block $L = 30$ cm
Diameter of the cylindrical block $D = 15$ cm
The density of the block $\rho = 2702\ kg/m^3$
Thermal Conductivity, $k = 236\ W/m \cdot °C$
Thermal Diffusivity, $\alpha = 9.75 \times 10^{-5}\ m^2/s$
Specific heat $C_p = 0.896\ kJ/kg \cdot K$
Heat transfer coefficient $h = 80\ W/m^2 \cdot °C$

Step 2 of 9

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
2*L=0.30 "[m]"
2*r_o=0.15 "[m]"
T_i=20 "[C]"
T_infinity=1200 "[C]"
"T_o_o=300 [C], parameter to be varied"
h=80 "[W/m^2-C]"
```

Step 3 of 9

```
"PROPERTIES"
k=236 "[W/m-C]"
rho=2702 "[kg/m^3]"
C_p=0.896 "[kJ/kg-C]"
alpha=9.75E-5 "[m^2/s]"
```

Step 4 of 9

```
"ANALYSIS"
"This short cylinder can physically be formed by the intersection of a long cylinder of
radius r_o and a plane wall of thickness 2L"
"For plane wall"
Bi_w=(h*L)/k
"From biot number Table corresponding to this Bi number, we read"
lambda_1_w=0.1439 "w stands for wall"
A_1_w=1.0035
tau_w=(alpha*time)/L^2
theta_o_w=A_1_w*exp(-lambda_1_w^2*tau_w) "theta_o_w=(T_o_w-T_infinity)/(T_i-
T_infinity)"
```

Step 5 of 9

```
"For long cylinder"
Bi_c=(h*r_o)/k "c stands for cylinder"
"From biot number Table corresponding to this Bi number, we read"
lambda_1_c=0.1762
A_1_c=1.0040
tau_c=(alpha*time)/r_o^2
theta_o_c=A_1_c*exp(-lambda_1_c^2*tau_c) "theta_o_c=(T_o_c-T_infinity)/(T_i-
T_infinity)"
(T_o_o-T_infinity)/(T_i-T_infinity)=theta_o_w*theta_o_c "center temperature of
cylinder"
V=pi*r_o^2*(2*L)
```

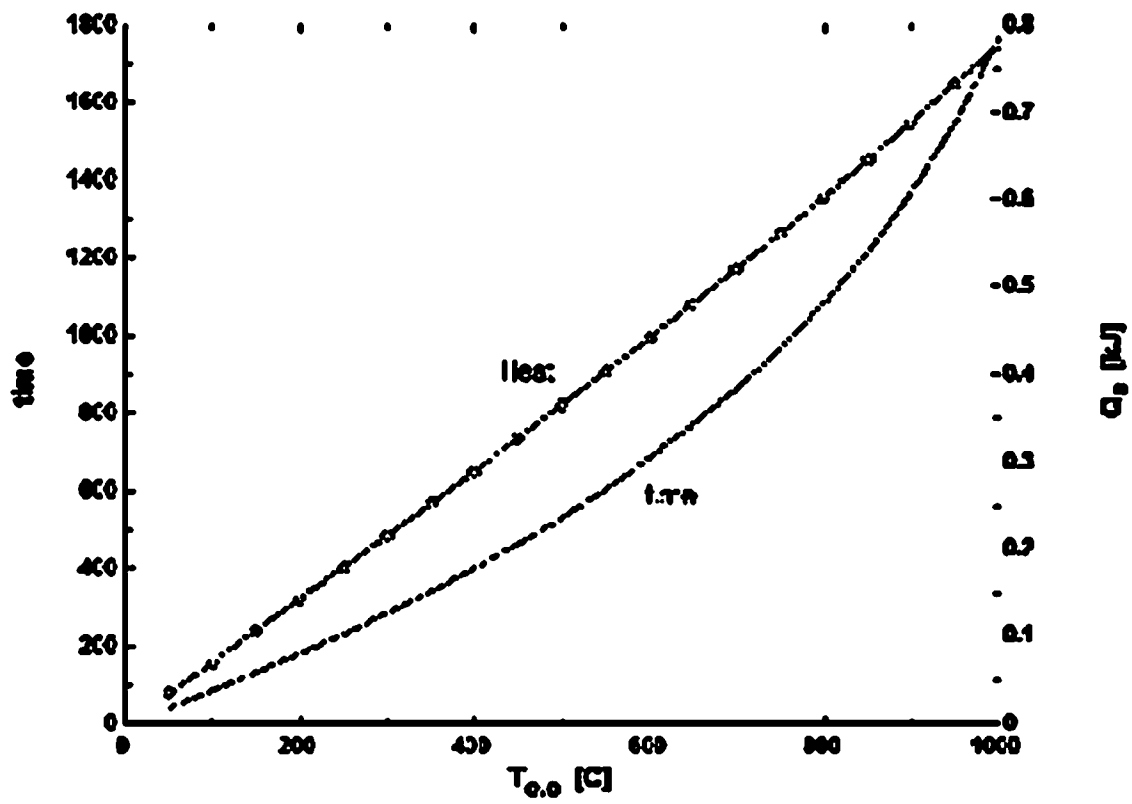
Step 6 of 9

```
m=rho*V
Q_max=m*C_p*(T_infinity-T_i)
Q_w=1-theta_o_w*Sin(lambda_1_w)/lambda_1_w "Q_w=(Q/Q_max)_w"
Q_c=1-2*theta_o_c*J_1/lambda_1_c "Q_c=(Q/Q_max)_c"
J_1=0.0876 "From Table at lambda_1_c"
Q/Q_max=Q_w+Q_c*(1-Q_w) "total heat transfer"
```

Step 7 of 9

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 20
Select variables in equations as $T_{o,o}$ and time press ADD and then press ok
A table will appear put values of $T_{o,o}$ as 50,100,150....1000 in run 1 to 20
Repeat procedure for $T_{o,o}$ and Q
Then from Calculate -> Solve table

Solution appear



Solution appear

Step 8 of 9

▷ 1..20	1 $T_{o,o}$ [C]	2 time	3 Q_c [kJ]
Run 1	50	42.43	0.036
Run 2	100	86.33	0.07138
Run 3	150	132.3	0.107
Run 4	200	180.4	0.1429
Run 5	250	231.1	0.1791
Run 6	300	284.5	0.2156
Run 7	350	340.9	0.2525
Run 8	400	400.8	0.2896

Run 19	950	1549	0.733
Run 20	1000	1770	0.7787

Step 9 of 9

Then from Plot -> New plot window -> X-Y Plot
Select X-axis Vel and Y-axis T_s
Repeat procedure for $T_{o,o}$ and Q
Press OK
Graph will be plotted.

Question: 18.093P

Spherical glass beads coming out of a kiln are allowed to cool in a room temperature of 30°C. A glass bead with a diameter of 10 mm and an initial temperature of 400°C is allowed to cool for 3 minutes. If the convection heat transfer coefficient is 28 W/m2 ·K. determine the temperature at the center of the glass bead using (*a*) Table 18-2 and (*b*) the Heisler chart (Figure 18-17). The glass bead has properties of ρ = 2800 kg/m3 , *cp* = 750 J/kg·K, and *k* = 0.7 W/m·K.

Step 1 of 7

Calculate the Biot number for the heating process of glass by using the relation,

$$\mathrm{Bi}=\frac{hL_c}{k} \quad \text{..... (1)}$$

Here, convective heat transfer coefficient is h , characteristic length of the glass is L_c , and conduction coefficient of the glass is k .

Calculate the characteristic length of the glass by using the relation,

$$L_c = r_o$$

Here, radius of the glass is r_o .

Substitute $0.005\ \mathrm{m}$ for r_o .

$$L_c = 0.005\ \mathrm{m}$$

Step 2 of 7

Calculate the Biot number for this process as shown.

Substitute $0.005\ \mathrm{m}$ for L_c , $28\ \mathrm{W/m^2 \cdot K}$ for h , and $0.7\ \mathrm{W/m \cdot K}$ for k in equation (1).

$$\mathrm{Bi}=\frac{28\times 0.005}{0.7}$$
$$=0.2$$

Write the formula for thermal diffusivity as shown.

$$\alpha=\frac{k}{\rho C_p}$$

Step 3 of 7

Calculate the Fourier number for this process by using the formula,

$$\tau=\frac{\alpha t}{r_o^2}$$

Here, diffusivity of glass is α , and time for which the glass is heated is t .

Substitute $\frac{k}{\rho C_p}$ for α .

$$\tau=\frac{\left(\frac{k}{\rho C_p}\right)t}{r_o^2} \quad \text{..... (2)}$$
$$=\frac{kt}{(\rho C_p)r_o^2}$$

Step 4 of 7

Calculate the Fourier number for this process as shown.

Substitute $0.7\ \mathrm{W/m \cdot K}$ for k , $(3\times 60)\ \mathrm{s}$ for t , $2800\ \mathrm{kg/m^3}$ for ρ , $750\ \mathrm{J/kg \cdot K}$ for C_p and $0.005\ \mathrm{m}$ for r_o in equation (2).

$$\tau=\frac{0.7\times 3\times 60}{(2800\times 750)(0.005)^2}$$
$$=\frac{126}{52.5}$$
$$=2.4$$

Step 5 of 7

(a).

Calculate the dimensionless temperature of a spherical glass bead at its centre by using the relation,

$$\theta_{0,sph}=A_1 e^{-\lambda_1^2 \tau} \quad \text{..... (3)}$$

Obtain the values of λ_1 and A_1 for $\mathrm{Bi}=0.2$ from table 4.2 as shown.

$$\lambda_1=0.7593$$
$$A_1=1.0592$$

Substitute 2.4 for τ , 1.0592 for A_1 , and 0.7593 for λ_1 in equation (2).

$$\theta_{0,sph}=(1.0592)e^{-\left[(0.7593)^2\times 2.4\right]}$$
$$=0.2655$$

Step 6 of 7

Calculate the temperature at the centre of the glass bead by using the relation,

$$\frac{T_0-T_\infty}{T_i-T_\infty}=\theta_{0,cyl}$$

Here, the temperature at the centre of the glass is T_0 , surroundings temperature is T_∞ , and initial temperature of the glass is T_i .

Substitute 0.2655 for $\theta_{0,cyl}$, $30\ ^\circ\mathrm{C}$ for T_∞ , and $400\ ^\circ\mathrm{C}$ for T_i .

$$\frac{T_0-30}{400-30}=0.2655$$
$$T_0-30=370\times 0.2655$$
$$T_0=30+98.23$$
$$=128.23\ ^\circ\mathrm{C}$$

Therefore, the temperature at the centre of the glass bead is $\boxed{128.23\ ^\circ\mathrm{C}}$.

Step 7 of 7

(b).

Calculate the value $\frac{1}{\mathrm{Bi}}$ as shown.

$$\frac{1}{\mathrm{Bi}}=\frac{1}{0.2}$$
$$=5$$

Obtain the value of dimensionless temperature at the centre, θ_0 corresponding to values $\frac{1}{\mathrm{Bi}}=5$ and $\tau=2.4$ from figure 4-17 as shown.

$$\theta_0=0.27$$

Calculate the temperature at the centre of the glass bead as shown.

$$\frac{T_0-T_\infty}{T_i-T_\infty}=\theta_{0,sph}$$

Substitute 0.27 for $\theta_{0,cyl}$, $30\ ^\circ\mathrm{C}$ for T_∞ , and $400\ ^\circ\mathrm{C}$ for T_i .

$$\frac{T_0-30}{400-30}=0.27$$
$$T_0-30=370\times 0.27$$
$$T_0=30+99.9$$
$$\approx 130\ ^\circ\mathrm{C}$$

Therefore, the temperature at the centre of the glass bead is $\boxed{130\ ^\circ\mathrm{C}}$.

Question: 18.094P

A large iron slab (ρ = 7870 kg/m3 , Cp = 447 J/kg·K. and k = 80.2 W/m·K) was initially heated to a uniform temperature of 150°C and then placed on concrete floor (ρ = 1600 kg/m3 , cp = 840 J/kg·K, and k = 0.79 W/m·K). concrete floor was initially at a uniform temperature of 30°C. Determine (*a*) The surface temperature between the iron slab and concrete floor and (*b*) The temperature of the concrete floor at the depth of 25 mm, if the surface temperature remains constant after 15 minutes.

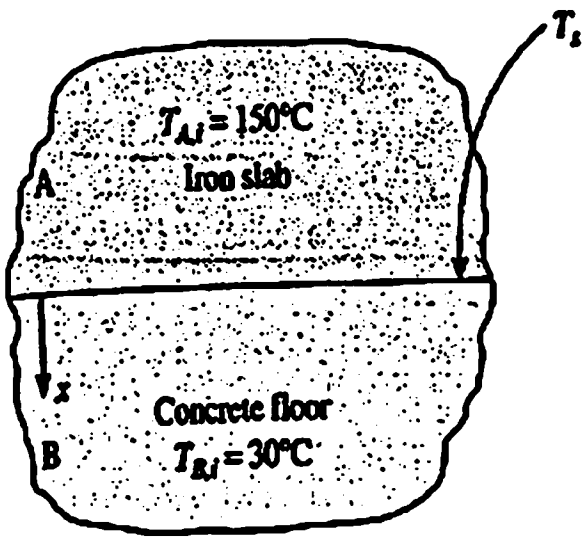

FIGURE P18–94

Step 1 of 2

(a) The surface temperature between the contact of two semi-infinite solids of different initial temperatures,

$$T_s = \frac{\sqrt{(k\rho c_p)_A}\,T_{A,i} + \sqrt{(k\rho c_p)_B}\,T_{B,i}}{\sqrt{(k\rho c_p)_A} + \sqrt{(k\rho c_p)_B}}$$

Substituting the values, $\rho_A = 7870\,\text{kg/m}^3$, $c_{A,p} = 447\,\text{J/kg·K}$, $k_A = 80.2\,\text{W/m·K}$, $T_{A,i} = 150°\text{C}$, $\rho_B = 1600\,\text{kg/m}^3$, $c_{B,p} = 840\,\text{J/kg·K}$, $k_B = 0.79\,\text{W/m·K}$ and $T_{B,i} = 30°\text{C}$, we get

$$T_s = \frac{\sqrt{(80.2\times7870\times447)}\times(150+273) + \sqrt{(0.79\times1600\times840)}\times(30+273)}{\sqrt{(80.2\times7870\times447)} + \sqrt{(0.79\times1600\times840)}}$$

$$= \frac{7105075.207 + 312216.469}{16796.86 + 1030.41}$$

$$\boxed{T_s = 416.06\,\text{K}}$$

Therefore, the surface temperature between the contacts of two semi-infinite solids of different initial temperatures is 416.06K

Step 2 of 2

(b) The temperature of the concrete floor at the depth of 25 mm

Thermal diffusivity of the concrete slab,

$$\alpha_B = \left(\frac{k}{\rho c_p}\right)_B$$

Substitute $0.79\,\text{W/m·K}$ for k_B, $1600\,\text{kg/m}^3$ for ρ_B and $840\,\text{J/kg·K}$ for $c_{B,p}$

$$\alpha_B = \left(\frac{k}{\rho c_p}\right)_B$$

$$= \left(\frac{0.79}{1600\times840}\right)$$

$$= 5.87\times10^{-7}\,\text{m}^2/\text{sec}$$

Substituting the values in below equation,

$$\frac{T(x,t) - T_i}{T_s - T_i} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{T(x,t) - (30+273)}{416.06 - 303} = \text{erfc}\left(\frac{25\times10^{-3}}{2\sqrt{(5.87\times10^{-7})(15\times60)}}\right)$$

$$\frac{T(x,t) - 303}{113.06} = \text{erfc}(0.5434)$$

By solving the above equation,

$$\boxed{T(x,t) = 352.995\,\text{K}}$$

Therefore, the temperature of the concrete floor at the depth of 25 mm is 352.995K

Question: 18.095P

In desert climates, rainfall is not a common occurrence since the rain droplets formed in the upper layer of the atmosphere often evaporate before they reach the ground. Consider a raindrop that is initially at a temperature of 5°C and has a diameter of 5 mm. Determine how long it will lake for the diameter of the raindrop to reduce to 3 mm as it falls through ambient air at 18°C with a heat transfer coefficient of 400 W/m2 ·K. The water temperature can be assumed to remain constant and uniform at 5°C at all times.

Step 1 of 5

Given data:

Initially temperature of the raindrop, $T_i = 5°C$

Initially Diameter of rain drop, $D_i = 5\,mm = 0.005\,m$

Final diameter of the rain drop, $D_i = 3mm = 0.003m$

Temperature of the air, $T_\infty = 18°C$

Step 2 of 5

From the properties of the various fluids

For water

Density, $\rho = 1000\,kg/m^3$

Latent heat vaporization, $h_{fg} = 2490\,kJ/kg$

Initially mass of the rain drop is

$$m_i = \rho V_i$$

$$= \rho\left(\frac{4}{3}\pi r_i^3\right)$$

$$= 1000\left(\frac{4}{3}\pi\left(\frac{0.005}{2}\right)^3\right)$$

$$= 0.0000654\,kg$$

Final mass of the rain drop is

$$m_f = \rho V_f$$

$$= \rho\left(\frac{4}{3}\pi r_f^3\right)$$

$$= 1000\left(\frac{4}{3}\pi\left(\frac{0.003}{2}\right)^3\right)$$

$$= 0.0000141\,kg$$

Step 3 of 5

Change in mass of the rain drop is

$$m = m_i - m_f$$

$$= 0.0000654 - 0.0000141$$

$$= 0.0000513\,kg$$

Heat transfer required for evaporation is

$$Q = mh_{fg}$$

$$= 0.0000513 \times 2490$$

$$= 0.1277\,kJ$$

Step 4 of 5

Average surface area of the rain drop is

$$A_s = \frac{4\pi\left(r_i^2 + r_f^2\right)}{2}$$

$$= \frac{4\pi\left(\left(\frac{0.005}{2}\right)^2 + \left(\frac{0.003}{2}\right)^2\right)}{2}$$

$$= \frac{4\pi\left(\left(2.25\times10^{-6}\right) + \left(6.25\times10^{-6}\right)\right)}{2}$$

$$= 5.340\times10^{-5}\,m^2$$

Rate of heat transfer due to convention is

$$Q_c = hA(T_i - T_\infty)$$

$$= 400 \times 5.341\times10^{-5}(18-5)$$

$$= 0.277\,J/s$$

Step 5 of 5

Then, time required to reduce the size of the rain drop is

$$\dot{Q} = \frac{Q}{\Delta t}$$

$$\Delta t = \frac{Q}{\dot{Q}}$$

$$= \frac{127.77\,J}{0.277\,J/s}$$

$$= 461s$$

$$= 7.68\,min$$

Therefore, time required to reduce the size of the rain drop is $\boxed{\Delta t = 7.68\,min}$.

Question: 18.096P

The water main in the cities must be placed at sufficient depth below the earth's surface to avoid freezing during extended periods of subfreezing temperatures. Determine the minimum depth at which the water main must be placed at a location where the soil is initially at 15°C and the earth's surface temperature under the worst conditions is expected to remain at -10°C for a period of 75 days. Take the properties of soil at that location to be k = 0.7 W/m·K and α = 1.4 × 10–5 m2 /s.

Step 1 of 2

Given:

Initial temperature of soil $T_i = 15^\circ C$

Expected surface temperature under worst conditions $T_s = -10^\circ C$

Thermal Conductivity of the soil, $k = 0.7\ W/m \cdot {}^\circ C$

Thermal Diffusivity of the soil, $\alpha = 1.4 \times 10^{-5}\ m^2/s$

Step 2 of 2

The water pipes are buried in the ground to prevent freezing. The temperature in the soil is affected by the thermal conditions at one surface only, and thus the soil can be considered to be a semi-infinite medium with a specified surface temperature of -10°C.

The thermal properties of the soil are constant.

The depth at which the temperature drops to 0°C in 75 days is determined using the analytical solution,

$$\frac{T(x,t)-T_i}{T_s-T_i} = erfc\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

Substituting,

$$\frac{0-15}{-10-15} = erfc\left(\frac{x}{2\sqrt{(1.4\times10^{-5}\ m^2/s)(75\ day\times24\ h/day\times3600\ s/h)}}\right)$$

$$\boxed{x=7.05\ m}$$

Therefore, the pipes must be buried at a depth of at least 7.05 m.

Question: 18.097P

A hot dog can be considered to be a 12-cm-long cylinder whose diameter is 2 cm and whose properties are ρ = 980 kg/m3 , cp = 3.9 kJ/kg·K, k = 0.76 W/m·K, and α = 2 × 10–7 m2 /s. A hot dog initially at 5°C is dropped into boiling water at 100°C. The heat transfer coefficient at the surface of the hot dog is estimated to be 600 W/m·K. If the hot dog is considered cooked when its center temperature reaches 80°C, determine how long it will take to cook it in the boiling water.

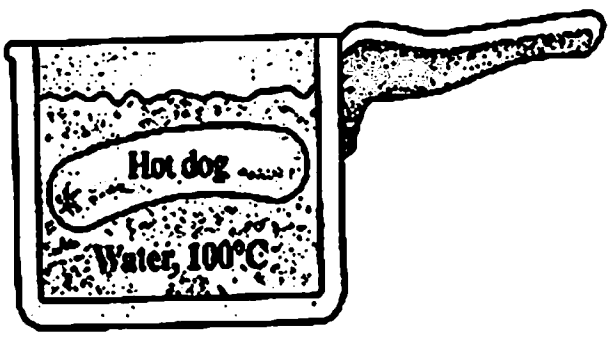

FIGURE P18–97

Step 1 of 4

Given:

Length of the cylindrical hot dog $L = 12$ cm

Diameter of the cylindrical hot dog $d = 2$ cm

Center temperature of the hot dog $T = 80°\,C$

Thermal Conductivity of the hot dog, $k = 0.76\ W/m \cdot °C$

Density of the hot dog, $\rho = 980\ \frac{kg}{m^3}$

Specific Heat, $Cp = 3.9\ \frac{kJ}{kg.\ C}$

Thermal Diffusivity of the hot dog, $\alpha = 2 \times 10^{-7}\ m^2/s$

Heat Transfer Coefficient, $h = 600\ \frac{W}{m^2 \cdot °C}$

Step 2 of 4

This hot dog can physically be formed by the intersection of an infinite plane wall of thickness $2L = 12$ cm, and a long cylinder of radius $r_o = D/2 = 1$ cm.

The Biot numbers and corresponding constants are first determined to be

$$Bi = \frac{hL}{k}$$

$$Bi = \frac{(600\ W/m^2.°C)(0.06\ m)}{(0.76\ W/m.°C)}$$

$$Bi = 47.37$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$\lambda_1 = 1.5381$ and $A_1 = 1.2726$

Length of the cylindrical hot dog $L = 12$ cm

Diameter of the cylindrical hot dog $d = 2$ cm

Center temperature of the hot dog $T = 80°\,C$

Thermal Conductivity of the hot dog, $k = 0.76\ W/m \cdot °C$

Density of the hot dog, $\rho = 980\ \frac{kg}{m^3}$

Specific Heat, $Cp = 3.9\ \frac{kJ}{kg.\ C}$

Thermal Diffusivity of the hot dog, $\alpha = 2 \times 10^{-7}\ m^2/s$

Heat Transfer Coefficient, $h = 600\ \frac{W}{m^2 \cdot °C}$

Step 2 of 4

This hot dog can physically be formed by the intersection of an infinite plane wall of thickness $2L = 12$ cm, and a long cylinder of radius $r_o = D/2 = 1$ cm.

The Biot numbers and corresponding constants are first determined to be

$$Bi = \frac{hL}{k}$$

$$Bi = \frac{(600\ W/m^2.°C)(0.06\ m)}{(0.76\ W/m.°C)}$$

$$Bi = 47.37$$

The constants λ_1 and A_1 corresponding to this Biot number are, from table 11-2

From interpolation method

$\lambda_1 = 1.5381$ and $A_1 = 1.2726$

Step 4 of 4

Therefore, it will take about 4.1 min for the hot dog to cook. Note that

$$\tau_{cyl} = \frac{\alpha t}{r_o^2}$$

$$\tau_{cyl} = \frac{(2 \times 10^{-7}\ m^2/s)(244\ s)}{(0.01\ m)^2}$$

$$\tau_{cyl} = 0.49 > 0.2$$

Thus the assumption $\tau > 0.2$ for the applicability of the one-term approximate solution is verified.

Question: 18.098P

A long roll of 2-m-wide and 0.5-cm-thick 1-Mn manganese steel plate coming off a furnace at 820°C is to be quenched in an oil bath (cp = 2.0 kJ/kg·K) at 185°C. The metal sheet is moving at a steady velocity of 20 m/min, and the oil bath is 9 m long. Taking the convection heat transfer coefficient on both sides of the plate to be 860 W/m2 ·K, determine the temperature of the sheet metal when it leaves the oil bath. Also, determine the required rate of heat removal from the oil to keep its temperature constant at 45°C.

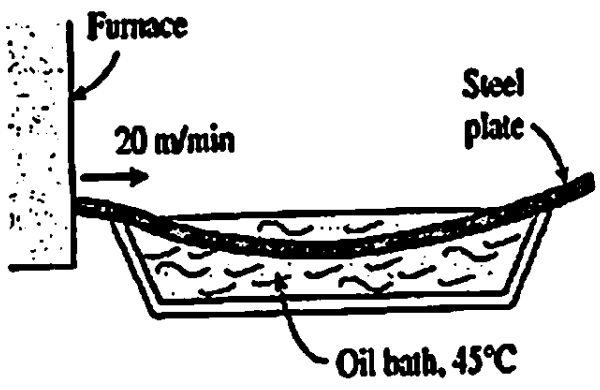

FIGURE P18–98

Question:

A long roll of 2-m-wide and 0.5-cm-thick 1-Mn manganese steel plate coming off a furnace at 820°C is to be quenched in an oil bath (cp = 2.0 kJ/kg·K) at 185°C. The metal sheet is moving at a steady velocity of 20 m/min, and the oil bath is 9 m long. Taking the convection heat transfer coefficient on both sides of the plate to be 860 W/m2 ·K, determine the temperature of the sheet metal when it leaves the oil bath. Also, determine the required rate of heat removal from the oil to keep its temperature constant at 45°C.

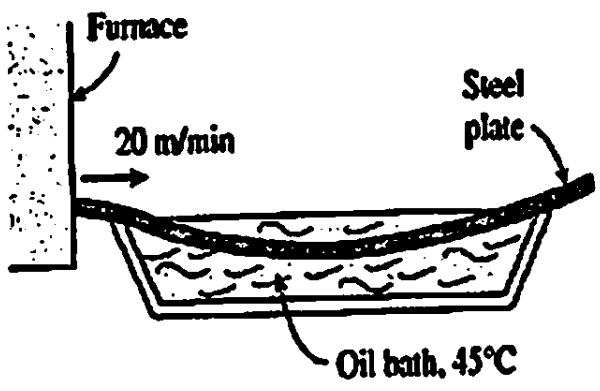

FIGURE P18–98

Step 1 of 6

Then, Biot number becomes

$$\text{Bi} = \frac{hL_c}{k}$$

$$= \frac{(860\ \text{W/m}^2.^\circ\text{C})(0.0025\ \text{m})}{60.5\ \text{W/m}.^\circ\text{C}}$$

$$= 0.036 < 0.1$$

Since Bi < 0.1, the lumped system analysis is applicable. Therefore,

$$b = \frac{hA_s}{\rho C_p V}$$

$$= \frac{h}{\rho C_p L_c}$$

$$= \frac{860\ \text{W/m}^2.^\circ\text{C}}{(7854\ \text{kg/m}^3)(434\ \text{J/kg.}^\circ\text{C})(0.0025\ \text{m})}$$

$$= 0.10092\ s^{-1}$$

Step 4 of 6

Time is

$$(t) = \frac{\text{length}}{\text{velocity}}$$

$$= \frac{9\ \text{m}}{20\ \text{m/min}}$$

$$= 0.45\ \text{min}$$

Then the temperature of the sheet metal when it leaves the oil bath is determined to be

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

$$\frac{T(t) - 45}{820 - 45} = e^{-(0.10092\ s^{-1})(27\ s)}$$

$$T(t) = 95.80^\circ\text{C}$$

Therefore, the temperature of the sheet metal when it leaves the oil bath is $T(t)$=95.80°C.

Step 5 of 6

The mass flow rate of the sheet metal through the oil bath is

$$\dot{m} = \rho \dot{V}$$

$$= \rho w t V$$

$$= (7854\ \text{kg/m}^3)(2\ \text{m})(0.005\ \text{m})(20\ \text{m/min})$$

$$= 1570.8\ \text{kg/min}$$

$$= 26.173\ \text{kg/s}$$

Step 6 of 6

Then the rate of heat transfer from the sheet metal to the oil bath and thus the rate at which heat needs to be removed from the oil in order to keep its temperature constant at 45°C becomes

$$\dot{Q} = \dot{m} C_p [T(t) - T_\infty]$$

$$= (26.173\ \text{kg/s})(434\ \text{J/kg.}^\circ\text{C})(95.80 - 45)^\circ\text{C}$$

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

$$\frac{T(t) - 45}{820 - 45} = e^{-(0.10092\ s^{-1})(27\ s)}$$

$$T(t) = 95.80^\circ\text{C}$$

Therefore, the temperature of the sheet metal when it leaves the oil bath is $T(t)$=95.80°C.

Step 5 of 6

Question: 18.099P

In *Betty Crocker's Cookbook*, it is stated that it takes 5 h to roast a 14-lb stuffed turkey initially at 40°F in an oven maintained at 325°F. It is recommended that a meat thermometer be used to monitor the cooking, and the turkey is considered done when the thermometer inserted deep into the thickest part of the breast or thigh without touching the bone registers 185°F. The turkey can be treated as a homogeneous spherical object with the properties ρ = lbm/ft3 , *cp* = 0.98 Btu/lbm·°F. *k* = 0.26 Btu/h·ft·°F, and *α* = 0.0035 ft2 /h. Assuming the tip of the thermometer is at one-third radial distance from the center of the turkey, determine (*a*) the average heat transfer coefficient at the surface of the turkey; (*b*) the temperature of the skin of the turkey when it is done; and (*c*) the total amount of heat transferred to the turkey in the oven. Will the reading of the thermometer be more or less than 185°F 5 min after the turkey is taken out of the oven?

Step 1 of 6

Given:

Weight of stuffed turkey $W = 14$ lb

Initial Temperature of the turkey $T_i = 40°F$

Oven Temperature $T_\infty = 325°F$

Thermal Conductivity of the turkey, k = 0.26 Btu/h.ft. °F

Density of the turkey, $\rho = 75 \frac{\text{lbm}}{\text{ft}^3}$

Specific Heat of the turkey, Cp =0.98 Btu/lbm.°F

Thermal Diffusivity of the turkey, $\alpha = 0.0035 \frac{\text{ft}^2}{\text{h}}$

Step 2 of 6

A stuffed turkey is cooked in an oven. The turkey is a homogeneous spherical object. Heat conduction in the turkey is one-dimensional because of symmetry about the midpoint. The thermal properties of the turkey are constant. Assuming the turkey to be spherical in shape, its radius is determined to be

The mass $m = \rho V$

The volume $V = \frac{m}{\rho}$

$$V = \frac{14 \text{ lbm}}{75 \text{ lbm/ft}^3}$$

$$V = 0.1867 \text{ ft}^3$$

$$V = \frac{4}{3}\pi r_o^3$$

The radius $r_o = \sqrt[3]{\frac{3V}{4\pi}}$

$$r_o = \sqrt[3]{\frac{3(0.1867 \text{ ft}^3)}{4\pi}}$$

$$r_o = 0.3545 \text{ ft}$$

The Fourier number is $\tau = \frac{\alpha t}{r_o^2}$

$$\tau = \frac{(3.5\times10^{-3} \text{ ft}^2/\text{h})(5 \text{ h})}{(0.3545 \text{ ft})^2}$$

$$\tau = 0.1392$$

Step 3 of 6

Which is close to 0.2 but a little below it. Therefore, assuming the one-term approximate solution for transient heat conduction to be applicable, the one-term solution formulation at one-third the radius from the center of the turkey can be expressed as

$$\theta(x,t)_{sph} = \frac{T(x,t) - T_\infty}{T_i - T_\infty}$$

$$\theta(x,t)_{sph} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r / r_o)}{\lambda_1 r / r_o}$$

$$\frac{185 - 325}{40 - 325} = 0.491$$

$$0.491 = A_1 e^{-\lambda_1^2 (0.14)} \frac{\sin(0.333\lambda_1)}{0.333\lambda_1}$$

By trial and error, it is determined from Biot number table that the equation above is satisfied when $Bi = 20$ corresponding to $\lambda_1 = 2.9857$ and $A_1 = 1.9781$. Then the heat transfer coefficient can be determined from

$$Bi = \frac{hr_o}{k}$$

$$h = \frac{kBi}{r_o}$$

$$h = \frac{(0.26 \text{ Btu/h.ft.°F})(20)}{(0.3545 \text{ ft})}$$

$$\boxed{h = 14.7 \text{Btu/h.ft.°F}}$$

Step 4 of 6

(*b*) The temperature at the surface of the turkey is

$$\frac{T(r_o,t) - 325}{40 - 325} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r_o / r_o)}{\lambda_1 r_o / r_o}$$

$$\frac{T(r_o,t) - 325}{40 - 325} = (1.9781) e^{-(2.9857)^2 (0.14)} \frac{\sin(2.9857)}{2.9857}$$

$$\frac{T(r_o,t) - 325}{40 - 325} = 0.02953$$

$$\boxed{T(r_o,t) = 317 \text{ °F}}$$

Step 5 of 6

(*c*) The maximum possible heat transfer is

$$Q_{max} = mC_p(T_\infty - T_i)$$

$$Q_{max} = (14 \text{ lbm})(0.98 \text{ Btu/lbm.°F})(325 - 40)°F$$

$$Q_{max} = 3910 \text{ Btu}$$

Step 6 of 6

Then the actual amount of heat transfer becomes

$$\frac{Q}{Q_{max}} = 1 - 3\theta_{o,sph} \frac{\sin(\lambda_1) - \lambda_1 \cos(\lambda_1)}{\lambda_1^3}$$

$$\frac{Q}{Q_{max}} = 1 - 3(0.491) \frac{\sin(2.9857) - (2.9857)\cos(2.9857)}{(2.9857)^3}$$

$$\frac{Q}{Q_{max}} = 0.828$$

$$Q = 0.828 Q_{max}$$

$$Q = (0.828)(3910 \text{ Btu})$$

$$\boxed{Q = 3238 \text{ Btu}}$$

Question: 18.100P

During a fire, the trunks of some dry oak trees (k = 0.17 W/m·K and α = 1.28 × 10–7 m2 /s) that are initially at a uniform temperature of 30°C are exposed to hot gases at 600°C for a period of 5 h, with a heat transfer coefficient of 65 W/m2 ·K on the surface. The ignition temperature of the trees is 410°C Treating the trunks of the trees as long cylindrical rods of diameter 20 cm, determine if these dry trees will ignite as the fire sweeps through them.

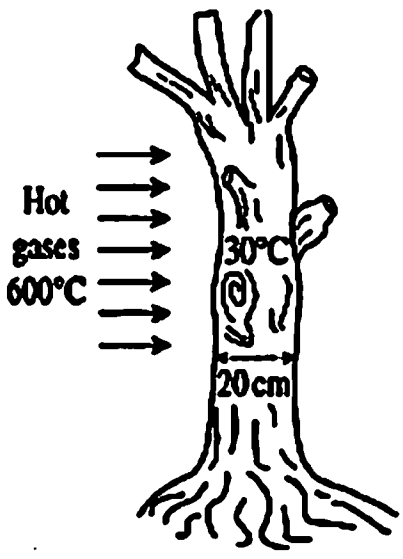

FIGURE P18–100

Step 1 of 5

Given data:

Thermal conductivity is $k = 0.17\,\text{W/m}\cdot\text{K}$

Thermal diffusivity is $\alpha = 1.28\times10^{-7}\,\text{m}^2/\text{s}$

Initially temperature is $T_i = 30\,^\circ\text{C}$

Time $t = 5\text{h}$

Diameter of the cylinder is $D = 20\,\text{cm}$

Heat transfer coefficient between man and ambiance is $h = 65\ \text{W/m}^2\cdot\text{K}$

Step 2 of 5

Characteristic length is

$$r_0 = \frac{r}{2}$$
$$= \frac{20}{2}$$
$$= 10\,\text{cm}$$
$$= 0.1\text{m}$$

Step 3 of 5

Then, biot number becomes

$$Bi = \frac{hL_c}{k}$$
$$= \frac{65\times0.1}{0.17}$$
$$= 38.2$$

Step 4 of 5

From the coefficient used in the one term approximation solution for transient heat conduction for cylinder

At Bi=38.2

We get: $\lambda = 2.34, A = 1.599$

Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$
$$= \frac{1.28\times10^{-7}\times(5\times3600\text{sec})}{0.1^2}$$
$$= 0.2304$$

Step 5 of 5

From the zeroth and first order Bessel functions of the first kind

At $J_o(2.34) = 0.033$

So, the dimensionless temperature after 5 hours of time is obtained as:

$$\frac{T-T_\alpha}{T_i-T_\alpha} = Ae^{-\lambda^2\tau}J_0\left(\frac{\lambda r}{r}\right)$$
$$\frac{T-T_\alpha}{T_i-T_\alpha} = 1.599\times e^{-2.34^2\times0.2304}\times J_0(2.34)$$
$$\frac{T-600}{30-600} = 1.599\times e^{-2.34^2\times0.2304}\times J_0(2.34)$$
$$\frac{T-600}{30-600} = 1.599\times e^{-2.34^2\times0.2304}\times 0.033$$
$$T = 591.481^\circ\text{C}$$

As this temperature is more than 410° C, the trees will ignite.

Question: 18.101P

Consider two 2-cm-thick large steel plates (k = 43 W/m·K and α = 1.17 × 10–5 m2 /s) that were put on top of each other while wet and left outside during a cold winter night at –10°C. The next day, a worker needs one of the plates, but the plates are stuck together because the freezing of the water between the two plates has bonded them together. In an effort to melt the ice between the plates and separate them, the worker takes a large hair dryer and blows hot air at 80°C all over the exposed surface of the plate on the top. The convection heat transfer coefficient at the top surface is estimated to be 40 W/m2 ·K. Determine how long the worker must keep blowing hot air before the two plates separate.

Step 1 of 3

The characteristic length of the plate,

$$L_c = L$$

Substitute 0.02 m for L,

$$L_c = L$$
$$= 0.02 \text{ m}$$

The Biot number,

$$Bi = \frac{hL_c}{k}$$

Substitute 40 $\text{W/m}^2\cdot^\circ\text{C}$ for h and 43 $\text{W/m}\cdot^\circ\text{C}$ for k

$$Bi = \frac{hL_c}{k}$$
$$= \frac{(40 \text{ W/m}^2.^\circ\text{C})(0.02)}{(43 \text{ W/m.}^\circ\text{C})}$$
$$= 0.019$$
$$Bi = 0.019 < 0.1$$

Since, the lumped system analysis is applicable. 9704044408

Step 2 of 3

The lumped system analysis,

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt} \qquad \text{..... (1)}$$

Here,

$$b = \frac{hA_s}{\rho C_p V}$$

Thermal diffusivity is $\alpha = \frac{k}{\rho c_p}$

Re-arranging the above relation we get

$$\rho c_p = \frac{k}{\alpha}$$

Hence,

$$b = \frac{h}{\rho C_p L_c}$$
$$= \frac{h}{\left(\frac{k}{\alpha}\right)L_c}$$

Substitute 40 $\text{W/m}^2\cdot^\circ\text{C}$ for h, 43 $\text{W/m}\cdot^\circ\text{C}$ for k and 1.17×10^{-5} m^2/s for α

$$b = \frac{h}{\left(\frac{k}{\alpha}\right)L_c}$$
$$= \frac{40 \text{ W/m}^2\cdot^\circ\text{C}}{\left(\frac{43}{1.17\times10^{-5}}\right)0.02}$$
$$= \frac{40 \text{ W/m}^2.^\circ\text{C}}{3.675\times10^6\times0.02 \text{ m}}$$
$$= 0.000544 \text{ s}^{-1}$$

Step 3 of 3

Now from equation (1),

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

Substitute 0 for $T(t)$, –10°C for T_i and 80°C for T_∞

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$
$$\frac{0-80}{-10-80} = e^{-(0.000544)x}$$
$$t = 216.513 \text{sec}$$

Therefore, time required for keeping the hot blow air before the two plates separate is

$$\boxed{t = 216.513 \text{sec}}$$

Question: 18.102P pg 1

Consider a plate of thickness 1 in, a long cylinder of diameter 1 in, and a sphere of diameter 1 in. all initially at 400°F and all made of bronze (k = 15.0 Btu/h·ft·°F and α = 0.333 ft2 /h). Now all three of these geometries are exposed to cool air at 75°F on all of their surfaces, with a heat transfer coefficient of 7 Btu/h·ft2 ·°F. Determine the center temperature of each geometry after 10 and 20 min. Explain why the center temperature of the sphere is always the lowest.

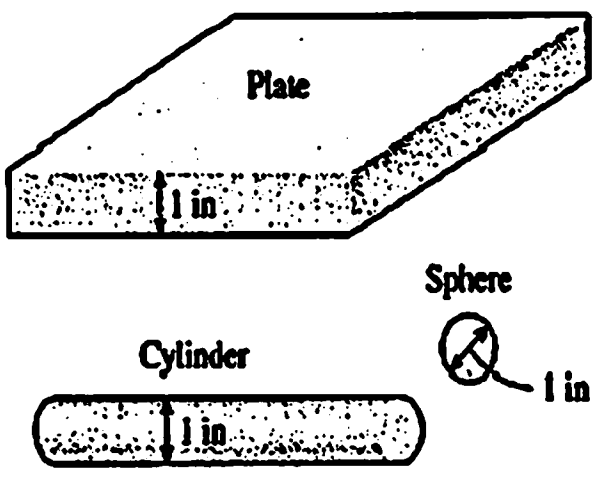

FIGURE P18–102E

Step 1 of 18

Given data:

Thickness of the plate = 1 in

Diameter of the cylindrical = 1 in

Initial Temperature = 400°F

Cool air temperature = 75°F

Thermal Conductivity, k = 15 Btu/h-ft·°F

Thermal Diffusivity, α = 0.333 ft^2 / hr

Heat transfer coefficient h = 7 Btu/h-ft^2 ·°F

Step 2 of 18

Calculation for 10 min. of time:

For the plate geometry:

Characteristic length of the plate is

$$L_c = \frac{L}{2}$$
$$= \frac{1}{2}$$
$$= 0.5\text{in}$$

Step 3 of 18

Then Biot number becomes

$$Bi = \frac{hL_c}{k}$$
$$= \frac{7 \times \left(\frac{0.5\text{in}}{12\text{ft}}\right)}{15}$$
$$= 0.019$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 4 of 18

Then, Fourier number becomes

$$\tau = \frac{\alpha t}{L_c^2}$$
$$= \frac{0.333 \times \left(\frac{10}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$
$$= 32$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 5 of 18

From the one dimension term approximation solution of transient heat conduction for plane wall

At $Bi = 0.019$,

$\lambda = 0.141, A = 1.003$

Step 6 of 18

Then the center temperature of the plate becomes

$$\theta_{0,wall} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$
$$A_1 e^{-\lambda_1^2 \tau} = (1.0033) e^{-(0.1410)^2 (31.97)}$$
$$A_1 e^{-\lambda_1^2 \tau} = 0.531$$
$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = A e^{-\lambda^2 \tau}$$
$$\frac{T(t) - 75}{400 - 75} = 1.003 e^{-0.141^2 \times 32}$$
$$T(t) = 248^\circ\text{F}$$

So the centre temperature of the flat plate after 10 min. is $\boxed{T(t) = 248^\circ\text{F}}$.

Step 7 of 18

For Cylinder:

From the one dimension term approximation solution of transient heat conduction for cylinder

At $Bi = 0.019$,

$\lambda_1 = 0.1995$ And $A_1 = 1.0050$

Then the center temperature of the plate becomes

$$\theta_{0,wall} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$
$$A_1 e^{-\lambda_1^2 \tau} = (1.0050) e^{-(0.1995)^2 (31.97)}$$
$$A_1 e^{-\lambda_1^2 \tau} = 0.282$$

$$\theta_{0,wall} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$A_1 e^{-\lambda_1^2 \tau} = (1.0050) e^{-(0.1995)^2 (31.97)}$$

$$A_1 e^{-\lambda_1^2 \tau} = 0.282$$

$$\frac{T_0 - 75}{400 - 75} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{T_0 - 75}{400 - 75} = 0.282$$

$$\boxed{T_0 = 167^\circ \text{F}}$$

So the centre temperature of the cylinder after 10 min. is $\boxed{T(t) = 166^\circ \text{F}}$.

Step 8 of 18

For Sphere:

From the one dimension term approximation solution of transient heat conduction for sphere

At $Bi = 0.019$,

Corresponding to this Biot number,

$\lambda_1 = 0.2445$ And $A_1 = 1.0060$

Step 9 of 18

Then the center temperature of the plate becomes

$$\theta_{0,wall} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$A_1 e^{-\lambda_1^2 \tau} = (1.0060) e^{-(0.2445)^2 (31.97)}$$

$$A_1 e^{-\lambda_1^2 \tau} = 0.149$$

$$\frac{T_0 - 75}{400 - 75} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{T_0 - 75}{400 - 75} = 0.149$$

$$\boxed{T_0 = 123^\circ \text{F}}$$

Therefore center temperature of the sphere is $\boxed{T(t) = 123^\circ \text{F}}$

Step 10 of 18

Calculation for 20 min of time:

For the plate geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12\text{ft}}\right)}{15}$$

$$= 0.019$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 11 of 18

So, for 20 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.333 \times \left(\frac{20}{60\text{min}}\right)}{\left(\frac{0.5}{12\text{ft}}\right)^2}$$

$$= 64$$

Since Fourier number greater than the 0.2.So one term approximation applicable.

Step 12 of 18

From the one dimension term approximation solution of transient heat conduction for plate

At $Bi = 0.019$,

We get: $\lambda = 0.141, A = 1.003$

Putting this into the expression for flat plate:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = A e^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.003 e^{-0.141^2 \times 64}$$

$$\boxed{T(t) = 166^\circ \text{F}}$$

So the centre temperature of the flat plate after 20 min. is $\boxed{T(t) = 166^\circ \text{F}}$.

Step 13 of 18

For the cylinder geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12\text{ft}}\right)}{15}$$

$$= 0.019$$

Step 14 of 18

From the one dimension term approximation solution of transient heat conduction for cylinder

At $Bi = 0.019$,

We get: $\lambda = 0.1995, A = 1.005$

So, for 20 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.333 \times \left(\frac{20}{60}\right)}{}$$

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.333 \times \left(\frac{20}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$

$$= 64$$

Since Fourier number greater than the 0.2.So one term approximation applicable.

Step 15 of 18

Putting this into the expression for cylinder:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\Rightarrow \frac{T(t) - 75}{400 - 75} = 1.005e^{-0.1995^2 \times 64}$$

$$\Rightarrow T(t) = \boxed{100^\circ \text{F}}$$

So the centre temperature of the cylinder after 20 min. is $\boxed{T(t) = 100^\circ \text{F}}$.

Step 16 of 18

For the sphere geometry:

Biot number is

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12}\right)}{15}$$

$$= 0.019$$

Step 17 of 18

From the one dimension term approximation solution of transient heat conduction for sphere

We get: $\lambda = 0.245, A = 1.006$

So, for 20 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.333 \times \left(\frac{20}{60\,\text{min}}\right)}{\left(\frac{0.5\text{in}}{12\text{ft}}\right)^2}$$

$$= 64$$

Step 18 of 18

Putting this into the expression for sphere:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.006e^{-0245^2 \times 64}$$

$$\boxed{T(t) = 82^\circ \text{F}}$$

So the centre temperature of the sphere after 20 min. is 82° F.

Sphere being have largest surface area among the given geometries, its heat dissipation rate is higher. So the temperature of the sphere is always the lowest.

Question:

Repeat Prob. 18-102E for cast iron geometries (k = 29 Btu/h·ft·°F and α = 0.61 ft2 /h).

Step 1 of 20

Given data:

Thickness of the plate $= 1$ in

Diameter of the cylindrical $= 1$ in

Initial Temperature $= 400°F$

Cool air temperature $= 75°F$

Thermal Conductivity, $k = 29$ Btu/h-ft·° F

Thermal Diffusivity, $\alpha = 0.61 ft^2 / hr$

Heat transfer coefficient $h = 7$ Btu/h-ft^2 ·° F

Step 2 of 20

For 10 min. of time:

For the plate geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12ft}\right)}{29}$$

$$= 0.01$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 3 of 20

So, for 10 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.61 \times \left(\frac{10}{60\,min}\right)}{\left(\frac{0.5}{12ft}\right)^2}$$

$$= 59$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 4 of 20

From the one dimension term approximation solution of transient heat conduction for plane wall

At $Bi = 0.01$,

We get: $\lambda = 0.099, A = 1.0017$

Putting this into the expression for flat plate:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.0017e^{-0.099^2 \times 59}$$

$$\boxed{T(t) = 258^\circ F}$$

So the centre temperature of the flat plate after 10 min. is $\boxed{T(t) = 258^\circ F}$.

Step 5 of 20

For the cylinder geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12}\right)}{29}$$

$$= 0.01$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 6 of 20

So, for 10 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.61 \times \left(\frac{10}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$

$$= 59$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 7 of 20

From the one dimension term approximation solution of transient heat conduction for cylinder

At $Bi = 0.01$,

We get: $\lambda = 0.141, A = 1.0025$

Putting this into the expression for cylinder:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.0025e^{-0.141^2 \times 59}$$

$$\boxed{T(t) = 176^\circ F}$$

So the centre temperature of the cylinder after 10 min. is $\boxed{T(t) = 176^\circ F}$.

Step 8 of 20

For the sphere geometry:

$$Bi = \frac{hL_c}{k}$$

$$7 \times \left(\frac{0.5}{12ft}\right)$$

For the sphere geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12\text{ft}}\right)}{29}$$

$$= 0.01$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 9 of 20

So, for 10 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.61 \times \left(\frac{10}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$

$$= 59$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 10 of 20

From the one dimension term approximation solution of transient heat conduction for sphere

We get: $\lambda = 0.173, A = 1.003$

So, for 10 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.61 \times \left(\frac{10}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$

$$= 59$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 11 of 20

Putting this into the expression for sphere:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.003e^{-0.173^2 \times 59}$$

$$T(t) = 131^\circ \text{F}$$

So the centre temperature of the sphere after 10 min. is $\boxed{T(t) = 131^\circ \text{F}}$.

Step 12 of 20

For 20 min. of time:

For the plate geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12}\right)}{29}$$

$$= 0.01$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 13 of 20

So, for 20 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.61 \times \left(\frac{20}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$

$$= 118$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 14 of 20

From the one dimension term approximation solution of transient heat conduction for plane wall

We get: $\lambda = 0.099, A = 1.0017$

Putting this into the expression for flat plate:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.0017e^{-0.099^2 \times 118}$$

$$T(t) = 177^\circ \text{F}$$

So the centre temperature of the flat plate after 20 min. is $\boxed{T(t) = 177^\circ \text{F}}$.

Step 15 of 20

And, for the cylinder geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12}\right)}{29}$$

$$= 0.01$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 16 of 20

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 16 of 20

So, for 20 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$\Rightarrow \tau = \frac{0.61 \times \left(\frac{10}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$

$$\Rightarrow \tau = 118$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 17 of 20

From the one dimension term approximation solution of transient heat conduction for cylinder

We get: $\lambda = 0.141, A = 1.0025$

Putting this into the expression for cylinder:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.0025e^{-0.141^2 \times 118}$$

$$T(t) = 106^\circ \text{F}$$

So the centre temperature of the cylinder after 20 min. is $\boxed{T(t) = 106^\circ \text{F}}$.

Step 18 of 20

for the sphere geometry:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{7 \times \left(\frac{0.5}{12}\right)}{29}$$

$$= 0.01$$

Since Biot number less than 0.1, therefore lumped system analysis applicable.

Step 19 of 20

So, for 20 min. of time, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$\Rightarrow \tau = \frac{0.61 \times \left(\frac{10}{60}\right)}{\left(\frac{0.5}{12}\right)^2}$$

$$\Rightarrow \tau = 118$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 20 of 20

From the one dimension term approximation solution of transient heat conduction for sphere

$\lambda = 0.173, A = 1.003$

Putting this into the expression for sphere:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 75}{400 - 75} = 1.003e^{-0.173^2 \times 118}$$

$$T(t) = 84^\circ \text{F}$$

So the centre temperature of the sphere after 20 min. is $\boxed{T(t) = 84^\circ \text{F}}$.

Question: 18.104P

Reconsider Prob. 18-102E. Using EES (or other) software, plot the center temperature of each geometry as a function of the cooling time as the time varies from 5 min to 60 min. and discuss the results.

Step 1 of 9

Given data:

Thickness of the plate, $t = 1$ in.

Diameter of the cylindrical, $d = 1$ in.

Initial Temperature, $T_i = 400°F$

Cool air temperature, $T_{air} = 75°F$

Thermal Conductivity, $k = 15$ Btu/h-ft·°F

Thermal Diffusivity, $\alpha = 0.333\ ft^2/hr$

Heat transfer coefficient $h = 7$ Btu/h-ft^2·°F

Step 2 of 9

To solve this question using EES software open EES software
Then FILE->New
A dailogbox will open type the following in dailog box

```
"GIVEN"
2*L=1/12 "[ft]"
2*r_o_c=1/12 "[ft], c stands for cylinder"
2*r_o_s=1/12 "[ft], s stands for sphere"
T_i=400 "[F]"
T_infinity=75 "[F]"
h=7 "[Btu/h-ft^2-F]"
"time=5 [min], parameter to be varied"
```

Step 3 of 9

```
"PROPERTIES"
k=15 "[Btu/h-ft-F]"
alpha=0.333*Convert(ft^2/h, ft^2/min) "[ft^2/min]"

"ANALYSIS"
"For plane wall"
Bi_w=(h*L)/k
"From biot number Table corresponding to this Bi number, we read"
lambda_1_w=0.1410
A_1_w=1.0033
tau_w=(alpha*time)/L^2
(T_o_w-T_infinity)/(T_i-T_infinity)=A_1_w*exp(-lambda_1_w^2*tau_w)
```

Step 4 of 9

```
"For long cylinder"
Bi_c=(h*r_o_c)/k
"From Table for biot number corresponding to this Bi number, we read"
lambda_1_c=0.1995
A_1_c=1.0050
tau_c=(alpha*time)/r_o_c^2
(T_o_c-T_infinity)/(T_i-T_infinity)=A_1_c*exp(-lambda_1_c^2*tau_c)
```

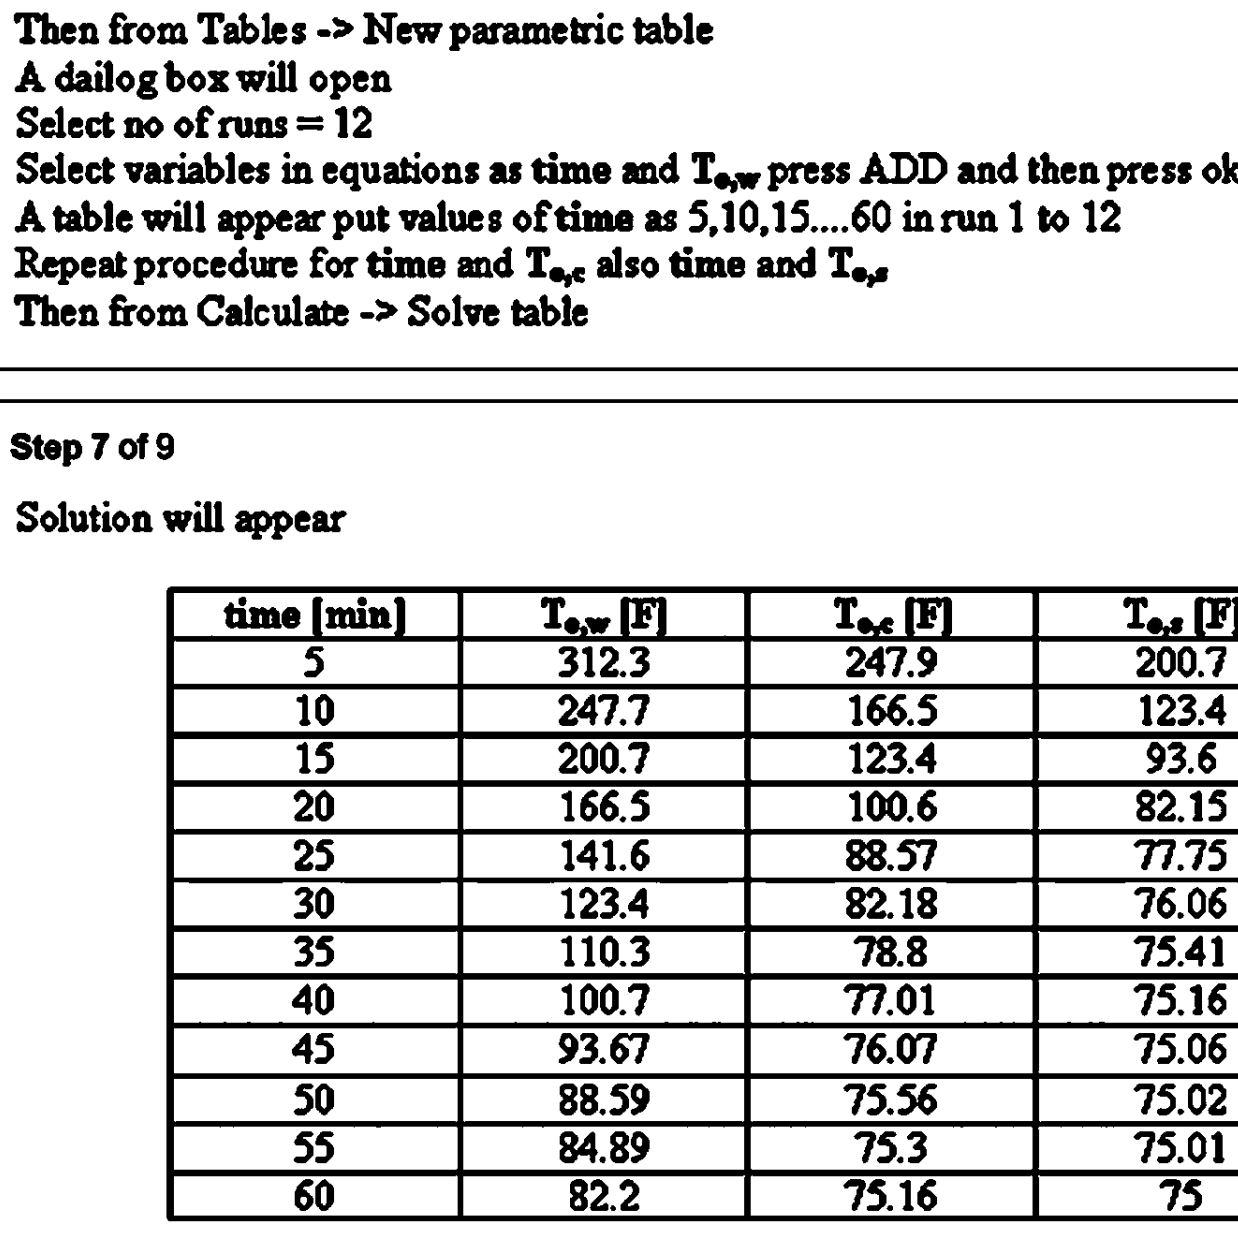
Step 5 of 9

```
"For sphere"
Bi_s=(h*r_o_s)/k
"From biot number Table corresponding to this Bi number, we read"
lambda_1_s=0.2445
A_1_s=1.0060
tau_s=(alpha*time)/r_o_s^2
(T_o_s-T_infinity)/(T_i-T_infinity)=A_1_s*exp(-lambda_1_s^2*tau_s)
```

Step 6 of 9

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 12
Select variables in equations as time and $T_{o,w}$ press ADD and then press ok
A table will appear put values of time as 5,10,15....60 in run 1 to 12
Repeat procedure for time and $T_{o,c}$ also time and $T_{o,s}$
Then from Calculate -> Solve table

Step 7 of 9



Solution will appear

time [min]	$T_{o,w}$ [F]	$T_{o,c}$ [F]	$T_{o,s}$ [F]
5	312.3	247.9	200.7
10	247.7	166.5	123.4
15	200.7	123.4	93.6
20	166.5	100.6	82.15
25	141.6	88.57	77.75
30	123.4	82.18	76.06
35	110.3	78.8	75.41
40	100.7	77.01	75.16
45	93.67	76.07	75.06
50	88.59	75.56	75.02
55	84.89	75.3	75.01
60	82.2	75.16	75

Step 8 of 9

Then from Plot -> New plot window -> X-Y Plot
Select X-axis time and Y-axis $T_{o,w}$
Repeat procedure for time and $T_{o,c}$ also time and $T_{o,s}$
Press OK
Graph will be plotted.

Step 9 of 9

Question: 18.105P

Engine valves (k = 48 W/m·K, cp = 440 J/kg·K, and ρ = 7840 kg/m3) are heated to 800°C in the heat treatment section of a valve manufacturing facility. The valves are then quenched in a large oil bath at an average temperature of 50°C. The heat transfer coefficient in the oil bath is 800 W/m2 ·K. The valves have a cylindrical stem with a diameter of 8 mm and a length of 10 cm. The valve head and the stem may be assumed to be of equal surface area, and the volume of the valve head can be taken to be 80 percent of the volume of stem. Determine how long it will take for the valve temperature to drop to (*a*) 400°C, (*b*) 200°C, and (*c*) 51 °C, and (*d*) the maximum heat transfer from a single valve.

Step 1 of 5

Given: Diameter of the watermelon = 20 cm

Initial Temperature of the watermelon T_i = 35°C

Lake temperature = 15°C

Center Temperature of the watermelon = 20°C

Time period =280min

$t = 4\text{h}\,40\text{min}$

$t = 16800\,\text{s}$

Thermal Conductivity, $k = 0.618\ \text{W/m°C}$

Thermal Diffusivity, $\alpha = 0.15\times10^{-6}\ \frac{\text{m}^2}{\text{s}}$

Density, $\rho = 995\ \frac{\text{kg}}{\text{m3}}$

Specific Heat, $C_p = 4.18\ \frac{\text{kJ}}{\text{kg°C}}$

Step 2 of 5

The Fourier number is

$$\tau = \frac{\alpha t}{r_o^2}$$

$$= \frac{(0.15\times10^{-6})(16800)}{(0.10)^2}$$

$$\tau = 0.252$$

$$\tau > 0.2$$

Step 3 of 5

Then the one-term solution can be written in the form

$$\theta_{0,sph} = \frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

$$\frac{20-15}{35-15} = A_1 e^{-\lambda_1^2 (0.252)}$$

$$0.25 = A_1 e^{-\lambda_1^2 (0.252)}$$

It is determined from Biot number table by trial and error that this equation is satisfied when $Bi = 10$, which corresponds to $\lambda_1 = 2.8363$ and $A_1 = 1.9249$.

Step 4 of 5

Then the heat transfer coefficient can be determined from

$$Bi = \frac{hr_o}{k}$$

$$h = \frac{kBi}{r_o}$$

$$= \frac{(0.618)(10)}{(0.10)}$$

$$h = 61.8\ \frac{\text{W}}{\text{m}^2\,°\text{C}}$$

Step 5 of 5

The temperature at the surface of the watermelon:

For sphere,

$$\theta(r_o,t)_{sph} = \frac{T(r_o,t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r_o / r_o)}{\lambda_1 r_o / r_o}$$

$$\theta(r_o,t)_{sph} = (1.9249)\times e^{-(2.8363)^2(0.252)} \times \frac{\sin(2.8363\ \text{rad})}{2.8363}$$

$$\frac{T(r_o,t) - 15}{35-15} = 0.0269$$

$$\boxed{T(r_o,t) = 15.5\ °\text{C}}$$

Question: 18.106P

Consider the engine block of a car made of cast iron (k = 52 W/m·K and α = 1.7 × 10–5 m2 /s). The engine can be considered to be a rectangular block whose sides are 80 cm, 40 cm, and 40 cm. The engine is at a temperature of 150°C when it is turned off. The engine is then exposed to atmospheric air at 17°C with a heat transfer coefficient of 6 W/m2 -K. Determine (*a*) the center temperature of the top surface whose sides are 80 cm and 40 cm and (*b*) the corner temperature after 45 min of cooling.

Step 1 of 12

Given:

Dimensions of engine = 80cmX 40cmX 40cm

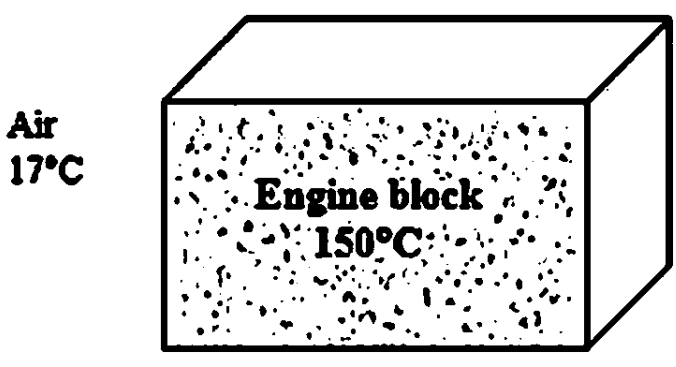
Engine temperature = 140^0C

Atmospheric temperature = 17^0C

Step 2 of 12

The engine block of a car is allowed to cool in atmospheric air. Heat conduction in the block is three-dimensional, and thus the temperature varies in all three directions. The thermal properties of the block are constant.

Step 3 of 12



The thermal properties of cast iron are

k = 52 W/m.°C

$\alpha = 1.7\times10^{-5}$ m^2/s.

This rectangular block can physically be formed by by the intersection of two infinite plane walls of thickness 2L = 40 cm (call planes A and B) and an infinite plane wall of thickness 2L = 80 cm (call plane C). We measure x from the center of the block.

Step 4 of 12

Step 5 of 12

A) The Biot number is calculated for each of the plane wall to be

$$Bi_A = Bi_B = \frac{hL}{k} = \frac{(6\ \text{W/m}^2.^\circ\text{C})(0.2\ \text{m})}{(52\ \text{W/m}.^\circ\text{C})} = 0.0231$$

$$Bi_C = \frac{hL}{k} = \frac{(6\ \text{W/m}^2.^\circ\text{C})(0.4\ \text{m})}{(52\ \text{W/m}.^\circ\text{C})} = 0.0462$$

Step 6 of 12

The constants λ_1 and A_1 corresponding to these Biot numbers are,

$\lambda_{1(A,B)} = 0.150$ and $A_{1(A,B)} = 1.0038$

$\lambda_{1(C)} = 0.212$ and $A_{1(C)} = 1.0076$

The Fourier numbers are

$$\tau_{A,B} = \frac{\alpha t}{L^2} = \frac{(1.70\times10^{-5}\ \text{m}^2/\text{s})(45\ \text{min}\times60\ \text{s/min})}{(0.2\ \text{m})^2} = 1.1475 > 0.2$$

$$\tau_C = \frac{\alpha t}{L^2} = \frac{(1.70\times10^{-5}\ \text{m}^2/\text{s})(45\ \text{min}\times60\ \text{s/min})}{(0.4\ \text{m})^2} = 0.2869 > 0.2$$

Step 7 of 12

The center of the top surface of the block (whose sides are 80 cm and 40 cm) is at the center of the plane wall with 2L = 80 cm, at the center of the plane wall with 2L = 40 cm, and at the surface of the plane wall with 2L = 40 cm. The dimensionless temperatures are

$$\theta_{0,\text{wall(A)}} = \frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}$$

$$= (1.0038)e^{-(0.150)^2(1.1475)}$$

$$= 0.9782$$

Step 8 of 12

$$\theta(L,t)_{\text{wall(B)}} = \frac{T(x,t) - T_\infty}{T_i - T_\infty}$$

$$= (1.0038)e^{-(0.150)^2(1.1475)}\cos(0.150)$$

$$= 0.9672$$

Step 9 of 12

$$\theta_{0,\text{wall(C)}} = \frac{T_0 - T_\infty}{T_i - T_\infty}$$

$$= (1.0076)e^{-(0.212)^2(0.2869)}$$

$$= 0.9947$$

Step 10 of 12

Then the center temperature of the top surface of the cylinder becomes

$$\left[\frac{T(L,0,0,t) - T_\infty}{T_i - T_\infty}\right]_{\substack{\text{short}\\ \text{cylinder}}} = \theta(L,t)_{\text{wall(B)}} \times \theta_{0,\text{wall(A)}} \times \theta_{0,\text{wall(C)}}$$

$$= 0.9672\times0.9782\times0.9947$$

$$= 0.9411$$

$$\frac{T(L,0,0,t) - 17}{150 - 17} = 0.9411$$

$$T(L,0,0,t) = 142.2^\circ\text{C}$$

$$\boxed{T(L,0,0,t) = 142.2^\circ\text{C}}$$

Step 11 of 12

(b) The corner of the block is at the surface of each plane wall. The dimensionless temperature for the surface of the plane walls with 2L = 40 cm is determined in part (a). The dimensionless temperature for the surface of the plane wall with 2L = 80 cm is determined from

$$\theta(L,t)_{\text{wall(C)}} = \frac{T(x,t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau}\cos(\lambda_1 L / L)$$

$$= (1.0076)e^{-(0.212)^2(0.2869)}\cos(0.212)$$

$$= 0.9724$$

Step 12 of 12

Then the corner temperature of the block becomes

$$\left[\frac{T(L,L,L,t) - T_\infty}{T_i - T_\infty}\right]_{\substack{\text{short}\\ \text{cylinder}}} = \theta(L,t)_{\text{wall,C}} \times \theta(L,t)_{\text{wall,B}} \times \theta(L,t)_{\text{wall,A}}$$

$$= 0.9724\times0.9672\times0.9672$$

$$= 0.9097$$

$$\frac{T(L,L,L,t) - 17}{150 - 17} = 0.9097$$

$$T(L,L,L,t) = 138.0^\circ\text{C}$$

$$\boxed{T(L,L,L,t) = 138.0^\circ\text{C}}$$

Question: 18.107P pg 1

8-cm-thick large food slabs tightly wrapped by thin paper are to be cooled in a refrigeration room maintained at 0°C. The heat transfer coefficient on the box surfaces is 25 W/m2 ·K and the boxes are to be kept in the refrigeration room for a period of 6 h. If the initial temperature of the boxes is 30°C determine the center temperature of the boxes if the boxes contain (*a*) margarine (k = 0.233 W/m·K and α = 0.11 × 10–6 m2 /s), (*b*) white cake (k = 0.082 W/m2·K and α = 0.10 × 10–6 m2 /s), and (*c*) chocolate cake (k = 0.106 W/m·K and α = 0.12 × 10–6 m2 /s).

Step 1 of 12

Given data:

Thickness of the food slabs $t = 8\text{ cm} = 0.08\text{ m}$

Initial Temperature of the watermelon $T_i = 30^\circ\text{C}$

Refrigeration room temperature $T_\infty = 0^\circ\text{C}$

Heat transfer coefficient $h = 25\text{ W/m}^2\,^\circ\text{C}$

Time period, $t = 6\text{ h}$

$= 6 \times 3600$

$= 21600\text{ s}$

Step 2 of 12

For margarine:

Thermal Conductivity, $k = 0.233\text{ W/m}\cdot\text{K}$

Thermal Diffusivity, $\alpha = 0.11\times10^{-6}\text{ m}^2/\text{s}$

For white cake:

Thermal Conductivity, $k = 0.082\text{ W/m}\cdot\text{K}$

Thermal Diffusivity, $\alpha = 0.10\times10^{-6}\text{ m}^2/\text{s}$

For chocolate cake:

Thermal Conductivity, $k = 0.106\text{ W/m}\cdot\text{K}$

Thermal Diffusivity, $\alpha = 0.12\times10^{-6}\text{ m}^2/\text{s}$

Step 3 of 12

Characteristic length of the slab is

$$L_c = \frac{L}{2}$$

$$= \frac{0.08}{2}$$

$$= 0.04\text{ m}$$

Step 4 of 12

For Margarine:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{25\times(0.04)}{0.233}$$

$$= 4.29$$

Since Biot number greater than 0.1, therefore lumped system analysis not applicable.

Step 5 of 12

So, for margarine, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.11\times10^{-6}\times(6\times3600\,\text{sec})}{(0.04)^2}$$

$$= 1.485$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 6 of 12

From the one dimension term approximation solution of transient heat conduction for plane wall
