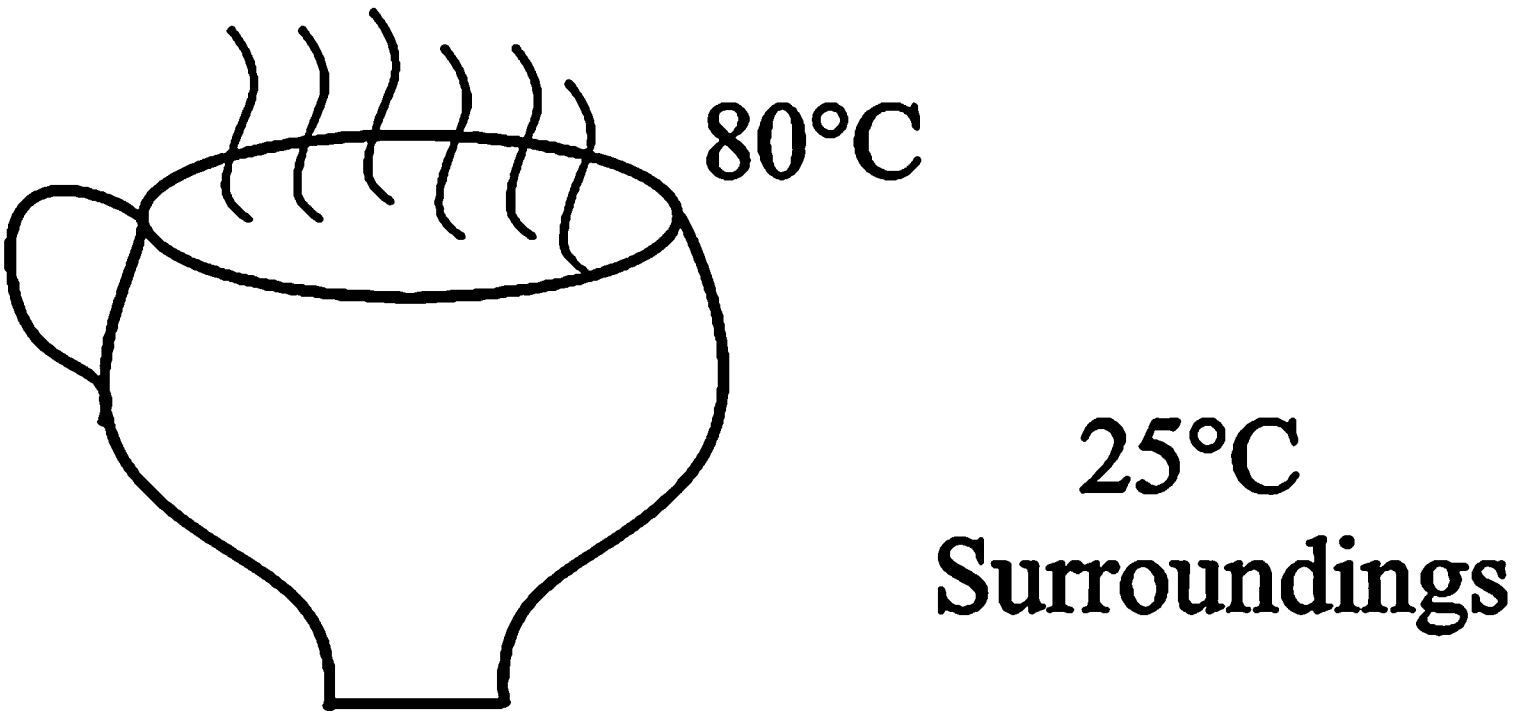
CHAPTER 01



SOLUTIONS

Question: 1.002P

An office worker claims that a cup of cold coffee on his table warmed up to 80°C by picking up energy from the surrounding air, which is at 25°C. Is there any truth to his claim? Does this process violate any thermodynamic laws?

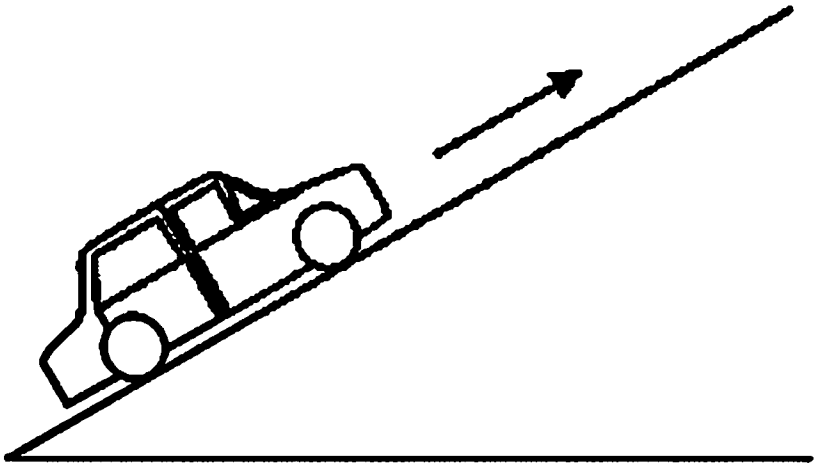
Step 1 of 1

A cup of hot coffee is kept in the living room; after a certain period of time, the coffee gets cold. To heat the coffee we have to spend some energy.

In our wash room, we get water by opening the tap (Valve). This water comes from the overhead tank which is located at an elevated place. To transfer this water back to the elevated place we need to spend some energy.

So, from the above naturally occurring processes, we can say that heat flows from a higher temperature to lower temperature. Water flows from an elevated place to a lower place.

Therefore, all the spontaneous processes occurring in nature are in one direction. To reverse the direction of process we need to spend energy.



So, without any external work, it is impossible to raise the temperature of a body higher than the surrounding temperature.

Therefore, there is no truth in his claim. It violates the second law of thermodynamics.

Question: 1.003P

One of the most amusing things a person can experience is that in certain parts of the world a still car on neutral going uphill when its brakes are released. Such occurrences are even broadcast on TV. Can this really happen or is it a bad eyesight? How can you verify if a road is really uphill or downhill?

Step 1 of 2

Step 2 of 2

A car cannot go uphill without the engine is running. Such things cannot happen. It violates the laws of physics. On TV shows it just a camera trick.
Using a spirit level or any level meters we can verify the steepness of a road

Question: 1.004P

How does the science of heat transfer differ from the science of thermodynamics?

Step 1 of 1

The science of thermodynamics deals with the amount of heat transfer as a system when it undergoes a process change from one equilibrium state to another state. While heat transfer on the other hand, deals with the rate of heat transfer as well as the temperature distribution within the system at a specified time.

For example when designing a radiator in an automobile, thermodynamics helps to determine the amount of energy transfer to be taken place by using the properties of the coolant used in the radiator. While heat transfer helps to design the radiator tubes like diameter of the tubes and shape of the tubes.

Question: 1.005P

What is the driving force for (*a*)heat transfer, (*b*) electric current, and (*c*) fluid flow?

Step 1 of 3

a)

Temperature difference is the driving force for heat transfer because without temperature difference heat can not to be flow from one body to the other.

Step 2 of 3

b)

The driving force for electric current flow is the electric potential difference (voltage).

Step 3 of 3

c)

The driving force for fluid flow is the pressure difference that exists in it.

Question: 1.006P

Why is heat transfer a nonequilibrium phenomenon?

Step 1 of 1

The science of Heat transfer deals with the amount of heat transfer as well as the temperature distribution within the system at a specified time. Two bodies are in thermal equilibrium means two bodies temperature are same. But in heat transfer without temperature difference heat can not to be flow from one body to the other. Hence in heat transfer state of the bodies are changed with respect to time. Thus it is a non-equilibrium phenomenon.

Question: 1.007P

Can there be any heat transfer between two bodies that are at the same temperature but at different pressures?

Step 1 of 1

If two bodies temperature are same then there is no driving force to transfer of heat because the driving force exists when there is temperature difference between them. So there will be no heat transfer.

Question: 1.008P

Define stress, normal stress, shear stress, and pressure. Mass, Force, and Units

Step 1 of 3

Stress: It is defined as the force acting per unit area.

Equation of stress:

$$\sigma = \frac{F}{A}\left(\mathrm{N/m^2}\right)$$

Here, F is the force acting and A is the area of cross-section.

Step 2 of 3

Force applied is acting in the normal direction to the cross section, then the stress is defined as **normal force.**

If the force applied is acting in the tangential direction to the cross-section, then the corresponding stress is called **shear stress.**

Step 3 of 3

Pressure: It is define as the force which is acted continuously on or against an object by which the force is in contact with it.

Question: 1.009P

In a news article, it is stated that a recently developed geared turbofan engine produces 15,000 pounds of thrust to propel the aircraft forward. Is "pound" mentioned here lbm or lbf? Explain.

Step 1 of 1

Pound force (lbf) is the force unit whereas pound-mass (lbm) is the mass unit in English system. One pound force is the force required to accelerate a mass of 32.174 lbm by $1 ft/s^2$. The 'pound' mentioned here is 'lbf' because of geared turbofan engine produces 15000 pounds of thrust (force) to propel the aircraft to move forward (accelerate).

Question: 1.010P

Explain why the light-year has the dimension of length.

Step 1 of 1

In space the distance between stars, planet – planet, planet – sun is usually measured in light – years.

The word 'light' refers to speed at which the light travels

So, light – year is then the product of velocity and time

$$\text{Velocity} = \frac{\text{displacement}}{\text{time}} \quad \frac{\text{m}}{\text{s}}$$

$$1\ \text{Light} - \text{year} = \text{Velocity} \times \text{time}$$

$$= \text{m/s} \times \text{s}$$

$$= \text{m}$$

Hence the unit of light – year is m

One light-year is equivalent to 9.461×10^{12} km, or 5.879×10^{12} mi

Question: 1.011P

What is the net force acting on a car cruising at a constant velocity of 70 km/h (*a*) on a level road and (*b*) on an uphill road?

Step 1 of 3

Given:
Constant velocity $= 70\,\text{km/h}$

Step 2 of 3

Since velocity is constant, acceleration becomes zero.
So,
(a)
On a level road:
Net force acting on car:
$F = \text{mass} \times \text{acceleration}$
$F = 0$

Step 3 of 3

(b)
On an uphill road:
Net force acting on car:
$F = \text{mass} \times \text{acceleration}$
$F = 0$

In both cases, net force acting on the car is zero as force depends upon acceleration but not on the type of surface i.e on a level road or on an uphill track.

Question: 1.012P

A man weighs 210 lbf at a location where g=32.10 ft/s2. Determine his weight on the moon, where g=5.47 ft/s2.

Step 1 of 1

Write the Newton's second law of motion.

$$W = mg$$

Here, W is the weight, m is the mass of the body, and g is the acceleration due to gravity.

Mass will be constant.

Write the relation between weight and gravity at a location and on the moon.

$$\frac{W_{moon}}{W} = \frac{g_{moon}}{g}$$

Here, W_{moon} is the weight of man on the moon, W is the weight of the man at a location, g_{moon} is the acceleration due to gravity on the moon, and g is the acceleration due to gravity at a location.

Substitute $210\,\text{lbf}$ for W , $5.47\,\text{ft/s}^2$ for g_{moon} , and $32.1\,\text{ft/s}^2$ for g .

$$\frac{W_{moon}}{210} = \frac{5.47}{32.1}$$
$$W_{moon} = 35.78\,\text{lbf}$$

Therefore, the weight of the man on the moon is $\boxed{35.78\,\text{lbf}}$.

Question: 1.013P

Determine the mass and the weight of the air contained in a room whose dimensions are 6 m × 6 m × 8 m. Assume the density of the air is 1.16 kg/m3.

Step 1 of 2

Calculate the mass of the air in the room.

$$m = \rho V$$

Here, V is volume and ρ is the density,

Substitute 1.16 kg/m^3 for ρ and 6 m×6 m×8 m for V in the equation.

$$m = \rho V$$
$$= 1.16 \times 6 \times 6 \times 8$$
$$= 334.08 \text{ kg}$$

Therefore, the mass of air in the room is **334.08 kg**.

Step 2 of 2

Calculate the weight of air in the room.

$$W = m \times g$$

Here, g is acceleration due to gravity.

Substitute 9.81 m/s^2 for g and 334.08 kg for m.

$$W = m \times g$$
$$= 334.08 \times 9.81$$
$$= 3277.32 \text{N}$$

Therefore, the weight of air in the room is **3277.32N**.

Question:

1.014P

At 45° latitude, the gravitational acceleration as a function of elevation zabove sea level is given by g =a-bz,where a=9.807 m/s2 and b= 3.32 × 10-6 s-2. Determine the height above sea level where the weight of an object will decrease by 0.5 percent.

Step 1 of 3

Given:
gravitational acceleration a function for elevation Z above sea level as
$g = a - bz$
Where
$a = 9.807 \frac{\text{m}}{s^2}$,
$b = 3.32 \times 10^{-6} s^{-2}$
Percentage of weight of the object decreased 0.5%

Step 2 of 3

The weight of object at the elevation z can be expressed as
$W = mg$
$= m(a - bz)$
$= m(9.807 - 3.32 \times 10^{-6} \times z)$.....(1)
According to our problem new weight of object is 0.995 times the weight at sea level
$W = 0.995W$,
$= 0.995m \times 9.807$.....(2)

Step 3 of 3

Equating the equation 1 and 2 we get
Height above the sea level is
$\Rightarrow m \times (9.81 - 3.32 \times 10^{-6} \times z) = 0.995 \times m \times 9.807$
$\Rightarrow z = 14,770m$
$\boxed{z = 14,770\text{m}}$

Question: 1.015P

What is the weight, in N, of an object with a mass of 200 kg at a location where g =9.6 m/s2?

Step 1 of 2

Given:

Mass $m = 200\,\text{kg}$

Acceleration due to gravity $g = 9.6\,\frac{\text{m}}{\text{s}^2}$

Step 2 of 2

Using Newton's second law

Weight of object

$W = mg$

$$W = 200(\text{kg}) \times 9.6\left(\frac{\text{m}}{\text{s}^2}\right)\left(\frac{1\text{N}}{\frac{1\text{kg}\cdot\text{m}}{\text{s}^2}}\right)$$

$$= 1920\text{N}$$

$$\boxed{W = 1920\text{N}}$$

Question: 1.016P

The constant-pressure specific heat of air at 25°C is 1.005 kJ/kg°C. Express this value in kJ/kg-K, J/g.°C, kcal/kg.°C, and Btu/lbm °F.

Step 1 of 4

From the unit conversion table

$$1\text{kJ/kg}\cdot\text{K}=1\text{kJ/kg}\cdot{}^\circ\text{C}$$

Use above conversion factor to convert the specific heat kJ/kg·°C to kJ/kg·K

$$c_p = 1.005\text{kJ/kg}\cdot{}^\circ\text{C}\left(\frac{1\text{kJ/kg}\cdot\text{K}}{1\text{kJ/kg}\cdot{}^\circ\text{C}}\right)$$

$$=1.0051\text{kJ/kg}\cdot\text{K}$$

Thus, constant pressure specific heat in terms of kJ/kg·K is $\boxed{1.0051\text{kJ/kg}\cdot\text{K}}$

Step 2 of 4

From the unit conversion table

$$1\text{kg}=1000\text{g}$$

$$1\text{kJ}=1000\text{J}$$

Use above conversion factor to convert the specific heat kJ/kg·°C to J/g·°C

$$c_p = 1.005\text{kJ/kg}\cdot{}^\circ\text{C}\left(\frac{1\text{kg}}{1000\text{g}}\right)\left(\frac{1000\text{J}}{1\text{kJ}}\right)$$

$$=1.0051\text{J/g}\cdot{}^\circ\text{C}$$

Hence, constant pressure specific heat in terms of J/g·°C is $\boxed{1.0051\text{J/g}\cdot{}^\circ\text{C}}$

Step 3 of 4

From the unit conversion table

$$1\text{kcal}=4.1868\text{kJ}$$

Use above conversion factor to convert the specific heat kJ/kg·°C to kcal/kg·°C

$$c_p = 1.005\text{kJ/kg}\cdot{}^\circ\text{C}\left(\frac{1\text{kcal}}{4.1868\text{ kJ}}\right)$$

$$=0.2400\text{kcal/kg}\cdot{}^\circ\text{C}$$

Hence, constant pressure specific heat in terms of kcal/kg·°C is $\boxed{0.2400\text{kcal/kg}\cdot{}^\circ\text{C}}$

Step 4 of 4

From the unit conversion table

$$1\text{Btu/lbm}\cdot{}^\circ\text{F}=4.1868\text{kJ/kg}\cdot{}^\circ\text{C}$$

Use above conversion factor to convert the specific heat kJ/kg·°C to Btu/lbm·°F

$$c_p = 1.005\text{kJ/kg}\cdot{}^\circ\text{C}\left(\frac{\text{Btu/lbm}\cdot{}^\circ\text{F}}{4.1868\text{kJ/kg}\cdot{}^\circ\text{C}}\right)$$

$$=0.2400\text{Btu/lbm}\cdot{}^\circ\text{F}$$

Hence, constant pressure specific heat in terms of Btu/lbm·°F is $\boxed{0.2400\text{Btu/lbm}\cdot{}^\circ\text{F}}$

Question: 1.017P

. A 3-kg rock is thrown upward with a force of 200 N at a location where the local gravitational acceleration is 9.79 m/s2. Determine the acceleration of the rock, in m/s2.

Step 1 of 4

Given:

Mass of the rock $m = 3\text{kg}$

Upward force $F_{up} = 200\,\text{N}$

Acceleration due to gravity $g = 9.79\frac{\text{m}}{s^2}$

Step 2 of 4

Weigh of the rock

$W = m \times g$

$$= 3(\text{kg}) \times 9.79\left(\frac{\text{m}}{s^2}\right)\left(\frac{1\text{N}}{\frac{1\text{kg}\cdot\text{m}}{s^2}}\right)$$

$$= 29.37\text{N}$$

From the equilibrium of the rock weight of the block is equal to the force acting on the downward. So

$W = F_{Downward} = 29.37\,\text{N}$

Step 3 of 4

Net force that acts on the rock is

$F_{net} = F_{up} - F_{down}$

$= (200 - 29.37)\text{N}$

$= 170.63\text{N}$

Step 4 of 4

From the Newton's second law,

$\text{Force}(F) = \text{mass}(m) \times \text{acceleration}(a)$

The acceleration of the rock becomes

$$a = \frac{F}{m}$$

$$= \frac{170.63\text{N}}{3\text{kg}}\left(\frac{\frac{1\text{kg}\cdot\text{m}}{s^2}}{1\text{N}}\right)$$

$$= 56.88\frac{\text{m}}{s^2}$$

$$\boxed{a = 56.88\frac{\text{m}}{s^2}}$$

Question: 1.018P

Solve Prob. 1–17 using EES (or other) software. Print out the entire solution, including the numerical results with proper units.

Step 1 of 4

Free body diagram.

Step 2 of 4

Figure (1)

Step 3 of 4

Question:

Solve Prob. 1–17 using EES (or other) software. Print out the entire solution, including the numerical results with proper units.

Step 1 of 4

Free body diagram.

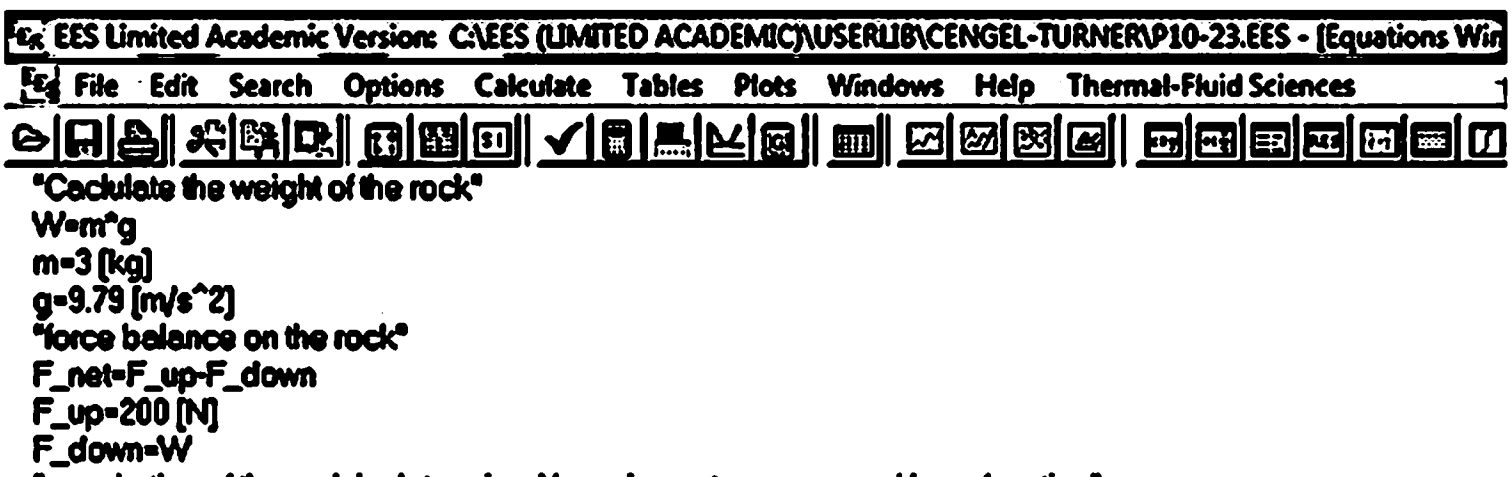
Step 2 of 4

Figure (1)

Step 3 of 4

Calculate the acceleration of the rock using EES software.

Write the following code in the software.



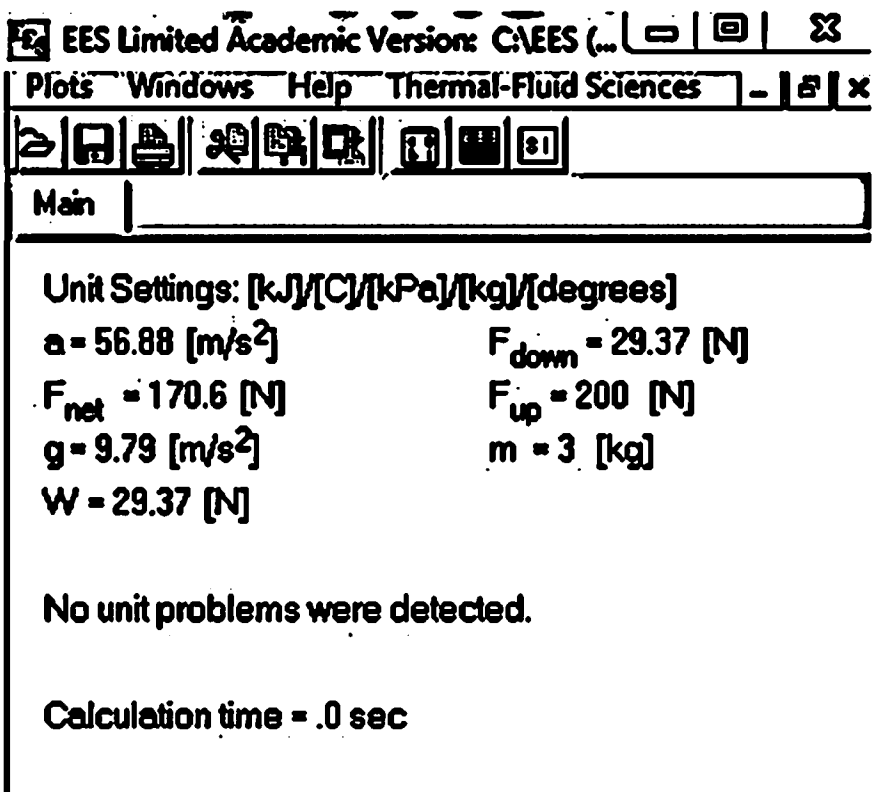


Figure (2).

Define the units of all variable by using "options" in the menu bar .

Step 4 of 4

Click on the "calculate" option in the menu bar and select solve and following output window will be displayed:

Question:

1.019P

While solving a problem, a person ends up with the equation E= 25 kJ + 7 kJ/kg at some stage. Here E is the total energy and has the unit of kilojoules. Determine how to correct the error and discuss what may have caused it.

Step 1 of 2

$E = 25\text{kJ} + 7\text{kJ/kg}$.

E has the unit of kilojoules. The cause of this problem is error in dimension of this formula. Since do not have the same units, therefore they can't be added to obtain the total energy.

To correct the answer we have to multiply the number 7 by mass of person. Then expression dimensionally homogenous.

Step 2 of 2

Then expression becomes,

$$E = 25\text{kJ} + 7\text{kJ/kg}$$

Question:

$$E = 25\text{kJ} + 7\text{kJ/kg}\,(\text{kg})$$

$$E(\text{kJ}) = 25\text{kJ} + 7\text{kJ}$$

Now above expression is dimensionally homogenous, therefore they can be added to obtain the total energy.

Question: 1.020P

A 4-kW resistance heater in a water heater runs for 2 hours to raise the water temperature to the desired level. Determine the amount of electric energy used in both kWh and kJ.

Step 1 of 3

Given:
Power rating of resistance heater $P = 4\text{kW}$
Time $t = 2\text{hr}$

Step 2 of 3

Amount of energy used in kJ is $= 28800\text{kJ}$

$$E = \left(4\frac{\text{kJ}}{\text{s}}\right) \times (2 \times 3600\text{s})$$

$$= 28800\text{kJ}$$

$$\boxed{E = 28800\text{kJ}}$$

Step 3 of 3

Electric energy used in kWh

$$E = 4\text{kW} \times 2\text{hour}$$

$$= 8\text{kWh}$$

$$\boxed{E = 8\text{kWh}}$$

Question: 1.021P

The gas tank of a car is filled with a nozzle that discharges gasoline at a constant flow rate. Based on unit considerations of quantities, obtain a relation for the filling time in terms of the volume u of the tank (in L) and the discharge rate of gasoline ú (in L/s).

Step 1 of 4

Given:
Volume of the tank 'V'
Rate of discharge $\dot{V}$

Step 2 of 4

Let filling time
$t \propto \left(V^a \times \dot{V}^b\right)$
Dimension of $t = T^1$
Dimension of $V = L^3$
Dimension of rate of Discharge $\dot{V} = L^3T^{-1}$
$t = kV_x^a\dot{V}^b$ .....(1)
Where
k = Constant

Step 3 of 4

$t = [T]^1$
$V^a \times \dot{V}^b = [L]^{3a} \times [L]^{3b}[T]^{-b}$
Equation dimension on both sides of equation (i)
$[L]^0[T]^1 = [L]^{3a+3b}[T]^{-b}$
Equating power of $[L]$
$3a + 3b = 0$
$a = -b$
Equating $[T]$
$-b = 1$
$b = -1$
So $a = 1$

Step 4 of 4

So the correct relation for filling tank is
$t \propto \frac{V}{\dot{V}}$
$t = \frac{kV}{\dot{V}}$
$\boxed{t = \frac{kV}{\dot{V}}}$

Question: 1.022P

A pool of volume *U*(in m3) is to be filled with water using a hose of diameter *D*(in m). If the average discharge velocity is *v*(in m/s) and the filling time is *t*(in s), obtain a relation for the volume of the pool based on until considerations of quantities involved.

Step 1 of 4

Given:

Volume of the pool $V\left(\mathrm{m}^3\right)$

Diameter of the hose $D(\mathrm{m})$

Average discharge velocity $V\left(\frac{\mathrm{m}}{\mathrm{s}}\right)$

Filling time $t(\mathrm{sec})$

Volume of the pool $U\left(\mathrm{m}^3\right)$

Step 2 of 4

Let volume of pool is related to D , V and t by

$U \propto (D^a V^b t^c)$

Dimension of $U = [L]^3$

Dimension of $D = [L]$

Dimension of $V = [LT^{-1}]$

Dimension of $t = [T]$

Step 3 of 4

So,

$U = k[D]^a [V]^b [t]^c$

Where k = proportionality constant

$[M]^0 [L]^3 [T]^0 = k[L]^a [LT^{-1}]^b [T]^c$

Equating power of T on both sides

$0 = -b + c \Rightarrow b = c$

Equation power of L on both sides

$3 = a + b$

Assuming value of b $= 1$

$a = 2$ And

$c = 1$

Step 4 of 4

Putting these values in our dimensional formula our dimensional relation satisfies so the correct relation is

$U = k(D^2 \times V \times t)$

$\boxed{U = k(D^2 \times V \times t)}$

Question: 1.023P

What is the value of the engineering software packages in (*a*) engineering education and (*b*) engineering practice?

Step 1 of 1

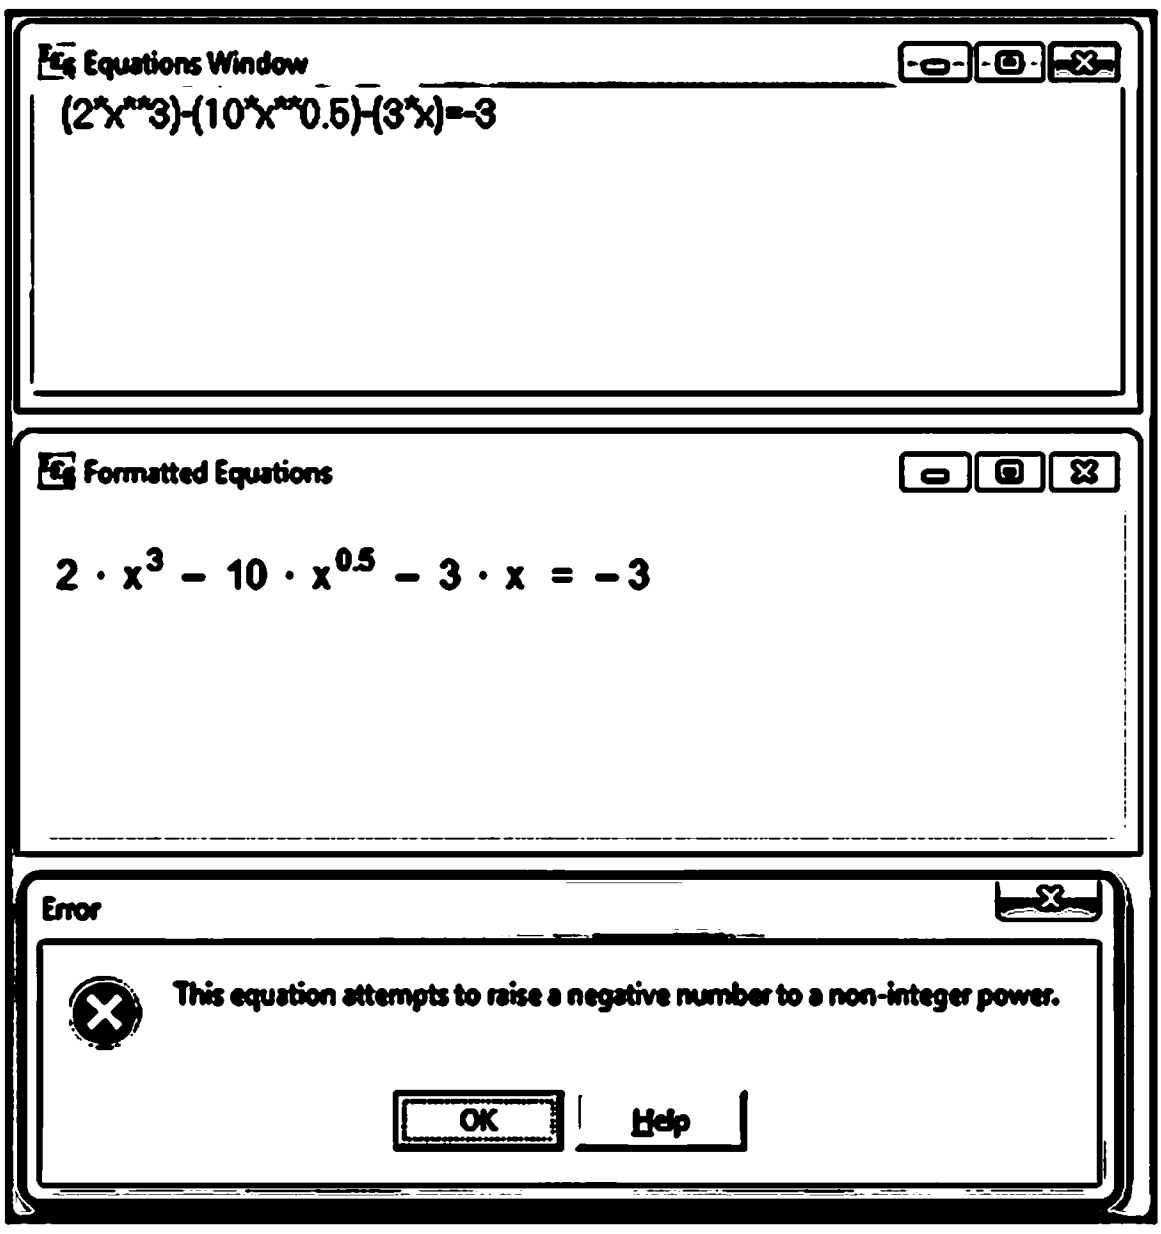
Engineering software packages are only tools though they are more convenient and capable. These packages cannot replace all time traditional engineering courses. But at the same time packages in practice are of great values. In these present days engineers mostly depend on software packages for evaluating big and complex problems within a short time for quick answer and to continue research studies effectively.

Question: 1.024P

Determine a positive real root of this equation using EES:

$2x3-10x0.5-3x=-3$

Step 1 of 4



The given equation is $2x^3-10x^{0.5}-3x=-3$

For solving this equation using EES, the below steps are to be followed.

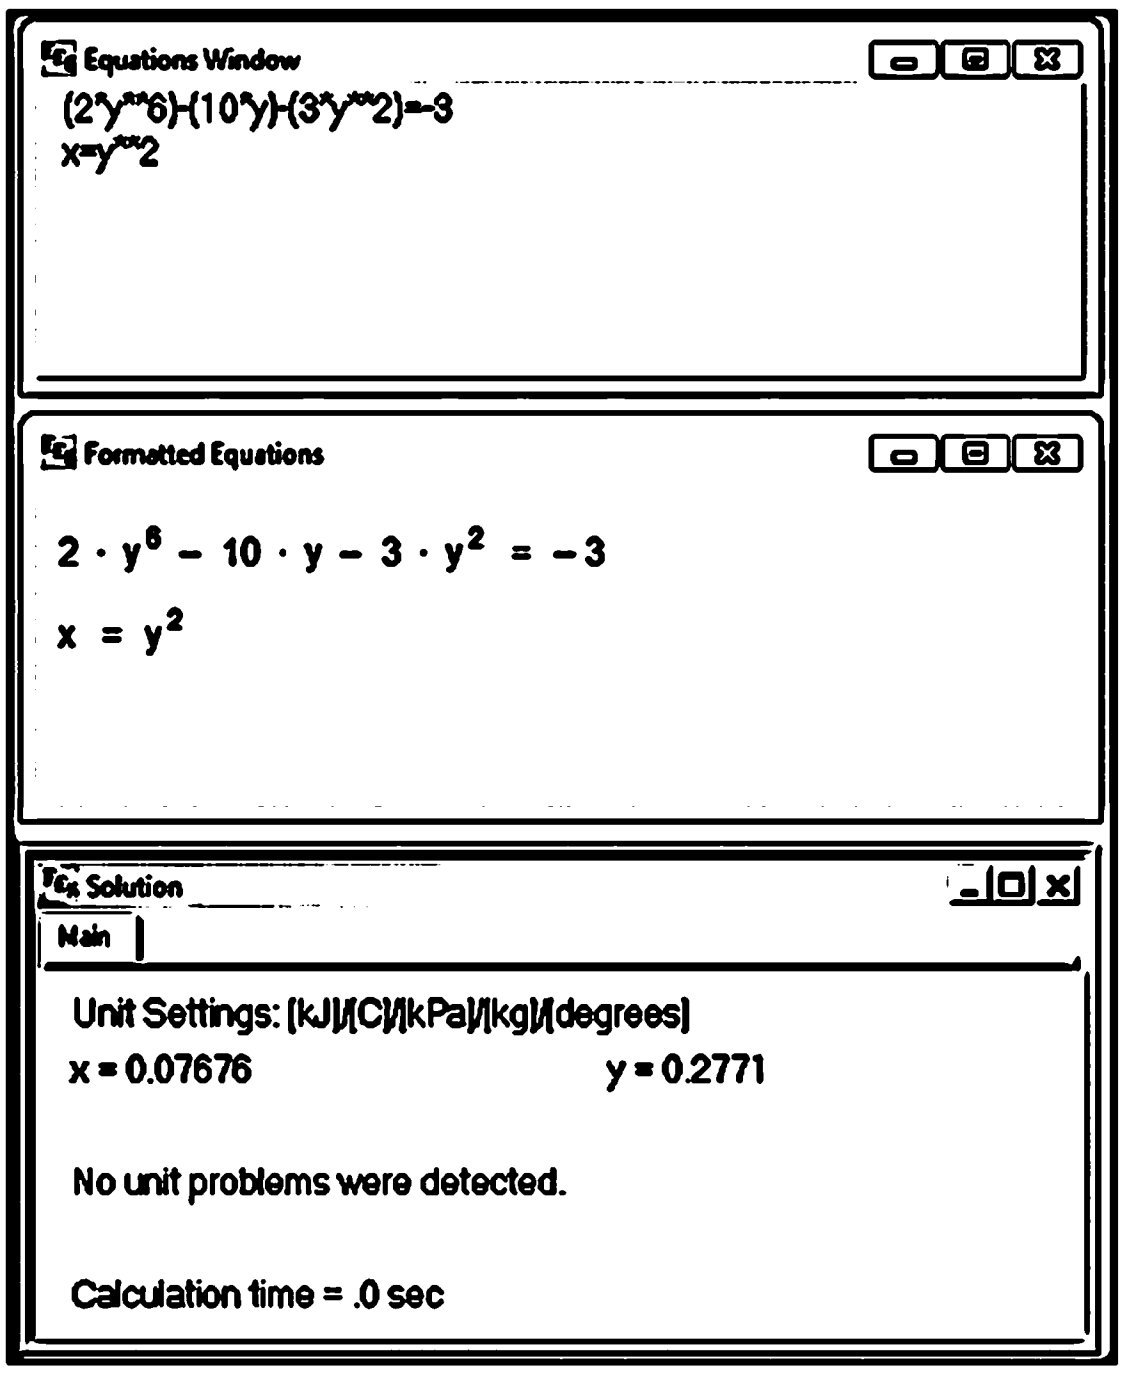
1. Enter the equation in new window of EES
2. Click on the 'windows tab' in the tool bar and then click on the 'formatted equations' (this will display the equations in mathematical form.)
3. Press F2 to solve the equation.

Step 2 of 4

Screenshot showing the EES output:

Step 3 of 4

The above error dialogue denotes that solving this equation requires a change of exponentials for variable.
In-order to find the solution to the given equation let us introduce a new variable y, so that the new equation can have a change of exponential.
Now the equations are



$2y^6-10y-3y^2=-3$

$x=y^2$

For solving this equation using EES; enter the equations, check the formatted equations and then press F2.

Step 4 of 4

Screenshot showing the EES output:

Hence the real positive root of the given equation is $\boxed{x=0.07676}$

Question: 1.025P

Solve this system of two equations with two unknowns using EES:

$x3-y2=7.75$

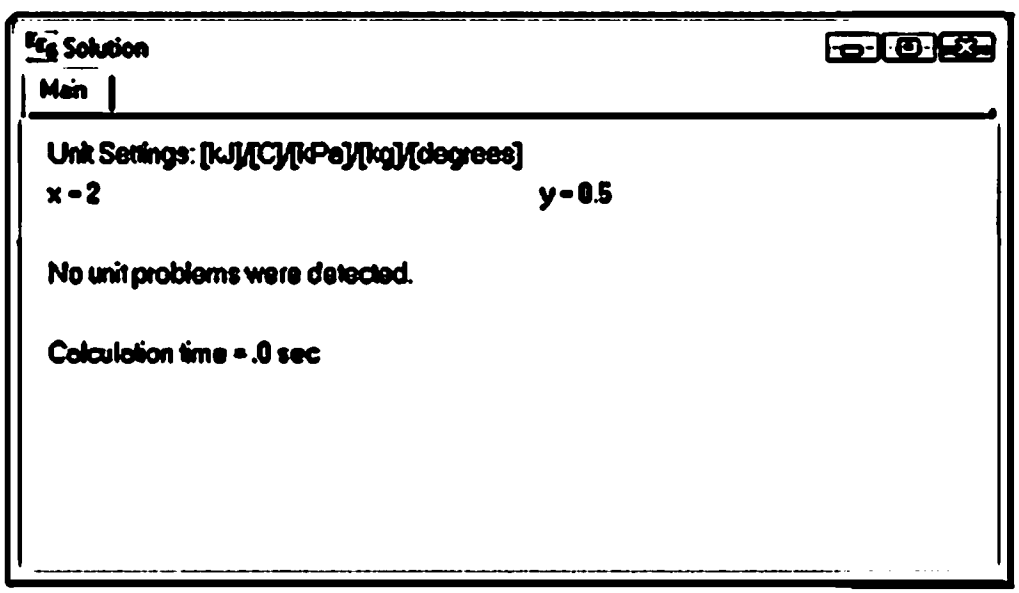
$3xy+y=3.5$

Step 1 of 2

Given data:

$x^3 - y^2 = 7.75$

$3xy + y = 3.5$



Step 2 of 2

By using EES software, writing the input equations as follows:

$(x\hat{}3)-(y\hat{}2)=7.75$

$(3*x*y)+y=3.5$

We get the final solution as;

Therefore, the two unknowns are $\boxed{x=2}$ and $\boxed{y=0.5}$

Question: 1.026P

Solve this system of three equations with three kiH unknowns using EES:

$2x-y+z=5$

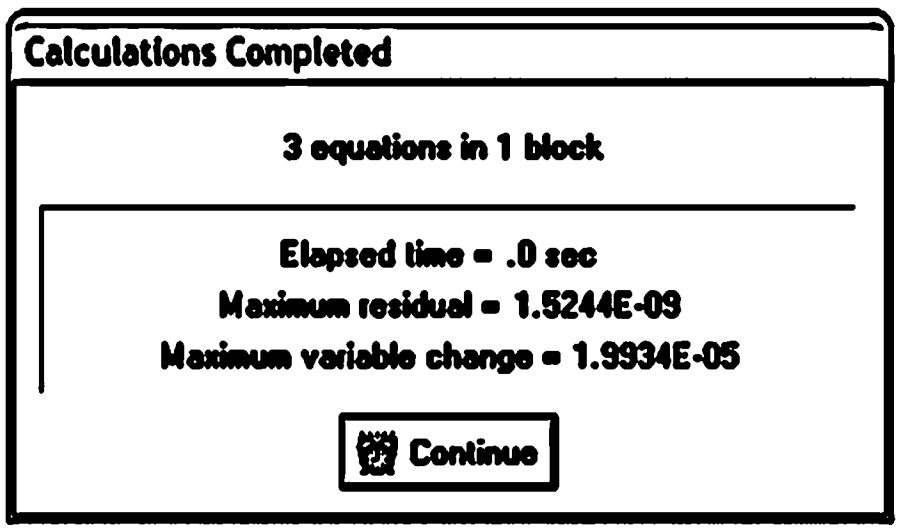
$3x2+2y=z+2$

$xy+2z=8$

Step 1 of 4

The three given equations are

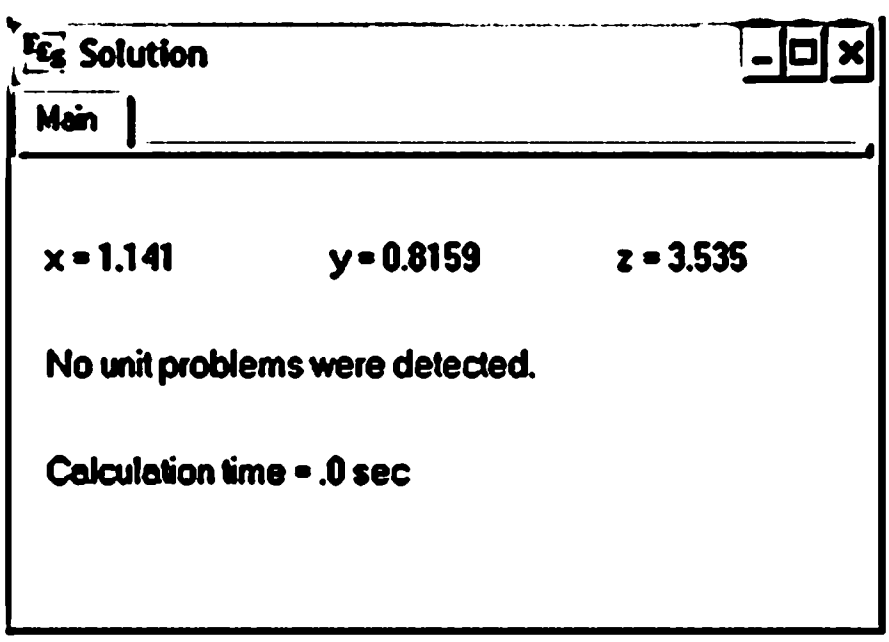
$$2x-y+z=5$$
$$3x^2+2y=z+2$$
$$xy+2z=8$$



Step 2 of 4

Solve the above three equations by using EES software. Open EES window and write the three given equation in that window.

$$2*x-y+z=5$$
$$3*x\text{^}2+2*y=z+2$$
$$x*y+2*z=8$$



Step 3 of 4

Solve these equations by pressing F2. Then you will get one popup menu,

Step 4 of 4

Then press continue to get the final result.

Therefore, the solution for the given equations is

$\boxed{x=1.141}$

$\boxed{y=0.8159}$

$\boxed{z=3.535}$

Question: 1.027P

Solve this system of three equations with three unknowns using EES:

$x2y-z=1$

$x-3y0.5+xz=-2$

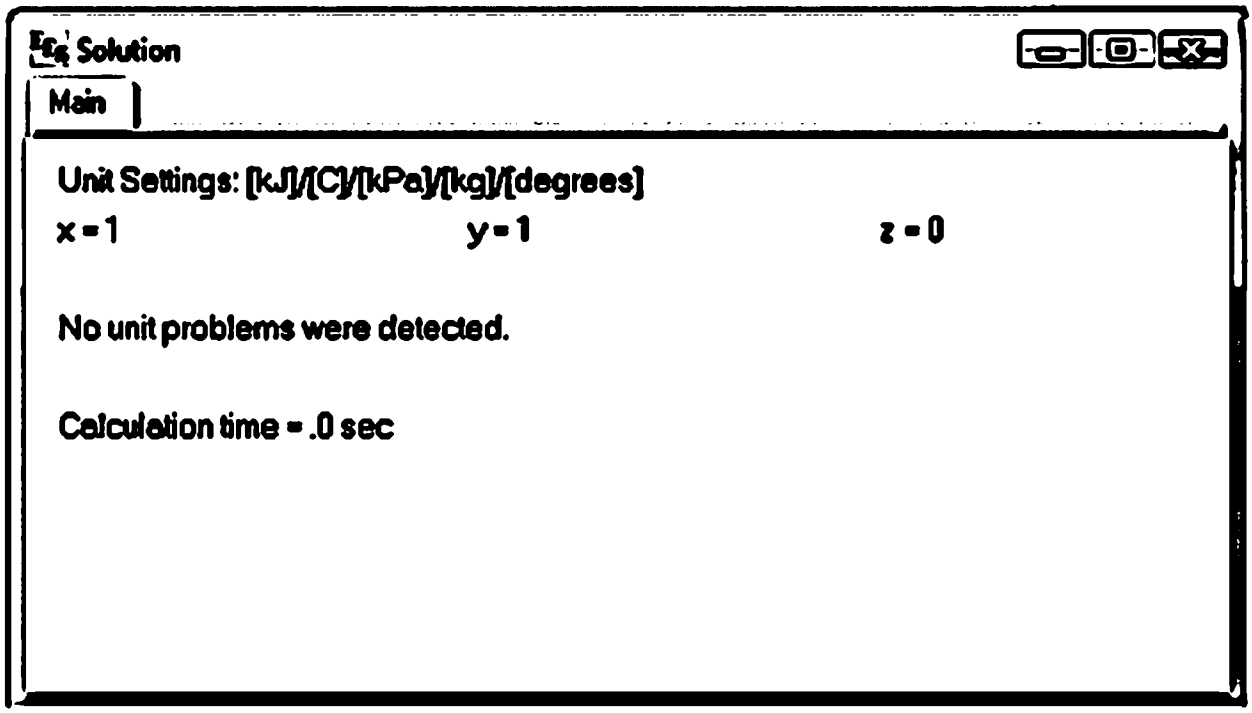
$x+y-z=2$

Step 1 of 2

Given data:

$$x^2y-z=1$$

$$x-3y^{0.5}+xz=-2$$



$$x+y-z=2$$

Step 2 of 2

By using EES software, writing the input equations as follows:

```
x^2*y-z=1
x-3*y^0.5+x*z=-2
x+y-z=2
```

We get the final solution as;

Therefore, the three unknowns are $\boxed{x=1}$, $\boxed{y=1}$ and $\boxed{z=0}$

Question: 1.028P

Specific heat is defined as the amount of energy needed to increase the temperature of a unit mass of a substance by one degree. The specific heat of water at room temperature is 4.18 kJ/kg·°C in SI unit system. Using the unit conversion function capability of EES, express the specific heat of water in (*a*) kJ/kg·K, (*b*) Btu/lbm-°F, (*c*) Btu/lbm-R, and (*d*) kcal/kg·°C units.

Step 1 of 4

Given data:

Specific heat of water at room temperature, $C_p = 4.18 \text{kJ/kg-°C}$

By using EES software, writing the input equations as follows:

Equations Window

```
"Given data:"
C_p=4.18 [kJ/kg-C]

"Using the below conversion formulae, we convert the units as:"
C_p_1=C_p*Convert(kJ/kg-C, kJ/kg-K)
C_p_2=C_p*Convert(kJ/kg-C, Btu/lbm-F)
C_p_3=C_p*Convert(kJ/kg-C, Btu/lbm-R)
C_p_4=C_p*Convert(kJ/kg-C, kCal/kg-C)
```

Step 2 of 4

We get the formatted equations as;

Formatted Equations

Given data:

$C_p = 4.18 \ [kJ/kg-C]$

Using the below conversion formulae, we convert the units as:

$$C_{p,1} = C_p \cdot \left| 1 \cdot \frac{\cdot kJ/kg-K}{kJ/kg-C} \right|$$

$$C_{p,2} = C_p \cdot \left| 0.238846 \cdot \frac{\cdot Btu/lbm-F}{kJ/kg-C} \right|$$

$$C_{p,3} = C_p \cdot \left| 0.238846 \cdot \frac{\cdot Btu/lbm-R}{kJ/kg-C} \right|$$

$$C_{p,4} = C_p \cdot \left| 0.238846 \cdot \frac{\cdot kCal/kg-C}{kJ/kg-C} \right|$$

Step 3 of 4

We get the final solution as;

Solution

Main

Unit Settings: [kJ]/[C]/[kPa]/[kg]/[degrees]

$C_p = 4.18$ [kJ/kg-C] $C_{p,1} = 4.18$ [kJ/kg-K] $C_{p,2} = 0.9984$ [Btu/lbm-F]

$C_{p,3} = 0.9984$ [Btu/lbm-R] $C_{p,4} = 0.9984$ [kCal/kg-C]

No unit problems were detected.

Purple units were automatically set. Right click on the variable to confirm or change the units.

Calculation time = .0 sec

Step 4 of 4

Therefore, the values after unit conversions are $\boxed{4.18 \text{kJ/kg-K}}$, $\boxed{0.9984 \text{Btu/lbm-°F}}$, $\boxed{0.9984 \text{Btu/lbm-R}}$ and $\boxed{0.9984 \text{kCal/kg-°C}}$

Question: 1.029P

A lunar exploration module weighs 4000 N at a location where g=9.8 m/s2. Determine the weight of this module in newtons when it is on the moon where g=1.64 m/s2.

Step 1 of 2

The weight of lunar module $W = 4000\ \text{N}$

The acceleration due to gravity on earth $g = 9.8\ \text{m/s}^2$

The acceleration due to gravity on moon $g = 1.64\ \text{m/s}^2$

Step 2 of 2

From Newton's second law

$$W = mg$$

$$m = \frac{W}{g}$$

$$= \frac{4000}{9.81}$$

$$= 407.7\ \text{kg}$$

As we all know mass is same everywhere in the universe

Weight of the lunar module in moon

$$W_{\text{moon}} = mg_{\text{moon}}$$

$$= 407.7 \times 1.64$$

$$\boxed{W_{\text{moon}} = 668.7\ \text{N}}$$

Question: 1.030P

The weight of bodies may change somewhat from one location to another as a result of the variation of the gravitational acceleration *g* with elevation. Accounting for this variation using the relation in Prob. 1–14, determine the weight of an 80-kg person at sea level (z= 0), in Denver (z = 1610 m), and on the top of Mount Everest (z=8848 m).

Step 1 of 5

The mass of a person $m = 80\,kg$

In problem 1-10, the gravitational acceleration as a function of elevation

$$g = a - bz$$

Where $a = 9.807\ m/s^2$

$b = 3.32\times10^{-6}\,s^{-2}$

$g = 9.807 - 3.32\times10^{-6}\times z$

z in m

Step 2 of 5

Weight $W = mg$

Here $W = m\left(9.807 - 3.32\times10^{-6}z\right)$

$W = 80\left(9.807 - 3.32\times10^{-6}z\right)$ .....(1)

Step 3 of 5

At sea level $z = 0$

Weight $W = 80\left(9.807 - 3.32\times10^{-6}\times0\right)$

$\boxed{W = 784.56\ N}$

Step 4 of 5

At Denver $z = 1610\ m$

$W = 80\left(9.807 - 3.32\times10^{-6}\times1610\right)$

$\boxed{W = 784.13\ N}$

Step 5 of 5

At mount Everest $z = 8848\ m$

$W = 80\left(9.807 - 3.32\times10^{-6}\times8848\right)$

$\boxed{= 782.2\ N}$

Question: 1.031P

A man goes to a traditional market to buy a steak for dinner. He finds a 12-oz steak (1 lbm = 16 oz) for $3.15. He then goes to the adjacent international market and finds a 300-g steak of identical quality for $2.95. Which steak is the better buy?

Step 1 of 2

The relation between pounds (lbm), ounces (oz) and kilograms (kg) is given as

$$1\,\text{lbm} = 16\,\text{oz} = 0.45359\,\text{kg}$$

Hence $1\,\text{oz} = \frac{0.45359}{16}\,\text{kg}$

$$12\,\text{oz} = 12 \times \frac{0.45359}{16}\,\text{kg}$$

$$12\,\text{oz} = 12 \times \frac{0.45359}{16}\,\text{kg}$$

$$12\,\text{oz} = 0.34\,\text{kg}$$

In traditional market cost of 0.34 kg of steak = $3.15

$$\text{Cost of 1kg steak} = \frac{(\$3.15)}{0.34\,\text{kg}}$$

$$= \$9.26/\text{kg}$$

Hence cost of 1kg of steak in traditional market is $ 9.26 per kg

Step 2 of 2

In international market, Cost of 300 gm of steak = $ 2.95

300 gram = 0.30 kg

$$\text{Cost of 1 kg steak in international market} = \frac{\$2.95}{0.3\,\text{kg}}$$

$$= \$9.83/\text{kg}$$

Hence cost of 1kg of steak in international market is $ 9.83 per kg

Therefore, the steak at the international market is the better buy.

Question: 1.032P

What is the weight of a 1-kg substance in N, kN, kg·m/s2, kgf, lbm·ft/s2, and lbf?

Step 1 of 2

Given

Mass of substance $m = 1\ \text{kg}$

Weight of substance $W = mg$

$$W = (1\ \text{kg}) \times (9.81\ \text{m/s}^2)$$

$$W = 9.81\ \text{kg} \cdot \text{m/s}^2$$

Hence weight of 1 kg substance in $\text{kg} \cdot \text{m/s}^2$ is $\boxed{W = 9.81\ \text{kg} \cdot \text{m/s}^2}$

But $9.81\ \text{kg} \cdot \text{m/s}^2 = 1\ \text{kgf}$

Hence weight of 1 kg substance in kgf is $\boxed{W = 1\ \text{kgf}}$

Also $1\ \text{kg} \cdot \text{m/s}^2 = 1\ \text{N}$,

Hence weight of 1 kg substance in N is $\boxed{W = 9.81\ \text{N}}$

$1\ \text{N} = 10^{-3}\ \text{kN}$

Hence weight of 1 kg substance in kN is $\boxed{W = 9.81 \times 10^{-3}\ \text{kN}}$

Step 2 of 2

From conversion data,

$1\ \text{kg} = 2.2\ \text{lbm}$

$1\ \text{m} = 3.28\ \text{ft}$

Units of weight can be converted into

$$W = 9.81\ \text{kg} \cdot \text{m/s}^2$$

$$W = 9.81 \times (2.2\ \text{lbm}) \cdot (3.28\ \text{ft})/\text{s}^2$$

$$W = 9.81 \times 2.2 \times 3.28\ \text{lbm} \cdot \text{ft/s}^2$$

$$W = 70.8\ \text{lbm} \cdot \text{ft/s}^2$$

Hence weight of 1 kg substance in $\text{lbm} \cdot \text{ft/s}^2$ is $\boxed{W = 70.8\ \text{lbm} \cdot \text{ft/s}^2}$

But $32.2\ \text{lbm} \cdot \text{ft/s}^2 = 1\ \text{lbf}$

Therefore, $W = 70.8\ \text{lbm} \cdot \text{ft/s}^2 \times \dfrac{1\ \text{lbf}}{32.2\ \text{lbm} \cdot \text{ft/s}^2}$

$$W = 2.2\ \text{lbf}$$

Hence weight of 1 kg substance in lbf is $W = 2.2\ \text{lbf}$

Question: 1.033P

Consider the flow of air through a wind turbine whose blades sweep an area of diameter D(in m). The average air velocity through the swept area is V(in m/s). On the bases of the units of the quantities involved, show that the mass flow rate of air (in kg/s) through the swept area is proportional to air density, the wind velocity, and the square of the diameter of the swept area.

Step 1 of 3

Mass flow rate of air depends on the following

Diameter, D in m

Velocity, V in m/s and

Air density, ρ in kg/m^3

Hence

$$\dot{m} \propto \left(D^a \times V^b \times \rho^c\right)$$

$$\dot{m} = kD^a V^b \rho^c$$

Where k = proportionality constant

Step 2 of 3

Dimension of $\dot{m} = [MT^{-1}]$

Dimension of $D = [L]$

Dimension of $V = [LT^{-1}]$

Dimension of $\rho = [ML^{-3}]$

Dimension of $k = [M^0L^0T^0]$

By replacing the terms in equation with dimensions, we get

$$[MT^{-1}] = [M^0L^0T^0][L]^a[LT^{-1}]^b[ML^{-3}]^c$$

$$[MT^{-1}] = [L]^{a+b-3c}[M]^c[T]^{-b}$$

Step 3 of 3

Comparing powers of M on both sides,

$$c = 1$$

Comparing powers of T on both sides,

$$b = 1$$

Comparing powers of L on both sides,

$$a + b - 3c = 0$$

$$a + 1 - 3 = 0$$

$$a = 2$$

Hence by substituting the values of a, b, c we get

$$\dot{m} \propto \left(D^2 \times V \times \rho\right)$$

So, the formula becomes $\boxed{\dot{m} \propto \left(D^2 \times V \times \rho\right)}$

Question: 1.034P

The drag force exerted on a car by air depends on a dimensionless drag coefficient, the density of air, the car velocity, and the frontal area of the car. That is, *F*D =function (CDrag *A*front *ρ*, *V*).Based on unit considerations alone, obtain a relation for the drag force.

FIGURE P1-34

Step 1 of 3

Drag force depends on

Drag coefficient, C_{Drag} (Dimensionless)

Frontal Area, A (m^2)

Air density, ρ $\left(kg/m^3\right)$

Velocity V (m/s)

Hence

$F_D \propto \left(C_{drag}, A_{front}, \rho, V\right)$

$F_D = C_{drag} A^a \rho^b V^c$

Step 2 of 3

Dimension of $F_D = [MLT^{-2}]$

Dimension of $A = [L^2]$

Dimension of $\rho = [ML^{-3}]$

Dimension of $V = [LT^{-1}]$

Dimension of $C_{Drag} = [M^0 L^0 T^0]$

By replacing the terms in equation with dimensions, we get

$[MLT^{-2}] = [M^0 L^0 T^0][L^2]^a [ML^{-3}]^b [LT^{-1}]^c$

$[MLT^{-2}] = M^b [L]^{2a-3b+c} [T]^{-c}$

Step 3 of 3

Comparing powers of M on both sides,

$b = 1$

Comparing powers of T on both sides,

$c = 2$

Comparing powers of L on both sides,

$2a - 3b + c = 1$

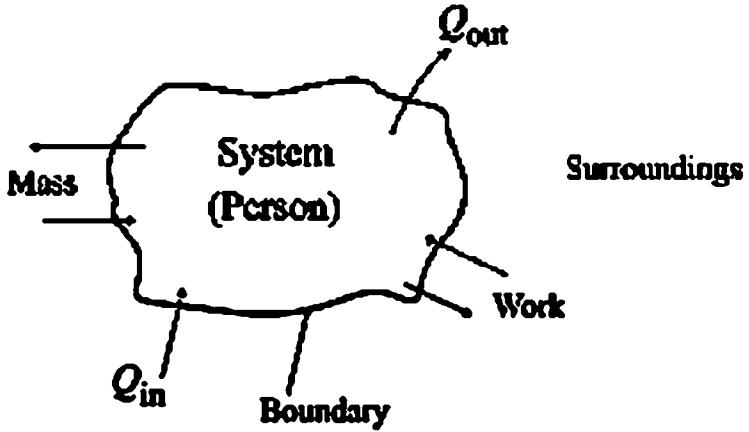
$\Rightarrow 2a = 2$

$a = 1$

Hence by substituting the values of a, b, c we get

$F_{Drag} = C_{Drag}(A_{Front})(\rho)(V)^2$

So, the formula becomes $\boxed{F_{Drag} = C_{Drag}(A_{Front})(\rho)(V)^2}$



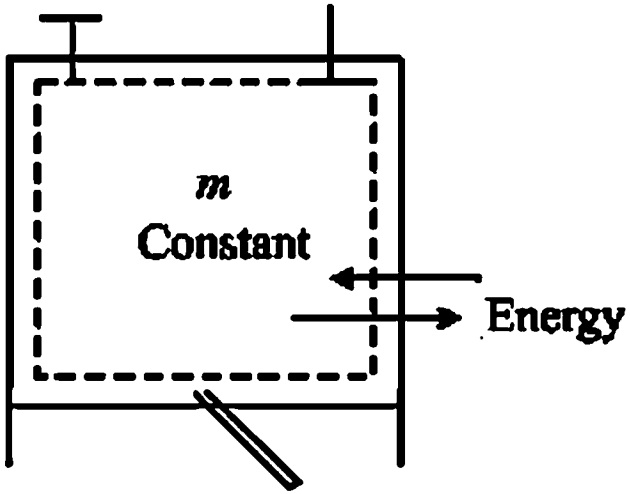
CHAPTER 02

SOLUTIONS

Question: 2.001P

You have been asked to do a metabolism (energy) analysis of a person. How would you define the system for this purpose? What type of system is this?

Step 1 of 2



Step 2 of 2

If we doe the energy analysis for a person there will be heat (Q) in and out, work (w) in and out, mass (m) in and out. So this type of system is said to be open system
There will be both mass and energy transfer

Question: 2.002P

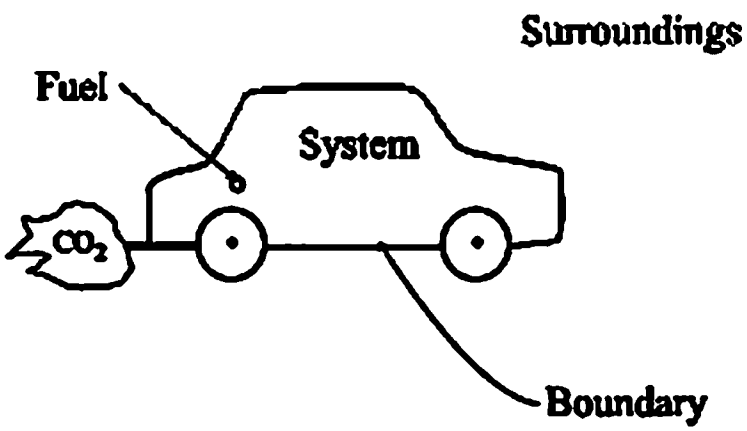
You are trying to understand how a reciprocating air compressor (a piston-cylinder device) works. What system would you use? What type of system is this?

Step 1 of 2

Step 2 of 2

In this type of system there will be energy transfer but no mass transfer, such type of system is called as closed system.
In this system air (refrigerant) is compressed by a pump which means work input is given so that it leads to increase in pressure/temperature.

Question: 2.003P



How might you define a system to study the depletion of ozone in the upper layers of the earth's atmosphere?

Step 1 of 3

Generation of CO_2, nitrogen oxide and hydrocarbons are the major cause of depletion of ozone layer.

Carbon dioxide, nitrogen oxide and hydrocarbons are generated by the combustion of fuel in the engine. Any system selected for this analysis must include the fuel and air while it is going combustion. The volume that contains the air-fuel mixture within piston-cylinder device can be used for this purpose.

Step 2 of 3

Step 3 of 3

One can also place the entire engine in a control boundary and trace the system surrounding interactions to determine the rate at which engine generates CO_2, nitrogen oxide and hydrocarbons by using the volumetric analysis. This gaseous produced due to unburned fuel in the combustion.

Nitrogen oxide and hydrocarbons react in the presence of sunlight on hot claim days to form smog which cause ground level ozone deflection. Since these gases have no boundary and it cross the entire global areas.

Question: 2.004P

What is the difference between intensive and extensive properties?

Step 1 of 1

Intensive properties	Extensive properties
It is independent of the mass of the system Example: Pressure, Temperature and density.	It is dependent on mass of the system Example:– total mass, Volume, and total momentum.

Question: 2.005P

Is the weight of a system an extensive or intensive property?

Step 1 of 1

Weight of a system = mass × acceleration due to gravity
So weight of system depends on mass and mass is an extensive property
So weight of a system is extensive property. Extensive properties are those whose values depend on the size or extent of the system. Because of its value changes with changes of the mass.

Question: 2.006P

The molar specific volume of a system $\bar{v}$ is defined as the ratio of the volume of the system to the number of moles of substance contained in the system. Is this an extensive or intensive property?

Step 1 of 2

$$\bar{v} = \frac{\text{volume of system}}{\text{number of mole}}$$

The number of moles of a substance in a system is directly proportional to the number of atomic particle contained in the system. If we divided the system into smaller portion, each portion contains fewer atomic particles than the original system. Therefore number moles are the extensive property.

And Volume also extensive property because of whose values depends on the size or extent of the system.

Step 2 of 2

An extensive property divided by extensive property is always intensive property.

Also we can state that all specific properties are intensive properties. Or extensive properties per unit mass are called specific properties.

So molar specific volume of a system $\bar{v}$ is an intensive property.

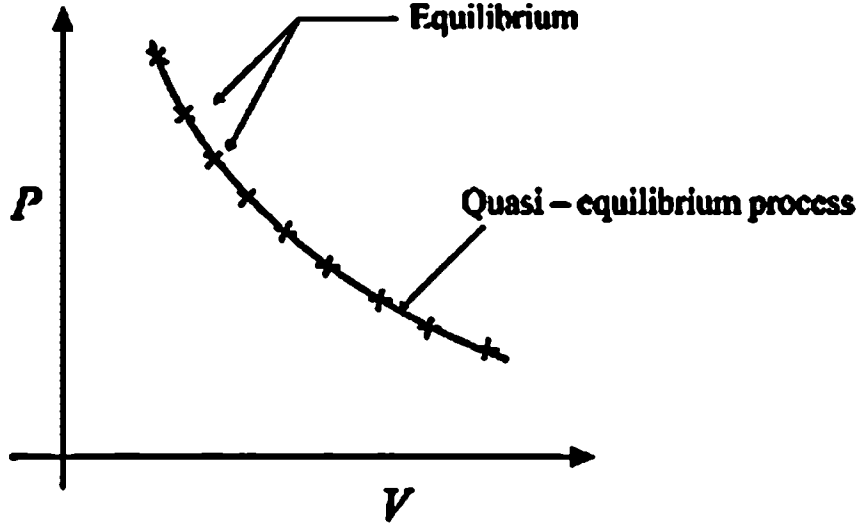
Question: 2.007P

For a system to be in thermodynamic equilibrium, do the temperature and the pressure have to be the same everywhere?

Step 1 of 1

If the temperature and pressure are same at every point, the system satisfies thermal and mechanical equilibrium respectively.

For a system to be in thermodynamic equilibrium, the temperature remains constant but the pressure may vary.



Question: 2.008P

What is a quasi-equilibrium process? What is its importance in engineering?

Step 1 of 3

Quasi – equilibrium process:–
The departure of the state of the system from the thermodynamic equilibrium state will be infinitesimally small. So every state passed through by the system will be an equilibrium state. Such a process, which is but a locus of all the equilibrium points passed through by the system is known as a quasi – equilibrium process. 'Quasi' meaning 'almost'

Step 2 of 3

Step 3 of 3

Quasi equilibrium process are easy to analyze and work – producing devices deliver the most work, so engineering applications can be approximated to quasi – equilibrium process.

Question: 2.009P

Define the isothermal, isobaric, and isochoric processes.

Step 1 of 1

Isothermal process:–

A process during which the temperature remains constant is called isothermal process

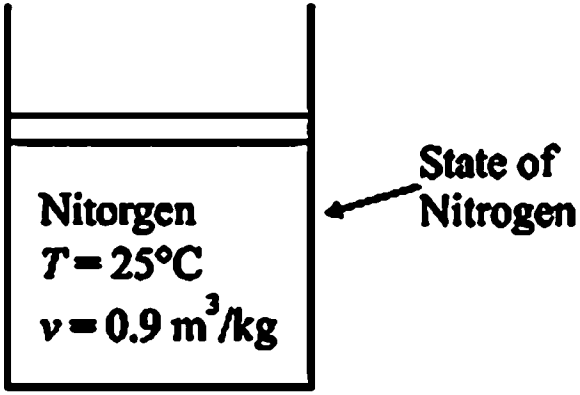
Isobaric process:–

A process during which the pressure remains constant is called isobaric process

Isochoric process:–

A process during which the volume remains constant is called isochoric process.

Question: 2.010P



What is the state postulate?

Step 1 of 2

The number of properties to fix the state of a system is given by the state postulate. The state postulate requires that the two properties specified be independent, intensive properties.

For example:– Nitrogen in a container is defined by temperature $T = 25°C$, specific volume $v = 0.9 m^3/kg$

Step 2 of 2

Question: 2.011P

How would you describe the state of the water in a bathtub? How would you describe the process that this water experiences as it cools?

Step 1 of 3

The state of water in a bathtub is described by taking its temperature and pressure.

Let us take the temperature of the water as room temperature say $26^{\circ}C$, and atmospheric pressure acts on the water surface $(P_{atm} = 101.325 kPa)$.

From the properties of saturated water

At $P_{atm} = 101.325 kPa$

Saturation temperature is $T_{sat} = 99.99^{\circ}C$

Step 2 of 3

The temperature of water decreases as it cools. So that $T < T_{sat@P}$, we have considered as compressed liquid. So compressed liquid properties depends upon only on the temperature much more strongly than they do on the pressure. Since increasing the pressure 100 times often causes the properties to change less than 1 percent.

Step 3 of 3

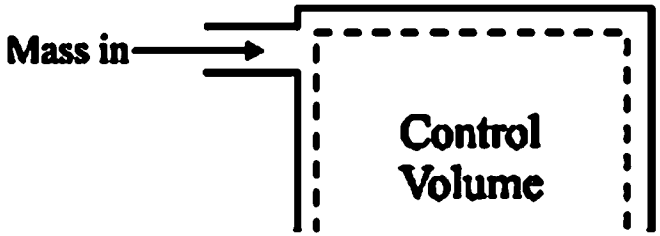
As the water cools pressure remains fixed. The cooling process becomes as constant pressure process.

Question: 2.012P

When analyzing the acceleration of gases as they flow through a nozzle, what would you choose as your system? What type of system is this?

Step 1 of 1

When analyzing the acceleration of gases as they flow through a nozzle, we consider the Volume within nozzle as the control surface. Bounded by entire inlet surface and cross section of the nozzle.



Question: 2.013P

When is a steady-flow process?

Step 1 of 3

The process which involves no change with time anywhere within the system is called steady process.
A large number of engineering devices operate for long periods of time under the same conditions, and they are classified as steady – flow devices. Process involving such devices can be some what idealized process, called the steady – flow process.

Step 2 of 3

Question: 2.014P

The density of atmospheric air varies with elevation, decreasing with increasing altitude. (*a*) Using the data given in the table, obtain a relation for the variation of density with elevation, and calculate the density at an elevation of 7000 m. (*b*) Calculate the mass of the atmosphere using the correlation you obtained. Assume the earth to be a perfect sphere with a radius of 6377 km, and take the thickness of the atmosphere to be 25 km.

z, km	ρ, kg/m3
6377	1.225
6378	1.112
6379	1.007
6380	0.9093
6381	0.8194
6382	0.7364
6383	0.6601
6385	0.5258
6387	0.4135
6392	0.1948
6397	0.08891
6402	0.04008

Step 1 of 4

Given data:

The earth is perfectly sphere with a radius of $r = 6377$ km

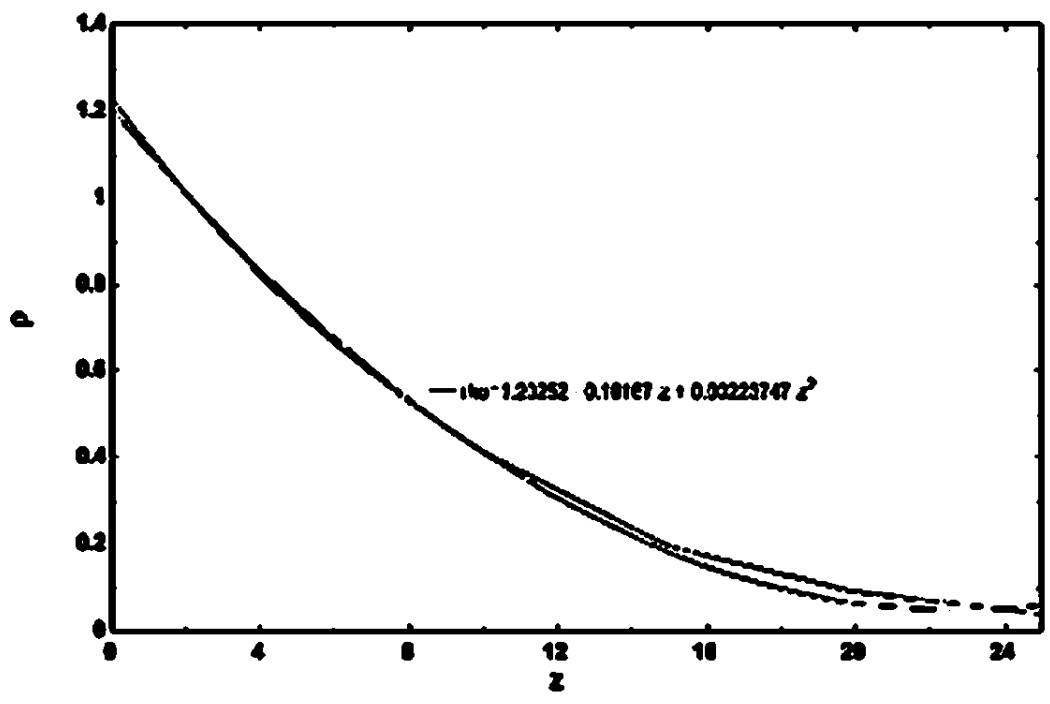
The thickness of the atmosphere is $z = 25$ km

Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

$rho = r + z$

After writing the equation in equation window, then select table on menu bar, then click new parameter table.

The dialog box will be appeared, then select the density, radius and elevation, then click ADD, then click OK button.



The following results are displayed

1..12	1 ρ	2 z	3 r
Run 1	1.225	0	6377
Run 2	1.112	1	6378
Run 3	1.007	2	6379
Run 4	0.9093	3	6380
Run 5	0.8194	4	6381
Run 6	0.7364	5	6382
Run 7	0.6601	6	6383
Run 8	0.5258	8	6385
Run 9	0.4135	10	6387
Run 10	0.1948	15	6392
Run 11	0.08891	20	6397
Run 12	0.04008	25	6402

Step 2 of 4

Select the plot on menu bar, then click x-y plot .Dialog box will appeared, then select variables to draw graph, then click ok button.

The graph will appear then click on curve fit and specify 2nd order polynomial and enter to get polynomial equation.

Step 3 of 4

a)

The second order polynomial equation is

$$\rho(z) = \left(1.20252 - 0.10167z + 0.00223747z^2\right) \text{ kg/m}^3$$

$$\rho(z) = \left(1.20252 - 0.10167z + 0.00223747z^2\right) \times 10^9 \text{ kg/km}^3 \quad \ldots\ldots (1)$$

At elevation of $z = 7$ m the density is given by

$$\rho = 1.20252 - 0.10167z + 0.00223747z^2$$

$$= 1.20252 - 0.10167(7) + 0.00223747(7)^2$$

$$= 1.20252 - 0.71169 + 0.10963$$

$$= 0.60046 \text{ kg/m}^3$$

The density at elevation $z = 7$ m is $\boxed{\rho = 0.60046 \text{ kg/m}^3}$

Step 4 of 4

b)

Volume of the sphere is given by

$$dV = 4\pi(r_o + z)^2 dz \quad \ldots\ldots (2)$$

The mass of atmosphere having the thickness $h = 0$ to 25 m and radius of the sphere $r = 6377$ km using the correlation is given by

$$m = \int_0^h \rho dV \quad \ldots\ldots (3)$$

Now by substituting the above equations (1) and (2) in (3) we get,

$$m = \int_0^{25} \left[\left(1.20252 - 0.10167z + 0.00223747z^2\right) 4\pi(6377 + z)^2 \times 10^3\right] dz$$

On solving the above equation we get the mass of the atmosphere,

$$m = 5.09234 \times 10^{18} \text{ kg}$$

Therefore, the mass of the atmosphere is $\boxed{m = 5.09234 \times 10^{18} \text{ kg}}$.

Question: 2.015P

What is the zeroth law of thermodynamics?

Step 1 of 1

When a body A is in thermal equilibrium with a body B, and also separately with abody C, then B and C will be in thermal equilibrium with each other. This is known as the Zeroth Law of Thermodynamics
It is used for temperature measurement

Question: 2.016P

What are the ordinary and absolute temperature scales in the SI and the English system?

Step 1 of 1

In SI system:–

Ordinary temperature – Celsius (°C)

Absolute temperature – Kelvin (K)

English system:–

Ordinary temperature – Fahrenheit (°F)

Absolute temperature – Rankine (R)

Question: 2.017P

Consider an alcohol and a mercury thermometer that read exactly 0°C at the ice point and 100°C at the steam point. The distance between the two points is divided into 100 equal parts in both thermometers. Do you think these thermometers will give exactly the same reading at a temperature of, say, 60°C? Explain.

Step 1 of 1

No, the alcohol and mercury are two different fluids, which will have different properties. Mainly the thermal expansions of fluids will be different for alcohol and mercury, so the thermometers will show different readings at 60°C.

Question: 2.018P

The deep body temperature of a healthy person is 37°C. What is it in kelvins?

Step 1 of 1

Given,

The temperature of a person $T(°C) = 37°C$

The Kelvin scale is related to the Celsius scale by

$$T(K) = T(°C) + 273.15$$

Here $T(K) = 37°C + 273.15$

$$\boxed{T(K) = 310.15K}$$

Question: 2.019P

What is the temperature of the heated air at 150°C in °F and R?

Step 1 of 3

Given:

Temperature of the heated air $T(°C) = 150°C$

Step 2 of 3

The temperature scale in the two unit system are related as

$$T(°F) = 1.8T(°C) + 32$$

$$T(°C) = 150°C$$

$$T(°F) = (1.8 \times 150) + 32$$

$$= 302°F$$

$$\boxed{T(°F) = 302°F}$$

Step 3 of 3

The Rankine scale is related to the Fahrenheit scale is given by

$$T(R) = T(°F) + 459.67$$

$$= 302 + 459.67$$

$$= 761.67R$$

$$\boxed{T(R) = 761.67R}$$

Question: 2.020P

The temperature of a system rises by 45°C during a heating process. Express this rise in temperature in kelvins.

Step 1 of 1

The magnitude of each division of 1K and 1°C are identical .Therefore, when we are dealing with temperature difference, the temperature interval on both scales is the same.

The temperature changes are always identical in Kelvin and Celsius scales.

Rise in temperature in Kelvin is,

$$\Delta T(\mathrm{K}) = \Delta T(^{\circ}\mathrm{C})$$
$$= 45\mathrm{K}$$

Therefore, the rise in temperature in Kelvins is $\boxed{45\,\mathrm{K}}$

Question: 2.021P

The flash point of an engine oil is 363°F. What is the absolute flash-point temperature in K and R?

Step 1 of 4

Given:

Flash point temperature of the engine oil $T(^\circ\text{F}) = 363^\circ\text{F}$

Step 2 of 4

Temperature scales in the two unit system are related as

$$T(^\circ\text{F}) = 1.8T(^\circ\text{C}) + 32$$

$$363 = 1.8T(^\circ\text{C}) + 32$$

$$\Rightarrow T(^\circ\text{C}) = \frac{363 - 32}{1.8}$$

$$= 183.89^\circ\text{C}$$

Step 3 of 4

Absolute Flash point temperature in Kelvin

$$T(\text{K}) = T(^\circ\text{C}) + 273.15$$

$$= 183.89 + 273.15$$

$$= 457.03\text{K}$$

$$\boxed{T(\text{K}) = 457.03\text{K}}$$

Step 4 of 4

Absolute Flash point temperature in Rankine

$$T(\text{R}) = T(^\circ\text{F}) + 459.67$$

$$= 363 + 459.67$$

$$= 822.67\text{R}$$

$$\boxed{T(\text{R}) = 822.67\text{R}}$$

Question: 2.022P

The temperature of ambient air in a certain location is measured to be −40°C. Express this temperature in Fahrenheit (°F), Kelvin (K), and Rankine (R) units.

Step 1 of 4

Given:

Temperature of ambient air $T(^\circ\text{C}) = -40^\circ\text{C}$

Step 2 of 4

The Kelvin scale is related to the Celsius scale is

$T(\text{K}) = T(^\circ\text{C}) + 273.15$

Temperature in Kelvin scale is

$T(\text{K}) = T(^\circ\text{C}) + 273.15$

$= -40 + 273.15$

$= 233.15\text{K}$

$\boxed{T(\text{K}) = 233.15\text{K}}$

Step 3 of 4

Temperature scales in the two unit system are related as

$T(^\circ\text{F}) = 1.8T(^\circ\text{C}) + 32$

Temperature in Fahrenheit scale is

$T(^\circ\text{F}) = 1.8T(^\circ\text{C}) + 32$

$= [1.8 \times (-40)] + 32$

$= -40^\circ\text{F}$

$\boxed{T(^\circ\text{F}) = -40^\circ\text{F}}$

Step 4 of 4

The Rankine scale related to the Fahrenheit scale is

$T(\text{R}) = T(^\circ\text{F}) + 459.67$

Temperature in Rankine scale is

$T(\text{R}) = T(^\circ\text{F}) + 459.67$

$= -40 + 459.67$

$= 419.67\text{R}$

$\boxed{T(\text{R}) = 419.67\text{R}}$

Question: 2.023P

The temperature of water changes by 10°F during a process. Express this temperature change in Celcius (°C), Kelvin (K), and Rankine (R) units.

Step 1 of 4

Given:

Temperature of water change $\Delta T = 10^\circ F$

Step 2 of 4

A temperature changes in Rankine scale

$$\Delta T(\mathrm{R}) = \Delta T(^\circ\mathrm{F})$$
$$= 10\mathrm{R}$$

Step 3 of 4

A temperature changes in Celsius scale

$$\Delta T(^\circ\mathrm{C}) = \Delta T(\mathrm{K})$$
$$= \frac{10}{1.8}$$
$$= 5.6^\circ\mathrm{C}$$

Step 4 of 4

Temperature changes in Kelvin is

$$\Delta T(\mathrm{K}) = \frac{T(\mathrm{R})}{1.8}$$
$$= \frac{10}{1.8}$$
$$= 5.6\mathrm{K}$$

Question: 2.024P

Humans are most comfortable when the temperature is between 65°F and 75°F. Express these temperature limits in °C. Convert the size of this temperature range (10°F) to K, °C, and R. Is there any difference in the size of this range as measured in relative or absolute units?

Step 1 of 9

Convert the temperature $65°F$ from degree Fahrenheit to degree Celsius.

$$T_1(°F) = 1.8 \times T_1(°C) + 32$$

Here, $T(°C)$ is the temperature in degree Celsius and $T(°F)$ is the temperature in degree Fahrenheit.

Substitute $65°F$ for $T_1(°F)$.

$$65 = 1.8 \times T_1(°C) + 32$$
$$T_1(°C) = 18.33°C$$

Therefore, the conversion of temperature from degree Fahrenheit to degree Celsius for $65°F$ is $\boxed{18.33°C}$.

Step 2 of 9

Convert the temperature $75°F$ from degree Fahrenheit to degree Celsius.

$$T_2(°F) = 1.8 \times T_2(°C) + 32$$

Substitute $75°F$ for $T_2(°F)$.

$$75 = 1.8 \times T_2(°C) + 32$$
$$T_2(°C) = 23.89°C$$

Therefore, the temperature limits from degree Fahrenheit to degree Celsius for $75°F$ is $\boxed{23.89°C}$.

Step 3 of 9

Convert the size of this temperature range $(65°F \text{ to } 75°F)$ from degree Fahrenheit to degree Celsius.

$$(\Delta T) = T_2(°C) - T_1(°C)$$

Substitute $23.89°C$ for $T_2(°C)$. $18.33°C$ for $T_1(°C)$.

$$(\Delta T) = 23.89 - 18.33$$
$$= 5.56°C$$
$$\approx 5.6°C$$

Therefore, the size of this temperature range $(65°F \text{ to } 75°F)$ from degree Fahrenheit to degree Celsius is $\boxed{5.6°C}$.

Step 4 of 9

Convert the temperature $65°F$ from degree Fahrenheit to degree Kelvin.

$$T_1(K) = (T_1(°F) - 32) \times \frac{5}{9} + 273.15$$

Substitute $65°F$ for $T_1(°F)$.

$$T_1(K) = (65 - 32) \times \frac{5}{9} + 273.15$$
$$= 291.483\ K$$

Therefore, the conversion of the temperature $65°F$ from degree Fahrenheit to degree Kelvin for $65°F$ is $\boxed{291.483K}$.

Step 5 of 9

Convert the temperature $75°F$ from degree Fahrenheit to degree Celsius.

$$T_2(K) = (T_2(°F) - 32) \times \frac{5}{9} + 273.15$$

Substitute $75°F$ for $T_2(°F)$.

$$T_2(K) = (75 - 32) \times \frac{5}{9} + 273.15$$
$$= 297.038\ K$$

Therefore, the conversion of the temperature $65°F$ from degree Fahrenheit to degree Kelvin for $75°F$ is $\boxed{297.038\ K}$.

Step 6 of 9

Convert the size of this temperature range $(65°F \text{ to } 75°F)$ from degree Fahrenheit to degree Kelvin.

$$(\Delta T) = T_2(K) - T_1(K)$$

Substitute $297.038\ K$ for $T_2(K)$. $291.483\ K$ for $T_1(K)$.

$$(\Delta T) = 297.083 - 291.483$$
$$= 5.6K$$

Therefore, the size of this temperature range $(65°F \text{ to } 75°F)$ from degree Fahrenheit to degree Kelvin is $\boxed{5.6\ K}$

Step 7 of 9

Convert the temperature $65°F$ from degree Fahrenheit to degree Rankine.

$$T_1(°F) = (T_1(°R) - 459.67)$$

Substitute $65°F$ for $T_1(°F)$.

$$65 = (T_1(°R) - 459.67)$$
$$T_1(°R) = 524.67°R$$

Therefore, the conversion of the temperature $65°F$ from degree Fahrenheit to degree Rankine for $65°F$ is $\boxed{524.67°R}$.

Step 8 of 9

Convert the temperature $75°F$ from degree Fahrenheit to degree Rankine.

$$T_2(°F) = (T_2(°R) - 459.67)$$

Substitute $75°F$ for $T_2(°F)$.

$$75 = (T_2(°R) - 459.67)$$
$$T_2(°R) = 534.67°R$$

Therefore, the conversion of the temperature $75°F$ from degree Fahrenheit to degree Rankine for $75°F$ is $\boxed{534.67°R}$.

Step 9 of 9

Convert the size of this temperature range $(65°F \text{ to } 75°F)$ from degree Fahrenheit to degree Rankine.

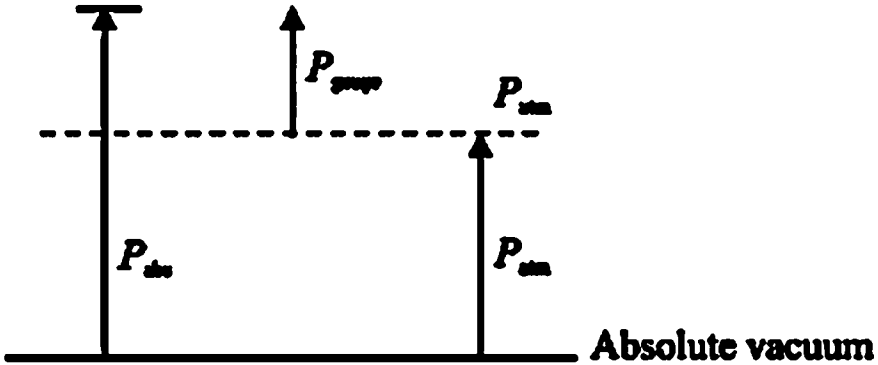
$$(\Delta T) = T_2(°R) - T_1(°R)$$

Substitute $524.67°R$ for $T_2(°R)$. $534.67°R$ for $T_2(°R)$.

$$(\Delta T) = 534.67 - 524.67$$
$$= 10°R$$

Therefore, the size of this temperature range $(65°F \text{ to } 75°F)$ from degree Fahrenheit to degree Rankine is $\boxed{10°R}$.

No difference found between relative and absolute units (within same system).



Question: 2.025P

What is the difference between gage pressure and absolute pressure?

Step 1 of 2

The pressure relative to the atmosphere is called gauge pressure
The pressure relative to a perfect Vacuum is called absolute pressure
Absolute pressure = Gauge pressure + Atmospheric pressure

Step 2 of 2

Question: 2.026P

A health magazine reported that physicians measured 100 adults' blood pressure using two different arm positions: parallel to the body (along the side) and perpendicular to the body (straight out). Readings in the parallel position were up to 10 percent higher than those in the perpendicular position, regardless of whether the patient was standing, sitting, or lying down. Explain the possible cause for the difference.

Step 1 of 1

When a person spreading his arms in t he parallel position will experience more strain i.e., pressure compared to the perpendicular position of arms.

The pressure exerted by the heart to pump the blood will be more in this case compared to the perpendicular position of arms. It is invariant of the position of a person whether sitting, lying or standing.

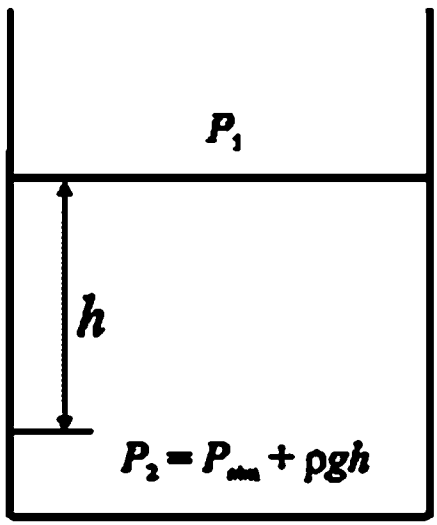
Since the parallel position the arms are in up position.

Question: 2.027P

Someone claims that the absolute pressure in a liquid of constant density doubles when the depth is doubled. Do you agree? Explain.

Step 1 of 3

The pressure at a depth 'h' from the free surface



$P = P_{atm} + \rho g h$

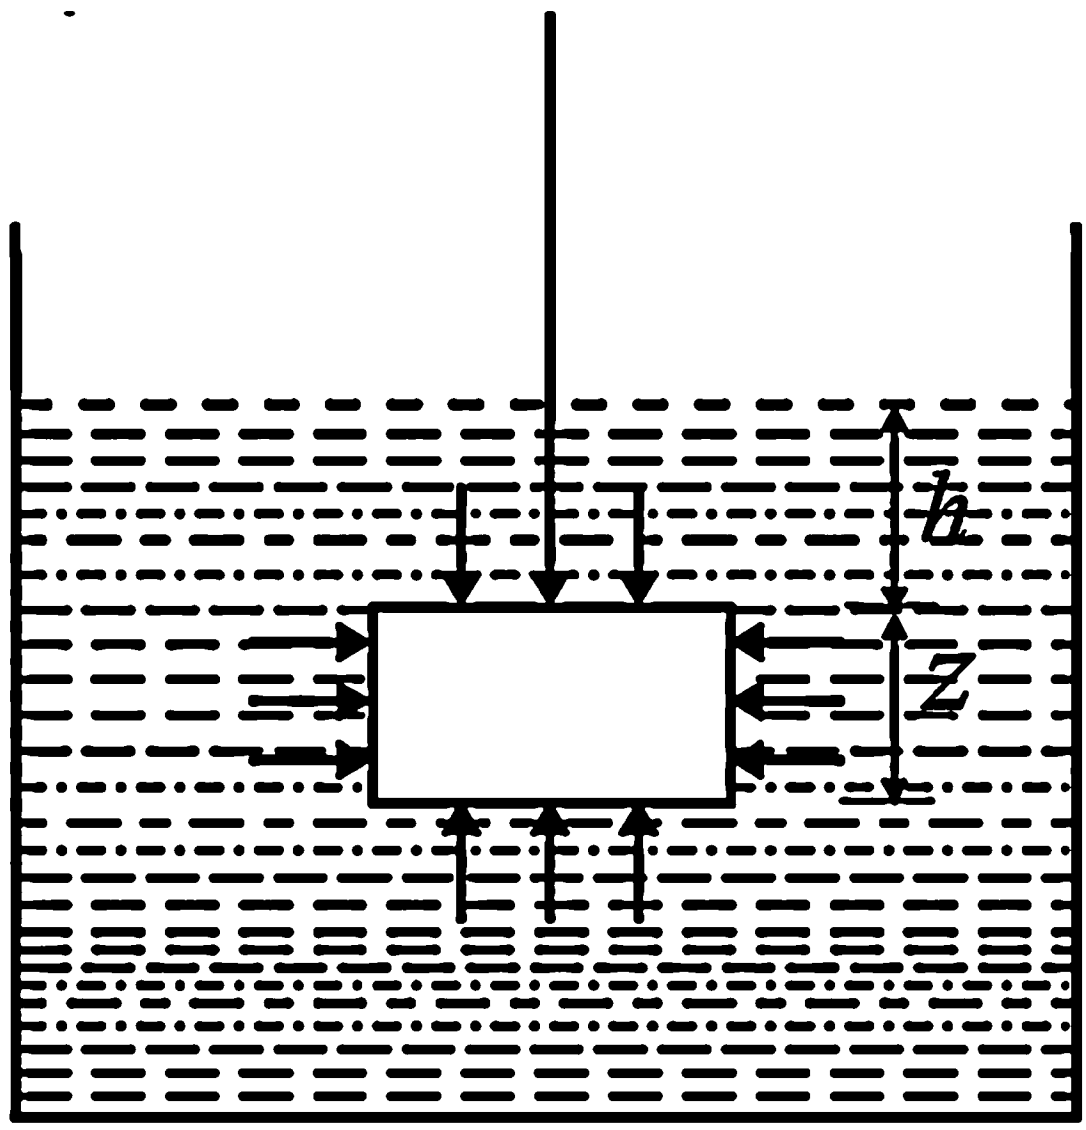
$P_{gauge} = \rho g h$,

P_{atm} = atmospheric pressure

P = absolute pressure

Step 2 of 3

Step 3 of 3



If the depth is double the gauge pressure gets double not the absolute pressure.
No, this statement is false.

Question: 2.028P

A tiny steel cube is suspended in water by a string. If the lengths of the sides of the cube are very small, how would you compare the magnitudes of the pressures on the top, bottom, and side surfaces of the cube?

Step 1 of 2

Draw the schematic diagram of a tiny steel cube in a beaker of water.

Step 2 of 2

Calculate the pressure at the top side of the cube.

$$P = P_{atm} + \rho g H$$

Here, atmospheric pressure is P_{atm}, density of the liquid is ρ, acceleration due to gravity is g and distance from the surface of the liquid is H.

Substitute h for H in the above equation.

$$P = P_{atm} + \rho g h \quad \text{..... (1)}$$

Calculate the pressure at the bottom side of the cube.

$$P = P_{atm} + \rho g H$$

Here, atmospheric pressure is P_{atm}, density of the liquid is ρ, acceleration due to gravity is g and distance from the surface of the liquid is H.

Substitute $(h+z)$ for H in the above equation.

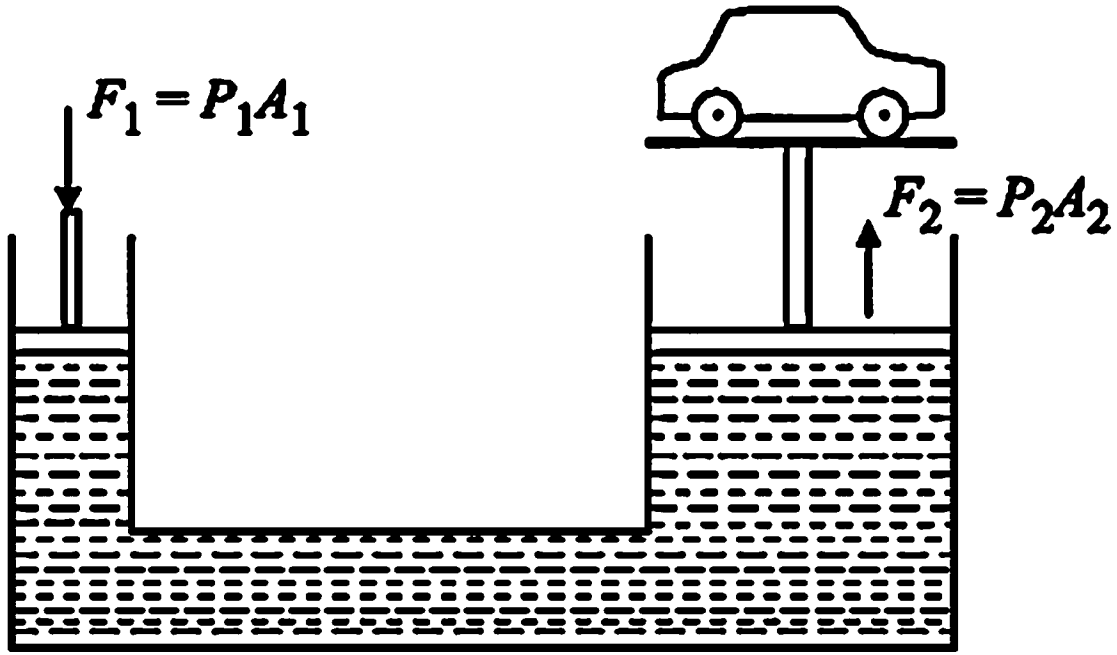
$$P = P_{atm} + \rho g (h+z) \quad \text{..... (2)}$$

Neglect z in equation (2) by substituting 0 for z.

$$P = P_{atm} + \rho g h$$

The above equation is similar to equation (1).

Therefore, if the length of the cube is neglected, then the cube will experience same pressure on all sides of the cubes.



Question: 2.029P

Express Pascal's law, and give a real-world example of it.

Step 1 of 3

Pascal's law states that the pressure applied to a confined fluid increases the pressure throughout the same amount. The pressure in a fluid remaining constant in the horizontal direction.
The Pascal's law used in our daily lives such as hydraulic brakes and lifts

Step 2 of 3

Step 3 of 3

Lifting of a large weight by a small force by the application of Pascal's law

Question: 2.030P

The pressure at the exit of an air compressor is 150 psia. What is this pressure in kPa?

Step 1 of 2

Given:

Pressure exit of the compressor $P = 150\text{psia}$

Step 2 of 2

We know that

$14.7\text{psi} = 101.3\text{kPa}$

$1\text{psi} = 6.891\text{kPa}$

$150\text{psi} = 150 \times 6.891\text{kPa}$

$= 1033.67\text{kPa}$

$\boxed{P = 1033.67\text{kPa}}$

Question: 2.031P

The pressure in a compressed air storage tank is 1500 kPa. What is the tank's pressure in (*a*) kN and m units; (*b*) kg, m, and s units; and (*c*) kg, km, and s units?

Step 1 of 5

Given pressure in a compressed tank

$P = 1500\,\text{kPa}$

Step 2 of 5

a) In $\text{k}\cdot\text{N}$ and m units

$1\text{pascal} = 1\ \text{N/m}^2$

$\therefore\ \boxed{P = 1500\,\text{kN/m}^2}$

Step 3 of 5

b) In kg, m and s units

$1\,\text{Pa} = 1\text{N/m}^2$

$1\text{N} = 1\text{kg}\cdot\text{m/s}^2$

$$P = 1500 \times 1000 \times \frac{\text{kg}}{s^2} \times \frac{1}{m}$$

Pressure $\boxed{P = 1{,}500{,}000\ \text{kg/ms}^2}$

Step 4 of 5

c) In kg, m and s units

$$P = 1500{,}000 \frac{\text{kg}}{\frac{m \times s^2}{10^3}}$$

$1\text{km} = 1000\,\text{m}$

$$\boxed{P = 1500{,}000 \times 10^3 \frac{\text{kg}}{\text{km}\cdot s^2}}$$

Step 5 of 5

Question: 2.032P

The pressure in a water line is 1500 kPa. What is the line pressure in (*a*) lb/ft2 units and (*b*) lbf/in2 (psi) units?

Step 1 of 2

a) We know that

$$1\,\text{kPa} = 20.8854\,\text{lbf/ft}^2$$

$$1500\,\text{kPa} = 1500 \times 20.8854\,\text{lbf/ft}^2$$

$$= 31328.153\,\text{lbf/ft}^2$$

Step 2 of 2

(b) We know that

$$1\text{kPa} = 0.145041\,\text{lbf/in}^2$$

$$1500\text{kPa} = 1500 \times 0.145041\,\text{lbf/in}^2$$

$$= 217.56\,\text{lbf/in}^2$$

Question: 2.033P

If the pressure inside a rubber balloon is 1500 mm Hg, what is this pressure in pounds-force per square inch (psi)?

Step 1 of 3

Given:
Pressure inside rubber balloon $P = 1500\,\text{mm of Hg}$

Step 2 of 3

$$\text{Pressure} = 1500\text{mm of Hg} = 1.5\text{m of Hg}$$

$$\text{Taking, density of Hg} = 13570\ \frac{\text{kg}}{\text{m}^3}$$

$$\begin{aligned}\text{Pressure} &= \rho \times g \times h \\ &= 13570 \times 9.81 \times 1.5 \\ &= 199.682\,\text{kPa}\end{aligned}$$

Step 3 of 3

$$6.88\text{kPa} = 1\text{psi}$$

$$1\text{kPa} = \frac{1}{6.88}\text{psi}$$

$$\begin{aligned}199.682\text{kPa} &= \frac{199.682}{6.88}\text{psi} \\ &= 29\text{psi}\end{aligned}$$

$$\boxed{P = 29\text{psi}}$$

Question: 2.034P

The pressure of the helium inside a toy balloon is 1250 mm Hg. What is this pressure in kPa?

Step 1 of 2

Given:

Pressure inside balloon $P = 1250 \text{ mm of Hg}$

$= 1.25 \text{ m of Hg}$

Step 2 of 2

Density of mercury

$\rho = 13570 \frac{\text{kg}}{\text{m}^3}$

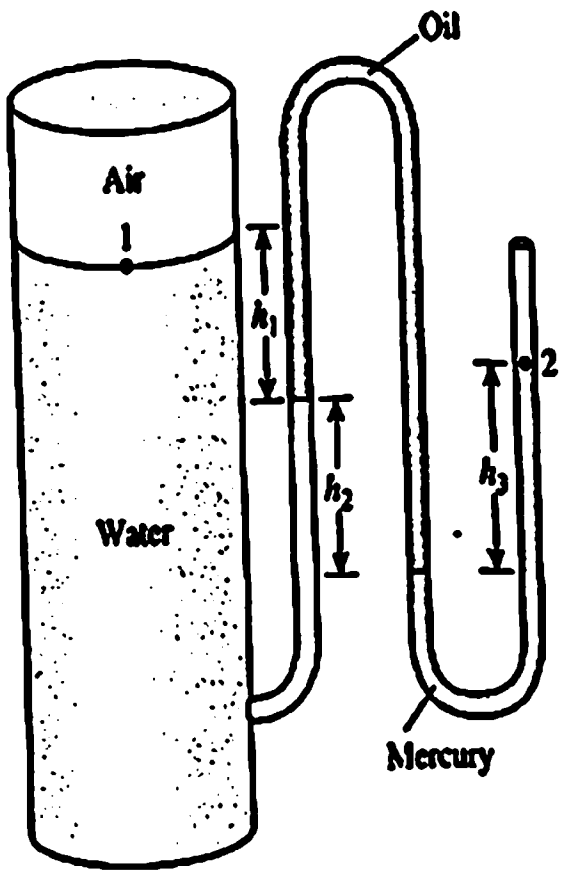
$P = \rho \times g \times h$

$= 13570 \times 9.81 \times 1.25$

$= 166.402 \text{kPa}$

Question: 2.035P

The water in a tank is pressurized by air, and the pressure is measured by a multifluid manometer as shown in Fig. P2-35. Determine the gage pressure of air in the tank if $h1$ = 0.2 m, $h2$ = 0.3 m, and $h3$=0.46 m. Take the densities of water, oil, and mercury to be 1000 kg/m3, 850 kg/ml and 13,600 kg/m3, respectively.



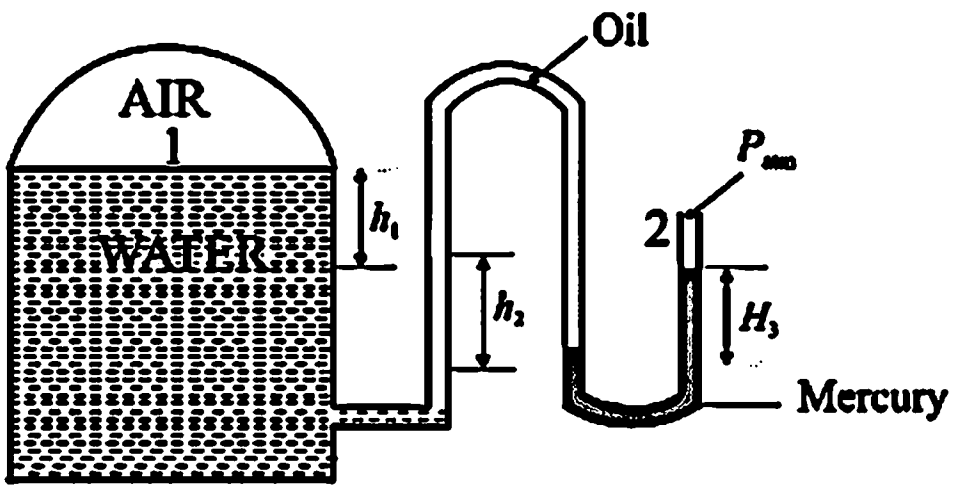


FIGURE P2-35

Step 1 of 4

Step 2 of 4

Let us consider the pressure at air – water enter phase is P_1

The pressure at point 2 is open to atmosphere i.e., $P_2 = P_{atm}$

The gauge pressure of air in tank is given by $P_{gauge} = P_1 - P_{atm}$ .....(1)

(Obtained from basic pressure relation $P_{abs} = P_{gauge} + P_{atm}$

The pressure inside tank can be determined by starting at air – water surface P_1, moving along the tube until we reach free surface, i.e., P_{atm}

Step 3 of 4

It gives

$$P_1 + \rho_{H_2O}\, g h_1 + \rho_{oil}\, g h_2 - \rho_{Hg}\, g h_3 = P_{atm}$$

$$\Rightarrow P_1 - P_{atm} = g\left(\rho_{Hg} h_3 - \rho_{oil} h_2 - \rho_{H_2O} h_1\right) \quad \text{.....(2)}$$

From equations (1) & (2)

$$P_{gauge} = g\left(\rho_{Hg} h_3 - \rho_{oil} h_2 - \rho_{H_2O} h_1\right) \quad \text{.....(3)}$$

Step 4 of 4

Given data

The height of water $h_1 = 0.2\,\text{m}$

The density of water $\rho_{water} = \rho_{H_2O} = 1000\,\text{kg/m}^3$

The height of water $h_2 = 0.3\,\text{m}$

The density of oil $\rho_{oil} = 850\ \text{kg/m}^3$

The height of mercury $h_3 = 0.46\,\text{m}$

The density of mercury $\rho_{mercury} = \rho_{Hg} = 13,600\,\text{kg/m}^3$

Substituting all these values in equation (3)

$$\therefore P_{gauge} = 9.81(13,600 \times 0.46 - 850 \times 0.3 - 1000 \times 0.2)$$

$$= 56907\,\text{Pa}$$

$$\boxed{P_{gauge} = 56.907\,\text{kPa}}$$

Substituting all these values in equation (3)

$$\therefore P_{gauge} = 9.81(13,600 \times 0.46 - 850 \times 0.3 - 1000 \times 0.2)$$

$$= 56907\,\text{Pa}$$

$$\boxed{P_{gauge} = 56.907\,\text{kPa}}$$

Question: 2.036P

Determine the atmospheric pressure at a location where the barometric reading is 750 mm Hg. Take the density of mercury to be 13,600 kg/m3.

Step 1 of 2

Given the barometric reading 750 mm Hg

The barometer measures the atmospheric pressure directly

So, the height of mercury column is $h = 750\,\text{mm}$

From the hydrostatic equation $P = \rho g h$ ……(1)

Here $P_{atm} = \rho_{mercury}\, g h$

$\rho_{mercury} = 13,600\ \text{kg/m}^3$

$g = 9.81\,\text{m/s}^2$

Step 2 of 2

Substitute in above equation (1)

$$P_{atm} = 13,600 \times 9.81 \times 750 \times 10^{-3}$$

$$1\text{m} = 1000\,\text{mm}$$

$$= 100,062\ \frac{\text{kg}}{\text{m}^3} \cdot \frac{\text{m}}{\text{s}^2} \cdot \text{m}$$

$$= 100.1 \times 10^3 \times \text{N/m}^2$$

$$\frac{1\text{kg} \cdot \text{m}}{\text{s}^2} = 1\text{N}$$

$$\boxed{P_{atm} = 100.1\text{kPa}}$$

Substitute in above equation (1)

$$P_{atm} = 13,600 \times 9.81 \times 750 \times 10^{-3}$$

$$1\text{m} = 1000\,\text{mm}$$

$$= 100,062\ \frac{\text{kg}}{\text{m}^3} \cdot \frac{\text{m}}{\text{s}^2} \cdot \text{m}$$

$$= 100.1 \times 10^3 \times \text{N/m}^2$$

$$\frac{1\text{kg} \cdot \text{m}}{\text{s}^2} = 1\text{N}$$

$$\boxed{P_{atm} = 100.1\text{kPa}}$$

Question: 2.037P

The gage pressure in a liquid at a depth of 3 m is read to be 42 kPa. Determi ne the gage pressure in the same liquid at a depth of 9 m.

Step 1 of 3

Given:

Depth of the liquid $h_1 = 3\text{m}$

Pressure of the liquid $P_1 = 42\text{kPa}$

Depth of the liquid $h_2 = 9\text{m}$

Step 2 of 3

Pressure at a certain depth 'h' can be expressed as

$P = \rho \times g \times h$

Where

$\rho =$ Density of the liquid

$g =$ Acceleration due to gravity

Since liquid is same so that density and acceleration due to gravity of the liquid does not change or its remains constant.

$P_1 = \rho \times g \times h_1 \ldots\ldots\ldots\ldots (1)$

$P_2 = \rho \times g \times h_2 \ldots\ldots\ldots\ldots (2)$

Step 3 of 3

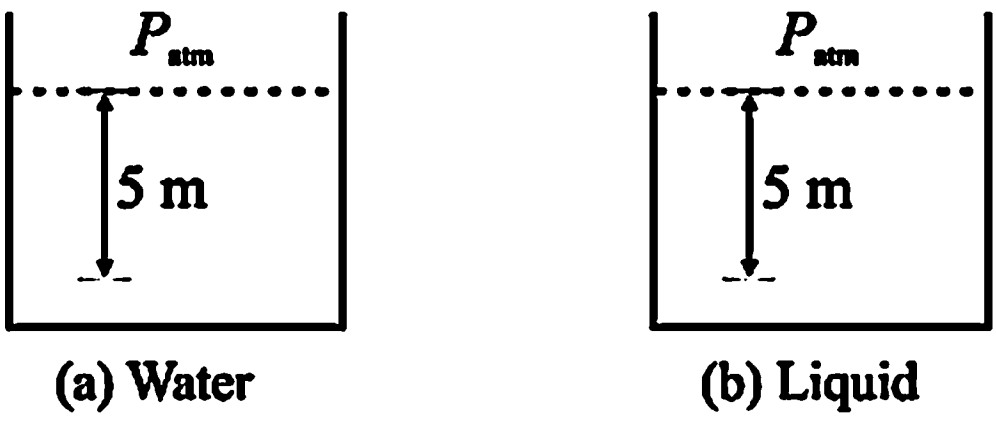
Dividing equation (1) by (2)

$$\frac{P_1}{P_2} = \frac{\rho \times g \times h_1}{\rho \times g \times h_2}$$

$$= \frac{h_1}{h_2}$$

$$\Rightarrow P_2 = \frac{P_1 \times h_2}{h_1}$$

$$= \frac{42 \times 9}{3}$$



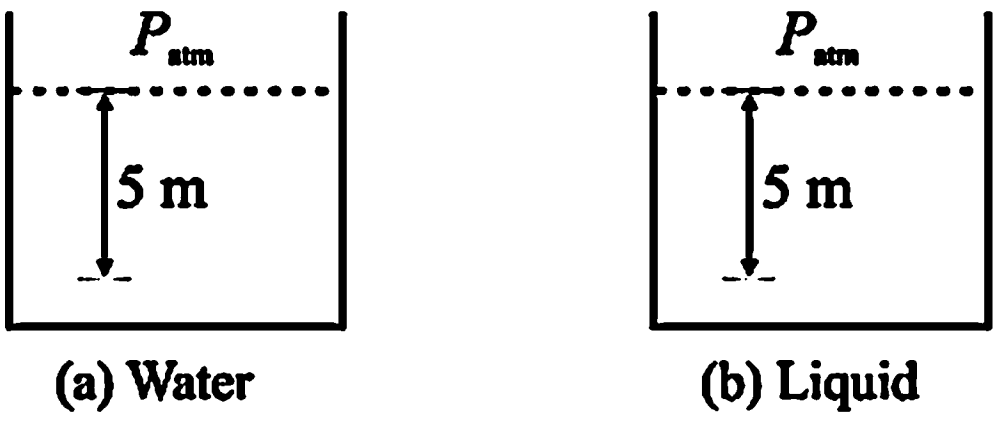
$$= 126\text{kPa}$$

$$\boxed{P_2 = 126\text{kPa}}$$

Question: 2.038P pg 1

The absolute pressure in water at a depth of 5 m is read to be 145 kPa. Determine (*a*) the local atmospheric pressure, and (*b*) the absolute pressure at a depth of 5 m in a liquid whose specific gravity is 0.85 at the same location.

Step 1 of 6



(a) Water (b) Liquid

Question:

The absolute pressure in water at a depth of 5 m is read to be 145 kPa. Determine (*a*) the local atmospheric pressure, and (*b*) the absolute pressure at a depth of 5 m in a liquid whose specific gravity is 0.85 at the same location.

Step 1 of 6

(a) Water (b) Liquid

Step 2 of 6

Specific gravity is defined as ratio of density of liquid to density of water

$$\text{i.e. } S.G = \frac{\rho_{liquid}}{\rho_{water}}$$

$$\therefore \rho_{liq} = 0.85 \times 1000$$

$$= 850 \text{ kg/m}^3$$

The absolute pressure in this liquid at a depth of 5m

$$P_{abs} = P_{atm} + \rho g h$$

$$= 95,950 + 850 \times 9.81 \times 5$$

$$= 137642 \text{ N/m}^2$$

$$\boxed{P_{abs} = 137.64 \text{ kPa}}$$

Step 5 of 6

Specific gravity is defined as ratio of density of liquid to density of water

$$\text{i.e. } S.G = \frac{\rho_{liquid}}{\rho_{water}}$$

$$\therefore \rho_{liq} = 0.85 \times 1000$$

$$= 850 \text{ kg/m}^3$$

The absolute pressure in this liquid at a depth of 5m

$$P_{abs} = P_{atm} + \rho g h$$

$$= 95,950 + 850 \times 9.81 \times 5$$

$$= 137642 \text{ N/m}^2$$

$$\boxed{P_{abs} = 137.64 \text{ kPa}}$$

Step 5 of 6

Step 6 of 6

Step 6 of 6

Question: 2.039P

Show that 1 kgf/cm2 = 14.223 psi.

Step 1 of 1

We have to prove that $1\text{kg f/cm}^2 = 14.223\text{psi}$

In English units

$\text{psi} = 1\,\text{pound} - \text{force per square inch}\ (\text{lbf/in}^2)$

$1\text{kg} = 2.2046\ \text{pounds}(\text{lbm})$

$1\text{kgf} = 2.2046\,\text{lbf}$

$1\text{inch} = 2.54\,\text{cm}$

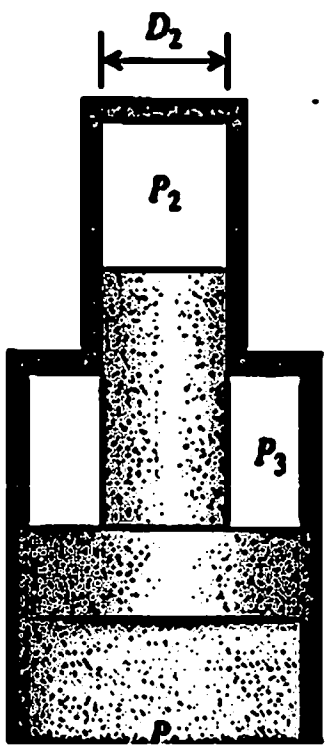
$$1\text{kgf/cm}^2 = \frac{2.2046\,\text{lbf}}{\frac{1}{(2.54)^2}\text{in}^2}$$

$$1\text{kgf/cm}^2 = 2.2046\times(2.54)^2\,\text{lbf/in}^2$$

$$= 14.223\,\text{lbf/in}^2$$

$\therefore$ $\boxed{1\text{kgf/cm}^2 = 14.223\ \text{psi}}$

Hence proved



$= 14.223\,\text{lbf/in}^2$

$\therefore$ $\boxed{1\text{kgf/cm}^2 = 14.223\ \text{psi}}$

Hence proved

Question:

The diameters of the pistons shown in Fig. P2-40E are $D1$ = 3 in and $D2$=1.5 in. Determine the pressure in chamber 3, in psia, when the other pressures are $p1$=150 psia and $P2$ = 250 psia.

Question:

The diameters of the pistons shown in Fig. P2-40E are $D1$ = 3 in and $D2$=1.5 in. Determine the pressure in chamber 3, in psia, when the other pressures are $p1$=150 psia and $P2$ = 250 psia.

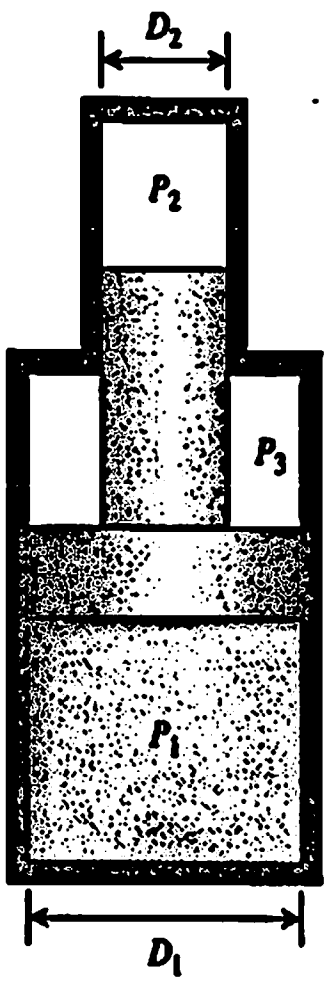


FIGURE P2-40E

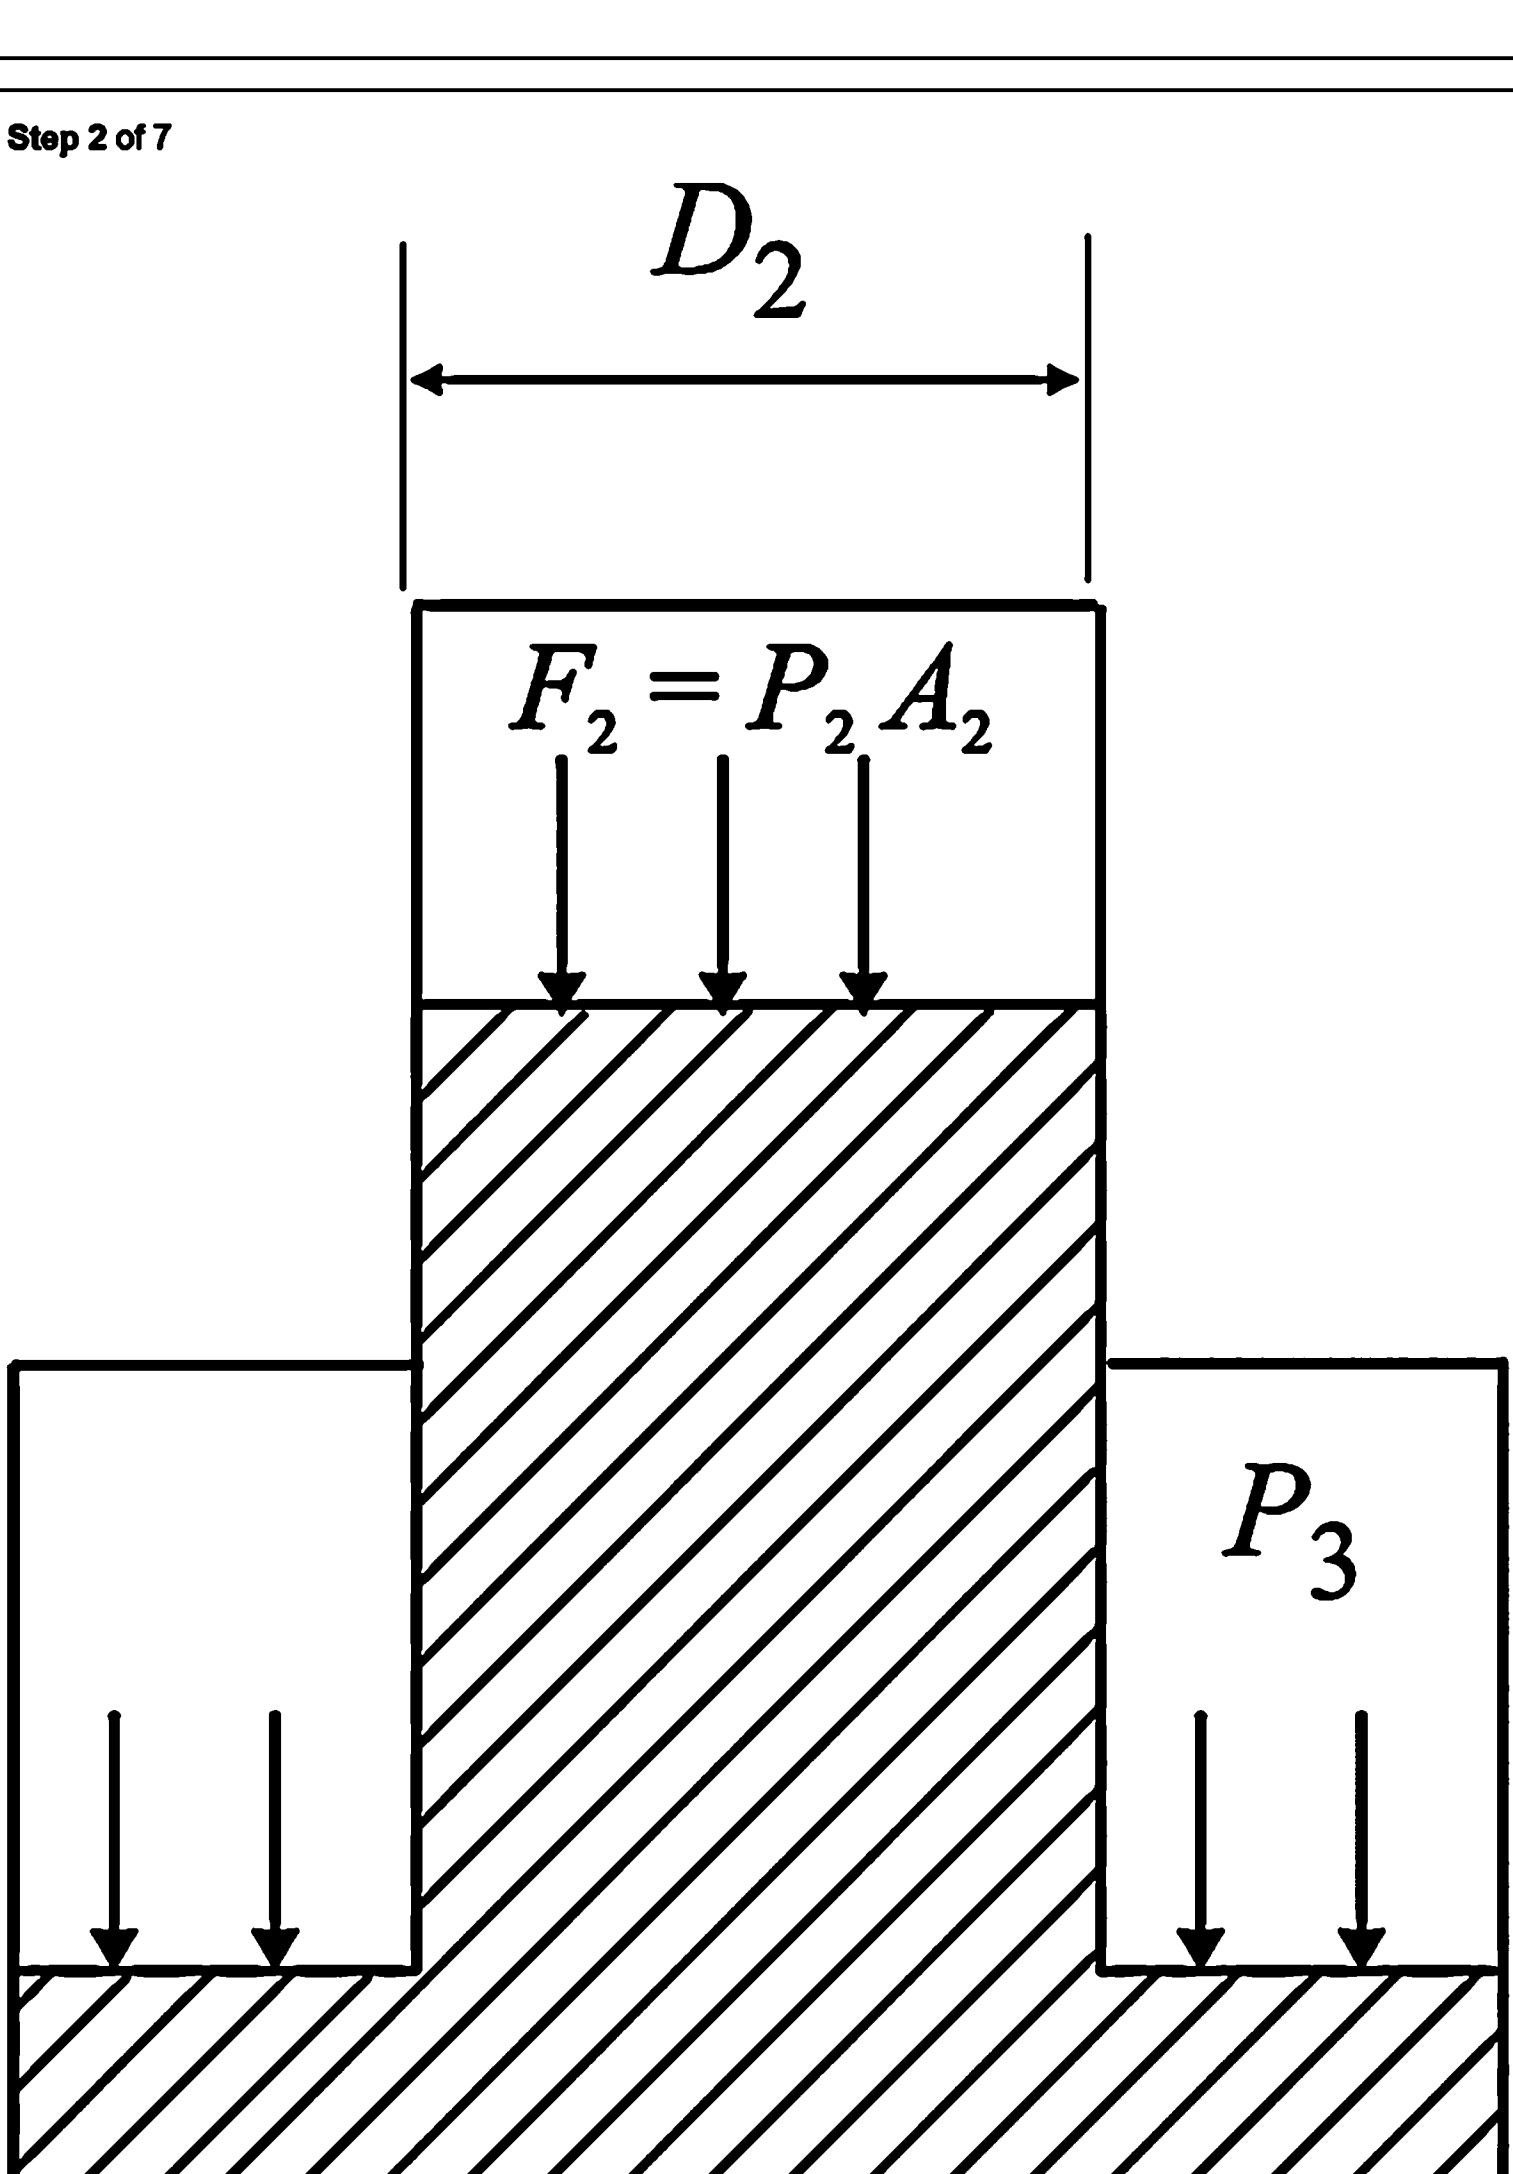
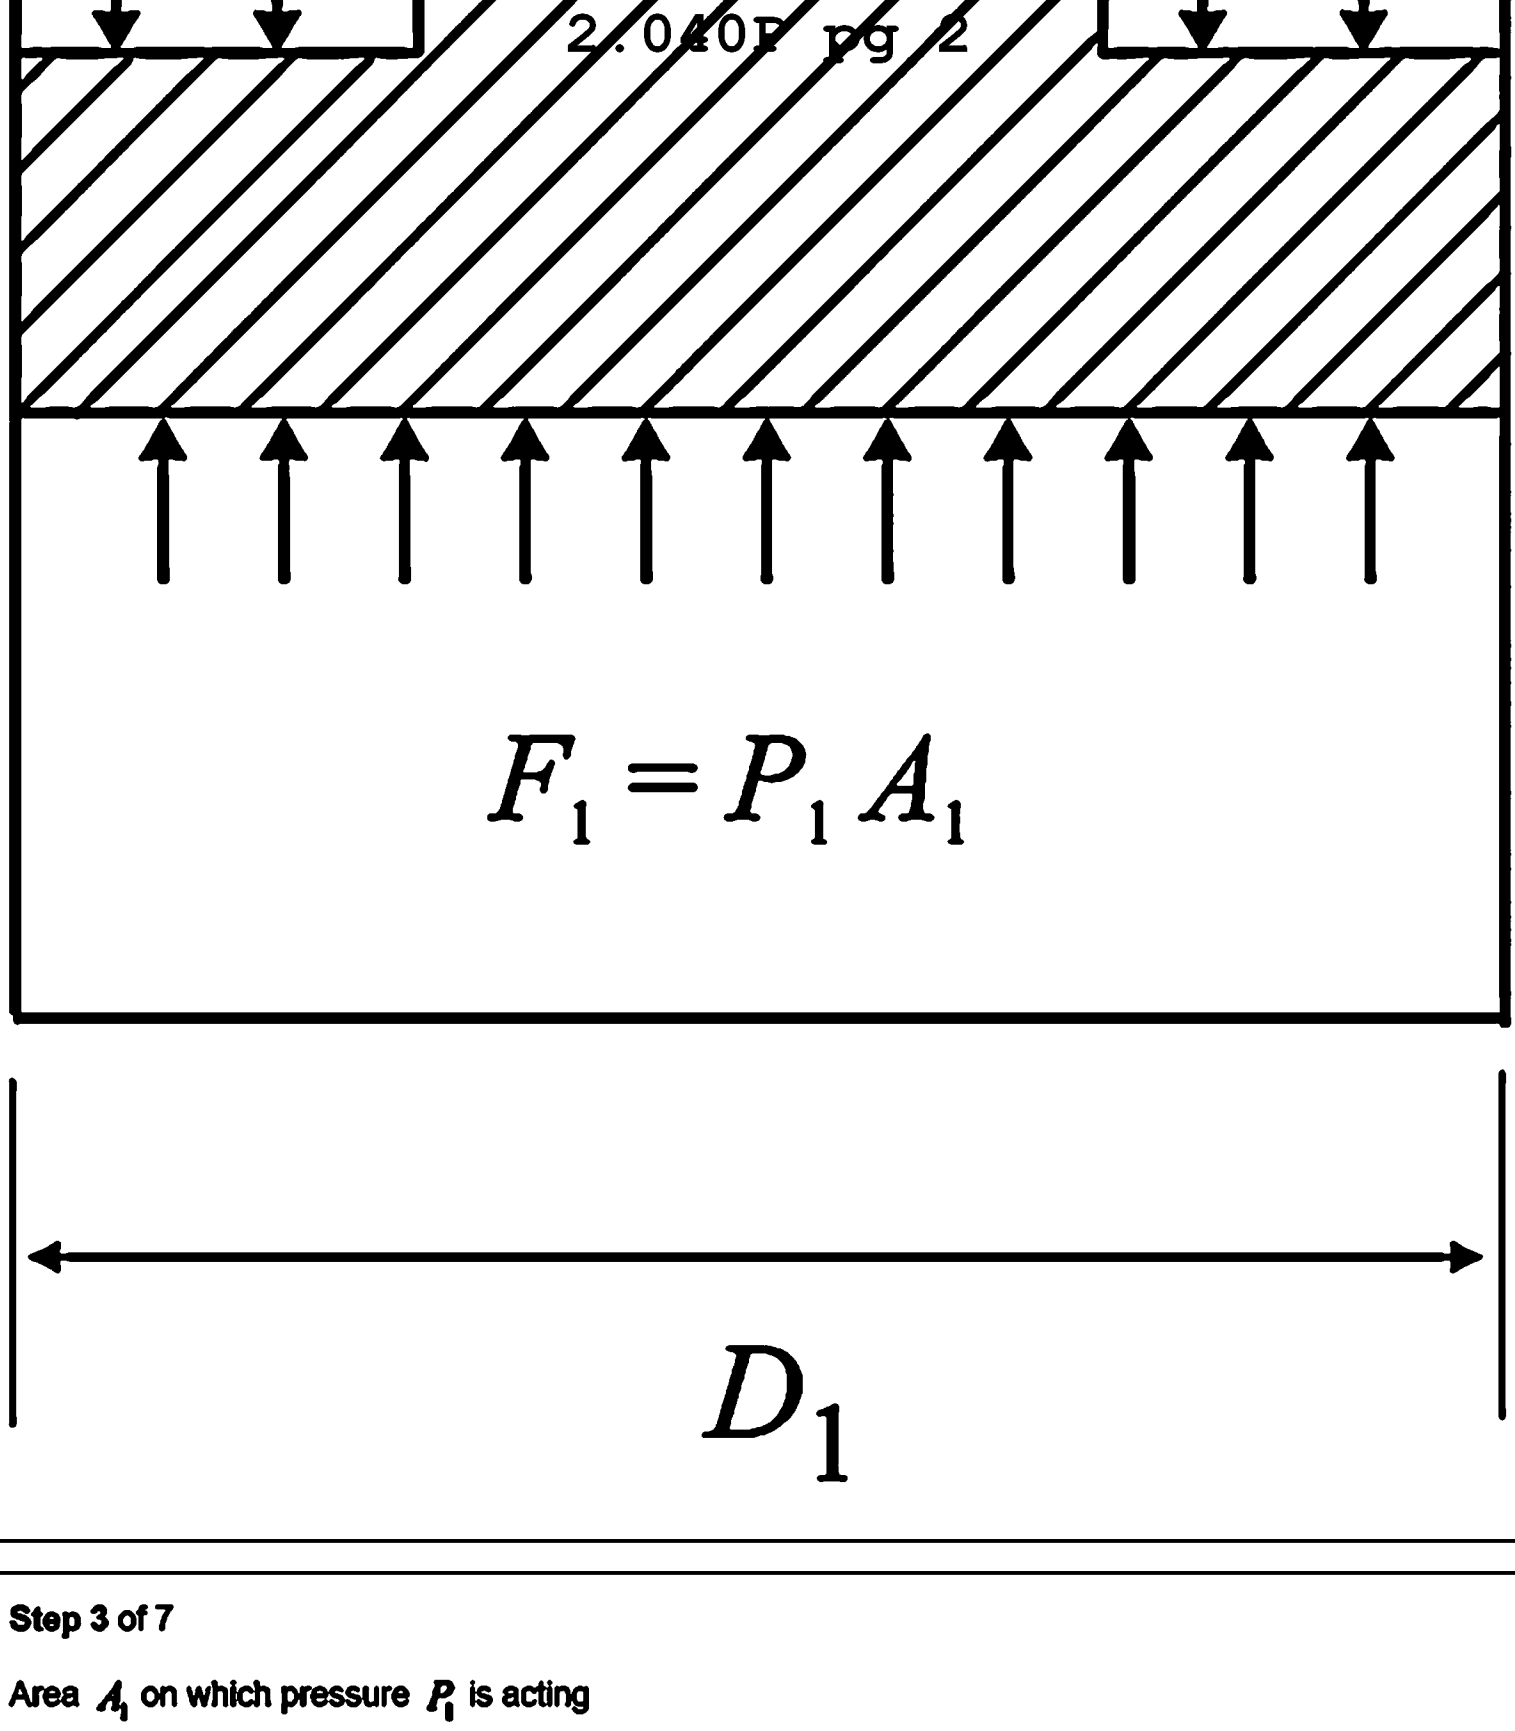
Step 1 of 7

Given:



Diameter of the piston 1 $D_1 = 3\,\text{in}$



Diameter of the piston 2 $D_2 = 1.5\,\text{in}$

Pressure in chamber 1 $P_1 = 150\,\text{psia}$

Pressure in chamber 1 $P_2 = 250\,\text{psia}$

Step 2 of 7

Step 3 of 7

Area A_1 on which pressure P_1 is acting

$$A_1 = \frac{\pi(D_1^2)}{4}$$

$$= \frac{\pi(3\text{in})^2}{4}$$

$$= 7.069\text{in}^2$$

Step 4 of 7

Force F_1 acting on piston

$$F_1 = P_1 A_1$$

$$= (150\text{psia})(7.069\text{in}^2)\left(\frac{1\frac{\text{lbf}}{\text{in}^2}}{1\text{psia}}\right)$$

$$= 1060.35\text{lbf}$$

Step 5 of 7

Area A_2 on which pressure P_2 is acting

$$A_2 = \frac{\pi(D_2^2)}{4}$$

$$= \frac{\pi(1.5\text{in})^2}{4}$$

$$= 1.76\text{in}^2$$

Force F_2 acting on piston

$$F_2 = P_2 A_2$$

$$= (250\text{psia})(1.76\text{in}^2)\left(\frac{1\frac{\text{lbf}}{\text{in}^2}}{1\text{psia}}\right)$$

$$= 441.78\text{lbf}$$

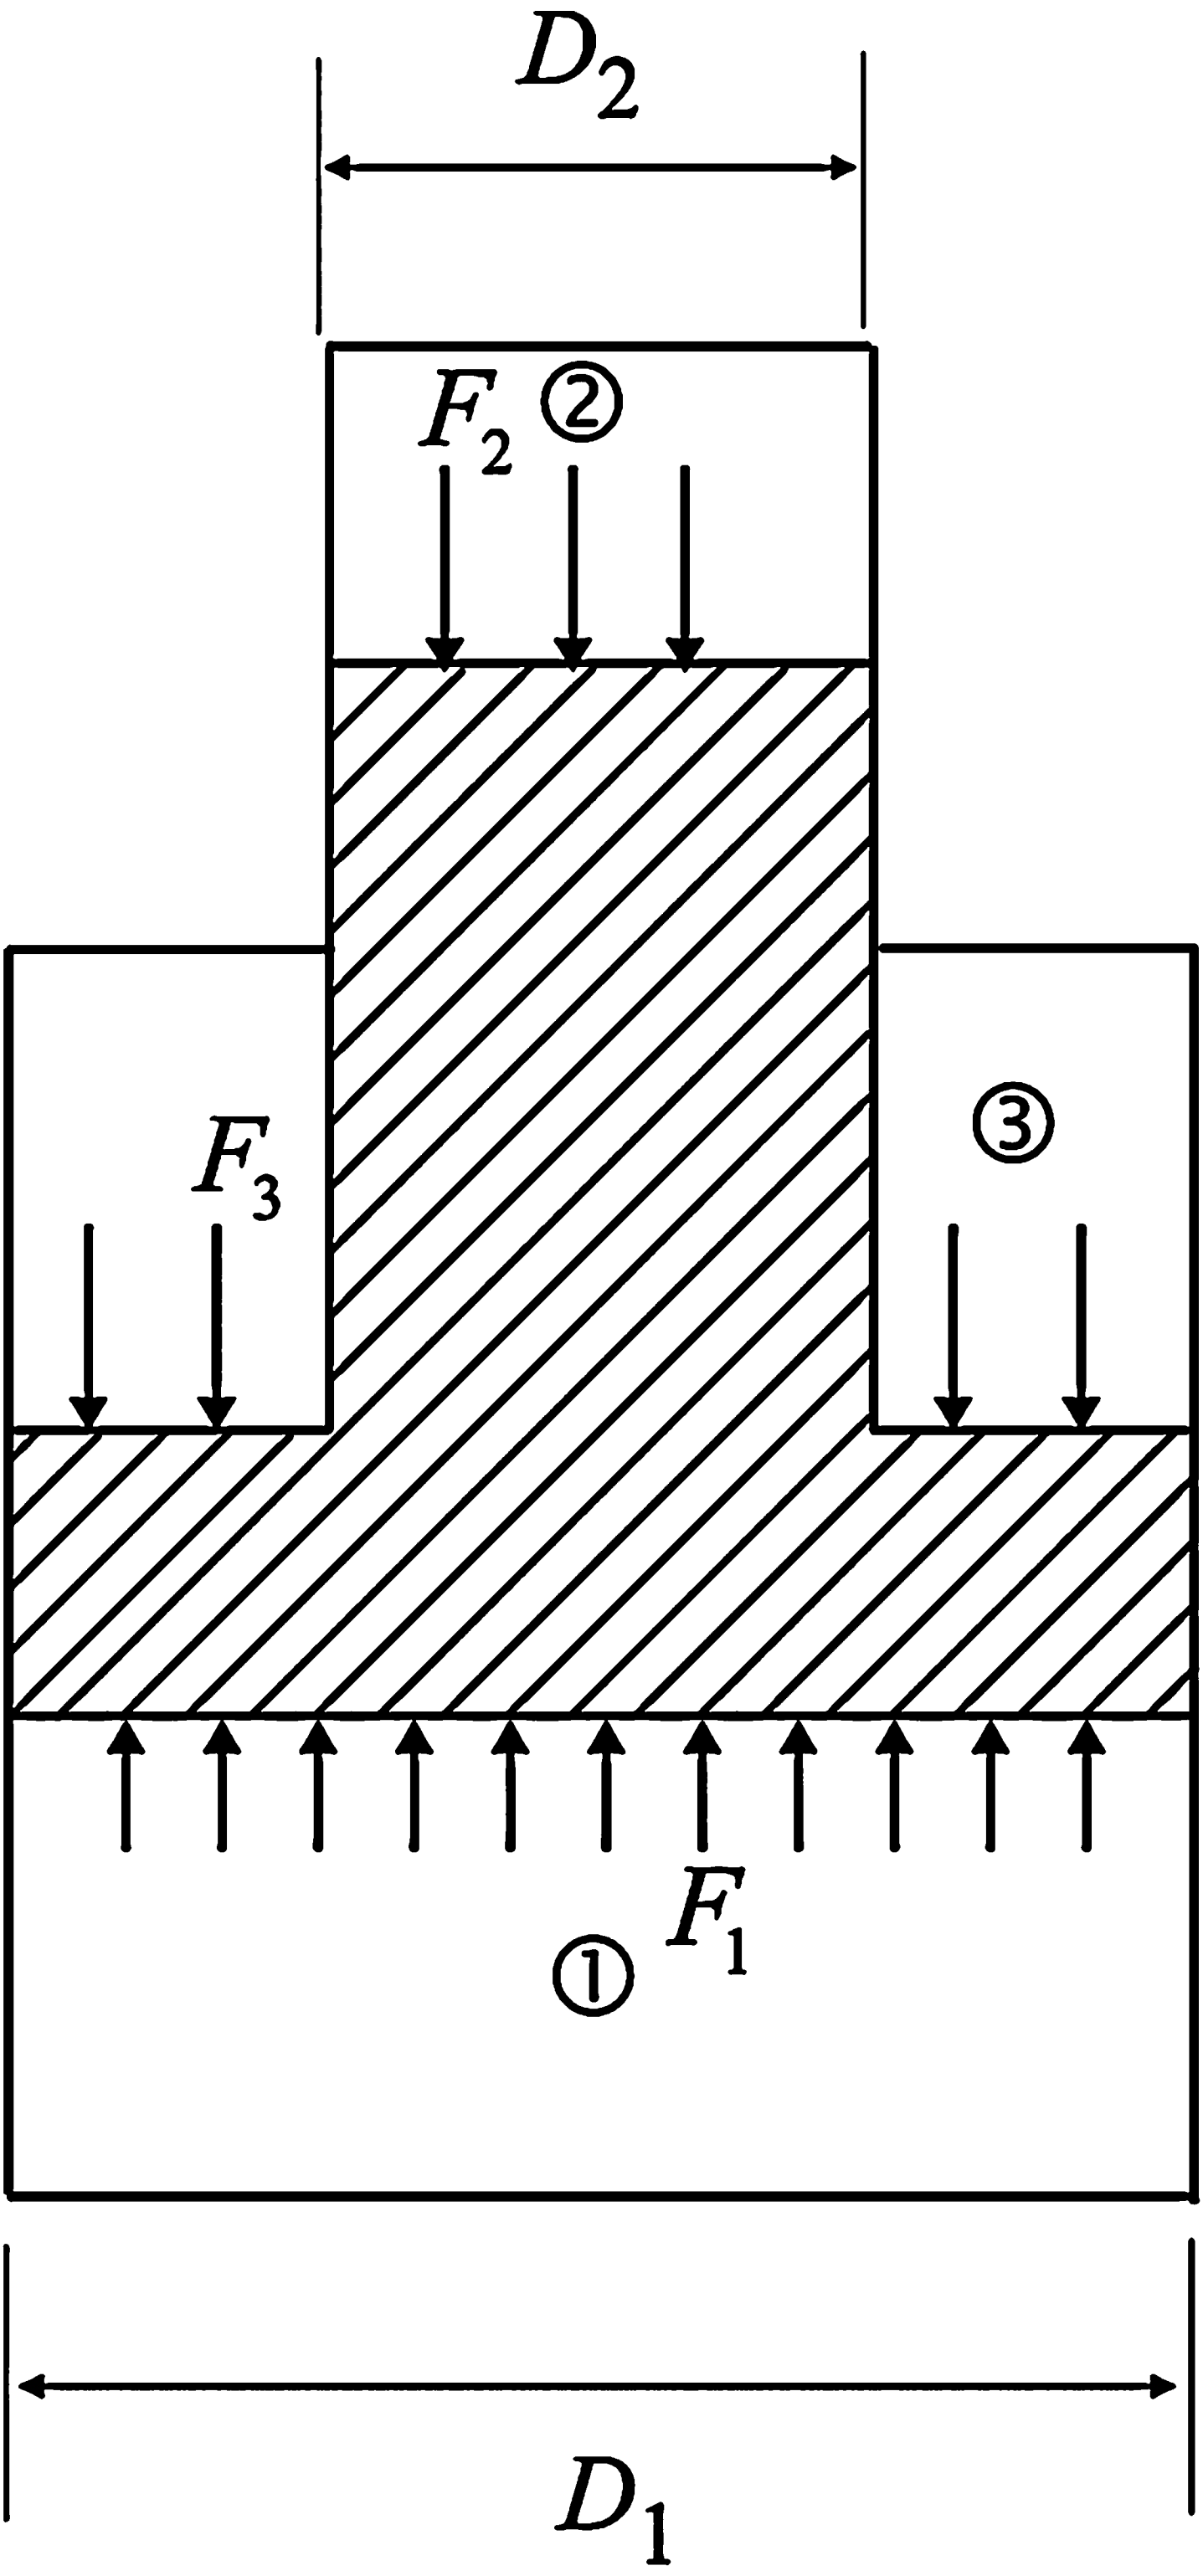
Step 6 of 7

So, net vertical force acting on the piston in downward direction to balance the piston

$$F_3 = F_1 - F_2$$

$$= (1060.35 - 441.78)\text{lbf}$$

$$= 618.56\text{lbf}$$



Area 'A_3' on which this force acts

Question: 2.041P pg 1

The piston diameters in Fig. P2-40E are $D1$ = 10 cm and $D2$ = 4 cm. When the pressure in chamber 2 is 2000 kPa and the pressure in chamber 3 is 700 kPa, what is the pressure in chamber 1, in kPa?

Step 1 of 5

Draw the schematic diagram of two-piston cylinder arrangement.

Step 2 of 5

Calculate the area of the piston on which force F_1 acts.

$$A_1 = \frac{\pi}{4} D_1^2$$

Here, diameter of the piston is D_1.

Substitute $0.1\,\text{m}$ for D_1.

$$A_1 = \frac{\pi}{4}(0.1)^2$$
$$= 7.854 \times 10^{-3}\ \text{m}$$

Step 3 of 5

Calculate the area of the piston on which force F_2 acts.

$$A_2 = \frac{\pi}{4} D_2^2$$

Here, diameter of the piston is D_2.

Substitute $0.04\,\text{m}$ for D_2.

$$A_2 = \frac{\pi}{4}(0.04)^2$$
$$= 1.257 \times 10^{-3}\ \text{m}$$

Step 4 of 5

Calculate the area of the piston on which force F_3 acts.

$$A_3 = A_1 - A_2$$

Step 4 of 5

Calculate the area of the piston on which force F_3 acts.

$$A_3 = A_1 - A_2$$

Here, the area of the piston on which force F_1 acts is A_1 and the area of the piston on which force F_2 acts is A_2.

Substitute $7.854\times10^{-3}\ \text{m}$ for A_1 and $1.257\times10^{-3}\ \text{m}$ for A_2.

$$\begin{aligned} A_3 &= \left(7.854\times10^{-3}\ \text{m}\right) - \left(1.257\times10^{-3}\ \text{m}\right) \\ &= 6.597\times10^{-3}\ \text{m} \end{aligned}$$

Step 5 of 5

According to Pascal's law, the force acting on the piston is given by the equation.

$$F = PA \quad \text{..... (1)}$$

Here, the pressure acting on the piston is P, and the area on which the pressure acting is A.

Calculate the sum of vertical forces acting on the piston.

$$\begin{aligned} \sum F_v &= 0 \\ F_2 + F_3 - F_1 &= 0 \end{aligned}$$

Substitute P_1A_1 for F_1, P_2A_2 for F_2 and P_3A_3 for F_3 in above equation according to equation (1).

$$\begin{aligned} P_2A_2 + P_3A_3 - P_1A_1 &= 0 \\ P_1A_1 &= P_2A_2 + P_3A_3 \\ P_1 &= \frac{P_2A_2 + P_3A_3}{A_1} \end{aligned} \quad \text{..... (2)}$$

Here, pressure in chamber 2 is P_2, pressure in chamber 3 is P_3, the area of the piston on which force F_1 acts is A_1, the area of the piston on which force F_2 acts is A_2 and the area of the piston on which force F_1 acts is A_3.

Substitute $2000\ \text{kPa}$ for P_2, $700\ \text{kPa}$ for P_3, $7.854\times10^{-3}\ \text{m}$ for A_1, $1.257\times10^{-3}\ \text{m}$ for A_2 and $6.597\times10^{-3}\ \text{m}$ for A_3 in equation (2).

$$\begin{aligned} P_1 &= \frac{\left(2000\times1.257\times10^{-3}\right) + \left(700\times6.597\times10^{-3}\right)}{7.854\times10^{-3}} \\ &= \frac{2.514 + 4.618}{7.854\times10^{-3}} \\ &= \frac{7.132}{7.854\times10^{-3}} \\ &= 908.07\ \text{kPa} \end{aligned}$$

Therefore, the pressure in chamber 1 of the two-piston cylinder is $\boxed{908\ \text{kPa}}$.

Question: 2.042P

Consider a 70-kg woman who has a total foot imprint area of 400 cm2. She wishes to walk on the snow, but the snow cannot withstand pressures greater than 0.5 kPa. Determine the minimum size of the snowshoes needed (imprint area per shoe) to enable her to walk on the snow without sinking.

Step 1 of 3

The maximum force exerted by a 70-kg women is her weight

Mass of a woman $m = 70\ \text{kg}$

Acceleration due to gravity of a earth $g = 9.81\ \text{m/s}^2$

The total foot imprints area $A = 400\ \text{cm}^2$

The maximum pressure the snow can withstand $p = 0.5\ \text{kPa}$

Step 2 of 3

$$\therefore \text{ Weight of the women} = mg$$
$$= 70 \times 9.81$$
$$= 686.7\ \text{kg} \cdot \text{m/s}^2$$
$$W = 686.7\ \text{N}$$

Step 3 of 3

The weight of the women will be acted on shown by her foot i.e., shoes

$$\therefore \text{ Weight of the women} = \text{pressure} \times \text{Area}$$
$$686.7 = 0.5 \times 10^3 \times A$$
$$\therefore \text{ Area of foot print } \boxed{A = 1.37\ \text{m}^2}$$

So, she can wear show-shoes which should not cover area more than $1.37\ \text{m}^2$

Question: 2.043P

A vacuum gage connected to a tank reads 30 kPa at a location where the barometric reading is 750 mm Hg. Determine the absolute pressure in the tank. Take ρHg = 13,590 kg/m3.

Step 1 of 3

Given:

Vacuum pressure $P_{vacuum} = 30\text{kPa}$

Density of $\rho_{Hg} = 13590\,\frac{\text{kg}}{\text{m}^3}$

Barometric reading $P = 750\,\text{mm of Hg}$

$= 0.75\text{m of Hg}$

Step 2 of 3

Atmospheric pressure in tank is

$$P_{atm} = \rho \times g \times h$$

$$= \left(13590\frac{\text{kg}}{\text{m}^3}\right)\left(9.81\frac{\text{m}}{\text{s}^2}\right)(0.75\text{m})\left(\frac{1\text{N}}{1\frac{\text{kg}\cdot\text{m}}{\text{s}^2}}\right)\left(\frac{1\text{kPa}}{1000\frac{\text{N}}{\text{m}^2}}\right)$$

$= 99.99\text{kPa}$

$= 100\text{kPa}$

Step 3 of 3

Absolute pressure in tank

$$P_{abs} = P_{atm} - P_{vac}$$

$= 100 - 30$

$= 70\text{kPa}$

$\boxed{P_{abs} = 70\text{kPa}}$

Question: 2.044P

The vacuum pressure of a condenser is given to be 80 kPa. If the atmospheric pressure is 98 kPa, what is the gage pressure and absolute pressure in kPa, kN/m2, lbf/in2, psi, and mm Hg.

Step 1 of 4

Calculate the Absolute pressure using the equation,

$$P_{abs} = P_{atm} - P_{vac}$$

Here, P_{atm} is the atmospheric pressure and P_{vac} is the vacuum pressure.

Substitute $98\,\text{kPa}$ for P_{atm} and $80\,\text{kPa}$ for P_{vac}.

$$\begin{aligned} P_{abs} &= 98\text{kPa} - 80\text{kPa} \\ &= 18\text{kPa} \end{aligned}$$

Therefore, the Absolute pressure is $\boxed{18\text{kPa}}$.

Calculate the Absolute pressure using the equation,

$$P_{gage} = P_{abs} - P_{atm}$$

Here, P_{atm} is the atmospheric pressure and P_{abs} is the absolute pressure.

Substitute $98\,\text{kPa}$ for P_{atm} and $18\,\text{kPa}$ for P_{abs}.

$$\begin{aligned} P_{gage} &= 18\text{kPa} - 98\text{kPa} \\ &= -80\text{kPa} \end{aligned}$$

Therefore, the gauge pressure is $\boxed{-80\text{kPa}}$.

Step 2 of 4

Convert the units of absolute pressure from kPa to kN/m^2

$$\begin{aligned} P_{abs} &= 18\text{kPa}\left|\frac{1\ \text{kN/m}^2}{1\,\text{kPa}}\right| \\ &= 18\,\text{kN/m}^2 \end{aligned}$$

Therefore, the absolute pressure in kN/m^2 is $\boxed{18\,\text{kN/m}^2}$.

Convert the units of gauge pressure from kPa to kN/m^2

$$\begin{aligned} P_{gage} &= -80\,\text{kPa}\left|\frac{1\ \text{kN/m}^2}{1\,\text{kPa}}\right| \\ &= -80\,\text{kN/m}^2 \end{aligned}$$

Therefore, the gauge pressure in kN/m^2 is $\boxed{-80\,\text{kN/m}^2}$.

Step 3 of 4

Convert the units of absolute pressure from kPa to lbf/in.^2

$$\begin{aligned} P_{abs} &= 18\text{kPa}\left|\frac{1.45\times10^{-1}\ \text{lbf/in.}^2}{1\,\text{kPa}}\right| \\ &= 2.61\,\text{lbf/in.}^2 \end{aligned}$$

Therefore, the absolute pressure in lbf/in.^2 is $\boxed{2.61\,\text{lbf/in.}^2}$.

Convert the units of gauge pressure from kPa to lbf/in.^2

$$\begin{aligned} P_{gage} &= -80\text{kPa}\left|\frac{1.45\times10^{-1}\ \text{lbf/in.}^2}{1\,\text{kPa}}\right| \\ &= 11.6\,\text{lbf/in.}^2 \end{aligned}$$

Therefore, the gauge pressure in lbf/in.^2 is $\boxed{11.6\,\text{lbf/in.}^2}$.

Step 4 of 4

Convert the units of absolute pressure from kPa to mm of Hg.

$$\begin{aligned} P_{abs} &= 18\text{kPa}\left|\frac{7.5\,\text{mm of Hg}}{1\,\text{kPa}}\right| \\ &= 135\,\text{mm of Hg.} \end{aligned}$$

Therefore, the absolute pressure in mm of Hg. is $\boxed{135\,\text{mm of Hg.}}$.

Convert the units of gauge pressure from kPa to mm of Hg.

$$\begin{aligned} P_{gage} &= -80\text{kPa}\left|\frac{7.5\,\text{mm of Hg}}{1\,\text{kPa}}\right| \\ &= -600\,\text{mm of Hg} \end{aligned}$$

Therefore, the gauge pressure in mm of Hg is $\boxed{-600\,\text{mm of Hg}}$.

The Negative sign indicates rise of mercury above sea level.

Question: 2.045P

The barometer of a mountain hiker reads 740 mbars at the beginning of a hiking trip and 630 mbars at the end. Neglecting the effect of altitude on local gravitational acceleration, determine the vertical distance climbed. Assume an average air density of 1.20 kg/m3.

Step 1 of 3

Given:-

Density of air $\rho_{air} = 1.20 \frac{kg}{m^3}$

Pressure at top of the mountain hiker $P_{Top} = 740 mbar$

Pressure at Bottom of the mountain hiker $P_{Bottom} = 630 mbar$

Step 2 of 3

We know that

Force balance equation we get

$(\rho g h)_{air} = P_{bottom} - P_{top} \ldots\ldots (1)$

$P_{bottom} - P_{top} = (740 - 630) mbar$

$= 110 m\,bar$

$= 0.11 bar$

Step 3 of 3

Substitute the values in equation we get

$\rho \times g \times h = 11 \times 10^3$

$$h = \frac{0.11 bar}{\left(1.20 \frac{kg}{m^3}\right) \times \left(9.81 \frac{m}{s^2}\right) \left(\frac{1N}{1 \frac{kg \cdot m}{s^2}}\right) \left(\frac{1 bar}{100000 \frac{N}{m^2}}\right)}$$

$= 934.42 m$

$\boxed{h \approx 934 m}$

Question: 2.046P

Consider a 1.75-m-tall man standing vertically in water and completely submerged in a pool. Determine the difference between the pressures acting at the head and at the toes of the man, in kPa.

Step 1 of 3

Given:

Height of man $h_2 - h_1 = 1.75\text{m}$

Taking density of water $\rho_{water} = 1000\ \frac{\text{kg}}{\text{m}^3}$

Step 2 of 3

Let h_1 and h_2 be the height of the man top and bottom respectively.

Pressure at depth

$h = \rho \times g \times h$

Where 'g' is the acceleration due to gravity $= 9.81\frac{\text{m}}{s^2}$

Pressure at the head of man

$P_{Head} = \rho \times g \times h_1$

Pressure at the toes of man

$P_{Bottom} = \rho \times g \times h_2$

$h_2 - h_1 =$ Height of man

Step 3 of 3

Pressure difference between toes and head of a man

$P_{Dif} = \rho \times g \times (h_2 - h_1)$

$$= \left(1000\frac{\text{kg}}{\text{m}^3}\right)\left(9.81\frac{\text{m}}{s^2}\right)(1.75\text{m})\left(\frac{1\text{N}}{1\frac{\text{kg}\cdot\text{m}}{s^2}}\right)\left(\frac{1\text{kPa}}{1000\frac{\text{N}}{\text{m}^2}}\right)$$

$$= 17.17\text{kPa}$$

$\boxed{P_{Dif} = 17.17\ \text{kPa}}$

Question: 2.048P

Reconsider Prob. 2–47. Using EES (or other) software, investigate the effect of the spring force in the range of 0 to 500 N on the pressure inside the cylinder. Plot the pressure against the spring force, and discuss the results.

Step 1 of 4

Given data:

The effect of the spring force initially on the cylinder, $F_i = 0$ N

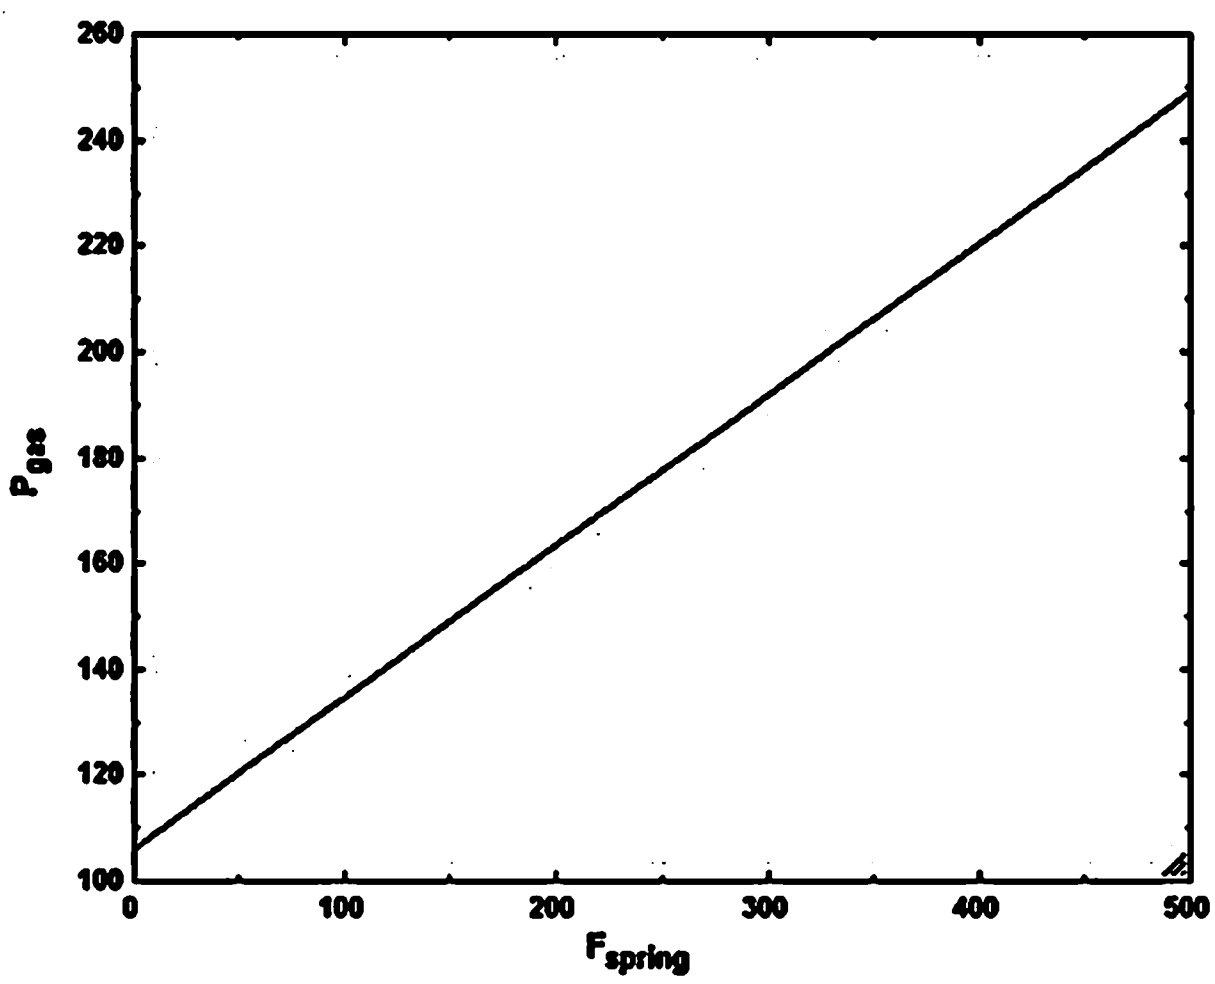
The effect of the spring force finally on the cylinder, $F_f = 500$ N

Step 2 of 4

By Using the EES software, we have to write the above equation in new window.

File Edit Search Options Calculate Tables Plots Windows Help Therm

```
g=9.807 [m/s^2]
P_atm=95 [kPa]
m_piston=4 [kg]
"{F_spring=60 [N]}"
A=35*CONVERT('cm^2','m^2')"[m^2]"
W_piston=m_piston*g"[N]"
F_atm=P_atm*A*CONVERT('kPa','N/m^2')"[N]"
"From the free body diagram of the piston, the balancing vertical forces yield:"
F_gas=F_atm+F_spring+W_piston"[N]"
"P_gas=F_gas/A*CONVERT('N/m^2','kPa')"[kPa]"
```



Step 3 of 4

After writing the equations in the Equation window then click on table in menu bar. Then select new parameter table. The spring force varying from the value $F = 0$ to 500 N we get

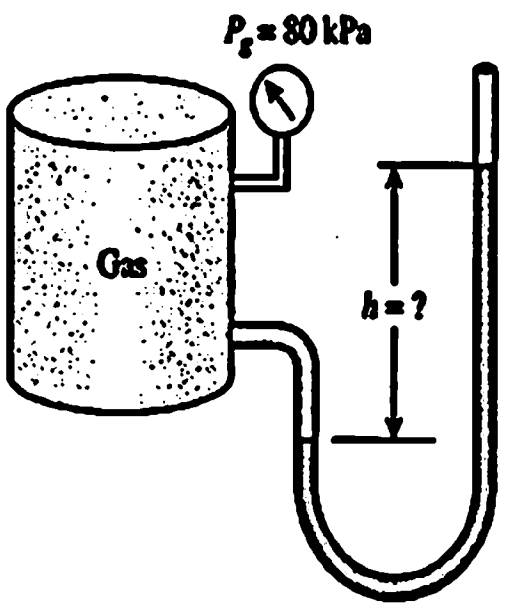
$\triangleright$ 1..10	1 F_{spring}	2 P_{gas}
Run 1	0	106.2
Run 2	55.56	122.1
Run 3	111.1	138
Run 4	166.7	153.8
Run 5	222.2	169.7
Run 6	277.8	185.6
Run 7	333.3	201.4
Run 8	388.9	217.3
Run 9	444.4	233.2
Run 10	500	249.1

Step 4 of 4

By plotting the graph between springs force versus Pressure of the gas:

Question: 2.049P

Both a gage and a manometer are attached to a gas tank to measure its pressure. If the reading on the pressure gage is 80 kPa, determine the distance between the two fluid levels of the manometer if the fluid is (*a*) mercury (ρ = 13,600 kg/m3) or (*b*) water (ρ = 1000 kg/m3).



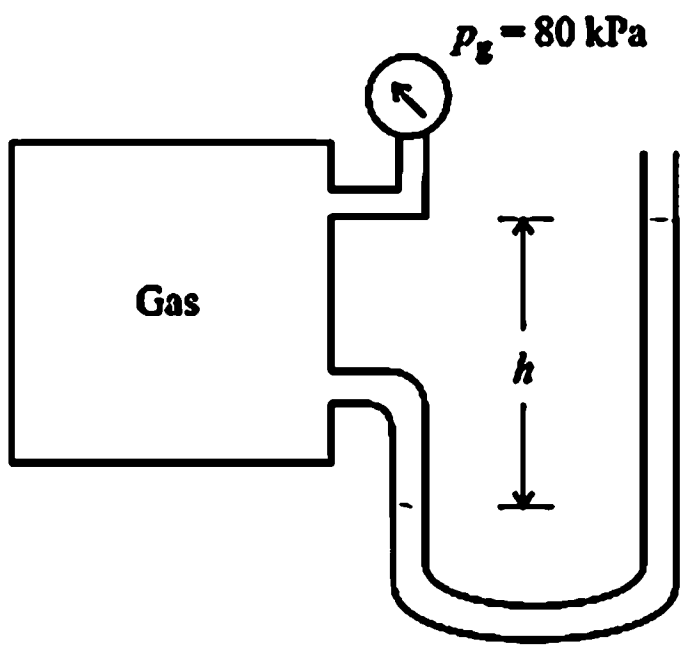


FIGURE P2–49

Step 1 of 4

Step 2 of 4

Given

The gage pressure $p_{gage} = 80$ kPa

The gage pressure related to the height of liquid in manometer is

$$p_{gage} = \rho g h$$

Step 3 of 4

(a) Fluid-Mercury (Hg)

The density of mercury $\rho_{Hg} = 13,600 \text{ kg/m}^3$,

$$g = 9.81 \text{ m/s}^2$$

$$p_{gage} = \rho_{Hg} g h$$

$$h = \frac{80 \times 10^3}{13,600 \times 9.81}$$

$$\boxed{h = 0.6 \text{ m}}$$

Step 4 of 4

(b) The density of Water $\rho = 1000 \text{ kg/m}^3$

$$\text{Here } h = \frac{p_{gage}}{\rho_{H_2O} \times g}$$

$$= \frac{80 \times 10^3}{10^3 \times 9.81}$$

$$\boxed{h = 8.155 \text{ m}}$$

Question: 2.050P

Reconsider Prob. 2–49. Using EES (or other) software, investigate the effect of the manometer fluid density in the range of 800 to 13,000 kg/m3 on the differential fluid height of the manometer. Plot the differential fluid height against the density, and discuss the results.

Step 1 of 1

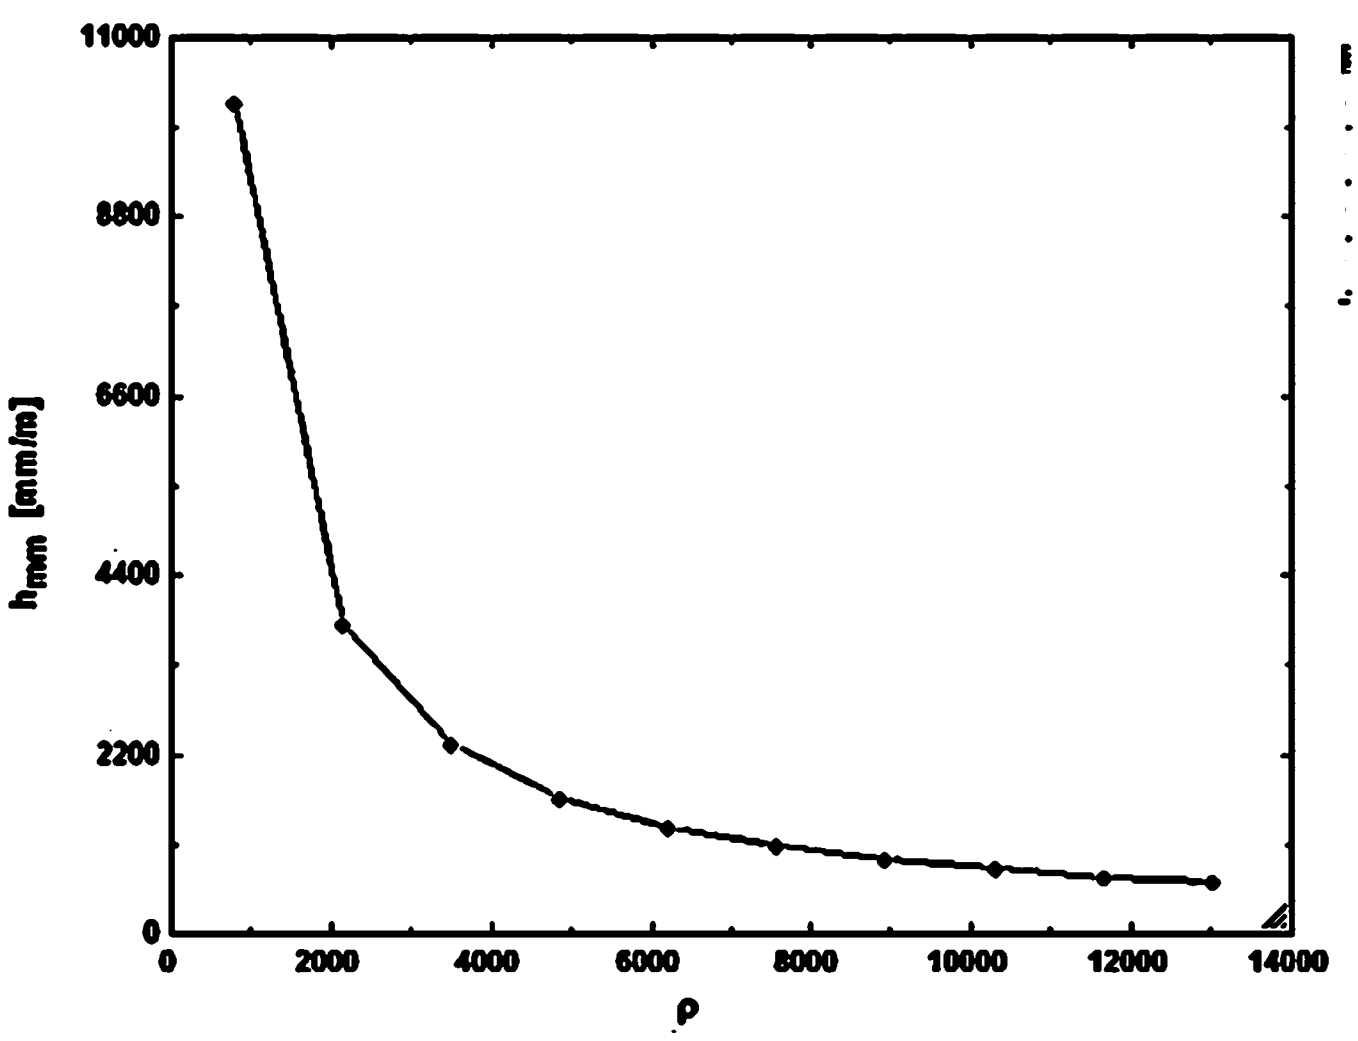
4749-2-50P **AID: 1118 | 23/5/2012**

Initial fluid density in the manometer, $\rho_i = 800\ kg/m^3$

Final fluid density in the manometer, $\rho_f = 13000\ kg/m^3$

By Using the EES software, we have to write the above equation in new window.

```
Function fluid_density(Fluid$)
If fluid$='Mercury' then fluid_density=13600[kg/m^3] else fluid_density=1000[kg/m^3]
end



Fluid$='Mercury'
    P_atm = 101.325 [kPa]
        DELTAP=80 [kPa]
g=9.807 [m/s^2]
"rho=Fluid_density(Fluid$)"  "Get the fluid density, either Hg or H2O, from the function."

"To plot fluid height against density place {} around the above equation. Then set up the
parametric table and solve."
DELTAP = rho*g*h*CONVERT(Pa, kPa)
h_mm=h*convert(m, mm)    "The fluid height in mm is found using the built-in CONVERT function."
P_abs= P_atm + DELTAP    "Definition relating gage and absolute pressure."
```

After writing the equations in the Equation window then click on table in menu bar. Then select new parameter table. The density varying from the value $\rho = 800$ to $13000\ kg/m^3$ we get

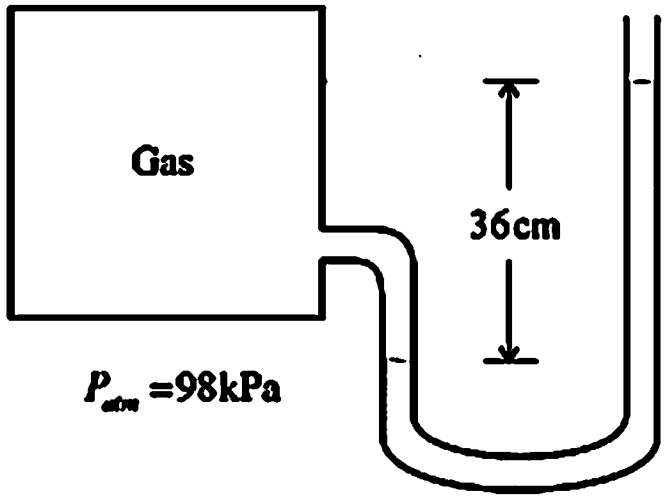
1..10	h_{mm} [mm/m]	ρ
Run 1	10197	800
Run 2	3784	2156
Run 3	2323	3511
Run 4	1676	4867
Run 5	1311	6222
Run 6	1076	7578
Run 7	913.1	8933
Run 8	792.8	10289
Run 9	700.5	11644
Run 10	627.5	13000

By plotting the graph between density versus manometer height:

Question: 2.051P

A manometer containing oil (ρ = 850 kg/m3) is attached to a tank filled with air. If the oil-level difference between the two columns is 36 cm and the atmospheric pressure is 98 kPa, determine the absolute pressure of the air in the tank.

Step 1 of 3



Density of oil $\rho_{oil} = 850 \frac{kg}{m^3}$

Oil level difference in the manometer $h = 36\,cm$

$= 0.36\,m$

Atmospheric pressure $P_{atm} = 98 kPa$

Step 2 of 3

Step 3 of 3

Absolute pressure of the air in the tank is

$P_{abs} = P_{atm} + P_{gauge}$

$P_{abs} = P_{atm} + (\rho \times g \times h)$

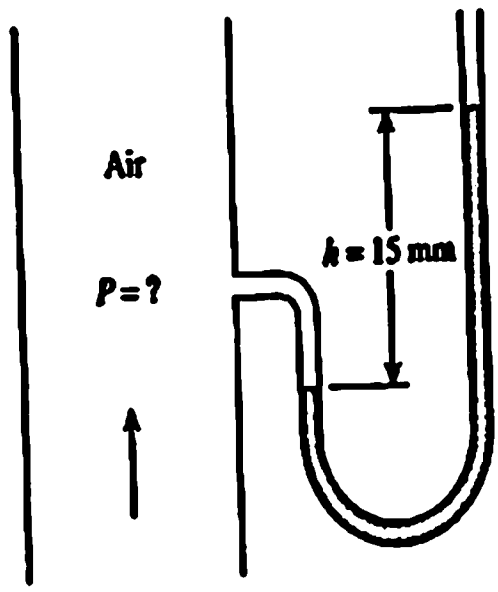
$$= 98 kPa + \left[\left(850 \frac{kg}{m^3} \right) \left(9.81 \frac{m}{s^2} \right) (0.36 m) \left(\frac{1 kPa}{1000 \frac{N}{m^2}} \right) \right]$$

$= 101 kPa$

$\boxed{P_{abs} = 101 kPa}$

Question: 2.052P

A mercury manometer (ρ = 13,600 kg/m3) is connected to an air duct to measure the pressure inside. The difference in the manometer levels is 15 mm, and the atmospheric pressure is 100 kPa. (*a*) Judging from Fig. P2-52, determine if the pressure in the duct is above or below the atmospheric pressure, (*b*) Determine the absolute pressure in the duct.



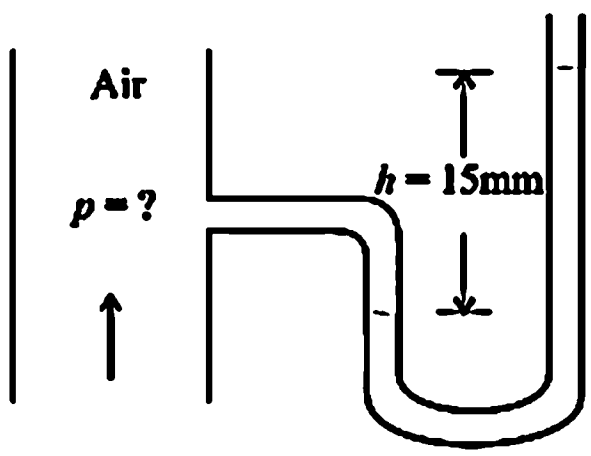


FIGURE P2-52

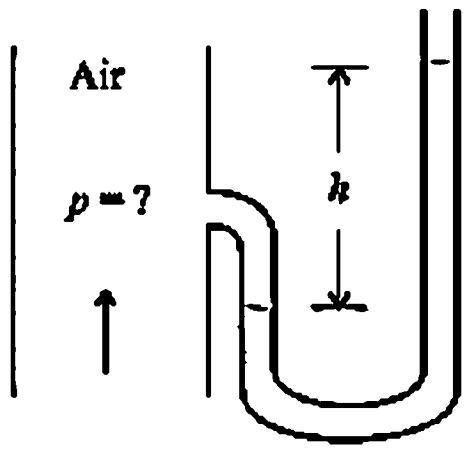
Step 1 of 4

Step 2 of 4

(a) From figure the mercury column is lower where our pressure is acting. So the pressure 'p' is more than atmospheric pressure, which pushes the mercury in the manometer.

Step 3 of 4

(b)
Given
The atmospheric pressure $p_{atm} = 100\ \text{kPa}$
The density of mercury $\rho_{Hg} = 13,600\ \text{kg/m}^3$
The difference in the manometer levels $h = 15\ \text{mm}$



Step 4 of 4

$$p_{absolute} = p_{atm} + \rho g h$$
$$1\ \text{mm} = 10^{-3}\ \text{m}$$
$$g = 9.81\ \text{m/s}^2$$
$$\therefore\ p_{abs} = 100\times10^3 + 13,600\times9.81\times15\times10^{-3}$$
$$= 100\times10^3 + 2\times10^3$$
$$= 102\times10^3\ \text{Pa}$$
$$\boxed{p = 102\ \text{kPa}}$$

Question: 2.053P

Repeat Prob. 2–52 for a differential mercury height of 45 mm.

Step 1 of 3

Step 2 of 3

Given

Atmospheric pressure $p_{atm} = 100\,\text{kPa}$

Density of mercury $\rho_{Hg} = 13,600\,\text{kg/m}^3$

The difference of mercury column in manometer $\left.\begin{array}{l} h = 45\,\text{mm} \\ \quad = 45\times10^{-3}\,\text{m} \end{array}\right\}$

$g = 9.81\,\text{m/s}^2$

Step 3 of 3

Absolute pressure $'p'_{abs} = p_{atm} + \rho g h$

Here $p = 100\times10^3 + 13600\times9.81\times45\times10^{-3}$

$= 100\times10^3 + 6\times10^3$

$= 106\times10^3\,\text{N/m}^2$

$\boxed{p = 106\,\text{kPa}}$

Question: 2.054P

Blood pressure is usually measured by wrapping a closed air-filled jacket equipped with a pressure gage around the upper arm of a person at the level of the heart. Using a mercury manometer and a stethoscope, the systolic pressure (the maximum pressure when the heart is pumping) and the diastolic pressure (the minimum pressure when the heart is resting) are measured in mm Hg. The systolic and diastolic pressures of a healthy person are about 120 mm Hg and 80 mm Hg, respectively, and are indicated as 120/80. Express both of these gage pressures in kPa, psi, and meter water column.

Step 1 of 5

The minimum heart pressure of a healthy person is 80 mmHg

The maximum heart (blood) pressure of a healthy person is 120 mmHg

The gage pressure $\boxed{p = \rho g h}$

Step 2 of 5

(a) In kPa

Low pressure $p_{low} = \rho g h$

Here ρ is $\rho_{Hg} = 13,600$

$h = 80 \text{ mm}$

$= 80 \times 10^{-3} \text{m}$

$g = 9.81 \text{ m/s}^2$

$\therefore \quad p_{low} = 13,600 \times 80 \times 10^{-3} \times 9.81$

$\boxed{p_{low} = 10.67 \text{ kPa}}$

High pressure $p_{high} = \rho_{Hg} g h$

Here $h = 120 \text{ mm}$

$\therefore \quad p_{high} = 13,600 \times 9.81 \times 120 \times 10^{-3}$

$p_{high} = 16,000 \text{ N/m}^2$

$\boxed{p_{high} = 16 \text{ kPa}}$

Step 3 of 5

(b) In psi

$1 \text{ psi} = 6.896 \text{ kPa}$

$p_{low} = 10.67 \text{ kPa}$

$= 10.67 \dfrac{1 \text{ psi}}{6.896}$

$\boxed{p_{low} = 1.54 \text{ psi}}$

$p_{high} = 16 \text{ kPa}$

$= 16 \cdot \dfrac{1 \text{ psi}}{6.896}$

$\boxed{p_{high} = 2.32 \text{ psi}}$

Step 4 of 5

(c) In meter water column

Given in mm of Hg

We have to convert into m of H_2O

Density of water $\rho_{H_2O} = 1000 \text{ kg/m}^3$

From the relation $p = \rho g h$

Here $\rho_{H_2O} g h_{H_2O} = \rho_{Hg} g h_{Hg}$

$$h_{H_2O} = \frac{\rho_{Hg}}{\rho_{H_2O}} \times h_{Hg}$$

Step 5 of 5

$\therefore$ Low pressure water column

$$h_{H_2O} = \frac{13,600}{1000} \times 80 \times 10^{-3}$$

$\boxed{h_{H_2O} = 1.088 \text{ m}}$

High pressure water column

$$h_{H_2O} = \frac{13,600}{1000} \times 120 \times 10^{-3}$$

$\boxed{h_{H_2O} = 1.632 \text{ m}}$

Question: 2.055P

The maximum blood pressure in the upper arm of a healthy person is about 120 mm Hg. If a vertical tube open to the atmosphere is connected to the vein in the arm of the person, determine how high the blood will rise in the tube. Take the density of the blood to be 1050 kg/m3.

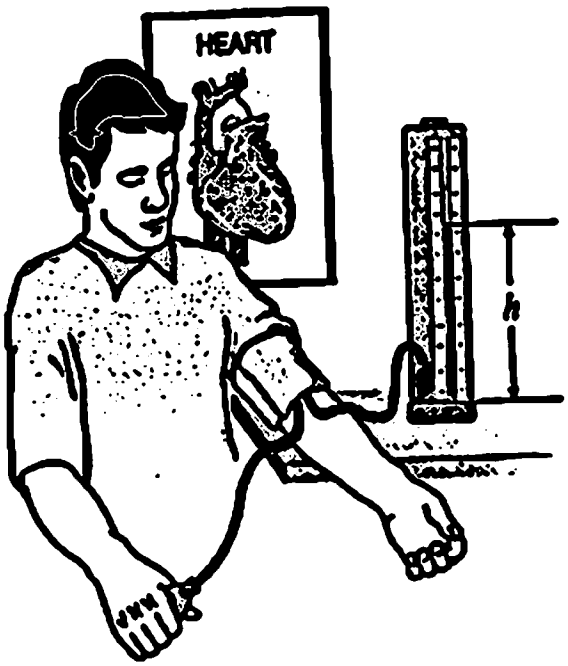


FIGURE P2-55

Step 1 of 1

Given

the maximum blood pressure of a healthy man = 120 mm of Hg

If a vertical cube open to the atmosphere is connected to the vain, the maximum height the blood rises will be equal to the 120 mmHg

i.e., $\rho_{blood} g h_{blood} = \rho_{Hg} g h_{Hg}$

$$\therefore \quad h_{blood} = \frac{\rho_{Hg}}{\rho_{blood}} \times h_{Hg}$$

Given $\rho_{blood} = 1050 \text{ kg/m}^3$

$\rho_{Hg} = 13,600$

$h_{Hg} = 120 \text{ mm}$

$$\therefore \quad h_{blood} = \frac{13,600}{1050} \times 120 \times 10^{-3} \text{m}$$

$$\boxed{h_{blood} = 1.55 \text{ m}}$$

The height raised by blood

Question: 2.056P

Determine the pressure exerted on a diver at 30 m below the free surface of the sea. Assume a barometric pressure of 101 kPa and a specific gravity of 1.03 for seawater.

Step 1 of 3

Given:

Specific gravity of sea water $S.G = 1.03$

Barometric pressure $P = 101\text{kPa}$

Height of the head From the free surface $h = 30\text{m}$

Step 2 of 3

Taking density of water $\rho_{Water} = 1000\ \frac{\text{kg}}{\text{m}^3}$

Density of sea water $\rho_{seawater} = \text{specific gravity} \times \rho_{water}$

$$= 1.03 \times 1000\ \frac{\text{kg}}{\text{m}^3}$$

$$= 1030\ \frac{\text{kg}}{\text{m}^3}$$

Step 3 of 3

The pressure exerted on diver at 30m below the fresh surface of the sea is the absolute pressure at that point

$P = P_{atm} + P_{gauge}$

$P = P_{atm} + (\rho \times g \times h)$

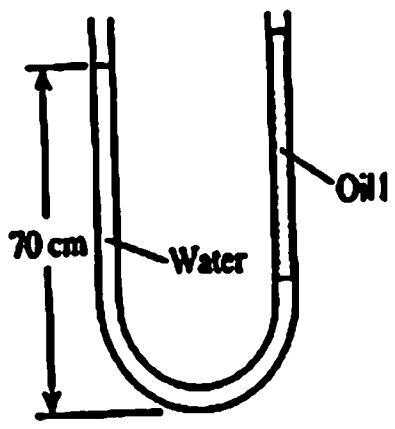
$$= 101\text{kPa} + \left(1030\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(30\text{m})\left(\frac{1\text{N}}{1\ \frac{\text{kg}\cdot\text{m}}{\text{s}^2}}\right)\left(\frac{1\text{kPa}}{1000\ \frac{\text{N}}{\text{m}^2}}\right)$$

$$= 404\,\text{kPa}$$

$\boxed{P = 404\ \text{kPa}}$

Question: 2.057P

Consider a U-tube whose arms are open to the atmosphere. Now water is poured into the U-tube from one arm, and light oil (ρ = 790 kg/m3) from the other. One arm contains 70-cm-high water, while the other arm contains both fluids with an oil-to-water height ratio of 4. Determine the height of each fluid in that arm.



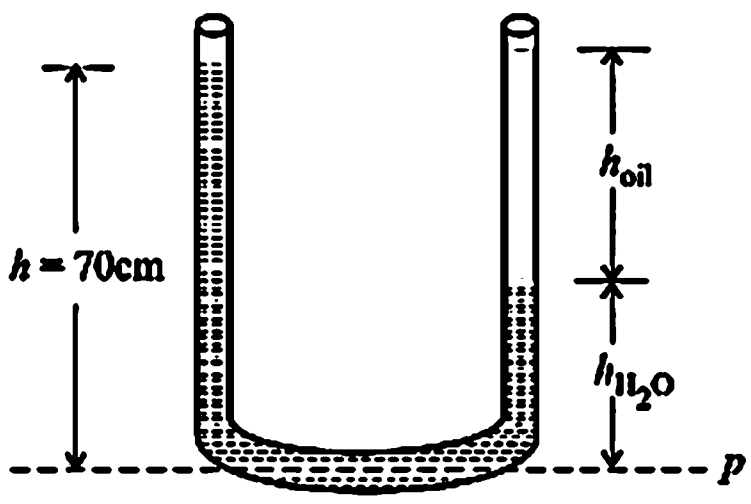


FIGURE P2–57

Step 1 of 5

Step 2 of 5

Let us take height of water column in left arm of U-tube manometer is $h = 70$ cm And on right arm as h_{oil}, h_{water}

The density of water $\rho_{H_2O} = 1000\ kg/m^3$

The density of oil $\rho_{oil} = 790\ kg/m^3$

Height of oil $h_{oil} = 4\ h_w$

$$h_w = \frac{1}{4} h_{oil}$$

Step 3 of 5

The pressure acting on the bottom of the U-tube manometer is same on considering the left and right arms.

$$p_{left} = p_{atm} + \rho_{H_2O} g h$$

$$p_{right} = p_{atm} + \rho_{oil} g\, h_{oil} + \rho_{H_2O} g\, h_{H_2O}$$

Step 4 of 5

On equating both

$$p_{atm} + \rho_{H_2O} g h = p_{atm} + \rho_{oil} g\, h_{oil} + \rho_{H_2O} g\, h_{H_2O}$$

$$\rho_{H_2O} = 1000\ kg/m^3$$

$$\rho_{oil} = 790\ kg/m^3$$

$$h_{oil} = 4\ hw$$

$$\therefore\ 1000 \times 70 \times 10^{-2} = 790 \times h_{oil} + 1000 \times \frac{1}{4} h_{oil}$$

$$1000 \times 70 \times 10^{-2} = (790 + 250) h_{oil}$$

$$\boxed{h_{oil} = 0.673\ m}$$

Step 5 of 5

Height of oil in U-tube manometer arm

$$h_{water} = \frac{1}{4} h_{oil}$$

$$h_{water} = \frac{1}{4} \times 0.673$$

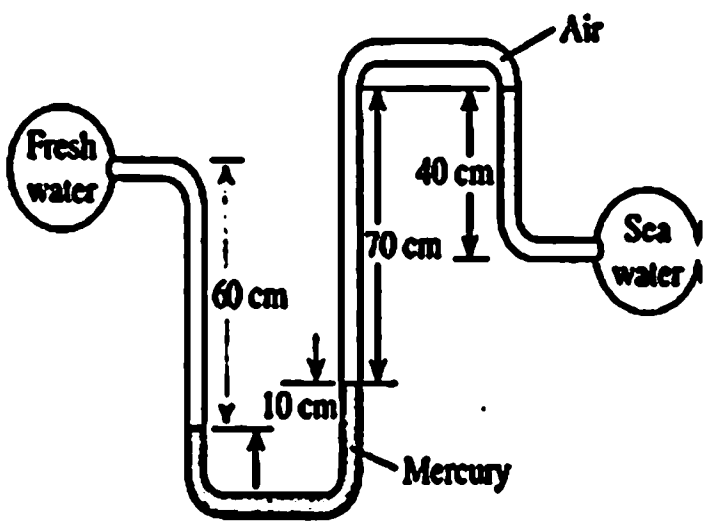
$$= 0.168\ m$$

$$\boxed{h_{water} = 0.168\ m}$$

Height of water in U-tube manometer right arm

Question: 2.058P

Freshwater and seawater flowing in parallel horizontal pipelines are connected to each other by a double U-tube manometer, as shown in Fig. P2-58. Determine the pressure difference between the two pipelines. Take the density of seawater at that location to be ρ = 1035 kg/m3. Can the air column be ignored in the analysis?



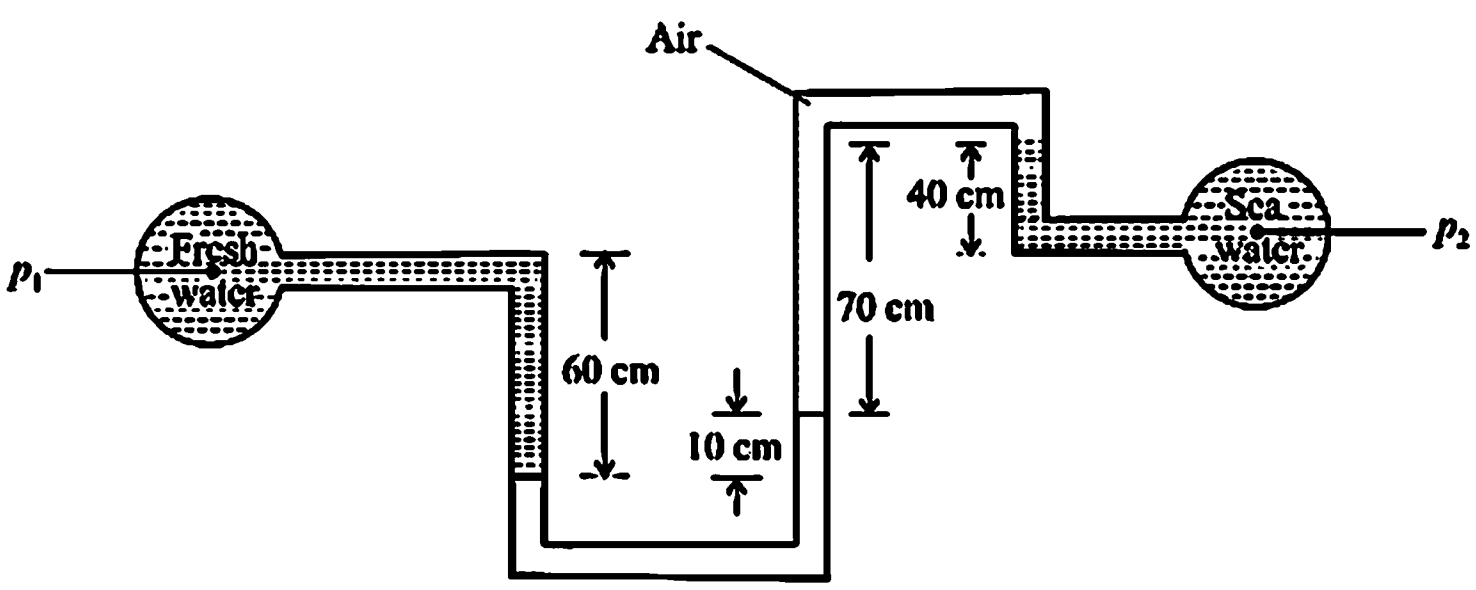


FIGURE P2–58

Step 1 of 4

Step 2 of 4

Given

The height of fresh water $h_w = 60$ cm (fresh water)

The height of mercury $h_{Hg} = 10$ cm (mercury)

The height of air $h_{air} = 70$ cm (air-column)

The height of sea water $h_{sea} = 40$ cm (sea-water)

The density of sea water $\rho_{sea} = 1035\ kg/m^3$

The density of air $\rho_{air} = 1.2256\ kg/m^3$ (density of air)

The density of fresh water $\rho_{water} = 1000\ kg/m^3$

The density of mercury $\rho_{Hg} = 13,600\ kg/m^3$

The acceleration due to gravity of earth $g = 9.81\ m/s^2$

Step 3 of 4

Let us consider the pressure in fresh water tube is p_1 and the pressure in sea water tube is p_2

As we go from p_1 to p_2 in the two U-tube manometers, various pressures are calculated according to the fluid levels in the manometer.

Taking positive as we go down and negative in upward direction

$$\therefore\ p_1 + \rho_{H_2O} g h_w - \rho_{Hg} g h_{Hg} - \rho_{air} g h_{air} + \rho_{sea} g h_{sea} = p_2 \quad \text{.....(1)}$$

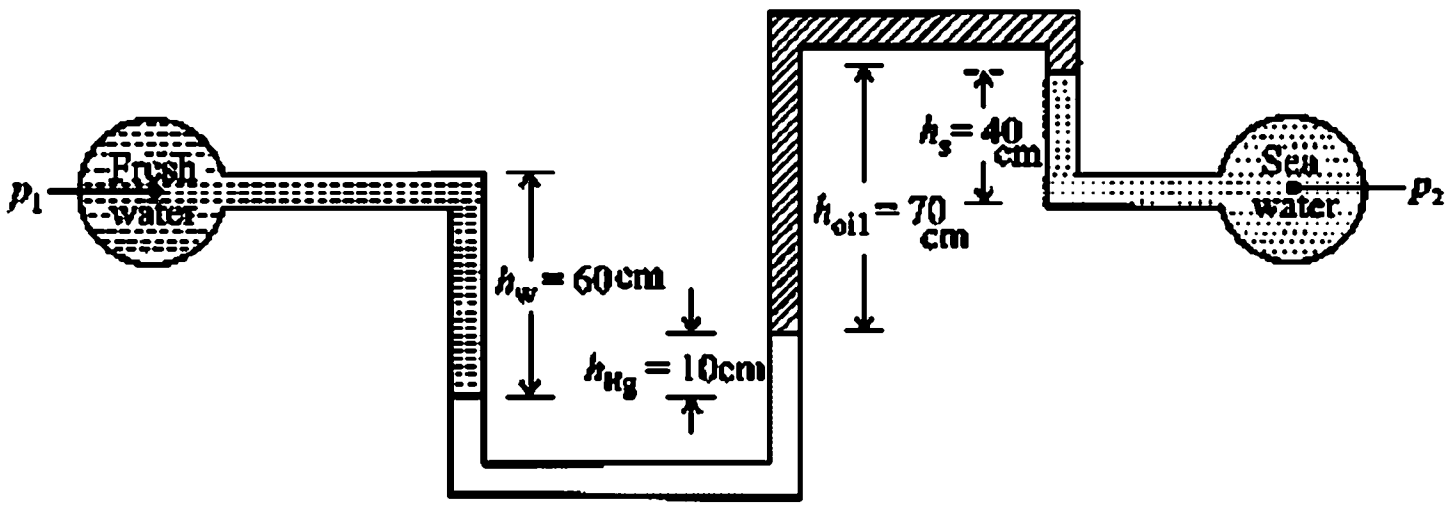
The pressure difference between two pipe lines is $p_1 - p_2$

$$\therefore\ p_1 - p_2 = \rho_{Hg} g h_{Hg} + \rho_{air} g h_{air} - \rho_{sea} g h_{sea} - \rho_{H_2O} g h_w$$

Step 4 of 4

Substituting all these values in above equation

$$\Rightarrow p_1 - p_2 = 13,600 \times 9.8 \times 10 \times 10^{-2} + 1.2256 \times 9.81 \times 10 \times 10^{-2} - 1035 \times 9.81 \times 40 \times 10^{-2} - 1000 \times 9.81 \times 60 \times 10^{-2}$$



$$\boxed{p_1 - p_2 = 3.4\ kPa}$$

The air column can be ignored because the air columns produce a very low pressure of 3.4 Pa

Question: 2.059P

Repeat Prob. 2–58 by replacing the air with oil whose specific gravity is 0.72.

Step 1 of 4

Step 2 of 4

The height of fresh water $h_w = 60$ cm (fresh water)

The height of mercury $h_{Hg} = 10$ cm (mercury)

The height of oil $h_{oil} = 70$ cm (oil-column)

The height of sea water $h_{sea} = 40$ cm (sea-water)

The density of sea water $\rho_{sea} = 1035\ \text{kg/m}^3$

The density of fresh water $\rho_{water} = 1000\ \text{kg/m}^3$

The density of mercury $\rho_{Hg} = 13,600\ \text{kg/m}^3$

The acceleration due to gravity of earth $g = 9.81\ \text{m/s}^2$

The specific gravity of oil S.G= 0.72

$$\text{S.G} = \frac{\rho_{oil}}{\rho_{water}}$$

The density of oil $\rho_{oil} = 0.72 \times 1000$

$= 720\ \text{kg/m}^3$

Step 3 of 4

Let us consider the pressure in fresh water tube is p_1 and the pressure in sea water tube is p_2

As we move from p_1 to p_2 in the two U-tube manometers, various pressures is calculated according to the fluid levels in the manometer.

Taking positive as we go down and negative pressure in upward direction

$\therefore\ p_1 + \rho_w g h_w - \rho_{Hg} g h_{Hg} - \rho_{oil} g h_{oil} + \rho_s g h_s = p_2$ .....(1)

The pressure difference between two pipe lines is $p_1 - p_2$

$\Rightarrow\ p_1 - p_2 = \rho_{Hg} g h_{Hg} + \rho_{oil} g h_{oil} - \rho_w g h_w - \rho_s g h_s$ .....(2)

Step 4 of 4

Substituting all the values in equation (2)

$$\Rightarrow\ p_1 - p_2 = 13,600 \times 9.81 \times 10 \times 10^{-2} + 720 \times 9.81 \times 70 \times 10^{-2} - 1000 \times 9.81 \times 60 \times 10^{-2} - 1035 \times 9.81 \times 40 \times 10^{-2}$$

$$= 13.34 \times 10^3 + 4.94 \times 10^3 - 5.88 \times 10^3 - 4.06 \times 10^3$$

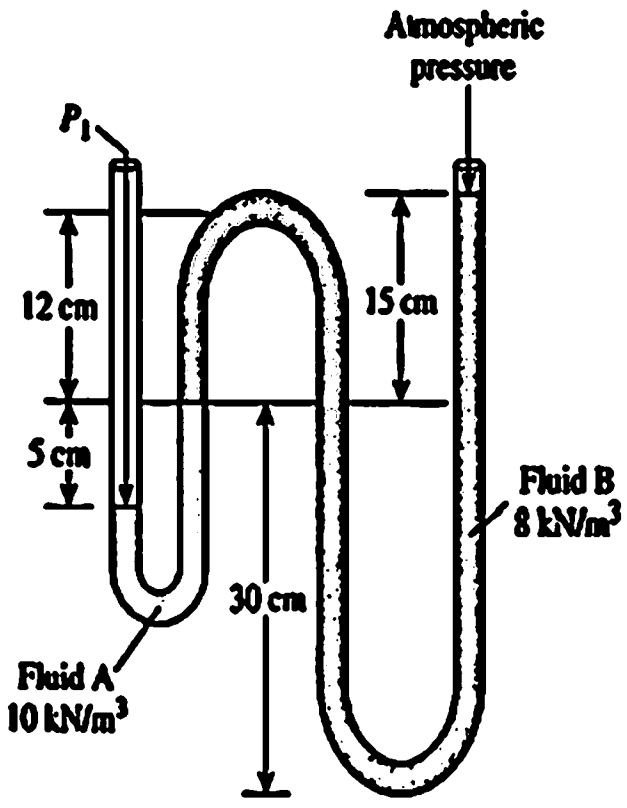
$$= 8.338 \times 10^3\ \text{N/m}^2$$

$10^3\ \text{N/m}^2 = 1\ \text{kPa}$

The pressure difference $\boxed{p_1 - p_2 = 8.338\ \text{kPa}}$

Question: 2.060P

Calculate the absolute pressure, $P1$ of the manometer shown in Fig. P2-60 in kPa. The local atmospheric pressure is 758 mm Hg.



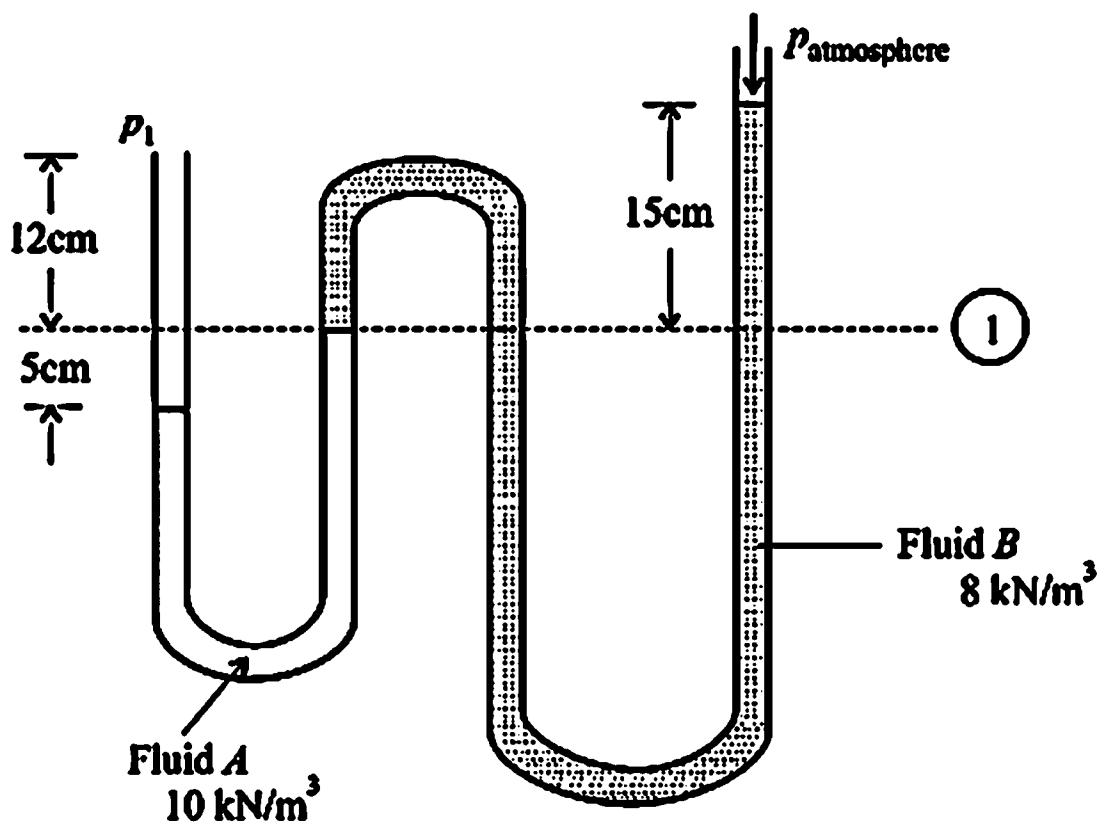


FIGURE P2–60

Step 1 of 4

Step 2 of 4

Given

Local atmospheric pressure = 758 mmHg

$\rho_{Hg} = 13,600 \text{ kg/m}^3$

$g = 9.81 \text{ m/s}^2$

$\therefore \quad p_{atm} = \rho_{Hg} g h$

$= 13,600 \times 9.81 \times 758 \times 10^{-3}$

$= 101.13 \text{ kPa}$

Step 3 of 4

The absolute pressure p_1 is calculated by

$p_1 = p_{atm} + \rho_a g h_a + \rho_B g h_B$ .....(1)

Given specific weights of fluids A and B

i.e., $\gamma_A = \rho_a g$

$= 10 \text{ kN/m}^3$

$\gamma_B = \rho_B g$

$= 8 \text{ kN/m}^3$

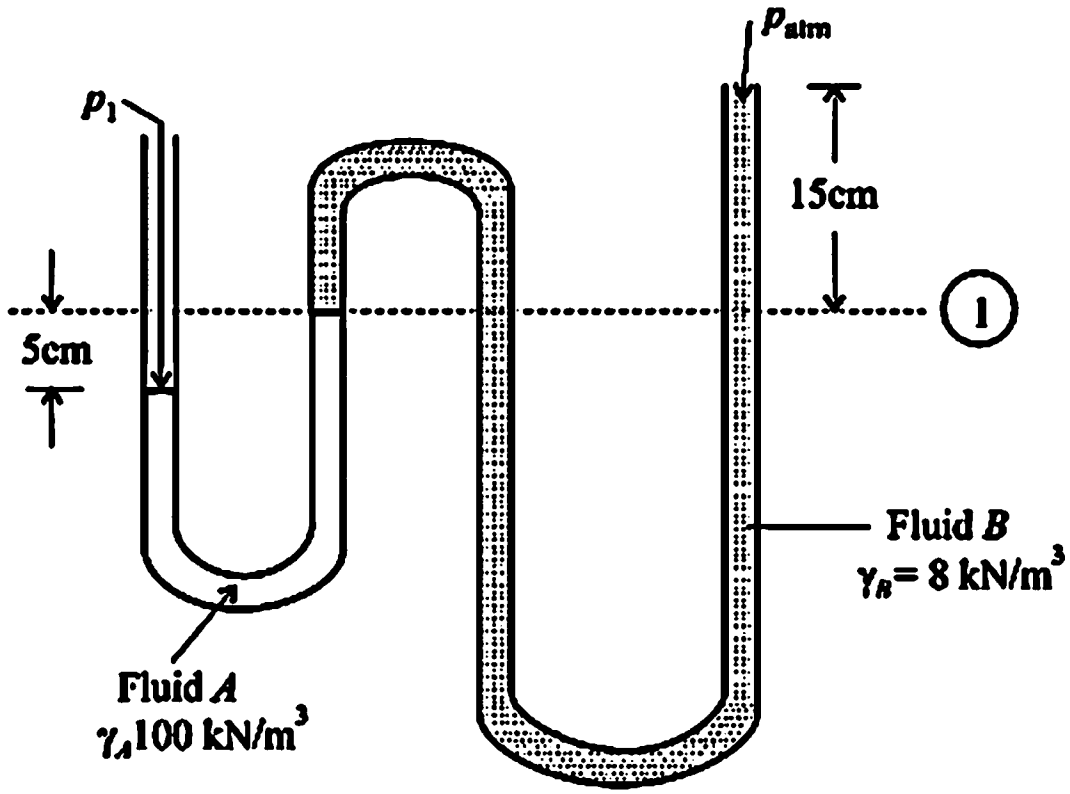
Step 4 of 4

Taking the line (1) in figure as reference the height $h_a = 5$ cm and $h_B = 15$ cm

Equation (1)

$\Rightarrow \quad p_1 = p_{atm} + \gamma_A h_a + \gamma_B h_B$

$= 101.13 \times 10^3 + 10 \times 10^3 \times 5 \times 10^{-2} + 8 \times 10^3 \times 15 \times 10^{-2}$



$= 102.83 \times 10^3 \text{ N/m}^2$

$\boxed{p_1 = 102.83 \text{ kPa}}$

Question: 2.061P

Consider the manometer in Fig. P2-60. If the specific weight of fluid A is 100 kN/m3, what is the absolute pressure, in kPa, indicated by the manometer when the local atmospheric pressure is 90 kPa?

Step 1 of 3

Step 2 of 3

Given

the local atmospheric pressure

i.e., $p_{atm} = 90$ kPa

Specific weight of

Fluid A $\gamma_A = 100$ kN/m^3

Fluid B $\gamma_B = 8$ kN/m^3

The height $h_A = 5$ cm

The height $h_B = 15$ cm

Step 3 of 3

The absolute pressure $p_1 = p_{atm} + \gamma_A h_A + \gamma_B h_B$

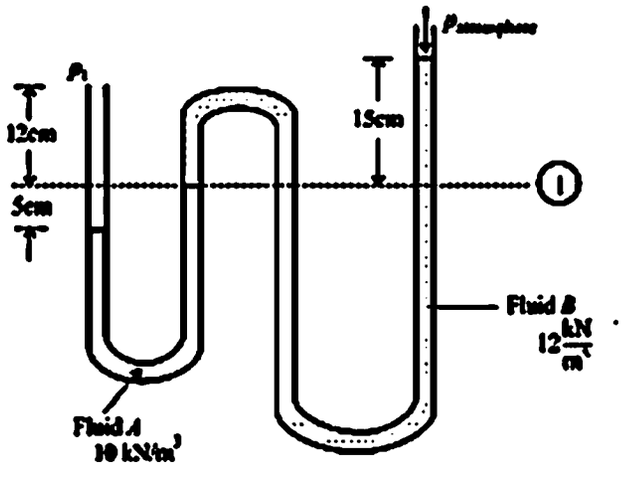
$$p_1 = 90\times10^3 + 100\times10^3 \times 5\times10^{-2} + 8\times10^3 \times 15\times10^{-2}$$

$$= 96.2\times10^3 \text{ N/m}^2$$

$$\boxed{p_1 = 96.2 \text{ kPa}}$$

Question: 2.062P

Consider the manometer in Fig. P2-60. If the specific weight of fluid B is 12 kN/m3, what is the absolute pressure, in kPa, indicated by the manometer when the local atmospheric pressure is 720 mm Hg?



Step 1 of 4

Given:

Specific weight of the fluid $\gamma_B = 12\frac{\text{kN}}{\text{m}^3}$

Atmospheric pressure $P_{atm} = 720\,\text{mm of Hg}$

Step 2 of 4

Step 3 of 4

Atmospheric pressure in kPa is

$$P_{atm} = 720\,\text{mm of Hg}$$

$$= (720\,\text{mm of Hg})\left(0.1333\frac{\text{kPa}}{\text{mm of Hg}}\right)$$

$$= 95.98\,\text{kPa}$$

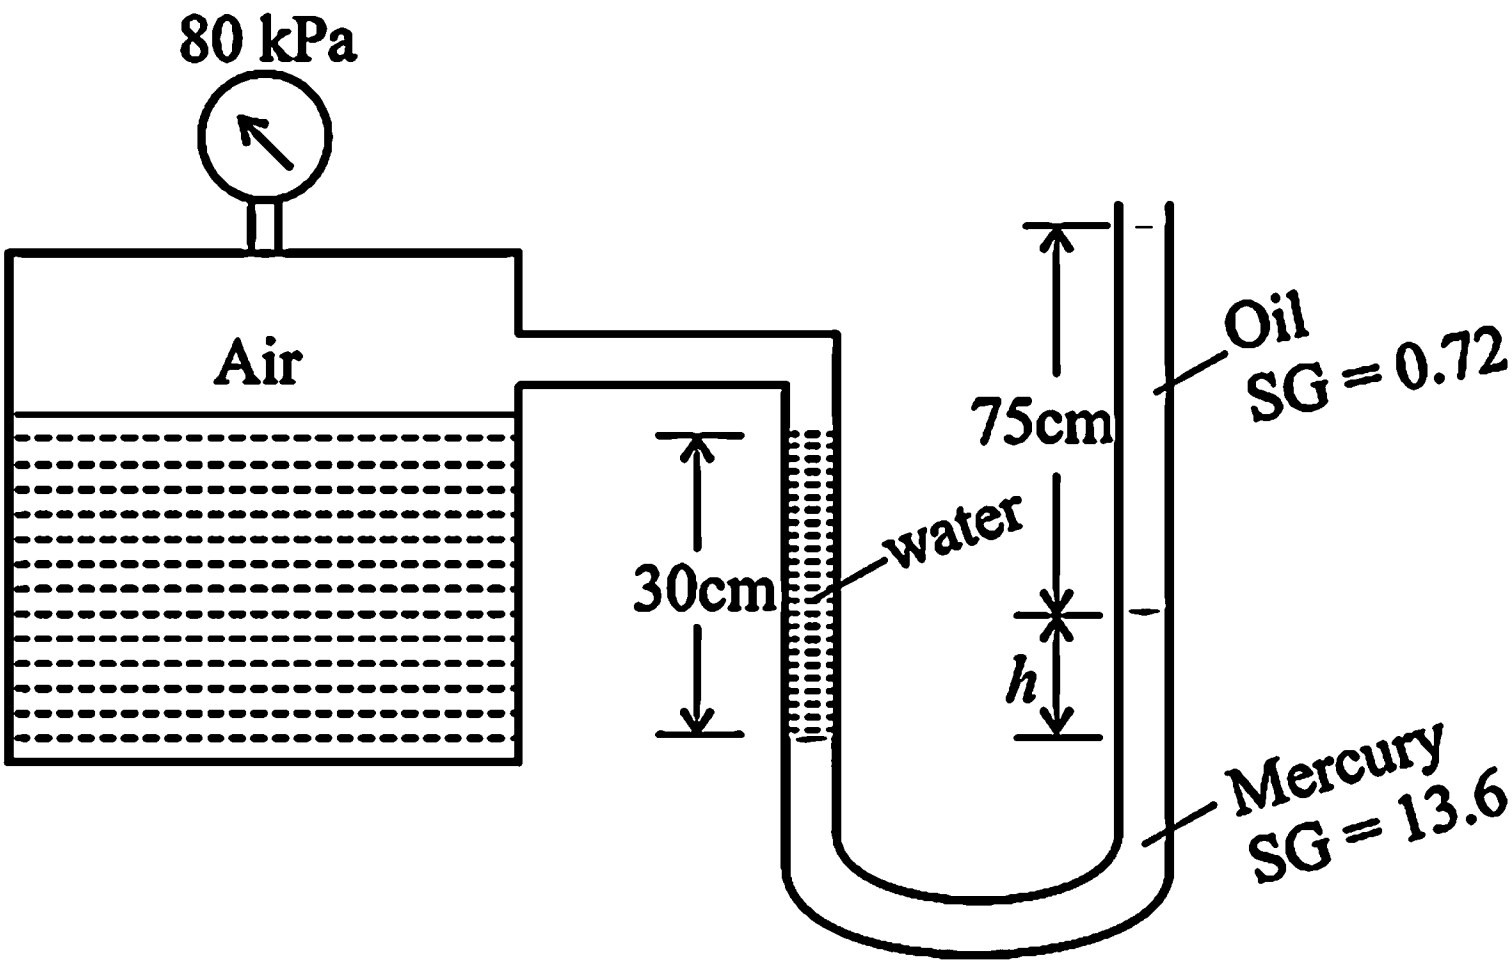
Step 4 of 4

Absolute pressure is

$$P_1 = P_{atm} + (\gamma_A h_1) + (\gamma_B h_2)$$

$$= 95.98\,\text{kPa} + \left(\left(10\frac{\text{kN}}{\text{m}^3}\right)(0.05\text{m}) + \left(12\frac{\text{kN}}{\text{m}^3}\right)(0.15\text{m})\right)$$

$$= 98.28\frac{\text{kN}}{\text{m}^2} \qquad \left(1\text{kPa} = \frac{\text{kN}}{\text{m}^2}\right)$$



$$\boxed{P_1 = 98.28\,\text{kPa}}$$

Question: 2.063P

The gage pressure of the air in the tank shown in Fig. P2-63 is measured to be 80 kPa. Determine the differential height *h* of the mercury column.

Step 1 of 2

Draw the tank that consists of air, and pressure of air is measured by pressure gage and the differential manometer as shown in figure:

Step 2 of 2

Find the density of mercury by using specific gravity of mercury

$$SG = \frac{\rho_{Hg}}{\rho_{H_2O}}$$

Here, ρ_{Hg} is density of mercury and ρ_{H_2O} is density of water.

Substitute 13.6 for SG and $1000\,kg/m^3$ for ρ_{H_2O}

$$13.6 = \frac{\rho_{Hg}}{1000}$$

$$\rho_{Hg} = 13600\,kg/m^3$$

Similarly find the density of oil by using the equation,

$$SG = \frac{\rho_{oil}}{\rho_{H_2O}}$$

Substitute 0.72 for SG

$$0.72 = \frac{\rho_{oil}}{1000}$$

$$\rho_{oil} = 720\,kg/m^3$$

Write the pressure equation starting from gage pressure in the tank and adding or subtracting the pressure terms along the length of the tube and equate to the atmospheric pressure (since the surface of oil is exposed to atmosphere).

$$P_1 + \rho_w g h_w - \rho_{Hg} g h_{Hg} - \rho_{oil} g h_{oil} = P_{atm}$$

$$\left(P_{gage} + P_{atm}\right) + \rho_w g h_w - \rho_{Hg} g h_{Hg} - \rho_{oil} g h_{oil} = P_{atm}$$

$$P_{gage} + \rho_w g h_w - \rho_{Hg} g h_{Hg} - \rho_{oil} g h_{oil} = 0$$

Here, P_1 is absolute air pressure in the tank measured by gage pressure, P_{gage} is gage pressure in the tank, P_{atm} is atmospheric pressure, h_w is height of water column, h_{Hg} is height of mercury column and h_{oil} is height of oil column and *g* is acceleration due to gravity.

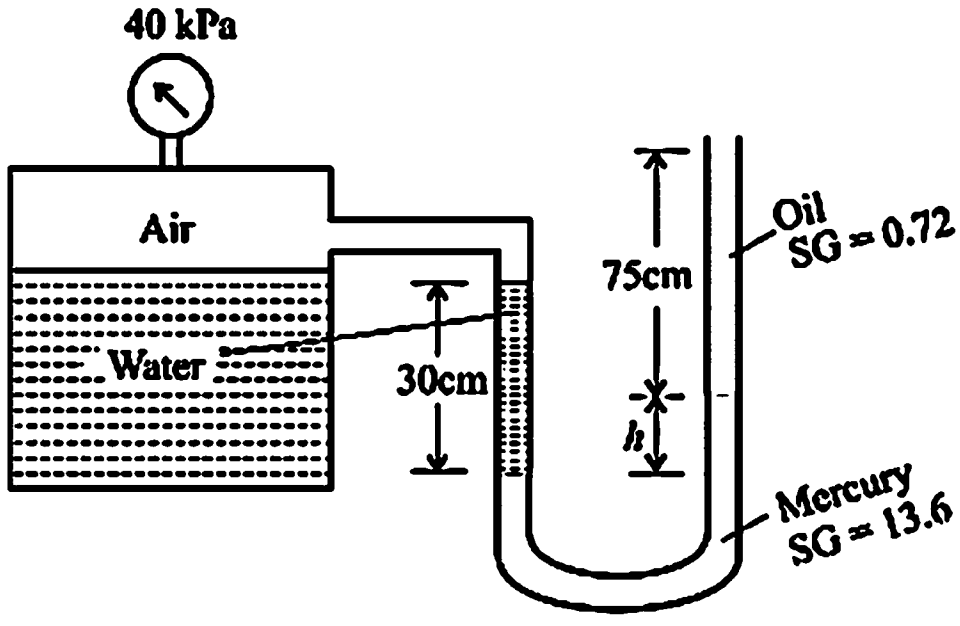
Substitute $80\times10^3\,Pa$ for P_{gage}, $30\,cm = 0.3\,m$ for h_w, $75\,cm = 0.75\,m$ for h_{oil} and $9.81\,m/s^2$ for g

$$80\times10^3 + 1000\times9.81\times0.3 - 13600\times9.81\times h_{Hg} - 720\times9.81\times0.75 = 0$$

$$80000 + 2943 - 133416h_{Hg} - 5297.4 = 0$$

$$77645.6 = 133416h_{Hg}$$

$$h_{Hg} = 0.5819\,m$$

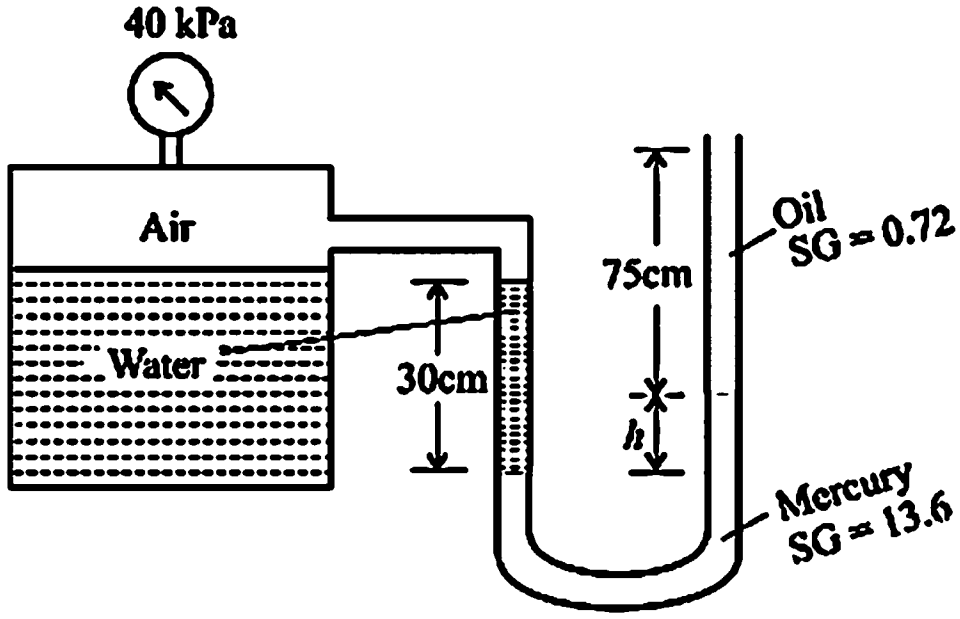


The differential height h of the mercury column is **0.5819 m**

Question:

2.064P

Repeat Prob. 2–63 for a gage pressure of 40 kPa.



Step 1 of 4

Question:

Repeat Prob. 2–63 for a gage pressure of 40 kPa.

Step 1 of 4

Mercury $h_{Hg} = ?$

$1\text{ cm} = 10^{-2}\text{m}$

$g = 9.81\text{ m/s}^2$

Step 4 of 4

Substituting all these values in equation (1)

$$p_{gage} = \rho_{oil} g h_{oil} + \rho_{Hg} g h_{Hg} - \rho_w g h_w$$

$$\Rightarrow 40\times10^3 = 720\times9.81\times75\times10^{-2} + 13,600\times9.81\times h_{Hg} - 1000\times9.81\times30\times10^{-2}$$

$$h_{Hg} = \frac{\left(40-(5.29-2.94)\right)\times10^3}{13,600\times9.81}$$

$$= 0.2832\text{ m}$$

The differential height h of the mercury column is $\boxed{h_{Hg} = 28.32\text{ cm}}$

Question: 2.065P

The top part of a water tank is divided into two compartments, as shown in Fig. P2-65. Now a fluid with an unknown density is poured into one side, and the water level rises a certain amount on the other side to compensate for this effect. Based on the final fluid heights shown on the figure, determine the density of the fluid added. Assume the liquid does not mix with water.

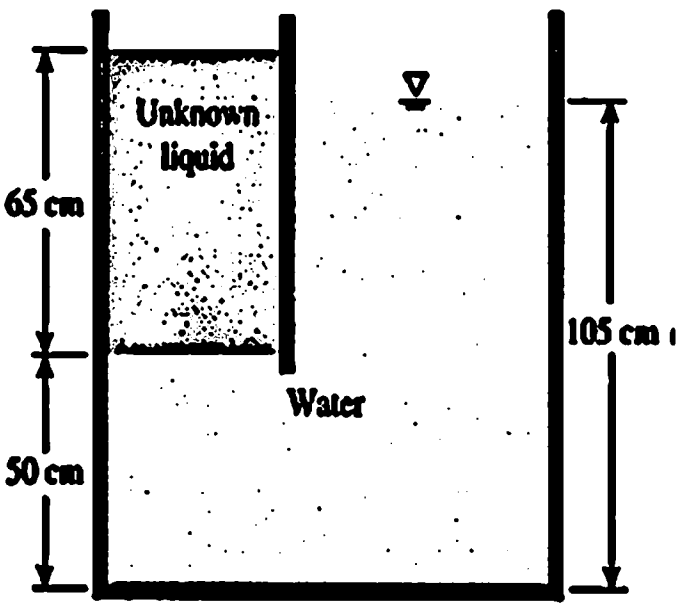


FIGURE P2-65

Question:

The top part of a water tank is divided into two compartments, as shown in Fig. P2-65. Now a fluid with an unknown density is poured into one side, and the water level rises a certain amount on the other side to compensate for this effect. Based on the final fluid heights shown on the figure, determine the density of the fluid added. Assume the liquid does not mix with water.

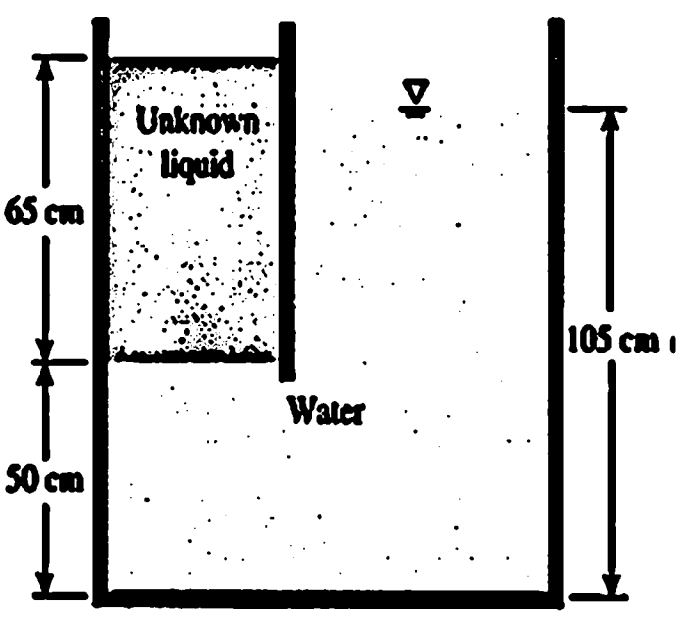

FIGURE P2-65

Step 3 of 3

Substituting the values we have,

$h_f = 65cm$

$h_w = 105\,\text{cm} - 50\,\text{cm}$

$= 55\,\text{cm}$

$$\rho_f = \frac{55}{65} \times 1000 \frac{\text{kg}}{\text{m}^3}$$

$$= 846.15 \frac{\text{kg}}{\text{m}^3}$$

$$\boxed{\rho_f = 846.15 \frac{\text{kg}}{\text{m}^3}}$$

Step 3 of 3

Substituting the values we have,

$h_f = 65cm$

$h_w = 105\,\text{cm} - 50\,\text{cm}$

$= 55\,\text{cm}$

$$\rho_f = \frac{55}{65} \times 1000 \frac{\text{kg}}{\text{m}^3}$$

$$= 846.15 \frac{\text{kg}}{\text{m}^3}$$

$$\boxed{\rho_f = 846.15 \frac{\text{kg}}{\text{m}^3}}$$

Question:

2.066P

Consider the system shown in Fig. P2-66.If a change of 0.7 kPa in the pressure of air causes the brine-mercury interface in the right column to drop by 5 mm in the brine level in the right column while the pressure in the brine pipe remains constant, determine the ratio of *A2/A1*.

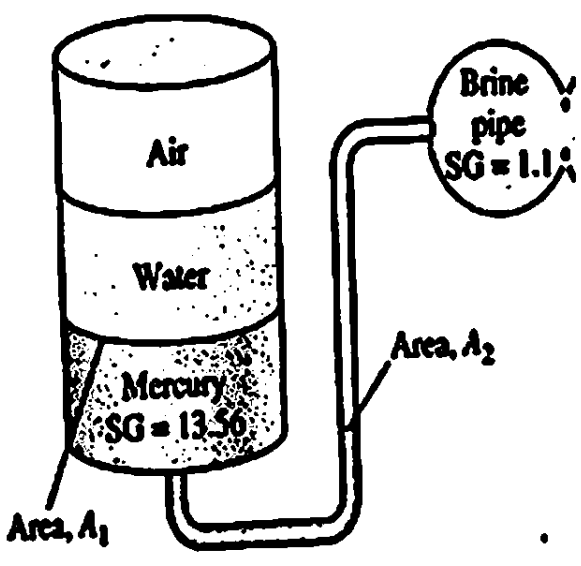

FIGURE P2–66

Question:

Consider the system shown in Fig. P2-66.If a change of 0.7 kPa in the pressure of air causes the brine-mercury interface in the right column to drop by 5 mm in the brine level in the right column while the pressure in the brine pipe remains constant, determine the ratio of *A2/A1*.

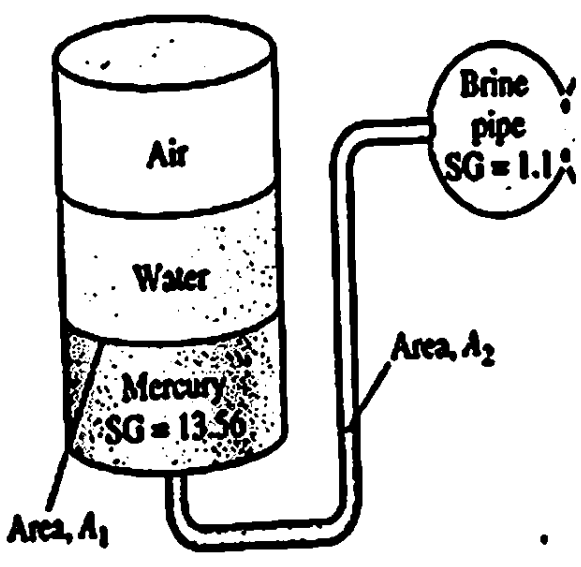

FIGURE P2–66

Consider the pressure drop in the left and right hand side of the area A_1 column.

Write the relation for pressure change in the column.

$$P_{A_1} + \rho_w g(h_w) + \rho_{Hg} g(h_{Hg})_{A_1} = \rho_{brine} g(h_{brine})_{A_1} + P_B$$

$$P_{A_1} + \rho_w g h_w + \rho_w (SG_{Hg}) g(h_{Hg})_{A_1} = \rho_w (SG_{brine}) g(h_{brine})_{A_1} + P_B \quad \text{..... (1)}$$

Consider the pressure drop in the left and right hand side of the area A_2 column.

Write the relation for pressure change in the column.

$$P_{A_2} + \rho_w g(h_w) + \rho_{Hg} g(h_{Hg})_{A_2} = \rho_{brine} g(h_{brine})_{A_2} + P_B$$

$$P_{A_2} + \rho_w g(h_w) + \rho_w (SG_{Hg}) g(h_{Hg})_{A_2} = \rho_w (SG_{brine}) g(h_{brine}) A_2 + P_B \quad \text{..... (2)}$$

Here, specific gravity of mercury is $SG_{(Hg)}$, specific gravity of brine solution is $SG_{(brine)}$, the density of water is ρ_w, change in pressure of the air from the area A_1 to A_2 is $P_{A_1} - P_{A_2}$, change in brine level in the right column is Δh_{brine}, the mercury level in the right column is $(h_{Hg})_{at A_2}$, and pressure in brine pipe is P_B .

Step 3 of 5

Subtract the equation (1) from (2).

$$\left\{\begin{array}{l}\left(P_{A_2} + \rho_w g(h_w) + \rho_w (SG_{Hg}) g(h_{Hg})_{A_2}\right) \\ \quad -\left(P_{A_1} + \rho_w g h_w + \rho_w (SG_{Hg}) g(h_{Hg})_{A_1}\right)\end{array}\right\} = \left\{\begin{array}{l}\left(\rho_w (SG_{brine}) g(h_{brine})_{A_2} + P_B\right) \\ \quad -\left(\rho_w (SG_{brine}) g(h_{brine})_{A_1} + P_B\right)\end{array}\right\}$$

$$P_{A_2} - P_{A_1} = \left\{\rho_w (SG_{brine}) g\left[(h_{brine})_{A_2} - (h_{brine})_{A_1}\right]\right\} - \left\{\rho_w (SG_{Hg}) g\left[(h_{Hg})_{A_2} - (h_{Hg})_{A_1}\right]\right\}$$

$$P_{A_2} - P_{A_1} = \rho_w (SG_{brine}) g \Delta h_{brine} - \rho_w (SG_{Hg}) g \Delta h_{Hg} \quad \text{..... (3)}$$

Step 4 of 5

As Mercury is incompressible, the volume of the mercury remains constant in the left and right limb.

$$V_{left} = V_{right}$$

$$A_1 (\Delta h_{Hg})_{left} = A_2 (\Delta h_{Hg})_{right}$$

Write the relation for the total change of the mercury height.

$$\Delta h_{Hg} = (\Delta h_{Hg})_{left} + (\Delta h_{Hg})_{right}$$

$$= (\Delta h_{Hg}) + \frac{A_2 (\Delta h_{Hg})}{A_1 (\Delta h_{Hg})}$$

$$\Delta h_{Hg} = \Delta h_{Hg} \left(1 + \frac{A_2}{\cdot}\right)$$

$$\left\{\begin{array}{l}\left(P_{A_2} + \rho_w g(h_w) + \rho_w (SG_{Hg}) g(h_{Hg})_{A_2}\right) \\ \quad -\left(P_{A_1} + \rho_w g h_w + \rho_w (SG_{Hg}) g(h_{Hg})_{A_1}\right)\end{array}\right\} = \left\{\begin{array}{l}\left(\rho_w (SG_{brine}) g(h_{brine})_{A_2} + P_B\right) \\ \quad -\left(\rho_w (SG_{brine}) g(h_{brine})_{A_1} + P_B\right)\end{array}\right\}$$

$$P_{A_2} - P_{A_1} = \left\{\rho_w (SG_{brine}) g\left[(h_{brine})_{A_2} - (h_{brine})_{A_1}\right]\right\} - \left\{\rho_w (SG_{Hg}) g\left[(h_{Hg})_{A_2} - (h_{Hg})_{A_1}\right]\right\}$$

$$P_{A_2} - P_{A_1} = \rho_w (SG_{brine}) g \Delta h_{brine} - \rho_w (SG_{Hg}) g \Delta h_{Hg} \quad \text{..... (3)}$$

Step 4 of 5

As Mercury is incompressible, the volume of the mercury remains constant in the left and right limb.

$$V_{left} = V_{right}$$

$$A_1 (\Delta h_{Hg})_{left} = A_2 (\Delta h_{Hg})_{right}$$

Write the relation for the total change of the mercury height.

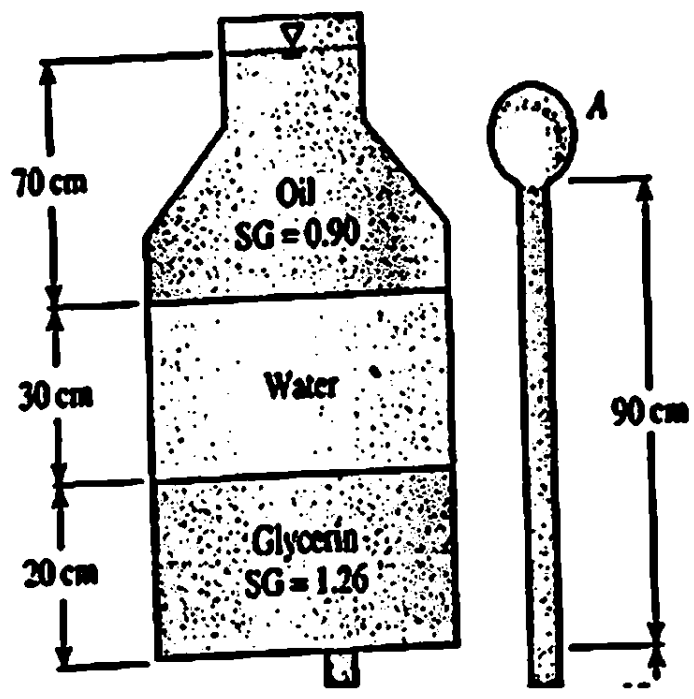
$$\Delta h_{Hg} = (\Delta h_{Hg})_{left} + (\Delta h_{Hg})_{right}$$

$$= (\Delta h_{Hg}) + \frac{A_2 (\Delta h_{Hg})}{A_1 (\Delta h_{Hg})}$$

$$\Delta h_{Hg} = \Delta h_{Hg} \left(1 + \frac{A_2}{A_1}\right)$$

$$\left(1 + \frac{A_2}{A_1}\right) = \frac{0.0768}{0.0678}$$

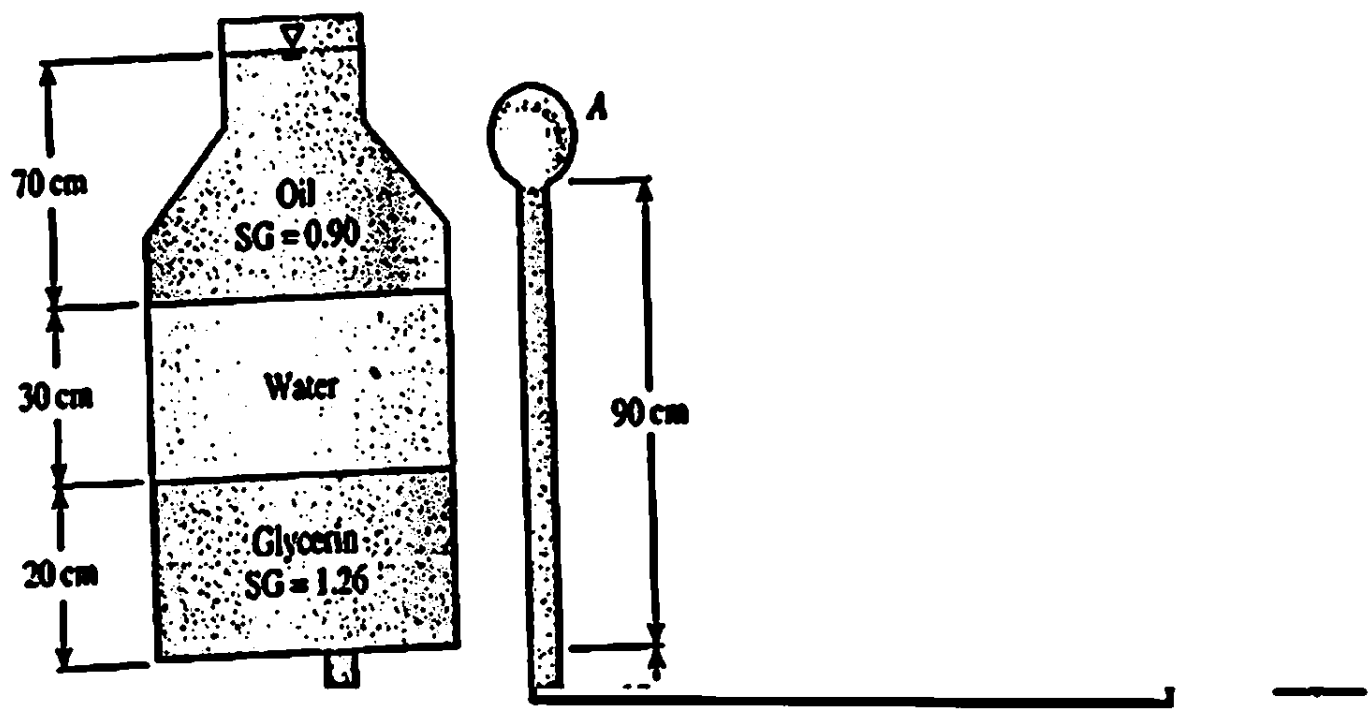
$$\frac{A_2}{A_1} = 1.133 - 1$$



$$= 0.133$$

Therefore, the $\frac{A_2}{A_1}$ ratio is $\boxed{0.133}$.

Question:



2.067P

A multifluid container is connected to a U-tube, as shown in Fig. P2-67. For the given specific gravities and fluid column heights, determine the gage pressure at *A*.Also determine the height of a mercury column that would create the same pressure at *A*.

Question:

A multifluid container is connected to a U-tube, as shown in Fig. P2-67. For the given specific gravities and fluid column heights, determine the gage pressure at *A*.Also determine the height of a mercury column that would create the same pressure at *A*.

Step 2 of 4

The gage pressure $p_{gage} = \rho gh$

Write the specific gravities of different fluids:

Oil $S.G = 0.9$

$S.G = \dfrac{\rho_{oil}}{\rho_w}$

$\rho_{oil} = 0.9 \times 1000$

$\rho_{oil} = 900 \text{ kg/m}^3$

$\rho_w = 1000 \text{ kg/m}^3$

Glycerin $S.G = 1.26$

$\rho_{gly} = 1.26 \times 1000$

$\rho_{gly} = 1260 \text{ kg/m}^3$

Step 3 of 4

Step 2 of 4

The gage pressure $p_{gage} = \rho gh$

Write the specific gravities of different fluids:

Oil $S.G = 0.9$

$S.G = \dfrac{\rho_{oil}}{\rho_w}$

$\rho_{oil} = 0.9 \times 1000$

$\rho_{oil} = 900 \text{ kg/m}^3$

$\rho_w = 1000 \text{ kg/m}^3$

Glycerin $S.G = 1.26$

$\rho_{gly} = 1.26 \times 1000$

$\rho_{gly} = 1260 \text{ kg/m}^3$

Step 3 of 4

$h_{Hg} = \dfrac{0.447 \times 10}{13,600 \times 9.81} \times 10^{-2}$

Therefore, the head produced due to mercury is $\boxed{h_{Hg} = 0.352 \text{ cm}}$.

$h_{Hg} = \dfrac{0.447 \times 10}{13,600 \times 9.81} \times 10^{-2}$

Therefore, the head produced due to mercury is $\boxed{h_{Hg} = 0.352 \text{ cm}}$.

Question: 2.068P

The pilot of an airplane reads the altitude 9000 m and the absolute pressure 25 kPa when flying over a city. Calculate the local atmospheric pressure in that city in kPa and in mm Hg. Take the densities of air and mercury to be 1.15 kg/m3 and 13,600 kg/m3, respectively.

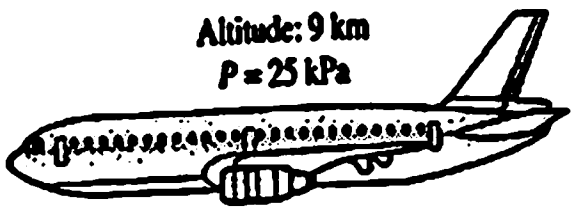


FIGURE P2–68

Step 1 of 2

Calculate the atmospheric pressure in kPa.

$$P_{abs} = P_{atm} + (-\rho_A g h)$$

Question:

The pilot of an airplane reads the altitude 9000 m and the absolute pressure 25 kPa when flying over a city. Calculate the local atmospheric pressure in that city in kPa and in mm Hg. Take the densities of air and mercury to be 1.15 kg/m3 and 13,600 kg/m3, respectively.

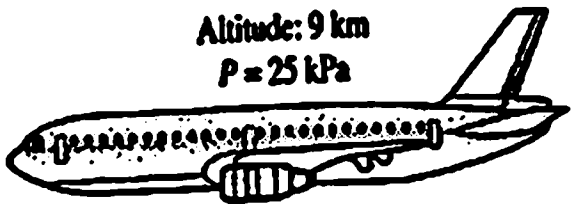

FIGURE P2–68

Step 1 of 2

Calculate the atmospheric pressure in kPa.

$$P_{abs} = P_{atm} + (-\rho_A g h)$$

$$h_{Hg} = \frac{\Delta P_{atm}}{\rho g}$$

$$= \frac{(126.4\,\text{kPa})}{\left(13600\,\frac{\text{kg}}{\text{m}^3}\right)\left(9.81\,\frac{\text{m}}{\text{s}^2}\right)}\left(\frac{1000\,\text{Pa}}{1\,\text{kPa}}\right)\left(\frac{1000\,\text{mm}}{1\,\text{m}}\right)$$

$$= 947.4\,\text{mm}$$

Therefore, the atmospheric pressure in mm of Hg is, $\boxed{h_{Hg} = 947.4\,\text{mm}}$.

$$h_{Hg} = \frac{\Delta P_{atm}}{\rho g}$$

$$= \frac{(126.4\,\text{kPa})}{\left(13600\,\frac{\text{kg}}{\text{m}^3}\right)\left(9.81\,\frac{\text{m}}{\text{s}^2}\right)}\left(\frac{1000\,\text{Pa}}{1\,\text{kPa}}\right)\left(\frac{1000\,\text{mm}}{1\,\text{m}}\right)$$

$$= 947.4\,\text{mm}$$

Therefore, the atmospheric pressure in mm of Hg is, $\boxed{h_{Hg} = 947.4\,\text{mm}}$.

Question: 2.069P

The efficiency of a refrigerator increases by 3 percent for each °C rise in the minimum temperature in the device. What is the increase in the efficiency for each (*a*) K, (*b*) °F, and (*c*) R rise in temperature?

Step 1 of 4

Given $\eta_{\text{in C}} = 3\%\ /°\text{C}$

Step 2 of 4

(a) $T(\text{K}) = 273.15 + °\text{C}$

So 3% for K rise in temperature

Step 3 of 4

(b) $\Delta T(°\text{F}) = \Delta T(\text{R}) = 1.8\Delta T(\text{K})$

Here the percentage increase in efficiency is $\frac{3}{1.8} = 1.67\%$ for each °F

Step 4 of 4

(c) 1.67% °R Rise in temperature

Question: 2.070P

The boiling temperature of water decreases by about 3°C for each 1000-m rise in altitude. What is the decrease in the boiling temperature in (*a*) K, (*b*) °F, and (*c*) R for each 1000-m rise in altitude?

Step 1 of 4

The decreases of boiling temperature of water for 1000 m rise in altitude is $\Delta T = 3°C$
The relation between Kelvins to degree-Centigrade is

$$T(\mathrm{K}) = 273.15 + T(°\mathrm{C})$$

$$\Delta T(\mathrm{K}) = \Delta T(°\mathrm{C})$$

Step 2 of 4

(a) The decrease in boiling temperature is same in K i.e, 3 K

Step 3 of 4

(b) The relation between Fahrenheit – Kelvin

$$T(°\mathrm{F}) = 1.8T(°\mathrm{C}) + 32$$

$$\Delta T(°\mathrm{F}) = 1.8\Delta T(°\mathrm{C})$$

$$= 1.8 \times 3$$

$$\boxed{\Delta T(°\mathrm{F}) = 5.4°\mathrm{F}}$$

Step 4 of 4

(c) The relation between Fahrenheit - Ranking

$$T(\mathrm{R}) = T(°\mathrm{F}) + 459.67$$

$$\Delta T(\mathrm{R}) = \Delta T(°\mathrm{F})$$

$$\therefore \boxed{\Delta T(\mathrm{R}) = 5.4\ \mathrm{R}}$$

Question: 2.071P

Hyperthermia of 5°C (i.e., 5°C rise above the normal body temperature) is considered fatal. Express this fatal level of hyperthermia in (*a*) K, (*b*) °F, and (*c*) R.

Step 1 of 4

Given $\Delta T(^\circ\text{C}) = 5^\circ\text{C}$

We have to express in K, °F and R

Step 2 of 4

(a) We know $\Delta T(\text{K}) = \Delta T(^\circ\text{C})$

$\therefore \boxed{\Delta T(\text{K}) = 5\,\text{K}}$

Step 3 of 4

(b) $\Delta T(^\circ\text{F}) = 1.8\Delta T(^\circ\text{C})$

$= 1.8 \times 5$

$\boxed{\Delta T(^\circ\text{F}) = 9^\circ\text{F}}$

Step 4 of 4

(c) $\Delta T(^\circ\text{F}) = \Delta T(\text{R})$

$\therefore \boxed{\Delta T(^\circ\text{F}) = 9\,\text{R}}$

Question: 2.072P

A house is losing heat at a rate of 2700 kJ/h per °C temperature difference between the indoor and the outdoor temperatures. Express the rate of heat loss from this house per (*a*) K, (*b*) °F, and (*c*) R difference between the indoor and the outdoor temperature.

Step 1 of 3

Given

Rate of loss of heat is $Q = 2700\ (\text{kJ/h})$ per ^0C

Change in magnitude of temperature is given by

$1\text{K} = 1^\circ\text{C} = 1.8\text{R} = 1.8^\circ\text{F}$

(a)

$1\text{K} = 1^\circ\text{C}$

Therefore the, rate of heat loss from the house is

$$Q = 2700\ (\text{kJ/h}^0\text{C}) \times \frac{1^0\text{C}}{1\text{K}}$$

$$Q = 2700\ (\text{kJ/h K})$$

$$Q = 2700\ (\text{kJ/h})\ \text{per K}$$

Hence rate of heat loss from the house per K is $\boxed{Q = 2700\ (\text{kJ/h})\ \text{per K}}$

Step 2 of 3

(b)

$1^\circ\text{C} = 1.8\text{R}$

Therefore the, rate of heat loss from the house is

$$Q = 2700\ (\text{kJ/h}^0\text{C}) \times \frac{1^0\text{C}}{1.8\text{R}}$$

$$Q = \frac{2700}{1.8}\ (\text{kJ/hR})$$

$$Q = 1500\ (\text{kJ/h})\text{per R}$$

Hence rate of heat loss from the house per R is $\boxed{Q = 1500\ (\text{kJ/h})\text{per R}}$

Step 3 of 3

(c)

$1^\circ\text{C} = 1.8^\circ\text{F}$

Therefore the, rate of heat loss from the house is

$$Q = 2700\ (\text{kJ/h}^0\text{C}) \times \frac{1^0\text{C}}{1.8^\circ\text{F}}$$

$$Q = \frac{2700}{1.8}\ (\text{kJ/h}^\circ\text{F})$$

$$Q = 1500\ (\text{kJ/h})\text{per }^\circ\text{F}$$

Hence rate of heat loss from the house per R is $\boxed{Q = 1500\ (\text{kJ/h})\text{per }^\circ\text{F}}$

Question: 2.073P

The average temperature of the atmosphere in the world is approximated as a function of altitude by the relation

$T_{atm} = 288.15 - 6.5z$

where T_{atm} is the temperature of the atmosphere in K and z is the altitude in km with $z = 0$ at sea level. Determine the average temperature of the atmosphere outside an airplane that is cruising at an altitude of 12,000 m.

Step 1 of 1

Given relation between average temperature to altitude

$T_{atm} = 288.15 - 6.5z$

Where T_{atm} = atmosphere temperature in K

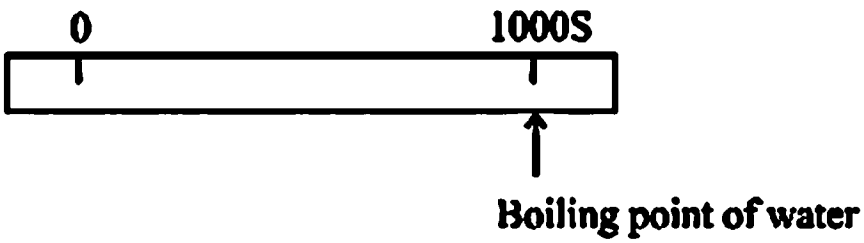
z is altitude in km

The average temperature at $z = 12,000$ m

$z = 12$ km

$\therefore T_{atm} = 288.15 - 6.5 \times 12$

$\boxed{T_{atm} = 210.15 \text{ K}}$



Question: 2.074P

Joe Smith, an old-fashioned engineering student, believes that the boiling point of water is best suited for use as the reference point on temperature scales. Unhappy that the boiling point corresponds to some odd number in the current absolute temperature scales, he has proposed a new absolute temperature scale that he calls the Smith scale. The temperature unit on this scale is *smith*, denoted by S, and the boiling point of water on this scale is assigned to be 1000 S. From a thermodynamic point of view, discuss if it is an acceptable temperature scale. Also, determine the ice point of water on the Smith scale and obtain a relation between the Smith and Celsius scales.

Step 1 of 4

The new absolute temperature scale is smith scale, unit is smith 's'

Step 2 of 4

Step 3 of 4

Boiling point of water in this scale is $(B.P)_S = 1000\ s$ .....(1)

We know that boiling point in our Kelvin scale is

$$(B.P)_K = 373.15\ K \quad .....(2)$$

i.e., point $(I.P)_K = 273.15\ K$

$\therefore$ From (1) and (2)

$$T_s = \frac{1000}{373.15} T_K$$

$$\boxed{T_s = 2.68\ T_K}$$

Step 4 of 4

$\therefore$ Ice point of water in Smith scale

$$(I.P)_S = 2.68(T_K)_{ice\ pt}$$

$$= 2.68 \times 273.15$$

$$\boxed{(I.P)_S = 732S}$$

Question: 2.075P

It is well-known that cold air feels much colder in windy weather than what the thermometer reading indicates because of the "chilling effect" of the wind. This effect is due to the increase in the convection heat transfer coefficient with increasing air velocities. The *equivalent wind chill temperature* in °F is given by [ASHRAE, *Handbook of Fundamentals* (Atlanta, GA, 1993), p. 8.15]

$$T_{equiv} = 91.4 - (91.4 - T_{ambient}) \times (0.475 - 0.0203V + 0.304\sqrt{V})$$

where V is the wind velocity in mi/h and Tambient is the ambient air temperature in °F in calm air, which is taken to be air with light winds at speeds up to 4 mi/h. The constant 91.4°F in the given equation is the mean skin temperature of a resting person in a comfortable environment. Windy air at temperature

TAmbient and velocity Vwill feel as cold as the calm air at temperature Tequiv. Using proper conversion factors, obtain an equivalent relation in SI units where $V$is the wind velocity in km/h and Tambient is the ambient air temperature in °C.

Step 1 of 2

Given the equivalent wind chill temperature in °F

$$T_{equiv} = 91.4 - (91.4 - T_{ambient}) \times \left(0.475 - 0.0203V + 0.304\sqrt{V}\right) \quad \text{.....(1)}$$

Here V is in mi/hr (miles per hour)

1 mi/hr = 1.609 km/hr

The relation between Fahrenheit - °C is

$$T(°F) = 1.8T(°C) + 32$$

Step 2 of 2

$$(1) \Rightarrow 1.8T_{eq}(°C) + 32 = 91.4 - \left\{\left[91.4 - (1.8 \times T_{amb}(°C) + 32)\right] \times \left(0.475 - 0.0203\frac{V}{1.609} + 0.304\sqrt{\frac{V}{1.609}}\right)\right\}$$

$$T_{eq}(°C) = \frac{91.4 - 32}{1.8} - \frac{1}{1.8}\left\{\left[(91.4 - 32) - 1.8T_{amb}(°C)\right] \times \left[0.475 - 0.0126V + 0.240\sqrt{V}\right]\right\}$$

The equivalent relation in SI units

$$\boxed{T_{equiv} = 33 - (33 - T_{ambient}) \times \left(0.475 - 0.0126V + 0.24\sqrt{V}\right)}$$

Question: 2.076P

Reconsider Prob. 2-75E. Using EES (or other) software, plot the equivalent wind chill temperatures in °F as a function of wind velocity in the range of 4 to 40 mph for the ambient temperatures of 20, 40, and 60°F. Discuss the results.

Step 1 of 5

Plot the equivalent wind chill temperature as a function of wind velocity 4 to **40 mph** for ambient temperature of **20° F** , **40° F** and **60° F** using EES software .

Write the following code in the software.

" T_equiv=91.4-(91.4-Tambient)*90.475-0.0203*V+0.304*sqrt(V)) "

Step 2 of 5

Use the parametric table option and tabulate the $T_{equivalent}$ for $T_{ambient}$ at **20°F** and varying the velocity value, *V* between **4 mph to 40 mph** .

▷ 1..10	1 $T_{ambient}$	2 T_{equiv}	3 V
Run 1	20	19.87	4
Run 2	20	7.688	8
Run 3	20	-0.3124	12
Run 4	20	-6.147	16
Run 5	20	-10.6	20
Run 6	20	-14.06	24
Run 7	20	-16.79	28
Run 8	20	-18.92	32
Run 9	20	-20.57	36
Run 10	20	-21.82	40

Table (1)

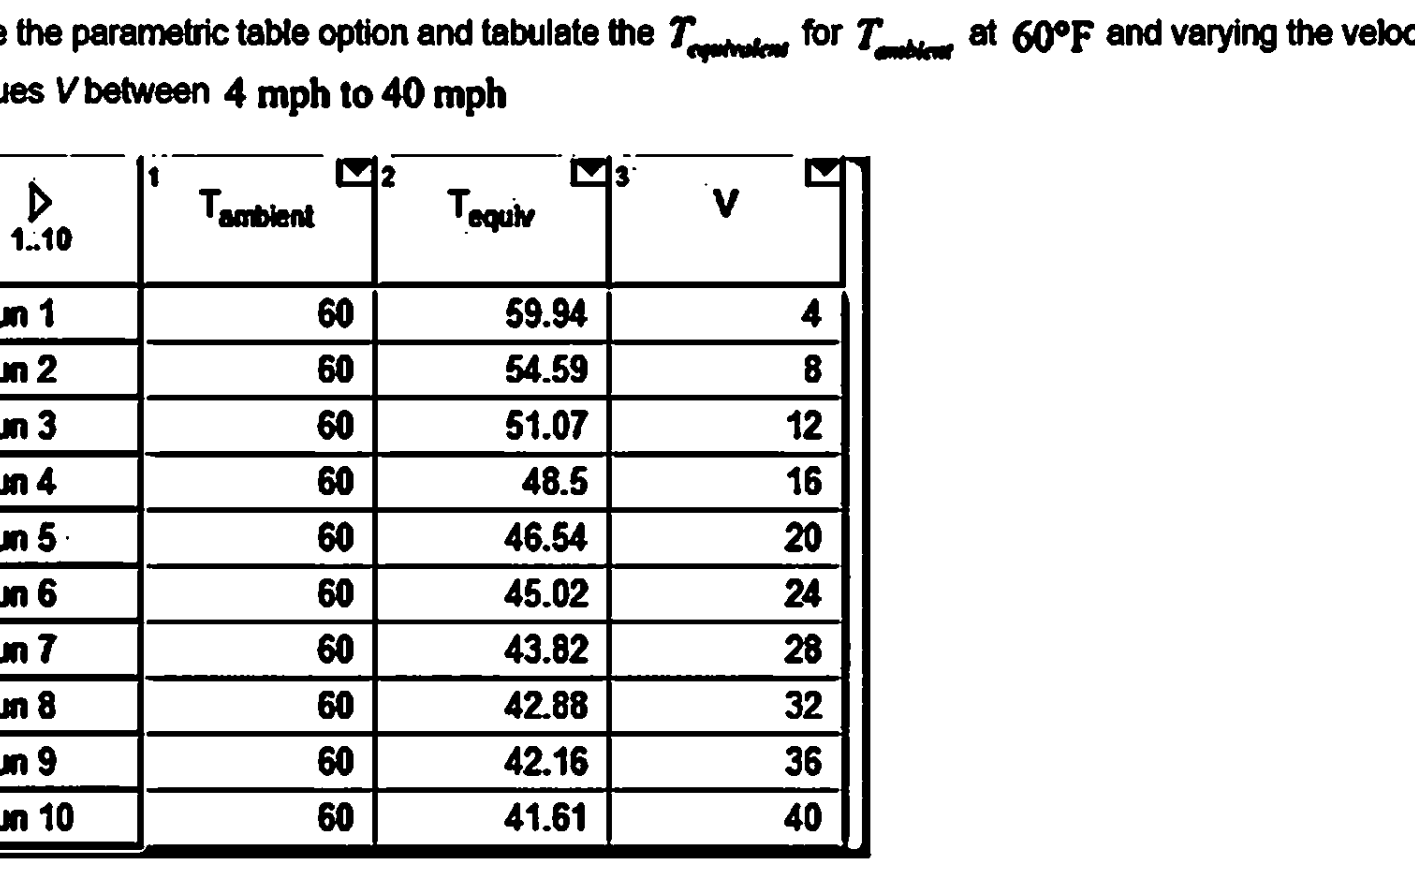
Step 3 of 5

Use the parametric table option and tabulate the $T_{equivalent}$ for $T_{ambient}$ at **40°F** and varying the velocity values *V* between **4 mph to 40 mph**

▷ 1..10	1 $T_{ambient}$	2 T_{equiv}	3 V
Run 1	40	39.91	4
Run 2	40	31.14	8
Run 3	40	25.38	12
Run 4	40	21.18	16
Run 5	40	17.97	20
Run 6	40	15.48	24
Run 7	40	13.52	28
Run 8	40	11.98	32
Run 9	40	10.79	36
Run 10	40	9.897	40

Table (2)

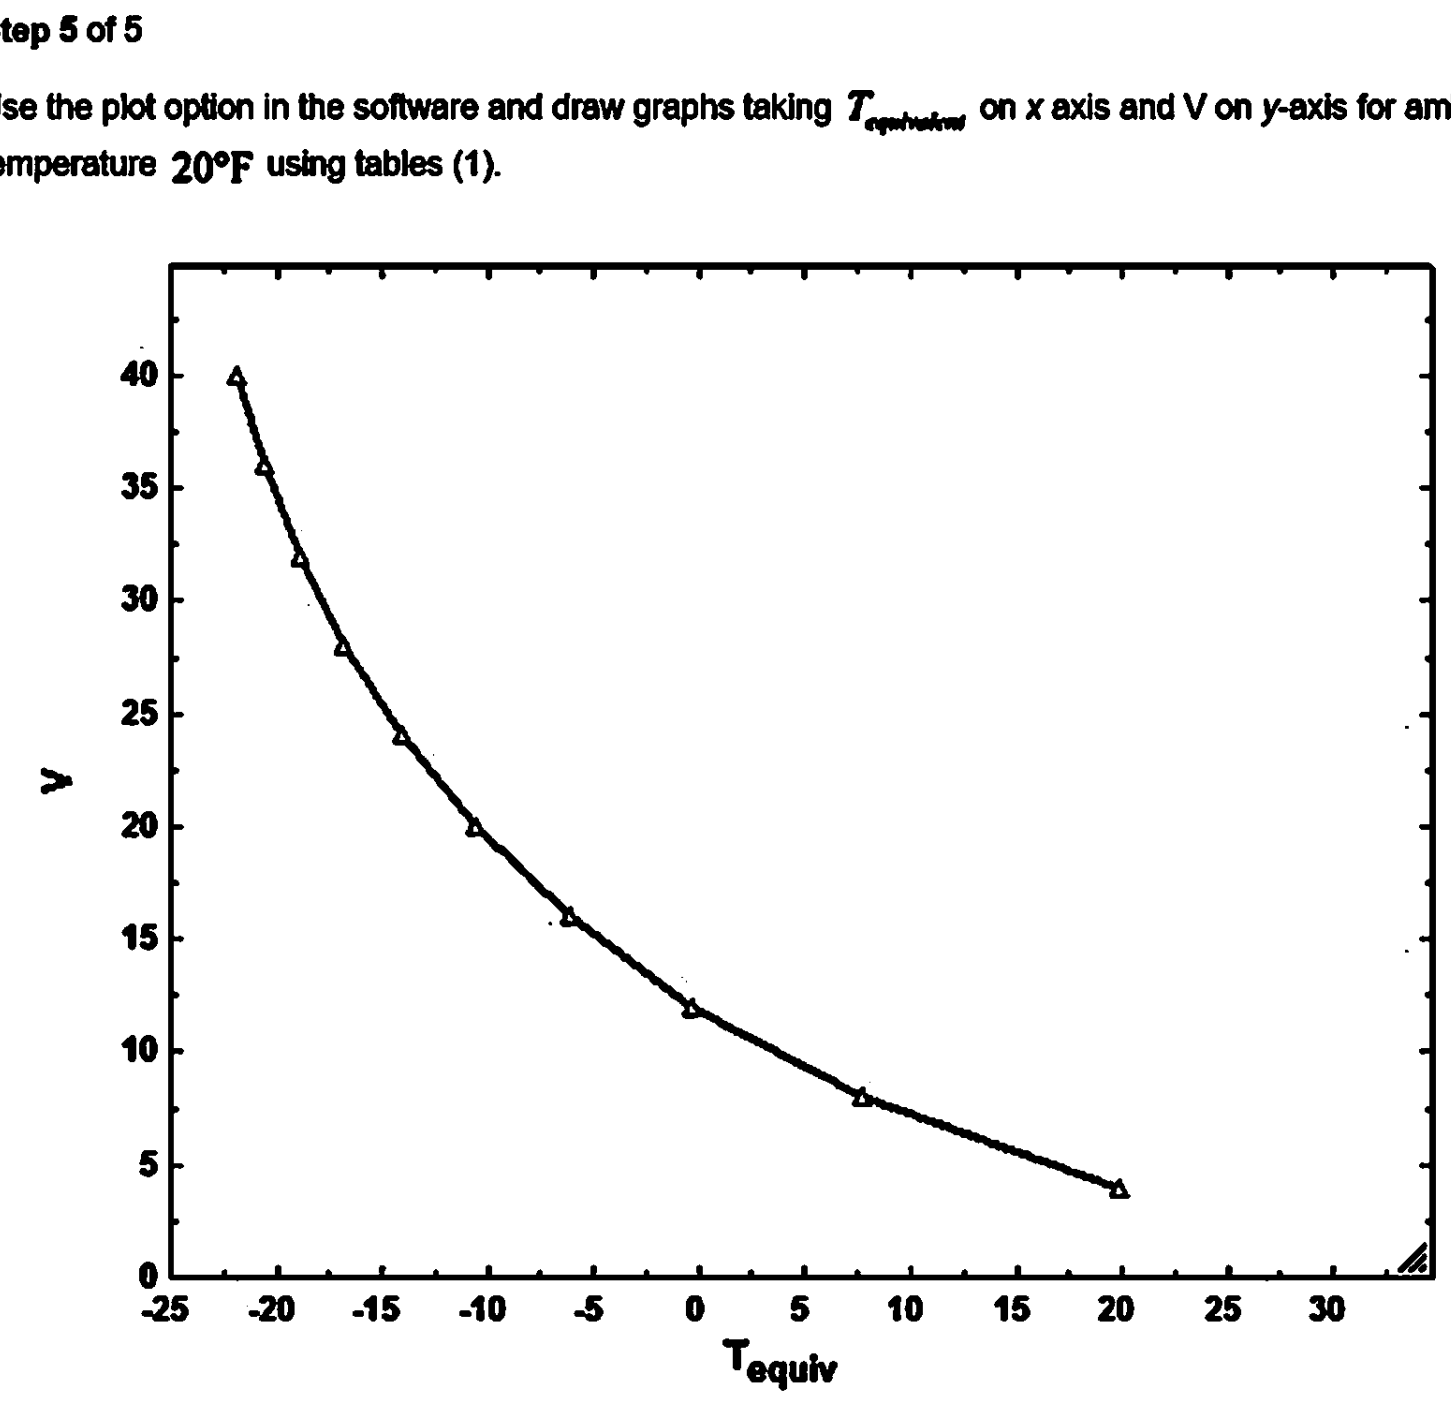
Step 4 of 5



Use the parametric table option and tabulate the $T_{equivalent}$ for $T_{ambient}$ at **60°F** and varying the velocity values *V* between **4 mph to 40 mph**

▷ 1..10	1 $T_{ambient}$	2 T_{equiv}	3 V
Run 1	60	59.94	4
Run 2	60	54.59	8
Run 3	60	51.07	12
Run 4	60	48.5	16
Run 5	60	46.54	20
Run 6	60	45.02	24
Run 7	60	43.82	28
Run 8	60	42.88	32
Run 9	60	42.16	36
Run 10	60	41.61	40

Table (3)

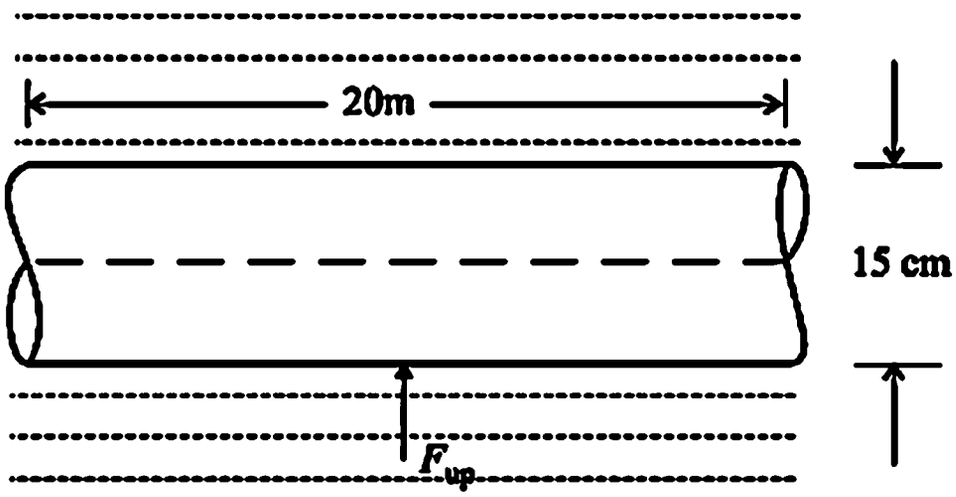


Step 5 of 5

Use the plot option in the software and draw graphs taking $T_{equivalent}$ on *x* axis and V on *y*-axis for ambient temperature **20°F** using tables (1).

Graph (1)

Use the overlay option and plot the curves at ambient temperature **40°F** using table (2) and at ambient temperature **60°F** using table (3) on the same graph.



Graph (2)

With the increase in the ambient temperature, slope of the curve increases.

Question: 2.077P

An air-conditioning system requires a 20-m-long section of 15-cm diameter duct work to be laid underwater. Determine the upward force the water will exert on the duct. Take the densities of air and water to be 1.3 kg/m3 and 1000 kg/m3, respectively.

Step 1 of 3

Step 2 of 3

Given

Length of duct $h = 20\ \text{m}$

Diameter of duct $d = 15\ \text{cm}$

$= 0.15\ \text{m}$ $\quad 1\ \text{cm} = 10^{-2}\text{m}$

The density of air $\rho_{air} = 1.3\ \text{kg/m}^3$

The density of water $\rho_w = 1000\ \text{kg/m}^3$

g is accelerating due to gravity $\left(9.81\ \text{m/s}^2\right)$

V is the volume of immersed body

Step 3 of 3

Where ρ is density in which it is immersed

The upward force acting here is the buoyancy force

$F_{buoyancy} = \rho g V$

$$V = \frac{\pi}{4} D^2 L$$

$$\therefore \quad F_{up} = \rho_w g V$$

$$= 1000 \times 9.81 \times \frac{\pi}{4} \times (0.15)^2 \times 20$$

$$= 3467.14\ \text{N}$$

$$\boxed{F_{up} = 3.467\ \text{kN}}$$

Question: 2.078P

Balloons are often filled with helium gas because it weighs only about one-seventh of what air weighs under identical conditions. The buoyancy force, which can be expressed as $Fb=\rho$ airguballon will Pusn me balloon upward. If the balloon has a diameter of 12 m and carries two people, 85 kg each, determine the acceleration of the balloon when it is first released. Assume the density of air is ρ = 1.16 kg/m3, and neglect the cage

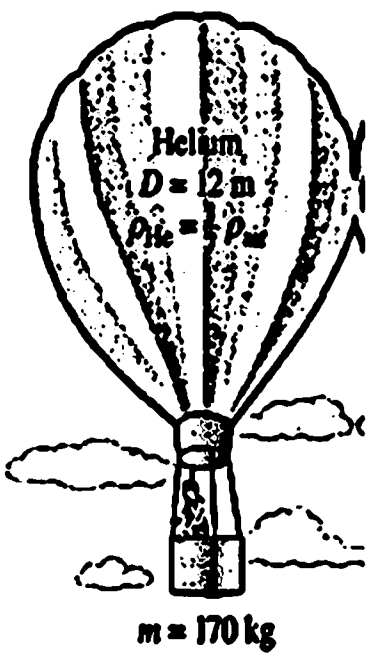


FIGURE P2–78

Step 1 of 5

Density of air $\rho_{air}=1.16\ \text{kg/m}^3$

Calculate the density of helium by using given relation between helium and air

$$\rho_{He}=\frac{1}{7}\rho_{air}$$

Substitute $1.16\ \text{kg/m}^3$ for ρ_{air}

$$\rho_{He}=\frac{1}{7}\rho_{air}$$
$$=\frac{1}{7}(1.16)$$
$$=0.166\text{kg/m}^3$$

Step 2 of 5

Calculate the volume of the spherical balloon

$$V_{balloon}=\frac{4}{3}\pi R^3$$

Here, R is the radius of the spherical balloon

Substitute 6m^3 for R

$$V_{balloon}=\frac{4}{3}\pi R^3$$
$$=\frac{4}{3}\pi(6)^3$$
$$=904.8\text{m}^3$$

Step 3 of 5

Calculate the buoyance force acting on balloon

$$F_B=\rho_{air}gV_{balloon}$$

Here, g is the acceleration due gravity

Substitute 9.81m/s^2 for g, 904.8m^3 for $V_{balloon}$

$$F_B=1.16\times9.81\times904.8$$
$$=10296.26\text{N}$$

Calculate the total mass of Helium,

$$m_{He}=\rho_{He}V$$

Substitute 0.166kg/m^3 for ρ_{He}, 9.81m/s^2 for g, 904.8m^3 for $V_{balloon}$

$$m_{He}=0.166\times904.8$$
$$=150.196\text{kg}$$

Calculate the total mass of the balloon by using the mass of the helium and mass of the people

$$m_{total}=m_{He}+m_{people}$$
$$=150.196+(2\times85)$$
$$=320.196\text{kg}$$

Now, total weight of the balloon

$$W=m_{total}\times g$$
$$=320.196\times9.81$$
$$=3141.130\text{N}$$

Step 4 of 5

Calculate the Net force acting on the balloon

$$F_{net}=W-F_B$$

Where F_{net} is the net force, F_B is the upward force due to buoyancy and W is the weight that pulls the balloon down

Substitute 10296.26N for F_B, 3141.130N for W

$$F_{net}=10296.26-3141.130$$
$$=7155.129\text{N}$$

Step 5 of 5

Calculate the net force

$$F_{net}=m_{total}\times a$$

Here, a is the acceleration of the balloon

Substitute 7155.129N for F_{net}

$$a=\frac{F_{net}}{m_{total}}$$
$$=\frac{7155.129}{320.196}$$
$$=22.346\text{m/s}^2$$

Thus, the acceleration of balloon is $\boxed{22.346\text{m/s}^2}$

Question: 2.079P

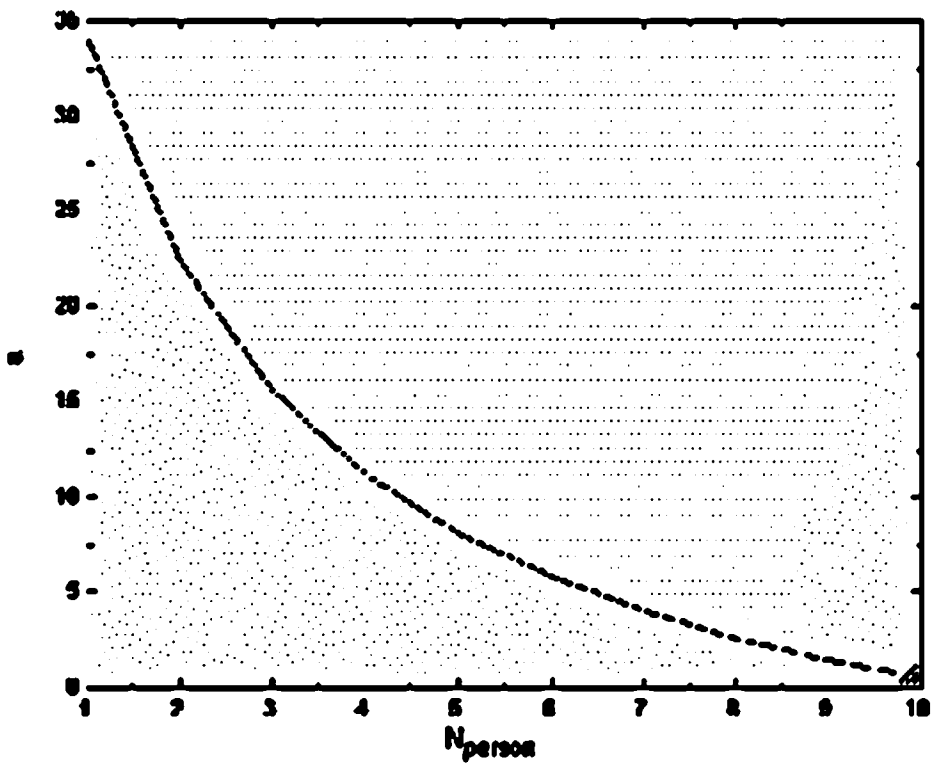
Reconsider Prob. 2–78. Using EES (or other) software, investigate the effect of the number of people carried in the balloon on acceleration. Plot the acceleration against the number of people, and discuss the results.

Step 1 of 4

"Given "
D=12 [m]
"N_person=2"
M_person=85[kg]
Rho_air=1.16[kg/m^3]
Rho_He=rho_air/7

Step 2 of 4

"Analysis"
g=9.81 [m/s^2]
V_ballon=pi*D^3/6
F_B=rho_air*g*V_ballon
M_he=rho_He*V_ballon
M_people=N_person*m_person
M_total=m_He+m_people
W=m_total*g
F_net=F_B-W
A+F_net/m_total



Step 3 of 4

From the menu bar, click the table, then select the new parameter table.
Then Run the table from 1 to 10.
Then click ok.

D 1..10	N_{person}	a
Run 1	1	34.02
Run 2	2	22.37
Run 3	3	15.62
Run 4	4	11.21
Run 5	5	8.093
Run 6	6	5.792
Run 7	7	4.011
Run 8	8	2.595
Run 9	9	1.443
Run 10	10	0.4867

Step 4 of 4

Graph:

Question: 2.080P

Determine the maximum amount of load, in kg, the balloon described in Prob. 2–78 can carry.

Step 1 of 5

Given

Density of air $\rho_{air} = 1.16 \text{ kg/m}^3$

Density of helium $\rho_{He} = \frac{1.16}{7} \text{ kg/m}^3$

$$\rho_{He} = 0.1657 \text{ kg/m}^3$$

Volume of balloon is $V_{balloon} = \frac{4}{3}\pi R^3$

$$V_{balloon} = \frac{4}{3} \times \pi \times 6^3$$

$$V_{balloon} = 904.32 \text{ m}^3$$

Step 2 of 5

Buoyancy force acting on the balloon is

$$F_B = \rho_{air} g V_{balloon}$$

$$F_B = 1.16 \times 9.81 \times 904.32$$

$$F_B = 10290.79 \text{ N}$$

Total mass of Helium,

$$m_{He} = \rho_{He} V$$

$$m_{He} = 0.1657 \times 904.32$$

$$m_{He} = 149.85 \text{ kg}$$

Step 3 of 5

Net force acting on the balloon is,

$F_{net} = W - F_B$

Where F_{net} is the net force

F_B is the upward force due to buoyancy

W is the weight that pulls the balloon down

Step 4 of 5

For maximum condition, the net force on balloon is zero. So,

$0 = W - F_B$

$W = F_B$

$m_{total} \times g = F_B$

$$m_{total} = \frac{F_B}{g}$$

$$m_{total} = \frac{10290.79}{9.81} \text{ kg}$$

$$m_{total} = 1049.01 \text{ kg}$$

Step 5 of 5

But total mass is due to mass of people and the mass of helium. Thus

$m_{total} = m_{people} + m_{He}$

$m_{people} = m_{total} - m_{He}$

$m_{people} = 1049.01 - 149.85$

$m_{people} = 899.16 \text{ kg}$

Hence mass of people is $\boxed{m_{people} = 899.16 \text{ kg}}$

Question:

2.081P

The lower half of a 10-m-high cylindrical container is filled with water (ρ = 1000 kg/m3) and the upper half with oil that has a specific gravity of 0.85. Determine the pressure difference between the top and bottom of the cylinder.

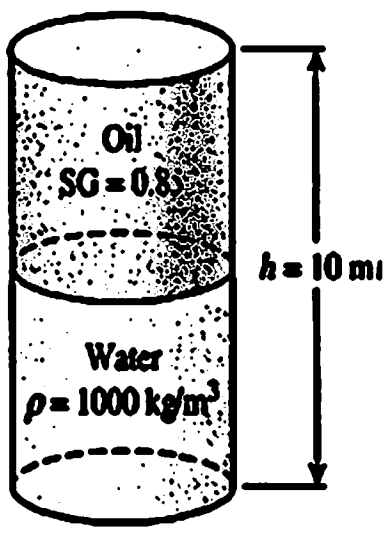


FIGURE P2–81

Question:

The lower half of a 10-m-high cylindrical container is filled with water (ρ = 1000 kg/m3) and the upper half with oil that has a specific gravity of 0.85. Determine the pressure difference between the top and bottom of the cylinder.

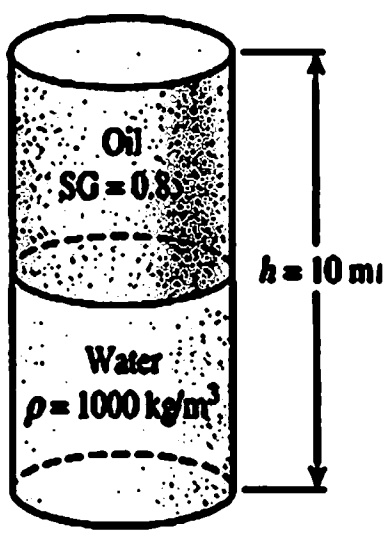

FIGURE P2–81

specific gravity of the oil $\times \rho_w = \rho_{oil}$

ρ_{oil} is the density of the oil and ρ_w is the density of water.

Substitute 0.85 for specific gravity of the oil and $1000\,^{kg}/_{m^3}$ for ρ_w.

$$\rho_{oil} = 0.85 \times 1000$$
$$= 850\,kg/m^3$$

Calculate the pressure exerted by the oil.

Write the formula for the pressure acting at a certain datum.

$$\Delta p = \rho g h$$

$$\Delta p = (\rho h)_{oil}\, g$$

Here, ρ_{oil} is the density of the oil, g is the gravity and h_{oil} is the height of the oil from the datum.

Substitute $850\,kg/m^3$ for ρ_{oil} and 9.81 for g and 5 m for h_{oil}.

$$\Delta p = (850 \times 5)_{oil} \times 9.81$$
$$= 41{,}692.5\ kPa$$

Step 3 of 3

Calculate the pressure exerted by the water.

Write the formula for the pressure acting at a certain datum.

$$\Delta p = \rho g h$$

$$\Delta p = (\rho h)_{water}\, g$$

Here, ρ_w is the density of the water, g is the gravity and h_w is the height of the water from the datum.

Substitute $1000\,kg/m^3$ for ρ_w and 9.81 for g and 5 m for h_w.

$$\Delta p = (1000 \times 5)_{oil} \times 9.81$$
$$= 49{,}050\ kPa$$

Calculate the pressure difference between the top and the bottom of the cylinder.

The pressure difference between the top and the bottom of the cylinder is the sum of the pressure differences across the two fluids.

$$\Delta p = (\rho g h)_{oil} + (\rho g h)_{water}$$

Substitute 41,692.5 kPa for the value $(\rho g h)_{oil}$ and 49,050 kPa for the value $(\rho g h)_{water}$.

$$\Delta P = (41{,}692.5 + 49{,}050)$$
$$= 90{,}742.5\,N/m^2$$
$$= 90.7\ kPa$$

Therefore, the pressure difference Δp between the top and the bottom of the cylinder is $\boxed{90.74\,kPa}$.

Question: 2.082P

A vertical, frictionless piston-cylinder device contains a gas at 180 kPa absolute pressure. The atmospheric pressure outside is 100 kPa, and the piston area is 25 cm2. Determine the mass of the piston.

Step 1 of 4

Given

Pressure on the piston $P = 180\ \text{kPa}$

Atmospheric pressure on piston $P_{atm} = 100\ \text{kPa}$

Area of the piston is $A = 25\ \text{cm}^2$

$A = 25 \times 10^{-4}\ \text{m}^2$

Acceleration due to gravity $g = 9.81\ \text{m/s}^2$

Let mass of the piston be m

Step 2 of 4

Free body diagram of the piston

Question:

A vertical, frictionless piston-cylinder device contains a gas at 180 kPa absolute pressure. The atmospheric pressure outside is 100 kPa, and the piston area is 25 cm2. Determine the mass of the piston.

Step 1 of 4

Given

Pressure on the piston $P = 180\ \text{kPa}$

Atmospheric pressure on piston $P_{atm} = 100\ \text{kPa}$

Area of the piston is $A = 25\ \text{cm}^2$

$A = 25 \times 10^{-4}\ \text{m}^2$

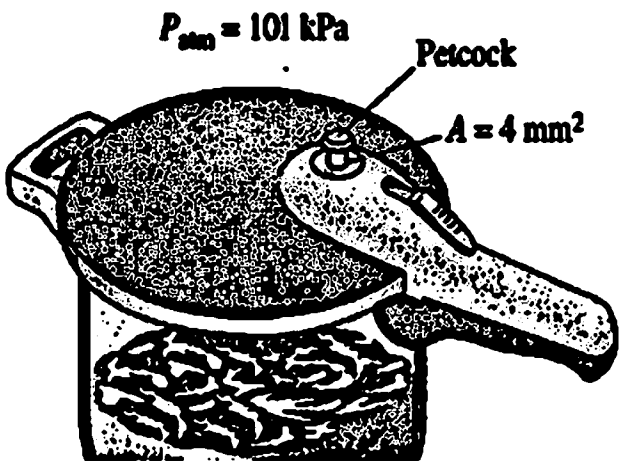
Acceleration due to gravity $g = 9.81\ \text{m/s}^2$

Let mass of the piston be m

Step 2 of 4

Free body diagram of the piston

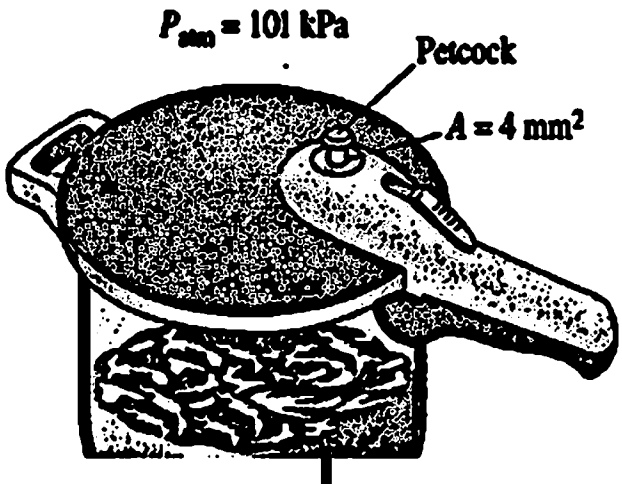
$m \times 9.81 = 80 \times 2.5$



$$m = \frac{200}{9.81}$$

$m = 20.39\ \text{kg}$

Hence the mass of the piston is $\boxed{m = 20.39\ \text{kg}}$



Question: 2.083P

A pressure cooker cooks a lot faster than an ordinary pan by maintaining a higher pressure and temperature inside. The lid of a pressure cooker is well sealed, and steam can escape only through an opening in the middle of the lid. A separate metal piece, the petcock, sits on top of this opening and prevents steam from escaping until the pressure force overcomes the weight of the petcock. The periodic escape of the steam m this manner prevents any potentially dangerous pressure buildup and keeps the pressure inside at a constant value. Determine the mass of the petcock of a pressure cooker whose operation pressure is 100 kPa gage and has an opening cross-sectional area of 4 mm2. Assume an atmospheric pressure of 101 kPa, and draw the free-body diagram of the petcock.

Question:

A pressure cooker cooks a lot faster than an ordinary pan by maintaining a higher pressure and temperature inside. The lid of a pressure cooker is well sealed, and steam can escape only through an opening in the middle of the lid. A separate metal piece, the petcock, sits on top of this opening and prevents steam from escaping until the pressure force overcomes the weight of the petcock. The periodic escape of the steam m this manner prevents any potentially dangerous pressure buildup and keeps the pressure inside at a constant value. Determine the mass of the petcock of a pressure cooker whose operation pressure is 100 kPa gage and has an opening cross-sectional area of 4 mm2. Assume an atmospheric pressure of 101 kPa, and draw the free-body diagram of the petcock.

Step 2 of 2

The weight of the petcock acts downwards and the pressure inside the cooker will act upwards. So the weight of petcock (W) is balanced by gage pressure inside the cooker.

$$W = P_{gage} \times A$$

$$mg = P_{gage} \times A$$

$$m = \frac{P_{gage} \times A}{g}$$

Here the mass of petcock is m

the gage pressure acting inside the cooker is P_{gage}

the cross sectional area of opening is A

Step 2 of 2

Question:

2.084P

A glass tube is attached to a water pipe, as shown in Fig. P2-84. If the water pressure at the bottom of the tube is 120 kPa and the local atmospheric pressure is 99 kPa, determine how high the water will rise in the tube, in m. Take the density of water to be 1000 kg/m3.

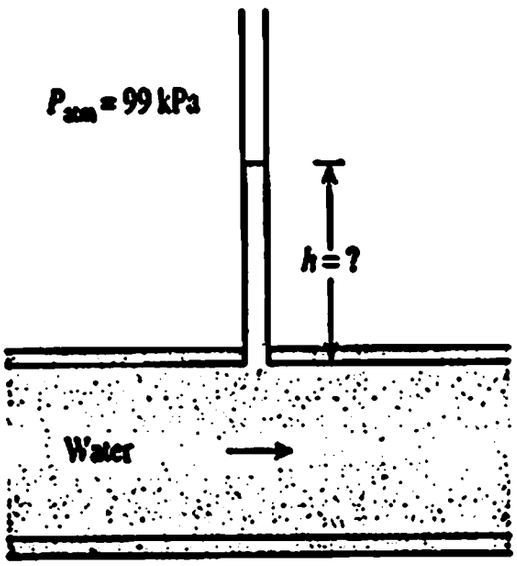


FIGURE P2–84

Question:

A glass tube is attached to a water pipe, as shown in Fig. P2-84. If the water pressure at the bottom of the tube is 120 kPa and the local atmospheric pressure is 99 kPa, determine how high the water will rise in the tube, in m. Take the density of water to be 1000 kg/m3.

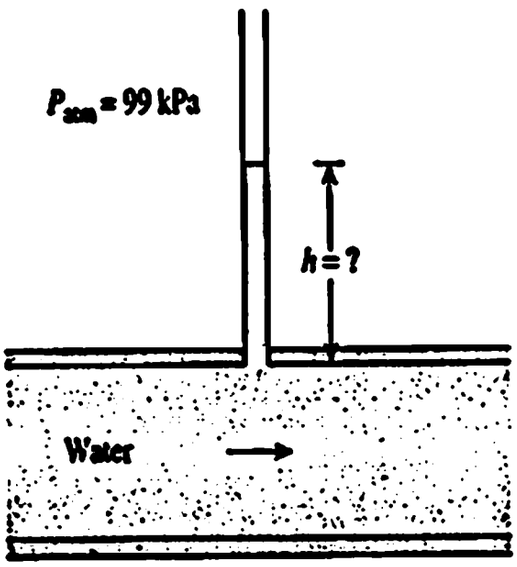

FIGURE P2–84

Step 1 of 1

Calculate the height the water will raise in the tube.

Therefore, the height the water will raise in the tube is $\boxed{2.140\,\text{m}}$.

Question: 2.085P

When measuring small pre ssure differences with a manometer, often one arm of the manometer is inclined to improve the accuracy of reading. (The pressure difference is still proportional to the *vertical* distance and not the actual length of the fluid along the tube.) The air pressure in a circular duct is to be measured using a manometer whose open arm is inclined 45° from the horizontal, as shown in Fig. P2-85 The density of the liquid in the manometer is 0.81 kg/L, and the vertical distance between the fluid levels in the two arms of the manometer is 12 cm. Determine the gage pressure of air in the duct and the length of the fluid column in the inclined arm above the fluid level in the vertical arm.

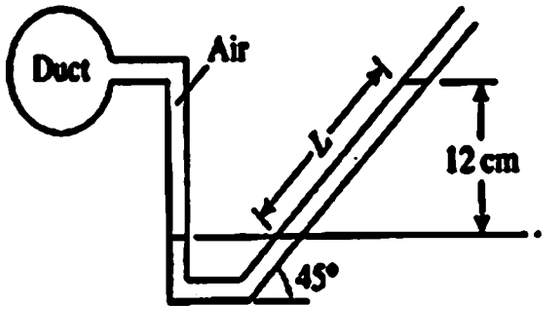

FIGURE P2–85

Question:

When measuring small pre ssure differences with a manometer, often one arm of the manometer is inclined to improve the accuracy of reading. (The pressure difference is still proportional to the *vertical* distance and not the actual length of the fluid along the tube.) The air pressure in a circular duct is to be measured using a manometer whose open arm is inclined 45° from the horizontal, as shown in Fig. P2-85 The density of the liquid in the manometer is 0.81 kg/L, and the vertical distance between the fluid levels in the two arms of the manometer is 12 cm. Determine the gage pressure of air in the duct and the length of the fluid column in the inclined arm above the fluid level in the vertical arm.

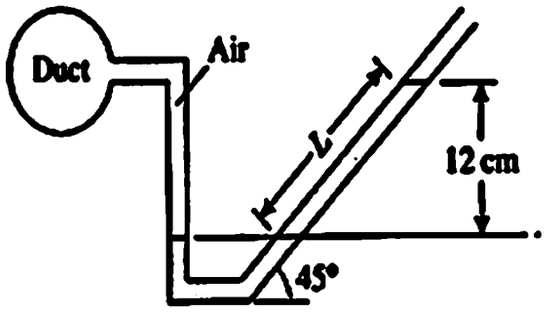

FIGURE P2–85

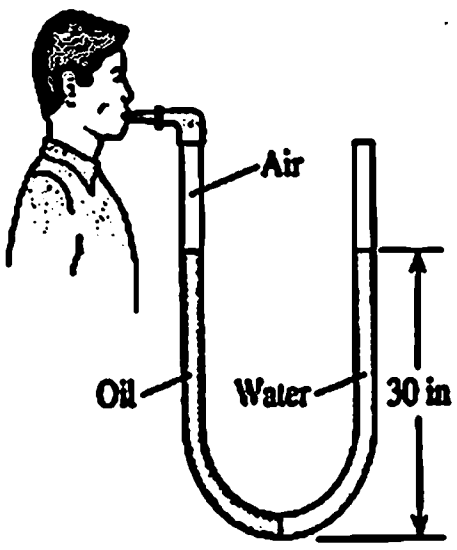
Step 1 of 2

Question: 2.086P

Consider a U-tube whose arms are open to the atmosphere. Now equal volumes of water and light oil (ρ = 49.3 lbm/ft3) are poured from different arms. A person blows from the oil side of the U-tube until the contact surface of the two fluids moves to the bottom of the U-tube, and thus the liquid levels in the two arms are the same. If the fluid height in each arm is 30 in, determine the gage pressure the person exerts on the oil by blowing.



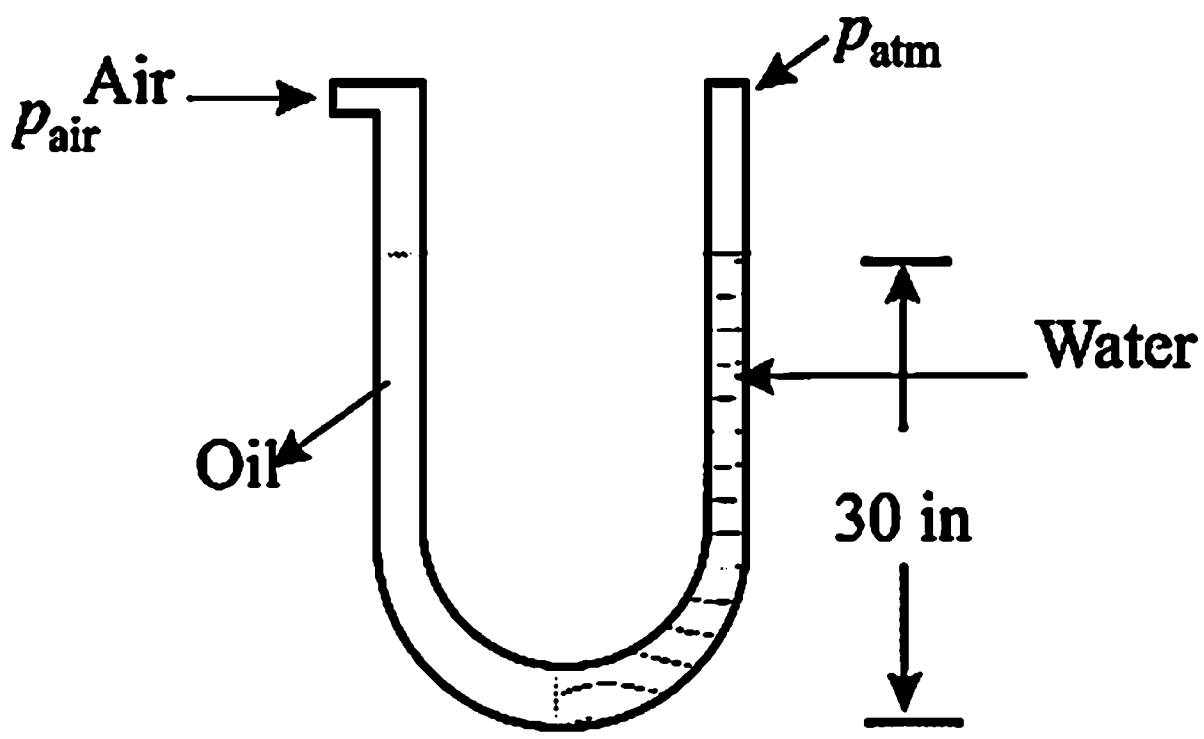


FIGURE P2–86E

Step 1 of 3

Step 2 of 3

The atmospheric pressure $p_{atm} = 14.3\text{Psi}$

The density of water $\rho_w = 62.4\ \text{lbm/ft}^3$

The density of oil $\rho_{oil} = 49.3\text{lbm/ft}^3$

The height of oil and water $h_{oil} = hw = 30\ \text{in}$

Step 3 of 3

In order to balance the level of two fluids in the manometer the pressure of air to atmospheric pressure is related as

$$p_{blow} + (\rho gh)_{oil} = p_{atm} + (\rho gh)_{water}$$

The acceleration due to gravity of earth $g = 32.174\text{ft/s}^2$

1ft=12in

$$1\text{lbf} = \frac{1}{32.174}\text{lbm ft/s}^2$$

$$p_{gage,blow} = p_{blow} - p_{atm}$$

$$p_{gage,blow} = (\rho_w - \rho_{oil})gh$$

$$p_{gage,blow} = (62.4 - 49.3)32.174 \times \frac{30}{12} \times \frac{1}{32.174} \times \frac{1}{(144)}$$

$$\boxed{p_{gage,blow} = 0.227\text{Psi}}$$

Question: 2.087P

Intravenous infusions are usually driven by gravity by hanging the fluid bottle at sufficient height to counteract the blood pressure in the vein and to force the fluid into the body. The higher the bottle is raised, the higher the flow rate of the fluid will be. (*a*) If it is observed that the fluid and the blood pressures balance each other when the bottle is 80 cm above the arm level, determine the gage pressure of the blood, (*b*) If the gage pressure of the fluid at the arm level needs to be 15 kPa for sufficient flow rate, determine how high the bottle must be placed. Take the density of the fluid to be 1020 kg/m3.

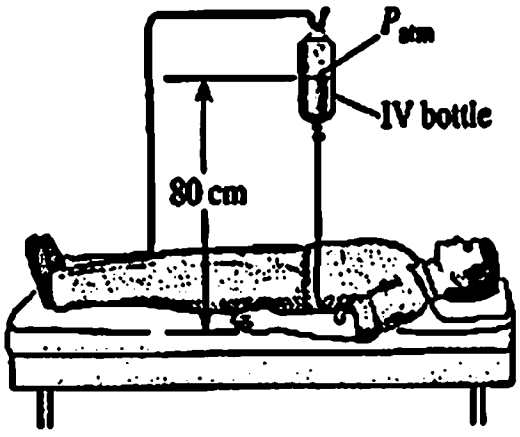

FIGURE P2–87

Step 1 of 3

Note the following data from the problem.

Density of the fluid is $\rho = 1020\ \text{kg/m}^3$

Height of bottle is $h = 80\ \text{cm}$

Step 2 of 3

(a)

Calculate the gage pressure of the blood using the relation,

$$P_{gauge,arm} = (\rho g h)_{air\ bottle}$$

Substitute 80 cm for h, $1020\ \text{kg/m}^3$ for ρ , and $9.81\ \text{m/s}^2$ for g.

$$\begin{aligned} P_{gauge,arm} &= \left(1020\ \frac{\text{Kg}}{\text{m}^3}\right)\left(9.81\frac{\text{m}}{\text{s}^2}\right)(0.8\ \text{m}) \\ &= 8004.96\ \text{Pa} \\ &= 8.00496\ \text{kPa} \end{aligned}$$

Gauge Pressure in the arm is $\boxed{P_{gauge,arm} = 8.00496\ \text{kPa}}$.

Step 3 of 3

(b)

If the Pressure in the arm level needs to be 15 kPa, calculate the height using the following relation.

$$P_{gauge,arm} = \rho g h_{arm-bottle}$$

$$h_{arm-bottle} = \frac{P_{gauge,arm}}{\rho g}$$

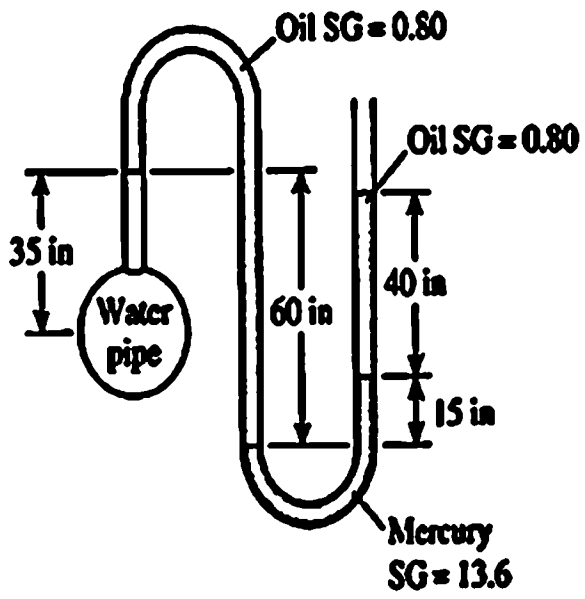
Substitute 15 kPa for $P_{gauge,arm}$, $1020\ \text{kg/m}^3$ for ρ , and $9.81\ \text{m/s}^2$ for g.

$$\begin{aligned} h_{arm-bottle} &= \frac{15\times 1000}{1020\times 9.81} \\ &= 1.5\ \text{m} \end{aligned}$$

Height of bottle from arm level is $\boxed{h_{arm-bottle} = 1.5\ \text{m}}$

Question: 2.088P

A water pipe is connected to a double-U manometer as shown in Fig. P2-88E at a location where the local atmospheric pressure is 14.2 psia. Determine the absolute pressure at the center of the pipe.



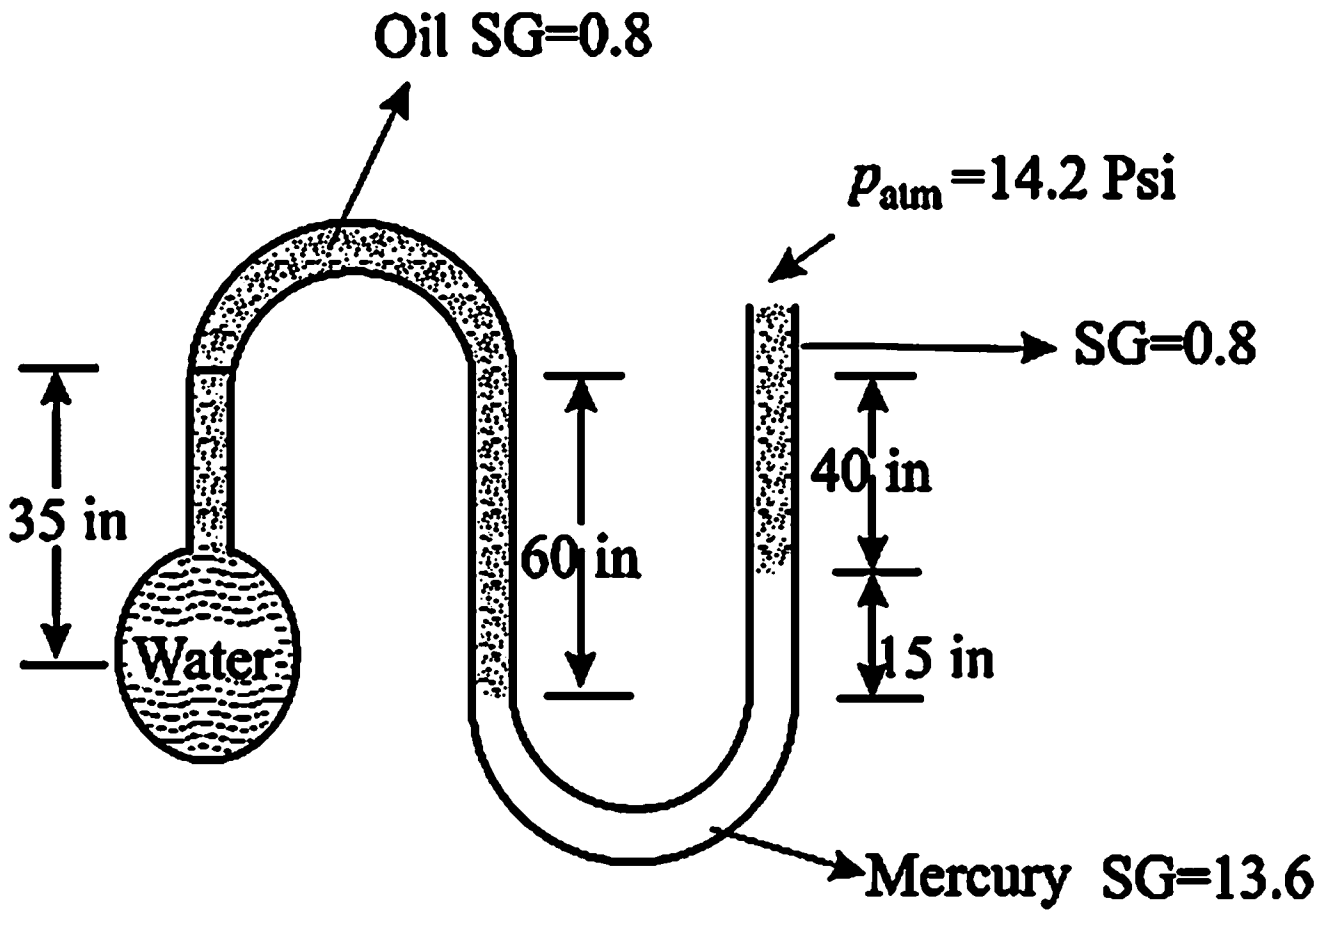


FIGURE P2–88E

Step 1 of 4

Step 2 of 4

Given

The local atmospheric pressure $p_{atm} = 14.2 \text{psia}$

Density of water $\rho_w = 62.4 \text{lbm/ft}^3$

Specific gravity of oil S.G=0.8

The height of oil $h_{1oil} = 40 \text{in}$

The height of mercury $h_{Hg} = 15 \text{in}$

The height of oil $h_{2oil} = 60 \text{in}$

The height of water $h_w = 35 \text{in}$

Step 3 of 4

The density of oil $\rho_{oil} = s.G \times \rho_w$

$$\rho_{oil} = 0.8 \times 62.4$$

$$\rho_{oil} = 49.92 \text{lbm/ft}^3$$

The acceleration due to gravity of earth $g = 32.174 \text{ft/s}^2$

Specific gravity of mercury $H_g = 13.6$ (mercury)

The density of oil $\rho_{H_g} = S.G \times \rho_w$

$$\rho_{Hg} = 13.6 \times 62.4$$

$$\rho_{Hg} = 848.64 \text{lbm/ft}^3$$

Step 4 of 4

The relation between absolute pressure and atmospheric pressure

$$p_{abs} = p_{atm} + \rho g h$$

The height column 'h'is taken positive while giving downwards and negative upwards.

In our problem, the absolute pressure at the center of pipe

$$p_{abs} = p_{atm} + (\rho_{oil} g h_{oil})_1 + \rho_{Hg} g h_{Hg} - (\rho_{oil} g h_{oil})_2 + \rho_w g h_w$$

$$\Rightarrow P_{abs} = 14.2 + (49.92 \times 40 + 848.64 \times 15 - 49.92 \times 60 + 624 \times 35) g$$

$$P_{abs} = 14.2 + (13915.2) g \cdot \frac{\text{lbm}}{\text{ft}^3} \cdot \text{in} \times \frac{1}{g} \frac{\text{ft}^3}{\text{in}^3 (12)^3}$$

$$P_{abs} = 14.2 + 8.054 \left(\frac{\text{lbf}}{\text{in}^2} \right)$$

$$\boxed{P_{abs} = 22.26 \text{Psi}}$$

Question: 2.089P

The average atmospheric pressure on earth is approximated as a function of altitude by the relation *p*atm=101.325 (1–0.02256*z*)5.256, where *P*atm is the atmospheric pressure in kPa and *z*is the altitude in km with $z = 0$ at sea level. Determine the approximate atmospheric pressures at Atlanta (z =306 m), Denver (z = 1610 m), Mexico City (z =2309 m), and the top of Mount Everest (z =8848 m).

Step 1 of 5

The approximate relation of atmospheric pressure is given by

$$P_{atm} = 101.325(1 - 0.02256z)^{5.256}$$

Where z is the altitude in km

P_{atm} is the atmospheric pressure in kPa

Step 2 of 5

Altitude of Atlanta is $z = 306$ m

$z = 0.306$ km

Therefore

$$P_{atm} = 101.325[1 - 0.02256(0.306)]^{5.256} \text{ kPa}$$

$$P_{atm} = 97.70 \text{ kPa}$$

Atmospheric Pressure at Atlanta is $\boxed{P_{atm} = 97.70 \text{ kPa}}$

Step 3 of 5

Altitude of Denver is $z = 1610$ m

$z = 1.61$ km

Therefore

$$P_{atm} = 101.325[1 - 0.02256(1.61)]^{5.256} \text{ kPa}$$

$$P_{atm} = 83.38 \text{ kPa}$$

Atmospheric Pressure at Denver is $\boxed{P_{atm} = 83.38 \text{kPa}}$

Step 4 of 5

Altitude of Mexico city is $z = 2309$ m

$z = 2.309$ km

Therefore

$$P_{atm} = 101.325[1 - 0.02256(2.309)]^{5.256} \text{ kPa}$$

$$P_{atm} = 76.53 \text{ kPa}$$

Atmospheric Pressure at Mexico city is $\boxed{P_{atm} = 76.53 \text{kPa}}$

Step 5 of 5

Altitude of Mount Everest is $z = 8848$ m

$z = 8.848$ km

Therefore

$$P_{atm} = 101.325[1 - 0.02256(8.848)]^{5.256} \text{ kPa}$$

$$P_{atm} = 31.36 \text{ kPa}$$

Atmospheric Pressure at Mount Everest is $\boxed{P_{atm} = 31.36 \text{kPa}}$

CHAPTER 03

SOLUTIONS

Question: 3.001P

What is the difference between the macroscopic and microscopic forms of energy?

Step 1 of 1

The macroscopic forms of energy are those a system possesses as a whole with respect to some outside reference frame, such as kinetic and potential energies.

The microscopic forms of energy are those related to the molecular structure of a system and the degree of the molecular activity, and they are independent of outside reference frames. The sum of all the microscopic forms of energy is called the internal energy of a system and is denoted by U.

Question: 3.002P

What is total energy? Identify the different forms of energy that constitute the total energy.

Step 1 of 5

Energy can exist in numerous forms such as thermal, mechanical, kinetic, potential, electric, magnetic, chemical, and nuclear, and their sum constitutes the total energy E of a system. The total energy of a system on a unit mass basis is denoted by '*e*' and is expressed as

$$e = \frac{E}{m} \quad (\text{kJ/kg})$$

Step 2 of 5

The magnet, electric, and surface tension effects are significant in some specialized cases only and are usually ignored. In the absence of such effects, the total energy of the system consists of the kinetic, potential, and internal energies and is expressed as

$$E = U + KE + PE \quad (\text{kJ})$$

Or, on a unit mass basics,

$$e = u + ke + pe \quad (\text{kJ/kg})$$

Step 3 of 5

Where KE is called as the energy that a system possesses as a result of its motion relative to some reference frame is called kinetic energy (KE).The kinetic energy is expressed as

$$KE = m\frac{V^2}{2} \quad (\text{kJ})$$

Step 4 of 5

PE is the called as potential energy, the energy that a system possesses as a result of its elevation in a gravitational field is called potential energy (PE) and is expressed as

$$PE = mgz \quad (\text{kJ})$$

Step 5 of 5

U is known as internal energy of a system.
Therefore the total energy of the system is expressed as

$$E = U + KE + PE \quad (\text{kJ})$$

$$\boxed{E = U + m\frac{V^2}{2} + mgz \quad (\text{kJ})}$$

Question: 3.003P

How are heat, internal energy, and thermal energy related to each other?

Step 1 of 1

Heat is defined as the form of energy that is transferred between two systems (or a system and its surroundings) by virtue of a temperature difference.
Heat is energy in transition. It is recognized only as it crosses the boundary of a system.

The sum of all the microscopic forms of energy is called the internal energy of a system and is denoted by U.

Thermal energy is generated and measured by heat of any kind. In daily life, we frequently refer to the sensible and latent forms of internal energy as heat, and we talk about heat content of bodies. In thermodynamics, however, we usually refer to those forms of energy as thermal energy to prevent any confusion with heat transfer.

Question: 3.004P

What is mechanical energy? How does it differ from thermal energy? What are the forms of mechanical energy of a fluid stream?

Step 1 of 3

The mechanical energy can be defined as the form of energy that can be converted to mechanical work completely and directly by an ideal mechanical device such as an ideal turbine. Kinetic and potential energies are the familiar forms of mechanical energy.

Step 2 of 3

Thermal energy is not mechanical energy, however, since it cannot be converted to work directly and completely, where mechanical energy converts to work directly.

Step 3 of 3

A pump transfer's mechanical energy to a fluid by raising its pressure, and a turbine extracts mechanical energy from a fluid by dropping its pressure. Therefore, the pressure of a flowing fluid is also associated with its mechanical energy. The pressure itself is not a form of energy. But a pressure force acting on a fluid through a distance produces work, called flow work.

Flow work is expressed in terms of fluid properties, and it is convenient to view it as part of the energy of a flowing fluid and call it flow energy. Therefore, the mechanical energy of a flowing fluid can be expressed on a unit mass basis as

$$e_{mech} = \frac{P}{\rho} + \frac{V^2}{2} + gz \quad (\text{kJ/kg})$$

Where $\frac{P}{\rho}$ is the flow energy, $\frac{V^2}{2}$ is the kinetic energy, and gz is the potential energy of the fluid, all per unit mass.

Question: 3.005P

Natural gas, which is mostly methane CH4, is a fuel and a major energy source. Can we say the same about hydrogen gas, H2?

Step 1 of 1

Since it can be burned, Hydrogen is also a fuel. It is not an energy source as there are no hydrogen reserves in the world. Water is the energy source which provides hydrogen. Hydrogen obtained from water can be used as fuel for cars and generators. Therefore hydrogen is more of an energy carrier than an energy source.

Question: 3.006P

Calculate the total kinetic energy, in Btu, of an object with a mass of 15 lbm when its velocity is 100 ft/s.

Step 1 of 2

Given

Mass of the object $m = 15$ lbm

Velocity of object, $V = 100$ ft/s

But 1 lbm $= 0.4536$ kg

And 1 ft $= 0.3048$ m

Hence $m = 15 \times 0.4536$ kg

$m = 6.804$ kg

$V = 100 \times 0.3048$ m/s

$V = 30.48$ m/s

Step 2 of 2

Kinetic energy of an object,

$$KE = \frac{1}{2}mv^2$$

$$KE = \frac{1}{2}(6.804\text{ kg}) \times (304.8\text{ m/s})^2$$

$$KE = 3160.56\text{ J}$$

$$KE = 3.16056\text{ kJ}$$

But 1 Btu $= 1.05435$ KJ

Hence $KE = 3.16056\text{ kJ} \times \frac{1\text{ Btu}}{1.05435\text{ KJ}}$

$KE = 2.9976$ Btu

$KE = 3$ Btu

Hence Kinetic energy of an object is $\boxed{KE = 3\text{ Btu}}$

Question: 3.007P

Calculate the total kinetic energy, in kJ, of an object whose mass is 100 kg and whose velocity is 20 m/s.

Step 1 of 1

Calculate the kinetic energy of the object using the equation,

$$KE = \frac{1}{2}mV^2$$

Here, m is mass of the object and V is velocity of the object.

Substitute 100 kg for m and $20\ \text{m/s}$ for V.

$$KE = \frac{1}{2} \times 100 \times 20^2$$

$$= 20 \times 10^3\ \text{J} \left| \frac{1\ \text{kJ}}{10^3\ \text{J}} \right|$$

$$= 20\ \text{kJ}$$

Therefore, the kinetic energy of the object is $\boxed{20\ \text{kJ}}$.

Question: 3.008P

The specific potential energy of an object with respect to some datum level is given by gz where g is the local gravitational acceleration and z is the elevation of the object above the datum. Determine the specific potential energy, in Btu/lbm, of an object elevated 100 ft above a datum at a location where g = 32.1 ft/s2.

Step 1 of 1

Find the specific potential energy of an object by using the following equation:

$$(pe) = gz$$

Here, g is acceleration due to gravity and z is the elevation of the object above the datum.

Substitute $32.2\ ft/s^2$ for g and 100 ft for z.

$$pe = 32.2 \times 100$$
$$= 3220\ ft^2/s^2$$

Convert potential energy from ft^2/s^2 to Btu/lbm by using conversion formula.

$$pe = 3220\ ft^2/s^2 \times \frac{1\ Btu/lbm}{25037\ ft^2/s^2}$$
$$= 0.128\ Btu/lbm$$

Therefore, the specific potential energy of an object is $\boxed{0.128\ Btu/lbm}$

Question: 3.009P

Calculate the total potential energy, in Btu, of an object with a mass of 200 lbm when it is 10 ft above a datum level at a location where standard gravitational acceleration exists.

Step 1 of 2

Mass of an object $m = 200$ lbm

Height of object $z = 10$ ft

Acceleration due to gravity is $g = 9.81\ \text{m/s}^2$

But $1\ \text{lbm} = 0.4536\ \text{kg}$

And $1\ \text{ft} = 0.3048\ \text{m}$

Hence $m = 200 \times 0.4536\ \text{kg}$

$m = 90.72\ \text{kg}$

$z = 10 \times 0.3048\ \text{m}$

$z = 3.048\ \text{m}$

Step 2 of 2

Potential energy possessed by an object

$PE = mgz$

$PE = 90.72 \times 9.81 \times 3.048$

$PE = 2712.61\ \text{J}$

$PE = 2.71261\ \text{kJ}$

But $1\ \text{Btu} = 1.05435\ \text{kJ}$

$$PE = 2.71261\ \text{kJ} \times \frac{1\ \text{Btu}}{1.05435\ \text{kJ}}$$

$PE = 2.573\ \text{Btu}$

Hence Potential energy is $\boxed{PE = 2.573\ \text{Btu}}$

Question: 3.010P

Calculate the total potential energy, in kJ, of an object whose mass is 20 kg when it is located 20 m below a datum level in a location where g =9.5 m/s2.

Step 1 of 1

The total potential energy possessed by a body can be calculated with the help of the following formula:

$$PE = mgz$$

Here, m is the mass of an object, z is the datum height of the object and g is the acceleration due to gravity

Since the object is located 20 m below the datum line, the value of z will be $-20\,\text{m}$.

Substitute 20 kg for m, -20 m for z and 9.5 m/s^2 for g.

$$\begin{aligned} PE &= 20(-20)(9.5) \\ &= -3800\ \text{J} \\ &= -3.8\ \text{kJ} \end{aligned}$$

Hence, the potential energy is $\boxed{-3.8\ \text{kJ}}$

Question: 3.011P

A person gets into an elevator at the lobby level of a hotel together with his 30-kg suitcase, and gets out at the 10th floor 35 m above. Determine the amount of energy consumed by the motor of the elevator that is now stored in the suitcase.

Step 1 of 2

Given data:

The mass of a suitcase, $m = 30$ kg

The height up to which he climbed in elevator, $h = 35$ m

Assume acceleration due to gravity, $g = 9.8\ m/s^2$

Step 2 of 2

The energy stored in the suitcase is in the form of potential energy due to the elevation which is given by

$$PE = mgh$$
$$= 30 \times 9.8 \times 35$$
$$= 10290\ J$$
$$\boxed{PE = 10.3\ kJ}$$

The suitcase posses 10.3 kJ of energy at 10^{th} floor compared to 1^{st}.

Question: 3.012P

Electric power is to be generated by installing a hydraulic turbine-generator at a site 160 m below the free surface of a large water reservoir that can supply water at a rate of 3500 kg/s steadily. Determine the power generation potential.

Step 1 of 1

Calculate the power generation potential of the hydraulic turbine using the following formula:

$$P = \dot{m} \times g \times z$$

Here, $\dot{m}$ is the mass flow rate of water, z is the height of the water reservoir, g is the and acceleration due to gravity.

Substitute $3500\,\text{kg/s}$ for $\dot{m}$, $9.81\,\text{m/s}^2$ for g, $160\,\text{m}$ for z

$$\begin{aligned} P &= 3500 \times 9.81 \times 160 \\ &= 5.493 \times 10^6\ \text{W} \\ &= 5.493\ \text{MW} \end{aligned}$$

Hence power generation potential is $\boxed{5.493\ \text{MW}}$

Question: 3.013P

At a certain location, wind is blowing steadily at 10 m/s. Determine the mechanical energy of air per unit mass and the power generation potential of a wind turbine with 60-m-diameter blades at that location. Take the air density to be 1.25 kg/m3.

Step 1 of 5

Given data:

The average velocity of wind, $(V) = 10 \text{ m/s}$

The diameter of the wind turbine, $(d) = 60 \text{ m}$

The density of air, $(\rho) = 1.25 \text{ kg/m}^3$

Step 2 of 5

The mechanical energy of a flowing fluid can be expressed on a unit mass basis as

$$e_{mech} = \frac{P}{\rho} + \frac{V^2}{2} + gz \quad \text{in (kJ/kg)}$$

Where $\frac{P}{\rho}$ is the flow energy,

$\frac{V^2}{2}$ is the kinetic energy,

and gz is the potential energy of the fluid, all per unit mass.

Step 3 of 5

Here flow energy and potential energy can be neglected as it not mentioned.

Therefore total mechanical energy of wind turbine per unit mass

$$e_{mech} = \frac{10^2}{2} \text{ J/kg}$$

$$= 50$$

$$= \frac{50}{1000} \text{ kJ/kg}$$

$$= 0.05 \text{ kJ/kg}$$

$\therefore$ Mechanical energy $\boxed{e_{mech} = 0.05 \text{ kJ/kg}}$

Step 4 of 5

The power generation potential of the wind turbine is obtained by expressing in rate form of total mechanical energy

$$E_{mech} = \dot{m} e_{mech}$$

Where $\dot{m}$ is the mass flow rate of the fluid, it can be expressed as

$$\dot{m} = \rho A V \text{ kg/s}$$

Where the density of air is $(\rho) = 1.25 \text{ kg/m}^3$

Area of wind turbine $A = \frac{\pi}{4} d^2 \text{ m}^2$

Mass flow rate $\dot{m} = \rho \left(\frac{\pi}{4} d^2 \right) V \text{ kg/s}$

$$\dot{m} = (1.25) \times \left(\frac{\pi}{4} \times 60^2 \right) \times (10) \text{ kg/s}$$

$$\dot{m} = 35{,}342.9 \text{ kg/s}$$

Step 5 of 5

Therefore power generation of the wind turbine is calculated by

$$= 35342.9 \times 0.05 \text{ kJ/s}$$

$$= 1767.145 \text{ kW}$$

$\therefore$ Power generation of the wind turbine, $\boxed{E_{mech} = 1767.145 \text{ kW}}$

3.014P

Question:

A water jet that leaves a nozzle at 60 m/s at a flow rate of 120 kg/s is to be used to generate power by striking the buckets located on the perimeter of a wheel. Determine the power generation potential of this water jet.

Step 1 of 3

Given data:

The velocity of water jet $(V) = 60\ m/s$

Mass flow rate of water $\dot{m} = 120\ kg/s$

Step 2 of 3

The mechanical energy of a flowing fluid can be expressed on a unit mass basis as

$$e_{mech} = \frac{P}{\rho} + \frac{V^2}{2} + gz \text{ in (kJ/kg)}$$

Where P is the flow energy

Question:

A water jet that leaves a nozzle at 60 m/s at a flow rate of 120 kg/s is to be used to generate power by striking the buckets located on the perimeter of a wheel. Determine the power generation potential of this water jet.

Step 1 of 3

Given data:

The velocity of water jet $(V) = 60\ m/s$

Mass flow rate of water $\dot{m} = 120\ kg/s$

Step 2 of 3

3.015P

Question:

Two sites are being considered for wind power generation. In the first site, the wind blows steadily at 7 m/s for 3000 hours per year, whereas in the second site the wind blows at 10 m/s for 2000 hours per year. Assuming the wind velocity is negligible at other times for simplicity, determine which is a better site for wind power generation. *Hint:*Note that the mass flow rate of air is proportional to wind velocity.

Step 1 of 4

Calculate the power generation by wind turbine at sight 1 as follows:

$$E_{mech1} = \dot{m}_1\left(\frac{V_1^2}{2}\right) \quad \text{..... (1)}$$

Here, the mass flow rate of wind at sight 1 is $\dot{m}_1$, and the velocity of wind at sight 1 is V_1.

Calculate the mass flow rate of the wind at sight 1 as follows:

$$\dot{m}_1 = \rho A V_1$$

Question:

Two sites are being considered for wind power generation. In the first site, the wind blows steadily at 7 m/s for 3000 hours per year, whereas in the second site the wind blows at 10 m/s for 2000 hours per year. Assuming the wind velocity is negligible at other times for simplicity, determine which is a better site for wind power generation. *Hint:*Note that the mass flow rate of air is proportional to wind velocity.

Step 1 of 4

Calculate the power generation by wind turbine at sight 1 as follows:

$$E_{mech1} = \dot{m}_1\left(\frac{V_1^2}{2}\right) \quad \text{..... (1)}$$

Here, the mass flow rate of wind at sight 1 is $\dot{m}_1$, and the velocity of wind at sight 1 is V_1.

Calculate the mass flow rate of the wind at sight 1 as follows:

$$\dot{m}_1 = \rho A V_1$$

$$E_{max1} = 0.2144 \times 3000$$
$$= 643.2\,\text{kWh/yr}$$

Therefore, the maximum power generation at sight 1 is $\boxed{643.2\,\text{kWh/yr}}$.

Step 3 of 4

Calculate the power generation by wind turbine at sight 2.

$$E_{mech2} = \dot{m}_2\left(\frac{V_2^2}{2}\right) \quad \text{..... (1)}$$

Here, the mass flow rate of wind at sight 2 is $\dot{m}_2$, and the velocity of wind at sight 2is V_2.

Calculate the mass flow rate of the wind at sight 2.

$$\dot{m}_2 = \rho A V_2$$

Here, the density of the air is ρ, and the flow area is A.

Substitute, $1.25\,\text{kg/m}^3$ for ρ, $1\,\text{m}^2$ for A and $10\,\text{m/s}$ for V_1 .

$$\dot{m}_2 = 1.25 \times 1 \times 10$$
$$= 12.50\,\text{kg/s}$$

Step 4 of 4

Substitute $10\,\text{m/s}$ for V_2 and $12.50\,\text{kg/s}$ for $\dot{m}_2$ in equation (1).

$$E_{mech2} = \dot{m}_2\left(\frac{V_2^2}{2}\right)$$
$$= 12.50\left(\frac{10^2}{2}\right)$$
$$= 625\,\text{W}$$
$$= 0.625\,\text{kW}$$

Calculate the maximum electric power generations per year as follows:

$$E_{max2} = E_{mech2} \times \Delta t_2$$

Here, the working hours per year at sight 2is Δt_2.

Substitute $0.625\,\text{kW}$ for E_{mech2} and $2000\,\text{h/yr}$ for Δt_2.

$$E_{max1} = 0.625 \times 2000$$
$$= 1250\,\text{kWh/yr}$$

Thus, the maximum power generation at sight 2 is $\boxed{1250\,\text{kWh/yr}}$.

Therefore, second site is better for power generation than first site.

Question: 3.016P

A river flowing steadily at a rate of 175 m3/s is considered for hydroelectric power generation. It is determined that a dam can be built to collect water and release it from an elevation difference of 80 m to generate power. Determine how much power can be generated from this river water after the dam is filled.

Step 1 of 2

Given

Volume flow rate $\dot{V} = 175\ \text{m}^3/s$

Density of the water $\rho = 1000\ \text{kg/m}^3$

Elevation difference $z = 80\ \text{m}$

Mass flow rate of water $\dot{m} = \rho \dot{V}$

$$\dot{m} = 1000 \times 175$$

$$\dot{m} = 1.75 \times 10^5\ \text{kg/s}$$

Step 2 of 2

Power generated, $P = \dot{m} \times g \times z$

$$P = \left(1.75 \times 10^5\right) \times (9.81) \times (80)$$

$$P = 137.34 \times 10^6\ \text{W}$$

$$P = 137.34\ \text{MW}$$

Hence power generated is $\boxed{P = 137.34\ \text{MW}}$

Question: 3.017P

Consider a river flowing toward a lake at an average velocity of 3 m/s at a rate of 500 m3/s at a location 90 m above the lake surface. Determine the total mechanical energy of the river water per unit mass and the power generation potential of the entire river at that location.

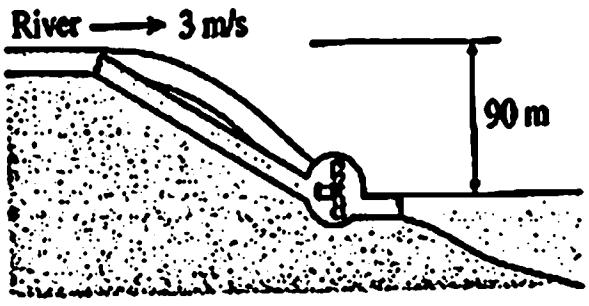

FIGURE P3–17

Step 1 of 3

Calculate the total mechanical energy of a flowing fluid using relation below.

$$e_{mech} = \frac{P}{\rho} + \frac{V^2}{2} + gz$$

Here, $\frac{P}{\rho}$ is the flow energy, $\frac{V^2}{2}$ is the kinetic energy and gz is the potential energy of the fluid per unit mass.

Neglect flow energy and substitute, $3\ \text{m/s}$ for V , $9.81\ \text{m/s}^2$ for g and $90\ \text{m}$ for z in relation above and calculate the total mechanical energy.

$$\begin{aligned} e_{mech} &= \frac{3^2}{2} + (9.81 \times 90) \\ &= 887.4 \times \left(\frac{1\ \text{kJ/kg}}{1000\ \text{m}^2/\text{s}^2} \right) \\ &= 0.8874\ \text{kJ/kg} \end{aligned}$$

Therefore the total mechanical energy (e_{mech}) of the river water per unit mass

is $\boxed{0.887\ \text{kJ/kg}}$.

Step 2 of 3

Calculate the power generation potential of the river using relation. $E_{mech} = \dot{m} e_{mech}$ ..... (1)

Here, $\dot{m}$ is the mass flow rate of the fluid and is expressed as,

$$\dot{m} = \rho \dot{v}\ \text{kg/s}$$

Here, volumetric flow rate is $\dot{v}$ and density of water is ρ.

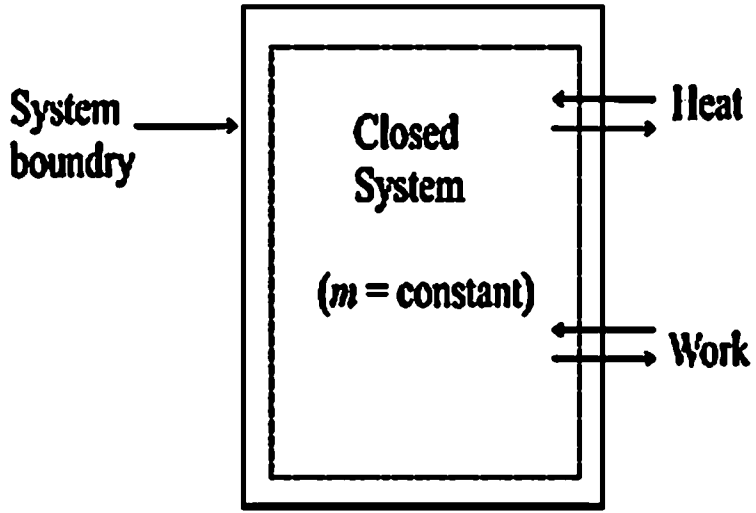
Step 3 of 3

Substitute, $1000\ \text{kg/m}^3$ for ρ and $500\ \text{m}^3/\text{s}$ for $\dot{v}$ in relation above and calculate the mass flow rate.

$$\begin{aligned} \dot{m} &= 1000 \times 500 \\ &= 500{,}000\ \text{kg/s} \end{aligned}$$

Substitute, $500{,}000\ \text{kg/s}$ for $\dot{m}$ and $0.887\ \text{kJ/kg}$ for e_{mech} in equation (1) and calculate the power generation.

$$\begin{aligned} E_{mech} &= 500000 \times 0.8874 \\ &= 443700\ \text{kW} \\ &= 443.7\ \text{MW} \\ &\approx 444\ \text{MW} \end{aligned}$$



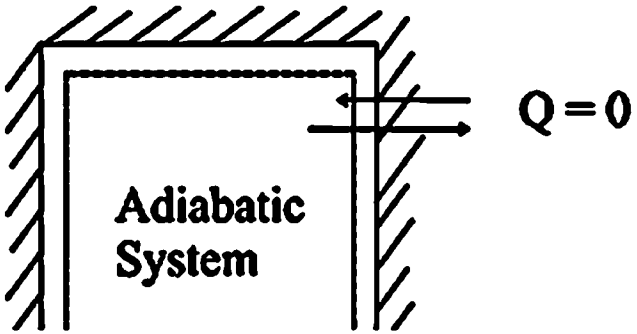
Therefore the power generation (E_{mech}) is $\boxed{444\ \text{MW}}$.

Question: 3.018P

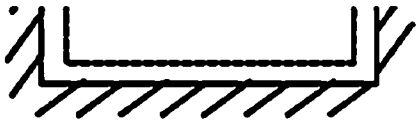
In what forms can energy cross the boundaries of a closed system?

Step 1 of 1

Energy can cross the boundaries of a closed system in the form of heat and work.



Question: 3.019P



When is the energy crossing the boundaries of a closed system heat and when is it work?

Step 1 of 2

In a closed system there will be energy transfer but no mass transfer occurs. So across boundaries the heat is transferred due to the temperature difference and work is due to all other forms except temperature difference.

Step 2 of 2

Question: 3.020P

What is an adiabatic process? What is an adiabatic system?

Step 1 of 1

A process during which there is no heat transfer is called an adiabatic process i.e. $dQ = 0$

The system which undergoes adiabatic process is called an adiabatic system, and it is said to be no heat is added or removed from the system

Question: 3.021P

What are point and path functions? Give some examples.

Step 1 of 2

Thermodynamic properties are point functions, since for a given state, there is a definite value for each property. The change in thermodynamic property of a system in a change of state is independent of the path, and depends only on the initial and final states of the system. The cyclic integral of a point function is zero

Examples: Temperature, pressure, volume etc.

Step 2 of 2

The path function depends on the path followed by the process. Path functions have inexact differentials designated by the symbol ∂. The cyclic integral of a path function is non-zero

Examples: Heat, work etc.

Question: 3.022P

Consider an automobile traveling at a constant speed along a road. Determine the direction of the heat and work interactions, taking the following as the system: (*a*) the car radiator, (*b*) the car engine, (*c*) the car wheels, (*d*) the road, and (*e*) the air surrounding the car.

Step 1 of 5

(a) The car radiator:

Heat transfer is occurred from radiator to atmosphere due to temperature difference of the hot fluid and coolant.

No work transfer

Step 2 of 5

(b) The car engine:

Chemical energy of the fuel is converted into mechanical energy so both heat and work transfer will occur due to burning of fuel and piston movement respectively.

Step 3 of 5

(c) The car wheels:

Highly pressured wheels have cool air inside, which allows heat to transfer to occur to the surrounding atmosphere

No work is transferred at rest, while motion the wheels possess kinetic energy which can produce work.

Step 4 of 5

(d) The road:

Due to friction between the wheels and the road the temperature of the road increases because of the heat transfer.

No work transfer.

Step 5 of 5

(e) The air surrounding the car:

Due to exhausts from the engine and other hotter components of car heat is added to atmosphere.

Work is done on the air by pushing air back and moving our car forward.

Question: 3.023P

The length of a spring can be changed by (*a*) applying a force to it or (*b*) changing its temperature (i.e., thermal expansion). What type of energy interaction between the system (spring) and surroundings is required to change the length of the spring in these two ways?

Step 1 of 1

The application of force on the spring causes its elongation, this force with displacement is a work interaction.

Heat transfer will occur in the second case, the spring will elongation due to temperature changes.

Question: 3.024P

A personal computer is to be examined from a thermodynamic perspective. Determine the direction of the work and heat transfers (in or out) when the (*a*) keyboard, (*b*) monitor, (*c*) processing unit, and (*d*) all of these are taken as the system.

Step 1 of 7

Step 2 of 7

(b)

Step 3 of 7

The monitor has a direct power supply, so electrical work is supplied to it. Due to the electrical components in the monitor, heat is generated. Therefore, heat transfer will occur from monitor to surroundings.

Step 4 of 7

(c)

Step 5 of 7

The CPU has a direct power supply, so electrical work is supplied to it. Due to electrical components in the CPU, heat is generated. Therefore, heat transfer will occur from CPU to surroundings.

Step 6 of 7

Step 7 of 7

(d)

The complete unit has an electrical work done on it and also transfers heat from all its electrical parts to the surroundings.

Question: 3.025P

A small electrical motor produces 5 W of mechanical power. What is this power in (*a*) N, m, and s units; and (*b*) kg, m, and s units?

Step 1 of 2

(a) Use the following conversion factor to convert the power from W to N·m/s:

$$1\,\text{W} = 1\,\text{Nm/s}$$

Calculate the power required for the electrical motor.

$$P = 5\,\text{W}\left(\frac{1\,\text{N-m/s}}{1\,\text{W}}\right)$$

$$= 5\,\text{N-m/s}$$

Therefore, power required for electrical motor in terms of Nm/s is $\boxed{5\,\text{N-m/s}}$.

Step 2 of 2

(b) Use the following conversion factors to convert the power from W to 1 kg·m/s³:

$$1\,\text{W} = 1\,\text{Nm/s}$$

$$1\,\text{Nm/s} = 1\,\text{kgm/s}^3$$

$$1\,\text{N} = 1\,\text{kg·m/s}^2$$

$$1\,\text{J} = 1\,\text{N·m}$$

$$1\,\text{W} = 1\,\text{J/s}/1\,\text{W}$$

Calculate the power required for the electrical motor.

$$P = 5\,\text{W}\left(\frac{1\,\text{J/s}}{1\,\text{W}}\right)\left(\frac{1\,\text{N-m}}{1\,\text{J}}\right)\left(\frac{1\,\text{kg·m/s}^2}{1\,\text{N}}\right)$$

$$= 5\,\text{kg·m}^2/\text{s}^3$$

Hence, power required for electrical motor in terms of kg·m²/s³ is $\boxed{5\,\text{kg·m}^2/\text{s}^3}$

Question: 3.026P

A model aircraft internal-combustion engine produces 10 W of power. How much power is this in (*a*) lbf·ft/s and (*b*) hp?

Step 1 of 2

Given that,
The power produced by an aircraft engine $(P) = 10\ \text{W}$

(a) In lbf · ft/s units:

$$1\ \text{Btu/s} = 1055\ \text{W}$$
$$1\ \text{Btu/s} = 778.2\ \text{lbf} \cdot \text{ft/s}$$
$$\therefore 1\ \text{W} = \frac{778.2}{1055}\ \text{lbf} \cdot \text{ft/s}$$
$$1\ \text{W} = 0.737\ \text{lbf} \cdot \text{ft/s}$$
$$10\ \text{W} = 0.737 \times 10\ \text{lbf} \cdot \text{ft/s}$$
$$\therefore \text{Power } \boxed{P = 7.37\ \text{lbf} \cdot \text{ft/s}}$$

Step 2 of 2

(b) In hp:

$$1\ \text{horse power} = 746\ \text{Watts}$$
$$\therefore 10\ \text{W} = \frac{10}{746}\ \text{hp}$$
$$\therefore \text{Power } \boxed{P = 0.0134\ \text{hp}}$$

Question: 3.027P

A car is accelerated from rest to 85 km/h in 10 s. Would the energy transferred to the car be different if it were accelerated to the same speed in 5 s?

Step 1 of 1

The kinetic energy depends only on the velocity of the object, but not on the time on which it travels.

$$KE = \frac{1}{2}mV^2$$

Here, m is mass of the object and V is velocity of the object.

Therefore, if a car accelerates at the e speed at different time durations, the energy transferred is e but the power is different.

Question: 3.028P

Determine the energy required to accelerate an 800-kg car from rest to 100 km/h on a level road.

Step 1 of 2

Given data:

Mass of the car, $(m) = 800$ kg

Initial velocity, $V_1 = 0$ m/s

Final velocity, $V_2 = 100$ km/h

$$\left(\because 1 \text{ km/h} = \frac{1000}{3600} \text{ m/s}\right)$$

$$V_2 = 100 \times \frac{1000}{3600} \text{ m/s}$$

$$\therefore V_2 = 27.78 \text{ m/s}$$

Step 2 of 2

The change in kinetic energy of the body is the energy required to accelerate the car

$$KE = \frac{1}{2} m(V_2^2 - V_1^2)$$

$$= \frac{1}{2}(800)(27.78^2 - 0^2) \text{ J}$$

$$= 308.69 \text{ kJ}$$

$\therefore$ The energy required to accelerate the car, $\boxed{KE = 308.69 \text{ kJ}}$

Question: 3.029P

A construction crane lifts a prestressed concrete beam weighing 3 tons from the ground to the top of piers that are 24 ft above the ground. Determine the amount of work done considering (*a*) the beam and (*b*) the crane as the system. Express your answers in both lbf·ft and Btu.

Step 1 of 4

a)

Use the conversion factor to convert the weight from ton to lbm

$$1\,\text{ton}=2000\,\text{lbm}$$

Calculate the weight of the concrete beam in terms of lbm

$$m=3\,\text{ton}\frac{2000\,\text{lbm}}{1\,\text{ton}}$$

$$=6000\,\text{lbm}$$

Step 2 of 4

From the conversion table

$$1\,\text{lbf}=32.174\,\text{lbm}\cdot\text{ft/s}^2$$

Calculate the work done in lbf - ft

$$W=mgh$$

Here, m is the mass of the car, g is the acceleration due to gravity

Substitute $32.2\,\text{ft/s}^2$ for g and $3\,\text{ton}$ for m

$$W=mgh$$

$$=\left(3\,\text{ton}\times\frac{2000\,\text{lbm}}{1\,\text{ton}}\right)(32.2)\left(\frac{1\,\text{lbf}}{32.2\,\text{lbm}\cdot\text{ft/s}^2}\right)(24)$$

$$=144000\,\text{lbf}\cdot\text{ft}$$

Therefore, the work done in lbf - ft is $\boxed{144000\,\text{lbf}\cdot\text{ft}}$

Step 3 of 4

Calculate the work done in Btu

$$W=(144000\,\text{lbf}\cdot\text{ft})\left(\frac{1\,\text{Btu}}{778.169\,\text{lbf}\cdot\text{ft}}\right)$$

$$=185.049\,\text{Btu}$$

Therefore, the work done in Btu is $\boxed{185.049\,\text{Btu}}$

Step 4 of 4

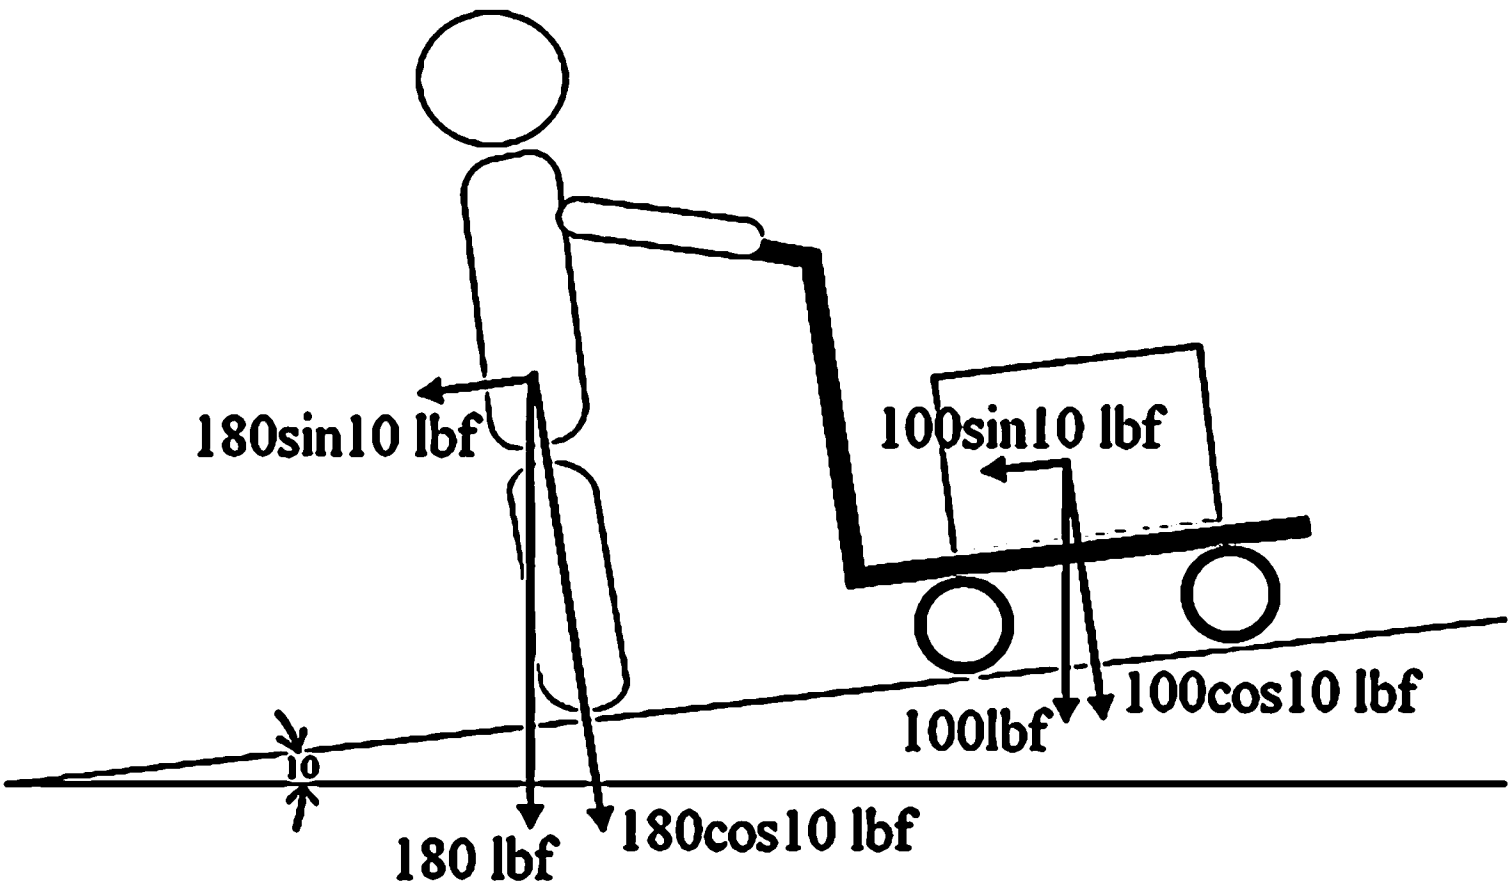
b)

If crane as considered as system, it must do same amount of work as is required to lift beam as calculated above,

Thus, amount of work done becomes $W=185.049\,\text{Btu}$

Therefore, the work done in Btu is $\boxed{185.049\,\text{Btu}}$

Question: 3.030P



A man weighing 180 lbf is pushing a cart that weighs 100 lbf with its contents up a ramp that is inclined at an angle of 10° from the horizontal. Determine the work needed to move along this ramp a distance of 100 ft considering (*a*) the man and (*b*) the cart and its contents as the system. Express your answers in both lbf-ft and Btu.

FIGURE P3–30E

Step 1 of 4

Draw the free body diagram of the weight of the man and weight of the cart.

Step 2 of 4

Write the weight component of cart along the ramp.

$$W_{cart} = 100\sin 10^\circ \text{ lbf}$$
$$= 17.3648 \text{ lbf}$$

Write weight component of man along the ramp.

$$W_{man} = 180\sin 10^\circ \text{ lbf}$$
$$= 31.256 \text{ lbf}$$

Step 3 of 4

(a)

Consider man and its contents as the system and find the work done by the man on cart.

$$W = (W_{man} \times d) + (W_{cart} \times d)$$

Here, d is the distance moved along the ramp.

Substitute 100 ft for d, 31.256 lbf for W_{man}, and 17.3648 lbf for W_{cart}

$$W = 31.256 \times 100 + 17.3648 \times 100$$
$$= 4862.08 \text{ lbf-ft}$$
$$= 4862.08 \text{ lbf-ft} \times \frac{1 \text{ Btu}}{778 \text{ lbf-ft}}$$
$$= 6.249 \text{ Btu}$$

Therefore, work needed to move along the ramp when the man and its contents are considered as the system is $\boxed{4862.08 \text{ lbf-ft}}$ or $\boxed{6.249 \text{ Btu}}$.

Step 4 of 4

(b)

Consider cart and its contents as the system and find the work needed to move along the ramp.

$$W = W_{cart} \times d$$

Substitute 100 ft for d and 17.3648 lbf for W_{cart}

$$W = 17.3648 \times 100$$
$$= 1736.48 \text{ lbf-ft}$$
$$= 1736.48 \text{ lbf-ft} \times \frac{1 \text{ Btu}}{778 \text{ lbf-ft}}$$
$$= 2.2319 \text{ Btu}$$

Therefore, work needed to move along the ramp when the cart and its contents as the system is $\boxed{1736.48 \text{ lbf-ft}}$ or $\boxed{2.2319 \text{ Btu}}$.

Question: 3.031P

The force *F* required to compress a spring a distance *x* is given by $F - F0 = kx$ where *k* is the spring constant and *F*0 is the preload. Determine the work required to compress a spring whose spring constant is $k = 200$ lbf/in a distance of one inch starting from its free length where $F0 = 0$ lbf. Express your answer in both lbf·ft and Btu.

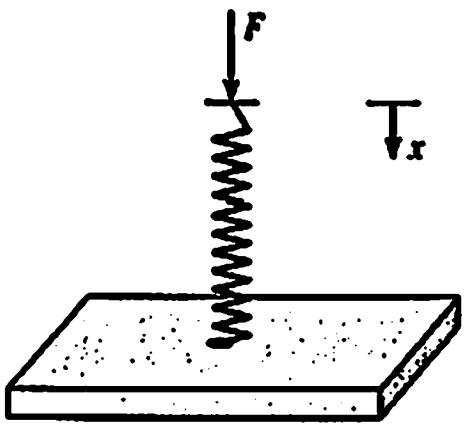


FIGURE P3–31E

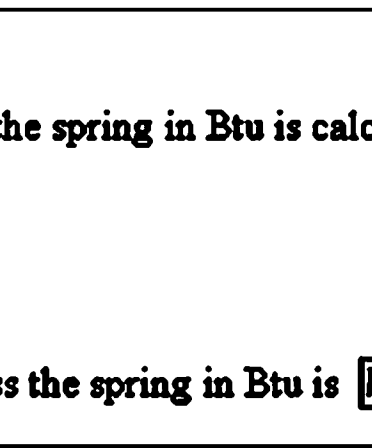
Step 1 of 5

Given data:



Preload, $F_o = 0$ lbf

Spring constant, $k = 200$ lbf/in

Initial length, $x_1 = 0$

Final length, $x_2 = 1$ in

Step 2 of 5

Step 3 of 5

The force at any point during the deflection of the spring is given by $F = F_o + kx$,

where F_o is the initial force

and x is the deflection as measured from the point where the initial force occurred.

The work required to compress the spring is

$$W = \int F ds$$

$$W = \int_1^2 (F_o + kx) dx$$

Step 4 of 5

Therefore work required to compress the spring is

$$W = \int_1^2 (kx) dx \qquad (\because F_o = 0 \text{ lbf})$$

$$= k\int_1^2 x dx$$

$$= k\frac{1}{2}(x^2_2 - x^2_1)$$

$$= 200 \times \frac{1}{2} \times (1^2 - 0) \text{ lbf} \cdot \text{in}$$

$$= \frac{100}{12} \text{ lbf} \cdot \text{ft} \qquad (\because 1\text{ft} = 12\text{in})$$

$$= 8.333 \text{ lbf} \cdot \text{f}$$

∴ The work required to compress the spring in lbf · ft is $\boxed{W = 8.333 \text{ lbf} \cdot \text{ft}}$

Step 5 of 5

The work required to compress the spring in Btu is calculated by

Where $1\text{Btu} = 778 \text{ lbf} \cdot \text{ft}$

$$= \frac{8.333}{778} \text{ Btu}$$

$$= 0.0107 \text{ Btu}$$

∴ The work required to compress the spring in Btu is $\boxed{W = 0.0107 \text{ Btu}}$

Question: 3.032P

A spherical soap bubble with a surface-tension of 0.005 lbf/ft is expanded from a diameter of 0.5 in to 2.0 in. How much work, in Btu, is required to expand this bubble?

Step 1 of 2

Convert the units of d_2 from in. to ft.

$$\begin{aligned} d_2 &= 2.0\,\text{in} \\ &= \frac{2\,\text{in.}}{12} \times \frac{\text{ft}}{\text{in.}} \\ &= 0.1667\,\text{ft} \end{aligned}$$

Here, d_2 is the final diameter of the bubble.

Convert the units of d_1 from in. to ft.

$$\begin{aligned} d_1 &= 0.5\,\text{in} \\ &= \frac{0.5\,\text{in.}}{12} \times \frac{\text{ft}}{\text{in.}} \\ &= 0.041667\,\text{ft} \end{aligned}$$

Here, d_1 is the initial diameter of the bubble.

Step 2 of 2

Calculate the work associated with the stretching of a film as follows:

$$\begin{aligned} W_{surface} &= \int_1^2 \sigma_s dA \\ &= \sigma(A_2 - A_1) \\ &= \sigma\left(4\pi d_2^2 - 4\pi d_1^2\right) \\ &= 4\pi\sigma \times \left(d_2^2 - d_1^2\right) \end{aligned}$$

Here, σ is the surface tension of the soap bubble.

Substitute $0.005\,\text{lb/ft}$ for σ, $0.1667\,\text{ft}$ for d_2, $0.041667\,\text{ft}$ for d_1.

$$\begin{aligned} W_{surface} &= 4\pi \times 0.005\left[(0.1667)^2 - (0.041667)^2\right] \\ &= 0.001637\,\text{lbf}\cdot\text{ft} \\ &= (0.001637\,\text{lbf}\cdot\text{ft})\left(\frac{1\,\text{Btu}}{778.169\,\text{lbf}\cdot\text{ft}}\right) \\ &= 2.104\times10^{-6}\,\text{Btu} \end{aligned}$$

Therefore, the work required to expand the bubble is $\boxed{2.104\times10^{-6}\,\text{Btu}}$.

Question: 3.033P

A 0.5-in diameter, 12-in-long steel rod with a Young's modulus of 30,000 lbf/in2 is stretched 0.125 in. How much work does this require, in Btu? The strain work is given by $W = \frac{V_0 E}{2}(\varepsilon_2^2 - \varepsilon_1^2)$ where is the original volume of the V_0 is the original volume of the solid, E is Young's modulus and ε is the strain at the beginning and ending of the process.

Step 1 of 3

Given data:

Diameter of the rod, $D = 0.5\text{in}$.

Length of the rod, $L = 12\text{in}$.

Young's modulus of the steel rod, $E = 30000\text{lbf/in}^2$.

Stretched to a length = 0.125 in.

Strain work is $W = \frac{V_0 E}{2}\left(\varepsilon_2^2 - \varepsilon_1^2\right)$.

Where V_0 is the original volume of the rod

E is Young's modulus

ε is the strain

Step 2 of 3

The original volume of the rod is calculated from

$$V_0 = \frac{\pi D^2}{4} L$$

$$= \frac{\pi(0.5)^2}{4} \times 12$$

$$= 2.356\text{in}^3$$

Step 3 of 3

The work required to stretch the rod 0.125 in is calculated from the given formula

$$W = \frac{V_0 E}{2}\left(\varepsilon_2^2 - \varepsilon_1^2\right)$$

$$= \frac{(2.356)(30,000)}{2}\left[(0.125/12)^2 - 0^2\right]$$

$$= 3.8346\text{lbf} \cdot \text{in}$$

$$= (3.8346\text{lbf} \cdot \text{in})\left(\frac{1\text{Btu}}{9331.78\text{lbf} \cdot \text{in}}\right)$$

$$= 4.109 \times 10^{-4}\text{Btu}$$

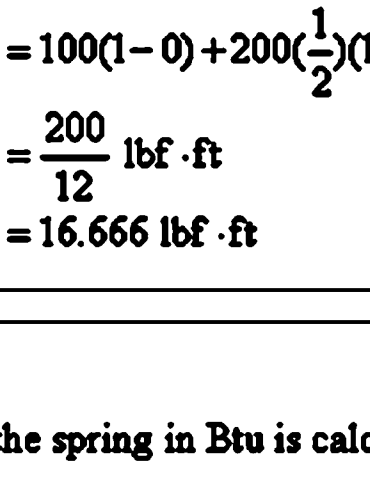
Therefore the work required in Btu is $\boxed{W = 4.109 \times 10^{-4}\text{Btu}}$

Question: 3.034P

A spring whose spring constant is 200 lbf/in has an initial force of 100 lbf acting on it. Determine the work, in Btu, required to compress it another 1 inch.

Step 1 of 5

Given data:



Initial force, $F_o = 100$ lbf

Spring constant, $k = 200$ lbf/in

Initial length, $x_1 = 0$

Final length, $x_2 = 1$ in

Step 2 of 5

Step 3 of 5

The force at any point during the deflection of the spring is given by $F = F_o + kx$,

where F_o is the initial force

and x is the deflection as measured from the point where the initial force occurred.

The work required to compress the spring is

$$W = \int F ds$$

$$W = \int_1^2 (F_o + kx)dx$$

Step 4 of 5

Therefore work required to compress the spring is

$$W = F_o(x_2 - x_1) + k\frac{1}{2}(x^2_2 - x^2_1)$$

$$= 100(1-0) + 200(\frac{1}{2})(1^2 - 0)\ \text{lbf} \cdot \text{in}$$

$$= \frac{200}{12}\ \text{lbf} \cdot \text{ft} \qquad (\because 1\text{ft} = 12\text{in})$$

$$= 16.666\ \text{lbf} \cdot \text{ft}$$

Step 5 of 5

The work required to compress the spring in Btu is calculated by

Where $1\text{Btu} = 778\ \text{lbf} \cdot \text{ft}$

$$= \frac{16.666}{778}\ \text{Btu}$$

$$= 0.0214\ \text{Btu}$$

$\therefore$ The work required to compress the spring, $\boxed{W = 0.0214\ \text{Btu}}$

3.035P

Question:

How much work, in kJ, can a spring whose spring constant is 3 kN/cm produce after it has been compressed 3 cm from its unloaded length?

Step 1 of 3

Given data:

Initial force, $F_o = 0$ N

Spring constant, $k = 3$ kN/cm

$k = 300$ kN/m

Initial length, $x_1 = 0$

Final length, $x_2 = 0.03$ m

Step 2 of 3

The force at any point during the deflection of the spring is given by $F = F_o + kx$, where F_o is the initial force and x is the deflection as measured from the point where the initial

Question:

How much work, in kJ, can a spring whose spring constant is 3 kN/cm produce after it has been compressed 3 cm from its unloaded length?

Step 1 of 3

Given data:

Initial force, $F_o = 0$ N

Spring constant, $k = 3$ kN/cm

$k = 300$ kN/m

Initial length, $x_1 = 0$

Question: 3.036P

A ski lift has a one-way length of 1 km and a vertical rise of 200 m. The chairs are spaced 20 m apart, and each chair can seat three people. The lift is operating at a steady speed of 10 km/h. Neglecting friction and air drag and assuming that the average mass of each loaded chair is 250 kg, determine the power required to operate this ski lift. Also estimate the power required to accelerate this ski lift in 5 s to its operating speed when it is first turned on.

Step 1 of 5

Find the total mass of the ski lift by using the equation,

$$M = m \times n$$

Here, m is average mass of each chair and n is number of chairs placed in 1 km length of ski lift.

Substitute 250 kg for m and $\frac{1000}{20}$ for n.

$$M = 250 \times \frac{1000}{20}$$

Question:

A ski lift has a one-way length of 1 km and a vertical rise of 200 m. The chairs are spaced 20 m apart, and each chair can seat three people. The lift is operating at a steady speed of 10 km/h. Neglecting friction and air drag and assuming that the average mass of each loaded chair is 250 kg, determine the power required to operate this ski lift. Also estimate the power required to accelerate this ski lift in 5 s to its operating speed when it is first turned on.

Step 1 of 5

Find the total mass of the ski lift by using the equation,

$M = m \times n$

Here, m is average mass of each chair and n is number of chairs placed in 1 km length of ski lift.

Substitute 250 kg for m and $\frac{1000}{20}$ for n.

$$\begin{aligned} M &= 250 \times \frac{1000}{20} \\ &= 0.1 \times 3600 \\ &= 360\,\text{s} \end{aligned}$$

Calculate the power required to operate the lift by using the equation,

$$\begin{aligned} P &= \frac{W}{t}\ \text{kJ/s} \\ &= \frac{24525}{360} \\ &= 68.125\,\text{kW} \end{aligned}$$

Therefore, the power required to raise the lift is $\boxed{68.125\ \text{kW}}$.

Step 3 of 5

Calculate the acceleration of the lift in 5 sec.

$$a = \frac{\Delta V}{t}$$

Here, ΔV is change in velocity.

$$\begin{aligned} a &= \frac{\left(10 \times \frac{1000}{3600}\right)\text{m/s} - 0}{5} \\ &= \frac{\left(10 \times \frac{5}{18}\right)\text{m/s} - 0}{5} \\ &= 0.556\,\text{m/s}^2 \end{aligned}$$

Step 4 of 5

Calculate the work needed to accelerate a body is simply the change in the kinetic energy of the body by using the equation.

$$\begin{aligned} W_a &= \frac{1}{2} M (V_2^2 - V_1^2)\ \text{kJ} \\ &= \frac{1}{2}(12500) \times \left(\left(10 \times \frac{5}{18}\right)^2 - 0^2\right) \\ &= 48225.308\,\text{J} \\ &= 48.225\,\text{kJ} \end{aligned}$$

Calculate the power required to accelerate the ski lift in 5s by using the expression.

$$\begin{aligned} \dot{W}_a &= \frac{W_a}{\Delta t}\ \text{kW} \\ &= \frac{48.225}{5} \\ &= 9.645\,\text{kW} \end{aligned}$$

Therefore, power required during the acceleration is $\boxed{9.645\ \text{kW}}$.

Therefore, the total power required to operate is $\boxed{43.734\ \text{kW}}$.

Question: 3.037P

Determine the power required for a 1150-kg car to climb a 100-m-long uphill road with a slope of 30° (from horizontal) in 12 s (*a*) at a constant velocity, (*b*) from rest to a final velocity of 30 m/s, and (c) from 35 m/s to a final velocity of 5 m/s. Disregard friction, air drag, and rolling resistance.

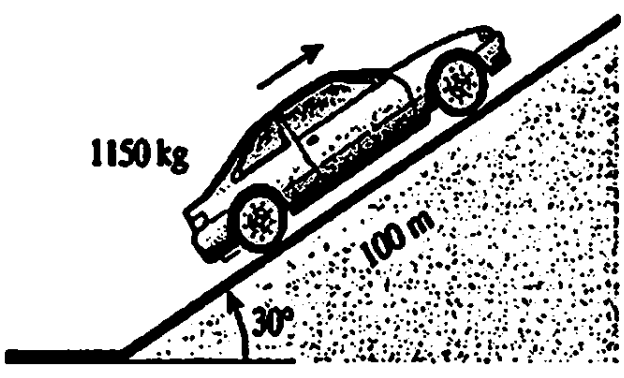


FIGURE P3–37

Question:

Determine the power required for a 1150-kg car to climb a 100-m-long uphill road with a slope of 30° (from horizontal) in 12 s (*a*) at a constant velocity, (*b*) from rest to a final velocity of 30 m/s, and (c) from 35 m/s to a final velocity of 5 m/s. Disregard friction, air drag, and rolling resistance.

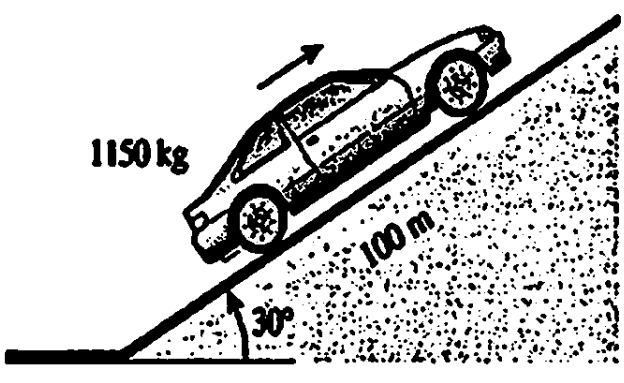

FIGURE P3–37

Step 1 of 8

Draw the diagram shows the slope of the uphill as shown below:

Step 1 of 8

Draw the diagram shows the slope of the uphill as shown below:

Calculate the work done in climbing the uphill road will be stored in the form of potential energy in the car

$$W = m \times g \times h$$

Here, m is the mass of the car, g is the acceleration due to gravity

Substitute 9.81m/s^2 for g and 1150kg for m

$$W = m \times g \times h$$
$$= 1150 \times 9.81 \times 50$$
$$= 564.075 \text{ kJ}$$

Step 4 of 8

Calculate the Power required for car

$$P = \frac{\text{Work}}{\text{time}}$$

Substitute 12s for time

$$P = \frac{\text{Work}}{\text{time}}$$
$$= \frac{564.075}{12}$$
$$= 47 \text{ kJ/s}$$
$$= 47 \text{ kW}$$

Power required for the car to climb uphill is $\boxed{47 \text{ kW}}$

Step 5 of 8

Calculate the work done in climbing the uphill road will be stored in the form of potential energy in the car

$$W = m \times g \times h$$

Here, m is the mass of the car, g is the acceleration due to gravity

Substitute 9.81m/s^2 for g and 1150kg for m

$$W = m \times g \times h$$
$$= 1150 \times 9.81 \times 50$$
$$= 564.075 \text{ kJ}$$

Step 4 of 8

Calculate the Power required for car

$$P = \frac{\text{Work}}{\text{time}}$$

Substitute 12s for time

$$P = \frac{\text{Work}}{\text{time}}$$
$$= \frac{564.075}{12}$$
$$= 47 \text{ kJ/s}$$
$$= 47 \text{ kW}$$

Power required for the car to climb uphill is $\boxed{47 \text{ kW}}$

Step 5 of 8

b)

Initial velocity, $V_1 = 0$

Final velocity, $V_2 = 30 \text{ m/s}$

On reaching 100 m uphill, the car has both potential and kinetic energy. This is due to the effect of work done on it.

Calculate the total work done

$$\text{Work} = PE + KE$$
$$= (m \times g \times h) + \left[\frac{1}{2} m \left(V_2^2 - V_1^2\right)\right]$$

Substitute 30m/s for V_2, 0m/s for V_1

$$Work = PE + KE$$
$$= (m \times g \times h) + \left[\frac{1}{2} m \left(V_2^2 - V_1^2\right)\right]$$
$$= (1150 \times 9.81 \times 50) + \left[\frac{1}{2} 1150 \left(30^2 - 0^2\right)\right]$$
$$= 564.07 + 517.5$$
$$= 1081.57 \text{ kJ}$$

Step 6 of 8

Calculate the Power required

$$P = \frac{\text{Work}}{\text{time}}$$
$$= \frac{1081.57}{12}$$
$$= 90.1 \text{ kW}$$

Therefore, Power required for the car to climb uphill is $\boxed{90.1 \text{kW}}$

Step 7 of 8

(c)

$$\text{time}$$
$$= \frac{-125.93}{12}$$
$$= -10.49 \text{ kW}$$

Power required for the car to climb uphill is $\boxed{-10.49 \text{ kW}}$

Question: 3.038P

A damaged 1200-kg car is being towed by a truck. Neglecting the friction, air drag, and rolling resistance, determine the extra power required (*a*) for constant velocity on a level road, (*b*) for constant velocity of 50 km/h on a 30° (from horizontal) uphill road, and (*c*) to accelerate on a level road from stop to 90 km/h in 12 s.

Step 1 of 7

Given data:

The mass of a the car, $(m) = 1200$ kg

The acceleration due to gravity, $(g) = 9.8$ m/s

Step 2 of 7

(a) For constant velocity on level road:

The work needed to accelerate a body is simply the change in the kinetic energy of the car on a level road

$$W_{ke} = W_a = \frac{1}{2}m(V_2^2 - V_1^2)\ \text{kJ}$$

Here at constant velocity the work done due to acceleration is zero.

∴ Power required, $\boxed{P = 0\ \text{kW}}$

Step 3 of 7

(b) On a uphill road with constant velocity $V = 50$ km/h

The slope of the uphill road $(\theta) = 30°$

The work needed to accelerate a body is simply the change in the kinetic energy of the car and the change in the potential energy of the car.

$$W_{total} = W_{ke} + W_{pe}$$

Where, $W_{ke} = W_a = 0$ since at constant velocity acceleration is zero.

$$W_{pe} = mgh$$

$$\therefore W_{total} = W_{pe}$$

Step 4 of 7

The power required is determined by work per unit time

$$P = \frac{W_{total}}{\Delta t}\ \text{kW}$$

$$= \frac{mgh}{\Delta t}$$

$$= \frac{mgd\sin\theta}{\Delta t}$$

We know that, $\frac{d}{\Delta t} = V$

The velocity of the car, given $V = 50$ km/h

Step 5 of 7

$$\therefore P = mgV\sin\theta$$

$$= 1200 \times 9.8 \times 50 \times \frac{5}{18} \times \sin 30° \quad \left(\because 1\ \text{km/h} = \frac{5}{18}\ \text{m/s}\right)$$

$$= \frac{81667}{1000}\ \text{kW}$$

$$= 81.7\ \text{kW}$$

∴ Power required, $\boxed{P = 81.7\ \text{kW}}$

Step 6 of 7

(c) Acceleration on a level road

Due to no elevation of the road the potential energy will be zero

i.e. $W_{pe} = 0$ kJ

The car accelerates from rest $(V_1 = 0\ \text{m/s})$ to $(V_2 = 90\ \text{km/h})$

Therefore kinetic energy $W_{ke} = W_a = \frac{1}{2}m(V_2^2 - V_1^2)\ \text{kJ}$

$$= \frac{1}{2}(1200)(25^2 - 0)\ \text{J}$$

$$= 375\ \text{kJ}$$

Step 7 of 7

Therefore the power required

$$P = \frac{W_{total}}{\Delta t}\ \text{kW}$$

$$= \frac{375}{12}\ \text{kJ}$$

$$= 31.25\ \text{kW}$$

∴ Power required, $\boxed{P = 31.25\ \text{kW}}$

Question: 3.039P

For a cycle, is the net work necessarily zero? For what kind of systems will this be the case?

Step 1 of 1

For a cyclic process, the network is not necessarily being zero for all systems except for adiabatic systems.

For adiabatic systems, the heat transfer, Q is zero. From first law of thermodynamics the work interaction is equal to heat interactions in a system undergoing cyclic process.

$$\Sigma Q = \Sigma W$$

For adiabatic systems, $\Sigma Q = 0$ then,

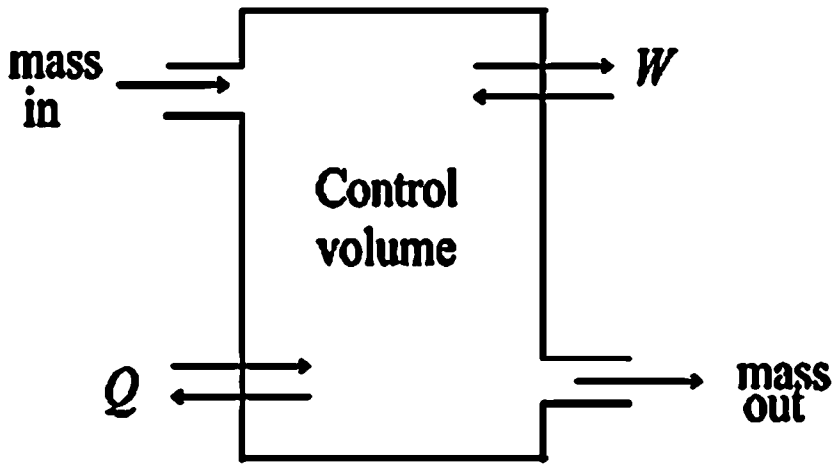
$$0 = \Sigma W$$

$$\Sigma W = 0$$

So, for adiabatic systems undergoing cyclic process the net work is also zero.

Question: 3.040P

What are the different mechanisms for transferring energy to or from a control volume?



Step 1 of 2

For a control volume (open system) the energy can be transferred to or from a system in three forms:

1. Heat
2. work
3. mass flow

Heat is the process of energy transfer from one body or system due to thermal contact, Energy transfer by heat can occur between objects by radiation, conduction and convection.

Step 2 of 2

Question: 3.041P

On a hot summer day, a student turns his fan on when he leaves his room in the morning. When he returns in the evening, will the room be warmer or cooler than the neighboring rooms? Why? Assume all the doors and windows are kept closed.

Step 1 of 1

Yes the room will be warmer, due to continuously running of the fan heat gets added in the room because of the air friction and electrical power in the room.

Question: 3.042P

One way to improve the fuel efficiency of a car is to use tires that have a lower rolling resistance—tires that roll with less resistance, and highway tests at 65 mph showed that tires with the lowest rolling resistance can improve the fuel efficiency by nearly 2 mpg (miles per gallon). Consider a car that gets 35 mpg on high rolling resistance tires and is driven 15,000 miles per year. For a fuel cost of $2.20/gal, determine how much money will be saved per year by switching to low rolling resistance tires.

Step 1 of 2

Given

Distance travelled by Car per year $d = 15000$ miles

Lowest rolling resistance will improve efficiency by 2 mpg

Fuel efficiency of car with high rolling resistance tires $= 35$ mpg

So, total fuel required by a car with high rolling resistance tires $= \frac{15000}{35}$ gallons

$= 428.57$ gallons

Step 2 of 2

Fuel efficiency of car with high rolling resistance tires $= 35$ mpg $+ 2$ mpg

$= 37$ mpg

So, total fuel required by a car with low rolling resistance tires $= \frac{15000}{37}$ gallons

$= 405.405$ gallons

So, fuel saved by switching to low resistance tires $= (428.57 - 405.405)$ gallon

$= 23.165$ gallon

Cost of 1 gallon $= \$\ 2.20$

Cost of 23.165 gallon $= 23.165 \times \$2.20$

$= \$\ 50.963$

Hence total cost saved by switching to low resistance tires is $\boxed{\$\ 50.963}$

Question: 3.043P

An adiabatic closed system is accelerated from 0 m/s to 30 m/s. Determine the specific energy change of this system, in kJ/kg.

Step 1 of 2

Given data:

The initial velocity of the system, $(V_1) = 0$ m/s

The final velocity of the system, $(V_2) = 30$ m/s

Step 2 of 2

The energy needed to accelerate a body is simply occurred due to change in velocity i.e. the kinetic energy.

The specific kinetic energy is expressed as

$$ke = \frac{V_2^2 - V_1^2}{2} \text{ kJ/kg}$$

$$ke = \left(\frac{30^2 - 0}{2}\right) \text{ J/kg}$$

$$ke = \frac{450}{1000} \text{ kJ/kg}$$

$$ke = 0.45 \text{ kJ/kg}$$

∴ Specific kinetic energy, $\boxed{ke = 0.45 \text{ kJ/kg}}$

Question: 3.044P

An adiabatic closed system is raised 100 m at a location where the gravitational acceleration is 9.8 m/s2. Determine the energy change of this system, in kJ/kg.

Step 1 of 1

2760-2-47P SA Code: 2981

SR Code: 5070 RID1: 3211 | 19/08/2013
As the system undergoes change in elevation, the potential energy comes into action. Therefore, the energy change of the system is called the specific potential energy change.

Calculate the potential energy using the following relation:

$$\Delta PE = mg(z_2 - z_1)$$
$$= g\Delta z$$

Here, mass is m, acceleration due to gravity is g, and change in head is $(z_2 - z_1)$.

Substitute, $9.81\ m/s^2$ for g and $100\ m$ for Δz in the relation above, and calculate the energy change in the system.

$$\Delta PE = (9.8) \times (100 - 0) \times \left(\frac{1\ kJ/kg}{1000\ m^2/s^2} \right)$$
$$= 0.98\ kJ/kg$$

Therefore, the specific potential energy change (ΔPE) for the system is $\boxed{0.98\ kJ/kg}$.

Question: 3.045P

A water pump increases the water pressure from 10 psia to 50 psia. Determine the power input required, in hp, to pump 1.2 ft3/s of water. Does the water temperature at the inlet have any significant effect on the required flow power?

Step 1 of 2

Given data:

The initial pressure in the water pump, $P_1 = 10$ psia

The increased pressure in the water pump, $P_2 = 50$ psia

The volume flow rate of the pump, $\dot{v} = 1.2\ \text{ft}^3/\text{s}$

Step 2 of 2

The power input required by the pump is expressed as

$$\begin{aligned}
\dot{W} &= \dot{v}(P_2 - P_1) \\
&= 1.2 \times (50 - 10) \times 144\ \text{lbf} \cdot \text{ft/s} \qquad (\because 1\ \text{ft} = 12\ \text{in}) \\
&= 6912\ \text{lbf} \cdot \text{ft/s} \\
&= \frac{6912}{778.2}\ \text{lbf} \cdot \text{ft/s} \qquad (\because 1\ \text{Btu/s} = 778.2\ \text{lbf} \cdot \text{ft/s}) \\
&= 8.882\ \text{Btu/s} \qquad (\because 1\ \text{Btu/s} = 1.42\ \text{hp}) \\
&= 8.882 \times 1.42\ \text{hp} \\
&= 12.6\ \text{hp}
\end{aligned}$$

$\therefore$ The power input required, $\boxed{\dot{W} = 12.6\ \text{hp}}$

No the temperature has no effect the power outflow.

Question: 3.046P

A classroom that normally contains 40 people is to be air-conditioned with window air-conditioning units of 5-kW cooling capacity. A person at rest may be assumed to dissipate heat at a rate of about 360 kJ/h. There are 10 light-bulbs in the room, each with a rating of 100 W. The rate of heat transfer to the classroom through the walls and the windows is estimated to be 15,000 kJ/h. If the room air is to be maintained at a constant temperature of 21°C, determine the number of window air-conditioning units required.

Step 1 of 6

Given data:

The classroom contains 40 people and 10 bulbs which generates the heat in the room

Cooling capacity of air-conditioning, $Q_{capacity} = 5\ \text{kW}$

Person at rest dissipate heat at a rate of $\dot{Q} = 360\ \text{kJ/h}$

The rate of heat transfer through the walls to be 15000 kJ/h

Step 2 of 6

In order to maintain the classroom at constant temperature we have to estimate the total heat generate.

Heat generated by single person $\dot{Q} = 360\ \text{kJ/h}$

So total heat generated by 40 people $\dot{Q}_p = 40 \times 360\ \text{kJ/h}$

$$= 14400\ \text{kJ/h}$$

$$= \frac{14400}{3600}\ \text{kJ/s} \qquad (\because 1\ \text{hr} = 3600\text{s})$$

$$= 4\ \text{kW}$$

Step 3 of 6

No. of light bulbs in the room = 10

Heat generated due to bulbs $\dot{Q}_b = 10 \times 100\ \text{W}$

$$= 1\ \text{kW}$$

Step 4 of 6

Heat transferred trough the walls $\dot{Q}_{walls} = 15000\ \text{kJ/h}$

$$= \frac{15000}{3600}\ \text{kJ/s}$$

$$= 4.167\ \text{kW}$$

Step 5 of 6

Total heat generated in the classroom $\dot{Q}_{heat} = \dot{Q}_p + \dot{Q}_b + \dot{Q}_{walls}$

$$\dot{Q}_{heat} = 4 + 1 + 4.167$$

$$\dot{Q}_{heat} = 9.167\ \text{kW}$$

Step 6 of 6

The no. of air conditioning units required is $\frac{9.167}{5} = 1.83 \approx 2$

2 air-conditioning units will be required to cool the classroom.

Question: 3.047P

The lighting needs of a storage room are being met by 6 fluorescent light fixtures, each fixture containing four lamps rated at 60 W each. All the lamps are on during operating hours of the facility, which are 6 am to 6 pm 365 days a year. The storage room is actually used for an average of 3 h a day. If the price of electricity is $0.08/kWh, determine the amount of energy and money that will be saved as a result of installing motion sensors. Also, determine the simple payback period if the purchase price of the sensor is $32 and it takes 1 hour to install it at a cost of $40.

Step 1 of 4

Given data:
The total number of the lamps in the storage room is 24 lamps
The power consumed by each bulb is $P = 60\ \text{W}$
The price of electricity, $\$0.08/\text{kWh}$

Step 2 of 4

By using the motion sensor the usage of the lights from 12 hrs can be reduced to 3 hrs, i.e. 9 hrs the lights will be off.
So the number of hours the lights will not be operated in a year is
$9 \times 365 = 3285$ hrs in a year

Step 3 of 4

The amount of energy saved by the lights in a year is $= \dfrac{24 \times 60 \times 3285}{1000}\ \text{kWh/year}$

$= 4730.4\ \text{kWh/year}$

The amount of money saved is $= 4730.4 \times 0.08/\text{year}$

$= \$378.432/\text{year}$

The amount of money saved per month is $\dfrac{\$378.432}{12} = \$31.5$

Step 4 of 4

The total investment cost for the sensor to install is $\$32 + \$40 = \$72$
The pay back period is calculated by

$$PP = \frac{\text{The cost of investment}}{\text{Annual cash inflows}}$$

Therefore the time required to pay back is $PP = \dfrac{\$72}{\$31.5}$

$PP = 2.28$

The pay back period will be about 2 months and 9 days

Question: 3.048P

Consider a room that is initially at the outdoor temperature of 20°C. The room contains a 100-W lightbulb, a 110-W TV set, a 200-W refrigerator, and a 1000-W iron. Assuming no heat transfer through the walls, determine the rate of increase of the energy content of the room when all of these electric devices are on.

Step 1 of 3

The net change (increase or decrease) in the total energy of the system during a process is equal to the difference between the total energy entering and the total energy leaving the system during that process. That is,

$$\begin{pmatrix}\text{Total energy}\\ \text{entering the system}\end{pmatrix}-\begin{pmatrix}\text{Total energy}\\ \text{leaving the system}\end{pmatrix}=\begin{pmatrix}\text{Total energy change}\\ \text{in the system}\end{pmatrix}$$

Or $$E_{in}-E_{out}=\Delta E_{system} \quad \text{---------- (1)}$$

Step 2 of 3

The amount of heat increased in the room due to usage of the electrical equipment is

Light bulb = 100-W

TV set = 110-W

Refrigerator = 200-W

Iron = 1000 W

So total amount of heat input to the room is $E_{in}=100+110+200+1000$

$$E_{in}=1410\ \text{W}$$

Given there is no heat transfer across the walls of the room so $E_{out}=0\ \text{W}$

Step 3 of 3

Therefore from equation (1)

$E_{in}-E_{out}=\Delta E_{system}$

$1410-0=\Delta E_{system}$

$\Delta E_{system}=1410\ \text{W}$

The rate of increase in the energy content of the room is $\boxed{\Delta E_{system}=1410\ \text{W}}$

Question: 3.049P

A fan is to accelerate quiescent air to a velocity of 8 m/s at a rate of 9 m3/s. Determine the minimum power that must be supplied to the fan. Take the density of air to be 1.18 kg/m3.

Step 1 of 3

Given

Velocity of air flow $V = 8\ \text{m/s}$

Rate of flow of air $\dot{V} = 9\ \text{m}^3/\text{s}$

Density of the air $\rho = 1.18\ \text{kg/m}^3$

Step 2 of 3

For a control volume that encloses the fan, the energy balance can be written as

$$\dot{E}_{in} - \dot{E}_{out} = \frac{dE_{system}}{dt}$$

For steady conditions,

$$\frac{dE_{system}}{dt} = 0$$

Hence $\dot{E}_{in} - \dot{E}_{out} = 0$

$$\dot{E}_{in} = \dot{E}_{out}$$

Step 3 of 3

Here Energy input is kinetic energy from fan shaft and this energy is used by the air. So,

$$\dot{W}_{sh,in} = \dot{m}_{air}\frac{V_{out}^2}{2}$$

Where $\dot{m}_{air} = \rho\dot{V}$

$$\dot{m}_{air} = \left(1.18\ \text{kg/m}^3\right)\left(9\ \text{m}^3/\text{s}\right)$$

$$\dot{m}_{air} = 10.62\ \text{kg/s}$$

The minimum power input required is

$$\dot{W}_{sh,in} = \left(10.62\ \text{kg/s}\right)\frac{\left(8\ \text{m/s}^2\right)}{2}\left(\frac{1\ \text{J/kg}}{1\ \text{m}^2/\text{s}^2}\right)$$

$$\dot{W}_{sh,in} = 339.84\ \text{J/s}$$

$$\dot{W}_{sh,in} = 339.84\ \text{W}$$

Hence the minimum power input required is $\boxed{\dot{W}_{sh,in} = 339.84\ \text{W}}$

Question: 3.050P

Consider a fan located in a 3 ft × 3 ft square duct. Velocities at various points at the outlet are measured, and the average flow velocity is determined to be 22 ft/s. Taking the air density to 0.075 lbm/ft3, estimate the minimum electric power consumption of the fan motor.

Step 1 of 4

Given data:

The area of the square duct, $(A) = 9\ \text{ft}^2$

The average velocity of air caused by fan is $(V) = 22\ \text{ft/s}$

The density of air is $(\rho) = 0.075\ \text{lbm/ft}^3$

Step 2 of 4

Considering a control volume across the fan, the energy balance equation in rate form is expressed as

$$\dot{E}_{in} - \dot{E}_{out} = dE_{system}/dt\ \text{kW}$$

For a steady state the derivative term with time will be zero.

$$\dot{E}_{in} = \dot{E}_{out}$$

The minimum power supplied to run the fan is kinetic energy generated by fan

$$\dot{E}_{in} = \dot{W}_{ke} = \dot{m}\frac{V^2}{2}$$

Step 3 of 4

Where $\dot{m}$ is the mass flow rate of the air and is given by the equation

$$\dot{m} = \rho AV\ \text{lbm/s}$$

$$\dot{m} = 0.075 \times 9 \times 22\ \text{lbm/s}$$

$$\dot{m} = 14.85\ \text{lbm/s}$$

Step 4 of 4

Therefore minimum power supplied

$$\dot{E}_{in} = 14.85 \times \frac{22^2}{2}\ \text{lbm/s} \cdot \text{ft}^2/\text{s}^2$$

$$= \frac{3593.7}{25000}\ \text{Btu/s} \qquad \left(\because 1\ \text{Btu/lbm} = 25{,}000\ \text{ft}^2/\text{s}^2\right)$$

$$= 0.1437\ \text{Btu/s}$$

$\therefore$ The minimum power consumption, $\boxed{\dot{E}_{in} = 0.1437\ \text{Btu/s}}$

Question: 3.051P

The driving force for fluid flow is the pressure difference, and a pump operates by raising the pressure of a fluid (by converting the mechanical shaft work to flow energy). A gasoline pump is measured to consume 3.8 kW of electric power when operating. If the pressure differential between the outlet and inlet of the pump is measured to be 7 kPa and the changes in velocity and elevation are negligible, determine the maximum possible volume flow rate of gasoline.

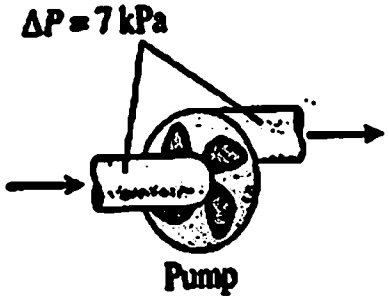


FIGURE P3–51

Step 1 of 1

Electric Power consumed by gasoline pump = 3.8 kW

Pressure difference between inlet and outlet of pump = 7 KPa

Power = pressure difference × volume flowrate

Volume flow rate $\dot{V} = \dfrac{3.8\ \text{kW}}{7\ \text{kPa}}$

$$\dot{V} = 0.5428\ \text{m}^3/\text{s}$$

Hence Volume flow rate of gasoline is $\boxed{\dot{V} = 0.5428\ \text{m}^3/\text{s}}$

Question: 3.052P

An escalator in a shopping center is designed to move 30 people, 75 kg each, at a constant speed of 0.8 m/s at 45° slope. Determine the minimum power input needed to drive this escalator. What would your answer be if the escalator velocity were to be doubled?

Step 1 of 3

Given data:
Mass of a person = 75 kg
Total number of persons = 30
Velocity of the escalator = 0.8 m/s
Angle of inclination = 45°

Step 2 of 3

Total mass on the escalators,

$$M = 30 \times 75$$
$$= 2250 \text{ kg}$$

Question:

An escalator in a shopping center is designed to move 30 people, 75 kg each, at a constant speed of 0.8 m/s at 45° slope. Determine the minimum power input needed to drive this escalator. What would your answer be if the escalator velocity were to be doubled?

Step 1 of 3

Given data:
Mass of a person = 75 kg
Total number of persons = 30
Velocity of the escalator = 0.8 m/s
Angle of inclination = 45°

Step 2 of 3

Total mass on the escalators,

$$M = 30 \times 75$$
$$= 2250 \text{ kg}$$

The actual velocity of the escalator used for lifting the mass is the vertical component of escalator velocity,

$$V_{\text{lift}} = V \sin 45$$
$$= 0.8 \times \sin 45$$
$$= 0.5657 \text{ m/s}$$

Power needed by escalators

$$P = \frac{\Delta PE}{\Delta t}$$
$$= mg\left(\frac{\Delta h}{\Delta t}\right)$$

Question: 3.053P

An automobile moving through the air causes the air velocity (measured with respect to the car) to decrease and fill a larger flow channel. An automobile has an effective flow channel area of 3 m2. The car is traveling at 90 km/h on a day when the barometric pressure is 70 cm of mercury and the temperature is 20°C. Behind the car, the air velocity (with respect to the car) is measured to be 82 km/h, and the temperature is 20°C. Determine the power required to move this car through the air and the area of the effective flow channel behind the car.

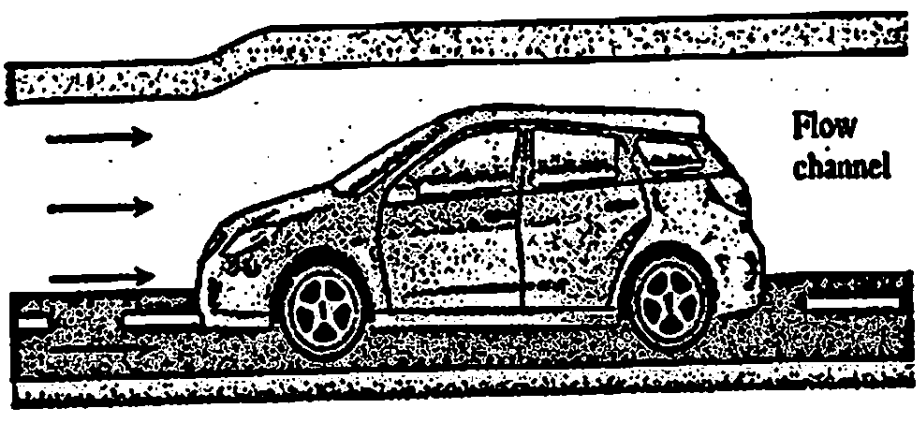

FIGURE P3-53

Step 1 of 5

Use the following conversion factor to convert the pressure from mm of Hg to kPa.

$$1\text{mmHg} = 0.1333\text{kPa}$$

Calculate the pressure in terms of kpa.

$$P = (700\text{mmHg})\left(\frac{0.1333\text{kPa}}{1\text{mmHg}}\right)$$

$$= 93.31\text{kPa}$$

Step 2 of 5

State the ideal gas equation.

$$Pv = RT$$

Here, P is the pressure , v is the specific volume , R is the gas constant and T is the temperature .

Substitute $0.287\text{kJ/kg}\cdot\text{K}$ for R, 293K for T, 93.31kPa for P

$$v = \frac{RT}{P}$$

$$= \frac{0.287 \times 293}{93.31}$$

$$= 0.9012\text{m}^3/\text{kg}$$

Step 1 of 5

Use the following conversion factor to convert the pressure from mm of Hg to kPa.

$$1\text{mmHg} = 0.1333\text{kPa}$$

Calculate the pressure in terms of kpa.

$$P = (700\text{mmHg})\left(\frac{0.1333\text{kPa}}{1\text{mmHg}}\right)$$

$$= 93.31\text{kPa}$$

Step 2 of 5

State the ideal gas equation.

$$Pv = RT$$

Here, P is the pressure , v is the specific volume , R is the gas constant and T is the temperature .

Substitute $0.287\text{kJ/kg}\cdot\text{K}$ for R, 293K for T, 93.31kPa for P

$$v = \frac{RT}{P}$$

$$= \frac{0.287 \times 293}{93.31}$$

$$= 0.9012\text{m}^3/\text{kg}$$

Step 3 of 5

$$= 83.22 \times \frac{(25)^2 - (22.78)^2}{2}\left(\frac{1\text{kJ/kg}}{1000\text{m}^2/\text{s}^2}\right)$$

$$= 4.413\text{kW}$$

Therefore the power required to move the car is $\boxed{4.413\text{kW}}$

Step 5 of 5

Calculate the outlet area by using the mass flow rate equation.

$$\dot{m} = \frac{A_2 V_2}{v}$$

$$A_2 = \frac{\dot{m} v}{V_2}$$

$$= \frac{83.22 \times 0.9012}{22.78}$$

$$= 3.29\text{m}^2$$

Therefore, the area of the effective flow channel behind the car is $\boxed{3.29\text{m}^2}$

$$= 83.22 \times \frac{(25)^2 - (22.78)^2}{2}\left(\frac{1\text{kJ/kg}}{1000\text{m}^2/\text{s}^2}\right)$$

$$= 4.413\text{kW}$$

Therefore the power required to move the car is $\boxed{4.413\text{kW}}$

Step 5 of 5

Calculate the outlet area by using the mass flow rate equation.

$$\dot{m} = \frac{A_2 V_2}{v}$$

$$A_2 = \frac{\dot{m} v}{V_2}$$

Question: 3.054P

What is mechanical efficiency? What does a mechanical efficiency of 100 percent mean for a hydraulic turbine?

Step 1 of 2

In the absence of any irreversibility's such as friction, mechanical energy can be converted entirely from one mechanical form to another, and the mechanical efficiency of a device or process can be defined as the ratio of the mechanical energy output to the mechanical energy input.

$$\eta_{mech} = \frac{\text{Mechanical energy output}}{\text{Mechanical energy input}}$$

$$= \frac{E_{mech,out}}{E_{mech,in}}$$

Question: 3.055P

How is the combined pump-motor efficiency of a pump and motor system defined? Can the combined pump-motor efficiency be greater than either the pump or the motor efficiency?

Step 1 of 1

2760-2-59P SA: 2981

SR: 5070 RID1: 3211 | 19/08/2013
The combined pump-motor efficiency of a pump/motor system is defined as the ratio of the increase in mechanical energy of the fluid to the electrical power consumed by the motor.

$$\eta_{\text{pump-motor}} = \eta_{\text{pump}} \times \eta_{\text{motor}}$$

$$= \frac{\dot{E}_{\text{mech,out}} - \dot{E}_{\text{mech,in}}}{\dot{W}_{\text{electric,in}}}$$

$$= \frac{\dot{W}_{\text{pump}}}{\dot{W}_{\text{elec,in}}}$$

Question: 3.056P

Define turbine efficiency, generator efficiency, and combined turbine-generator efficiency.

Step 1 of 3

The turbine efficiency is the ratio of energy developed by the turbine to the energy available in the fluid that rotates turbine

$$\eta_{\text{turbine}} = \frac{\text{Mechanical energy output}}{\text{energy in the fluid}}$$

$$= \frac{\dot{W}_{\text{shaft,out}}}{\left|\Delta \dot{E}_{\text{mech,fluid}}\right|}$$

Hence the turbine efficiency is $\boxed{\eta_{\text{turbine}} = \frac{\dot{W}_{\text{shaft,out}}}{\left|\Delta \dot{E}_{\text{mech,fluid}}\right|}}$

Step 2 of 3

The generator efficiency is the ratio of the electrical power output to the mechanical power input to generator

$$\eta_{\text{generator}} = \frac{\text{Electrical power output}}{\text{Mechanical power input}}$$

$$= \frac{\dot{W}_{\text{elect,out}}}{\dot{W}_{\text{shaft,in}}}$$

Hence the generator efficiency is $\boxed{\eta_{\text{generator}} = \frac{\dot{W}_{\text{elect,out}}}{\dot{W}_{\text{shaft,in}}}}$

Step 3 of 3

The combined turbine generator efficiency is the product of the turbine efficiency and generator efficiency

$$\eta_{\text{turbine-generator}} = \eta_{\text{turbine}}\eta_{\text{generator}}$$

$$= \frac{\dot{W}_{\text{shaft}}}{\left|\Delta \dot{E}_{\text{mech,fluid}}\right|} \times \frac{\dot{W}_{\text{elect,out}}}{\dot{W}_{\text{shaft}}}$$

$$= \frac{\dot{W}_{\text{elect,out}}}{\left|\Delta \dot{E}_{\text{mech,fluid}}\right|}$$

Hence the combined turbine generator efficiency is $\boxed{\eta_{\text{turbine-generator}} = \frac{\dot{W}_{\text{elect,out}}}{\left|\Delta \dot{E}_{\text{mech,fluid}}\right|}}$

Question: 3.057P

Can the combined turbine-generator efficiency be greater than either the turbine efficiency or the generator efficiency? Explain.

Step 1 of 1

No, the combined turbine-generator efficiency cannot be grater than the either the turbine efficiency or the generator efficiency.

We know that $\eta_{\text{turbine-gen}} = \eta_{\text{turbine}}\eta_{\text{gen}}$,

So, the efficiency of turbine and generator will always be less than one, the product will be smaller than the individual efficiencies.

Question: 3.058P

Consider a 24-kW hooded electric open burner in an area where the unit costs of electricity and natural gas are \$0.10/kWh and \$1.20/therm (1 therm = 105,500 kJ), respectively. The efficiency of open burners can be taken to be 73 percent for electric burners and 38 percent for gas burners. Determine the rate of energy consumption and the unit cost of utilized energy for both electric and gas burners.

Step 1 of 3

Given

Power Consumption of burner, $P = 24$ kW

Unit cost of electricity = \$ 0.10/kWh

Unit cost of natural gas = \$ 1.20/therm

Efficiency of electric burner $\eta_{electric} = 73\%$

Efficiency of gas burner $\eta_{gas} = 38\%$

Step 2 of 3

Utilized energy of an electric burner is

$$\dot{Q}_{utilized} = (\text{Energy input}) \times (\text{Efficiency})$$

$$\dot{Q}_{utilized} = (24\ \text{kW})(0.73)$$

$$\dot{Q}_{utilized} = 17.52\ \text{kW}$$

Energy consumption rate, $\boxed{\dot{Q}_{utilized} = 17.52\ \text{kW}}$

The unit cost of utilized energy is inversely proportional to the efficiency,

$$\text{Cost of utilized energy} = (\text{energy input}) \times \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

$$= 17.52 \times \frac{\$0.1/\text{kWh}}{0.73}$$

$$= \$2.4/\text{h}$$

Cost of utilized energy $\boxed{\$2.4/\text{h}}$

Step 3 of 3

Utilized energy of a gas burner is

$$\dot{Q}_{utilized} = (\text{Energy input}) \times (\text{Efficiency})$$

$$\dot{Q}_{utilized} = (24\ \text{kW})(0.38)$$

$$\dot{Q}_{utilized} = 9.12\ \text{kW}$$

Energy consumption rate $\boxed{\dot{Q}_{utilized} = 9.12\ \text{kW}}$

The unit cost of utilized energy is inversely proportional to the efficiency,

$$\text{Cost of utilized energy} = (\text{energy input}) \times \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

$$= 9.12 \times \frac{\$1.2/\text{therm}}{0.38}$$

1 therm = 105500 kJ Hence 1 therm = 29.307 kWh

$$= 9.12 \times \frac{\$1.2/\text{therm}}{0.38} \times \frac{1\ \text{therm}}{105500\ \text{kJ}}$$

$$= 9.12 \times \frac{\$1.2/\text{therm}}{0.38} \times \frac{1\ \text{therm}}{29.307\ \text{kWh}}$$

$$= \$0.983/\text{h}$$

Cost of utilized energy $\boxed{\$0.983/\text{h}}$

Question: 3.059P

A 75-hp (shaft output) motor that has an efficiency of 91.0 percent is worn out and is replaced by a high-efficiency 75-hp motor that has an efficiency of 95.4 percent. Determine the reduction in the heat gain of the room due to higher efficiency under full-load conditions.

Step 1 of 4

Given data:

The shaft output power of a motor $\dot{W}_{sh} = 75\text{ hp}$

The efficiency of the motor, $\eta_{motor} = 91\%$

The high-efficiency of the motor, $\eta_{motor-inc} = 95.4\%$

Step 2 of 4

The efficiency of the motor is defined as $\eta_{motor} = \dfrac{\dot{W}_{sh}}{\dot{W}_{elec}}$

The electric input given to motor is $\dot{W}_{elec} = \dfrac{75\times746}{0.91}$ $(\because 1\text{ hp} = 746\text{ W})$

$$= \frac{61483.5}{1000}\text{ kW}$$

$$= 61.48\text{ kW}$$

Step 3 of 4

The electric input given to motor due to increased efficiency

$$\dot{W}_{elec-inc} = \frac{75\times746}{0.954} \quad (\because 1\text{ hp} = 746\text{ W})$$

$$= \frac{58647.79}{1000}$$

$$= 58.647\text{ kW}$$

Step 4 of 4

The reduction of the heat gain of the room due to higher efficiency is

$$\dot{Q} = \dot{W}_{elec} - \dot{W}_{elec-inc}$$

$$= 61.48 - 58.647$$

$$= 2.833\text{ kW}$$

$\therefore$ The reduction in the heat gain, $\boxed{\dot{Q} = 2.833\text{ kW}}$

Question: 3.060P

A 90-hp (shaft output) electric car is powered by an electric motor mounted in the engine compartment. If the motor has an average efficiency of 91 percent, determine the rate of heat supply by the motor to the engine compartment at full load.

Step 1 of 2

Convert the units of input power.

$$\dot{W}_{shaft} = 90\ \text{hp}$$

$$= 90\ \text{hp} \times \left(\frac{746\ \text{W}}{1\ \text{hp}}\right)$$

$$= 67140\ \text{W}$$

$$\dot{W}_{shaft} = 67.14\ \text{kW}$$

Consider the efficiency of the electric motor.

$$\eta_{motor} = \frac{\dot{W}_{shaft}}{\dot{W}_{elec}}$$

$$\dot{W}_{elec} = \frac{\dot{W}_{shaft}}{\eta_{motor}}$$

$$\dot{W}_{elec} = \frac{67140}{0.91}$$

$$= \frac{73780.2}{1000}\ \text{kW}$$

$$= 73.78\ \text{kW}$$

Step 2 of 2

Calculate the heat generated in the electric car.

$$\dot{Q} = \dot{W}_{input} - \dot{W}_{output}$$

$$\dot{Q} = 73.78 - 67.14$$

$$= 6.64\ \text{kW}$$

Therefore, the heat generated is $\boxed{6.64\ \text{kW}}$.

Question: 3.061P

A 75-hp (shaft output) motor that has an efficiency of 91.0 percent is worn out and is to be replaced by a high-efficiency motor that has an efficiency of 95.4 percent. The motor operates 4368 hours a year at a load factor of 0.75. Taking the cost of electricity to be $0.08/kWh, determine the amount of energy and money saved as a result of installing the high-efficiency motor instead of the standard motor. Also, determine the simple payback period if the purchase prices of the standard and high-efficiency motors are $5449 and $5520, respectively.

Step 1 of 6

Given data:

Shaft power output $= 75\,\text{hp}$

Motor efficiency, $\eta_{low} = 91.0\%$

Motor with high efficiency, $\eta_{high} = 95.4\%$

Operating time of the motor $= 4368$ hours

Load factor $= 0.75$

Cost of electricity $= \$0.08/\text{kWh}$

Step 2 of 6

The electric power drawn by each motor and their difference can be expressed as

$$\dot{W}_{\text{electric in}} = \dot{W}_{\text{shaft}} / \eta_{low}$$
$$= (\text{Rated power} \times \text{Load factor}) / \eta_{low}$$

$$\dot{W}_{\text{electric high}} = \dot{W}_{\text{shaft}} / \eta_{high}$$
$$= (\text{Rated power} \times \text{Load factor}) / \eta_{high}$$

Step 3 of 6

$$\therefore \text{Power savings} = \dot{W}_{\text{elec low}} - \dot{W}_{\text{elec high}}$$
$$= (\text{Rated power} \times \text{Load factor}) \times (1/\eta_{low} - 1/\eta_{high})$$

Where η_{low} is the efficiency of the standard motor,

η_{high} is the efficiency of the comparable high-efficiency motor.

Step 4 of 6

Then the annual energy and cost savings associated with the installation of the high-efficiency motor become

$$\text{Energy savings} = \text{Power savings} \times \text{Operating hours}$$
$$= (\text{Rated power} \times \text{Load factor} \times \text{Operating hours}) \times (1/\eta_{low} - 1/\eta_{high})$$

Substituting values we get

$$\text{Therefore energy savings} = (75 \times 0.746 \times 4368 \times 0.75) \times \left[\frac{1}{0.91} - \frac{1}{0.954}\right] \text{kWh/year}$$
$$= 9289.8\ \text{kWh/year}$$

$$\boxed{\text{Energy savings} = 9289.8\ \text{kWh/year}}$$

Step 5 of 6

$$\text{Cost savings} = (\text{Energy savings})\ (\text{Unit cost of energy})$$
$$= 9290 \times \$0.08$$
$$= \$743.2/\text{year}$$

$$\boxed{\text{Cost savings} = \$743.2/\text{year}}$$

Step 6 of 6

$$\text{Also, Excess intial cost} = \text{Purchase price differential}$$
$$= \$5520 - \$5449$$
$$= \$71$$

This gives a simple pay back period

$$\text{Simple pay back period} = \frac{\text{Excess intial cost}}{\text{Annual cost savings}}$$
$$= \frac{\$71}{\$743.2}$$
$$= 0.0955\ \text{years}$$

The pay back period in months can be calculated as

$$0.0955 \times 12 = 1.15\ \text{Months} \qquad (\because 1\ \text{year} = 12\ \text{months})$$

$\therefore$ Simple pay back period, $\boxed{\approx 1\ \text{month 2 days}}$

Question: 3.062P

The steam requirements of a manufacturing facility are being met by a boiler whose rated heat input is 5.5 × 106 Btu/h. The combustion efficiency of the boiler is measured to be 0.7 by a hand-held flue gas analyzer. After tuning up the boiler, the combustion efficiency rises to 0.8. The boiler operates 4200 hours a year intermittently. Taking the unit cost of energy to be $4.35/106 Btu, determine the annual energy and cost savings as a result of tuning up the boiler.

Step 1 of 5

Given

The current rate of heat input to the boiler is given to be $\dot{Q}_{in,current} = 5.5\times10^6$ Btu/h

Operating hours $t = 4200$h

Unit cost of energy $= \$4.35/10^6$ Btu

Step 2 of 5

The heat output of boiler is related to the fuel energy input to the boiler by

Boiler output = (Boiler input)(Combustion efficiency)

$$\dot{Q}_{out} = \dot{Q}_{in}\eta_{furnace}$$

The rate of useful heat output of the boiler becomes

$$\dot{Q}_{out} = \left(\dot{Q}_{in}\eta_{furnace}\right)_{current}$$

$$= \left(5.5\times10^6 \text{ Btu/h}\right)(0.7)$$

$$\dot{Q}_{out} = 3.85\times10^6 \text{ Btu/h}$$

Step 3 of 5

The boiler must supply useful heat at the same rate after the tune up. Therefore, the rate of heat input to the boiler after the tune up and the rate of energy savings become

$$\dot{Q}_{in,new} = \dot{Q}_{out} / \eta_{furnace,new}$$

$$= \left(3.85\times10^6\right)/0.8$$

$$\dot{Q}_{in,new} = 4.81\times10^6 \text{ Btu/h}$$

Step 4 of 5

$$\dot{Q}_{in,saved} = \dot{Q}_{in,current} - \dot{Q}_{in,new}$$

$$= 5.5\times10^6 - 4.81\times10^6$$

$$\dot{Q}_{in,saved} = 0.69\times10^6 \text{ Btu/h}$$

Step 5 of 5

Then the annual energy and cost savings associated with tuning up the boiler become

Energy Savings $= \dot{Q}_{in,saved}$ (Operation hours)

$= (0.69\times10^6 \text{ Btu/h})(4200 \text{ h/year})$

Energy Savings $= 2898\times10^6$ Btu/yr

Cost Savings = (Energy Savings)(Unit cost of energy)

$= (2898\times10^6 \text{ Btu/yr})(\$4.35 \text{ per } 10^6 \text{ Btu})$

Cost Savings = $12606.3/year

Question: 3.063P

Reconsider Prob. 3-62E. Using EES (or other) software, study the effects of the unit cost of energy, the new combustion efficiency on the annual energy, and cost savings. Let the efficiency vary from 0.7 to 0.9, and the unit cost to vary from $4 to $6 per million Btu. Plot the annual energy and cost savings against the efficiency for unit costs of $4, $5, and $6 per million Btu, and discuss the results.

Step 1 of 5

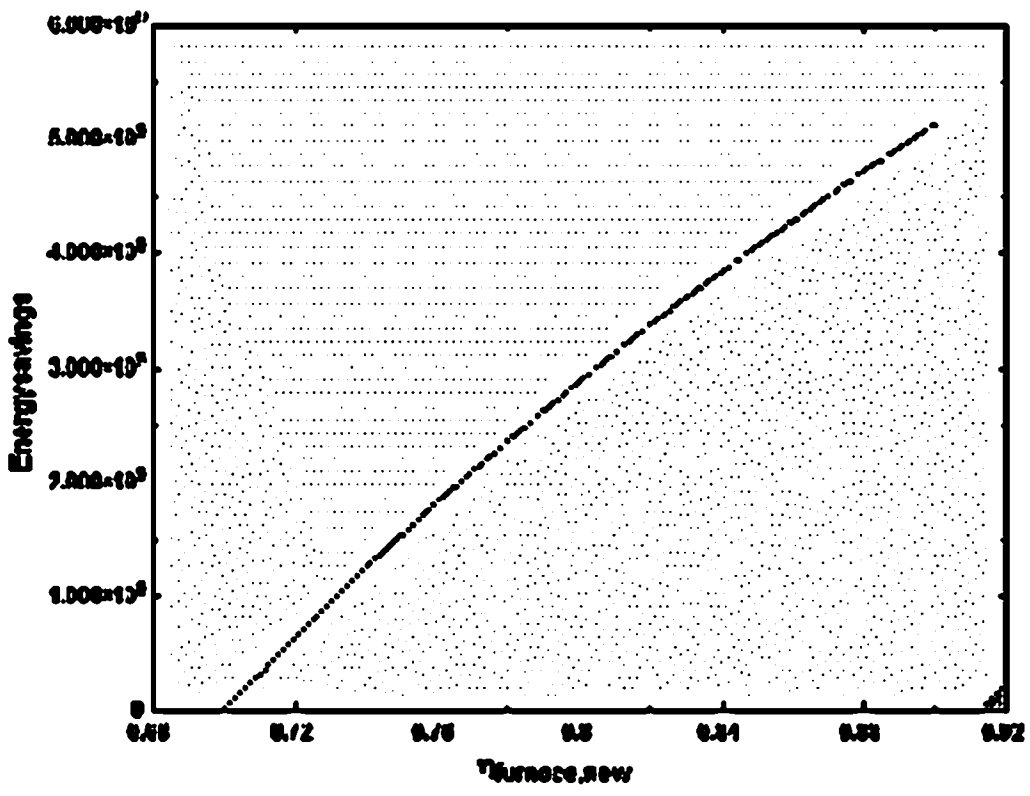
Writing the program of the given conditions

"Given"
Q_dot_in_current=5.5E6 [Btu/h]
eta_furnace_current=0.7
"eta_furnace_new=0.8"
Hours=4200 [h/year]
UnitCost=4.35E-6 [$/Btu]

"Analysis"
Q_dot_out=Q_dot_in_current×η_furnace_current
Q_dot_in_new=Q_dot_out/η_furnace_new
Q_dot_in_saved=Q_dot_in_current-Q_dot_in_new
Energysavings=Q_dot_in_saved×Hours
CostSavings=EnergySavings×UnitCost

Step 2 of 5

Procedure to solve EES software:
File → Open the new file
Copy the given program in the file
Then go to tables → new parametric table
Select the input parameters and set the range of the input quantities
Then solve the program
To obtain the graphs go to plots and select the x and y axis parameters then click ok



Step 3 of 5

Parametric table:

1..11	1 $\eta_{furnace,new}$	2 Energysavings	3 CostSavings
Run 1	0.7	0	0
Run 2	0.72	6.417E+08	2791
Run 3	0.74	1.249E+09	5432
Run 4	0.76	1.824E+09	7933
Run 5	0.78	2.369E+09	10306
Run 6	0.8	2.888E+09	12561
Run 7	0.82	3.380E+09	14705
Run 8	0.84	3.850E+09	16748
Run 9	0.86	4.298E+09	18695
Run 10	0.88	4.725E+09	20554

Step 4 of 5

Graph between furnace efficiency and energy savings:

Step 5 of 5

Graph between furnace efficiency and cost savings:

Question: 3.064P

An exercise room has eight weight-lifting machines that have no motors and four treadmills each equipped with a 2.5-hp (shaft output) motor. The motors operate at an average load factor of 0.7, at which their efficiency is 0.77. During peak evening hours, all 12 pieces of exercising equipment are used continuously, and there are also two people doing light exercises while waiting in line for one piece of the equipment. Assuming the average rate of heat dissipation from people in an exercise room is 525 W, determine the rate of heat gain of the exercise room from people and the equipment at peak load conditions.

Step 1 of 2

Calculate the total shaft power output from the motor as follows:

$$\begin{aligned}\dot{W}_{out} &= 4\times 2.5\times 746 \quad (\because 1\text{ hp} = 746\text{ W})\\ &= 7460\text{ W}\end{aligned}$$

Load factor, $= 0.7$

Efficiency, $\eta = 0.77$

We know that efficiency $\eta = \dfrac{\text{Work output}}{\text{Heat input}}$

Calculate the heat generated by the motors as follows:

$$\dot{Q}_{motor} = \frac{\dot{W}_{out}\times load\ factor}{\eta}$$

Here, η is the efficiency.

Substitute 7460 W for $\dot{Q}_{input}$, 0.7 for *load factor*, and 0.77 for η.

$$\begin{aligned}\dot{Q}_{motor} &= \frac{7460\times 0.7}{0.77}\\ &= 6781.8\text{ W}\end{aligned}$$

Step 2 of 2

There are 12 exercising equipment and 2 people doing light exercise, so at peak hours there will be total 14 people and each person dissipates a average heat of 525 W.

Therefore, calculate the heat generated from people as follows:

$$\begin{aligned}\dot{Q}_{people} &= 14\times 525\\ &= 7350\text{ W}\end{aligned}$$

Calculate the rate of heat gain from the people and the motor as follows:

$$\dot{Q}_{total} = \dot{Q}_{motor} + \dot{Q}_{people}$$

Substitute 6781.8 W for $\dot{Q}_{motor}$ and 7350 W for $\dot{Q}_{people}$.

$$\begin{aligned}\dot{Q}_{total} &= 6781.8 + 7350\\ &= 14131.8\text{ W}\end{aligned}$$

Therefore, the rate of heat gain is $\boxed{14131.8\text{ W}}$.

Question: 3.065P

A room is cooled by circulating chilled water through a heat exchanger located in a room. The air is circulated through the heat exchanger by a 0.25-hp (shaft output) fan. Typical efficiency of small electric motors driving 0.25-hp equipment is 54 percent. Determine the rate of heat supply by the fan-motor assembly to the room.

Step 1 of 2

Given data:

The shaft power output of the fan, $\dot{W}_{shaft} = 0.25\ \text{hp}$

The efficiency of the fan motor, $\eta = 54\%$

Step 2 of 2

The efficiency of the motor is defined as $\eta = \dfrac{\text{Energy output}}{\text{Energy input}}$

Here the energy input is the electrical energy, so the electrical energy consumed by the motor will be dissipated as heat.

$$\text{Therefore } \eta = \frac{\dot{W}_{shaft}}{\dot{Q}_{heat}} \quad (\because 1\ \text{hp} = 746\ \text{W})$$

$$\dot{Q}_{heat} = \frac{\dot{W}_{shaft}}{\eta}$$

$$\dot{Q}_{heat} = \frac{0.25 \times 746}{0.54}$$

$$\dot{Q}_{heat} = 345.37\ \text{W}$$

$\therefore$ The rate of heat supply by the fan-motor assembly, $\boxed{\dot{Q}_{heat} = 345.37\ \text{W}}$

Question: 3.066P

The water in a large lake is to be used to generate electricity by the installation of a hydraulic turbine-generator at a location where the depth of the water is 50 m (Fig. 3–62). Water is to be supplied at a rate of 5000 kg/s. If the electric power generated is measured to be 1862 kW and the generator efficiency is 95 percent, determine (*a*) the overall efficiency of the turbine—generator, (*b*) the mechanical efficiency of the turbine, and (c) the shaft power supplied by he turbine to the generator.

Step 1 of 6

Given

Depth of water $h = 50\text{m}$

Rate of water supply $\dot{m} = 5000\text{kg/s}$

Electric power generated $\dot{W} = 1862\text{kW}$

Generator efficiency $\eta_{gen} = 95\%$

Step 2 of 6

(a) We are taking the bottom of the lake as the reference level for convenience. Then kinetic and potential energies of water are zero, and the mechanical energy of water consists of pressure energy only which is

$$e_{mech,in} - e_{mech,out} = \frac{P}{\rho} = gh$$

$$e_{mech,in} - e_{mech,out} = (9.81\text{m/s}^2)(50\text{m})\left(\frac{1\text{kJ/kg}}{1000\text{m}^2/\text{s}^2}\right)$$

$$e_{mech,in} - e_{mech,out} = 0.491\text{kJ/kg}$$

Step 3 of 6

The rate at which mechanical energy of fluid supplied to the turbine

$$\left|\Delta\dot{E}_{mech,fluid}\right| = \dot{m}\left(e_{mech,in} - e_{mech,in}\right)$$

$$= (5000)(0.491)$$

$$\left|\Delta\dot{E}_{mech,fluid}\right| = 2455\text{kW}$$

Step 4 of 6

The overall efficiency become

$$\eta_{overall} = \frac{\dot{W}_{elect,out}}{\left|\Delta\dot{E}_{mech,fluid}\right|}$$

$$= \frac{1862}{2455}$$

$$\boxed{\eta_{overall} = 75.8\%}$$

Step 5 of 6

(b)The mechanical efficiency of the turbine is

$$\eta_{turbine} = \frac{\eta_{overall}}{\eta_{generator}}$$

$$= \frac{0.758}{0.95}$$

$$\boxed{\eta_{turbine} = 79.78\%}$$

Step 6 of 6

(c) The shaft power supplied by the turbine to the generator

$$\dot{W}_{shaft,out} = \eta_{turbine}\left|\Delta\dot{E}_{mech,fluid}\right|$$

$$= (0.7978)(2455)$$

$$\boxed{\dot{W}_{shaft,out} = 1958.59\text{kW}}$$

Therefore, the lake supplies 2455 kW of mechanical energy to the turbine, which converts 1958.59 kW of it to shaft work that drives the generator, which generates 1862 kW of electric power.

Question: 3.067P

At a certain location, wind is blowing steadily at 7 m/s. Determine the mechanical energy of air per unit mass and the power generation potential of a wind turbine with 80-m-diameter blades at that location. Also determine the actual electric power generation assuming an overall efficiency of 30 percent. Take the air density to be 1.25 kg/m3.

Step 1 of 4

Given data:

Velocity of the wind blow $V = 7\,\text{m/s}$.

Diameter of the blades $d = 80\,\text{m}$.

Overall efficiency is $\eta_{overall} = 30\%$.

The density of air, $\rho = 1.25\,\text{kg/m}^3$.

Taking the density of water, $\rho = 1000\,\text{kg/m}^3$.

Step 2 of 4

The mechanical energy of air per unit mass is calculated from the kinetic energy of the wind blowing

$$\dot{e}_{mech} = \frac{\dot{m}V^2}{2}$$

Where $\dot{m}$ is the mass flow rate of air

$$\dot{m} = \rho AV$$

$$= 1.25 \times \frac{\pi}{4}(80)^2 \times 7$$

$$= 43982.29\,\text{kg/s}$$

Step 3 of 4

Therefore the mechanical energy and the power generation potential of the wind turbine is calculated as

$$\dot{W} = \dot{E}_{mech} = \frac{\dot{m}V^2}{2}$$

$$= \frac{4398.29 \times 7^2}{2}$$

$$= 1077566.1\,\text{W}$$

$$= 1077.566\,\text{kW}$$

Power generation is $\boxed{\dot{W} = \dot{E}_{mech} = 1077.566\,\text{kW}}$

Step 4 of 4

Then the actual electric power generation with the consideration of an overall efficiency of 30 percent is

$$\dot{W}_{electric} = \eta_{overall} \times \dot{W}$$

$$\dot{W}_{electric} = 0.3 \times 1077.566$$

$$\dot{W}_{electric} = 323.26\,\text{kW}$$

Therefore the electric power is $\boxed{\dot{W}_{electric} = 323.26\,\text{kW}}$

Question: 3.068P

Reconsider Prob. 3–67. Using EES (or other) software, investigate the effect of wind velocity and the blade span diameter on wind power generation. Let the velocity vary from 5 to 20 m/s in increments of 5 m/s, and the diameter vary from 20 to 120 m in increments of 20 m. Tabulate the results, and discuss their significance.

Step 1 of 4

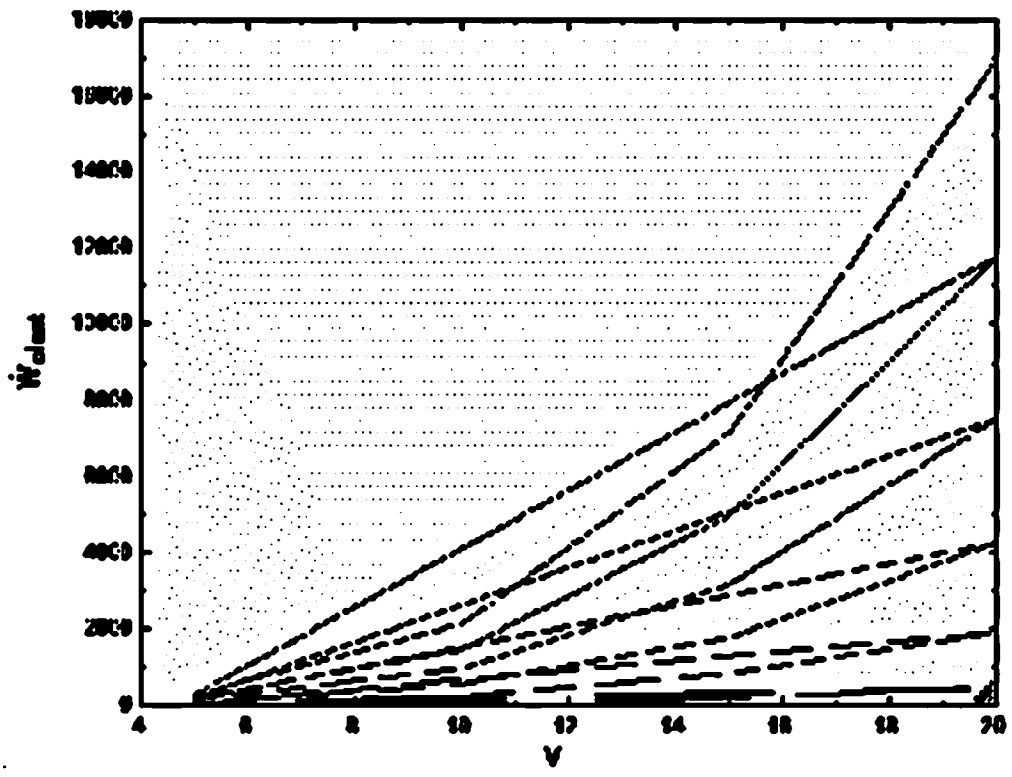
Writing the program of the given conditions

```
"Given"
V=7 [m/s]
D=80 [m]
eta_overall=0.30
rho=1.25 [kg/m^3]
"Analysis"
g=9.81 [m/s^2]
A=pi*D^2/4
m_dot=rho*A*V
W_dot_max=m_dot*V^2/2*Convert(m^2/s^2, kJ/kg)
W_dot_elect=eta_overall*W_dot_max
```

Step 2 of 4

Procedure to solve EES software:
File → Open the new file
Copy the given program in the file
Then go to tables → new parametric table
Select the input parameters and set the range of the input quantities
And select the diameter as a range of 20 to 120m
And select the velocity as a range of 5 to 20m/s
Then solve the program
To obtain the graphs go to plots and select the *x* and *y* axis parameters then click ok

Step 3 of 4



Parametric table:

Table 1

Step 4 of 4

Graph between velocity and electric power generation with different diameters as follows:

Question: 3.069P

Water is pumped from a lake to a storage tank 20 m above at a rate of 70 L/s while consuming 20.4 kW of electric power. Disregarding any frictional losses in the pipes and any changes in kinetic energy, determine (*a*) the overall efficiency of the pump–motor unit and (*b*) the pressure difference between the inlet and the exit of the pump.

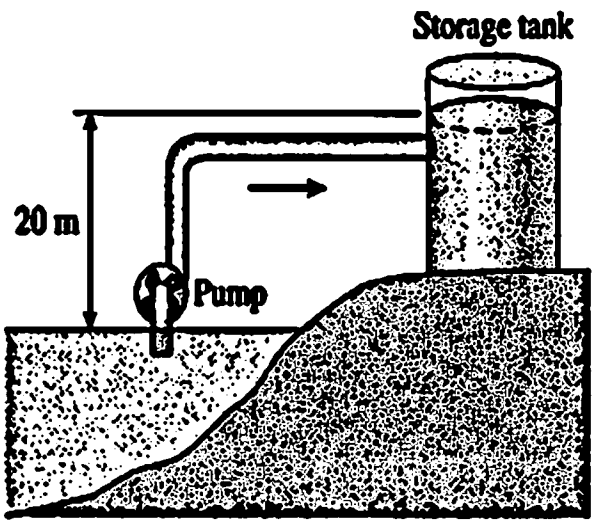

FIGURE P3–69

Step 1 of 5

Given data:

The height of the storage tank, $h = 20\ \text{m}$

The volume flow rate of the pump, $\dot{V} = 70\ \text{L/s}\ \left(\because 1\ \text{L/s} = 10^{-3}\ \text{m}^3/\text{s}\right)$

The electric power supplied the pump, $\dot{W}_{elec} = 20.4\ \text{kW}$

Taking density of water, $\rho = 1000\ \text{kg/m}^3$

Acceleration due to gravity $(g) = 9.8\ \text{m/s}^2$

Step 2 of 5

(a) The overall efficiency of the pump-motor unit:

Neglecting the frictional losses in the pipe and changes in kinetic energy, the power needed to deliver the water into the storage tank is expressed as

$$\dot{E}_{mech} = \dot{m}\,\Delta pe\ \text{kW}$$

Where $\dot{m}$ mass flow rate $\dot{m} = \rho A V$

$$= \rho \dot{V}\ \text{kg/s}\ \left(\because \dot{V} = AV\right)$$

Step 3 of 5

Δpe is the change in specific potential energy

$$\therefore \Delta pe = gh$$

Therefore power delivered by pump

$$\dot{E}_{mech} = \rho \dot{V} gh$$

$$= 1000 \times \frac{70}{1000} \times 9.8 \times 20\ \ (1000\ \text{J/s} = 1\ \text{kW})$$

$$= 13.72\ \text{kW}$$

Step 4 of 5

The efficiency of the fan-motor is expressed as

$$\eta = \frac{\dot{E}_{mech}}{\dot{W}_{elec}}$$

$$= \frac{13.72}{20.4}$$

$$= 0.6725$$

$\therefore$ The overall efficiency of the pump-motor unit, $\boxed{\eta = 67.25\%}$

Step 5 of 5

(b) The pressure difference ΔP between inlet and exit of the pump:

If considering pump alone as a system the pressure difference at the inlet and exit of the pump can be calculated as

$$\dot{E}_{mech} = \dot{V}\,\Delta P_{pump}$$

Therefore the pressure difference

$$\Delta P_{pump} = \frac{\dot{E}_{mech}}{\dot{V}}$$

$$= \frac{13.72}{0.07}$$

$$= 196\ \text{kPa}$$

$\therefore$ The pressure difference, $\boxed{\Delta P_{pump} = 196\ \text{kPa}}$

Question: 3.070P

Large wind turbines with blade span diameters of over 100 m are available for electric power generation. Consider a wind turbine with a blade span diameter of 100 m installed at a site subjected to steady winds at 8 m/s. Taking the overall efficiency of the wind turbine to be 32 percent and the air density to be 1.25 kg/m3, determine the electric power generated by this wind turbine. Also, assuming steady winds of 8 m/s during a 24-hour period, determine the amount of electric energy and the revenue generated per day for a unit price of $0.06/kWh for electricity.

Step 1 of 5

Find the amount of mechanical energy per unit mass generated by the turbine.

$$KE = \frac{1}{2}mv^2$$

$$\frac{KE}{m} = \frac{1}{2}v^2$$

$$\frac{KE}{m} = \frac{1}{2}v^2$$

Here, kinetic energy of the turbine is *KE*, mass of the wind due to which turbine rotates is *m*, and velocity of the turbine is *v*.

Substitute $8\ \text{m/s}$ for *v*.

$$\frac{KE}{m} = \frac{1}{2}(8)^2$$
$$= 32\ \text{J/kg}$$
$$= 0.032\ \text{kJ/kg}$$

Step 2 of 5

Find the power generated from wind turbine using the relation.

$$P_{mech} = \dot{m}\left(\frac{KE}{m}\right)$$
$$= \rho A v\left(\frac{KE}{m}\right)$$
$$= \rho\left(\frac{\pi}{4}d^2\right)v\left(\frac{KE}{m}\right)$$

Here, mass flow rate of the wind is $\dot{m}$, density of air is ρ, area covered by the turbine is *A*, diameter of the turbine wing area is *d*, and velocity of the flow is *V*.

Substitute, $1.25\ \text{kg/m}^3$ for ρ, 100 m for *d*, 8 m/s for *v*, 0.032 kJ/kg

$$P_{mech} = 1.25\left(\frac{\pi}{4}100^2\right)\times 8\times(0.032)$$
$$= 2513.27\ \text{kW}$$

Step 3 of 5

Find the electricity generated using the relation.

$$\eta = \frac{P_{elect}}{P_{mech}}$$

$$P_{elect} = \eta \times P_{mech}$$
$$= 0.32\times(2513.27)$$
$$= 804.2464\ \text{kW}$$

Therefore, the electric power generated is $\boxed{804.2464\ \text{kW}}$.

Step 4 of 5

Find the amount of energy electricity generated if the turbine operated for 24 hours.

$$P_{E\text{-}day} = P_{elect} \times t$$

Here, time of operation is *t*.

Substitute, 804.2464 kW for P_{elect} and 24 hr for *t*.

$$P_{E\text{-}day} = 804.2464\times 24$$
$$= 19301.9136\ \text{kW-h}$$

Therefore, the amount of electric energy generated, $\boxed{19{,}301.9136\ \text{kW-h}}$

Step 5 of 5

Find the amount of revenue generated per day using.

$$C = P_{E\text{-}day} \times u_p$$

Here, unit price of electricity is u_p.

Substitute, 19301.9136 kW-h for $P_{E\text{-}day}$, and $0.06\frac{\$}{\text{kW-h}}$ for u_p.

$$C = 19301.9136\times 0.06$$
$$= 1158.1148\frac{\$}{\text{day}}$$

Therefore, the revenue generated per day is $\boxed{\$1158.1148(\text{per day})}$.

Question: 3.071P

A water pump delivers 6 hp of shaft power when operating. If the pressure differential between the outlet and the inlet of the pump is measured to be 1.2 psi when the flow rate is 15 ft3/s and the changes in velocity and elevation are negligible, determine the mechanical efficiency of this pump.

Step 1 of 3

Given

Power of pump $\dot{W} = 6\,\text{hp}$

Pressure difference between outlet and inlet of the pump is $\Delta P = 1.2\,\text{psi}$

Flow rate of water $Q = 1.5\,\text{ft}^3/\text{s}$

Step 2 of 3

To determine the mechanical efficiency of the pump, we need to know the increase in the mechanical energy of the fluid as it flows through the pump, which is

$$\Delta \dot{E}_{mech,fluid} = \dot{m}\left(e_{mech,out} - e_{mech,in}\right)$$

$$\Delta \dot{E}_{mech,fluid} = \Delta P \times Q$$

$$= \left(15\,\text{ft}^3/\text{s}\right)\left(1.2\,\text{psi}\right)\left(\frac{1\,\text{Btu}}{5.404\,\text{psi}\times\text{ft}^3}\right)$$

$$= 3.33\,\text{Btu/s}$$

We know $1\,\text{hp} = 0.7068\,\text{Btu/s}$

$$\Delta \dot{E}_{mech,fluid} = 3.33 \times \frac{1}{0.7068}$$

$$\Delta \dot{E}_{mech,fluid} = 4.71\,\text{hp}$$

Step 3 of 3

The mechanical efficiency of the pump becomes

$$\eta_{pump} = \frac{\Delta \dot{E}_{mech,fluid}}{\dot{W}_{pump,shaft}}$$

$$= \frac{4.71}{6}$$

$$= 0.785$$

$$\boxed{\eta_{pump} = 78.5\%}$$

Question: 3.072P

Water is pumped from a lower reservoir to a higher reservoir by a pump that provides 20 kW of shaft power. The free surface of the upper reservoir is 45 m higher than that of the lower reservoir. If the flow rate of water is measured to be 0.03 m3/s, determine mechanical power that is converted to thermal energy during this process due to frictional effects.

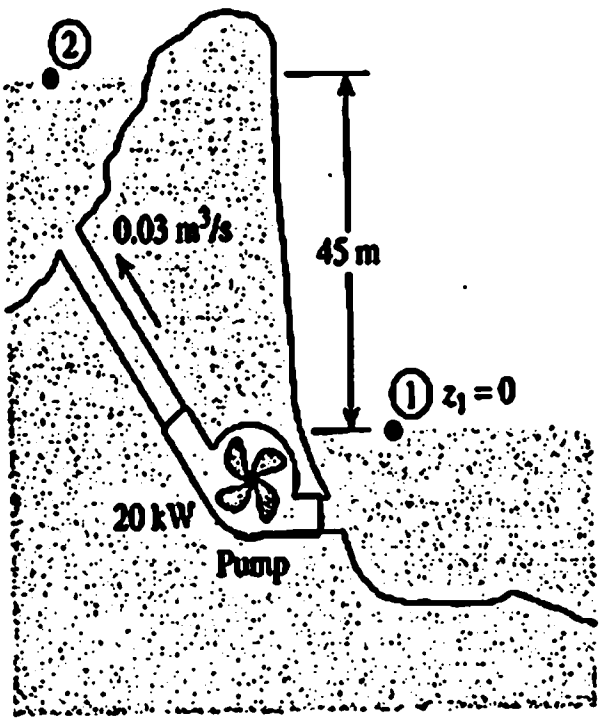

FIGURE P3–72

Step 1 of 4

Calculate the mass flow rate,

$$\dot{m} = \rho A V \text{ kg/s}$$
$$= \rho \dot{V} \text{ kg/s}$$

Here, ρ is the density of the water, and $\dot{V}$ is the volume flow rate of the water

Substitute 1000 kg/m^3 for ρ, and $0.03 \text{ m}^3/\text{s}$ for $\dot{V}$

$$\dot{m} = 1000 \times 0.03$$
$$= 30 \text{ kg/s}$$

Step 2 of 4

Calculate the change in specific potential energy,

$$\Delta pe = gh$$

Here, g is the acceleration due to gravity, and h is the height of the reservoir

Substitute 9.8 m/s^2 for g, and 45 m for h

$$\Delta pe = 9.8 \times 45$$
$$= 441 \text{ m}^2/\text{s}^2$$

Step 3 of 4

Calculate the power needed to deliver the water into the storage tank,

$$\dot{E}_{mech} = \dot{m} \Delta pe$$

Substitute the known values

$$\dot{E}_{mech} = 30 \times 441$$
$$= 13230 \text{ W}$$
$$= 13.23 \text{ kW}$$

Step 4 of 4

Calculate the mechanical power that is converted to thermal energy during this process due to friction effects,

$$\dot{W}_{fric} = \dot{W}_{shaft} - \dot{E}_{mech}$$

Here, $\dot{W}_{shaft}$ is the shaft power of the pump

Substitute 20 kW for $\dot{W}_{shaft}$, and 13.23 kW for $\dot{E}_{mech}$

$$\dot{W}_{fric} = (20 - 13.23)$$
$$= 6.77 \text{ kW}$$

Therefore, the mechanical power due to friction effect, $\dot{W}_{fric}$ is **6.77 kW**

Question: 3.073P

The water behind Hoover Dam in Nevada is 206 m higher than the Colorado River below it. At what rate must water pass through the hydraulic turbines of this dam to produce 100 MW of power if the turbines are 100 percent efficient?

FIGURE P3–73

Step 1 of 2

Given data:

The height of the dam, $h = 206$ m

The power produced by the turbines, $\dot{W} = 100$ MW

The efficiency of the turbine is considered as $\eta = 100\%$

Taking acceleration due to gravity, $g = 9.8\ m/s^2$

Step 2 of 2

The work done on the turbines is due to change in potential energy

$$\dot{W}_{mech} = \dot{m}\Delta pe$$

Δpe is the change in specific potential energy, i.e. $\Delta pe = gh$

$$= \dot{m}gh$$

The mass flow rate is determined from

$$\dot{m} = \frac{\dot{W}}{gh}$$

$$= \frac{100\times10^6}{9.8\times206} \qquad (1\ MW = 10^6\ W)$$

$$= 49{,}534\ kg/s$$

$\therefore$ The mass flow rate through the turbine, $\boxed{\dot{m} = 49{,}534\ kg/s}$

Question: 3.074P

An oil pump is drawing 35 kW of electric power while pumping oil with ρ = 860 kg/m3 at a rate of 0.1 m3/s. The inlet and outlet diameters of the pipe are 8 cm and 12 cm, respectively. If the pressure rise of oil in the pump is measured to be 400 kPa and the motor efficiency is 90 percent, determine the mechanical efficiency of the pump.

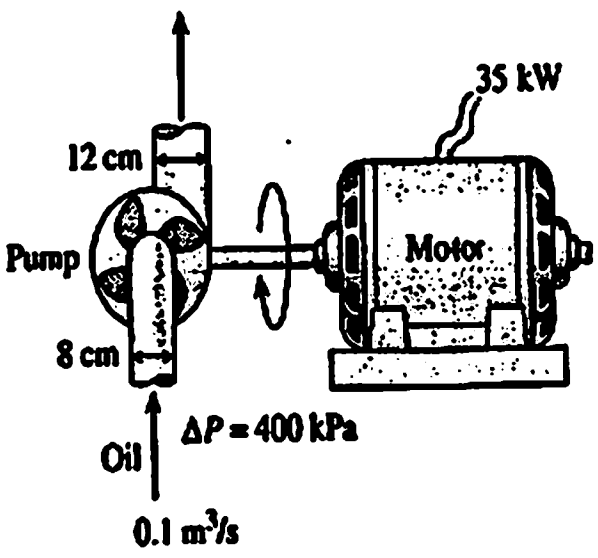

FIGURE P3–74

Step 1 of 6

Given data:

The power supplied to the motor, $\dot{W}_{elec-in} = 35$ kW

The density of oil, $\rho = 860$ kg/m^3

The volume flow rate of the pump, $\dot{V} = 0.1$ m^3/s

The inlet diameter of the pump, $d_{in} = 8$ cm

$= 0.08$ m

The outlet diameter of the pump, $d_{out} = 12$ cm

$= 0.12$ m

The pressure rise across the pump, $\Delta P = 400$ kPa

The efficiency of the motor, $\eta_{motor} = 90\%$

Step 2 of 6

The total mechanical energy by neglecting potential energy is given by

$$\dot{E}_{mech} = \dot{m}(P_2 v_2 - P_1 v_1) + \dot{m}\frac{V_2^2 - V_1^2}{2}$$

where $\Delta P = (P_2 - P_1)$,

and $\dot{m} = \frac{\dot{V}}{v}$

$\because$ volume flow rate remains constant $\dot{V} = \dot{m}v$ $\quad (\because v_1 = v_2 = v)$

$$\dot{E}_{mech} = \dot{m}v(P_2 - P_1) + \dot{m}\frac{V_2^2 - V_1^2}{2}$$

$$\dot{E}_{mech} = \dot{V}(P_2 - P_1) + (\dot{V} \times \rho)\frac{V_2^2 - V_1^2}{2} \quad \text{---------- (1)}$$

Step 3 of 6

The initial velocity $V_1 = \frac{\dot{V}}{A}$

$$= \frac{0.1}{\left(\frac{\pi \times 0.08^2}{4}\right)}$$

$= 19.89$ m/s

Similarly final velocity

$$V_2 = \frac{\dot{V}}{A_2}$$

$$= \frac{0.1}{\left(\frac{\pi}{4} \times 0.12^2\right)}$$

$= 8.84$ m/s

Step 4 of 6

By substituting values in the equation (1) we get

Therefore the power delivered by pump is

$$\dot{E}_{mech} = (0.1) \times (400) + (0.1) \times 860\left(\frac{8.84^2 - 19.89^2}{2}\right)\left(\frac{1}{1000}\right) \text{kW}$$

$= 26.3$ kW

Step 5 of 6

The shaft power of the pump is

$$\dot{W}_{shaft} = \eta_{motor}\dot{W}_{elec-in}$$

$= 0.9(35)$

$= 31.5$ kW

Step 6 of 6

Therefore the mechanical efficiency of the pump is expressed as

$$\eta_{pump} = \frac{\dot{E}_{mech}}{\dot{W}_{shaft}}$$

$$= \frac{26.3}{31.5}$$

$= 0.8349$

$\therefore$ The mechanical efficiency of the pump, $\boxed{\eta_{pump} = 83.49\%}$

Question: 3.075P

An 80-percent efficient pump with a power input of 20 hp is pumping water from a lake to a nearby pool at a rate of 1.5 ft3/s through a constant-diameter pipe. The free surface of the pool is 80 ft above that of the lake. Determine the mechanical power used to overcome frictional effects in piping.

Step 1 of 4

Given

Power input of the pump $\dot{W}_{pump} = 20\,\text{hp}$

Efficiency of the pump $\eta = 80\%$

Flow rate of water $Q = 1.5\,\text{ft}^3/\text{s}$

Height of the pool from the lake $z = 80\,\text{ft}$

Step 2 of 4

Specific weight of water

$\rho = 62.4\,\text{lbm/ft}^3$

The useful mechanical pumping power delivered to water is

$$\dot{W}_{pump,u} = \eta_{pump}\dot{W}_{pump}$$
$$= (0.80)(20)$$
$$\dot{W}_{pump,u} = 16\,\text{hp}$$

Step 3 of 4

The elevation of water and thus its potential energy changes during pumping, but it experiences no changes in its velocity and pressure. Therefore, the change in the total mechanical energy of water is equal to the change in its potential energy

$$\Delta\dot{E}_{mech} = \dot{m}\Delta pe$$
$$= \dot{m}g\Delta z$$
$$\Delta\dot{E}_{mech} = \rho Qg\Delta z$$

Substituting the known values rate of change of mechanical energy of water becomes

$$\Delta\dot{E}_{mech} = \left(62.4\,\frac{\text{lbm}}{\text{ft}^3}\right)\left(1.5\,\frac{\text{ft}^3}{\text{s}}\right)\left(32.2\,\frac{\text{ft}}{\text{s}^2}\right)(80\,\text{ft})\left(\frac{1\,\text{lbf}}{32.2\,\text{lbm}\times\text{ft/s}^2}\right)\left(\frac{1\,\text{hp}}{550\,\text{lbf}\times\text{ft/s}}\right)$$

$$\Delta\dot{E}_{mech} = 13.614\,\text{hp}$$

Step 4 of 4

Then the mechanical power lost in piping because of frictional effects becomes

$$\dot{W}_{fric} = \dot{W}_{pump,u} - \Delta\dot{E}_{mech}$$
$$= 16 - 13.614$$
$$\boxed{\dot{W}_{fric} = 2.386\,\text{hp}}$$

Question: 3.076P

A wind turbine is rotating at 15 rpm under steady winds flowing through the turbine at a rate of 42,000 kg/s. The tip velocity of the turbine blade is measured to be 250 km/h. If 180 kW power is produced by the turbine, determine (*a*) the average velocity of the air and (*b*) the conversion efficiency of the turbine. Take the density of air to be 1.31 kg/m3.

Step 1 of 5

Given data:

The rpm of the wind turbine is $(N) = 15$ rpm

The mass flow rate trough the turbine $(\dot{m}) = 42,000$ kg/s

The tip velocity of the blade $(V_{tip}) = 250$ km/h

The power output from the turbine $(\dot{W}_{out}) = 180$ kW

Taking the density of air $(\rho) = 1.31\ \text{kg/m}^3$

Step 2 of 5

(a) The average velocity of the air

We know that mass flow rate $\dot{m} = \rho A V$ kg/s

The velocity is expressed as $V_{tip} = \dfrac{\pi dN}{60}$ m/s

The diameter of the turbine can be calculated as

$$d = \frac{V_{tip} \times 60}{\pi N}\ \text{m}$$

$$= \frac{(250 \times \frac{5}{18})(60)}{\pi(15)} \qquad \left(\because 1\ \text{km/h} = \frac{5}{18}\ \text{m/s}\right)$$

$$= 88.42\ \text{m}$$

Step 3 of 5

The average velocity of the wind turbine can be determined as

$$V = \frac{\dot{m}}{\rho A}\ \text{m/s}$$

Where $A = \dfrac{\pi}{4} \times d^2\ \text{m}^2$

$$= \frac{42,000}{(1.31)(\frac{\pi}{4} \times 88.42^2)}$$

$$= 5.22\ \text{m/s}$$

∴ The average velocity of the wind turbine, $\boxed{V = 5.22\ \text{m/s}}$

Step 4 of 5

(b) The conversion efficiency of turbine

Here efficiency is defined as $\eta_{turbine} = \dfrac{\dot{W}_{out}}{\dot{W}_{ke}}$

The kinetic energy of the turbine is expressed as

$$\dot{W}_{ke} = \frac{1}{2}\dot{m}V^2$$

$$= \frac{1}{2} \times 42,000 \times (5.22)^2$$

$$= \frac{572216}{1000}\ \text{kW}$$

$$= 572.2\ \text{kW}$$

Step 5 of 5

Therefore efficiency $\eta_{turbine} = \dfrac{\dot{W}_{out}}{\dot{W}_{ke}}$

$$= \frac{180}{572.2}$$

$$= 0.3145$$

∴ The efficiency of the turbine, $\boxed{\eta_{turbine} = 31.45\%}$

Question:

3.077P

Consider a classroom for 55 students and one instructor, each generating heat at a rate of 100 W. Lighting is provided by 18 fluorescent lightbulbs, 40 W each, and the ballasts consume an additional 10 percent. Determine the rate of internal heat generation in this classroom when it is fully occupied.

Step 1 of 5

Given data:
The total number of people in the classroom = 56
Heat generated by each person, $Q = 100$ W
There are 18 fluorescent light bulbs of 40 W each
The ballasts consume 10% of the heat generated by bulbs

Step 2 of 5

The rate of internal heat generation in the classroom when it is fully occupied is the sum of heat generated due to light bulbs, ballasts and persons is given by

$\dot{Q}$ $\dot{Q}$ $\dot{Q}$ W

Question:

Consider a classroom for 55 students and one instructor, each generating heat at a rate of 100 W. Lighting is provided by 18 fluorescent lightbulbs, 40 W each, and the ballasts consume an additional 10 percent. Determine the rate of internal heat generation in this classroom when it is fully occupied.

Step 1 of 5

Given data:
The total number of people in the classroom = 56
Heat generated by each person, $Q = 100$ W
There are 18 fluorescent light bulbs of 40 W each
The ballasts consume 10% of the heat generated by bulbs

Step 2 of 5

The rate of internal heat generation in the classroom when it is fully occupied is the sum of heat generated due to light bulbs, ballasts and persons is given by

$\dot{Q}$ $\dot{Q}$ $\dot{Q}$ W

$$\dot{Q}_{total} = \dot{Q}_{people} + \dot{Q}_{lights}$$
$$= 5600 + 720 + 72$$
$$= 6392 \text{ W}$$

∴ Total heat generated, $\boxed{\dot{Q}_{total} = 6392 \text{ W}}$

Question: 3.078P

Consider a homeowner who is replacing his 25-year-old natural gas furnace that has an efficiency of 55 percent. The homeowner is considering a conventional furnace that has an efficiency of 82 percent and costs $1600 and a high-efficiency furnace that has an efficiency of 95 percent and costs $2700. The homeowner would like to buy the high-efficiency furnace if the savings from the natural gas pay for the additional cost in less than 8 years. If the homeowner presently pays $1200 a year for heating, determine if he should buy the conventional or high-efficiency model.

Step 1 of 4

Given data:

The old heater furnace efficiency, $\eta_{old\ furnace} = 55\%$

The efficiency of a conventional furnace, $\eta_c = 82\%$

The efficiency of a high efficient furnace, $\eta_h = 95\%$

The cost of a conventional furnace, $1600

The cost of a high efficient furnace, $2700

Step 2 of 4

The home owner pays $1200 a year for heating the furnace. The old heater has an efficiency of 55%

So the useful amount utilized for heating is $= 0.55 \times \$1200$

$= \$660/year$

The cost utilized by conventional furnace is $\dfrac{\$660/year}{0.82}$

$= \$805/year$

The cost utilized by high efficient furnace is $= \dfrac{\$660/year}{0.95}$

$= \$695/year$

Step 3 of 4

The excess initial cost of the efficient heater is calculated as

$= 2700 - 1600$

$= \$1100$

The annual saving cost with efficient heating is calculated as

$= 805 - 695$

$= \$110$

Step 4 of 4

Thus the simple pay back period is given by

$$\text{Simple pay back period} = \frac{\text{Excess intial cost}}{\text{Annual cost savings}}$$

$$= \frac{\$1100}{\$110}$$

$$= 10 \text{ years}$$

From the above we know that the high efficient furnace will cost high heating than the conventional type. So in this case purchase less efficient and cheaper heater.

Question: 3.079P

The energy contents, unit costs, and typical conversion efficiencies of various energy sources for use in water heaters are given as follows: 1025 Btu/ft3, $0.012/ft3 and 55 percent for natural gas; 138,700 Btu/gal, $ 1.15/gal, and 55 percent for heating oil; and 1 kWh/kWh, $0.084/kWh, and 90 percent for electric heaters, respectively. Determine the lowest-cost energy source for water heaters.

Step 1 of 5

Given data:

Natural gas heaters:

Energy content, $E = 1025\,\text{Btu/ft}^3$

Unit cost $= \$0.012/\text{ft}^3$

Efficiency, $\eta = 55\%$

Oil heating:

Energy content, $E = 138700\,\text{Btu/gal}$

Unit cost $= \$1.15/\text{gal}$

Efficiency, $\eta = 55\%$

Electric heaters:

Energy content, $E = 1\,\text{kWh/kWh}$

Unit cost $= \$0.084/\text{kWh}$

Efficiency, $\eta = 90\%$

Step 2 of 5

The unit cost of utilized energy is inversely proportional to the efficiency, and is determined from

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

Calculating the various energy sources used in water heaters.

Step 3 of 5

Natural gas heaters:

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

$$\text{Cost of utilized energy} = \frac{\$0.012}{0.55} \times \frac{1}{1025} \qquad (\because 1\,\text{kWh} = 3410\,\text{Btu})$$

$$\text{Cost of utilized energy} = \$2.12 \times 10^{-5}\ /\text{Btu}$$

Step 4 of 5

Oil heating heaters:

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

$$\text{Cost of utilized energy} = \frac{\$1.25}{0.55} \times \frac{1}{138,700}$$

$$\text{Cost of utilized energy} = \$163 \times 10^{-5}\ /\text{Btu}$$

Step 5 of 5

Electrical heaters:

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

$$\text{Cost of utilized energy} = \frac{\$0.084}{0.90} \times \frac{1}{3410}$$

$$\text{Cost of utilized energy} = \$2.73 \times 10^{-5}\ /\text{Btu}$$

So from the above 3 cases the lowest cost energy source for water heating is by using heating oil. With a lowest cost of $\boxed{\$1.63 \times 10^{-5}\ /\text{Btu}}$

Question: 3.080P

A homeowner is considering these heating systems for heating his house: Electric resistance heating with \$0.09/kWh and 1 kWh = 3600 kJ, gas heating with \$1.24/therm and 1 therm = 105,500 kJ, and oil heating with \$1.25/gal and 1 gal of oil = 138,500 kJ. Assuming efficiencies of 100 percent for the electric furnace and 87 percent for the gas and oil furnaces, determine the heating system with the lowest energy cost.

Step 1 of 5

Given data:
Electric heaters:
Unit cost = \$0.09/kWh
Where 1kWh = 3600kJ
Efficiency, $\eta = 100\%$
Gas heaters:
Unit cost = \$1.24/therm
Where 1therm = 105,500kJ
Efficiency, $\eta = 87\%$
Oil heating:
Unit cost = \$1.25/gal
Where 1gal = 138,500kJ
Efficiency, $\eta = 87\%$

Step 2 of 5

The unit cost of utilized energy is inversely proportional to the efficiency, and is determined from

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

Calculating the various energy sources used for heating a house

Step 3 of 5

Electrical heating:

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

$$\text{Cost of utilized energy} = \frac{\$0.09}{1} \times \frac{1}{3600}$$

$$\text{Cost of utilized energy} = \$2.5 \times 10^{-5}\ /\text{kJ}$$

Step 4 of 5

Gas heating:

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{}$$

Unit cost = \$1.25/gal
Where 1gal = 138,500kJ
Efficiency, $\eta = 87\%$

Step 2 of 5

The unit cost of utilized energy is inversely proportional to the efficiency, and is determined from

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

Calculating the various energy sources used for heating a house

Step 3 of 5

Electrical heating:

$$\text{Cost of utilized energy} = \frac{\text{Cost of energy input}}{\text{Efficiency}}$$

$$\text{Cost of utilized energy} = \frac{\$0.09}{1} \times \frac{1}{3600}$$

Question: 3.081P

A typical household pays about $1200 a year on energy bills, and the U.S. Department of Energy estimates that 46 percent of this energy is used for heating and cooling, 15 percent for heating water, 15 percent for refrigerating and freezing, and the remaining 24 percent for lighting, cooking, and running other appliances. The heating and cooling costs of a poorly insulated house can be reduced by up to 30 percent by adding adequate insulation. If the cost of insulation is $200, determine how long it will take for the insulation to pay for itself from the energy it saves.

Step 1 of 3

Given data:

Nitrogen oxides released by the car per year, $(NO_x)_{car} = 11\ \text{kg}$

Nitrogen oxides released from natural gas, $(NO_x)_{gas} = 4.3\ \text{g/therm}$

Nitrogen oxides released for power generation, $(NO_x)_{power} = 7.1\ \text{g/kWh}$

Power consumption of the house per year, $E_{power} = 9000\ \text{kWh}$

Natural gas consumption of the house per year, $E_{gas} = 1200\ \text{therms}$

Step 2 of 3

The Nitrogen oxides released by the two cars per year,

$$\begin{aligned} 2(NO_x)_{car} &= 2\times 11 \\ &= 22\ \text{kg} \end{aligned}$$

The Nitrogen oxides released due to power consumption per year,

$$\begin{aligned} E_{gas}\times(NO_x)_{gas} &= (1200\ \text{therms})\times(4.3\ \text{g/therm}) \\ &= 5160\ \text{g} \\ &= 5.16\ \text{kg} \end{aligned}$$

The Nitrogen oxides released due to natural gas consumption per year,

$$\begin{aligned} E_{power}\times(NO_x)_{power} &= (9000\ \text{kWh})\times(7.1\ \text{g/kWh}) \\ &= 63900\ \text{g} \\ &= 63.9\ \text{kg} \end{aligned}$$

Step 3 of 3

The total amount of nitrogen oxides released per year by the house is,

$$\begin{aligned} (NO_x)_{house} &= \left[2(NO_x)_{car}\right]+\left[E_{gas}\times(NO_x)_{gas}\right]+\left[E_{power}\times(NO_x)_{power}\right] \\ &= 22+5.16+63.9 \\ &= 91.06\ \text{kg} \end{aligned}$$

Hence the amount of nitrogen oxides released per year, $\boxed{(NO_x)_{house} = 91.06\ \text{kg}}$

Question: 3.082P

The U.S. Department of Energy estimates that up to 10 percent of the energy use of a house can be saved by caulking and weatherstripping doors and windows to reduce air leaks at a cost of about $60 for materials for an average home with 12 windows and 2 doors. Caulking and weather-stripping every gas-heated home properly would save enough energy to heat about 4 million homes. The savings can be increased by installing storm windows. Determine how long it will take for the caulking and weatherstripping to pay for itself from the energy they save for a house whose annual energy use is $1500.

Step 1 of 2

Given
Percentage of energy saved by caulking and weather stripping doors and windows is 10%
Cost of annual energy used is $1500
Money saved by air leaks at a cost of $60

Step 2 of 2

The amount of money that would be saved per year is determined directly from
Money saved = ($1500/year)(0.10)
Money saved= $150/yr
Then the simple payback period becomes

$$\text{Payback period} = \frac{\text{Cost}}{\text{Money saved}}$$

$$\text{Payback period} = \frac{\$60}{\$150/\text{yr}}$$

$$\boxed{\text{Payback period} = 0.4\,\text{yr}}$$

Therefore, the proposed measure will pay for it less than half a year.

Question: 3.083P

The energy stored in the spring of a railroad car is 5000 lbf·ft. What is this energy in (*a*) lbm, ft, and s units; (*b*) lbf and yd units; and (*c*) lbm, mile, and hour units?

Step 1 of 3

Given

Energy stored in the spring is $W = 5000\,\text{lbf-ft}$

Using appropriate conversion factors, we obtain

(a) $$W = (5000\,\text{lbf.ft})\left(\frac{32.174\,\text{lbm.ft/s}^2}{1\,\text{lbf}}\right)$$

$$\boxed{W = 160{,}870\,\text{lbm.ft}^2/\text{s}^2}$$

Step 2 of 3

(b) $$W = (5000\,\text{lbf}\cdot\text{ft})\left(\frac{0.33303\,\text{yd}}{1\,\text{ft}}\right)$$

$$\boxed{W = 1665.15\,\text{lbm}\cdot\text{yd}}$$

Step 3 of 3

(c) $$W = (5000\,\text{lbf.ft})\left(\frac{32.174\,\text{lbm.ft/s}^2}{1\,\text{lbf}}\right)\left(\frac{1\,\text{mile}}{5280\,\text{ft}}\right)^2\left(\frac{3600\,\text{s}}{1\,\text{h}}\right)^2$$

$$\boxed{W = 74784.607\,\text{mile}^2/\text{h}^2}$$

Question: 3.084P

The force required to expand the gas in a gas spring a distance x is given by Constant

$$F = \frac{\text{Constant}}{x^k}$$

where the constant is determined by the geometry of this device and k is determined by the gas used in the device. One such device has a constant of 200 lbf·in1.4 and k =1.4. Determine the work, in Btu, required to compress this device from 1 in to 4 in.

Step 1 of 2

Given

Force required in expanding the gas in a gas spring, by a distance x is

$$F = \frac{\text{constant}}{x^k}$$

$\text{Constant} = 200 \text{lbf-in}^{1.4}$

Isentropic index $k = 1.4$

Compress the device from 1in to 4in

Step 2 of 2

The work integral relation

$$W = \int_1^2 F ds$$

$$= \int_1^2 \frac{\text{Constant}}{x^k} dx$$

$$= \frac{\text{Constant}}{1-k}\left(x_2^{1-k} - x_1^{1-k}\right)$$

Where $x_2 = 4\text{in}$ and $x_1 = 1\text{in}$

Then

$$W = \frac{200}{1-1.4}\left[(4)^{-0.4} - (1)^{-0.4}\right]$$

$$W = 212.825 \text{lbf-in}$$

$$W = 212.825 \times \frac{1}{12}$$

$$W = 17.735 \text{lbf-ft}$$

$$W = 17.735 \times \frac{1}{778}$$

$$\boxed{W = 0.02279 \text{Btu}}$$

Question: 3.085P

A man weighing 180 lbf pushes a block weighing 100 lbf along a horizontal plane. The dynamic coefficient of friction between the block and plane is 0.2. Assuming that the block is moving at constant speed, calculate the work required to move the block a distance of 100 ft considering (*a*) the man and (*b*) the block as the system. Express your answers in both lbf·ft and Btu.

Step 1 of 2

a)

Consider man as the system.

Find the work required to move the block by using the formula.

$$W = \mu F d$$
$$= \mu (W_B + W_m) d$$

Here, μ is the coefficient of the dynamic friction, W_B is weight of the block, d is the distance travelled by the block, and W_m is the weight of the man.

Substitute 0.2 for μ, 100 lbf for W_B, 180 lbf for W_m, and 100 ft for d.

$$W = 0.2(180+100)(100)$$
$$= 5600\,\text{lbf}\cdot\text{ft}$$
$$= (5600\,\text{lbf}\cdot\text{ft})\left(\frac{1}{778}\frac{\text{Btu}}{\text{lbf}\cdot\text{ft}}\right)$$
$$= 7.198\,\text{Btu}$$

Therefore, the work required in $\text{lbf}\cdot\text{ft}$ is $\boxed{5600\,\text{lbf}\cdot\text{ft}}$.

Therefore, the work required in Btu is $\boxed{7.198\,\text{Btu}}$.

Step 2 of 2

b)

Consider block as the system.

Find the work required to move the block by using the formula.

$$W = \mu F d$$
$$= \mu (W_B) d$$

Substitute 0.2 for μ, 100 lbf for W_B and 100 ft for d.

$$W = 0.2(100)(100)$$
$$= 2000\,\text{lbf}\cdot\text{ft}$$
$$= (2000\,\text{lbf}\cdot\text{ft})\left(\frac{1}{778}\frac{\text{Btu}}{\text{lbf}\cdot\text{ft}}\right)$$
$$= 2.57\,\text{Btu}$$

Therefore, the work required in $\text{lbf}\cdot\text{ft}$ is $\boxed{2000\,\text{lbf}\cdot\text{ft}}$.

Therefore, the work required in Btu is $\boxed{2.57\,\text{Btu}}$.

Question: 3.086P

Water is pumped from a 200-ft-deep well into a 100-ft-high storage tank. Determine the power, in kW, that would be required to pump 200 gallons per minute.

Step 1 of 2

Given data:

The difference between the heights trough which water should be pumped is

$$\Delta h = 200 - (-100)$$
$$= 300\,\text{ft}$$

Take density of water, $\rho = 62.4\,\text{lbm/ft}^3$

Acceleration due to gravity, $g = 32.174\,\text{ft/s}^2$

Discharge through the pump, $\dot{V} = 200\,\text{gal/min}$
$$= 0.4456\,\text{ft}^3/\text{s}$$

Step 2 of 2

The power required to pump the water trough a given height is expressed as

$$\dot{P} = \dot{m}g\Delta h$$
$$= \rho \dot{V} g \Delta h$$
$$= (62.4)(0.4456)(32.174)(300)\,\frac{\text{lbm-ft}^2}{s^3}$$
$$= \left(268392.78\,\frac{\text{lbm}\cdot\text{ft}^2}{s^3}\right)\left(\frac{1}{32.174}\,\frac{\text{lbf}}{\text{lbm}\cdot\text{ft/s}^2}\right)$$
$$= 8341.9\,\frac{\text{lbf-ft}}{s}$$
$$= \frac{8341.9}{737.56}\,\text{kW}$$
$$= 11.3\,\text{kW}$$

∴ The power required, $\boxed{\dot{P} = 11.3\,\text{kW}}$

Question: 3.087P

A grist mill of the 1800s employed a water wheel that was 14 m high; 320 liters per minute of water flowed on to the wheel near the top. How much power, in kW, could this water wheel have produced?

Step 1 of 3

Given

Height of water wheel $z = 14\,\text{m}$

$$\text{Flow rate of water} = Q = \frac{320\,\text{litres}}{\text{min}}$$

$$Q = \frac{320\times10^{-3}}{60}\,\text{m}^3/\text{s}$$

$$Q = 0.00533\,\text{m}^3/\text{s}$$

Step 2 of 3

Mass flow rate

$$\dot{m} = \rho \times Q$$

Where ρ is density of water

$$\dot{m} = 1000\times0.00533$$

$$\dot{m} = 5.333\,\text{kg/s}$$

Step 3 of 3

Power produced by water wheel

$$\dot{W} = \dot{m}gz$$

$$= 5.333\times9.81\times14$$

$$\dot{W} = 732.48\,\text{W}$$

$$\boxed{\dot{W} = 0.732\,\text{kW}}$$

Question: 3.088P

Windmills slow the air and cause it to fill a larger channel as it passes through the blades. Consider a circular windmill with a 7-m-diameter rotor in a 10 m/s wind on a day when the atmospheric pressure is 100 kPa and the temperature is 20°C. The wind speed behind the windmill is measured at 9 m/s. Determine the diameter of the wind channel downstream from the rotor and the power produced by this windmill, presuming that the air is incompressible.

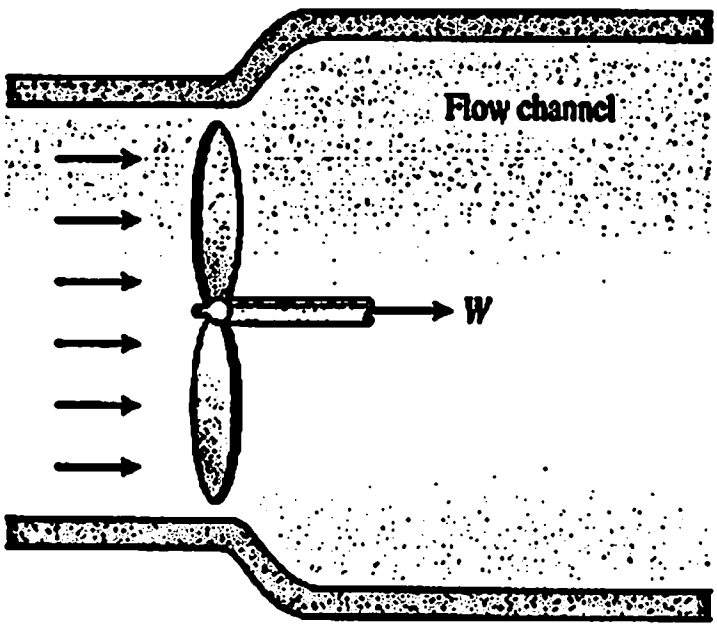

FIGURE P3–88

Step 1 of 4

Given data:

The atmospheric pressure is $P = 100$ kPa

The velocity of the wind at this pressure is $V_1 = 10$ m/s

The temperature is $T = 20°C$

The velocity behind the wind mill, $V_2 = 9$ m/s

The diameter of the rotor, $(d_1) = 7$ m

Step 2 of 4

The power required to drive the car is given by

$$\dot{W} = \dot{m}\left(\frac{V_1^2 - V_2^2}{2}\right)$$

Where $\dot{m}$ the mass flow rate of the air flow in the channel is expressed as

From the continuity equation, $\dot{m} = \rho AV$ kg/s

From the ideal gas equation $Pv = RT$

Density, $\rho = \dfrac{P}{RT} \quad \left(\because \rho = \dfrac{1}{v}\right)$

where $R = 0.287$ kJ/kg·K

$P = 100$ kPa

$T = 20°C$

$= 20 + 273$

$= 293$ K

$$\therefore \rho = \frac{100}{(0.287)(293)}$$

$\rho = 1.189$ kg/m^3

Step 3 of 4

Mass flow rate

$$\dot{m} = 1.189 \times \left(\frac{\pi}{4} \times 7^2\right) \times 10$$

$\dot{m} = 457.6$ kg/s

Therefore the power required is

$$\dot{W} = 457.6 \times \left(\frac{10^2 - 9^2}{2}\right)$$

$$= \frac{4347.2}{1000} \text{ kW}$$

$= 4.347$ kW

∴ The power required, $\boxed{\dot{W} = 4.347 \text{kW}}$

Step 4 of 4

From the continuity equation $\dot{m} = \rho A_2 V_2$

Since $\dot{m}$ remains constant in the channel

$$A_2 = \frac{\dot{m}}{\rho V_2}$$

$$\frac{\pi}{4} d_2^2 = \frac{457.6}{1.189 \times 9}$$

$d_2^2 = 54.44$

$d_2 = 7.37$m

∴ The diameter of the wind channel downstream, $\boxed{d_2 = 7.37\text{m}}$

Question: 3.089P

In a hydroelectric power plant, 65 m3/s of water flows from an elevation of 90 m to a turbine, where electric power is generated. The overall efficiency of the turbine– generator is 84 percent. Disregarding frictional losses in piping, estimate the electric power output of this plant.

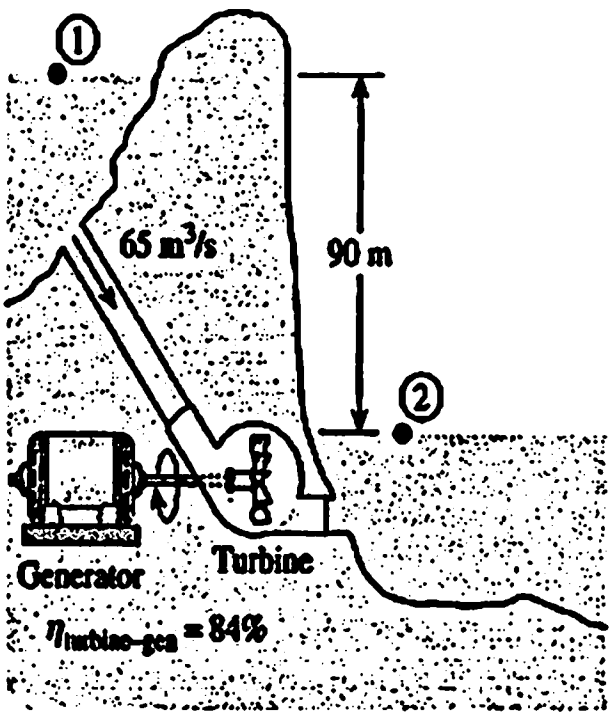

FIGURE P3–89

Step 1 of 6

Given

Flow rate of water $Q = 65\,\mathrm{m^3/s}$

Elevation $z = 90\mathrm{m}$

Overall efficiency of the turbine generator is $\eta = 84\%$

Step 2 of 6

Step 3 of 6

Density of water, $\rho = 1000\ \mathrm{kg/m^3}$

Mechanical energy is nothing but potential energy

$$e_{mech} = pe = gz$$

$$= (9.81\mathrm{m/s^2})(90\mathrm{m})\left(\frac{1\mathrm{kJ/kg}}{1000\mathrm{m^2/s^2}}\right)$$

$$e_{mech} = 0.8829\mathrm{kJ/kg}$$

Step 4 of 6

The mass flow rate is

$$\dot{m} = \rho Q$$

$$= (1000)\times(65)$$

$$\dot{m} = 65000\mathrm{kg/s}$$

Step 5 of 6

The maximum electric power generation becomes

$$\dot{W}_{max} = \dot{E}_{mech} = \dot{m} e_{mech}$$

$$= (65000\mathrm{kg/s})(0.8829\mathrm{kJ/kg})\left(\frac{1\mathrm{MW}}{1000\mathrm{kJ/s}}\right)$$

$$\dot{W}_{max} = 57.39\mathrm{MW}$$

Step 6 of 6

Actual electric power generation

$$\dot{W}_{electric} = \eta_{overall}\dot{W}_{max}$$

$$= 0.84(57.39)$$

$$\boxed{\dot{W}_{electric} = 48.2\mathrm{MW}}$$

Question: 3.090P

The demand for electric power is usually much higher during the day than it is at night, and utility companies often sell power at night at much lower prices to encourage consumers to use the available power generation capacity and to avoid building new expensive power plants that will be used only a short time during peak periods. Utilities are also willing to purchase power produced during the day from private parties at a high price.

Suppose a utility company is selling electric power for $0.03/kWh at night and is willing to pay $0.08/kWh for power produced during the day. To take advantage of this opportunity, an entrepreneur is considering building a large reservoir 40 m above the lake level, pumping water from the lake to the reservoir at night using cheap power, and letting the water flow from the reservoir back to the lake during the day, producing power as the pump-motor operates as a turbine-generator during reverse flow. Preliminary analysis shows that a water flow rate of 2 m3/s can be used in either direction. The combined pump-motor and turbine-generator efficiencies are expected to be 75 percent each. Disregarding the frictional losses in piping and assuming the system operates for 10 h each in the pump and turbine modes during a typical day, determine the potential revenue this pump-turbine system can generate per year.

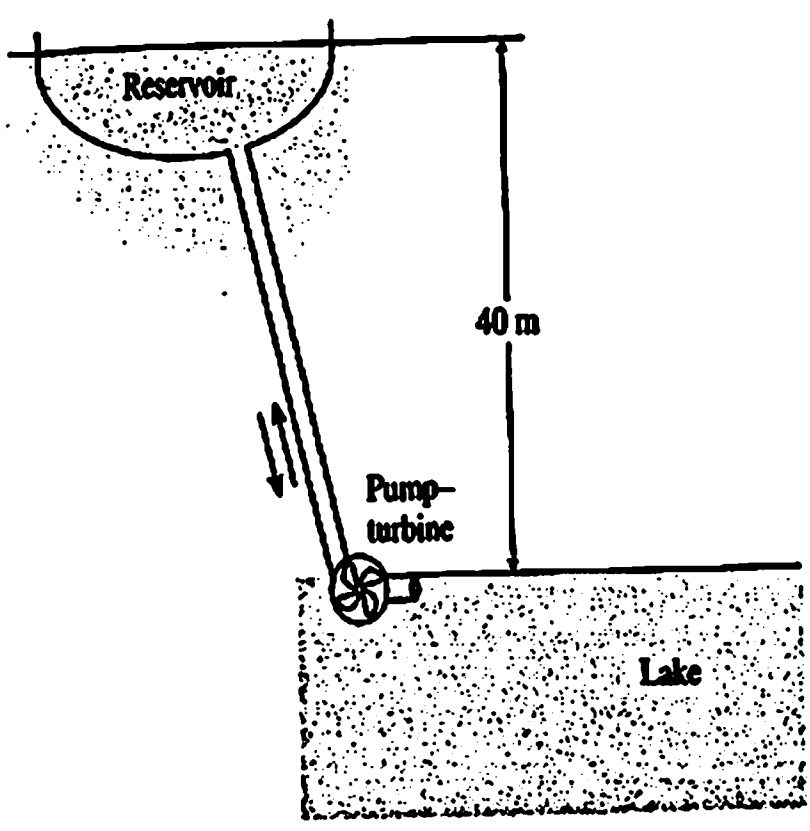

FIGURE P3–90

Step 1 of 6

Given data:

The height of the reservoir, $h = 40$ m

The volume flow rate of the water, $\dot{V} = 2\ m^3/s$

The overall turbine-generator efficiency and pump- motor efficiency is $\eta = 75\%$

Acceleration due to gravity, $(g) = 9.81\ m/s^2$

Step 2 of 6

The power generated by the operation of turbine or a pump is expressed as

$$\dot{E}_{mech} = \dot{m}\Delta pe$$

Where $\dot{m}$ mass flow rate

$$\dot{m} = \rho A V$$

$$\dot{m} = \rho \dot{V}$$

Δpe is the change in specific potential energy

$\Delta pe = gh$ J/kg

Step 3 of 6

Therefore power generated

$$\dot{E}_{mech} = \rho \dot{V} g h$$
$$= (1000)(2)(9.81)(40)\ J/s$$
$$= 784800\ J/s\ (or)\ W$$
$$= 784.8\ kW \qquad (10^3\ J/s = 1\ kW)$$

Step 4 of 6

The actual turbine work will be

$$\dot{W}_{turbine} = \eta_{gr-gn}\dot{E}_{mech}$$
$$= (0.75)(784.8)$$
$$= 588.6\ kW$$

Step 5 of 6

The minimum pump work is

$$\dot{W}_{pump} = \frac{\dot{E}_{mech}}{\eta_{pump-motor}}$$
$$= \frac{784.8}{0.75}$$
$$= 1046.4\ kW$$

Step 6 of 6

The cost to run a pump for 10hrs in a year is

Cost = (1046.4)(365×10)($0.03)/year

Cost = $114,580.8/year

The revenue developed by the turbine is

Revenue = (588.6)(365×10)($0.08)/year

Revenue = $171,871.2/year

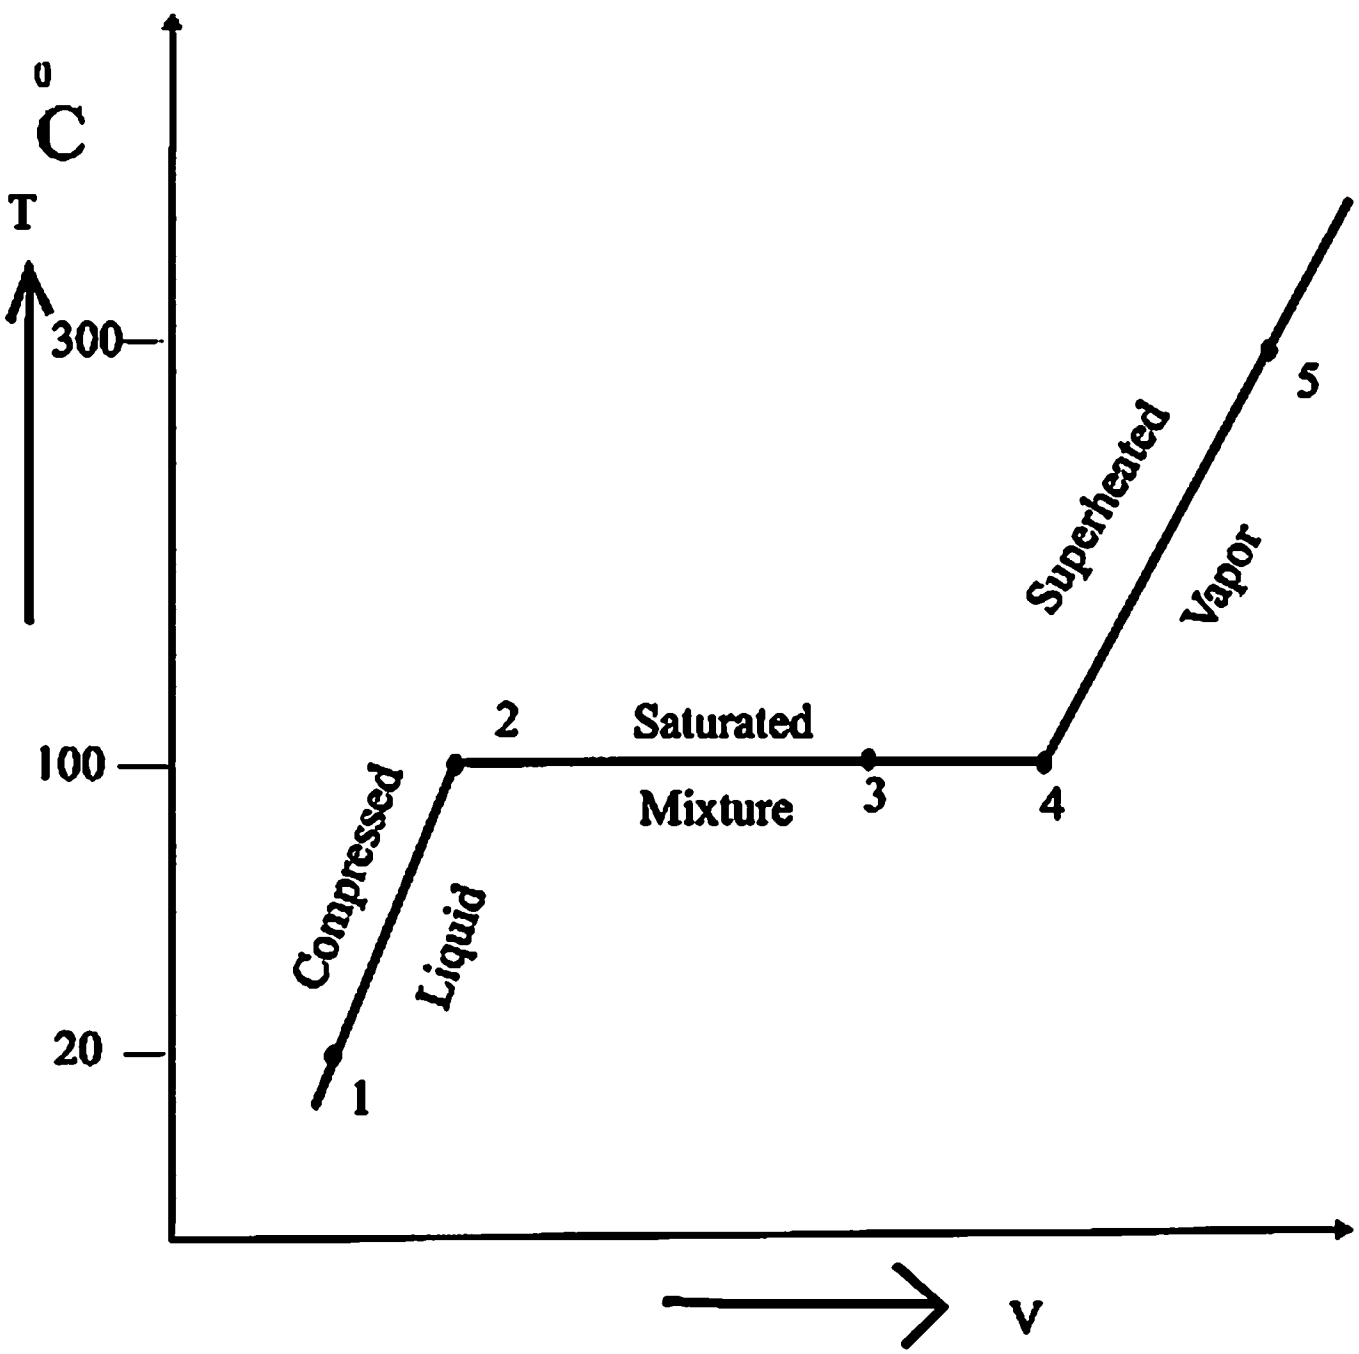
Net profit generated by running pump-turbine is

Net profit = $171,871.2 − $114,580.8

Profit = $57290.4/year

CHAPTER 04

SOLUTIONS



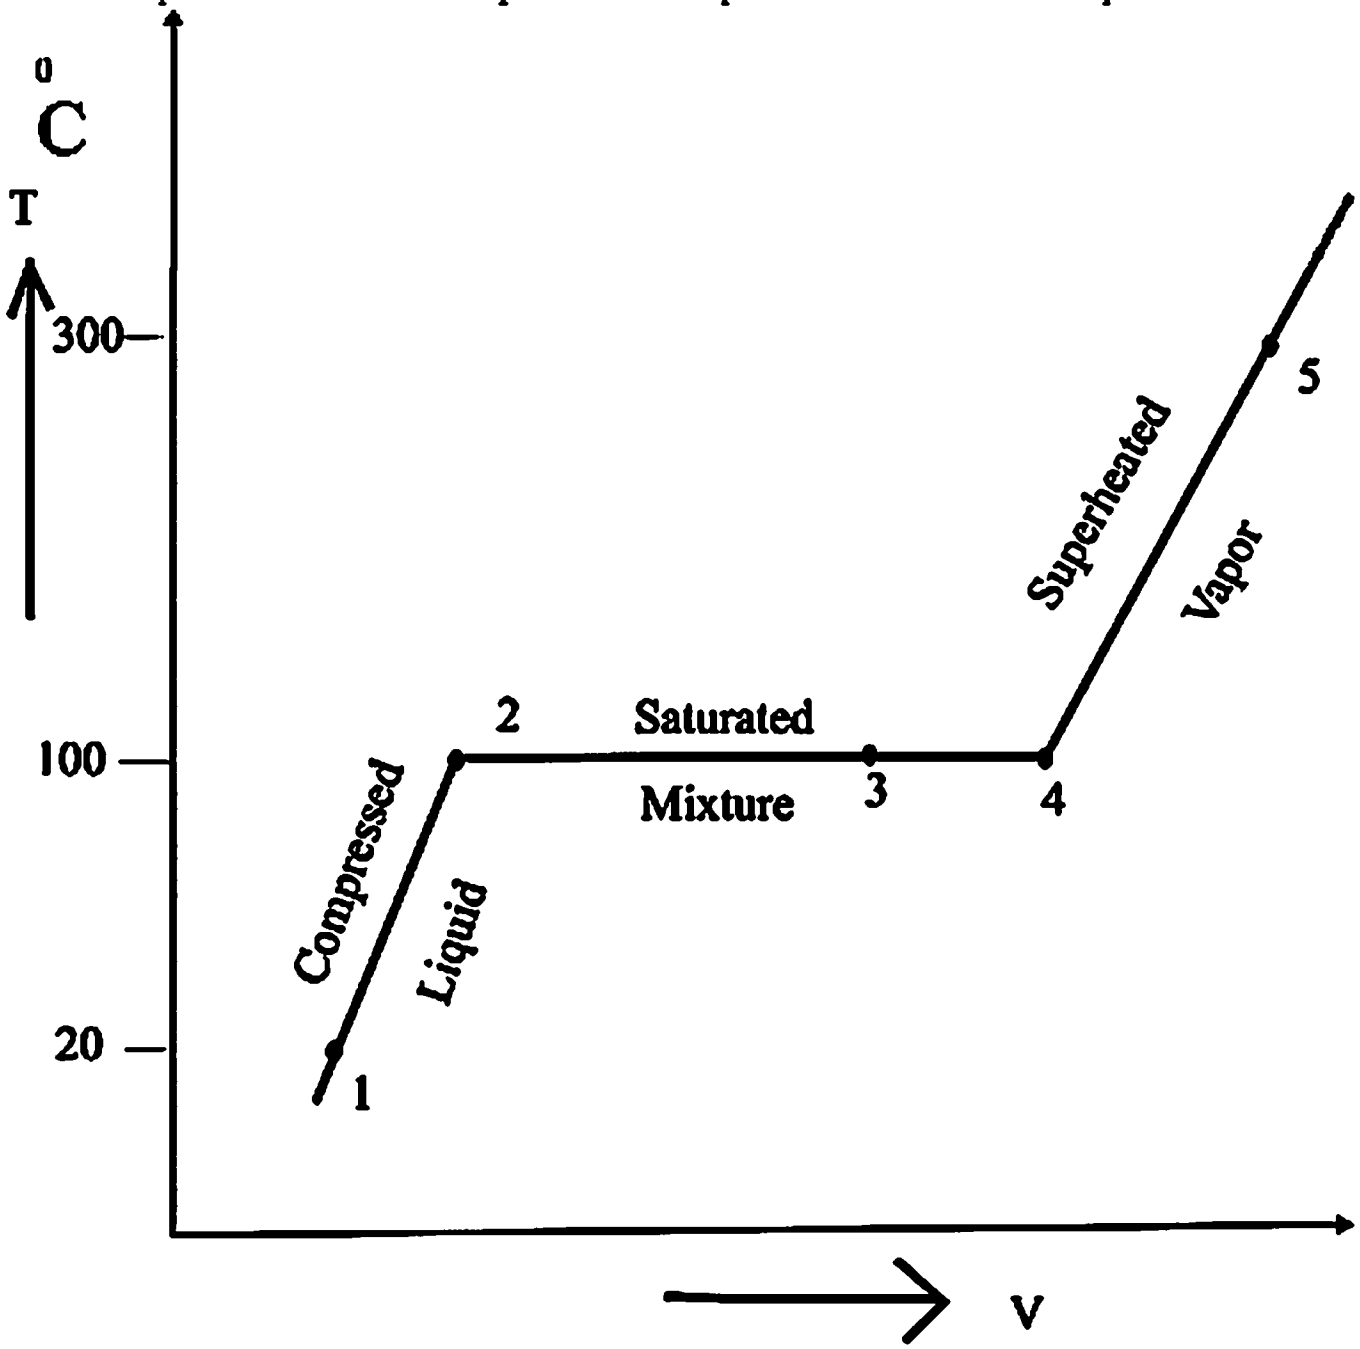
Question: 4.001P

What is the difference between saturated liquid and compressed liquid?

Step 1 of 1

A liquid that is about to vaporize is called saturated liquid. And a liquid that is not about to vaporize is called compressed liquid or subcooled liquid. A small amount of heat addition at the saturated condition will cause the liquid to vaporise i.e., phase change occurs from liquid to vapor but whereas in supercooled condition a small amount of heat addition or small increase in temperature will not cause any phase change.

The saturated liquid condition and compressed liquid can also be explained from the T-v diagram shown in figure. Point 2 indicates the saturated liquid condition and below point 2 it is supercooled condition.



Question: 4.002P

What is the difference between saturated vapor and superheated vapor?

Step 1 of 1

A vapour that is about to condense is called saturated vapor. And a vapor that is not about to condense is called superheated vapor. A small amount of heat loss from the vapor at saturated condition will cause the vapor to condense i.e., phase changes from vapor to liquid but whereas in superheated condition a small amount of heat loss or small decrease in temperature will not cause any phase change.

The saturated vapor state and superheated vapor states can also be explained from the T-v diagram shown in figure. Point 4 in the figure indicates the saturated vapor state and after point 4 and between point 5 the vapor can be treated as superheated.

Question: 4.003P

Is there any difference between the intensive properties of saturated vapor at a given temperature and the vapor of a saturated mixture at the same temperature?

Step 1 of 3

No.

Consider the tank contains a saturated liquid vapour mixture. Now volume occupied by saturated liquid is v_f and saturated vapour is v_g :

Now find the total volume of the mixture in tank.

$$V = V_f + V_g$$

But, $V = mv$

Here, specific volume is *v*.

Substitute mv for V in above expression:

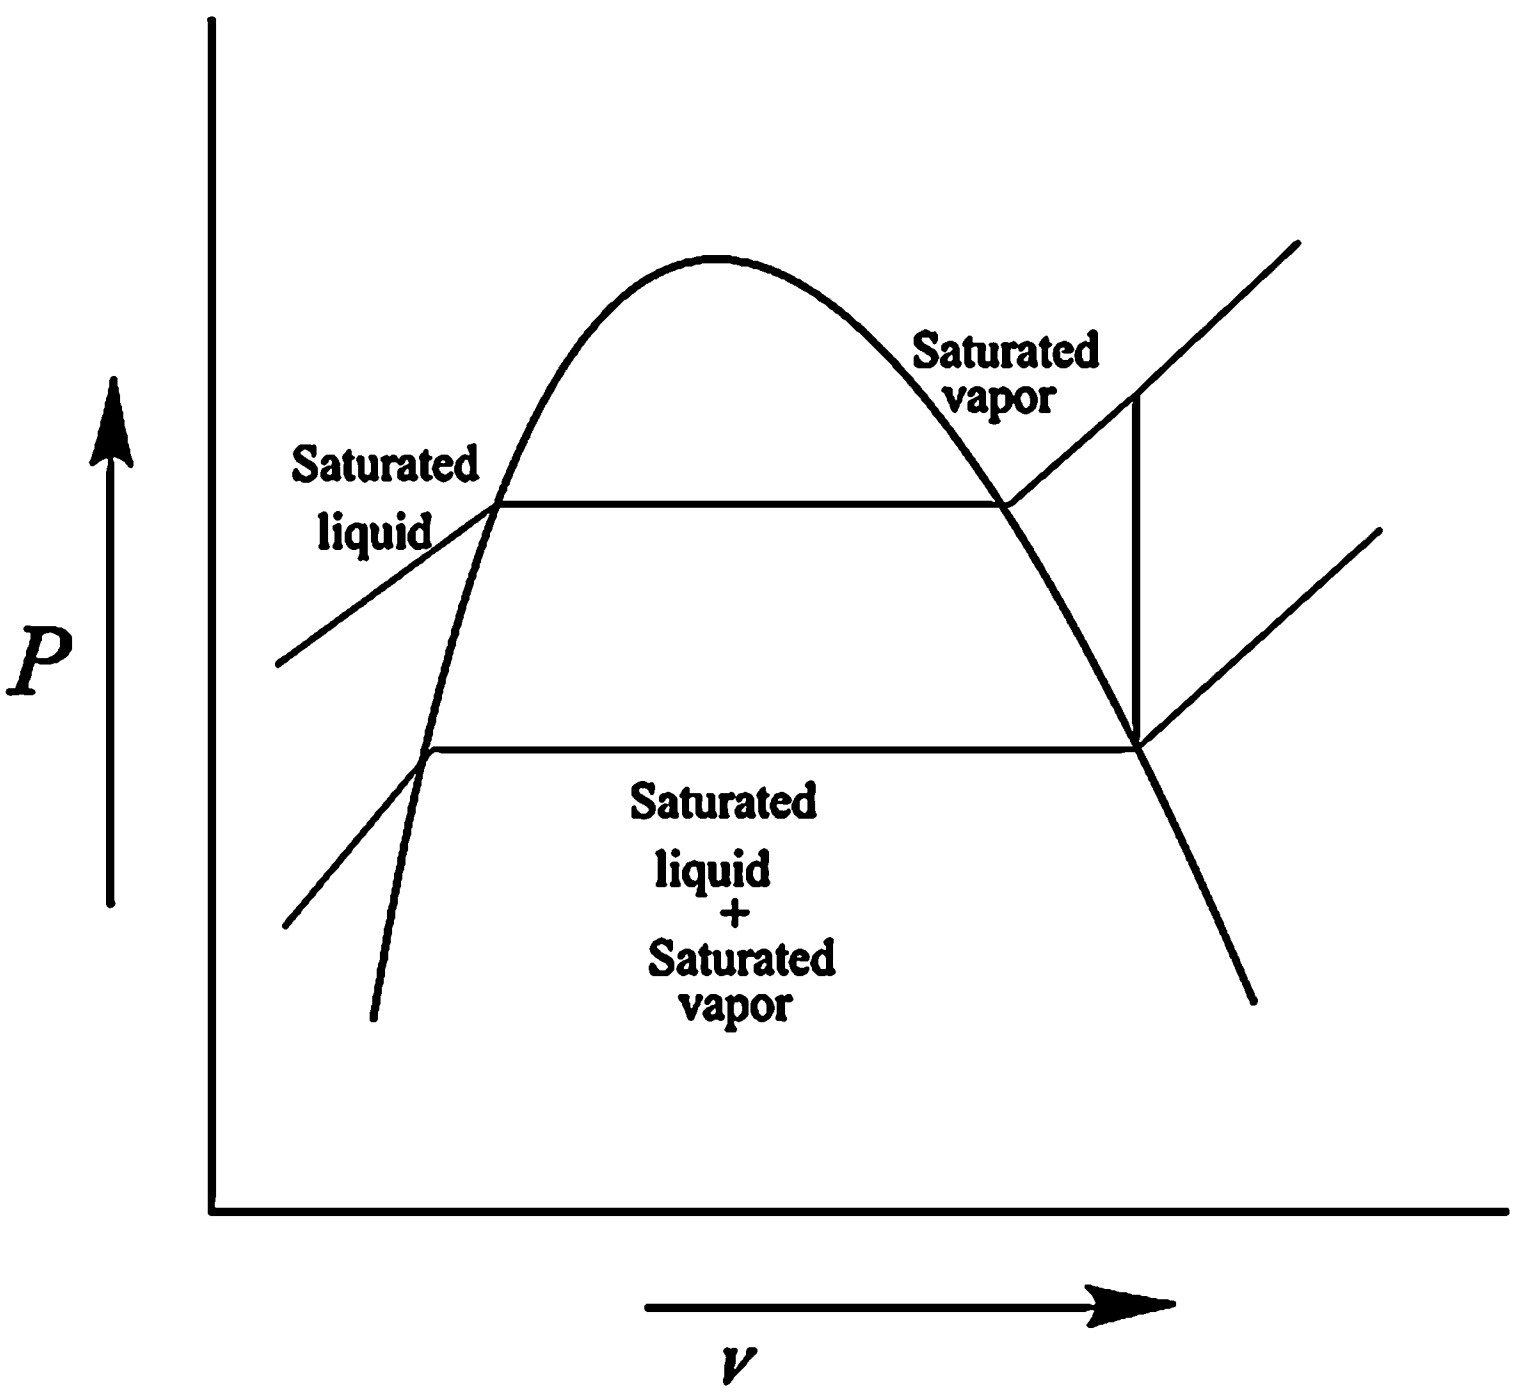
$$V = V_f + V_g$$
$$mv = m_f v_f + m_g v_g \quad \left(\because m = m_f + m_g\right)$$
$$mv = \left(m - m_g\right)v_f + m_g v_g$$

Step 2 of 3

Divide the above equation by *m* above expression:

$$v = \left(1 - \frac{m_g}{m}\right)v_f + \frac{m_g}{m}v_g$$
$$= \left(1 - x\right)v_f + xv_g \quad \left(\because x = \frac{m_g}{m}\right)$$

Here, dryness fraction is *x*.



Re-write the above equation for the value of *x*:

$$x = \frac{v - v_f}{v_g}$$

From the above expression, the properties of saturated vapour mixture lie between the saturated liquid line and saturated vapour line. Therefore, there is no change in the intensive properties of saturated vapour at a given temperature and the vapour of saturated mixture at the same temperature. Because, both resemble the same horizontal axis on *P-v* and *T-s* diagram.

Step 3 of 3

Draw the *P-V* diagram:

Question: 4.004P

If the pressure of a substance is increased during a boiling process, will the temperature also increase or will it remain constant? Why?

Step 1 of 1

The temperature at which a liquid starts boiling depends on the pressure, and hence if the pressure is increased the boiling temperature also increases. For example water starts boiling at 100°C if the pressure is fixed at 1 atm. If the pressure during the boiling process is increased to 500 kPa, water would start boiling at 151.8°C.

Question: 4.005P

Why are the temperature and pressure dependent properties in the saturated mixture region?

Step 1 of 1

The pressure and temperature are dependant properties in the saturated mixture region because the phase change process i.e., either boiling or condensation occur at certain temperature only if the pressure is held constant. As the pressure changes the temperature also changes and hence the saturated mixture line also changes as shown in the T-v diagram.

Question: 4.006P

What is the difference between the critical point and the triple point?

Step 1 of 1

The critical point is the point at which the saturated liquid and saturated vapor states are identical. We can see from figure 3-16 that as the pressure increases the saturation line continues to shrink and finally it reaches to a point (i.e., at 22.06 MPa pressure for the case of water) and that point is called the critical point.

The point at which all the three phases of pure substance coexist in equilibrium is called triple point. The triple can also be explained from the P-T diagram of pure substances shown in figure 3-25.

Question: 4.007P

Is it possible to have water vapor at −10°C?

Step 1 of 1

Yes, it is possible to have water vapor at -10°C. We can see from table 3-1 that when the saturation pressure is maintained at 0.26 kPa, the saturation temperature is -10°C. Thus if the pressure is maintained at 0.26 kPa, water starts boiling at -10°C.

Question: 4.008P

A househusband is cooking beef stew for his family in a pan that is (*a*) uncovered, (*b*) covered with a light lid, and (*c*) covered with a heavy lid. For which case will the cooking time be the shortest? Why?

Step 1 of 1

The cooking time will be the shortest in the third case i.e., when the pan is covered with a heavy lid. Because heavier the lid, greater the pressure in the pan. And we can see from table 3-1 as the pressure is high the saturation temperature at which water starts boiling will be high. And higher boiling temperatures mean shorter cooking times.

Question: 4.009P

How does the boiling process at supercritical pressures differ from the boiling process at subcritical pressures?

Step 1 of 1

At supercritical pressures there is no distinct phase change process. The liquid uniformly and gradually expands into vapor. At subcritical pressures, there is always distinct surface between the phases.

Question: 4.010P

A perfectly fitting pot and its lid often stick after cooking, and it becomes very difficult to open the lid when the pot cools down. Explain why this happens and what you would do to open the lid.

Step 1 of 1

As the pot cools down, the temperature inside the pot drops and the corresponding saturation pressure also drops creating a vacuum inside the pot, and hence it will become difficult to open the lid after cooking. An easy way of removing the lid is to reheat the pot, so that the temperature rises to boiling level and the corresponding saturation pressure rises to atmospheric level and thus the lid will easily come off the pot.

Question: 4.011P

It is well known that warm air in a cooler environment rises. Now consider a warm mixture of air and gasoline on top of an open gasoline can. Do you think this gas mixture will rise in a cooler environment?

Step 1 of 1

The molar mass of air is 29 kg/kmol and the molar mass of gasoline is 114 kg/kmol which is much larger than that of air. Therefore, the gasoline vapor will settle down instead of rising even if it is at a much higher temperature than the surrounding air. Hence, the warm mixture of air and gasoline on top of an open gasoline can will most likely settle down instead of rising in a cooler environment.

Question: 4.012P

Does the amount of heat absorbed as 1 kg of saturated liquid water boils at 100°C have to be equal to the amount of heat released as 1 kg of saturated water vapor condenses at 100°C?

Step 1 of 1

Yes, the amount of heat absorbed as 1 kg of saturated liquid water boils at 100°C is equal to the amount of heat released as 1 kg of saturated water vapor condenses at 100°C. If they are not equal, energy can be created by alternately vaporizing and condensing the substance.

Question: 4.013P

Does the reference point selected for the properties of a substance have any effect on thermodynamic analysis? Why?

Step 1 of 1

No, the reference point selected for properties of substance doesn't have any effect on thermodynamic analysis. This is because, in thermodynamic analysis, we are concerned with the changes in the properties, and the reference state chosen is of no consequence in calculations as long as we use values from single consistent set of tables and charts.

Question: 4.014P

What is the physical significance of *hfg*? Can it be obtained from a knowledge of *hf* and *hg*? How?

Step 1 of 1

The quantity of h_{fg} is called the enthalpy of vaporization. It represents the amount of energy needed to vaporize a unit mass of saturated liquid at a given temperature or pressure. It can be determined from

$$h_{fg} = h_g - h_f$$

where h_f is the enthalpy of saturated liquid

h_g is the enthalpy of saturated vapor.

Question: 4.015P

Does *hfg* change with pressure? How?

Step 1 of 1

Yes, h_{fg} changes with pressure. It decreases with increase in pressure and becomes zero at the critical point.

Question: 4.016P

Is it true that it takes more energy to vaporize 1 kg of saturated liquid water at 100°C than it would at 120°C?

Step 1 of 1

Yes, it takes more energy to vaporize 1 kg of saturated liquid water at 100°C than it would at 120°C. This is because, as the temperature goes on increasing the amount of energy needed to vaporize a unit mass of saturated liquid i.e., h_{fg} goes on decreasing and it becomes zero at the critical point. Hence higher the temperatures lower the h_{fg} value.

Question: 4.017P

What is quality? Does it have any meaning in the superheated vapor region?

Step 1 of 1

Quality(x) is the ratio of mass of vapor to the total mass of the mixture. It has significance for saturated mixtures only. It has no meaning in the superheated vapor region.

$$x = \frac{m_{vapor}}{m_{total}}$$

where $m_{total} = m_{liquid} + m_{vapor}$

Question: 4.018P

Which process requires more energy: completely vaporizing 1 kg of saturated liquid water at 1 atm pressure or completely vaporizing 1 kg of saturated liquid water at 8 atm pressure?

Step 1 of 1

It requires more energy for completely vaporizing 1 kg of saturated liquid water at 1 atm pressure. Because higher the pressure the lower the h_{fg} value.

Question: 4.019P

Can quality be expressed as the ratio of the volume occupied by the vapor phase to the total volume? Explain.

Step 1 of 1

No, quality cannot be expressed as the ratio of volume occupied by the vapor phase to the total volume. Quality is the mass ratio and it is not identical to the volume ratio

$$\text{Quality, } x = \frac{m_{vapor}}{m_{total}}$$

we can see that the quality can also be rewritten as

$$x = \frac{v_{avg} - v_f}{v_{fg}}$$

where v_f is the specific volume of saturated liquid
v_g is the specific volume of saturated vapor
v_{avg} is the average specific volume.

Question: 4.020P

In the absence of compressed liquid tables, how is the specific volume of a compressed liquid at a given P and T determined?

Step 1 of 3

Treat the compressed liquid at a given state as a saturated liquid, when the compressible liquid tables are not available.

Step 2 of 3

Obtain the value of specific volume of the saturated liquid, v_f from, "Properties of saturated water-Temperature table", at the given temperature.

Step 3 of 3

Thus, the specific volume of compressible liquid at given P and T ($v_{P,T}$) is equal to the specific volume of saturated liquid at that temperature (v_f @ T).

i.e., $v_{P,T} = v_f @ T$.

Question: 4.021P

In 1775, Dr. William Cullen made ice in Scotland by evacuating the air in a water tank. Explain how that device works, and discuss how the process can be made more efficient.

Step 1 of 1

Ice can be made by evacuating the air in a water tank. This process is called vacuum freezing. The evacuation process can be seen in figure 3-15. As seen from the figure 3-15, during evacuation of air, vapor is also thrown out and thus the vapor pressure in the tank drops, causing a difference between the vapor pressures of water surface and in the tank. Whatever the heat is required for vaporization of liquid is taken from the liquid and the air in the neighbourhood, causing the temperature in the tank to drop. The process continues until water starts freezing. The process can be made more efficient by insulating the tank well so that the entire heat of vaporization comes from the water only.

Question: 4.022P

Complete this table for H20:

T,°C	P, kPa	v,m3/kg	Phase description
50		7.72	
	400		Saturated vapor
250	500		
110	350		

Step 1 of 4

Obtain the properties of water from "Table A-4: saturated water-Temperature table" in the textbook at $T = 50°C$.

$p_{sat} = 12.352\,kPa$

Question:

Complete this table for H20:

T,°C	P, kPa	v,m3/kg	Phase description
50		7.72	
	400		Saturated vapor
250	500		
110	350		

Step 1 of 4

Obtain the properties of water from "Table A-4: saturated water-Temperature table" in the textbook at $T = 50°C$.

$p_{sat} = 12.352\,kPa$

Obtain the properties of refrigerant R-134a from "Table A-6: superheated water" in the textbook at $p = 500\,kPa$ and $T = 250°C$.

$v = 0.47443\,m^3/kg$

Therefore, the specific volume at $p = 500\,kPa$ and $T = 250°C$ is $\boxed{0.47443\,m^3/kg}$.

Step 4 of 4

Obtain the properties of water from "Table A-4: saturated water-Temperature table" in the textbook at $T = 110°C$.

$p_{sat} = 143.38\,kPa$

Since the pressure $350\,kPa$ is greater than saturation pressure the water is in compressed liquid region.

Obtain the properties of water from "Table A-7: compressed liquid water" in the textbook at $p = 350\,kPa$ and $T = 110°C$.

$v = 0.0011\,m^3/kg$

Therefore, the specific volume at $p = 350\,kPa$ and $T = 110°C$ is $\boxed{0.0011\,m^3/kg}$.

Write the completed table.

T (°C)	P (kPa)	v (m^3/kg)	Phase description
50	12.352	7.72	Saturated mixture
143.61	400	0.46242	Saturated vapor
250	500	0.47443	Superheated vapor
110	350	0.0011	Compressed liquid

Obtain the properties of refrigerant R-134a from "Table A-6: superheated water" in the textbook at $p = 500\,kPa$ and $T = 250°C$.

$v = 0.47443\,m^3/kg$

Therefore, the specific volume at $p = 500\,kPa$ and $T = 250°C$ is $\boxed{0.47443\,m^3/kg}$.

Step 4 of 4

Obtain the properties of water from "Table A-4: saturated water-Temperature table" in the textbook at

Question: 4.023P

Reconsider Prob. 4–22. Using EES (or other) software, determine the missing properties of water. Repeat the solution for refrigerant-134a, refrigerant 22, and ammonia.

Step 1 of 8

The problem is solved using EES, and the solution is given below.
For steam,

```
"Given"
T[1]=50 [C]
v[1]=7.72 [m^3/kg]
P[2]=400 [kPa]
x[2]=1
T[3]=250 [C]
P[3]=500 [kPa]
T[4]=110 [C]
P[4]=350 [kPa]
"Analysis"
Fluid$='steam_iapws'
P[1]=pressure(Fluid$, T=T[1], v=v[1])
x[1]=quality(Fluid$, T=T[1], v=v[1])
T[2]=temperature(Fluid$, P=P[2], x=x[2])
v[2]=volume(Fluid$, P=P[2], x=x[2])
v[3]=volume(Fluid$, P=P[3], T=T[3])
x[3]=quality(Fluid$, P=P[3], T=T[3])
v[4]=volume(Fluid$, P=P[4], T=T[4])
x[4]=quality(Fluid$, P=P[4], T=T[4])
"x = 100 for superheated vapor and x = -100 for compressed liquid"
```

Step 2 of 8

Now from menu bar, select 'calculate' and then click on 'solve'. The array table is displayed as

	P kPa	T_i ^{0}C	v_i m^3/kg	x_i
1	12.35	50	7.72	0.6419
2	400	143.6	0.4624	1
3	500	250	0.4744	100
4	350	110	0.001051	-100

Step 3 of 8

For R134a,

```
"Given"
T[1]=50 [C]
v[1]=7.72 [m^3/kg]
P[2]=400 [kPa]
x[2]=1
T[3]=250 [C]
P[3]=500 [kPa]
T[4]=110 [C]
P[4]=350 [kPa]
"Analysis"
Fluid$='R134a'
P[1]=pressure(Fluid$, T=T[1], v=v[1])
x[1]=quality(Fluid$, T=T[1], v=v[1])
T[2]=temperature(Fluid$, P=P[2], x=x[2])
v[2]=volume(Fluid$, P=P[2], x=x[2])
v[4]=volume(Fluid$, P=P[4], T=T[4])
x[4]=quality(Fluid$, P=P[4], T=T[4])
"x = 100 for superheated vapor and x = -100 for compressed liquid"
```

Step 4 of 8

Now from menu bar, select 'calculate' and then click on 'solve'. The array table is displayed as

	P kPa	T_i ^{0}C	v_i m^3/kg	x_i
1	3.409	50	7.72	100
2	400	8.91	0.05127	1
3	500	250		
4	350	110	0.08666	100

Step 5 of 8

For R22,

```
"Given"
T[1]=50 [C]
v[1]=7.72 [m^3/kg]
P[2]=400 [kPa]
x[2]=1
T[3]=250 [C]
P[3]=500 [kPa]
T[4]=110 [C]
P[4]=350 [kPa]
"Analysis"
Fluid$='R22'
P[1]=pressure(Fluid$, T=T[1], v=v[1])
x[1]=quality(Fluid$, T=T[1], v=v[1])
T[2]=temperature(Fluid$, P=P[2], x=x[2])
v[2]=volume(Fluid$, P=P[2], x=x[2])
v[3]=volume(Fluid$, P=P[3], T=T[3])
x[3]=quality(Fluid$, P=P[3], T=T[3])
v[4]=volume(Fluid$, P=P[4], T=T[4])
x[4]=quality(Fluid$, P=P[4], T=T[4])
"x = 100 for superheated vapor and x = -100 for compressed liquid"
```

Step 6 of 8

Now from menu bar, select 'calculate' and then click on 'solve'. The array table is displayed as

	P kPa	T_i ^{0}C	v_i m^3/kg	x_i
1	4.023	50	7.72	100
2	400	-6.564	0.0586	1
3	500	250	0.09959	100
4	350	110	0.103	100

Step 7 of 8

For Ammonia,

```
"Given"
T[1]=50 [C]
v[1]=7.72 [m^3/kg]
P[2]=400 [kPa]
x[2]=1
T[3]=250 [C]
P[3]=500 [kPa]
T[4]=110 [C]
P[4]=350 [kPa]
"Analysis"
Fluid$='Ammonia'
P[1]=pressure(Fluid$, T=T[1], v=v[1])
x[1]=quality(Fluid$, T=T[1], v=v[1])
T[2]=temperature(Fluid$, P=P[2], x=x[2])
v[2]=volume(Fluid$, P=P[2], x=x[2])
v[3]=volume(Fluid$, P=P[3], T=T[3])
x[3]=quality(Fluid$, P=P[3], T=T[3])
v[4]=volume(Fluid$, P=P[4], T=T[4])
x[4]=quality(Fluid$, P=P[4], T=T[4])
"x = 100 for superheated vapor and x = -100 for compressed liquid"
```

Step 8 of 8

Now from menu bar, select 'calculate' and then click on 'solve'. The array table is displayed as

	P kPa	T_i ^{0}C	v_i m^3/kg	x_i
1	20.4	50	7.72	100
2	400	-1.891	0.3083	1
3	500	250	0.5076	100
4	350	110	0.5269	100

Question: 4.024P

Complete this table for H20:

T, °F	P,psia	u,Btu/lbm	Phase description
300		782	
	40		Saturated liquid
500	120		
400	400		

Step 1 of 4

(a)

Only temperature and internal energy are given. Obtain the internal energy from the table A-4E, "Saturated Water-Temperature table" in the textbook at $300°F$.

$u_f = 269.51$ Btu/lb

$u_g = 1099.8$ Btu/lb

Since the given value, $u = 782$ Btu/lbm is in-between the values of u_f and u_g. Therefore, the mixture will be in saturated stated and obtain the saturation pressure.

Hence,

$P_{sat@300°F} = 67.028$ psia

Therefore the phase is **saturated mixture** and the value for saturated pressure is **67.028 psia**.

Step 2 of 4

(b)

Obtain the internal energy from the table A-5E, "Saturated Water-Pressure table" in the textbook at a pressure of 40 psia .

At, $P_{sat} = 40$ psia and since dryness fraction $x = 0$,

$T_{sat} = 267.22°F$

$u_{f@40\,psia} = 236.02$ Btu/lb

Therefore, the value for saturation temperature is **267.22°F** and the value for internal energy is **236.02 Btu/lb** .

Step 3 of 4

(c)

Obtain the value of saturated temperature at pressure $P = 120$ psia energy from the table A-5E, "Saturated Water-Pressure table" in the textbook at a pressure of 120 psia .

$T_{sat} = 341.25°F$

Since the given temperature is greater than saturation temperature, the phase is in superheated state.

From the relations,

If $T < T_{sat\ @\ given\ P}$ we have compressed liquid

If $T = T_{sat\ @\ given\ P}$ we have saturated mixture

If $T > T_{sat\ @\ given\ P}$ we have superheated vapor.

Obtain the internal energy from the table-6E, "Superheated Water" at a pressure of 120 psia and at a temperature of $500°F$ in the textbook.

$u = u_g$ @ $500°F$

$= 1174.4$ Btu/lbm

Therefore the phase is **superheated state** and the value for internal energy is **1174.4 Btu/lbm**.

Step 4 of 4

(d)

Obtain the value of saturated temperature at pressure $P = 120$ psia energy from the table A-5E, "Saturated Water-Pressure table" in the textbook at a pressure of 400 psia . $T_{sat} = 444.62°F$

Since the given temperature is less than saturation temperature, the phase is in saturated state.

From the relations,

If $T < T_{sat\ @\ given\ P}$ we have compressed liquid

If $T = T_{sat\ @\ given\ P}$ we have saturated mixture

If $T > T_{sat\ @\ given\ P}$ we have superheated vapor.

Obtain the internal energy from the table A-4E, "Saturated Water-Temperature table" in the textbook at $400°F$.

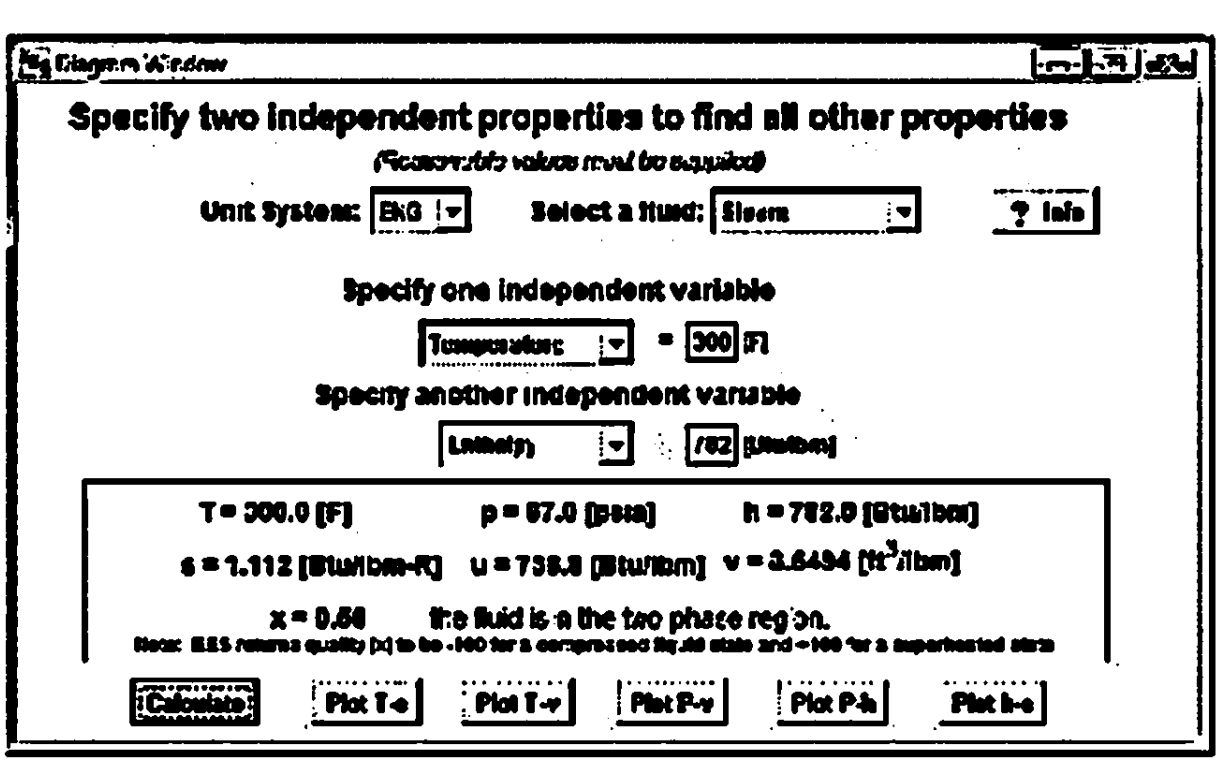
$u = u_f$ @ $400°F$

$= 374.19$ Btu/lbm

Therefore, the phase is **compressed liquid state** and the value for internal energy is **374.19 Btu/lbm**.

Question: 4.025P

Reconsider Prob. 4–24E. Using EES (or other) software, determine the missing properties of water. Repeat the solution for refrigerant-134a, refrigerant-22, and ammonia.



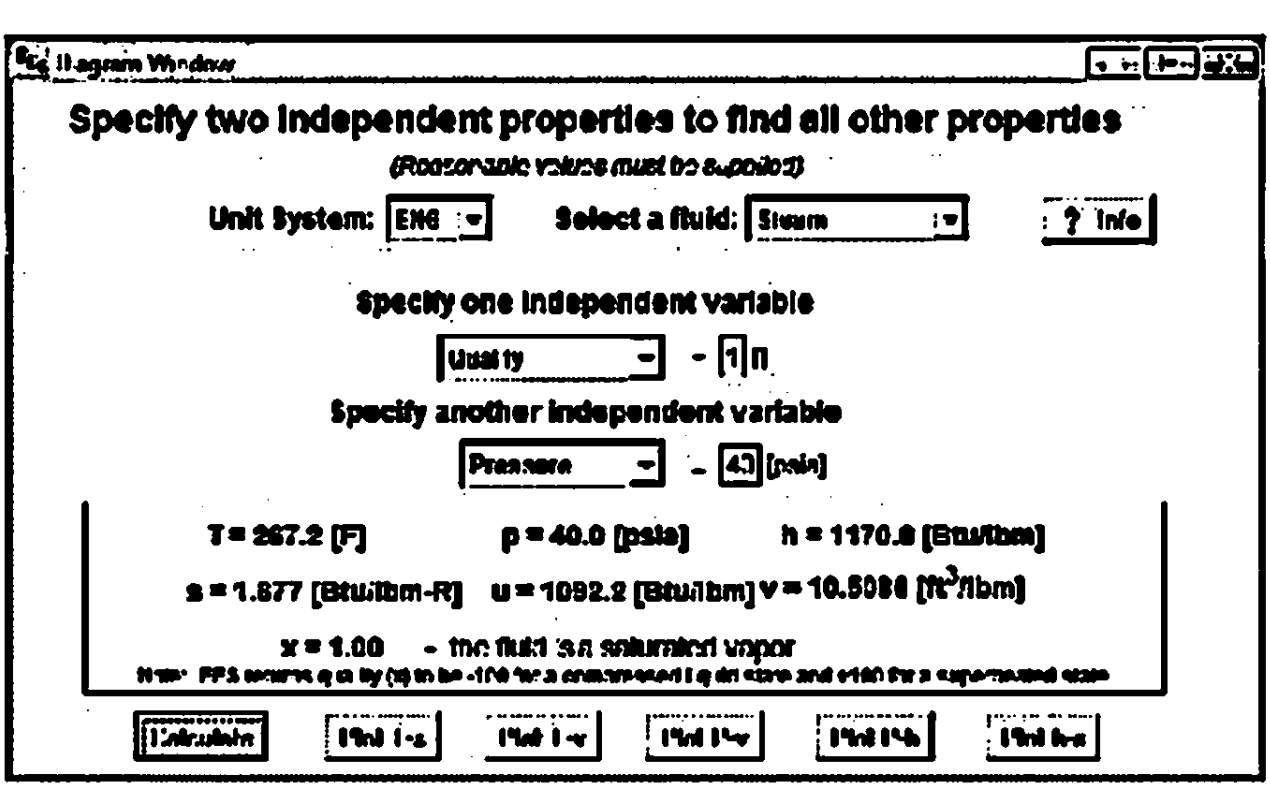
Step 1 of 8

Given table:

T	P	u Btu/lbm	phase description
300		782	
	40		saturated liquid
500	120		
400	400		

Step 2 of 8

For the properties of water
Temperature, $T = 300°F$
Internal energy, $u = 785 Btu/lbm$
By using the Engineering Equation Solver (EES) software



Step 3 of 8

So, the missing properties,
Pressure, $P = 67$ psia
Dryness fraction , $x = 0.56$
So, the fluid is in two phase condition.

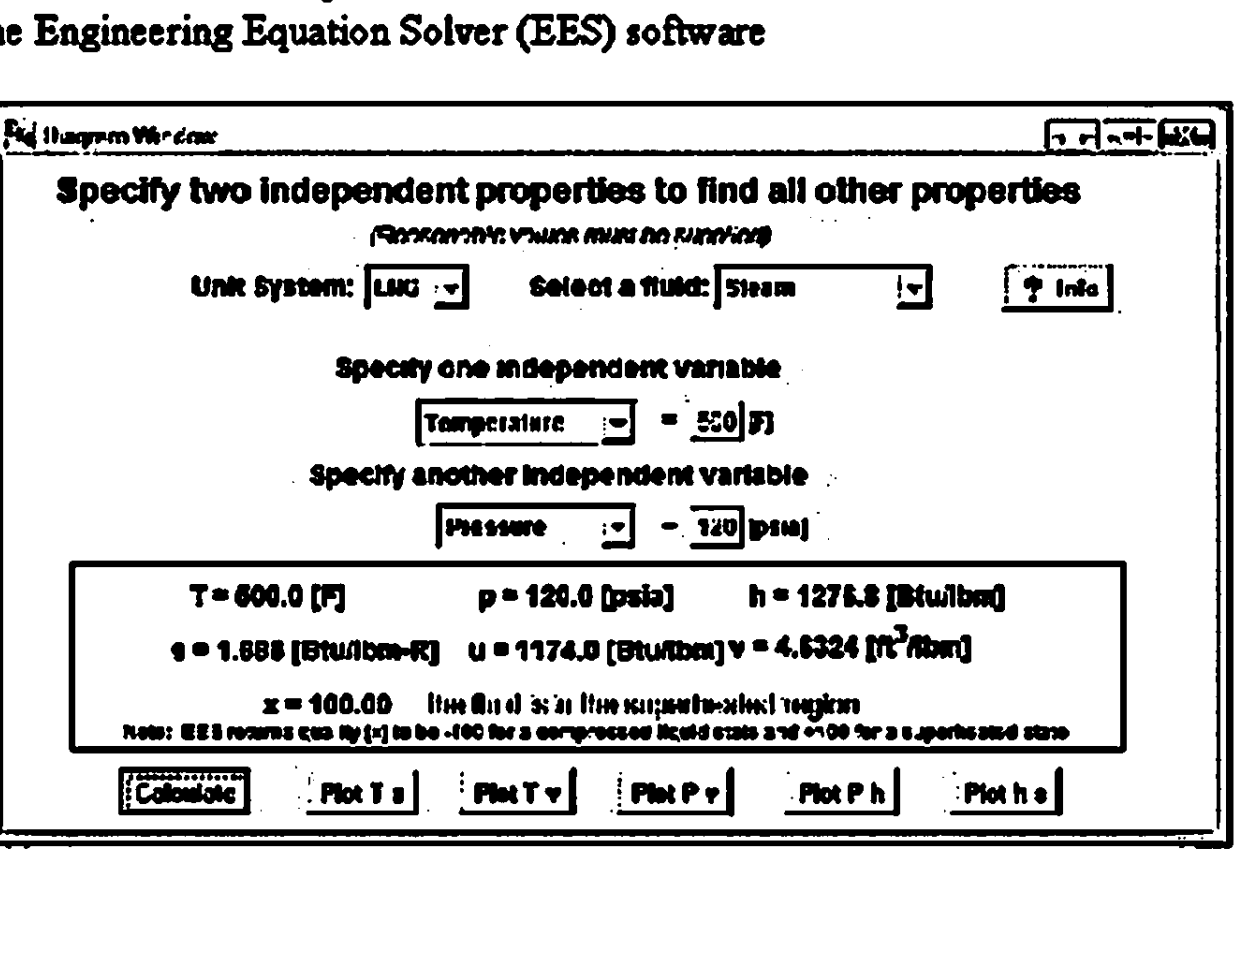
Step 4 of 8

For the second row,
Pressure of the water, $P = 40$psia
water is in saturated vapor.
Means that $x = 1$
By using the Engineering Equation Solver (EES) software

Step 5 of 8

The missing properties of the water,
Temperature, $T = 267.2°F$
Internal energy, $u = 1092.2 Btu/lbm$

Step 6 of 8



For the third row in the given table
Temperature of the steam, $T = 500°F$
Pressure of the steam, $P = 120$psia
By using the Engineering Equation Solver (EES) software

The missing properties of the water

Step 7 of 8

Internal energy, $u = 1174 Btu/lbm$
Dryness fraction, $x = 100$
So, the water is in superheated region.

For the last row in the given table
Temperature of the steam, $T = 400°F$
Pressure of the steam, $P = 400$psia
By using the Engineering Equation Solver (EES) software

Step 8 of 8

The missing properties of the water,
Internal energy, $u = 373.9 Btu/lbm$
Dryness fraction, $x = 100$
So, the water is in superheated region.

Question: 4.026P

Complete this table for H2O:

T,°C	*P*, kPa	*h*, kJ/kg	*x*	Phase description
	200		0.7	
140		1800		
	950		0.0	
80	500			
	800	3162.2		

Step 1 of 5

a) Given Pressure, P = 200 kPa

quality, x = 0.7

The quality, x = 0.7 implies that 70 percent of the mass is in the vapor state and the remaining 30 percent is in the liquid phase. Therefore, we have saturated liquid-vapor mixture at pressure of 200 kPa. From the saturated water – pressure table (Table A-4)

$T = T_{sat}$ @ 200 kPa = 120.21 °C.

and also h_f = 504.71 kJ/kg

h_{fg} = 2201.6 kJ/kg

Thus, the average enthalpy of the mixture is

$h = h_f + x h_{fg}$

= 504.71 + (0.7)*(2201.6)

= 2045.83 kJ/kg.

Step 2 of 5

b) Given T = 140 °C

h = 1800 kJ/kg

Only temperature and enthalpy are given. We do not know which table to use to determine the missing properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the enthalpy of saturated liquid (h_f) and enthalpy of saturated vapor (h_g) from the saturated water – temperature table (Table A-4).

At T= 140 °C

h_f = 589.16 kJ/kg

h_{fg} = 2144.3 kJ/kg

h_g = 2733.5 kJ/kg

Thus, the given value h = 1800 kJ/kg is in between the values of h_f and h_g. Therefore, we have saturated liquid-vapor mixture and the pressure is the saturation pressure at given temperature (Table A-4)

Hence, $P = P_{sat}$ @ 140 °C = 361.53 kPa.

The quality is determined from

$$x = \frac{h - h_f}{h_{fg}}$$

$$= \frac{1800 - 589.16}{2144.3}$$

$$= 0.565$$

Step 3 of 5

c) Given Pressure, P = 950 kPa

quality, x = 0.0

The quality, x = 0.0 implies that 100 percent of the mass is in the liquid state. Therefore, we have saturated liquid at pressure of 950 kPa. From the saturated water – pressure table (Table A-5)

$T = T_{sat}$ @ 950 kPa = 177.66 °C.

and $h = h_f$ = 752.74 kJ/kg

Step 4 of 5

d) Given T = 80 °C

P = 500 kPa

In this case, the temperature and pressure are given, but again we do not know whether we have saturated mixture, compressed liquid or superheated vapor. To determine the region we are in, we go the saturation water – pressure table (Table A-5) and determine the saturation temperature at the given pressure. Thus, for P = 500 kPa, we have T_{sat} = 151.83 °C. We then compare the given T value to this T_{sat} value, keeping in mind that

if $T < T_{sat\ @\ given\ P}$ we have compressed liquid

if $T = T_{sat\ @\ given\ P}$ we have saturated mixture

if $T > T_{sat\ @\ given\ P}$ we have superheated vapor.

In our case, the given T value is 80 °C, which is less than the T_{sat} value at the given pressure. Therefore, we have compressed liquid and normally we would determine the enthalpy value from the compressed liquid table (Table A-7). But in this case the given pressure is lower than the lowest pressure value in the compressed liquid table (which is 5 MPa), and therefore we are justified to treat the compressed liquid as saturated liquid at the given temperature (not pressure) and obtain the value of enthalpy from Table A-4.

$h = h_f$ @ 80 °C = 335.02 kJ/kg.

As we have compressed liquid, there is no meaning for quality in the compressed liquid region.

Step 5 of 5

e) Given P = 800 kPa

h = 3162.2 kJ/kg

Only pressure and enthalpy are given. We do not know which table to use to determine the missing properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the enthalpy of saturated liquid (h_f) and enthalpy of saturated vapor (h_g) from the saturated water – pressure table (Table A-5).

At P= 800 kPa

h_f = 720.87 kJ/kg

h_g = 2768.3 kJ/kg

Thus, the given value h = 3162.2 kJ/kg is greater than the value of h_g. Therefore, we have superheated vapor and the temperature is determined from the superheated vapor table (Table A-6) at pressure, P=0.8 MPa and h= 3162.2 kJ/kg

Hence, T = 350 °C.

The quality has no meaning as we have superheated vapor.

Question: 4.027P

Complete this table for refrigerant-134a:

T, °C	P, kPa	v, m3/kg	Phase description
−12	320		
30		0.0065	
	550		Saturated vapor
60	600		

Step 1 of 4

Obtain the properties of refrigerant R-134a from "Table A-11: saturated refrigerant-134a-Temperature table" in the textbook at $T = -12°C$.

$p_{sat} = 185.37\,\text{kPa}$

$v_f = 0.00074\,\text{m}^3/\text{kg}$

Since the pressure $320\,\text{kPa}$ is greater than the saturation pressure the liquid is in compressed liquid state.

Therefore, the specific volume at $T = -12^0C$ and $P = 320\text{kPa}$ is $\boxed{0.0007\,\text{m}^3/\text{kg}}$

Step 2 of 4

Obtain the properties of refrigerant R-134a from "Table A-11: saturated refrigerant-134a-Temperature table" in the textbook at $T = 30°C$.

$p_{sat} = 770.64\,\text{kPa}$

$v_f = 0.0008421\,\text{m}^3/\text{kg}$

$v_g = 0.026622\,\text{m}^3/\text{kg}$

Since the specific volume $0.0065\,\text{m}^3/\text{kg}$ is in-between v_f and v_g the refrigerant is in two phase region.

Therefore, the pressure at $T = 30°C$ and $v = 0.0065\,\text{m}^3/\text{kg}$ is $\boxed{770.6\,\text{kPa}}$.

Step 3 of 4

Obtain the properties of refrigerant R-134a from "Table A-12: saturated refrigerant-134a-Pressure table" in the textbook at $p = 550\,\text{kPa}$ and saturated vapor condition.

$T_{sat} = 18.73°C$

$v_g = 0.0374\,\text{m}^3/\text{kg}$

Therefore, the specific volume and temperature at $p = 550\,\text{kPa}$ and saturated vapor condition is $\boxed{0.0374\,\text{m}^3/\text{kg}, 18.73°C}$.

Step 4 of 4

Obtain the properties of refrigerant R-134a from "Table A-12: saturated refrigerant-134a-Pressure table" in the textbook at $p = 600\,\text{kPa}$.

$T_{sat} = 21.55°C$

Since the temperature $60°C$ is greater than saturation temperature the refrigerant is in superheated region.

Obtain the properties of refrigerant R-134a from "Table A-13: superheated refrigerant-134a" in the textbook at $p = 600\,\text{kPa}$ and $T = 60°C$.

$v = 0.04138\,\text{m}^3/\text{kg}$

Therefore, the specific volume at $p = 600\,\text{kPa}$ and $T = 60°C$ is $\boxed{0.04138\,\text{m}^3/\text{kg}}$.

Write the completed table.

T, °C	P, kPa	v, m ^{3} /kg	Phase description
-12	320	0.0007	Compressed liquid
30	770.6	0.0065	Saturated mixture
18.73	550	0.0374	Saturated vapor
60	600	0.4138	Superheated vapor

Question: 4.028P

If sufficient data are provided, complete the blank cells in the following table of properties of water. In the last column describe the condition of water as compressed liquid, saturated mixture, superheated vapor, or insufficient information; and, if applicable, give the quality.

P, kPa	*T*,°C	v,m3/kg	*h*,kJ/kg	Condition description and quality (if applicable)
200			2706.3	
	130			0.650
	400		3277.0	
800	30			
450	147.90			

Step 1 of 6

Given

Pressure $P = 200\,\text{kPa}$

Enthalpy $h = 2706.3\,\text{kJ/kg}$

At $P = 200\,\text{kPa}$ and $h = 2706.3\,\text{kJ/kg}$ from saturated water tables

$h = h_g = 2706.3\,\text{kJ/kg}$ so the state is in saturated vapor condition

Then specific volume at this state is

$v = v_g = 0.88578\,\text{m}^3/\text{kg}$

$\boxed{v = 0.88578\,\text{m}^3/\text{kg}}$

Condition at this state is

$\boxed{x = 1}$

Temperature

$\boxed{T = 120.21^0\,\text{C}}$

Step 2 of 6

Given

Temperature $T = 130^0\,\text{C}$

Dryness fraction $x = 0.650$

At $T = 130^0\,\text{C}$ from saturated water tables

$P = P_{sat} = 270.28\,\text{kPa}$

$\boxed{P = 270.28\,\text{kPa}}$

Specific volume

$v = v_{f@130C} + x v_{fg@130C}$

$v = 0.001070 + 0.65 \times 0.66701$

$\boxed{v = 0.4346\,\text{m}^3/\text{kg}}$

Specific enthalpy

$h = h_{f@130C} + x h_{fg@130C}$

$h = 546.38 + 0.65 \times 2173.7$

$\boxed{h = 1959.285\,\text{kJ/kg}}$

Step 3 of 6

Given

Temperature $T = 400^0\,\text{C}$

Enthalpy $h = 3277.0\,\text{kJ/kg}$

At $T = 400^0\,\text{C}$ and $h = 3277.0\,\text{kJ/kg}$ from superheated water tables

$\boxed{P = 200\,\text{kPa}}$

Specific volume

$\boxed{v = 1.54934\,\text{m}^3/\text{kg}}$

Step 4 of 6

Given

Pressure $P = 800\,\text{kPa}$

Temperature $T = 30^0\,\text{C}$

At these properties the state is in compressed liquid region

Specific volume $\boxed{v = 0.0010\,\text{m}^3/\text{kg}}$

Specific enthalpy $\boxed{h = 126.4\,\text{kJ/kg}}$

Step 5 of 6

Given

Pressure $P = 450\,\text{kPa}$

Temperature $T = 147.90^0\,\text{C}$

At these properties the state is in saturated condition but it is not mentioned that whether the state is in saturated liquid or saturated vapor state.

Step 6 of 6

P(kPa)	T(°C)	v (m^3/kg)	h (kJ/kg)	Quality (x)	Condition
200	120.21	0.88578	2706.3	1	Saturated vapor
270.28	130	0.4346	1959.285	0.650	Saturated mixture
200	400	1.54934	3277.0		Superheated state
800	30	0.0010	126.4	-	Compressed liquid
450	147.9				Insufficient information

Question: 4.029P

Complete this table for refrigerant -134a:

T, °F	*P*, psia	*h*, Btu/lbm	*x*	Phase description
	80	78		
15			0.6	
10	70			
	180	129.46		
110		1.0	1.0	

Step 1 of 5

a) Given P = 80 psia

h = 78 Btu/lbm

Only pressure and enthalpy are given. We do not know which table to use to determine the missing properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the enthalpy of saturated liquid (h_f) and enthalpy of saturated vapor (h_g) from the saturated refrigerant-134a-pressure table .

At P= 80 psia

h_f = 33.394 Btu/lbm

h_{fg} = 78.804 Btu/lbm

h_g = 112.20 Btu/lbm

Thus, the given value h = 78 Btu/lbm is in between the values of h_f and h_g. Therefore, we have saturated liquid-vapor mixture at pressure of 80 psia. The temperature is the saturation temperature at given pressure.

Hence, $T = T_{sat}$ @ 80 psia = 65.89 °F.

The quality is determined from

$$x = \frac{h - h_f}{h_{fg}}$$

$$= \frac{78 - 33.394}{78.804}$$

$$= 0.566$$

Step 2 of 5

b) Given Temperature, T = 15 °F

Quality, x = 0.6

The quality, x = 0.6 implies that 60 percent of the mass is in the vapor state and the remaining 40 percent is in the liquid phase. Therefore, we have saturated liquid-vapor mixture at temperature of 15 °F. From the saturated refrigerant-134a-temperature table

$P = P_{sat}$ @ 15 °F = 29.759 psia.

and also h_f = 16.889 Btu/lbm

h_{fg} = 88.377 Btu/lbm

Thus, the average enthalpy of the mixture is

$h = h_f + x h_{fg}$

= 16.889 + (0.6)*(88.377)

= 69.915 Btu/lbm

Step 3 of 5

c) Given T = 10 °F

P = 70 psia

In this case, the temperature and pressure are given, but again we do not know whether we have saturated mixture, compressed liquid or superheated vapor. To determine the region we are in, we go the saturation refrigerant-134a–pressure table (Table A-12E) and determine the saturation temperature at the given pressure. Thus, for P = 70 psia, we have T_{sat} = 58.30 °F. We then compare the given T value to this T_{sat} value, keeping in mind that

if $T < T_{sat\ @\ given\ P}$ we have compressed liquid

if $T = T_{sat\ @\ given\ P}$ we have saturated mixture

if $T > T_{sat\ @\ given\ P}$ we have superheated vapor.

In our case, the given T value is 10 °F, which is less than the T_{sat} value at the given pressure. Therefore, we have compressed liquid and normally we would determine the enthalpy value from the compressed liquid tables of refrigerant 134a. But in this case, we do not have compressed liquid tables for the refrigerant and therefore we are justified to treat the compressed liquid as saturated liquid at the given temperature (not pressure) and obtain the value of enthalpy from Table.

$h = h_f$ @ 10 °F = 15.318 Btu/lbm

As we have compressed liquid, there is no meaning for quality in the compressed liquid region.

Step 4 of 5

d) Given P = 180 psia

h = 129.46 Btu/lbm

Only pressure and enthalpy are given. We do not know which table to use to determine the missing properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the enthalpy of saturated liquid (h_f) and enthalpy of saturated vapor (h_g) from the saturated refrigerant-134a-pressure table (Table A-12E).

At P= 180 psia

h_f = 51.497 Btu/lbm

h_g = 117.96 Btu/lbm

Thus, the given value h = 124.96 Btu/lbm is greater than the value of h_g. Therefore, we have superheated vapor and the temperature is determined from the superheated vapor table at pressure, P=180 psia and h= 124.96 Btu/lbm

Hence, T = 160 °F.

The quality has no meaning as we have superheated vapor.

Step 5 of 5

e) Given Temperature, T = 110 °C

Quality, x = 1.0

The quality, x = 1.0 implies that 100 percent of the mass is in the vapor state. Therefore, we have saturated vapor at temperature of 110 °C. From the saturated refrigerant-134a-temperature table.

$P = P_{sat}$ @ 110 °F = 161.16 psia

and $h = h_g$ = 117.23 Btu/lbm

Question: 4.030P

A piston–cylinder device contains 0.85 kg of refriger-ant-134a at −10°C. The piston that is free to move has a mass of 12 kg and a diameter of 25 cm. The local atmospheric pressure is 88 kPa. Now, heat is transferred to refrigerant-134a until the temperature is 15°C. Determine (*a*) the final pressure, (*b*) the change in the volume of the cylinder, and (*c*) the change in the enthalpy of the refrigerant-134a.

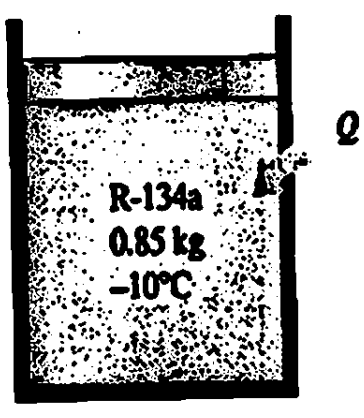


FIGURE P4–30

Step 1 of 5

(a)

Calculate the final pressure in the cylinder by using the equation.

$$P_1 = P_2$$
$$= P_{atm} + \frac{m_p g}{\pi D^2/4}$$

Here, P_{atm} is atmospheric pressure, m_p is mass of the piston, and D is diameter of the cylinder.

Substitute $88\,\text{kPa}$ for P_{atm}, $12\,\text{kg}$ for m_p, $9.81\,\text{m/s}^2$ for g and 0.25 m for D.

$$P_1 = 88\ \text{kPa} + \frac{(12\ \text{kg})\times(9.81\ \text{m/s}^2)}{\frac{\pi\times(0.25\ \text{m})^2}{4}} \times \frac{1\ \text{kN}}{10^3\ \text{kg}\cdot\text{m/s}^2}$$
$$= 88 + 2.4$$
$$= 90.4\ \text{kPa}$$

Therefore, the final pressure of the given system is $\boxed{90.4\ \text{kPa}}$.

Step 2 of 5

(b)

Obtain the properties of R-134a at pressure $P_1 = 90.4\ \text{kPa}$ and $T_1 = -10°\text{C}$ from the superheated tables of A-13 "Properties of the refrigerant R-134a" using linear interpolation.

Specific volume,

$$\frac{0.0904-0.06}{0.1-0.06} = \frac{v_1 - 0.35048}{0.20743-0.35048}$$
$$v_1 = 0.24176\ \text{m}^3/\text{kg}$$

Specific Enthalpy,

$$\frac{0.0904-0.06}{0.1-0.06} = \frac{h_1 - 248.58}{247.49-248.58}$$
$$h_1 = 247.752\ \text{kJ/kg}$$

Obtain the properties of R-134a at temperature $T_2 = 15°\text{C}$ at pressure 0.06 MPa and 0. 1 MPa from the superheated tables of A-13 "Properties of the refrigerant R-134a".

Specific volume,

$$v_{0.06\,\text{MPa}} = \frac{0.37893+0.39302}{2}$$
$$= 0.385975\ \text{m}^3/\text{kg}$$
$$v_{0.1\,\text{MPa}} = \frac{0.22506+0.23373}{2}$$
$$= 0.229395\ \text{m}^3/\text{kg}$$

Specific Enthalpy,

$$h_{0.06\,\text{MPa}} = \frac{264.66+272.94}{2}$$
$$= 268.8\ \text{kJ/kg}$$
$$h_{0.1\,\text{MPa}} = \frac{263.81+272.17}{2}$$
$$= 267.99\ \text{kJ/kg}$$

Step 3 of 5

Obtain the properties of R-134a at pressure $P_2 = 90.4\ \text{kPa}$ and $T_2 = 15°\text{C}$ from the superheated tables of "Properties of the refrigerant R-134a" using linear interpolation.

Specific volume,

$$\frac{0.0904-0.06}{0.1-0.06} = \frac{v_2 - 0.385975}{0.229395-0.385975}$$
$$v_2 = 0.26697\ \text{m}^3/\text{kg}$$

Specific Enthalpy,

$$\frac{0.0904-0.06}{0.1-0.06} = \frac{h_2 - 268.8}{267.99-268.8}$$
$$h_2 = 268.18\ \text{kJ/kg}$$

Step 4 of 5

Find the initial volume by using the expression.

$$V_1 = mv_1$$

Here, m is mass of the refrigerant.

Substitute 0.85 kg for m and $0.24176\ \text{m}^3/\text{kg}$ for v_1.

$$V_1 = 0.85\times 0.24176$$
$$= 0.205496\ \text{m}^3$$

Calculate the final volume by using the expression.

$$V_2 = mv_2$$
$$= 0.85\times 0.26697$$
$$= 0.2269245\ \text{m}^3$$

Now find the change in volume of the entire system.

$$\Delta V = V_2 - V_1$$

Substitute $0.205496\ \text{m}^3$ for V_1, and $0.2269245\ \text{m}^3$ for V_2.

$$\Delta V = (0.2269245 - 0.205496)$$
$$= 0.0214\ \text{m}^3$$

Therefore, the change in volume of the system is $\boxed{0.0214\ \text{m}^3}$.

Step 5 of 5

(c)

Find the total enthalpy change in the given system by using the expression.

$$\Delta H = m(h_2 - h_1)$$

Substitute 0.85 kg for m, $268.18\ \text{kJ/kg}$ for h_2, and $247.752\ \text{kJ/kg}$ for h_1.

$$\Delta H = 0.85(268.18 - 247.752)$$
$$= 17.36\ \text{kJ/kg}$$

Therefore, total change in enthalpy of the given system is $\boxed{17.36\,\text{kJ/kg}}$.

Question:

4.031P

R-134a. whose specific volume is 0.4618 ft3/lbm, flows through a tube at 120 psia. What is the temperature in the tube?

Step 1 of 2

Given

Specific volume of R-134a is $v = 0.4618\,\text{ft}^3/\text{lbm}$

Pressure $P = 120\text{psia}$

Step 2 of 2

At $P = 120\text{psia}$ from saturated R-134a tables

$v_g = 0.39644\,\text{ft}^3/\text{lbm}$

And given $v > v_g$ so the state is in superheated region

Therefore at $P = 120\,\text{psia}$ and $v = 0.4618\,\text{ft}^3/\text{lbm}$ from superheated R-134a tables

$$T = 120 + (140 - 120)\left(\frac{0.4618 - 0.43692}{0.46190 - 0.43692}\right)$$

$$\boxed{T = 139.919^0\text{F}}$$

Question: 4.032P

One kilogram of water fills a 150-L rigid container at an initial pressure of 2 MPa. The container is then cooled to 40°C. Determine the initial temperature and the final pressure of the water.

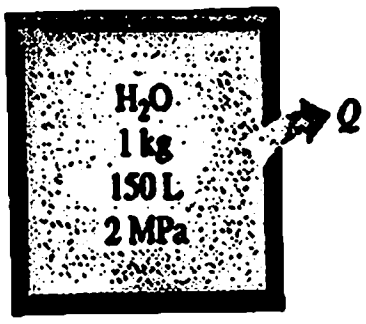

FIGURE P4–32

Step 1 of 4

Given

Mass of water $m = 1\text{kg}$

Volume of container $V = 150\text{L} = 150\times10^{-3}\text{m}^3$

Initial pressure $P_1 = 2\text{MPa}$

Final temperature $T_2 = 40^0\text{C}$

Step 2 of 4

Specific volume

$$v_1 = \frac{V}{m}$$

$$v_1 = \frac{150\times10^{-3}}{1}$$

$$v_1 = 0.15\text{m}^3/\text{kg}$$

Step 3 of 4

At $P_1 = 2\text{MPa}$ and $v_1 = 0.15\,\text{m}^3/\text{kg}$ from superheated water tables

$$T_1 = 350+(400-350)\left(\frac{0.15-0.13860}{0.15122-0.13860}\right)$$

$$\boxed{T_1 = 395.17^{\circ}\text{C}}$$

Step 4 of 4

Since it is rigid container, so the volume remains constant

$v_2 = v_1 = 0.15\text{m}^3/\text{kg}$

At $T_2 = 40^0\text{C}$ from saturated water tables

$v_f = 0.001008\text{m}^3/\text{kg}$

$v_g = 19.515\text{m}^3/\text{kg}$

And $v_f < v_2 < v_g$ so the final state is in two phase region

Therefore at $T_2 = 40^0\text{C}$ from saturated water table, we have

$P_2 = P_{sat} = 7.3851\text{kPa}$

$$\boxed{P_2 = 7.3851\text{kPa}}$$

Question: 4.033P

10-kg of R-134a fill a 1.348-m3 rigid container at an initial temperature of −40°C. The container is then heated until the pressure is 200 kPa. Determine the final temperature and the initial pressure.

Step 1 of 4

Calculate the specific volume at state 1.

$$v_1 = \frac{V}{m}$$

Here, the volume of rigid container is V and the mass of refrigerant is m.

Substitute 1.348m^3 for V and 10 kg for m.

$$v_1 = \frac{1.348}{10}$$
$$= 0.1348\ \text{m}^3/\text{kg}$$

Step 2 of 4

Obtain the properties of R-134a from saturated R-134a temperature table.

At $T_1 = -40^0\text{C}$, volumes are as follows:

The specific volume of saturated liquid, $v_f = 0.0007054\ \text{m}^3/\text{kg}$

The specific volume of saturated vapor, $v_g = 0.36081\ \text{m}^3/\text{kg}$

Saturation pressure, $P_{sat} = 51.25\text{kPa}$

Step 3 of 4

From the above calculated values, $v_f < v_1 < v_g$, so the initial state is in wet region.

Therefore initial pressure is saturation pressure at temperature $T_1 = -40^0\text{C}$.

$$P_1 = P_{sat} = 51.25\text{kPa}$$

Therefore, the initial pressure is $\boxed{51.25\ \text{kPa}}$.

Step 4 of 4

The specific volume remains constant, as it is a rigid tank.

$$v_2 = v_1$$
$$= 0.1348\ \text{m}^3/\text{kg}$$

Here, the specific volume at state 2 is v_2.

Calculate the final temperature of the refrigerant-134a as follows:

Obtain the properties of R-134a from saturated R-134a temperature table.

At $P_2 = 200\text{kPa}$ and $v_2 = v_1 = 0.1348\ \text{m}^3/\text{kg}$ from superheated R-134a tables.

$$\frac{T_2 - 60}{(70-60)} = \left(\frac{0.1348 - 0.13206}{0.13641 - 0.13206}\right)$$

$$T_2 = 60 + (70-60)\left(\frac{0.1348 - 0.13206}{0.13641 - 0.13206}\right)$$

$$T_2 = 66.3^0\text{C}$$

Therefore, the final temperature is $\boxed{66.3^\circ\text{C}}$.

Question: 4.034P

2-lbm of water at 500 psia intially fill the 1,5-ft3 left chamber of a partitioned system. The left chamber's volume is also 1.5 ft3, and it is initially evacuated. The partition is now ruptured, and heat is transferred to the water until its temperature is 300°F. Determine the final pressure of water, in psia, and the total internal energy, in Btu, at the final state.

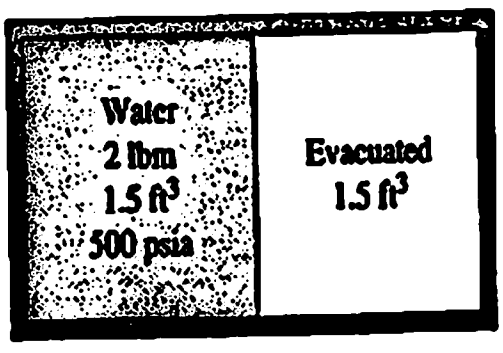

FIGURE P4–34E

Step 1 of 7

Given

Mass of water $m = 2\text{lbm}$

Initial pressure $P_1 = 500\text{psia}$

Volume of left chamber $V_{1L} = 1.5\text{ft}^3$

Volume of right chamber $V_{1R} = 1.5\text{ft}^3$

Final temperature $T_2 = 300\text{F}$

Step 2 of 7

The initial specific volume is

$$v_1 = \frac{V}{m}$$

$$= \frac{1.5}{2}$$

$$v_1 = 0.75\text{ft}^3/\text{lbm}$$

Step 3 of 7

At the final state, the water occupies two times the initial volume, then,

$$v_2 = 2v_1$$

$$= 2\times 0.75$$

$$v_2 = 1.5\,\text{ft}^3/\text{lbm}$$

Step 4 of 7

At $T_2 = 300\text{F}$ from saturated water tables

$v_f = 0.01745\text{ft}^3/\text{lbm}$

$v_g = 6.4663\text{ft}^3/\text{lbm}$

And $v_f < v_2 < v_g$ the state is in wet region

So the final pressure

$P_2 = P_{sat} = 67.028\text{psia}$

$\boxed{P_2 = 67.028\,\text{psia}}$

Step 5 of 7

$$v_2 = v_f + x_2(v_g - v_f)$$

$$1.5 = 0.01745 + x_2(6.4663 - 0.01745)$$

$$x_2 = 0.2298$$

Step 6 of 7

Specific Internal energy at final state

$$u_2 = u_{f@300F} + x_2 u_{fg@300F}$$

$$u_2 = 269.51 + 0.2298\times 830.25$$

$$u_2 = 460.301\,\text{btu/lbm}$$

Step 7 of 7

Internal energy at final state

$$U_2 = mu_2$$

$$U_2 = 2\times 460.301$$

$$\boxed{U_2 = 920.602\,\text{btu}}$$

Question: 4.035P

A 9-m3 container is filled with 300 kg of R-134a at 10°C. What is the specific enthalpy of the R-134a in the container?

Step 1 of 4

Given

Mass of R-134a $m = 300\text{kg}$

Volume of the container $V = 9\text{m}^3$

Temperature of R-134a $T = 10°\text{C}$

Step 2 of 4

Specific volume

$$v = \frac{V}{m}$$

$$v = \frac{9}{300}$$

$$v = 0.03\text{m}^3/\text{kg}$$

Step 3 of 4

At $T = 10°\text{C}$ from saturated R-134a tables

$v_f = 0.0007930\text{m}^3/\text{kg}$

$v_g = 0.049403\text{m}^3/\text{kg}$

We know

$$v = v_f + x(v_g - v_f)$$

$$0.03 = 0.0007930 + x \times (0.049403 - 0.0007930)$$

$$x = 0.601$$

Step 4 of 4

Specific enthalpy of R-134a in the container

$$h = h_{f@10C} + xh_{fg@10C}$$

$$= 65.43 + (0.601 \times 190.73)$$

$$\boxed{h = 180.06\text{ kJ/kg}}$$

Question: 4.036P

Refrigerant-134a at 200 kPa and 25°C flows through a refrigeration line. Determine its specific volume.

Step 1 of 1

At $P_1 = 200\text{kPa}$ from saturated R-134a tables

$$T_{sat} = -10.09^{\circ}\text{C}$$

And the given temperature 25°C is greater than the saturation temperature so the fluid is in superheated state.

Obtain specific value at given state using interpolation between two values.

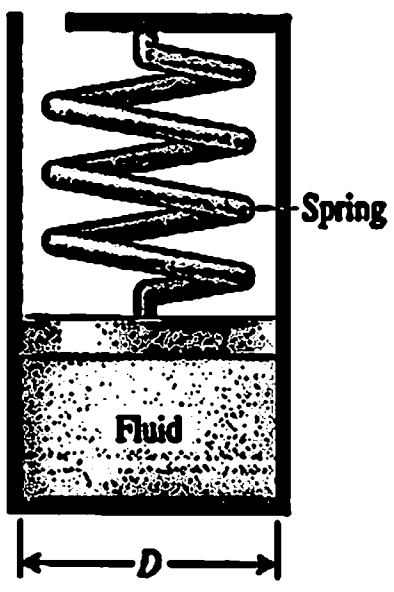
$$v = 0.11418 + (0.11874 - 0.11418)\left(\frac{25-20}{30-20}\right)$$

$$= 0.11646\,\text{m}^3/\text{kg}$$

Therefore, the specific volume of the refrigerant at $200\,\text{kPa}, 25^{\circ}\text{C}$ is $\boxed{0.11646\,\text{m}^3/\text{kg}}$.

Question: 4.037P pg 1

A spring-loaded piston-cylinder device is initially filled with 0.2 lbm of an R-134a liquid-vapor mixture whose temperature is −30°F and whose quality is 80 percent. The spring constant in the spring force relation $F = kx$ is 37 lbf/in, and the piston diameter is 12 in. The R-134a undergoes a process that increases its volume by 40 percent. Calculate the final temperature and enthalpy of the R-134a.



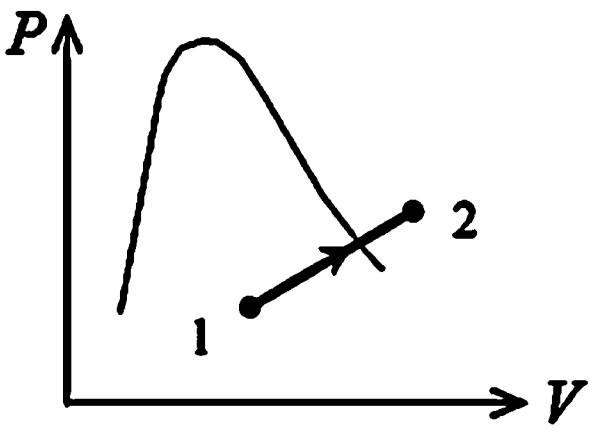


FIGURE P4–37E

Step 1 of 7

Draw the *p-v* diagram for the process.

Step 2 of 7

Calculate specific volume at state1 using the following relation.

$$v_1 = v_f + x_1\left(v_g - v_f\right) \quad \text{..... (1)}$$

Here, specific volume at state 1 is v_1 and quality of steam at state 1 is x_1 .

Obtain the values of specific volume of fluid and gas for R-134a from Table

A-16E, "Properties of saturated refrigerant-134a" in the text book at $\left(T_1 = -30^\circ\text{F}\right)$.

Specific volume of fluid, $v_f = 0.01143\ \text{ft}^3/\text{lbm}$.

Specific volume of gas, $v_g = 4.4300\ \text{ft}^3/\text{lbm}$

Substitute $0.01143\ \text{ft}^3/\text{lbm}$ for v_f , $4.4300\ \text{ft}^3/\text{lbm}$ for v_g , and 0.80 for x_1 in equation (1) .

$$\begin{aligned} v_1 &= 0.01143 + (0.80)(4.4300 - 0.01143) \\ &= 3.5463\ \text{ft}^3/\text{lbm} \end{aligned}$$

Step 3 of 7

Obtain the value of saturated pressure at temperature $\left(T_1 = -30^\circ\text{C}\right)$ from Table

A-16E, "Properties of saturated refrigerant-134a" in the text book.

$$\begin{aligned} P_1 &= P_{sat} \\ &= 9.9\ \text{psia} \end{aligned}$$

Calculate the volume of refrigerant at state1 using the following relation.

$$V_1 = mv_1$$

Substitute $0.2\ \text{lbm}$ for m and $3.5463\ \text{ft}^3/\text{lbm}$ for v_1 .

$$\begin{aligned} V_1 &= (0.2)(3.5463) \\ &= 0.7093\ \text{ft}^3 \end{aligned}$$

Since the volume is increased by 40% , calculate the volume at state 2 from the following relation.

$$V_2 = 1.4V_1$$

Substitute $0.7093\ \text{ft}^3$ for V_1 .

$$\begin{aligned} V_2 &= 1.4(0.7093) \\ &= 0.9930\ \text{ft}^3 \end{aligned}$$

Step 4 of 7

Calculate the distance that the piston moves between the initial and final conditions using the following relation.

$$\Delta x = \frac{\Delta V}{A_p}$$

Here, change in volume is ΔV , area of the piston is A_p , and displacement of the piston is Δx .

$$\begin{aligned} \Delta x &= \frac{\Delta V}{A_p} \\ &= \frac{(V_2 - V_1)}{\pi D^2/4} \end{aligned}$$

Substitute $0.9930\ \text{ft}^3$ for V_2 , $0.7093\ \text{ft}^3$ for V_1 and $1\ \text{ft}$ for D in the equation and calculate the displacement of the piston.

$$\begin{aligned} \Delta x &= \frac{(0.9930 - 0.7093)}{\frac{\pi(1)^2}{4}} \\ &= 0.3612\ \text{ft} \end{aligned}$$

$$\Delta x = \frac{(0.9930-0.7093)}{\frac{\pi(1)^2}{4}}$$
$$= 0.3612 \text{ ft}$$

Step 5 of 7

Calculate the pressure difference between the initial and final states from the following relation.

$$\Delta P = \frac{\Delta F}{A_p}$$
$$= \frac{k\Delta x}{A_p}$$
$$= \frac{k\Delta x}{\pi D^2/4}$$

Substitute 37 lbf/in for k, (0.3612×12) ft for Δx and 12 in. for D in the equation.

$$\Delta P = \frac{(37 \text{ lbf/in})(0.3612\times12 \text{ in})}{\left(\frac{\pi(12 \text{ in})^2}{4}\right)}$$
$$= 1.418 \text{ lbf/in}^2$$
$$= 1.418 \text{ psia}$$

Step 6 of 7

Calculate the final pressure using the following relation.

$$P_2 = P_1 + \Delta P$$

Substitute 9.9 psia for P_1 and 1.418 psia for ΔP.

$$P_2 = 9.9 + 1.418$$
$$= 11.318 \text{ psia}$$

Calculate the specific volume at state 2 using the following relation.

$$v_2 = \frac{V_2}{m}$$

Here, specific volume at state 2 is v_2.

Substitute 0.9930 ft^3 for V_2 and 0.2 lbm for m.

$$v_2 = \frac{0.9930}{0.2}$$
$$= 4.965 \text{ ft}^3/\text{lbm}$$

Step 7 of 7

Obtain the following properties of R-134a from Table A-13E, "Superheated refrigerant-134a" in the text book at a pressure of $(p_2 = 11.318 \text{ psia})$ and specific volume of $(v_2 = 4.965 \text{ ft}^3/\text{lbm})$.

Temperature, $T_2 = 81.5°\text{F}$.

Specific enthalpy, $h_2 = 120 \text{ Btu/lbm}$

Therefore, the final temperature is $\boxed{81.5°\text{F}}$ and final enthalpy is $\boxed{120 \text{ Btu/lbm}}$.

Question: 4.038P

One pound-mass of water fills a 2.4264.ft3 weighted piston-cylinder device at a temperature of 600°F. The piston-cylinder device is now cooled until its temperature is 200°F. Determine the final pressure of water, in psia, and the volume, in ft3.

Step 1 of 4

Find the specific volume using the following relation:

$$v_1 = \frac{V_1}{m}$$

Here, volume of the piston is V_1 and mass of the water is m.

Substitute $2.4264\,\text{ft}^3$ for V_1 and 1 lbm for m in the equation.

$$\begin{aligned} v_1 &= \frac{V_1}{m} \\ &= \frac{2.4264}{1} \\ &= 2.4264\ \text{ft}^3/\text{lbm} \end{aligned}$$

Step 2 of 4

Since the specific volume obtained is greater than gaseous and liquid state, this initial stage is under superheated conditions. So, form the superheated water table, at a temperature of $600°\text{F}$ and specific volume of $2.4264\text{ft}^3/\text{lbm}$, pressure is found to be $250\ \text{psia}$.

Step 3 of 4

Since this is a constant pressure process, $P_1 = P_2 = 250\text{psia}$

Step 4 of 4

From the saturated water table, the saturation temperature at pressure 250 psia is $400.97°\text{F}$.

Since the saturation temperature is greater than the final temperature $(T_2 = 200°\text{F})$, this stage is in compressed region.

The final volume will approximately be equal to the following value at $T_2 = 200°\text{F}$ from saturated water table.,

$$v_2 = v_f = 0.01663\ \text{ft}^3/\text{lbm}$$

Therefore, the final pressure is obtained as $\boxed{250\ \text{psia}}$.

The final volume is $\boxed{0.01663\ \text{ft}^3/\text{lbm}}$.

Question: 4.039P

Ten kilograms of R-134a fill a 1.595-m3 weighted piston-cylinder device at a temperature of −26.4°C. The container is now heated until the temperature is 100°C. Determine the final volume of the R-134a.

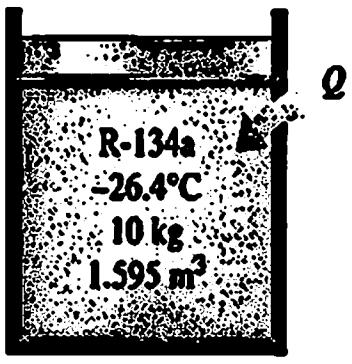

FIGURE P4–39

Step 1 of 2

The values of specific volume of saturated liquid (v_f) and specific volume of saturated vapor (v_g) at T = -26.4 °C lie in the range of values of specific volume of above two temperatures. We can see that the given value, v = 0.1595 m^3/kg lies in between the values of v_f and v_g. Hence we have saturated liquid-vapor mixture and the mixture pressure is the saturation pressure at that temperature which is determined by interpolation from Table-11

We have,

At T_A = -28 °C

P_{Asat} = 92.76 kPa

At T_B = -26 °C

P_{Bsat} = 101.73 kPa

By interpolation, we have

$$\frac{T-T_{Asat}}{T_{Bsat}-T_{Asat}} = \frac{P_{sat}-P_{Asat}}{P_{Bsat}-P_{Asat}}$$

$$\frac{-26.4+28}{-26+28} = \frac{P_{sat}-92.76}{101.73-92.76}$$

Therefore, $P_1 = P_{sat} = 100$ kPa

Step 2 of 2

As this is a constant-pressure process, $P_2 = P_1 = 100$ kPa.

In the final case, the temperature and pressure are given, but again we do not know whether we have saturated mixture, compressed liquid or superheated vapor. To determine the region we are in, we go the saturation refrigerant-134a-pressure table (Table A-12) and determine the saturation temperature at the given pressure.

We have,

For P =100 kPa, T_{sat} = -26.37 °C

if $T < T_{sat\ @\ given\ P}$ we have compressed liquid

if $T = T_{sat\ @\ given\ P}$ we have saturated mixture

if $T > T_{sat\ @\ given\ P}$ we have superheated vapor.

In our case, the given T value is 100 °C, which is greater than the T_{sat} value at the given pressure. Therefore, we have superheated vapor. From the superheated refrigerant-134a table (Table A-13)

At P_2 = 0.100 MPa and temperature T_2= 100 °C

$v_A = 0.30138\ m^3/kg$

Final specific volume, $v_2 = 0.30138\ m^3/kg$ (approximately)

Therefore, final volume,. $V_2 = 10 \times 0.30138$

$$V_2 = m \times v_2$$

$$\boxed{V_2 = 3.0138\ m^3}$$

Question: 4.040P

One pound-mass of water fills a container whose volume is 2 ft3. The pressure in the container is 100 psia. Calculate the total internal energy and enthalpy in the container.

Step 1 of 4

Given

Mass of water inside the container, $m = 1$ lbm

Volume of the container, $V = 2\ ft^3$

Pressure inside the container, $P = 100$ psia

Step 2 of 4

Specific volume, $v = \frac{V}{m}$

Therefore, $v = 2\ ft^3/lbm$

Hers, the state is defined by pressure and specific volume. We do not know which table to use to determine the missing properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the specific volume of saturated liquid (v_f) and specific volume of saturated vapor (v_g) from the saturated water – pressure table (Table A-5E).

Therefore, at $P = 100$ psia

$v_f = 0.01774\ ft^3/lbm$

$v_g = 4.4327\ ft^3/lbm$

Thus, the given value $v = 2\ ft^3$ lies in between the values of v_f and v_g. Hence we have saturated liquid-vapor mixture. The quality of the mixture is given by

$$x = \frac{v - v_f}{v_g - v_f}$$

$$x = \frac{2 - 0.01774}{4.4327 - 0.01774}$$

$$x = 0.4489$$

Step 3 of 4

At $P = 100$ psia from Table A-5E

we have,

$u_f = 298.19$ Btu/lbm

$u_{fg} = 807.29$ Btu/lbm

Hence, the internal energy of this quality mixture is

$u = u_f + (x * u_{fg})$

$u = 298.19 + (0.4489 * 807.29)$

$u = 660.58$ Btu/lbm

Therefore, total internal energy in the container is

$U = m \times u = 1 \times 660.58$

$\boxed{U = 660.58\ \text{Btu.}}$

Step 4 of 4

At $P = 100$ psia from Table A-5E

we have,

$h_f = 298.51$ Btu/lbm

$h_{fg} = 888.99$ Btu/lbm

Hence, the enthalpy of this quality mixture is

$h = h_f + (x \times h_{fg})$

$h = 298.51 + (0.4489 \times 888.99)$

$h = 697.58$ Btu/lbm

Therefore, total enthalpy in the container is

$H = m \times u = 1 \times 697.58$

$\boxed{H = 697.58\ \text{Btu.}}$

4.041P

Question:

Three kilograms of water in a container have a pressure of 100 kPa and temperature of 250°C. What is the volume of this container?

Step 1 of 4

Given

Mass of water $m = 3\text{kg}$

Pressure $P = 100\text{kPa}$

Temperature $T = 250°\text{C}$

Step 2 of 4

At $P = 100\text{kPa}$ from saturated water tables

$T_{sat} = 99.61^0\text{C}$

And given temperature $T > T_{sat}$ and the given state is in superheated state.

Question:

Three kilograms of water in a container have a pressure of 100 kPa and temperature of 250°C. What is the volume of this container?

Question: 4.042P pg 1

10-kg of R-134a at 300 kPa fills a rigid container whose volume is 14 L. Determine the temperature and total enthalpy in the container. The container is now heated until the pressure is 600 kPa. Determine the temperature and total enthalpy when the heating is completed.

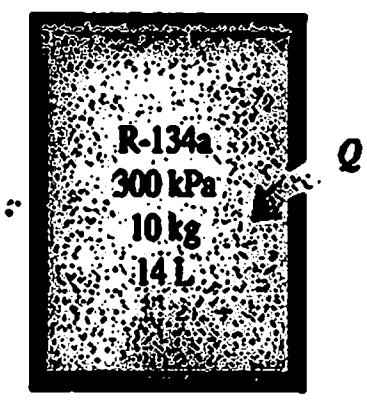

FIGURE P4–42

Question:

10-kg of R-134a at 300 kPa fills a rigid container whose volume is 14 L. Determine the temperature and total enthalpy in the container. The container is now heated until the pressure is 600 kPa. Determine the temperature and total enthalpy when the heating is completed.

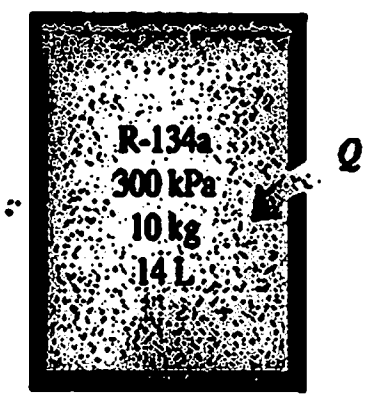

FIGURE P4–42

Step 1 of 12

At $P_B = 320$ kPa

$v_{fB} = 0.0007772\ m^3/kg$

$v_{gB} = 0.063604\ m^3/kg$

By interpolation,

$$\frac{v_f - v_{fA}}{v_{fB} - v_{fA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{v_f - 0.0007699}{0.0007772 - 0.0007699} = \frac{300 - 280}{320 - 280}$$

Step 4 of 12

Therefore, specific volume of saturated liquid at $P = 300$ kPa is $v_f = 0.0007735\ m^3/kg$

Similarly, by interpolation

$$\frac{v_g - v_{gA}}{v_{gB} - v_{gA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{v_g - 0.072352}{0.063604 - 0.072352} = \frac{300 - 280}{320 - 280}$$

Therefore, specific volume of saturated vapor at $P = 300$ kPa, $v_g = 0.067978\ m^3/kg$

Step 5 of 12

Hence, we can see that the given value, $v = 0.0014\ m^3/kg$ lies in between the values of v_f and v_g. Thus, we have saturated liquid-vapor mixture and the temperature is the saturation temperature at the given pressure which can be obtained from interpolation.

At $P_A = 280$ kPa

At $P_B = 320$ kPa

$v_{fB} = 0.0007772\ m^3/kg$

$v_{gB} = 0.063604\ m^3/kg$

By interpolation,

$$\frac{v_f - v_{fA}}{v_{fB} - v_{fA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{v_f - 0.0007699}{0.0007772 - 0.0007699} = \frac{300 - 280}{320 - 280}$$

Step 4 of 12

Therefore, specific volume of saturated liquid at $P = 300$ kPa is $v_f = 0.0007735\ m^3/kg$

Similarly, by interpolation

$$\frac{v_g - v_{gA}}{v_{gB} - v_{gA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{v_g - 0.072352}{0.063604 - 0.072352} = \frac{300 - 280}{320 - 280}$$

Therefore, specific volume of saturated vapor at $P = 300$ kPa, $v_g = 0.067978\ m^3/kg$

Step 5 of 12

Hence, we can see that the given value, $v = 0.0014\ m^3/kg$ lies in between the values of v_f and v_g. Thus, we have saturated liquid-vapor mixture and the temperature is the saturation temperature at the given pressure which can be obtained from interpolation.

At $P_A = 280$ kPa

The values of h_f and h_g at given pressure can be determined by interpolation, from the table.

At $P_A = 280$ kPa

$h_{fA} = 50.18$ kJ/kg

$h_{fgA} = 199.54$ kJ/kg

At $P_B = 320$ kPa

$h_{fB} = 55.16$ kJ/kg

$h_{fgB} = 196.71$ kJ/kg

By interpolation

$$\frac{h_f - h_{fA}}{h_{fB} - h_{fA}} = \frac{P - P_A}{P_B - P_A}$$

$h_{fgA} = 199.54$ kJ/kg

At $P_B = 320$ kPa

$h_{fB} = 55.16$ kJ/kg

$h_{fgB} = 196.71$ kJ/kg

By interpolation

$$\frac{h_f - h_{fA}}{h_{fB} - h_{fA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{h_f - 50.18}{55.16 - 50.18} = \frac{300 - 280}{320 - 280}$$

Therefore, enthalpy of saturated liquid, $h_f = 52.67$ kJ/kg

Step 8 of 12

Similarly,

$$\frac{h_{fg} - h_{fgA}}{h_{fgB} - h_{fgA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{h_{fg} - 199.54}{196.71 - 199.54} = \frac{300 - 280}{320 - 280}$$

Therefore, $h_{fg} = 198.125$ kJ/kg

Step 9 of 12

The values of h_f and h_{fg} at given pressure can be determined by interpolation, from the table.

At $P_A = 280$ kPa

$h_{fA} = 50.18$ kJ/kg

$h_{fgA} = 199.54$ kJ/kg

At $P_B = 320$ kPa

$h_{fB} = 55.16$ kJ/kg

$h_{fgB} = 196.71$ kJ/kg

By interpolation

$$\frac{h_f - h_{fA}}{h_{fB} - h_{fA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{h_f - 50.18}{55.16 - 50.18} = \frac{300 - 280}{320 - 280}$$

Therefore, enthalpy of saturated liquid, $h_f = 52.67$ kJ/kg

Step 8 of 12

Similarly,

$$\frac{h_{fg} - h_{fgA}}{h_{fgB} - h_{fgA}} = \frac{P - P_A}{P_B - P_A}$$

$$\frac{h_{fg} - 199.54}{196.71 - 199.54} = \frac{300 - 280}{320 - 280}$$

Therefore, $h_{fg} = 198.125$ kJ/kg

Step 9 of 12

Substituting, the values of h_f and h_{fg} in equation (1), we have

$$h = 52.67 + (0.009322 \times 198.125)$$

Therefore, $h = 54.517$ kJ/kg

Total enthalpy, $H = m \times h$

$H = 10 \times 54.517$

$\boxed{H = 545.17 \text{ kJ}}$

Step 10 of 12

As the container is rigid, the specific volume remains the same throughout the process.

Hence the final specific volume, $v = 0.0014$ m^3/kg

The final state is defined by pressure and specific volume. We do not know which table to use to determine the missing properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the specific volume of saturated liquid (v_f) and specific volume of saturated vapor (v_g) from the saturated refrigerant-134a-pressure table

At $P = 600$ kPa

$v_f = 0.0008199$ m^3/kg

$v_g = 0.034295$ m^3/kg

Hence, we can see that the given value, $v = 0.0014$ m^3/kg lies in between the values of v_f and v_g. Thus, we have saturated liquid-vapor mixture and the temperature is the saturation temperature at the given pressure.

Therefore, $T_2 = T_{sat\,@\,600\,kPa} = 21.55\,^{\circ}C$

Final temperature, $\boxed{T_2 = 21.55^{0}C}$

Question: 4.043P

100-kg of R-134a at 200 kPa are contained in a piston-cylinder device whose volume is 12.322 m3. The piston is now moved until the volume is one-half its original size. This is done such that the pressure of the R-134a does not change. Determine the final temperature and the change in the total internal energy of the R-134a.

Step 1 of 5

Given

Mass of R-134a in the piston cylinder device, $m = 100\ kg$

This is constant pressure process

Pressure inside the device, $P = 200\ kPa$

Initial volume, $V_1 = 12.322\ m^3$

Final volume, $V_2 = 0.5 \times V_1$

$$V_2 = 6.161 m^3$$

Question:

100-kg of R-134a at 200 kPa are contained in a piston-cylinder device whose volume is 12.322 m3. The piston is now moved until the volume is one-half its original size. This is done such that the pressure of the R-134a does not change. Determine the final temperature and the change in the total internal energy of the R-134a.

Step 1 of 5

Given

Mass of R-134a in the piston cylinder device, $m = 100\ kg$

This is constant pressure process

Pressure inside the device, $P = 200\ kPa$

Initial volume, $V_1 = 12.322\ m^3$

Final volume, $V_2 = 0.5 \times V_1$

$$V_2 = 6.161 m^3$$

Step 2 of 5

At $P = 200\ kPa$

$v_f = 0.0007533\ m^3/kg$

$v_g = 0.099867\ m^3/kg$

We can see that, the final specific volume $v_2 = 0.06161\ m^3/kg$ lies between the values of v_f and v_g at given pressure. Thus, we have saturated liquid-vapor mixture and the temperature of the mixture is the saturation temperature at that pressure, which can be obtained from saturated refrigerant-134a-pressure table.

Therefore, final temperature, $\boxed{T_2 = T_{sat}@200\ kPa = -10.09°C}$

Step 4 of 5

The quality (x) of the mixture can be obtained from

$$v_2 = v_f + x \times (v_g - v_f)$$

Therefore, $x = \dfrac{v_2 - v_f}{v_g - v_f}$

$$x = \frac{0.06161 - 0.0007533}{0.099867 - 0.0007533}$$

$$x = 0.614$$

Step 5 of 5

The internal energy of the final mixture can be obtained from

$$u_2 = u_f + (x \times u_{fg}) \text{ ---- (1)}$$

The values of u_f and u_{fg} at given pressure can be obtained from the table

At $P = 200\ kPa$

At $P = 200\ kPa$

$v_f = 0.0007533\ m^3/kg$

$v_g = 0.099867\ m^3/kg$

We can see that, the final specific volume $v_2 = 0.06161\ m^3/kg$ lies between the values of v_f and v_g at given pressure. Thus, we have saturated liquid-vapor mixture and the temperature of the mixture is the saturation temperature at that pressure, which can be obtained from saturated refrigerant-134a-pressure table.

Therefore, final temperature, $\boxed{T_2 = T_{sat}@200\ kPa = -10.09°C}$

Step 4 of 5

The quality (x) of the mixture can be obtained from

Question: 4.044P

Water initially at 300 kPa and 250°C is contained in a piston-cylinder device fitted with stops. The water is allowed to cool at constant pressure until it exists as a saturated vapor and the piston rests on the stops. Then the water continues to cool until the pressure is 100 kPa. On the *T*-v diagrams sketch, with respect to the saturation lines, the process curves passing through both the initial, intermediate, and final states of the water. Label the *T*, *P*, and v values for end states on the process curves. Find the overall change in internal energy between the initial and final states per unit mass of water.

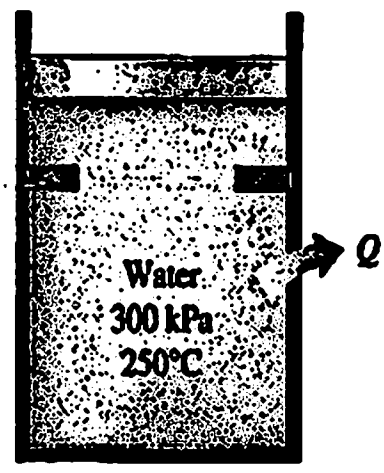

FIGURE P4–44

Question:

Water initially at 300 kPa and 250°C is contained in a piston-cylinder device fitted with stops. The water is allowed to cool at constant pressure until it exists as a saturated vapor and the piston rests on the stops. Then the water continues to cool until the pressure is 100 kPa. On the *T*-v diagrams sketch, with respect to the saturation lines, the process curves passing through both the initial, intermediate, and final states of the water. Label the *T*, *P*, and v values for end states on the process curves. Find the overall change in internal energy between the initial and final states per unit mass of water.

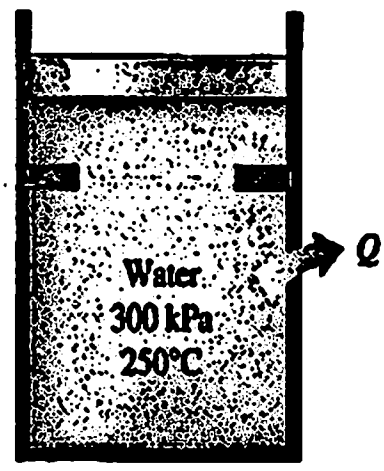

FIGURE P4–44

$0.0030 = 0.001043 + x_3 \times 1.03303$

$x_3 = 0.35719$

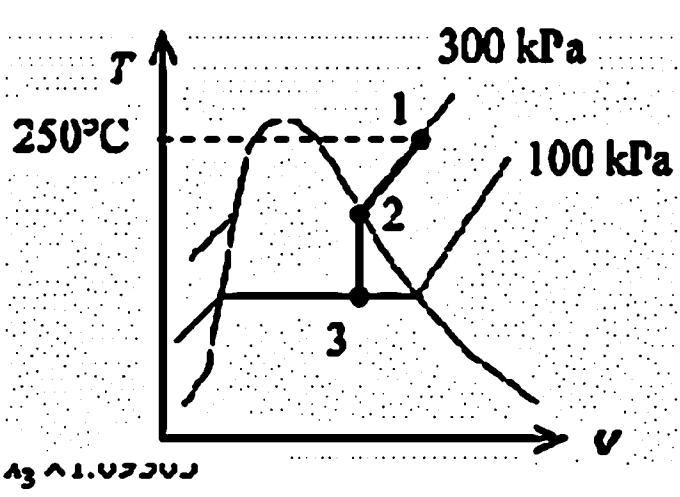
Then internal energy at state 3 is

$u_3 = u_f + x_3 u_{fg}$

$u_3 = 417.40 + 0.35719 \times 2088.2$

$u_3 = 1163.3\ \text{kJ/kg}$

Step 4 of 5



The overall change in internal energy is

$\Delta u = u_1 - u_3$

$= 2728.9 - 1163.3$

$\boxed{\Delta u = 1566\ \text{kJ/kg}}$

Step 5 of 5

$0.0030 = 0.001043 + x_3 \times 1.03303$

$x_3 = 0.35719$

Then internal energy at state 3 is

Question:

4.045P

The atmospheric pressure at a location is usually specified at standard conditions, but it changes with the weather conditions. As the weather forecasters frequently state, the atmospheric pressure drops during stormy weather and it rises during clear and sunny days. If the pressure difference between the two extreme conditions is given to be 0.2 in of mercury, determine how much the boiling temperatures of water will vary as the weather changes from one extreme to the other.

Step 1 of 2

The saturation pressure of water at 200°F is 11.538 psia
The saturation pressure of water at 212°F is 14.709 psia
One inch of mercury is equivalent to 0.491 psia
Hence the change of 0.2 in of mercury in atmospheric pressure corresponds to

$$\Delta P = (0.2)(0.491)$$
$$= 0.0982 \text{ psia}$$

At about boiling temperature the change in boiling temperature per 1 psia change in pressure is determined using data at 200°F and 212°F to be

$$\frac{\Delta T}{} = \frac{(212-200)}{}$$

Question:

The atmospheric pressure at a location is usually specified at standard conditions, but it changes with the weather conditions. As the weather forecasters frequently state, the atmospheric pressure drops during stormy weather and it rises during clear and sunny days. If the pressure difference between the two extreme conditions is given to be 0.2 in of mercury, determine how much the boiling temperatures of water will vary as the weather changes from one extreme to the other.

Step 1 of 2

$$\Delta P \quad (14.709-11.538)$$
$$= 3.783°\text{F/psia}$$

Step 2 of 2

Then the change in saturation (boiling) temperature corresponding to a change of 0.0982 psia becomes

$$\Delta T_{boiling} = (3.783)\Delta P$$
$$= (3.783)(0.0982)$$
$$= 0.03715°\text{F}$$

The calculated temperature difference value is very small; therefore the effect of variation of atmospheric pressure on the boiling pressure on the boiling temperature is negligible.

Question:

4.046P

A person cooks a meal in a 30-cm-diameter pot that is covered with a well-fitting lid and lets the food cool to the room temperature of 20°C. The total mass of the food and the pot is 8 kg. Now the person tries to open the pan by lifting the lid up. Assuming no air has leaked into the pan during cooling, determine if the lid will open or the pan will move up together with the lid.

Step 1 of 3

Given data:

Diameter of the pot, $D = 30\text{cm}$

Room temperature of the food, $T_1 = 20°\text{C}$

Total mass of the food and the pot, $m = 8\text{kg}$

Step 2 of 3

Let the reaction force on the lid is F due to the cooling.

Pressure in the pot $P_p = 1\text{atm} = 1.0325\text{bar}$

Area of the pot is

Question:

A person cooks a meal in a 30-cm-diameter pot that is covered with a well-fitting lid and lets the food cool to the room temperature of 20°C. The total mass of the food and the pot is 8 kg. Now the person tries to open the pan by lifting the lid up. Assuming no air has leaked into the pan during cooling, determine if the lid will open or the pan will move up together with the lid.

Step 1 of 3

Given data:

Diameter of the pot, $D = 30\text{cm}$

Room temperature of the food, $T_1 = 20°\text{C}$

Total mass of the food and the pot, $m = 8\text{kg}$

Step 2 of 3

Let the reaction force on the lid is F due to the cooling.

Pressure in the pot $P_p = 1\text{atm} = 1.0325\text{bar}$

Area of the pot is

$$A_p = \frac{\pi D^2}{4}$$

$$= \frac{\pi(0.3)^2}{4}$$

$$= 0.071\text{m}^2$$

By the force balance equation

Force in the pot due to the pressure is equal to the force on the pot due to the atmosphere.

So,

$$P_p A_p + F = P_{atm} A_p$$

$$F = A_p (P_{atm} - P_p)$$

$$W = mg$$

$$= 8 \times 9.81$$

$$= 78.48\text{N}$$

Therefore, weight of the food and pot, $\boxed{W = 78.48\text{N}}$

Hence,

The reaction force on the lid is far greater than the weight of the food and pot.

So, the pan will move up together with the lid when the person attempts to open the pan by lifting the lid up.

Question: 4.047P

Water is boiled at 1 atm pressure in a 25-cm-internal-diameter stainless steel pan on an electric range. If it is observed that the water level in the pan drops by 10 cm in 45 min, determine the rate of heat transfer to the pan.

Step 1 of 5

Given

Pressure at which water is boiled, $P = 1\ atm = 101.325\ kPa$

Diameter of pan, $d = 25\ cm = 0.25\ m$

The drop in water level due to evaporation, $h = 10\ cm = 0.1\ m$

Time taken, $t = 45\ min$

Step 2 of 5

Water in the pan is in the state of saturated liquid-vapor mixture at 1 atm pressure and thus at saturation temperature of 99.97 °C (from Table A-5)

The rate of heat transfer ($\dot{Q}$) to the pan for water to evaporate is given by

$$\dot{Q} = \dot{m} h_{fg} \qquad \text{----- (1)}$$

Where $\dot{m}$ = the rate of evaporation of water, kg/s

h_{fg} = enthalpy of evaporation at 1 atm pressure

= 2256.5 kJ/kg (from Table)

Step 3 of 5

Volume of water evaporated in 45 min is

V_{evap} = Area of the pan × drop in water level

$$V_{evap} = A \times h$$

$$V_{evap} = \frac{\pi}{4} d^2 \times h$$

$$V_{evap} = \frac{\pi}{4} \times 0.25^2 \times 0.1$$

$$V_{evap} = 0.00491\ m^3$$

Step 4 of 5

The mass of water evaporated can be obtained from

$$m = \frac{V_{evap}}{v_f}$$

where v_f = specific volume of saturated liquid at 1 atm pressure from table A-5, at $P = 1\ atm = 101.325\ kPa$

specific volume of saturated liquid, $v_f = 0.001043\ m^3/kg$

therefore,

$$m = \frac{0.00491}{0.001043}$$

$$= 4.7075\ kg$$

Rate of evaporation is given by

$$\dot{m} = \frac{\text{mass of water evaporated}}{\text{time taken for evaporation}}$$

$$\dot{m} = \frac{4.7075}{45 \times 60}$$

$$\dot{m} = 0.001743\ kg/s$$

Step 5 of 5

Therefore, from equation (1), rate of heat transfer is

$$\dot{Q} = 0.001743 \times 2256.5$$

$$\dot{Q} = 3.933\ kJ/s$$

$$\boxed{\dot{Q} = 3.933\ kW}$$

Question: 4.048P

Repeat Prob. 4–47 for a location at 2000-m elevation where the standard atmospheric pressure is 79.5 kPa.

Step 1 of 5

Given

Atmospheric pressure at 2000 m elevation, $P = 79.5$ kPa

Diameter of pan, $d = 25$ cm $= 0.25$ m

Drop in water level, $h = 10$ cm $= 0.1$ m

Time taken, $t = 45$ min

Step 2 of 5

The properties of water at pressure $P = 79.5$ kPa are obtained from saturated water-pressure table (Table A-5) by interpolation.

We have

At $P_1 = 75$ kPa

$v_{f1} = 0.001037\ m^3/kg$

$h_{fg1} = 2278.0$ kJ/kg

At $P_2 = 100$ kPa

$v_{f2} = 0.001043\ m^3/kg$

$h_{fg2} = 2257.5$ kJ/kg

By interpolation

$$\frac{v_f - v_{f1}}{v_{f2} - v_{f1}} = \frac{P - P_1}{P_2 - P_1}$$

$$\frac{v_f - 0.001037}{0.001043 - 0.001037} = \frac{79.5 - 75}{100 - 75}$$

Specific volume of saturated liquid at 79.5 kPa, $v_f = 0.001038\ m^3/kg$

Similarly

$$\frac{h_{fg} - h_{fg1}}{h_{fg2} - h_{fg1}} = \frac{P - P_1}{P_2 - P_1}$$

$$\frac{h_{fg} - 2278.0}{2257.5 - 2278.0} = \frac{79.5 - 75}{100 - 75}$$

Enthalpy of evaporation at 79.5 kPa, $h_{fg} = 2274.31$ kJ/kg

Step 3 of 5

Volume of water evaporated in 45 min is

V_{evap} = Area of the pan × drop in water level

$V_{evap} = A \times h$

$$V_{evap} = \frac{\pi}{4} d^2 \times h$$

$$V_{evap} = \frac{\pi}{4} \times 0.25^2 \times 0.1$$

$$V_{evap} = 0.00491\ m^3$$

Step 4 of 5

The mass of water evaporated can be obtained from

$$m = \frac{V_{evap}}{v_f}$$

$$m = \frac{0.00491}{0.001038}$$

$$= 4.73025\ kg$$

Rate of evaporation is given by

$$\dot{m} = \frac{\text{mass of water evaporated}}{\text{time taken for evaporation}}$$

$$\dot{m} = \frac{4.73025}{45 \times 60}$$

$$\dot{m} = 0.001752\ kg/s$$

Step 5 of 5

The rate of heat transfer ($\dot{Q}$) to the pan for water to evaporate is given by

$$\dot{Q} = \dot{m} h_{fg}$$

$$\dot{Q} = 0.001752 \times 2274.31$$

$$\dot{Q} = 3.984\ kJ/s$$

$$\boxed{\dot{Q} = 3.984\ kW}$$

Question:

4.049P

Saturated steam coming off the turbine of a steam power plant at 40°C condenses on the outside of a 3-cm-outer-diameter, 35-m-long tube at a rate of 130 kg/h. Determine the rate of heat transfer from the steam to the cooling water flowing through the pipe.

Step 1 of 1

Take the values of enthalpy of evaporation at $T = 40°C$ from saturated water tables.

$$h_{fg} = 2406\ \text{kJ/kg}$$

Calculate the rate of heat transfer from the steam to the cooling water flowing through the pipe using the below given formula.

$$Q = \dot{m} \times h_{fg}$$

Here, the mass flow rate is $\dot{m}$.

Substitute 130 kg/hr in the equation.

$$\begin{aligned} Q &= 130 \times 2406 \\ &= 312,780\ \text{kJ/h} \\ &= 312,780 \times \frac{1}{3600}\ \text{kJ/s} \\ Q &= 86.88\ \text{kW} \end{aligned}$$

Thus, the rate of heat transfer Q is $\boxed{86.88\ \text{kW}}$.

Question: 4.050P

Water in a 5-cm-deep pan is observed to boil at 98°C. At what temperature will the water in a 40-cm-deep pan boil? Assume both pans are full of water.

Step 1 of 4

Given

Boiling temperature of water in 5 cm deep pan, $T_1 = 98\,^\circ C$

Step 2 of 4

In the first case, as the water starts boiling at 98 °C, the pressure at the bottom of the 5 cm deep pan will be the saturation pressure at that temperature (i.e., 98 °C) which can be obtained from the saturated water-temperature table.

From table we have

At $T = 95\,^\circ C$

$P_{sat} = 84.609$ kPa

At $T = 100\,^\circ C$

$P_{sat} = 101.42$ kPa

The saturation pressure at the given temperature 98 °C can be obtained by interpolating between the above two values as

$$\frac{P_{sat} - 84.609}{101.42 - 84.609} = \frac{98 - 95}{100 - 95}$$

Therefore, $P_1 = P_{sat\,@\,98^\circ C} = 94.695$ kPa

Step 3 of 4

Now, consider 40 cm deep pan.

The pressure at the bottom of 40 cm deep pan = pressure at the bottom of 5cm deep pan + pressure due to the extra height (35 cm) of water

Therefore, $P_2 = P_1 + \rho gh$

Where ρ = density of water = $1000\ kg/m^3$

h = difference in heights = 35 cm = 0.35 m

Thus,

$$P_2 = 94.695 + \frac{1000 \times 9.81 \times 0.35}{1000}\ kPa$$

$$P_2 = 98.13\ kPa$$

Step 4 of 4

Thus the boiling temperature (T_2) of water in 40 cm deep pan will be the saturation temperature at the pressure 98.13 kPa which can be obtained from the saturation water-pressure table.

From table A-5, we have

At $P = 75$ kPa

$T_{sat} = 91.76\,^\circ C$

At $P = 100$ kPa

$T_{sat} = 99.61\,^\circ C$

The saturation temperature at the given pressure 104.85 kPa can be obtained by interpolating between the above two values as

$$\frac{T_{sat} - 91.76}{99.61 - 91.76} = \frac{98.13 - 75}{100 - 75}$$

Therefore, $T_2 = T_{sat\,@}\ 104.85$ kPa

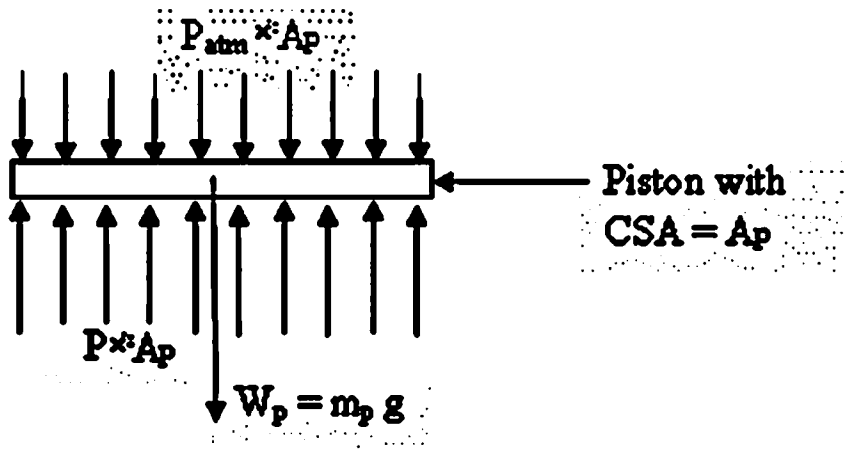
$$\boxed{T_2 = 99.022^0 C}$$

Question: 4.051P

Water is being heated in a vertical piston-cylinder device. The piston has a mass of 20 kg and a cross-sectional area of 100 cm2. If the local atmospheric pressure is 100 kPa, determine the temperature at which the water starts boiling.

Step 1 of 3

Given



Mass of piston, $m_p = 20\ kg$

Cross-sectional area of piston, $A_p = 100\ cm^2 = 0.01\ m^2$

Local atmospheric pressure, $P_{atm} = 100\ kPa$

Step 2 of 3

The pressure inside the cylinder can be obtained from a force balance on the piston as shown in the figure below

Therefore, from the force balance, we have

$$P \times A_p = (P_{atm} \times A_p) + W_p$$

where P = pressure inside the cylinder, Pa

W_P = weight of the piston = $m_p g$, N

Therefore,

$$P = P_{atm} + \frac{m_p g}{A_p}$$

$$P = \left(100 \times 10^3\right) + \frac{20 \times 9.81}{0.01}$$

$$P = 119620\ Pa$$

Pressure inside the cylinder, P = 119.62 kPa

Step 3 of 3

The temperature at which water starts boiling will be the saturation temperature at this pressure, P = 119.62 kPa which can be obtained from saturated water-pressure table (Table A-5).

From Table A-5, we have

At $P_1 = 101.325\ kPa$

$T_{1sat} = 99.97\ °C$

At $P_2 = 125\ kPa$

$T_{2sat} = 105.97\ °C$

The value of saturation temperature at the pressure 119.62 kPa can be obtained by interpolating between the above specified pressures.

By interpolation

$$\frac{T_{sat} - T_{1sat}}{T_{2sat} - T_{1sat}} = \frac{P - P_1}{P_2 - P_1}$$

$$\frac{T_{sat} - 99.97}{105.97 - 99.97} = \frac{119.62 - 101.325}{125 - 101.325}$$

Therefore, $T_{sat} = 104.60\ °C$

Hence the boiling temperature, $\boxed{T = 104.60^0 C}$.

Question: 4.052P

A rigid tank with a volume of 1.8 m3 contains 15 kg of saturated liquid–vapor mixture of water at 90°C. Now the water is slowly heated. Determine the temperature at which the liquid in the tank is completely vaporized. Also, show the process on a *T*-v diagram with respect to saturation lines.

Step 1 of 4

Given

Volume of the container $V = 1.8\,\text{m}^3$

Mass of saturated liquid vapor mixture $m = 15\,\text{kg}$

Temperature $T = 90^0\,\text{C}$

Step 2 of 4

This is a constant volume process and the specific volume is determined to be

$$v = \frac{V}{m}$$

$$= \frac{1.8}{15}$$

$$v = 0.12\,\text{m}^3/\text{kg}$$

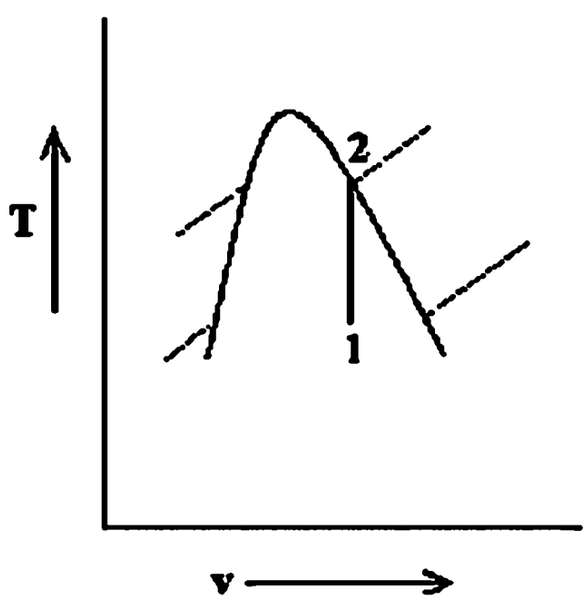
Step 3 of 4

When the liquid is completely vaporized, the tank will contain saturated vapor only

Thus,

$v_2 = v_g = 0.12\,\text{m}^3/\text{kg}$

The temperature at this point is the temperature that corresponds to this



$v_2 = v_g = 0.12\,\text{m}^3/\text{kg}$ value from saturated water tables using method of interpolation

$$T = 200 + (205 - 200)\left(\frac{0.12 - 0.12721}{0.11508 - 0.12721}\right)$$

$$\boxed{T = 202.97^\circ\text{C}}$$

Step 4 of 4

T-v diagram will be

Question: 4.053P

A piston-cylinder device contains 0.005 m3 of liquid water and 0.9 m3 of water vapor in equilibrium at 600 kPa. Heat is transferred at constant pressure until the temperature reaches 200°C.

(*a*) What is the initial temperature of the water?

(*b*) Determine the total mass of the water.

(*c*) Calculate the final volume.

(*d*) Show the process on a *P-V* diagram with respect to saturation lines.

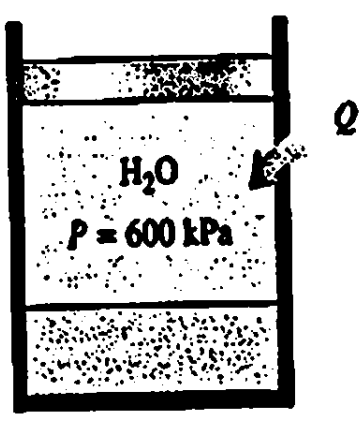


FIGURE P4–53

Step 1 of 6

(a)

Initially two phases co-exist in equilibrium, thus we have a saturated liquid vapor mixture. Then the temperature in the tank must be saturation temperature at the specified pressure.

Obtain the temperature from EES software, at 0 for quality (x) , and pressure $P = 600\ \text{kPa}$ as follows:

The saturation temperature, $T_1 = 158.8°\text{C}$

Therefore, the initial temperature of the water is, $\boxed{158.8°\text{C}}$.

Step 2 of 6

(b)

Obtain the specific volume of liquid water from EES software at pressure $600\ \text{kPa}$, and quality, 0 as follows:

The specific volume of the liquid, $v_f = 0.0011\ \text{m}^3/\text{kg}$

Calculate the mass of the liquid water.

$$m_f = \frac{V_f}{v_f}$$

Here, V_f is the volume of the saturated liquid.

Substitute $0.005\ \text{m}^3$ for V_f , and $0.0011\ \text{m}^3/\text{kg}$ for v_f .

$$m_f = \frac{0.005}{0.0011}$$
$$m_f = 4.545\ \text{kg}$$

Step 3 of 6

Obtain the specific volume of water vapor from EES software at pressure $600\ \text{kPa}$, and quality, 1 as follows:

The specific volume of the liquid, $v_g = 0.3158\ \text{m}^3/\text{kg}$

Calculate the mass of the water vapor.

$$m_g = \frac{V_g}{v_g}$$

Here, V_g is the volume of the saturated vapor.

Substitute $0.9\ \text{m}^3$ for V_g , and $0.3158\ \text{m}^3/\text{kg}$ for v_g .

$$m_g = \frac{0.9}{0.3158}$$
$$m_g = 2.849\text{kg}$$

Calculate the total mass.

$$m_t = m_f + m_g$$

Substitute $4.545\ \text{kg}$ for m_f and 2.849kg for m_g .

$$m_t = 4.545 + 2.849$$
$$= 7.394\ \text{kg}$$

Therefore, the total mass is, $\boxed{7.394\ \text{kg}}$.

Step 4 of 6

(c)

Heat is transferred at constant pressure. Hence, the pressure at state 2 is same as pressure at state 1.

$$P_2 = P_1$$
$$= 600\ \text{kPa}$$

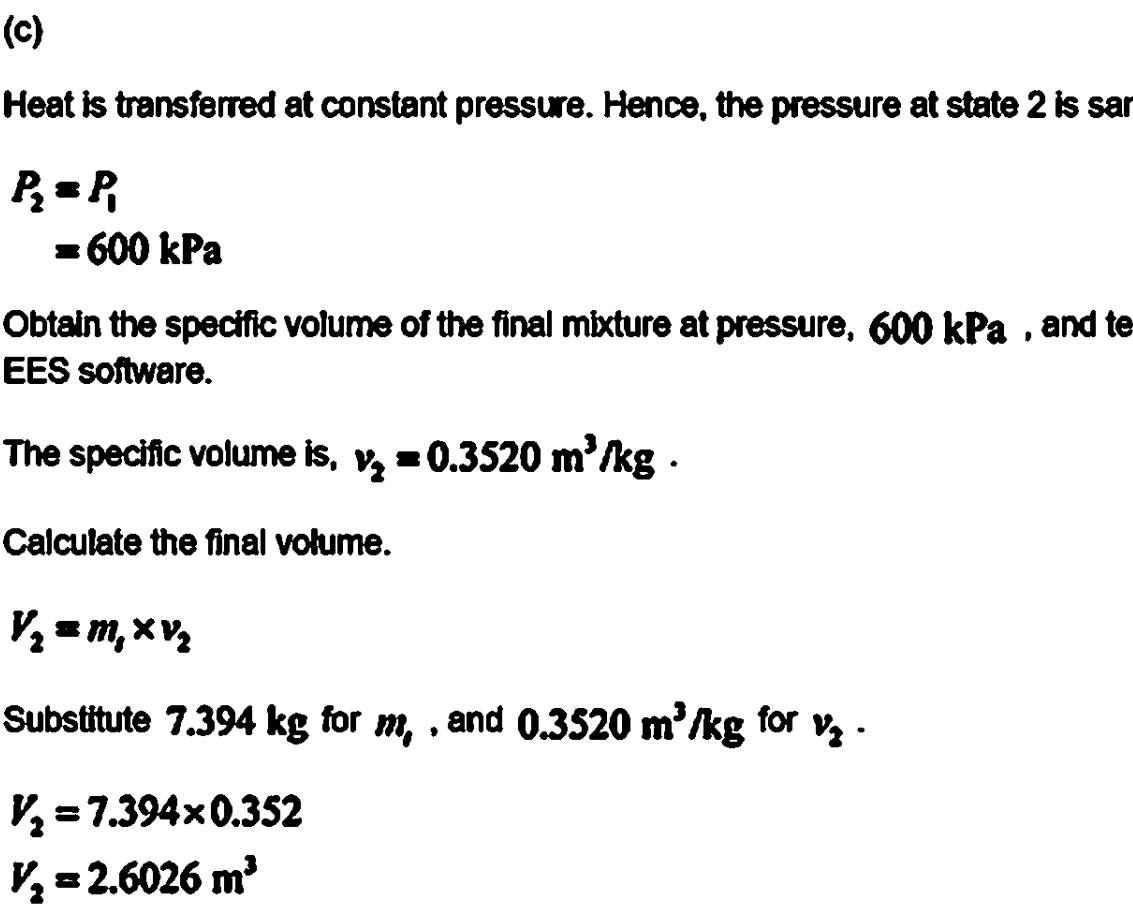
Obtain the specific volume of the final mixture at pressure, $600\ \text{kPa}$, and temperature $200°\text{C}$ from the EES software.

The specific volume is, $v_2 = 0.3520\ \text{m}^3/\text{kg}$.

Calculate the final volume.

$$V_2 = m_t \times v_2$$

Substitute $7.394\ \text{kg}$ for m_t , and $0.3520\ \text{m}^3/\text{kg}$ for v_2 .



$$V_2 = 7.394 \times 0.352$$
$$V_2 = 2.6026\ \text{m}^3$$

Therefore, the final volume is, $\boxed{2.6026\ \text{m}^3}$.

Step 5 of 6

(d)

Draw the schematic representation of process on *P-v* diagram.

Step 6 of 6

Therefore, the required process is represented on saturation lines.

Question: 4.054P

Reconsider Prob. 4–53. Using EES (or other) software, investigate the effect of pressure on the total mass of water in the tank. Let the pressure vary from 0.1 MPa to 1 MPa. Plot the total mass of water against pressure, and discuss the results. Also, show the process in Prob. 4–53 on a *P*-v diagram using the property plot feature of EES.

Step 1 of 1

4672-3-54E SA 0261

Analysis: The problem is solved using EES, and the solution is given below.

```
P[1]=600[kPa]

P[2]=P[1]

T[2]=200[C]

V_f1 = 0.005[m^3]

V_g1 = 0.9[m^3]

spvsat_f1=volume (Steam_iapws, P = P[1], x=0) "sat. liq. Specific volume, m^3/kg"

spvsat_g1=volume (Steam_iapws, P = P[1], x=1) "sat. vap. Specific volume, m^3/kg"

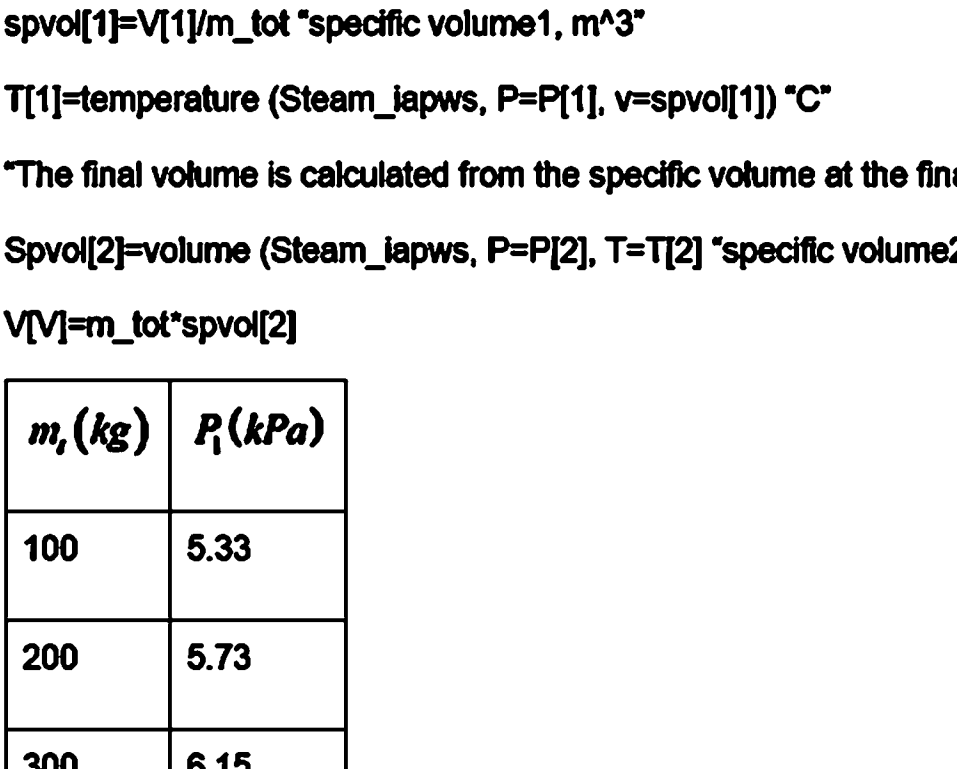
m_f1=V_f1/spvsat_f1 "sat. liq. mass, kg"

m_g1=V_g1/spvsat_g1 "sat. vap. mass, kg"

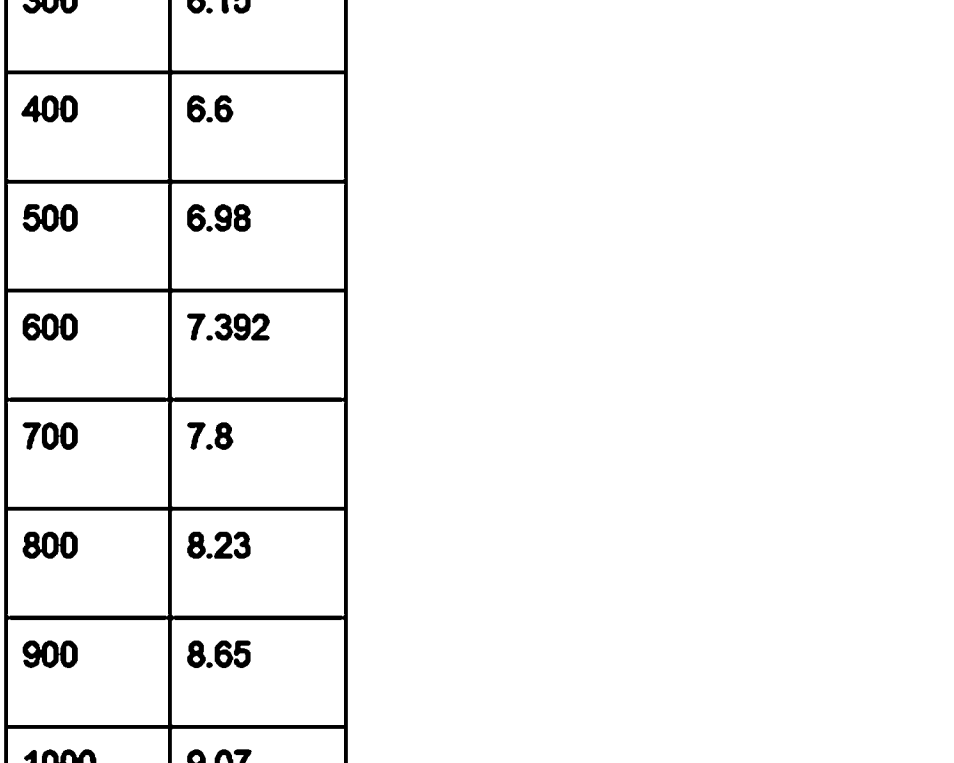
m_tot=m_f1+m_g1

v[1]=V_f1+V_g1

spvol[1]=V[1]/m_tot "specific volume1, m^3"



T[1]=temperature (Steam_iapws, P=P[1], v=spvol[1]) "C"



"The final volume is calculated from the specific volume at the final T and P"

Spvol[2]=volume (Steam_iapws, P=P[2], T=T[2] "specific volume2, m^3/kg"

V[V]=m_tot*spvol[2]
```

$m_t\,(kg)$	$P_1\,(kPa)$
100	5.33
200	5.73
300	6.15
400	6.6
500	6.98
600	7.392
700	7.8
800	8.23
900	8.65
1000	9.07

Question: 4.055P

Superheated water vapor at 180 psia and 500°F is allowed to cool at constant volume until the temperature drops to 250°F. At the final state, determine (*a*) the pressure, (*b*) the quality, and (*c*) the enthalpy. Also, show the process on a *T-V* diagram with respect to saturation lines.

Step 1 of 5

Given

Pressure of superheated water vapor, $P_1 = 180$ psia

Initial temperature, $T_1 = 500\ ^\circ F$

Final temperature, $T_2 = 250\ ^\circ F$

Constant volume process

Step 2 of 5

a) As the initial state is superheated vapor, the specific volume at the initial pressure and temperature can be obtained from superheated water table

At $P_1 = 180$ psia and $T_1 = 500\ ^\circ F$

Specific volume, $v = 3.0433\ ft^3/lbm$

As the volume is constant throughout the process,

Final specific volume $= v = 3.0433\ ft^3/lbm$

Therefore, the final state is defined by temperature and specific volume.). We do not know which table to use to determine the other properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the specific volume of saturated liquid (v_f) and specific volume of saturated vapor (v_g) from the saturated water-temperature table .

At $T_2 = 250\ ^\circ C$

$v_f = 0.01700\ ft^3/lbm$

$v_g = 13.816\ ft^3/lbm$

In our case, the given specific volume $v = 3.0433\ ft^3/lbm$ lies in between the values of v_f and v_g at the given temperature. Thus, we have saturated liquid-vapor mixture. Thus the final pressure of the state will be the saturation pressure at the final temperature which can be obtained from saturated water-temperature table.

Therefore, at $T = 250\ ^\circ F$

Final pressure, $P_2 = P_{sat}$ @ 250°F

$$\boxed{P_2 = 29.844 \text{ psia}}$$

Step 3 of 5

b) The quality (x) of mixture can be determined from

$$v = v_f + (x \times (v_g - v_f))$$

Therefore, quality $x = \dfrac{v - v_f}{v_g - v_f}$

$$x = \frac{3.0433 - 0.01700}{13.816 - 0.01700}$$

$$\boxed{x = 0.219}$$

Step 4 of 5

c) From saturated water-temperature table (Table A-4E)

at $T_2 = 250\ ^\circ F$

$h_f = 218.63$ Btu/lbm

$h_{fg} = 945.41$ Btu/lbm

Therefore, enthalpy of mixture is

$h = h_f + (x \times h_{fg})$

$h = 218.63 + (0.219 \times 945.41)$

$$\boxed{h = 425.67 \text{ Btu/lbm}}$$

Step 5 of 5

d) The total process on a T-v diagram can be shown as

Question: 4.056P

Reconsider Prob. 4–55E. Using EES (or other) software, investigate the effect of initial pressure on the quality of water at the final state. Let the pressure vary from 100 psi to 300 psi. Plot the quality against initial pressure, and discuss the results. Also, show the process in Prob. 4–55E on a *T-V* diagram using the property plot feature of EES.

Step 1 of 5

Initial pressure of the super heated water vapor, $P_1 = 180\,\text{psia}$

Initial temperature of the super heated water vapor, $T_1 = 500°\text{F}$

Final temperature, $T_2 = 250°\text{F}$

Step 2 of 5

By the EES (Engineering Equation software),
The effect of initial pressure on the quality of the water at the final state,

Equations Window

```
T[1]=500 [F]
"P[1]=180 [psia]"
T[2]=250 [F]
v[ 1]=volume(steam_iapws,T=T[1],P=P[1])
v[2]=v[1]
P[2]=pressure(steam_iapws,T=T[2],v=v[2])
h[2]=enthalpy(steam_iapws,T=T[2],v=v[2])
x[2]=quality(steam_iapws,T=T[2],v=v[2])
```

Step 3 of 5

Result:

Step 4 of 5

Graph for the quality Vs initial pressure:

T-V diagram:

Step 5 of 5

Question: 4.057P

Determine the specific volume, internal energy, and enthalpy of compressed liquid water at 80°C and 20 MPa using the saturated liquid approximation. Compare these values to the ones obtained from the compressed liquid tables.

Step 1 of 6

Given
Pressure $P = 20\text{MPa}$
Temperature $T = 80^0\text{C}$

Step 2 of 6

Assuming saturated liquid approximation
T = 80°C from saturated water tables
$v \cong v_f = 0.001029\text{m}^3/\text{kg}$
$u \cong u_f = 334.97\text{kJ/kg}$
$h \cong h_f = 335.02\text{kJ/kg}$

Step 3 of 6

Using Compressed liquid approximation
At $P = 20\text{MPa}$ and $T = 80°\text{C}$
$v = 0.0010199\text{m}^3/\text{kg}$
$u = 330.50\text{kJ/kg}$
$h = 350.90\text{kJ/kg}$

Step 4 of 6

The percentage error involved in specific volume is

$$v_{y.error} = \frac{(0.001029 - 0.0010199)}{0.001029} \times 100$$

$$\boxed{v_{y.error} = 0.884\%}$$

Step 5 of 6

The percentage error involved in enthalpy is

$$h_{y.error} = \frac{(350.90 - 335.02)}{350.90} \times 100$$

$$\boxed{h_{y.error} = 4.525\%}$$

Step 6 of 6

The percentage error involved in internal energy is

$$u_{y.error} = \frac{(334.97 - 330.50)}{334.97} \times 100$$

$$\boxed{u_{y.error} = 1.334\%}$$

Question: 4.058P

Reconsider Prob. 4–57. Using EES (or other) software, determine the indicated properties of compressed liquid, and compare them to those obtained using the saturated liquid approximation.

Step 1 of 2

Analysis: The problem is solved using EES, and the solution is given below.

```
"Given"
T=80 [C]
P=20000 [kPa]
"Analysis"
Fluid$='steam_iapws'
"Saturated liquid assumption"
v_f=volume(Fluid$, T=T, x=0)
u_f=intenergy(Fluid$, T=T, x=0)
h_f=enthalpy(Fluid$, T=T, x=0)
"Compressed liquid treatment"
v=volume(Fluid$, T=T, P=P)
u=intenergy(Fluid$, T=T, P=P)
h=enthalpy(Fluid$, T=T, P=P)
"Percentage Errors"
error_v=100*(v_f-v)/v
error_u=100*(u_f-u)/u
error_h=100*(h-h_f)/h
```

Step 2 of 2

Solution to the above EES program is as below

$h = 350.90[\text{kJ/kg}]$

$h_{app} = 335.02$

$P = 20000[\text{kPa}]$

$T = 80[\text{C}]$

$u = 330.50[\text{kJ/kg}]$

$u_{app} = 334.97[\text{kJ/kg}]$

$v = 0.0010199[\text{m}^3/\text{kg}]$

$v_{app} = 0.001029[\text{m}^3/\text{kg}]$

Question: 4.059P

A piston–cylinder device contains 0.8 kg of steam at 300°C and 1 MPa. Steam is cooled at constant pressure until one-half of the mass condenses.

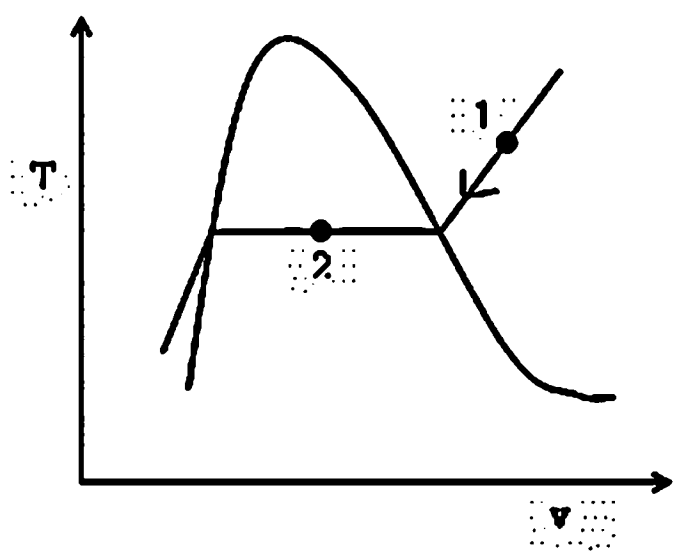
(*a*) Show the process on a *T-V* diagram.

(*b*) Find the final temperature.

(*c*) Determine the volume change.

Step 1 of 6

Given



Mass of steam inside the cylinder, $m = 0.8\ kg$

Initial temperature, $T_1 = 300\ °C$

Final pressure = Initial pressure = $P = 1\ MPa$

Step 2 of 6

a) Given the initial state is superheated steam. And then the superheated steam is cooled at constant pressure until one half of the mass condenses. Thus the final state is a saturated water-vapor mixture. Thus the constant pressure process can be shown on a T-v diagram as

Step 3 of 6

b) The temperature of the saturated liquid-vapor mixture is the saturation temperature at the given pressure, P = 1 1MPa which can be obtained from saturated water-pressure table (Table A-5)

Therefore,

Final temperature, $T_2 = T_{sat}$ @ 1 MPa

$$\boxed{T_2 = 179.88°C}$$

Step 4 of 6

c) The initial state i.e., superheated steam is defined by temperature and pressure. The specific volume of superheated vapor at given temperature and pressure can be obtained from superheated water table (Table A-6)

Therefore, at $P = 1MPa$ and $T_1 = 300\ °C$

Initial specific volume, $v_1 = 0.25799\ m^3/kg$

Step 5 of 6

We know that steam is cooled till half of the mass gets condensed. Thus, finally the quality (x) of the mixture will be 0.5.

From the saturated water-pressure table (Table A-5)

At P = 1MPa

Specific volume of saturated liquid, $v_f = 0.001127\ m^3/kg$

Specific volume of saturated vapor, $v_g = 0.19436\ m^3/kg$

Step 6 of 6

Thus, the final specific volume (v_2) of the mixture with quality 0.5 can be determined as

$$v = v_f + (x \times (v_g - v_f))$$

$$v_2 = 0.001127 + (0.5 \times (0.19436 - 0.001127))$$

$$v_2 = 0.097743\ m^3/kg$$

Therefore, change in volume

$$\Delta V = m \times (v_2 - v_1)$$

$$\Delta V = 0.8 \times (0.097743 - 0.25799)$$

$$\boxed{\Delta V = -0.12819\ m^3}$$

Question: 4.060P

A rigid tank contains water vapor at 250°C and an unknown pressure. When the tank is cooled to 124°C, the vapor starts condensing. Estimate the initial pressure in the tank.

Step 1 of 3

At exit temperature $T_2 = 124°C$ the vapor starts condensing, and then the specific volume at this state is equal to the specific volume of saturated vapor. Obtain the specific volume from the saturated water table at temperature $T_2 = 124°C$. Now tabulate the values of specific volume at respective temperatures.

Temperature $(°C)$	Specific Volume (m^3/kg)
$120°\ (y_1)$	$0.89133\ m^3/kg\ (x_1)$
$125°\ (y_2)$	$0.77012\ m^3/kg\ (x_2)$
$124°\ (y)$	$v_2 = ?\ (x)$

Step 2 of 3

Relation for linear interpolation is expressed as,

$$\frac{x - x_1}{x_2 - x_1} = \frac{y - y_1}{y_2 - y_1}$$

Using linear interpolation calculate the specific volume.

$$v_2 = v_x$$
$$= 0.89133 + (0.77012 - 0.89133)\left(\frac{124 - 120}{125 - 120}\right)$$
$$= 0.794\,m^3/kg$$

Since it is a constant volume process, the initial specific volume is equal to the final specific volume. This can be expressed mathematically as follows:

$$v_1 = v_2 = 0.794\,m^3/kg$$

Step 3 of 3

Obtain the initial pressure at the initial tank temperature $T_1 = 250°C$ and specific volume $v_1 = 0.794\,m^3/kg$ from superheated water tables. Now tabulate the values of specific volume at respective temperatures.

Pressure (MPa) @ $250°C$ Superheated Water	Specific Volume
$0.2\ MPa$	$1.19890\ m^3/kg$
$0.3\ MPa$	$0.79645\ m^3/kg$
$P_1 = ?$	$0.794\,m^3/kg$

Using linear interpolation calculate the initial pressure.

$$P_1 = 0.2 + (0.3 - 0.2)\left(\frac{0.794 - 1.1989}{0.79645 - 1.1989}\right)$$
$$= 0.3006\,MPa$$
$$\simeq 0.3\,MPa$$

Therefore, initial pressure, P_1 in the tank is $\boxed{0.3\,MPa}$.

Question: 4.061P

A piston-cylinder device initially contains 1.4-kg saturated liquid water at 200°C. Now heat is transferred to the water until the volume quadruples and the cylinder contains saturated vapor only. Determine (*a*) the volume of the tank, (*b*) the final temperature and pressure, and (*c*) the internal energy change of the water.

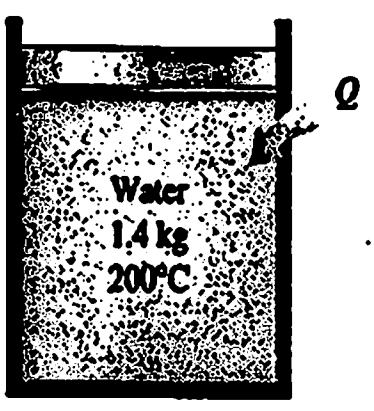


FIGURE P4–61

Step 1 of 6

Given

Initial state = saturated liquid

Initial temperature, $T_1 = 200\ °C$

Final state = saturated vapor

Final volume, $V_2 = 4 \times$ Initial volume $= 4V_1$

Mass inside the cylinder, $m = 1.4\ kg$

Step 2 of 6

a) We know that initial state is saturated liquid. The specific volume of the saturated liquid at the temperature T_1 can be obtained from the saturated water-temperature table

Therefore, at $T_1 = 200\ °C$

Initial specific volume, $v_1 = v_{f@200\,°C}$

$= 0.001157\ m^3/kg$

Therefore,

Initial volume of the tank, $V_1 = m \times v_1$

$V_1 = 1.4 \times 0.001157$

$V_1 = 0.0016198\ m^3$

Final volume of the tank, $V_2 = 4 \times V_1$

$$\boxed{V_2 = 0.0064792\ m^3}$$

Step 3 of 6

b) We know the final state is saturated vapor. The specific volume of saturated vapor is

$V_2 = 4 \times V_1$

$v_2 = 4 \times 0.001157$

$v_2 = 0.004628\ m^3/kg$

Thus we have a saturated vapor with specific volume 0.004628 m^3/kg. The temperature and pressure of this saturated vapor can be obtained from either saturated water- temperature table (Table A-4) or saturated water-pressure table (Table A-5).

From table A-4, we can see that we don't have the direct value of given specific volume of saturated vapor i.e., 0.004628 m^3/kg. Therefore, the temperature and pressure of this saturated vapor are obtained by interpolation

We have,

For $v_{gA} = 0.004953\ m^3/kg$

$T_A = 370\ °C$

$P_A = 21044\ kPa$

For $v_{gB} = 0.003106\ m^3/kg$

$T_B = 373.95\ °C$

$P_B = 22064\ kPa$

Step 4 of 6

By interpolation

$$\frac{T_2 - T_A}{T_B - T_A} = \frac{v_g - v_{gA}}{v_{gB} - v_{gA}}$$

$$\frac{T_2 - 370}{373.95 - 370} = \frac{0.004628 - 0.004953}{0.003106 - 0.004953}$$

Therefore, final temperature, $T_2 = 370.695\ °C$

Similarly

$$\frac{P_2 - P_A}{P_B - P_A} = \frac{v_g - v_{gA}}{v_{gB} - v_{gA}}$$

$$\frac{P_2 - 21044}{22064 - 21044} = \frac{0.004628 - 0.004953}{0.003106 - 0.004953}$$

Therefore, final pressure, $\boxed{P_2 = 21223.48\ kPa}$

Step 5 of 6

c) The initial internal energy i.e., internal energy of saturated liquid at 200 °C can be obtained from saturated water-temperature table (Table A-4)

The initial internal energy, $u_1 = u_{f@200\,°C} = 850.46\ kJ/kg$

The final internal energy i.e., internal energy of saturated liquid at 370.695 °C can be obtained from saturated water-temperature table (Table A-4) by interpolation.

For $T_A = 370\ °C$

$u_{gA} = 2230.1\ kJ/kg$

For $T_B = 373.95\ °C$

$u_{gB} = 2015.7\ kJ/kg$

Step 6 of 6

By interpolation

$$\frac{u_2 - u_{gA}}{u_{gB} - u_{gA}} = \frac{T_2 - T_A}{T_B - T_A}$$

$$\frac{u_2 - 2230.1}{2015.7 - 2230.1} = \frac{370.695 - 370}{373.95 - 370}$$

Therefore, final internal energy, $u_2 = 2192.376\ kJ/kg$

Therefore, total change in internal energy

$\Delta U = m \times (u_2 - u_1)$

$\Delta U = 1.4 \times (2192.376 - 850.46)$

$$\boxed{\Delta U = 1878.68\ kJ}$$

Question: 4.062P

How much error would one expect in determining the specific enthalpy by applying the incompressible-liquid approximation to water at 1500 psia and 400°F?

Step 1 of 4

Given

Pressure of compressed liquid water, $P = 1500$ psia

Temperature of compressed liquid, $T = 400\ ^\circ F$

Step 2 of 4

If we apply the incompressible liquid approximation i.e., the compressed liquid water is treated as saturated liquid at given temperature. The enthalpy of saturated liquid at 400 °F can obtained from saturated water-temperature table (Table A-4E)

Therefore at $T = 400\ ^\circ F$

Approximated enthalpy of compressed liquid, $h_{approx} = h_{f@400\ ^\circ F} = 375.04$ Btu/lbm

Step 3 of 4

Actual enthalpy of compressed liquid at given temperature and pressure can be obtained from compressed liquid water table (Table A-7E).

Therefore, at $P = 1500$ psia and $T = 400\ ^\circ F$

Actual enthalpy of compressed liquid, $h_{actual} = 376.51$ Btu/lbm

Step 4 of 4

Therefore, error involved in approximation is

$$\text{Percent error} = \frac{h_{actual} - h_{approx}}{h_{actual}} \times 100$$

$$\text{Percent error} = \frac{376.51 - 375.04}{376.51} \times 100$$

$$= 0.3904\ \%$$

Question: 4.063P

How much error would result in calculating the specific volume and enthalpy of water at 20 MPa and 140°C by using the incompressible-liquid approximation?

Step 1 of 5

Given
Water at pressure $P = 20\text{MPa}$
Water at temperature $T = 140°\text{C}$

Step 2 of 5

The state of water is in compressed liquid region
At $P = 20\text{MPa}$ and $T = 140°\text{C}$ from compressed liquid water tables
$v = 0.0010679\text{m}^3/\text{kg}$
$h = 602.07\text{kJ/kg}$

Step 3 of 5

Based upon the incompressible liquid approximation
$v = v_{f@140\text{kPa}} = 0.001080\text{m}^3/\text{kg}$
$h = h_{f140°C} = 589.16\text{kJ/kg}$

Step 4 of 5

The percent error involved in specific volume is

$$v_{\text{error}} = \frac{(0.001080 - 0.0010679)}{0.0010679} \times 100$$

$$\boxed{v_{\text{error}} = 1.1331\%}$$

Step 5 of 5

The percent error involved in enthalpy is

$$h_{\text{error}} = \frac{(602.07 - 589.16)}{602.07} \times 100$$

$$\boxed{h_{\text{error}} = 2.144\%}$$

Step 3 of 5

Based upon the incompressible liquid approximation
$v = v_{f@140\text{kPa}} = 0.001080\text{m}^3/\text{kg}$
$h = h_{f140°C} = 589.16\text{kJ/kg}$

Step 4 of 5

The percent error involved in specific volume is

$$v_{\text{error}} = \frac{(0.001080 - 0.0010679)}{0.0010679} \times 100$$

$$\boxed{v_{\text{error}} = 1.1331\%}$$

Question: 4.064P

100 grams of R-134a initially fill a weighted piston-cylinder device at 60 kPa and −20°C. The device is then heated until the temperature is 100°C. Determine the change in the device's volume as a result of the heating.

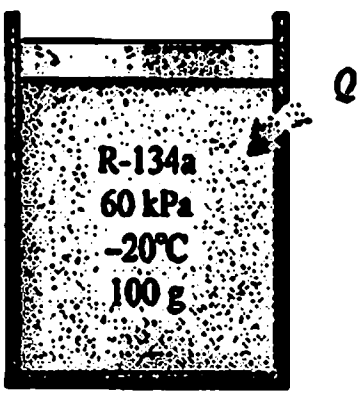

FIGURE P4–64

Step 1 of 4

Question:

100 grams of R-134a initially fill a weighted piston-cylinder device at 60 kPa and −20°C. The device is then heated until the temperature is 100°C. Determine the change in the device's volume as a result of the heating.

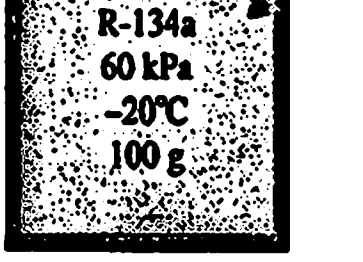

FIGURE P4–64

Step 1 of 4

Given

Mass of refrigerant-134a inside the cylinder, $m = 100\ g = 0.1\ kg$
Initial temperature, $T_1 = -20\ °C$.
Initial pressure, $P_1 = 60\ kPa$
Final temperature, $T_2 = 100\ °C$

Step 2 of 4

The initial state of refrigerant-134a is defined by temperature and pressure only. We do not know whether we have saturated mixture, compressed liquid or superheated vapor. To determine the region we are in, we go the saturated refrigerant-134a–pressure table (Table A-12) and determine the saturation temperature at the given pressure. Thus, for P = 60 kPa, we have $T_{sat} = -36.95\ °C$. We then compare the given T value to this T_{sat} value, keeping in mind that

if $T < T_{sat\ @\ given\ P}$ we have compressed liquid
if $T = T_{sat\ @\ given\ P}$ we have saturated mixture
if $T > T_{sat\ @\ given\ P}$ we have superheated vapor.

In our case, the given T value is -20 °C, which is greater than the T_{sat} value at the given pressure. Therefore, we have superheated refrigerant initially. The specific volume of superheated refrigerant-134a can be obtained from superheated refrigerant-134a table (Table A-13)

Therefore, at $P_1 = 0.06\ MPa$ and $T_1 = -20\ °C$
Initial specific volume, $v_1 = 0.33608\ m^3/kg$

Step 3 of 4

As this is a constant pressure process

Question: 4.065P

A rigid vessel contains 2 kg of refrigerant-134a at 800 kPa and 120°C. Determine the volume of the vessel and the total internal energy.

Step 1 of 3

Given

Mass of refrigerant-134a inside the rigid vessel, $m = 2\ kg$

Pressure, $P = 800\ kPa$

Temperature, $T = 120°C$

Step 2 of 3

In this case, the temperature and pressure are given, but again we do not know whether we have saturated mixture, compressed liquid or superheated vapor. To determine the region we are in, we go the saturation refrigerant-134a-pressure table and determine the saturation temperature at the given pressure. Thus, for $P = 800$ kPa, we have $T_{sat} = 31.31$ °C. We then compare the given T value to this T_{sat} value, keeping in mind that

if $T < T_{sat\ @\ given\ P}$ we have compressed liquid

if $T = T_{sat\ @\ given\ P}$ we have saturated mixture

if $T > T_{sat\ @\ given\ P}$ we have superheated vapor.

In our case, the given T value is 120 °C, which is greater than the T_{sat} value at the given pressure. Therefore, we have superheated vapor. From the superheated refrigerant-134a table at pressure = 800 kPa = 0.8 MPa

Specific volume, $v = v\ @\ 120\ °C = 0.037625\ m^3/kg$

Hence, volume of the vessel, $V = m \times v$

$V = 2 \times 0.037625$

$\boxed{V = 0.07525\ m^3}$

Step 3 of 3

From the superheated refrigerant-134a table at pressure = 800 kPa = 0.8 MPa

Internal energy, $u = 327.87\ kJ/kg$

Therefore, total internal energy,

$U = m \times u$

$U = 2 \times 327.87$

$\boxed{U = 655.74\ kJ}$

Question: 4.066P

A 0.5-m3 vessel contains 10 kg of refrigerant-134a at −20°C. Determine (*a*) the pressure, (*b*) the total internal energy, and (*c*) the volume occupied by the liquid phase.

Step 1 of 5

Given

Volume of vessel, $V = 0.5\ m^3$

Mass of refrigerant-134a, $m = 10\ kg$

Temperature, $T = -20\ °C$

Step 2 of 5

Specific volume, $v = \frac{V}{m}$

$v = 0.05\ m^3/kg$

In this case the state is defined by temperature (T) and specific volume (v). We do not know which table to use to determine the other properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the specific volume of saturated liquid (v_f) and specific volume of saturated vapor (v_g) from the saturated refrigerant-134a-temperature table (Table A-11).

At $T = -20\ °C$

$v_f = 0.0007362\ m^3/kg$

$v_g = 0.14729\ m^3/kg$

In our case, the given specific volume $v = 0.05\ m^3/kg$ lies in between the values of v_f and v_g at the given temperature. Thus, we have saturated liquid-vapor mixture. Thus the other properties of the state can be obtained from saturated refrigerant-134a table (Table A-11)

Step 3 of 5

a) Therefore, at $T = -20\ °C$

Pressure, $P = P_{sat\ @\ -20\ °C}$

$\boxed{P = 132.82\ kPa}$

Step 4 of 5

b) To determine the internal energy and volume occupied by the liquid phase, we need the quality of mixture. The quality (x) of mixture can be determined from

$$v = v_f + x \times (v_g - v_f)$$

Therefore, quality $x = \frac{v - v_f}{v_g - v_f}$

$$x = \frac{0.05 - 0.0007362}{0.14729 - 0.0007362}$$

$$x = 0.3361$$

From Table A-11, at $T = -20\ °C$

We have, $u_f = 25.39\ kJ/kg$

$u_{fg} = 193.45\ kJ/kg$

Therefore, the internal energy (u) of the mixture is

$u_2 = u_f + (x \times u_{fg})$

$u = 25.39 + (0.3361 * 193.45)$

$u = 90.41\ kJ/kg$

Thus, total internal energy,

$U = m \times u$

$U = 10 \times 90.41$

$\boxed{U = 904.1\ kJ}$

Step 5 of 5

c) The quality, x= 0.3361 implies that 33.61 percent of the mixture is vapor and the remaining 66.39 percent is liquid.

Hence, the mass of liquid phase,

$m_f = (1 - x) \times$ total mass of refrigerant

$m_f = (1 - 0.3361) \times 10$

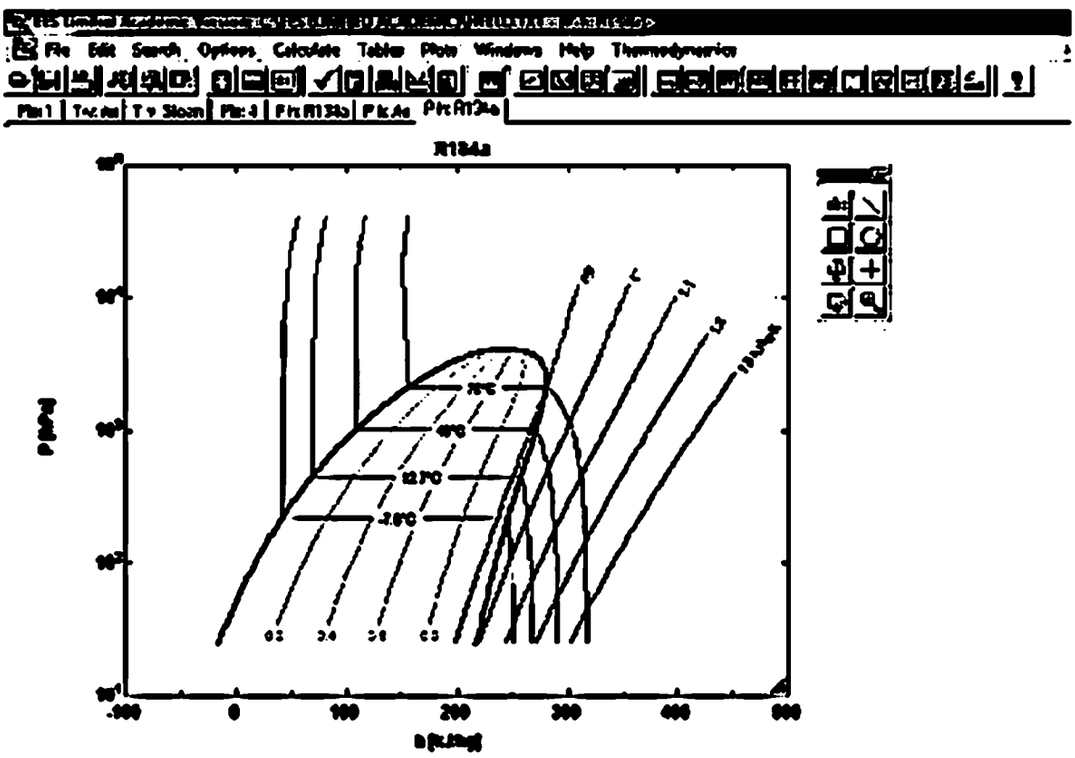
$m_f = 6.639\ kg$

Volume occupied by the liquid phase,

$V_f =$ mass of liquid phase × specific volume of saturated liquid

$V_f = m_f \times v_f$

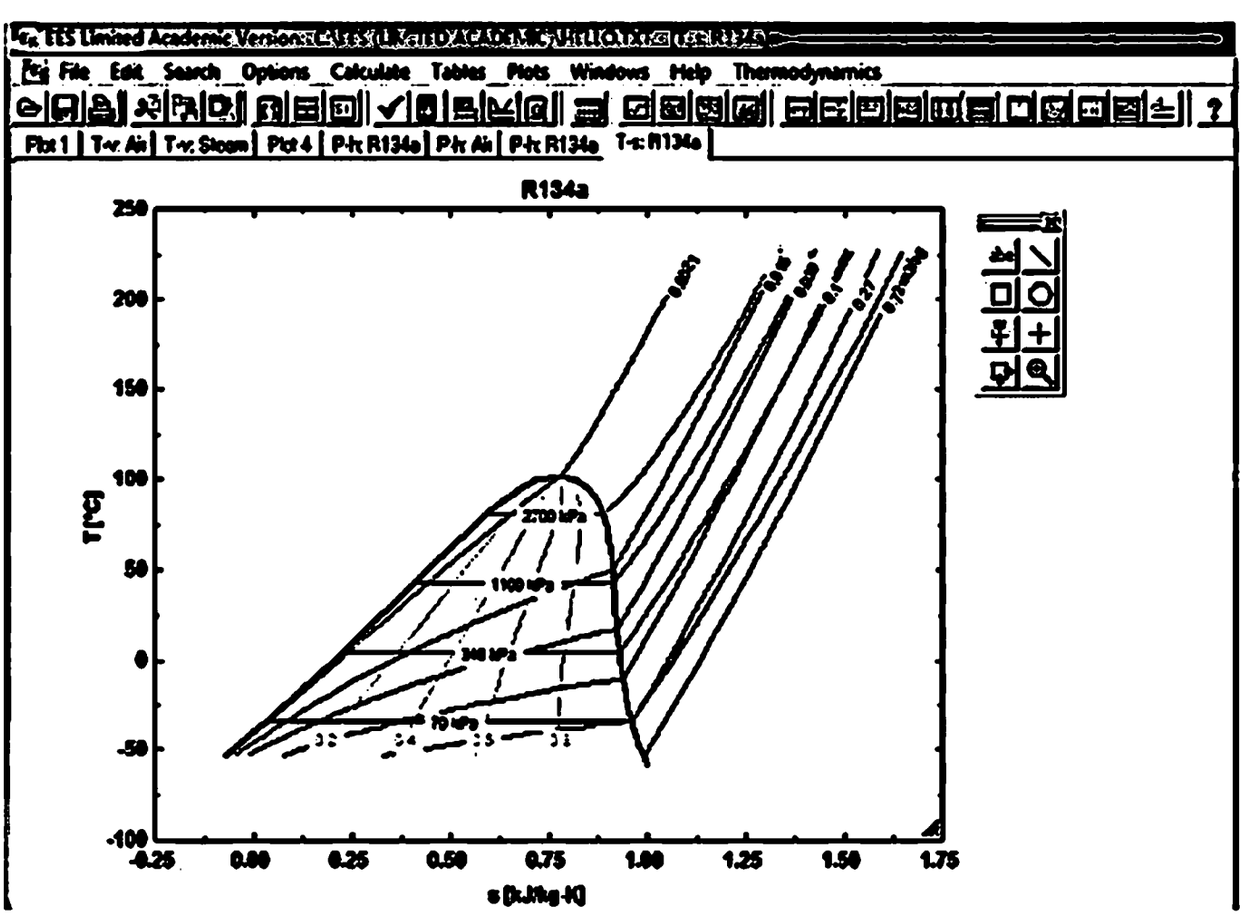
$V_f = 6.639 \times 0.0007362$



$\boxed{V_f = 0.00489\ m^3}$

Question: 4.067P

Pressure-enthalpy state diagrams are useful for studying refrigeration and like systems. Using EES (or other) software and actual property data, plot a pressure-enthalpy diagram for R-134a that includes the saturation lines. Also, sketch isothermal and constant-entropy processes on this diagram.



Step 1 of 2

Pressure-enthalpy diagram for refrigerator R-134a by using EES software:

Step 2 of 2

Temperature and entropy diagram for R-134a:

Question: 4.068P

A 0.3-m3 rigid vessel initially contains saturated liquid-vapor mixture of water at 150°C. The water is now heated until it reaches the critical state. Determine the mass of the liquid water and the volume occupied by the liquid at the initial state.

Step 1 of 6

Given

Volume of the rigid vessel, $V = 0.3\ m^3$

Temperature of saturated liquid-vapor mixture of water, $T_1 = 150\ °C$

Step 2 of 6

As the vessel is rigid, the process is a constant volume process. Hence the water is heated at constant volume till critical point. Thus the initial specific volume of the saturated mixture will be equal to the final specific volume which is the specific volume at critical state.

We know, the critical temperature of water is 373.95 °C. Thus the final specific volume can be obtained from saturated water-temperature table (Table A-4)

At $T = 373.95\ °C$

$v_{cr} = 0.003106\ m^3/kg$

Thus, initial specific volume, $v_1 = v_{cr} = 0.003106\ m^3/kg$.

Step 3 of 6

Total mass (m) of the saturated liquid-vapor mixture is

$$m = \frac{V}{v_1}$$

$$m = \frac{0.3}{0.003106}$$

$$m = 96.587\ kg$$

Step 4 of 6

The mass of liquid water can be obtained, once we know the quality of the saturated liquid-vapor mixture. The quality (x) of the mixture can be obtained from

$$v = v_f + (x \times (v_g - v_f))$$

From saturated water – temperature table (Table A-4)

At $T_1 = 150\ °C$

Specific volume of saturated liquid, $v_f = 0.001091\ m^3/kg$

Specific volume of saturated vapor, $v_g = 0.39248\ m^3/kg$

Therefore, quality $x = \frac{v_1 - v_f}{v_g - v_f}$

$$x = \frac{0.003106 - 0.001091}{0.39248 - 0.001091}$$

$$x = 0.00515$$

Step 5 of 6

Thus mass of liquid water, $m_L = (1-x) \times$ total mass

$$m_L = (1 - 0.00515) \times 96.587$$

$$\boxed{m_L = 96.089\ kg}$$

Step 6 of 6

Volume occupied by liquid at the initial state is

V_L = mass of liquid water (m_L) × specific volume of saturated liquid (v_f)

$$V_L = 96.089 \times 0.001091$$

$$\boxed{V_L = 0.1048\ m^3}$$

Question: 4.069P

What is the difference between mass and molar mass? How are these two related?

Step 1 of 1

Mass (m) is the total amount of matter or substance. Molar mass (M) is the mass of one mole of a substance in grams, or the mass of one kmol in kilograms. Molar mass is also called as molecular weight. Mass and molar mass can be related as

$$m = NM$$

where N= number of moles.

Question: 4.070P

Under what conditions is the ideal-gas assumption suitable for real gases?

Step 1 of 1

A gas can be treated as ideal gas when it is at higher temperatures or low pressures relative to its critical temperature and pressure. Because, at high temperatures and low pressures, the density of gas decreases and at low densities real gases behave as ideal gases.

Question: 4.071P

What is the difference between *R* and *R*u? How are these two related?

Step 1 of 1

R_u is the universal gas constant and is same for all the gases whereas R is the specific gas constant that is different for different gases. These two can be related as

$$R = \frac{R_u}{M}$$

Where M = molar mass of the gas or the molecular weight of the gas.

Question: 4.072P

Propane and methane are commonly used for heating in winter, and the leakage of these fuels, even for short periods, poses a fire danger for homes. Which gas leakage do you think poses a greater risk for fire? Explain.

Step 1 of 2

From table
Molar mass of propane, $M_P = 44.097$ kg/kmol
Molar mass of methane, $M_M = 16.043$ kg/kmol
Molar mass of air, $M_A = 28.97$ kg/kmol

Step 2 of 2

We can see that, the molar mass of propane is greater than the molar mass of air i.e, propane is heavier than air whereas methane is lighter than air.
Hence, when these gases leak out, propane will settle near the floor and methane will rise.
Thus leakage of propane poses a greater risk for fire.

Question: 4.073P

What is the specific volume of nitrogen at 300 kPa and 227°C?

Step 1 of 2

Given

Pressure of nitrogen $P = 300\text{kPa}$

Temperature of nitrogen $T = 227^0\text{C}$

Step 2 of 2

From properties of gas constant table, we get

Gas constant of nitrogen $R = 0.2968\text{kJ/kg.K}$

Assuming nitrogen behaves as an ideal gas, then by using ideal gas equation

$PV = mRT$

Specific volume of N_2

$$\frac{V}{m} = \frac{RT}{P}$$

$$v = \frac{0.2968 \times (227 + 273)}{300}$$

$$\boxed{v = 0.4946\,\text{m}^3/\text{kg}}$$

Question:

4.074P

A 3-ft3 container is filled with 2-lbm of oxygen at a pressure of 80 psia. What is the temperature of the oxygen?

Step 1 of 2

Given

Volume of the container $V = 3\text{ft}^3$

Mass of oxygen $m = 2\text{lbm}$

Pressure $P = 80\text{ psia}$

Step 2 of 2

From properties of gas constants gas constant of oxygen is

$R_{O_2} = 0.3353\text{ psia-ft}^3/\text{lbmR}$

Applying ideal gas equation of state

$$PV = mRT$$

$$T = \frac{PV}{mR}$$

$$= \frac{80 \times 3}{2 \times 0.3353}$$

$$T = 357.9\text{R}$$

Temperature of the oxygen in the container

$$\boxed{T = 357.9\text{R}}$$

Question:

4.075P

A 2-kg mass of helium is maintained at 300 kPa and 27°C in a rigid container. How large is the container, in m3?

Step 1 of 2

Given

Mass of Helium $m = 2\text{kg}$

Pressure $P = 300\text{kPa}$

Temperature $T = 27^0\text{C}$

Step 2 of 2

Assuming helium behaves as an ideal gas

From properties of gas constants

The gas constant of helium is

$R = 2.0769\text{kJ/kgK}$

According to the ideal gas equation of state,

$$PV = mRT$$

$$V = \frac{mRT}{P}$$

$$= \frac{2 \times 2.0769 \times (27+273)}{300}$$

$$V = 4.1538\text{m}^3$$

Volume of the container

$$\boxed{V = 4.1538\text{m}^3}$$

Question: 4.076P

A spherical balloon with a diameter of 9 m is filled with helium at 27°C and 200 kPa. Determine the mole number and the mass of the helium in the balloon.

Step 1 of 3

Calculate the volume of the sphere by using the following relation:

$$V = \frac{4\pi R^3}{3}$$

Here, R is the radius of the sphere.

Substitute $D/2$ for R.

$$V = \frac{4\pi (D/2)^3}{3}$$

Here, D is the diameter of the sphere.

Substitute $9\ \text{m}$ for D.

$$V = \frac{4\pi (9/2)^3}{3}$$
$$= 381.703\ \text{m}^3$$

Step 2 of 3

(a)

Calculate the number of moles of helium by using the following ideal gas equation:

$$n = \frac{PV}{R_u T}$$

Here, P is the pressure of the helium, T is the temperature of helium, and R_u is the universal gas constant.

Substitute $200\ \text{kPa}$ for P, $381.703\ \text{m}^3$ for V, $8.314\ \text{kJ/kg·K}$ for R_u, and $27°\text{C}$ for T.

$$n = \frac{200 \times 381.703}{8.314 \times ([27°\text{C} + 273]\ \text{K})}$$
$$= 30.6\ \text{kmol}$$

Therefore, the mole number of helium is $\boxed{30.6\ \text{kmol}}$.

Step 3 of 3

(b)

Obtain the molar mass of Helium from Table A-1, "Molar mass, gas constant, and critical-point properties," from the text book.

Molar mass of helium, $M = 4.003\ \text{kg/kmol}$

Calculate the mass of the helium in the balloon by using the following relation:

$$m = nM$$

Substitute $30.6\ \text{kmol}$ for n and $4.003\ \text{kg/kmol}$ for M.

$$m = 30.6 \times 4.003$$
$$= 122.5\ \text{kg}$$

Therefore, the mass of the Helium in the balloon is $\boxed{122.5\ \text{kg}}$.

Question: 4.077P

 Reconsider Prob. 4–76. Using EES (or other) software, investigate the effect of the balloon diameter on the mass of helium contained in the balloon for the pressures of (*a*) 100 kPa and (*b*) 200 kPa. Let the diameter vary from 5 m to 15 m. Plot the mass of helium against the diameter for both cases.

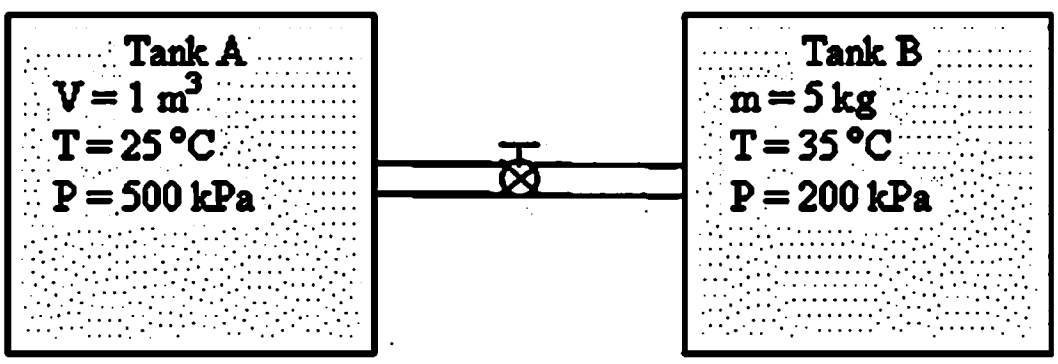
Step 1 of 2

Analysis: The problem is solved using EES, and the solution is given below.

```
"Given Data"
{D=9 [m]}
T=27 [C]
P=200 [kPa]
R_u=8.314 [kJ/kmol-K]
"Solution"
P*V=N*R_u*(T+273)
V=4*pi*(D/2)^3/3
m=N*MOLARMASS(Helium)
```

Step 2 of 2

Solution to the above EES program is as below



D[m]	m[kg]
5	21.02
6.111	38.37
7.222	63.33
8.333	97.28
9.444	141.7
10.56	197.745
11.67	266.92
12.78	350.743
13.89	450.397
15	567.344

Question: 4.078P

A 1-m3 tank containing air at 25 °C and 500 kPa is connected through a valve to another tank containing 5 kg of air at 35°C and 200 kPa. Now the valve is opened, and the entire system is allowed to reach thermal equilibrium with the surroundings, which are at 20°C. Determine the volume of the second tank and the final equilibrium pressure of air.

Step 1 of 4

Let the two tanks be represented by A and B as shown in the figure below.

Step 2 of 4

Given

Volume of the tank A, $V_A = 1\ m^3$

Temperature of air in tank A, $T_A = 25\ °C = 298\ K$

Pressure of air in tank A, $P_A = 500\ kPa$

Mass of air in tank B, $m_B = 5\ kg$

Temperature of air in tank B, $T_B = 35\ °C = 308\ K$

Pressure of air in tank B, $P_B = 200\ kPa$

Surrounding temperature, $T_{surr} = 20\ °C = 293\ K$

Step 3 of 4

Assuming, at given conditions air behaves as an ideal gas.

For air, gas constant $R = 0.287\ kJ/kmol\ K$

From ideal gas equation, mass of air in tank A is determined by

$$m_A = \frac{P_A V_A}{RT_A}$$

$$= \frac{500 \times 1}{0.287 \times 298}$$

$$m_A = 5.846\ kg$$

Volume of the tank B can be determined from

$$V_B = \frac{m_B R T_B}{P_B}$$

$$= \frac{5 \times 0.287 \times 308}{200}$$

$$V_B = 2.21\ m^3$$

Step 4 of 4

Now, when the valve is opened

Total volume, $V = V_A + V_B = 1 + 2.21 = 3.21\ m^3$

Total mass of air, $m = m_A + m_B = 5 + 5.846 = 10.846\ kg$

The final equilibrium pressure (P) can be obtained from the ideal gas equation applied to total volume

$$\text{Therefore, } P = \frac{mRT_{surr}}{V}$$

$$P = \frac{10.846 \times 0.287 \times 293}{3.21}$$

$$\boxed{P = 284.13\ kPa}.$$

Question:

4.079P

2.3 lbmol of air at 65°F and 32 psia is contained in an elastic tank. What is the volume of the tank? If the volume is doubled at the same pressure, determine the final temperature.

Step 1 of 3

Given

Number of moles of air $n = 2.3\text{lbmol}$

Initial temperature of air $T_1 = 65°\text{F}$

$$T_1 = 65+459.67$$

$$T_1 = 524.67\text{R}$$

Initial pressure of air $P_1 = 32\,\text{psia}$

Step 2 of 3

Universal gas constant

$R_u = 10.7316\text{psia-ft}^3/\text{lbmol-R}$

Question:

2.3 lbmol of air at 65°F and 32 psia is contained in an elastic tank. What is the volume of the tank? If the volume is doubled at the same pressure, determine the final temperature.

Step 1 of 3

Given

Number of moles of air $n = 2.3\text{lbmol}$

Initial temperature of air $T_1 = 65°\text{F}$

$$T_1 = 65+459.67$$

$$T_1 = 524.67\text{R}$$

Initial pressure of air $P_1 = 32\,\text{psia}$

Step 2 of 3

Question:

4.080P

A rigid tank contains an ideal gas at 1227°C and 200 kPa gage. The gas is cooled until the gage pressure reads 50 kPa. If the atmospheric pressure is 100 kPa, determine the final temperature of the gas.

Step 1 of 3

Given

Temperature of ideal gas $T_1 = 1227°C$

$$T_1 = 1227 + 273$$

$$T_1 = 1500K$$

Initial gage pressure of the ideal gas $P_1 = 200kPa$

Final gage pressure $P_2 = 50kPa$

Atmospheric pressure $P_{atm} = 100kPa$

Step 2 of 3

Initial absolute pressure of the gas

Question:

A rigid tank contains an ideal gas at 1227°C and 200 kPa gage. The gas is cooled until the gage pressure reads 50 kPa. If the atmospheric pressure is 100 kPa, determine the final temperature of the gas.

Step 1 of 3

Given

Temperature of ideal gas $T_1 = 1227°C$

$$T_1 = 1227 + 273$$

$$T_1 = 1500K$$

Initial gage pressure of the ideal gas $P_1 = 200kPa$

Final gage pressure $P_2 = 50kPa$

Atmospheric pressure $P_{atm} = 100kPa$

Question: 4.081P

A rigid tank whose volume is unknown is divided into two parts by a partition. One side of the tank contains an ideal gas at 927°C. The other side is evacuated and has a volume twice the size of the part containing the gas. The partition is now removed and the gas expands to fill the entire tank. Heat is now applied to the gas until the pressure equals the initial pressure. Determine the final temperature of the gas.

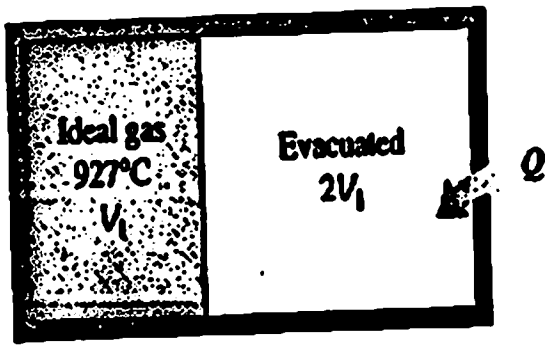


FIGURE P4–81

Step 1 of 3

Question:

A rigid tank whose volume is unknown is divided into two parts by a partition. One side of the tank contains an ideal gas at 927°C. The other side is evacuated and has a volume twice the size of the part containing the gas. The partition is now removed and the gas expands to fill the entire tank. Heat is now applied to the gas until the pressure equals the initial pressure. Determine the final temperature of the gas.

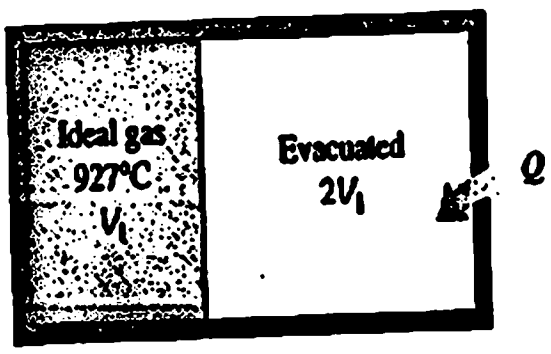

FIGURE P4–81

Step 1 of 3

Initial temperature $T_1 = 927°C$

$T_1 = 927 + 273$

$T_1 = 1200K$

Initial volume V_1

Evacuated volume $2V_1$

Step 2 of 3

$= 3 \times 1200$

$T_2 = 3600K$

$T_2 = 3327^0C$

Final temperature of the gas

$\boxed{T_2 = 3327^0C}$

Question: 4.082P

Argon in the amount of 0.6 kg fills a 0.05-m3 piston-cylinder device at 550 kPa. The piston is now moved by changing the weights until the volume is twice its original size. During this process, argon's temperature is maintained constant. Determine the final pressure in the device.

Step 1 of 2

Given

Mass of Argon $m = 0.6\text{kg}$

Initial volume $V_1 = 0.05\text{m}^3$

Initial pressure $P_1 = 550\text{kPa}$

Final volume $V_2 = 2V_1$

Step 2 of 2

Since temperature remains constant

Applying ideal gas equation

$$P_1V_1 = P_2V_2$$

$$P_2 = \frac{P_1V_1}{V_2}$$

$$= \frac{550 \times V_1}{2V_1}$$

$$P_2 = 275\text{kPa}$$

So, final pressure in the device

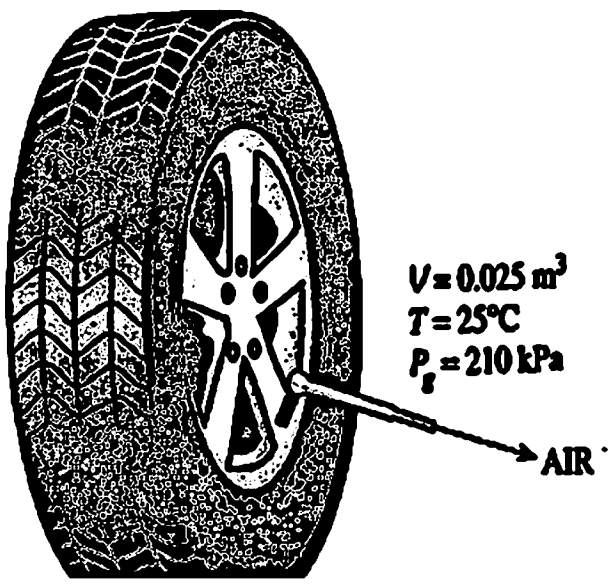
$$\boxed{P_2 = 275\text{kPa}}$$

$$P_1V_1 = P_2V_2$$

$$P_2 = \frac{P_1V_1}{V_2}$$

$$= \frac{550 \times V_1}{2V_1}$$

$$P_2 = 275\text{kPa}$$



So, final pressure in the device

$$\boxed{P_2 = 275\text{kPa}}$$

Question:

4.083P

The pressure in an automobile tire depends on the temperature of the air in the tire. When the air temperature is 25 °C, the pressure gage reads 210 kPa. If the volume of the tire is 0.025 m3, determine the pressure rise in the tire when the air temperature in the tire rises to 50°C. Also, determine the amount of air that must be bled off to restore pressure to its original value at this temperature. Assume the atmospheric pressure is 100 kPa.

Question:

The pressure in an automobile tire depends on the temperature of the air in the tire. When the air temperature is 25 °C, the pressure gage reads 210 kPa. If the volume of the tire is 0.025 m3, determine the pressure rise in the tire when the air temperature in the tire rises to 50°C. Also, determine the amount of air that must be bled off to restore pressure to its original value at this temperature. Assume the atmospheric pressure is 100 kPa.

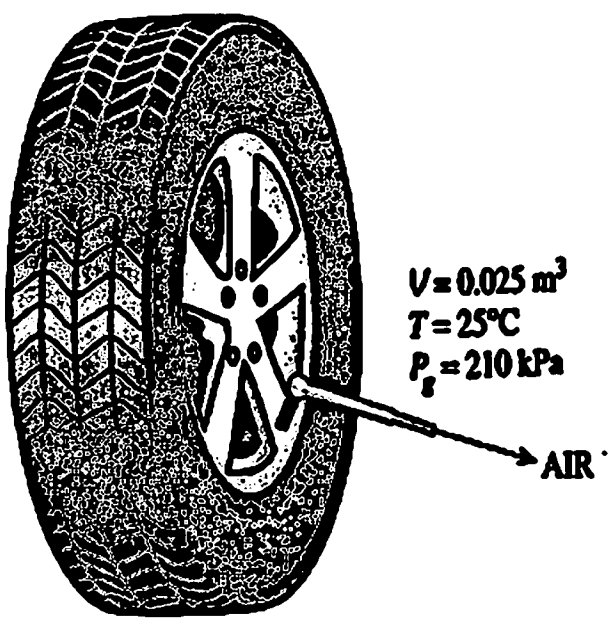


FIGURE P4–83

Step 1 of 4

Given

Initial air temperature, $T_1 = 25\,°C = 298\ K$
Initial gage pressure, $P_g = 210\ kPa$
Volume of the tire, $V = 0.025\ m^3$
Final Temperature, $T_2 = 50\,°C = 323\ K$
Atmospheric pressure, $P_{atm} = 100\ kPa$

Step 2 of 4

Assuming, at given conditions air behaves as an ideal gas.
Initially the absolute pressure in the tire is, $P_1 = P_g + P_{atm} = 210 + 100 = 310\ kPa$
From the ideal gas equation, we have

$$P_1V_1 = mRT_1 \quad \text{------ (1)}$$
$$P_2V_2 = mRT_2 \quad \text{------ (2)}$$

Assuming the volume of the tire remains constant
i.e., $V_1 = V_2$
From equations (1) and (2), eliminating m and R, we can write

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

Therefore, $P_2 = \dfrac{P_1T_2}{T_1}$

$$= \frac{310 \times 323}{298}$$

$$P_2 = 336\ kPa$$

Therefore pressure rise $\Delta p = P_2 - P_1$

$$= 336 - 310$$

Pressure rise $\Delta p = 26\ kPa$

Step 3 of 4

Therefore, $m_2 = \dfrac{310 \times 0.025}{0.287 \times 323}$

$$m_2 = 0.0836\ kg$$

The amount of air that must be bled off to restore pressure to its original value is,

$$\Delta m = m_1 - m_2$$
$$= 0.0906 - 0.0836$$
$$\boxed{\Delta m = 0.0070\ kg}$$

Question: 4.084P

What is the physical significance of the compressibility factor Z?

Step 1 of 1

Generally, gases deviate from the ideal-gas behaviour significantly at states near to the saturation region and the critical point (can be seen in fig. 3-49). This deviation from ideal-gas behaviour at a given temperature and pressure is accurately accounted by a correction factor called compressibility factor Z.

Question: 4.085P

What is the principle of corresponding states?

Step 1 of 1

The principle of corresponding states says that the compressibility factor for all gases is approximately the same at the same reduced pressure and temperature.

Question: 4.086P

How are the reduced pressure and reduced temperature defined?

Step 1 of 1

Reduced pressure and reduced temperature are the normalized pressure and temperature with respect to their critical pressure and temperature respectively.

Reduced pressure, P_R is

$$P_R = \frac{P}{P_{cr}}$$

where P_{cr} = critical pressure

Reduced temperature, T_R is

$$T_R = \frac{T}{T_{cr}}$$

where Tcr = critical temperature.

Question: 4.087P

Determine the specific volume of superheated water vapor at 15 MPa and 350°C, using (*a*) the ideal-gas equation, (*b*) the generalized compressibility chart, and (*c*) the steam tables. Also determine the error involved in the first two cases.

Step 1 of 6

Given
Superheated water at pressure $P = 15\text{MPa}$
Temperature $T = 350^0\,\text{C}$

Step 2 of 6

(a) Using ideal gas equation of state

$$v = \frac{RT}{P}$$

Where gas constant for superheated steam is

$$R = 0.4615\text{kJ/kg.K}$$

$$v = \frac{(0.4615)\times(350+273)}{(15000)}$$

$$\boxed{v = 0.01917\text{m}^3/\text{kg}}$$

Step 3 of 6

(b) Using compressibility chart
Critical state of water is

$$P_{cr} = 22.06\text{MPa}$$

$$T_{cr} = 647.1\text{K}$$

Reduced pressure is

$$P_R = \frac{P}{P_{cr}}$$

$$= \frac{15}{22.06}$$

$$P_R = 0.68$$

Reduced temperature is

$$T_R = \frac{T}{T_{cr}}$$

$$= \frac{350+273}{647.1}$$

$$T_R = 0.963$$

Using compressibility chart at $P_R = 0.68$ and $T_R = 0.963$

Compressibility factor $Z = 0.65$

Thus,

$$v_1 = Z\, v_{ideal}$$

$$= 0.65\times 0.01917$$

$$\boxed{v_1 = 0.01246\,\text{m}^3/\text{kg}}$$

Step 4 of 6

(c) From the superheated steam table
At $P = 15\text{MPa}, T = 350°\text{C}$

$$\boxed{v = 0.011481\text{m}^3/\text{kg}}$$

Step 5 of 6

Error involved by using ideal gas equation and by using superheated steam tables

$$\text{percentage error} = \frac{0.01917 - 0.011481}{0.011481}$$

$$\boxed{\text{Percentage error}=66.97\%}$$

Step 6 of 6

Error involved by using generalized compressibility chart and by using superheated steam tables

$$\text{percentage error} = \frac{0.01246 - 0.011481}{0.011481}$$

$$\boxed{\text{percentage error} = 8.52\%}$$

Question: 4.088P

Reconsider Prob. 4–87. Solve the problem using the generalized compressibility factor feature of the EES software. Again using EES, compare the specific volume of water for the three cases at 15 MPa over the temperature range of 350 to 600°C in 25°C intervals. Plot the percent error involved in the ideal-gas approximation against temperature, and discuss the results.

Step 1 of 1

4672-3-88E SA 0261

Analysis: The problem is solved using EES, and the solution is given below.

$$P = 15[MPa] \times Convert(MPa, kPa)$$

$$\{T_{Celsius} = 350[C]\}$$

$$T = T_{Celsius} + 273[K]$$

$$T_{critical} = T_{CRIT}(Steam_{IAPWS})$$

$$P_{critical} = P_{CRIT}(Steam_{IAPWS})$$

$$\{v = Vol / m\}$$

$$P_{table} = P; P_{comp} = P; P_{ideal\ gas} = P$$

$$T_{table} = T; T_{comp} = T; T_{ideal\ gas} = T$$

$$v_{table} = volume(Steam_{IAPWS}, P = P_{table}, T = T_{table})$$ "EES data for steam as a real gas"

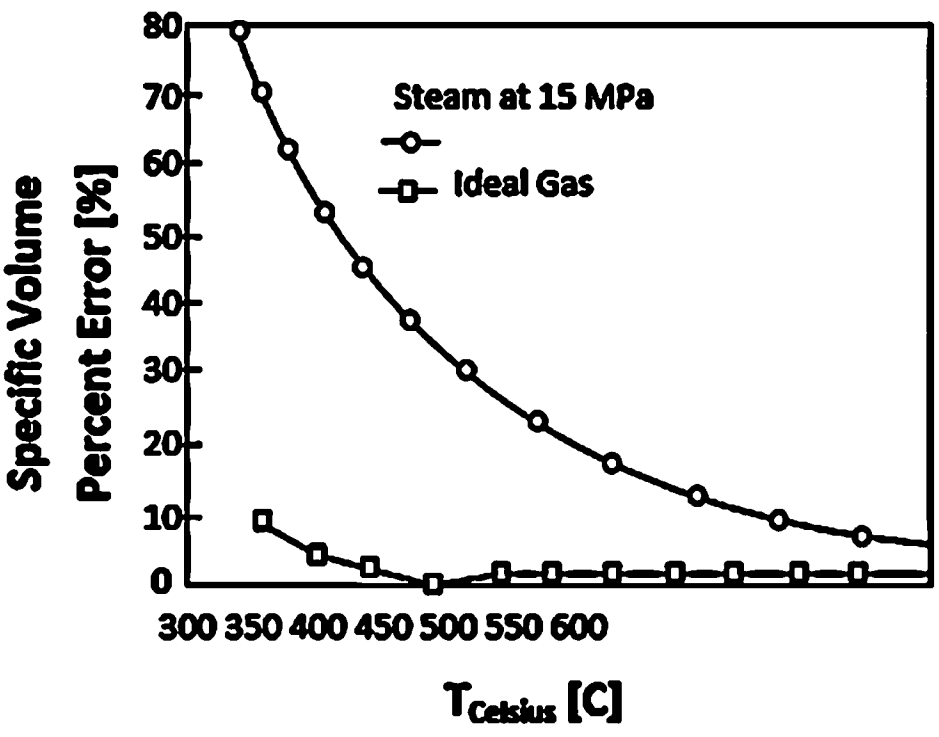
$$\{P_{table} = pressure(Steam_{IAPWS}, T = T_{table}, v = v)\}$$

$$\{T_{sat} = temperature(Steam_{IAPWS}, P = P_{table}, v = v)\}$$

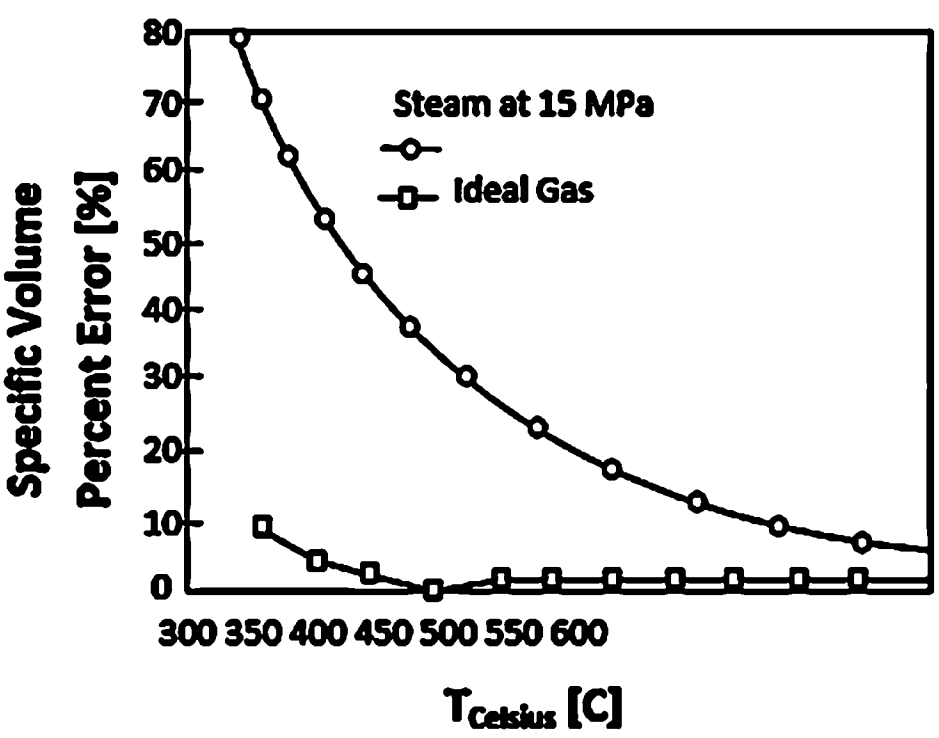
MM = MOLARMASS (water)

$$R_u = 8.314[kJ / kmol - K]$$ "Universal gas constant"

$$R = R_u / MM$$ "[kJ/kg-K], Particular gas constant"



$$P_{ideal\ gas} \times v_{ideal\ gas} = R \times T_{ideal\ gas}$$ "Ideal gas equation"



Z = COMPRESS $(T_{comp} / T_{critical}, P_{comp} / P_{critical})$

$$P_{comp} \times v_{comp} = z \times R \times T_{comp}$$ "generalized Compressibility factor"

$$Error_{ideal\ gas} = Abs(v_{table} - v_{ideal\ gas}) / v_{table} \times Convert(,\%)$$

$$Error_{comp} = Abs(v_{table} - v_{comp}) / v_{table} \times Convert(,\%)$$

Question: 4.089P

Determine the specific volume of refrigerant-134a vapor at 0.9 MPa and 70°C based on (*a*) the ideal-gas equation, (*b*) the generalized compressibility chart, and (*c*) data from tables. Also, determine the error involved in the first two cases.

Step 1 of 6

Given

Pressure, $P = 0.9$ MPa

Temperature, $T = 70\,^{\circ}C = 343$ K

Step 2 of 6

a) Assuming, the superheated refrigerant-134a behaves as an ideal gas at specified conditions.

For refrigerant-134a, gas constant $R = 0.08149$ kJ/kg K

From the ideal gas equation, specific volume is given by

$$v = \frac{RT}{P}$$

$$= \frac{0.08149 \times 343}{0.9 \times 1000}$$

$v = 0.03105$ m^3/kg.

Step 3 of 6

b) The critical pressure and temperature of refrigerant-134a are

$P_{cr} = 4.059$ MPa

$T_{cr} = 374.2$ K

Therefore,

$$\text{Reduced pressure, } P_r = \frac{P}{P_{cr}}$$

$$= \frac{0.9}{4.059}$$

$$P_r = 0.22$$

$$\text{Reduced temperature, } T_r = \frac{T}{T_{cr}}$$

$$= \frac{343}{374.2}$$

$$T_r = 0.916$$

Step 4 of 6

From compressibility chart (A-15), corresponding to the obtained P_r and T_r values, we have

$Z = 0.895$

Therefore, actual specific volume is

$$v_{actual} = Z \times v_{ideal}$$

$$= 0.895 \times 0.03105$$

$v_{actual} = 0.02778$ m^3/kg

Step 5 of 6

c) For superheated refrigerant-134a

for pressure, $P = 0.9$ MPa

and $T = 70\,^{\circ}C$

We have, $v = 0.027413$ m^3/kg.

Step 6 of 6

The error involved in the first case is,

$$\text{Error} = \frac{0.03105 - 0.027413}{0.027413} \times 100 = 13.26\%$$

The error involved in the second case is,

$$\text{Error} = \frac{0.02778 - 0.027413}{0.027413} \times 100 = 1.34\%$$

Question: 4.090P

Determine the specific volume of superheated water vapor at 3.5 MPa and 450°C based on (*a*) the ideal-gas equation, (*b*) the generalized compressibility chart, and (*c*) the steam tables. Determine the error involved in the first two cases.

Step 1 of 1

2760-3-92P

SA: 3801
SR: 4584

Given

Pressure, $P = 3.5$ MPa

Temperature, $T = 450\,^{\circ}C = 723$ K

---

a) Assuming, the superheated water behaves as an ideal gas at specified conditions.

For water, gas constant $R = 0.4615$ kJ/kg K (from Table-1)

From the ideal gas equation, specific volume is given by

$$v = \frac{RT}{P}$$

$$= \frac{0.4615 \times 723}{3.5 \times 1000}$$

$$\boxed{v = 0.09533\ m^3/kg}.$$

---

b) The critical pressure and temperature of water are

$P_{cr} = 22.06$ MPa

$T_{cr} = 647.1$ K

Therefore,

$$\text{Reduced pressure, } P_r = \frac{P}{P_{cr}}$$

$$= \frac{3.5}{22.06}$$

$$P_r = 0.158$$

$$\text{Reduced temperature, } T_r = \frac{T}{T_{cr}}$$

$$= \frac{723}{647.1}$$

$$T_r = 1.12$$

From compressibility chart (A-15), corresponding to the obtained P_r and T_r values, we have

$Z = 0.96$

Therefore, actual specific volume is

$$v_{actual} = Z \times v_{ideal}$$

$$= 0.96 \times 0.09533$$

$$v_{actual} = 0.09152\ m^3/kg$$

---

c) For superheated water (from Table A-6)

For pressure, $P = 3.5$ MPa

and $T = 450\,^{\circ}C$

We have, $\boxed{v = 0.09198\ m^3/kg}$

The error involved in the first case is,

$$\text{Error} = \frac{0.09533 - 0.09198}{0.09198} \times 100 = 3.64\%$$

The error involved in the second case is,

$$\text{Error} = \frac{0.09198 - 0.09152}{0.09198} \times 100 = 0.5\%$$

Question: 4.091P

Ethane in a rigid vessel is to be heated from 80 psia and 100°F until its temperature is 540°F. What is the final pressure of the ethane as predicted by the compressibility chart?

Step 1 of 6

Given

Initial pressure of Ethane $P_1 = 80\,\text{psia}$

Initial temperature $T_1 = 100^0\text{F}$

Final temperature $T_2 = 540^0\text{F}$

Step 2 of 6

The gas constant, the critical pressure, and the critical temperature of ethane are from table Molar mass, gas constant, and critical point properties

$R = 0.3574\,\text{psia.ft}^3\text{/lbm.R}$

$T_{cr} = 549.8\,\text{R}$

$P_{cr} = 708\,\text{psia}$

Step 3 of 6

Reduced parameters at state 1

$$T_{R_1} = \frac{T_1}{T_{cr}}$$

$$= \frac{(100+459.67)}{549.8}$$

$$T_{R1} = 1.018$$

$$P_{R_1} = \frac{P_1}{P_{cr}}$$

$$= \frac{80}{708}$$

$$P_{R_1} = 0.113$$

From compressibility chart at $T_{R1} = 1.018$ and $P_{R_1} = 0.113$

$Z_1 = 0.961$

Step 4 of 6

The specific volume does not change during the process. Then,

$$v_1 = v_2 = \frac{Z_1 R T_1}{P_1}$$

$$= \frac{0.961\times(0.3574)\times(559.67)}{80}$$

$$v_1 = v_2 = 2.403\,\text{ft}^3\text{/lbm}$$

Step 5 of 6

At the final state the reduced parameters are

$$T_{R_2} = \frac{T_2}{T_{cr}}$$

$$= \frac{(540+459.67)}{549.8}$$

$$T_{R_2} = 1.82$$

$$v_{R_2} = \frac{v_{2actual}}{RT_{cr}/P_{cr}}$$

$$= \frac{(2.403)}{(0.3574\times549.8)/708}$$

$$v_{R_2} = 8.66\text{ft}^3\text{/lbm}$$

Step 6 of 6

From compressibility chart at $T_{R_2} = 1.82$ and $v_{R_2} = 8.66\text{ft}^3\text{/lbm}$

$Z_2 = 0.98$

Thus,

$$P_2 = \frac{Z_2 R T_2}{v_2}$$

$$= \frac{(0.98\times0.3574\times999.67)}{2.403}$$

$$\boxed{P_2 = 145.71\,\text{psia}}$$

Question: 4.092P

Ethylene is heated at constant pressure from 5 MPa and 20°C to 200°C. Using the compressibility chart, determine the change in the ethylene's specific volume as a result of this heating.

Step 1 of 6

Given

Initial temperature of ethylene, $T_1 = 20\,^\circ C = 293\,K$

Final temperature, $T_2 = 200\,^\circ C = 473\,K$

Initial pressure = final pressure = $P = 5\,MPa$

Step 2 of 6

The gas constant, critical pressure and temperature of ethylene are

$R = 0.2964\ kJ/kg\,K$

$P_{cr} = 5.12\ MPa$

$T_{cr} = 282.4\ K$

The reduced pressure and temperature of initial state are

$$P_{R1} = \frac{P}{P_{cr}} = \frac{5}{5.12} = 0.9765$$

$$T_{R1} = \frac{T_1}{T_{cr}} = \frac{293}{282.4} = 1.0375$$

From the compressibility chart (Figure A-15), corresponding to P_{R1} and T_{R1},

The compressibility factor, $Z_1 = 0.58$ (approximately)

Step 3 of 6

Thus, initial specific volume (v_1) can be obtained from

$$v_1 = \frac{Z_1 R T_1}{P} = \frac{0.58 \times 0.2964 \times 293}{5000} = 0.01007\ m^3/kg$$

Step 4 of 6

The reduced pressure and temperature of final state are

$$P_{R2} = \frac{P}{P_{cr}} = \frac{5}{5.12} = 0.9765$$

$$T_{R2} = \frac{T_2}{T_{cr}} = \frac{473}{282.4} = 1.675$$

From the compressibility chart (Figure A-15), corresponding to P_{R2} and T_{R2},

The compressibility factor, $Z_2 = 0.95$ (approximately)

Step 5 of 6

Thus, final specific volume (v_2) can be obtained from

$$v_2 = \frac{Z_2 R T_2}{P} = \frac{0.95 \times 0.2964 \times 473}{5000} = 0.02664\ m^3/kg$$

Step 6 of 6

Therefore, change in specific volume of ethylene due to heating is

$$\Delta v = v_2 - v_1 = 0.02664 - 0.01007$$

$$\boxed{\Delta v = 0.01637\ \frac{m^3}{kg}}$$

Question: 4.093P

Saturated water vapor at 350°C is heated at constant pressure until its volume has doubled. Determine the final temperature using the ideal gas equation of state, the compressibility charts, and the steam tables.

Step 1 of 7

(a)

Calculate the temperature of steam from ideal gas equation.

$$\frac{P_1 v_1}{T_1} = \frac{P_2 v_2}{T_2}$$

Here, pressure of steam at state 1 is P_1, volume of steam at state 1 is v_1, temperature of steam at state 1 is T_1, pressure of steam at state 2 is P_2, volume of steam at state 2 is v_2 and temperature of steam at state 2 is T_2.

Substitute $P_1 = P_2$ because the process is isobaric pressure, $v_2 = 2v_1$ and $623\ \text{K}$ for T_1.

$$\frac{v_1}{623} = \frac{2v_1}{T_2}$$
$$T_2 = 1246\ \text{K}$$

Therefore, final temperature of steam is $\boxed{1246\ \text{K}}$.

Step 2 of 7

(b)

Write the gas constant, critical pressure and critical temperature of water from Table A-1.

$$R = 0.4615\ \text{kJ/kg}\cdot\text{K}$$
$$P_{cr} = 22.06\ \text{MPa}$$
$$T_{cr} = 647.1\ \text{K}$$

Calculate the initial pressure of saturated water vapour from Table A-4: saturated water-temperature table.

$$P_1 = P_{sat@350°C}$$
$$= 16.529\ \text{MPa}$$

Step 3 of 7

Calculate the reduced pressure at state 1.

$$P_{R1} = \frac{P_1}{P_{cr}}$$

Here, pressure at state 1 is P_1 and critical pressure of water is P_{cr}.

Substitute $16.529\ \text{MPa}$ for P_1 and $22.06\ \text{MPa}$ for P_{cr}.

$$P_{R1} = \frac{16.529}{22.06}$$
$$= 0.7493$$

Step 4 of 7

Calculate the reduced temperature at state 1.

$$T_{R1} = \frac{T_1}{T_{cr}}$$

Here, temperature of water at state 1 is T_1 and critical temperature of water is T_{cr}.

Substitute $623\ \text{K}$ for T_1 and $647.1\ \text{K}$ for T_{cr}.

$$T_{R1} = \frac{623}{647.1}$$
$$= 0.962$$

Step 5 of 7

Write the compressibility factor by using the compressibility chart from figure A-15 corresponding to $P_{R1} = 0.7493$ and $T_{R1} = 0.962$.

$$Z_1 = 0.593$$

Write the pseudo-reduced specific volume by using the compressibility chart from figure A-15 corresponding to $P_{R1} = 0.7493$ and $T_{R1} = 0.962$.

$$v_{R1} = 0.75$$

Step 6 of 7

Calculate the reduced pressure at state 2.

$$P_{R2} = P_{R1}$$

Here, reduced pressure at state 1 is P_{R1} and reduced pressure at state 2 is P_{R2}.

Substitute 0.7493 for P_{R1}.

$$P_{R2} = 0.7493$$

Calculate the reduced specific volume at state 3.

$$v_{R2} = 2v_{R1}$$

Here, reduced specific volume at state 1 is v_{R1} and reduced specific volume at state 2 is v_{R2}.

Substitute 0.75 for v_{R1}.

$$v_{R2} = 2 \times 0.75$$
$$= 1.5$$

Write the compressibility factor by using the compressibility chart from figure A-15 corresponding to $P_{R2} = 0.7493$ and $v_{R2} = 1.5$.

$$Z_2 = 0.88$$

Calculate the temperature at state 2.

$$T_2 = \frac{P_2 v_2}{Z_2 R}$$
$$= \frac{P_2 v_{R2} T_{cr}}{Z_2 P_{cr}}$$

Substitute $16529\ \text{kPa}$ for P_2, 1.5 for v_{R2}, $647.1\ \text{K}$ for T_{cr}, 0.88 for Z_2 and $22060\ \text{kPa}$ for P_{cr}.

$$T_2 = \frac{16529 \times 1.5 \times 647.1}{0.88 \times 22060}$$
$$= 826\ \text{K}$$

Therefore, the temperature of steam at exit is $\boxed{826\ \text{K}}$.

Step 7 of 7

(c)

Write the specific volume at state 1 corresponding to saturated temperature of $350°\text{C}$ from Table A-4: superheated steam table.

$$v_g = v_{g@350°C}$$
$$= 0.008806\ \text{m}^3/\text{kg}$$

Calculate the final specific volume.

$$v_2 = 2v_1$$

Substitute $0.008806\ \text{m}^3/\text{kg}$ for v_1.

$$v_2 = 2 \times 0.008806$$
$$= 0.017612\ \text{m}^3/\text{kg}$$

Write the temperature of the steam at exit from Table: A-6 corresponding to pressure $16529\ \text{kPa}$ and specific volume of $0.017612\ \text{m}^3/\text{kg}$.

$$T_{2@16529\ \text{kPa}, 0.017612\ \text{m}^3/\text{kg}} = 477°\text{C}$$
$$= 750\ \text{K}$$

Therefore, the temperature of steam at exit is $\boxed{750\ \text{K}}$.

Question: 4.094P pg 1

Saturated water vapor at 400°F is heated at constant pressure until its volume has doubled. Determine the final temperature using the ideal gas equation of state, the compressibility charts, and the steam tables.

Step 1 of 1

2760-3-96P SA: 3801

Given

Initial temperature of saturated water vapor, $T_1 = 400\ ^oF = 859.67\ R$

Final volume, $V_2 = 2 * \text{initial volume} = 2V_1$

---

a) From the ideal gas equation, we have

$P_1v_1 = RT_1$ ---- (1)

and $P_2v_2 = RT_2$ ---- (2)

This is constant pressure process.

Therefore, $P_2 = P_1$

From equations (1) and (2), eliminating pressure, mass and gas constant terms, we can write

$$\frac{v_2}{v_1} = \frac{T_2}{T_1}$$

Therefore, $T_2 = 2 * T_1$ (since $v_2 = 2v_1$)

$T_2 = 2 * 859.67$
Final temperature, $T_2 = 1719.34\ R$

---

b) The gas constant, critical pressure and temperature of water are (from Table A-1E)

$R = 0.5956$ psia ft^3/lbm R

$P_{cr} = 3200$ psia

$T_{cr} = 1164.8\ R$

Initial pressure of the saturated vapor is the saturation pressure at the given temperature which can be obtained from saturated water-temperature table (Table A-4E).

Therefore, $P_1 = P_{sat\ @\ 4000\ ^oF} = 247.26$ psia.

The reduced pressure and temperature of initial state are

$$P_{R1} = \frac{P_1}{P_{cr}}$$

$$= \frac{247.26}{3200}$$

$= 0.0773$

$$T_{R1} = \frac{T_1}{T_{cr}}$$

$$= \frac{859.67}{1164.8}$$

$= 0.738$

From the compressibility chart (Figure A-15), corresponding to P_{R1} and T_{R1},

The compressibility factor, $Z_1 = 0.93$ (approximately)

Thus, initial specific volume (v_1) can be obtained from

$$v_1 = \frac{Z_1RT_1}{P_1}$$

$$= \frac{0.93 \times 0.5956 \times 859.67}{247.26}$$

$v_1 = 1.9258\ ft^3$/lbm

Thus, final specific volume, $v_2 = 2v_1 = 3.8516\ ft^3$/lbm.

Therefore pseudo-reduced specific volume of final state is

$$v_{R2} = \frac{v_{actual}}{RT_{cr}/P_{cr}}$$

$$= \frac{3.8516}{0.5956 \times 1164.8 / 3200}$$

$= 17.766$

At the final state, we have

Reduced pressure, $P_{R2} = P_{R1} = 0.0773$

Pseudo- reduced specific volume, $v_{R2} = 17.766$

From the compressibility chart (Figure A-15), corresponding to P_{R2} and v_{R2},

The compressibility factor, $Z_2 = 0.98$ (approximately)

Therefore, final temperature is

$$T_2 = \frac{P_2v}{Z_2R}$$

$$= \frac{247.26 \times 3.8516}{0.98 \times 0.5956}$$

$T_2 = 1631.60\ R$

$$= \frac{247.26 \times 3.8516}{0.98 \times 0.5956}$$

$T_2 = 1631.60$ R

---

c) Given that the initial state is saturated water vapor at 400 °F. Thus the pressure of the saturated water vapor will be the saturation pressure at the given temperature and specific volume will be the specific volume of saturated vapor at the given temperature which can be determined from saturated water-temperature table (Table A-4E)

Therefore,

Initial pressure, $P_1 = P_{sat\ @\ 400\ °C} = 247.26$ psia

Initial specific volume = $v_1 = v_g = 1.8639$ ft^3/lbm.

Thus final pressure, $P_2 = P_1 = 247.26$ psia.

Final specific volume, $v_2 = 2 * v_1 = 2 * 1.8639$

$v_2 = 3.7278$ ft^3/lbm

Thus, the final state is defined by pressure and specific volume. We do not know which table to use to determine the missing properties because we have no clue as to whether we have saturated mixture, compressed liquid or superheated vapor, which can be determined from the specific volume of saturated liquid (v_f) and specific volume of saturated vapor (v_g) from the saturated water – pressure table (Table A-5E).

Actually from table A-5E, we have

At $P_A = 200$ psia

$v_{fA} = 0.01839$ ft^3/lbm

$v_{gA} = 2.2882$ ft^3/lbm

At $P_B = 250$ psia

$v_{fB} = 0.01865$ ft^3/lbm

$v_{gB} = 1.8440$ ft^3/lbm

It is known that the values of specific volume of saturated liquid (v_f) and specific volume of saturated vapor (v_g) at P = 247.26 psia lie in the range of values of specific volume of above two pressures. We can see that the given value, v = 3.7278 ft^3/lbm is greater than the value v_g. Thus we have superheated vapor and the temperature of the superheated vapor at given pressure can be obtained from superheated water table (Table A-6E)

At P = 247.26 psia and v = 3.7278 ft^3/lbm
We get T = 1100 °F = 155.67 R (approximately)

Question: 4.095P

Methane at 8 MPa and 300 K is heated at constant pressure until its volume has increased by 50 percent. Determine the final temperature using the ideal gas equation of state and the compressibility factor. Which of these two results is more accurate?

Step 1 of 5

Let V_1 be the initial volume.

Given

Initial pressure of methane, $P_1 = 8\ MPa$

Initial temperature, $T_1 = 300\ K$

Final volume, $V_2 = 1.5\ V_1$ (50 % more than initial volume)

Step 2 of 5

a) From the ideal gas equation, we have

$P_1 v_1 = RT_1$ ------ (1)

and $P_2 v_2 = RT_2$ -------- (2)

This is constant pressure process.

Therefore, $P_2 = P_1$

From equations (1) and (2), eliminating pressure, mass and gas constant terms, we can write

$$\frac{v_2}{v_1} = \frac{T_2}{T_1}$$

Therefore, $T_2 = 1.5T_1$ (since $v_2 = 1.5v_1$)

$T_2 = 1.5 \times 300$

Final temperature, $\boxed{T_2 = 450\ K}$

Step 3 of 5

b) The gas constant, critical pressure and temperature of methane are (from Table A-1)

$R = 0.5182\ kJ/kg\ K$

$P_{cr} = 4.64\ MPa$

$T_{cr} = 191.1\ K$

The reduced pressure and temperature of initial state are

$$P_{R1} = \frac{P_1}{P_{cr}} = \frac{8}{4.64} = 1.724$$

$$T_{R1} = \frac{T_1}{T_{cr}} = \frac{300}{191.1} = 1.57$$

From the compressibility chart (Figure A-15), corresponding to P_{R1} and T_{R1},

The compressibility factor, $Z_1 = 0.88$ (approximately)

Thus, initial specific volume (v_1) can be obtained from

$$v_1 = \frac{Z_1 RT_1}{P_1} = \frac{0.88 \times 0.5182 \times 300}{8000}$$

$v_1 = 0.0171006\ m^3/kg$

Step 4 of 5

Thus, final specific volume, $v_2 = 1.5v_1 = 0.02565\ m^3/kg$.

Therefore pseudo-reduced specific volume of final state is

$$v_{R2} = \frac{v_{actual}}{R\frac{T_{cr}}{P_{cr}}} = \frac{0.02565}{0.5182 \times \frac{191.1}{4640}} = 1.2018$$

At the final state, we have

Reduced pressure, $P_{R2} = P_{R1} = 1.724$

Pseudo- reduced specific volume, $v_{R2} = 1.2018$

From the compressibility chart (Figure A-15), corresponding to P_{R2} and v_{R2},

The compressibility factor, $Z_2 = 0.97$ (approximately)

Therefore, final temperature is

$$T_2 = \frac{P_2 v}{Z_2 R} = \frac{8000 \times 0.02565}{0.97 \times 0.5182}$$

$\boxed{T_2 = 408.23\ K}$

Step 5 of 5

Of these two results, the second result will be more accurate as it takes into account the real behaviour of the gases. The accuracy of the second result is only affected by the error in reading the charts.

Question: 4.096P

What is the percentage of error involved in treating carbon dioxide at 5 MPa and 25°C as an ideal gas?

Step 1 of 4

Obtain the properties of CO_2 from table "gas constant and critical point properties".

Critical temperature $T_{cr} = 304.2\text{K}$

Critical pressure $P_{cr} = 7.39\text{MPa}$

Gas constant $R = 0.1889\text{kJ/kg}\cdot\text{K}$

State the ideal gas equation.

$$Pv_{ideal} = RT$$

Here, P is pressure of the gas, v is specific volume and T is temperature of the gas.

Substitute $5\text{MPa} = 5\times10^3\text{ kPa}$ for P and $25°\text{C} = (25+273)\text{K}$ for T to find the specific volume.

$$5\times10^3\times v_{ideal} = 0.1889\times(25+273)$$

$$v_{ideal} = 0.01125\text{m}^3/\text{kg}$$

Step 2 of 4

Find the reduced pressure by using the following equation.

$$P_R = \frac{P}{P_{cr}}$$

$$= \frac{5}{7.39}$$

$$= 0.68$$

Find the reduced temperature by using the following equation.

$$T_R = \frac{T}{T_{cr}}$$

$$= \frac{25+273}{304.2}$$

$$= 0.98$$

Step 3 of 4

Note down the compressibility factor value from the "compressibility chart" at $P_R = 0.68$ and $T_R = 0.98$.

$$Z = 0.7$$

Now find the specific volume by using the following equation:

$$Pv = ZRT$$

$$5\times10^3\times v = 0.7\times0.1889\times(25+273)$$

$$v = 0.0078\text{m}^3/\text{kg}$$

Step 4 of 4

Then find the error involved in treating CO_2 as an ideal gas by using the following expression:

$$\%\text{ error} = \frac{v_{ideal} - v}{v}\times100$$

$$= \frac{0.01125 - 0.0078}{0.0078}\times100$$

$$= 44.23\%$$

Therefore, the percentage of error involved in treating Carbon dioxide as an ideal gas is $\boxed{44.23\%}$.

Question: 4.097P

Carbon dioxide gas enters a pipe at 3 MPa and 500 K at a rate of 2 kg/s. CO2 is cooled at constant pressure as it flows in the pipe and the temperature of CO2 drops to 450 K at the exit. Determine the volume flow rate and the density of carbon dioxide at the inlet and the volume flow rate at the exit of the pipe using (*a*) the ideal-gas equation and (*b*) the generalized compressibility chart. Also, determine (*c*) the error involved in the first case.

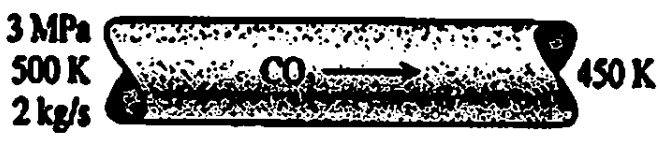


FIGURE P4–97

Step 1 of 3

(a)

From the properties table of carbon dioxide, the gas constant (*R*) is 0.1889 kJ/kg-K. Now find the density at inlet substituting 500 K for T_1 and 3000 kPa for P_1

$$P_1 = \rho_1 R T_1$$

$$\rho_1 = \frac{P_1}{RT_1}$$

$$= \frac{3000}{0.1889 \times 500}$$

$$= 31.763 \text{ kg/m}^3$$

Thus the density of carbon dioxide at inlet is $\boxed{31.763 \text{ kg/m}^3}$

Determine the ideal volume flow rate by using the density of carbon dioxide at inlet and mass flow rate $(\dot{m})$ of 2 kg/s.

$$\dot{V}_1 = \frac{\dot{m}}{\rho_1}$$

$$= \frac{2}{31.763}$$

$$= 0.0629 \text{ m}^3/\text{s}$$

Thus the ideal volume flow rate of carbon dioxide at inlet is $\boxed{0.0629 \text{ m}^3/\text{s}}$

Determine the ideal volume flow rate at exit by applying the ideal gas relation to carbon dioxide whose exit temperature (T_2) is 450 K and exit pressure (P_2) is 3000 kPa.

$$\dot{V}_2 = \frac{\dot{m} R T_2}{P_2}$$

$$= \frac{2 \times 0.1889 \times 450}{3000}$$

$$= 0.05667 \text{ m}^3/\text{s}$$

Thus the ideal volume flow rate of carbon dioxide at exit is $\boxed{0.05667 \text{ m}^3/\text{s}}$

Step 2 of 3

(b)

From the critical properties table, for carbon dioxide the critical pressure (P_{cr}) value is 7390 kPa and critical temperature (T_{cr}) is 304.2 K

The reduced properties (reduced temperature and reduced pressure) at inlet are

$$T_{R1} = \frac{T_1}{T_{cr}}$$

$$= \frac{500}{304.2}$$

$$= 1.644$$

$$P_{R1} = \frac{P_1}{P_{cr}}$$

$$= \frac{3000}{7390}$$

$$= 0.406$$

From the compressibility chart, the factor (Z_1) corresponding to the reduced temperature and pressure is 0.97

So determine the actual volume flow rate using the compressibility factor.

$$\dot{V}_1 = Z_1 \left(\frac{\dot{m} R T_1}{P_1} \right)$$

$$= 0.97 \left(\frac{2 \times 0.1889 \times 500}{3000} \right)$$

$$= 0.061077 \text{ m}^3/\text{s}$$

Thus the actual volume flow rate of carbon dioxide at inlet is $\boxed{0.061077 \text{ m}^3/\text{s}}$

Step 3 of 3

Find the actual density at inlet using the mass flow rate and actual inlet volume flow rate

$$\rho_1 = \frac{\dot{m}}{\dot{V}_1}$$

$$= \frac{2}{0.061077}$$

$$= 32.745 \text{ kg/m}^3$$

Thus the actual density of carbon dioxide at inlet is $\boxed{32.745 \text{ kg/m}^3}$

The reduced properties (reduced temperature and reduced pressure) at exit are

$$T_{R2} = \frac{T_2}{T_{cr}}$$

$$= \frac{450}{304.2}$$

$$= 1.48$$

$$P_{R2} = \frac{P_2}{P_{cr}}$$

$$= \frac{3000}{7390}$$

$$= 0.406$$

From the compressibility chart, the factor (Z_1) corresponding to the reduced temperature and pressure is 0.9656

So determine the actual volume flow rate using the compressibility factor.

$$\dot{V}_2 = Z_2 \left(\frac{\dot{m} R T_2}{P_2} \right)$$

$$= 0.9656 \left(\frac{2 \times 0.1889 \times 450}{3000} \right)$$

$$= 0.05472 \text{ m}^3/\text{s}$$

Thus the actual volume flow rate of carbon dioxide at exit is $\boxed{0.05472 \text{ m}^3/\text{s}}$

Question: 4.098P

Determine the specific volume of nitrogen gas at 10 MPa and 150 K based on (*a*) the idea-gas equation and (*b*) the generalized compressibility chart. Compare these results with the experimental value of 0.002388 m3/kg, and determine the error involved in each case.

Step 1 of 5

Given

Pressure, $P = 10\ MPa$

Temperature, $T = 150\ K = -123\ °C$

Step 2 of 5

a) Assuming, the nitrogen behaves as an ideal gas at specified conditions.

For nitrogen, gas constant $R = 0.2968\ kJ/kg\ K$

From the ideal gas equation, specific volume is given by

$$v = \frac{RT}{P}$$

$$= \frac{0.2968 \times 150}{10 \times 1000}$$

$$\boxed{v = 0.004452\ m^3/kg}$$

Step 3 of 5

b) The critical pressure and temperature of nitrogen are (from Table-1)

$P_{cr} = 3.39\ MPa$

$T_{cr} = 126.2\ K$

Therefore,

$$\text{Reduced pressure, } P_r = \frac{P}{P_{cr}}$$

$$= \frac{10}{3.39}$$

$$P_r = 2.95$$

$$\text{Reduced temperature, } T_r = \frac{T}{T_{cr}}$$

$$= \frac{150}{126.2}$$

$$T_r = 1.188$$

Step 4 of 5

From compressibility chart (A-15), corresponding to the obtained P_r and T_r values, we have

$Z = 0.54$

Therefore, actual specific volume is

$$v_{actual} = Z \times v_{ideal}$$

$$= 0.54 \times 0.004452$$

$$v_{actual} = 0.002403\ m^3/kg$$

Step 5 of 5

c) Given the experimental value is, $v = 0.002388\ m^3/kg$

The error involved in the first case is,

$$\text{Error} = \frac{0.004452 - 0.002388}{0.002388} \times 100 = 86.43\%$$

The error involved in the second case is,

$$\text{Error} = \frac{0.002403 - 0.002388}{0.002388} \times 100 = 0.628\%$$

Question: 4.099P

A rigid tank contains nitrogen gas at 227°C and 100 kPa gage. The gas is heated until the gage pressure reads 250 kPa. If the atmospheric pressure is 100 kPa, determine the final temperature of the gas, in °C.

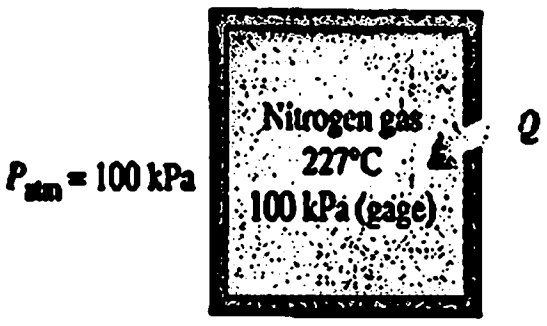

FIGURE P4–99

Step 1 of 3

Given

Initial temperature of nitrogen $T_1 = 227^\circ C$

Question:

A rigid tank contains nitrogen gas at 227°C and 100 kPa gage. The gas is heated until the gage pressure reads 250 kPa. If the atmospheric pressure is 100 kPa, determine the final temperature of the gas, in °C.

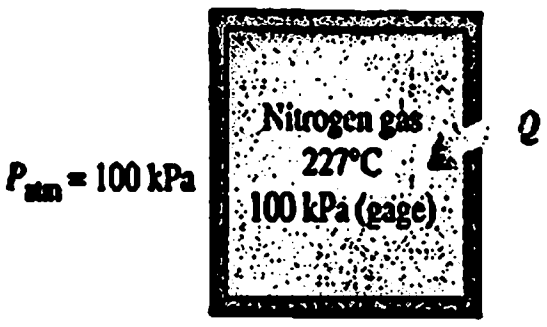

FIGURE P4–99

Step 1 of 3

Given

Initial temperature of nitrogen $T_1 = 227^\circ C$

$t_1 \quad t_2$

$$T_2 = \frac{P_2 T_1}{P_1}$$

$$= \frac{350 \times 500}{200}$$

$$T_2 = 875K$$

$$T_2 = 602^\circ C$$

Therefore final temperature of gas

$$\boxed{T_2 = 602^\circ C}$$

$t_1 \quad t_2$

$$T_2 = \frac{P_2 T_1}{P_1}$$

$$= \frac{350 \times 500}{200}$$

$$T_2 = 875K$$

$$T_2 = 602^\circ C$$

Therefore final temperature of gas

$$\boxed{T_2 = 602^\circ C}$$

Question: 4.100P

Carbon-dioxide gas at 3 MPa and 500 K flows steadily in a pipe at a rate of 0.4 kmol/s. Determine (*a*) the volume and mass flow rates and the density of carbon dioxide at this state. If CO2 is cooled at constant pressure as it flows in the pipe so that the temperature of CO2 drops to 450 K at the exit of the pipe, determine (*b*) the volume flow rate at the exit of the pipe.

FIGURE P4–100

Step 1 of 4

Find the volume flow rate of carbon dioxide at the entrance of the pipe by using the following equation:

$$p_1\dot{v}_1 = \dot{n}R_uT_1$$

$$\dot{v}_1 = \frac{\dot{n}R_uT_1}{p_1}$$

Question:

Carbon-dioxide gas at 3 MPa and 500 K flows steadily in a pipe at a rate of 0.4 kmol/s. Determine (*a*) the volume and mass flow rates and the density of carbon dioxide at this state. If CO2 is cooled at constant pressure as it flows in the pipe so that the temperature of CO2 drops to 450 K at the exit of the pipe, determine (*b*) the volume flow rate at the exit of the pipe.

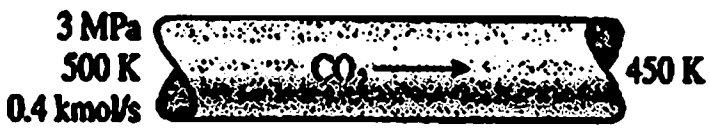

FIGURE P4–100

Step 1 of 4

Find the volume flow rate of carbon dioxide at the entrance of the pipe by using the following equation:

$$p_1\dot{v}_1 = \dot{n}R_uT_1$$

$$\dot{v}_1 = \frac{\dot{n}R_uT_1}{p_1}$$

$$= \frac{0.1889\times500}{3}$$

$$= 17.596\,\text{kg/s}$$

Therefore, mass flow rate of carbon dioxide at the entrance of the pipe is $\boxed{17.596\,\text{kg/s}}$

Step 3 of 4

Find the density of carbon dioxide at the entrance of the pipe by using the following equation:

$$p_1 = \rho_1 RT_1$$

$$\rho_1 = \frac{p_1}{RT_1}$$

Substitute 3 MPa for p_1, 500 K for T_1, and $0.1889\,\text{kJ/kg.K}$ for R.

$$\rho_1 = \frac{3\times1000}{0.1889\times500}$$

$$= 31.76\,\text{kg/m}^3$$

Therefore, the density of carbon dioxide at the entrance of the pipe is $\boxed{31.76\,\text{kg/m}^3}$.

Step 4 of 4

Find the volume flow rate of carbon dioxide at the exit of the pipe by using the following equation:

$$\dot{v}_1 = \frac{0.1889\times500}{3}$$

$$= 17.596\,\text{kg/s}$$

Therefore, mass flow rate of carbon dioxide at the entrance of the pipe is $\boxed{17.596\,\text{kg/s}}$

Step 3 of 4

Find the density of carbon dioxide at the entrance of the pipe by using the following equation:

$$p_1 = \rho_1 RT_1$$

$$\rho_1 = \frac{p_1}{RT_1}$$

Substitute 3 MPa for p_1, 500 K for T_1, and $0.1889\,\text{kJ/kg.K}$ for R.

$$\rho_1 = \frac{3\times1000}{0.1889\times500}$$

$$= 31.76\,\text{kg/m}^3$$

Therefore, the density of carbon dioxide at the entrance of the pipe is $\boxed{31.76\,\text{kg/m}^3}$.

Question:

4.101P

The combustion in a gasoline engine may be approximated by a constant volume heat addition process. There exists the air–fuel mixture in the cylinder before the combustion and the combustion gases after it, and both may be approximated as air, an ideal gas. In a gasoline engine, the cylinder conditions are 1.4 MPa and 450°C before the combustion and 1600°C after it. Determine the pressure at the end of the combustion process.

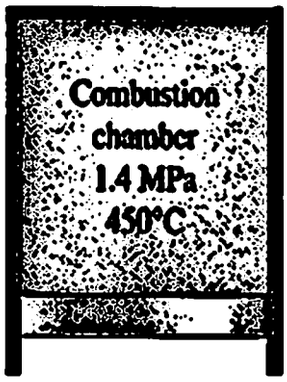

FIGURE P4–101

Step 1 of 2

Given

Pressure before combustion $P_1 = 1.4\,\text{MPa}$

Temperature before combustion $T_1 = 450^0\text{C}$

$$T_1 = 450 + 273$$

$$T_1 = 723\,\text{K}$$

Temperature after combustion $T_2 = 1600^0\text{C}$

$$T_2 = 1600 + 273$$

$$T_2 = 1873\,\text{K}$$

Step 2 of 2

Assume air fuel mixture is an ideal gas

Since the Process is constant volume

Applying the ideal gas equation

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

$$P_1 T_2 = P_2 T_1$$

$$P_2 = \frac{P_1 T_2}{T_1}$$

$$= \frac{1.4 \times 1873}{723}$$

$$\boxed{P_2 = 3.63\,\text{MPa}}$$

Question: 4.102P

Combustion in a diesel engine may be modeled as a constant-pressure heat addition process with air in the cylinder before and after combustion. Consider a diesel engine with cylinder conditions of 950 K and 75 cm3 before combustion, and 150 cm3 after it. The engine operates with an air-fuel ratio of 22 kg air/kg fuel (the mass of the air divided by the mass of the fuel). Determine the temperature after the combustion process.

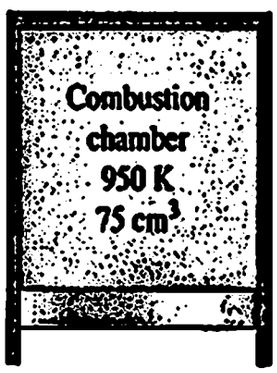

FIGURE P4–102

Step 1 of 2

Given data:

Temperature of the air before combustion, $T_1 = 950\text{K}$

Volume of the air before combustion, $V_1 = 75\,\text{cm}^3$

Volume of the air after the combustion, $V_2 = 150\,\text{cm}^3$

Air fuel ratio, $\frac{m_a}{m_f} = 22\,\text{kg air/kg fuel}$

Step 2 of 2

The ratio of initial and final mass of the air,

$$\frac{m_1}{m_2} = \frac{AF}{AF+1}$$
$$= \frac{22}{22+1}$$
$$= 0.956$$

From the ideal gas equation, $PV = mRT$

$$\frac{T_2}{T_1} = \left(\frac{m_1}{m_2}\right)\left(\frac{V_2}{V_1}\right)$$
$$T_2 = \left(\frac{m_1}{m_2}\right)\left(\frac{V_2}{V_1}\right)T_1$$
$$= 0.956\left(\frac{150}{75}\right)(950)$$
$$= 1816.4\text{K}$$

Therefore, the temperature of the air after the combustion process is $\boxed{T_2 = 1816.4\text{K}}$

Question: 4.103P

One kilogram of R-134a fills a 0.090 m3 rigid container at an initial temperature of −40°C. The container is then heated until the pressure is 280 kPa. Determine the initial pressure and final temperature.

Step 1 of 3

Given

Mass of R-134a $m = 1\text{kg}$

Volume of the rigid container $V = 0.090\text{m}^3$

Initial temperature $T_1 = -40^0\text{C}$

Final pressure $P_2 = 280\text{kPa}$

Step 2 of 3

Specific volume

$v_1 = V / m$

$v_1 = 0.090 / 1$

$v_1 = 0.090\text{m}^3/\text{kg}$

At $T_1 = -40^0\text{C}$ from saturated R-134a tables

$v_f < v_1 < v_g$

Therefore the state is in liquid and vapor mixture

Then initial pressure will be the saturation pressure at temperature $T_1 = -40^0\text{C}$ from saturated R-134a tables

$P_1 = P_{sat} = 51.25\text{kPa}$

$\boxed{P_1 = 51.25\text{kPa}}$

Step 3 of 3

Since the process is constant volume

At $P_2 = 280\text{kPa}$ and $v_2 = v_1 = 0.090\text{m}^3/\text{kg}$ from superheated R-134a tables

$T_2 = 50°\text{C}$

Therefore the final temperature is $\boxed{T_2 = 50°\text{C}}$

Question: 4.104P

One pound-mass of water fills a 2.649 ft3 weighted piston-cylinder device at a temperature of 400°F. The piston-cylinder device is now cooled until its temperature is 100°F. Determine the final pressure and volume of the water.

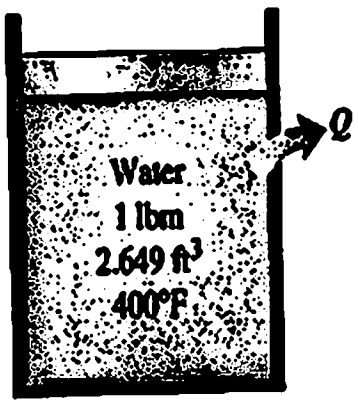

FIGURE P4–104E

Step 1 of 2

Calculate the Initial specific volume of the water,

$$v_1 = \frac{V}{m}$$

Here,

Volume of the water the device, V

Mass of the water, m

Substitute $2.649\,\text{ft}^3$ for V , $1\,\text{lb}$ for m

$$\begin{aligned} v_1 &= \frac{V}{m} \\ &= \frac{2.649}{1} \\ &= 2.649\,\text{ft}^3/\text{lbm} \end{aligned}$$

From the properties of the superheated water tables,

At $T_1 = 400°\text{F}$ and specific volume $v_1 = 2.649\,\text{ft}^3/\text{lbm}$

Pressure $P_1 = 180\,\text{psia}$

Since, the cooling process in piston cylinder device is constant pressure process,

The final pressure of the water in the piston cylinder device, $\boxed{180\,\text{psia}}$

Step 2 of 2

From the saturated water –temperature table

Specific volume of the water at $T_2 = 100°\text{F}$,

$$v_2 = 0.01613\,\text{ft}^3/\text{lbm}$$

Here,

Specific volume of the water is v_2

Calculate the Final volume of the water in the device,

$$V_2 = mv_2$$

Substitute $0.01613\,\text{ft}^3/\text{lbm}$ for v_2

$$\begin{aligned} V_2 &= mv_2 \\ &= (1)(0.01613) \\ &= 0.01613\,\text{ft}^3 \end{aligned}$$

Therefore, volume of the water after the cooling process, $\boxed{0.01613\,\text{ft}^3}$

Question: 4.105P

Ethane at 10 MPa and 100°C is heated at constant pressure until its volume has increased by 60 percent. Determine the final temperature using (*a*) the ideal gas equation of state and (*b*) the compressibility factor. Which of these two results is the more accurate?

Step 1 of 5

Given data:

Initial temperature of ethane $T_1 = 100°C$

Initial pressure of the nitrogen $P_1 = 10MPa$

Step 2 of 5

Let the initial volume of the gas V_1

Increased volume after the heating process

$$V_2 = V_1 + 0.6V_1$$
$$= 1.6V_1$$

(a) By the ideal gas equation $PV = mRT$

For the constant pressure process

$$\frac{RT_1}{V_1} = \frac{RT_2}{V_2}$$
$$T_2 = \frac{T_1V_2}{V_1}$$
$$= \frac{(100+273)(1.6V_1)}{V_1}$$
$$= 596.8K$$

Therefore, final temperature of the ethane gas, $\boxed{T_2 = 596.8K}$

Step 3 of 5

(b) Using the compressibility factor:

From the properties of the ethane,

Critical temperature $T_{cr} = 305.5K$

Critical pressure $P_{cr} = 4.48MPa$

critical volume $V_{cr} = 0.148 m^3/kmol$

Reduced pressure

$$P_R = \frac{P_1}{P_{cr}}$$
$$= \frac{10}{4.48}$$
$$= 2.23$$

Reduced temperature

$$T_R = \frac{T_1}{T_{cr}}$$
$$= \frac{100}{305.5}$$
$$= 0.327$$

Step 4 of 5

From the Nelson- Obert compressibility chart at $P_{R1} = 2.23$ and $T_{R1} = 0.327$

Compressibility factor $Z_1 = 0.6$

At $P_{R1} = 2.23$ and $Z_1 = 0.6$

Reduced volume $V_{R1} = 0.351$

For the final conditions,

Reduced pressure $P_{R1} = P_{R2} = 2.23$

Reduced volume

$$V_{R2} = 1.6V_{R1}$$
$$= 1.6(0.351)$$
$$= 0.562$$

At $P_{R2} = 2.23$ and $V_{R2} = 0.562$

Compressibility factor $Z_2 = 0.83$

Step 5 of 5

Final temperature of the ethane,

$$T_2 = \frac{P_2V_2}{Z_2R}$$

Pseudo- reduced specific volume

$$V_R = \frac{V_{actual}}{(RT_{cr}/P_{cr})}$$

Therefore,

$$T_2 = \frac{P_2V_2}{Z_2R}$$
$$= \left(\frac{P_2}{Z_2R}\right)\left(\frac{V_{R2}RT_{cr}}{P_{cr}}\right)$$
$$= \left(\frac{P_2}{Z_2}\right)\left(\frac{V_{R2}T_{cr}}{P_{cr}}\right)$$
$$= \left(\frac{P_1}{Z_2}\right)\left(\frac{V_{R2}T_{cr}}{P_{cr}}\right) \qquad (\text{since } P_2 = P_1)$$
$$= \left(\frac{10MPa}{0.83}\right)\left(\frac{0.562\times305.5K}{4.48MPa}\right)$$
$$= 461.733K$$

Therefore, the final temperature of the ethane, $\boxed{T_2 = 461.733K}$

Extracting the error associated with the chart reading, temperature found by the compressibility chart is more accurate.

Question:

4.106P

A 20-m3 tank contains nitrogen at 23°C and 600 kPa. Some nitrogen is allowed to escape until the pressure in the tank drops to 400 kPa. If the temperature at this point is 20°C, determine the amount of nitrogen that has escaped.

Step 1 of 3

Given data:

Volume of the tank $V = 20\,\text{m}^3$

Initial temperature of nitrogen $T_1 = 23°\text{C}$

Initial pressure of the nitrogen $P_1 = 600\,\text{kPa}$

Final pressure of the nitrogen $P_2 = 400\,\text{kPa}$

Final temperature of the nitrogen $T_2 = 20°\text{C}$

Step 2 of 3

From the ideal gas equation

$PV = mRT$

For the initial conditions $T_1 = 23°\text{C}$ and $P_1 = 600\,\text{kPa}$

$$P_1V_1 = m_1RT_1$$

$$m_1 = \frac{P_1V_1}{RT_1}$$

$$= \frac{600\,\text{kPa} \times 20\,\text{m}^3}{\left(\frac{8.314}{28}\right)\frac{\text{kPa}\cdot\text{m}^3}{\text{kg}\cdot\text{K}} \times (23+273)\,\text{K}}$$

$$= 136.533\,\text{kg}$$

Step 3 of 3

For the final condition $T_2 = 20°\text{C}$ and $P_2 = 400\,\text{kPa}$

$$P_2V_2 = m_2RT_2$$

$$m_2 = \frac{P_2V_2}{RT_2}$$

$$= \frac{400\,\text{kPa} \times 20\,\text{m}^3}{\left(\frac{8.314}{28}\right)\frac{\text{kPa}\cdot\text{m}^3}{\text{kg}\cdot\text{K}} \times (20+273)\,\text{K}}$$

$$= 91.954\,\text{kg}$$

By the mass balance equation

Amount of nitrogen escaped from the tank,

$$\Delta m = m_1 - m_2$$

$$= 136.533 - 91.954$$

$$= 44.58\,\text{kg}$$

Therefore, the amount of nitrogen escaped from the tank, $\boxed{\Delta m = 44.58\,\text{kg}}$

Question: 4.107P

A 4-L rigid tank contains 2 kg of saturated liquid–vapor mixture of water at 50°C. The water is now slowly heated until it exists in a single phase. At the final state, will the water be in the liquid phase or the vapor phase? What would your answer be if the volume of the tank were 400 L instead of 4 L?

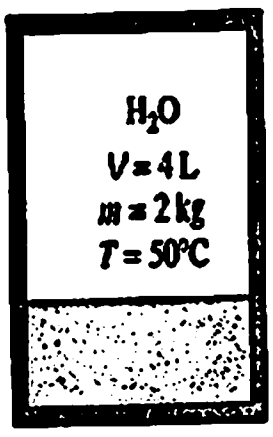

FIGURE P4–107

Step 1 of 3

The water is heated in rigid tank and the volume is constant after the heating process.

Therefore, the heating process is a constant volume process ($v = V/m = \text{constant}$).

Thus the final specific volume of mixture, v_f , is equal to initial specific volume v_i .

$$v_f = v_i = v$$

Obtain the critical specific volume of water from table A-1, "The critical-point properties table".

$$\begin{aligned} v_{cr} &= 0.0560\,\text{m}^3/\text{kmol} \\ &= 0.0560\,\text{m}^3/\text{kmol} \times \frac{1}{18.015\,\text{kg/kmol}} \\ &= 0.0031\,\text{m}^3/\text{kg} \end{aligned}$$

Step 2 of 3

If the final specific volume of water is less than the critical specific volume (v_{cr}), then the water is in liquid state, otherwise the water is in vapor state.

Find the specific volume of the $4\,\text{L}$ tank volume.

$$v = \frac{V}{m}$$

Here, m is mass of liquid-vapor mixture of water, V is the total volume.

Substitute 2 kg for m and $4\,\text{L}$ for V.

$$\begin{aligned} v &= \frac{4\,\text{L} \times \dfrac{10^{-3}\,\text{m}^3}{\text{L}}}{2\,\text{kg}} \\ &= \frac{0.004}{2} \\ &= 0.002\,\text{m}^3/\text{kg} \\ &< v_{cr} \end{aligned}$$

Therefore, the water will exist in liquid state.

Step 3 of 3

If the rigid tank volume is considered as $400\,\text{L}$, then calculate the specific volume of tank by using the following equation:

$$v = \frac{V}{m}$$

Substitute 2 kg for m and $400\,\text{L}$ for V.

$$\begin{aligned} v &= \frac{400\,\text{L} \times \dfrac{10^{-3}\,\text{m}^3}{\text{L}}}{2\,\text{kg}} \\ &= \frac{0.4}{2} \\ &= 0.2\,\text{m}^3/\text{kg} > v_{cr} \end{aligned}$$

Therefore, the water will exist in vapor state.

Question:

4.108P

The gage pressure of an automobile tire is measured to be 200 kPa before a trip and 220 kPa after the trip at a location where the atmospheric pressure is 90 kPa. Assuming the volume of the tire remains constant at 0.035 m3, determine the percent increase in the absolute temperature of the air in the tire.

Step 1 of 3

Given data:

The gage pressure of an automobile tire before trip, $P_{gauge,1} = 200\,\text{kPa}$

The gage pressure of an automobile tire after trip, $P_{gauge,2} = 220\,\text{kPa}$

The atmospheric pressure, $P_{atm} = 90\,\text{kPa}$

The constant volume of tire, $V_1 = V_2 = 0.035\,\text{m}^3$

Step 2 of 3

The absolute pressure of an automobile tire before trip,

$$P_1 = P_{gauge,1} + P_{atm}$$
$$= 200 + 90$$
$$= 290\,\text{kPa}$$

The absolute pressure of an automobile tire after trip,

$$P_2 = P_{gauge,2} + P_{atm}$$
$$= 220 + 90$$
$$= 310\,\text{kPa}$$

Step 3 of 3

By using ideal gas law, we get $\frac{PV}{T} = \text{constant}$

Therefore we can write,

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$

$$\frac{T_2}{T_1} = \frac{P_2V_2}{P_1V_1}$$

$$\frac{T_2}{T_1} = \frac{P_2}{P_1} \quad (\text{since}, V_1 = V_2)$$

$$= \frac{310}{290}$$
$$= 1.069$$

$$T_2 = 1.069T_1$$

Therefore, the percentage increase in absolute temperature of the air in the tire is 6.9.

Question: 4.109P

Steam at 400°C has a specific volume of 0.02 m3/kg. Determine the pressure of the steam based on (*a*) the ideal-gas equation, (*b*) the generalized compressibility chart, and (*c*) the steam tables.

Step 1 of 6

Given data:

The temperature of steam,

$T = 400\,^{\circ}\mathrm{C}$

$= 400+273$

$= 673\mathrm{K}$

The specific volume of steam, $v = 0.02\,\mathrm{m}^3/\mathrm{kg}$

Step 2 of 6

From the property tables, the properties of water:

Gas constant, $R = 0.4615\,\mathrm{kJ/kg\cdot K}$

Critical temperature, $T_c = 647.1\mathrm{K}$

Critical pressure, $P_c = 22.06\,\mathrm{MPa}=22060\,\mathrm{kPa}$

Step 3 of 6

(a)

By using ideal gas equation, we get

$$P = \frac{RT}{v}$$

$$= \frac{0.4615\times 673.1}{0.02}$$

$$= 15531.782\,\mathrm{kPa}$$

The pressure of steam, $\boxed{P = 15531.782\,\mathrm{kPa}}$.

Step 4 of 6

(b)

From the compressibility chart, we have

Reduced temperature,

$$T_R = \frac{T}{T_c}$$

$$= \frac{673.1}{647.1}$$

$$= 1.0401$$

Pseudo reduced volume,

$$v_R = \frac{v_{actual}}{RT_c/P_c}$$

$$= \frac{0.02}{(0.4615\times 647.1)/22060}$$

$$= 1.477$$

Step 5 of 6

From compressibility chart at reduced pressure and pseudo reduced volume, the value of reduced pressure, $P_R = 0.57$

By using formula for pressure of steam, we get

$$P = P_R P_c$$

$$= 0.57\times 22060$$

$$= 12574.2\,\mathrm{kPa}$$

Therefore, the pressure of steam by using compressibility chart, $\boxed{P = 12574.2\,\mathrm{kPa}}$.

Step 6 of 6

(c)

From super heated water tables,

At temperature $400\,^{\circ}\mathrm{C}$ and volume $0.020030\,\mathrm{m}^3/\mathrm{kg}$, the value of pressure is $12.5\mathrm{MPa}$

At temperature $400\,^{\circ}\mathrm{C}$ and volume $0.015671\,\mathrm{m}^3/\mathrm{kg}$, the value of pressure is $15.0\mathrm{MPa}$

By using interpolation, at temperature $400\,^{\circ}\mathrm{C}$ and volume $0.02\,\mathrm{m}^3/\mathrm{kg}$, the value of pressure P is calculated as follows

$$\frac{0.02-0.020030}{0.015671-0.020030} = \frac{P-12.5}{15.0-12.5}$$

$$6.882\times 10^{-3} = \frac{P-12.5}{2.5}$$

$$0.017205 = P-12.5$$

$$P = 0.017205+12.5$$

$$= 12.517\mathrm{MPa}$$

Therefore, the pressure of steam by using super heated water tables, $\boxed{P = 12.517\mathrm{MPa}}$.

Question: 4.110P

A tank whose volume is unknown is divided into two parts by a partition. One side of the tank contains 0.03 m3 of refrigerant-134a that is a saturated liquid at 1.2 MPa, while the other side is evacuated. The partition is now removed, and the refrigerant fills the entire tank. If the final state of the refrigerant is 30°C and 400 kPa, determine the volume of the tank.

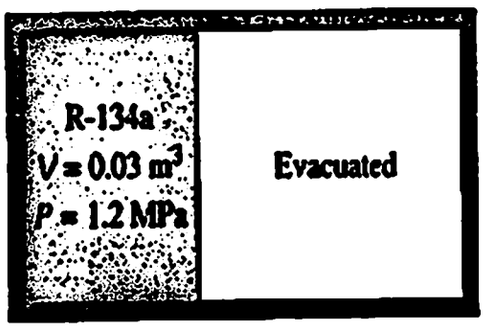

FIGURE P4–110

Step 1 of 3

Given

Volume of the refrigerant occupied in the tank $V_{ref} = 0.03\text{m}^3$

Refrigerant occupied as saturated liquid at pressure $P_1 = 1.2\text{MPa}$

Final state of the refrigerant at temperature $T_2 = 30^0\text{C}$

Final state of the refrigerant at pressure $P_2 = 400\text{kPa}$

Step 2 of 3

At $P_1 = 1.2\text{MPa}$ from R-134a saturated tables

$v_1 = v_f = 0.0008934\,\text{m}^3/\text{kg}$

The mass of the refrigerant contained in the tank is

$$m = \frac{V_1}{v_1}$$

$$= \frac{0.03}{0.0008934}$$

$$m = 33.58\text{kg}$$

Step 3 of 3

At the final state $P_2 = 400\text{kPa}$ and $T_2 = 30^0\text{C}$ from superheated R-134a tables

$v_2 = 0.056796\text{m}^3/\text{kg}$

Since mass of R-134a remains constant

$V_{tank} = V_2 = mV_2$

$V_{tank} = (33.58 \times 0.056796)$

$$\boxed{V_{tank} = 1.91\text{m}^3}$$

Question: 4.111P

 Reconsider Prob. 4–110. Using EES (or other) software, investigate the effect of the initial pressure of refrigerant-134a on the volume of the tank. Let the initial pressure vary from 0.5 to 1.5 MPa. Plot the volume of the tank versus the initial pressure, and discuss the results.

Step 1 of 1

4672-3-130E SA 0261

The problem is solved using EES, and the solution is given below.

"Given Data"

$x_1 = 0.0$

$Vol_1 = 0.03[m^3]$

$P_1 = 1200[kPa]$

$T_2 = 30[C]$

$P_2 = 400[kPa]$

"Solution"

$v_1 = volume(R134a, P = P_1, x = x_1)$

$Vol_1 = m \times v_1$

$v_2 = volume(R134a, P = P_2, T_2)$

$Vol_2 = m \times v_2$

P_1	V_2	m
500	2.1132	37.21
600	2.08	36.6
700	2.043	36
800	2.016	35.49
900	1.985	34.95
1000	1.96	34.47
1100	1.931	34
1200	1.91	33.58
1300	1.884	33.17
1400	1.86	32.73
1500	1.835	32.3

Question: 4.112P

Liquid propane is commonly used as a fuel for heating homes, powering vehicles such as forklifts, and filling portable picnic tanks. Consider a propane tank that initially contains 5 L of liquid propane at the environment temperature of 20°C. If a hole develops in the connecting tube of a propane tank and the propane starts to leak out, determine the temperature of propane when the pressure in the tank drops to 1 atm. Also, determine the total amount of heat transfer from the environment to the tank to vaporize the entire propane in the tank.

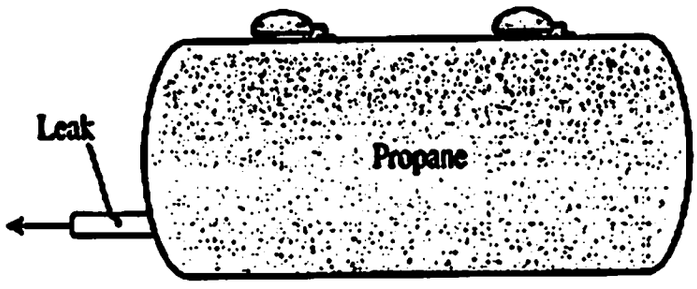

FIGURE P4–112

Step 1 of 3

Given data:

The volume of the propane tank, $V = 5\text{L}$

The atmospheric temperature, $T_{atm} = 20\,^{\circ}\text{C}$

The pressure after leak out, $P = 1\text{atm}$

Step 2 of 3

From the properties of common liquids, solids, and foods table,

The properties of propane at 1atm pressure:

Density, $\rho = 581\text{kg}/\text{m}^3$

Latent heat of vaporization, $h_{fg} = 427.8\text{kJ/kg}$

Saturation temperature, $T_{sat} = -42.1\,^{\circ}\text{C}$

Therefore, the temperature of propane when the pressure drops to 1atm, $\boxed{T = T_{sat} = -42.1\,^{\circ}\text{C}}$.

Step 3 of 3

The initial mass of liquid propane,

$$m = \rho V$$
$$= 581 \times 0.005$$
$$= 2.905\text{kg}$$

By using formula for heat transfer, we get

$$Q_{absorbed} = mh_{fg}$$
$$= 2.905 \times 427.8$$
$$= 1242.759\text{kJ}$$

Therefore, the heat absorbed by the propane to vaporize completely,

$\boxed{Q_{absorbed} = 1242.759\text{kJ}}$.

Question: 4.113P

Repeat Prob. 4–112 for isobutane.

Step 1 of 3

From the table of Isobutene

At pressure $P = 1\text{atm}$

Saturation temperature is $T = -11.70°\text{C}$

Since temperature of isobutene at pressure drops 1 atm is simply equals to saturation temperature corresponding to pressure of 1 atm.

Hence, temperature of the isobutene when pressure drops to 1 atm is $\boxed{-11.70°\text{C}}$

Step 2 of 3

From the table of Isobutene

At pressure $P = 1\text{atm}$

Density is $\rho = 593.80\text{kg/m}^3$

Latent heat of vaporization is $h_{fg} = 367.10\text{kJ/kg}$

Find the initially of the isobutene is

$$m = \rho V$$

Here,

Mass of the isobutene is m

Density of the isobutene is ρ

Volume of the tank is V

Substitute 593.80kg/m^3 for ρ, 0.005m^3 for V

$$\begin{aligned} m &= \rho V \\ &= 593.80 \times 0.005 \\ &= 2.969\text{kg} \end{aligned}$$

Step 3 of 3

Calculate the amount of heat transfer is

$$Q = mh_{fg}$$

Substitute 367.10kJ/kg for h_{fg}, 2.969kg for m

$$\begin{aligned} Q &= mh_{fg} \\ &= 2.969 \times 367.01 \\ &= 1089.65\text{kJ} \end{aligned}$$

Hence, the amount of heat transfer is $\boxed{1089.65\text{kJ}}$

Question:

4.114P

A tank contains helium at 77°C and 110 kPa gage. The helium is heated in a process by heat transfer from the surroundings such that the helium reaches a final equilibrium state at 300°C. Determine the final gage pressure of the helium. Assume atmospheric pressure is 100 kPa.

Step 1 of 4

Given

Initial temperature $T_1 = 77^0\,C = 350K$

Initial gage pressure $P_1 = 110kPa$

Final temperature $T_2 = 300^0\,C = 573K$

Atmospheric pressure $P_{atm} = 100kPa$

Step 2 of 4

Initial absolute pressure

$$P_1 = P_1(gage) + P_{atm}$$

$$P_1 = 110 + 100$$

$$P_1 = 210kPa$$

Step 3 of 4

Since volume remains constant by using ideal gas equation

$$P_2 = \frac{P_1 T_2}{T_1}$$

$$= \frac{210 \times 573}{350}$$

$$P_2 = 343.8kPa$$

Step 4 of 4

Then the final gauge pressure becomes

$$P_{gauge,2} = P_2 - P_{atm}$$

$$= 343.8 - 100$$

$$\boxed{P_{gauge,2} = 243.8kPa}$$

Question: 4.115P

If sufficient data are provided, complete the blank cells in the following table of properties of water. In the last column describe the condition of water as compressed liquid, saturated mixture, superheated vapor, or insufficient information; and, if applicable, give the quality.

P, kPa	*T*,°C	v,m3/kg	u,kJ/kg	Condition description and quality (if applicable)
	250		2728.9	
300			1560.0	
101.42	100			
3000	180			

Step 1 of 5

Given

Temperature $T = 250^0 \text{C}$

Internal energy $u = 2728.9 \text{kJ/kg}$

At $T = 250^0 \text{C}$ and $u = 2728.9 \text{kJ/kg}$ from superheated water tables

Pressure $P = 300 \text{kPa}$

Specific volume $v = 0.79645 \text{m}^3/\text{kg}$

Step 2 of 5

Pressure $P = 300 \text{kPa}$

Specific volume $u = 1560.0 \text{kJ/kg}$

At $P = 300 \text{kPa}$ from saturated water tables

$u = u_{f@300\text{kPa}} + x u_{fg@300\text{kPa}}$

$1560.0 = 561.11 + x \times 1982.1$

$x = 0.5039$

$T = T_{sat@300\text{kPa}} = 133.52^0 \text{C}$

$v = v_{f@300\text{kPa}} + x v_{fg@300\text{kPa}}$

$v = 0.001073 + 0.5039 \times 0.6047$

$v = 0.30578 \text{m}^3/\text{kg}$

Step 3 of 5

Pressure $P = 101.42$ kPa

Temperature $T = 100^0 \text{C}$

At $T = 100^0 \text{C}$ and $P = 101.42 \text{kPa}$ it is in saturated condition but it is not mentioned that whether it is in saturated liquid or saturated vapor state

Step 4 of 5

Pressure $P = 3000 \text{kPa}$

Temperature $T = 180^0 \text{C}$

At $P = 3000 \text{kPa}$ and $T = 180^0 \text{C}$ from compressed water tables

$v = 0.0011 \text{m}^3/\text{kg}$

$u = 760.9 \text{kJ/kg}$

Step 5 of 5

P (kPa)	T(°C)	v (m^3/kg)	u(kJ/kg)	Phase
300	250	0.79645	2728.9	Superheated steam
300	133.52	0.30578	1560	Saturated mixture $x = 0.5039$
101.42	100	-	-	Insufficient data
3000	180	0.0011	760.9	Compressed liquid

Question: 4.116P

If sufficient data are provided, complete the blank cells in the following table of properties of water. In the last column describe the condition of water as compressed liquid, saturated mixture, superheated vapor, or insufficient information; and, if applicable, give the quality.

P, kPa	T,°C	v,m3/kg	u,kJ/kg	Condition description and quality (if applicable)
200			2529.1	
	125			$x = 0.650$
	400		2967.2	
1000	30			
120.90	150			

Step 1 of 6

Given

Pressure $P = 200\text{kPa}$

Internal energy $u = 2529.1\text{kJ/kg}$

From saturated water tables at $P = 200\text{kPa}$ and $u = 2529.1\text{kJ/kg}$ the state is in saturated vapor state

Temperature $\boxed{T = 120.21^0\text{C}}$

Specific volume

$v = v_g = 0.88578\text{m}^3\text{/kg}$

$\boxed{v = 0.88578\text{m}^3\text{/kg}}$

Step 2 of 6

Given

Temperature $T = 125^0\text{C}$

Dryness fraction $x = 0.65$

From saturated water tables

$P = P_{sat} = 232.23\text{kPa}$

$\boxed{P = 232.23\text{kPa}}$

Specific volume

$v = v_{f@125C} + xv_{fg@125C}$

$v = 0.001065 + 0.65 \times 0.769$

$\boxed{v = 0.5009\text{m}^3\text{/kg}}$

Internal energy

$u = u_{f@125C} + xu_{fg@125C}$

$u = 524.83 + 0.65 \times 2009.5$

$\boxed{u = 1831.005\text{kJ/kg}}$

Step 3 of 6

Given

Temperature $T = 400^0\text{C}$

Internal energy $u = 2967.2\text{kJ/kg}$

The state is in superheated state

So from superheated water tables at $T = 400^0\text{C}$ and $u = 2967.2\text{kJ/kg}$

$\boxed{P = 200\text{kPa}}$

$\boxed{v = 1.54934\text{m}^3\text{/kg}}$

Step 4 of 6

Given

Pressure $P = 1000\text{kPa}$

Temperature $T = 30^0\text{C}$

The state is in compressed liquid state

So at $P = 1000\text{kPa}$ and $T = 30^0\text{C}$ from compressed liquid water tables

$\boxed{v = 0.0010\text{m}^3\text{/kg}}$

$\boxed{u = 125.6\text{kJ/kg}}$

Step 5 of 6

Given

Pressure $P = 120.90\text{kPa}$

Temperature $T = 150^0\text{C}$

From superheated water tables

Specific volume $\boxed{v = 1.5088\text{m}^3\text{/kg}}$

Internal energy $\boxed{u = 2581.2\text{kJ/kg}}$

Step 6 of 6

P(kPa)	T(°C)	v (m³/kg)	u(kJ/kg)	Phase
200	120.21	0.88578	2529.1	Saturated vapor
232.23	125	0.5009	1831.005	$x = 0.650$
200	400	1.54394	2967.2	Superheated steam
1000	30	0.0010	125.6	Compressed state
120.9	150	1.5988	2581.2	Superheated steam

Question: 4.117P

Water initially at 300 kPa and 250°C is contained in a constant volume tank. The water is allowed to cool until its pressure is 150 kPa. On the *P-V*and *T-V* diagrams sketch, with respect to the saturation lines, the process curve passing through both the initial and final states of the water. Label the end states on the process curve. Also, on both the *P-V* and *T-V* diagrams, sketch the isotherms passing through both states and show their values, in °C, on the isotherms.

Step 1 of 3

Given

Initial pressure $P_1 = 300\text{kPa}$

Initial temperature $T_1 = 250^0\text{C}$

Final pressure $P_2 = 150\text{kPa}$

Step 2 of 3

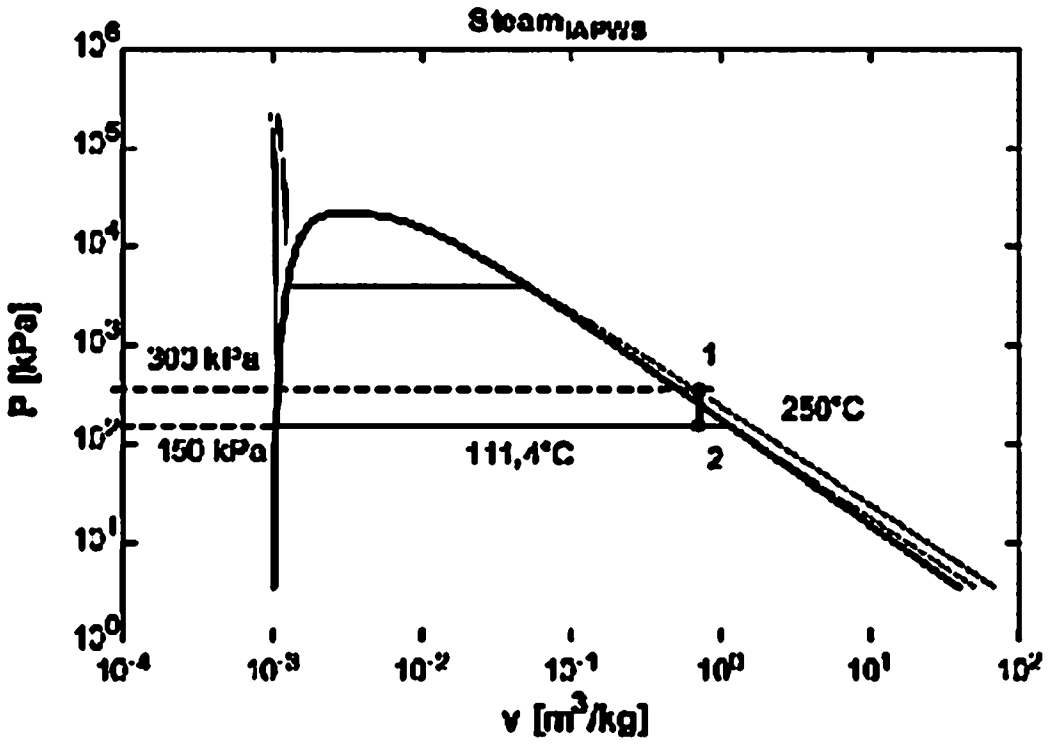
At $P_1 = 300$ kPa and $T_1 = 250^0\text{C}$ from superheated water tables

$v_1 = 0.79645\text{m}^3/\text{kg}$

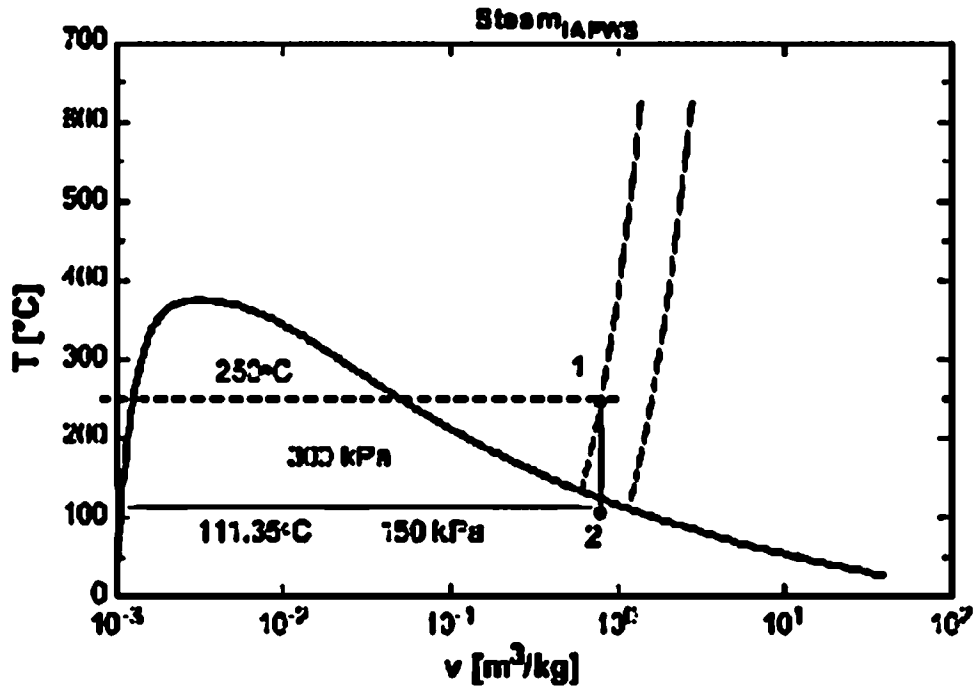
Since volume remains constant

At $P_2 = 150\text{kPa}$ and $v_2 = v_1 = 0.79645\text{m}^3/\text{kg}$ from saturated water tables

$v_2 = v_{f@150kPa} + x_2 v_{fg@150kPa}$



$0.79645 = 0.001053 + x_2 \times 1.15834$



$x_2 = 0.686$

$T_2 = T_{sat@150kPa} = 111.35^0\text{C}$

Step 3 of 3

Using Property Plot feature of EES, and by adding state points we obtain following diagrams.

CHAPTER 05
SOLUTIONS

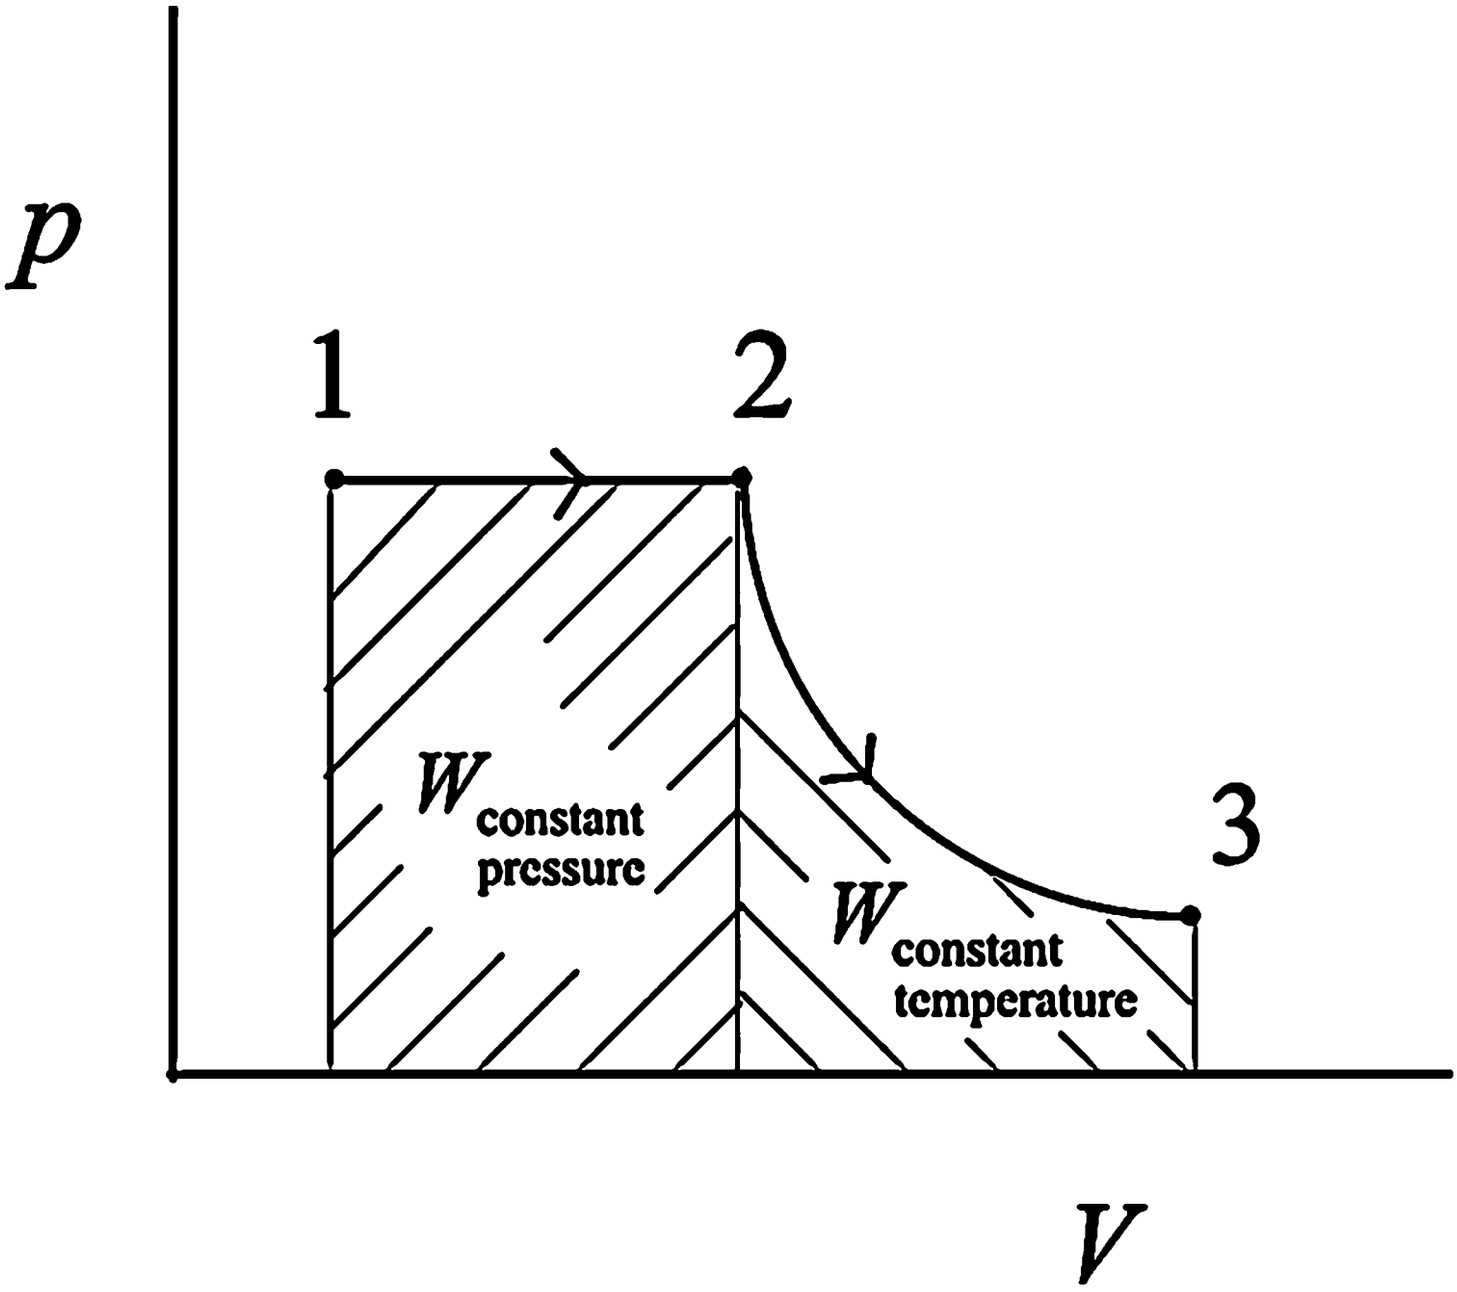
Question: 5.001P

Is the boundary work associated with constant-volume systems always zero?

Step 1 of 1

The boundary work during a quasi-equilibrium process is expressed as

$$Area = A = \int_1^2 dA = \int_1^2 PdV$$



For a constant volume process $dV = 0$.
Therefore the boundary work is zero.

Question: 5.002P

An ideal gas at a given state expands to a fixed final volume first at constant pressure and then at constant temperature For which case is the work done greater?

Step 1 of 2

Draw the two expansion processes on the $p-V$ diagram.

Step 2 of 2

The process $1-2$ is a constant pressure expansion process and the process $2-3$ is an isothermal expansion process.

The area under the curve in a $p-V$ diagram represents the work done during the process.

From figure, the area under the curve in a constant pressure process is more as compared to the area in a constant temperature process.

Therefore, the work done is greater for constant pressure process.

Question: 5.003P

Show that 1 kPa-m3 = 1 kJ.

Step 1 of 1

We know that $1\,Pa = 1\,N/m^2$

$$1\,kPa.m^3 = 1\,kN/m^2.m^3$$

$$= 1\,kNm \qquad (1Nm = 1J)$$

Therefore $1\,kPa.m^3 = 1\,kJ$

Question: 5.004P

The volume of 1 kg of helium in a piston-cylinder device is initially 7 m3. Now helium is compressed to 3 m3 while its pressure is maintained constant at 150 kPa. Determine the initial and final temperatures of helium as well as the work required to compress it, in kJ.

Step 1 of 3

Obtain the characteristic gas constant of helium from "Table A-1: Molar mass, gas constant, and critical-point properties" in the textbook.

$$R = 2.0769\,\text{kJ/kg}\cdot\text{K}$$

Write the ideal gas equation to find the initial temperature of helium.

$$P_1V_1 = mRT_1$$

Here, P_1 is the initial pressure of the gas , V_1 is the initial volume of the gas, m is the mass of the helium gas, R is the characteristic gas constant, and T_1 is the initial temperature of the helium gas.

Substitute $150\,\text{kPa}$ for P_1 , $7\,\text{m}^3$ for V_1 , $1\,\text{kg}$ for m , and $2.0769\,\text{kJ/kg}\cdot\text{K}$ for R .

$$150\times 7 = 1\times 2.0769\times T_1$$
$$T_1 = 505.5\,\text{K}$$

Therefore, the initial temperature of the helium gas is $\boxed{505.5\,\text{K}}$.

Step 2 of 3

Write the ideal gas equation to find the final temperature of helium.

$$P_2V_2 = mRT_2$$

Here, P_2 is the final pressure of the gas , V_2 is the final volume of the gas, and T_2 is the final temperature of the helium gas.

Substitute $150\,\text{kPa}$ for P_2 , $3\,\text{m}^3$ for V_2 , $1\,\text{kg}$ for m , and $2.0769\,\text{kJ/kg}\cdot\text{K}$ for R .

$$150\times 3 = 1\times 2.0769\times T_2$$
$$T_2 = 216.66\,\text{K}$$

Therefore, the final temperature of the helium gas is $\boxed{216.66\,\text{K}}$.

Step 3 of 3

Find the work required to compress the helium.

$$W = \int_1^2 P\,dV$$
$$= P(V_2 - V_1)$$

Substitute $150\,\text{kPa}$ for P , $7\,\text{m}^3$ for V_1 , and $3\,\text{m}^3$ for V_2 .

$$W = 150(3-7)$$
$$= -600\,\text{kJ}$$

Since work is done by the system work is negative.

Therefore, the work required to compress the helium is $\boxed{600\,\text{kJ}}$.

Question: 5.005P

A piston-cylinder device initially contains 0.07 m3 of nitrogen gas at 130 kPa and 120°C. The nitrogen is now expanded polytropically to a state of 100 kPa and 100°C. Determine the boundary work done during this process.

Step 1 of 3

Calculate the mass of the nitrogen gas inside the piston cylinder

$$P_1V_1 = mRT_1$$

$$m = \frac{P_1V_1}{RT_1}$$

Here, P_1 is the pressure at initial state, V_1 is the Initial volume, T_1 is the Initial Temperature and R is the gas constant

Use the conversion factor to convert the temperature from $1°C$ to $1K$

$$1K = 1°C + 273$$

Substitute $130\ kPa$ for P_1, $0.07\ m^3$ for V_1, $0.2968\ kJ/kg \cdot K$ for R and $120°C$ for T_1

$$m = \frac{130(0.07)}{(0.2968)(120+273)}$$
$$= 0.0780\ kg$$

Step 2 of 3

Calculate the volume after expansion

$$V_2 = \frac{mRT_2}{P_2}$$

Here, T_2 is the final temperature and P_2 is the final pressure

Substitute $100°C$ for T_2, $100\ kPa$ for P_2 and $0.0780\ kg$ for m

$$V_2 = \frac{mRT_2}{P_2}$$
$$= \frac{(0.078)(0.2968)(100+273)}{100}$$
$$= 0.08635\ m^3$$

Step 3 of 3

Calculate the polytropic index by using the expression,

$$P_1V_1^n = P_2V_2^n$$

$$P_1V_1^n = P_2V_2^n$$
$$130(0.07)^n = 100(0.08635)^n$$
$$n = 1.24986$$

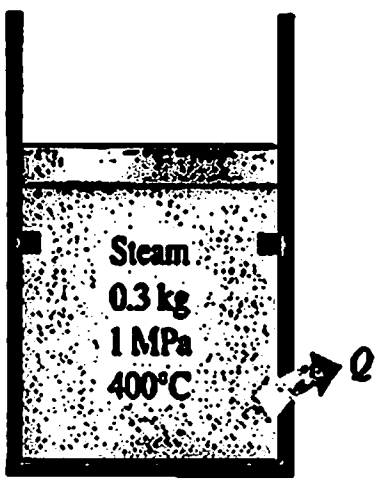
Calculate the work done during the process by using the equation,

$$W = \frac{P_2V_2 - P_1V_1}{1-n}$$
$$= \frac{100(0.08635) - 130(0.07)}{1-1.24986}$$
$$= 1.86\ kJ$$

Therefore, work done is $\boxed{1.86\ kJ}$

Question: 5.006P

A piston-cylinder device with a set of stops initially contains 0.3 kg of steam at 1.0 MPa and 400°C. The location of the stops corresponds to 60 percent of the initial volume. Now the steam is cooled. Determine the compression work if the final state is (*a*) 1.0 MPa and 250°C and (*b*) 500 kPa. (*c*) Also determine the temperature at the final state in part (*b*).



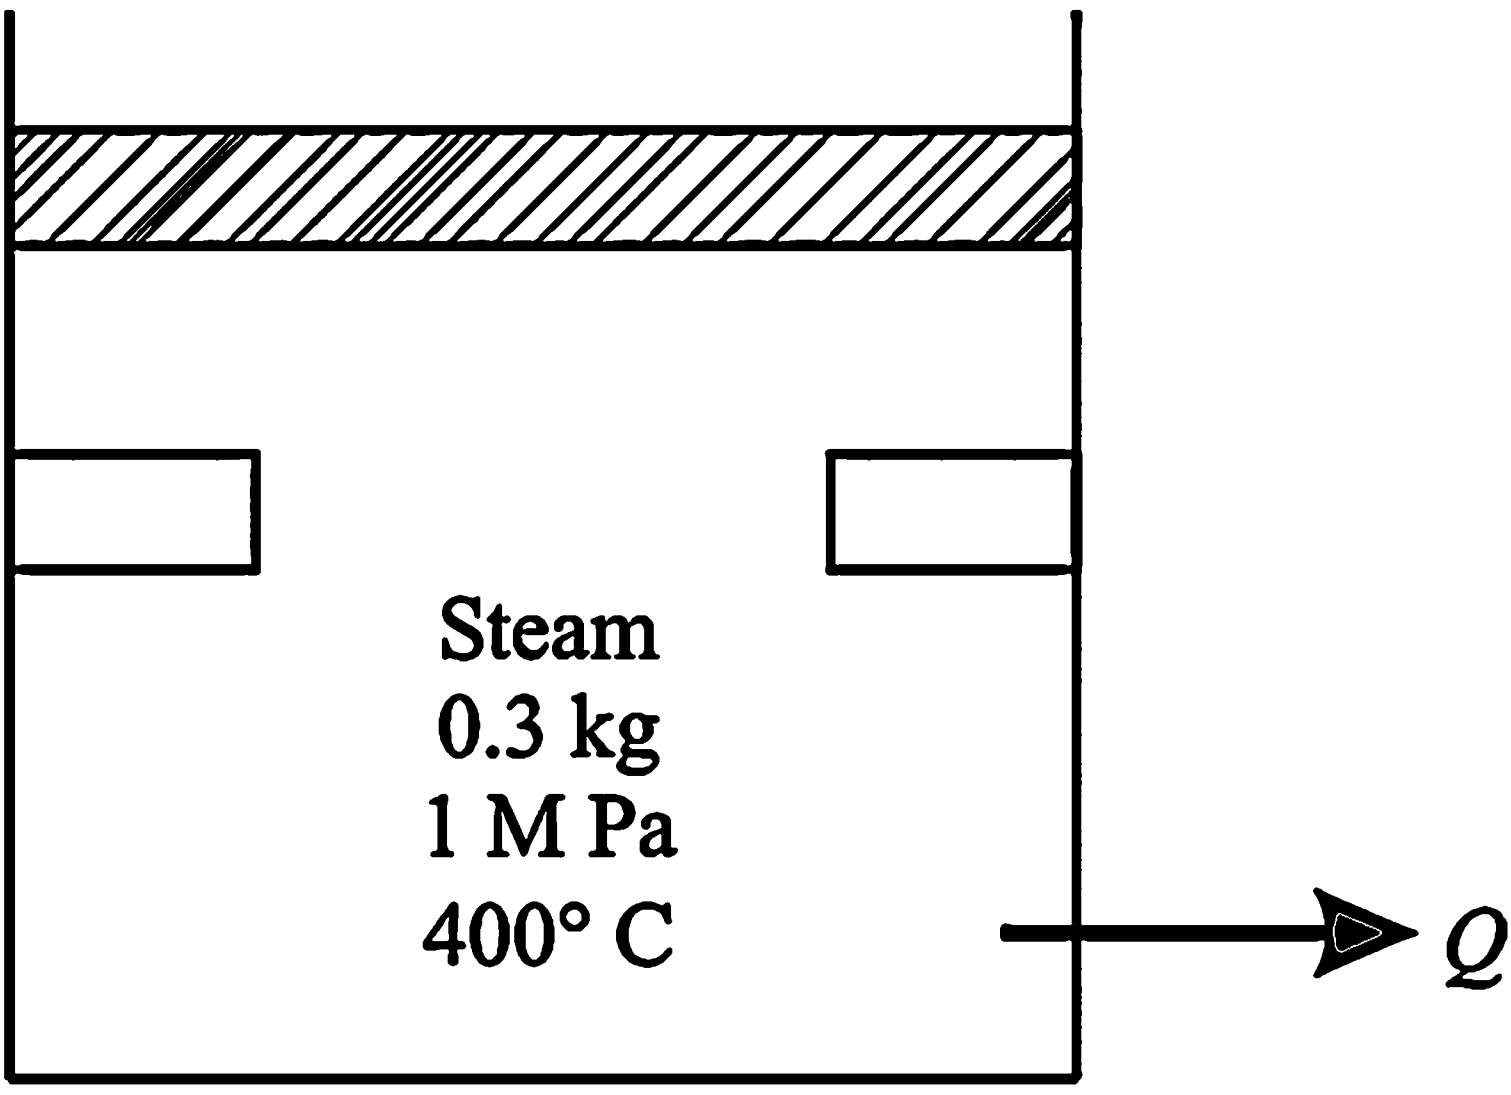


FIGURE P5–6

Step 1 of 4

Draw the piston-cylinder device with set of stops as follows:

Step 2 of 4

(a)

Obtain the specific volume of the steam at a pressure of 1 MPa and at a temperature of $400°C$ from the table A-6, "Superheated water" in the textbook.

$$v_1 = 0.30661\ \text{m}^3/\text{kg}$$

Obtain the specific volume of the steam at a pressure of 1 MPa and at a temperature of $250°C$ from the table A-6, "Superheated water" in the textbook.

$$v_2 = 0.23275\ \text{m}^3/\text{kg}$$

Calculate the compression work as follows:

$$W = mP_1(v_1 - v_2)$$

Here, m is the mass of the steam.

Substitute 0.3 kg for m, 1 MPa for P_1, $0.30661\ \text{m}^3/\text{kg}$ for v_1, and $0.23275\ \text{m}^3/\text{kg}$ for v_2.

$$\begin{aligned} W &= 0.3(1000)(0.30661 - 0.23275) \\ &= 22.158\ \text{kJ} \end{aligned}$$

Therefore, the compression work is $\boxed{22.158\ \text{kJ}}$.

Step 3 of 4

(b)

Here pressure $P_2 = 500\ \text{kPa}$

Calculate the compression work as follows:

$$W = mP_1(v_1 - v_2)\ \text{kJ}$$

Here the $v_2 = 0.6v_1$, re-write the equation as follows:

$$W = mP_1(v_1 - 0.6v_1)$$

Substitute 0.3 kg for m, 1 MPa for P_1, and $0.30661\ \text{m}^3/\text{kg}$ for v_1.

$$\begin{aligned} W &= 0.3(1000)(0.30661 - 0.6 \times 0.30661) \\ &= 36.8\ \text{kJ} \end{aligned}$$

Therefore, the compression work is $\boxed{W = 36.8\ \text{kJ}}$.

Step 4 of 4

(c)

Obtain the specific volume of the steam at a pressure of 500 kPa and from the table A-5, "Saturated water-Pressure table" in the textbook.

$$T_2 = 151.83°C$$

Therefore, the temperature is $\boxed{152°C}$.

Question: 5.007P

A piston-cylinder device initially contains 0.07 m3 of nitrogen gas at 130 kPa and 180°C. The nitrogen is now expanded to a pressure of 80 kPa polytropically with a polytropic exponent whose value is equal to the specific heat ratio (called *isentropic expansion*) . Determine the final temperature and the boundary work done during this process.

Step 1 of 6

Given:
Process: polytropic process
Initially volume $V_1 = 0.07\,\mathrm{m}^3$
Initially pressure $P_1 = 130\,\mathrm{kPa}$
Initially temperature $T_1 = 180^\circ\mathrm{C}$
Final pressure $P_2 = 80\,\mathrm{kPa}$

Step 2 of 6

From the ideal gas specific heat of various gases
For nitrogen

$$R = 0.2968\frac{\mathrm{kJ}}{\mathrm{kg}\cdot\mathrm{K}}$$

$k = 1.4$

Step 3 of 6

Now applying the idea gas equation

$$P_1V_1 = mRT_1$$

$$\Rightarrow m = \frac{P_1V_1}{RT_1}$$

$$= \frac{(130)(0.07)}{(0.2968\mathrm{K})(180+273\mathrm{K})}$$

$$= 0.0676\,\mathrm{kg}$$

Step 4 of 6

We know that
For polytropic process

$$P_1V_1^k = P_2V_2^k$$

$$V_2^k = \frac{(130)\times(0.07)^{1.4}}{80}$$

$$V_2 = (0.0393)^{1/1.4}$$

$$= 0.0991\mathrm{m}^3$$

Step 5 of 6

The final temperature is
Applying the ideal gas equation

$$P_2V_2 = mRT_2$$

$$\Rightarrow T_2 = \frac{P_2V_2}{mR}$$

$$= \frac{80\times0.0991}{0.0677\times0.2968}$$

$$= 394.55\mathrm{K}$$

$$\boxed{T_2 = 394.55\mathrm{K}}$$

Step 6 of 6

The boundary work for polytropic process is

$$W_b = \frac{P_2V_2 - P_1V_1}{1-k}$$

$$= \frac{(80\times0.0991)-(130\times0.07)}{1-1.4}$$

$$= 2.93\mathrm{kJ}$$

$$\boxed{W_b = 2.93\mathrm{kJ}}$$

Question: 5.008P

A mass of 5 kg of saturated water vapor at 300 kPa is heated at constant pressure until the temperature reaches 200°C. Calculate the work done by the steam during this process.

Step 1 of 3

Given

Mass of water vapor $m = 5\ \text{kg}$

Initial Pressure $P_1 = 300\ \text{kPa}$

Initial Temperature $T_2 = 200°\text{C}$

Step 2 of 3

From superheated steam tables

The properties of steam at $P_1 = 300\ \text{kPa}$

Specific volume is $v_1 = 0.60582\ \text{m}^3/\text{kg}$

From superheated steam tables

The properties of steam at $P_2 = 300\ \text{kPa}$ and $T_2 = 200°\text{C}$

Specific volume is $v_2 = 0.71643\ \text{m}^3/\text{kg}$

Step 3 of 3

The work done during the process to

$$W = mP_1(v_2 - v_1)\ \text{kJ}$$

$$W = 5(300)(0.71643 - 0.60582)\ \text{kJ}$$

$$\boxed{W = 165.915\ \text{kJ}}$$

Question: 5.009P

A frictionless piston-cylinder device initially contains 50 L of saturated liquid refrigerant-134a. The piston is free to move, and its mass is such that it maintains a pressure of 500 kPa on the refrigerant. The refrigerant is now heated until its temperature rises to 70°C. Calculate the work done during this process.

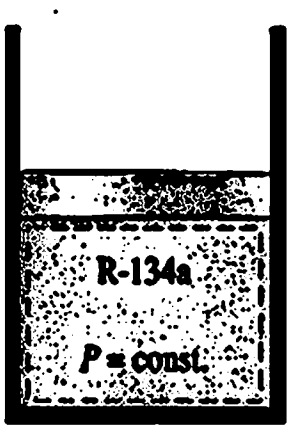

FIGURE P5–9

Step 1 of 5

Given:
Working fluid: R-134a
Initially volume $V_1 = 50\text{L}$
Pressure of the refrigerant $P_1 = P_2 = 500\ \text{kPa}$
Final temperature $T_2 = 70°\text{C}$

Step 2 of 5

State1:
From the Properties of saturated refrigerant -134a
At $P_1 = 500\text{kPa}$

$$v_1 = v_f == 0.0008059\ \frac{\text{m}^3}{\text{kg}}$$

Step 3 of 5

State2:
$T_{sat} < T_2$
$15.71°\text{C} < 70°\text{C}$
So state 2 is superheated state.
From the superheated refrigerant-134a
At $P_2 = 500\text{kPa}$ and $T_2 = 70°\text{C}$

$$v_2 = 0.052427\ \frac{\text{m}^3}{\text{kg}}$$

Step 4 of 5

Initially volume
$V_1 = 50\text{L}$

$$= (50\text{L})\left(\frac{1\text{m}^3}{1000\text{L}}\right)$$

$$= 50\times10^{-3}\ \text{m}^3$$

Then mass of the system is

$$m = \frac{V_1}{v_1}$$

$$= \frac{50\times10^{-3}}{0.0008059}$$

$$= 62.042\text{kg}$$

Step 5 of 5

The boundary work is

$$W = mP(v_2 - v_1)$$

$$= 62.042\times500(0.052427 - 0.0008059)$$

$$= 1601.33\text{kJ}$$

$$\boxed{W = 1601.33\ \text{kJ}}$$

Question: 5.010P

Reconsider Prob. 5–9. Using EES (or other) software, investigate the effect of pressure on the work done. Let the pressure vary from 200 to 1200 kPa. Plot the work done versus the pressure, and discuss the results. Explain why the plot is not linear. Also plot the process described in Prob. 5–9 on the *P- V* diagram.

We don't have the solution to this problem yet.

Get help from a Chegg subject expert.

Ask an expert

Question: 5.011P

1-m3 of saturated liquid water at 200°C is expanded isothermally in a closed system until its quality is 80 percent. Determine the total work produced by this expansion, in kJ.

Step 1 of 3

Obtain the properties from the saturated temperature table at temperature $T_1 = 200°C$

Saturated pressure is $P = 1554.9\,\text{kPa}$

Specific volume at state point 1 is $v_1 = v_f = 0.001157\,\text{m}^3/\text{kg}$

Specific volume of saturated mixture is $v_g = 0.12721\,\text{m}^3/\text{kg}$

Calculate the Specific volume at state2 .

$$\begin{aligned} v_2 &= v_f + xv_{fg} \\ &= v_f + x\left(v_g - v_f\right) \\ &= 0.001157 + [0.8\times(0.12721 - 0.001157)] \\ &= 0.102\,\text{m}^3/\text{kg} \end{aligned}$$

Step 2 of 3

Calculate the volume of the liquid at state point 2

$$\frac{V_2}{V_1} = \frac{v_2}{v_1}$$

Here, V_1 and V_2 is the volume of the state point 1 and 2 respectively.

Substitute $1\,\text{m}^3$ for V_1, $0.001157\,\text{m}^3/\text{kg}$ for v_1 and $0.102\,\text{m}^3/\text{kg}$ for v_2

$$\frac{V_2}{V_1} = \frac{v_2}{v_1}$$
$$\frac{V_2}{1} = \frac{0.102}{0.001157}$$
$$V_2 = 88.16\,\text{m}^3$$

Step 3 of 3

Calculate the work done during the isothermal process, since there is only phase change we can consider pressure constant.

$${}_1W_2 = P\left(V_2 - V_1\right)$$

Substitute $88.16\,\text{m}^3$ for V_2, $1\,\text{m}^3$ for V_1, $1554.9\,\text{kPa}$ for P

$$\begin{aligned} {}_1W_2 &= P\left(V_2 - V_1\right) \\ &= 1554.9(88.16 - 1) \\ &= 1.355\times10^5\,\text{kJ} \end{aligned}$$

Hence, the work done is $\boxed{1.355\times10^5\,\text{kJ}}$

Question: 5.012P

A mass of 2.4 kg of air at 150 kPa and 12°C is contained in a gas-tight, frictionless piston-cylinder device. The air is now compressed to a final pressure of 600 kPa. During the process, heat is transferred from the air such that the temperature inside the cylinder remains constant. Calculate the work input during this process.

Step 1 of 2

Obtain the properties from the tables of ideal-gas specific heats of various common gases.

The gas constant of air is $R = 0.287\ \text{kJ/kg}\cdot\text{K}$.

Calculate the work done during the process by using the equation as shown below.

$$W = \int_1^2 PdV\ \text{kJ}$$

$$= P_1V_1 \ln\frac{V_2}{V_1}\ \text{kJ}$$

$$= mRT_1 \ln\frac{P_1}{P_2}\ \text{kJ}$$

Here, the mass of air is m , the gas constant of air is R , the temperature at state 1 and state 2 is T_1 , the pressure at state 1 is P_1 , and the pressure at state 2 is P_2 .

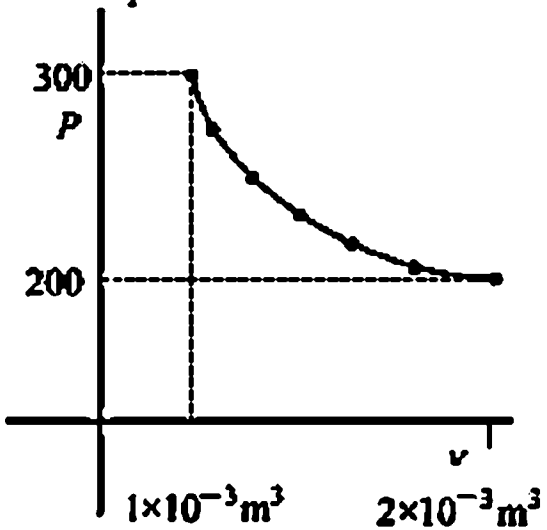
Step 2 of 2

Substitute $2.4\ \text{kg}$ for m , $150\ \text{kPa}$ for P_1 , $600\ \text{kPa}$ for P_2 and $12°\text{C}$ for T_1 .

$$W = 2.4(0.287)(12+273)\ln\left(\frac{150}{600}\right)$$

$$= -272.14\ \text{kJ}$$

Therefore, the work done during the process is $\boxed{-272.14\ \text{kJ}}$.



The negative sign indicates that the work is done on the system to compress the air.

Question: 5.013P

Determine the boundary work done by a gas during an expansion process if the pressure and volume values at various states are measured to be 300 kPa, 1 L;290 kPa, 1.1 L; 270 kPa, 1.2 L; 250 kPa, 1.4 L; 220 kPa, 1.7 L; and 200 kPa, 2 L.

Step 1 of 2

The work done in the process 1-2 equal to area under the curve

Step 2 of 2

The area under the curve is expressed as

$$W=\frac{P_1+P_2}{2}(V_2-V_1)$$

$$W=\frac{300+200}{2}(2-1)\times10^{-3}$$

$$\boxed{W=0.25\,\text{kJ}}$$

Question: 5.014P

During some actual expansion and compression processes in piston-cylinder devices, the gases have been observed to satisfy the relationship *PVn* = *C*, where *n* and *C* are constants. Calculate the work done when a gas expands from 350 kPa and 0.03 m3 to a final volume of 0.2 m3 for the case of *n* = 1.5.

Step 1 of 4

Given:

Process: $PV^n = C$

Initially pressure $P_1 = 350\,\text{kPa}$

Initially volume $v_1 = 0.03\text{m}^3$

Final volume $V_2 = 0.2\,\text{m}^3$

Process constant $n = 1.5$

Step 2 of 4

We know that

$$PV^n = C$$

$$C = P_1V_1^n$$

$$= 350\times(0.03)^{1.5}$$

$$= 1.81$$

Step 3 of 4

And also

Final pressure process is

$$P_2V_2^n = C$$

$$\Rightarrow P_2 = \frac{C}{V_2^n}$$

$$= \frac{1.81}{(0.2)^{1.5}}$$

$$= 20.23\text{kPa}$$

Step 4 of 4

Work done

$$W = \frac{P_1V_1 - P_2V_2}{n-1}$$

$$= \frac{(350\times0.03)-(20.23\times0.2)}{1.5-1}$$

$$= 12.908\text{kJ}$$

$$\boxed{W = 12.908\ \text{kJ}}$$

Question: 5.015P

Reconsider Prob. 5–14. Using the EES (or other) software, plot the process described in the problem on a *P*- *V* diagram, and investigate the effect of the polytropic exponent *n* on the boundary work. Let the polytropic exponent vary from 1.1 to 1.6. Plot the boundary work versus the polytropic exponent, and discuss the results.

We don't have the solution to this problem yet.

Get help from a Chegg subject expert.

Ask an expert

Question: 5.016P

A frictionless piston–cylinder device contains 2 kg of nitrogen at 100 kPa and 300 K. Nitrogen is now compressed slowly according to the relation $PV1.4$ = constant until it reaches a final temperature of 360 K. Calculate the work input during this process.

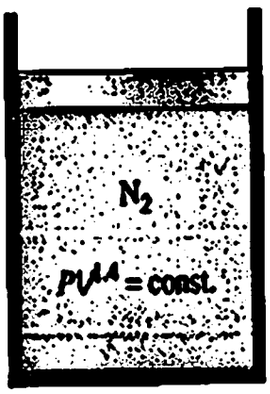


FIGURE P5–16

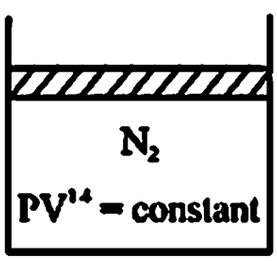
Step 1 of 3

Given

The mass of nitrogen $m = 2\,\text{kg}$



Initial Pressure $P_1 = 100\,\text{kPa}$

Initial Temperature $T_1 = 300\text{K}$

Final temperature $T_2 = 360\text{K}$

The polytrophic process index $n = 1.4$

Step 2 of 3

Step 3 of 3

From tables of ideal gas specific heats of various common gases

R = 0.2968 kJ/kg.K

The boundary work during the process is

$$W = \frac{P_2V_2 - P_1V_1}{1-n}\ \text{kJ} \qquad (PV = mRT)$$

$$W = \frac{mR(T_2 - T_1)}{1-1.4}$$

$$W = \frac{2(0.2968)(360-300)}{1-1.4}$$

$$\boxed{W = -89\ \text{kJ}}$$

The negative sign indicates that work is done on the system

Question: 5.017P

The equation of state of a gas is given as $\bar{v}(P + 10/\bar{v}^2) = Ru\,T$, where the units of $\bar{v}$ and P are m3/kmol and kPa, respectively. Now 0.2 kmol of this gas is expanded in a quasi-equilibrium manner from 2 to 4 m3 at a constant temperature of 350 K. Determine (*a*) the unit of the quantity 10 in the equation and (*b*) the work done during this isothermal expansion process.

Step 1 of 2

Write the equation of state of gas

$$\bar{v}\left(P+\frac{10}{\bar{v}^2}\right)=R_u T$$

Here, $\bar{v}$ is specific molar volume in $\mathrm{m^3/kmol}$, P is pressure in kPa, R_u is universal gas constant, and T is temperature.

a)

Since the term $\frac{10}{\bar{v}^2}$ is added to pressure, so it must have pressure units.

$$\frac{10}{\bar{v}^2}=\mathrm{kPa}$$

Substitute $\frac{\mathrm{m^3}}{\mathrm{kmol}}$ for $\bar{v}$

$$\frac{10}{\left(\frac{\mathrm{m^3}}{\mathrm{kmol}}\right)^2}=\mathrm{kPa}$$

$$10=\mathrm{kPa}\times\frac{\mathrm{m^6}}{\mathrm{kmol^2}}$$

Therefore, the unit of quantity 10 in the equation is $\boxed{\mathrm{kPa}\times\frac{\mathrm{m^6}}{\mathrm{kmol^2}}}$

Step 2 of 2

(b)

Find the boundary work done during the isothermal expansion process by using the following equation:

$$W_{b,out}=\int_1^2 P\,dV$$

Write the equation of state of a gas

$$\bar{v}\left(P+\frac{10}{\bar{v}^2}\right)=R_u T$$

$$P=\frac{R_u T}{\bar{v}^2}-\frac{10}{\bar{v}^2}$$

Substitute $\frac{R_u T}{\bar{v}^2}-\frac{10}{\bar{v}^2}$ for P in work done equation.

$$\begin{aligned}
W_{b,out} &= \int_1^2\left(\frac{R_u T}{\bar{v}}-\frac{10}{\bar{v}^2}\right)dV \\
&= \int_1^2\left(\frac{R_u T}{V/N}-\frac{10}{(V/N)^2}\right)dV \\
&= NR_u T\int_1^2\left(\frac{1}{V}\right)dV-10N^2\int_1^2\left(\frac{1}{V^2}\right)dV \\
&= NR_u T(\ln V)_1^2-10N^2\left(\frac{-1}{V}\right)_1^2 \\
&= NR_u T\ln\left(\frac{V_2}{V_1}\right)+10N^2\left(\frac{1}{V_2}-\frac{1}{V_1}\right)
\end{aligned}$$

Substitute 0.2 kmol for N, $8.314\,\mathrm{kJ/kmol.K}$ for R, 350 K for T, $2\,\mathrm{m^3}$ for V_1, and $4\,\mathrm{m^3}$ for V_2.

$$\begin{aligned}
W_{b,out} &= (0.2)(8.314)(350)\ln\left(\frac{4}{2}\right)+(10)(0.2)^2\left[\frac{1}{4}-\frac{1}{2}\right] \\
&= 403.397+(-0.1) \\
&= 403.297\,\mathrm{kJ}
\end{aligned}$$

Therefore, the work done during the isothermal expansion process is $\boxed{403.297\,\mathrm{kJ}}$

Question: 5.018P

Reconsider Prob. 5–17. Using the integration feature of the EES software, calculate the work done, and compare your result with the "hand-calculated" result obtained in Prob. 5–17. Plot the process described in the problem on a *P- v* diagram.

We don't have the solution to this problem yet.

Ask an expert

Question: 5.019P

Carbon dioxide contained in a piston-cylinder device is compressed from 0.3 to 0.1 m3. During the process, the pressure and volume are related by $P = a\,V^{-2}$, where $a = 8$ kPam6. Calculate the work done on the carbon dioxide during this process.

Step 1 of 2

Given

Initial volume $V_1 = 0.3\ \text{m}^3$

Final volume $V_2 = 0.1\ \text{m}^3$

The relation between pressure and volume is

$P = aV^{-2}$ (Where $a = 8\ \text{kPa.m}^6$)

Step 2 of 2

The work done during any process involving boundary work is expressed as

$$W = \int_1^2 P\,dV\ \text{kJ}$$

$$W = \int_1^2 \frac{a}{V^2}\,dV\ \text{kJ}$$

$$W = -a\left(\frac{1}{V_2} - \frac{1}{V_1}\right)$$

$$W = -8\left(\frac{1}{0.1} - \frac{1}{0.3}\right)$$

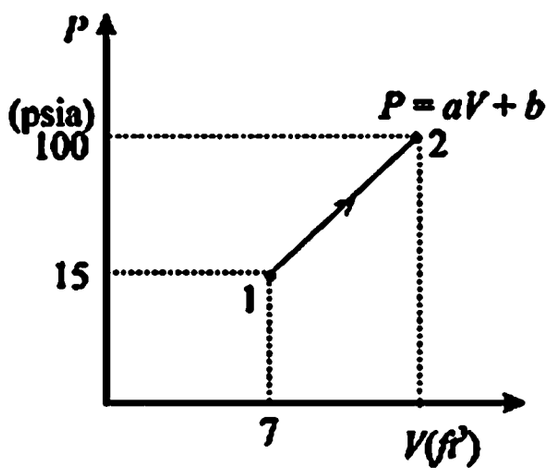
$$\boxed{W = -53.3\ \text{kJ}}$$

The negative sign indicates work is done on the system

Question: 5.020P

During an expansion process, the pressure of a gas changes from 15 to 100 psia according to the relation $P = a\,V + b$, where $a = 5$ psia/ft3 and b is a constant. If the initial volume of the gas is 7 ft3, calculate the work done during the process.

Step 1 of 4



Given

Initial Pressure $P_1 = 15$ psia

Final Pressure $P_2 = 100$ psia

Initial volume $V_1 = 7\ \text{ft}^3$

Step 2 of 4

Step 3 of 4

The relation $P = aV + b$, where a = 5 psia/ft^3, b is constant

Initial state

$$P_1 = aV_1 + b$$
$$15 = (5)(7) + b$$
$$b = -20$$

Final state

$$P_2 = aV_2 + b$$
$$100 = (5)V_2 - 20$$
$$V_2 = 24\ \text{ft}^3$$

Step 4 of 4

The work done during the process is

Area under the curve $W = \dfrac{P_1 + P_2}{2}(V_2 - V_1)$

$$W = \frac{15+100}{2}(24-7) \qquad (1\ \text{Btu} = 5.404\ \text{psia.ft}^3)$$

$$W = 977.5 \times \frac{1\ \text{Btu}}{5.404}$$

$$\boxed{W = 181\ \text{Btu}}$$

Question: 5.021P

A piston-cylinder device initially contains 0.25 kg of nitrogen gas at 130 kPa and 180°C. The nitrogen is now expanded isothermally to a pressure of 80 kPa. Determine the boundary work done during this process.

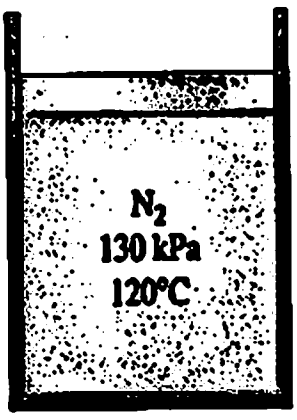


FIGURE P5–21

Step 1 of 4

From the ideal gas specific heat of various gases
For nitrogen
Gas constant is $R = 0.2968 \text{kJ/kg·K}$
Specific heat ratio is $k = 1.4$

Step 2 of 4

Use the conversion factor to convert the temperature from 1°C to 1K

$$1\text{K} = 1^\circ\text{C} + 273$$

$$T_1 = 180 + 273$$

$$= 453\text{K}$$

Calculate the initially volume by using the ideal gas equation

$$P_1V_1 = mRT_1$$

$$V_1 = \frac{mRT}{P_1}$$

Here, P_1 is the pressure at state point 1, V_1 is the volume at state point 1, m is the mass flow rate and T_1 is the initially temperature

Substitute 0.25kg for m, 0.2968kJ/kg·K for R, 453K for T_1 and 130kPa for P_1

$$V_1 = \frac{mRT}{P_1}$$

$$= \frac{(0.25)(0.2968)(453)}{(130)}$$

$$= 0.2586\text{m}^3$$

Step 3 of 4

Calculate the final volume

$$P_2V_2 = mRT_2$$

$$V_2 = \frac{mRT}{P_2}$$

$$= \frac{(0.25)(0.2968)(180+273)}{(80)}$$

$$= 0.420\text{m}^3$$

Step 4 of 4

Calculate the Work done in isothermal process

$$W = P_1V_1 \ln\left(\frac{V_2}{V_1}\right)$$

Substitute 130kPa for P_1, 0.2586m³ for V_1 and 0.420m³ for V_2

$$W = P_1V_1 \ln\left(\frac{V_2}{V_1}\right)$$

$$= (130)(0.2586)\ln\left(\frac{0.420}{0.2586}\right)$$

$$= 16.30\text{kJ}$$

Hence, the Work done in isothermal process is $\boxed{16.30\text{kJ}}$

Question: 5.022P

A piston-cylinder device contains 0.15 kg of air initially at 2 MPa and 350°C. The air is first expanded isothermally to 500 kPa, then compressed polytropically with a polytropic exponent of 1.2 to the initial pressure, and finally compressed at the constant pressure to the initial state. Determine the boundary work for each process and the net work of the cycle.

Step 1 of 6

Given

The mass of air $m = 0.15\ \text{kg}$

Initial Pressure $P_1 = 2\ \text{MPa}$

Temperature $T_1 = 350°\text{C}$

State 2 pressure $P_2 = 500\ \text{kPa}$

Final pressure $P_3 = P_1$

The polytrophic process index $n = 1.2$

Question:

A piston-cylinder device contains 0.15 kg of air initially at 2 MPa and 350°C. The air is first expanded isothermally to 500 kPa, then compressed polytropically with a polytropic exponent of 1.2 to the initial pressure, and finally compressed at the constant pressure to the initial state. Determine the boundary work for each process and the net work of the cycle.

Step 1 of 6

Given

The mass of air $m = 0.15\ \text{kg}$

Initial Pressure $P_1 = 2\ \text{MPa}$

Temperature $T_1 = 350°\text{C}$

State 2 pressure $P_2 = 500\ \text{kPa}$

Final pressure $P_3 = P_1$

The polytrophic process index $n = 1.2$

$$W_{1-2} = \frac{(2000)(0.0134)\ln\dfrac{}{0.0134}}{}$$

$$W_{1-2} = 37.18\ \text{kJ}$$

Step 4 of 6

In process 2-3

The boundary work during the process is

$$W_{2-3} = \frac{P_3V_3 - P_2V_2}{1-n}\ \text{kJ}$$

The polytrophic process $PV^n = C$

$$P_2V_2^n = P_3V_3^n$$

$$500(0.0536)^{12} = 2000(V_3)^{12}$$

Volume $V_3 = 0.0169\ \text{m}^3$

$$W_{2-3} = \frac{2000(0.0169) - 500(0.0536)}{1-1.2}\ \text{kJ}$$

$$W_{2-3} = -35\ \text{kJ}$$

Step 5 of 6

For the process3-1

The boundary work in constant pressure process is

$$W_{3-1} = P_1(V_1 - V_3)\ \text{kJ}$$

$$W_{3-1} = 2000(0.0134 - 0.0169)\ \text{kJ}$$

$$W_{1-2} = \frac{(2000)(0.0134)\ln\dfrac{}{0.0134}}{}$$

$$W_{1-2} = 37.18\ \text{kJ}$$

Step 4 of 6

In process 2-3

The boundary work during the process is

$$W_{2-3} = \frac{P_3V_3 - P_2V_2}{1-n}\ \text{kJ}$$

Question: 5.023P

1-kg of water that is initially at 90°C with a quality of 10 percent occupies a spring-loaded piston-cylinder device, such as that in Fig. P5-23. This device is now heated until the pressure rises to 800 kPa and the temperature is 250°C. Determine the total work produced during this process, in kJ.

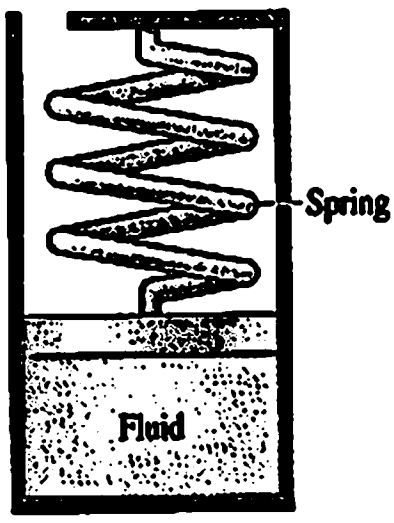

FIGURE P5–23

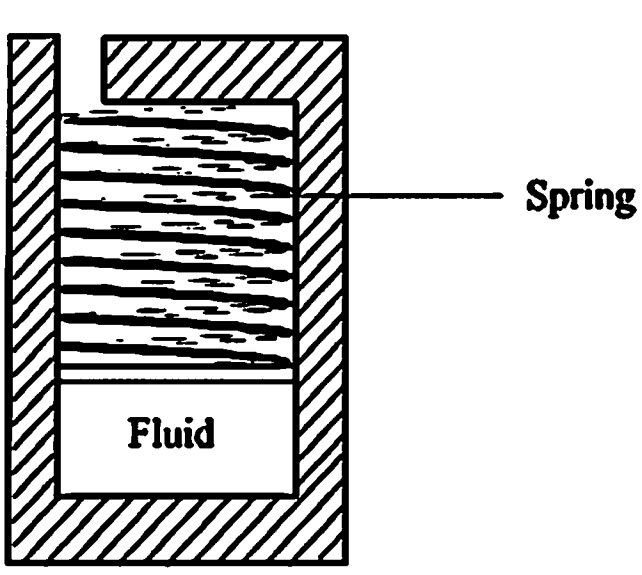
Step 1 of 4

Given

Mass of water $m = 1\text{kg}$



Initial temperature $T_1 = 90°\text{C}$

Dryness fraction $x = 0.1$

The final pressure $P_2 = 800\text{ kPa}$

Final Temperature $T_2 = 250°\text{C}$

Step 2 of 4

Step 3 of 4

From Saturated water Temperature table at $T = 90°\text{C}$

Step 1 of 4

Given

Mass of water $m = 1\text{kg}$

Initial temperature $T_1 = 90°\text{C}$

Dryness fraction $x = 0.1$

The final pressure $P_2 = 800\text{ kPa}$

Final Temperature $T_2 = 250°\text{C}$

Step 2 of 4

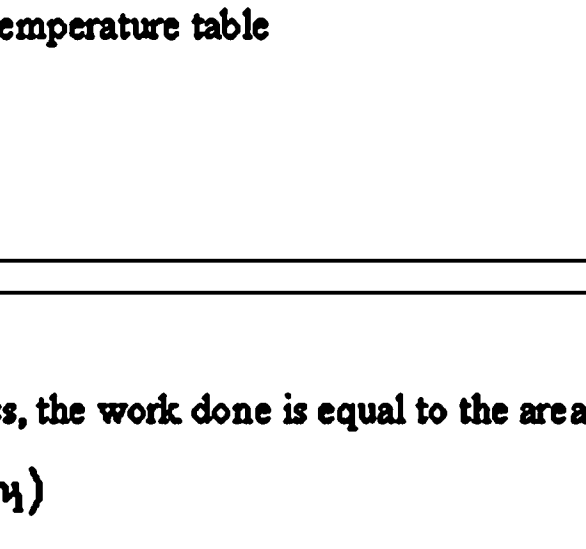
Question: 5.024P

1.5-kg water that is initially at 1 MPa and 30 percent quality occupies a spring-loaded piston-cylinder device. This device is now cooled until the water is a saturated liquid at 100°C. Calculate the total work produced during this process, in kJ.

Step 1 of 5

Given:

Mass of the water $m = 1.5\text{kg}$



Initially pressure $P_1 = 1\text{MPa}$

Quality of the steam $x = 30\%$

Final temperature $T_2 = 100^\circ\text{C}$

Step 2 of 5

P-V Diagram:

Step 3 of 5

The initial state is saturated mixture

From the saturated water pressure table

At 1MPa

$$v_f = 0.001127\frac{\text{m}^3}{\text{kg}}$$

$$v_g = 0.19436\frac{\text{m}^3}{\text{kg}}$$

$$v_1 = v_f + xv_{fg}$$

$$v_1 = v_f + x(v_g - v_f)$$

$$= 0.001127 + (0.3)(0.19436 - 0.001127)$$

$$= 0.0590\frac{\text{m}^3}{\text{kg}}$$

Step 4 of 5

The final state is saturated liquid

$P_2 = 101.42kPa$

From the saturated water Temperature table

At 100°C

$$v_2 = v_f = 0.001043\frac{\text{m}^3}{\text{kg}}$$

Step 5 of 5

Since this is a linear process, the work done is equal to the area under the process line 1-2

$$W_{b,out} = \left(\frac{P_1 + P_2}{2}\right)(m)(v_2 - v_1)$$

$$= \left(\frac{1000 + 101.42}{2}\right)(1.5)(0.001043 - 0.0590)$$

$$= -47.82\text{kJ}$$

$$\boxed{W_{b,out} = -47.82\text{kJ}}$$

The negative sign shows that the work is done on the system

Question: 5.025P

An ideal gas undergoes two processes in a piston-cylinder device as follows:

1-2 Polytropic compression from T 1 and P 1 with a polytropic exponent n and a compression ratio of r = V1 /V2.

2-3 Constant pressure expansion at P 3 = P 2 until V3 = V1.

(*a*) Sketch the processes on a single P- V diagram.

(*b*) Obtain an expression for the ratio of the compression-to-expansion work as a function of n and r.

(*c*) Find the value of this ratio for values of n = 1.4 and

$r = 6$. *Answers:* (*b*) $\frac{1}{n-1}\left(\frac{1-r^{1-n}}{r-1}\right)$, (*c*) 0.256

We don't have the solution to this problem yet.

Question: 5.026P

Complete the table below on the basis of the conservation of energy principle for a closed system.

Q in Btu	W out Btu	E 1 Btu	E 2 Btu	m lbm	e 2 – e 1 Btu/lbm
350	-	1020	860	3	-
350	130	550	-	5	-
-	260	600	-	2	150
-500	-	1400	900	7	-
-	-50	1000	-	3	-200

Step 1 of 8

Given:

Q_{in} Btu	W_{out} Btu	E_1 Btu	E_2 Btu	m lbm	$e_2 - e_1$ $\frac{\text{Btu}}{\text{lbm}}$
350	-				
350	130	550	-	5	-
-	260	600	-	2	150
-500	-	1400	900	7	-
-	-50	1000	-	3	-200

Step 2 of 8

The energy balance for a closed system can be expressed as

$$\underbrace{E_{in} - E_{out}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{system}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$Q_{in} - W_{out} = E_2 - E_1 = m(e_2 - e_1)$$

Step 3 of 8

Row 1:

$$Q_{in} - W_{out} = E_2 - E_1$$
$$350 - W_{out} = 860 - 1020$$
$$W_{out} = 510\,\text{Btu}$$
$$Q_{in} - W_{out} = m(e_2 - e_1)$$
$$350 - 510 = 3(e_2 - e_1)$$
$$(e_2 - e_1) = -53.333$$

Step 4 of 8

Row 2:

$$Q_{in} - W_{out} = E_2 - E_1$$
$$350 - 130 = E_2 - 550$$
$$E_2 = 770\,\text{Btu}$$
$$Q_{in} - W_{out} = m(e_2 - e_1)$$
$$350 - 130 = 5(e_2 - e_1)$$
$$(e_2 - e_1) = 44.0\,\frac{\text{Btu}}{\text{lbm}}$$

Step 5 of 8

Row 3:

$$Q_{in} - W_{out} = E_2 - E_1 = m(e_2 - e_1)$$
$$Q_{in} - W_{out} = m(e_2 - e_1)$$
$$Q_{in} - 260 = 2(150)$$
$$Q_{in} = 560\,\text{Btu}$$
$$Q_{in} - W_{out} = E_2 - E_1$$
$$560 - 260 = E_2 - 600$$
$$E_2 = 900\,\text{Btu}$$

Step 6 of 8

Row 4:

$$Q_{in} - W_{out} = E_2 - E_1$$
$$-500 - W_{out} = 900 - 1400$$
$$W_{out} = 0$$
$$Q_{in} - W_{out} = m(e_2 - e_1)$$
$$-500 - 0 = 7(e_2 - e_1)$$
$$(e_2 - e_1) = -71.4\,\frac{\text{Btu}}{\text{lbm}}$$

Step 7 of 8

Row 5:

$$E_2 - E_1 = m(e_2 - e_1)$$
$$E_2 - 1000 = 3(-200)$$
$$E_2 = 400\,\text{Btu}$$
$$Q_{in} - W_{out} = E_2 - E_1$$
$$Q_{in} - (-50) = 400 - 1000$$
$$Q_{in} = -650\,\text{Btu}$$

Step 8 of 8

Application of this equation gives the following completed table:

Q_{in} Btu	W_{out} Btu	E_1 Btu	E_2 Btu	m lbm	$e_2 - e_1$ $\frac{\text{Btu}}{\text{lbm}}$
350	510	1020	860	3	-53.3
350	130	550	770	5	44.0
560	260	600	900	2	150
-500	0	1400	900	7	-71.4
-650	-50	1000	400	3	-200

Question: 5.027P

A closed system like that shown in Fig. P5-27E is operated in an adiabatic manner. First, 15,000 lbf·ft of work are done by this system. Then, work is applied to the stirring device to raise the internal energy of the fluid by 10.28 Btu. Calculate the net increase in the internal energy of this system.

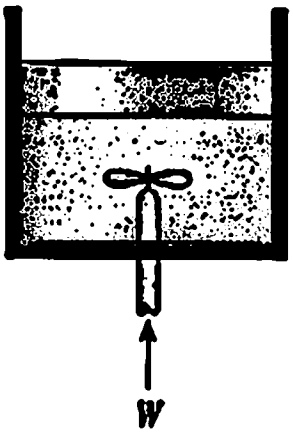

FIGURE P5–27E

Step 1 of 2

Use the conversion factor to convert the work output from $\text{lbf}\cdot\text{ft}$ to Btu

$$1\text{Btu} = 778.169\ \text{lbf}\cdot\text{ft}$$

Find the work output in Btu

$$W_{out} = (15000\ \text{lbf}\cdot\text{ft})\left(\frac{1\text{Btu}}{778.169\ \text{lbf}\cdot\text{ft}}\right)$$

$$= 19.276\text{Btu}$$

Step 2 of 2

Write the energy balance equation for a closed system

$$\dot{E}_{in} - \dot{E}_{out} = \Delta E_{system}$$

$$\dot{W}_{in} - \dot{W}_{out} = \Delta U$$

Here, ΔU is the change in internal energy and $\dot{W}_{in}$ is the work done by the system

Since process is adiabatic, therefore, rate of heat transfer is zero

$$\dot{W}_{in} - \dot{W}_{out} = \Delta U$$

Substitute 19.276Btu for W_{out} and 10.28Btu for $\dot{W}_{in}$

$$\dot{W}_{in} - \dot{W}_{out} = \Delta U$$

$$10.28 - 19.276 = \Delta U$$

$$\Delta U = -8.996\text{Btu}$$

Hence, change in internal energy of the system is $\boxed{-8.996\text{Btu}}$

Question: 5.028P

A closed system undergoes a process in which there is no internal energy change. During this process, the system produces 1.1 ×106 lbf·ft of work. Calculate the heat transfer for this process, in Btu.

Step 1 of 2

Given:

$W = 1.1\times10^{6}\,\text{lbf}\cdot\text{ft}$

Change in internal energy $\Delta U = 0$

Step 2 of 2

Applying the energy balance equation

$$E_{in} - E_{out} = \Delta E_{system}$$

$$Q_{in} - W_{out} = \Delta U = 0$$

$$(Since\ K\cdot E = P\cdot E = 0)$$

$$Q_{in} = W_{out}$$

$$Q_{in} = 1.1\times10^{6}\,\text{lbf}\cdot\text{ft}\left(\frac{1\text{Btu}}{778.171\text{bf}\cdot\text{ft}}\right)$$

$$= 1413.573\text{Btu}$$

$$\boxed{Q_{in} = 1413.573\text{Btu}}$$

Question: 5.029P

A rigid container equipped with a stirring device contains 1.5 kg of motor oil. Determine the rate of specific energy increase when heat is transferred to the oil at a rate of 1 W, and 1.5 W of power is applied to the stirring device.

Step 1 of 2

Consider the energy balance equation for a system undergoing a process.

$$E_{in} - E_{out} = \Delta E_{system}$$

Here, ΔE_{system} is the change in energy of the system, which include kinetic and potential energies.

Neglect the kinetic and potential energies for the system.

Apply energy balance for the system

$$\begin{aligned}\dot{Q}_{in} + \dot{W}_{in} &= \dot{E}_{in} - \dot{E}_{out} \\ &= \Delta \dot{E}_{system}\end{aligned}$$

Here, $\dot{Q}_{in}$ is the rate of heat transfer and $\dot{W}_{in}$ is the rate of work transfer.

Substitute 1 W for $\dot{Q}_{in}$ and 1.5 W for $\dot{W}_{in}$

$$\begin{aligned}\Delta \dot{E} &= 1 + 1.5 \\ &= 2.5 \text{ W}\end{aligned}$$

Step 2 of 2

Calculate the rate of specific energy increase using the relation

$$\Delta \dot{e} = \frac{\Delta \dot{E}}{m}$$

Here, m is the mass of the motor oil.

Substitute 1.5 kg for m

$$\begin{aligned}\Delta \dot{e} &= \frac{2.5}{1.5} \\ &= 1.67 \text{ J/kg} \cdot \text{s}\end{aligned}$$

Therefore, the rate of specific energy increase is $\boxed{1.667 \text{ J/kg} \cdot \text{s}}$

Question: 5.030P

A well-insulated rigid tank contains 2 kg of a saturated liquid–vapor mixture of water at 150 kPa. Initially, three-quarters of the mass is in the liquid phase. An electric resistor placed in the tank is connected to a 110-V source, and a current of 8 A flows through the resistor when the switch is turned on. Determine how long it will take to vaporize all the liquid in the tank. Also, show the process on a *T*- v diagram with respect to saturation lines.

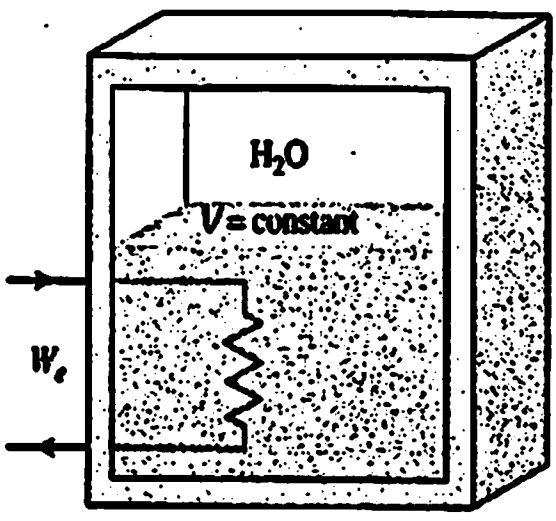

FIGURE P5–30

Step 1 of 6

From the energy balance equation

$$E_{in} - E_{out} = \Delta E_{system}$$
$$W_{e,in} = \Delta U$$
$$= m(u_2 - u_1)$$
$$VI \times \Delta t = m(u_2 - u_1)$$

Here, Voltage supplied by the electrical heater is V ,Current flow through a system is I and mass flow rate of mixture is m

Step 2 of 6

From the saturated water-pressure table

At $P_1 = 150\text{kPa}$

Specific volume of liquid vapor mixture is $v_f = 0.001053\,\text{m}^3/\text{kg}$

Specific volume of vapor is $v_g = 1.1594\,\text{m}^3/\text{kg}$

Internal energy of liquid state is $u_f = 446.97\,\text{kJ/kg}$

Internal energy of liquid vapor mixture is $u_{fg} = 2052.3\,\text{kJ/kg}$

Step 3 of 6

Calculate the Specific volume at state point 1

$$v_1 = v_f + x_1 v_{fg}$$
$$= 0.001053 + [0.25(1.1594 - 0.001053)]$$
$$= 0.290\,\text{m}^3/\text{kg}$$

Step 4 of 6

Calculate the Internal energy at state point 1

$$u_1 = u_f + x_1 u_{fg}$$
$$= 466.97 + [0.25 \times 2052.3]$$
$$= 980.045\,\text{kJ/kg}$$

Since tank is rigid so volume remains constant.

$$v_1 = v_2 = 0.290\,\text{kJ/kg}$$

Step 5 of 6

From the saturated water-pressure table

At $v_1 = v_2 = 0.290\,\frac{\text{kJ}}{\text{kg}}$ and saturated vapor

Which is lies between the $650\,\text{kPa}$ and 700kPa

Use the method of interpolation

$$\frac{0.290 - 0.27278}{0.29260 - 0.27278} = \frac{u_2 - 2571.8}{2569.4 - 2571.8}$$
$$u_2 = 2569.71\,\text{kJ/kg}$$

Step 6 of 6

Calculate the Time required

$$VI\Delta t = m(u_2 - u_1)$$

Substitute $110\,\text{V}$ for V, $8\,\text{A}$ for I , 2kg for m, $2569.71\,\text{kJ/kg}$ for u_2

$$(110 \times 8)\Delta t = (2)(2569.71 - 980.045)(1000)$$
$$\Delta t = 3612.87\,\text{s}$$
$$= \frac{3612.87\,\text{s} \times 1\,\text{min}}{60\,\text{s}}$$
$$= 60.21\,\text{min}$$

Therefore, time required to vaporize all liquid in tank is $\boxed{60.21\,\text{min}}$

Question: 5.031P

Reconsider Prob. 5–30. Using EES (or other) software, investigate the effect of the initial mass of water on the length of time required to completely vaporize the liquid. Let the initial mass vary from 1 to 10 kg. Plot the vaporization time against the initial mass, and discuss the results.

Step 1 of 9

Given:

Mass of the liquid vapor $m = 2\text{kg}$

Pressure of mixture $P = 150\text{kPa}$

Amount of liquid phase $x = 0.25$

Source voltage $V = 110\text{V}$

Source current $I = 8\text{A}$

Mass of the liquid varies from the 1kg to10kg

Step 2 of 9

```
PROCEDURE P2X2(v[1]:P[2],x[2])
Fluid$='Steam_IAPWS'
If v[1] > V_CRIT(Fluid$) then
P[2]=pressure(Fluid$,v=v[1],x=1)
x[2]=1
else
P[2]=pressure(Fluid$,v=v[1],x=0)
x[2]=0
End If
End
```

Step 3 of 9

```
"Knowns"

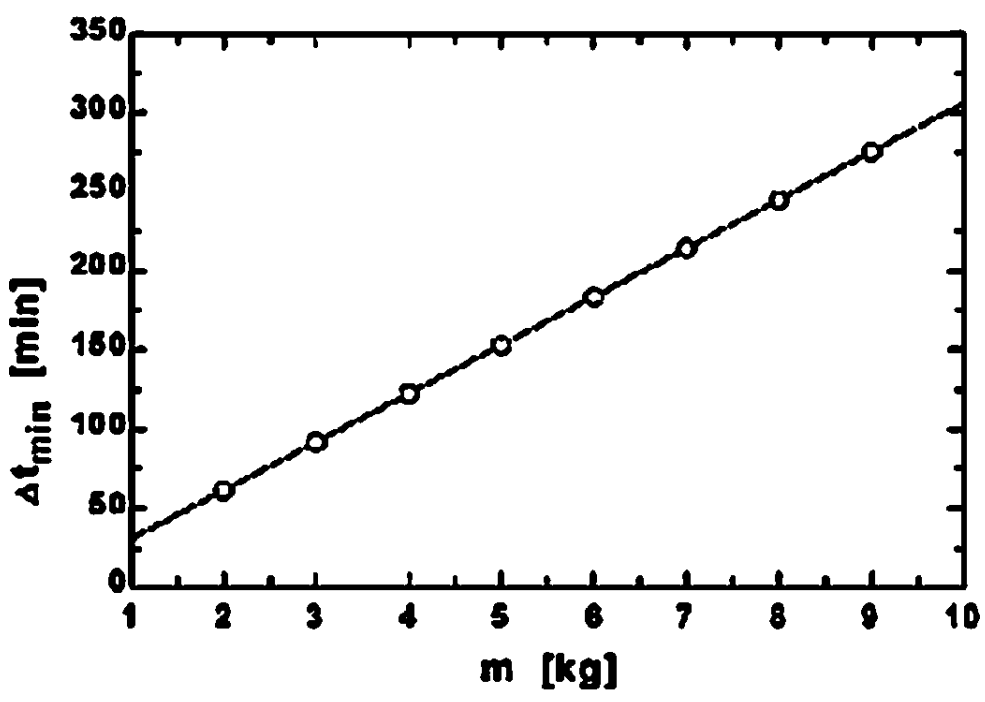
v[1]=volume(Fluid$,P=P[1], x=x[1]) "[m^3/kg]"
T[1]=temperature(Fluid$,P=P[1], x=x[1]) "[C]"
"Check to see if state 2 is on the saturated liquid line or saturated vapor line:"
Call P2X2(v[1]:P[2],x[2])
u[2]=INTENERGY(Fluid$,P=P[2], x=x[2]) "[kJ/kg]"
v[2]=volume(Fluid$,P=P[2], x=x[2]) "[m^3/kg]"
T[2]=temperature(Fluid$,P=P[2], x=x[2]) "[C]"
```

Step 6 of 9

Run the new parameter table on manu bar.

Then select the m_kg and Δt(min) then click ok

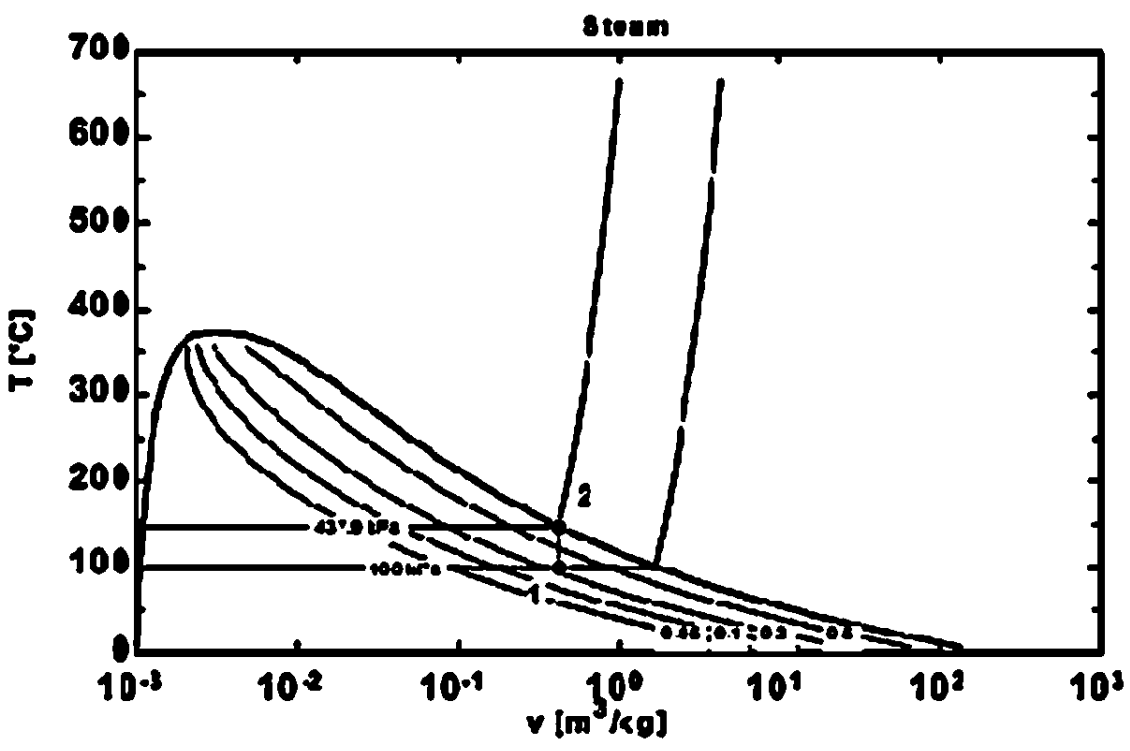
Vary the mass 1kg to 10kg then solve .



Step 7 of 9

Solution table:

Δt_{min} (min)	m_kg
30.11	1
60.22	2
90.31	3
120.42	4
150.525	5
180.63	6
210.735	7
240.84	8
270.945	9
301.05	10



Step 8 of 9

Graph between m_kg and Δt(min)

Step 9 of 9

P-v Daigram:

Question: 5.032P

Saturated water vapor at 200°C is isothermally condensed to a saturated liquid in a piston-cylinder device. Calculate the heat transfer and the work done during this process, in kJ/kg.

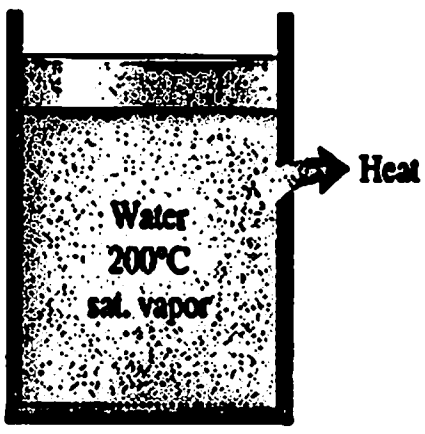


FIGURE P5–32

Step 1 of 5

Apply energy balance to the closed system by neglecting the change in kinetic and potential energies.

$$E_{in} - E_{out} = \Delta E_{system}$$

$$W_{in} - Q_{out} = \Delta U$$
$$W_{in} - Q_{out} = U_2 - U_1$$

Here, W_{in} is the amount of energy transferred as work input, Q_{out} is the amount of energy transferred as heat output and ΔU is change in internal energy.

Step 2 of 5

Represent the equation for a unit mass: $w_{in} - q_{out} = u_2 - u_1$ ..... (1)

Step 3 of 5

At the initial state that is at state 1 the state of steam in the piston cylinder device is in the form of saturated vapor; at the final state that is at state 2 the state of steam is in the form of saturated liquid.

Quote the following values from the saturated water temperature table at temperature $T_1 = 200°C$:

Saturated vapor $P_{sat} = P_1 = P_2 = 1554.9\ \text{kPa}$, Saturated vapor of specific volume $v_1 = v_g = 0.12721\ \text{m}^3/\text{kg}$ and Saturated vapor of specific internal energy $u_1 = u_g = 2594.2\ \text{kJ/kg}$.

Since the condensation process is isothermal process, the temperature remains constant. Hence at temperature $T_1 = T_2 = 200°C$, the following can be stated from the saturated water temperature table:

Saturated liquid of specific volume $v_2 = v_f = 0.001157\ \text{m}^3/\text{kg}$, saturated liquid of specific internal energy $u_2 = u_f = 850.46\ \text{kJ/kg}$

Step 4 of 5

Represent the boundary work done during this condensation process by using the following equation:

$$\begin{aligned} w_{out} &= \int_1^2 P dv \\ &= P(v_2 - v_1) \\ &= 1554.9 \times (0.001157 - 0.12721) \\ &= -195.99\ \text{kJ/kg} \end{aligned}$$

The negative sign indicates work input to the system. Therefore, the amount of work input w_{in} is $\boxed{195.99\ \text{kJ/kg}}$.

Step 5 of 5

Calculate the heat transfer by substituting the known values in equation (1).

$$\begin{aligned} w_{in} - q_{out} &= u_2 - u_1 \\ 195.99 - q_{out} &= 850.46 - 2594.2 \\ 195.99 - q_{out} &= -1743.74 \\ q_{out} &= 1939.73\ \text{kJ/kg} \end{aligned}$$

Therefore, heat transfer from the system is $\boxed{1939.73\ \text{kJ/kg}}$.

Question: 5.033P

A rigid 10-L vessel initially contains a mixture of liquid water and vapor at 100°C with 12.3 percent quality. The mixture is then heated until its temperature is 150°C. Calculate the heat transfer required for this process.

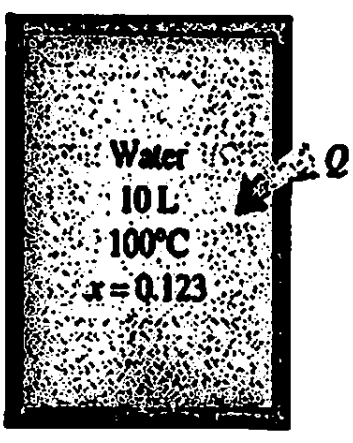

FIGURE P5–33

Step 1 of 8

Write the energy balance for closed rigid tank system

$$E_{in} - E_{out} = \Delta E_{system}$$

Since kinetic and potential energy are negligible, therefore, KE = PE = 0

$$Q_{in} = \Delta U$$
$$= m(u_2 - u_1)$$

Here, m is the mass flow rate of the mixture, u_2 and u_1 are the internal energy at state points 2 and 1 respectively.

Step 2 of 8

From the saturated water temperature table

At Inlet temperature $T_1 = 100^\circ C$ and quality of the mixture is $x_1 = 0.123$

Specific volume of the liquid is $v_f = 0.001043\ m^3/kg$

Specific volume of the liquid vapor mixture is $v_g = 1.6720\ m^3/kg$

Calculate the Specific volume at state 1

$$v_1 = v_f + x_1 v_{fg}$$
$$= v_f + x_1 (v_g - v_f)$$

Substitute $0.001043\ m^3/kg$ for v_f, $1.6720\ m^3/kg$ for v_g

$$v_1 = 0.001043 + [0.123 \times (1.6720 - 0.001043)]$$
$$= 0.2065 \frac{m^3}{kg}$$

Step 3 of 8

From the saturated water temperature table

At $T_1 = 100^\circ C$ and $x_1 = 0.123$

$$u_f = 419.06 \frac{kJ}{kg}$$

$$u_{fg} = 2087.0 \frac{kJ}{kg}$$

Calculate the Internal energy at state 1

$$u_1 = u_f + x_1 u_{fg}$$
$$= 419.06 + [0.123 \times 2087]$$
$$= 675.761 kJ/kg$$

Step 4 of 8

Since tank is rigid so volume remains constant.

$$v_2 = v_1 = 0.2065 m^3/kg$$

From the saturated water temperature table

At $T_2 = 150^\circ C$

$$v_f = 0.001091 \frac{m^3}{kg}$$

$$v_g = 0.39248 \frac{m^3}{kg}$$

Step 5 of 8

Find the Quality of the mixture at final state

$$v_2 = v_f + x_2 v_{fg}$$

$$x_2 = \frac{v_2 - v_f}{v_{fg}}$$
$$= \frac{0.2065 - 0.001091}{0.39248 - 0.001091}$$
$$= 0.524$$

Step 6 of 8

From the saturated water temperature table

At $T_2 = 150^\circ C$

$$u_f = 631.66 \frac{kJ}{kg}$$

$$u_{fg} = 1927.4 \frac{kJ}{kg}$$

Calculate the internal energy at final state point 2

$$u_2 = u_f + x_2 u_{fg}$$
$$= 631.66 + [0.524 \times 1927.4]$$
$$= 1641.61 kJ/kg$$

Step 7 of 8

Calculate the mass in the system

$$m = \frac{V_1}{v_1}$$
$$= \frac{10 \times 10^{-3}}{0.2065}$$
$$= 0.04842\ kg$$

Step 8 of 8

Calculate the heat transfer

$$Q_{in} = m(u_2 - u_1)$$

Substitute $1641.61 kJ/kg$ for u_2, $675.761 kJ/kg$ for u_1 and $0.04842\ kg$ for m

$$Q_{in} = m(u_2 - u_1)$$
$$= (0.04842)(1641.61 - 675.761)$$
$$= 46.76 kJ$$

Therefore, the heat transfer is $\boxed{46.76 kJ}$

Question: 5.034P

A fixed mass of saturated water vapor at 300 kPa is isothermally cooled until it is a saturated liquid. Calculate the amount of heat rejected during this process, in kJ/kg.

Step 1 of 6

Given:
Process: isothermal
Saturated water vapor pressure $P_1 = P_2 = 300\text{kPa}$

Step 2 of 6

The energy balance equation for the closed system can be expressed as:-

$$W_{b,in} - Q_{out} = \Delta U$$

$$Q_{out} = W_{b,in} - m(u_2 - u_1)$$

Step 3 of 6

From the saturated water pressure table
At $P_1 = P_2 = 300\text{kPa}$ and $x_1 = 1$
Since water initially saturated state.

$$T_1 = T_2 = 133.52^\circ\text{C}$$

$$v_1 = v_g = 0.60582\frac{\text{m}^3}{\text{kg}}$$

$$u_1 = u_g = 2543.2\frac{\text{kJ}}{\text{kg}}$$

Step 4 of 6

We know that
Final state is saturated liquid, So that

$$x_2 = 0$$

From the saturated water pressure table
At $P_1 = P_2 = 300\text{kPa}$ and $x_2 = 1$

$$v_2 = v_f = 0.001073\frac{\text{m}^3}{\text{kg}}$$

$$u_2 = u_f = 561.11\frac{\text{kJ}}{\text{kg}}$$

Step 5 of 6

The work done during this process is

$$W_{b,out} = \int_1^2 PdV = P(v_2 - v_1)$$
$$= 300(0.001073 - 0.60582)$$
$$= -181.4241\frac{\text{kJ}}{\text{kg}}$$

Negative sign indicated that on the system.
Now take the entire process as the system, so work done by the system so take the positive sign

$$W_{b,in} = 181.4241\frac{\text{kJ}}{\text{kg}}$$

Step 6 of 6

Substituting the energy balance equation, we get

$$q_{out} = W_{b,in} - (u_2 - u_1)$$
$$= W_{b,in} + u_{fg}$$
$$= 181.424 + 1982.1$$
$$= 2163.524\frac{\text{kJ}}{\text{kg}}$$

$$\boxed{q_{out} = 2163.524\frac{\text{kJ}}{\text{kg}}}$$

Question: 5.035P

Saturated water vapor in a closed system is condensed by cooling it at constant pressure to a saturated liquid at 40 kPa. Determine the heat transferred and the work done during this process, in kJ/kg.

Step 1 of 2

Obtain the properties from saturated water pressure table at $P_1 = P_2 = 40\text{kPa}$

Specific volume of saturated vapor at state point 1 is $v_1 = v_g = 3.9933\text{m}^3/\text{kg}$

Specific volume of saturated liquid $v_2 = v_f = 0.001026\text{m}^3/\text{kg}$

Internal energy of vaporization $u_{fg} = 2158.8\text{kJ/kg}$

Calculate the Work done for closed system

$$W_{b,out} = \int_1^2 P dV$$
$$= P(v_2 - v_1)$$

Substitute 40kPa for P, $0.001026\text{m}^3/\text{kg}$ for v_2 and $3.9933\text{m}^3/\text{kg}$ for v_1

$$W_{b,out} = 40(0.001026 - 3.9933)$$
$$= -159.7\text{kJ/kg}$$

Negative sign indicates work done on the system

Thus, Work done on closed system is $\boxed{159.7\text{kJ/kg}}$

Step 2 of 2

Calculate the heat transfer for closed system

$$Q_{out} = W_{b,in} - m(u_2 - u_1)$$
$$q_{out} = W_{b,in} - (u_2 - u_1)$$
$$= W_{b,in} - (u_2 - u_1)$$

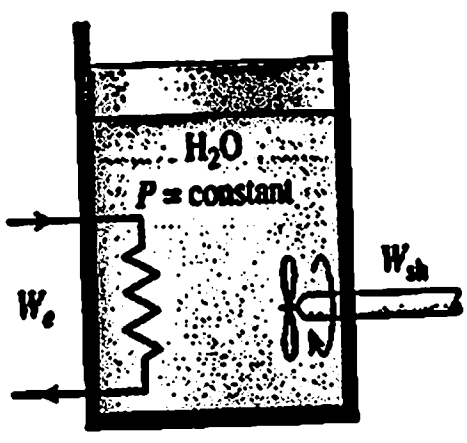
Substitute 159.7kJ/kg for $W_{b,in}$ and 2158.8kJ/kg for u_{fg}

$$q_{out} = W_{b,in} + u_{fg}$$
$$= 159.7 + 2158.8$$
$$= 2318.5\text{kJ/kg}$$

Therefore, heat transfer for closed system is $\boxed{2318.5\text{kJ/kg}}$

Question: 5.036P pg 1

An insulated piston-cylinder device contains 5 Lof saturated liquid water at a constant pressure of 175 kPa. Water is stirred by a paddle wheel while a current of 8 A flows for 45 min through a resistor placed in the water. If one-half of the liquid is evaporated during this constant-pressure process and the paddle-wheel work amounts to 400 kJ, determine the voltage of the source. Also, show the process on a *P*-v diagram with respect to saturation lines.



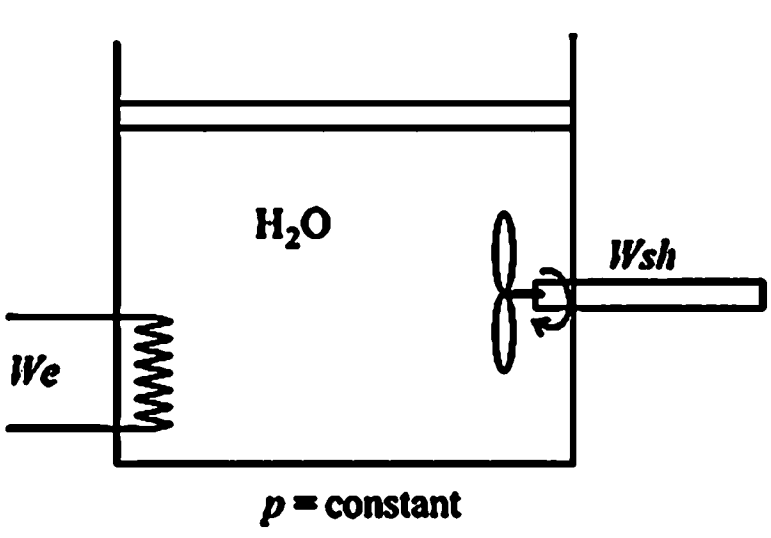


FIGURE P5–36

Step 1 of 7

Draw the diagram for the system of the piston cylinder arrangement.

Step 2 of 7

Obtain the properties of saturated liquid water from, "TABLE A-5 Saturated Water-Pressure table" in the textbook.

At pressure 175 kPa,

Specific enthalpy of liquid, $h_f = h_1 = 487.01\,\text{kJ/kg}$.

Specific enthalpy of evaporation, $h_{fg} = 2213.1\,\text{kJ/kg}$.

Specific volume of liquid, $v_f = v_1 = 0.001057\,\text{m}^3/\text{kg}$

Step 3 of 7

Calculate the total mass of water.

$$m = \frac{V}{v_1}$$

Here, total volume of the water is V .

Substitute $0.001057\,\text{m}^3/\text{kg}$ for v_1 , and $\left(5\times10^{-3}\right)\text{m}^3$ for *V*.

$$m = \frac{5\times10^{-3}}{0.001057}$$
$$= 4.730\,\text{kg}$$

Determine the quality of steam at final state.

$$x_2 = \frac{V_v}{V}$$

Here, volume of the evaporated liquid is V_v ,

◊

Substitute 2.5 L for V_v , and 5L for V ◊

$$x_2 = \frac{2.5}{5}$$
$$= 0.5\,\text{dry}$$

Step 4 of 7

Determine the enthalpy at final state using the relation:

$$h_2 = h_f + x_2\left(h_{fg}\right)$$

Substitute $487.01\,\text{kJ/kg}$ for h_f , $2213.1\,\text{kJ/kg}$ for h_{fg} , and 0.5 for x_2 .

$$h_2 = 487.01 + 0.5(2213.1)$$
$$= 1593.56\,\text{kJ/kg}$$

Write the expression to calculate the enthalpy change within the system.

$$\Delta H = m\left(h_2 - h_1\right)$$

Here, the specific enthalpy at the initial state is h_1 , specific enthalpy at final state is h_2 , mass of the water is m .

Substitute $487.01\,\text{kJ/kg}$ for h_1 , $1593.56\,\text{kJ/kg}$ for h_2 , and $4.730\,\text{kg}$ for m .

$$\Delta H = 4.730(1593.56 - 487.01)$$
$$= 5234.389\,\text{kJ}$$

Step 5 of 7

Express the energy balance for any system undergoing any kind of process.

$$E_{in} - E_{out} = \Delta E_{system}$$

Neglect the changes in potential and kinetic energies:

Express the energy balance for any system undergoing any kind of process.

$$E_{in} - E_{out} = \Delta E_{system}$$

Neglect the changes in potential and kinetic energies:

$$\Delta PE = \Delta KE = Q = 0$$

Rewrite the equation as follows:

$$W_{in} = W_{out} + \Delta U$$

Here, the input work is W_{in} , output work is W_{out} and change in internal energy is ΔU .

Substitute ΔH for $W_{out} + \Delta U$.

$$W_{in} = \Delta H \qquad \left[\because \Delta U + W = \Delta H = m(h_2 - h_1)\right]$$

Rewrite the expression introducing the paddle and electrical works in the place of input work respectively.

$$W_{elec} + W_{sh} = \Delta H \quad \text{..... (1)}$$

Step 6 of 7

Calculate the work supplied in the form of electrical energy

$$W_{elec} = VI\Delta t$$

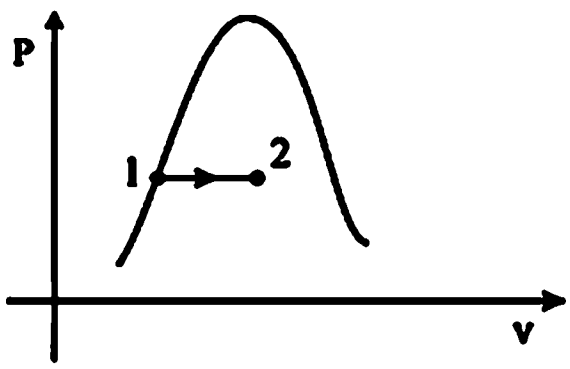
Here, voltage is , current is *I* and time is *t*.

Substitute $VI\Delta t$ for W_{elec} in the equation (1).

$$VI\Delta t + W_{sh} = \Delta H$$

Substitute 8 A for I, (45×60)sec for Δt , 400 kJ for W_{sh} , $5234.389\,\text{kJ}$ for ΔH and calculate the voltage.

$$(V\times 8\times 45\times 60) + 400 = 5234.389$$



$$V = \frac{5234.389 - 400}{8\times 45\times 60}\times 1000$$

$$= 223.8\,\text{V}$$

Therefore, the voltage of the source is $\boxed{223.8\,\text{V}}$.

Step 7 of 7

Sketch the process on the p-V diagram.

Question: 5.037P

A piston-cylinder device initially contains steam at 200 kPa, 200°C, and 0.4 m3. At this state, a linear spring ($F \propto x$) is touching the piston but exerts no force on it. Heat is now slowly transferred to the steam, causing the pressure and the volume to rise to 250 kPa and 0.6 m3, respectively. Show the process on a *P*-*v* diagram with respect to saturation lines and determine (*a*) the final temperature, (*b*) the work done by the steam, and (*c*) the total heat transferred.

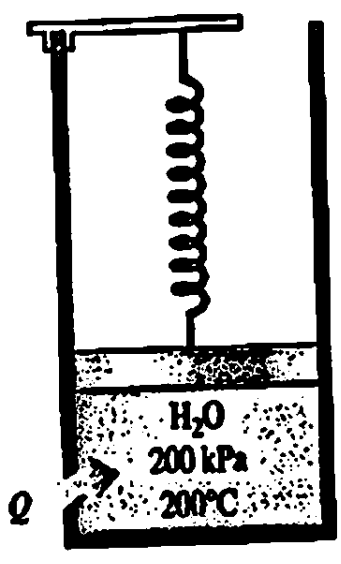


FIGURE P5–37

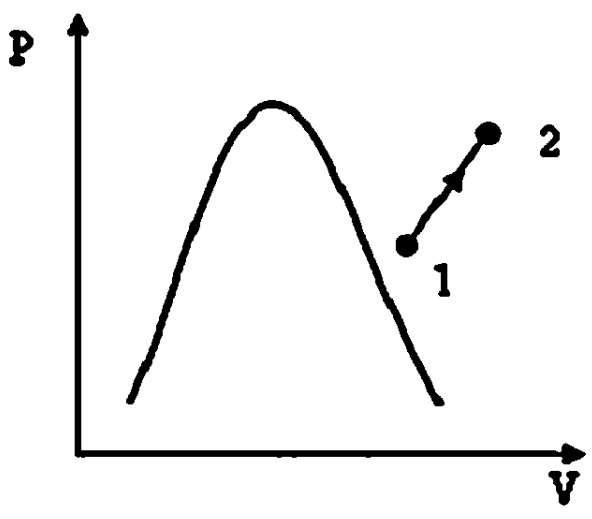
Step 1 of 8

Given:

Initially pressure $P_1 = 200\text{kPa}$

Initially temperature $T_1 = 200^\circ\text{C}$



Initially Volume $V_1 = 0.4\text{m}^3$

Final pressure $P_2 = 250\text{kPa}$

Final volume $V_2 = 0.6\text{m}^3$

Step 2 of 8

P-V Diagram:

Step 3 of 8

a) The energy balance for this stationary closed system can be expressed as
From the superheated water

$P_1 = 200\text{kPa}$, and $T_1 = 200^\circ\text{C}$

$$v_1 = 1.08049\frac{\text{m}^3}{\text{kg}}$$

$$u_1 = 2654.6\frac{\text{kJ}}{\text{kg}}$$

Step 4 of 8

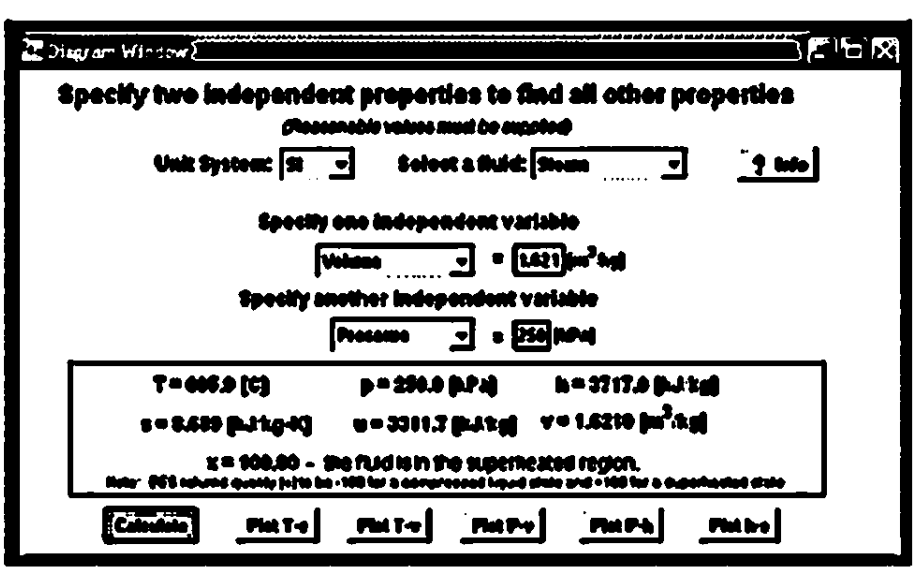
Mass of the system is

$$m = \frac{V_1}{v_1}$$
$$= \frac{0.4}{1.08049}$$
$$= 0.3702\text{kg}$$

Step 5 of 8

Final specific volume is

$$v_2 = \frac{V_2}{m}$$
$$= \frac{0.6}{0.3702}$$
$$= 1.621\frac{\text{m}^3}{\text{kg}}$$



Step 6 of 8

We have,

$P_2 = 250\text{kPa}$

$$v_2 = 1.621\frac{\text{m}^3}{\text{kg}}$$

Using method of interpolation or EES

We get

$T_2 = 606.9^\circ\text{C}$

$\boxed{T_2 = 606^\circ\text{C}}$

$$u_2 = 3311.7\frac{\text{kJ}}{\text{kg}}$$

Step 7 of 8

(b) The pressure of the gas changes linearly with volume, and thus the prcess curve on a P-V diagram will be a straight line. The boundary work during this process is simply the area under the process curve, which is a trapezoidal. Thus

$$W_b = \frac{(P_1 + P_2)}{2}(V_2 - V_1)$$
$$= \frac{(200 + 250)}{2}(0.6 - 0.4)$$
$$= 45\text{kJ}$$
$$\boxed{W_b = 45\text{kJ}}$$

Step 8 of 8

(c) From the energy balance, we have

$$Q_{in} = m(u_2 - u_1) + W_b$$
$$Q_{in} = [(0.3702)(3311.002 - 2654.6)] + 45$$
$$= 288\text{kJ}$$
$$\boxed{Q_{in} = 288\text{kJ}}$$

Question: 5.038P

Reconsider Prob. 5–37. Using EES (or other) software, investigate the effect of the initial temperature of steam on the final temperature, the work done, and the total heat transfer. Let the initial temperature vary from 150 to 250°C. Plot the final results against the initial temperature, and discuss the results.

Step 1 of 9

Given:

Initially pressure $P_1 = 200\text{kPa}$

Initially temperature varies from $T_1 = 150^\circ\text{C to } 250^\circ\text{C}$

Initially Volume $V_1 = 0.4\,\text{m}^3$

Final pressure $P_2 = 250\text{kPa}$

Final volume $V_2 = 0.6\,\text{m}^3$

Step 2 of 9

"The process is given by:"
"P[2]=P[1]+k*x*A/A, and as the spring moves 'x' amount, the volume changes by V[2]-V[1]."
P[2]=P[1]+(Spring_const)*(V[2] - V[1]) "P[2] is a linear function of V[2]"
"where Spring_const = k/A, the actual spring constant divided by the piston face area"

"Conservation of mass for the closed system is:"
m[2]=m[1]

Step 3 of 9

"The conservation of energy for the closed system is"
"E_in - E_out = DeltaE, neglect DeltaKE and DeltaPE for the system"
Q_in - W_out = m[1]*(u[2]-u[1])
DELTAU=m[1]*(u[2]-u[1])

"Input Data"
P[1]=200 [kPa]
V[1]=0.4 [m^3]
"T[1]=200 [C]"
P[2]=250 [kPa]
V[2]=0.6 [m^3]

Step 4 of 9

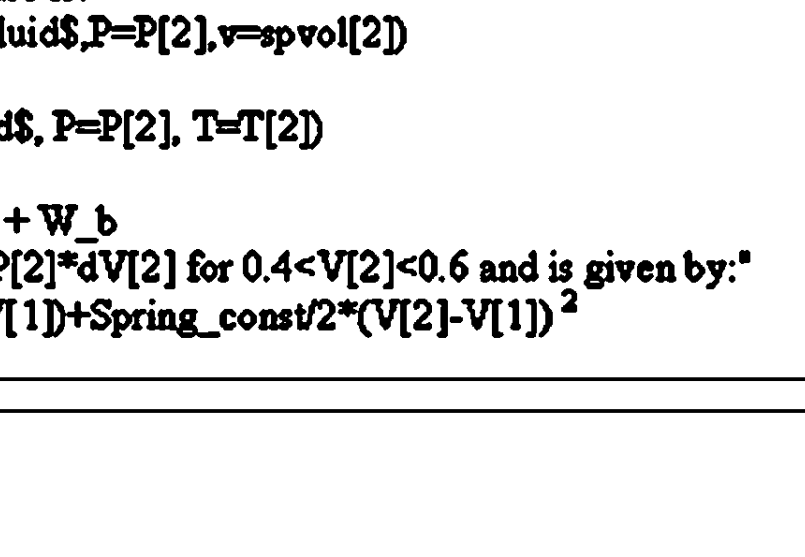
Fluid$='Steam_IAPWS'

m[1]=V[1]/spvol[1]
spvol[1]=volume(Fluid$,T=T[1], P=P[1])
u[1]=intenergy(Fluid$, T=T[1], P=P[1])
spvol[2]=V[2]/m[2]

Step 5 of 9

"The final temperature is:"
T[2]=temperature(Fluid$,P=P[2],v=spvol[2])

u[2]=intenergy(Fluid$, P=P[2], T=T[2])
Wnet_other = 0
W_out=Wnet_other + W_b
"W_b = integral of P[2]*dV[2] for 0.4<V[2]<0.6 and is given by:"
W_b=P[1]*(V[2]-V[1])+Spring_const/2*(V[2]-V[1])^2



Step 6 of 9

Solution table:

1..11	Q_{in}	T_1 [C]	T_2 [C]	W_{out}
Run 1	281.5	150	508.2	45
Run 2	282.8	160	527.9	45
Run 3	284.2	170	547.5	45

Step 8 of 9

Graph between T_1 and Q_in

Step 9 of 9

Graph between pressure and volume

Question: 5.039P

A 30-L electrical radiator containing heating oil is placed in a 50-m3 room. Both the room and the oil in the radiator are initially at 10°C. The radiator with a rating of 1.8 kW is now turned on. At the same time, heat is lost from the room at an average rate of 0.35 kJ/s. After some time, the average temperature is measured to be 20°C for the air in the room, and 50°C for the oil in the radiator. Taking the density and the specific heat of the oil to be 950 kg/m3 and 2.2 kJ/kg·°C, respectively, determine how long the heater is kept on. Assume the room is well-sealed so that there are no air leaks.

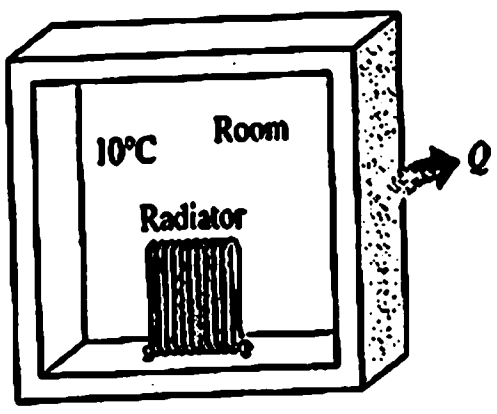

FIGURE P5–39

Step 1 of 5

Given

Volume of room $V = 50\ \text{m}^3$

Initial temperature of radiator $T_{1air} = 10°\text{C}$

Capacity of radiator 30L

Power input of radiator $W_{in} = 1.8\ \text{kW}$

Heat lost $\dot{Q}_{out} = 0.35\ \text{kJ/s}$

Final temperature of radiator $T_{2air} = 20°\text{C}$

Temperature of oil $T_{2oil} = 50°\text{C}$

Density of oil $\rho = 950\ \text{kg/m}^3$

Specific heat of oil $c = 2.2\ \text{kJ/kg.}^0\text{C}$

Step 2 of 5

From table ideal gases table properties of air are

$R = 0.287\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$Q_{in} - W_{out} = \Delta U$

$Q_{in} - W_{out} = m(u_2 - u_1)$

$\left(\dot{Q}_{in} - \dot{W}_{out}\right)\Delta t = mc_v(T_2 - T_1)_{air} + mc(T_2 - T_1)_{oil}$

Step 3 of 5

The mass of oil is determined by

$m_{oil} = \rho_{oil} V_{oil}$

$= 950 \times \left(30 \times 10^{-3}\right)$

$m_{oil} = 28.5\ \text{kg}$

Step 4 of 5

Mass of air can be obtained by using ideal gas equation

$$m_{air} = \frac{P_1 V}{R T_1}$$

$$= \frac{100 \times (50)}{0.287 \times (10 + 273)}$$

$m_{air} = 61.56\ \text{kg}$

Step 5 of 5

Therefore substituting all the values in the equation

$\left(\dot{Q}_{in} - \dot{W}_{out}\right)\Delta t = (mc_v)_{air}(T_2 - T_1)_{air} + (mc)_{oil}(T_2 - T_1)_{oil}$

$(1.8 - 0.35)\Delta t = (61.56)(0.718)(20 - 10) + (28.5)(2.2)(50 - 10)$

$1.45 \times \Delta t = 442.0008 + 2508$

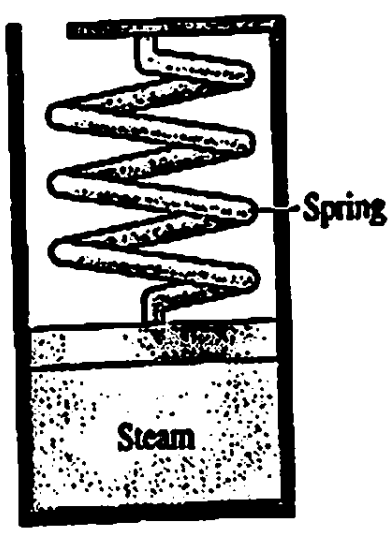
$\Delta t = 2034.48\ \text{sec}$

$$\Delta t = 2034.48 \times \frac{1}{60}$$

$\boxed{\Delta t = 33.9\ \text{min}}$

Question: 5.040P

Steam at 75 kPa and 8 percent quality is contained in a spring-loaded piston-cylinder device, as shown in Fig. P5-40, with an initial volume of 2 m3. Steam is now heated until its volume is 5 m3 and its pressure is 225 kPa. Determine the heat transferred to and the work produced by the steam during this process.



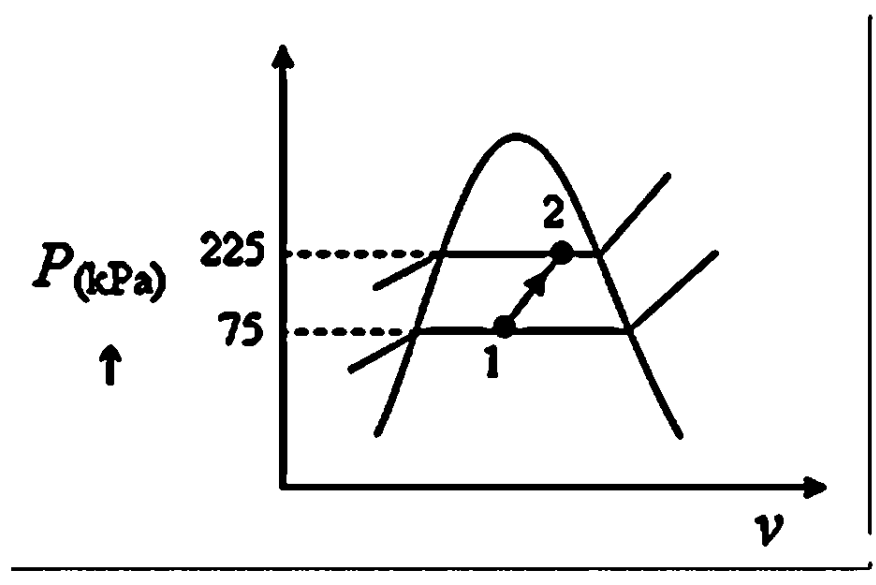


FIGURE P5–40

Step 1 of 11

Draw 1-2 process on *P-V* diagram is as shown below:

Step 2 of 11

Write the energy balance for this stationary closed system

$$Q_{in} - W_{b,out} = \Delta U$$
$$= m(u_2 - u_1)$$
$$Q_{in} = W_{b,out} + m(u_2 - u_1)$$

Here, Heat input to the system is Q_{in}, work produced by the system is $W_{b,out}$, mass flow rate of the system is m and u_1 and u_2 are internal energy of the system at state point 1 and 2 respectively.

Step 3 of 11

Obtain the properties from "saturated water pressure table" at pressure P_1=75 kPa

Specific volume of saturated liquid is $v_f = 0.001037\,m^3/kg$

Specific volume of saturated vapor is $v_g = 2.2173\,m^3/kg$

Internal energy of saturated liquid is $u_f = 384.36 kJ/kg$

Internal energy of the liquid vapor mixture is $u_{fg} = 2111.8 kJ/kg$

Step 4 of 11

Calculate the Specific volume at state 1

$$v_1 = v_f + x_1 v_{fg}$$
$$= 0.001037 + [0.08 \times (2.2172 - 0.001037)]$$
$$= 0.17833\,m^3/kg$$

Step 5 of 11

Calculate Internal energy at state 1

$$u_1 = u_f + x_1 u_{fg}$$
$$= 384.36 + [0.08 \times (2111.8)]$$
$$= 553.304 kJ/kg$$

Step 6 of 11

Calculate the mass of water

$$m = \frac{V_1}{v_1}$$
$$= \frac{2}{0.17833}$$
$$= 11.22 kg$$

Step 7 of 11

Calculate the final specific volume

$$v_2 = \frac{V_2}{m}$$
$$= \frac{5}{11.22}$$
$$= 0.445633\,m^3/kg$$

Obtain the properties from saturated water pressure table at P_2=225kPa

Specific volume of saturated liquid is $v_f = 0.001064\,m^3/kg$

Specific volume of saturated vapor is $v_g = 0.79329\,m^3/kg$

Internal energy of saturated liquid is $u_f = 520.47 kJ/kg$

Internal energy of liquid vapor mixture is $u_{fg} = 2012.7 kJ/kg$

Step 8 of 11

Calculate the dryness fraction at state 2 by using specific volume at state 2

$$v_2 = v_f + x_2 v_{fg}$$
$$x_2 = \frac{v_2 - v_f}{v_{fg}}$$
$$= \frac{0.445633 - 0.001064}{(0.79329 - 0.001064)}$$
$$= 0.5612$$

Step 9 of 11

Calculate the internal energy

$$u_2 = u_f + x_2 u_{fg}$$
$$= 520.47 + [0.5612 \times 2012.7]$$
$$= 1649.997 kJ/kg$$

Step 10 of 11

Calculate the work done is equal to the area under the process line 1-2

$$W_{b,out} = \frac{(P_1 + P_2)(V_2 - V_1)}{2}$$
$$= \frac{(75 + 225)(5 - 2)}{2}$$
$$= 450 kJ$$

Therefore, work done processes 1-2 is $\boxed{450 kJ}$

Step 11 of 11

Calculate the heat transfer

$$Q_{in} = W_{b,out} + m(u_2 - u_1)$$
$$= 450 + [11.22(1649.997 - 553.304)]$$
$$= 12,754.9 kJ$$

Therefore, the heat transfer is $\boxed{12,754.9 kJ}$

Question: 5.041P

Refrigerant-134a at 600 kPa and 150°C is contained in a spring-loaded piston-cylinder device with an initial volume of 0.3 m3. The refrigerant is now cooled until its temperature is -30°C and its volume is 0.1 m3. Determine the heat transferred to and the work produced by the refrigerant during this process.

Step 1 of 6

Given

Initial pressure $P_1 = 600$ kPa

Initial Temperature $T_1 = 150°C$

Initial Volume $V_1 = 0.3\ m^3$

Final temperature $T_2 = -30°C$

Final Volume $V_2 = 0.1\ m^3$

Step 2 of 6

Energy balance for any system undergoing any kind of process was expressed as

$$E_{in} - E_{out} = \Delta E_{system} \quad \text{(kJ)} \quad \text{----------(1)}$$

In the process $\Delta PE = \Delta KE = 0$

Therefore equation (1) $-Q_{out} + W_{in} = \Delta U$

$$-Q_{out} = -W_{in} + \Delta U \qquad (\text{since } \Delta U = m(u_2 - u_1))$$

$$Q_{out} = W_{in} - m(u_2 - u_1)$$

Step 3 of 6

From Superheated Refrigerant R-134a table

At $P_1 = 600$ kPa , $T_1 = 150°C$

The specific volume $v_1 = 0.055522\ m^3/kg$

Internal energy $u_1 = 357.96$ kJ/kg

The mass of water is determined by

$$m = \frac{V}{v_1} = \frac{0.3}{0.055522} = 5.4\ kg$$

Therefore the specific volume is expressed as $v_2 = \frac{V_2}{m}\ m^3/kg$

$$v_2 = \frac{0.1}{5.4} = 0.0185\ m^3/kg$$

Step 4 of 6

From Saturated Refrigerant-134a temperature table

At temperature $T_2 = -30°C$

$$v_2 = v_f + x_2 v_{fg}$$

$$0.0185 = 0.0007203 + x_2(0.225)$$

$$x_2 = 0.079$$

Enthalpy $u_2 = u_f + x_2 u_{fg}$

$$u_2 = 12.59 + 0.079(200.52)$$

$$u_2 = 28.43\ kJ/kg$$

Final pressure $P_2 = 84.4$ kPa

Step 5 of 6

The work done is expressed as the area under the curve

The area under the curve is expressed as

$$W = \frac{P_1 + P_2}{2}(V_2 - V_1)$$

$$W = \frac{600 + 84.4}{2}(0.1 - 0.3)$$

$\boxed{W_{in} = -68.44\ kJ}$ (Negative sign for work done on the system)

Step 6 of 6

Therefore heat supplied to the system

$$Q_{out} = 68.44 - 5.4(28.43 - 357.96)$$

$$Q_{out} = 68.44 - 5.4(28.43 - 357.96)$$

$$\boxed{Q_{out} = 1847.9\ kJ}$$

Question: 5.042P

Saturated R-134a vapor at 100°F is condensed at constant pressure to a saturated liquid in a closed piston-cylinder system. Calculate the heat transfer and work done during this process, in Btu/lbm.

Step 1 of 5

Given

Temperature $T_1 = 100°F$

Step 2 of 5

Saturated vapor condensed to saturated liquid at constant pressure

Energy balance for any system undergoing any kind of process was expressed as

$$E_{in} - E_{out} = \Delta E_{system} \quad \text{(kJ)} \text{----------(1)}$$

In the process $\Delta PE = \Delta KE = 0$

Therefore equation (1) $\quad -Q_{out} + W_{in} = \Delta U$

$$-Q_{out} = -W_{in} + \Delta U \qquad (\text{since } \Delta U = m(u_2 - u_1))$$

$$Q_{out} = W_{in} - m(u_2 - u_1)$$

Step 3 of 5

From Saturated Refrigerant R-134a table

At $T_1 = 100°F$, $x_1 = 1$

$v_1 = v_g = 0.34045 \text{ ft}^3/\text{lbm}$

$u_1 = u_g = 107.45 \text{ Btu/lbm}$

At $T_2 = 100°F$, $x_2 = 0$

$v_2 = v_f = 0.01386 \text{ ft}^3/\text{lbm}$

$u_2 = u_f = 44.768 \text{ Btu/lbm}$

Step 4 of 5

From Saturated Refrigerant R-134a table

At $T_1 = 100°F$

Pressure $P_1 = P_2 = 138.93 \text{ psia}$

$h_{fg} = 71.08 \text{ Btu/lbm}$

$u_{fg} = 62.68 \text{ Btu/lbm}$

The work done during the process to

$$w_{out} = P_1(v_1 - v_2) \text{ psia.ft}^3/\text{lbm}$$

$$w_{out} = 138.93(0.01386 - 0.34045)\ \frac{1 \text{ Btu}}{5.41} \qquad (1 \text{ Btu} = 5.41 \text{ psia.ft}^3)$$

$$\boxed{w_{out} = -8.386 \text{ Btu/lbm}} \text{ (Negative since work done on the system)}$$

Step 5 of 5

Substituting into equation (1) gives

$$Q_{out} = W_{in} - m(u_2 - u_1)$$

$$q_{out} = w_{in} - (u_2 - u_1)$$

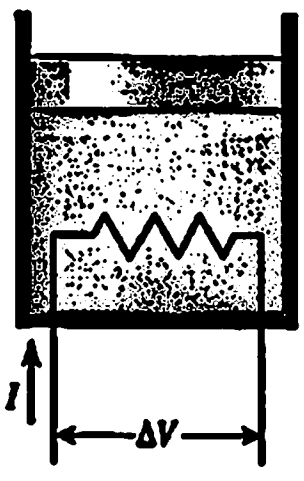
$$q_{out} = +8.386 - (44.768 - 107.45)$$

$$q_{out} = 8.386 + 62.68$$

$$\boxed{q_{out} = 71.068 \text{ Btu/lbm}}$$

Question: 5.043P

0.8-kg of saturated liquid R-134a with an initial temperature of −5°C is contained in a well-insulated, weighted piston-cylinder device. This device contains an electrical resistor, as shown in Fig.P5-43, to which 10 volts are applied causing a current of 2 amperes to flow through the resistor. Determine the time required for the refrigerant to be converted to a saturated vapor, and the final temperature.



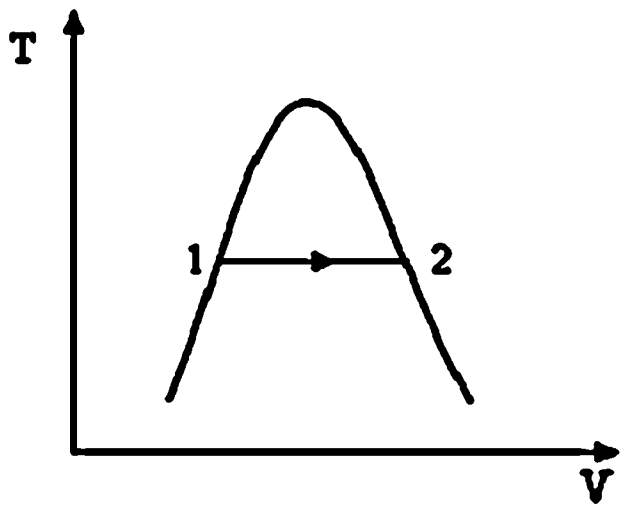


FIGURE P5–43

Step 1 of 6

Given:
Working fluid: Refrigerant-134a
Mass $m = 0.8\text{kg}$
Initially temperature $T = -5^{\circ}\text{C}$
Supply voltage $V = 10\text{V}$
Supply current $I = 2\text{amp}$

Step 2 of 6

T-V Diagram:

Step 3 of 6

From the first law of thermodynamics

$$W_{e,in} - W_{b,out} = \Delta U$$
$$= m(u_2 - u_1)$$
$$W_{e,in} = W_{b,out} + m(u_2 - u_1)$$
$$W_{e,in} = H_2 - H_1 = m(h_2 - h_1)$$
$$= mh_{fg}$$
$$W_{e,in}\Delta t = mh_{fg}$$

Step 4 of 6

Since $\Delta U + W_b = \Delta H$
During a constant pressure quasi-equilibrium process
The electrical power is
$$W_{e,in} = VI$$
$$= 10 \times 2$$
$$= 20\text{W}$$

Step 5 of 6

The enthalpy of vaporization of $R-134a$
From the saturated refrigerant-134a
At $T = -5^{\circ}\text{C}$

$$h_{fg} = 203.07 + \frac{(-5-(-6))(201.60-203.07)}{(-4-(-6))}$$

$$h_{fg} = 202.335\frac{\text{kJ}}{\text{kg}}$$

Step 6 of 6

Substituting values in energy balance equation
$$W_{e,in}\Delta t = mh_{fg}$$
$$(0.020)\Delta t = (0.8)(202.335)$$
$$\Rightarrow \Delta t = 8093.4\text{s}$$
$$= 2.25\text{hour}$$
$$\boxed{\Delta t = 2.25\text{hour}}$$
The temperature remains constant during this phase change process, so we have
$$T_2 = T_1 = -5^{\circ}\text{C}$$
$$\boxed{T_2 = T_1 = -5^{\circ}\text{C}}$$

Question: 5.044P

Two tanks (Tank A and Tank B) are separated by a partition. Initially Tank A contains 2-kg steam at 1 MPa and 300°C while Tank B contains 3-kg saturated liquid–vapor mixture at 150°C with a vapor mass fraction of 50 percent. The partition is now removed and the two sides are allowed to mix until the mechanical and thermal equilibrium are established. If the pressure at the final state is 300 kPa, determine (*a*) the temperature and quality of the steam (if mixture) at the final state and (*b*) the amount of heat lost from the tanks.

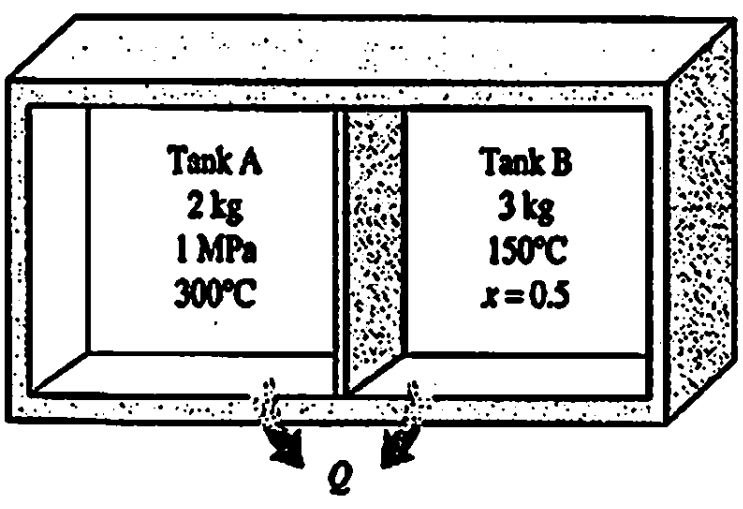

FIGURE P5–44

Step 1 of 8

Given

Mass of steam in tank A $m_A = 2\text{kg}$

Pressure in tank A $P_{1A} = 1\text{MPa}$

Temperature in tank A $T_{1A} = 300°\text{C}$

Mass of saturated liquid vapor mixture in tank B $m_B = 3\text{kg}$

Temperature of saturated liquid vapor mixture in tank B at $T_{1B} = 150°\text{C}$

Dryness fraction in tank B $x = 0.5$

Final Pressure $P_2 = 300\,\text{kPa}$

Step 2 of 8

At $P_{1A} = 1000\ \text{kPa}$ and $T_{1A} = 300°\text{C}$ from superheated steam tables

$u_{1A} = 2793.7\ \text{kJ/kg}$

$v_{1A} = 0.25799\ \text{m}^3/\text{kg}$

Step 3 of 8

At $T_B = 150°\text{C}$ from saturated water tables

$u_f = 631.66\ \text{kJ/kg}$

$u_{fg} = 1927.4\ \text{kJ/kg}$

$v_f = 0.001091\ \text{m}^3/\text{kg}$

$v_g = 0.39248\ \text{m}^3/\text{kg}$

Therefore specific volume of saturated liquid vapor mixture in tank B is

$$v_{1B} = v_f + x v_{fg}$$
$$= 0.001091 + 0.5(0.001091 - 0.39248)$$
$$v_{1B} = 0.19679\ \text{m}^3/\text{kg}$$

Internal energy of saturated liquid vapor mixture in tank B is

$$u_{1B} = u_f + x u_{fg}$$
$$= 631.66 + 0.5(1927.4)$$
$$u_{1B} = 1595.36\ \text{kJ/kg}$$

Step 4 of 8

The total volume of the system

$$V_2 = m_{1A} v_{1A} + m_{1B} v_{1B}$$
$$V = 2 \times 0.25799 + 3 \times 0.19679$$
$$V = 1.10635\ \text{m}^3$$

The total mass of the system

$$m_2 = m_A + m_B$$
$$= 2 + 3$$
$$m_2 = 5\ \text{kg}$$

Step 5 of 8

The final specific volume of the system

$$v_2 = \frac{V_2}{m_2}$$
$$= \frac{1.10635}{5}$$
$$v_2 = 0.22127\ \text{m}^3/\text{kg}$$

Step 6 of 8

(a)

At $P_2 = 300\ \text{kPa}$ from saturated water tables

$T_{sat} = 133.52^0\text{C}$

$v_f = 0.001073\ \text{m}^3/\text{kg}$

$v_{fg} = 0.60474\ \text{m}^3/\text{kg}$

$$v_2 = v_f + x_2 v_{fg}$$
$$0.22127 = 0.001073 + x_2 \times 0.60474$$
$$x_2 = 0.3641$$

Therefore quality at state 2 is

$$\boxed{x_2 = 0.3641}$$

Since the state is in mixture of liquid vapor region the final temperature be saturation temperature at $P_2 = 300\ \text{kPa}$

$$T_2 = T_{sat} = 133.52^0\text{C}$$

$$\boxed{T_2 = 133.52^0\text{C}}$$

Step 7 of 8

Internal energy at state2

$$u_2 = u_{f@300kPa} + x_2 u_{fg@300kPa}$$
$$= 561.11 + 0.3641 \times (1982.1)$$
$$u_2 = 1282.79\ \text{kJ/kg}$$

Step 8 of 8

(b) Heat loss from the tanks

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

Work energy transfer from the system is zero $W = 0$.

$$-Q_{out} = \Delta U$$
$$-Q_{out} = \Delta U_A + \Delta U_B$$
$$-Q_{out} = m_A(u_2 - u_{1A}) + m_B(u_2 - u_{1B})$$
$$-Q_{out} = 2(1282.79 - 2793.7) + 3(1282.79 - 1595.36)$$
$$= -3021.82 + (-937.71)$$
$$-Q_{out} = -3959.53\ \text{kJ}$$

Therefore heat loss from the tank is

$$\boxed{Q_{out} = 3959.53\ \text{kJ}}$$

Question: 5.045P

In the relation $\Delta u = mc_v \Delta T$, what is the correct unit of c_v :kJ/kg·°C or kJ/kg·K?

Step 1 of 1

Here $\Delta u = mc_{v,avg}\Delta T$

We can use kJ/kg.K or kJ/kg. °C, since the difference in temperature will be same for both the cases.

Question: 5.046P

Is the relation $\Delta u = mc_{v,avg} \Delta T$ restricted to constant-volume processes only, or can it be used for any kind of process of an ideal gas?

Step 1 of 1

The relation $\Delta u = mc_{v,avg}\Delta T$ can be used for any kind of process of an ideal gas.

Reason:

It shows that the internal energy of an ideal gas is also a function of temperature only.

So the process can be used for any kind of process of an ideal gas.

Question: 5.047P

Is the relation $\Delta h = mcp,\text{avg}\,\Delta T$ restricted to constant-pressure processes only, or can it be used for any kind of process of an ideal gas?

Step 1 of 1

The relation $\Delta h = mc_{p,avg}\Delta T$ follows that the enthalpy of an ideal gas is also a function of temperature only. So the process can be used for any kind of process of an ideal gas.

Question: 5.048P

Is the energy required to heat air from 295 to 305 K the same as the energy required to heat it from 345 to 355 K? Assume the pressure remains constant in both cases.

Step 1 of 1

We know that $Q = mc_p\Delta T$

Specific gas constant c_p remains constant as pressure remains constant then the heat transfer will be same since dT is same.

If we consider the change c_p with temperature then the heat required will be higher for 345K to 355K.

Question: 5.049P

A fixed mass of an ideal gas is heated from 50 to 80°C at a constant pressure of (*a*) 1 atm and (*b*) 3 atm. For which case do you think the energy required will be greater? Why?

Step 1 of 1

We know that $Q = mc_p\Delta T$

For both the cases it will be same since c_p is function of temperature only and c_p of ideal gas does not vary with pressure.

Question: 5.050P

A fixed mass of an ideal gas is heated from 50 to 80°C at a constant volume of (*a*) 1 m3 and (*b*) 3 m3. For which case do you think the energy required will be greater? Why?

Step 1 of 1

We know that $Q = mc_v\Delta T$

For both the cases it will be same since c_v is function of temperature only and for ideal gas it doesn't vary with volume.

Question: 5.051P

When undergoing a given temperature change, which of the two gases—air or oxygen—experiences the largest change in its (*a*) enthalpy, *h* and (*b*) internal energy, *u* ?

Step 1 of 1

We know $\Delta u = mc_{v,avg}\Delta T$

$\Delta h = mc_{p,avg}\Delta T$

Both undergoing the same temperature change, we also know that

$c_p = kc_v$ Where k = specific heat ratio

Since value of k will be more for air than oxygen

The air experiences more change for enthalpy h and internal energy u.

Question: 5.052P

Show that for an ideal gas $\bar{c}_p = \bar{c}_v + R_u$.

Step 1 of 1

A special relationship between c_p and c_v for ideal gases can be obtained by differentiating the relation

$$h = u + RT$$
$$dh = du + RdT$$

We know that $dh = c_p dT$, $du = c_v dT$ on substituting in the above equation

$$c_p dT = c_v dT + RdT$$

Dividing with dT on both sides

$$c_p - c_v = R$$

Multiplying both sides by molar mass M

$$\boxed{\bar{c}_p - \bar{c}_v = R_u}$$

Question: 5.053P

What is the change in the enthalpy, in kJ/kg, of oxygen as its temperature changes from 150 to 200°C? Is there any difference if the temperature change were from 0 to 50°C? Does the pressure at the beginning and end of this process have any effect on the enthalpy change?

Step 1 of 3

Given:

Initially temperature $T_1 = 150\,^{\circ}C$

Final temperature $T_2 = 200\,^{\circ}C$

Step 2 of 3

Enthalpy equation is

$$\Delta H = mC_p\Delta t$$

From the molar mass constants of various gases, we have

For oxygen:

$$C_{P\text{oxygen}} = 0.918\frac{kJ}{kg\cdot K}$$

$$\Delta t_1 = (200-150)$$

$$= 50^{\circ}C$$

$$\Delta H = 0.918\times 50$$

$$= 45.9\frac{kJ}{kg}$$

Step 3 of 3

No there is no change in enthalpy when temperature changes from 0 to 50°C because C_p remains same. Also,

$$\Delta t_2 = 50^{\circ}C = \Delta t_1$$

No, pressure at the beginning and end of this process does not have any effect on the enthalpy change because C_p of an ideal gas does not vary with pressure.

Question: 5.054P

Air is compressed from 20 psia and 70°F to 150 psia in a compressor. The compressor is operated such that the air temperature remains constant. Calculate the change in the specific volume of air as it passes through this compressor.

Step 1 of 3

Find the initial specific volume by using ideal gas equation of state.

$$P_1 v_1 = RT_1$$

$$v_1 = \frac{RT_1}{P_1}$$

Here, P_1 is initial pressure, T_1 is initial temperature, and R is gas constant.

Substitute $20\,\text{psia}$ for P_1, $(70+460)\,\text{R}$ for T_1, and $0.3704\,\frac{\text{psia.ft}^3}{\text{lbm.R}}$ for R.

$$v_1 = \frac{0.3704\times(70+460)}{20}$$

$$= 9.8156\,\text{ft}^3/\text{lbm}$$

Step 2 of 3

Similarly, find the specific volume at the compressor exit.

$$v_2 = \frac{RT_2}{P_2}$$

Here, P_2 is exit pressure and T_2 is exit temperature.

Substitute $150\,\text{psia}$ for P_1, $(70+460)\,\text{R}$ for T_1, and $0.3704\,\frac{\text{psia.ft}^3}{\text{lbm.R}}$ for R.

$$v_2 = \frac{0.3704\times(70+460)}{150}$$

$$= 1.3087\,\text{ft}^3/\text{lbm}$$

Step 3 of 3

Find the change in specific volume by using the following equation:

$$\Delta v = v_1 - v_2$$

Substitute $1.3087\,\text{ft}^3/\text{lbm}$ for v_2 and $9.8156\,\text{ft}^3/\text{lbm}$ for v_1

$$\Delta v = 9.8156 - 1.3087$$

$$= 8.5069\,\text{ft}^3/\text{lbm}$$

Therefore, the change in specific volume is $\boxed{8.5069\,\text{ft}^3/\text{lbm}}$

Question: 5.055P

The temperature of 2 kg of neon is increased from 20 to 180°C. Calculate the change in the total internal energy of the neon, in kJ. Would the internal energy change be any different if the neon were replaced with argon?

Step 1 of 2

Obtain the specific heat of neon at constant volume from the table A-2, "Ideal-gas specific heats of various common gases" in the textbook.

$$c_v = 0.6179 \text{ kJ/kg} \cdot \text{K}$$

Calculate the change in internal energy of neon as follows:

$$\Delta U = mc_v(T_2 - T_1)$$

Here, m is the mass of the neon, T_1 is the initial temperature, and T_2 is the final temperature.

Substitute 2 kg for m, $0.6179 \text{ kJ/kg} \cdot \text{K}$ for c_v, $20°\text{C}$ for T_1, and $180°\text{C}$ for T_2.

$$\begin{aligned}\Delta U &= 2 \times 0.6179 \times (180 - 20) \\ &= 197.728 \text{ kJ}\end{aligned}$$

Therefore, the change in internal energy for neon is $\boxed{197.728 \text{ kJ}}$.

Step 2 of 2

Obtain the specific heat of argon at constant volume from the table A-2, "Ideal-gas specific heats of various common gases" in the textbook.

$$c_v = 0.0756 \text{ kJ/kg} \cdot \text{K}$$

Calculate the change in internal energy of argon as follows:

$$\Delta U = mc_v(T_2 - T_1)$$

Substitute 2 kg for m, $0.6179 \text{ kJ/kg} \cdot \text{K}$ for c_v, $20°\text{C}$ for T_1, and $180°\text{C}$ for T_2.

$$\begin{aligned}\Delta U &= 2 \times 0.0756 \times (180 - 20) \\ &= 24.192 \text{ kJ}\end{aligned}$$

Therefore, the change in internal energy for argon is $\boxed{24.192 \text{ kJ}}$.

Question: 5.056P

Calculate the change in the enthalpy of argon, in kJ/kg, when it is cooled from 100 to 25°C. If neon had undergone this same change of temperature, would its enthalpy change have been any different?

Step 1 of 4

Given:
Working fluid: argon
Initial temperature $T_1 = 100\,^{\circ}\mathrm{C}$
Final temperature $T_2 = 25\,^{\circ}\mathrm{C}$

Step 2 of 4

From the molar mass and specific heat of various gases
For argon

$$C_{P,Ar} = 0.5203 \frac{\mathrm{kJ}}{\mathrm{kg \cdot K}}$$

For neon

$$C_{P,Ne} = 1.0299 \frac{\mathrm{kJ}}{\mathrm{kg \cdot K}}$$

Step 3 of 4

At specified conditions, Neon and Argon behave like ideal gases.
The enthalpy change in argon is

$$\begin{aligned} \Delta h_{argon} &= C_P \Delta T \\ &= (0.5203) \times (100 - 25) \\ &= 39.0225 \frac{\mathrm{kJ}}{\mathrm{kg}} \end{aligned}$$

Step 4 of 4

The enthalpy change in Neon is

$$\begin{aligned} \Delta h_{neon} &= C_{P,Ne} \times \Delta T \\ &= (1.0299) \times (100 - 25) \\ &= 77.243 \frac{\mathrm{kJ}}{\mathrm{kg}} \end{aligned}$$

So if Ne had undergone this change of temperature, enthalpy change will be different.

Question: 5.057P

Determine the enthalpy change Δh of oxygen, in Btu/lbm, as it is heated from 800 to 1500 R, using (*a*) the empirical specific heat equation as a function of temperature (Table A-2E *c*), (*b*) the *cp* value at the average temperature (Table A - 2E *b*) , and (*c*) the *cp* value at room temperature (Table A-2E *a*).

Step 1 of 1

2760-4-62P

SA: 2981
SR: 3246

(a) The empirical specific heat equation (Table A-2Ec)

$$c_p(T) = a + bT + cT^2 + dT^3$$

Where a = 6.085, b = 0.2017×10^{-2}, c = -0.05275×10^{-5}, and d = 0.05372×10^{-9}.
The enthalpy of an ideal gas is expressed as

$$\Delta\bar{h} = \int_1^2 c_p(T)\,dT \text{ Btu/lbm}$$

$$\Delta\bar{h} = \int_1^2 (a + bT + cT^2 + dT^3)\,dT \text{ Btu/lbm}$$

$$\Delta\bar{h} = a(T_2 - T_1) + 1/2b\left(T^2{}_2 - T_1^2\right) + 1/3c\left(T^3{}_2 - T_1^3\right) + 1/4d\left(T^4{}_2 - T_1^4\right) \text{ kJ/kg}$$

$$\Delta\bar{h} = 6.085(1500-800) + 1/2\left(0.2017\times10^{-2}\right)\left(1500^2 - 800^2\right) + 1/3\left(-0.05275\times10^{-5}\right)\left(1500^3 - 800^3\right)$$

$$+1/4\left(0.05372\times10^{-9}\right)\left(1500^4 - 800^4\right) \text{ Btu/lbmol.R}$$

$$\Delta\bar{h} = 5442 \text{ Btu/lbmol.R}$$

From tables of Molar mass, gas constant, and critical-point properties.
Molecular weight of oxygen $M_{o_2} = 31.999$lbm/lbmol

Specific enthalpy $\Delta h = \dfrac{\Delta\bar{h}}{M_{o_2}} = \dfrac{5442}{31.999} = 170.1$Btu/lbm

$\boxed{\Delta h = 170.1 \text{Btu/lbm}}$

(b)
The constant *cp* value from Table of ideal gas specific heats of various common gases at the average temperature of 1150 R

$$c_p = 0.255 \text{ Btu/lbm.R}$$

The enthalpy of an ideal gas is expressed as

$$\Delta h = c_p \Delta T \text{ Btu/lbm}$$

$$\Delta h = 0.255(1500-800) \text{ Btu/lbm}$$

$\boxed{\Delta h = 178.5 \text{ Btu/lbm}}$

(c) The constant c_p value from Table of ideal gas specific heats of various common gases at room temperature

$$c_p = 0.219 \text{ Btu/lbm.R}$$

The enthalpy of an ideal gas is expressed as

$$\Delta h = c_p \Delta T \text{ Btu/lbm}$$

$$\Delta h = 0.219(1500-800) \text{ Btu/lbm}$$

$\boxed{\Delta h = 153.3 \text{ Btu/lbm}}$

Question: 5.058P

Determine the internal energy change Δu of hydrogen, in kJ/kg, as it is heated from 200 to 800 K, using (*a*) the empirical specific heat equation as a function of temperature (Table A-2*c*), (*b*) the *c* v value at the average temperature (Table A-2 *b*) , and (*c*) the *c* v value at room temperature (Table A-2*a*).

Step 1 of 3

The internal energy change of hydrogen gas during a heating process is to be determined using an empirical specific heat relation, constant specific heat at average temperature, and constant specific heat at room temperature.

(a)

Using the empirical relation for $\overline{c}_p(T)$

From ideal gas specific heat of various gases

As a function of temperature

For hydrogen

$a = 29.11$

$b = -0.1916\times10^{-2}$

$c = 0.4003\times10^{-5}$

$d = -0.8704\times10^{-9}$

Relating it to $\overline{c}_v(T)$

$$\overline{c}_v(T) = \overline{c}_p - R_u$$

$$= (a - R_u) + bT + cT^2 + dT^3$$

Then,

$$\Delta\overline{u} = \int_1^2 \overline{c}_v(T)\,dT$$

$$= \int_1^2 \left[(a - R_u) + bT + cT^2 + dT^3\right] dT$$

$$= (a - R_u)(T_2 - T_1) + \frac{1}{2}b\left(T_2^2 + T_1^2\right) + \frac{1}{3}c\left(T_2^3 - T_1^3\right) + \frac{1}{4}d\left(T_2^4 - T_1^4\right)$$

$$= (29.11 - 8.314)(800 - 200) - \frac{1}{2}(0.1961\times10^{-2})(800^2 - 200^2)$$

$$+ \frac{1}{3}(0.4003\times10^{-5})(800^3 - 200^2) - \frac{1}{4}(0.8704\times10^{-9})(800^4 - 200^4)$$

$$= 12{,}487\,\frac{\text{kJ}}{\text{kmol}}$$

Step 2 of 3

Calculate the internal energy as follows:

$$\Delta u = \frac{\Delta\overline{u}}{M}$$

$$= \frac{12{,}487}{2.016}$$

$$= 6194\,\frac{\text{kJ}}{\text{kg}}$$

$$\boxed{\Delta u = 6194\,\frac{\text{kJ}}{\text{kg}}}$$

(b)

Using a constant c_p value

Average temperature

$$T_{avg} = \frac{200 + 800}{2}$$

$$= 500\,\text{K}$$

From ideal gas specific heat of various gases

At various temperature table

At the average temperature of 500 K

$$c_{v,avg} = C_{v@500k}$$

$$= 10.389\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$\Delta u = c_{v,avg}\left(T_2 - T_1\right)$$

$$= (10.389)(800 - 200)$$

$$= 6233\,\frac{\text{kJ}}{\text{kg}}$$

$$\boxed{\Delta u = 6233\,\frac{\text{kJ}}{\text{kg}}}$$

Step 3 of 3

(c)

Using a constant c_p value at room temperature

Take room temperature

$$T_{room} = 27^\circ\text{C}$$

$$= 27 + 273$$

$$= 300\text{K}$$

$$c_{v,avg} = C_{v@300k}$$

$$= 10.183\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Calculate the internal energy as follows:

$$\Delta u = c_{v,avg}\left(T_2 - T_1\right)$$

$$= (10.183)(800 - 200)$$

$$= 6110\,\frac{\text{kJ}}{\text{kg}}$$

$$\boxed{\Delta u = 6110\,\frac{\text{kJ}}{\text{kg}}}$$

Question: 5.059P

Is it possible to compress an ideal gas isothermally in an adiabatic piston-cylinder device? Explain.

Step 1 of 1

No,

Energy balance for any system undergoing any kind of process was expressed as

$$E_{in} - E_{out} = \Delta E_{system} \quad \text{(kJ)} \text{ ----------(1)}$$

In the process $\Delta PE = \Delta KE = 0$

In a isothermal process $\Delta u = 0$, for adiabatic process $Q = 0$

From the above equation

$$Q - W = \Delta U$$

$$W = 0$$

So it is not possible to compress air at constant temperature in an adiabatic piston cylinder process.

Question: 5.060P

1-kg of oxygen is heated from 20 to 120°C. Determine the amount of heat transfer required when this is done during a (*a*) constant-volume process and (*b*) isobaric process.

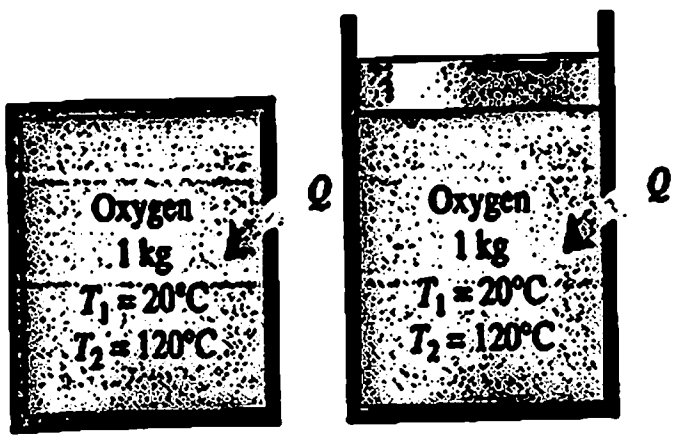

FIGURE P5–60

Step 1 of 6

Given:

Mass of the oxygen $m = 1\text{kg}$

Initially temperature $T_1 = 20°C$

Final temperature $T_2 = 120°C$

Step 2 of 6

The average temperature of oxygen is

$$T_{avg} = \frac{(20+120)}{2}$$
$$= 70°C$$
$$= 70+273$$
$$= 343\text{K}$$

Step 3 of 6

The specific heats of oxygen

From the ideal gases and specific heat of various gases

For oxygen

$$C_p = 0.926\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$C_v = 0.664\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 4 of 6

The energy balance for a constant – volume process is

$$Q = \Delta u + W$$

$$W = 0$$

Since constant volume work done is zero

$$Q_{in} = \Delta U$$
$$= mC_v(T_2 - T_1)$$

The energy balance during a constant pressure process can be expressed as

$$Q_{in} = \Delta H$$
$$= mC_p(T_2 - T_1)$$

Step 5 of 6

(a) Heat transfer in constant volume process is

$$Q_{in,\,v-const} = mC_v(T_2 - T_1)$$
$$= (1)(0.664)(120-20)$$
$$= 66.4\text{kJ}$$

$$\boxed{Q_{in,\,v-const} = 66.4\text{kJ}}$$

Step 6 of 6

(b) Heat transfer in constant pressure process is

$$Q_{in,\,p-const} = mC_p(T_2 - T_1)$$
$$= (1)(0.926)(120-20)$$
$$= 92.6\text{kJ}$$

$$\boxed{Q_{in,\,p-const} = 92.6\text{kJ}}$$

Question: 5.061P

A rigid tank contains 20 lbm of air at 50 psia and 80°E The air is now heated until its pressure doubles. Determine (*a*) the volume of the tank and (*b*) the amount of heat transfer.

Step 1 of 4

Given

Mass of air in the rigid tank $m = 20$ lbm

Initial pressure $P_1 = 50$ psia

Initial temperature $T_1 = 80°F = 80+460 = 540R$

Final pressure $P_2 = 100$ psia

Step 2 of 4

(a)

The volume of the tank

The gas constant of air is $R = 0.3704$ psia.ft^3/lbm.R (From table Molar mass, gas constant, and critical-point properties).

From ideal relation

$$PV = mRT$$

$$V = \frac{mRT_1}{P_1} \text{ ft}^3$$

$$V = \frac{20(0.3704)(80+460)}{50} \text{ ft}^3$$

$$\boxed{V = 80 \text{ ft}^3}$$

Step 3 of 4

(b) The amount of heat transfer

Energy balance for any system undergoing any kind of process was expressed as

$$E_{in} - E_{out} = \Delta E_{system} \quad \text{(Btu)} \quad \text{----------(1)}$$

In the process $\Delta PE = \Delta KE = W = 0$

Therefore equation (1) $Q_{in} + W_{in} = \Delta U$

$$Q_{in} = \Delta U \qquad \left(\text{since } \Delta U = m(u_2 - u_1)\right)$$

$$Q_{in} = m(u_2 - u_1)$$

Step 4 of 4

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

$$T_2 = \frac{T_1}{P_1} \times P_2$$

$$T_2 = \frac{540}{50} \times 100$$

$$T_2 = 1080\text{R}$$

From ideal-gas properties of air

At $T_1 = 540$R

$u_1 = 92.04$ Btu/lbm

At $T_2 = 1080$ R

$u_2 = 186.93$ Btu/lbm

Substituting in above relation

$$Q_{in} = 20(186.93 - 92.04)$$

$$\boxed{Q_{in} = 1898 \text{ Btu}}$$

Question: 5.062P

Determine the internal energy change of air in a rigid container as its temperature is increased by transferring 50 Btu/lbm of heat.

Step 1 of 2

We know the first law of thermodynamics as:

$$Q = \Delta U + W$$

$$W = 0$$

$$Q = \Delta U$$

Since rigid container volume remains constant so work done is zero.

Step 2 of 2

We take the air as the system. This is a closed system since no mass crosses the boundaries of the system. The energy balance for this system can be expressed as

$$Q = \Delta U$$

$$= mC_v\left(T_2 - T_1\right)$$

Since temperature is increasing heat is coming in

$$\Delta U = q_{in}$$

$$= 50\frac{\text{Btu}}{\text{lbm}}$$

$$\boxed{\Delta U = 50\frac{\text{Btu}}{\text{lbm}}}$$

Question: 5.063P

Nitrogen gas to 20 psia and 100°F initially occupies a volume of 1 ft3 in a rigid container equipped with a stirring paddle wheel. After 5000 lbf·ft of paddle wheel work is done on nitrogen, what is its final temperature?

Step 1 of 3

From the table A-1E for nitrogen gas, the gas constant value is,

$$R = 0.3830 \text{ psia.ft}^3/\text{lbm.R}$$

The temperature conversion of °F to R scale ,

$$100°\text{F} = 560\text{R}$$

Step 2 of 3

From the Ideal gas equation

$$P_1V_1 = mRT_1$$

$$m = \frac{P_1V_1}{RT_1}$$

Here P_1 is the initial pressure of the gas, V_1 is the volume of the gas, R is the gas constant, T_1 is the initial temperature of the gas, m is the mass of the gas.

Substitute 20 psia for P_1, 1 ft^3 for V_1, 0.3830 psia.ft^3/lbm.R for R and 560R for T_1.

$$m = \frac{P_1V_1}{RT_1}$$

$$= \frac{20 \times 1}{(0.3830 \times 560)}$$

$$= 0.0932 \text{ lbm}$$

Step 3 of 3

The paddle work done over the gas is,

$$W = mc_v(T_2 - T_1)$$

Consider the work done to be 5000lbf·ft,

But,

$$1\text{lbf} \cdot \text{ft} = 1.28507 \times 10^{-3}\text{Btu}$$

So,

$$5000\text{lbf} \cdot \text{ft} = 6.43\text{Btu}$$

Substitute 6.43Btu for W, 0.177 Btu/lbm.R for c_v, and 560 for T_1.

$$W = mc_v(T_2 - T_1)$$

$$6.43 = 0.0932 \times 0.177 \times (T_2 - 560)$$

$$T_2 = 949.78\text{R}$$

$$= 489°\text{F}$$

Therefore the final temperature after the paddling of the nitrogen gas is, $\boxed{489°\text{F}}$.

Question: 5.064P

Consider a piston-cylinder device that contains nitrogen gas as the system. Initially, the system is at 1 MPa and 427°C. It now undergoes an isobaric process until its temperature is 27°C. Determine the final pressure and the heat transfer, in kJ/kg, associated with this process.

Step 1 of 5

Obtain the properties from the ideal gas specific heats of various common gases table.
For nitrogen:

Gas constant, $R = 0.2968 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$

Specific heat at constant pressure, $C_p = 1.039 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$

Specific heat at constant volume, $C_v = 0.743 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$

Step 2 of 5

In an isobaric process, the pressure remains constant.
Thus, the final pressure will be the same as the initial pressure.

$$P_2 = P_1$$
$$= 1\text{MPa}$$

Therefore, the final pressure is $\boxed{1\text{MPa}}$.

Step 3 of 5

Consider the energy balance equation for this system.

$$\Delta Q = \Delta U + W_{b,out}$$
$$Q_{in} - Q_{out} = mC_v(T_2 - T_1) + W_{b,out}$$
$$0 - Q_{out} = mC_v(T_2 - T_1) + W_{b,out}$$
$$Q_{out} = -mC_v(T_2 - T_1) - W_{b,out} \quad \text{..... (1)}$$

Step 4 of 5

Calculate the boundary work during the isobaric process by using the equation as shown below.

$$W_{b,out} = P(v_2 - v_1)$$
$$= R(T_2 - T_1)$$

Here, the gas constant is R, the initial temperature is T_1 and the final temperature is T_2.

Substitute $0.2968 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$ for R, 27°C for T_2 and 427°C for T_1.

$$W_{b,out} = 0.2968(27 - 427)$$
$$= -118.72 \frac{\text{kJ}}{\text{kg}} \quad \text{..... (2)}$$

Step 5 of 5

Calculate the heat transfer in the process.

Substitute equation (2) in equation (1).

$$Q_{out} = -[0.743(27 - 427)] - (-118.72)$$
$$= 297.2 + 118.72$$
$$= 415.921 \frac{\text{kJ}}{\text{kg}}$$

Therefore, the heat transferred is $\boxed{416 \frac{\text{kJ}}{\text{kg}}}$.

Question: 5.065P

A 4-m × 5-m × 6-m room is to be heated by a baseboard resistance heater. It is desired that the resistance heater be able to raise the air temperature in the room from 5 to 25°C within 11 min. Assuming no heat losses from the room and an atmospheric pressure of 100 kPa, determine the required power of the resistance heater. Assume constant specific heats at room temperature.

Step 1 of 5

Given:

Dimension of the room $= 4\,\text{m} \times 5\,\text{m} \times 6\,\text{m}$

Initially temperature $T_1 = 5^\circ\text{C}$

Final temperature $T_2 = 25^\circ\text{C}$

Time $\Delta t = 11\,\text{min}$

Atmospheric pressure $P_{atm} = 100\,\text{kPa}$

Step 2 of 5

From the ideal gas properties of the various gases

For air

The gas constant of air is

$$R = 0.287\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$C_v = 0.718\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 3 of 5

The energy balance for this stationary constant volume closed system can be expressed as

$E_{in} - E_{out} = \Delta E_{system}$

Since there is no heat losses, So

$W_{e,in} = \Delta U$

$= mC_v(T_2 - T_1)$

$W_{e,in} \times \Delta t = mC_v(T_2 - T_1) \ldots\ldots(1)$

Step 4 of 5

The mass of the air is

$V = 4 \times 5 \times 6$

$= 120\,\text{m}^3$

$$m = \frac{P_1 V}{R T_1}$$

$$= \frac{100 \times 120}{(0.287 \times 278)}$$

$= 150.4\,\text{kg}$

Step 5 of 5

Substituting values in equation 1 we get the power rating of the heater becomes

$$W_{e,in} = \frac{(150.4)(0.718)(25-5)}{(11 \times 60)}$$

$= 3.272\,\text{kW}$

$\boxed{W_{e,in} = 3.272\,\text{kW}}$

Question: 5.066P

A student living in a 4-m × 6-m × 6-m dormitory room turns on her 150-W fan before she leaves the room on a summer day, hoping that the room will be cooler when she comes back in the evening. Assuming all the doors and windows are tightly closed and disregarding any heat transfer through the walls and the windows, determine the temperature in the room when she comes back 10 h later. Use specific heat values at room temperature, and assume the room to be at 100 kPa and 15°C in the morning when she leaves.

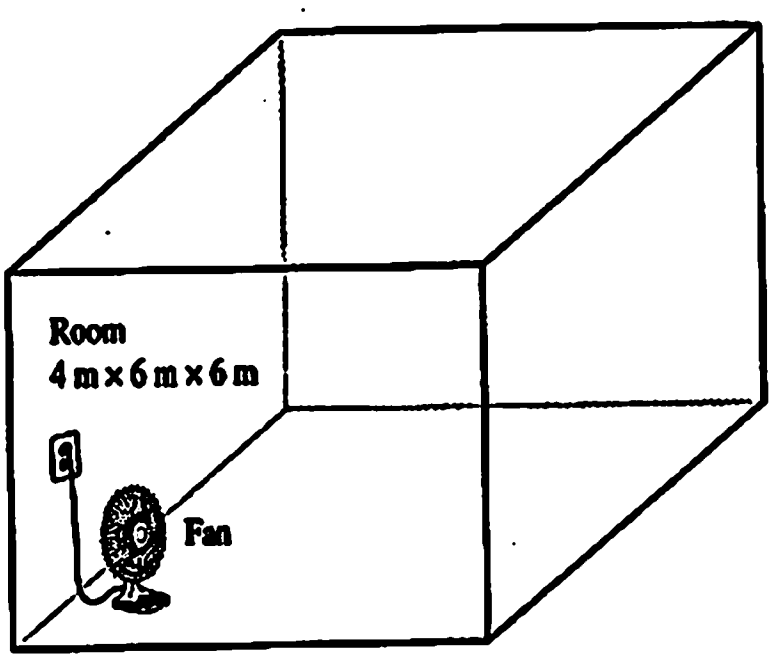

FIGURE P5–66

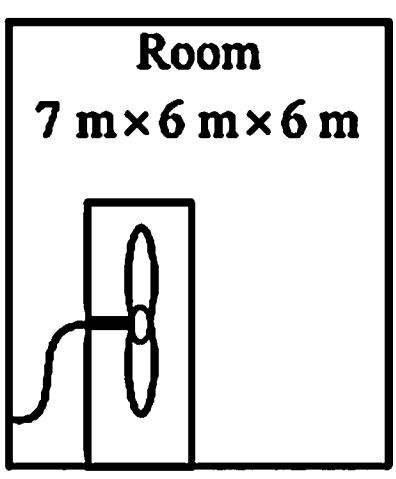
Step 1 of 4

Given

Volume of the room $V = 4 \times 6 \times 6 = 144\ \text{m}^3$



Initial temperature $T_1 = 15°\text{C}$

Atmospheric pressure $P_1 = 100\ \text{kPa}$

Time = 10 hr

Power of the fan P = 150 W

Step 2 of 4

Step 3 of 4

From ideal gas specific heats of various common gases

The gas constant of air R = 0.287 kJ/kg.k, $c_v = 0.718$ kJ/kg.K

The room is a closed system and applying energy balance for a closed system

$$E_{in} - E_{out} = \Delta E_{system}$$

Here $\Delta PE = \Delta KE = Q = 0$

$$W_{in} = \Delta U \qquad \left(\text{Since } \Delta U = m(u_2 - u_1)\right)$$

$$W_{in} = mc_v(T_2 - T_1)$$

The mass of air is expressed $m = \dfrac{P_1 V}{R T_1}$ kg

$$m = \frac{100(144)}{(0.287)(15+273)} = 174.2\ \text{kg}$$

Step 4 of 4

The work supplied to the heater is

$$W_{in} = (174.2)(0.718)(T_2 - 15)$$

The power supplied is

$$P = \frac{W_{in}}{t}$$

$$150 = \frac{174.2(0.718 \times 1000)(T_2 - 15)}{10 \times 60 \times 60}$$

The final temperature of the room

$$\boxed{T_2 = 58.2°\text{C}}$$

10×60×60

The final temperature of the room

$$\boxed{T_2 = 58.2°\text{C}}$$

Question: 5.067P

A 3-ft3 adiabatic rigid container is divided into two equal volumes by a thin membrane, as shown in Fig. P5-67E. Initially, one of these chambers is filled with air at 100 psia and 100°F while the other chamber is evacuated. Determine the internal energy change of the air when the membrane is ruptured. Also determine the final air pressure in the container.

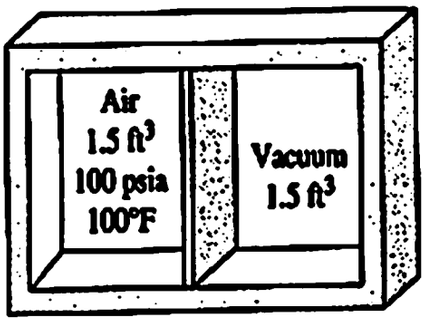


FIGURE P5–67E

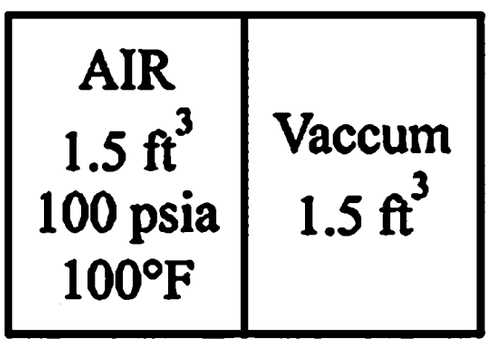
Step 1 of 3



Given

Volume of the room $V = 3\ \text{ft}^3$

Initial pressure $P_1 = 100$ psia

Initial Temperature $T_1 = 100°\text{F}$

Step 2 of 3

Step 3 of 3

The container is a closed system and applying energy balance for a closed system

$$E_{in} - E_{out} = \Delta E_{system}$$

Here $\Delta PE = \Delta KE = W = Q = 0$

$$0 = \Delta U$$

So the internal energy of the rigid body does not change

Applying ideal gas equation

$$P_1V_1 = P_2V_2 \qquad (T_1 = T_2)$$

$$100(1.5) = P_2(3)$$

Final pressure $\boxed{P_2 = 50 \text{ psia}}$

Question:

5.068P

A closed system containing 2-kg of air undergoes an isothermal process from 600 kPa and 200°C to 80 kPa. Determine the initial volume of this system, the work done, and the heat transfer during this process.

Step 1 of 4

Given

Mass of air $m = 2$ kg

Initial pressure $P_1 = 600$ kPa

Final pressure $P_2 = 80$ kPa

Isothermal process $T_1 = T_2 = 200°C$

Step 2 of 4

Initial volume of the system

We know that $PV = mRT$

From molar mass, gas constant, and critical point properties table

Question:

A closed system containing 2-kg of air undergoes an isothermal process from 600 kPa and 200°C to 80 kPa. Determine the initial volume of this system, the work done, and the heat transfer during this process.

Step 1 of 4

Given

Mass of air $m = 2$ kg

Initial pressure $P_1 = 600$ kPa

Final pressure $P_2 = 80$ kPa

Isothermal process $T_1 = T_2 = 200°C$

Step 2 of 4

Initial volume of the system

We know that $PV = mRT$

From molar mass, gas constant, and critical point properties table

$$Q_{in} - W_{out} = \Delta U = mc_v(T_2 - T_1)$$

$$Q_{in} - W_{out} = 0 \qquad \text{Since } T_1 = T_2$$

$$Q_{in} = W_{out}$$

$$\boxed{Q_{in} = 547 \text{ kJ}}$$

$$Q_{in} - W_{out} = \Delta U = mc_v(T_2 - T_1)$$

$$Q_{in} - W_{out} = 0 \qquad \text{Since } T_1 = T_2$$

$$Q_{in} = W_{out}$$

$$\boxed{Q_{in} = 547 \text{ kJ}}$$

Question: 5.069P

A piston-cylinder device containing argon gas as the system undergoes an isothermal process from 200 kPa and 100°C to 50 kPa. During the process, 1500 kJ of heat is transferred to the system. Determine the mass of this system and the amount of work produced.

Step 1 of 3

Given

Initial pressure $P_1 = 200$ kPa

Final pressure $P_2 = 50$ kPa

Isothermal process $T_1 = T_2 = 100°C$

Heat supplied $Q_{in} = 1500$ kJ

Step 2 of 3

The work done for an isothermal process is expressed as

$$W_{out} = m\int_1^2 pdV = mRT\ln\frac{P_1}{P_2}\ \text{kJ}$$

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

$$Q_{in} - W_{out} = \Delta U = mc_v(T_2 - T_1)$$

$$Q_{in} - W_{out} = 0 \qquad \text{Since } T_1 = T_2$$

$$Q_{in} = W_{out}$$

The amount of work produced is

$$\boxed{W_{out} = 1500\ \text{kJ}}$$

Step 3 of 3

The mass of the system

$$m = \frac{W_{in}}{RT\ln\frac{P_1}{P_2}}$$

$$m = \frac{1500}{(0.2081\times 373)\ln\frac{200}{50}}$$

$$\boxed{m = 13.94\ \text{kg}}$$

Question: 5.070P

Argon is compressed in a polytropic process with n = 1.2 from 120 kPa and 10°C to 800 kPa in a piston-cylinder device. Determine the work produced and heat transferred during this compression process, in kJ/kg.

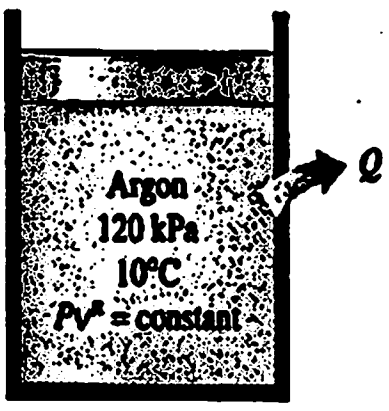


FIGURE P5–70

Step 1 of 5

From properties of ideal gases, the gas constant value of Argon is,

$$R = 0.2081 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$$

Specific heat value at constant volume is,

$$c_v = 0.3122 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$$

Step 2 of 5

Consider a closed system of Argon, since no mass crosses the boundaries of the system the energy balance for the system is,

$$Q - W = \Delta U$$

Here Q is the amount of the heat interaction of the system, W is the work interaction of the system, and ΔU is the change in internal energy.

The internal energy for a closed system per unit mass is,

$$\Delta U = c_v (T_2 - T_1)$$

Step 3 of 5

The temperature at the final state is,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{\frac{n-1}{n}}$$

Here, T_1 is the initial temperature of the system, T_2 is the final temperature of the system, P_1 is the initial pressure condition, P_2 is the final pressure condition and n is the polytropic index.

Substitute 120 kPa for P_1, 800 kPa for P_2, 1.2 for n and 10°C = 283K for T_1.

$$\begin{aligned} T_2 &= T_1 \left(\frac{P_2}{P_1} \right)^{\frac{n-1}{n}} \\ &= 283 \left(\frac{800}{120} \right)^{\frac{1.2-1}{1.2}} \\ &= 388.49 \text{K} \end{aligned}$$

Step 4 of 5

Find the work done in a polytropic process by using the expression,

$$\begin{aligned} W &= \frac{R(T_2 - T_1)}{1-n} \\ &= \frac{0.2081 \times (388.5 - 283)}{1 - 1.2} \\ &= -109.77 \text{kJ/kg} \end{aligned}$$

Step 5 of 5

Find the heat transfer by using energy balance equation,

$$\begin{aligned} Q - W &= \Delta U \\ Q &= W + \Delta U \\ &= W + c_v (T_2 - T_1) \\ &= -109.76 + (0.3122)(388.49 - 283) \\ &= -76.83 \text{kJ/kg} \end{aligned}$$

The negative sign indicates that the heat is dissipated from the system of Argon.

Therefore the work done on the system of Argon is, $\boxed{109.77 \text{kJ/kg}}$ and heat dissipated is, $\boxed{76.83 \text{kJ/kg}}$.

Question: 5.071P

A spring-loaded piston-cylinder device contains 1 kg of carbon dioxide. This system is heated from 100 kPa and 25°C to 1000 kPa and 300°C. Determine the total heat transfer to and work produced by this system.

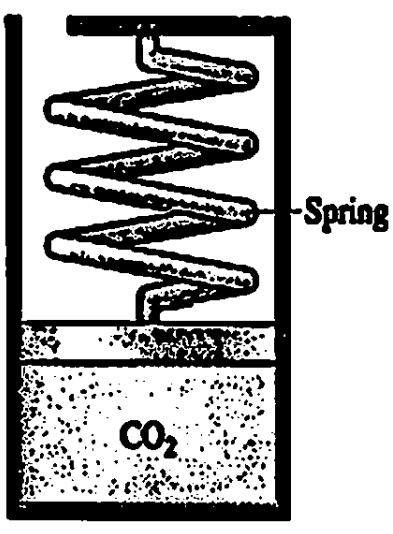

FIGURE P5–71

Step 1 of 5

Obtain the properties of carbon dioxide from Table A-2, "Ideal-gas specific heats of various common gases," from the text book.

Gas constant for carbon dioxide, $R = 0.1889\ \text{kJ/kg·K}$

Specific heat value at constant volume, $c_v = 0.657\ \text{kJ/kg·K}$

Write the ideal gas equation at initial state.

$$P_1V_1 = mRT_1$$

$$V_1 = \frac{mRT_1}{P_1}$$

Here, P_1 is the initial pressure of the system, V_1 is the initial volume of the system, m is the mass of the system, and T_1 is the initial temperature of the system.

Substitute $100\ \text{kPa}$ for P_1, $25°\text{C}$ for T_1, $1\ \text{kg}$ for m, and $0.1889\ \text{kJ/kg·K}$ for R.

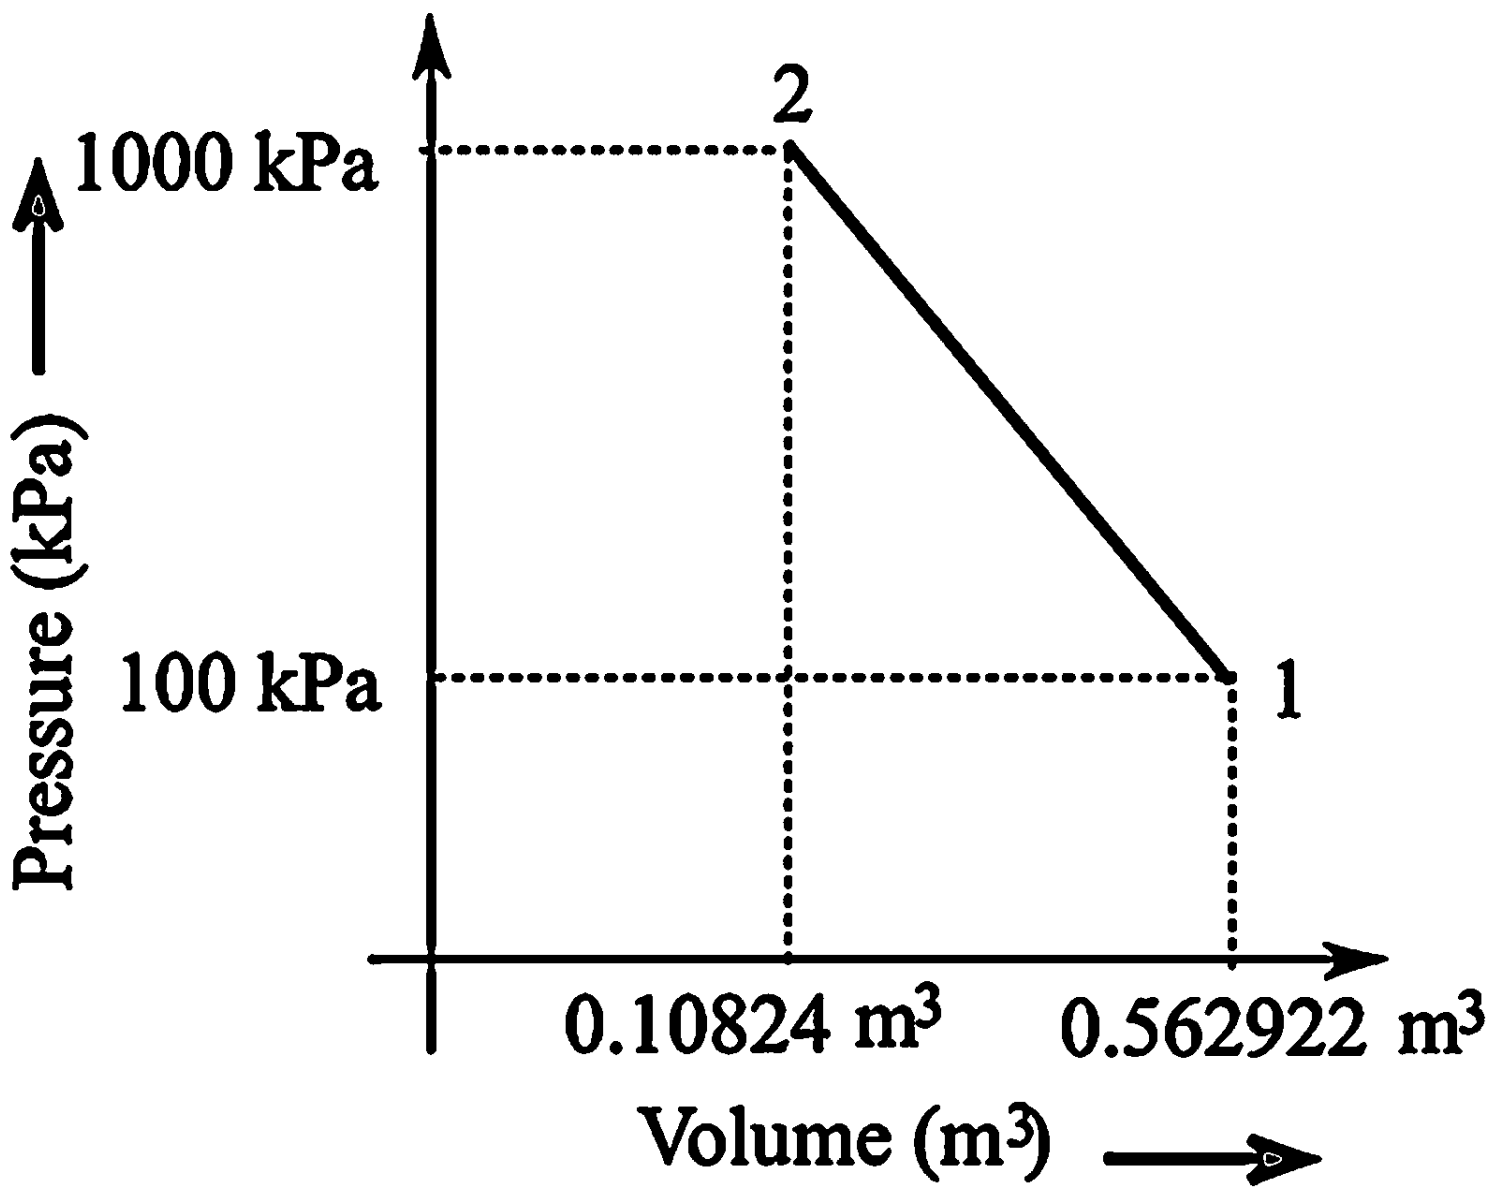
$$V_1 = \frac{(1)(0.1889)(25°\text{C}+273)\ \text{K}}{100}$$
$$= 0.562922\ \text{m}^3$$

Step 2 of 5

Write the ideal gas equation at final state.

$$P_2V_2 = mRT_2$$

$$V_2 = \frac{mRT_2}{P_2}$$



Here, P_2 is the final pressure of the system, V_2 is the final volume of the system, and T_2 is the final temperature of the system.

Substitute $1000\ \text{kPa}$ for P_2, $300°\text{C}$ for T_2, $1\ \text{kg}$ for m, and $0.1889\ \text{kJ/kg·K}$ for R.

$$V_2 = \frac{(1)(0.1889)(300°\text{C}+273)\ \text{K}}{1000}$$
$$= 0.10824\ \text{m}^3$$

Step 3 of 5

Draw the $P-V$ diagram for the system of gas.

Step 4 of 5

The pressure changes linearly with volume, and the work done is equal to the area under the process line 1-2.

Write the relation for the work done during the process by using the following relation:

$$W = \left(\frac{P_1+P_2}{2}\right)(V_2-V_1)$$

Substitute $100\ \text{kPa}$ for P_1, $1000\ \text{kPa}$ for P_2, $0.10824\ \text{m}^3$ for V_2, and $0.562922\ \text{m}^3$ for V_1.

$$W = \left(\frac{100+1000}{2}\right)(0.10824-0.562922)$$
$$= -250.08\ \text{kJ}$$

Here, negative sign indicates that the work is produced by the system.

Therefore, the work produced by the system is $\boxed{250.08\ \text{kJ}}$.

Step 5 of 5

Calculate the heat transfer by using the following relation:

$$Q = W + \Delta U$$

Here, ΔU is the change in internal energy.

Substitute $mc_v(T_2-T_1)$ for ΔU.

$$Q = W + mc_v(T_2-T_1)$$

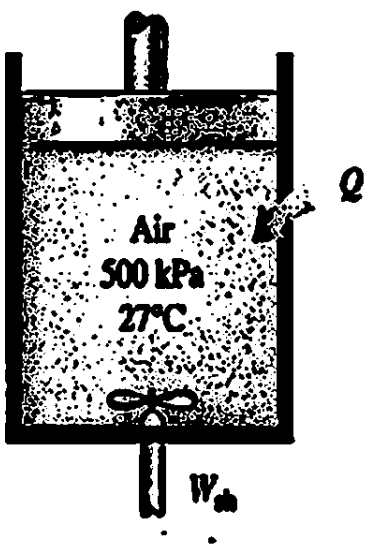
Substitute $-250.08\ \text{kJ}$ for W, $1\ \text{kg}$ for m, $0.657\ \text{kJ/kg·K}$ for c_v, $300°\text{C}$ for T_2, and $25°\text{C}$ for T_1.

$$Q = -250.08+(1)(0.657)(300-25)$$
$$= -250.08+180.675$$
$$= -69.405\ \text{kJ}$$

Therefore, the heat dissipated from the system is $\boxed{69.405\ \text{kJ}}$.

Question: 5.072P

Air is contained in a variable-load piston-cylinder device equipped with a paddle wheel. Initially, air is at 500 kPa and 27°C. The paddle wheel is now turned by an external electric motor until 50 kJ/kg of work has been transferred to air. During this process, heat is transferred to maintain a constant air temperature while allowing the gas volume to triple. Calculate the required amount of heat transfer, in kJ/kg.



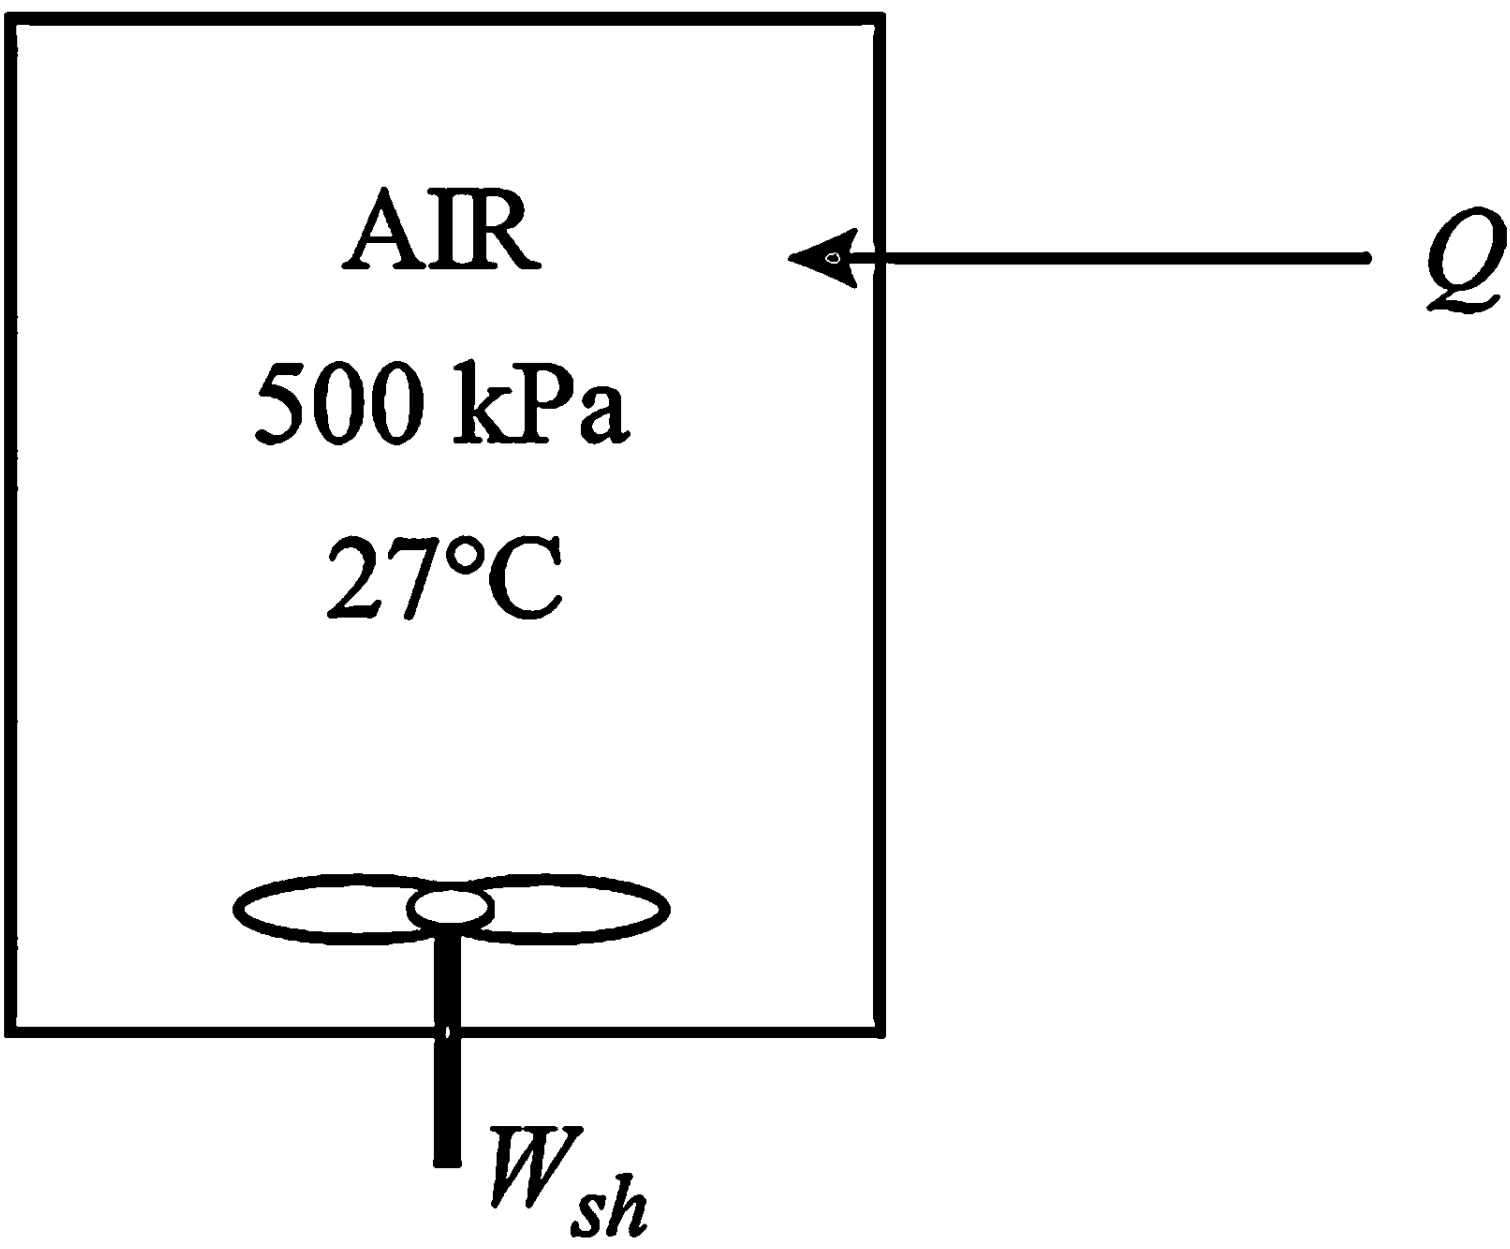


FIGURE P5–72

Step 1 of 4

Schematic diagram of the variable-load piston-cylinder device is shown below.

Step 2 of 4

Calculate the initial specific volume of the system using the ideal gas equation

$$P_1 v_1 = RT_1$$
$$v_1 = \frac{RT_1}{P_1}$$

Here, R is the gas constant and P_1 is the initial pressure.

Substitute $287\ \text{J/kg.K}$ for R $(27+273)\text{K}$ for T_1 and $500\times10^3\ \text{Pa}$ for P_1

$$v_1 = \frac{287(27+273)}{500\times10^3}$$
$$= 0.1722\ \text{m}^3/\text{kg}$$

Calculate the final specific volume of the system using the following relation

$$v_2 = 3v_1$$
$$= 3\times0.1722$$
$$= 0.5166\ \text{m}^3/\text{kg}$$

Step 3 of 4

Calculate the boundary work for isothermal process

$$w_{out} = P_1 v_1 \ln\left(\frac{v_2}{v_1}\right)$$
$$= 500\times10^3\times0.1722\times\ln\left(\frac{0.5166}{0.1722}\right)$$
$$= 94.59\ \text{kJ/kg}$$

Here, the kinetic and potential energy changes are negligible.

$$\Delta PE = \Delta KE = 0$$

Step 4 of 4

Apply the energy balance equation for the system

$$E_{in} - E_{out} = \Delta E_{system}$$

$$\Delta U = W_{in} - Q_{out} - W_{out}$$
$$m(u_2 - u_1) = W_{in} - Q_{out} - W_{out}$$
$$mc_v(T_2 - T_1) = W_{in} - Q_{out} - W_{out}$$

Here, initial temperature T_1 is equal to final temperature T_2

$$W_{in} - Q_{out} - W_{out} = 0$$
$$Q_{out} = W_{in} - W_{out}$$
$$q_{out} = w_{sh,in} - w_{out}$$

Here, $w_{sh,in}$ is the work input and w_{out} is the work output

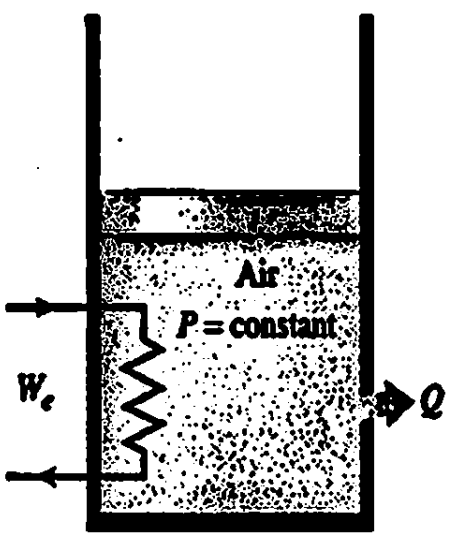
$$q_{out} = w_{sh,in} - w_{out}$$
$$= 50 - 94.59$$
$$= -44.59\ \text{kJ/kg}$$

Here, negative sign indicates heat is transferred from system to air.

Therefore, the required amount of heat transfer is $\boxed{-44.59\ \text{kJ/kg}}$.

Question: 5.073P

A mass of 15 kg of air in a piston-cylinder device is heated from 25 to 77°C by passing current through a resistance heater inside the cylinder. The pressure inside the cylinder is held constant at 300 kPa during the process, and a heat loss of 60 kJ occurs. Determine the electric energy supplied, in kWh.



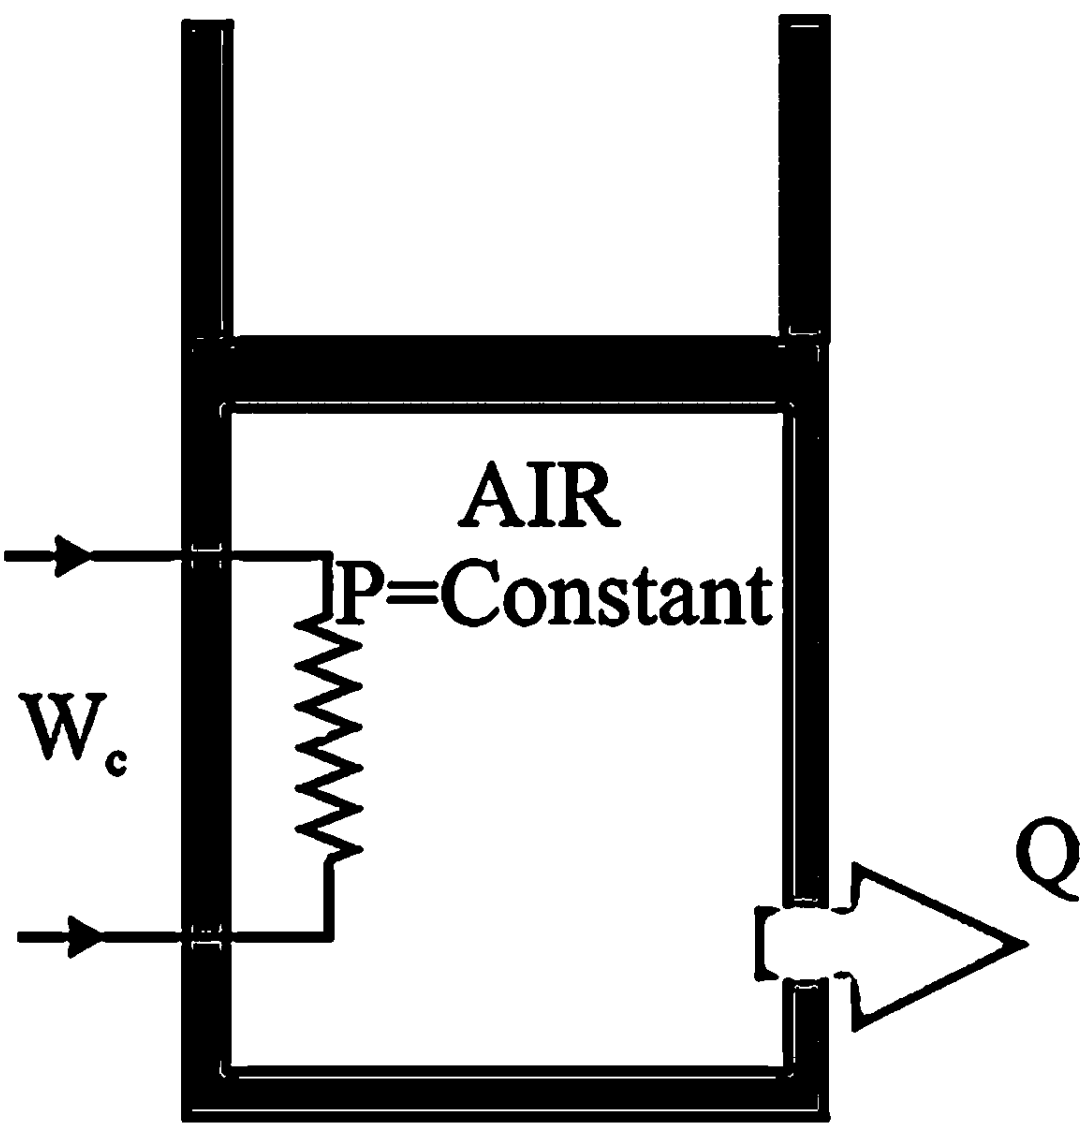


FIGURE P5–73

Step 1 of 4

Draw the schematic diagram.

Step 2 of 4

Obtain the properties of air from Table A1, "Molar mass, gas constant, and critical-point properties," from the text book.

Gas constant, $R = 0.287\ \text{kJ/kg.K}$

Write the energy balance of the system.

$$\underbrace{E_{in} - E_{out}}_{\text{Net energy transfer by heat, work and mass}} = \underbrace{\Delta E_{system}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

Since the system is stationary, the change in potential and kinetic energies are equal to zero.

Rewrite the energy balance equation.

$$W_{c,in} - Q_{out} - W_{b,out} = \Delta U$$
$$W_{c,in} - Q_{out} = \Delta U + W_{b,out}$$

Here, $W_{c,in}$ is the work done on the system, $W_{b,out}$ is the work done by the system, Q_{out} is the heat flowing out of the system, and ΔU is the change in internal energy of the system.

Substitute ΔH for $\Delta U + W_{b,out}$.

$$W_{c,in} - Q_{out} = \Delta H$$
$$W_{c,in} = \Delta H + Q_{out}$$

Here, ΔH is the change in enthalpy.

Substitute $mc_p(T_2 - T_1)$ for ΔH.

$$W_{c,in} = mc_p(T_2 - T_1) + Q_{out} \quad \text{..... (1)}$$

Here, m is the mass of the air, T_1, T_2 are the temperatures at the initial and the final temperatures.

Step 3 of 4

Calculate the mean temperature.

$$T_{mean} = \frac{T_1 + T_2}{2}$$

Substitute $77°C$ for T_1 and $25°C$ for T_2.

$$T_{mean} = \frac{77 + 25}{2}$$
$$= (51°C + 273)\ \text{K}$$
$$= 324\ \text{K}$$

Obtain the specific heat constants for air at $324\ \text{K}$ temperature from table A-2(b), "Ideal gas specific heats of various common gases," from the text book by interpolation.

Specific heat at constant pressure is as follows:

$$\frac{1.008 - c_p}{1.008 - 1.005} = \frac{350 - 324}{350 - 300}$$
$$c_p = 1.00644\ \text{kJ/kg·K}$$

Specific heat at constant volume is as follows:

$$\frac{0.721 - c_v}{0.721 - 0.718} = \frac{350 - 324}{350 - 300}$$
$$c_p = 1.00644\ \text{kJ/kg·K}$$
$$c_v = 0.71944\ \text{kJ/kg·K}$$

Step 4 of 4

Substitute $15\ \text{kg}$ for m, $1.00644\ \text{kJ/kg·K}$ for c_p, $77°C$ for T_2, $25°C$ for T_1, and $60\ \text{kJ}$ for Q in equation (1).

$$W_{c,in} = mc_p(T_2 - T_1) + Q_{out}$$
$$= 15 \times (1.00644) \times \left([(77°C) + 273]\ \text{K} - [(25°C) + 273]\ \text{K} \right) + 60$$
$$= 845.0232\ \text{kJ} \times \frac{1\ \text{kWh}}{3600}$$
$$= 0.235\ \text{kWh}$$

Therefore, the electrical energy supplied to the system is $\boxed{0.235\ \text{kWh}}$.

Question: 5.074P

A piston-cylinder device contains 1.5 kg of nitrogen initially at 100 kPa and 17°C. The nitrogen is now compressed slowly in a polytropic process during which $PV1.3$ = constant until the volume is reduced by one-half. Determine the work done and the heat transfer for this process.

Step 1 of 5

For a polytropic process,

$$P_2V_2^n = P_1V_1^n$$

Here, P_1 is Initial pressure, V_1 is the initial volume, P_2 is the final pressure and V_2 is the final volume and n is the polytropic index.

Substitute 100 kPa for P_1 and $V_2 = 0.5V_1$ as final volume is half of initial volume, 1.3 for n.

$$P_2 = \left(\frac{V_1}{V_2}\right)^{1.3} \times P_1$$
$$= 2^{1.3} \times (100)$$
$$= 246.22 \text{ kPa}$$

Step 2 of 5

From ideal gas equation,

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$
$$T_2 = \frac{P_2V_2 \times T_1}{P_1V_1}$$

Here, T_1 is the initial temperature, T_2 is the final temperature of the system.

$$T_2 = \frac{P_2V_2 \times T_1}{P_1V_1}$$
$$= \frac{246.22 \times 0.5 \times 290}{(100)}$$
$$= 357.031 \text{K}$$

Step 3 of 5

Find the properties of N_2 at the average temperature

$$T_{avg} = \left(\frac{357.034 + 290}{2}\right)$$
$$= 323.517 \text{K}$$

From properties of ideal gases for Nitrogen gas, the gas constant value is,

$$R = 0.2968 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$$

Specific heat value at constant volume is,

$$C_v = 0.7435 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}$$

Step 4 of 5

Determine the boundary work for this polytropic process by using the expression,

$$W = \frac{mR(T_2 - T_1)}{n-1}$$

Here m is the mass of the gas

Substitute 1.5 kg for m

$$W = \frac{mR(T_2 - T_1)}{n-1}$$
$$= \frac{(1.5 \times 0.2968)(357.031 - 290)}{1.3 - 1}$$
$$= 99.5 \text{kJ}$$

Step 5 of 5

Find the amount of heat transfer by using the energy balance:

$$Q = W + mc_v(T_2 - T_1)$$
$$= -99.5 + (1.5)(0.7435)(357.031 - 290)$$
$$= -24.7 \text{ kJ}$$

Therefore, the work done by the gas is, $\boxed{99.5\text{kJ}}$ and the amount of heat dissipated from the system is, $\boxed{24.7 \text{ kJ}}$.

Question: 5.075P

Reconsider Prob. 5–74. Using EES (or other) software, plot the process described in the problem on a *P*- V diagram, and investigate the effect of the polytropic exponent *n* on the boundary work and heat transfer. Let the polytropic exponent vary from 1.1 to 1.6. Plot the boundary work and the heat transfer versus the polytropic exponent, and discuss the results.

We don't have the solution to this problem yet.

Question:

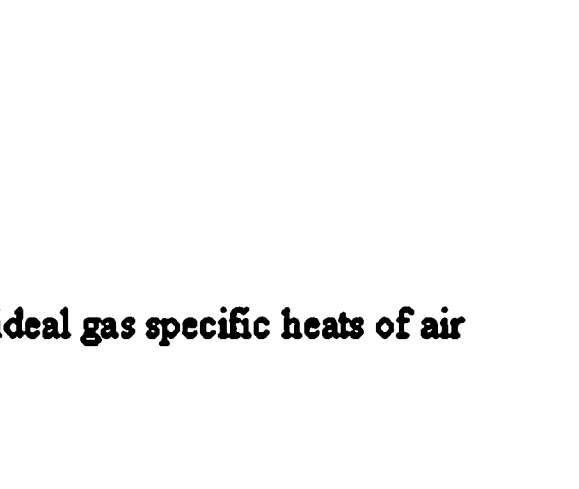
5.076P

A piston-cylinder device, with a set of stops on the top, initially contains 3 kg of air at 200 kPa and 27°C. Heat is now transferred to the air, and the piston rises until it hits the stops, at which point the volume is twice the initial volume. More heat is transferred until the pressure inside the cylinder also doubles. Determine the work done and the amount of heat transfer for this process. Also, show the process on a *P*- v diagram.

Step 1 of 7

Given

Mass of air $m = 3\,\text{kg}$



Initial pressure $P_1 = 200\ \text{kPa}$

Initial temperature $T_1 = 27°\text{C}$

Volume at state 2 is $V_2 = 2V_1$

Pressure at state 3 is $P_3 = 2P_2$

Step 2 of 7

Step 3 of 7

By using ideal gas equation temperature at state 3 is

$$\frac{P_1V_1}{T_1} = \frac{P_3V_3}{T_3}$$

$$T_3 = \frac{P_3V_3}{P_1V_1} \times T_1$$

Since $V_3 = V_2$ and $P_2 = P_1$

$$T_3 = \frac{P_3V_2}{P_2V_1} \times T_1$$

$$T_3 = \frac{2P_2 \times 2V_1}{P_2V_1} \times T_1$$

$$T_3 = 4 \times T_1$$

$$T_3 = 4 \times (27 + 273)$$

$$T_3 = 1200\text{K}$$

Step 4 of 7

At average temperature

$$T_{avg} = \frac{T_1 + T_3}{2}$$

$$T_{avg} = \frac{300 + 1200}{2}$$

$$T_{avg} = 750\text{K}$$

At $T_{avg} = 750\text{K}$ from table ideal gas specific heats of air

$c_v = 0.800\text{kJ/kg.K}$

$R = 0.287\text{kJ/kg.K}$

Step 5 of 7

Initial volume at state 1 is

$$P_1V_1 = mRT_1$$

$$V_1 = \frac{mRT_1}{P_1}$$

$$V_1 = \frac{3 \times (0.287) \times (27 + 273)}{200}$$

$$V_1 = 1.2915\ \text{m}^3$$

Volume at state 2 is

$$V_2 = 2V_1$$

$$V_2 = 2(1.2915)$$

$$V_2 = 2.583\ \text{m}^3$$

Step 6 of 7

The boundary work done is expressed as

$$W_{net} = \int_1^3 pdV$$

$$= W_{1-2} + W_{2-3}$$

$$W_{net} = P_1(V_2 - V_1) + 0$$

$$W_{net} = 200(2.583 - 1.2915)$$

$$\boxed{W_{net} = 258.3\ \text{kJ}}$$

Step 7 of 7

The amount of heat supplied is

$$Q = W_{net} + m(u_3 - u_1)$$

$$Q = W_{net} + mc_v(T_3 - T_1)$$

$$Q = 258.3 + 3(0.800)(1200 - 300)$$

$$\boxed{Q = 2418.3\ \text{kJ}}$$

Question: 5.077P

Air is contained in a cylinder device fitted with a piston-cylinder. The piston initially rests on a set of stops, and a pressure of 300 kPa is required to move the piston. Initially, the air is at 100 kPa and 27°C and occupies a volume of 0.4 m3. Determine the amount of heat transferred to the air, in kJ, while increasing the temperature to 1200 K. Assume air has constant specific heats evaluated at 300 K.

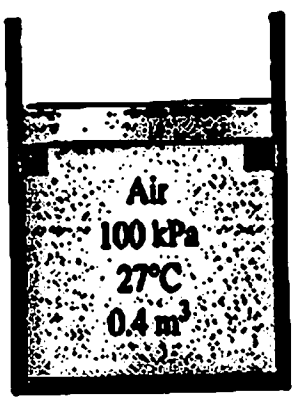


FIGURE P5–77

Step 1 of 6

Given:

Initially pressure $P_1 = 100\text{kPa}$

Initially temperature $T_1 = 27\,^{\circ}\text{C}$

Initially volume $V_1 = 0.4\,\text{m}^3$

Required pressure $P = 300\text{kPa}$

Final temperature $T_2 = 1200\,\text{K}$

Step 2 of 6

From the molar gas, constant and critical point properties

For air

$$R = 0.287\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Specific heat of air $C_v = 0.718\,\dfrac{\text{kJ}}{\text{kg}\cdot\text{K}}$

Step 3 of 6

Mass of the air in the system is

We know that ideal gas equation

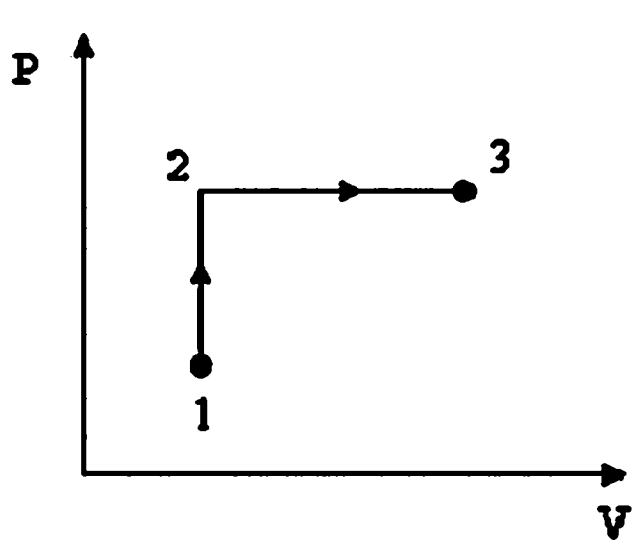
$$P_1V_1 = mRT_1$$

$$\Rightarrow m = \frac{P_1V_1}{RT_1}$$

$$= \frac{(0.4)(100)}{0.287\times 300}$$

$$= 0.464\text{kg}$$

Final volume



$$V_3 = \frac{mRT_3}{P_3}$$

$$= \frac{0.464\times 0.287\times 1200}{300}$$

$$= 0.533\text{m}^3$$

Step 4 of 6

P-v Diagram:

Step 5 of 6

No work is done during process 1-2 since $V_1 = V_2$.

The pressure remains constant during process 2-3 and

Work done during the process is

$$W_{b,out} = \int_1^2 P\,dV$$

$$= P_2(V_3 - V_2)$$

$$= 300\times(0.533-0.4)$$

$$= 39.6\text{kJ}$$

Step 6 of 6

Then from the energy balance

We take the air in the cylinder as the system.

$$Q_{in} = m(u_3 - u_1) + W_{b,out}$$

$$Q_{in} = \Delta U + W_{b,out}$$

$$= mC_v(T_3 - T_1) + 40.14$$

$$= [0.464\times 0.718(1200-300)] + 39.9$$

$$= 339.73\text{kJ}$$

$$\boxed{Q_{in} = 339.73\text{kJ}}$$

Question: 5.078P

Air is contained in a piston-cylinder device at 600 kPa and 927°C, and occupies a volume of 0.8 m3. The air undergoes and isothermal (constant temperature) process until the pressure in reduced to 300 kPa. The piston is now fixed in place and not allowed to move while a heat transfer process takes place until the air reaches 27°C.

(*a*) Sketch the system showing the energies crossing the boundary and the *P*- V diagram for the combined processes.

(*b*) For the combined processes determine the net amount of heat transfer, in kJ, and its direction.

Assume air has constant specific heats evaluated at 300 K.

Step 1 of 7

Given:
Process: isothermal
Initially pressure $P_1 = 600\text{kPa}$
Initially temperature $T_1 = 927^\circ\text{C}$
Initially volume $V_1 = 0.8\text{m}^3$
Final pressure $P_2 = P_3 = 300\text{kPa}$
Final temperature $T_3 = 27^\circ\text{C}$

Step 2 of 7

From the molar gas, constant and critical point properties
For air

$$R = 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

We take the air as the system.
The energy balance equation can be expressed as

$$Q_{in} - W_{b,out} = \Delta U$$
$$= mC_v(T_2 - T_1)$$

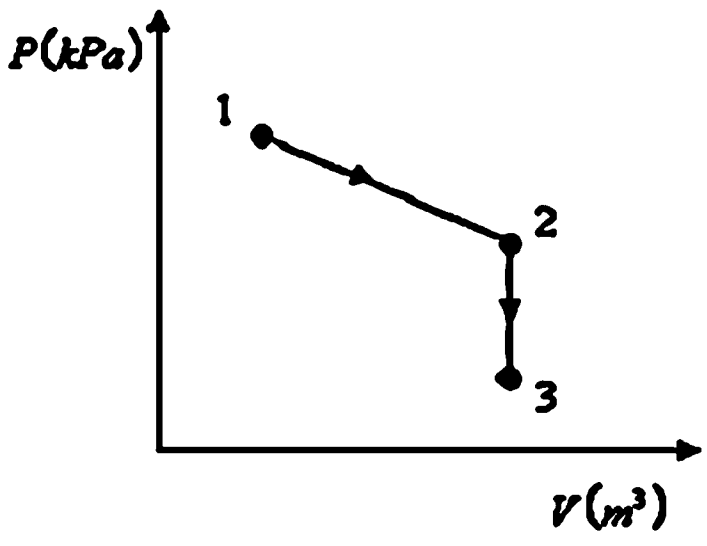
Since $T_2 = T_1$

$$Q_{in} = W_{b,out}$$

Step 3 of 7

Mass of the air in a system

$$m = \frac{P_1V_1}{RT_1}$$
$$= \frac{600\times0.8}{0.287\times1200}$$
$$= 1.394\text{kg}$$



Step 4 of 7

Using the boundary work relation for the isothermal process of an ideal gas gives

$$W_{b,out} = mRT\ln\left(\frac{P_1}{P_2}\right)$$
$$= 1.394\times0.287\times1200\ln\left(\frac{600}{300}\right)$$
$$= 332.78\text{kJ}$$

Step 5 of 7

A)

Step 6 of 7

(b) $(Q_{in})_{1-2} = W_{b,out}$
$= 332.78\text{kJ}$
$(Q_{in})_{2-3} = \Delta U$
$= mC_v(T_3 - T_2)$
$= 1.394\times0.718(27-927)$
$= -900.803\text{kJ}$

Step 7 of 7

Net amount of heat transfer
$Q_{net} = W_{in} + \Delta U$
$Q_{net} = 332.78 - 900.803$
$= -568.023\text{kJ}$

$\boxed{Q_{net} = -568.023\text{kJ}}$

Negative sign indicates that heat rejection take place from the system to surrounding.

Question: 5.079P

Argon is contained in a cylinder device fitted with a piston. Initially, the argon is at 100 kPa and 27°C and occupies a volume of 0.4 m3. The argon is first compressed while the temperature is held constant until the volume is 0.2 m3. Then the argon expands while the pressure is held constant until the volume is 0.6 m3.

(*a*) Sketch both processes on a single *P*- V diagram showing the direction of the processes and label the end states as 1, 2, and 3.

(*b*) Determine the total amount of net heat transferred to the argon, in kJ, during the combined processes.

Step 1 of 12

Given:

Working fluid: argon

Initially pressure $P_1 = 100\text{kPa}$

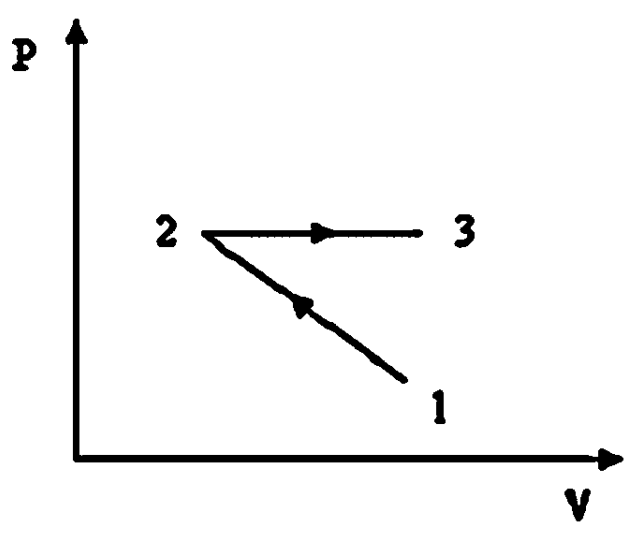
Initially temperature $T_1 = 27\,^\circ\text{C}$

Initially volume $V_1 = 0.4\text{m}^3$

Volume at state 2 $V_2 = 0.2\text{m}^3$

Final volume $V_3 = 0.6\text{m}^3$

Step 2 of 12



From the molar gas, constant and critical point properties

For argon

$$R = 0.2081\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 3 of 12

(a) P-v Diagram:

Step 4 of 12

(b) The energy balance equation is

$$Q_{in} - W_{b,out} = \Delta U$$
$$= mC_v(T_2 - T_1)$$

Since process 1 to 2 is isothermal $T_2 = T_1$

$$Q_{in} = W_{b,out}$$

$$W_{b,out} = mRT\ln\left(\frac{V_2}{V_1}\right)$$

Step 5 of 12

Mass of the argon in the system is

$$m = \frac{P_1V_1}{RT_1}$$
$$= \frac{100\times0.4}{0.2081\times300}$$
$$= 0.641\text{kg}$$

Step 6 of 12

Work done is

$$W_{b,out} = mRT\ln\left(\frac{V_2}{V_1}\right)$$

$$W_{b,out} = 0.641\times0.2081\times300\ln\left(\frac{0.2}{0.4}\right)$$
$$= -27.74\text{kJ}$$

Since process 1 to 2 is isothermal $T_2 = T_1$

$$Q_{in} = W_{b,out}$$

$$(Q_{in})_{1-2} = -27.74\text{kJ}$$

Step 7 of 12

Process 2 to 3 is isobaric

$$V_2T_3 = V_3T_2$$

$$\Rightarrow T_3 = \frac{V_3T_2}{V_2}$$
$$= \frac{0.6\times300}{0.2}$$
$$= 900\text{K}$$

Step 8 of 12

We know that

$$P_1V_1 = P_2V_2$$

$$P_2 = \frac{P_1V_1}{V_2}$$
$$= \frac{100\times0.4}{0.2}$$
$$= 200\text{kPa}$$

Step 9 of 12

$$W_{b,out} = P_2(V_3 - V_2)$$

$$W_{b,out} = 200(0.6-0.2)$$
$$= 80\text{kJ}$$

Step 10 of 12

Internal energy is

$$\Delta U = mC_v(T_3 - T_2)$$
$$= 0.641\times0.3122(900-300)$$
$$= 120.072\text{kJ}$$

Step 11 of 12

Heat transfer is

$$(Q_{in})_{2-3} = W_{b,out} + mC_v(T_3 - T_2)$$

$$(Q_{in})_{2-3} = 80 + 120.072$$
$$= 200.072\text{kJ}$$

Step 12 of 12

Total amount of heat transferred to Argon

$$Q_{net} = Q_{1-2} + Q_{2-3}$$

$$Q_{net} = 200.072 - 27.74$$
$$= 172.332\text{kJ}$$

$$\boxed{Q_{net} = 172.332\text{kJ}}$$

Question: 5.080P

An ideal gas contained in a piston-cylinder device undergoes an isothermal compression process which begins with an initial pressure and volume of 100 kPa and 0.6 m3, respectively. During the process there is a heat transfer of 60 kJ from the ideal gas to the surroundings. Determine the volume and pressure at the end of the process.

Step 1 of 3

Given:
Process: isothermal compression
Initially pressure $P_1 = 100\text{kPa}$
Initially volume $V_1 = 0.6\text{m}^3$
Heat transfer $Q = 60\text{kJ}$

Step 2 of 3

The energy balance equation is
$Q_{in} = W_{b,out}$
Since temperature remains constant so internal energy is zero.
Work done isothermal process is

$$-60 = P_1V_1 \ln\left(\frac{V_2}{V_1}\right)$$

$$\ln\left(\frac{V_2}{V_1}\right) = \frac{-60}{P_1V_1}$$

$$= \frac{-60}{(100\times 06)}$$

$$\Rightarrow V_2 = 0.221\text{m}^3$$

$$\boxed{V_2 = 0.221\text{m}^3}$$

Step 3 of 3

And also we know that
For isothermal process control equation

$$P_1V_1 = P_2V_2$$

$$P_2 = \frac{P_1V_1}{V_2}$$

$$= \frac{100\times 0.6}{0.221}$$

$$= 271.49\text{kPa}$$

$$\boxed{P_2 = 271.49\text{kPa}}$$

Question: 5.081P

A 1-kg block of iron is heated from 25 to 75°C. What is the change in the iron's total internal energy and enthalpy?

Step 1 of 3

Given:

Mass of the iron block $m = 1\text{kg}$

Initially temperature $T_1 = 25^\circ\text{C}$

Final temperature $T_2 = 75^\circ\text{C}$

Step 2 of 3

Iron is an incompressible substance with a constant specific heat.

From the properties of common liquids, solids and foods

For iron

The specific heat of iron is

$$C_p = 0.45\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 3 of 3

The internal energy and enthalpy changes are equal for a solid.

Then,

$$\Delta H = \Delta U = mC_p\Delta T$$

$$= 1(0.45)(75-25)$$

$$= 22.5\text{kJ}$$

$$\boxed{\Delta H = \Delta U = 22.5\text{kJ}}$$

Question: 5.082P

The state of liquid water is changed from 50 psia and 50°F to 2000 psia and 100°F. Determine the change in the internal energy and enthalpy of water on the basis of the (*a*) compressed liquid tables, (*b*) incompressible substance approximation and property tables, and (*c*) specific-heat model.

Step 1 of 6

a)

Obtain the properties of the water from EES software at $T_1 = 50°F$ and $p_1 = 50\,\text{psia}$

Internal energy, $u_1 = u_f = 18.07\ \text{Btu/lbm}$,

Enthalpy, $h_f = 18.07\ \text{Btu/lbm}$

At $T_1 = 50°F$, saturation pressure is given as $P_{sat} = 0.17812\ \text{psia}$

Calculate the enthalpy of compressed liquid as follows:

$$h_1 = h_f + v_f(P_1 - P_{sat})$$
$$= 18.07\ \text{Btu/lbm} + 0.01602\ \text{ft}^3/\text{lbm} \times (50\,\text{psia} - 0.17812\ \text{psia}) \times \frac{\text{Btu}}{\text{psia.ft}^3}$$
$$= 18.87\ \text{Btu/lbm}$$

Step 2 of 6

Obtain the properties of water from the table A-7E "compressed liquid water" at $P_2 = 2000\ \text{psia}$ and $T_2 = 100°F$.

Internal energy, $u_2 = 67.36\ \text{Btu/lbm}$.

Enthalpy, $h_2 = 73.30\ \text{Btu/lbm}$

Calculate the change in internal energy.

Calculate the change in internal energy.

$$\Delta u = u_2 - u_1$$

Substitute $67.36\ \text{Btu/lbm}$ for u_2 and $18.07\ \text{Btu/lbm}$ for u_1 .

$$\Delta u = 67.36\ \text{Btu/lbm} - 18.07\ \text{Btu/lbm}$$
$$= 49.29\ \text{Btu/lbm}$$

Therefore, the change in internal energy is $\boxed{49.29\ \text{Btu/lbm}}$.

Step 3 of 6

Calculate the change in Enthalpy.

$$\Delta h = h_2 - h_1$$

$$\Delta h = 73.3\ \text{Btu/lbm} - 18.87\ \text{Btu/lbm}$$
$$= 54.43\ \text{Btu/lbm}$$

Therefore, the change in enthalpy is $\boxed{54.43\ \text{Btu/lbm}}$.

Step 4 of 6

(b)

Consider the incompressible substance approximation

Neglecting the pressure condition, using the saturated liquid properties at given temperature

$u_1 = u_f = 18.07\ \text{Btu/lbm}$, $h_1 = h_f = 18.07\ \text{Btu/lbm}$

$u_2 = u_f = 68.03\ \text{Btu/lbm}$, $h_2 = h_f = 68.03\ \text{Btu/lbm}$

Calculate the change in internal energy.

Calculate the change in internal energy.

$$\Delta u = u_2 - u_1$$
$$= 68.03\ \text{Btu/lbm} - 18.07\ \text{Btu/lbm}$$
$$= 49.96\ \text{Btu/lbm}$$

Therefore, the change in enthalpy is $\boxed{49.96\ \text{Btu/lbm}}$.

Step 5 of 6

Calculate the change in enthalpy.

$$\Delta h = h_2 - h_1$$
$$= 68.03\ \text{Btu/lbm} - 18.07\ \text{Btu/lbm}$$
$$= 49.96\ \text{Btu/lbm}$$

Therefore, the change in enthalpy is $\boxed{49.96\ \text{Btu/lbm}}$.

Step 6 of 6

(c)

Consider the Specific heat model.

Obtain the properties from the table of 'properties common liquids, solids and foods' for water

The specific heat of water is $1\ \text{Btu/lbm} \cdot \text{R}$

Calculate the enthalpy and internal energy are same for a solid.

$$\Delta h = \Delta u = c\Delta T$$
$$= \left(1 \frac{\text{Btu}}{\text{lbm.R}}\right) \times (100 - 50)\,\text{R}$$
$$= 50\ \text{Btu/lbm}$$

Therefore change in internal energy and enthalpies are $\boxed{50\ \text{Btu/lbm}}$ and $\boxed{50\ \text{Btu/lbm}}$.

Question: 5.083P

During a picnic on a hot summer day, all the cold drinks disappeared quickly, and the only available drinks were those at the ambient temperature of 75°F. In an effort to cool a 12-fluid-oz drink in a can, a person grabs the can and starts shaking it in the iced water of the chest at 32°F. Using the properties of water for the drink, determine the mass of ice that will melt by the time the canned drink cools to 45°F.

Step 1 of 5

Given

12 oz of fluid drink at ambient temperature $T_1 = 75°F$

Canned drink cools at temperature $T_2 = 45°F$

Step 2 of 5

The specific heat of water is 1 Btu/lbm.R

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

Work done on the system is zero $W = 0$.

$-Q_{out} = \Delta U$

$-Q_{out} = m(u_2 - u_1)$

$-Q_{out} = mc(T_2 - T_1)$

Step 3 of 5

The mass of water is

$m = \rho V$ lbm/can

$1 \text{ oz} = \frac{1}{957.5}$ ft^3 And

Density of water $\rho = 62.34$ lbm/ft^3

$m = \rho V$ lbm/can

$m = 62.34\left(\frac{12}{957.5}\right)$ lbm/can

$m = 0.7812$ lbm/can

Step 4 of 5

Therefore

$-Q_{out} = mc(T_2 - T_1)$

$-Q_{out} = (0.7812)(1)(45-75)$

$Q_{out} = 23.43$ Btu/lbm

Step 5 of 5

The amount of heat required to melt one lbm of ice is heat of fusion of water

$h_{fusion} = 143.5$ Btu/lbm

Therefore the amount of ice melted in order to dissipate 23.43 Btu/lbm of heat is

$m_{ice} = \frac{Q_{out}}{h_{fusion}}$

$m_{ice} = \frac{23.43}{143.5}$

$\boxed{m_{ice} = 0.163 \text{ lbm}}$

The mass of ice melted to cool one can is 0.163 lbm

Question: 5.084P

Consider a 1000-W iron whose base plate is made of 0.5-cm-thick aluminum alloy 2024-T6 (ρ = 2770 kg/m3 and cp = 875 J/kg·°C). The base plate has a surface area of 0.03 m2. Initially, the iron is in thermal equilibrium with the ambient air at 22°C. Assuming 90 percent of the heat generated in the resistance wires is transferred to the plate, determine the minimum time needed for the plate temperature to reach 200°C.

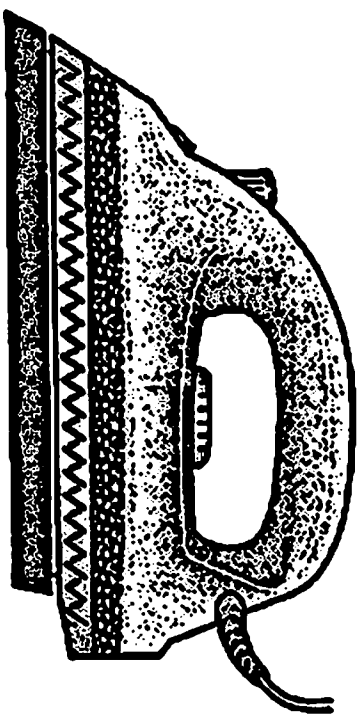


FIGURE P5–84

Step 1 of 4

Given:

Capacity of iron $\dot{Q}_{in} = 1000\,\text{W}$

Thickness of base plate $t = 0.5\,\text{cm}$

Density of aluminum alloy $\rho = 2770\,\frac{\text{kg}}{\text{m}^3}$

Specific heat of aluminum alloy $C_p = 875\,\frac{\text{J}}{\text{kg}\cdot^\circ\text{C}}$

Ambient temperature $T_1 = 22^\circ\text{C}$

Efficiency $\eta = 0.9$

Plate temperature $T_2 = 200^\circ\text{C}$

Surface area of the base plate $A = 0.03\,\text{m}^2$

Step 2 of 4

Mass of the iron is

$$m = \rho \times t \times A$$

$$= \left(2770\,\frac{\text{kg}}{\text{m}^3} \times 0.005\text{m} \times 0.03\text{m}^2\right)$$

$$= 0.4155\text{kg}$$

Step 3 of 4

Noting that only 90% of the heat generated is transferred to the plate, the rate of heat transfer to the iron's base plate is

$$\dot{Q}_{in} = 0.9 \times 1000\,\text{W}$$

$$= 900\,\text{W}$$

Step 4 of 4

We take plate to be the system

The energy balance for this closed system can be expressed as

$$\dot{Q}_{in} = \Delta U_{plate}$$

$$= m(u_2 - u_1)$$

$$\dot{Q}_{in}\Delta t = mc_p(T_2 - T_1)$$

Solving for Δt and substituting

$$\Delta t = \frac{mC\Delta T_{plate}}{\dot{Q}_{in}}$$

$$= \frac{(0.4155)(875)(200-22)}{900}$$

$$= 71.904\,\text{sec}$$

$$\boxed{\Delta t = 71.904\,\text{sec}}$$

Question: 5.085P

Stainless steel ball bearings (ρ = 8085 kg/m3 and cp = 0.480 kJ/kg·°C) having a diameter of 1.2 cm are to be quenched in water at a rate of 800 per minute. The balls leave the oven at a uniform temperature of 900°C and are exposed to air at 25 °C for a while before they are dropped into the water. If the temperature of the balls drops to 850°C prior to quenching, determine the rate of heat transfer from the balls to the air.

Step 1 of 5

Given

Diameter of ball bearings $d = 1.2\text{ cm} = 0.012\text{m}^3$

Ambient air temperature $T_{amb} = 25°\text{C}$

Initial uniform temperature $T_1 = 900°\text{C}$

Final heated temperature $T_2 = 850°\text{C}$

Number of steel ball bearings quenched $n = 800\text{per/min}$

Density of steel ball bearings $\rho = 8085\text{ kg/m}^3$

Specific heat of steel ball bearings $c_p = 0.48\text{ kJ/kg.°C}$

Step 2 of 5

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

Work done on the system is zero W = 0.

$-Q_{out} = \Delta U$

$-Q_{out} = m(u_2 - u_1)$

$-Q_{out} = mc_p(T_2 - T_1)\text{ kJ}$

Step 3 of 5

The mass of steel ball is

$m = \rho V\text{ kg}$

$m = \rho \times \frac{\pi}{6} d^3$

$m = 8085 \times \left(\frac{\pi}{6}(0.012)^3\right)$

$m = 0.007315\text{ kg}$

Step 4 of 5

The amount of heat transfer from the balls to the air

$-Q_{out} = mc_p(T_2 - T_1)\text{ kJ}$

$-\dot{Q}_{out} = 0.007315 \times (0.48) \times (850 - 900)$

$Q_{out} = 0.17556\text{ kJ}$

Step 5 of 5

Total rate of heat transfer from the balls to the air

$\dot{Q}_{out} = n \times Q_{out}$

$\dot{Q}_{out} = 800 \times 0.17556\text{ kJ/min}$

$\dot{Q}_{out} = 140.448\text{ kJ/min}$

$\dot{Q}_{out} = 140.448 \times \frac{1}{60}$

$\boxed{\dot{Q}_{out} = 2.3408\text{ kW}}$

Question: 5.086P

Carbon steel balls (ρ = 7833 kg/m3 and cp = 0.465 kJ/kg·°C) 8 mm in diameter are annealed by heating them first to 900°C in a furnace, and then allowing them to cool slowly to 100°C in ambient air at 35°C. If 2500 balls are to be annealed per hour, determine the total rate of heat transfer from the balls to the ambient air.

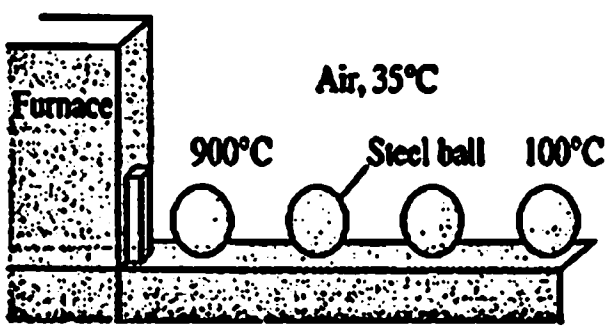

FIGURE P5–86

Step 1 of 5

Given

Diameter of steel ball $d = 8$ mm

Density of steel ball $\rho = 7833\ \text{kg/m}^3$

Specific heat of steel ball $c_p = 0.465$ kJ/kg.°C

Ambient air temperature $T_a = 35°C$

Initial uniform temperature $T_1 = 900°C$

Final heated temperature $T_2 = 100°C$

Number of steel ball bearings annealed per hour $n = 2500$

Step 2 of 5

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

Work done on the system is zero W = 0.

$-Q_{out} = \Delta U$

$-Q_{out} = m(u_2 - u_1)$

$-Q_{out} = mc_p(T_2 - T_1)$

Step 3 of 5

The mass of steel ball is

$m = \rho V$ kg

Given π ,3

Diameter of steel ball $d = 8$ mm

Density of steel ball $\rho = 7833\ \text{kg/m}^3$

Specific heat of steel ball $c_p = 0.465$ kJ/kg.°C

Ambient air temperature $T_a = 35°C$

Initial uniform temperature $T_1 = 900°C$

Final heated temperature $T_2 = 100°C$

Number of steel ball bearings annealed per hour $n = 2500$

Step 2 of 5

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

Work done on the system is zero W = 0.

$-Q_{out} = \Delta U$

$-Q_{out} = m(u_2 - u_1)$

$-Q_{out} = mc_p(T_2 - T_1)$

Step 3 of 5

The mass of steel ball is

$m = \rho V$ kg

π ,3

Question: 5.087P

An ordinary egg can be approximated as a 5.5-cm-diameter sphere. The egg is initially at a uniform temperature of 8°C and is dropped into boiling water at 97°C. Taking the properties of the egg to be ρ = 1020 kg/m3 and *cp* = 3.32 kJ/kg·°C, determine how much heat is transferred to the egg by the time the average temperature of the egg rises to 80°C.

Step 1 of 4

Given

Diameter of egg $d = 5.5\ \text{cm} = 0.055\ \text{m}$

Initial temperature of egg $T_1 = 8°\text{C}$

Final temperature of egg $T_2 = 80°\text{C}$

Density of the egg $\rho = 1020\ \text{kg/m}^3$

Specific heat of the egg $c_p = 3.32\ \text{kJ/kg.°C}$

Step 2 of 4

Question:

An ordinary egg can be approximated as a 5.5-cm-diameter sphere. The egg is initially at a uniform temperature of 8°C and is dropped into boiling water at 97°C. Taking the properties of the egg to be ρ = 1020 kg/m3 and *cp* = 3.32 kJ/kg·°C, determine how much heat is transferred to the egg by the time the average temperature of the egg rises to 80°C.

Step 1 of 4

Given

Diameter of egg $d = 5.5\ \text{cm} = 0.055\ \text{m}$

Initial temperature of egg $T_1 = 8°\text{C}$

Final temperature of egg $T_2 = 80°\text{C}$

Density of the egg $\rho = 1020\ \text{kg/m}^3$

Specific heat of the egg $c_p = 3.32\ \text{kJ/kg.°C}$

Step 2 of 4

Step 4 of 4

The amount of heat transfer

$$Q_{in} = mc_p(T_2 - T_1)$$

$$Q_{in} = 0.089(3.32)(80-8)$$

$$\boxed{Q_{in} = 21.274\ \text{kJ}}$$

Question: 5.088P

In a production facility, 1.2-in-thick 2-ft × 2-ft square brass plates (ρ = 532.5 lbm/ft3 and cp = 0.091 Btu/lbm. °F) that are initially at a uniform temperature of 75°F are heated by passing them through an oven at 1300°F at a rate of 300 per minute. If the plates remain in the oven until their average temperature rises to 1000°F, determine the rate of heat transfer to the plates in the furnace.

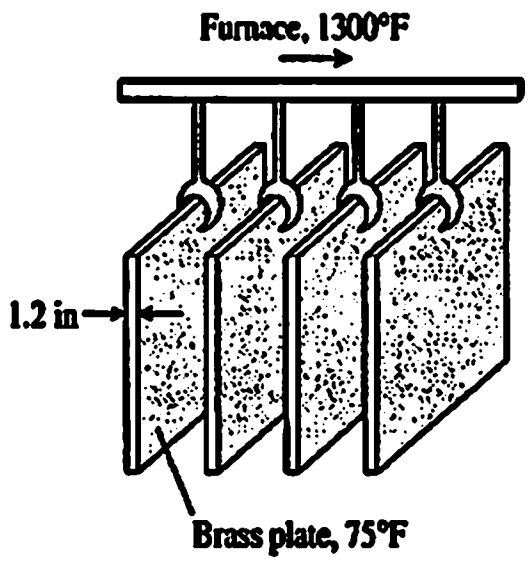

FIGURE P5–88E

Step 1 of 5

Given

Thickness of plate $t = 1.2$ in ,

Cross section of the brass plate $2\text{ft} \times 2\text{ft}$

Initial temperature of the plate $T_1 = 75°\text{F}$

Final temperature of the plate $T_2 = 1000°\text{F}$

Density of the brass plate $\rho = 532.5\text{lbm/ft}^3$

Specific heat of the brass plate $c_p = 0.091\text{Btu/lbm.}^0\text{F}$

Number of plates moving per minute is $N = 300\text{plates/min}$

Step 2 of 5

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

Work done on the system is zero $W = 0$.

$Q_{in} = \Delta U$

$Q_{in} = m(u_2 - u_1)$

$Q_{in} = mc_p(T_2 - T_1)$ kJ

Step 3 of 5

The mass of each aluminum plate

$m = \rho V$

$m = \rho AL$

$m = 532.5 \times (2 \times 2) \times \left(\frac{1.2}{12}\right)$

$m = 213$ lbm

Step 4 of 5

The amount of heat transfer

$Q_{in} = mc_p(T_2 - T_1)$ kJ

$Q_{in} = 213 \times (0.091) \times (1000 - 75)$

$Q_{in} = 17929.275$ Btu/plate

Step 5 of 5

The total rate of heat transfer for 300 plates per minute

$\dot{Q}_{in} = \frac{300}{60} \times 17929.275$ Btu/s

$\boxed{\dot{Q}_{in} = 89646.375\text{ Btu/s}}$

Question: 5.089P

Long cylindrical steel rods (ρ = 7833 kg/m3 and cp = 0.465 kJ/kg·°C) of 8-cm diameter are heat-treated by drawing them at a velocity of 2 m/min through an oven maintained at 900°C. If the rods enter the oven at 30°C and leave at a mean temperature of 700°C, determine the rate of heat transfer to the rods in the oven.

Step 1 of 4

Given:

Density of ball bearing $\rho = 7833\frac{\text{kg}}{\text{m}^3}$

Specific heat $c_p = 0.465\frac{\text{kJ}}{\text{kg}\cdot^\circ\text{C}}$

Diameter of ball $D = 8\text{cm}$

Velocity $V = 2\frac{\text{m}}{\text{min}}$

Temperature of the oven $T_2 = 700^\circ\text{C}$

Inlet temperature rod $T_1 = 30^\circ\text{C}$

Step 2 of 4

The energy balance for this closed system can be expressed as:-

$Q_{in} = mC(T_1 - T_2)$

The mass of rod heated in 1 minute is

$m = \rho VA$

$= \rho V\left(\frac{\pi D^2}{4}\right)$

$= (7833)(2)\left[\frac{\pi(0.08)^2}{4}\right]$

$= 78.745\text{kg}$

Step 3 of 4

We take the 2m section of the rod in the oven as the system

$Q_{in} = mC(T_2 - T_1)$

$= (78.74)(0.465)(700-30)$

$= 24533.286\text{kJ}$

Step 4 of 4

Noting that this much heat is transferred in 1 min., the rate of heat transfer to the rod becomes

$Q_{in} = \frac{Q_{in}}{\Delta t}$

$= \frac{24533.2861\text{kJ}}{1\text{min}}$

$= \frac{408.88\text{kJ}}{60\text{sec}}$

$= 408.88\text{kW}$

$\boxed{Q_{in} = 408.88\text{kW}}$

Question: 5.090P

An electronic device dissipating 25 W has a mass of 20 g and a specific heat of 850 J/kg·°C. The device is lightly used, and it is on for 5 min and then off for several hours, during which it cools to the ambient temperature of 25°C. Determine the highest possible temperature of the device at the end of the 5-min operating period. What would your answer be if the device were attached to a 0.5-kg aluminum heat sink? Assume the device and the heat sink to be nearly isothermal.

Step 1 of 5

Given:

Heat dispatching rate $Q = 25\,\text{W}$

Mass of heater $m = 20\,\text{g}$

Specific heat $c_p = 850\,\frac{\text{J}}{\text{kg}\cdot^\circ\text{C}}$

Working time $\Delta t = 5\,\text{min}$

Ambient temperature $T_1 = 25^\circ\text{C}$

Mass of the heat sink $m_H = 0.5\text{kg}$

Step 2 of 5

Take the specific heat of aluminum
From the properties of common liquids and solids and gases
At room temperature of 300K is

$$c_{p,al} = 902\,\frac{\text{J}}{\text{kg}\cdot^\circ\text{C}}$$

Step 3 of 5

The energy balance for this closed system can be expressed as

$$W_{e,in} = \Delta U_{device} = m(u_2 - u_1)$$

$$W_{e,in} = \Delta T_{device} = mc_p(T_2 - T_1)$$

$$Q \times \Delta t = mc_p(T_2 - T_1)$$

Step 4 of 5

Substituting values in above expression
the temperature of the deice at the end of the process is

$$25\text{W} \times (5 \times 60\,\text{sec}) = (0.02\text{kg})\left(850\,\frac{\text{J}}{\text{kg}\cdot^\circ\text{C}}\right)(T_2 - 25)^\circ\text{C}$$

$$\Rightarrow T_2 = 466.18^\circ\text{C}$$

$$\boxed{T_2 = 466.18^\circ\text{C}}$$

Step 5 of 5

Case II:-
When a heat sink is attached the energy balance can be expressed as

$$W_{e,in} = \Delta U_{device} + \Delta U_{heat\,sink}$$

$$W_{e,in}\Delta t = mc_p(T_2 - T_1)_{device} + m_{al}c_{p,al}(T_2 - T_1)_{sink}$$

$$(25) \times (5 \times 60) = (0.02)(850)(T_2 - 25) + (0.5)(902)(T_2 - 25)$$

$$\Rightarrow T_2 = 41.03^\circ\text{C}$$

$$\boxed{T_2 = 41.03^\circ\text{C with heat sink}}$$

Question: 5.091P

Reconsider Prob. 5–90. Using EES (or other) software, investigate the effect of the mass of the heat sink on the maximum device temperature. Let the mass of heat sink vary from 0 to 1 kg. Plot the maximum temperature against the mass of heat sink, and discuss the results.

Step 1 of 7

Given:
Given:
Heat dispatching rate $Q = 25\,\text{W}$
Mass of heater $m = 20\,\text{g}$
Specific heat $c_p = 850\,\frac{\text{J}}{\text{kg}\cdot{}^\circ\text{C}}$
Working time $\Delta t = 5\,\text{min}$
Ambient temperature $T_1 = 25^\circ\text{C}$
Mass of the heat sink varies from $m_H = 0\text{kg}$ to 1kg

Step 2 of 7

"Knowns:"
"T_1 is the maximum temperature of the device"
Q_dot_out = 25 [W]
m_device=20 [g]
Cp_device=850 [J/kg-C]
A=5 [cm^2]
DELTAt=5 [min]
T_amb=25 [C]
{m_sink=0.5 [kg]}
"Cp_al taken from Table A-3(b) at 300K"
Cp_al=0.902 [kJ/kg-C]
T_2=T_amb

Step 3 of 7

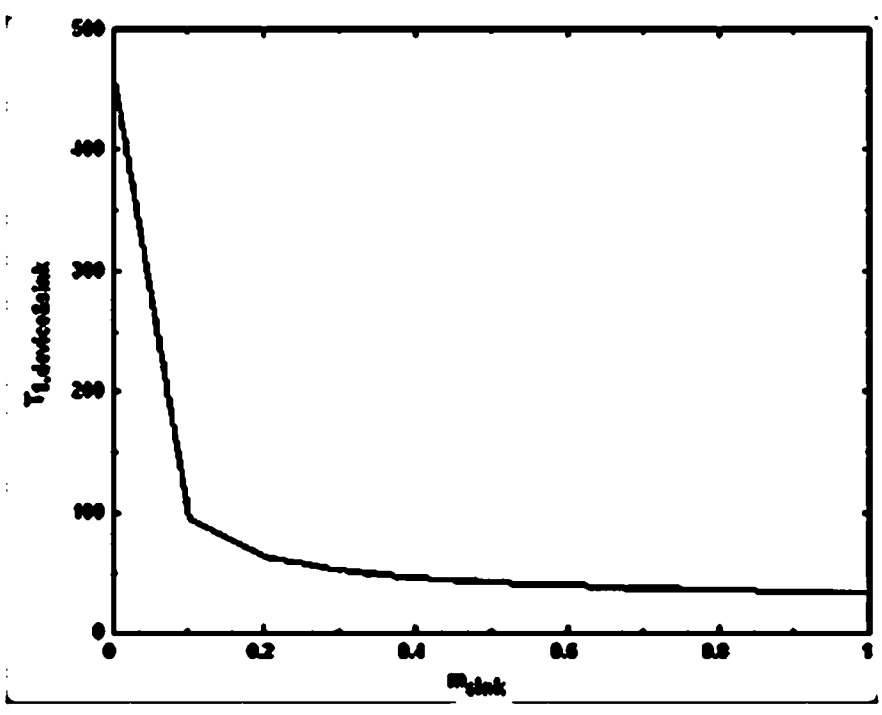
"Solution:"
"The device without the heat sink is considered to be a closed system."
"Conservation of Energy for the closed system:"
"E_dot_in - E_dot_out = DELTAE_dot, we neglect DELTA KE and DELTA PE for the system, the device."
E_dot_in - E_dot_out = DELTAE_dot
E_dot_in =0
E_dot_out = Q_dot_out
"Use the solid material approximation to find the energy change of the device."
DELTAE_dot= m_device*convert(g,kg)*Cp_device*(T_2-
_1_device)/(DELTAt*convert(min,s))
"The device with the heat sink is considered to be a closed system."
"Conservation of Energy for the closed system:"

Step 4 of 7

"E_dot_in - E_dot_out = DELTAE_dot, we neglect DELTA KE and DELTA PE for the device with the heat sink."
E_dot_in - E_dot_out = DELTAE_dot_combined
"Use the solid material approximation to find the energy change of the device."
DELTAE_dot_combined= (m_device*convert(g,kg)*Cp_device*(T_2-
T_1_device&sink)+m_sink*Cp_al*(T_2-
T_1_device&sink)*convert(kJ,J))/(DELTAt*convert(min,s))

Step 5 of 7

Run the parameter table on menu bar.
Then select the m_sink and $T_{1\text{device\&sink}}$ then click ok



Step 6 of 7

Solution table :

1..11	m_{sink}	$T_{1,device\&sink}$
Run 1	0	466.2
Run 2	0.1	94.96
Run 3	0.2	62.99
Run 4	0.3	51.08
Run 5	0.4	44.85
Run 6	0.5	41.03
Run 7	0.6	38.44
Run 8	0.7	36.57
Run 9	0.8	35.15
Run 10	0.9	34.05
Run 11	1	33.16

Step 7 of 7

Graph between m_sink nad T_sinkdevice

Question: 5.092P

If you ever slapped someone or got slapped yourself, you probably remember the burning sensation. Imagine you had the unfortunate occasion of being slapped by an angry person, which caused the temperature of the affected area of your face to rise by 1.8°C (ouch!). Assuming the slapping hand has a mass of 1.2 kg and about 0.150 kg of the tissue on the face and the hand is affected by the incident, estimate the velocity of the hand just before impact. Take the specific heat of the tissue to be 3.8 kJ/kg·K.

Step 1 of 2

Given:

Rise in temperature $\Delta T = 1.8^{\circ}\mathrm{C}$

Mass of the hands $m_1 = 1.2\,\mathrm{kg}$

Mass of the tissue on face $m_2 = 0.150\,\mathrm{kg}$

Specific heat of tissue $c_p = 3.8\,\dfrac{\mathrm{kJ}}{\mathrm{kg}\cdot\mathrm{K}}$

Step 2 of 2

In this process kinetic energy of hand is converted into heat energy

$$\frac{1}{2}m_1V^2 = m_2c_p\Delta t$$

$$\frac{1}{2}\times(1.2)(V^2) = 0.15\times3.8\times10^3\times1.8$$

$$\Rightarrow V = 41.352\,\frac{\mathrm{m}}{s}$$

$$\boxed{V = 41.352\,\frac{\mathrm{m}}{s}}$$

Question: 5.093P

Does the concept of a specific heat property (either at constant volume or constant pressure) have a meaning for substances that are undergoing a phase change? Why or why not?

Step 1 of 2

For a substance undergoing phase change, the temperature during the phase change remains constant at constant pressure process.

Therefore we know that specific heat at constant pressure is

$$c_p = \left(\frac{\partial h}{\partial T}\right)_p$$

$$= \left(\frac{\partial h}{0}\right)_p$$

$$c_p = \infty$$

So specific heat property undergoing phase change at constant pressure process has no meaning.

Step 2 of 2

For specific heat at constant volume

$$c_v = \left(\frac{\partial u}{\partial T}\right)_v$$

It gives some finite value and it has some meaning since at constant volume process during phase change there might be finite amount of heat transfer to the system.

Question: 5.094P

10-kg of nitrogen is heated from 20°C to 250°C. Determine the total amount of heat required when this is done in (*a*) a constant-volume process and (*b*) an isobaric process.

Step 1 of 4

Given

Mass of nitrogen $m = 10\ \text{kg}$

Initial temperature $T_1 = 20°\text{C}$

Final temperature $T_2 = 250°\text{C}$

Step 2 of 4

For nitrogen the specific heats at average temperatures

$$T_{avg} = \frac{T_1 + T_2}{2}$$

$$= \frac{20 + 250}{2}$$

$$T_{avg} = 135°\text{C} = 408\text{K}$$

At $T_{avg} = 135°\text{C} = 408\text{K}$ from table ideal gas specific heats of common gases

$$c_p = 1.044 + (1.049 - 1.044)\left(\frac{408 - 400}{450 - 400}\right)$$

$$c_p = 1.0448\ \text{kJ/kg.K}$$

$$c_v = 0.747 + (0.752 - 0.747)\left(\frac{408 - 400}{450 - 400}\right)$$

$$c_v = 0.7478\ \text{kJ/kg.K}$$

Step 3 of 4

(a) If the process is constant volume process

By applying energy equation and neglecting kinetic and potential energies

$$Q = W + \Delta U$$

Since the process is constant volume process work done is zero then

$$Q_{in} = \Delta U$$

$$Q_{in} = mc_v(T_2 - T_1)$$

$$Q_{in} = 10(0.7478)(250 - 20)$$

$$\boxed{Q_{in} = 1719.94\ \text{kJ}}$$

Step 4 of 4

(b) If the process is an isobaric process

$$Q = W + \Delta U$$

Where work done during constant pressure process is

$$W = P(V_2 - V_1)$$

Then the amount of heat required is

$$Q_{in} = P(V_2 - V_1) + mc_v(T_2 - T_1)$$

$$Q_{in} = mR(T_2 - T_1) + mc_v(T_2 - T_1)$$

$$Q_{in} = m(T_2 - T_1)(R + c_v)$$

$$Q_{in} = m(T_2 - T_1)c_p$$

$$Q_{in} = mc_p(T_2 - T_1)$$

$$Q_{in} = 10(1.0448)(250 - 20)$$

$$\boxed{Q_{in} = 2403.04\ \text{kJ}}$$

Question: 5.095P

Consider a classroom that is losing heat to the outdoors at a rate of 12,000 kJ/h. If there are 40 students in class, each dissipating sensible heat at a rate of 84 W, determine if it is necessary to turn the heater in the classroom on to prevent the room temperature from dropping.

Step 1 of 2

Given:

Number of students $n = 40$

Rate of heat dissipation of classroom $Q_l = 12000 \ \frac{\text{kJ}}{\text{h}}$

Rate of heat dissipation of sensible heat $Q = 84\text{W}$

Step 2 of 2

Rate of heat dissipation of classroom

$$Q_l = 12000 \ \frac{\text{kJ}}{\text{h}}$$

$$Q_l = \frac{12000}{3600} \frac{\text{kJ}}{\text{sec}}$$

$$= 3.333\text{kW}$$

Rate of heat produced by students

$$Q_{prod} = n \times Q$$

$$= 40 \times 0.084\text{kW}$$

$$= 3.36\text{kW}$$

So, rate of heat production in room is greater than rate of heat dissipation to the outdoors. So it is not necessary to turn the heater on in the classroom to prevent the room temperature from dropping.

Question: 5.096P

Air in the amount of 2 lbm is contained in a well-insulated, rigid vessel equipped with a stirring paddle wheel. The initial state of this air is 30 psia and 60°F. How much work, in Btu, must be transferred to the air with the paddle wheel to raise the air pressure to 40 psia? Also, what is the final temperature of air?

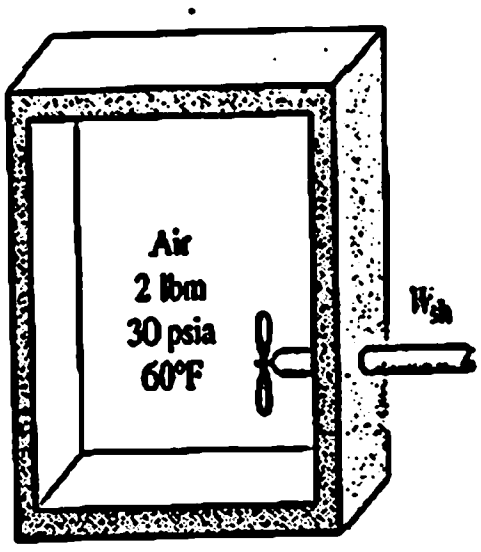


FIGURE P5–96E

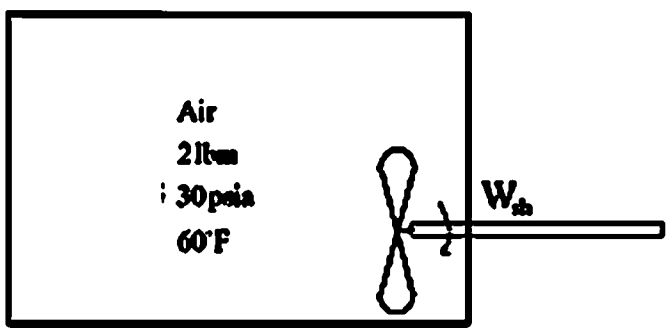
Step 1 of 6

Given:



Mass of the air $m = 2\text{lbm}$

Initially pressure $P_1 = 30\text{psia}$

Initially temperature $T_1 = 60^\circ\text{F}$

Final pressure $P_2 = 40\text{psia}$

Step 2 of 6

Step 3 of 6

From the ideal gas specific heat of various common gases

For air

The specific heats of air at room temperature are

$$C_p = 0.240\frac{\text{Btu}}{\text{lbm}\cdot\text{R}} \text{ And}$$

$$C_v = 0.171\frac{\text{Btu}}{\text{lbm}\cdot\text{R}}$$

Step 4 of 6

The energy balance for this system can be expressed as

$Q = W + \Delta U$

Since tank is insulated so heat transfer is zero,and work done on the system so take as negative.

$$-\left(-W_{sh,in}\right) = \Delta U$$

$$W_{sh,in} = \Delta U$$

$$= mC_v\left(T_2 - T_1\right)$$

Step 5 of 6

As the specific volume remains constant during this process, the ideal gas equation gives

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)$$

$$= (60+459.67\text{R})\left(\frac{40}{30}\right)$$

$$= 692.893\text{R}$$

$$= 692.893\text{-}459.67\text{R}$$

$$= 233.233^\circ\text{F}$$

$$\boxed{T_2 = 233.233^\circ\text{F}}$$

Step 6 of 6

Substituting,

Work input is

$$W_{sh,in} = mC_v\left(T_2 - T_1\right)$$

$$= (2)(0.171)(692.893 - 519.67)$$

$$= 59.24\text{Btu}$$

$$\boxed{W_{sh,in} = 59.24\text{Btu}}$$

Question: 5.097P

Air is expanded in a polytropic process with n =1.5 from 2 MPa and 300°C to 80 kPa in a piston-cylinder device. Determine the final temperature of the air.

Step 1 of 3

Write the governing law for a polytropic process.

$$P_1V_1^n = P_2V_2^n$$

Here, p_1 is the initial pressure, p_2 is the final pressure, T_1 is the initial temperature and T_2 is the final temperature.

Also, for an ideal gas like air:

$$PV = mRT$$

$$V = \frac{mRT}{P}$$

Since m and R are constants:

$$V \propto \frac{T}{P}$$

Step 2 of 3

Hence, for a polytropic process:

$$P_1\left(\frac{T_1}{P_1}\right)^n = P_2\left(\frac{T_2}{P_2}\right)^n$$

$$P_1^{1-n}T_1^n = P_2^{1-n}T_2^n$$

$$P_1^{n-1}T_1^n = P_2^{n-1}T_2^n$$

$$\left(\frac{T_2}{T_1}\right)^n = \left(\frac{P_2}{P_1}\right)^{n-1}$$

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}$$

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}$$

Step 3 of 3

Convert the initial temperature from Celsius to Kelvin.

$$T_1 = 300°C$$

$$T_1 = (300+273)\ K$$

$$T_1 = 573\ K$$

Substitute 573 K for T_1, 80 kPa for P_2 and 2000 kPa for P_1.

$$T_2 = 573\times\left(\frac{80}{2000}\right)^{\frac{1.5-1}{1.5}}$$

$$= 195.96\ K$$

Therefore, the final temperature of air is $\boxed{195.96K}$.

Question: 5.098P

Nitrogen at 100 kPa and 25 °C in a rigid vessel is heated until its pressure is 300 kPa. Calculate the work done and the heat transferred during this process, in kJ/kg.

Step 1 of 4

Loading solution. Please wait ...

Step 2 of 4

Since the vessel is rigid, so volume remains constant.
So work done

$$W = PdV$$
$$= P(0-0)$$
$$= 0$$
$$\boxed{W = 0}$$

Step 3 of 4

From the ideal gas relation

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$
$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$
$$\Rightarrow T_2 = T_1\left(\frac{P_2}{P_1}\right)$$
$$= 298\left(\frac{300}{100}\right)$$
$$= 894\text{K}$$

Step 4 of 4

c_v is the specific heat of nitrogen
From the ideal gas specific heat of various gases
For nitrogen

$$c_v = 0.743\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Heat transferred

$$Q = c_v(T_2 - T_1)$$
$$= 0.743(894-298)$$
$$= 442.828\frac{\text{kJ}}{\text{kg}}$$
$$\boxed{Q = 442.828\frac{\text{kJ}}{\text{kg}}}$$

Question: 5.099P

A well-insulated rigid vessel contains 3 kg of saturated liquid water at 40°C. The vessel also contains an electrical resistor that draws 10 amperes when 50 volts are applied. Determine the final temperature in the vessel after the resistor has been operating for 30 minutes.

Step 1 of 3

Given data:

Mass of the saturated water $m = 3\,\text{kg}$

Initial temperature of the water $T_1 = 40°\text{C} = 313\,\text{K}$

Current drawn by the resister, $I = 10\,\text{A}$

Voltage rating of the resistor, $V = 50\,\text{V}$

Operation time for heat application, $t = 30\,\text{min} = 1800\,\text{sec}$

Internal energy of the saturated water at given conditions, $u_1 = 167.53\,\text{kJ/kg}$

Step 2 of 3

Heat added to the system due to electric resistance is given by,

$$\begin{aligned} Q_{in} &= V \times I \times t \\ &= 50 \times 10 \times 1800 \\ &= 900000\,\text{J} \\ &= 900\,\text{kJ} \end{aligned}$$

The energy balance is given by the formula,

$$Q - W = \Delta E$$

Since the given tank is well-insulated heat lost $Q_{out} = 0$,

The tank is said to be rigid therefore $W = 0$

Step 3 of 3

The entire change in energy is given by change in internal energy alone,

$$\begin{aligned} \Delta E &= m(\Delta u) \\ &= m(u_2 - u_1) \\ &= 3(u_2 - 167.53) \end{aligned}$$

On substitution of the obtained data in the energy balance equation we have,

$$Q - W = \Delta E$$

$$Q_{in} - 0 = m(\Delta u)$$

$$900 - 0 = 3(u_2 - 167.53)$$

$$u_2 = 467.53\,\text{kJ}$$

The water at its initial condition is in saturated state the further increase in its temperature will cause compression of water. Therefore for the internal energy 467.53 kJ we obtain the final temperature of the water as $\boxed{T_2 = 118.9°\text{C}}$ for the compressed water tables of EES.

Question: 5.100P

A frictionless piston-cylinder device initially contains air at 100 kPa and 0.15 m3. At this state, a linear spring ($F \propto x$) is touching the piston but exerts no force on it. The air is now heated to a final state of 0.45 m3 and 800 kPa. Determine (*a*) the total work done by the air and (*b*) the work done against the spring. Also, show the process on a *P*- v diagram.

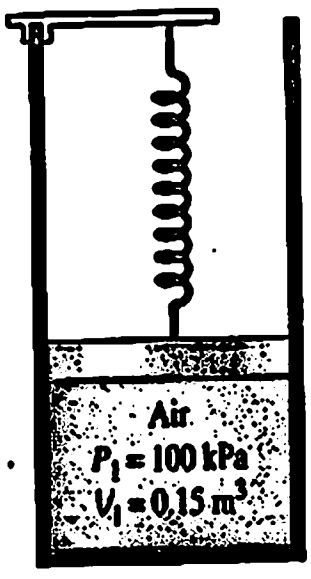


FIGURE P5–100

Step 1 of 5

Given:

Initially pressure $P_1 = 100\text{kPa}$

Initially volume $V_1 = 0.15\text{m}^3$

Final pressure. $P_2 = 800\text{kPa}$

Final volume $V_2 = 0.45\text{m}^3$

Step 2 of 5

P-v Diagram:

Step 3 of 5

(a) The boundary work during this process is simply the area under the process curve Here Displacement is a linear function of fore . Thus,

$W_{b,out}$ = Area under the Pv Diagram

$$= \left(\frac{P_1 + P_2}{2}\right)(V_2 - V_1)$$

$$= \frac{(100+800)}{2}(0.45-0.15)$$

$$= 135\text{kJ}$$

$$\boxed{W_{b,out} = 135\text{kJ}}$$

Step 4 of 5

(b) If there were no spring, we would have a constant process at $P = 100kPa$. The work done during this process is

$$W_{b,out,no\ spring} = \int_1^2 PdV$$

$$= P(V_2 - V_1)$$

$$= 100(0.45-0.15)$$

$$= 30\text{kJ}$$

Step 5 of 5

Thus,

$$W_{spring} = W_b - W_{b,no\ spring}$$

$$= 135 - 30$$

$$= 105\text{kJ}$$

$$\boxed{W_{spring} = 105\text{kJ}}$$

Question: 5.101P

A mass of 5 kg of saturated liquid–vapor mixture of water is contained in a piston-cylinder device at 125 kPa. Initially, 2 kg of the water is in the liquid phase and the rest is in the vapor phase. Heat is now transferred to the water, and the piston, which is resting on a set of stops, starts moving when the pressure inside reaches 300 kPa. Heat transfer continues until the total volume increases by 20 percent. Determine (*a*) the initial and final temperatures, (*b*) the mass of liquid water when the piston first starts moving, and (*c*) the work done during this process. Also, show the process on a P-v diagram.

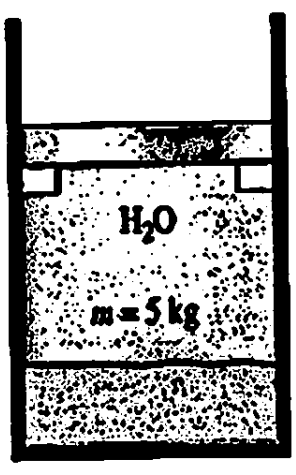

FIGURE P5–101

Step 1 of 9

Given

Mass of saturated vapor liquid $m = 5$ kg

Initial mass of liquid water $m_f = 2$ kg

Initial mass of vapor $m_g = 3$ kg

Initial pressure $P_1 = 125$ kPa

Final pressure $P_3 = 300$ kPa

Volume $V_1 = V_2, V_3 = 1.2V_1$

Step 2 of 9

(a)

At $P_1 = 125$ kPa from saturated water tables

$v_f = 0.001048\ \text{m}^3/\text{kg}$

$v_g = 1.375\ \text{m}^3/\text{kg}$

$T_{sat} = 105.97^0\text{C}$

Since initial state is in wet region then the initial temperature will be the saturation temperature at pressure $P_1 = 125$ kPa

$T_{sat} = T_1$

$\boxed{T_1 = 105.97^\circ\text{C}}$

Step 3 of 9

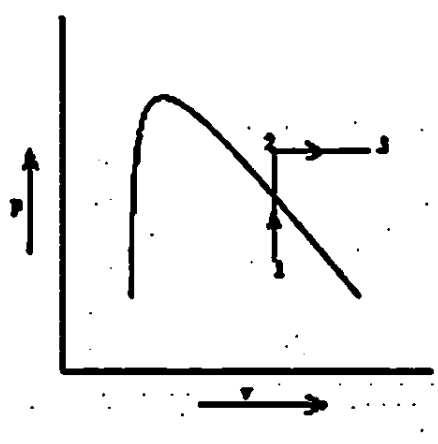
The initial volume is expressed as

$V_1 = m_f v_f + m_g v_g$

$V_1 = 2(0.001048) + 3(1.375)$

$V_1 = 4.127\ \text{m}^3$

Step 4 of 9



Piston final volume is

$V_3 = 1.2V_1$

$V_3 = 1.2(4.127)$

$V_3 = 4.95\ \text{m}^3$

Step 5 of 9

Step 6 of 9

Therefore the final specific volume will be

$$v_3 = \frac{V_3}{m}$$

$$= \frac{4.95}{5}$$

$v_3 = 0.99\ \text{m}^3/\text{kg}$

Step 7 of 9

So at $P_3 = 300$ kPa and $v_3 = 0.99\ \text{m}^3/\text{kg}$ from superheated water tables by using interpolation

$$T_3 = 300 + (400 - 300)\left(\frac{0.99 - 0.87535}{1.03155 - 0.87535}\right)$$

$\boxed{T_3 = 373.4^0\text{C}}$

Step 8 of 9

(b) The mass of liquid water

When the piston first starts moving $P_2 = 300$ kPa, $V_1 = V_2$, The mass of liquid will be converted into gaseous phase

$\boxed{m_f = 0\ \text{kg}}$

Step 9 of 9

(c) The work done during the process

No work is done during process 1-2 since it's a constant volume process. The pressure remains constant during process 2-3

Therefore the work done in constant pressure process is

$W = W_{1-2} + W_{2-3}$

$W = 0 + W_{2-3}$

$W = \int P dV$

$W = P_2(V_3 - V_2)$

$W = 300(4.95 - 4.127)$

$\boxed{W = 247\ \text{kJ}}$

Question: 5.102P

A spherical balloon contains 7 lbm of air at 30 psia and 600 R. The balloon material is such that the pressure inside is always proportional to the square of the diameter. Determine the work done when the volume of the balloon doubles as a result of heat transfer.

Step 1 of 7

Given:

Mass of the air $m = 7\text{lbm}$

Initially pressure $P_1 = 30\text{psia}$

Initially temperature $T_1 = 600\text{R}$

Pressure is directly proportional to square of the diameter $P \propto D^2$

Step 2 of 7

Step 3 of 7

From the molar mass, gas constant and critical points properties
For air

The gas constant of air is $\text{R} = 0.06855 \dfrac{\text{Btu}}{\text{lbm} \cdot \text{R}}$

The dependence of pressure on volume can be expressed as

$$V = \frac{1}{6}\pi D^3$$

$$\Rightarrow D = \left(\frac{6V}{\pi}\right)^{1/3}$$

Step 4 of 7

$$P \propto D^2$$

$$\Rightarrow P = kD^2$$

$$= k\left(\frac{6V}{\pi}\right)^{2/3}$$

$$k\left(\frac{6}{\pi}\right)^{2/3} = P_1V_1^{-2/3} = P_2V_2^{-2/3}$$

Also,

$$\frac{P_2}{P_1} = \left(\frac{V_2}{V_1}\right)^{2/3}$$

$$= 2^{2/3}$$

$$= 1.587$$

Step 5 of 7

And
From the ideal gas relationship ,we know that

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$

$$\Rightarrow T_2 = \frac{P_2V_2}{P_1V_1}T_1$$

$$= 1.587 \times 2 \times (600\text{R})$$

$$= 1904.4\text{R}$$

Step 6 of 7

Thus,
The work done in this process is

$$W = \int_1^2 P\,dV$$

$$W = \int C\left(\frac{6V}{\pi}\right)^{\frac{2}{3}} dV$$

$$W = \int_1^2 C\left(\frac{6V}{\pi}\right)^{\frac{2}{3}} dV$$

$$W = C\left(\frac{6}{\pi}\right)^{\frac{2}{3}} \frac{\left(V_2^{5/3} - V_1^{5/3}\right)}{\frac{5}{3}}$$

$$W = C\left(\frac{6}{\pi}\right)^{\frac{2}{3}} \times \frac{3}{5} \times \left(V_2^{5/3} - V_1^{5/3}\right)$$

$$W = \left(\frac{6}{\pi}\right)^{\frac{2}{3}} \times \frac{3}{5} \times \left(CV_2^{5/3} - CV_1^{5/3}\right)$$

$$W = \left(\frac{6}{\pi}\right)^{\frac{2}{3}} \times \frac{3}{5} \times \left(\frac{P_2}{\left(\frac{6}{\pi}\right)^{2/3}(V_2)^{\frac{2}{3}}} V_2^{5/3} - \frac{P_1}{\left(\frac{6}{\pi}\right)^{2/3}(V_1)^{\frac{2}{3}}} V_1^{5/3}\right)$$

$$W = \frac{3}{5} \times (P_2V_2 - P_1V_1)$$

$$W = \frac{3}{5} \times mR(T_2 - T_1)$$

Step 7 of 7

Substitute the values in above expression

$$W_b = \frac{3}{5}(7)(0.06855)(1904.4 - 600)$$

$$= 375.55\text{Btu}$$

$$\boxed{W_b = 375.55\text{Btu}}$$

Question: 5.103P

Reconsider Prob. 5-102E. Using the integration feature of the EES software, determine the work done. Compare the result with your "hand-calculated" result.

Step 1 of 6

Given:
Given:
Mass of the air $m = 7\,\text{lbm}$
Initially pressure $P_1 = 30\,\text{psia}$
Initially temperature $T_1 = 600\text{R}$
Pressure is directly proportional to square of the diameter $P \propto D^2$

Step 2 of 6

The problem is solved using EES, and the solution is given below.

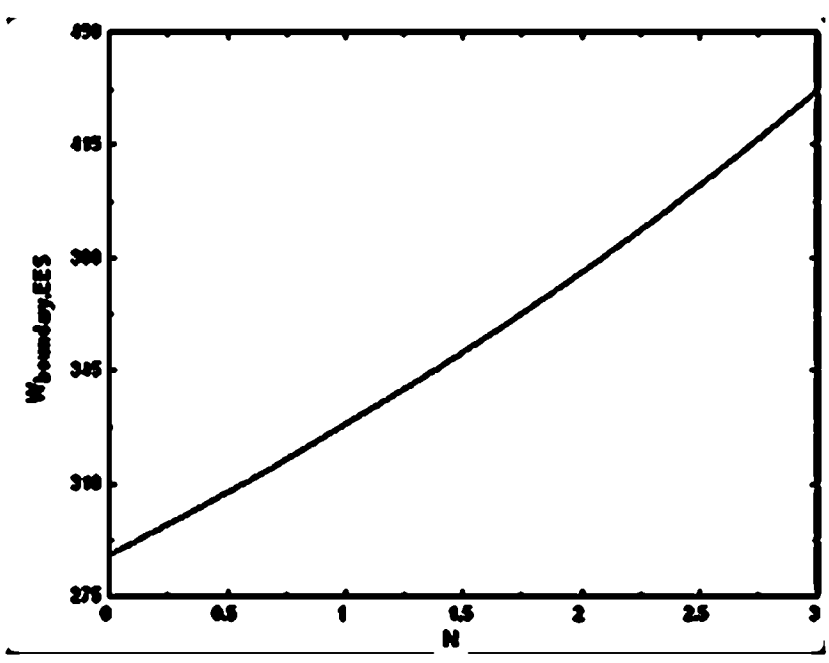
```
"N=2"
m=7 [lbm]
P_1=30 [psia]
T_1=600 [R]
V_2=2*V_1
R=R_u/molarmass(air)
R=1545 [ft-lbf/lbmol-R]
P_1*Convert(psia,lbf/ft^2)*V_1=m*R*T_1
V_1=4*pi*(D_1/2)^3/3"[ft^3]"
C=P_1/D_1^N
(D_1/D_2)^3=V_1/V_2
P_2=C*D_2^N"[psia]"
P_2*Convert(psia,lbf/ft^2)*V_2=m*R*T_2
```

Step 3 of 6

```
P=C*D^N*Convert(psia,lbf/ft^2)"[ft^2]"
V=4*pi*(D/2)^3/3"[ft^3]"
W_boundary_EES=integral(P,V,V_1,V_2)*convert(ft-lbf,Btu)"[Btu]"
W_boundary_HAND=pi*C/(2*(N+3))*(D_2^(N+3)-D_1^(N+3))*convert(ft-lbf,Btu)*convert(ft^2,in^2)"[Btu]"
```

Step 4 of 6

Run the parameter table on menu bar.
Then select the N and $W_{boundary,EES}$ then click ok



Step 5 of 6

Solution table:

1..10	N	$W_{boundary,HAND}$
Run 1	0	287.9
Run 2	0.3333	300.6
Run 3	0.6667	314
Run 4	1	328.1
Run 5	1.333	343.1
Run 6	1.667	359.9
Run 7	2	375.6
Run 8	2.333	393.3
Run 9	2.667	412
Run 10	3	431.8

Step 6 of 6

Graph between the N and $W_{boundary,EES}$

Question: 5.104P

A mass of 12 kg of saturated refrigerant-134a vapor is contained in a piston-cylinder device at 240 kPa. Now 300 kJ of heat is transferred to the refrigerant at constant pressure while a 110-V source supplies current to a resistor within the cylinder for 6 min. Determine the current supplied if the final temperature is 70°C. Also, show the process on a *T*- v diagram with respect to the saturation lines.

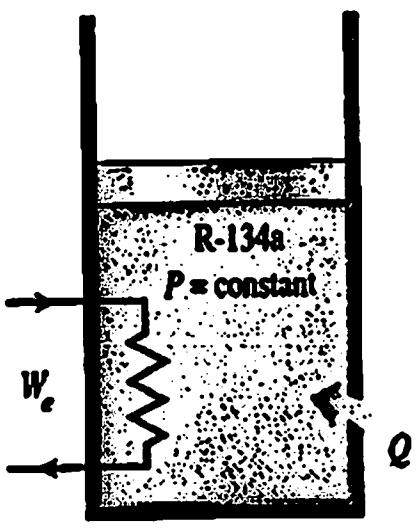


FIGURE P5–104

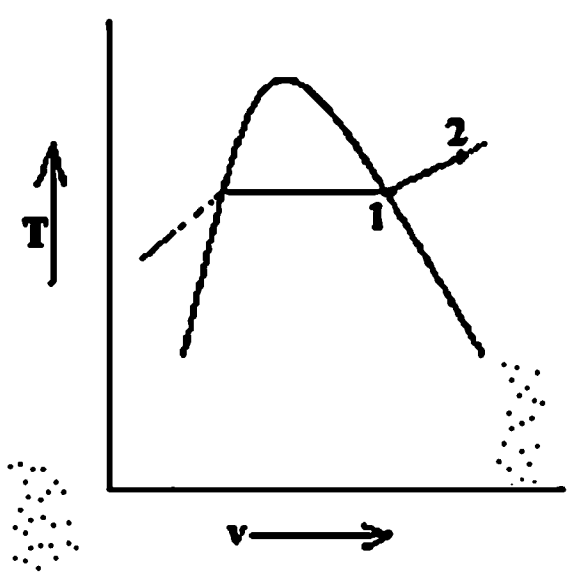
Step 1 of 5

Given

Mass of saturated vapor refrigerant-134a $m = 12\ \text{kg}$

Saturated vapor in the cylinder $P_1 = 240\ \text{kPa}$



Amount of heat transferred to the refrigerant $Q_{in} = 300\ \text{kJ}$

Voltage supplied $V = 110\ \text{V}$

Voltage supplied for a period of $t = 6\ \text{min}$

Final temperature $T_2 = 70°\text{C}$

Step 2 of 5

Step 3 of 5

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$Q_{in} + W_{in} = \Delta H$

$Q_{in} + VI\Delta t = m(h_2 - h_1)$ (Since $W_{in} = VI\Delta t$)

Step 4 of 5

At pressure $P_1 = 240\ \text{kPa}$ from saturated R-134a tables

$h_1 = h_g = 247.28\ \text{kJ/kg}$

Since the process is constant pressure process

At $P_2 = P_1 = 240\ \text{kPa}$ and $T_2 = 70°\text{C}$ from superheated R-134a tables

$h_2 = 314.51\ \text{kJ/kg}$

Step 5 of 5

Substituting known values in the above equation

$Q_{in} + VI\Delta t = m(h_2 - h_1)$

$300 \times 1000 + 110I(6 \times 60) = 12(314.51 - 247.28) \times 1000$

$300000 + 39600I = 806760$

$39600I = 506760$

$I = 12.796\ \text{A}$

Therefore the current supplied is

$\boxed{I = 12.796\ \text{A}}$

Question:

5.105P

Saturated water vapor at 200°C is condensed to a saturated liquid at 50°C in a spring-loaded piston-cylinder device. Determine the heat transfer for this process, in kJ/kg.

Step 1 of 6

Given:

Initially temperature $T_1 = 200°C$

Final temperature $T_2 = 50°C$

Step 2 of 6

P-v Daigram:

Question:

Saturated water vapor at 200°C is condensed to a saturated liquid at 50°C in a spring-loaded piston-cylinder device. Determine the heat transfer for this process, in kJ/kg.

Step 1 of 6

Given:

Initially temperature $T_1 = 200°C$

Final temperature $T_2 = 50°C$

Step 2 of 6

P-v Daigram:

$v_2 = v_f = 0.001012 \frac{m^3}{kg}$

$u_2 = u_g = 209.33 \frac{kJ}{kg}$

From the ideal gas constants specific heat properties of various gases
For steam

$C_v = 1.4108 \frac{kJ}{kg \cdot K}$

Step 5 of 6

The energy balance for this stationary system can be expressed as

$Q_{in} + W_{b,out} = \Delta U$

Boundary work will be the area under the process 1-2 projected on volume axis.

$$W_{b,out} = \frac{1}{2}(P_1 + P_2)(v_2 - v_1)$$
$$= \frac{1}{2}(1554.9 + 12.352)(0.001012 - 0.12721)$$
$$= -98.892 \frac{kJ}{kg}$$

Step 6 of 6

Heat transferred is

$$Q_{in} = \Delta U - W_{b,out}$$
$$= C_v (T_2 - T_1) - (-98.892)$$
$$= 1.4108(50 - 200) + 98.892$$
$$= -112.728 \frac{kJ}{kg}$$

$$\boxed{Q_{in} = -112.728 \frac{kJ}{kg}}$$

Question: 5.106P

A piston-cylinder device contains helium gas initially at 150 kPa, 20°C, and 0.5 m3. The helium is now compressed in a polytropic process (PV^n = constant) to 400 kPa and 140°C. Determine the heat loss or gain during this process.

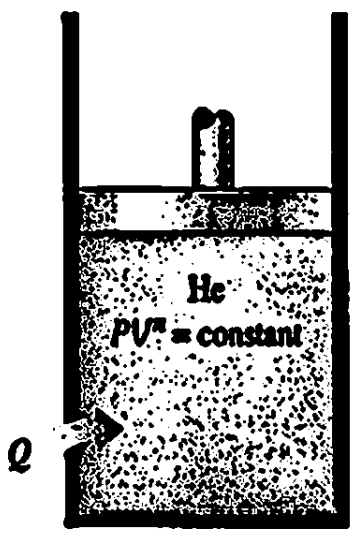


FIGURE P5–106

Step 1 of 8

Given
Piston cylinder contains Helium
Initial pressure $P_1 = 150\ \text{kPa}$
Initial temperature $T_1 = 20°\text{C} = 293\text{K}$
Initial volume $V_1 = 0.5\ \text{m}^3$
Final pressure $P_2 = 400\ \text{kPa}$
Final temperature $T_2 = 140°\text{C} = 413\text{K}$

Step 2 of 8

From table ideal gas specific heats of common gases
Properties of helium are
$R = 2.0769\ \text{kPa.m}^3/\text{kg.K}$
$c_v = 3.1156\ \text{kJ/kg.K}$

Step 3 of 8

The boundary work input for a polytropic process is expressed as

$$W_{b,in} = \int_1^2 P dV$$
$$= \frac{P_2V_2 - P_1V_1}{n-1}$$
$$W_{b,in} = \frac{mR(T_2 - T_1)}{n-1}$$

Step 4 of 8

The mass of helium is determined by

$$m = \frac{P_1V_1}{RT_1}$$
$$m = \frac{(150)(0.5)}{(2.0769)(293)}$$
$$m = 0.123\ \text{kg}$$

Step 5 of 8

The volume after compression is determined by using Ideal gas relation

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$
$$\frac{(150)\times 0.5}{293} = \frac{(400)\times V_2}{413}$$
$$V_2 = 0.264\ \text{m}^3$$

Step 6 of 8

The power index n is determined by polytropic process

$$P_1V_1^n = P_2V_2^n$$
$$\frac{P_1}{P_2} = \left(\frac{V_2}{V_1}\right)^n$$
$$\frac{150}{400} = \left(\frac{0.264}{0.5}\right)^n$$
$$0.375 = 0.528^n$$

Taking logarithm on both sides

$$\ln 0.375 = n \times \ln 0.528$$
$$n = 1.536$$

Step 7 of 8

Substituting all the known values in above work relation
The boundary work is obtained as

$$W_{b,in} = \frac{mR(T_2 - T_1)}{n-1}$$
$$W_{b,in} = \frac{(0.123)(2.0769)(413-293)}{1.536-1}$$
$$W_{b,in} = 57.19\ \text{kJ}$$

Step 8 of 8

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$
Therefore

$$Q_{in} + W_{in} = \Delta U$$
$$Q_{in} + W_{in} = m(u_2 - u_1)$$
$$Q_{in} + W_{in} = mc_v(T_2 - T_1)$$
$$Q_{in} + 57.19 = 0.123(3.1156)(413-293)$$
$$Q_{in} + 57.19 = 45.986$$
$$Q_{in} = -11.204\ \text{kJ}$$

Therefore the heat transfer is

$$\boxed{Q_{in} = -11.2\ \text{kJ}}$$

The negative symbol indicates that heat loss from the system.

Question: 5.107P

Nitrogen gas is expanded in a polytropic process with $n = 1.45$ from 2MPa and 1200 K to 200 kPa in a piston-cylinder device. How much work is produced and heat is transferred during this expansion process, in kJ/kg?

Step 1 of 4

Obtain the properties of nitrogen from the ideal gas specific heat of various common gases

$$R = 0.2968\,\text{kJ/kg}\cdot\text{K}$$

$$C_v = 0.743\ \text{kJ/kg}\cdot\text{K}$$

Here, R is the universal gas constant of nitrogen and C_v is the specific heat at constant volume of nitrogen.

Step 2 of 4

Calculate the work done by using the boundary work relation for the polytropic process of an ideal gas.

$$w_{b,out} = \frac{RT_1}{1-n}\left[\left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}} - 1\right]$$

Here, $W_{b,out}$ is the work done, T_1 is the initial temperature, n is the polytropic index, P_2 is the final temperature and P_1 is the initial temperature.

Substitute $0.2968\ \text{kJ/kg}\cdot\text{K}$ for R, $1200\,\text{K}$ for T_1, 1.45 for n, $200\,\text{kPa}$ for P_2 and $2000\,\text{kPa}$ for P_1.

$$w_{b,out} = \frac{(0.2968)(1200)}{1-1.45}\left[\left(\frac{200}{2000}\right)^{\frac{1.45-1}{1.45}} - 1\right]$$
$$= 404.13\,\text{kJ/kg}$$

Therefore, the work produced is $\boxed{404.13\,\text{kJ/kg}}$.

Step 3 of 4

Calculate the temperature at the final state by using the equation,

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}$$

Substitute $1200\,\text{K}$ for T_1, $200\,\text{kPa}$ for P_2 and $2000\,\text{kPa}$ for P_1.

$$T_2 = 1200\times\left(\frac{200}{2000}\right)^{\frac{1.45-1}{1.45}}$$
$$= 587.275\,\text{K}$$

Step 4 of 4

Calculate the heat transferred by using the energy balance for this system.

$$q_{in} = w_{b,out} + C_v\left(T_2 - T_1\right)$$

Substitute $404.13\,\text{kJ/kg}$ for $w_{b,out}$, $0.743\,\text{kJ/kg}\cdot\text{K}$ for C_v, $587.275\,\text{K}$ for T_2 and $1200\,\text{K}$ for T_1.

$$q_{in} = 404.13 + (0.743)(587.275 - 1200)$$
$$= -51.125\,\text{kJ/kg}$$

Therefore, the amount of heat transferred is $\boxed{51.125\,\text{kJ/kg}}$.

Question: 5.108P

A frictionless piston-cylinder device and a rigid tank initially contain 12 kg of an ideal gas each at the same temperature, pressure, and volume. It is desired to raise the temperatures of both systems by 15°C. Determine the amount of extra heat that must be supplied to the gas in the cylinder which is maintained at constant pressure to achieve this result. Assume the molar mass of the gas is 25.

Step 1 of 3

Given

Mass of ideal gas $m = 12$ kg

Change in temperature $\Delta t = 15°C$

Molar mass of the gas $M = 25$

Step 2 of 3

The gas constant for the ideal gas is determined by

$$R = \frac{R_u}{M}$$

$$= \frac{8.314}{25}$$

$$R = 0.33256 \text{ kJ/kg.K}$$

Step 3 of 3

The process in the piston cylinder is constant pressure process and the process in rigid tank is constant volume process

If there is no work interaction the heat transfer to the cylinder is constant enthalpy process and the heat transfer to the rigid tank is constant internal energy process

Therefore the extra amount of heat must be supplied to the gas in the cylinder is determined by

$$Q_{in} = \Delta H - \Delta U$$

$$Q_{in} = mc_p\Delta T - mc_v\Delta T$$

$$Q_{in} = m\Delta T\left(c_p - c_v\right) \qquad \text{(Since } R = c_p - c_v\text{)}$$

$$Q_{in} = mR\Delta T$$

$$Q_{in} = (12)(0.33256)(15)$$

$$\boxed{Q_{in} = 59.86 \text{ kJ}}$$

Question: 5.109P

A passive solar house that is losing heat to the outdoors at an average rate of 50,000 kJ/h is maintained at 22°C at all times during a winter night for 10 h. The house is to be heated by 50 glass containers each containing 20 L of water that is heated to 80°C during the day by absorbing solar energy. A thermostat-controlled 15-kW back-up electric resistance heater turns on whenever necessary to keep the house at 22°C.

(*a*) How long did the electric heating system run that night?

(*b*) How long would the electric heater run that night if the house incorporated no solar heating?

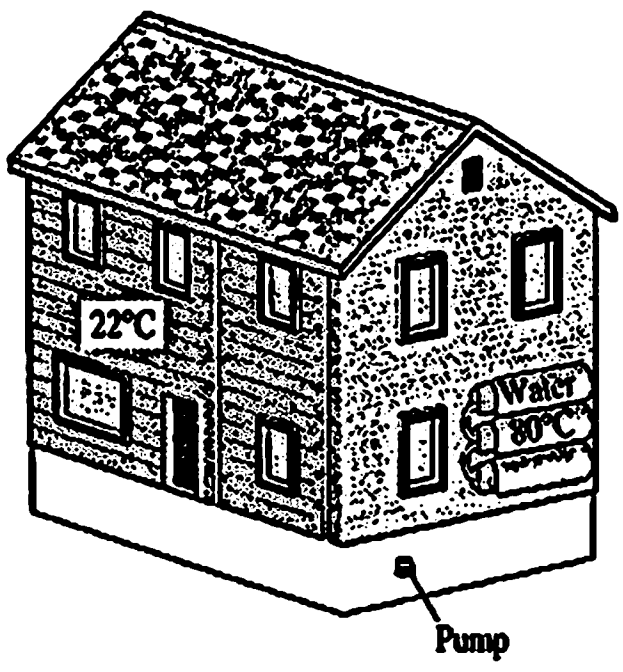

FIGURE P5–109

Step 1 of 4

Given

The amount of heat loss from the solar house $Q_{out} = 50,000\ \text{kJ/h}$

The temperature maintained in the house $T_{room} = 22°\text{C}$

Winter night duration $t = 10\ \text{h}$

Volume contained in glass container $V = 20\ \text{L} = 20 \times \frac{1}{1000}\ \text{m}^3$

Number of glass containers $n = 50$

Final temperature $T_2 = 80°\text{C}$

The capacity of heater is 15kW

Step 2 of 4

Density of water $\rho = 1000\ \text{kg/m}^3$

Specific heat of water $c = 4.18\ \text{kJ/kg.°C}$

(a) Time taken for the electric heating system run that night

The total mass of system

$$m_{water} = n\rho V$$

$$= 50 \times 1000 \times 20 \times \frac{1}{1000}$$

$$m_{water} = 1000\ \text{kg}$$

Step 3 of 4

Considering the house as the system

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$$W_{in} - Q_{out} = \Delta U$$

$$W_{in} - Q_{out} = m(u_2 - u_1)$$

$$W_{in} - Q_{out} = mc(T_2 - T_1)$$

$$\dot{W}_{in} \times t - \dot{Q}_{out} \times t = mc(T_2 - T_1)$$

$$15 \times \Delta t - 50000 \times 10 = -1000 \times 4.18 \times (80 - 22)$$

$$15 \times \Delta t - 500000 = -242440$$

$$15 \times \Delta t = 257560$$

$$\Delta t = 17170.66\ \text{s}$$

$$= \frac{17170.66}{60 \times 60}$$

$$= 4.77h$$

Therefore the electric heating system run that night is

$$\boxed{\Delta t = 4.77h}$$

Step 4 of 4

(b)

If there is no solar heating there will be no water supply then the energy equation is written as

$$W_{in} - Q_{out} = \Delta U$$

$$\dot{W}_{in} \times t - \dot{Q}_{out} \times t = 0$$

$$15 \times \Delta t - 50000 \times 10 = 0$$

$$\Delta t = 33333.33\ \text{s}$$

$$= \frac{33333.33}{60 \times 60}$$

$$= 9.26\ \text{h}$$

Therefore the electric heater run that night if the house incorporated no solar heating is

$$\boxed{\Delta t = 9.26\ \text{h}}$$

Question:

5.110P

An 1800-W electric resistance heating element is immersed in 40 kg of water initially at 20°C. Determine how long it will take for this heater to raise the water temperature to 80°C.

Step 1 of 3

Given

Mass of water $m = 40\ \text{kg}$

Initial temperature of water $T_1 = 20°\text{C}$

Final temperature of water $T_2 = 80°\text{C}$

Capacity of electric heater $\dot{W} = 1800\ \text{W} = 1.8\ \text{kW}$

Step 2 of 3

Density of water $\rho = 1000\ \text{kg/m}^3$

Specific heat of water $c = 4.18\ \text{kJ/kg.°C}$

Applying energy balance to the system

$$E_{in} - E_{out} = \Delta E_{system}$$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$$W_{in} - Q_{out} = \Delta U$$

$$W_{in} - Q_{out} = m(u_2 - u_1)$$

$$W_{in} - Q_{out} = mc(T_2 - T_1)$$

Step 3 of 3

Assuming there is no heat loss during heating $Q_{out} = 0$

$$W_{in} - Q_{out} = mc(T_2 - T_1)$$

$$\dot{W}\Delta t - Q_{out} = mc(T_2 - T_1)$$

$$1.8\Delta t - 0 = 40(4.18)(80 - 20)$$

$$1.8\Delta t = 10032$$

$$\Delta t = 5573.33\ s$$

$$= \frac{5573.33}{60 \times 60}$$

$$= 1.548\ \text{h}$$

Therefore the time taken for the heater to raise the temperature is

$$\boxed{\Delta t = 1.548\ \text{h}}$$

Question: 5.111P

One ton (1000 kg) of liquid water at 50°C is brought into a well-insulated and well-sealed 4-m × 5-m × 6-m room initially at 15°C and 95 kPa. Assuming constant specific heats for both air and water at room temperature, determine the final equilibrium temperature in the room.

Step 1 of 5

Given:

Mass of liquid water $m = 1000\,\text{kg}$

Temperature of water $T_1 = 50^\circ\text{C}$

Dimension of the room $V = 4\text{m} \times 5\text{m} \times 6\text{m}$

Initially temperature of air $T_{air} = 15^\circ\text{C}$

Pressure of air $P_1 = 95\,\text{kPa}$

Step 2 of 5

From the molar mass gas constant and critical properties

The gas constant of air is

$$R = 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

The specific heat of water at room temperature is

From the properties of liquids and solids gases

For water

$$C = 4.18\frac{\text{kJ}}{\text{kg}\cdot^\circ\text{C}}$$

Step 3 of 5

The volume and the mass of the air in the room are

$$V = 4\times5\times6$$
$$= 120\text{m}^3$$

We know that

Ideal gas equation

$$P_1V_1 = mRT_1$$
$$\Rightarrow m_{air} = \frac{P_1V_1}{RT_1}$$
$$= \frac{(95)\times(120)}{(0.2870)\times(288)}$$
$$= 137.921\text{kg}$$

Step 4 of 5

The energy balance can be written as

$$E_{in} - E_{out} = \Delta E_{system}$$

Since well insulated and sealed so amount of heat transfer is zero.

$$0 = \Delta U = (\Delta U)_{water} + (\Delta U)_{air}$$
$$\left[mC(T_2 - T_1)\right]_{water} + \left[mC_v(T_2 - T_1)\right]_{air} = 0$$
$$\left[mC(T_f - T_1)\right]_{water} + \left[mC_v(T_f - T_1)\right]_{air} = 0$$

Where T_f is the final equilibrium temperature in the room.

Step 5 of 5

Substituting

$$(1000)(4.180)(T_f - 50) + (137.92)(0.718)(T_f - 15) = 0$$

Solving for T_f, gives

$$T_f = 49.19^\circ\text{C}$$

$$\boxed{T_f = 49.19^\circ\text{C}}$$

Question: 5.112P

A 4-m × 5-m × 6-m room is to be heated by one ton (1000 kg) of liquid water contained in a tank that is placed in the room. The room is losing heat to the outside at an average rate of 8000 kJ/h. The room is initially at 20°C and 100 kPa and is maintained at an average temperature of 20°C at all times. If the hot water is to meet the heating requirements of this room for a 24-h period, determine the minimum temperature of the water when it is first brought into the room. Assume constant specific heats for both air and water at room temperature.

Step 1 of 3

Given

Mass of water $m_w = 1000$ kg

Initial temperature of room $T_1 = 20°C$

The amount of heat lost from the room $\dot{Q}_{out} = 8000$ kJ/h

Initial temperature of air $T_{air} = 20^0$ C

Initial pressure of air $P_{air} = 100$ kPa

Volume of the room $V = 4 \times 5 \times 6 = 120$ m^3

Final equilibrium temperature of air and water $T_2 = 20^0$ C

Step 2 of 3

From properties table

Specific heat of water $c = 4.18$ kJ/kg.°C

The heat is lost for 24 hr from the room, so heat lost during that period is determined by

$$Q_{out} = \dot{Q}_{out} \times t$$
$$= 8000 \times 24$$
$$Q_{out} = 192,000 \text{ kJ}$$

Step 3 of 3

Applying energy balance to the room and water as the system

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

And there in work transfer the energy balance of the system is

$$-Q_{out} = \Delta U$$
$$-Q_{out} = \left[mc(T_2 - T_1)\right]_{water} + \left[mc(T_2 - T_1)\right]_{air}$$
$$-Q_{out} = \left[mc(T_2 - T_1)\right]_{water} + 0$$
$$-192000 = \left[1000 \times (4.18) \times (20 - T_1)\right]$$
$$-45.933 = 20 - T_1$$
$$T_1 = 65.933^0 C$$

Therefore the minimum (initial) temperature of the water when it is first brought into the room

$$\boxed{T_1 = 65.933°C}$$

Question: 5.113P

The energy content of a certain food is to be determined in a bomb calorimeter that contains 3 kg of water by burning a 2-g sample of it in the presence of 100 g of air in the reaction chamber. If the water temperature rises by 3.2°C when equilibrium is established, determine the energy content of the food, in kJ/kg, by neglecting the thermal energy stored in the reaction chamber and the energy supplied by the mixer. What is a rough estimate of the error involved in neglecting the thermal energy stored in the reaction chamber?

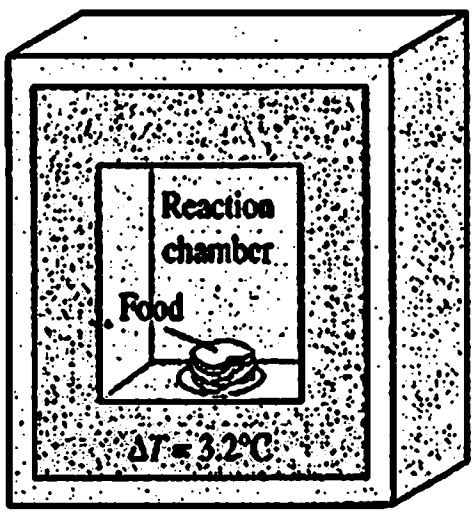

FIGURE P5–113

Step 1 of 4

Given

Mass of water $m_w = 3\,\text{kg}$

Temperature rise of water $\Delta T = 3.2°\text{C}$

Mass of sample food $m = 2\,\text{g}$

Mass of air $m_{air} = 100\,\text{g}$

Step 2 of 4

From properties table

Specific heat of water $c = 4.18\,\text{kJ/kg.°C}$

Specific heat of air $c = 0.718\,\text{kJ/kg.°C}$

Gas constant of air $R = 0.287\,\text{kJ/kg.K}$

Step 3 of 4

The chemical energy produced during the combustion of the sample is transferred to the water as heat. The energy content of the food is simply the heat transferred to the water.

Considering the water as our system,

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$Q_{in} = \Delta U$ As there in no work involved

$$Q_{in} = \left[mc(T_2 - T_1)\right]_{water}$$

Therefore

$$Q_{in} = \left[3(4.18)(3.2)\right]_{water}$$

$$Q_{in} = 40.13\,\text{kJ}$$

For 2-g sample the energy content of the food is

$$q_{in} = \frac{40.13}{2\,\text{g}}\left(\frac{1000\,\text{g}}{1\,\text{kg}}\right)$$

$$\boxed{q_{in} = 20065\,\text{kJ/kg}}$$

Step 4 of 4

We can estimate the error by considering air as the working medium where heat transfer occurred

$$Q_{in} = \left[mc(T_2 - T_1)\right]_{air}$$

$$Q_{in} = \left[\frac{100\,\text{g}}{1000\,\text{kg}} \times (0.718) \times (3.2)\right]_{air}$$

$$Q_{in} = 0.23\,\text{kJ}$$

Internal change of air $(Q_{in} = 0.23\,\text{kJ})$ is very much less than the internal energy change of water $(Q_{in} = 40.13\,\text{kJ})$ so we can neglect the internal energy change of air

Question:

5.114P

A 68-kg man whose average body temperature is 39°C drinks 1 L of cold water at 3°C in an effort to cool down. Taking the average specific heat of the human body to be 3.6 kJ/kg·°C, determine the drop in the average body temperature of this person under the influence of this cold water.

Step 1 of 4

Given

Mass of man $m = 68\ \text{kg}$

The average body temperature of the man $T_{man} = 39°\text{C}$

The temperature of the cold water $T_{cold} = 3°\text{C}$

The volume of the cold water $V = 1\ \text{L} = 1 \times \frac{1}{1000}\ \text{m}^3$

Average specific heat of the human body $c = 3.6\text{kJ/kg.}^0\text{C}$

Step 2 of 4

From properties of water

Specific heat of water $c = 4.18\ \text{kJ/kg.°C}$

Density of water $\rho = 1000\text{kg/m}^3$

The total mass of water

$$m_{water} = \rho V$$

$$= 1000 \times 1 \times \frac{1}{1000}$$

$$m_{water} = 1\ \text{kg}$$

Step 3 of 4

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

Consider body of the man as system, where there is no work and heat transfer involved in the system, only there is a change in the internal energy of the system due to transfer of temperature due to drinking cold water

Therefore

$$(\Delta U)_{water} + (\Delta U)_{man} = 0$$

$$\left[mc(T_2 - T_1)\right]_{water} + \left[mc(T_2 - T_1)\right]_{man} = 0$$

$$\left[1 \times (4.18) \times (T_f - 3)\right]_{water} + \left[68 \times (3.6) \times (T_f - 39)\right]_{man} = 0$$

$$4.18T_f - 12.54 + 244.8T_f - 9547.2 = 0$$

$$248.98T_f - 9559.74 = 0$$

$$T_f = 38.4^0\text{C}$$

The final equilibrium temperature is

$$T_f = 38.4°\text{C}$$

Step 4 of 4

The drop in the average body temperature is

$$\Delta T = T_{man} - T_f$$

$$\Delta T = 39 - 38.4$$

$$= 0.6°\text{C}$$

$$\boxed{\Delta T = 0.6°\text{C}}$$

Question: 5.115P

A 0.3-L glass of water at 20°C is to be cooled with ice to 5°C. Determine how much ice needs to be added to the water, in grams, if the ice is at (*a*) 0°C and (*b*) -20°C. Also determine how much water would be needed if the cooling is to be done with cold water at 0°C. The melting temperature and the heat of fusion of ice at atmospheric pressure are 0°C and 333.7 kJ/kg, respectively, and the density of water is 1 kg/L.

Step 1 of 8

Loading solution. Please wait ...

Step 2 of 8

The specific heat of water at room temperature
From the properties of liquids solids and foods

$$c = 4.18 \frac{kJ}{kg \cdot K}$$

The specific heat of ice at about 0°C is

$$c_{ice} = 2.11 \frac{kJ}{kg \cdot K}$$

Step 3 of 8

(a) The mass of the water is

$$m_w = \rho V$$
$$= (1)(0.3)$$
$$= 0.3kg$$

Step 4 of 8

We take the ice and the water as our system, and disregard any heat and mass transfer. This is a reasonable assumption since the time period of the process is very short. Then the energy balance can be written as
Net energy transferby heat, work, and mass

=Change in internal, kinetic, potential, etc. energies

$$E_{in} - E_{out} = \Delta E_{system}$$

Since steady state system.

$$0 = \Delta U$$
$$0 = \Delta U_{ice} + \Delta U_{water}$$
$$\left[mc(0°C - T_1)_{solid} + mh_{if} + mc(T_2 - 0°C)_{liquid}\right]_{ice} + \left[mc(T_2 - T_1)\right]_{water} = 0$$

Step 5 of 8

Noting that $T_{1,ice} = 0°C$ and $T_2 = 5°C$

Substituting gives

$$m[0 + 333.7 + (4.18)(5-0)] + (0.3)(4.18)(5-20) = 0$$
$$m = 0.053kg$$
$$\boxed{m = 0.053kg}$$

Step 6 of 8

(b) When $T_{1,ice} = -20°C$ instead of 0°C,

$$\left[mc(0°C - T_1)_{solid} + mh_{if} + mc(T_2 - 0°C)_{liquid}\right]_{ice} + \left[mc(T_2 - T_1)\right]_{water} = 0$$

Substituting gives

$$m[(2.11)[0-(-20)] + 333.7 + (4.18)(5-0)] + (0.3)(4.18)(5-20) = 0$$
$$m = 0.0474kg$$
$$\boxed{m = 0.0474kg}$$

Step 7 of 8

Cooling with cold water can be handled the same way. All we need to do is replace the terms for ice by a term for cold water at 0°C

$$(\Delta U)_{cold\ water} + (\Delta U)_{water} = 0$$
$$\left[mc(T_2 - T_1)\right]_{cold\ water} + \left[mc(T_2 - T_1)\right]_{water} = 0$$

Step 8 of 8

Substituting,

$$\left[m_{cold\ water}(4.18)(5-0)\right] + (0.3)(4.18)(5-20) = 0$$

It gives

$$m_{Cold\ water} = 0.9kg$$
$$= 900gm$$
$$\boxed{m_{Cold\ water} = 900gm}$$

Question: 5.116P

Reconsider Prob. 5–115. Using EES (or other) software, investigate the effect of the initial temperature of the ice on the final mass required. Let the ice temperature vary from −26 to 0°C. Plot the mass of ice against the initial temperature of ice, and discuss the results.

Step 1 of 8

Given:

The density of water is $\rho_w = 1\ \frac{kg}{L}$

The melting temperature $T = 0°C$

The heat of fusion of ice at $L = 333.7\ \frac{kJ}{kg}$

Capacity of glass water $m = 0.3L$

Temperature of water $T_w = 20°C$

Temperature of the ice varies from $-26°C$ to $0°C$

Step 2 of 8

The problem is solved using EES, and the solution is given below.

```
"Knowns"
rho_water = 1 [kg/L]
V = 0.3 [L]
T_1_ice = 0 [C]
T_1 = 20 [C]
T_2 = 5 [C]
C_ice = 2.11 [kJ/kg-C]
C_water = 4.18 [kJ/kg-C]
h_if = 333.7 [kJ/kg]
T_1_ColdWater = 0 [C]
```

Step 3 of 8

```
"The mass of the water is:"
m_water = rho_water*V "[kg]"
"The system is the water plus the ice. Assume a short time period and neglect any heat
and mass transfer. The energy balance becomes:"
E_in - E_out = DELTAE_sys "[kJ]"
E_in = 0 "[kJ]"
E_out = 0"[kJ]"
```

Step 4 of 8

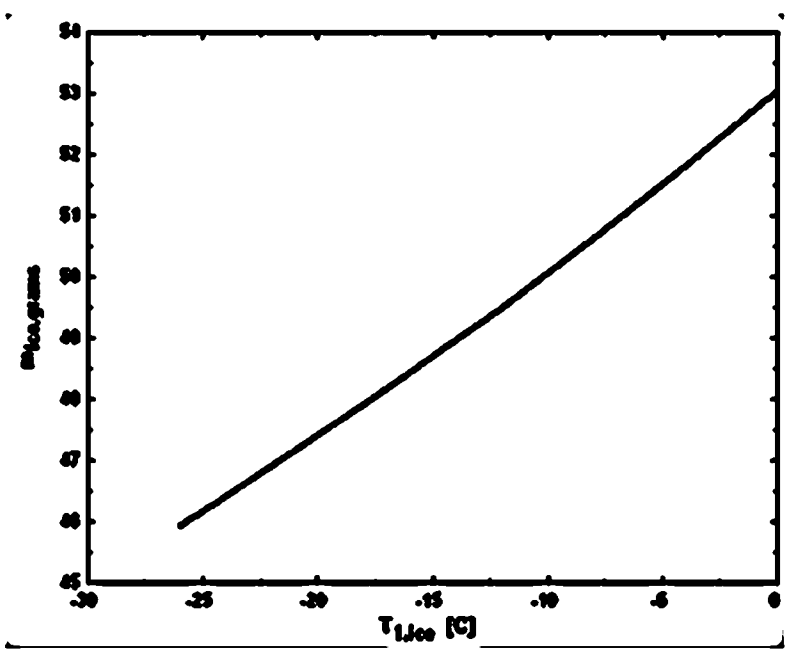
```
DELTAE_sys = DELTAU_water+DELTAU_ice"[kJ]"
DELTAU_water = m_water*C_water*(T_2 - T_1)"[kJ]"
DELTAU_ice = DELTAU_solid_ice+DELTAU_melted_ice"[kJ]"
DELTAU_solid_ice =m_ice*C_ice*(0-T_1_ice) + m_ice*h_if"[kJ]"
DELTAU_melted_ice=m_ice*C_water*(T_2 - 0)"[kJ]"
m_ice_grams=m_ice*convert(kg,g)"[g]"
```

Step 5 of 8

```
"Cooling with Cold Water:"
DELTAE_sys = DELTAU_water+DELTAU_ColdWater"[kJ]"
DELTAU_water = m_water*C_water*(T_2_ColdWater - T_1)"[kJ]"
DELTAU_ColdWater = m_ColdWater*C_water*(T_2_ColdWater -
T_1_ColdWater)"[kJ]"
m_ColdWater_grams=m_ColdWater*convert(kg,g)"[g]"
```

Step 6 of 8

select the table in menu bar then select the parameter table .
then select the T_1ice and m_ice grams then cleck ok.
Then run the table from the $-26°C$ to $0°C$



Step 7 of 8

Solution table:

D 1_14	$T_{1,ice}$ [C]	$m_{ice,grams}$
Run 1	-26	45.94
Run 2	-24	46.42
Run 3	-22	46.91
Run 4	-20	47.4
Run 5	-18	47.91
Run 6	-16	48.43
Run 7	-14	48.97
Run 8	-12	49.51
Run 9	-10	50.07
Run 10	-8	50.64
Run 11	-6	51.22
Run 12	-4	51.81
Run 13	-2	52.42
Run 14	0	53.05

Step 8 of 8

Graph between the T_1 ice and m_ice grams

Question: 5.117P

A rigid tank containing 0.4 m3 of air at 400 kPa and 30°C is connected by a valve to a piston-cylinder device with zero clearance. The mass of the piston is such that a pressure of 200 kPa is required to raise the piston. The valve is now opened slightly, and air is allowed to flow into the cylinder until the pressure in the tank drops to 200 kPa. During this process, heat is exchanged with the surroundings such that the entire air remains at 30°C at all times. Determine the heat transfer for this process.

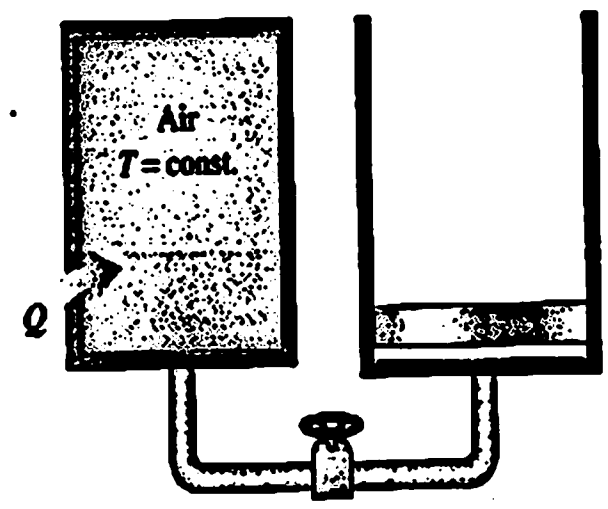


FIGURE P5–117

Step 1 of 2

Obtain the *R* value of air from the table A-1, "Molar mass, gas constant, and critical-point properties" in the textbook.

$$R = 0.287 \text{ kJ/kg.K}$$

Consider the tank and cylinder as a system.

Apply the energy balance equation of the system.

$$E_{in} - E_{out} = \Delta E_{system}$$

Neglect the kinetic and potential energy changes.

$$Q_{in} - W_{out} = \Delta U$$

Since, the temperature remains constant therefore, the internal energy is zero.

$$Q_{in} - W_{out} = \Delta U = 0$$
$$Q_{in} = W_{out}$$

Step 2 of 2

Calculate the volume by using Ideal gas relation.

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2}$$

Here, P_1 is the initial pressure, V_1 is the initial volume, T_1 is the initial temperature, P_2 is the final pressure, V_2 is the final volume, and T_2 is the final temperature.

Substitute 400 kPa for P_1, 0.4 m^3 for V_1, $(30+273)$ K for T_1, $(30+273)$ K for T_2, and 200 kPa for P_2.

$$\frac{400 \times 0.4}{(30+273)} = \frac{200 \times V_2}{(30+273)}$$
$$V_2 = 0.8 \text{ m}^3$$

Since, the pressure remains constant the boundary work for this process is expressed as

$$W_{b,out} = \int_1^2 P dV$$
$$= P_2 (V_2 - V_1)$$

Substitute 200 kPa for P_2, 0.4 m^3 for V_1, and 0.8 m^3 for V_2.

$$W_{b,out} = 200(0.8 - 0.4)$$
$$W_{b,out} = 80 \text{ kJ}$$

From energy balance of the system the heat transfer for this process is

$$Q_{in} = W_{out}$$
$$= 80 \text{ kJ}$$

Therefore, the heat transfer for this process is **80 kJ**.

Question: 5.118P

A well-insulated 4-m × 4-m × 5-m room initially at 10°C is heated by the radiator of a steam heating system. The radiator has a volume of 15 L and is filled with superheated vapor at 200 kPa and 200°C. At this moment both the inlet and the exit valves to the radiator are closed. A 120-W fan is used to distribute the air in the room. The pressure of the steam is observed to drop to 100 kPa after 30 min as a result of heat transfer to the room. Assuming constant specific heats for air at room temperature, determine the average temperature of air in 30 min. Assume the air pressure in the room remains constant at 100 kPa.

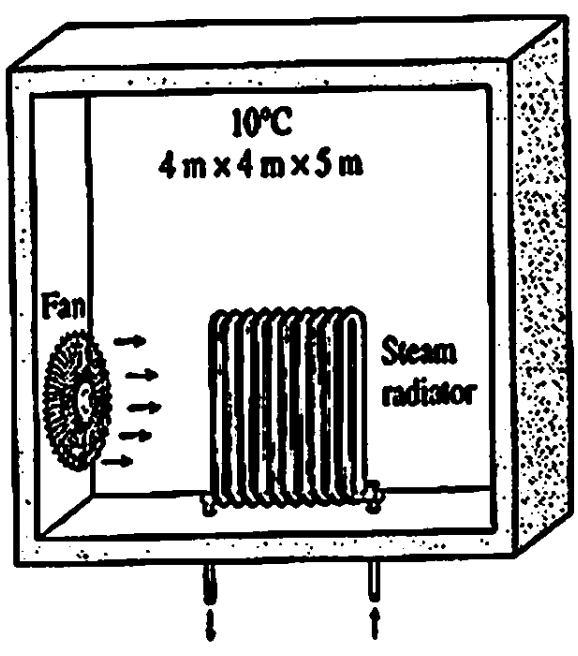

FIGURE P5–118

Step 1 of 9

Given

Volume of the room $V_{room} = 4\times4\times5 = 80\ \text{m}^3$

Initial temperature of the room $T_{room} = 10°\text{C}$

The volume of the radiator $V_{rad} = 15L$

The pressure of the super heated vapor in radiator $P_1 = 200\ \text{kPa}$

The temperature of the super heated vapor in radiator $T_1 = 200°\text{C}$

The final pressure of the vapor $P_2 = 200\ \text{kPa}$

The power of the fan used $\dot{W}_{fan} = 120\ \text{W}$

The time for the pressure to fall down $t = 30\ \text{min} = 30\times60\ \text{sec}$

Step 2 of 9

The gas constant of air is

$R = 0.287\ \text{kJ/kg.K}$

Specific heat of air

$c_v = 1.005\ \text{kJ/kg}$

Considering radiator alone as the system and both the inlet and exit valves to the radiator are closed

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$-Q_{out} = \Delta U = 0$

$-Q_{out} = m(u_2 - u_1)$

Step 3 of 9

At $P_1 = 200\ \text{kPa}$ and $T_1 = 200°\text{C}$ from superheated water tables

Specific volume $v_1 = 1.08049\ \text{m}^3/\text{kg}$

Internal energy $u_1 = 2654.6\ \text{kJ/kg}$

At $P_2 = 200\ \text{kPa}$ from saturated water tables

$v_f = 0.001043\ \text{m}^3/\text{kg}$

$v_g = 1.6941\ \text{m}^3/\text{kg}$

$u_f = 417.4\ \text{kJ/kg}$

$u_{fg} = 2088.2\ \text{kJ/kg}$

Step 4 of 9

Since $v_1 = v_2$

$v_1 = v_f + x_2(v_g - v_f)$

$1.08049 = 0.001043 + x_2(1.6941 - 0.001043)$

$x_2 = 0.6376$

Specific volume at state 2

$u_2 = u_f + xu_{fg}$

$u_2 = 417.4 + (0.6376)\times(2088.2)$

$u_2 = 1748.83\ \text{kJ/kg}$

Step 5 of 9

Mass of the steam is

$$m = \frac{V_{rad}}{v_1}$$

$$= \frac{0.015}{1.08049}$$

$m = 0.014\ \text{kg}$

Step 6 of 9

Substituting the energy relation

$-Q_{out} = m(u_2 - u_1)$

$-Q_{out} = (0.014)(1748.83 - 2654.6)$

$= -12.68\ \text{kJ}$

$Q_{out} = 12.68\ \text{kJ}$

Step 7 of 9

The mass of air in the room is determined by ideal gas relation

$$m_{air} = \frac{P_1V_1}{RT_1}$$

$$m_{air} = \frac{(100)(80)}{(0.287)(283)}$$

$m_{air} = 98.5\ \text{kg}$

Step 8 of 9

Consider room air as the system, the energy balance for a closed system is expressed as

$Q_{in} + W_{fan} - W_{out} = \Delta U$

$Q_{in} + W_{fan} = \Delta U + W_{out}$

Since the air pressure in the room remains constant

$Q_{in} + W_{fan} = mc_v(T_2 - T_1) + P(V_2 - V_1)$

$Q_{in} + W_{fan} = mc_v(T_2 - T_1) + mR(T_2 - T_1)$

$Q_{in} + W_{fan} = (T_2 - T_1)(c_v + R)$

$Q_{in} + W_{fan} = m(T_2 - T_1)c_p$

$Q_{in} + W_{fan} = mc_p(T_2 - T_1)$

Step 9 of 9

Here the heat rejected by the radiator will be gained by the air in the room

$Q_{in} = Q_{out} = 12.68\ \text{kJ}$

Then by using energy balance equation

$Q_{in} + W_{fan} = mc_p(T_2 - T_1)$

$Q_{in} + \dot{W}_{fan} \times t = mc_p(T_2 - T_1)$

$12.68 + 0.12\times30\times60 = 98.5\times(1.005)\times(T_2 - 10)$

$228.68 = 98.9925\times(T_2 - 10)$

$2.31007 = (T_2 - 10)$

$T_2 = 12.31007^0\text{C}$

The final air temperature of air in the room in 30 minutes is

$\boxed{T_2 = 12.31°\text{C}}$

Question:

5.119P

Consider a well-insulated horizontal rigid cylinder that is divided into two compartments by a piston that is free to move but does not allow either gas to leak into the other side. Initially, one side of the piston contains 1 m3 of N2 gas at 500 kPa and 120°C while the other side contains 1 m3 of He gas at 500 kPa and 40°C Now thermal equilibrium is established in the cylinder as a result of heat transfer through the piston. Using constant specific heats at room temperature, determine the final equilibrium temperature in the cylinder. What would your answer be if the piston were not free to move?

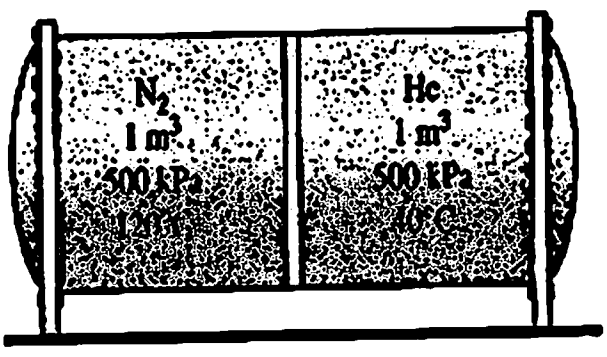

FIGURE P5–119

Step 1 of 6

Given:
Compartment Nitrogen:
Volume $V_1 = 1\text{m}^3$
Pressure $P_1 = 500\text{kPa}$
Temperature $T = 120^\circ\text{C}$
Compartment of helium:
Volume $V_{1H} = 1\text{m}^3$
Pressure $P_{1H} = 500\text{kPa}$
Temperature $T_{1H} = 40^\circ\text{C}$

Step 2 of 6

From the ideal gas specific heat of various common gases
For Nitrogen
The gas constants and the constant volume specific heats are

$$R = 0.2968\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$c_v = 0.743\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

From the ideal gas specific heat of various common gases
For helium

$$R = 2.0769\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$c_v = 3.1156\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 3 of 6

We know that
$PV = mRT$
The mass of the nitrogen is

$$m_{N_2} = \left(\frac{P_1V_1}{RT_1}\right)_{N_2}$$
$$= \frac{(500)(1)}{(0.2968)(393)}$$
$$= 4.29\text{kg}$$

Step 4 of 6

Mass of the helium

$$m_{He} = \left(\frac{P_{1H}V_{1H}}{RT_{1H}}\right)_{He}$$
$$= \frac{(500)(1)}{(2.0769)(313)}$$
$$= 0.769\text{kg}$$

Step 5 of 6

Taking the entire contents of the cylinder as our system, the 1st law relation can be written as

$$\underbrace{E_{in} - E_{out}}_{\substack{\text{Net energy transfer}\\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{system}}_{\substack{\text{Change in internal, kinetic,}\\ \text{potential, etc. energies}}}$$

$$0 = \Delta U = (\Delta U)_{N_2} + (\Delta U)_{He}$$

$$0 = \left[mc_v(T_2 - T_1)\right]_{N_2} + \left[mc_v(T_2 - T_1)\right]_{He}$$

Since $T_2 = T_f$

$$0 = \left[mc_v(T_f - T_1)\right]_{N_2} + \left[mc_v(T_f - T_1)\right]_{He}$$

Step 6 of 6

Substituting,

$$(4.29)(0.743)(T_f - 120) + (0.769)(3.1156)(T_f - 40) = 0$$

It gives

$$T_f = 85.67^\circ\text{C}$$

$$\boxed{T_f = 85.67^\circ\text{C}}$$

Where T_f is the final equilibrium temperature in the cylinder.

The answer would be the same if the piston were not free to move since it would effect only pressure and not the specific heats.

Question: 5.120P

Repeat Prob. 5–119 by assuming the piston is made of 8 kg of copper initially at the average temperature of the two gases on both sides.

Step 1 of 6

Given:
Compartment Nitrogen:
Volume $V_1 = 1\text{m}^3$
Pressure $P_1 = 500\text{kPa}$
Temperature $T = 120^\circ\text{C}$
Compartment of helium:
Volume $V_{1H} = 1\text{m}^3$
Pressure $P_{1H} = 500\text{kPa}$
Temperature $T_{1H} = 40^\circ\text{C}$
Average temperature of cooper $T_{1,Cu} = 80^\circ\text{C}$

Step 2 of 6

From the ideal gas specific heat of various common gases
For Nitrogen
The gas constants and the constant volume specific heats are

$$R = 0.2968\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$c_v = 0.743\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

From the ideal gas specific heat of various common gases
For helium

$$R = 2.0769\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

$$c_v = 3.1156\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

From the properties of common liquids, solids and foods
At room temperature
The specific heat of copper piston

$$c = 0.386\frac{\text{kJ}}{\text{kg}\cdot\text{K}}$$

Step 3 of 6

We know that
$PV = mRT$
The mass of the nitrogen is
The mass of the nitrogen is

$$m_{N_2} = \left(\frac{P_1V_1}{RT_1}\right)_{N_2}$$
$$= \frac{(500)(1)}{(0.2968)(393)}$$
$$= 4.29\text{kg}$$

Step 4 of 6

Mass of the helium

$$m_{He} = \left(\frac{P_{1H}V_{1H}}{RT_{1H}}\right)_{He}$$
$$= \frac{(500)(1)}{(2.0769)(313)}$$
$$= 0.769\text{kg}$$

Step 5 of 6

Taking the entire contents of the cylinder as our system, the 1st law relation can be written as

$$\underbrace{E_{in} - E_{out}}_{\substack{\text{Net energy transfer}\\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{system}}_{\substack{\text{Change in internal, kinetic,}\\ \text{potential, etc. energies}}}$$

$$0 = \Delta U = (\Delta U)_{N_2} + (\Delta U)_{He} + (\Delta U)_{Cu}$$

$$0 = \left[mc_v(T_2 - T_1)\right]_{N_2} + \left[mc_v(T_2 - T_1)\right]_{He} + \left[mc(T_2 - T_1)\right]_{Cu}$$

$$0 = \left[mc_v(T_f - T_1)\right]_{N_2} + \left[mc_v(T_f - T_1)\right]_{He} + \left[mc(T_f - T_1)\right]_{Cu}$$

Where T_f is the final equilibrium temperature in the cylinder.

Step 6 of 6

Where
Average temperature of the cooper is

$$T_{1,Cu} = \frac{120+40}{2}$$
$$= 80^\circ\text{C}$$

Substituting,

$$(4.29)(0.743)(T_f - 120) + (0.769)(3.1156)(T_f - 40) + (8)(0.386)(T_f - 80) = 0$$

It gives

$$T_f = 83.7^\circ\text{C}$$

$$\boxed{T_f = 83.7^\circ\text{C}}$$

Question: 5.121P

Reconsider Prob. 5–120. Using EES (or other) software, investigate the effect of the mass of the copper piston on the final equilibrium temperature. Let the mass of piston vary from 1 to 10 kg. Plot the final temperature against the mass of piston, and discuss the results.

Step 1 of 8

Given:
Working fluid: helium
Inlet pressure of the compressor $P_1 = 100\,\text{kPa}$
Inlet temperature of the compressor $T_1 = 17^\circ\text{C}$
Final pressure of the compressor $P_2 = 400\,\text{kPa}$
Inlet temperature of the turbine $T_3 = 20^\circ\text{C}$
Mass flow rate $\dot{m} = 0.2\frac{\text{kg}}{\text{s}}$
Mass of the piston varies from 1 to 10 kg.

Step 2 of 8

The problem is solved using EES, and the solution is given below.

```
"Knowns:"
R_u=8.314 [kJ/kmol-K]
V_N2[1]=1 [m^3]
Cv_N2=0.743 [kJ/kg-K]  "From Table A-2(a) at 27C"
R_N2=0.2968 [kJ/kg-K]  "From Table A-2(a)"
T_N2[1]=120 [C]
P_N2[1]=500 [kPa]
V_He[1]=1 [m^3]
Cv_He=3.1156 [kJ/kg-K] "From Table A-2(a) at 27C"
T_He[1]=40 [C]
P_He[1]=500 [kPa]
R_He=2.0769 [kJ/kg-K]  "From Table A-2(a)"
"m_Pist=8 [kg]"
Cv_Pist=0.386 [kJ/kg-K]  "Use Cp for Copper from Table A-3(b) at 27C"
```

Step 3 of 8

```
"Solution:"

"mass calculations:"
P_N2[1]*V_N2[1]=m_N2*R_N2*(T_N2[1]+273)
P_He[1]*V_He[1]=m_He*R_He*(T_He[1]+273)

"The entire cylinder is considered to be a closed system, neglecting the piston."
"Conservation of Energy for the closed system:"
"E_in - E_out = DELTAE_negPist,  we neglect DELTA KE and DELTA PE for the
cylinder."
E_in - E_out = DELTAE_neglPist
E_in =0 [kJ]
E_out = 0 [kJ]
```

Step 4 of 8

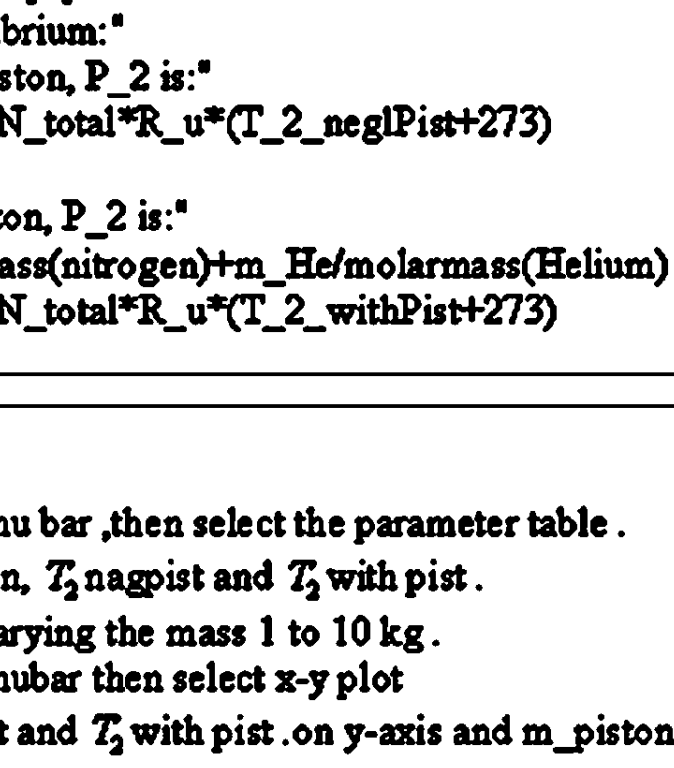
```
"At the final equilibrium state, N2 and He will have a common temperature."
DELTAE_neglPist= m_N2*Cv_N2*(T_2_neglPist-
T_N2[1])+m_He*Cv_He*(T_2_neglPist-
T_He[1])
"The entire cylinder is considered to be a closed system, including the piston."
"Conservation of Energy for the closed system:"
"E_in - E_out = DELTAE_withPist,  we neglect DELTA KE and DELTA PE for the
cylinder."
E_in - E_out = DELTAE_withPist
```

Step 5 of 8

```
"At the final equilibrium state, N2 and He will have a common temperature."
DELTAE_withPist= m_N2*Cv_N2*(T_2_withPist-
T_N2[1])+m_He*Cv_He*(T_2_withPist-
T_He[1])+m_Pist*Cv_Pist*(T_2_withPist-T_Pist[1])
T_Pist[1]=(T_N2[1]+T_He[1])/2
"Total volume of gases:"
V_total=V_N2[1]+V_He[1]
"Final pressure at equilibrium:"
"Neglecting effect of piston, P_2 is:"
P_2_neglPist*V_total=N_total*R_u*(T_2_neglPist+273)

"Including effect of piston, P_2 is:"
N_total=m_N2/molarmass(nitrogen)+m_He/molarmass(Helium)
P_2_withPist*V_total=N_total*R_u*(T_2_withPist+273)
```

Step 6 of 8



Now click tables in menu bar ,then select the parameter table .
Then select the m_piston, T_2 nagpist and T_2 with pist .
Then run the table by varying the mass 1 to 10 kg .
Then plot From the menubar then select x-y plot
Then click on T_2 nagpist and T_2 with pist .on y-axis and m_piston x-axis.

Step 7 of 8

▷ 1..10	m_{Pist} [kg]	$T_{2,negPist}$	$T_{2,withPist}$
Run 1	1	85.65	85.29
Run 2	2	85.65	84.96
Run 3	3	85.65	84.68
Run 4	4	85.65	84.43
Run 5	5	85.65	84.2
Run 6	6	85.65	83.99
Run 7	7	85.65	83.81
Run 8	8	85.65	83.64
Run 9	9	85.65	83.48
Run 10	10	85.65	83.34

Step 8 of 8

Graph between the T_2 nagpist and T_2 with pist and m_ piston

Question: 5.122P

An insulated piston-cylinder device initially contains 1.4-kg saturated liquid water at 200°C. Now an electric resistor placed in the tank is turned on for 20 min until the volume quadruples. Determine (*a*) the volume of the tank, (*b*) the final temperature, and (*c*) the electrical power rating of the resistor.

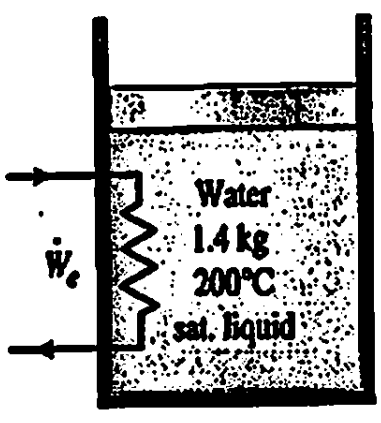


FIGURE P5–122

Step 1 of 12

Given

Mass of the saturated liquid water $m = 1.4$ kg

Temperature of water $T_1 = 200°C$

Final volume $V_2 = 4V_1$

Electric resistor placed in the tank is turned on for 20 minutes

Step 2 of 12

(a) Final volume of the tank

At $T_1 = 200°C$ from saturated water tables

$P_1 = P_{sat} = 1554.9$ kPa

$v_1 = v_f = 0.001157\ m^3/kg$

$h_1 = h_f = 852.26$ kJ/kg

Step 3 of 12

The initial volume of the tank is

$$V_1 = mv_1$$
$$= 1.4 \times (0.001157)$$
$$V_1 = 0.00162\ m^3$$

Step 4 of 12

Final volume of the tank is

$$V_2 = 4V_1$$
$$= 4(0.00162)$$
$$\boxed{V_2 = 0.00648\ m^3}$$

Step 5 of 12

(b) The final temperature

The saturated mixture in the final state has same pressure and temperature.

Therefore final temperature is

$$\boxed{T_2 = T_1 = 200°C}$$

Step 6 of 12

(c) The electrical power rating of the resistor

Considering the piston cylinder as a system, and doesn't involve any heat transfer.

From energy balance of the system

$$E_{in} - E_{out} = \Delta E_{system}$$
$$W_{in} - W_{out} = \Delta U$$
$$W_{in} = \Delta U + W_{out}$$
$$W_{in} = \Delta H$$
$$W_{in} = m(h_2 - h_1)\ \text{kJ}$$

Step 7 of 12

At $T_2 = 200°C$ from saturated water tables

$v_f = 0.001157\ m^3/kg$

$v_g = 0.12721\ m^3/kg$

$h_f = 852.26$ kJ/kg

$h_{fg} = 1939.8$ kJ/kg

Step 8 of 12

Specific volume at state 2

$$v_2 = \frac{V_2}{m}$$
$$= \frac{0.00648}{1.4}$$
$$v_2 = 0.00463\ m^3/kg$$

Step 9 of 12

We know that

$$v_2 = v_f + x_2 v_{fg}$$
$$W_{in} = m(h_2 - h_1)\ \text{kJ}$$

Step 7 of 12

At $T_2 = 200°C$ from saturated water tables

$v_f = 0.001157\ m^3/kg$

$v_g = 0.12721\ m^3/kg$

$h_f = 852.26$ kJ/kg

$h_{fg} = 1939.8$ kJ/kg

Step 8 of 12

Specific volume at state 2

$$v_2 = \frac{V_2}{m}$$
$$= \frac{0.00648}{1.4}$$
$$v_2 = 0.00463\ m^3/kg$$

Step 9 of 12

We know that

$$v_2 = v_f + x_2 v_{fg}$$
$$\dot{W}_{in} = \frac{m(h_2 - h_1)\ \text{kJ}}{20 \times 60}$$
$$= 0.0623\ \text{kW}$$
$$\boxed{\dot{W}_{in} = 0.0623\ \text{kW}}$$

Question: 5.123P

A vertical 12-cm diameter piston-cylinder device contains an ideal gas at the ambient conditons of 1 bar and 24°C. Initially, the inner face of the piston is 20 cm from the base of the cylinder. Now an external shaft connected to the piston exerts a force corresponding to a boundary work input of 0.1 kJ. The temperature of the gas remains constant during the process. Determine (*a*) the amount of heat transfer, (*b*) the final pressure in the cylinder, and (*c*) the distance that the piston is displaced.

Step 1 of 7

Given

The diameter of the piston $d = 12$ cm

The pressure inside the cylinder $P_1 = 1$ bar

Initial temperature in the cylinder $T_1 = 24°C$

The boundary input to the system $W_{in} = 0.1$ kJ

At initial condition the inner face of the piston from base of the cylinder $L_1 = 20$ cm

Step 2 of 7

(a) The amount of heat transfer

Considering piston cylinder arrangement as closed system

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$W_{in} - Q_{out} = \Delta U$

Since the temperature remains constant $T_1 = T_2$

Change in internal energy is zero $\Delta U = 0$

$W_{in} - Q_{out} = \Delta U = 0$

$Q_{out} = W_{in}$

$Q_{out} = 0.1$kJ

The amount of heat transfer

$\boxed{Q_{out} = 0.1\,\text{kJ}}$

Step 3 of 7

(b) The final pressure in the cylinder can be calculated by the relation, for a isothermal process

$P_1V_1 = P_2V_2$

Where initial volume

$$V_1 = \frac{\pi D^2}{4} L_1$$

Step 2 of 7

(a) The amount of heat transfer

Considering piston cylinder arrangement as closed system

From energy balance of the system

$E_{in} - E_{out} = \Delta E_{system}$

The kinetic and potential energy changes are negligible $\Delta PE = \Delta KE = 0$

$W_{in} - Q_{out} = \Delta U$

Since the temperature remains constant $T_1 = T_2$

Change in internal energy is zero $\Delta U = 0$

$W_{in} - Q_{out} = \Delta U = 0$

$Q_{out} = W_{in}$

$Q_{out} = 0.1$kJ

The amount of heat transfer

$\boxed{Q_{out} = 0.1\,\text{kJ}}$

Step 3 of 7

(b) The final pressure in the cylinder can be calculated by the relation, for a isothermal process

$P_1V_1 = P_2V_2$

Where initial volume

$$V_1 = \frac{\pi D^2}{4} L_1$$

Step 4 of 7

(c) The distance moved by the piston

We know the final volume is

$$V_2 = \frac{\pi D^2}{4} L_2$$

$$0.00145 = \frac{\pi (0.12)^2}{4} L_2$$

$$L_2 = 0.1282 \text{ m}$$

Step 7 of 7

The distance that the piston is displaced

$\Delta L = L_1 - L_2$

$= 0.2 - 0.1282$

$= 0.0718$ m

$\boxed{\Delta L = 7.18 \text{ cm}}$

Question: 5.124P pg 1

A piston-cylinder device initially contains 0.35-kg steam at 3.5 MPa, superheated by 7.4°C. Now the steam loses heat to the surroundings and the piston moves down, hitting a set of stops at which point the cylinder contains saturated liquid water. The cooling continues until the cylinder contains water at 200°C. Determine (*a*) the final pressure and the quality (if mixture), (*b*) the boundary work, (*c*) the amount of heat transfer when the piston first hits the stops, (*d*) and the total heat transfer.

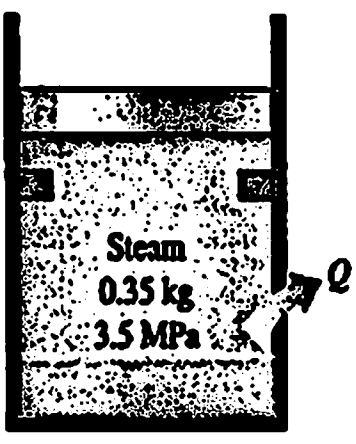

FIGURE P5–124

Step 1 of 10

(a)

Write the saturated temperature at initial state from Table A-5: Saturated water-Pressure table corresponding to pressure 3.5 MPa.

$$T_{sat@3.5\,MPa} = 242.56°C$$

Calculate the superheated temperature at initial state.

$$T_1 = T_{sat} + \Delta T$$

Here, saturated temperature at initial state is T_{sat} and superheated temperature is ΔT.

Substitute 242.56°C for T_{sat} and 7.4°C for ΔT.

$$T_1 = 242.56 + 7.4$$
$$= 249.96°C$$

Step 2 of 10

Write the specific volume of superheated water from Table A-6 corresponding to pressure of 3.5 MPa and 249.96°C by using interpolation.

$$\frac{v_1 - v_{@242.56°C}}{v_{@250°C} - v_{@242.56°C}} = \frac{T_1 - T_{@242.56°C}}{T_{@250°C} - T_{@242.56°C}}$$

Substitute 0.05706 m^3/kg for $v_{@242.56°C}$, 0.05876 m^3/kg for $v_{@250°C}$ and 249.96°C for T_1.

$$\frac{v_1 - 0.05706}{0.05876 - 0.05706} = \frac{249.96 - 242.56}{250 - 242.56}$$
$$v_1 - 0.05706 = \frac{7.4 \times 0.0017}{7.44}$$
$$v_1 = 0.00169 + 0.05706$$
$$v_1 = 0.05875\ m^3/kg$$

Step 3 of 10

Write the internal energy of superheated water from Table A-6 corresponding to pressure of 3.5 MPa and 249.96°C by using interpolation.

$$\frac{u_1 - u_{@242.56°C}}{u_{@250°C} - u_{@242.56°C}} = \frac{T_1 - T_{@242.56°C}}{T_{@250°C} - T_{@242.56°C}}$$

Substitute 0.05706 m^3/kg for $u_{@242.56°C}$, 0.05876 m^3/kg for $u_{@250°C}$ and 249.96°C for T_1.

$$\frac{u_1 - 2603.0}{2624.0 - 2603.0} = \frac{249.96 - 242.56}{250 - 242.56}$$
$$u_1 - 2603.0 = \frac{7.4 \times 21}{7.44}$$
$$u_1 = 20.887 + 2603.0$$
$$u_1 = 2623.9\ kJ/kg$$

Step 4 of 10

Calculate the pressure of steam at state 2 when the piston is hitting the stops.

$$P_2 = P_1$$

Substitute 3.5 MPa for P_1.

$$P_2 = 3.5\ MPa$$

Write the specific volume of steam at state 2 corresponding to pressure of 3.5 MPa and dryness fraction of 0.

$$v_2 = 0.001235\ m^3/kg$$

Write the internal energy of steam at state 2 corresponding to pressure of 3.5 MPa and dryness fraction of 0.

$$u_2 = 1045.4\ kJ/kg$$

Step 5 of 10

Calculate the specific volume of steam at state 3 when the piston stops.

$$v_3 = v_2$$

Here, specific volume of steam at state 2 is v_2 and specific volume of steam at state 3 is v_3.

Substitute 0.001235 m^3/kg for v_2.

$$v_3 = 0.001235\ m^3/kg$$

Calculate the saturated pressure of steam at state 3 by using saturated water-temperature table.

$$P_3 = P_{sat@200°C}$$
$$= 1554.9\ kPa$$

Therefore, the final pressure of steam is $\boxed{1554.9\ kPa}$.

Step 6 of 10

Calculate the dryness fraction of steam at state 3 by using saturated water-temperature table.

$$v_3 = v_f + x_3 v_{fg}$$

Calculate the dryness fraction of steam at state 3 by using saturated water-temperature table.

$$v_3 = v_f + x_3 v_{fg}$$
$$= v_f + x_3 (v_g - v_f)$$

Here, specific volume of saturated liquid is v_f, specific volume of saturated vapor is v_g and dryness fraction is x_3.

Substitute $0.001235\,\text{m}^3/\text{kg}$ for v_3, $0.001157\,\text{m}^3/\text{kg}$ for v_f and $0.12721\,\text{m}^3/\text{kg}$ for v_g.

$$0.001235 = 0.001157 + x_3 (0.12721 - 0.001157)$$
$$0.126 x_3 = 0.000078$$
$$x_3 = 0.000619$$

Therefore, the dryness fraction of steam at exit is $\boxed{0.000619}$.

Step 7 of 10

(b)

Calculate the internal energy of steam at state 3 by using saturated water-temperature table.

$$u_3 = u_f + x_3 u_{fg}$$

Here, internal energy of saturated liquid is u_f, internal energy of evaporation is u_{fg} and dryness fraction is x_3.

Substitute 0.000619 for x_3, $850.46\,\text{kJ/kg}$ for u_f and $1743.7\,\text{kJ/kg}$ for u_{fg}.

$$u_3 = 850.46 + (0.000619 \times 1743.7)$$
$$= 850.46 + 1.079$$
$$= 851.54\,\text{kJ/kg}$$

Step 8 of 10

Calculate the boundary work done by the steam.

$$W_b = mP_1 (v_1 - v_2)$$

Here, mass of steam is m.

Substitute $0.35\,\text{kg}$ for m, $3500\,\text{kPa}$ for P_1, $0.05875\,\text{m}^3/\text{kg}$ for v_1 and $0.001235\,\text{m}^3/\text{kg}$ for v_2.

$$W_b = 0.35 \times 3500 \times (0.05875 - 0.001235)$$
$$= 70.45\,\text{kJ}$$

Therefore, the boundary work is $\boxed{70.45\,\text{kJ}}$.

Step 9 of 10

(c)

Calculate the heat transfer at stop position by applying energy balance equation.

$$W_b - Q_{out\,1\text{-}2} = m(u_2 - u_1)$$

Here, heat lost during process $1-2$ is $Q_{out\,1\text{-}2}$, internal energy at state 2 is u_2 and internal energy at state 1 is u_1.

Substitute $70.45\,\text{kJ}$ for W_b, $0.35\,\text{kg}$ for m, $1045.4\,\text{kJ/kg}$ for u_2 and $2623.9\,\text{kJ/kg}$ for u_1.

$$Q_{out,1\text{-}2} = 70.45 - [0.35(1045.4 - 2623.9)]$$
$$= 622.925\,\text{kJ}$$

Therefore, heat transfer at stop position is $\boxed{622.925\,\text{kJ}}$.

Step 10 of 10

(d)

Calculate the total heat transfer.

$$W_b - Q_{out\,1\text{-}3} = m(u_3 - u_1)$$

Here, total heat lost during process $1-3$ is $Q_{out\,1\text{-}3}$, internal energy at state 3 is u_3 and internal energy at state 1 is u_1.

Substitute $70.45\,\text{kJ}$ for W_b, $0.35\,\text{kg}$ for m, $851.537\,\text{kJ/kg}$ for u_3 and $2623.9\,\text{kJ/kg}$ for u_1.

$$Q_{out,1\text{-}3} = 70.45 - [0.35(851.537 - 2623.9)]$$
$$= 690.78\,\text{kJ}$$

Therefore, the total heat transfer is $\boxed{690.78\,\text{kJ}}$.

CHAPTER 06

SOLUTIONS

Question: 6.001P

Define mass and volume flow rates. How are they related to each other?

Step 1 of 1

Mass Flow Rate:

Mass flow rate is defined as mass per unit time.

It is represented by $\dot{m}$. The SI units of mass flow rate is $\mathrm{kg/s}$.

Volumetric Flow Rate:

Volumetric flow rate is defined as the volume of fluid per unit time.

It is represented by $\dot{V}$. The SI units of volumetric flow rate is $\mathrm{m^3/s}$.

Relation between mass flow rate and volumetric flow rate:

Mass flow rate is directly proportional to the volumetric flow rate.

$$\dot{m} \propto \dot{V}$$

$$\dot{m} = \rho \dot{V} \qquad \left(\text{since } \rho = \frac{1}{v}\right)$$

$$= \frac{\dot{V}}{v}$$

Here, ρ is the density and v is the specific volume of the fluid.

Question: 6.002P

When is the flow through a control volume steady?

Step 1 of 1

If the properties in a control volume involve no change with time at any fixed position, then the flow through the control volume is said to be steady.

Question: 6.003P

Does the amount of mass entering a control volume have to be equal to the amount of mass leaving during an unsteady-flow process?

Step 1 of 1

No, the amount of mass entering a control volume does not have to be equal to the amount of mass leaving during an unsteady-flow process.

Question: 6.004P

Consider a device with one inlet and one outlet. If the volume flow rates at the inlet and at the outlet are the same, is the flow through this device necessarily steady? Why?

Step 1 of 1

No, the flow through the device is not steady unless the mass flow rate at inlet and outlet should be same

Question: 6.005P

A pneumatic accumulator arranged to maintain a constant pressure as air enters or leaves it is set for 200 psia. Initially, the volume is 0.2 ft3 and the temperature is 80°F. Air is now added to the accumulator until its volume is 1 ft3 and its temperature is 80°F. How much air has been added to the accumulator?

Step 1 of 3

Given

The initial pressure of the pneumatic accumulator $P_1 = 200$ psia

Initial volume, $V_1 = 0.2\ \text{ft}^3$

Initial temperature, $T_1 = 80°\text{F}$

$T_1 = 540\text{R}$

The final pressure of the pneumatic accumulator $P_2 = 200$ psia

Final volume, $V_2 = 1\ \text{ft}^3$

Finial temperature, $T_2 = 80°\text{F}$

$T_2 = 540\text{R}$

Step 2 of 3

From ideal gas properties of air, gas constant of air is $R = 0.3704$ psia·ft^3/lbm·R

The amount of mass added is $\Delta m = m_2 - m_1$

From the ideal gas equation, $P_1V_1 = m_1RT_1$,

$$m_1 = \frac{P_1V_1}{RT_1}$$

$$m_1 = \frac{(200)(0.2)}{(0.3704)(540)}$$

$$m_1 = 0.2\ \text{lbm}$$

The initial mass of air contained in the container is $m_1 = 0.2$ lbm

Step 3 of 3

From the ideal gas equation, $P_2V_2 = m_2RT_2$,

The final mass of air in the container,

$$m_2 = \frac{P_2V_2}{RT_2}$$

$$m_2 = \frac{(200)(1)}{(0.3704)(540)}$$

$$m_2 = 1\ \text{lbm}$$

Therefore the air added to the accumulator is

$$\Delta m = m_2 - m_1$$

$$\Delta m = 1 - 0.2$$

$$\Delta m = 0.8\ \text{lbm}$$

Hence air added to the accumulator is $\boxed{\Delta m = 0.8\ \text{lbm}}$

Question: 6.006P

A steady-flow compressor is used to compress helium from 15 psia and 70°F at the inlet to 200 psia and 600°F at the outlet. The outlet area and velocity are 0.01 ft2and 100 ft/s, respectively, and the inlet velocity is 50 ft/s. Determine the mass flow rate and the inlet area.

Step 1 of 3

Given

The initial pressure of the helium, $P_1 = 15$ psia

Initial temperature, $T_1 = 70°F$

$T_1 = 530R$

Inlet velocity, $V_1 = 50$ ft/s

Final pressure, $P_2 = 200$ psia

Finial temperature, $T_2 = 600°F$

$T_2 = 1060°F$

Outlet area, $A_2 = 0.01\ ft^2$

Outlet velocity, $V_2 = 100$ ft/s

Step 2 of 3

From ideal gas properties of air table, $R = 2.6809$ psia·ft^3/lbm·R

The mass flow rate is expressed as $\dot{m} = \rho_1 A_1 V_1 = \rho_2 A_2 V_2$

From the ideal gas equation, $P_2 = \rho_2 R T_2$

$$\rho_2 = \frac{P_2}{R T_2}$$

Therefore, $\dot{m} = \frac{P_2}{R T_2} A_2 V_2$

$$\dot{m} = \frac{200}{(2.6809)1060}(0.01)(100)$$

$$\dot{m} = 0.0704 \text{ lbm/s}$$

Hence mass flow rate is $\boxed{\dot{m} = 0.0704 \text{ lbm/s}}$

Step 3 of 3

From the ideal gas equation, $P_1 = \rho_1 R T_1$

$$\rho_1 = \frac{P_1}{R T_1}$$

Therefore, $\dot{m} = \frac{P_1}{R T_1} A_1 V_1$

$$A_1 = \frac{\dot{m} R T_1}{P_1 V_1}$$

$$A_1 = \frac{0.0704 \times 2.6809 \times 530}{15 \times 50}$$

$$A_1 = 0.133\ ft^2$$

Hence inlet area is $\boxed{A_1 = 0.133\ ft^2}$

Question: 6.007P

Air enters a nozzle steadily at 2.21 kg/m3 and 40 m/s and leaves at 0.762 kg/m3 and 180 m/s. If the inlet area of the nozzle is 90 cm2, determine (a) the mass flow rate through the nozzle, and (b) the exit area of the nozzle.

Step 1 of 3

Given data

The density at the inlet of the nozzle $\rho_1 = 2.21\ \text{kg/m}^3$

The velocity at the inlet is $V_1 = 40\ \text{m/s}$

The inlet area $A_1 = 90\ \text{cm}^2 = 90\times10^{-4}\ \text{m}^2$

The density at the outlet of the nozzle $\rho_2 = 0.762\ \text{kg/m}^3$

The velocity at the outlet is $V_2 = 180\ \text{m/s}$

Step 2 of 3

(a)

The mass flow rate

$$\dot{m} = \rho_1 A_1 V_1$$
$$= (2.21)\left(90\times10^{-4}\right)(40)$$
$$= 0.7956\ \text{kg/s}$$

$$\boxed{\dot{m} = 0.796\ \text{kg/s}}$$

Step 3 of 3

(b) The exit area of the nozzle

Since the process is steady mass flow rate remains constant in the nozzle, the exit area can be determined as

$$A_2 = \frac{\dot{m}}{\rho_2 V_2}$$
$$= \frac{0.796}{0.762(180)}$$
$$= 5.8\times10^{-3}\ \text{m}^2$$

$$\boxed{A_2 = 58\ \text{cm}^2}$$

Question: 6.008P

Water enters the constant 130-mm inside-diameter tubes of a boiler at 7 MPa and 65°C, and leaves the tubes at 6 MPa and 450°C with a velocity of 80 m/s. Calculate the velocity of the water at the tube inlet and the inlet volume flow rate.

Step 1 of 4

Given

Inside diameter of boiler tube $d = 130 \text{ mm} = 0.13 \text{ m}$

Inlet pressure $P_1 = 7 \text{ MPa}$

Inlet temperature $T_1 = 65°C$

Exit pressure $P_2 = 6 \text{ MPa}$

Exit temperature $T_2 = 450°C$

Exit velocity $V_2 = 80 \text{ m/s}$

Step 2 of 4

At $P_1 = 7 \text{ MPa}$ and $T_1 = 65°C$ state is in sub cooled region so we can take specific volume at $T_1 = 65°C$ from saturated water tables

$v_1 = v_f = 0.001020 \text{ m}^3/\text{kg}$

At $P_2 = 6 \text{ MPa}$ and $T_2 = 450°C$ from superheated steam tables

Specific volume $v_2 = 0.05217 \text{ m}^3/\text{kg}$

Step 3 of 4

For a steady state the mass flow rate remains constant.

$$\dot{m} = \frac{V_1 A}{v_1} = \frac{V_2 A}{v_2}$$

Since it is a constant area duct the area is constant.

The inlet velocity is

$$\frac{V_1 A}{v_1} = \frac{V_2 A}{v_2}$$

$$V_1 = \frac{v_1}{v_2} V_2$$

$$= \frac{0.001020}{0.05217} \times 80$$

$$\boxed{V_1 = 1.56 \text{ m/s}}$$

Step 4 of 4

The inlet volume flow rate

$$\dot{V}_1 = A V_1$$

$$= \frac{\pi}{4}\left(0.13^2\right) 1.56$$

$$\boxed{\dot{V}_1 = 0.0207 \text{ m}^3/\text{s}}$$

Question: 6.009P

A hair dryer is basically a duct of constant diameter in which a few layers of electric resistors are placed. A small fan pulls the air in and forces it through the resistors where it is heated. If the density of air is 1.20 kg/m3 at the inlet and 0.95 kg/m3 at the exit, determine the percent increase in the velocity of air as it flows through the dryer.

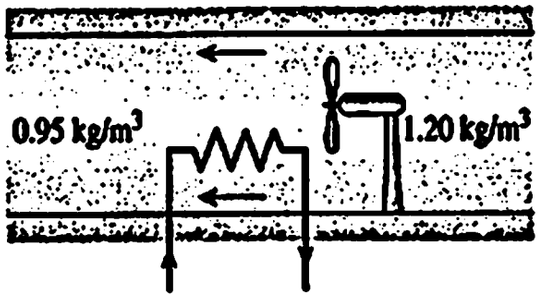

FIGURE P6–9

Step 1 of 3

Given

The density of air at inlet, $\rho_1 = 1.2\ \text{kg/m}^3$

The density of air at exit, $\rho_2 = 0.95\ \text{kg/m}^3$

Step 2 of 3

The mass flow rate is expressed as $\dot{m} = \rho A V$

$$A = \frac{\dot{m}}{\rho V}$$

For a constant area duct, $A_1 = A_2$

$$\frac{\dot{m}_1}{\rho_1 V_1} = \frac{\dot{m}_2}{\rho_2 V_2}$$

But the mass flow rate is constant, $\dot{m}_1 = \dot{m}_2$. Hence

$$\frac{V_2}{V_1} = \frac{\rho_1}{\rho_2}$$

$$\frac{V_2}{V_1} = \frac{1.2}{0.95}$$

$$\frac{V_2}{V_1} = 1.263$$

Step 3 of 3

Percentage increase in volume is $\%\Delta V = \dfrac{V_2 - V_1}{V_1} \times 100$

$$\%\Delta V = \left(\frac{V_2}{V_1} - 1\right) \times 100$$

$$\%\Delta V = (1.263 - 1) \times 100$$

$$\%\Delta V = 26.3\%$$

Percentage increase in volume is $\boxed{\%\Delta V = 26.3\%}$

Question: 6.010P

A 1-m3 rigid tank initially contains air whose density is 1.18 kg/m3. The tank is connected to a high-pressure supply line through a valve. The valve is opened, and air is allowed to enter the tank until the density in the tank rises to 7.20 kg/m3. Determine the mass of air that has entered the tank.

Step 1 of 3

Given data

The volume of the rigid tank $V = 1\ \text{m}^3$

The density of air $\rho_1 = 1.18\ \text{kg/m}^3$

The density of air in the tank at state 2 $\rho_2 = 7.20\ \text{kg/m}^3$

Step 2 of 3

By applying mass balance to the system

$$\Delta m_{system} = m_{in} - m_{out}$$

Since

$$\rho = \frac{m}{V}$$

$$m = \rho V$$

Step 3 of 3

Therefore mass balance in terms of densities we can write it as

$$\Delta m_{system} = \rho_2 V - \rho_1 V$$

$$= (\rho_2 - \rho_1) V$$

$$= (7.20 - 1.18)(1)$$

The mass of air entering the system is

$$\boxed{\Delta m_{system} = 6.02\ \text{kg}}$$

Question: 6.011P

Air enters the 1-m2 inlet of an aircraft engine at 100 kPa and 20°C with a velocity of 180 m/s. Determine the volume flow rate, in m3/s, at the engine's inlet and the mass flow rate, in kg/s, at the engine's exit.

Step 1 of 4

Given

Inlet cross-section area $A_1 = 1\ \text{m}^2$

Inlet pressure $P_1 = 100\ \text{kPa}$

Inlet temperature $T_1 = 20°\text{C} = 293\text{K}$

Inlet velocity $V_1 = 180\ \text{m/s}$

Step 2 of 4

The volume flow rate at the inlet

$$\dot{V}_1 = A_1 V_1$$
$$= (1)(180)$$
$$\boxed{\dot{V}_1 = 180\ \text{m}^3/\text{s}}$$

Step 3 of 4

The mass flow rate remains constant since the flow is steady.

Therefore

$$\dot{m} = \rho_1 \dot{V}_1$$

From ideal gas equation

$$\rho_1 = \frac{P_1}{RT_1}$$

Where R is the gas constant for air $R = 0.287\ \text{kJ/kg.K}$

Then

$$\rho_1 = \frac{100}{(0.287)(293)}$$
$$\rho_1 = 1.189\ \text{kg/m}^3$$

Step 4 of 4

The mass flow rate at the exit is

$$\dot{m} = \rho_1 \dot{V}_1$$
$$= 1.189(180)\ \text{kg/s}$$
$$\boxed{\dot{m} = 214.02\ \text{kg/s}}$$

Question: 6.012P

A pump increases the water pressure from 70 kPa at the inlet to 700 kPa at the outlet. Water enters this pump at 15°C through a 1-cm-diameter opening and exits through a 1.5-cm-diameter opening. Determine the velocity of the water at the inlet and outlet when the mass flow rate through the pump is 0.5 kg/s. Will these velocities change significantly if the inlet temperature is raised to 40°C?

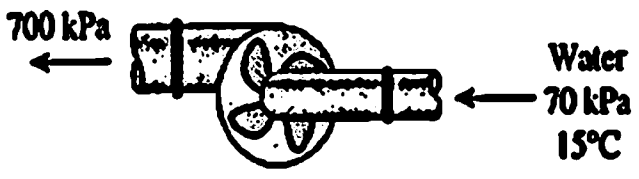

FIGURE P6–12

Step 1 of 6

Given

Inlet pressure $P_1 = 70\ \text{kPa}$

Inlet temperature $T_1 = 15°\text{C} = 288\ \text{K}$

Inlet diameter $d_1 = 1\ \text{cm} = 0.01\ \text{m}$

Exit pressure $P_2 = 700\ \text{kPa}$

Exit diameter $d_2 = 1.5\ \text{cm} = 0.015\ \text{m}$

Mass flow rate of water $\dot{m}_w = 0.5\ \text{kg/s}$

The increased inlet temperature is $T_1' = 40°\text{C} = 313\ \text{K}$

Step 2 of 6

From properties of water tables

At $T_1 = 15°\text{C}$

Specific volume $v_1 = v_f = 0.001001\ \text{m}^3/\text{kg}$

At $T_1' = 40°\text{C}$

Specific volume $v_1' = v_f = 0.001008\ \text{m}^3/\text{kg}$

Step 3 of 6

The velocity at the inlet

$$\dot{m} = \rho_1 A_1 V_1$$

$$\dot{m} = \frac{A_1 V_1}{v_1}$$

$$V_1 = \frac{\dot{m} v_1}{A_1}$$

$$= \frac{(0.5)(0.001001)}{\pi\left(\frac{0.01^2}{4}\right)}$$

$$\boxed{V_1 = 6.37\ \text{m/s}}$$

Step 4 of 6

The velocity at the outlet

Since the specific volume and mass flow rate remains constant

$$\dot{m} = \frac{A_1 V_1}{v} = \frac{A_2 V_2}{v}$$

$$A_1 V_1 = A_2 V_2$$

$$V_2 = V_1 \frac{A_1}{A_2}$$

$$= 6.37 \times \frac{(\pi/4)0.01^2}{(\pi/4)0.015^2}$$

$$\boxed{V_2 = 2.83\ \text{m/s}}$$

Step 5 of 6

Velocity of the water at inlet when the temperature is raised to 40^0C

$$\dot{m} = \rho_1 A_1 V_1$$

$$\dot{m} = \frac{A_1 V_1'}{v_1'}$$

$$V_1' = \frac{\dot{m} v_1'}{A_1}$$

$$= \frac{(0.5)(0.001008)}{\pi\left(\frac{0.01^2}{4}\right)}$$

$$\boxed{V_1' = 6.417\ \text{m/s}}$$

Step 6 of 6

Percentage change in velocity

$$\% = \frac{V_1' - V_1}{V_1} \times 100$$

$$= \frac{6.417 - 6.37}{6.37} \times 100$$

$$\% = 0.7378\%$$

If the inlet temperature changes from 15^0C to 40^0C the velocity increased by only 0.73%

Question: 6.013P

Refrigerant-134a enters a 28-cm diameter pipe steadily at 200 kPa and 20°C with a velocity of 5 m/s. The refrigerant gains heat as it flows and leaves the pipe at 180 kPa and 40°C. Determine (a) the volume flow rate of the refrigerant at the inlet, (b) the mass flow rate of the refrigerant, and (c) the velocity and volume flow rate at the exit.

Step 1 of 6

Loading solution. Please wait ...

Step 2 of 6

At $P_1 = 200$ kPa and $T_1 = 20°C$ from superheated R-134a tables

Specific volume $v_1 = 0.11418\ m^3/kg$

At $P_2 = 180$ kPa and $T_2 = 40°C$ from superheated R-134a tables

Specific volume $v_2 = 0.13741\ m^3/kg$

Step 2 of 6

At $P_1 = 200$ kPa and $T_1 = 20°C$ from superheated R-134a tables

Specific volume $v_1 = 0.11418\ m^3/kg$

At $P_2 = 180$ kPa and $T_2 = 40°C$ from superheated R-134a tables

Specific volume $v_2 = 0.13741\ m^3/kg$

Step 3 of 6

(a)

The inlet volume flow rate

$$\dot{V}_1 = AV_1$$

$$= \frac{\pi}{4}(0.28^2)5$$

$$\boxed{\dot{V}_1 = 0.3078\ m^3/s}$$

Step 4 of 6

(b)

The mass flow rate of the refrigerant

$$\dot{m} = \rho_1 \dot{V}_1$$

$$\dot{m} = \frac{\dot{V}_1}{v_1}$$

$$= \frac{0.3078}{0.11418}$$

$$\boxed{\dot{m} = 2.695\ kg/s}$$

Step 5 of 6

(c)

Since mass flow rate remains constant

$$\dot{m} = \dot{m}_1 = \dot{m}_2$$

$$\frac{V_1}{v_1} = \frac{V_2}{v_2}$$

$$V_2 = \frac{v_2}{v_1} V_1$$

$$= \frac{0.13741}{0.11418} \times 5$$

$$\boxed{V_1 = 6.017\ m/s}$$

Step 6 of 6

The exit volume flow rate

$$\dot{V}_2 = \dot{m} v_2$$

$$= (2.695)(0.13741)$$

$$\boxed{\dot{V}_2 = 0.3703\ m^3/s}$$

Question: 6.014P

A smoking lounge is to accommodate 15 heavy smokers. The minimum fresh air requirement for smoking lounges is specified to be 30 L/s per person (ASHRAE, Standard 62, 1989). Determine the minimum required flow rate of fresh air that needs to be supplied to the lounge, and the diameter of the duct if the air velocity is not to exceed 8 m/s.

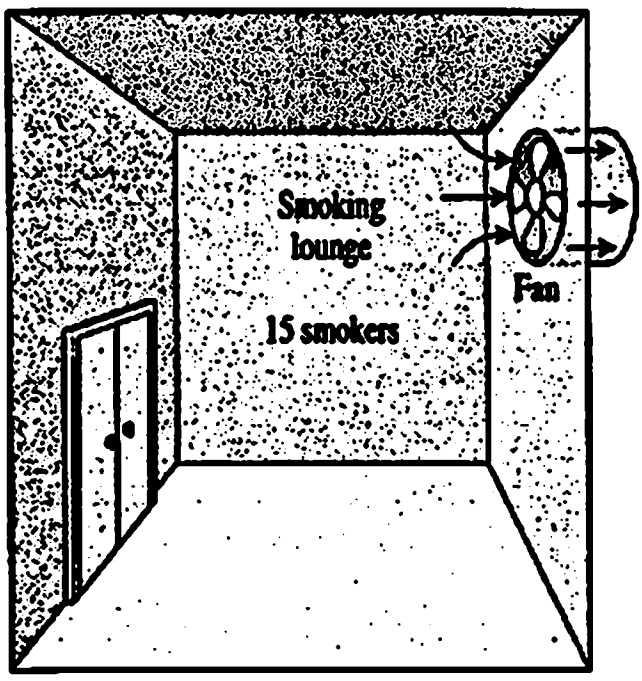

FIGURE P6–14

Step 1 of 3

Given data

The flow rate of the fresh air per person is $\dot{V} = 30\ \text{L/s}$

The velocity of air in to the lounge $V = 8\ \text{m/s}$

Number of persons $N = 15$

Step 2 of 3

The total volume flow rate of fresh air required in to the lounge is

$$\dot{V}_{total} = N\dot{V}$$

$$\dot{V}_{total} = 15 \times 30$$

$$= 450\ \text{L/s}$$

$$= 450 \times 10^{-3}\ \text{m}^3/\text{s} \qquad (1\ \text{L} = 10^{-3}\ \text{m}^3)$$

$$\boxed{\dot{V}_{total} = 0.45\ \text{m}^3/\text{s}}$$

Step 3 of 3

We know $\dot{V}_{total} = A \times V$

The area of the duct

$$A = \frac{\dot{V}_{total}}{V}$$

$$\pi\frac{d^2}{4} = \frac{0.45}{8}$$

$$d^2 = \frac{0.45 \times 4}{8 \times \pi}$$

$$d^2 = 0.0716\ \text{m}^2$$

$$\boxed{d = 0.267\ \text{m}}$$

Question: 6.015P

The minimum fresh air requirement of a residential building is specified to be 0.35 air change per hour (ASHRAE, Standard 62, 1989). That is, 35 percent of the entire air contained in a residence should be replaced by fresh outdoor air every hour. If the ventilation requirement of a 3.0-m-high, 200-m2 residence is to be met entirely by a fan, determine the flow capacity in L/min of the fan that needs to be installed. Also determine the diameter of the duct if the air velocity is not to exceed 4 m/s.

Step 1 of 3

Given

The area of the residence, $A = 200\ \text{m}^2$

The height of the building, $h = 3\ \text{m}$

Percentage of air that should be replaced by fresh air is 35%

The maximum velocity of air in the duct, $V = 4\ \text{m/s}$

Step 2 of 3

The volume of the entire building, $Vol = 3 \times 200\ \text{m}^3$

$$Vol = 600\ \text{m}^3$$

The flow capacity of the fan is $\dot{V} = \dfrac{(0.35)(600)}{60}\ \text{m}^3/\text{min}$

$$\dot{V} = 3.5\ \text{m}^3/\text{min}$$

But $1\ \text{L} = 10^{-3}\ \text{m}^3$, Hence $\dot{V} = 3500\ \text{L}/\text{min}$

Therefore the minimum flow rate should be $\boxed{\dot{V} = 3500\ \text{L}/\text{min}}$

Step 3 of 3

Volume flow rate of fresh air is $\dot{V} = A \times V$

$$\dot{V} = \frac{\pi d^2}{4} \times V$$

The diameter of the duct, $d = \sqrt{\dfrac{4\dot{V}}{\pi V}}$

$$d = \sqrt{\frac{4 \times 3.5\ \text{m}^3/\text{min}}{\pi \times 4\ \text{m/s}}}$$

$$d = \sqrt{\frac{4 \times 3.5\ \text{m}^3/\text{s}}{\pi \times 4 \times 60\ \text{m/s}}}$$

$$d = \sqrt{0.01857\ \text{m}^2}$$

$$d = 0.136\ \text{m}$$

Hence diameter of duct should be $\boxed{d = 0.136\ \text{m}}$

Question: 6.016P

What are the different mechanisms for transferring energy to or from a control volume?

Step 1 of 1

The different mechanisms which transfer energy to or from control volume are heat, work and mass.

Question: 6.017P

What is flow energy? Do fluids at rest possess any flow energy?

Step 1 of 1

Control volumes involve mass flow across their boundaries, and some work is required to push the mass into or out of the control volume. This work is known as the flow work, or flow energy.

No, fluids at rest do not posses any flow energy.

Question: 6.018P

How do the energies of a flowing fluid and a fluid at rest compare? Name the specific forms of energy associated with each case.

Step 1 of 2

The fluid at rest has total energy

$$e = u + ke + pe$$

$$e = u + \frac{v^2}{2} + gz \qquad \text{(kJ/kg)}$$

The total energy of fluid at rest consists of internal, kinetic and potential energies.

Step 2 of 2

The fluid entering or leaving a control volume possess an additional form of energy, i.e. the flow energy. Then the total energy of a flowing fluid on a unit mass basis becomes

Question:

6.019P

A water pump increases the water pressure from 10 psia to 50 psia. Determine the flow work, in Btu/lbm, required by the pump.

Step 1 of 2

Given

Initial pressure $p_1 = 10\,\text{psia}$

Final pressure $p_2 = 50\,\text{psia}$

Step 2 of 2

From properties of saturated water tables at $p_1 = 10\,\text{psia}$

$v = v_f = 0.01659\ \text{ft}^3/\text{lbm}$

Here the working substance is water and the specific volume remains constant then the flow work becomes

Question:

A water pump increases the water pressure from 10 psia to 50 psia. Determine the flow work, in Btu/lbm, required by the pump.

Question: 6.020P

An air compressor compresses 6 L of air at 120 kPa and 20°C to 1000 kPa and 400°C. Determine the flow work, in kJ/kg, required by the compressor.

Step 1 of 1

From ideal gas properties of air table, gas constant of air, $R = 0.287\ \text{kJ/kg}\cdot\text{K}$

From ideal gas equation, $Pv = RT$

Calculate the flow work,

$$\begin{aligned} W &= P_2 v_2 - P_1 v_1 \\ &= R(T_2 - T_1) \end{aligned}$$

Here,

Initial Temperature of air, T_1

Final Temperature of air, T_2

Gas constant of air, R

Inlet pressure of the air, P_1

Outlet pressure of the air, P_2

Substitute 400°C or 673K for T_2 , 0.287 kJ/kg·K for R , 20°C or 293K for T_1 , 1000 kpa for P_2 ,

$$\begin{aligned} W &= 0.287(673 - 293) \\ &= 109\ \text{kJ/kg} \end{aligned}$$

Therefore, flow work is $\boxed{109\ \text{kJ/kg}}$

Question: 6.021P

Steam is leaving a pressure cooker whose operating pressure is 20 psia. It is observed that the amount of liquid in the cooker has decreased by 0.6 gal in 45 minutes after the steady operating conditions are established, and the cross-sectional area of the exit opening is 0.15 in2. Determine (a) the mass flow rate of the steam and the exit velocity, (b) the total and flow energies of the steam per unit mass, and (c) the rate at which energy is leaving the cooker by steam.

Step 1 of 6

(a)

Calculate the mass of water that converted into steam.

$$m = \frac{V}{v_f}$$

Here, m is the mass of water that converted into steam, V is the volume of the steam, and v_f is the specific volume of the liquid.

Take the values of steam from the table "properties of saturated water" recorded at pressure $20\ \text{psia}$ at saturated state

Specific volume, $v_f = 0.01683\ \text{ft}^3/\text{lbm}$.

Substitute $0.01683\ \text{ft}^3/\text{lbm}$ for v_f and $0.6\ \text{gal}$ for V.

$$m = \frac{0.6\text{gal}}{0.01683\ \text{ft}^3/\text{lbm}}$$
$$= \frac{0.6 \times 0.1336\text{ft}^3}{0.01683\ \text{ft}^3/\text{lbm}}$$
$$= 4.762\text{lbm}$$

Step 2 of 6

Calculate the mass flow rate of the steam leaving the pressure cooker.

Water that converted into steam leaves the pressure cooker from the valve.

$$\dot{m} = \frac{m}{t}$$

Here, $\dot{m}$ is the mass flow rate of the steam and t is time.

$$\dot{m} = \frac{4.762}{45 \times 60}$$
$$\dot{m} = 1.7637 \times 10^{-3}\ \text{lbm/sec}$$

Thus, the mass flow rate of the steam is $\boxed{1.7637 \times 10^{-3}\ \text{lbm/sec}}$.

Step 3 of 6

Calculate the exit velocity of the steam.

Consider the equation of continuity.

$$\dot{m} = \frac{AV'}{v_g}$$

Here, A is the cross sectional area of the exit opening, v_g is the specific volume of vapor, and V' is the velocity of the steam.

Here, v_g is the specific volume of vapor is considered since the steam leave as vapor from the valve.

$$V' = \frac{\dot{m}v_g}{A}$$

Take the values of steam from the table "properties of super-heated steam," recorded at pressure $20\ \text{psia}$ at saturated state.

Specific volume, $v_g = 20.093\ \text{ft}^3/\text{lbm}$.

Substitute $20.093\ \text{ft}^3/\text{lbm}$ for v_g , $1.477 \times 10^{-6}\ \text{lbm/sec}$ for $\dot{m}$, and $0.15\ \text{in}^2$ for A.

$$V' = \frac{1.7637 \times 10^{-3} \times 20.093}{0.15\left(\frac{1}{12}\right)^2}$$
$$V' = 34.020\ \text{ft/s}$$

Thus, the exit velocity of the steam is $\boxed{34.020\ \text{ft/s}}$.

Step 4 of 6

(b)

Calculate the flow energy of the steam per unit mass.

$$\text{flow energy, } E_f = PV$$

Write the relation between specific enthalpy, h and internal energy, u.

$$h = u + PV$$
$$PV = h - u$$
$$E_f = h - u$$

Take the values of steam from the table "properties of saturated water" recorded at pressure $20\ \text{psia}$ at saturated state.

Specific volume, $v_g = 20.093\ \text{ft}^3/\text{lbm}$.

Specific internal energy, $u = 1081.8\ \text{Btu/lbm}$.

Specific enthalpy, $h = 1156.2\ \text{Btu/lbm}$.

Substitute $1156.2\ \text{Btu/lbm}$ for h and $1081.8\ \text{Btu/lbm}$ for u.

$$E_f = 1156.2 - 1081.8$$
$$E_f = 74.4\ \text{Btu/lbm}$$

Thus, the flow energy of the steam per unit mass is $\boxed{74.4\ \text{Btu/lbm}}$.

Step 5 of 6

Calculate the total energy of steam per unit mass.

$$\theta = h + ke + pe$$

Here, θ is the total energy of steam per unit mass, ke is the kinetic energy, and pe is the potential energy.

$$\theta = h + \frac{1}{2}(V')^2 + pe$$

Substitute $1156.2\ \text{Btu/lbm}$ for h, $0.02849\ \text{ft/s}$ for V' , and 0 for pe .

$$\theta = 1156.2\ \text{Btu/lbm} + \frac{1}{2}(34.020\ \text{ft/s})^2 + 0$$
$$\theta = 1156.2\ \text{Btu/lbm} + 578.6802 \times \frac{1}{25037}\ \text{Btu/lbm}$$
$$\theta = 1156.2231\ \text{Btu/lbm}$$

Thus, the total energy of the steam per unit mass is $\boxed{1156.2231\ \text{Btu/lbm}}$.

Step 6 of 6

(c)

Calculate the total energy flow rate.

$$\dot{E} = \dot{m}\theta$$

Here, $\dot{E}$ is the total energy flow rate.

Substitute $1156.2231\ \text{Btu/lbm}$ for θ and $1.7637 \times 10^{-3}\ \text{lbm/sec}$ for $\dot{m}$.

$$\dot{E} = 1156.2231 \times 1.7637 \times 10^{-3}$$
$$\dot{E} = 2.039\ \text{Btu/s}$$

Thus, the total energy flow rate is $\boxed{2.039\ \text{Btu/s}}$.

Question: 6.022P

Air flows steadily in a pipe at 300 kPa, 77°C, and 25 m/s at a rate of 18 kg/min. Determine (a) the diameter of the pipe, (b) the rate of flow energy, (c) the rate of energy transport by mass, and (d) the error involved in part (c) if the kinetic energy is neglected.

Step 1 of 8

Given

Pressure $P = 300$ kpa

Temperature $T = 77°C = 350K$

Velocity $V = 25$ m/s

Mass flow rate $\dot{m} = 18$ kg/min

$$= \frac{18}{60}$$

$$= 0.3 \text{ kg/s}$$

Step 2 of 8

From table ideal gas specific heats of air at $T = 350K$,

$c_p = 1.008$ kJ/kg.K

$c_v = 0.721$ kJ/kg.K

$R = C_p - C_v$

$= 1.008 - 0.721$

$R = 0.287$ kJ/kg.K

Step 3 of 8

From ideal gas equation

$$\frac{P}{\rho} = RT$$

$$\rho = \frac{P}{RT}$$

$$= \frac{300}{(0.287)(350)}$$

$\rho = 2.98656$ kg/m^3

Step 4 of 8

(a)

The diameter of the pipe

We know the mass flow rate is

$$\dot{m} = \rho A V$$

$$A = \frac{\dot{m}}{\rho V}$$

$$\pi \frac{d^2}{4} = \frac{\dot{m}}{\rho V}$$

$$d^2 = \frac{4\dot{m}}{\pi \rho V}$$

$$d = \sqrt{\frac{4}{\pi}\left(\frac{0.3}{2.98656 \times 25}\right)}$$

$\boxed{d = 0.0715 \text{ m}}$

Step 5 of 8

(b)

The rate of flow energy

$$\dot{W} = \dot{m} P v \qquad \left(\text{since } v = \frac{1}{\rho}\right)$$

$$\dot{W} = \frac{\dot{m} P}{\rho}$$

$$= (0.3)(300)\left(\frac{1}{2.98656}\right)$$

$\boxed{\dot{W} = 30.13 \text{ kW}}$

Step 6 of 8

(c)

The rate of energy transport by mass

$$\dot{E}_{mass} = \dot{m}\theta = \dot{m}\left(h + \frac{V^2}{2} + gz\right)$$

Neglecting potential energy and substituting $h = c_p T$

Then

$$\dot{E}_{mass} = \dot{m}\left(c_p T + \frac{V^2}{2}\right)$$

$$\dot{E}_{mass} = 0.3\left(1.008 \times 10^3 (350) + \frac{25^2}{2}\right)$$

$$= 0.3(352800 + 312.5)$$

$$= 105933.75 \text{W}$$

$\boxed{\dot{E}_{mass} = 105.93 \text{ kW}}$

Step 7 of 8

(d)

If the kinetic energy is neglected

The rate of energy transport by mass

$$\dot{E}_{mass} = \dot{m} h$$

$$= \dot{m} c_p T$$

$$= 0.3\left(1.008 \times 10^3\right)(350)$$

$$= 105840 \text{ W}$$

$\dot{E}_{mass} = 105.84$ kW

Step 8 of 8

The error involved in part (c) is

error $= 105.93 - 105.84$

$\boxed{\text{error} = 0.09}$

i.e. 9% of error will occur if we neglect Kinetic energy.

Question: 6.023P

Can a steady-flow system involve boundary work?

Step 1 of 1

No, in a steady flow system the fluid properties at an inlet or exit remain constant, so there will be no boundary work involved.

Question: 6.024P

A diffuser is an adiabatic device that decreases that kinetic energy of the fluid by slowing it down. What happens to this *lost* kinetic energy?

Step 1 of 1

A diffuser is a device that increases the pressure of a fluid by slowing it down. The lost kinetic energy is converted as internal energy.

Question: 6.025P

The kinetic energy of a fluid increases as it is accelerated in an adiabatic nozzle. Where does this energy come from?

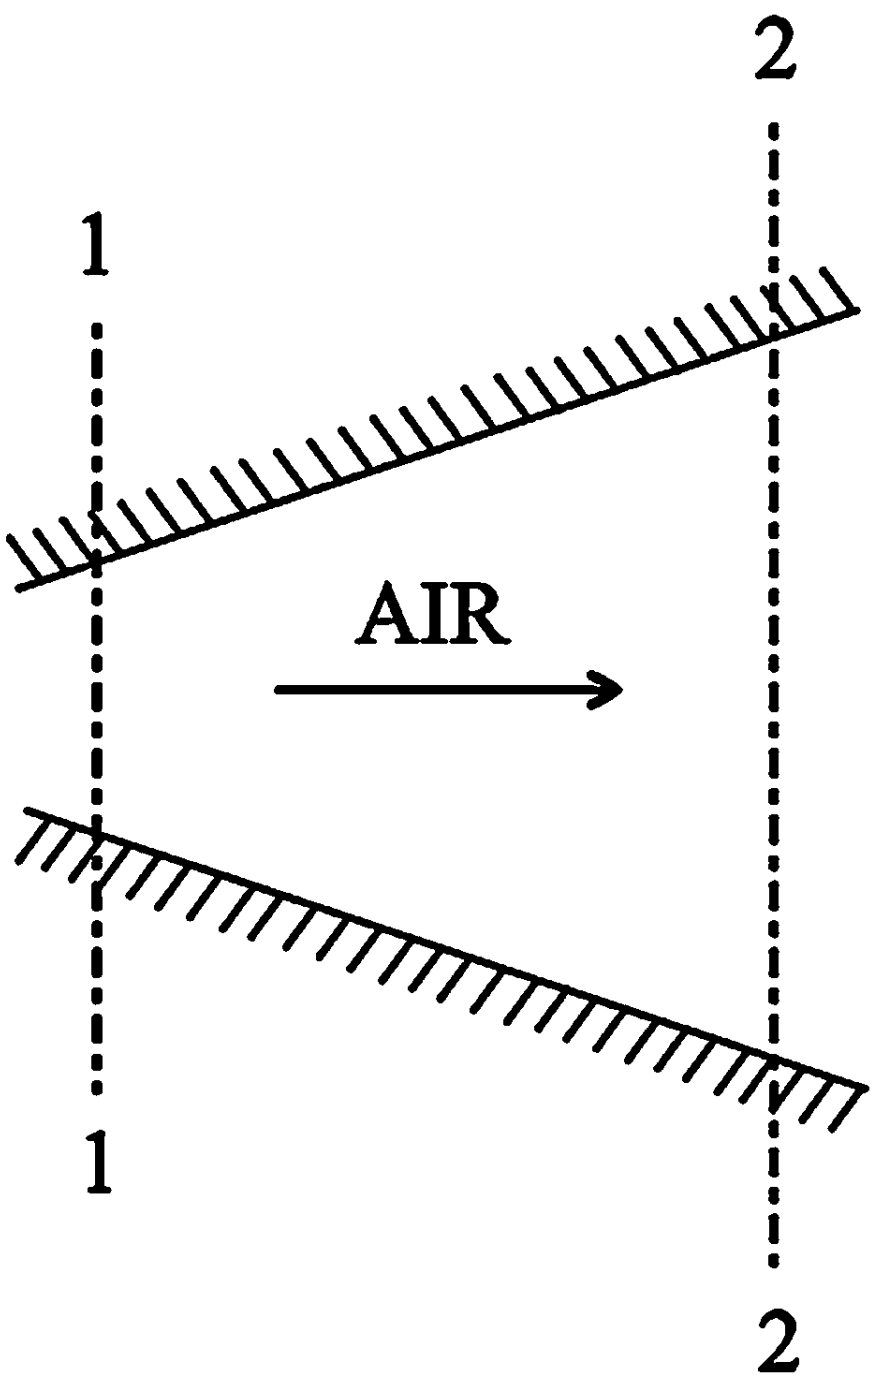
Step 1 of 1

The nozzle is a device that increases the velocity of the fluid at the expense of pressure.
The internal energy of the fluid will be converted into kinetic energy.

Question: 6.026P

Is heat transfer to or from the fluid desirable as it flows through a nozzle? How will heat transfer affect the fluid velocity at the nozzle exit?

Step 1 of 1



Heat transfer to the fluid as it flows through a nozzle is desirable since it will probably increase the kinetic energy of the fluid. Heat transfer from the fluid will decrease the exit velocity

Question: 6.027P

Air at 80 kPa and 127°C enters an adiabatic diffuser steadily at a rate of 6000 kg/h and leaves at 100 kPa. The velocity of the air stream is decreased from 230 to 30 m/s as it passes through the diffuser. Find (a) the exit temperature of the air and (b) the exit area of the diffuser.

Step 1 of 5

Draw the schematic diagram of the diffuser.

Step 2 of 5

Assumptions:

1. The flow of air is a steady-flow process

2. Device is adiabatic and heat transfer is negligible

3. Potential energy changes are negligible

4. Work interactions are negligible

Determine the enthalpy of air at state 1 corresponding to a temperature of 400K from ideal gas properties of air.

$$h_1 = 400.98 \text{ kJ/kg}$$

Step 3 of 5

Write the conversion factor to convert kg/h to kg/s.

$$1 \text{ kg/h} = 2.78\times10^{-4} \text{ kg/s}$$

Convert the mass flow rate from 6000 kg/h to kg/s.

$$6000 \text{ kg/h} = 6000 \text{ kg/h} \times \frac{2.78\times10^{-4} \text{ kg/s}}{1 \text{ kg/h}}$$
$$= 1.67 \text{ kg/s}$$

Step 4 of 5

(a)

Calculate the enthalpy at state 2 by using energy balance equation per unit mass for steady state process.

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

Here, heat supplied to the system is q .work done by the system is w , enthalpy at state 1 is h_1 , enthalpy at state 2 is h_2 , velocity of air at state 1 is V_1 , velocity of air at state 2 is V_2 , potential head at state 1 is z_1 and potential head at state 2 is z_2.

Substitute 230 m/s for V_1, 30 m/s for V_2, $400.98\times10^3 \text{ J/kg}$ for h_1, 9.81 m/s^2 for g, 0 for q, 0 for w and $z_1 = z_2$.

$$0 - 0 = h_2 - (400.98\times10^3) + \frac{(30)^2 - (230)^2}{2} + (9.81\times0)$$
$$h_2 = (400.98\times10^3) + 26000$$
$$h_2 = 426.98 \text{ kJ/kg}$$

Step 5 of 5

Calculate the temperature at state 2 by use of interpolation of values from ideal gas properties of air.

$$\frac{T_{@426.98\text{ kJ/kg}} - T_{@421.26\text{ kJ/kg}}}{T_{@431.43\text{ kJ/kg}} - T_{@421.26\text{ kJ/kg}}} = \frac{h_{@426.98\text{ kJ/kg}} - h_{@421.26\text{ kJ/kg}}}{h_{@431.43\text{ kJ/kg}} - h_{@421.26\text{ kJ/kg}}}$$
$$T_2 = 420 + (430 - 420)\left(\frac{426.98 - 421.26}{431.43 - 421.26}\right)$$
$$T_2 = 425.62 \text{ K}$$

Therefore, the temperature at exit is $\boxed{425.62 \text{ K}}$.

(b)

Calculate the density of air at the exit of the diffuser from ideal gas equation.

$$\rho_2 = \frac{P_2}{RT_2}$$

Here, pressure of air at exit is P_2, gas constant for air is R and temperature of air at exit is T_2.

Substitute $0.287 \text{ kJ/kg}\cdot\text{K}$ for R, 100 kPa for P_2 and T_2 for 425.62 K.

$$\rho_2 = \frac{100}{(0.287)\times(425.62)}$$
$$= 0.818 \text{ kg/m}^3$$

Calculate the exit area of the diffuser by maintain the mass flow rate constant.

$$\dot{m} = \rho_1 A_1 V_1 = \rho_2 A_2 V_2$$

$$A_2 = \frac{\dot{m}}{V_2 \rho_2}$$

Here, mass flow rate of air is $\dot{m}$, area of the diffuser at inlet is A_1, density of air at inlet is ρ_1, density of air at exit is ρ_2, velocity of air at state 1 is V_1 and velocity of air at state 2 is V_2.

Substitute 1.67 kg/s for $\dot{m}$, 0.818 kg/m^3 for ρ_2 and 30 m/s for V_2.

$$A_2 = \frac{1.67}{30\times0.818}$$
$$= 0.068 \text{ m}^2$$

Therefore, the exit area of the diffuser is $\boxed{0.068 \text{ m}^2}$.

Question: 6.028P

Air enters an adiabatic nozzle steadily at 300 kPa, 200°C, and 45 m/s and leaves at 100 kPa and 180 m/s. The inlet area of the nozzle is 110 cm2. Determine (*a*) the mass flow rate through the nozzle, (b) the exit temperature of the air, and (*c*) the exit area of the nozzle.

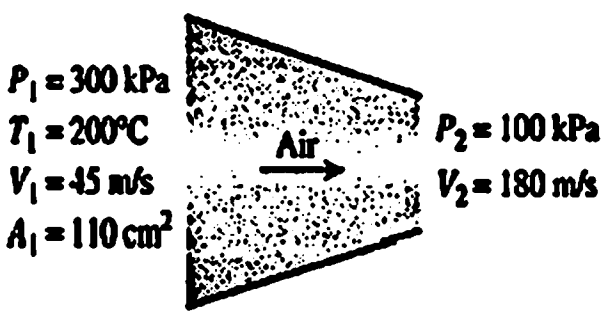


FIGURE P6–28

Step 1 of 5

Given

Inlet Pressure of air, $P_1 = 300$ kPa

Inlet Temperature of air, $T_1 = 200°C$

$$T_1 = 473K$$

Inlet Velocity of air, $V_1 = 45$ m/s

Inlet area of nozzle, $A_1 = 110$ cm^2

$$A_1 = 0.011\ \text{m}^2$$

Exit Pressure of air, $P_2 = 100$ kPa

Exit velocity of air, $V_2 = 180$ m/s

Ideal gas properties of air table,

The gas constant for air $R = 0.287$ kJ/kg.K and

Specific heat of air, $C_p = 1.02$ kJ/kg.K

Step 2 of 5

(a)

From ideal gas equation, $P = \rho RT$

Density of air, $\rho = \dfrac{P}{RT}$

$$\rho_1 = \frac{P_1}{RT_1}$$

$$\rho_1 = \frac{300}{(0.287)(473)}$$

$$\rho_1 = 2.21\ \text{kg/m}^3$$

Mass flow rate, $\dot{m} = \rho A_1 V_1$

$$\dot{m} = (2.21)(0.011)(45)\ \text{kg/s}$$

$$\dot{m} = 1.094\ \text{kg/s}$$

Therefore mass flow rate is $\boxed{\dot{m} = 1.094\ \text{kg/s}}$

Step 3 of 5

(b)

The energy balance equation per unit mass for a steady state process is

$$(q - w) = (h_2 - h_1) + \left(\frac{V_2^2 - V_1^2}{2}\right) + g(z_2 - z_1)$$

As the process is adiabatic, heat transfer is $q = 0$

And external work done on this process is $w = 0$

Also the nozzle entrance and exit are at same level. So $z_1 = z_2$

Enthalpy $h = C_p T$

Therefore $0 = C_p(T_2 - T_1) + \dfrac{V_2^2 - V_1^2}{2}$

$$(T_1 - T_2) = \frac{V_2^2 - V_1^2}{2C_p}$$

$$T_2 = T_1 - \left(\frac{V_2^2 - V_1^2}{2C_p}\right)$$

$$T_2 = 200 - \left(\frac{180^2 - 45^2}{2 \times 1.02 \times 10^3\ \text{J/kg}}\right)$$

$$T_2 = 200 - (14.89)$$

$$T_2 = 185.11°C$$

The exit temperature of the air $\boxed{T_2 = 185.11°C}$

Step 4 of 5

(c)

From ideal gas equation, $P = \rho RT$

$$\rho_2 = \frac{P_2}{RT_2}$$

$$\rho_2 = \frac{100}{(0.287)(185.11 + 273)}$$

$$\rho_2 = 0.762\ \text{kg/m}^3$$

Step 5 of 5

Mass flow rate, $\dot{m} = \rho AV$

Mass flow rate remains constant throughout the nozzle, $\dot{m} = \rho_1 A_1 V_1 = \rho_2 A_2 V_2$

Therefore $A_2 = \dfrac{\dot{m}}{\rho_2 V_2}$

$$A_2 = \frac{1.1}{0.762 \times 180}$$

$$A_2 = 80 \times 10^{-4}\ \text{m}^2$$

$$A_2 = 80\ \text{cm}^2$$

The exit area of the nozzle $\boxed{A_2 = 80\ \text{cm}^2}$

Question: 6.029P pg 1

Reconsider Prob. 6-28. Using EES (or other) IIII software, investigate the effect of the inlet area on the mass flow rate, exit temperature, and the exit area. Let the inlet area vary from 50 cm2 to 150 cm2. Plot the final results against the inlet area, and discuss the results.

Step 1 of 8

a)The ideal gas equation,

$$P = \rho RT$$

The Density of air,

$$\rho = \frac{P}{RT}$$

$$\rho_1 = \frac{P_1}{RT_1}$$

Here, the Inlet Pressure of air is P_1, the Inlet Temperature of air is T_1 and the gas constant for air R.

Substitute $300\ \text{kPa}$ for P_1 . $200+273 = 473\text{K}$ for T_1 .

From Ideal gas properties of air table,

The gas constant for air is $R = 0.287\,\text{kJ/kg.K}$ and Specific heat of air is $C_p = 1.02\,\text{kJ/kg.K}$

$$\rho_1 = \frac{300}{(0.287)(473)}$$
$$= 2.21\ \text{kg/m}^3$$

The Mass flow rate of air,

$$\dot{m} = \rho A_1 V_1$$

Here, the Inlet area of nozzle is A_1 and the Inlet Velocity of air is V_1 .

Substitute $0.011\,\text{m}^2$ for A_1 and $45\,\text{m/s}$ for V_1

$$\dot{m} = \rho A_1 V_1$$
$$= (2.21)(0.011)(45)$$
$$= 1.094\,\text{kg/s}$$

The mass flow rate of air $\dot{m}$ is $\boxed{1.094\,\text{kg/s}}$

Step 2 of 8

b) The energy balance equation per unit mass for a steady state process is

$$(q - w) = (h_2 - h_1) + \left(\frac{V_2^2 - V_1^2}{2}\right) + g(z_2 - z_1)$$

As the process is adiabatic, heat transfer is $q = 0$, the external work done on this process is $w = 0$ and Also the nozzle entrance and exit are at same level. So $z_1 = z_2$

Enthalpy $h = C_p T$

$$0 = C_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$
$$(T_1 - T_2) = \frac{V_2^2 - V_1^2}{2C_p}$$
$$T_2 = T_1 - \left(\frac{V_2^2 - V_1^2}{2C_p}\right)$$

Here, the exit Velocity of air is V_2 and Specific heat of air is C_p.

Substitute $1.02\,\text{kJ/kg.K}$ for C_p and $180\,\text{m/s}$ for V_2.

$$T_2 = T_1 - \left(\frac{V_2^2 - V_1^2}{2C_p}\right)$$
$$= 200 - \left(\frac{180^2 - 45^2}{2\times 1.02\times 10^3}\right)$$
$$= 200 - (14.89)$$
$$= 185.11°\text{C}$$

The exit temperature of the air T_2 is $\boxed{185.11°\text{C}}$

Step 3 of 8

c) Ideal gas equation, $P = \rho RT$

$$\rho = \frac{P}{RT}$$
$$\rho_2 = \frac{P_2}{RT_2}$$

Here, the exit Pressure of air is P_2, the exit Temperature of air is T_2 and the gas constant for air R.

Substitute $100\ \text{kPa}$ for P_2 . $185.11°\text{C} + 273 = 458.11\text{K}$ for T_2.

$$\rho_2 = \frac{P_2}{RT_2}$$
$$\rho_2 = \frac{100}{(0.287)(185.11+273)}$$
$$\rho_2 = 0.762\ \text{kg/m}^3$$

Step 4 of 8

Mass flow rate,

$$\dot{m} = \rho AV$$

Mass flow rate remains constant throughout the nozzle,

Mass flow rate,

$$\dot{m} = \rho A V$$

Mass flow rate remains constant throughout the nozzle,

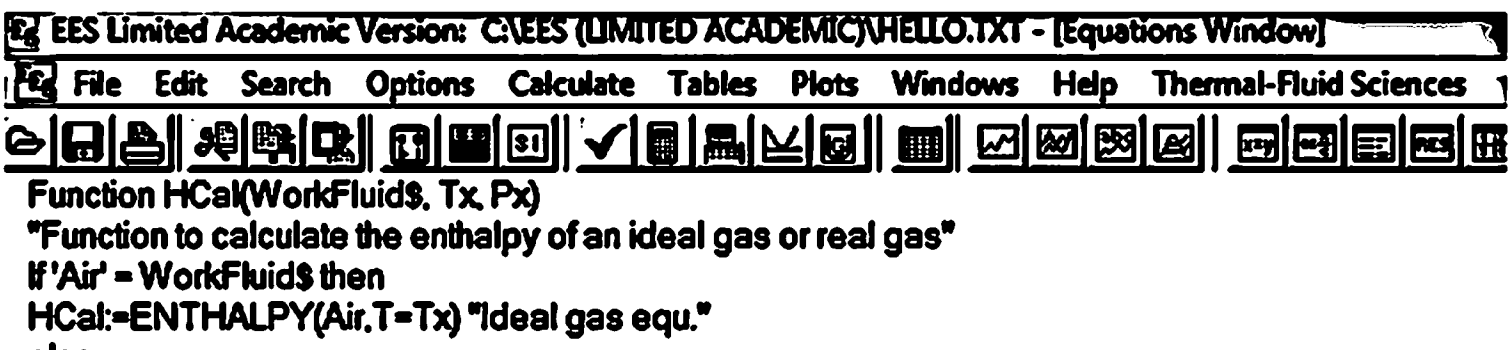
$$\dot{m} = \rho_1 A_1 V_1 = \rho_2 A_2 V_2$$

$$A_2 = \frac{\dot{m}}{\rho_2 V_2}$$

$$= \frac{1.1}{0.762 \times 180}$$

$$= 80 \times 10^{-4}\ \text{m}^2$$

$$= 80\ \text{cm}^2$$



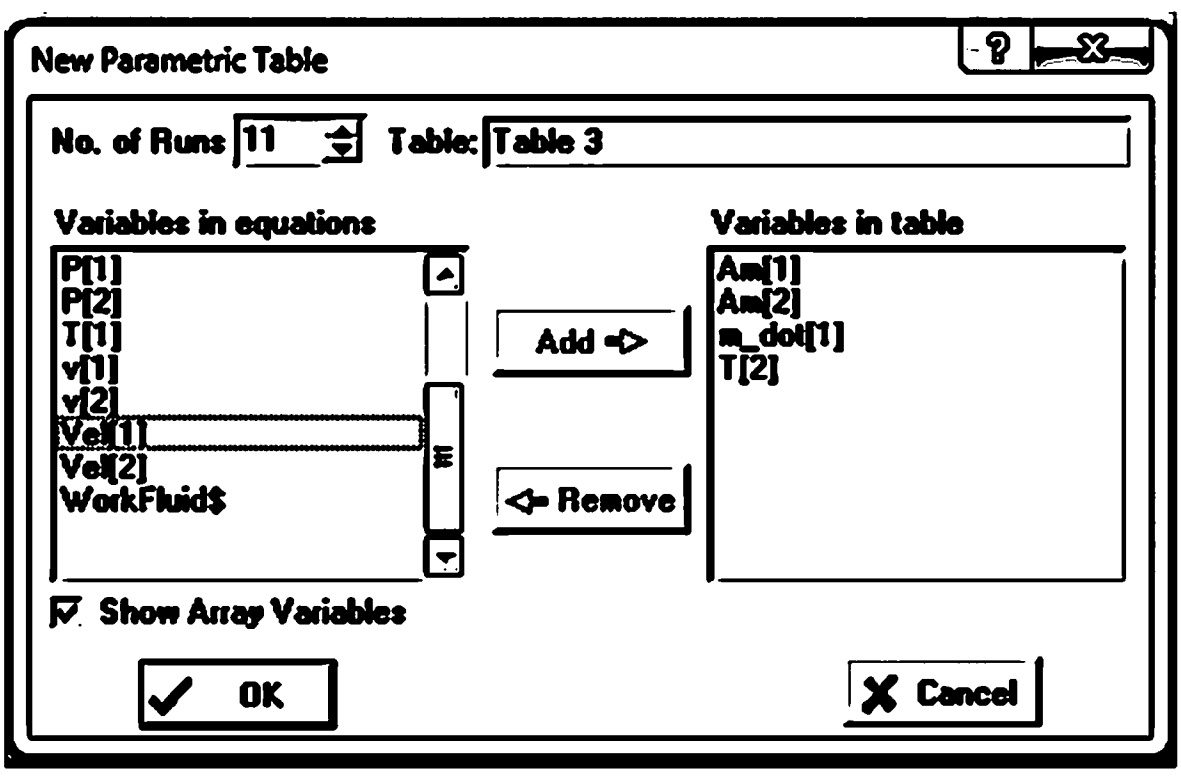
The exit area of the nozzle A_2 is $\boxed{80\ \text{cm}^2}$

The given problem can be solved using EES software by following the below steps.

1. Open EES software

2. Create a new file by clicking on the 'New' of the 'File menu'

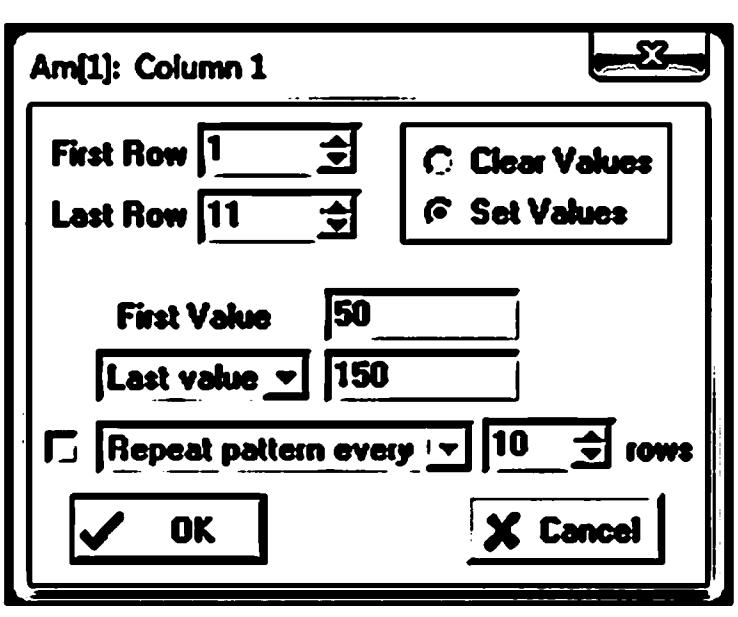
3. Now type the following code in dailog box



Step 5 of 8

Now to solve the equation for a range of Area values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.

A dailog box will open.



Select no of runs = 11.

Select variables in equations as "Am[1]" "Am[2]" "m_doT[1]"and "T[2]" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

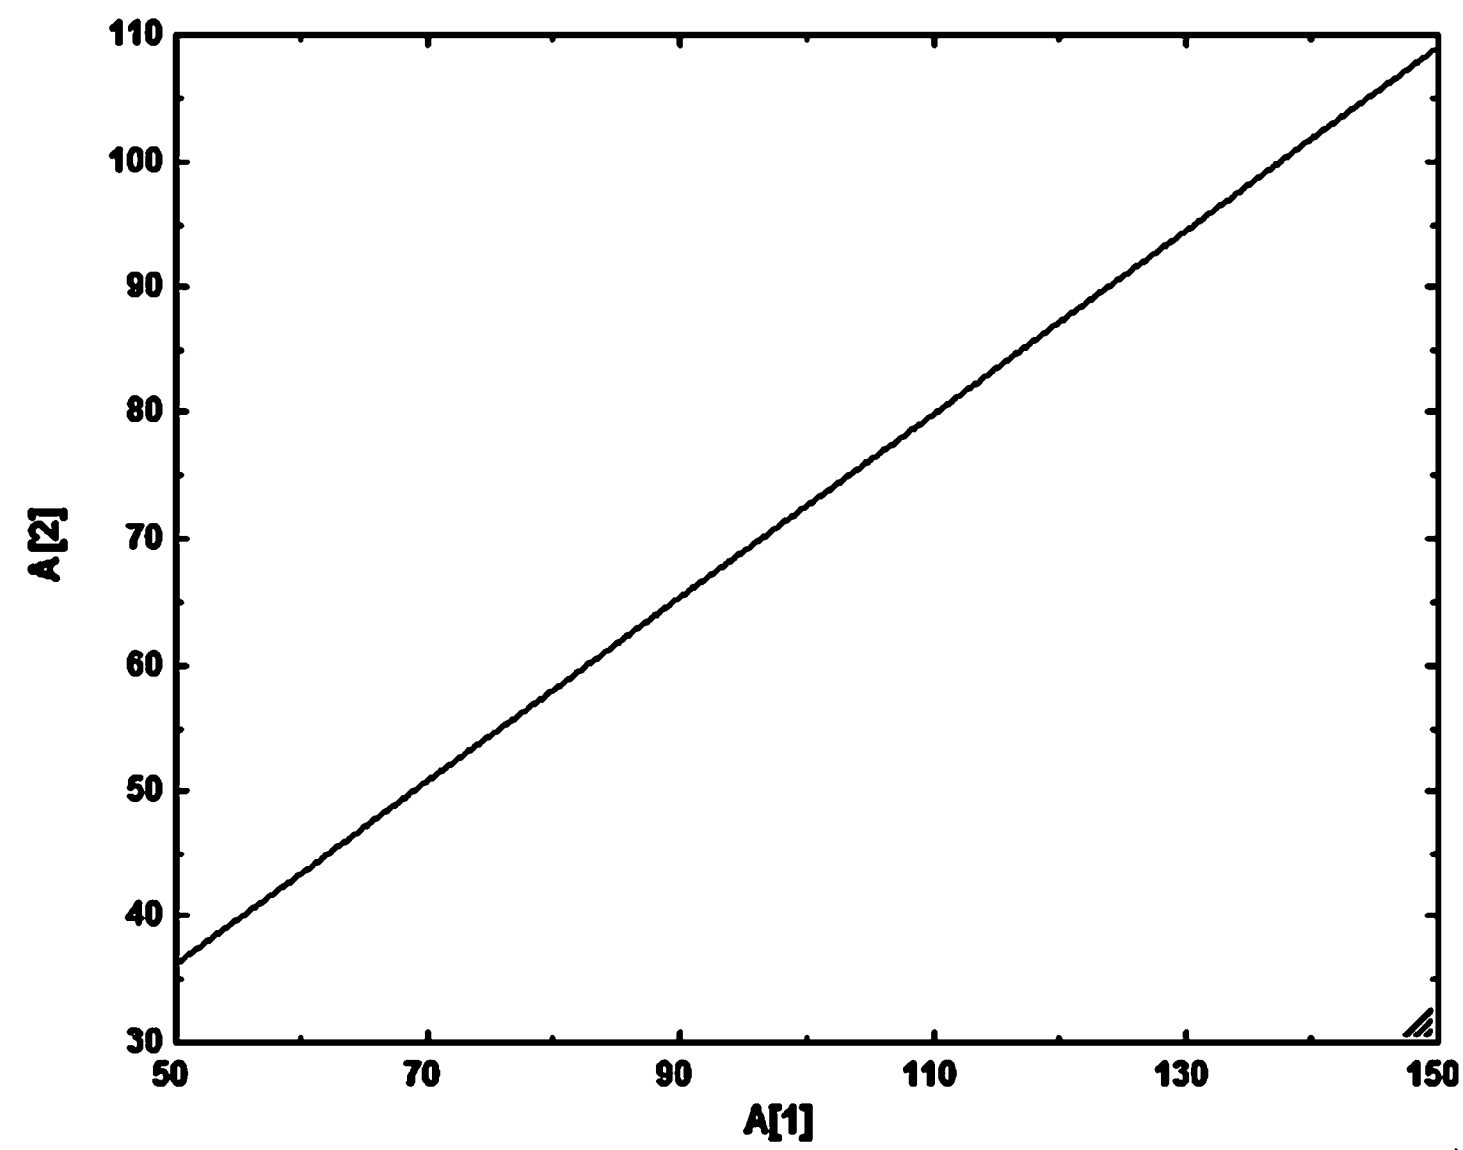
Step 6 of 8

To enter the values in the "Am[1]" column click on the drop tab in "Am[1]" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Now click on 'Solve table' of 'Calculate' menu.

The Solution will appear as shown below:

1..11	1 A_1	2 A_2	3 $\dot{m}_1$	4 T_2 [C]
Run 1	50	36.32	0.497	185.2
Run 2	60	43.59	0.5964	185.2
Run 3	70	50.85	0.6958	185.2
Run 4	80	58.12	0.7952	185.2
Run 5	90	65.38	0.8946	185.2
Run 6	100	72.65	0.9941	185.2
Run 7	110	79.91	1.093	185.2
Run 8	120	87.18	1.193	185.2



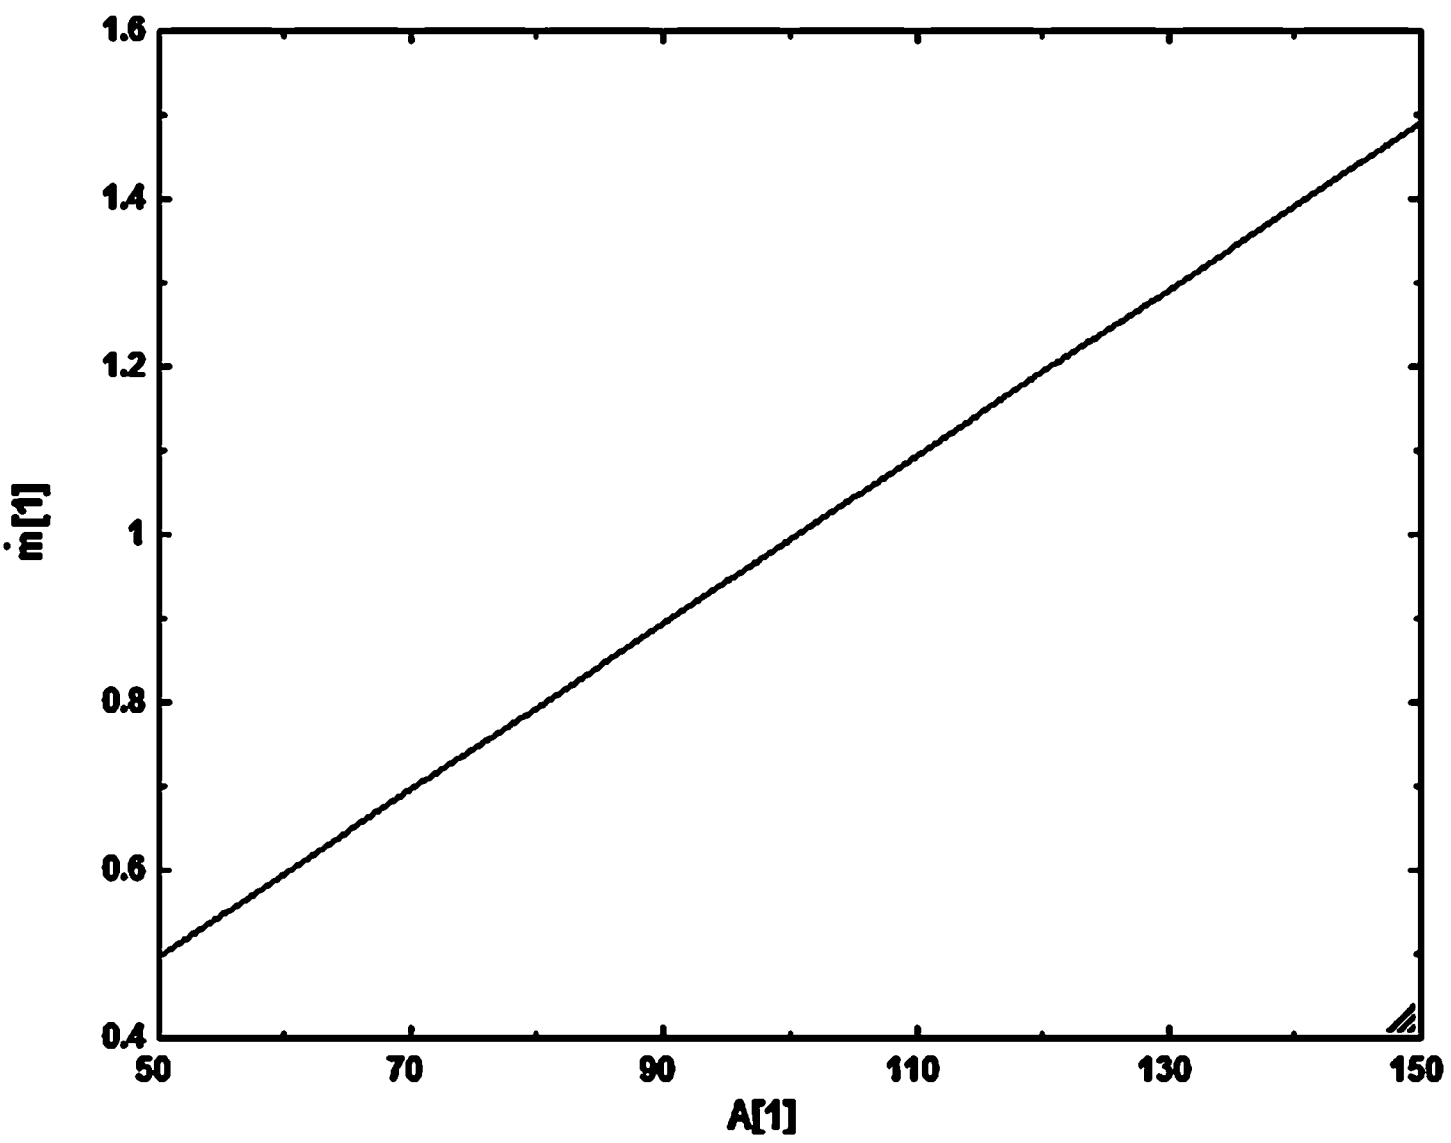
Run 4	80	58.12	0.7952	185.2
Run 5	90	65.38	0.8946	185.2
Run 6	100	72.65	0.9941	185.2
Run 7	110	79.91	1.093	185.2
Run 8	120	87.18	1.193	185.2
Run 9	130	94.44	1.292	185.2
Run 10	140	101.7	1.392	185.2
Run 11	150	109	1.491	185.2

Step 7 of 8

Inorder to plot the area A1 versus the area A2, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.

Select X-axis as "A[1]" and Y-axis as "A[2]" and press 'OK'

The Graph will be plotted as shown below:



Step 8 of 8

Inorder to plot the area A1 versus the Mass flow rate $\dot{m}[1]$, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.

Select X-axis as "A[1]" and Y-axis as "$\dot{m}[1]$" and press 'OK'

The Graph will be plotted as shown below:

Question: 6.030P

The stators in a gas turbine are designed to increase the kinetic energy of the gas passing through them adiabatically. Air enters a set of these nozzles at 300 psia and 700°F with a velocity of 80 ft/s and exits at 250 psia and 645°F. Calculate the velocity at the exit of the nozzles.

Step 1 of 4

Given

Inlet pressure $P_1 = 300$ psia

Inlet temperature $T_1 = 700°F = 1160^0R$

Inlet velocity $V_1 = 80$ ft/s

Exit pressure $P_2 = 250$ psia

Exit temperature $T_2 = 645°F = 1105^0R$

Step 2 of 4

The energy balance equation per unit mass for a steady state process is

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

Here $q = w = 0$ and $z_1 = z_2$

$$0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \text{ ---------- (1)}$$

Step 3 of 4

At $T_1 = 700°F = 1160^0R$ from ideal gas properties of air

$h_1 = 281.14$ Btu/lbm

At $T_2 = 645°F = 1105^0R$ from ideal gas properties of air

$$h_2 = 260.97 + (271.03 - 260.97)\left(\frac{1105 - 1080}{1120 - 1080}\right)$$

$h_2 = 267.2575$ Btu/lbm

Step 4 of 4

Then from equation (1)

$$0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

$$0 = (267.2575 - 281.14) \times 25047 + \frac{V_2^2 - 80^2}{2}$$

$V_2^2 = 701829.955 ft^2/s^2$

$\boxed{V_2 = 837.752 ft/s}$

Question: 6.031P

The diffuser in a jet engine is designed to decrease the kinetic energy of the air entering the engine compressor without any work or heat interactions. Calculate the velocity at the exit of a diffuser when air at 100 kPa and 20°C enters it with a velocity of 500 m/s and the exit state is 200 kPa and 90°C.

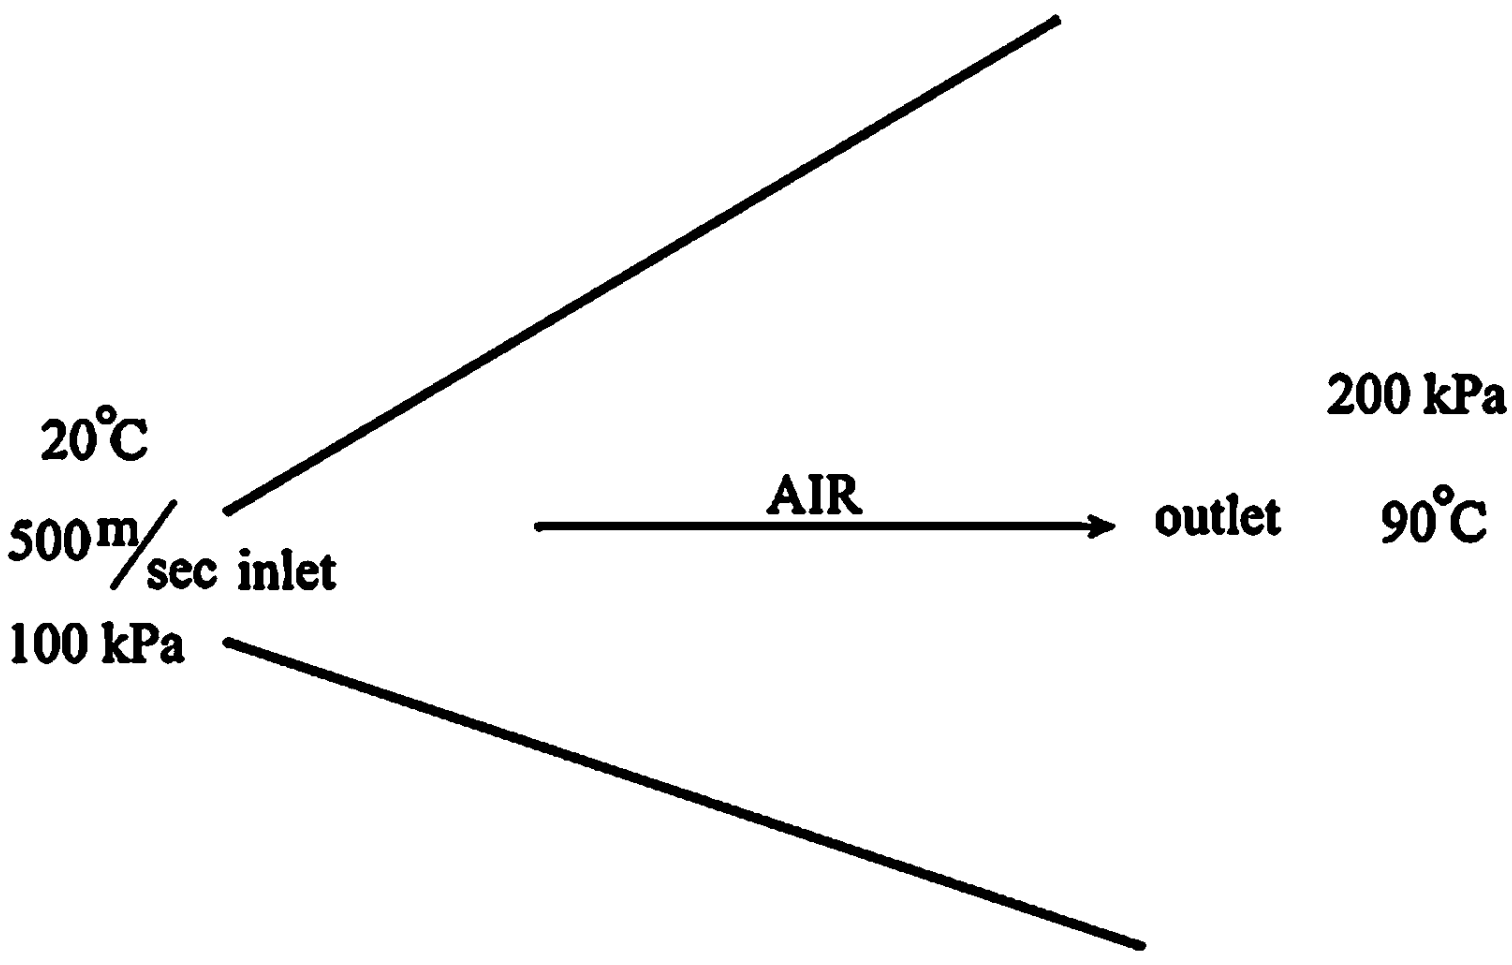


FIGURE P6–31

Step 1 of 6

Sketch the system as follows.

Consider the diffuser as the control volume system, as the mass crosses the boundary.

Step 2 of 6

The energy balance equation per unit mass for a steady state process is below.

Rate of net energy transfer by heat, work and mass is equal to the rate of change of internal kinetic, potential energies.

Therefore, the energy balance equation per unit mass for a steady state process is as follows.

$$\dot{E}_{in}-\dot{E}_{out}=\frac{\Delta \dot{E}_{system}}{dt}=0$$

Since it is a steady state process, hence the above equation becomes as follows.

$$\dot{E}_{in}-\dot{E}_{out}=0$$
$$\dot{m}_1\left(h_1+\frac{V_1^2}{2}\right)=\dot{m}_2\left(h_2+\frac{V_2^2}{2}\right)$$

Step 3 of 6

Since there is only one entry and exit the mass flow rate at the inlet and the outlet is equal.

$$\dot{m}_1=\dot{m}_2=\dot{m}$$

Therefore, write the above equation as follows.

$$\left(h_1+\frac{V_1^2}{2}\right)=\left(h_2+\frac{V_2^2}{2}\right)$$

Rewrite the above equation for V_2 as follows.

$$V_2=\left[V_1^2+2(h_1-h_2)\right]^{0.5}$$

Since $h_1=h_2=c_p(T)_{1,2}$, V_2 becomes as follows.

$$V_2=\left[V_1^2+2c_p(T_1-T_2)\right]^{0.5} \quad \text{..... (1)}$$

Here, c_p is the specific heat capacity, V_1 is the initial velocity, T_1 and T_2 are the initial and final temperatures.

Step 4 of 6

Calculate the average temperatures.

The average temperature of the air is below.

$$T=\frac{T_1+T_2}{2}$$

Here, T_1 and T_2 are the initial and final temperatures.

Substitute $293\,\text{K}$ for T_1 and $363\,\text{K}$ for T_2.

$$T=\frac{293+363}{2}$$
$$=328\,\text{K}$$

Step 5 of 6

Calculate the value for the c_p.

Obtain the value for the value c_p at the average temperature of the air from the table A-2 of ideal gas specific heats of various common gases at various temperatures.

Calculate the specific heat capacity, for the temperature values at $T_2=350\,\text{K}$ and $T_1=300\,\text{K}$ by interpolating the specific heat capacities values at $c_{p2}=1.008$ and $c_{p1}=1.005$

$$(c_p)=c_{p,300\text{K}}+(c_{p,350\text{K}}-c_{p,350\text{K}})\left(\frac{328-300}{350-300}\right)$$
$$=1.007+(1.008-1.007)(0.56)$$
$$=1.007+5.6\times10^{-4}$$
$$=1.00756\ \text{kJ/kg}\cdot\text{k}$$

Step 6 of 6

Substitute $1.00756\ \text{kJ/kg}\cdot\text{k}$ for c_p, $500\ \text{m}^2/\text{sec}^2$ for V_1 and $293\,\text{K}$ for T_1 and $363\,\text{K}$ for T_2 in equation (1).

$$V_2=\left[V_1^2+2c_p(T_1-T_2)\right]^{0.5}$$
$$=\left[500^2+2\times1.00756(20-90)\,\text{K}\left(\frac{1000\ \text{m}^2/\text{s}^2}{1\ \text{kJ/kg}}\right)\right]^{0.5}$$
$$=330.06\ \text{m/s}$$

Therefore, velocity at the exit V_2 is $\boxed{330.06\ \text{m/s}}$.

Question: 6.032P

Steam enters a nozzle at 400°C and 800 kPa with a velocity of 10 m/s, and leaves at 300°C and 200 kPa while losing heat at a rate of 25 kW. For an inlet area of 800 cm2, determine the velocity and the volume flow rate of the steam at the nozzle exit.

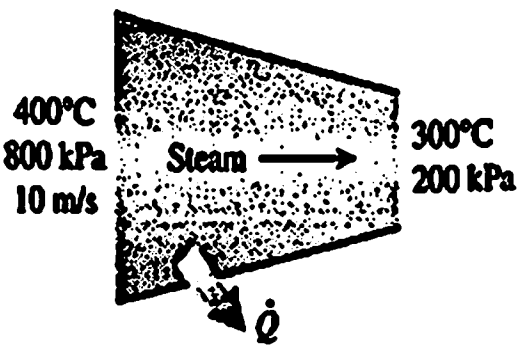

FIGURE P6–32

Step 1 of 5

Given

Inlet pressure $P_1 = 800$ kPa

Inlet temperature $T_1 = 400°C$

Inlet velocity $V_1 = 10$ m/s

Inlet cross-sectional area $A_1 = 800\ \text{cm}^2 = 0.08\ \text{m}^2$

Exit pressure $p_2 = 200$ kPa

Exit temperature $T_2 = 300°C$

The rate of heat loss $\dot{Q} = -25$ kW

Step 2 of 5

At $P_1 = 800$ kPa , $T_1 = 400°C$ from super heated steam tables

$v_1 = 0.38429\ \text{m}^3/\text{kg}$ And

$h_1 = 3267.7$ kJ/kg

At $P_2 = 200$ kPa , $T_2 = 300°C$

$v_2 = 1.31623\ \text{m}^3/\text{kg}$ and

$h_2 = 3072.1$ kJ/kg

Step 3 of 5

(a) The exit velocity

The energy balance equation per unit mass for a steady state process is

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

Here $w = 0$ and $z_1 = z_2$ and $q = \frac{\dot{Q}}{\dot{m}}$

The mass flow rate of steam can be obtained by using

$$\dot{m} = \frac{A_1 V_1}{v_1}$$

$$= \frac{(0.08)(10)}{0.38429}$$

$$\dot{m} = 2.08\ \text{kg/s}$$

Step 4 of 5

Therefore

$$-\frac{\dot{Q}}{\dot{m}} = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

$$-\frac{25\times10^3}{2.08} = (3072.1 - 3267.7)\times10^3 + \frac{V_2^2 - 10^2}{2}$$

$$-12.019\times10^3 = -195.6\times10^3 + \frac{V_2^2 - 10^2}{2}$$

$$V_2^2 = 367162 + 10^2$$

$$\boxed{V_2 = 606.02\ \text{m/s}}$$

Step 5 of 5

(b) The volume flow rate at the exit.

The volume flow rate is expressed as

$$\dot{V}_2 = \dot{m} v_2$$

$$= 2.08(1.31623)$$

$$\boxed{\dot{V} = 2.737\ \text{m}^3/\text{s}}$$

Question: 6.033P

Steam at 3 MPa and 400°C enters an adiabatic nozzle steadily with a velocity of 40 m/s and leaves at 2.5 MPa and 300 m/s. Determine (a) the exit temperature and (b) the ratio of the inlet to exit area *A1/A2*.

Step 1 of 6

Given

Inlet pressure $P_1 = 3\ \text{MPa}$

Inlet temperature $T_1 = 400°\text{C}$

Inlet velocity $V_1 = 40\ \text{m/s}$

Exit pressure $P_2 = 2.5\ \text{MPa}$

Exit velocity $V_2 = 300\ \text{m/s}$

Step 2 of 6

At $P_1 = 3\ \text{MPa}$, $T_1 = 400°\text{C}$ from superheated steam tables

$v_1 = 0.09938\ \text{m}^3/\text{kg}$

$h_1 = 3231.7\ \text{kJ/kg}$

Step 3 of 6

(a)

The exit temperature can be obtained by using energy balance equation per unit mass for a steady state process is

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

Here $q = w = 0$ and $z_1 = z_2$

Therefore

$$0 = (h_2 - h_1) + \frac{V_2^2 - V_1^2}{2}$$

$$0 = (h_2 - 3231.7) + \frac{300^2 - 40^2}{2}\left(\frac{1}{1000}\right)$$

$$h_2 = 3187.5\ \text{kJ/kg}$$

Step 4 of 6

At $P_2 = 2.5\ \text{MPa}$ and $h_2 = 3187.5\ \text{kJ/kg}$ from superheated steam tables by using interpolation

$$T_2 = 350 + (400 - 350)\left(\frac{3187.5 - 3127.0}{3240.1 - 3127.0}\right)$$

$$\boxed{T_2 = 376.746°\text{C}}$$

Step 5 of 6

(b) The ratio of the inlet to exit area A_1 / A_2

We know that mass flow rate remains constant

$$\dot{m} = \frac{A_1 V_1}{v_1} = \frac{A_2 V_2}{v_2}$$

$$\frac{A_1}{A_2} = \frac{V_2 v_1}{V_1 v_2}$$

At $P_2 = 2.5\ \text{MPa}$ and $T_2 = 376.746°\text{C}$ from superheated steam tables

$$v_2 = 0.10979 + (0.12012 - 0.10979)\left(\frac{376.746 - 350}{400 - 350}\right)$$

$$v_2 = 0.11531\ \text{m}^3/\text{kg}$$

Step 6 of 6

Then

$$\frac{A_1}{A_2} = \frac{V_2 v_1}{V_1 v_2}$$

$$\frac{A_1}{A_2} = \frac{300(0.09938)}{40(0.11531)}$$

$$\boxed{\frac{A_1}{A_2} = 6.463}$$

Question: 6.034P

Air at 13 psia and 50°F enters an adiabatic diffuser steadily with a velocity of 600 ft/s and leaves with a low velocity at a pressure of 14.5 psia. The exit area of the diffuser is 4 times the inlet area. Determine (a) the exit temperature and (b) the exit velocity of the air.

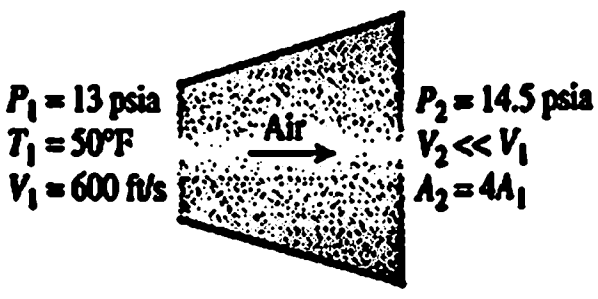

FIGURE P6–34E

Step 1 of 3

(a)

Apply energy balance equation per unit mass for a steady state diffuser

$$(q-w)=(h_2-h_1)+\left(\frac{V_2^2-V_1^2}{2}\right)+g(z_2-z_1)$$

Here, q is the amount of heat transfer, w is the work transfer; h_1, h_2 are the enthalpies at diffuser entrance and exit; V_1, V_2 are the velocities at diffuser entrance and exit; z_1, z_2 are the datum heads at diffuser entrance and exit and g is acceleration due to gravity.

Since Diffuser is adiabatic diffuser, there is no change in heat transfer $q=0$, there is no work transfer during the process $w=0$

Also the diffuser entrance and exit are at same level, so $z_1 = z_2$

Substitute all those known values in energy equation,

$$(q-w)=(h_2-h_1)+\left(\frac{V_2^2-V_1^2}{2}\right)+g(z_2-z_1)$$

$$0-0=(h_2-h_1)+\left(\frac{V_2^2-V_1^2}{2}\right)+g(0)$$

$$0=(h_2-h_1)+\left(\frac{V_2^2-V_1^2}{2}\right)$$

$$h_2=h_1-\left(\frac{V_2^2-V_1^2}{2}\right)$$

At the diffuser exit, velocity is very much less than the velocity at diffuser inlet. So neglect the exit velocity then the energy equation becomes,

$$h_2=h_1+\frac{V_1^2}{2} \qquad \text{..... (1)}$$

Step 2 of 3

Obtain enthalpy at diffuser inlet temperature $T_1 = 50°F = 510°R$ from "ideal gas properties of air table" by using interpolation,

$$h_1=119.48+(124.27-119.48)\left(\frac{510-500}{520-500}\right)$$

$$=121.875\,\text{Btu/lbm}$$

Substitute 600 ft/s for V_1 in equation (1)

$$h_2=h_1+\frac{V_1^2}{2}$$

$$=(121.88\ \text{Btu/lbm})+\frac{600^2}{2}\text{ft}^2/\text{s}^2\times\frac{1\,\text{Btu/lbm}}{25047\,\text{ft}^2/\text{s}^2}$$

$$=121.88+7.186$$

$$=129.066\,\text{Btu/lbm}$$

Obtain the exit temperature from table "ideal gas properties of air" at exit enthalpy $h_2 = 129.066$ Btu/lbm

$$T_2=540\text{R}$$

Therefore, the exit temperature of diffuser is $\boxed{540\text{R}}$

Step 3 of 3

(b)

Find the exit velocity of air by using the mass flow rate.

Mass flow rate remains constant throughout the diffuser,

$$\dot{m}=\frac{A_1V_1}{v_1}=\frac{A_2V_2}{v_2}$$

Here, A_1, A_2 is the cross sectional areas at inlet and exit of the diffuser V_1, V_2 are the velocities at inlet and exit of the diffuser and v_1, v_2 are the specific volumes at state 1 and state 2.

Obtain exit velocity from the mass flow rate,

$$V_2=\frac{A_1}{A_2}\frac{v_2}{v_1}V_1$$

Substitute $\frac{RT}{P}$ for v by using ideal gas equation, $Pv=RT$

$$V_2=\frac{A_1}{A_2}\times\frac{\frac{RT_2}{P_2}}{\frac{RT_1}{P_1}}\times V_1$$

$$=\frac{A_1}{A_2}\times\frac{P_1T_2}{P_2T_1}V_1$$

Substitute $4A_1$ for A_2, 14.5 psia for P_2 and 13 psia for P_1

$$V_2=\frac{A_1}{4\times A_1}\frac{(540\text{R})\times(13\,\text{psia})}{(50+460\text{R})\times(14.5\,\text{psia})}\times 600\,\text{ft/s}$$

$$=\frac{1}{4}\times\frac{7020}{7395}\times 600\,\text{ft/s}$$

$$=142.39\,\text{ft/s}$$

Therefore, the exit velocity of the air is $\boxed{142.39\,\text{ft/s}}$

Question: 6.035P

Carbon dioxide enters an adiabatic nozzle steadily at 1 MPa and 500°C with a mass flow rate of 6000 kg/h and leaves at 100 kPa and 450 m/s. The inlet area of the nozzle is 40 cm2. Determine (a) the inlet velocity and (b) the exit temperature.

Step 1 of 6

Given

Inlet pressure $P_1 = 1\ \text{MPa}$

Inlet temperature $T_1 = 500°\text{C}$

Inlet cross sectional area $A_1 = 40\ \text{cm}^2 = 0.004\ \text{m}^2$

Exit pressure $P_2 = 100\ \text{kPa}$

Exit velocity $V_2 = 450\ \text{m/s}$

Mass flow rate of carbon dioxide $\dot{m} = 6000\ \text{kg/h}$

$$= \frac{6000}{60 \times 60}$$

$$\dot{m} = 1.67\ \text{kg/s}$$

Step 2 of 6

From the table molar mass, gas constant and critical point properties

The gas constant of Carbon dioxide is $R = 0.1889\ \text{kJ/kg.K}$

Molar mass $M = 44\ \text{kg/kmol}$

Step 3 of 6

(a) The inlet velocity

The mass flow rate is expressed as

$$\dot{m} = \rho_1 A_1 V_1$$

From ideal gas equation

$$\rho_1 = \frac{P_1}{RT_1}$$

$$= \frac{1000}{(0.1889)(500+273)}$$

$$\rho_1 = 6.848\ \text{kg/m}^3$$

Step 4 of 6

Therefore the inlet velocity is

$$V_1 = \frac{\dot{m}}{\rho_1 A_1}$$

$$= \frac{1.67}{6.848 \times 0.004}$$

$$\boxed{V_1 = 60.96\ \text{m/s}}$$

Step 5 of 6

(b) The exit temperature

The energy balance equation per unit mass for a steady state process is

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

Here $q = w = 0$ and $z_1 = z_2$ (Since adiabatic and no boundary work)

And $h = c_p T$

Step 6 of 6

Therefore

$$0 = c_p (T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

From ideal gas specific heats of common gases at $T_1 = 500^0\text{C}$

$c_p = 1.156\ \text{kJ/kg.K}$

Then

$$0 = 1.156(T_2 - 500) + \frac{450^2 - 60.96^2}{2}\left(\frac{1}{1000}\right)$$

$$T_2 - 500 = -85.979$$

$$T_2 = 414.021^0\text{C}$$

$$T_2 = 687.021\text{K}$$

The exit temperature $\boxed{T_2 = 687.021\text{K}}$

Question: 6.036P

Refrigerant-134a at 700 kPa and 120°C enters an adiabatic nozzle steadily with a velocity of 20 m/s and leaves at 400 kPa and 30°C. Determine (a) the exit velocity and (b) the ratio of the inlet to exit area A1/A2.

Step 1 of 4

Given

Inlet pressure $P_1 = 700$ kPa

Inlet temperature $T_1 = 120°C$

Inlet velocity $V_1 = 20$ m/s

Exit pressure $P_2 = 400$ kPa

Exit temperature $T_2 = 30°C$

Step 2 of 4

At $P_1 = 700$ kPa , $T_1 = 120°C$ from superheated R-134a tables

$v_1 = 0.043358\ m^3/kg$ and

$h_1 = 358.9$ kJ/kg

At $P_2 = 400$ kPa , $T_2 = 30°C$ from super heated R-134a tables

$v_2 = 0.056796\ m^3/kg$ and

$h_2 = 275.07$ kJ/kg

Step 3 of 4

(a)

The exit velocity can be obtained by applying energy balance equation per unit mass for a steady state process is

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

$q = w = 0$ and $z_1 = z_2$ Since the process is adiabatic and there is no boundary work

$$0 = (h_2 - h_1) + \frac{V_2^2 - V_1^2}{2}$$

$$0 = (275.07 - 358.9) + \frac{V_2^2 - 20^2}{2}\left(\frac{1}{1000}\right)$$

$$0 = -83.83 + \frac{V_2^2 - 20^2}{2}\left(\frac{1}{1000}\right)$$

$$V_2^2 = 167660 + 20^2$$

$$\boxed{V_2 = 409.951\ m/s}$$

Step 4 of 4

(b)

The ratio of inlet to exit area

We know that mass flow rate remains constant throughout the nozzle

$$\dot{m} = \frac{A_1 V_1}{v_1} = \frac{A_2 V_2}{v_2}$$

$$\frac{A_1}{A_2} = \frac{V_2 v_1}{V_1 v_2}$$

$$\frac{A_1}{A_2} = \frac{409.951 \times 0.043358}{20 \times 0.056796}$$

$$\boxed{\frac{A_1}{A_2} = 15.647}$$

Question: 6.037P

Refrigerant-134a enters a diffuser steadily as saturated vapor at 800 kPa with a velocity of 120 m/s, and it leaves at 900 kPa and 40°C. The refrigerant is gaining heat at a rate of 2 kJ/s as it passes through the diffuser. If the exit area is 80 percent greater than the inlet area, determine (a) the exit velocity and (b) the mass flow rate of the refrigerant.

Step 1 of 4

Given

Inlet pressure $P_1 = 800$ kPa

Inlet velocity $V_1 = 120$ m/s

Exit pressure $P_2 = 900$ kPa

Exit temperature $T_2 = 40°C$

The rate of heat gain $\dot{Q} = 2$ kJ/s

Exit area is 80% greater than the inlet area $A_2 = A_1 + 80\% A_1$

$$A_2 = 1.8 A_1$$

Step 2 of 4

From the refrigerant R-134a tables

At $P_1 = 800$ kPa

$v_1 = v_g = 0.025621 \text{ m}^3/\text{kg}$ and

$h_1 = h_g = 267.29$ kJ/kg

At $P_2 = 900$ kPa and $T_2 = 40°C$ from super heated R-134a table

$v_2 = 0.023375 \text{ m}^3/\text{kg}$ and

$h_2 = 274.17$ kJ/kg

Step 3 of 4

(a)

The exit velocity

We know that mass flow rate remains constant throughout the diffuser

$$\dot{m} = \frac{A_1 V_1}{v_1} = \frac{A_2 V_2}{v_2}$$

$$V_2 = \frac{A_1}{A_2}\frac{v_2}{v_1} V_1$$

$$= \frac{1(0.023375)}{1.8(0.025621)} 120$$

$$\boxed{V_2 = 60.8 \text{ m/s}}$$

Step 4 of 4

(b) The mass flow rate of the refrigerant

The energy balance equation per unit mass for a steady state process is

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

Here $w = 0$ and $z_1 = z_2$ and $q = \frac{\dot{Q}}{\dot{m}}$

$$\frac{\dot{Q}}{\dot{m}} = (h_2 - h_1) + \frac{V_2^2 - V_1^2}{2}$$

$$\frac{2}{\dot{m}} = (274.17 - 267.29) + \frac{60.8^2 - 120^2}{2}\left(\frac{1}{1000}\right)$$

$$\frac{2}{\dot{m}} = 6.88 + (-5.35168)$$

$$\dot{m} = \frac{2}{1.528}$$

$$\boxed{\dot{m} = 1.308 \text{ kg/s}}$$

Question: 6.038P

Steam at 4 MPa and 400°C enters a nozzle steadily with a velocity of 60 m/s, and it leaves at 2 MPa and 300°C. The inlet area of the nozzle is 50 cm2, and heat is being lost at a rate of 75 kJ/s. Determine (a) the mass flow rate of the steam, (b) the exit velocity of the steam, and (*c*) the exit area of the nozzle.

Step 1 of 6

Given

Inlet Pressure of steam, $P_1 = 4\ \text{MPa}$

Inlet Temperature of steam, $T_1 = 400°\text{C}$

Inlet Velocity of steam, $V_1 = 60\ \text{m/s}$

Area of inlet, $A_1 = 50\ \text{cm}^2$

$$A_1 = 0.005\ \text{m}^2$$

Exit Pressure of steam, $P_2 = 2\ \text{MPa}$

Exit Temperature of steam, $T_2 = 300°\text{C}$

The rate of heat loss, $\dot{Q} = 75\ \text{kJ/s}$

Step 2 of 6

From the superheated steam tables, at 4 MPa and 400°C

Specific volume of steam, $v_1 = 0.07343\ \text{m}^3/\text{kg}$

Enthalpy of steam, $h_1 = 3214.5\ \text{kJ/kg}$

From the superheated steam tables, At 2 MPa and 300°C

Specific volume of steam, $v_2 = 0.12551\ \text{m}^3/\text{kg}$

Enthalpy of steam, $h_2 = 3024.2\ \text{kJ/kg}$

Step 3 of 6

(a)

The mass flow rate, $\dot{m} = \dfrac{A_1 V_1}{v_1}$

$$\dot{m} = \frac{(0.005)(60)}{0.07343}$$

$$\dot{m} = 4.085\ \text{kg/s}$$

The mass flow rate of the steam, $\boxed{\dot{m} = 4.085\ \text{kg/s}}$

Step 4 of 6

(b)

From the energy balance equation per unit mass for a steady state process,

$$q - w = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)$$

Here boundary work is $w = 0$

Entrance and exit are at same levels, $z_1 = z_2$

Heat transfer per unit mass, $q = \dfrac{\dot{Q}}{\dot{m}}$

And Enthalpy, $h = C_p T$

Step 5 of 6

Hence energy balance equation becomes,

$$-\frac{\dot{Q}}{\dot{m}} = (h_2 - h_1) + \left(\frac{V_2^2 - V_1^2}{2}\right)$$

$$\left[-\frac{75\times10^3}{4.085}\right] = \left[(3024.2 - 3214.5)\times10^3\right] + \left[\frac{V_2^2 - 60^2}{2}\right]$$

$$-18359.85 = -190300 + \left[\frac{V_2^2 - 60^2}{2}\right]$$

$$\frac{V_2^2 - 60^2}{2} = 171940.15$$

$$V_2^2 = 343880.3 + 60^2$$

$$V_2 = 589.5\ \text{m/s}$$

The exit velocity $\boxed{V_2 = 589.5\ \text{m/s}}$

Step 6 of 6

(c)

Mass flow rate, $\dot{m} = \dfrac{A_2 V_2}{v_2}$

Area at exit, $A_2 = \dfrac{\dot{m} \times v_2}{V_2}$

$$A_2 = \frac{4.0855\times0.12551}{589.5}$$

$$A_2 = 8.7\times10^{-4}\ \text{m}^2$$

The exit area of the nozzle, $\boxed{A_2 = 8.7\ \text{cm}^2}$

Question: 6.039P

Consider an adiabatic turbine operating steadily. Does the work output of the turbine have to be equal to the decrease in the energy of the steam flowing through it?

Step 1 of 1

Yes, the work output of the turbine has to be equal to the decrease in the energy of the steam flowing thought it. During the adiabatic process heat transfer is zero

From the energy equation

$$W = \dot{m}\left(h_1 + \frac{V_1^2}{2} + z_1\right) - \dot{m}\left(h_2 + \frac{V_2^2}{2} + z_2\right)$$

Question: 6.040P

Consider an air compressor operating steadily. How would you compare the volume flow rates of the air at the compressor inlet and exit?

Step 1 of 1

Compressor is a device which increases the pressure of the fluid at the cost of energy input. As pressure increases volume decreases, so at the inlet the volume flow rate is more compared to outlet as specific volume decreases along the compressor.

Question: 6.041P

Will the temperature of air rise as it is compressed by an adiabatic compressor? Why?

Step 1 of 1

Yes, the temperature and pressure increases during an adiabatic compression process.
Since energy is added to the working fluid which raises the temperature.

Question: 6.042P

Somebody proposes the following system to cool a house in the summer: Compress the regular outdoor air, let it cool back to the outdoor temperature, pass it through a turbine, and discharge the cold air leaving the turbine into the house. From a thermodynamic point of view, is the proposed system sound?

Step 1 of 1

No, since compressing process involves the raise of temperature of the air.

Question: 6.043P

Refrigerant-134a enters a compressor at 100 kPa and −24°C with a flow rate of 1.35m3/min and leaves at 800 kPa and 60°C. Determine the mass flow rate of R-134a and the power input to the compressor.

Step 1 of 4

Given

Inlet Pressure, $P_1 = 100\ \text{kPa}$

Inlet Temperature, $T_1 = -24°\text{C}$

Volume flow rate, $\dot{V}_1 = 1.35\ \text{m}^3/\text{min}$,

Exit Pressure, $P_2 = 800\ \text{kPa}$

Exit Temperature, $T_2 = 60°\text{C}$

Step 2 of 4

From the property table of refrigerant R-134a table, at 100 kPa and −24°C

Specific volume, $v_1 = 0.1947\ \text{m}^3/\text{kg}$

Enthalpy, $h_1 = 236.34\ \text{kJ/kg}$

From the property table of refrigerant R-134a table, at 800 kPa and 60°C

Enthalpy $h_2 = 296.81\ \text{kJ/kg}$

Step 3 of 4

The mass flow rate, $\dot{m} = \dfrac{\dot{V}_1}{v_1}$

$$\dot{m} = \frac{(1.35/60)}{0.1947}$$

$$\dot{m} = 0.1155\ \text{kg/s}$$

The mass flow rate of the refrigerator, $\boxed{\dot{m} = 0.1155\ \text{kg/s}}$

Step 4 of 4

Work input, $\dot{W}_{in} = \dot{m}(h_2 - h_1)$

$$\dot{W}_{in} = (0.1155)(296.81 - 236.34)$$

$$\dot{W}_{in} = 6.9843\ \text{kW}$$

The power output $\boxed{\dot{W}_{in} = 6.9843\ \text{kW}}$

Question: 6.044P

Refrigerant-134a enters a compressor at 180 kPa as a saturated vapor with a flow rate of 0.35 m3/min and leaves at 700 kPa. The power supplied to the refrigerant during compression process is 2.35 kW. What is the temperature of R-134a at the exit of the compressor?

Step 1 of 4

Given

Inlet Pressure $P_1 = 180\ \text{kPa}$

Volume flow rate, $\dot{V}_1 = 0.35\ \text{m}^3/\text{min}$

Exit Pressure, $P_2 = 700\ \text{kPa}$

The power supplied to the refrigerator $\dot{W}_{in} = 2.35\ \text{kW}$

Step 2 of 4

The mass flow rate, $\dot{m} = \dfrac{\dot{V}_1}{v_1}$

$$\dot{m} = \frac{(0.35/60)}{0.1104}$$

$$\dot{m} = 0.0528\ \text{kg/s}$$

The mass flow rate of the refrigerator, $\dot{m} = 0.0528\ \text{kg/s}$

Step 3 of 4

From the property table of refrigerant R-134a table at 180 kPa, saturated vapor has

Specific volume, $v_1 = 0.1104\ \text{m}^3/\text{kg}$

Enthalpy, $h_1 = 242.86\ \text{kJ/kg}$

Work input, $\dot{W}_{in} = \dot{m}(h_2 - h_1)$

Enthalpy at exit, $h_2 = h_1 + \dfrac{\dot{W}_{in}}{\dot{m}}$

$$h_2 = 242.86 + \frac{2.35}{0.0528}$$

$$h_2 = 287.4\ \text{kJ/kg}$$

Step 4 of 4

From the property table of refrigerant R-134a table at 700 kPa

$h = 278.57\ \text{kJ/kg}$, $T = 40^\circ\text{C}$

$h = 288.53\ \text{kJ/kg}$, $T = 50^\circ\text{C}$

At $h_2 = 287.4\ \text{kJ/kg}$, $P_2 = 700\ \text{kPa}$ By interpolation

$$\frac{T_2 - 40}{50 - 40} = \frac{287.4 - 278.57}{288.53 - 278.57}$$

$$\frac{T_2 - 40}{10} = 0.8865$$

$$\frac{T_2 - 40}{10} = 0.8865$$

$$T_2 = 48.86\ ^0\text{C}$$

So at $h_2 = 287.4\ \text{kJ/kg}$, $T_2 = 48.86\ ^0\text{C}$

Therefore exit temperature is $\boxed{T_2 = 48.86\ ^0\text{C}}$

Question: 6.045P

Steam enters an adiabatic turbine at 10 MPa and 500°C and leaves at 10 kPa with a quality of 90 percent. Neglecting the changes in kinetic and potential energies, determine the mass flow rate required for a power output of 5 MW.

Step 1 of 4

Given

Inlet pressure $P_1 = 10$ MPa

Inlet temperature $T_1 = 500°C$

Outlet pressure $P_2 = 10$ kPa

Outlet velocity $V_2 = 50$ m/s

Exit quality $x_2 = 0.90$

Power output $\dot{W} = 5$ MW

Step 2 of 4

At $P_1 = 10$ MPa and $T_1 = 500°C$ from super heated steam tables

$h_1 = 3375.1$ kJ/kg

At $P_2 = 10$ kPa from saturated water tables

$h_f = 191.81$kJ/kg

$h_{fg} = 2392.1$kJ/kg

$h_2 = h_f + x_2 h_{fg}$

$h_2 = 191.81 + 0.9 \times 2392.1$

$h_2 = 2344.7$kJ/kg

Step 3 of 4

The energy balance equation for a steady state process is

$$\dot{Q} - \dot{W} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)\right)$$

Since the process is adiabatic $q = 0$

And neglecting the kinetic and potential energies $ke \approx 0, pe \approx 0$

Step 4 of 4

Therefore

$$0 - \dot{W} = \dot{m}(h_2 - h_1) + 0 + 0$$

$$-5000 = \dot{m}(2344.7 - 3375.1)$$

$$\dot{m} = -4.852 \text{kg/s}$$

The mass flow rate is

$$\boxed{\dot{m} = 4.852 \text{ kg/s}}$$

Question: 6.046P

Steam flows steadily through a turbine at a rate of 45,000 lbm/h, entering at 1000 psia and 900°F and leaving at 5 psia as saturated vapor. If the power generated by the turbine is 4 MW, determine the rate of heat loss from the steam.

Step 1 of 3

Given

Inlet pressure $P_1 = 1000$ psia

Inlet temperature $T_1 = 900°F$

Outlet pressure as saturated vapor $P_2 = 5$ psia

Power output $\dot{W} = 4$ MW $\quad (1\ \text{Btu/s} = 1055\ \text{J/s})$

$$\dot{W} = \frac{12\times10^9}{1055}\ \text{Btu/s}$$

Mass flow rate of the steam $\dot{m} = 45000$ lbm/h

$$= \frac{45000}{3600}$$

$$\dot{m} = 12.5\ \text{lbm/s}$$

Step 2 of 3

At $P_1 = 1000$ psia, $T_1 = 900°F$ from superheated steam tables

$h_1 = 1448.6$ Btu/lbm

At $P_2 = 5$ psia from saturated water tables

$h_2 = h_g = 1130.7$ Btu/lbm

Step 3 of 3

The energy balance equation for a steady state process is

$$\dot{Q} - \dot{W} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)\right)$$

Assuming there is no change in kinetic and potential energy changes

$$\dot{Q} - \dot{W} = \dot{m}(h_2 - h_1)$$

$$\dot{Q} - \frac{4\times10^6}{1055} = 12.5(1130.7 - 1448.6)$$

$$\dot{Q} - 3791.469 = -3973.75$$

$$\boxed{\dot{Q} = -182.281\ \text{Btu/s}} \text{ or}$$

$$\dot{Q} = -182.281\times1055$$

$$\boxed{\dot{Q} = -192.306\ \text{MW}}$$

Negative sign indicates heat lost to the surroundings

Question: 6.047P

An adiabatic air compressor compresses 10 L/s of air at 120 kPa and 20°C to 1000 kPa and 300°C. Determine (a) the work required by the compressor, in kJ/kg, and (b) the power required to drive the air compressor, in kW.

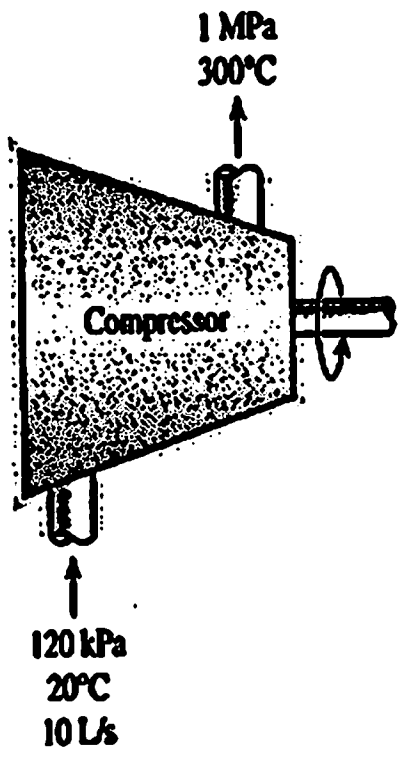

FIGURE P6–47

Step 1 of 4

Hence, the steady state equation for compressor is reduced to,

$$\dot{W} = \dot{m}(h_2 - h_1)$$

$$w_{in} = c_p(T_2 - T_1) \text{ ..... (1)}$$

Note the value for specific heat which is taken at average temperature of the air,

$$T_{avg} = \frac{T_1 + T_2}{2}$$

Here, temperature at inlet is T_1 and temperature at outlet is T_2.

Substitute, $20°C$ for T_1 and $300°C$ for T_2 in relation above and calculate average temperature.

$$T_{avg} = \frac{20 + 300}{2}$$
$$= 160^0C$$
$$= 433K$$

Step 2 of 4

Note the value for specific heat at $433K$ from ideal gas specific heats of common gases

$$\frac{c_p - 1.013}{(1.02 - 1.013)} = \left(\frac{433 - 400}{450 - 400}\right)$$
$$c_p = 1.01762 kJ/kg \cdot K$$

Substitute, $1.01762 kJ/kg \cdot K$ for c_p, $300°C$ for T_2 and $20°C$ for T_1 in equation (1) and calculate the work required by the compressor.

$$w_{in} = 1.01762(300 - 20)$$
$$= 284.933 kJ/kg$$

Therefore the work input to the compressor (w_{in}) is $\boxed{284.933 kJ/kg}$.

Step 3 of 4

(b)

Calculate the power required to drive the air compressor using relation.

$$\dot{W} = \dot{m} w$$

Where the mass flow rate is expressed as

$$\dot{m} = \rho_1 \dot{V}_1$$

From ideal gas equation, calculate the density using relation.

$$\rho_1 = \frac{P_1}{RT_1}$$

Here, density of air is ρ_1, pressure at inlet in Pascal's is P_1, gas constant is R and temperature at inlet in kelvin is T_1.

Substitute, (120×10^3) Pa for P_1, $287 J/kg \cdot K$ for R and $293 K$ for T_1 in relation above and calculate ρ_1.

$$\rho_1 = \frac{120 \times 10^3}{(0.287 \times 10^3)(20 + 273)}$$
$$= 1.427 kg/m^3$$

Step 4 of 4

Calculate the power required to drive the air compressor using relation,

$$\dot{W} = \rho_1 \dot{V}_1 w_{in} \text{ ..... (2)}$$

Here, volumetric flow rate of air is $\dot{V}_1$.

Substitute, $1.427 kg/m^3$ for ρ_1, $284.933 kJ/kg$ for w_{in} and $(10 \times 10^{-3}) m^3/s$ for $\dot{V}_1$ in equation (2) and calculate the power required.

$$\dot{W} = 1.427 \times 0.01 \times 284.933$$
$$= 4.0659 kW$$

Therefore the power required to drive the air compressor $(\dot{W})$ is $\boxed{4.066 kW}$.

Question: 6.048P

Argon gas enters an adiabatic turbine steadily at 1600 kPa and 450°C with a velocity of 55 m/s and leaves at 150 kPa with a velocity of 150 m/s. The inlet area of the turbine is 60 cm2. If the power output of the turbine is 190 kW, determine the exit temperature of the argon.

Step 1 of 5

Given

Inlet Pressure, $P_1 = 1600\ \text{kPa}$

Inlet Temperature, $T_1 = 450°C$

Inlet Velocity, $V_1 = 55\ \text{m/s}$

Inlet Area, $A_1 = 60\ \text{cm}^2$

$$A_1 = 0.006\ \text{m}^2$$

Exit Pressure, $P_2 = 150\ \text{kPa}$

Exit Velocity, $V_2 = 150\ \text{m/s}$

Power output, $\dot{W} = 190\ \text{kW}$

Step 2 of 5

From ideal gas equation, $P = \rho RT$

$$\rho = \frac{P}{RT}$$

$$\rho_1 = \frac{P_1}{RT_1}$$

From ideal gas property table of Argon,

Gas constant, $R = 0.2081\ \text{kJ/kg.K}$

Specific heat, $C_p = 0.5203\ \text{kJ/kg.K}$

Step 3 of 5

Hence density, $\rho_1 = \dfrac{1600}{(0.2081)(450+273)}$

$$\rho_1 = 10.63\ \text{kg/m}^3$$

Therefore mass flow rate, $\dot{m} = \rho_1 A_1 V_1$

$$\dot{m} = (10.63)(0.006)(55)\ \text{kg/s}$$

$$\dot{m} = 3.51\ \text{kg/s}$$

Step 4 of 5

From the energy balance equation for a steady state process,

$$\dot{Q} - \dot{W} = \dot{m}\left[(h_2 - h_1) + \left(\frac{V_2^2 - V_1^2}{2}\right) + g(z_2 - z_1)\right]$$

As the process is adiabatic, $\dot{Q} = 0$

Also potential energy change, $pe \approx 0$ and

Enthalpy, $h = C_p T$

Step 5 of 5

Therefore $0 - \dot{W} = \dot{m}\left[C_p(T_2 - T_1) + \left(\dfrac{V_2^2 - V_1^2}{2}\right)\left(\dfrac{1}{1000}\right) + 0\right]$

$$-190 = 3.51\left[0.5203(T_2 - 450) + \left(\frac{150^2 - 55^2}{2000}\right)\right]$$

$$(T_2 - 450) = \frac{-54.13 - 9.7375}{0.5203}$$

$$T_2 = 327.24\ ^0\text{C}$$

The exit temperature, $\boxed{T_2 = 327.24\ ^0\text{C}}$

Question: 6.049P

Helium is to be compressed from 120 kPa and 310 K to 700 kPa and 430 K. A heat loss of 20 kJ/kg occurs during the compression process. Neglecting kinetic energy changes, determine the power input required for a mass flow rate of 90 kg/min.

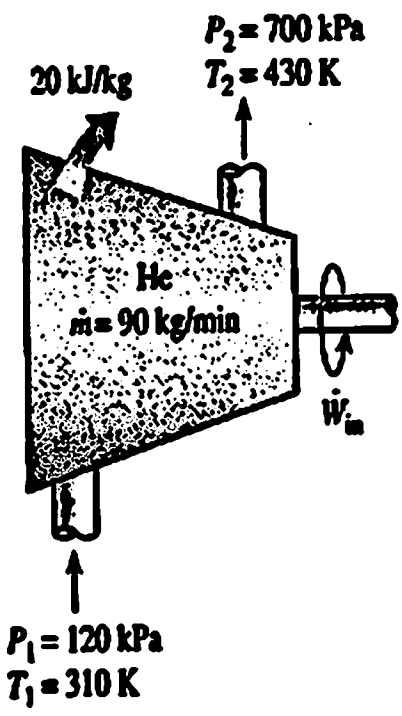

FIGURE P6–49

Step 1 of 5

Given

Working substance is Helium

Inlet pressure $P_1 = 120$ kPa

Inlet temperature $T_1 = 310$K

Mass flow rate $\dot{m} = 90$ kg/min

$$= \frac{90}{60}$$

$$\dot{m} = 1.5 \text{ kg/s}$$

Final pressure $P_2 = 700$ kPa

Final temperature $T_2 = 430$K

Heat loss $q = -20$ kJ/kg

Step 2 of 5

From the table ideal gas specific heats of various common gases

The gas constant for Helium is $R = 2.0769$ kJ/kg.K

Specific heat $c_p = 5.1926$ kJ/kg.K

Step 3 of 5

The energy balance equation for a steady state process is

$$q - w = \left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1) \right)$$

Assuming there is no change in kinetic and potential energy changes $ke \approx 0, pe \approx 0$

and $h = c_p T$

Step 4 of 5

Therefore

$$q - w = \left(c_p (T_2 - T_1) + 0 + 0 \right)$$

$$q - w = \left(c_p (T_2 - T_1) \right)$$

$$\left(-20 \times 10^3 \right) - w = \left(5.1926 \times 10^3 (430 - 310) \right)$$

$$\left(-20 \times 10^3 \right) - w = 623.112 \times 10^3$$

$$w = -643112 \text{ J/kg}$$

Step 5 of 5

Power input to the compressor

$$\dot{W} = \dot{m} w$$

$$= 1.5 \times (-643112)$$

$$\boxed{\dot{W} = -964.668 \text{ kW}}$$

Negative sign indicates power supplied to compressor

Question: 6.050P

Carbon dioxide enters an adiabatic compressor at 100 kPa and 300 K at a rate of 0.5 kg/s and leaves at 600 kPa and 450 K. Neglecting kinetic energy changes, determine (a) the volume flow rate of the carbon dioxide at the compressor inlet and (b) the power input to the compressor.

Step 1 of 4

Obtain the gas constant for carbon dioxide at 300 K from the table A-2, "ideal gas specific heats of common gases" from the textbook.

The gas constant for Carbon dioxide gas, $R = 0.1889\ \text{kJ/kg.K}$.

Calculate the average temperature.

$$T_{av} = \frac{T_1 + T_2}{2}$$

Here, T_1 is the inlet temperature, and T_2 is the outlet temperature.

Substitute 300 K for T_1 , and 450 K for T_2 .

$$T_{av} = \frac{300 + 450}{2}$$
$$= 375\,\text{K}$$

Step 2 of 4

Obtain the specific heat at constant pressure for carbon dioxide at 350 K, and 400 K from the table A-2, "ideal gas specific heats of common gases" from the textbook.

At 350 K, $c_p = 0.895\ \text{kJ/kg} \cdot \text{K}$

At 400 K, $c_p = 0.939\ \text{kJ/kg} \cdot \text{K}$

Calculate the Specific heat at $T_{av} = 375\,\text{K}$ using interpolation.

$$c_p = 0.895 + (0.939 - 0.895)\left(\frac{375 - 350}{400 - 350}\right)$$
$$c_p = 0.917\ \text{kJ/kg.K}$$

Step 3 of 4

(a)

Calculate the volume flow rate using the following expression.

$$\dot{V} = \frac{\dot{m}}{\rho} \quad \text{..... (1)}$$

Here, $\dot{m}$ is the mas flow rate, and ρ is the density.

From ideal gas equation,

$$\rho_1 = \frac{P_1}{RT_1}$$

Substitute 300 K for T_1 , $0.1889\ \text{kJ/kg.K}$ for R, and 100 kPa for P_1 .

$$\rho_1 = \frac{100}{(0.1889)(300)}$$
$$= 1.765\ \text{kg/m}^3$$

Substitute $1.765\ \text{kg/m}^3$ for ρ , and 0.5 kg/s for $\dot{m}$ in equation 1.

$$\dot{V}_1 = \frac{\dot{m}}{\rho_1}$$
$$= \frac{0.5}{1.765}$$
$$= 0.283\ \text{m}^3/\text{s}$$

Therefore volume flow rate is $\boxed{\dot{V}_1 = 0.283\ \text{m}^3/\text{s}}$.

Step 4 of 4

(b)

Calculate the power input to the compressor by applying the energy balance equation for a steady state process.

$$\dot{Q} - \dot{W} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)\right)$$

Since the compressor is adiabatic, $\dot{Q} = 0$.

As there is no change in kinetic and potential energies $ke \approx 0, pe \approx 0$

Also, $h = c_p T$

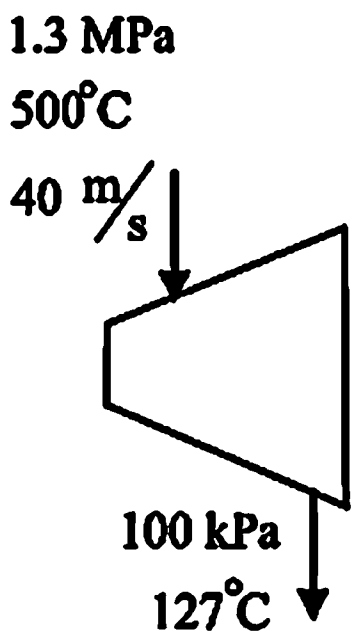
Then the equation simplifies to,

$$0 - \dot{W}_{in} = \dot{m}\left(c_p(T_2 - T_1) + 0 + 0\right)$$

Substitute $0.917\ \text{kJ/kg.K}$ for c_p , 300 K for T_1 , 0.5 kg/s for $\dot{m}$, and $450\ \text{K}$ for T_2

$$-\dot{W} = 0.5\left(0.917 \times 10^3 (450 - 300)\right)$$
$$W = -68.775 \times 10^3$$

Negative sign indicates power input to compressor



Therefore, the power input required for the compressor is $\boxed{68.775\ \text{kW}}$.

Question: 6.051P pg 1

An adiabatic gas turbine expands air at 1300 kPa and 500°C to 100 kPa and 127°C. Air enters the turbine through a 0.2-m2 opening with an average velocity of 40 m/s, and exhausts through a 1-m2 opening. Determine (a) the mass flow rate of air through the turbine and (b) the power produced by the turbine.

Step 1 of 9

Sketch the turbine as follows.
Consider the turbine as the control volume system, as the mass crosses the boundary.

Step 2 of 9

The energy balance equation per unit mass for a steady state process is below.
Rate of net energy transfer by heat, work and mass is equal to the rate of change of internal kinetic, potential energies.
Therefore, the energy balance equation per unit mass for a steady state process is as follows.

$$\dot{E}_{in}-\dot{E}_{out}=\frac{\Delta \dot{E}_{system}}{dt}=0$$

Since and there is only one entry and exit the mass flow rate at the inlet and the outlet is equal.

$$\dot{m}_1=\dot{m}_2=\dot{m}$$

It is a steady state process, hence the above equation becomes as follows.

$$\dot{E}_{in}-\dot{E}_{out}=0$$

$$\dot{m}\left(h_1+\frac{V_1^2}{2}\right)=\dot{m}\left(h_2+\frac{V_2^2}{2}\right)+\dot{W}_{out}$$

$$\dot{W}_{out}=\dot{m}\left(h_1-h_2+\frac{V_1^2-V_2^2}{2}\right)$$

Step 3 of 9

Since $h_1=h_2=c_p\ T_{1,2}$, the above equation becomes as follows.

$$\dot{W}_{out}=\dot{m}\left(c_p\ T_1-T_2+\frac{V_1^2-V_2^2}{2}\right) \quad \text{..... (1)}$$

Here, c_p is the specific heat capacity, V_1 is the initial velocity, T_1 and T_2 are the initial and final temperatures, $\dot{m}$ is the mass flow rate and $\dot{W}_{out}$ is the power output produced by the turbine.

Calculate the average temperatures.
The average temperature of the air is below.

$$T=\frac{T_1+T_2}{2}$$

Here, T_1 and T_2 are the initial and final temperatures.
Substitute 500°C for T_1 and 127°C for T_2.

$$T=\frac{500+127}{2}$$
$$=314°C$$
$$=527\ K$$

Step 4 of 9

Calculate the value for the c_p.
Obtain the value for the value c_p at the average temperature of the air from the table A-2 of ideal gas specific heats of various common gases at various temperatures.
Calculate the specific heat capacity, for the temperature values at $T_2=600\ K$ and $T_1=550\ K$ by interpolating the specific heat capacities values at $c_{p1}-1.040\ kJ/kg\cdot k$ and $c_{p2}=1.051\ kJ/kg\cdot k$.

$$(c_p)=c_{p,550K}+(c_{p,600K}-c_{p,550K})\left(\frac{587-550}{600-550}\right)$$
$$=1.040+(1.051-1.040)(0.74)$$
$$=1.040+8.14\times10^{-3}$$
$$=1.04814\ kJ/kg\text{-}k$$

Step 5 of 9

Calculate the density at point 1.
From the ideal gas property table of air the value for the universal gas constant R is 0.287 kJ/kg.K.
The ideal gas equation is below.

$$P=\rho RT$$

Rewrite the above equation for density at the inlet.

$$\rho_1=\frac{P_1}{RT_1}$$

Here, P_1 is the pressure at the inlet, R is the universal gas constant; T_1 is the temperature at inlet and ρ_1 is the density of the air at inlet.

Step 6 of 9

Substitute the value 1300 kPa for P_1, 0.287 kJ/kg.K for R and 773 K for T_1 in the above equation.

$$\rho_1=\frac{1300}{(0.287)(500+273)}\ kg/m^3$$

Substitute the value 1300 kPa for P_1, 0.287 kJ/kg.K for R and 773 K for T_1 in the above equation.

$$\rho_1 = \frac{1300}{(0.287)(500+273)} \text{ kg/m}^3$$
$$= 5.86 \text{ kg/m}^3$$

a)

Calculate the mass flow rate.

$$\dot{m} = \rho_1 A_1 V_1$$

Here, ρ_1 is the density of the air at inlet, A_1 is the area at inlet and V_1 is the velocity at inlet.

Substitute 0.2m^2 for A_1, 5.86 kg/m^3 for ρ_1 and 40 m/s for V_1.

$$\dot{m} = (5.86)(0.2)(40)$$
$$= 46.88 \text{ kg/s}$$

Therefore, the mass flow rate $\dot{m}$ is $\boxed{46.88 \text{ kg/s}}$.

b)

Calculate the density at the outlet.

$$\rho_2 = \frac{P_2}{RT_2}$$

Here, P_2 is the pressure at the outlet, R is the universal gas constant; T_2 is the temperature at outlet and ρ_2 is the density of the air at outlet.

Substitute 100 kPa for P_2, 0.287 kJ/kg.K for R and 400 K for T_2.

$$\rho_2 = \frac{100}{(0.287)(400)}$$
$$= 0.871 \text{ kg/m}^3$$

Calculate the exit velocity.

The formula for the mass flow rate is below.

$$\dot{m} = \rho_1 A_1 V_1 = \rho_2 A_2 V_2$$

Rewrite the above equation for exit velocity V_2.

Substitute 46.88 kg/s for $\dot{m}$, 0.871 kg/m^3 for ρ_2 and 1m^2 for A_2.

$$V_2 = \frac{\dot{m}}{\rho_2 A_2}$$
$$= \frac{46.88}{0.871 \times (1)}$$
$$= 53.82 \text{ m/s}$$

Substitute 53.82 m/s for V_2, 40 m/s for V_1, 400 K for T_2, 773 K for T_1 and 1.04814 kJ/kg·k for c_p and 46.88 kg/s for $\dot{m}$ in equation (1).

$$\dot{W}_{out} = 46.88 \text{ kg/s} \left(1.04814 \text{kJ/kg} \cdot \text{k} \ 500 - 127 + \frac{40^2 - 53.82^2}{2} \left(\frac{1 \text{kJ/kg}}{1000 \text{m}^2/\text{s}^2} \right) \right)$$
$$= 18295.187 \text{ kW}$$

Therefore, work output from the turbine is $\boxed{18295.187 \text{ kW}}$

Question: 6.052P

Air is expanded by an adiabatic gas turbine from 500 psia and 800°F to 60 psia and 250°F. If the volume flow rate at the exit is 50 ft3/s; the inlet area is 0.6 ft2; and the outlet area is 1.2 ft2; determine the power produced by this turbine.

Step 1 of 5

From the table molar mass, gas constant and critical point properties,

The gas constant for air $R = 0.3704\ \text{psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$

Find the density of air at the exit by using ideal gas equation

$$\rho_2 = \frac{P_2}{RT_2}$$

Here, P_2 is exit pressure, T_2 is exit temperature of air.

Substitute $60\,\text{psia}$ for P_2 and $(250+460)°\text{R}$ for T_2

$$\rho_2 = \frac{60}{(0.3704)(250+460)}$$
$$= 0.228\,\text{lbm/ft}^3$$

Step 2 of 5

Find the mass flow rate of air by using the equation,

$$\dot{m} = \rho_2 \dot{V}_2$$

Here, $\dot{V}_2$ is volume flow rate at the exit and $\dot{m}$ is mass flow rate of air

Substitute $50\,\text{ft}^3/\text{s}$ for $\dot{V}_2$

$$\dot{m} = (0.228)(50)$$
$$= 11.4\,\text{lbm/s}$$

Find the velocity of air at exit by using the equation,

$$\dot{m} = \rho_2 A_2 V_2$$

Here, A_2 is exit area

$$V_2 = \frac{\dot{m}}{\rho_2 A_2}$$

Substitute $1.2\,\text{ft}^2$ for A_2

$$V_2 = \frac{11.4}{0.228 \times 1.2}$$
$$= 41.67\,\text{ft/s}$$

Step 3 of 5

Find the inlet density of air by using ideal gas equation,

$$\rho_1 = \frac{P_1}{RT_1}$$

Here, P_1 is inlet pressure and T_1 is inlet temperature.

Substitute $500\,\text{psia}$ for P_1 and $(800+460)°\text{R}$ for T_1

$$\rho_1 = \frac{500}{(0.3704)(800+460)}$$
$$= 1.0713\,\text{lbm/ft}^3$$

Step 4 of 5

Find the inlet velocity by using the mass flow rate equation,

$$V_1 = \frac{\dot{m}}{\rho_1 A_1}$$

Here, A_1 is inlet area

Substitute $0.6\,\text{ft}^2$ for A_1

$$V_1 = \frac{11.4}{1.07 \times 0.6}$$
$$= 17.75\,\text{ft/s}$$

Step 5 of 5

Take the properties of air average temperature of inlet and exit temperatures of air,

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{800+250}{2}$$
$$= 525°\text{F}$$

Take the specific heat of air at temperature $T_{avg} = 525°\text{F}$, from ideal gas properties of air,

$$c_p = 0.2472 + (0.2503 - 0.2472)\left(\frac{525-500}{600-500}\right)$$
$$= 0.2479\,\text{Btu/lbm} \cdot \text{R}$$

Calculate the power produced by the turbine by using the energy balance equation for a steady state process:

$$\dot{Q} - \dot{W} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)\right)$$

Since the process is adiabatic, heat transfer $\dot{Q} = 0$

And assuming there is no change in potential energy, then $g(z_2 - z_1) = 0$

Then the above equation becomes,

$$\dot{Q} - \dot{W} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} + g(z_2 - z_1)\right)$$
$$0 - \dot{W} = \dot{m}\left(c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2} + 0\right)$$
$$-\dot{W} = \dot{m}\left(c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}\right)$$

Substitute all the known values in energy equation,

$$-\dot{W} = 11.41\left(0.2479 \times (250-800) + \frac{41.67^2 - 17.75^2}{2} \times \frac{1}{25047}\right)$$

(Since $1\,\text{Btu/lbm} = 25047\,\text{ft}^2/\text{sec}^2$)

$$-\dot{W} = 11.41(-136.345 + 0.02837)$$
$$\dot{W} = 1555.372\,\text{Btu/s}$$

Therefore, the power produced by the turbine is **1555.372 Btu/s**

Question: 6.053P

Steam flows steadily into a turbine with a mass flow rate of 26 kg/s and a negligible velocity at 6 MPa and 600°C. The steam leaves the turbine at 0.5 MPa and 200°C with a velocity of 180 m/s. The rate of work done by the steam in the turbine is measured to be 20 MW. If the elevation change between the turbine inlet and exit is negligible, determine the rate of heat transfer associated with this process.

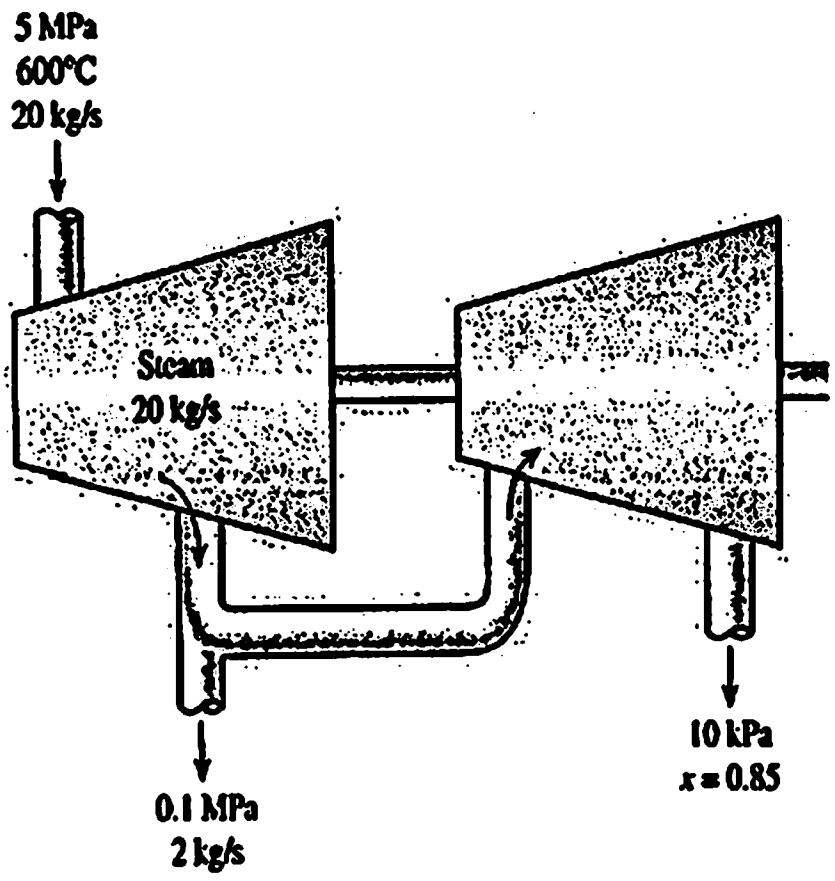


FIGURE P6–53

Step 1 of 2

Obtain properties of steam at inlet temperature, $T_1 = 600°C$ and inlet pressure, $p_1 = 6\,MPa$ from table A-6, "Properties of superheated water tables" in the text book.

Specific enthalpy, $h_1 = 3658.8\ kJ/kg$

Similarly, obtain properties of steam at exit temperature, $T_2 = 200°C$ and exit pressure, $p_2 = 0.5\,MPa$ from table A-6, "Properties of superheated water tables" in the text book.

Specific enthalpy, $h_2 = 2855.8\ kJ/kg$

Apply energy balance equation for a steady state flow process.

$$\dot{Q} + \dot{m}h_1 + \dot{m}\frac{V_1^2}{2} + \dot{m}gz_1 = \dot{m}h_2 + \dot{m}\frac{V_2^2}{2} + \dot{m}gz_2 + \dot{W}$$

$$\dot{Q} = \dot{W} + \dot{m}(h_2 - h_1) + \dot{m}\left(\frac{V_2^2 - V_1^2}{2}\right) + \dot{m}g(z_2 - z_1)$$

Here, $\dot{m}$ is mass flow rate of steam, $\dot{Q}$ is rate of heat transfer, $\dot{W}$ is rate of work transfer, V_1 is velocity of steam at inlet, V_2 is velocity of steam at exit, z_1 is datum head at turbine inlet, z_2 is datum head at turbine exit, and g is acceleration due to gravity.

Since there is no change in datum head, difference at inlet and exit, $(z_2 - z_1) = 0$

Hence, the energy balance equation becomes,

$$\dot{Q} = \dot{W} + \dot{m}(h_2 - h_1) + \dot{m}\left(\frac{V_2^2 - V_1^2}{2}\right) + 0$$

$$\dot{Q} = \dot{W} + \dot{m}(h_2 - h_1) + \dot{m}\left(\frac{V_2^2 - V_1^2}{2}\right) \quad \text{..... (1)}$$

Step 2 of 2

Substitute $3658.8\ kJ/kg$ for h_1, $2855.8\ kJ/kg$ for h_2, 26 kg/s for $\dot{m}$, $(20\times10^3)kW$ for $\dot{W}$, 0 m/s for V_1, 180 m/s for V_2 in equation (1).

$$\dot{Q} = \dot{W} + \dot{m}(h_2 - h_1) + \dot{m}\left(\frac{V_2^2 - V_1^2}{2}\right)$$

$$= 20\times10^3 + 26\times(2855.8 - 3658.8) + 26\times\left(\frac{180^2 - 0^2}{2}\right)\times\frac{1}{1000}$$

$$= 20\times10^3 - 20878 + 421.2$$

$$= -456.8\,kW$$

Negative sign indicates heat rejected from the turbine.

Therefore, the amount of heat transfer during the process is $\boxed{456.8\,kW}$.

Question: 6.054P

Determine the power input for a compressor that compresses helium from 150 kPa and 20°C to 400 kPa and 200°C. Helium enters this compressor through a 0.1-m2 pipe at a velocity of 15 m/s. What is the increase in the flow power during this process?

Step 1 of 4

Given

Inlet pressure of Helium, $P_1 = 150\ \text{kPa}$

Inlet temperature of Helium, $T_1 = 20°\text{C}$

$T_1 = 293\text{K}$

Inlet velocity of Helium, $V_1 = 0.1\ \text{m}^2$

Inlet Area of Compressor, $A_1 = 0.1\ \text{m}^2$

Exit pressure of Helium, $P_2 = 400\ \text{kPa}$

Final temperature of Helium, $T_2 = 200°\text{C}$

$T_2 = 473\text{K}$

Step 2 of 4

From the property table of ideal gasses for Helium,

The gas constant, $R = 2.0769\ \text{kJ/kg.K}$

Specific heat, $C_p = 5.1926\ \text{kJ/kg.K}$

From ideal gas equation $P = \rho RT$

Hence $\rho_1 = \dfrac{P_1}{RT_1}$

$$\rho_1 = \frac{150}{(2.0769)(293)}$$

$$\rho_1 = 0.2465\ \text{kg/m}^3$$

Step 3 of 4

The mass flow rate $\dot{m} = \rho AV$

$$\dot{m} = (0.2465)(0.1)(15)$$

$$\dot{m} = 0.37\ \text{kg/s}$$

Work input for compressor, $\dot{W}_{in} = \dot{m}(h_2 - h_1)$

But Enthalpy, $h = C_p T$. Hence

$$\dot{W}_{in} = \dot{m}C_p(T_2 - T_1)$$

$$\dot{W}_{in} = 0.37 \times 5.1926 \times (200 - 20)$$

$$\dot{W}_{in} = 346\ \text{kW}$$

Hence power input to the compressor is $\boxed{\dot{W}_{in} = 346\ \text{kW}}$

Step 4 of 4

The increase in flow power,

$$\dot{W}_f = \dot{m}(P_2 v_2 - P_1 v_1)$$

$$\dot{W}_f = \dot{m}R(T_2 - T_1)$$

$$\dot{W}_f = (0.37)(2.0769)(200 - 20)$$

$$\dot{W}_f = 138.22\ \text{kW}$$

Increase in flow power is $\boxed{\dot{W}_f = 138.22\ \text{kW}}$

Question: 6.055P

Someone claims, based on temperature measurements, that the temperature of a fluid rises during a throttling process in a well-insulated valve with negligible friction, How do you evaluate this claim? Does this process violate thermodynamic laws?

Step 1 of 1

During throttling process, the temperature of the fluid can increase, decrease, or remain the same. Therefore, this claim is valid since no thermodynamic laws are violated

Question: 6.056P

Would you expect the temperature of air to drop as it undergoes a steady-flow throttling process? Explain.

Step 1 of 1

No, since the temperature of an ideal gas does not change during a throttling (h =constant) process because enthalpy is a function of temperature only

$h = h(T)$

Question: 6.057P

Would you expect the temperature of a liquid to change as it is throttled? Explain.

Step 1 of 1

If the fluid remains in the liquid phase, then there will not be any change in temperature of the liquid. But if some part of the liquid vaporizes during throttling, change in the temperature may take place.

Question: 6.058P

During a throttling process, the temperature of a fluid drops from 30 to −20°C. Can this process occur adiabatically?

Step 1 of 1

Yes, the process can occur adiabatically.

The throttling devices are very small and the flow through them is assumed as adiabatic, since there is neither sufficient time, nor a large enough area for an effective heat transfer. During throttling, a significant pressure drop occurs in the fluid, along with a large temperature drop. The magnitude of temperature drop during a throttling process is governed by a property called Joule-Thomson coefficient.

Joule-Thomson coefficient μ is defined as follows:

$$\mu = \left(\frac{\partial T}{\partial P}\right)_h$$

Question: 6.059P

An adiabatic capillary tube is used in some refrigeration systems to drop the pressure of the refrigerant from the condenser level to the evaporator level. The R-134a enters the capillary tube as a saturated liquid at 50°C, and leaves at −20°C. Determine the quality of the refrigerant at the inlet of the evaporator.

Step 1 of 3

Given

Temperature of R-134a at inlet of capillary tube, $T_1 = 50°C$

Temperature of R-134a at exit of capillary tube, $T_2 = -20°C$

Step 2 of 3

From saturated R-134a tables, at 50°C,

Saturated liquid- Enthalpy, $h_1 = h_f = 123.49$ kJ/kg

From saturated R-134a tables, at −20°C,

Saturated liquid- Enthalpy, $h_f = 25.49$ kJ/kg

Enthalpy of evaporation, $h_{fg} = 212.91$ kJ/kg

Step 3 of 3

The process in adiabatic capillary tube is isenthalpic. So, $h_2 = h_1$

$h_2 = 123.49$ kJ/kg

The quality at the exit, $x_2 = \dfrac{h_2 - h_f}{h_{fg}}$

$$x_2 = \frac{123.49 - 25.49}{212.91}$$

$$x_2 = 0.46$$

The steam at exit of capillary tube enters evaporator. So

Quality of steam at inlet of evaporator is $\boxed{x_2 = 0.46}$

Question: 6.060P

Saturated liquid-vapor mixture of water, called wet steam, in a steam line at 2000 kPa is throttled to 100 kPa and 120°C. What is the quality in the steam line?

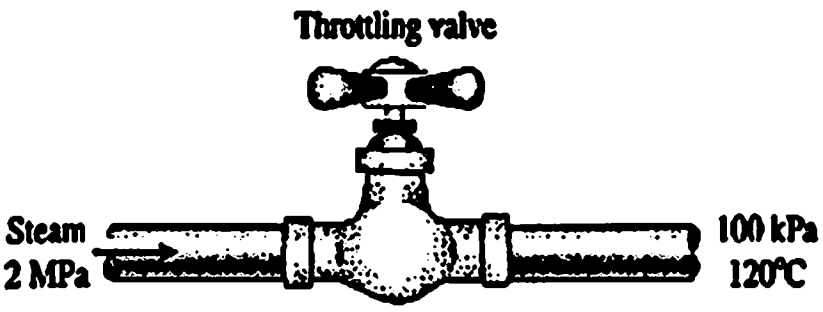

FIGURE P6–60

Step 1 of 4

Loading solution. Please wait ...

Step 2 of 4

Throttling valves are usually small devices, and the flow through them may be assumed to be adiabatic $(q \approx 0)$, there is no work done $(w \approx 0)$, and changes in kinetic and potential energies are insignificant $(ke \approx 0, pe \approx 0)$.

So the conservation of energy equation for this single steam steady flow devices reduces to $h_2 = h_1$ kJ/kg

Step 3 of 4

From superheated water tables

At $P_2 = 100$ kPa, $T_2 = 120°C$

$$h_2 = 2675.8 + (2776.6 - 2675.8)\left(\frac{120-100}{150-100}\right)$$

$h_2 = 2716.12$ kJ/kg

At $P_1 = 2000$ kPa from saturated water tables

$h_f = 908.47$ kJ/kg

$h_{fg} = 1889.8$ kJ/kg

Step 4 of 4

Since $h_2 = h_1$

$h_2 = h_1 = 2716.12$ kJ/kg

We know that $h_1 = h_f + x_1 h_{fg}$

Therefore the quality at inlet is

$$x_1 = \frac{h_1 - h_f}{h_{fg}}$$

$$x_1 = \frac{2716.12 - 908.47}{1889.8}$$

$$\boxed{x_1 = 0.9565}$$

Question: 6.061P

Refrigerant-134a at 800 kPa and 25°C is throttled to a temperature of −20°C. Determine the pressure and the internal energy of the refrigerant at the final state.

Step 1 of 6

Given

Inlet pressure $P_1 = 800$ kPa

Inlet temperature $T_1 = 25°C$

Exit temperature $T_2 = -20°C$

Step 2 of 6

Throttling valves are usually small devices, and the flow through them may be assumed to be adiabatic $(q \approx 0)$, there is no work done $(w \approx 0)$, and changes in kinetic and potential energies are insignificant $(ke \approx 0, pe \approx 0)$.

So the conservation of energy equation for this steady flow device reduces to

$h_2 = h_1$ kJ/kg

Step 3 of 6

At $P_1 = 800$ kPa and $T_1 = 25°C$ the state is in wet condition

So from saturated R-134a temperature table at $T_1 = 25°C$

$$h_1 = h_f = 84.98 + (87.83 - 84.98)\left(\frac{25-24}{26-24}\right)$$

$h_1 = h_f = 86.405$ kJ/kg

At $T_2 = -20°C$ from saturated R-134a tables

$h_f = 25.49$ kJ/kg

$h_{fg} = 212.91$ kJ/kg

$u_f = 25.39$ kJ/kg

$u_{fg} = 193.45$ kJ/kg

Step 4 of 6

The pressure at the exit will be the saturation pressure at $T_2 = -20°C$

So from saturated R-134a tables

$P_2 = P_{sat} = 132.82$ kPa

$\boxed{P_2 = 132.82 \text{ kPa}}$

Step 5 of 6

The exit quality can be obtained from

$h_2 = h_f + x_2 h_{fg}$ (Since $h_1 = h_2$)

$$x_2 = \frac{h_2 - h_f}{h_{fg}}$$

$$x_2 = \frac{86.405 - 25.49}{212.91}$$

$x_2 = 0.2861$

Step 6 of 6

The exit internal energy can be determined as

$u_2 = u_f + x_2 u_{fg}$

$u_2 = 25.39 + (0.2861)(193.45)$

$\boxed{u_2 = 80.736 \text{ kJ/kg}}$

Question:

6.062P

A well-insulated valve is used to throttle steam from 8 MPa and 350°C to 2 MPa. Determine the final temperature of the steam.

Step 1 of 1

In throttling process 1-2, enthalpy remains constant.

$$h_1 = h_2$$

Obtain the properties of steam at inlet pressure $P_1 = 8$ MPa and inlet temperature $T_1 = 350°C$ from superheated water tables.

Enthalpy, $h_1 = 2988.1$ kJ/kg

Since enthalpy remains constant in throttling process, enthalpy at state 2 is

$$h_2 = 2988.1 \text{ kJ/kg}$$

Now obtain the exit temperature of steam at final pressure $P_2 = 2$ MPa and enthalpy $h_2 = 2988.1$ kJ/kg from superheated water tables by using linear interpolation,

$$T_2 = 250 + (300 - 250)\left(\frac{2988.1 - 2903.3}{3024.2 - 2903.3}\right)$$

$$= 285.07°C$$

Hence, exit temperature of the steam is $\boxed{285.07°C}$

Question:

Reconsider Prob. 6–62. Using EES (or other) software, investigate the effect of the exit pressure of steam on the exit temperature after throttling. Let the exit pressure vary from 6 to 1 MPa. Plot the exit temperature of steam against the exit pressure, and discuss the results.

Step 1 of 7

State 1

From superheated steam tables,

The inlet pressure of steam at 8 MPa and $250°C$.

The Enthalpy is, $h_1 = 2988.1 kJ/kg$

State 2

From superheated steam tables,

The exit pressure of steam at 2 MPa,

The temperature at $T = 250°C$ the Enthalpy is , $h = 2903.3\ kJ/kg$.

The temperature at $T = 300°C$ the Enthalpy is , $h = 3024.2\ kJ/kg$.

Step 2 of 7

Throttling valves are devices wherein the process is isenthalpic. So, $h_2 = h_1$

$h_2 = 2988.1\ kJ/kg$ And $P_2 = 2\ MPa$

Use the method of interpolation,

$$\frac{T_2 - 250}{300 - 250} = \frac{2988.1 - 2903.3}{3024.2 - 2903.3}$$

$$T_2 = 250 + (0.7014 \times 50)$$

$$T_2 = 285.07°C$$

Hence temperature at exit T_2 is $\boxed{285.07°C}$

Step 3 of 7

The given problem can be solved using EES software by following the below steps.

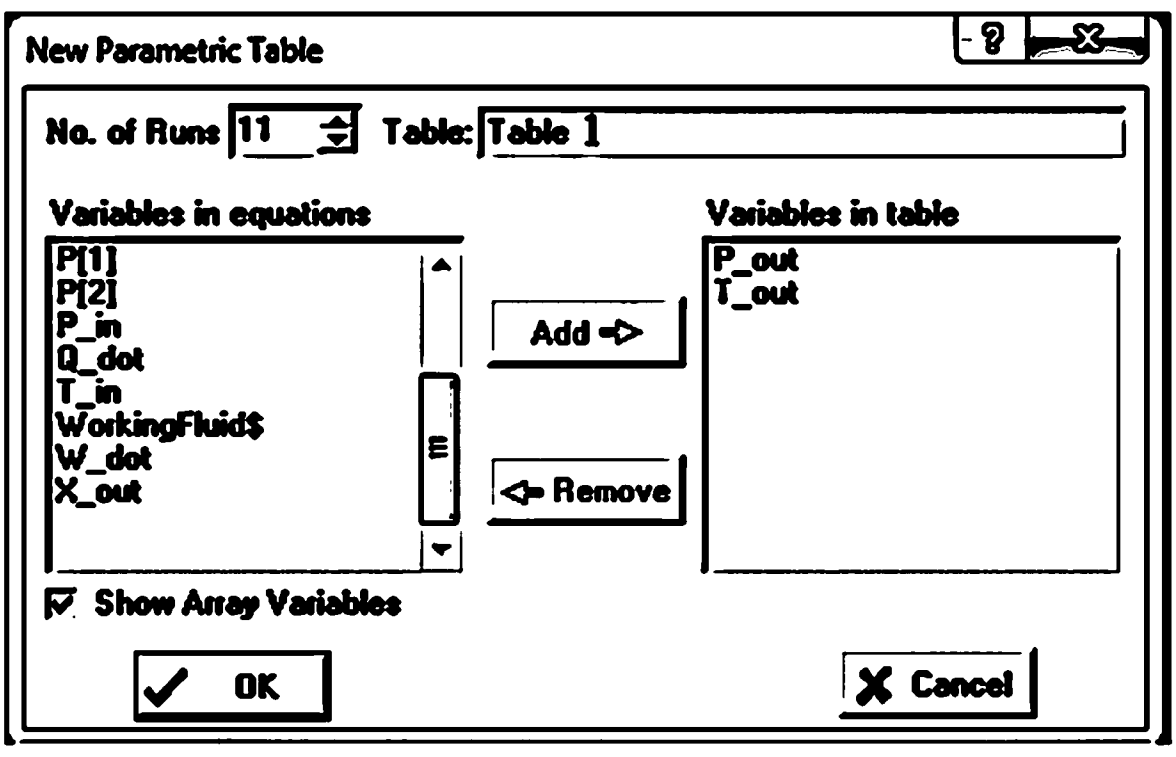
1. Open EES software

2. Create a new file by clicking on the 'New' of the 'File menu'

3. Now type the following code in dailog box

Equations Window

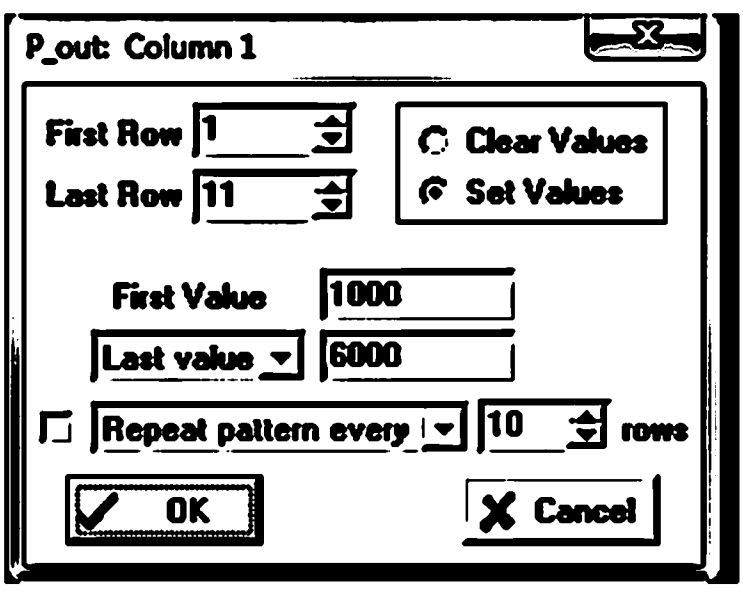
```
WorkingFluid$='Steam_iapws' "WorkingFluid can be changed to ammonia or other fluids"
P_in=8000 [kPa]
T_in=350 [C]
"P_out=2000 "
"Analysis"
m_dot_in=m_dot_out "steady-state mass balance"
m_dot_in=1 "mass flow rate is arbitrary"
m_dot_in*h_in+Q_dot-W_dot-m_dot_out*h_out=0 "steady-state energy balance"
Q_dot=0 "assume the throttle to operate adiabatically"
W_dot=0 "throttles do not have any means of producing power"
h_in=enthalpy(WorkingFluid$,T=T_in,P=P_in) "property table lookup"
T_out=temperature(WorkingFluid$,P=P_out,h=h_out) "property table lookup"
X_out=quality(WorkingFluid$,P=P_out,h=h_out) "x_out is the quality at the outlet"
P[1]=P_in; P[2]=P_out; h[1]=h_in; h[2]=h_out "use arrays to place points on property plot"
```



Step 4 of 7

Now to solve the equation for a range of pressure values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.

A dailog box will open.



Select no of runs = 11.

Select variables in equations as "P_out" and"T_out" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 5 of 7

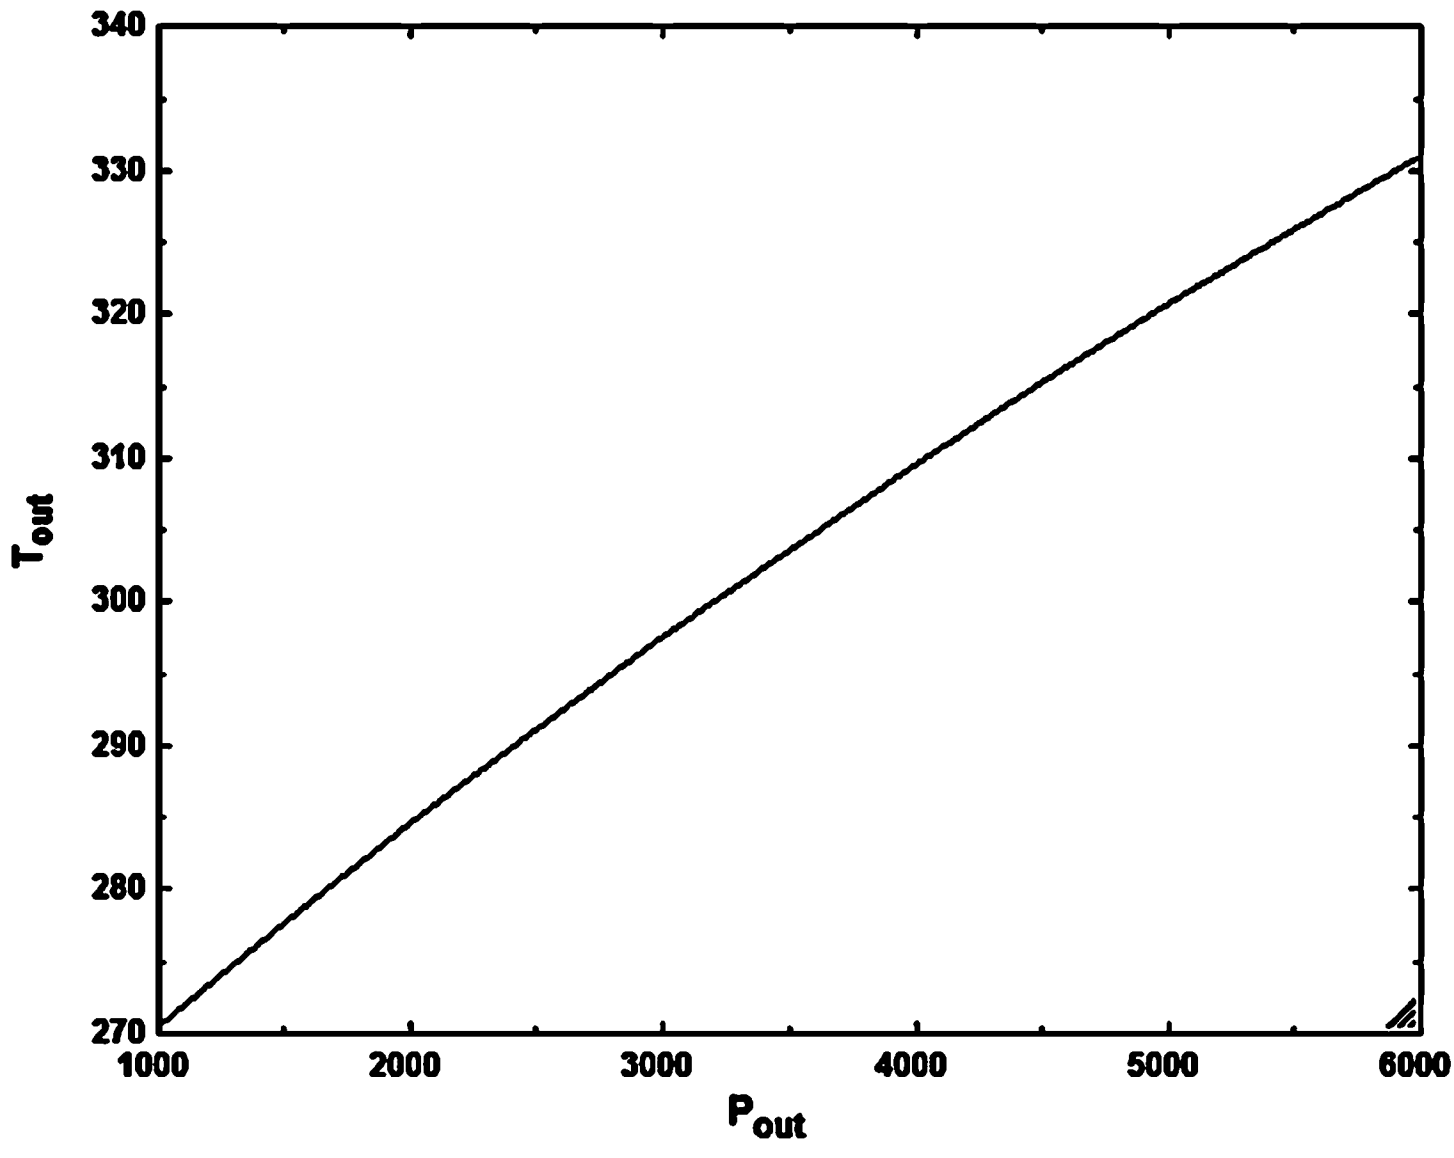
To enter the values in the "P_out" column click on the drop tab in "P_out" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Now click on 'Solve table' of 'Calculate' menu.

6.06P pg 2

Now click on 'Solve table' of 'Calculate' menu.

The Solution will appear as shown below:



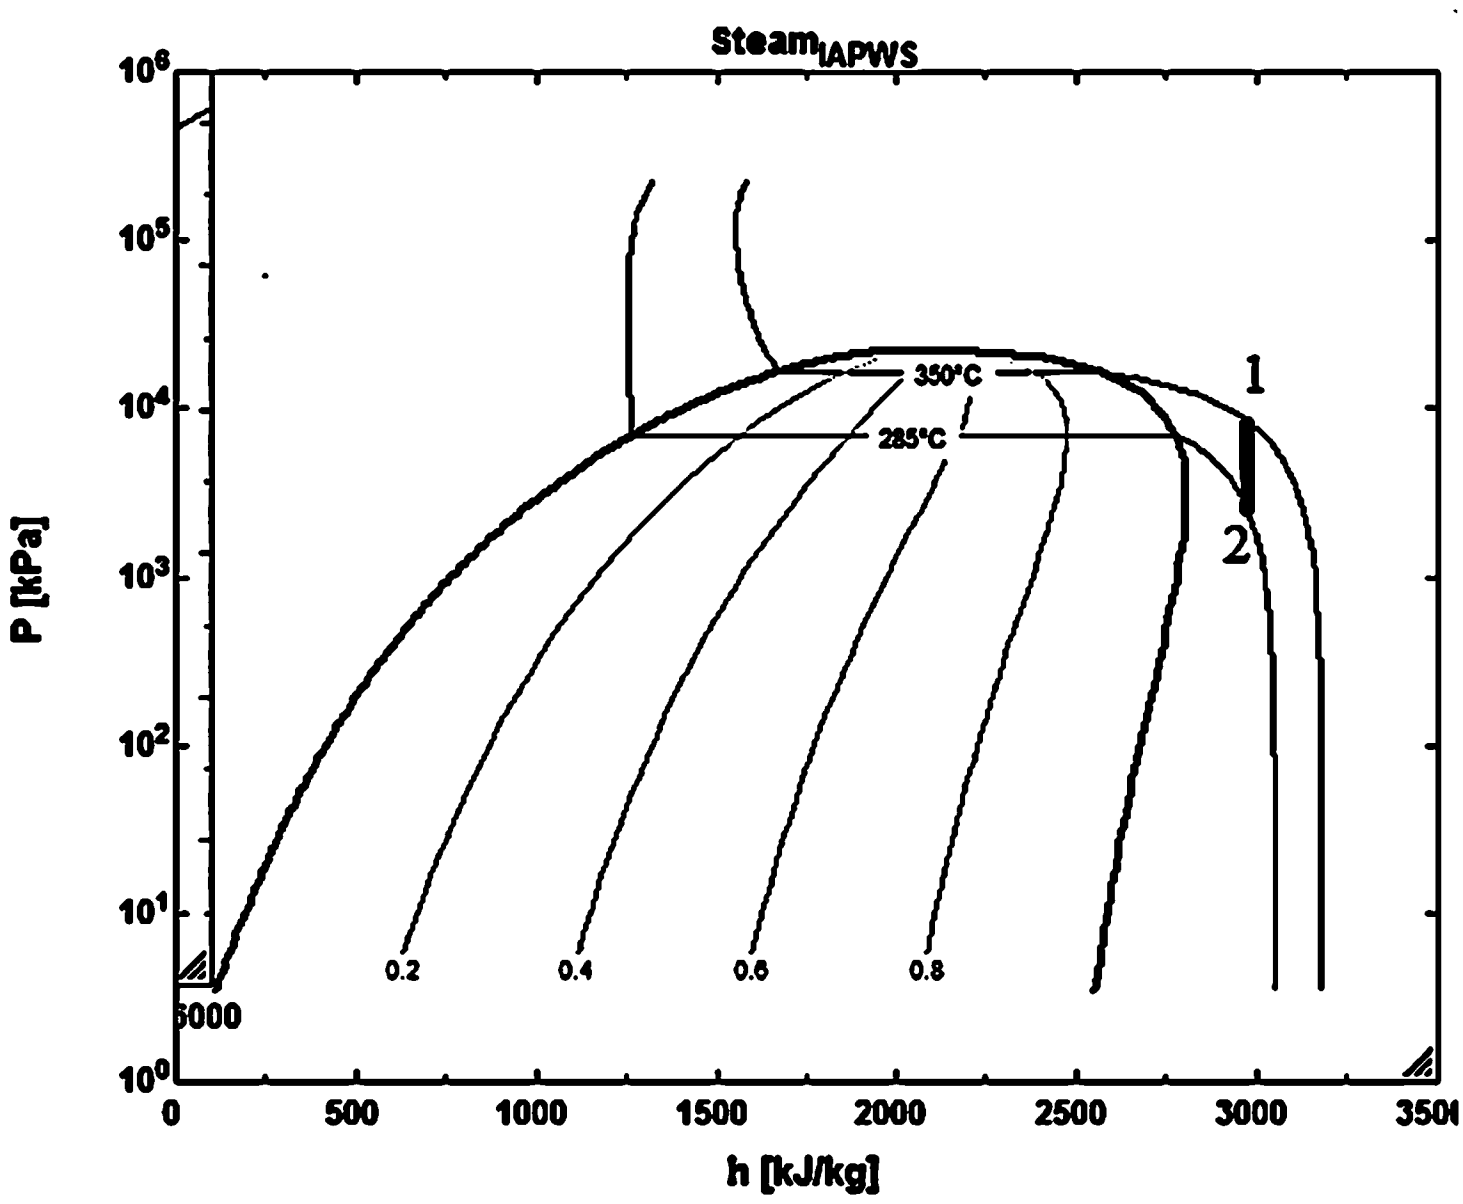
1..11	1 P_{out}	2 T_{out}
Run 1	1000	270.5
Run 2	1500	277.7
Run 3	2000	284.6
Run 4	2500	291.2
Run 5	3000	297.6
Run 6	3500	303.7
Run 7	4000	309.5
Run 8	4500	315.2
Run 9	5000	320.7
Run 10	5500	325.9
Run 11	6000	331

Step 6 of 7

Inorder to plot the pressure verses the temperature, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.

Select X-axis as "P_out" and Y-axis as "T_out" and press 'OK'

The Graph will be plotted as shown below:



Step 7 of 7

Inorder to plot the cable enthalpy verses the pressure, click on the 'properties Plot' of 'New Plot window' from 'Plots' menu.

Select X-axis as "h" and Y-axis as "P" and press 'OK'

The Graph will be plotted as shown below:

Question: 6.064P

Refrigerant-134a enters the expansion valve of a refrigeration system at 160 psia as a saturated liquid and leaves at 30 psia. Determine the temperature and internal energy changes across the valve.

Step 1 of 5

Obtain the following properties from the table of A-12E "saturated refrigerant-134a pressure tables" at pressure 160 psia.

Enthalpy at inlet,

$$h_1 = h_f$$
$$= 48.519 \text{ Btu/lbm}$$

Internal energy at inlet,

$$u_1 = u_f$$
$$= 48.101 \text{ Btu/lbm}$$

Saturated temperature is,

$$T_1 = T_{sat}$$
$$= 109.5°\text{F}$$

Since, the enthalpy at inlet is equal to the enthalpy at outlet in expansion, hence

$$h_2 = h_1$$

Substitute 48.519 Btu/lbm for h_1.

$$h_2 = h_1$$
$$= 48.519 \text{ Btu/lbm}$$

Step 2 of 5

Obtain the following properties from the table of A-12E "saturated refrigerant-134a pressure tables" at pressure 160 psia.

Saturated liquid enthalpy, $h_{2f} = 17.006 \text{ Btu/lbm}$

Saturated vapor enthalpy, $h_{2g} = 105.32 \text{ Btu/lbm}$

Saturated liquid internal energy, $u_{2f} = 16.939 \text{ Btu/lbm}$

Saturated vapor internal energy, $u_{2g} = 96.72 \text{ Btu/lbm}$

Saturated temperature is,

$$T_2 = T_{sat}$$
$$= 15.37°\text{F}$$

Step 3 of 5

Find the quality at state using the following expression.

$$h_2 = h_{2f} + x\left(h_g - h_f\right)$$
$$x = \frac{\left(h_2 - h_{2f}\right)}{\left(h_g - h_f\right)}$$

Substitute 48.519 Btu/lbm for h_2, 17.006 Btu/lbm for h_{2f}, and 105.32 Btu/lbm for h_{2g}.

$$x = \frac{\left(h_2 - h_{2f}\right)}{\left(h_g - h_f\right)}$$
$$= \frac{48.519 - 17.006}{105.32 - 17.006}$$
$$= 0.356$$

Step 4 of 5

Find the internal energy at outlet using the equation.

Find the Internal energy at exit using the following expression.

$$u_2 = u_{2f} + x\left(u_g - u_f\right)$$
$$= 16.939 + 0.356\left(96.72 - 16.939\right)$$
$$= 45.34 \text{ Btu/lbm}$$

Find the change in temperatures using the equation.

$$\Delta T = T_2 - T_1$$

Substitute $15.37°\text{F}$ for T_2 and $109.5°\text{F}$ for T_1.

$$\Delta T = T_2 - T_1$$
$$= 109.5 - 15.37$$
$$= 94.13°\text{F}$$

Therefore, the required change in temperature is $\boxed{94.13°\text{F}}$.

Step 5 of 5

Find the change in internal energy using the equation.

$$\Delta u = u_2 - u_1$$

Substitute 48.101 Btu/lbm for u_1, and 45.34 Btu/lbm for u_2.

$$\Delta u = u_2 - u_1$$
$$= 45.34 - 48.101$$
$$= -2.761 \text{ Btu/lbm}$$

Therefore, the change in internal energy is $\boxed{-2.761 \text{ Btu/lbm}}$.

Question: 6.065P

Consider a steady-flow mixing process. Under what conditions will the energy transported into the control volume by the incoming streams be equal to the energy transported out of it by the outgoing stream?

Step 1 of 1

Mixing chambers are usually well insulated ($q = 0$) and usually do not involve any kind of work ($w = 0$). Also, the kinetic and potential energies of the fluid streams are usually negligible ($ke = 0, pe = 0$).

Under all these conditions the energy transport in and out of the control volume are same.

Question: 6.066P

Consider a steady-flow heat exchanger involving two different fluid streams. Under what conditions will the amount of heat lost by one fluid be equal to the amount of heat gained by the other?

Step 1 of 1

Heat exchangers typically involve no work interactions ($w = 0$) and negligible kinetic and potential energy changes ($ke = 0, pe = 0$) for each fluid stream.

Under these conditions the amount of heat lost by one fluid is equal to the amount of heat gained by the other.

Question: 6.067P

When two fluid streams are mixed in a mixing chamber, can the mixture temperature be lower than the temperature of both streams? Explain.

Step 1 of 1

Answer: Yes.

When the mixing chamber loses heat to the surrounding medium, the mixture temperature will be lower than the temperature of both streams. But usually, mixing chambers are well insulated. Therefore, the case violates the statement that the mixing chambers are insulated.

Question: 6.068P

Hot and cold streams of a fluid are mixed in a rigid mixing chamber. The hot fluid flows into the chamber at a mass flow rate of 5 kg/s with an energy in the amount of 150 kJ/kg. The cold fluid flows into the chamber with a mass flow rate of 15 kg/s and carries energy in the amount of 50 kJ/kg. There is heat transfer to the surroundings from the mixing chamber in the amount of 5.5 kW. The mixing chamber operates in a steady-flow manner and does not gain or loose energy or mass with time. Determine the energy carried from the mixing chamber by the fluid mixture per unit mass of fluid, in kJ/kg.

Step 1 of 2

Apply mass balance for the mixing chamber system,

$$\dot{m}_{out} = \dot{m}_{in}$$

$$\dot{m}_3 = \dot{m}_1 + \dot{m}_2$$

Here, $\dot{m}_1$ is mass flow rate of hot fluid stream, $\dot{m}_2$ is mass flow rate of cold fluid stream and $\dot{m}_3$ is mass flow rate of mixture.

Substitute $5\,\text{kg/s}$ for $\dot{m}_1$, $15\,\text{kg/s}$ for $\dot{m}_2$

$$\dot{m}_3 = 5+15$$

$$= 20\,\text{kg/s}$$

Step 2 of 2

Apply energy balance to the mixing chamber system,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} e_{in} = \dot{m}_{out} e_{out} + \dot{Q}_{out}$$

$$\dot{m}_1 e_1 + \dot{m}_2 e_2 = \dot{m}_3 e_3 + \dot{Q}_{out}$$

Here, e_1 is the amount of energy of hot fluid, e_2 is the amount of energy of cold fluid and $\dot{Q}_{out}$ is the amount of heat transfer to the surroundings from the mixing chamber.

Substitute $150\,\text{kJ/kg}$ for e_1, $50\,\text{kJ/kg}$ for e_2 and $5.5\,\text{kW}$ for $\dot{Q}_{out}$

$$5\times150+15\times50 = 20\times e_3 + 5.5$$

$$1500 = 20\times e_3 + 5.5$$

$$e_3 = 74.725\,\text{kJ/kg}$$

Therefore, the energy carried from the mixing chamber is $\boxed{74.725\,\text{kJ/kg}}$

Question: 6.069P

A hot-water stream at 80°C enters a mixing chamber with a mass flow rate of 0.5 kg/s where it is mixed with a stream of cold water at 20°C. If it is desired that the mixture leave the chamber at 42°C, determine the mass flow rate of the cold-water stream. Assume all the streams are at a pressure of 250 kPa.

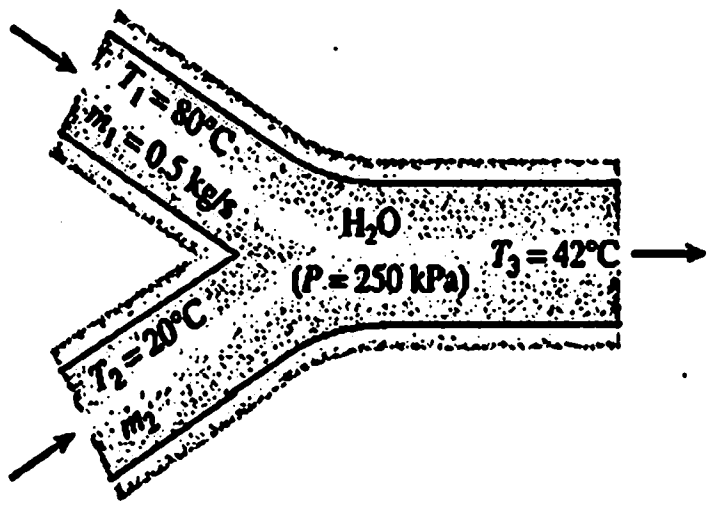


FIGURE P6–69

Step 1 of 5

Given

Hot water stream temperature $T_1 = 80°C$

Mass flow rate of hot water stream $\dot{m}_1 = 0.5$ kg/s

Cold water stream temperature $T_2 = 20°C$

Mixture temperature $T_3 = 42°C$

Pressure of all the streams $P = 250$ kPa

Step 2 of 5

Mixing chambers are usually well insulated ($q = 0$) and usually do not involve any kind of work ($w = 0$). Also, the kinetic and potential energies of the fluid streams are usually negligible ($ke = 0, pe = 0$).

Applying mass balance and energy balance for the mixing chamber system, we obtain the equations as

$$\dot{m}_{in} = \dot{m}_{out}$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

Step 3 of 5

Here there are two inlet streams and one outlet stream

By mass balance

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3 \quad \text{---------- (1)}$$

By Energy balance

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \quad \text{---------- (2)}$$

Substituting equation 1 in equation 2

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \left(\dot{m}_1 + \dot{m}_2\right) h_3$$

$$\dot{m}_1 h_3 - \dot{m}_1 h_1 = \dot{m}_2 h_2 - \dot{m}_2 h_3$$

$$\dot{m}_1 (h_3 - h_1) = \dot{m}_2 (h_2 - h_3)$$

$$\dot{m}_2 = \frac{h_3 - h_1}{h_2 - h_3} \dot{m}_1$$

Step 4 of 5

At $T_1 = 80°C$ from saturated water tables

$h_1 = h_f = 335.02$ kJ/kg

At $T_2 = 20°C$ from saturated water tables

$h_2 = h_f = 83.915$ kJ/kg

At $T_3 = 42°C$ from saturated water tables

$$h_3 = h_f = 167.53 + (188.44 - 167.53)\left(\frac{42-40}{45-40}\right)$$

$h_f = h_3 = 175.894$ kJ/kg

Step 5 of 5

Therefore

$$\dot{m}_2 = \frac{h_3 - h_1}{h_2 - h_3} \dot{m}_1$$

$$\dot{m}_2 = \frac{175.894 - 335.02}{83.915 - 175.894} \times 0.5$$

$$\boxed{\dot{m}_2 = 0.865}$$

Question: 6.070P

Water at 65 °F and 20 psia is heated in a chamber by mixing it with saturated water vapor at 20 psia. If both streams enter the mixing chamber at the same mass flow rate, determine the temperature and the quality of the exiting stream.

Step 1 of 6

Apply mass balance to the mixing chamber system,

$$\dot{m}_{out} = \dot{m}_{in}$$

$$\dot{m}_3 = \dot{m}_1 + \dot{m}_2$$

Here, $\dot{m}_1$ is mass flow rate of water, $\dot{m}_2$ is mass flow rate of water vapor and $\dot{m}_3$ is mass flow rate of mixture

But $\dot{m}_1 = \dot{m}_2$ then,

$$\dot{m}_3 = \dot{m}_1 + \dot{m}_1$$

$$\dot{m}_3 = 2\dot{m}_1$$

Step 2 of 6

Assume mixing chambers are usually well insulated, so $\dot{Q}_{out} = 0$ and they do not involve any kind of work so $\dot{W} = 0$.

Also, the changes in kinetic and potential energies of the fluid streams are usually negligible in the chamber. So,

$$ke = 0,$$

$$pe = 0$$

Apply energy balance to the mixing chamber system,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$$

$$\dot{m}_1 h_1 + \dot{m}_1 h_2 = 2\dot{m}_1 h_3$$

Here, h_1 is enthalpy of water, h_2 is enthalpy of vapor and h_3 is enthalpy of the mixture.

$$h_1 + h_2 = 2h_3 \qquad \text{..... (1)}$$

Step 3 of 6

From saturated water tables at temperature $T_1 = 65°\text{F}$,

Saturated enthalpy of liquid,

$$h_1 = h_f$$

$$h_1 = 33.08 \text{ Btu/lbm}$$

From saturated water tables at pressure $P_2 = 20 \text{ psia}$

Saturated enthalpy of vapor,

$$h_2 = h_g$$

$$h_2 = 1156.2 \text{ Btu/lbm}$$

Step 4 of 6

Substitute the known enthalpy values in equation (1),

$$h_1 + h_2 = 2h_3$$

$$33.08 + 1156.2 = 2h_3$$

$$h_3 = 594.64 \text{ Btu/lbm}$$

Assume the mixture pressure is also at pressure $P_3 = 20 \text{ psia}$

Obtain the properties of enthalpy values from saturated water tables at pressure $P_3 = 20 \text{ psia}$

Enthalpy of saturated water, $h_f = 196.27 \text{ Btu/lbm}$

Enthalpy of evaporation, $h_{fg} = 959.93 \text{ Btu/lbm}$

Step 5 of 6

Find the exit quality of steam by using enthalpy value at state 3

$$h_3 = h_f + x_3 h_{fg}$$

$$x_3 = \frac{h_3 - h_f}{h_{fg}}$$

$$= \frac{594.64 - 196.27}{959.93}$$

$$= 0.415$$

Therefore, the quality of the mixture, x_3 is $\boxed{0.415}$

Step 6 of 6

The exit flow is a saturated mixture, because the enthalpy value (h_3) lies between saturated enthalpy values of vapor, h_g and liquid, h_f

Therefore, the temperature of the exiting stream is equal to the saturation temperature at pressure 20 psia

Now obtain the temperature from saturated water tables at pressure $P_3 = 20 \text{ psia}$

$$T_{sat} = T_3 = 227.92°\text{F}$$

Hence, the temperature of the exiting stream is $\boxed{227.92°\text{F}}$

Question: 6.071P

A stream of refrigerant-134a at 1 MPa and 20°C is mixed with another stream at 1 MPa and 80°C. If the mass flow rate of the cold stream is twice that of the hot one, determine the temperature and the quality of the exit stream.

Step 1 of 5

Apply mass balance equation to the mixing chamber system

$$\dot{m}_{out} = \dot{m}_{in}$$

$$\dot{m}_3 = \dot{m}_1 + \dot{m}_2$$

Here, $\dot{m}_1$ is mass flow rate of cold stream 1 and $\dot{m}_2$ is mass flow rate of hot stream and $\dot{m}_3$ is mass flow rate of mixing stream.

Substitute $2\dot{m}_2$ for $\dot{m}_1$

$$\dot{m}_3 = 2\dot{m}_2 + \dot{m}_2$$

$$= 3\dot{m}_2$$

Step 2 of 5

Assume the Mixing chambers are usually well insulated, $q = 0$ and they do not involve any kind of work, $w = 0$

Also, the changes in kinetic and potential energies of the fluid streams are usually negligible, $ke = 0, pe = 0$

Then energy balance equation for the mixing chamber becomes,

$$\dot{m}_{out} h_{out} = \dot{m}_{in} h_{in}$$

$$\dot{m}_3 h_3 = \dot{m}_1 h_1 + \dot{m}_2 h_2$$

$$3\dot{m}_2 h_3 = 2\dot{m}_2 h_1 + \dot{m}_2 h_2$$

$$3h_3 = 2h_1 + h_2$$

Here, h_1 is enthalpy of cold stream, h_2 is enthalpy of hot stream and h_3 is enthalpy of mixture.

Step 3 of 5

Obtain enthalpy at state 1 from saturated R-134a tables at temperature $T_1 = 20°C$

$$h_1 = h_f = 79.32 \text{ kJ/kg}$$

Obtain enthalpy at state 2 from superheated R-134a tables at pressure $P_2 = 1\text{MPa}$ and temperature $T_2 = 80°C$

$$h_2 = 314.25 \text{ kJ/kg}$$

Substitute these enthalpy values in the equation,

$$3h_3 = 2h_1 + h_2$$

$$3h_3 = (2 \times 79.32) + (314.25)$$

$$h_3 = \frac{472.89}{3}$$

$$h_3 = 157.63 \text{kJ/kg}$$

Step 4 of 5

Assume mixture is also at same inlet and exit pressure, $P_3 = 1 \text{ MPa}$

Obtain the properties of saturated R-134a tables at mixture pressure $P_3 = 1 \text{ MPa}$

Enthalpy of saturated liquid R-134a, $h_f = 107.32 \text{ kJ/kg}$

Enthalpy of evaporation of R-134a, $h_{fg} = 163.67 \text{ kJ/kg}$

Enthalpy of saturated vapor R-134a, $h_g = 270.99 \text{ kJ/kg}$

The exit flow is a saturated mixture since the enthalpy value (h_3) lies between saturated enthalpy values of vapor (h_g) and fluid (h_f).

Find the dryness fraction at state 3 by using enthalpy equation,

$$h_3 = h_f + x_3 h_{fg}$$

$$157.63 = 107.32 + x_3 \times 163.67$$

$$x_3 = 0.307$$

The quality of the mixture is $\boxed{0.3079}$

Step 5 of 5

The temperature at exit is the saturation temperature at mixture pressure $P_3 = 1 \text{ MPa}$

Obtain the temperature from saturated R-134a tables at $P_3 = 1 \text{ MPa}$

Saturation temperature, $T_{sat} = T_3 = 39.37°C$

Hence, temperature of the exit stream is $\boxed{39.37°C}$

Question:

Reconsider Prob. 6–71. Using EES (or other)software, investigate the effect of the mass flow rate of the cold stream of R-134a on the temperature and the quality of the exit stream. Let the ratio of the mass flow rate of the cold stream to that of the hot stream vary from 1 to 4. Plot the mixture temperature and quality against the cold-to-hot mass flow rate ratio, and discuss the results.

Step 1 of 7

Mixing chambers are usually well insulated, $q = 0$ and usually do not involve any kind of work, $w = 0$.

Also, the changes in kinetic and potential energies of the fluid streams are usually negligible, $ke = 0, pe = 0$

Applying mass balance for the mixing chamber system

$$\dot{m}_{out} = \dot{m}_{in}$$
$$\dot{m}_3 = \dot{m}_1 + \dot{m}_2$$

Mass flow rate relation, $\dot{m}_1 = 2\dot{m}_2$

$$\dot{m}_3 = 2\dot{m}_2 + \dot{m}_2$$
$$\dot{m}_3 = 3\dot{m}_2$$

Applying energy balance for the mixing chamber system,

$$\dot{m}_{out} h_{out} = \dot{m}_{in} h_{in}$$
$$\dot{m}_3 h_3 = \dot{m}_1 h_1 + \dot{m}_2 h_2$$
$$3\dot{m}_2 h_3 = 2\dot{m}_2 h_1 + \dot{m}_2 h_2$$
$$3h_3 = 2h_1 + h_2$$

Step 2 of 7

From Saturated R-134a tables,

Inlet Temperature of Cold R-134a stream, $T_1 = 20°C$ The Enthalpy is $h_1 = h_f = 79.32\,kJ/kg$

From superheated R-134a tables,

Outlet Temperature of Hot R-134a stream, $T_2 = 80°C$ The Enthalpy is,

$$h_2 = 314.25\,kJ/kg$$

$$3h_3 = 2h_1 + h_2$$
$$3h_3 = (2 \times 79.32) + (314.25)$$
$$h_3 = \frac{427.89}{3}$$
$$h_3 = 157.63\,kJ/kg$$

Step 3 of 7

The mixture is also at same pressure. So, $P_3 = 1\ MPa$

From Saturated R-134a tables, at $P_3 = 1\ MPa$

Enthalpy of saturated liquid R-134a, $h_f = 107.32\,kJ/kg$

Enthalpy of evaporation of R-134a, $h_{fg} = 163.67\,kJ/kg$

Enthalpy of saturated vapor R-134a, $h_g = 270.99\,kJ/kg$

In saturated region,

$$x_3 = \frac{h_3 - h_f}{h_{fg}}$$
$$= \frac{157.63 - 107.32}{163.67}$$
$$= 0.3079$$

The quality of the mixture at outlet x_3 is $\boxed{0.3079}$

The exit flow is a saturated mixture since the enthalpy value (h_3) lies between enthalpy values of vapor (h_g) and fluid (h_f)

Therefore the temperature at exit is the saturation temperature,

At $P_3 = 1\ MPa$, from saturated R-134a tables, saturation temperature is $T_3 = 39.37°C$

Hence temperature at outlet T_3 is $\boxed{39.37°C}$

Step 4 of 7

The given problem can be solved using EES software by following the below steps.

1. Open EES software

2. Create a new file by clicking on the 'New' of the 'File menu'

3.Now type the following code in dailog box

Equations Window

```
"Input Data"
"m_frac = 2" "m_frac =m_dot_cold/m_dot_hot= m_dot_1/m_dot_2"
T[1]=20 [C]
P[1]=1000 [kPa]
T[2]=80 [C]
P[2]=1000 [kPa]
m_dot_1=m_frac*m_dot_2
P[3]=1000 [kPa]
m_dot_1=1
"Conservation of mass for the R134a: Sum of m_dot_in=m_dot_out"
m_dot_1+ m_dot_2 =m_dot_3
"Conservation of Energy for steady-flow: neglect changes in KE and PE"
"We assume no heat transfer and no work occur across the control surface."
E_dot_in - E_dot_out = DELTAE_dot_cv
DELTAE_dot_cv=0 "Steady-flow requirement"
E_dot_in=m_dot_1*h[1] + m_dot_2*h[2]
E_dot_out=m_dot_3*h[3]
"Property data are given by:"

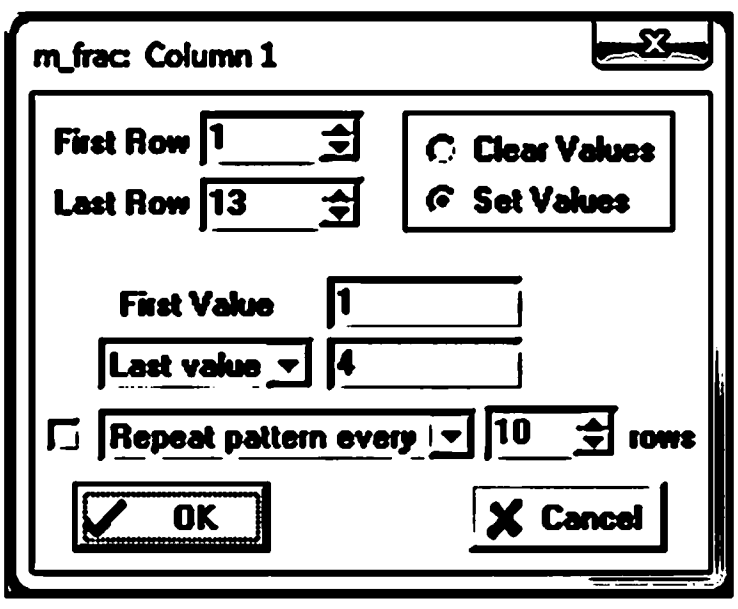
E_dot_out=m_dot_3*h[3]
"Property data are given by:"
h[1] =enthalpy(R134a,T=T[1],P=P[1])
h[2] =enthalpy(R134a,T=T[2],P=P[2])
T[3] =temperature(R134a,P=P[3],h=h[3])
x_3=QUALITY(R134a,h=h[3],P=P[3])
```

Now to solve the equation for a range of m fraction, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.

A dailog box will open.



Select no of runs = 13.

Select variables in equations as "P_out" and"T_out" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

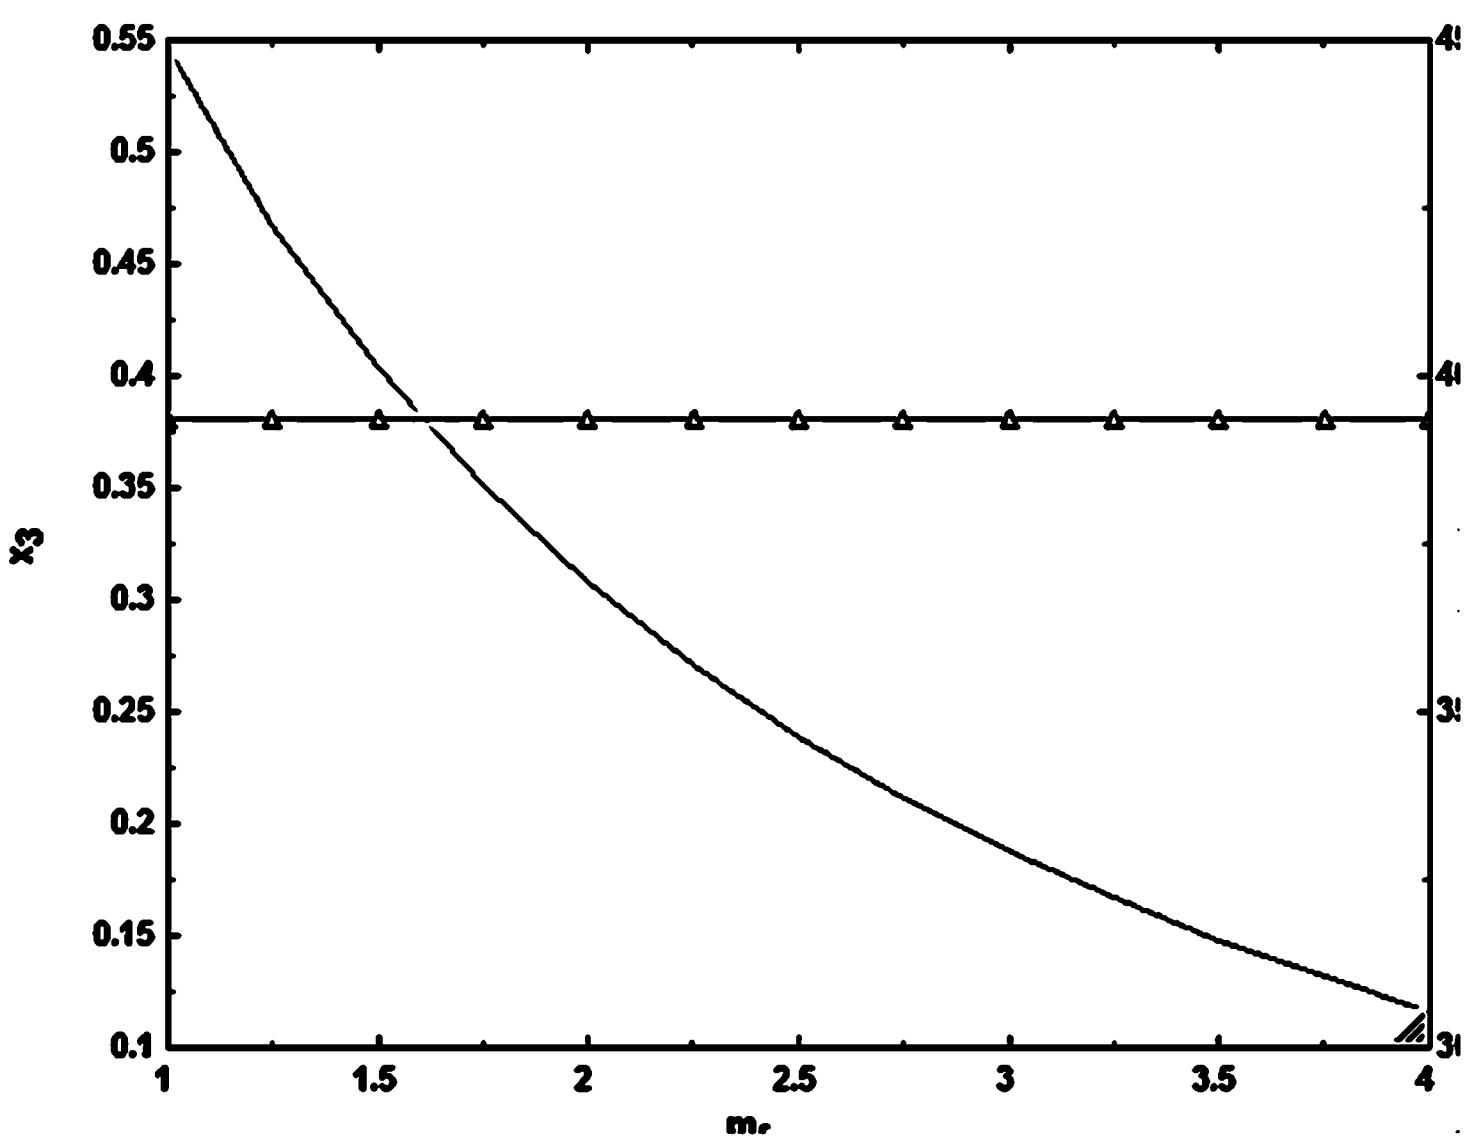
Step 5 of 7

To enter the values in the "m fraction" column click on the drop tab in "m fraction" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 6 of 7

Now click on 'Solve table' of 'Calculate' menu.

The Solution will appear as shown below:



1..13	1 m_{frac}	2 T_3 [C]	3 x_3
Run 1	1	39.37	0.5467
Run 2	1.25	39.37	0.4669
Run 3	1.5	39.37	0.4032
Run 4	1.75	39.37	0.351
Run 5	2	39.37	0.3075
Run 6	2.25	39.37	0.2707
Run 7	2.5	39.37	0.2392
Run 8	2.75	39.37	0.2118
Run 9	3	39.37	0.1879
Run 10	3.25	39.37	0.1668
Run 11	3.5	39.37	0.1481
Run 12	3.75	39.37	0.1313
Run 13	4	39.37	0.1162

Step 7 of 7

Inorder to plot the m fraction versus the dryness fraction and temperature , click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu. And again use overlay plot.

Select X-axis as "m fraction" and Y-axis as "X_3 and T3" and press 'OK'

The Graph will be plotted as shown below:

6.072Pm.pg 3

Question: 6.073P

Steam is to be condensed on the shell side of a heat exchanger at 85°F. Cooling water enters the tubes at 60°F at a rate of 138 lbm/s and leaves at 73°F. Assuming the heat exchanger to be well-insulated, determine the rate of heat transfer in the heat exchanger and the rate of condensation of the steam.

Step 1 of 5

Given

Inlet temperature of cooling water $T_1 = 60°F$

Exit temperature of cooling water $T_2 = 73°F$

The mass flow rate of cooling water $\dot{m}_{cw} = 138\ \text{lbm/s}$

The temperature of steam in heat exchanger $T = 85°F$

Step 2 of 5

Heat exchangers typically involve no work interactions ($w = 0$) and negligible kinetic and potential energy changes ($ke = 0, pe = 0$) for each fluid stream.

Applying mass balance and energy balance for the heat exchanger system, we obtain the equations as

$$\dot{m}_{in} = \dot{m}_{out}$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

Step 3 of 5

The specific heat of water $c_p = 1\ \text{Btu/lbm.°F}$

Applying energy equation to the cooling water stream

Therefore

$$\dot{Q} + \dot{m}_w h_1 = \dot{m}_w h_2$$

$$\dot{Q} = \dot{m}_w (h_2 - h_1) \qquad \text{(since } h = c_p T\text{)}$$

$$\dot{Q} = \dot{m}_w c_{pw} (T_2 - T_1)$$

Substituting the values

$$\dot{Q} = 138(1)(73 - 60)$$

The rate of heat transfer

$$\boxed{\dot{Q} = 1794\ \text{Btu/s}}$$

Step 4 of 5

Heat lost by the hot fluid is equal to the heat gained by the cold fluid

Since the temperature of steam remains constant it changes from saturated vapor to saturated liquid

Therefore

$$\dot{Q}_{water} = -\dot{Q}_{steam}$$

Applying energy equation to steam

$$\dot{Q}_{steam} + \dot{m}_s h_3 = \dot{m}_s h_4$$

$$\dot{Q}_{steam} + \dot{m}_s h_g = \dot{m}_s h_f$$

$$\dot{Q}_{out} = \dot{m}_s (h_f - h_g)$$

Where h_f *and* h_g are taken from $T = 85°F$

At $T = 85°F$ from saturated water tables

$h_f = 53.06\ \text{Btu/lbm}$

$h_g = 1098.3\ \text{Btu/lbm}$

Step 5 of 5

$$\dot{Q}_{out} = \dot{m}_s (h_f - h_g)$$

$$-1794 = \dot{m}_s (53.06 - 1098.3)$$

$$\boxed{\dot{m}_s = 1.7163\ \text{lbm/s}}$$

Question: 6.074P

Steam enters the condenser of a steam power plant at 20 kPa and a quality of 95 percent with a mass flow rate of 20,000 kg/h. It is to be cooled by water from a nearby river by circulating the water through the tubes within the condenser. To prevent thermal pollution, the river water is not allowed to experience a temperature rise above 10°C. If the steam is to leave the condenser as saturated liquid at 20 kPa, determine the mass flow rate of the cooling water required.

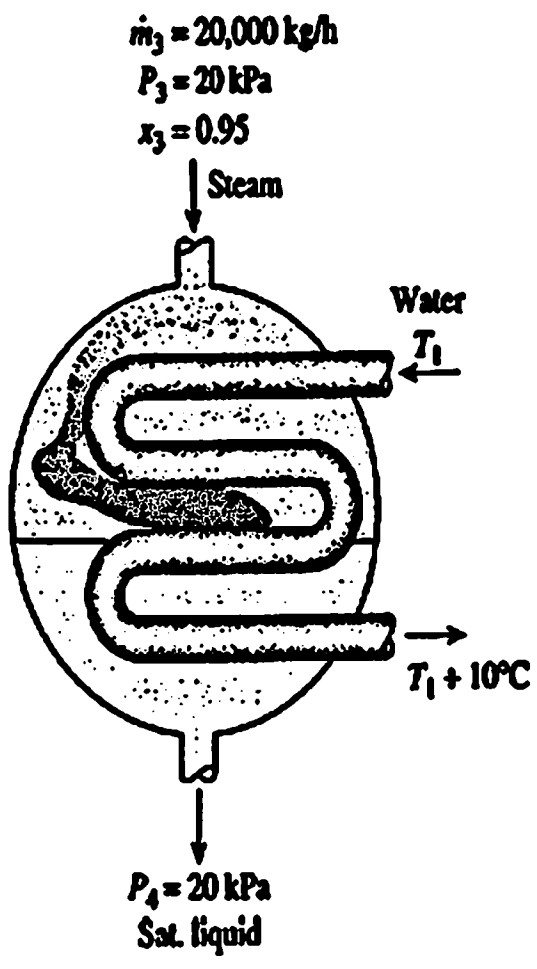


FIGURE P6–74

Step 1 of 5

Given

Properties of steam

Inlet pressure $P_3 = 20$ kPa

Inlet quality $x_3 = 0.95$

Exit pressure as saturated liquid $P_4 = 20$ kPa

Mass flow rate of steam $\dot{m}_s = 20000$ kg/hr

$$= \frac{20000}{3600}$$

$$\dot{m}_s = 5.56 \text{ kg/s}$$

Inlet water temperature is T_1

Exit water temperature is $T_2 = T_1 + 10°C$

Step 2 of 5

Mixing chambers are usually well insulated ($q = 0$) and usually do not involve any kind of work ($w = 0$). Also, the kinetic and potential energies of the fluid streams are usually negligible ($ke = 0, pe = 0$).

Applying mass balance and energy balance for the mixing chamber system, we obtain the equations as

$$\dot{m}_{in} = \dot{m}_{out}$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

Step 3 of 5

In our problem we have two inlets and two exits, the mass flow rate of water and steam remains same at inlet and exit.

Therefore from above energy equation

$$\dot{m}_w h_1 + \dot{m}_s h_3 = \dot{m}_w h_2 + \dot{m}_s h_4$$

$$\dot{m}_w (h_1 - h_2) = \dot{m}_s (h_4 - h_3) \quad \text{---------- (1)}$$

Step 4 of 5

At $P_3 = 20$ kPa from properties of saturated liquid water

$$h_f = 251.42 \text{ kJ/kg}$$

$$h_{fg} = 2357.5 \text{ kJ/kg}$$

$$h_3 = h_f + x_3 h_{fg}$$

$$h_3 = 251.42 + (0.95)2357.5$$

$$h_3 = 2491.045 \text{ kJ/kg}$$

At $P_4 = 20$ kPa from properties of saturated liquid water

$$h_f = h_4 = 251.42 \text{ kJ/kg}$$

Assume the specific heat of water is $C_p = 4.18$ kJ/kg.K

Step 5 of 5

In equation 1 the enthalpy values of water can be write it as $h = c_p T$ and substituting all the known values in equation 1

$$\dot{m}_w (h_1 - h_2) = \dot{m}_s (h_4 - h_3)$$

$$\dot{m}_w c_p (T_1 - T_2) = \dot{m}_s (h_4 - h_3)$$

$$\dot{m}_w \times 4.18 (T_1 - (T_1 + 10)) = 5.56 (251.42 - 2491.045)$$

$$\dot{m}_w \times 4.18 (-10) = 5.56 (251.42 - 2491.045)$$

$$\dot{m}_w = \frac{2239.6}{10 \times 4.18} \times 5.56$$

$$= 297.89 \text{ kg/s}$$

The mass flow rate of water is

$$\boxed{\dot{m}_w = 297.89 \text{ kg/sec}}$$

Question: 6.075P

A heat exchanger is to cool ethylene glycol (cp = 2.56 kJ/kg•°C) flowing at a rate of 3.2 kg/s from 80°C to 40°C by water (cp = 4.18 kJ/kg•°C) that enters at 20°C and leaves at 70°C. Determine (*a*) the rate of heat transfer and (b) the mass flow rate of water.

Step 1 of 3

Given

The mass flow rate of ethylene glycol, $\dot{m}_{gly} = 3.2$ kg/s

The temperatures of glycol at inlet, $T_1 = 80°C$

The temperatures of glycol at exit, $T_2 = 40°C$

The specific heat value of water, $(C_p)_{water} = 4.18$ kJ/kg°C

The specific heat value of glycol, $(C_p)_{gly} = 2.56$ kJ/kg°C

The temperature of water at inlet, $T_3 = 20°C$

The temperature of water at exit, $T_4 = 70°C$

Step 2 of 3

Heat exchangers typically involve no work interactions. So, $w = 0$

The changes in kinetic and potential energies are negligible. So, $ke = 0, pe = 0$

Applying mass balance for the heat exchanger system

$$\dot{m}_{in} = \dot{m}_{out}$$

Applying energy balance for the heat exchanger system,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{m}_{out} h_{out} + \dot{Q}$$

and energy balance for the heat exchanger system, we obtain the equations as

$$\dot{m}_{in} = \dot{m}_{out}$$

$$\dot{E}_{in} = \dot{E}_{out}$$

i.e. $\dot{m}_{in} h_{in} = \dot{Q} + \dot{m}_{out} h_{out}$ $(w = 0 \text{ and } ke = 0, pe = 0)$

(a)

Taking glycol as a system, $\dot{m}_{gl} h_1 = \dot{Q} + \dot{m}_{gl} h_2$

Hence heat transferred, $\dot{Q} = \dot{m}_{gl}(h_1 - h_2)$

But enthalpy, $h = C_p T$, Hence

$$\dot{Q} = \dot{m}_{gl} C_p (T_1 - T_2)$$

$$\dot{Q} = 3.2 \times 2.56 (80 - 40)$$

$$\dot{Q} = 327.68 \text{ kJ/kg}$$

The rate of heat transfer, $\boxed{\dot{Q} = 327.68 \text{ kJ/kg}}$

Step 3 of 3

(b)

Taking water as a system, $\dot{m}_w h_1 = \dot{Q} + \dot{m}_w h_2$

But enthalpy, $h = C_p T$, Hence

$$\dot{Q} = \dot{m}_w C_p (T_1 - T_2)$$

Hence mass flow rate, $\dot{m}_w = \dfrac{\dot{Q}}{C_p (T_1 - T_2)}$

But heat transferred to water is from glycol therefore $\dot{Q} = 327.68$ kJ/kg

$$\dot{m}_w = \frac{327.68}{(4.18)(70 - 20)}$$

$$\dot{m}_w = 1.568 \text{ kg/s}$$

The mass flow rate of water is $\boxed{\dot{m}_w = 1.568 \text{ kg/s}}$

Question: 6.076P

Reconsider Prob. 6–75. Using EES (or other) software, investigate the effect of the inlet temperature of cooling water on the mass flow rate of water. Let the inlet temperature vary from 10 to 40°C, and assume the exit temperature to remain constant. Plot the mass flow rate of water against the inlet temperature, and discuss the results.

Step 1 of 4

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click Calculate on menu bar, select solve.

Finally, Solution window displayed the unknown parameters

Step 2 of 4

Equation window:

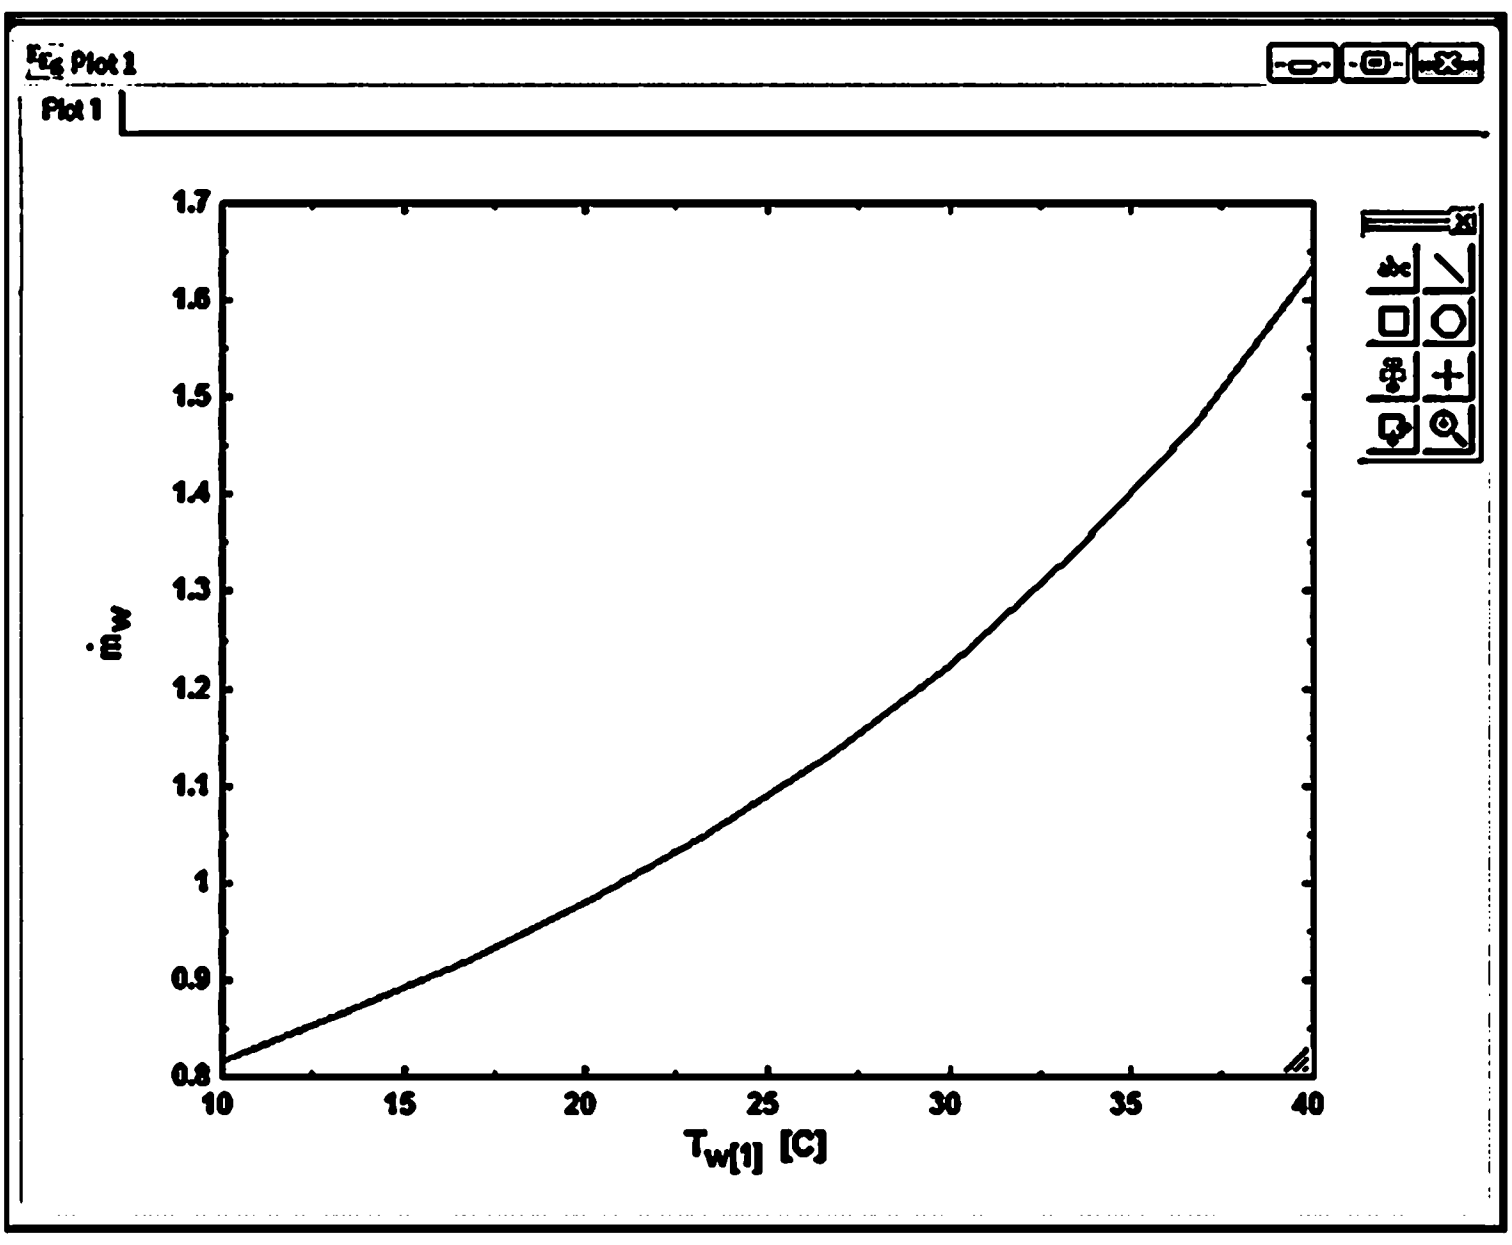
h_eg[2] =C_p_eg*T_eg[2]

Step 3 of 4

Table for $\dot{m}_w$ as a function of $T_{w,1}$:



Parametric Table

Table 1 | Table 2

1..10	$T_{w,1}$ [C]	$\dot{m}_w$
Run 1	10	0.8166
Run 2	13.33	0.8646
Run 3	16.67	0.9187
Run 4	20	0.9799
Run 5	23.33	1.05
Run 6	26.67	1.131
Run 7	30	1.225
Run 8	33.33	1.336
Run 9	36.67	1.47
Run 10	40	1.633

Step 4 of 4

Graph between the $\dot{m}_w$ Vs. $T_{w,1}$:

Question: 6.077P

Cold water (cp = 4.18 kJ/kg•°C) leading to a shower enters a thin-walled double-pipe counter-flow heat exchanger at 15°C at a rate of 0.60 kg/s and is heated to 45°C by hot water (cp = 4.19 kJ/kg•°C) that enters at 100°C at a rate of 3 kg/s. Determine the rate of heat transfer in the heat exchanger and the exit temperature of the hot water.

Step 1 of 4

Given

The mass flow rate of cold water $\dot{m}_{cw} = 0.6$ kg/s

Inlet temperature of cold water $T_1 = 15°C$

Exit temperature of cold water $T_2 = 45°C$

Specific heat of cold water $c_{p_{cw}} = 4.18$ kJ/kg.°C

Specific heat of hot water $c_{p_{hw}} = 4.19$ kJ/kg.°C

Inlet temperature of hot water $T_3 = 100°C$

Mass flow rate of hot water $\dot{m}_{hw} = 3$ kg/s

Step 2 of 4

Heat exchangers typically involve no work interactions ($w = 0$) and negligible kinetic and potential energy changes ($ke = 0, pe = 0$) for each fluid stream.

Applying mass balance and energy balance for the heat exchanger system, we obtain the equations as

$$\dot{m}_{in} = \dot{m}_{out}$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

Step 3 of 4

Applying energy equation to cold water

$$\dot{Q} + \dot{m}_{cw} h_1 = \dot{m}_{cw} h_2$$

$$\dot{Q} = \dot{m}_{cw}(h_2 - h_1) \qquad \text{(since } h = c_p T\text{)}$$

$$\dot{Q} = \dot{m}_{cw} c_{p_{cw}} (T_2 - T_1)$$

Substituting the values

$$\dot{Q} = 0.6(4.18)(45 - 15)$$

$$\boxed{\dot{Q} = 75.24 \text{ kW}}$$

Step 4 of 4

All the heat loss by the hot fluid will be equal to heat gained by the cold fluid.
So the rate of heat transfer of the hot water will be same as above.
Therefore

$$-\dot{Q} = \dot{m}_{hw} c_{p_{hw}} (T_4 - T_3)$$

$$-75.24 = (3)(4.19)(T_4 - 100)$$

$$-5.985 = T_4 - 100$$

$$T_4 = 94.015°C$$

The exit temperature of hot water is

$$\boxed{T_4 = 94.015°C}$$

Question: 6.078P

Air (cp = 1.005 kJ/kg•°C) is to be preheated by hot exhaust gases in a cross-flow heat exchanger before it enters the furnace. Air enters the heat exchanger at 95 kPa and 20°C at a rate of 0.6 m3/s. The combustion gases (*cp* = 1.10 kJ/kg•°C) enter at 160°C at a rate of 0.95 kg/s and leave at 95°C. Determine the rate of heat transfer to the air and its outlet temperature.

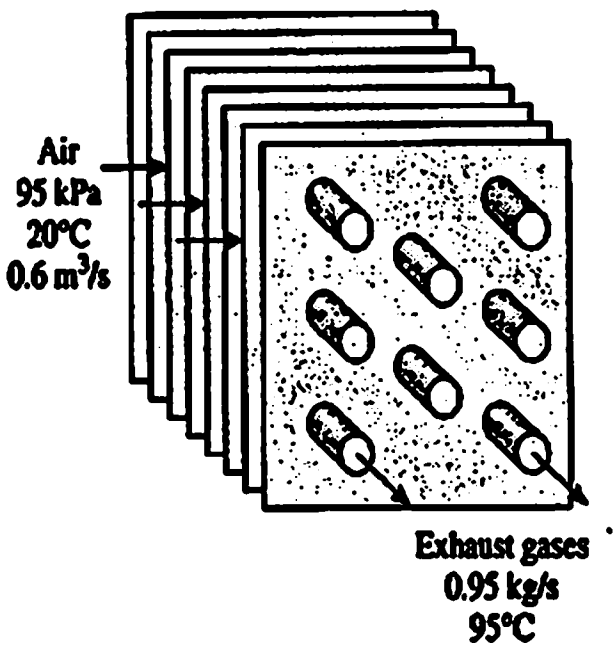


FIGURE P6–78

Step 1 of 4

Given

The volume flow rate of air at inlet, $\dot{V}_{air} = 0.6\ m^3/s$

The temperatures of air at inlet, $T_1 = 20°C$

The pressure of inlet air at inlet, $P_1 = 95\ kPa$

The specific heat values of air, $(C_P)_{air} = 1.005\ kJ/kg°C$

The specific heat values of gases, $(C_P)_{gases} = 1.10\ kJ/kg°C$

The temperatures of combustion gases at inlet, $T_3 = 160°C$

The temperatures of combustion gases at exit, $T_4 = 95°C$

Mass flow rate of gases $\dot{m}_{gas} = 0.95\ kg/s$

Step 2 of 4

(a)

Heat exchangers involve no work interactions ($w = 0$) and negligible kinetic and potential energy changes ($ke = 0, pe = 0$) for each fluid stream. Hence by applying mass balance, $\dot{m}_{in} = \dot{m}_{out}$

and from energy balance for the heat exchanger system, we obtain

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_{in} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

$$\dot{Q}_{in} + \dot{m}_{gas} h_4 = \dot{m}_{gas} h_3$$

$$\dot{Q}_{in} = \dot{m}_{gas} (h_3 - h_4)$$

$$\dot{Q}_{in} = \dot{m}_{gas} (C_P)_{gas} (T_3 - T_4)$$

$$\dot{Q}_{in} = 0.95(1.1)(160 - 95)$$

$$\dot{Q}_{in} = 67.925\ kW$$

Hence heat transfer rate is $\boxed{\dot{Q}_{in} = 67.925\ kW}$

Step 3 of 4

(b)

From Ideal gas equation, $P = \rho RT$

$$\rho_1 = \frac{P_1}{RT_1}$$

$$\rho_1 = \frac{95}{0.287 \times (20 + 273)}$$

$$\rho_1 = 1.129\ kg/m^3$$

Mass of air, $\dot{m}_{air} = \rho \dot{V}$

$$\dot{m}_{air} = 1.129 \times 0.6$$

$$\dot{m}_{air} = 0.677\ kg/s$$

Step 4 of 4

In an ideal heat exchanger, all the heat lost by the working fluid will be equal to heat gained by the cooling fluid.

$$\dot{Q}_{in} = \dot{m}_{air} (C_P)_{air} (T_2 - T_1)$$

$$(T_2 - T_1) = \frac{\dot{Q}_{in}}{\dot{m}_{air} (C_P)_{air}}$$

$$T_2 = T_1 + \frac{\dot{Q}_{in}}{\dot{m}_{air} (C_P)_{air}}$$

$$T_2 = 20 + \frac{67.93}{0.677 \times 1.005}$$

$$T_2 = 20 + 99.84$$

$$T_2 = 119.84\ C$$

Temperature at exit is $\boxed{T_2 = 119.84\ C}$

Question: 6.079P

An open feedwater heater heats the feedwater by mixing it with hot steam. Consider an electrical power plant with an open feedwater heater that mixes 0.1 lbm/s of steam at 10 psia and 200°F with 2.0 lbm/s of feedwater at 10 psia and 100°F to produce 10 psia and 120°F feedwater at the outlet. The diameter of the outlet pipe is 0.5 ft. Determine the mass flow rate and feedwater velocity at the outlet. Would the outlet flow rate and velocity be significantly different if the temperature at the outlet were 180°F?

Step 1 of 6

Given

Inlet conditions of cool feed water

Mass flow rate $\dot{m}_w = 2$ lbm/s

Pressure $P_1 = 10$ Psia

Temperature $T_1 = 100°F$

Steam inlet conditions

Mass flow rate $\dot{m}_{steam} = 0.1$ lbm/s

Pressure $P_2 = 10$ Psia

Temperature $T_2 = 200°F$

Properties of warm feed water at exit

Pressure $P_3 = 10$ Psia

Temperature $T_3 = 120°F$

The outlet diameter of the pipe $d = 0.5$ ft

Step 2 of 6

The outlet mass flow rate is the sum of both feed water and steam mass flow rates respectively

By mass balance

$$\dot{m}_{in} = \dot{m}_{out}$$

Therefore

$$\dot{m}_{outlet} = \dot{m}_w + \dot{m}_s$$

$$\dot{m}_{outlet} = 2 + 0.1$$

$$\boxed{\dot{m}_{outlet} = 2.1 \text{ lbm/s}}$$

Step 3 of 6

The mass flow rate is expressed as

$$\dot{m} = \frac{AV}{v} \text{ lbm/s}$$

At $T_3 = 120°F$ from saturated water tables

$$v_3 = v_f = 0.0162 \text{ ft}^3/\text{lbm}$$

And area

$$A = \pi \frac{d^2}{4}$$

$$A = \pi \frac{0.5^2}{4}$$

Step 4 of 6

Therefore the outlet velocity is

$$V_3 = \frac{\dot{m}_{outlet} v_3}{A_3}$$

$$= \frac{2.1 \times 0.0162}{\pi \frac{0.5^2}{4}}$$

$$\boxed{V_3 = 0.173 \text{ ft/s}}$$

Step 5 of 6

If the temperature at outlet is $T_3 = 180°F$

The mass flow rate remains the same value $\dot{m}_{outlet} = 2.1$ lbm/s

The outlet velocity changes due to change in specific volume

At $T_3 = 180°F$ from saturated water tables

$$v_3 = 0.01651 \text{ ft}^3/\text{lbm}$$

Step 6 of 6

$$V_3 = \frac{\dot{m} v_2}{A}$$

$$= \frac{2.1 \times 0.01651}{\pi \frac{0.5^2}{4}}$$

$$\boxed{V_3 = 0.1765 \text{ ft/s}}$$

If the temperature changes from $T_3 = 120^0 F$ to $T_3 = 180^0 F$ there is no significant change in velocity

Question: 6.080P

In a steam heating system, air is heated by being passed over some tubes through which steam flows steadily. Steam enters the heat exchanger at 30 psia and 400°F at a rate of 15 lbm/min and leaves at 25 psia and 212°F. Air enters at 14.7 psia and 80°F and leaves at 130°F. Determine the volume flow rate of air at the inlet.

Step 1 of 8

Given

Properties of steam

Inlet pressure $P_1 = 30$ psia

Inlet temperature $T_1 = 400°F$

Exit pressure $P_2 = 25$ psia

Exit temperature $T_2 = 212°F$

Mass flow rate of steam $\dot{m}_s = 15$ lbm/min

$$= \frac{15}{60}$$

$$\dot{m}_s = 0.25 \text{ lbm/s}$$

Properties of air

Inlet pressure $P_3 = 14.7$ psia

Inlet temperature $T_3 = 80°F$

Exit temperature $T_4 = 130°F$

Step 2 of 8

Mixing chambers are usually well insulated ($q = 0$) and usually do not involve any kind of work ($w = 0$). Also, the kinetic and potential energies of the fluid streams are usually negligible ($ke = 0, pe = 0$).

Applying mass balance and energy balance for the mixing chamber system, we obtain the equations as

$$\dot{m}_{in} = \dot{m}_{out}$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

Step 3 of 8

In our problem we have two inlets and two exits, the mass flow rate of air and steam remains same at inlet and exit.

Therefore from above energy equation

$$\dot{m}_a h_3 + \dot{m}_s h_1 = \dot{m}_a h_4 + \dot{m}_s h_2$$

$$\dot{m}_a (h_3 - h_4) = \dot{m}_s (h_2 - h_1) \quad \text{---------- (1)}$$

Step 4 of 8

At $P_1 = 30$ psia and $T_1 = 400°F$ from superheated water tables by using interpolation

$$h_1 = 1239.3 + (1236.5 - 1239.3)\left(\frac{30-20}{40-20}\right)$$

$$h_1 = 1237.9 \text{ Btu/lbm}$$

At $P_2 = 25$ psia from saturated water tables

$$T_{sat} = 240.03^0 F$$

And given $T_2 < T_{sat}$

So at $T_2 = 212°F$ from saturated water tables

$$h_2 = h_f = 180.21 \text{ Btu/lbm}$$

Step 5 of 8

The specific heat at constant pressure of air can be obtained at average temperature of air

$$T_{avg} = \frac{T_3 + T_4}{2}$$

$$T_{avg} = \frac{80 + 130}{2}$$

$$T_{avg} = 105^0 F$$

At $T_{avg} = 105^0 F$ from ideal gas specific heats of common gases

$$c_p = 0.24 \text{ Btu/lbm.R}$$

From molar mass, gas constant table

The gas constant for air $R = 0.3704$ psia.ft^3/lbm.R

Step 6 of 8

In equation 1 the enthalpy values we can write it as $h = c_p T$, on substituting all the known values in equation 1

$$\dot{m}_a (h_3 - h_4) = \dot{m}_s (h_2 - h_1)$$

$$\dot{m}_a c_p (T_3 - T_4) = \dot{m}_s (h_2 - h_1)$$

$$\dot{m}_a 0.24(80 - 130) = 0.25(180.21 - 1237.9)$$

$$\dot{m}_a = \frac{1057.69}{50 \times 0.24} \times 0.25$$

$$\dot{m}_a = 22.035 \text{ lbm/s}$$

Step 7 of 8

We know that volume flow rate of air is expressed as

$$\dot{V} = \frac{\dot{m}}{\rho} \text{ ft}^3/\text{s}$$

And density of air at inlet can be determined by using ideal gas equation

$$\frac{P}{\rho} = RT$$

$$\rho_3 = \frac{P_3}{RT_3}$$

$$= \frac{14.7}{(0.3704)(80+460)}$$

$$\rho_3 = 0.0735 \text{ lbm/ft}^3$$

Step 8 of 8

Therefore volume flow rate of air at the inlet is

$$\dot{V}_3 = \frac{22.035}{0.0735}$$

$$\boxed{\dot{V}_3 = 299.795 \text{ ft}^3/\text{s}}$$

Question: 6.081P

Hot exhaust gases of an internal combustion engine are to be used to produce saturated water vapor at 2 MPa pressure. The exhaust gases enter the heat exchanger at 400°C at a rate of 32 kg/min while water enters at 15°C. The heat exchanger is not well insulated, and it is estimated that 10 percent of heat given up by the exhaust gases is lost to the surroundings. If the mass flow rate of the exhaust gases is 15 times that of the water, determine (a) the temperature of the exhaust gases at the heat exchanger exit and (b) the rate of heat transfer to the water. Use the constant specific heat properties of air for the exhaust gases.

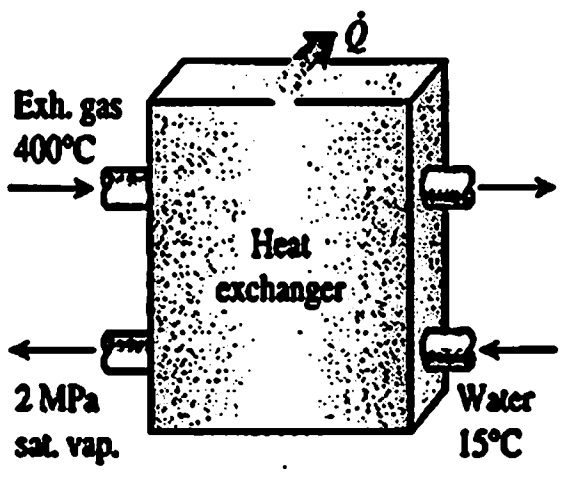

FIGURE P6–81

Step 1 of 4

Calculate the mass flow rate of exhaust gases as follows:

$$\dot{m}_{gases} = 32 \text{ kg/min}$$
$$= \frac{32}{60}$$
$$\dot{m}_{gases} = 0.534 \text{ kg/s}$$

Heat lost to the surroundings $\dot{Q}_{surr} = 0.1\dot{Q}_{gases}$

Calculate the mass flow rate of the water as follows:

$$\dot{m}_w = \frac{\dot{m}_{gases}}{15}$$

Substitute 0.534 kg/s for $\dot{m}_{gases}$.

$$\dot{m}_w = \frac{(0.534)}{15}$$
$$= 0.0356 \text{ kg/s}$$

Step 2 of 4

(b)

Obtain the enthalpy of water at inlet from the table A-4, "Saturated water-Temperature table" in the textbook.

$$h_1 = 62.98 \text{ kJ/kg}$$

Obtain the enthalpy of water at inlet from the table A-5, "Saturated water-Pressure table" in the textbook.

$$h_2 = 2798.3 \text{ kJ/kg}$$

Calculate the rate of heat transfer to the water as follows:

$$\dot{Q}_w = \dot{m}_w(h_2 - h_1)$$

Substitute 0.0356 kg/s for $\dot{m}_w$, 62.98 kJ/kg for h_1, and 2798.3 kJ/kg for h_2.

$$\dot{Q}_w = (0.0355)(2798.3 - 62.98)$$
$$= 97.1 \text{ kW}$$

Therefore, the rate of heat transfer to the water is $\boxed{97.1 \text{ kW}}$.

Step 3 of 4

(a)

Since, there is a 10 percent heat is lost to surroundings and the remaining 90 percent will be absorbed by the water.

Therefore,

$$Q_{exhaust} = Q_{surr} + Q_w$$
$$Q_{exhaust} = 0.1Q_{exhaust} + Q_w$$
$$Q_{exhaust} = \frac{Q_w}{0.9}$$

Substitute 97.1 kW for Q_w.

$$Q_{exhaust} = \frac{97.1}{0.9}$$
$$= 107.8 \text{ kW}$$

Step 4 of 4

Write the equation for heat transfer rate in exhaust gases as follows:

$$Q_{exhaust} = \dot{m}_{gases} c_p (t_{in} - t_{out})$$

Substitute $1.005 \text{ kJ/kg} \cdot \text{K}$ for c_p, 0.534 kg/s for $\dot{m}_{gases}$, 107.8 kW for $Q_{exhaust}$, and $400°\text{C}$ for t_{in}.

$$107.8 \times 10^3 = 0.534 \times 1.005 \times (400 - t_{out})$$
$$t_{out} = 199.14°\text{C}$$

Therefore, the temperature of exhaust gases exit is $\boxed{199.14°\text{C}}$.

Question: 6.082P

A chilled-water heat-exchange unit is designed to cool 5 m3/s of air at 100 kPa and 30°C to 100 kPa and 18°C by using water at 8°C. Determine the maximum water outlet temperature when the mass flow rate of the water is 2 kg/s.

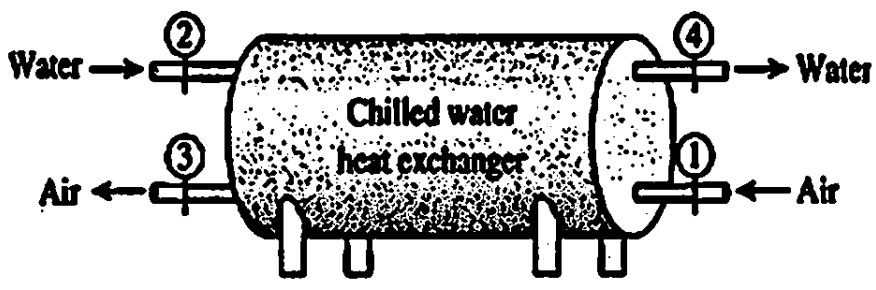

FIGURE P6–82

Step 1 of 4

Heat exchangers typically involve no work interactions ($w=0$) and negligible kinetic and potential energy changes ($ke=0, pe=0$) for each fluid stream.

Apply mass balance for the heat exchanger system, to obtain the equation:

$$\dot{m}_{in}=\dot{m}_{out}$$

Here, input and output mass flow rates are $\dot{m}_{in}$ and $\dot{m}_{out}$ respectively.

Apply energy balance for the heat exchanger system, to obtain the equation:

$$\dot{E}_{in}=\dot{E}_{out}$$
$$\dot{Q}+\dot{m}_{in}h_{in}=\dot{m}_{out}h_{out}$$

Here, input and output energy flow rate are $\dot{E}_{in}$ and $\dot{E}_{out}$ respectively; heat flow rate is $\dot{Q}$; input and output enthalpy are h_{in} and h_{out} .

Step 2 of 4

Consider the mass flow rate of air:

$$\dot{m}_{air}=\rho_1\dot{V}_{air} \quad \text{..... (1)}$$

Here, the density of air is ρ_1 , and volume flow rate of air is $\dot{V}_{air}$.

Consider the ideal gas equation:

$$\rho_1=\frac{P_1}{RT_1}$$

Assume gas constant for air as;

$$R=0.287\ \text{kJ/kg.K}$$

Here, inlet pressure of air is P_1 , and inlet temperature of air is T_1 .

Substitute $100\ \text{kPa}$ for P_1 , $30°\text{C}$ for T_1 , $0.287\ \text{kJ/kg.K}$ for R:

$$\rho_1=\frac{100}{(0.287)(30+273)}$$
$$=1.15\ \text{kg/m}^3$$

Substitute $1.15\ \text{kg/m}^3$ for ρ_1 , and $5\ \text{m}^3/\text{s}$ for $\dot{V}_{air}$ in equation (1):

$$\dot{m}_{air}=\rho_1\dot{V}_{air}$$
$$=(1.15)(5)$$
$$=5.75\ \text{kg/s}$$

Step 3 of 4

Take the specific heat value at average temperature of air:

$$T_{avg}=\frac{T_1+T_3}{2}$$

Here, the exit temperature is T_3 .

Substitute $30°\text{C}$ for T_1 , and $18°\text{C}$ for T_3 :

$$T_{avg}=\frac{30+18}{2}$$
$$=24°\text{C}$$
$$=297\ \text{K}$$

At $T_{avg}=297\text{K}$, consider the ideal gas properties of air:

$$c_{p_{air}}=1.003+(1.005-1.003)\left(\frac{297-250}{300-250}\right)$$
$$=1.00488\ \text{kJ/kg.K}$$

Consider the rate of transfer in the air stream:

$$\dot{Q}_{air}+\dot{m}_{air}h_1=\dot{m}_{air}h_3$$
$$\dot{Q}_{air}=\dot{m}_{air}(h_3-h_1)$$
$$=\dot{m}_{air}c_{p_{air}}(T_3-T_1)$$

Substitute $1.00488\ \text{kJ/kg.K}$ for $c_{p_{air}}$, $5.75\ \text{kg/s}$ for $\dot{m}_{air}$, $30°\text{C}$ for T_1 , and $18°\text{C}$ for T_3 :

$$\dot{Q}_{air}=5.75\times1.00488(18-30)$$
$$=-69.336\ \text{kW}$$

Step 4 of 4

Heat lost by the air stream is equal to the heat gained by the water stream:

$$\dot{Q}_{water}=\dot{m}_w(h_4-h_2)$$
$$=\dot{m}_wc_{p_w}(T_4-T_2)$$

Here, mass flow rate of water is $\dot{m}_w$.

Substitute $69.336\ \text{kW}$ for $\dot{Q}_{water}$, $2\ \text{kg/s}$ for $\dot{m}_w$, and $8°\text{C}$ for T_2 :

$$69.336=2\times4.18(T_4-8)$$
$$T_4=16.29°\text{C}$$

Therefore, the exit temperature of water is $\boxed{16.29°\text{C}}$.

Question: 6.083P

The condenser of a refrigeration cycle is basically a heat exchanger in which a refrigerant is condensed by rejecting heat to a cooling fluid. Refrigerant-134a enters a condenser at 1200 kPa and 85°C with a flow rate of 0.042 kg/s and leaves at the same pressure subcooled by 6.3°C. The condensation is done by cooling water which experiences a temperature rise of 12°C in the condenser. Determine (a) the rate of heat transferred to the water in the condenser, in kJ/min and (b) the mass flow rate of water, in kg/min.

Step 1 of 5

Given

Inlet pressure of R-134a, $P_1 = 1200\ \text{kPa}$

Inlet temperature of R-134a, $T_1 = 85°\text{C}$

Mass flow rate of R-134a $\dot{m}_{ref} = 0.042\ \text{kg/s}$

Exit pressure of R-134a, $P_2 = 1200\ \text{kPa}$

Exit state of R-134a is sub cooled by $6.3°\text{C}$

The raise of water temperature, $\Delta T_w = 12°\text{C}$

Step 2 of 5

Condenser typically involve no work interactions ($w = 0$) and negligible kinetic and potential energy changes ($ke = 0, pe = 0$) for each fluid stream.

Applying mass balance,

$$\dot{m}_{in} = \dot{m}_{out}$$

Energy balance for the condenser system,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{Q} + \dot{m}_{out} h_{out}$$

Step 3 of 5

(a)

The properties of R-134a from superheated tables,

At 1200 kPa and $85°\text{C}$, Enthalpy $h_1 = 316.73\ \text{kJ/kg}$

The properties of R-134a from saturated tables,

At 1200 kPa, saturation temperature, $T_{sat} = T_1 = 46.29°\text{C}$

At final state, R-134a is sub cooled by 3.6, $T_2 = T_1 - 6.3$

$$T_2 = 46.29 - 6.3$$

$$T_2 = 40°\text{C}$$

At 1200 kPa and $40°\text{C}$, Enthalpy $h_2 = h_f = 108.26\ \text{kJ/kg}$

Step 4 of 5

The rate of heat rejected to water is

$$\dot{Q}_{out} = \dot{m}_{ref}(h_1 - h_2)$$

$$\dot{Q}_{out} = 0.042 \times (316.72 - 108.26)$$

$$\dot{Q}_{out} = 8.76\ \text{kJ/s}$$

$$\dot{Q}_{out} = 8.76 \times 60\ \text{kJ/min}$$

$$\dot{Q}_{out} = 525.32\ \text{kJ/min}$$

Hence rate of heat rejected to water is $\boxed{\dot{Q}_{out} = 525.32\ \text{kJ/min}}$

Step 5 of 5

(b)

Heat transferred to water is $\dot{Q}_{out} = \dot{m}_w C_p \Delta T_w$

$$\dot{m}_w = \frac{\dot{Q}_{out}}{C_p \Delta T_w}$$

$$\dot{m}_w = \frac{525.32}{4.18 \times 12}$$

$$\dot{m}_w = 10.48\ \text{kg/min}$$

Hence mass flow rate of water is $\boxed{\dot{m}_w = 10.48\ \text{kg/min}}$

Question: 6.084P

The evaporator of a refrigeration cycle is basically a heat exchanger in which a refrigerant is evaporated by absorbing heat from a fluid. Refrigerant-22 enters an evaporator at 200 kPa with a quality of 22 percent and a flow rate of 2.25 L/h. R-22 leaves the evaporator at the same pressure superheated by 5°C. The refrigerant is evaporated by absorbing heat from air whose flow rate is 0.5 kg/s. Determine (a) the rate of heat absorbed from the air and (b) the temperature change of air. The properties of R-22 at the inlet and exit of the condenser are h1 = 220.2 kJ/kg, *V*1 = 0.0253 m3/kg, and h2 = 398.0 kJ/kg.

Step 1 of 5

Given

Inlet pressure of R-22, $P_1 = 200\ \text{kPa}$

Inlet quality of R-22, $x_1 = 0.22$

Inlet volume flow rate of R-22, $\dot{V} = 2.25\ \text{L/h}$

$$\dot{V} = \frac{2.25\times10^{-3}}{3600}\ \text{m}^3/\text{s}$$

$$\dot{V} = 6.25\times10^{-7}\ \text{m}^3/\text{s}$$

Exit state of R-22 is superheated by 5°C, $T_2 = T_1 + 5$

Mass flow rate of air, $\dot{m}_{air} = 0.5\ \text{kg/s}$

Step 2 of 5

Evaporator typically involve no work interactions ($w = 0$) and negligible kinetic and potential energy changes ($ke = 0, pe = 0$) for each fluid stream.

Applying mass balance,

$$\dot{m}_{in} = \dot{m}_{out}$$

Energy balance for the Evaporator system,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in}h_{in} = \dot{Q} + \dot{m}_{out}h_{out}$$

Step 3 of 5

(a)

The properties of R-22 from saturated tables,

At 200 kPa and $x_1 = 0.22$, Enthalpy $h_1 = 220.2\ \text{kJ/kg}$

Saturation temperature, $T_{sat} = T_1$

Specific volume, $v_1 = 0.0253\ \text{m}^3/\text{kg}$

The properties of R-22 from superheated tables,

At 200 kPa and T_2 Exit enthalpy $h_2 = 398\ \text{kJ/kg}$

Step 4 of 5

The mass flow rate of refrigerant is expressed as

$$\dot{m}_{ref} = \frac{\dot{V}}{v_1}$$

$$\dot{m}_{ref} = \frac{6.25\times10^{-7}}{0.0253}$$

$$\dot{m}_{ref} = 2.47\times10^{-5}\ \text{kg/s}$$

The rate of heat absorbed from air is

$$\dot{Q}_{in} = \dot{m}_{ref}(h_2 - h_1)$$

$$\dot{Q}_{in} = \left(2.47\times10^{-5}\right)\times(398 - 220.2)$$

$$\dot{Q}_{in} = 4.39\times10^{-3}\ \text{kJ/s}$$

Hence rate of heat absorbed is $\boxed{\dot{Q}_{in} = 4.39\times10^{-3}\ \text{kJ/s}}$

Step 5 of 5

(b)

Heat transferred from air is $\dot{Q}_{in} = \dot{m}_{air}C_p\Delta T_{air}$

$$\Delta T_{air} = \frac{\dot{Q}_{in}}{\dot{m}_{air}C_p}$$

$$\Delta T_{air} = 8.73\times10^{-3}\ ^\circ\text{C}$$

The change in temperature for air $\boxed{\Delta T_{air} = 8.73\times10^{-3}\ ^\circ\text{C}}$

Question: 6.085P

Argon steadily flows into a constant pressure heater at 300 K and 100 kPa with a mass flow rate of 6.24 kg/s. Heat transfer in the rate of 150 kW is supplied to the argon as it flows through the heater, (a)Determine the argon temperature at the heater exit, in °C. (b)Determine the argon volume flow rate at the heater exit, in m3/s.

Step 1 of 4

Given

Inlet pressure of Argon, $P_1 = 100\ \text{kPa}$

Inlet temperature of Argon, $T_1 = 300\ \text{K}$

The mass flow rate of Argon, $\dot{m}_{Argon} = 6.24\ \text{kg/s}$

Heat transfer rate to Argon, $\dot{Q}_{in} = 150\ \text{kW}$

Step 2 of 4

(a)

From the energy balance equation for the conservation of energy,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

But Enthalpy, $h = C_p T$. So

$$\dot{Q} + \dot{m}_{Argon} C_p T_1 = \dot{m}_{Argon} C_p T_2$$

$$\dot{Q} = \dot{m}_{Argon} C_p (T_2 - T_1) \qquad \text{---- (1)}$$

Step 3 of 4

From ideal gas properties table for Argon,

$$R = 0.2801\ \text{kJ/kgK}$$

$$C_p = 0.5203\ \text{kJ/kg°C}$$

Substituting all the values in equation (1),

$$150 = 6.24 \times 0.5203 \times (T_2 - 300)$$

$$(T_2 - 300) = 46.2$$

$$T_2 = 46.2 + 300$$

$$T_2 = 346.2\ ^0\text{C}$$

Hence temperature of the Argon at the exit is $\boxed{T_2 = 346.2\ ^0\text{C}}$

Step 4 of 4

(b)

From Ideal gas equation, $Pv = RT$. We get

$$v_2 = \frac{RT_2}{P_2}$$

$$v_2 = \frac{0.2081 \times 346.2}{100}$$

$$v_2 = 0.7204\ \text{m}^3/\text{kg}$$

Mass flow rate of argon is $\dot{m} = \frac{\dot{V}_2}{v_2}$. Therfore,

$$\dot{V}_2 = \dot{m} v_2$$

$$\dot{V}_2 = 6.24 \times 0.7204$$

$$\dot{V}_2 = 4.5\ \text{m}^3/\text{s}$$

Hence final volume of argon at exit is $\boxed{\dot{V}_2 = 4.5\ \text{m}^3/\text{s}}$

Question: 6.086P

Saturated liquid water is heated in a steady-flow steam boiler at a constant pressure of 2 MPa at a rate of 4 kg/s to an outlet temperature of 250°C. Determine the rate of heat transfer in the boiler.

Step 1 of 3

Given

The inlet pressure of the saturated water, $P = 2\ \text{MPa}$

The inlet mass flow rate of the saturated water, $\dot{m}_w = 4\ \text{kg/s}$

The exit pressure of the superheated water, $P = 2\ \text{MPa}$

The exit temperature of the superheated water, $T_2 = 250°\text{C}$

Step 2 of 3

From mass balance equation,

$$\dot{m}_{in} = \dot{m}_{out}$$

From the energy balance equation for the conservation of energy,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

$$\dot{Q} = \dot{m}(h_{out} - h_{in}) \qquad \text{---- (1)}$$

Step 3 of 3

From saturated water tables, at 2 MPa,

Saturated liquid enthalpy, $h_1 = h_f = 908.47\ \text{kJ/kg}$

From superheated water tables, at 2 MPa, and 250°C,

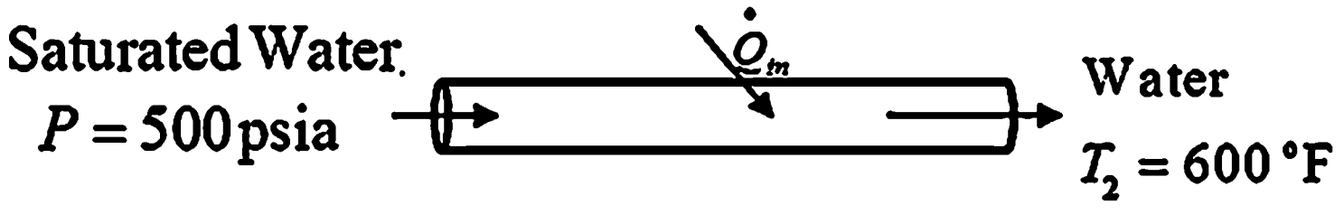
Enthalpy, $h_2 = 2903.3\ \text{kJ/kg}$

Substituting all the values in equation (1), we get

$$\dot{Q} = 4 \times (2903.3 - 908.47)$$

$$\dot{Q} = 7979.32\ \text{kW}$$

$$\dot{Q} = 7.98\ \text{MW}$$



Hence rate of heat transfer in the boiler is $\boxed{\dot{Q} = 7.98\ \text{MW}}$

Question: 6.087P

Water enters a boiler at 500 psia as a saturated liquid and leaves at 600°F at the same pressure. Calculate the heat transfer per unit mass of water.

Step 1 of 3

Draw the flow process through pipe system as below:

Here, pressure of the boiler is P and exit temperature of the water is T_2.

Step 2 of 3

Obtain the properties of steam from saturated water tables at pressure $P_1 = 500\,\text{psia}$ and quality and quality $x_1 = 0$

Enthalpy, $h_1 = h_f$
$= 449.51\,\text{kJ/kg}$

Obtain the properties of steam from the Super - heated water tables at $P_2 = 500\,\text{psia}$ and $T_2 = 600°\text{F}$

$h_2 = 1298.6\,\text{Btu/lbm}$

Step 3 of 3

Consider control volume as the steam pipe as the system, since mass crosses the boundary. There is only one inlet and one exit. Hence, mass entering is equal to mass leaving.

$\dot{m}_1 = \dot{m}_2$

Apply energy conservation for the system

For a steady state condition energy stored within the system is zero.

$\dot{E}_{in} = \dot{E}_{out}$

$\dot{m}\left(h_1 + V_1^2/2\right)_{in} + \dot{Q}_{in} = \dot{Q}\left(h_2 + V_2^2/2\right)_{out}$

$\dot{m}h_1 + 0 + \dot{Q}_{in} = \dot{m}h_2$

$\dot{Q}_{in} = \dot{m}(h_2 - h_1)$

$= (h_2 - h_1)$

Calculate the heat transfer per unit mass of water as shown below:

$\dot{Q}_{in} = (h_2 - h_1)$

$= 1298.6\,\text{Btu/lbm} - 449.5\,\text{Btu/lbm}$

$= 849.1\,\text{Btu/lbm}$

Therefore, the heat transfer per unit mass of water is $\boxed{849.1\,\text{Btu/lbm}}$.

Question: 6.088P

A 110-volt electrical heater is used to warm 0.3 m3/s of air at 100 kPa and 15°C to 100 kPa and 30°C. How much current in amperes must be supplied to this heater?

Step 1 of 5

Given

The volume flow rate of air $\dot{V}_1 = 0.3\ m^3/s$

Inlet temperature of air $T_1 = 15°C$

Exit temperature of air $T_2 = 30°C$

Inlet and exit pressures of air $P_1 = P_2 = 100$ kPa

The voltage for an electrical heater $V = 110$ volts

Step 2 of 5

For a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

Step 3 of 5

The mass flow rate of air is expressed as

$$\dot{m} = \rho \dot{V}_1$$

From ideal gas equation

$$\rho_1 = \frac{P_1}{RT_1}$$

$$= \frac{100}{(0.287)(15+273)} \qquad \text{(For air } R = 0.287 \text{ kJ/kg.K)}$$

$$\rho_1 = 1.21\ kg/m^3$$

Therefore

$$\dot{m} = \rho \dot{V}_1$$

$$\dot{m}_{air} = (1.21)(0.3)$$

$$\dot{m}_{air} = 0.363\ kg/s$$

Step 4 of 5

Taking specific heat of air $c_p = 1.005$ kJ/kg°C

And enthalpy we can write it as $h = c_p T$

By using mass balance

$\dot{m}_{in} = \dot{m}_{out}$

Then the energy equation becomes

$$\dot{Q} = \dot{m}_{air} c_p (T_2 - T_1)$$

$$\dot{Q} = 0.363(1.005)(30-15)$$

$$\dot{Q} = 5.47\ kW$$

Step 5 of 5

The amount of electrical energy supplied will be converted into heat.

i.e. $\dot{Q} = VI$

Where

V is voltage and

I is current supplied to electrical heater.

Therefore the current I is

$$I = \frac{\dot{Q}}{V}$$

$$= \frac{5.47 \times 10^3}{110}$$

$$\boxed{I = 49.727\ A}$$

Question: 6.089P

The fan on a personal computer draws 0.5 ft3/s of air at 14.7 psia and 70°F through the box containing the CPU and other components. Air leaves at 14.7 psia and 80°F. Calculate the electrical power, in kW, dissipated by the PC components.

FIGURE P6–89E

© Vol. 55/PhotoDisc/Getty Images.

Step 1 of 4

Given

The volume flow rate of air $\dot{V}_{air} = 0.5\ ft^3/s$

Inlet temperature of air $T_1 = 70°F$

Exit temperature of air $T_2 = 80°F$

Inlet pressure of air $P_1 = 14.7$ psia

Exit pressure of air $P_2 = 14.7$ psia

Step 2 of 4

For a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{W} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

Step 3 of 4

The mass flow rate is expressed as

$$\dot{m} = \rho \dot{V}_{air}$$

From ideal gas equation

$$\rho_1 = \frac{P_1}{RT_1}$$

$$= \frac{14.7}{(0.3704)(70+460)} \qquad (\text{For air } R = 0.3704 \text{ psia.ft}^3/\text{lbm.R})$$

$$\rho_1 = 0.0748\ \text{lbm/ft}^3$$

Therefore

$$\dot{m} = \rho \dot{V}_{air}$$

$$\dot{m}_{air} = (0.0748)(0.5)$$

$$\dot{m}_{air} = 0.0374\ \text{kg/s}$$

Step 4 of 4

Taking specific heat of air $c_p = 0.24$ Btu/lbm°F

By using mass balance

$$\dot{m}_{in} = \dot{m}_{out} = \dot{m}_{air}$$

From energy equation

$$\dot{W} = \dot{m}_{out}(h_{out} - h_{in})$$

$$\dot{W} = \dot{m}_{air} c_p (T_2 - T_1)$$

$$\dot{W} = 0.0374(0.24)(80-70)$$

$$\dot{W} = 0.08976\ \text{Btu/s}$$

Since $(1\ \text{Btu/s} = 1.055\ \text{kW})$

$$\dot{W} = 0.08976 \times 1.055$$

$$\boxed{\dot{W} = 0.0946\ \text{kW}}$$

Question: 6.090P

A desktop computer is to be cooled by a fan. The electronic components of the computer consume 60 W of power under full-load conditions. The computer is to operate in environments at temperatures up to 45°C and at elevations up to 3400 m where the average atmospheric pressure is 66.63 kPa. The exit temperature of air is not to exceed 60°C to meet the reliability requirements. Also, the average velocity of air is not to exceed 110 m/min at the exit of the computer case where the fan is installed to keep the noise level down. Determine the flow rate of the fan that needs to be installed and the diameter of the casing of the fan.

Step 1 of 7

Given

The power consumed by electronic components $\dot{W} = -60\ \text{W} = -0.06\ \text{kW}$

Inlet temperature of air $T_1 = 45°\text{C}$

Exit temperature of air $T_2 = 60°\text{C}$

The atmospheric pressure of air $P = 66.63\ \text{kPa}$

The average velocity of air $V = 110\ \text{m/min}$

$$= \frac{110}{60}$$

$$V = 1.8334\ \text{m/s}$$

Step 2 of 7

For a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{m}_{out} h_{out} + \dot{W} \qquad \text{(Assuming } q = 0 \text{ and } ke = 0, pe = 0\text{)}$$

By using mass balance

$$\dot{m}_{in} = \dot{m}_{out}$$

Then energy equation becomes

$$\dot{m}_{in}\left(h_{in} - h_{out}\right) = \dot{W}$$

We know that $h = c_p T$

$$\dot{m}_{in}\, c_{p_{air}}\left(T_1 - T_2\right) = \dot{W}$$

Step 3 of 7

At average temperature of air

$$T_{avg} = \left(\frac{T_1 + T_2}{2}\right)$$

$$= \left(\frac{45 + 60}{2}\right)$$

$$T_{avg} = 52.5^0\text{C} = 325.5\text{K}$$

At $T_{avg} = 325.5\text{K}$ from ideal gas properties of air

$$c_{p_{air}} = 1.005 + (1.008 - 1.005)\left(\frac{325.5 - 300}{350 - 300}\right)$$

$$c_{p_{air}} = 1.0065\ \text{kJ/kg.K}$$

Step 4 of 7

Substituting all the values in energy equation we get

$$\dot{m}_{in}\, c_{p_{air}}\left(T_1 - T_2\right) = \dot{W}$$

$$\dot{m}(1.0065)(45 - 60) = -0.06$$

$$\dot{m} = 0.00397\ \text{kg/s}$$

Step 5 of 7

The mass flow rate is expressed as

$$\dot{m} = \rho \dot{V}_{air}$$

From ideal gas equation

$$\rho_2 = \frac{P}{RT_2}$$

$$= \frac{66.63}{(0.287)(60 + 273)} \qquad \text{(For air } R = 0.287\ \text{kJ/kg.K)}$$

$$\rho_2 = 0.697\ \text{kg/m}^3$$

Step 6 of 7

Therefore volume flow rate of fan which is installed at the exit of the CPU so,

$$\dot{V}_{air} = \frac{\dot{m}}{\rho}$$

$$\dot{V}_{air} = \frac{0.00397}{0.697}$$

$$= 0.00569\ \text{m}^3\text{/s}$$

$$\boxed{\dot{V}_{fan} = 0.00569\ \text{m}^3\text{/s}}$$

Step 7 of 7

The diameter of the fan casing is obtained as

$$\dot{m} = \rho A V$$

Therefore

$$A_2 = \frac{\dot{m}}{V \rho_2}$$

$$\pi \frac{d^2}{4} = \frac{0.00397}{1.8334(0.697)}$$

$$\boxed{d_2 = 0.0628\text{m}}$$

Question: 6.091P

Repeat Prob. 6–90 for a computer that consumes 100 W of power.

Step 1 of 7

Given

The power consumed by electronic components $\dot{W} = -100\ \text{W} = -0.1\text{kW}$

Inlet temperature of air $T_1 = 45°\text{C}$

Exit temperature of air $T_2 = 60°\text{C}$

The atmospheric pressure of air $P = 66.63\ \text{kPa}$

The average velocity of air $V = 110\ \text{m/min}$

$$= \frac{110}{60}$$

$$V = 1.8334\ \text{m/s}$$

Step 2 of 7

For a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{m}_{out} h_{out} + \dot{W} \qquad \text{(Assuming } q = 0 \text{ and } ke = 0, pe = 0\text{)}$$

By using mass balance

$$\dot{m}_{in} = \dot{m}_{out}$$

Then energy equation becomes

$$\dot{m}_{in}\left(h_{in} - h_{out}\right) = \dot{W}$$

We know that $h = c_p T$

$$\dot{m}_{in}\, c_{p_{air}}\left(T_1 - T_2\right) = \dot{W}$$

Step 3 of 7

At average temperature of air

$$T_{avg} = \left(\frac{T_1 + T_2}{2}\right)$$

$$= \left(\frac{45+60}{2}\right)$$

$$T_{avg} = 52.5^0\text{C} = 325.5\text{K}$$

At $T_{avg} = 325.5\text{K}$ from ideal gas properties of air

$$c_{p_{air}} = 1.005 + (1.008 - 1.005)\left(\frac{325.5-300}{350-300}\right)$$

$$c_{p_{air}} = 1.0065\ \text{kJ/kg.K}$$

Step 4 of 7

Substituting all the values in energy equation we get

$$\dot{m}_{in}\, c_{p_{air}}\left(T_1 - T_2\right) = \dot{W}$$

$$\dot{m}(1.0065)(45 - 60) = -0.1$$

$$\dot{m} = 0.00662\ \text{kg/s}$$

Step 5 of 7

The mass flow rate is expressed as

$$\dot{m} = \rho \dot{V}_{air}$$

From ideal gas equation

$$\rho_2 = \frac{P}{RT_2}$$

$$= \frac{66.63}{(0.287)(60+273)} \qquad \text{(For air } R = 0.287\ \text{kJ/kg.K)}$$

$$\rho_2 = 0.697\ \text{kg/m}^3$$

Step 6 of 7

Therefore volume flow rate of fan which is installed at the exit of the CPU so,

$$\dot{V}_{air} = \frac{\dot{m}}{\rho}$$

$$\dot{V}_{air} = \frac{0.00662}{0.697}$$

$$= 0.00949\ \text{m}^3\text{/s}$$

$$\boxed{\dot{V}_{fan} = 0.00949\ \text{m}^3\text{/s}}$$

Step 7 of 7

The diameter of the fan casing is obtained as

$$\dot{m} = \rho A V$$

Therefore

$$A_2 = \frac{\dot{m}}{V \rho_2}$$

$$\pi \frac{d^2}{4} = \frac{0.00662}{1.8334(0.697)}$$

$$\boxed{d_2 = 0.0812\text{m}}$$

Question:

6.092P

Water enters the tubes of a cold plate at 70°F with an average velocity of 40 ft/min and leaves at 105°F. The diameter of the tubes is 0.25 in. Assuming 15 percent of the heat generated is dissipated from the components to the surroundings by convection and radiation, and the remaining 85 percent is removed by the cooling water, determine the amount of heat generated by the electronic devices mounted on the cold plate.

Step 1 of 4

Given

The inlet temperatures of water, $T_1 = 70°F$

The exit temperatures of water, $T_2 = 105°F$

The diameter of the tubes, $d = 0.25\ \text{in}$

The average velocity of water, $V = 40\ \text{ft/min}$

$$V = \frac{40}{60}$$

$$V = 0.667\ \text{ft/s}$$

The amount of the generated from the electronic device be $\dot{Q}$

Question:

Water enters the tubes of a cold plate at 70°F with an average velocity of 40 ft/min and leaves at 105°F. The diameter of the tubes is 0.25 in. Assuming 15 percent of the heat generated is dissipated from the components to the surroundings by convection and radiation, and the remaining 85 percent is removed by the cooling water, determine the amount of heat generated by the electronic devices mounted on the cold plate.

Step 1 of 4

Given

The inlet temperatures of water, $T_1 = 70°F$

The exit temperatures of water, $T_2 = 105°F$

The diameter of the tubes, $d = 0.25\ \text{in}$

The average velocity of water, $V = 40\ \text{ft/min}$

$$V = \frac{40}{60}$$

$$V = 0.667\ \text{ft/s}$$

The amount of the generated from the electronic device be $\dot{Q}$

Also $1\ \text{Btu/hr} = 0.000293\ \text{kW}$. Hence

$$\dot{Q}_{water} = 1779.05 \times 0.000293\ \text{kW}$$

$$\dot{Q}_{water} = 0.52126\ \text{kW}$$

Step 4 of 4

Energy received by water is 85% of total energy. Hence

$$\dot{Q}_{water} = \frac{\dot{Q}_{total}}{100} \times 85$$

$$\dot{Q}_{total} = \frac{\dot{Q}_{water}}{0.85}$$

$$\dot{Q}_{total} = \frac{0.52126}{0.85}$$

$$\dot{Q}_{total} = 0.6132\ \text{kW}$$

$$\dot{Q}_{total} = 613.2\ \text{W}$$

Hence total energy generated is $\boxed{\dot{Q}_{total} = 613.2\ \text{W}}$

Question: 6.093P

The components of an electronic system dissipating 180 W are located in a 1.4-m-long horizontal duct whose cross section is 20 cm × 20 cm. The components in the duct are cooled by forced air that enters the duct at 30°C and 1 atm at a rate of 0.6 m3/min and leaves at 40°C. Determine the rate of heat transfer from the outer surfaces of the duct to the ambient.

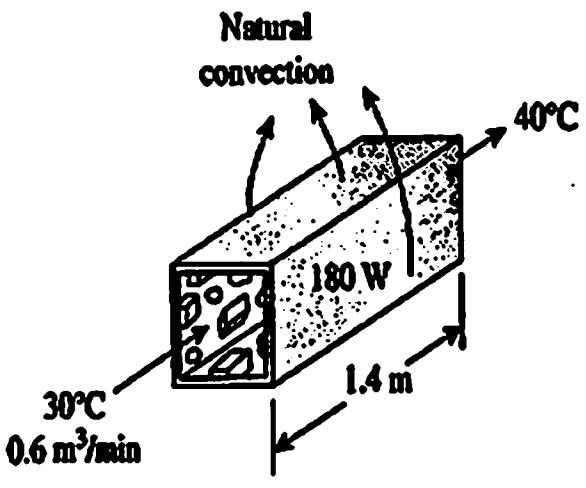


FIGURE P6–93

Step 1 of 6

Given

The heat dissipated by electronic components $\dot{Q}_{ele} = 180\ \text{W}$

The inlet temperature of air $T_1 = 30°\text{C}$

Exit temperature of air $T_2 = 40°\text{C}$

The atmospheric pressures of air $P = 1\ \text{atm} = 101.325\ \text{kPa}$

The volume flow rate of air at inlet $\dot{V}_1 = 0.6\ \text{m}^3/\text{min}$

Length of the duct $L = 1.4\,\text{m}$

Cross section of the duct $A = 20 \times 20\,\text{cm}^2$

Step 2 of 6

For a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out} \quad (w = 0 \text{ And } \Delta ke = 0, \Delta pe = 0)$$

Using mass balance

$$\dot{m}_{in} = \dot{m}_{out} = \dot{m}_{air}$$

Then

$$\dot{Q} = \dot{m}_{air}(h_{out} - h_{in})$$

We know that $h = c_p T$

$$\dot{Q} = \dot{m}_{air} c_p (T_2 - T_1)$$

Step 3 of 6

Taking specific heat of air at average temperature

$$T_{avg} = \frac{40+30}{2}$$

$$T_{avg} = 35^0\text{C} = 308\,\text{K}$$

At $T_{avg} = 308\,\text{K}$ from ideal gas properties of air

$$c_p = 1.005 + (1.008 - 1.005)\left(\frac{308-300}{350-300}\right)$$

$$c_p = 1.00548\ \text{kJ/kg°C}$$

Step 4 of 6

Substituting all the values in above equation we get the amount of heat transferred occurred due to forced air

$$\dot{Q} = \dot{m}_{air} c_p (T_2 - T_1)$$

The mass flow rate of air is

$$\dot{m} = \rho \dot{V}_{air}$$

From ideal gas equation

$$\rho_1 = \frac{P}{RT_1}$$

$$= \frac{101.325}{(0.287)(30+273)} \qquad (\text{For air } R = 0.287\ \text{kJ/kg.K})$$

$$\rho_1 = 1.165\ \text{kg/m}^3$$

Step 5 of 6

Therefore rate of heat transfer due to forced air is

$$\dot{Q} = \dot{m}_{air} c_p (T_2 - T_1)$$

$$\dot{Q} = \rho_1 \dot{V}_{air} c_p (T_2 - T_1)$$

$$\dot{Q} = (1.165)\left(\frac{0.6}{60}\right)(1.00548)(40-30)$$

$$\dot{Q} = 0.117\ \text{kW}$$

$$\dot{Q} = 117\ \text{W}$$

Step 6 of 6

Total rate of heat transfer=rate of heat transfer due to forced air + rate of heat transfer from the outer surface of the duct

$$\dot{Q}_{ele} = \dot{Q} + \dot{Q}_{atm}$$

$$\dot{Q}_{atm} = \dot{Q}_{ele} - \dot{Q}$$

$$\dot{Q}_{atm} = 180 - 117$$

$$= 63\ \text{W}$$

$$\boxed{\dot{Q}_{atm} = 63\ \text{W}}$$

Question: 6.094P

Repeat Prob. 6–93 for a circular horizontal duct of diameter 10 cm.

Step 1 of 6

Given

The heat dissipated by electronic components $\dot{Q}_{ele} = 180\ \text{W}$

The inlet temperature of air $T_1 = 30°\text{C}$

Exit temperature of air $T_2 = 40°\text{C}$

The atmospheric pressures of air $P = 1\ \text{atm} = 101.325\ \text{kPa}$

The volume flow rate of air at inlet $\dot{V}_1 = 0.6\ \text{m}^3/\text{min}$

Length of the duct $L = 1.4\,\text{m}$

Diameter of the duct $A = 20 \times 20\,\text{cm}^2$

Step 2 of 6

For a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out} \quad (w = 0 \text{ And } \Delta ke = 0, \Delta pe = 0)$$

Using mass balance

$$\dot{m}_{in} = \dot{m}_{out} = \dot{m}_{air}$$

Then

$$\dot{Q} = \dot{m}_{air}(h_{out} - h_{in})$$

We know that $h = c_p T$

$$\dot{Q} = \dot{m}_{air} c_p (T_2 - T_1)$$

Step 3 of 6

Taking specific heat of air at average temperature

$$T_{avg} = \frac{40+30}{2}$$

$$T_{avg} = 35^0\text{C} = 308\,\text{K}$$

At $T_{avg} = 308\,\text{K}$ from ideal gas properties of air

$$c_p = 1.005 + (1.008 - 1.005)\left(\frac{308-300}{350-300}\right)$$

$$c_p = 1.00548\ \text{kJ/kg°C}$$

Step 4 of 6

Substituting all the values in above equation we get the amount of heat transferred occurred due to forced air

$$\dot{Q} = \dot{m}_{air} c_p (T_2 - T_1)$$

The mass flow rate of air is

$$\dot{m} = \rho \dot{V}_{air}$$

From ideal gas equation

$$\rho_1 = \frac{P}{RT_1}$$

$$= \frac{101.325}{(0.287)(30+273)} \qquad (\text{For air } R = 0.287\ \text{kJ/kg.K})$$

$$\rho_1 = 1.165\ \text{kg/m}^3$$

Step 5 of 6

Therefore rate of heat transfer due to forced air is

$$\dot{Q} = \dot{m}_{air} c_p (T_2 - T_1)$$

$$\dot{Q} = \rho_1 \dot{V}_{air} c_p (T_2 - T_1)$$

$$\dot{Q} = (1.165)\left(\frac{0.6}{60}\right)(1.00548)(40-30)$$

$$\dot{Q} = 0.117\ \text{kW}$$

$$\dot{Q} = 117\ \text{W}$$

Step 6 of 6

Total rate of heat transfer=rate of heat transfer due to forced air + rate of heat transfer from the outer surface of the duct

$$\dot{Q}_{elec} = \dot{Q} + \dot{Q}_{atm}$$

$$\dot{Q}_{atm} = \dot{Q}_{ele} - \dot{Q}$$

$$\dot{Q}_{atm} = 180 - 117$$

$$= 63\ \text{W}$$

$$\boxed{\dot{Q}_{atm} = 63\ \text{W}}$$

If it is circular duct, or square duct the rate of heat from the outer surface of the duct remains same. Since the flow rate doesn't change.

Question: 6.095P

Consider a hollow-core printed circuit board 9 cm high and 18 cm long, dissipating a total of 15 W. The width of the air gap in the middle of the PCB is 0.25 cm. If the cooling air enters the 12-cm-wide core at 25°C and 1 atm at a rate of 0.8 L/s, determine the average temperature at which the air leaves the hollow core.

Step 1 of 4

Given

The total heat dissipated by a circuit board $\dot{Q} = 15\ \text{W}$

The temperature of air at inlet, $T_1 = 25°\text{C}$

Atmospheric pressures of air, $P = 1\ \text{atm}$

$$P = 101.325\ \text{kPa}$$

The volume flow rate of air, $\dot{V} = 0.8\ \text{L/s}$

$$\dot{V} = 0.8 \times 10^{-3}\ \text{m}^3/\text{s}$$

Step 2 of 4

From ideal gas equation $P = \rho RT$

$$\rho = \frac{P}{RT}$$

$$\rho = \frac{101.325}{0.287 \times (25+273)}$$

$$\rho = 1.1847\ \text{kg/m}^3$$

Mass flow rate of air is $\dot{m} = \rho \dot{V}$

$$\dot{m} = (1.1847) \times (0.8 \times 10^{-3})$$

$$\dot{m} = 9.4776 \times 10^{-4}\ \text{kg/s}$$

Step 3 of 4

From the energy balance equation for the conservation of energy,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

From mass balance, $\dot{m}_{in} = \dot{m}_{out}$. Hence

$$\dot{Q} = \dot{m}(h_{out} - h_{in})$$

But enthalpy, $h = C_p T$, and $C_p = 1.005\ \text{kJ/kg°C}$ for air.

Also from properties of ideal gasses table for air, $R = 0.287\ \text{kJ/kg.K}$

Step 4 of 4

Hence by substituting the values,

$$\dot{Q} = \dot{m}_{out} C_p (T_{out} - T_{in})$$

$$15 = (9.4776 \times 10^{-4}) \times (1.005 \times 10^{3}) \times (T_2 - 25)$$

$$(T_2 - 25) = \frac{15}{0.9525}$$

$$T_2 = 15.7 + 25$$

$$T_2 = 40.7^0\text{C}$$

Hence final temperature of air is $\boxed{T_2 = 40.7^0\text{C}}$

Question: 6.096P

A computer cooled by a fan contains eight PCBs, each dissipating 10 W power. The height of the PCBs is 12 cm and the length is 18 cm. The cooling air is supplied by a 25-W fan mounted at the inlet. If the temperature rise of air as it flows through the case of the computer is not to exceed 10°C, determine (*a*) the flow rate of the air that the fan needs to deliver and (b) the fraction of the temperature rise of air that is due to the heat generated by the fan and its motor.

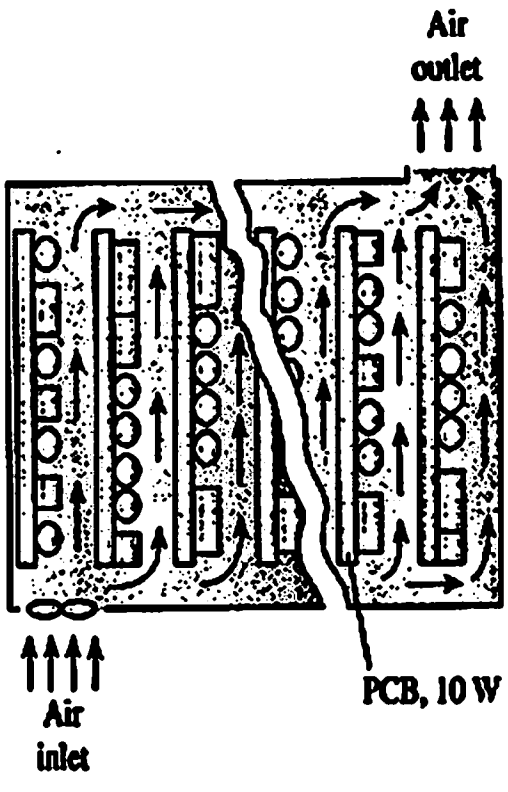

FIGURE P6–96

Step 1 of 5

Given

Number of PCBs in a computer is N=8

Amount of heat dissipated by each PCB $\dot{Q} = 10\,\text{W}$

The power supplied to the fan $\dot{W} = -25\ \text{W}$

The temperature rise of the air $\Delta T = 10^0\,\text{C}$

Step 2 of 5

The amount of heat dissipated by a complete circuit board

$$\dot{Q}_T = N \times \dot{Q}$$

$$\dot{Q}_T = 8 \times 10$$

$$\dot{Q}_T = 80\ \text{W}$$

Step 3 of 5

The energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_T + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out} + \dot{W} \qquad (\text{since } \Delta ke = 0, \Delta pe = 0)$$

By using mass balance

$$\dot{m}_{in} = \dot{m}_{out} = \dot{m}_{air}$$

Then energy equation becomes

$$\dot{Q}_T = \dot{m}_{air}\left(h_{out} - h_{in}\right) + \dot{W}$$

We know that $h = c_p T$

$$\dot{Q}_T = \dot{m}_{air}\, c_{p_{air}}\left(T_{out} - T_{in}\right) + \dot{W}$$

Step 4 of 5

Taking specific heat of air $c_{p_{air}} = 1.005\ \text{kJ/kg°C}$

Gas constant $R = 0.287\ \text{kJ/kg.K}$

Substituting the known values in energy equation

$$\dot{Q}_T = \dot{m}_{air}\, c_{p_{air}}\left(T_{out} - T_{in}\right) + \dot{W}$$

$$80 = \dot{m}_{air} \times 1.005 \times\times 10^3 \times 10 + (-25)$$

$$\boxed{\dot{m}_{air} = 0.0104\,\text{kg/s}}$$

Step 5 of 5

b) The amount of heat generated by fan neglecting all the losses is

$$\dot{Q}_{fan} = \dot{W} = \dot{m}_{air} c_p \Delta T$$

$$25 = 0.0104(1005)\Delta T$$

$$\Delta T = 2.391$$

$$\Delta T = 2.4$$

The fraction of temperature rise is

$$\text{fraction} = \frac{2.4}{10} \times 100$$

$$\boxed{\text{fraction} = 24\%}$$

Question: 6.097P

Hot water at 90°C enters a 22-m section of a cast iron pipe whose inner diameter is 2.5 cm at an average velocity of 0.6 m/s. The outer surface of the pipe is exposed to the cold air at 10°C in a basement. If water leaves the basement at 88°C, determine the rate of heat loss from the 1 water.

Step 1 of 3

Given

The temperature of water at inlet, $T_1 = 90°C$

The temperature of water at exit, $T_2 = 88°C$

The diameter of the pipe, $d = 2.5$ cm

$d = 0.025$ m

The average velocity of water, $V = 0.6$ m/s

Step 2 of 3

The density of water, $\rho = 1000\ kg/m^3$

The mass flow rate, $\dot{m}_w = \rho AV$

$$\dot{m}_w = \rho \times \frac{\pi d^2}{4} \times V$$

$$\dot{m}_w = 1000 \times \frac{\pi (0.025)^2}{4} \times 0.6$$

$$\dot{m}_w = 0.2945\ kg/s$$

Step 3 of 3

From the energy balance equation for the conservation of energy,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{Q} + \dot{m}_{out} h_{out}$$

From mass balance, $\dot{m}_{in} = \dot{m}_{out}$

$$\dot{Q} = \dot{m}_w (h_{in} - h_{out})$$

Also Enthalpy, $h = C_p T$. Where, $C_p = 4.18$ kJ/kg°C for water. Hence

$$\dot{Q} = \dot{m}_w C_p (T_{in} - T_{out})$$

$$\dot{Q} = \dot{m}_w C_p (T_1 - T_2)$$

$$\dot{Q} = 0.2945 \times 4.18 \times (90 - 88)$$

$$\dot{Q} = 2.462\ kW$$

Hence Rate of heat loss from water, $\boxed{\dot{Q} = 2.462\ kW}$

Question: 6.098P

Reconsider Prob. 6–97. Using EES (or other) software, investigate the effect of the inner pipe diameter on the rate of heat loss. Let the pipe diameter vary from 1.5 to 7.5 cm. Plot the rate of heat loss against the diameter, and discuss the results.

Step 1 of 4

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click Calculate on menu bar, select solve.

Finally, Solution window displayed the unknown parameters

Step 2 of 4

Equation window:

"Knowns:"

D = 0.025 [m]

rho = 965 [kg/m^3]

Vel = 0.6 [m/s]

T_1 = 90 [C]

T_2 = 88 [C]

c_p = 4.21 [kJ/kg-C]

"Analysis:" "The mass flow rate of water is:"

Area = pi*D^2/4

m_dot = rho*Area*Vel

"We take the section of the pipe in the basement to be the system, which is a control volume. The energy

Balance for this steady-flow system can be expressed in the rate form as"

E_dot_in - E_dot_out = DELTAE_dot_sys

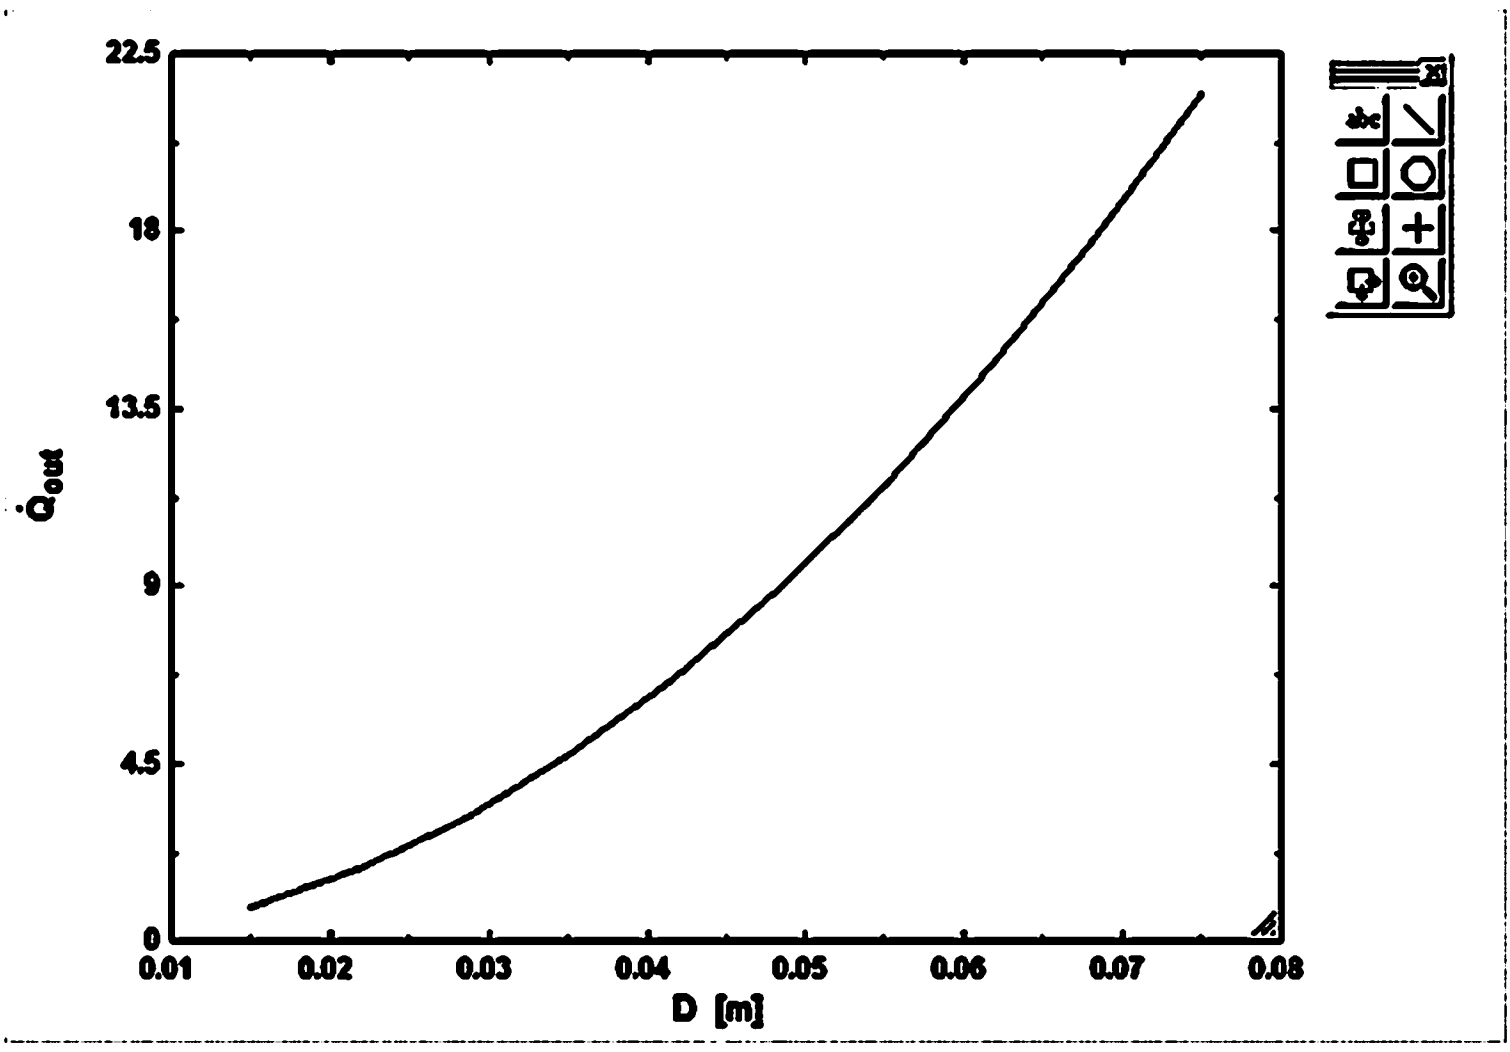
DELTAE_dot_sys = 0 "Steady-flow assumption"

E_dot_in = m_dot*h_in

doE_dot_out =Q_dot_out+m_dot*h_out

h_out = c_p * T_1

h_out = c_p * T_2



Step 3 of 4

Table for $\dot{Q}_{out}$ as a function of *D*:

$\triangleright_{1..10}$	1 D [m]	2 $\dot{Q}_{out}$
Run 1	0.015	0.8615
Run 2	0.02167	1.797
Run 3	0.02833	3.074
Run 4	0.035	4.69
Run 5	0.04167	6.647
Run 6	0.04833	8.945
Run 7	0.055	11.58
Run 8	0.06167	14.56
Run 9	0.06833	17.88
Run 10	0.075	21.54

Step 4 of 4

Graph between the $\dot{Q}_{out}$ Vs. D :

Question: 6.099P

A 5-m × 6-m × 8-m room is to be heated by an electric resistance heater placed in a short duct in the room. Initially, the room is at 15°C, and the local atmospheric pressure is 98 kPa. The room is losing heat steadily to the outside at a rate of 200 kJ/min. A 200-W fan circulates the air steadily through the duct and the electric heater at an average mass flow rate of 50 kg/min. The duct can be assumed to be adiabatic, and there is no air leaking in or out of the room. If it takes 15 min for the room air to reach an average temperature of 25°C, find (*a*) the power rating of the electric heater and (*b*) the temperature rise that the air experiences each time it passes through the heater.

Step 1 of 6

Given

The volume of the room $V = 5\times6\times8$

$$V = 240\ \text{m}^3$$

The initial temperature of the room $T_1 = 15°\text{C}$

The local atmospheric pressure $P = 98\ \text{kPa}$

The amount of heat lost to the surroundings $\dot{Q} = -200\ \text{kJ/min}$

$$= -\frac{200}{60}$$

$$\dot{Q} = -3.334\ \text{kJ/s}$$

The work input to the fan $\dot{W}_{fan} = -200\ \text{W} = -0.2\text{kW}$

Mass flow rate of air $\dot{m}_{air} = 50\ \text{kg/min}$

The final temperature of the room $T_2 = 25°\text{C}$

The time taken to reach the final temperature is t=15 min

Step 2 of 6

(a) The power rating of the electrical heater

Taking the gas constant $R = 0.287\ \text{kJ/kg.K}$

Specific heat of gas at constant pressure is $c_p = 1.005\ \text{kJ/kg.K}$

Specific heat of gas at constant volume $c_v = 0.718\ \text{kJ/kg.K}$

From first law of thermodynamics for a closed system

$Q = W + \Delta E$

Here considering room as a closed system, the system is stationary so $\Delta E = \Delta U$.

$$\dot{Q} = \dot{W}_{ele} + \dot{W}_{fan} + \frac{m}{t}\left(c_v\left(T_2 - T_1\right)\right) \text{ ---------- (1)}$$

Step 3 of 6

The density of air at initial condition

$$\rho_1 = \frac{P_1}{RT_1}$$

$$\rho_1 = \frac{98}{(0.287)(15+273)}$$

$$\rho_1 = 1.185\ \text{kg/m}^3$$

Mass flow rate of air

$m = \rho_1 V$

$= 1.185(240)$

$m = 284.5\ \text{kg}$

Step 4 of 6

Substituting all the values in equation (1)

$$\dot{Q} = \dot{W}_{ele} + \dot{W}_{fan} + \frac{m}{t}\left(c_v\left(T_2 - T_1\right)\right)$$

$$-3.334 = \dot{W}_{ele} - 0.200 + \frac{284.5}{15\times60}\times0.718(25-15)$$

$$-3.334 = \dot{W}_{ele} - 0.2 + 2.2696$$

$$\boxed{\dot{W}_{ele} = -5.403\ \text{kW}}$$

Step 5 of 6

(b) The rise of temperature of the heater

Here taking only the duct as a system, so for a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{W} + \dot{m}_{out} h_{out} \quad (Q = 0 \text{ And } ke = 0, pe = 0)$$

By using mass balance

$$\dot{m}_{in} = \dot{m}_{out} = \dot{m}_{air}$$

Then

$$0 = \dot{W}_{fan} + \dot{W}_{ele} + \dot{m}_{air}\left(h_2 - h_1\right)$$

We know that $h = c_p T$

$$0 = \dot{W}_{fan} + \dot{W}_{ele} + \dot{m}_{air} c_p \left(T_2 - T_1\right)$$

Step 6 of 6

Substituting all the values in above equation we get

$$0 = -0.2 - 5.403 + \frac{50}{60}\left(1.005\right)\left(T_2 - T_1\right)$$

$$0 = -0.2 - 5.403 + 0.8375\left(T_2 - T_1\right)$$

$$T_2 - T_1 = 6.69^0\text{C}$$

The rise in temperature is

$$\boxed{T_2 - T_1 = 6.69°\text{C}}$$

Question: 6.100P

The hot-water needs of a household are to be met by heating water at 55°F to 180°F by a parabolic solar collector at a rate of 4 lbm/s. Water flows through a 1.25-in-diameter thin aluminum tube whose outer surface is black-anodized in order to maximize its solar absorption ability. The centerline of the tube coincides with the focal line of the collector, and a glass sleeve is placed outside the tube to minimize the heat losses. If solar energy is transferred to water at a net rate of 400 Btu/h per ft length of the tube, determine the required length of the parabolic collector to meet the hot-water requirements of this house.

Step 1 of 3

Given

Inlet temperature of water $T_1 = 55°F$

Exit temperature of water $T_2 = 180°F$

The diameter of the aluminum tube $d = 1.25\,\text{in}$

The mass flow rate of water $\dot{m} = 4\ \text{lbm/s}$

Solar energy transferred to water per ft length of the tube $\frac{\dot{Q}}{L} = 400\,\text{Btu/h}$

$$= \frac{400}{3600}$$

$$\frac{\dot{Q}}{L} = 0.1111\,\text{Btu/s}$$

Step 2 of 3

For a steady flow device such as pipe or duct, the energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out} \qquad (w = 0, \Delta ke = 0, \Delta pe = 0)$$

Since $\dot{m}_{in} = \dot{m}_{out} = \dot{m}_w$ by using mass balance

$$\dot{Q} = \dot{m}_w (h_{out} - h_{in})$$

We know that $h = c_p T$

$$\dot{Q} = \dot{m}_w c_p (T_2 - T_1)$$

Taking specific heat of water $c_p = 1$ Btu/lbm.°F

Therefore

$$\dot{Q} = (4)(1)(180 - 55)$$

$$\dot{Q} = 500\ \text{Btu/s}$$

Step 3 of 3

The total length of the tube is determined as

$$\frac{\dot{Q}}{L} = 0.1111$$

$$L = \frac{\dot{Q}}{0.1111}$$

$$= \frac{500}{0.1111}$$

$$\boxed{L = 4500.45\ \text{ft}}$$

Question: 6.101P

A house has an electric heating system that consists of a 300-W fan and an electric resistance heating element placed in a duct. Air flows steadily through the duct at a rate of 0.6 kg/s and experiences a temperature rise of 7°C. The rate of heat loss from the air in the duct is estimated to be 300 W. Determine the power rating of the electric resistance heating element.

Step 1 of 3

Given

The work input to the fan $\dot{W}_{fan} = -300$ W

The mass flow rate of air in the duct $\dot{m}_{air} = 0.6$ kg/s

The rise in temperature of the air in the duct $\Delta T = 7$

The amount of heat lost to the surroundings $\dot{Q} = -300$ W

Step 2 of 3

The energy balance equation for the conservation of energy is written as

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{W} + \dot{m}_{out} h_{out} \quad (\text{Since } \Delta ke = 0, \Delta pe = 0)$$

By using mass balance

$$\dot{m}_{in} = \dot{m}_{out} = \dot{m}_{air}$$

$$\dot{Q} = \dot{W}_{fan} + \dot{W}_{elec} + \dot{m}_{air}(h_{out} - h_{in})$$

Step 3 of 3

Substituting the values in above equation

$$\dot{Q} = \dot{W}_{fan} + \dot{W}_{elec} + \dot{m}_{air}(h_{out} - h_{in})$$

We know that $h = c_p T$

Taking specific heat of air $c_p = 1.005$ kJ/kg°C

$$-0.3 = -0.3 + \dot{W}_{elec} + 0.6 \times 1.005 \times 7$$

$$\boxed{\dot{W}_{elec} = -4.221 \text{kW}}$$

Question: 6.102P

Steam enters a long, horizontal pipe with an inlet diameter of D1= 12 cm at 2 MPa and 300°C with a velocity of 3 m/s. Farther downstream, the conditions are 800 kPa and 250°C, and the diameter is *D*2 = 10 cm. Determine (a) the mass flow rate of the steam and (b) the rate of heat transfer.

Step 1 of 3

Given

Inlet Pressure of air, $P_1 = 2\,\text{MPa}$

Inlet temperature of air, $T_1 = 300°\text{C}$

Inlet diameter of pipe, $d_1 = 12\ \text{cm}$

Inlet velocity of air, $V_1 = 3\ \text{m/s}$

Exit pressure of air, $P_2 = 800\ \text{kPa}$

Exit temperature of air, $T_2 = 250°\text{C}$

Exit diameter of pipe, $D_2 = 10\ \text{cm}$

Step 2 of 3

(a)

From superheated steam tables, at 2MPa and 300°C

Specific volume, $v_1 = 0.12551\ \text{m}^3/\text{kg}$

Enthalpy, $h_1 = 3024.2\ \text{kJ/kg}$

From superheated steam tables, at 800kPa and 250°C

Enthalpy, $h_2 = 2950.4\ \text{kJ/kg}$

The mass flow rate of steam, $\dot{m} = \dfrac{A_1 V_1}{v_1}$

$$\dot{m} = \frac{\pi d_1^2 V_1}{4 v_1}$$

$$\dot{m} = \frac{\pi \times (0.12)^2 \times 3}{4 \times 0.12551}$$

$$\dot{m} = 0.27\ \text{kg/s}$$

Hence mass flow a rate of steam is $\boxed{\dot{m} = 0.27\ \text{kg/s}}$

Step 3 of 3

(b)

From the energy balance equation for the conservation of energy

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{Q} + \dot{m}_{out} h_{out}$$

$$\dot{Q} = \dot{m}_{in} (h_{in} - h_{out})$$

$$\dot{Q} = \dot{m}(h_1 - h_2)$$

$$\dot{Q} = 0.27 \times (3024.2 - 2950.4)$$

$$\dot{Q} = 19.92\ \text{kJ/s}$$

The rate of heat transfer $\boxed{\dot{Q} = 19.92\ \text{kJ/s}}$

Question: 6.103P

Refrigerant-134a enters the condenser of a refrigerator at 900 kPa and 60°C, and leaves as a saturated liquid at the same pressure. Determine the heat transfer from the refrigerant per unit mass.

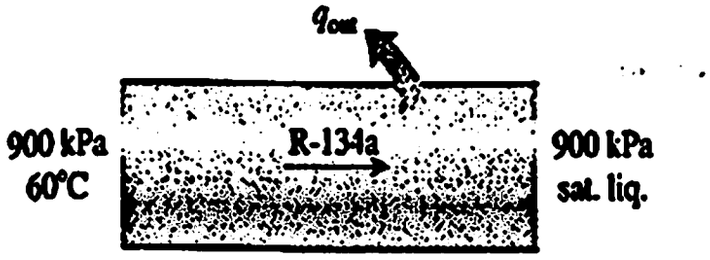


FIGURE P6–103

Step 1 of 3

Given

Inlet Pressure of R-134a, $P_1 = 900$ kPa

Inlet temperature of R-134a, $T_1 = 60°C$

Exit pressure of R-134a, $P_2 = P_1$

$P_2 = 900$ kPa

Exit state of R-134a is saturated liquid $(x_2 = 0)$.

Step 2 of 3

From superheated tables of R-134a at 900 kPa and 60°C ,

Enthalpy, $h_1 = 295.13$ kJ/kg

From saturated tables of R-134a at 900 kPa,

Enthalpy, $h_2 = h_f = 101.61$ kJ/kg

From the energy balance equation for the conservation of energy,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in} h_{in} = \dot{Q} + \dot{m}_{out} h_{out}$$

Step 3 of 3

From mass balance, $\dot{m}_{in} = \dot{m}_{out}$. So

$$\dot{Q} = \dot{m}(h_1 - h_2)$$

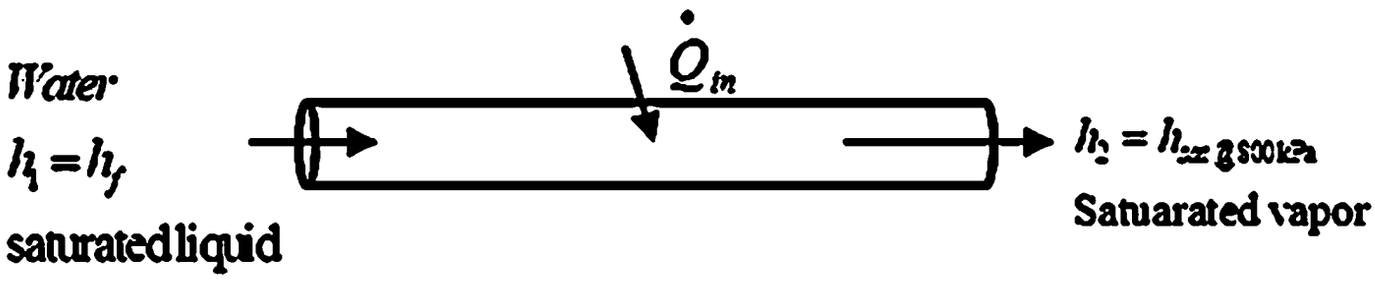
$$\frac{\dot{Q}}{\dot{m}} = (h_1 - h_2)$$

$$\dot{q} = (h_1 - h_2)$$

$$\dot{q} = (295.13 - 101.61)$$

$$\dot{q} = 193.52 \text{ kJ/kg}$$

Hence the heat transfer per unit mass is $\boxed{\dot{q} = 193.52 \text{ kJ/kg}}$



6.104P

Question:

Saturated liquid water is heated at constant pressure in a steady-flow device until it is a saturated vapor. Calculate the heat transfer, in kJ/kg, when the vaporization is done at a pressure of 800 kPa.

Step 1 of 2

Draw the flow diagram as shown:

Step 2 of 2

Obtain the value of enthalpy from the table: "Saturated water – Pressure table" at $P_1 = 800\,\text{kPa}$

$$h_{fg} = 2047.5\,\text{kJ/kg}$$

Consider control volume as the steam pipe as the system, since mass crosses the boundary. There is only one inlet and one exit, so mass entering is equal to mass leaving.

$$\dot{m}_1 = \dot{m}_2$$

Apply energy conservation for the system.

For a steady state condition energy stored within the system is zero.

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}\left(h_1 + V_1^2/2\right)_{in} + \dot{Q}_{in} + \dot{W}_{in} = \dot{m}\left(h_2 + V_2^2/2\right)_{out}$$

$$\dot{Q}_{in} + \dot{m}h_1 = \dot{m}h_2$$

$$\dot{Q}_{in} = \dot{m}(h_2 - h_1)$$

$$\dot{q}_{in} = (h_2 - h_1)$$

Here, $\dot{m}$ is the mass flow rate, V_1, V_2 are the mass flows rate at inlet and exit respectively and $\dot{q}_{out}$ is the heat transfer per unit mass.

$$\begin{aligned}\dot{q}_{in} &= (h_1 - h_2)\\ &= h_{fg}\\ &= 2047.5\ \text{kJ/kg}\end{aligned}$$

Therefore, the heat transfer per unit mass of water is $\boxed{2047.5\,\text{kJ/kg}}$

Question: 6.105P

Air at 300 K and 100 kPa steadily flows into a hair dryer having electrical work input of 1500 W. Because of the size of the air intake, the inlet velocity of the air is negligible. The air temperature and velocity at the hair dryer exit are 80°C and 21 m/s, respectively. The flow process is both constant pressure and adiabatic. Assume air has constant specific heats evaluated at 300 K. (a) Determine the air mass flow rate into the hair dryer, in kg/s. (b) Determine the air volume flow rate at the hair dryer exit, in m3/s.

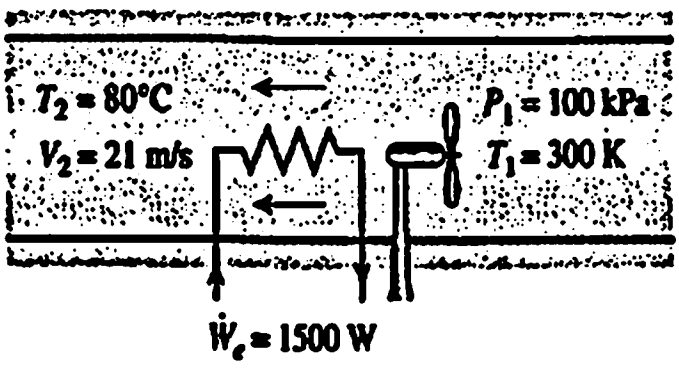


FIGURE P6–105

Step 1 of 3

(a)

The steady state energy equation is,

$$\dot{Q}-\dot{W}=\dot{m}\left[(h_1-h_2)+\left(\frac{V_1^2-V_2^2}{2000}\right)+g(z_1-z_2)\right]$$

Here, $\dot{Q}$ is the amount of heat interaction, $\dot{W}$ is the word done, $\dot{m}$ is the mass flow, h_1 is the initial enthalpy, h_2 is the final enthalpy, V_1 is the initial velocity, V_2 is the final velocity, g is the acceleration due to gravity, z_1 is the level from datum to initial point or inlet point and z_2 is the level from datum to the final point or outlet.

Because the process takes place along same level, so the potential energy is same and assuming the process to be adiabatic, the heat interaction is nullified.
So,

$$\dot{W}=\dot{m}\left[(h_2-h_1)+\left(\frac{V_2^2-V_1^2}{2000}\right)\right]$$

But Enthalpy is $h=c_pT$. So,

$$\dot{W}=\dot{m}\left[c_p(T_2-T_1)+\left(\frac{V_2^2-V_1^2}{2000}\right)\right] \quad \text{..... (1)}$$

Here, c_p is the Specific heat at constant pressure.

Step 2 of 3

Substitute 100 kPa for P_1, 300K for T_1, 1500 W for $\dot{W}$, 353K for T_2, 21 m/s for V_1, 0 m/s for V_2 and 1.005 kJ/kg.K for c_p in (1).

$$\dot{W}=\dot{m}\left[c_p(T_2-T_1)+\left(\frac{V_2^2-V_1^2}{2000}\right)\right]$$

$$1.5=\dot{m}\left[1.005(353-300)+\left(\frac{21^2-0^2}{2000}\right)\right]$$

$$1.5\text{ kW}=\dot{m}\times(53.4855\text{ kJ/kg})$$

$$\dot{m}=\frac{1.5\text{ kW}}{53.4855\text{ kJ/kg}}$$

$$\dot{m}=0.028044\text{ kg/s}$$

Therefore mass flow rate of air drier is, $\boxed{0.28044\text{ kg/s}}$

Step 3 of 3

(b)

From properties of ideal gases, the gas constant of air is, $R=0.287\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$
Find the density at final condition by using the ideal gas equation,

$$\rho_2=\frac{P_2}{RT_2}$$

$$=\frac{100}{0.287\times353}$$

$$=0.987\text{ kg/m}^3$$

The mass flow rate is the product of the density and the discharge,

$$\dot{m}=\rho_2\dot{Q}_2$$

Here

$$\dot{Q}_2=\frac{\dot{m}}{\rho_2}$$

$$=\frac{0.028044}{0.987}$$

$$=0.02841\text{ m}^3/\text{s}$$

The volume flow rate is, $\boxed{0.02841\text{ m}^3/\text{s}}$

Question: 6.106P

Reconsider Prob. 6–105. Using EES (or other) software, investigate the effect of the exit velocity on the mass flow rate and the exit volume flow rate. Let the exit velocity vary from 5 to 25 m/s. Plot the mass flow rate and exit volume flow rate against the exit velocity, and discuss the results.

Step 1 of 5

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click Calculate on menu bar, select solve.

Finally, Solution window displayed the unknown parameters

Step 2 of 5

Equation window:

"Given"

T1=300 [K]

P=100 [kPa]

Vel_1=0 [m/s]

W_dot_e_in=1.5 [kW]

T2=(80+273) [K]

Vel_2=21 [m/s]

"Properties"

c_p=1.005 [kJ/kg-K]

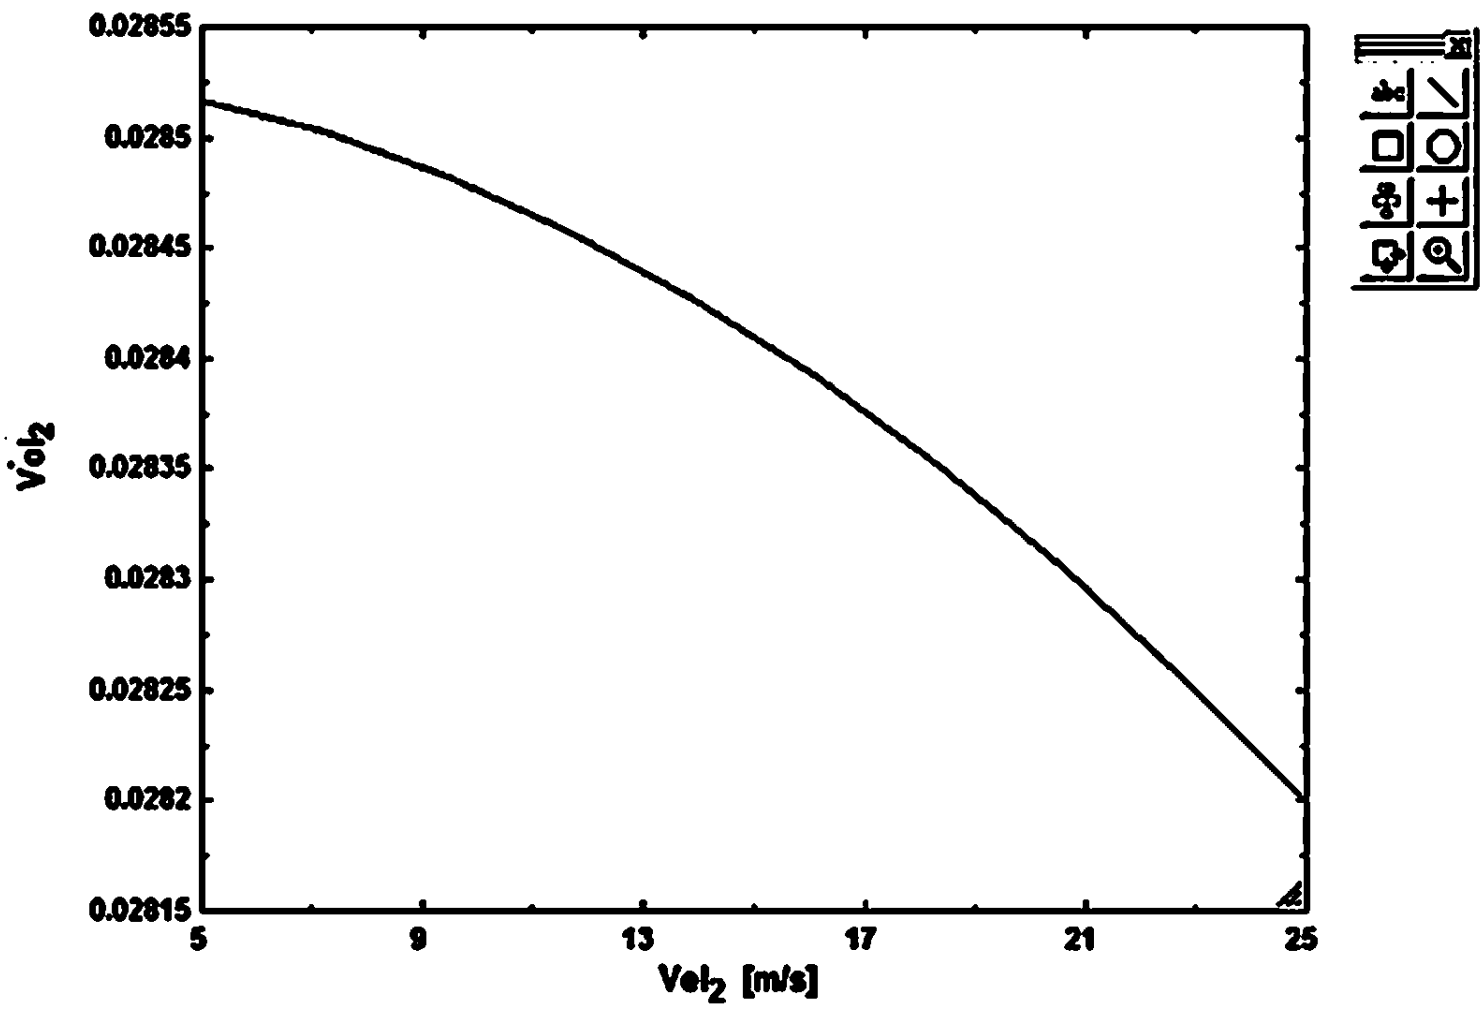
R=0.287 [kJ/kg-K]

"Analysis"

W_dot_e_in=m_dot*c_p*(T2-T1)+m_dot*(Vel_2^2-Vel_1^2)*Convert(m^2/s^2,kJ/kg) "energy balance on hair dryer"

v2=(R*T2)/P

Vol_dot_2=m_dot*v2



Step 3 of 5

Table for $\dot{Q}_{out}$ as a function of *D*:

1..10	1 Vel_2 [m/s]	2 $\dot{m}$	3 $\dot{Vol}_2$
Run 1	5	0.02815	0.02852
Run 2	7.222	0.02813	0.0285
Run 3	9.444	0.02811	0.02848
Run 4	11.67	0.02809	0.02846
Run 5	13.89	0.02806	0.02843
Run 6	16.11	0.02802	0.02839
Run 7	18.33	0.02798	0.02835

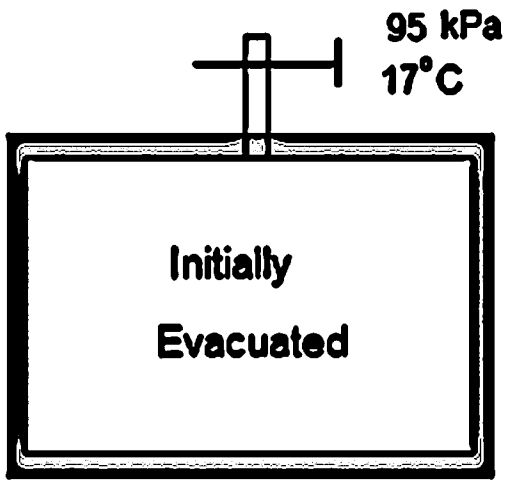
Step 4 of 5

Graph between the $\dot{Vol}_2$ Vs. Vel_2 :

Step 5 of 5

Graph between the $\dot{m}$ Vs. Vel_2 :



Question: 6.107P

An insulated rigid tank is initially evacuated. A valve is opened, and atmospheric air at 95 kPa and 17°C enters the tank until the pressure in the tank reaches 95 kPa, at which point the valve is closed. Determine the final temperature of the air in the tank. Assume constant specific heats.

Step 1 of 4

Figure shows the insulated rigid tank:

Step 2 of 4

From table A-2a, ratio of specific heats of air is

$$R = 0.287 \text{ kJ/kg°K}$$

The mass balance is

$$m_{in} - m_{out} = \Delta m_{sys}$$

For steady flow $\Delta m_{sys} = 0$ and so

$$m_{in} - m_{out} = 0$$

$$m_1 - m_2 = 0$$

$$m_1 = m_2 \qquad \text{..... (1)}$$

As the tank valve is opened to atmosphere, the initial temperature of the bottle is same as the atmospheric pressure & temperature.

$$T_1 = T_{atm}$$

The energy balance is given by

$$E_{in} - E_{out} = E_{sys}$$

Here, initial energy of system is E_{in}

The final energy of the system is E_{out}

The system energy is E_{sys}

For a steady process, $E_{sys} = 0$ and so

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

Step 3 of 4

As there is flow of air initially, initial energy is given by enthalpy and as there is no flow of air finally, final energy is given by internal energy.

$$m_1 h_1 = m_2 u_2$$

Here initial mass of the air is m_1

Final mass of the air is m_2

Enthalpy of the air at Initial state is h_1

Internal energy of the air at Final state is u_2

Substitute equation (1) in the above equation

$$m_1 h_1 = m_1 u_2$$

$$h_1 = u_2$$

Step 4 of 4

$$h_1 = u_2$$

$$c_p \times T_1 = c_v \times T_2$$

Here specific heat at constant pressure is c_p

Specific heat at constant volume is c_v

Temperature at Initial state is T_1

Temperature at final state is T_2

$$T_2 = \frac{c_p \times T_1}{c_v}$$

$$T_2 = \frac{c_p}{c_v} \times T_1$$

Since specific heat ratio $\frac{c_p}{c_v} = k$

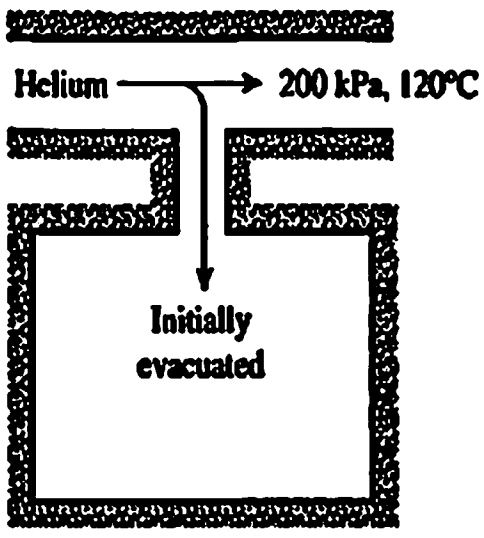
$$T_2 = k \times T_1$$

$$T_2 = 1.4 \times 290$$

Therefore final temperature in the tank is $\boxed{T_2 = 406 \text{ K}}$

Question: 6.108P

A rigid, insulated tank that is initially evacuated is connected through a valve to a supply line that carries helium at 200 kPa and 120°C. Now the valve is opened, and helium is allowed to flow into the tank until the pressure reaches 200 kPa, at which point the valve is closed. Determine the flow work of the helium in the supply line and the final temperature of the helium in the tank.



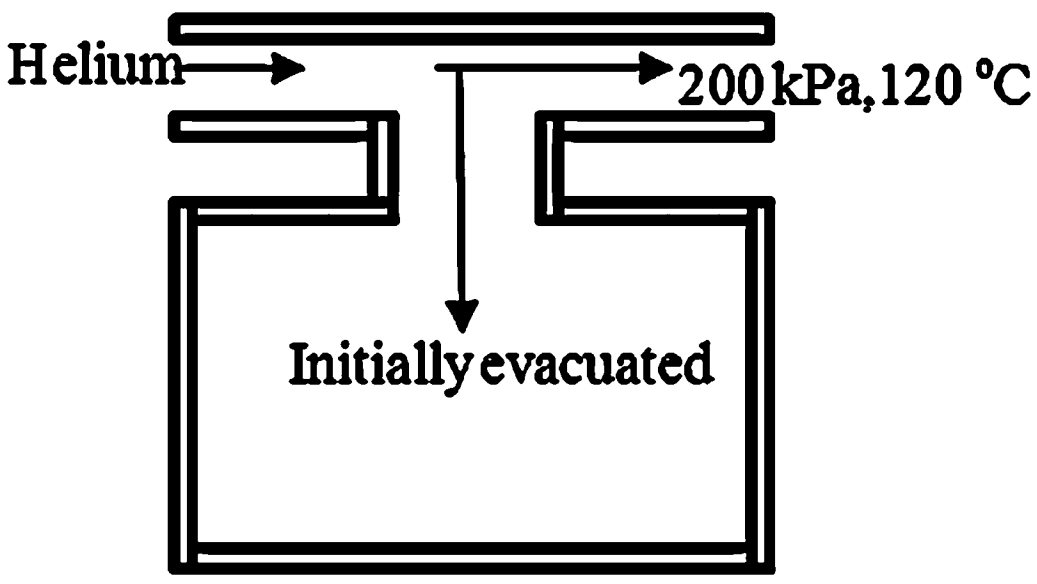


FIGURE P6–108

Step 1 of 3

Schematic diagram of the flow

Step 2 of 3

From the properties of gases in the helium column, obtain the following values

$R = 2.0769$ kJ/kg-K,

$C_p = 5.1926$ kJ/kg-K,

$C_v = 3.1156$ kJ/kg-K

Find the specific volume of the helium gas as shown below:

$$v = \frac{RT}{P}$$

Here R is the universal gas constant, T is temperature and P is the pressure.

Substitute $R = 2.0769$ kJ/kg-K , $P = 200$ kPa and $T = 120°c = (120+273)$ K

$$v = \frac{2.0769(\text{kJ/kg-K}) \times (120+273)\text{K}}{200\text{kPa}}$$
$$= 4.08\,\text{m}^3/\text{kg}$$

Find the flow work of gas as shown below:

$$W_{flow} = Pv$$

Substitute $P = 200$ kPa and $v = 4.08\,\text{m}^3/\text{kg}$ in above formula,

$$W_{flow} = 200(\text{kPa}) \times 4.08(\text{m}^3/\text{kg})$$
$$= 816\,\text{kJ/kg}$$

Therefore, the flow work is $\boxed{816\,\text{kJ/kg}}$

Step 3 of 3

Since the flow work in the supply line is converted to sensible internal energy in the tank.

Find the final helium temperature in the tank as follows

$$u_{tank} = h_{line}$$
$$h_{line} = C_p T_{line}$$
$$u_{tank} = C_v T_{tank}$$

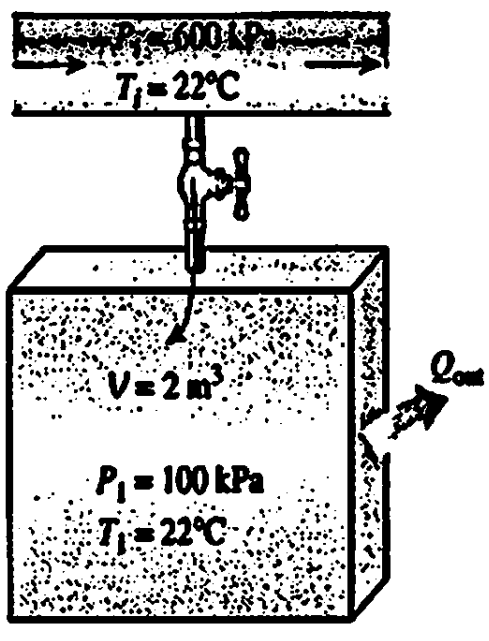
Find the temperature of the helium in the tank is

$$T_{tank} = \frac{C_p T_{line}}{C_v}$$
$$= \frac{5.1926(\text{kJ/kg-K})}{3.1156(\text{kJ/kg-K})} \times 393(\text{K})$$
$$= 655\,\text{K}$$

Therefore, the final temperature of the helium is $\boxed{655\,\text{K}}$

Question: 6.109P

A 2-m3 rigid tank initially contains air at 100 kPa and 22°C. The tank is connected to a supply line through a valve. Air is flowing in the supply line at 600 kPa and 22°C. The valve is opened, and air is allowed to enter the tank until the pressure in the tank reaches the line pressure, at which point the valve is closed. A thermometer placed in the tank indicates that the air temperature at the final state is 77°C. Determine (a) the mass of air that has entered the tank and (b) the amount of heat transfer.



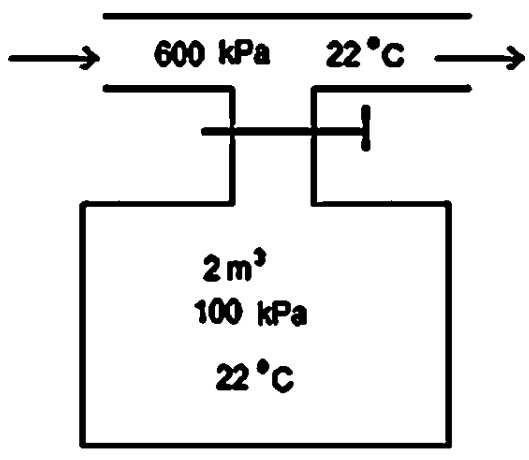


FIGURE P6–109

Step 1 of 6

Figure shows the rigid tank

Step 2 of 6

From table A-2a, gas constant of air is

$$R = 0.287 \text{ kJ/kg°K}$$

From table A-17, at temperature $T_1 = 295$ K specific internal energy of air is

$$u_1 = 210.49 \text{ kJ/kg}$$

From table A-17, at temperature $T_2 = 350$ K specific internal energy of air is

$$u_2 = 250.02 \text{ kJ/kg}$$

From table A-17, at temperature $T_s = 295$ K specific enthalpy of air is

$$h_s = 295.17 \text{ kJ/kg}$$

Step 3 of 6

Calculate the Initial mass in the tank by using the following equation

$$m_1 = \frac{P_1 \times V}{T_1 \times R}$$

Here, volume of the tank is V

Initial pressure of the air P_1

Initial temperature of the air T_1

Substitute, 100 kPa for P_1, 295 K for T_1 and 0.287 kJ/kg°K for R

$$m_1 = \frac{100 \times 2}{295 \times 0.287}$$

$$m_1 = \frac{200}{84.665}$$

$$m_1 = 2.362 \text{ kg}$$

Step 4 of 6

Calculate the Final mass by using the following equation

$$m_2 = \frac{P_2 \times V}{T_2 \times R}$$

Here,

Final pressure of the air P_2

Final temperature of the air T_2

Substitute, 600 kPa for P_2, 350 K for T_2 and 0.287 kJ/kg°K for R

$$m_2 = \frac{600 \times 2}{350 \times 0.287}$$

$$m_2 = \frac{1200}{100.45}$$

$$m_2 = 11.946 \text{ kg}$$

Step 5 of 6

Calculate the mass of air by using the mass balance

$$m_{in} - m_{out} = \Delta m_{sys}$$

$$m_s - 0 = m_2 - m_1$$

Substitute, 11.946 kg for m_2 and 2.362 kg for m_1

$$m_s = m_2 - m_1$$

$$m_s = 11.946 - 2.362$$

$$\boxed{m_s = 9.584 \text{ kg}}$$

Step 6 of 6

Calculate heat transfer by using the following energy balance

$$E_{in} - E_{out} = E_{sys}$$

For a steady process, $E_{sys} = 0$ and so

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$m_s h_s - Q_{out} = m_2 u_2 - m_1 u_1$$

$$Q_{out} = m_s h_s - m_2 u_2 + m_1 u_1$$

$$Q_{out} = (9.584 \times 295.17) - (11.946 \times 250.02) + (2.362 \times 210.49)$$

$$Q_{out} = 2828.909 - 2986.739 + 497.177$$

$$\boxed{Q_{out} = 339.347 \text{ kJ}}$$

Therefore, the mass of air that has entered the tank is $\boxed{9.584 \text{ kg}}$

The heat transferred out through the wall of the tank is $\boxed{339.347 \text{ kJ}}$

Question: 6.110P

A 0.2-m3 rigid tank equipped with a pressure regulator contains steam at 2 MPa and 300°C. The steam in the tank is now heated. The regulator keeps the steam pressure constant by letting out some steam, but the temperature inside rises. Determine the amount of heat transferred when the steam temperature reaches 500°C.

Step 1 of 2

Calculate the initial mass using the following equation

$$\begin{aligned} m_t &= m_i - m_f \\ &= \frac{V}{v_i} - \frac{V}{v_f} \end{aligned}$$

Here, the total mass, initial mass and final mass are denote by m_t, m_i and m_f respectively.

The volume is denoted by V

Substitute $0.2\,\mathrm{m}^3$ for V

$$\begin{aligned} m_i &= \frac{0.2}{0.12551} - \frac{0.2}{0.17568} \\ &= 0.45\,\mathrm{kg} \end{aligned}$$

Assume that at exit, the enthalpy of the steam maintains an average value.

Calculate the enthalpy at exit using the following equation

$$\begin{aligned} h_t &= \frac{h_i + h_f}{2} \\ &= \frac{3024.20 + 3468.30}{2}\,\frac{\mathrm{kJ}}{\mathrm{kg}} \\ &= 3246.25\,\frac{\mathrm{kJ}}{\mathrm{kg}} \end{aligned}$$

Step 2 of 2

Consider the energy balance equation

$$Q - m_t h_t = m_f u_f - m_i u_i$$

$$Q - m_t h_t = \frac{V}{v_f} \times u_f - \frac{V}{v_i} u_i$$

$$Q - 0.45 \times 3246.25 = \left(\frac{0.2}{0.1757} \times 3116.9\right) - \left(\frac{0.2}{0.1255} \times 2773.2\right)$$

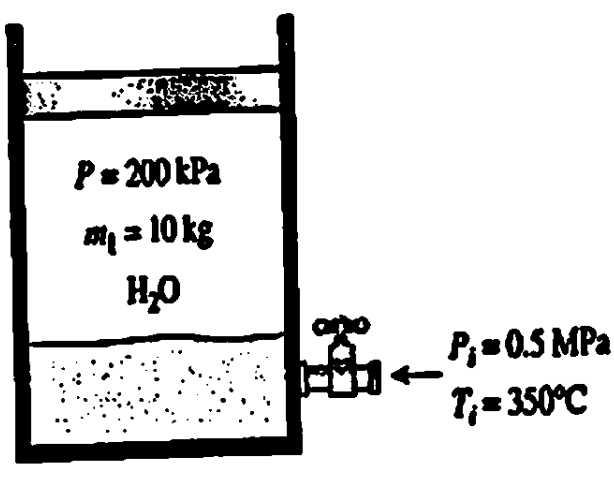
$$Q - 0.45 \times 3246.25_t = (0.138 \times 3116.9) - (1.59 \times 2773.2)$$

$$Q = 599\,\mathrm{kJ/kg}$$

Therefore, the total heat transfer is $\boxed{599\ \mathrm{kJ}}$.

Question: 6.111P

An insulated, vertical piston–cylinder device initially contains 10 kg of water, 6 kg of which is in the vapor phase. The mass of the piston is such that it maintains a constant pressure of 200 kPa inside the cylinder. Now steam at 0.5 MPa and 350°C is allowed to enter the cylinder from a supply line until all the liquid in the cylinder has vaporized. Determine (a) the final temperature in the cylinder and (b) the mass of the steam that has entered.



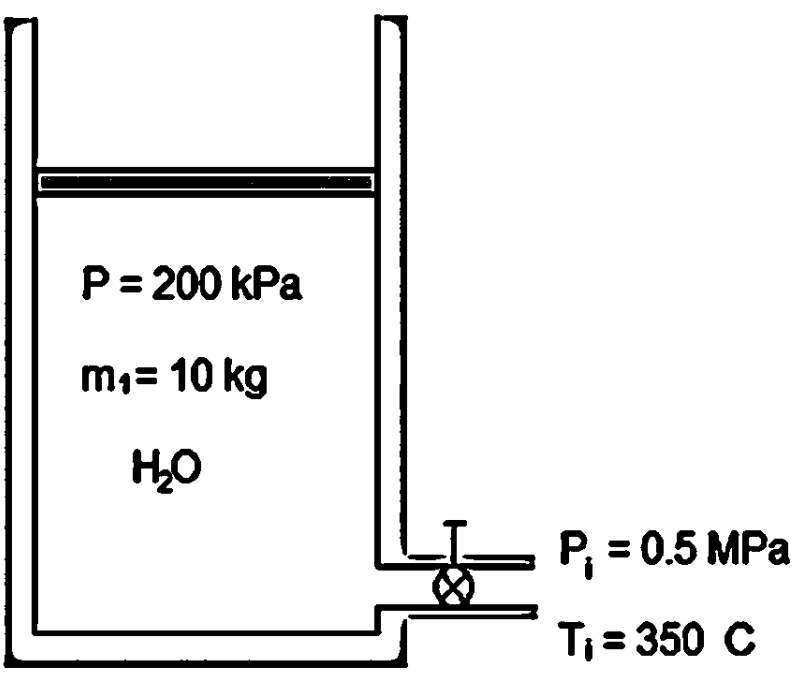


FIGURE P6–111

Step 1 of 8

Figure shows the rigid tank:

Step 2 of 8

Calculate the initial quality of steam in the device by using the following equation: $x_1 = \frac{m_v}{m_1}$ $x_1 = \frac{6}{10}$

$x_1 = 0.6$

Step 3 of 8

From table properties of water, at pressure $P_1 = 200\ \text{kPa}$: The specific enthalpy of saturated liquid at initial state is $h_{f1} = 504.71\ \text{kJ/kg}$. The specific enthalpy of saturated vapor at initial state is $h_{fg1} = 2201.6\ \text{kJ/kg}$. From table A-5, at pressure $P_2 = 200\ \text{kPa}$ and saturated vapor condition enthalpy of water are The specific enthalpy of saturated vapor at final state is, $h_2 = h_{g2} = 2706.3\ \text{kJ/kg}$. From table A-6, at pressure $P_s = 0.5\ \text{MPa}$ and temperature $T_s = 350\ ^\circ\text{C}$ properties of water:

$h_s = 3168.1\ \text{kJ/kg}$

Step 4 of 8

Calculate the Initial specific enthalpy of water by using the following equation:

$$h_1 = h_{f1} + \left(x_1 \times h_{fg1}\right)$$

Substitute, $504.71\ \text{kJ/kg}$ for h_{f1} and $2201.6\ \text{kJ/kg}$ for h_{fg1}:

$$h_1 = 504.71 + \left(0.6 \times 2201.6\right)$$

$$h_1 = 504.71 + 1320.96$$

$$h_1 = 1825.67\ \text{kJ/kg}$$

Step 5 of 8

(a)

As the final condition of water in the device is saturated vapor, the final temperature can be taken as the saturated temperature at that pressure.

From table properties of water are, at pressure $P_2 = 200\ \text{kPa}$.

Therefore, saturated temperature is $\boxed{T_2 = 120.21\ ^\circ\text{C}}$.

Step 6 of 8

(b)

Calculate mass of water that has entered the device mass balance:

$$m_{in} - m_{out} = \Delta m_{sys}$$
$$m_s - 0 = m_2 - m_1$$

$$m_s = m_2 - m_1 \quad \ldots\ldots (1)$$

Step 7 of 8

Calculate the Final mass of the air by using the following energy balance:

$$E_{in} - E_{out} = E_{sys}$$

$m_s \times h_s - 0 = \left(m_2 \times h_2\right) - \left(m_1 \times h_1\right)$ Substitute equation (1) in the above equation:

$$m_s \times h_s = \left(m_2 \times h_2\right) - \left(m_1 \times h_1\right)$$
$$\left(m_2 - m_1\right) \times h_s = \left(m_2 \times h_2\right) - \left(m_1 \times h_1\right)$$
$$\left(m_2 \times h_s\right) - \left(m_1 \times h_s\right) = \left(m_2 \times h_2\right) - \left(m_1 \times h_1\right)$$
$$\left(m_1 \times h_1\right) - \left(m_1 \times h_s\right) = \left(m_2 \times h_2\right) - \left(m_2 \times h_s\right)$$
$$m_1 \times \left(h_1 - h_s\right) = m_2 \times \left(h_2 - h_s\right)$$
$$m_2 = \frac{m_1 \times \left(h_1 - h_s\right)}{\left(h_2 - h_s\right)}$$

Step 8 of 8

Substitute 10 kg for m_1 , $1825.67\ \text{kJ/kg}$ for h_1 , $3168.1\ \text{kJ/kg}$ for h_s :

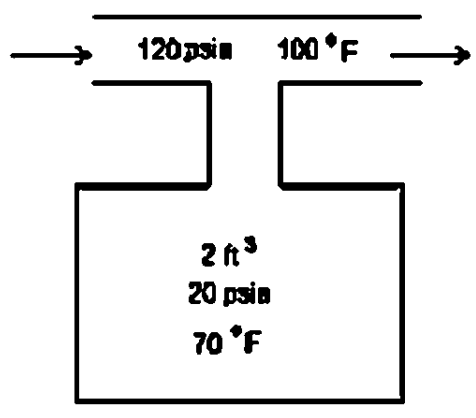
$$m_2 = \frac{10 \times \left(1825.67 - 3168.1\right)}{\left(2706.3 - 3168.1\right)}$$
$$= \frac{10 \times \left(-1342.43\right)}{\left(-461.8\right)}$$
$$= \frac{-13424.3}{-461.8}$$
$$= 29.069\ \text{kg}$$

From equation (1),

$$m_s = m_2 - m_1$$

Substitute, $29.069\ \text{kg}$ for m_2, $10\ \text{kg}$ for m_1 :

$$m_s = 29.069 - 10$$
$$= 19.069\ \text{kg}$$



Therefore, mass of water that has entered the device is $\boxed{19.069\ \text{kg}}$.

Question: 6.112P

A scuba diver's 2-ft3 air tank is to be filled with air from a compressed air line at 120 psia and 100°F.Initially, the air in this tank is at 20 psia and 70°F. Presuming that the tank is well insulated, determine the temperature and mass in the tank when it is filled to 120 psia.

Step 1 of 8

Figure shows the scuba divers tank:

Step 2 of 8

From table A-1E, gas constant of air is $R = 0.3704$ psia.ft^3/lbm.R

From table A-2E (a), specific heats of air are

Specific heat at constant pressure is $c_p = 0.240$ Btu/lbm.R

Specific heat at constant volume is $c_v = 0.171$ Btu/lbm.R

Step 3 of 8

Calculate the Initial mass of air by using the following equation

$$m_1 = \frac{P_1 \times V}{T_1 \times R}$$

Here, volume of the tank is V

Initial pressure of the air P_1

Initial temperature of the air T_1

Substitute, 20 psia for P_2, 530 R for T_1 and 0.3704 psia.ft^3/lbm.R for R

$$m_1 = \frac{20 \times 2}{530 \times 0.3704}$$

$$m_1 = \frac{40}{196.312}$$

$$m_1 = 0.20375 \text{ lbm}$$

Calculate the Final mass by using the following equation

$$m_2 = \frac{P_2 \times V}{T_2 \times R}$$

Here,

Final pressure of the air P_2

Final temperature of the air T_2

Substitute, 120 psia for P_2 and 0.3704 psia.ft^3/lbm.R for R

$$m_2 = \frac{120 \times 2}{T_2 \times 0.3704}$$

$$m_2 = \frac{240}{T_2 \times 0.3704}$$

$$m_2 = \frac{647.948}{T_2} \quad \text{..... (1)}$$

Step 4 of 8

The mass balance is given by

$$m_{in} - m_{out} = \Delta m_{sys}$$

$$m_s - 0 = m_2 - m_1$$

$$m_s = m_2 - m_1 \quad \text{..... (2)}$$

The energy balance is given by

$$E_{in} - E_{out} = E_{sys}$$

$$m_s \times h_s - 0 = (m_2 \times u_2) - (m_1 \times u_1)$$

$$m_s \times h_s = (m_2 \times u_2) - (m_1 \times u_1)$$

$$m_s \times c_p \times T_s = (m_2 \times c_v \times T_2) - (m_1 \times c_v \times T_1)$$

Step 5 of 8

Substituting equation (2) in the above equation

$$(m_2 - m_1) \times c_p \times T_s = (m_2 \times c_v \times T_2) - (m_1 \times c_v \times T_1)$$

$$(m_2 \times c_p \times T_s) - (m_1 \times c_p \times T_s) = (m_2 \times c_v \times T_2) - (m_1 \times c_v \times T_1)$$

$$(m_1 \times c_v \times T_1) - (m_1 \times c_p \times T_s) = (m_2 \times c_v \times T_2) - (m_2 \times c_p \times T_s)$$

$$m_1 \times ((c_v \times T_1) - (c_p \times T_s)) = m_2 \times ((c_v \times T_2) - (c_p \times T_s))$$

Step 6 of 8

Substitute 0.20375 lbm for m_1, 0.240 Btu/lbm.R for c_p, 0.171 Btu/lbm.R for c_v, $\frac{647.948}{T_2}$ for m_2, 560 R for the values in the above equation we get,

$$0.20375 \times ((0.171 \times 530) - (0.24 \times 560)) = \frac{647.948}{T_2} \times ((0.171 \times T_2) - (0.24 \times 560))$$

$$0.20375 \times (90.63 - 134.4) = \frac{647.948}{T_2} \times (0.171 \times T_2 - 134.4)$$

$$0.20375 \times (-43.77) = \left(\frac{647.948}{T_2} \times 0.171 \times T_2\right) - \left(\frac{647.948}{T_2} \times 134.4\right)$$

$$-8.918 = 110.799 - \left(\frac{87084.2112}{T_2}\right)$$

$$-119.717 = -\frac{87084.2112}{T_2}$$

Step 7 of 8

Calculate the final temperature by using the following equation

$$119.717 = \frac{87084.2112}{T_2}$$

$$T_2 = \frac{87084.2112}{119.717}$$

$$T_2 = 727.417 \text{ R}$$

$$= 267.417 \text{°F}$$

Therefore the final temperature of air is $\boxed{T_2 = 267.417 \text{ °F}}$

Step 8 of 8

From equation (1), calculate the final mass of the air in the tank

$$m_2 = \frac{647.948}{T_2}$$

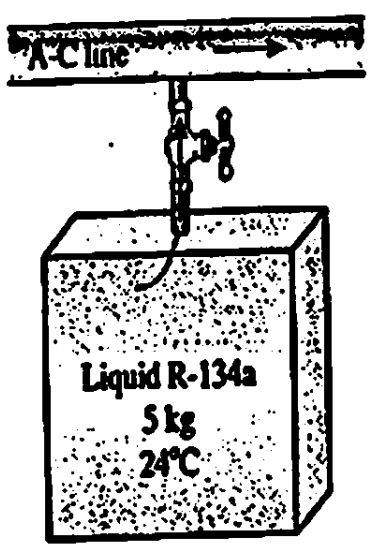
$$m_2 = \frac{647.948}{727.417}$$

$$m_2 = 0.89075 \text{ lbm}$$

Therefore, final mass of air in the tank is $\boxed{0.89075 \text{ lbm}}$

Question: 6.113P

An air-conditioning system is to be filled from a rigid container that initially contains 5 kg of liquid R-134a at 24°C. The valve connecting this container to the air-conditioning system is now opened until the mass in the container is 0.25 kg, at which time the valve is closed. During this time, only liquid R-134a flows from the container. Presuming that the process is isothermal while the valve is open, determine the final quality of the R-134a in the container and the total heat transfer.



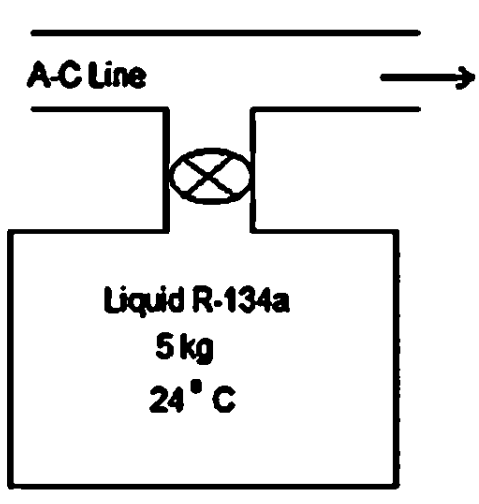


FIGURE P6–113

Step 1 of 10

Figure shows the air conditioning tank:

Step 2 of 10

From table A-11, at temperature $T_1 = 24\ ^\circ C$ properties of R-134a are

The specific volume of saturated liquid at initial state is $v_1 = v_f = 0.0008261\ m^3/kg$

The specific volume of saturated vapor at initial state is $v_g = 0.031834\ m^3/kg$

The internal energy of saturated liquid at initial state is $u_1 = u_f = 84.44\ kJ/kg$

The internal energy of saturated liquid-vapor at initial state is $u_{fg} = 158.65\ kJ/kg$

The enthalpy is $h_e = 84.98\ kJ/kg$

Step 3 of 10

Calculate the Volume of R-134a by using the following equation

$$V = m_1 \times v_1$$

Here initial mass of refrigerant is m_1, specific volume of the refrigerant at initial state is v_1

Substitute, $5\ kg$ for m_1, $0.0008261\ m^3/kg$ for v_1

$$V = 5 \times 0.0008261$$
$$V = 0.0041305\ m^3$$

Step 4 of 10

Calculate the final specific volume of R-134a by using the following equation

$$v_2 = \frac{V}{m_2}$$

Here the final mass of the refrigerant is m_2

Substitute, $0.0041305\ m^3$ for V, $0.25\ kg$ for m_2

$$v_2 = \frac{0.0041305}{0.25}$$
$$v_2 = 0.01652\ m^3/kg$$

Step 5 of 10

(a) Calculate the dryness fraction by using the Final specific volume equation

$$v_2 = v_f + x_2 \times v_{fg}$$
$$v_2 = v_f + \left[x_2 \times \left(v_g - v_f\right)\right]$$

Substitute, $0.0008261\ m^3/kg$ for v_f, $0.01652\ m^3/kg$ for v_2, $0.031834\ m^3/kg$ for v_g

$$0.01652 = 0.0008261 + \left[x_2 \times (0.031834 - 0.0008261)\right]$$
$$0.01652 = 0.0008261 + (x_2 \times 0.031008)$$

So, final quality of R-134a is given by

$$x_2 = \frac{0.01652 - 0.0008261}{0.031008}$$
$$x_2 = \frac{0.015694}{0.031008}$$
$$\boxed{x_2 = 0.50613}$$

Step 6 of 10

Calculate the Final specific internal energy by using the following equation

$$u_2 = u_f + \left(x_2 \times u_{fg}\right)$$

Substitute, $84.44\ kJ/kg$ for u_f, 0.50613 for x_2, $158.65\ kJ/kg$ for u_{fg}

$$u_2 = 84.44 + (0.50613 \times 158.65)$$
$$u_2 = 84.44 + 80.297$$
$$u_2 = 164.737\ kJ/kg$$

Step 7 of 10

(b) The mass balance is

$$m_{in} - m_{out} = \Delta m_{sys}$$
$$0 - m_e = m_2 - m_1$$
$$-m_e = m_2 - m_1$$
$$m_e = m_1 - m_2 \qquad \ldots\ldots (1)$$

Step 8 of 10

The energy balance is given by

$$E_{in} - E_{out} = E_{sys}$$
$$Q_{in} - m_e \times h_e = m_2 \times u_2 - m_1 \times u_1$$
$$Q_{in} = (m_2 \times u_2) - (m_1 \times u_1) + (m_e \times h_e)$$

Step 9 of 10

Substitute equation (1) in the above equation

$$Q_{in} = (m_2 \times u_2) - (m_1 \times u_1) + (m_1 - m_2) \times h_e$$
$$Q_{in} = (0.25 \times 164.737) - (5 \times 84.44) + \left[(5 - 0.25) \times 84.98\right]$$

Step 10 of 10

$$Q_{in} = (0.25 \times 164.737) - (5 \times 84.44) + (4.75 \times 84.98)$$
$$Q_{in} = 41.184 - 422.2 + 403.655$$
$$\boxed{Q_{in} = 22.639\ kJ}$$

Therefore, the final quality of R-134a is $\boxed{0.50613}$ and the total heat transfer is $\boxed{22.639\ kJ}$

Question: 6.114P

Oxygen is supplied to a medical facility from ten 1.5-ft3 compressed oxygen tanks. Initially, these tanks are at 1500 psia and 80°F. The oxygen is removed from these tanks slowly enough that the temperature in the tanks remains at 80°F. After two weeks, the pressure in the tanks is 300 psia. Determine the mass of oxygen used and the total heat transfer to the tanks.

Step 1 of 4

Given

Total volume of the oxygen tank, $V = 10 \times \left(1.5\ \text{ft}^3\right)$

$$V = 15\ \text{ft}^3$$

Initial pressure of oxygen, $P_2 = 1500$ psia

Initial temperature of oxygen, $T_2 = 80°\text{F}$

$$T_2 = 540\text{R}$$

Final pressure of oxygen, $P_2 = 300$ psia

Final temperature of oxygen, $T_2 = 80°\text{F}$

$$T_2 = 540\text{R}$$

Step 2 of 4

From ideal gas properties table for oxygen, $R = 0.3553$ psia·ft^3/lbm·R

From ideal gas equation, $PV = mRT$

$$m_1 = \frac{P_1 V_1}{RT_1}$$

$$m_1 = \frac{1500 \times 15}{0.3353 \times 540}$$

$$m_1 = 124.27\ \text{lbm}$$

Similarly, $m_2 = \dfrac{P_2 V_2}{RT_2}$

$$m_2 = \frac{300 \times 15}{0.3353 \times 540}$$

$$m_2 = 24.85\ \text{lbm}$$

Step 3 of 4

From mass balance, $\dot{m}_{in} - \dot{m}_{out} = \Delta m_{system}$

$$m_{exit} = \dot{m}_{in} - \dot{m}_{out}$$

$$m_{exit} = \dot{m}_1 - \dot{m}_2$$

$$m_{exit} = 124.27 - 24.85$$

$$m_{exit} = 99.41\ \text{lbm}$$

The mass of oxygen used is $\boxed{m_{exit} = 99.41\ \text{lbm}}$

Step 4 of 4

From energy balance, $E_{in} - E_{out} = \Delta E_{system}$

$$Q_{in} - m_e h_e = m_2 u_2 - m_1 u_1$$

But $h = c_p T$ and $u = c_v T$. Also

From ideal gas properties table for oxygen,

Specific heat at constant pressure, $c_p = 0.219$ BTu/lbm.R

Specific heat at constant volume, $c_v = 0.157$ BTu/lbm.R

Substituting the values in the energy equation,

$$Q_{in} - m_e c_p T_e = m_2 c_v T_2 - m_1 c_v T_1$$

$$Q_{in} - (99.41 \times 0.219 \times 540) = (24.85 \times 0.157 \times 540) - (124.27 \times 0.157 \times 540)$$

$$Q_{in} - 11756.2266 = 2106.783 - 10535.6$$

$$Q_{in} = 3327.4\ \text{Btu}$$

Hence net heat transfer in the tank $\boxed{Q_{in} = 3327.4\ \text{Btu}}$

Question: 6.115P

A 0.03-m3 rigid tank initially contains refrigerant-134a at 1.4 MPa and 100 percent quality. The tank is connected by a valve to a supply line that carries refrigerant-134a at 1.6 MPa and 36°C. Now the valve is opened, and the refrigerant is allowed to enter the tank. The valve is closed when it is observed that the tank contains saturated liquid at 1.6 MPa. Determine (*a*) the mass of the refrigerant that has entered the tank and (b) the amount of heat transfer.

Step 1 of 3

(a)

Obtain the properties of refrigerant R-134a from "properties of R-134a tables"

At pressure of 1.4 MPa :

Internal energy, $u_1 = u_g = 256.37 \text{ kJ/kg}$

Specific volume, $v_1 = v_g = 0.01411 \text{ m}^3/\text{kg}$

At pressure of 1.6 MPa :

Enthalpy, $h_{in} = h_f = 102.33 \text{ kJ/kg}$ **(at** $T_{in} = 36°\text{C}$**)**

Internal energy, $u_2 = u_f = 134.43 \text{ kJ/kg}$

Specific volume, $v_2 = v_f = 0.00094 \text{ m}^3/\text{kg}$

Step 2 of 3

The change of mass in the system is,

$$\Delta m_{system} = m_2 - m_1$$

Here, m_2 **is the final mass in the system, and** m_1 **is the initial mass in the system.**

The mass of refrigerant is the ratio of the volume of tank to the specific volume of gas at the particular parameters.

$$m = \frac{V}{v}$$

Initial mass of gas in the tank is,

$$m_1 = \frac{V_1}{v_1}$$

Substitute 0.03 m^3 **for** V_1 **, and** $v_1 = 0.01411 \text{ m}^3/\text{kg}$**.**

$$m_1 = \frac{V_1}{v_1}$$
$$= \frac{0.03}{0.01411}$$
$$= 2.126 \text{ kg}$$

Final mass of gas in the tank is,

$$m_2 = \frac{V_2}{v_2}$$

Substitute 0.03 m^3 **for** V_2 **and** v_2 **for** $0.00094 \text{ m}^3/\text{kg}$**.**

$$m_2 = \frac{V_2}{v_2}$$
$$= \frac{0.03}{0.00094}$$
$$= 31.92 \text{ kg}$$

Therefore the change in the mass of the system is,

$$\Delta m_{system} = m_2 - m_1$$
$$= 31.92 - 2.126$$
$$= 29.79 \text{ kg}$$
$$= 29.8 \text{ kg}$$

Therefore the mass entered the tank is $\boxed{29.8 \text{ kg}}$

Step 3 of 3

(b)

The change of energy in the system is,

$$\Delta E_{system} = E_2 - E_1$$

Here, E_1 **is the initial energy of the system, and** E_2 **is the final energy of the system.**

The above energy equation can be rewritten as,

$$Q + m_{in} h_{in} = m_2 u_2 - m_1 u_1$$

Here, Q **is the heat transferred in the system.**

Substitute the corresponding values in the above equation.

$$Q + m_{in} h_{in} = m_2 u_2 - m_1 u_1$$
$$= m_2 u_2 - m_1 u_1 - m_{in} h_{in}$$
$$= (31.92)(134.43) - (2.127)(256.37) - (29.8)(102.33)$$
$$= 696.266 \text{ kJ}$$

The amount of heat transfer $\boxed{Q = 696.266 \text{ kJ}}$

Question: 6.116P

A 0.3-m3 rigid tank is filled with saturated liquid water at 200°C. A valve at the bottom of the tank is opened, and liquid is withdrawn from the tank. Heat is transferred to the water such that the temperature in the tank remains constant. Determine the amount of heat that must be transferred by the time one-half of the total mass has been withdrawn.

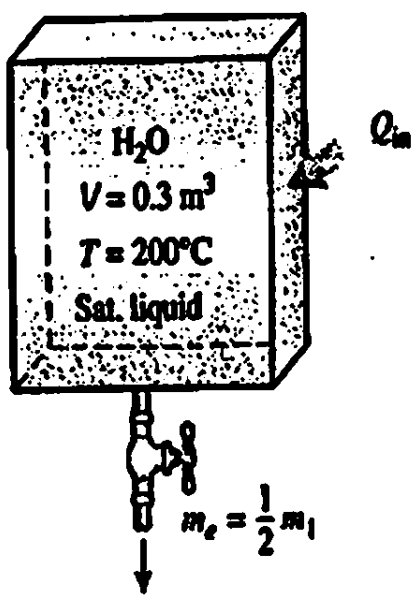

FIGURE P6–116

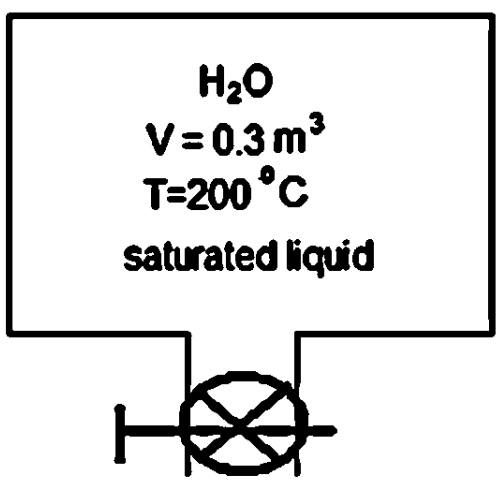
Step 1 of 5

From tables, at temperature of water in the tank $T = 200\ °C$ and saturated liquid condition, properties of water are

$$v_1 = v_f = 0.001157\ m^3/kg$$

$$u_1 = u_f = 850.46\ kJ/kg$$

$$h_1 = h_f = 852.26\ kJ/kg$$



From tables, at temperature $T = 200\ °C$, properties of water are

$$v_g = 0.12721\ m^3/kg$$

$$u_{fg} = 1743.7\ kJ/kg$$

Step 2 of 5

Draw the figure representing the given system,

Step 3 of 5

Initial mass in the tank is calculated by dividing volume of the tank V by initial specific volume

$$m_1 = \frac{V}{v_1}$$

Where,
V is the volume of the tank.

Substitute $0.3\ m^3$ for V in the above equation,

$$m_1 = \frac{0.3}{0.001157}$$
$$= 259.29\ kg$$

Calculate the final mass of the given sytem,

$$m_2 = \frac{m_1}{2}$$

Where,
m_1 is the initial mass of the system,

$$m_2 = \frac{259.29}{2}$$
$$= 129.645\ kg$$

Step 4 of 5

Apply the mass balance to the given system,

$$m_e = m_1 - m_2$$
$$= 259.29 - 129.645$$
$$= 129.645\ kg$$

Calculate the final specific volume of the given system,

$$v_2 = \frac{V}{m_2}$$
$$= \frac{0.3}{129.645}$$
$$= 0.00231\ m^3/kg$$

Calculate the final quality of the given system,

$$x_2 = \frac{v_2 - v_f}{v_{fg}}$$
$$= \frac{v_2 - v_f}{v_g - v_f}$$
$$= \frac{0.00231 - 0.001157}{0.12721 - 0.001157}$$
$$= \frac{0.001153}{0.126053}$$
$$= 0.009147$$

Step 5 of 5

Calculate the final internal energy of the given system,

$$u_2 = u_f + x_2 \times u_{fg}$$
$$= 850.46 + 0.009147 \times 1743.7$$
$$= 850.46 + 15.9496$$
$$= 866.4096\ kJ/kg$$

Apply the energy balance to the given system,

$$E_{in} - E_{out} = E_{sys}$$

$$Q_{in} - m_e \times h_e = m_2 \times u_2 - m_1 \times u_1$$

$$Q_{in} = m_e \times h_e + m_2 \times u_2 - m_1 \times u_1$$
$$= 129.645 \times 852.26 + 129.645 \times 866.4096 - 259.29 \times 850.46$$
$$= 110491.247 + 112325.672 - 220515.773$$
$$= 2301.146\ kJ$$

Therefore, the heat transferred into the tank is $\boxed{2301.146\ kJ}$

Question: 6.117P

A 0.12-m3 rigid tank contains saturated refrigerant-134a at 800 kPa. Initially, 25 percent of the volume is occupied by liquid and the rest by vapor. A valve at the bottom of the tank is now opened, and liquid is withdrawn from the tank. Heat is transferred to the refrigerant such that the pressure inside the tank remains constant. The valve is closed when no liquid is left in the tank and vapor starts to come out. Determine the total heat transfer for this process.

Step 1 of 7

From tables, at pressure of R-134a in the tank $P=800\ \text{kPa}$ properties of R-134a are

$$v_f = 0.0008458\ \text{m}^3/\text{kg}$$

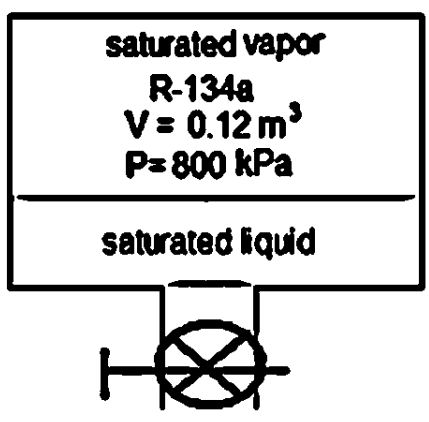
$$v_g = 0.025621\ \text{m}^3/\text{kg}$$

$$u_f = 94.79\ \text{kJ/kg}$$

$$u_g = 246.79\ \text{kJ/kg}$$

From tables, at pressure of R-134a in the tank $P=800\ \text{kPa}$ and saturated vapor condition, properties of R-134a are

$$v_2 = v_g = 0.025621\ \text{m}^3/\text{kg}$$



$$u_2 = u_g = 246.79\ \text{kJ/kg}$$

From tables, at pressure of R-134a in the tank $P=800\ \text{kPa}$ and saturated liquid condition, properties of R-134a are

$$h_1 = h_f = 95.47\ \text{kJ/kg}$$

Step 2 of 7

Draw the figure representing the given system,

Step 3 of 7

As 25% of refrigerant is in liquid phase, volume of liquid refrigerant is

$$V_f = 0.25 \times V$$

Where,
V is the volume of the tank.
Substitute $\left(0.12\ \text{m}^3\right)$ for V in the above equation,

$$V_f = 0.25 \times 0.12$$

$$= 0.03\ \text{m}^3$$

Step 4 of 7

As 75% of refrigerant is in vapor phase, volume of vapor refrigerant is

$$V_g = 0.75 \times V$$

Where,
V is the volume of the tank.
Substitute $\left(0.12\ \text{m}^3\right)$ for V in the above equation,

$$V_g = 0.75 \times 0.12$$

$$= 0.09\ \text{m}^3$$

Initial mass in the tank is calculated by adding the mass of liquid and vapor phases

$$m_1 = m_f + m_g$$

Mass of liquid refrigerant is calculated by dividing volume with specific volume and so

$$m_1 = \frac{V_f}{v_f} + \frac{V_g}{v_g}$$

$$= \frac{0.03}{0.0008458} + \frac{0.09}{0.025621}$$

$$= 35.4694 + 3.5127$$

$$= 38.9821\ \text{kg}$$

Step 5 of 7

Calculate the initial internal energy of the given system,

$$U_1 = m_1 \times u_1$$

$$= m_f \times u_f + m_g \times u_g$$

$$= \frac{V_f}{v_f} \times u_f + \frac{V_g}{v_g} \times u_g$$

$$= \frac{0.03}{0.0008458} \times 94.79 + \frac{0.09}{0.025621} \times 246.79$$

$$= 35.4694 \times 94.79 + 3.5127 \times 246.79$$

$$= 3362.144 + 866.899$$

$$= 4229.043\ \text{kJ}$$

Calculate the final mass of refrigerant,

$$m_2 = \frac{V}{v_2}$$

$$= \frac{0.12}{0.025621}$$

$$= 4.6837\ \text{kg}$$

Step 6 of 7

Apply the mass balance to the given system,

$$m_e = m_1 - m_2$$

$$= 38.9821 - 4.6837$$

$$= 34.2984\ \text{kg}$$

Apply the energy balance to the given system,

$$E_{in} - E_{out} = E_{sys}$$

$$Q_{in} - m_e \times h_e = m_2 \times u_2 - m_1 \times u_1$$

$$Q_{in} = m_e \times h_e + m_2 \times u_2 - U_1$$

Step 7 of 7

Substitute the respective values in the above equation,

$$Q_{in} = 34.2984 \times 95.47 + 4.6837 \times 246.79 - 4229.043$$

$$= 3274.468 + 1155.89 - 4229.043$$

$$= 201.315\ \text{kJ}$$

Therefore, the heat transferred into the tank is $\boxed{201.315\ \text{kJ}}$

Question: 6.118P

A 2-ft3 rigid tank contains saturated refrigerant-134a at 160 psia. Initially, 5 percent of the volume is occupied by liquid and the rest by vapor. A valve at the top of the tank is now opened, and vapor is allowed to escape slowly from the tank. Heat is transferred to the refrigerant such that the pressure inside the tank remains constant. The valve is closed when the last drop of liquid in the tank is vaporized. Determine the total heat transfer for this process.

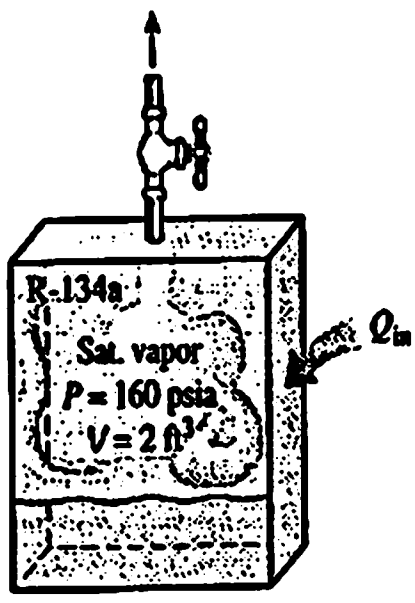


FIGURE P6–118E

Step 1 of 5

Given

The volume of the rigid tank, $V = 2\ \text{ft}^3$

Initial pressure of R-134a, $P_1 = 160$ psia

5% volume is liquid 95% is vapor of refrigerant R-134a

Step 2 of 5

From saturated R-134a tables, at 160 psia,

Specific volume of liquid, $v_f = 0.01413\ \text{ft}^3/\text{lbm}$

Specific volume of vapor, $v_g = 0.29316\ \text{ft}^3/\text{lbm}$

Internal energy of liquid, $u_f = 48.1$ Btu/lbm

Internal energy of vapor, $u_g = 108.5$ Btu/lbm

Enthalpy of vapor, $h_g = 117.18$ Btu/lbm

Step 3 of 5

The initial mass of refrigerant, $m_1 = m_f + m_g$

$$m_1 = \frac{V_f}{v_f} + \frac{V_g}{v_g}$$

$$m_1 = \frac{0.05 \times 2}{0.01413} + \frac{0.95 \times 2}{0.29316}$$

$$m_1 = 7.077 + 6.48$$

$$m_1 = 13.557\ \text{lbm}$$

Final mass of refrigerant, $m_2 = \frac{V}{v_2}$

$$m_2 = \frac{V}{v_g}$$

$$m_2 = \frac{2}{0.29316}$$

$$m_2 = 6.82\ \text{lbm}$$

Step 4 of 5

From mass balance, $m_{in} - m_{out} = \Delta m_{system}$

$$m_1 - m_2 = m_e$$

$$m_e = m_1 - m_2$$

$$m_e = 13.56 - 6.822$$

$$m_e = 6.738\ \text{lbm}$$

The initial internal energy, $U_1 = m_1 u_1$

$$U_1 = m_f u_f + m_g u_g$$

$$U_1 = (7.077)48.1 + (6.48)(108.5)$$

$$U_1 = 340.4 + 703.08$$

$$U_1 = 1043.48\ \text{Btu}$$

Step 5 of 5

The final internal energy, $U_2 = m_2 u_2$

$$U_2 = 6.82 \times 108.5$$

$$U_2 = 739.97\ \text{Btu}$$

From Energy balance, $E_{in} - E_{out} = \Delta E_{system}$

$$Q_{in} - m_e h_e = m_2 u_2 - m_1 u_1$$

$$Q_{in} = m_e h_e + U_2 - U_1$$

$$Q_{in} = (6.738 \times 117.18) + 739.97 - 1043.48$$

$$Q_{in} = 486\ \text{Btu}$$

Hence, the heat that must be transferred is $\boxed{Q_{in} = 486\ \text{Btu}}$

Question: 6.119P

A 0.4-m3 rigid tank initially contains refrigerant-134a at 14°C. At this state, 70 percent of the mass is in the vapor phase, and the rest is in the liquid phase. The tank is connected by a valve to a supply line where refrigerant at 1 MPa and 100°C flows steadily. Now the valve is opened slightly, and the refrigerant is allowed to enter the tank. When the pressure in the tank reaches 700 kPa, the entire refrigerant in the tank exists in the vapor phase only. At this point the valve is closed. Determine (a) the final temperature in the tank, (b) the mass of refrigerant that has entered the tank, and (*c*) the heat transfer between the system and the surroundings.

Step 1 of 6

Given

Volume of the rigid tank, $V = 0.4\ \text{m}^3$

Initial temperature of R-134a, $T_1 = 14°\text{C}$

Initial quality of R-134a, $x_1 = 70\%$

Pressure of R-134a in supply line, $P_{in} = 1\ \text{MPa}$

Temperature of R-134a in supply line, $T_{in} = 100°\text{C}$

Final pressure of R-134a, $P_2 = 700\ \text{kPa}$

Final quality of R-134a, $x_2 = 100\%$

Step 2 of 6

(a)

From saturated R-134a tables, at 14°C

Specific volume of liquid, $v_f = 0.0008\ \text{m}^3/\text{kg}$

Specific volume of vapor, $v_g = 0.04342\ \text{kJ/kg}$

Specific volume initially, $v_1 = v_f + xv_{fg}$

$$v_1 = v_f + x\left(v_g - v_f\right)$$

$$v_1 = 0.0008 + 0.7(0.04342 - 0.0008)$$

$$v_1 = 0.0008 + 0.02983$$

$$v_1 = 0.03063\ \text{m}^3/\text{kg}$$

Step 3 of 6

From saturated R-134a tables, at 14°C

Internal energy of liquid, $u_f = 70.57\ \text{kJ/kg}$

Internal energy for vaporization, $u_{fg} = 167.26\ \text{kJ/kg}$

Internal energy initially, $u_1 = u_f + xu_{fg}$

$$u_1 = 70.57 + (0.7 \times 167.26)$$

$$u_1 = 70.57 + 117.082$$

$$u_1 = 187.652\ \text{kJ/kg}$$

Step 4 of 6

From saturated R-134a tables, at 700kPa

Specific volume of vapor, $v_2 = v_g = 0.02936\ \text{m}^3/\text{kg}$

Internal energy of vapor, $u_2 = u_g = 244.48\ \text{kJ/kg}$

From superheated R-134a tables, at 1 MPa and 100°C

Enthalpy of vapor, $h_i = 335.06\ \text{kJ/kg}$

Saturation temperature, $T_{sat} = 26.69°\text{C}$

As the tank contains saturated vapor, the temperature also corresponds to saturation temperature. Hence final temperature of the tank is $\boxed{T_2 = 26.69°\text{C}}$

Step 5 of 6

(b)

The initial mass in tank, $m_1 = \dfrac{V_1}{v_1}$

$$m_1 = \frac{0.4}{0.0306}$$

$$m_1 = 13.06\ \text{kg}$$

The final mass in tank, $m_2 = \dfrac{V_2}{v_2}$

$$m_2 = \frac{0.4}{0.02936}$$

$$m_2 = 13.62\ \text{kg}$$

From Mass balance, $m_{in} - m_{out} = \Delta m_{system}$

$$m_1 - m_2 = m_{in}$$

$$m_{in} = m_1 - m_2$$

$$m_{in} = 13.62 - 13.06$$

$$m_{in} = 0.56\ \text{kg}$$

Therefore the mass entered to the tank $\boxed{m_{in} = 0.56\ \text{kg}}$

Step 6 of 6

(c)

From energy balance, $E_{in} - E_{out} = \Delta E_{system}$

$$Q_{in} + m_{in}h_{in} = m_2u_2 - m_1u_1$$

$$Q_{in} = m_2u_2 - m_1u_1 - m_{in}h_{in}$$

$$Q_{in} = m_2u_2 - m_1u_1 - m_{in}h_{in}$$

$$Q_{in} = (13.62)(244.48) - (13.06)(187.65) - (0.56)(335.06)$$

$$Q_{in} = 3329.8 - 2450.71 - 187.6336$$

$$Q_{in} = 691.4565\ \text{kJ}$$

The amount of heat transfer $\boxed{Q_{in} = 691.4565\ \text{kJ}}$

Question: 6.120P

The air-release flap on a hot-air balloon is used to release hot air from the balloon when appropriate. On one hot-air balloon, the air release opening has an area of 0.5 m2, and the filling opening has an area of 1 m2. During a two minute adiabatic flight maneuver, hot air enters the balloon at 100 kPa and 35°C with a velocity of 2 m/s; the air in the balloon remains at 100 kPa and 35°C; and air leaves the balloon through the air-release flap at velocity 1 m/s. At the start of this maneuver, the volume of the balloon is 75 m3. Determine the final volume of the balloon and work produced by the air inside the balloon as it expands the balloon skin.

FIGURE P6–120

© Vol. 55/PhotoDisc/Getty Images.

Step 1 of 6

From tables, universal gas constant of air,

$$R = 0.287\ \text{kJ/kg}\cdot\text{K}$$

Specific volume of air at inlet & exit of balloon is given by gas equation, where T is temperature and P is the pressure inside the balloon

$$v = \frac{R \times T}{P}$$

$$= 0.88396\ \text{m}^3/\text{kg}$$

Substitute 35°C for T and 100 Pa for P in the above equation,

$$v = \frac{R \times T}{P}$$

$$= \frac{0.287 \times (35+273)}{100}$$

$$= \frac{0.287 \times 308}{100}$$

$$= 0.88396\ \text{m}^3/\text{kg}$$

Step 2 of 6

Mass flow rate at the entrance of the balloon is given by

$$m_i = \frac{A_i \times C_i}{v}$$

where A_i is the area of cross section and C_i is the velocity of air at entrance

Substitute 1m^2 for A_i, 2 m/s for C_i and 2 kg/s for v in the above equation,

$$m_i = \frac{1 \times 2}{0.88396}$$

$$= \frac{2}{0.88396}$$

$$= 2.249\ \text{kg/s}$$

Step 3 of 6

Mass flow rate at the exit of the balloon is given by

$$m_e = \frac{A_e \times C_e}{v}$$

where A_e is the area of cross section and C_e is the velocity of air at entrance

Substitute 0.5m^2 for A_i, 1 m/s for C_i and .88396 kg/s for v in the above equation,

$$m_e = \frac{0.5 \times 1}{0.88396}$$

$$= \frac{0.5}{0.88396}$$

$$= 0.5656\ \text{kg/s}$$

Step 4 of 6

Apply mass balance to the given system,

$$m_{in} - m_{out} = \Delta m_{sys}$$

In order to convert mass flow rate into mass we multiply it with time (Δt) and so

$$m_i \times \Delta t - m_e \times \Delta t = m_2 - m_1$$

$$m_2 - m_1 = (m_i - m_e) \times \Delta t$$

Substitute the respective values in the above equation,

$$m_2 - m_1 = (2.249 - 0.5656) \times (2 \times 60)$$

$$= 1.6834 \times 120$$

$$= 202.008\ \text{kg}$$

Step 5 of 6

Calculate the change in the volume of the balloon,

$$\Delta V = (m_2 - m_1) \times v$$

$$= (202.008) \times 0.88396$$

$$= 178.567\ \text{m}^3$$

Calculate the final volume of air in the balloon,

$$V_2 = V_1 + \Delta V$$

where V_1 is the initial volume of air in the balloon

Substitute the respective values in the above equation,

$$V_2 = 75 + 178.567$$

$$= 253.567\ \text{m}^3$$

Step 6 of 6

Calculate the work done by the air,

$$W = P \times \Delta V$$

$$= 100 \times 178.567$$

$$= 17856.7\ \text{kJ}$$

Therefore, the final volume of air in the balloon is $\boxed{V_2 = 253.567\ \text{m}^3}$ and the work done by the air is $\boxed{W = 17856.7\ \text{kJ}}$

Question: 6.121P

An insulated 0.15-m3 tank contains helium at 3 MPa and 130°C. A valve is now opened, allowing some helium to escape. The valve is closed when one-half of the initial mass has escaped. Determine the final temperature and pressure in the tank.

Step 1 of 4

Given

Volume of the insulated tank $V = 0.4\ \text{m}^3$

Initial temperature $T_1 = 130°C = 130+273 = 403K$, Initial pressure $P_1 = 3\ \text{MPa}$

$$m_2 = \frac{m_1}{2}$$

Step 2 of 4

Mass balance

$$\dot{m}_{in} - \dot{m}_{out} = \Delta m_{system}$$

$$m_e = m_1 - m_2$$

Energy balance

$$E_{in} - E_{out} = \Delta E_{system}$$

$$Q_{in} - m_e(h_e) = m_2(u_2) - m_1u_1$$

(Since $w = 0$ and $ke = 0, pe = 0$)

Step 3 of 4

From mass balance

$$m_e = m_1 - \frac{m_1}{2} = \frac{m_1}{2}$$

Energy balance

Since insulated $Q_{in} = 0$

$$0 - \frac{m_1}{2}(h_e) = \frac{m_1}{2}(u_2) - m_1u_1$$

We have $h = c_pT, u = c_vT$

Removing m_1 $$0 - \frac{1}{2}\left(c_p\left(\frac{T_1+T_2}{2}\right)\right) = \frac{1}{2}(c_vT_2) - c_vT_1$$

We know gas constant $k = \frac{c_p}{c_v}$, here for helium k = 1.667 (table A-2)

$$0 - \frac{1}{2}\left(kc_v\left(\frac{T_1+T_2}{2}\right)\right) = \frac{1}{2}(c_vT_2) - c_vT_1$$

Removing c_v $$0 - \frac{1}{2}\left((1.667)\left(\frac{403+T_2}{2}\right)\right) = \frac{1}{2}(T_2) - 403$$

The final temperature $\boxed{T_2 = 257K}$

Step 4 of 4

The final pressure in the tank

$$P_1V = m_1RT_1, P_2V = m_2RT_2$$

$$\frac{P_2}{P_1} = \frac{m_2T_2}{m_1T_1}$$

$$\frac{P_2}{3000} = \frac{1(257)}{2(403)}$$

$$\boxed{P_2 = 956.5\ \text{kPa}}$$

Question: 6.122P

An insulated 60-ft3 rigid tank contains air at 75 psia and 120°F. A valve connected to the tank is now opened, and air is allowed to escape until the pressure inside drops to 30 psia. The air temperature during this process is maintained constant by an electric resistance heater placed in the tank. Determine the electrical work done during this process.

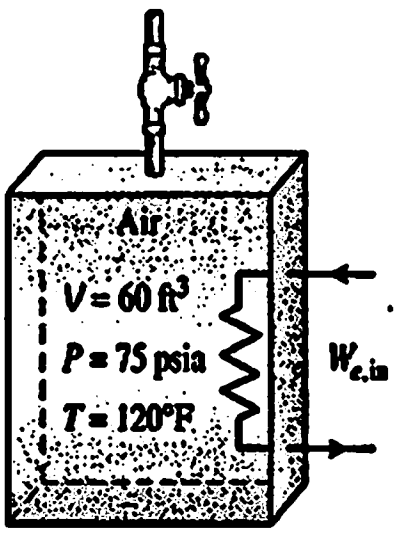

FIGURE P6–122E

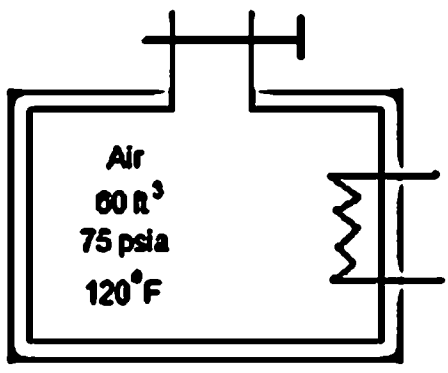
Step 1 of 5

From tables, gas constant of air is

$$R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$$

From tables, at temperature of air in the tank $T = 120°\text{F} = 580 \text{ R}$, properties of air are



$$h_1 = 138.66 \text{ Btu/lbm}$$

$$u_1 = 98.9 \text{ Btu/lbm}$$

$$u_2 = 98.9 \text{ Btu/lbm}$$

Step 2 of 5

Draw the figure representing the given system,

Step 3 of 5

From the gas equation, initial mass of air in the tank,

$$m_1 = \frac{P_1 \times V}{T_1 \times R}$$

Substituting the value of the volume of the tank V and initial pressure P_1 in the above equation we get

$$m_1 = \frac{75 \times 60}{580 \times 0.3704}$$
$$= \frac{4500}{214.832}$$
$$= 20.947 \text{ kg}$$

Step 4 of 5

From the gas equation, final mass of air in the tank is given by

$$m_2 = \frac{P_2 \times V}{T_2 \times R}$$

Substituting the value of the volume of the tank V and initial pressure P_1 in the above equation we get

$$m_2 = \frac{30 \times 60}{580 \times 0.3704}$$
$$= \frac{1800}{214.832}$$
$$= 8.379 \text{ kg}$$

Step 5 of 5

Apply the mass balance to the given system,

$$m_e = m_1 - m_2$$
$$= 20.947 - 8.379$$
$$= 12.568 \text{ lbm}$$

Apply the energy balance to the given system,

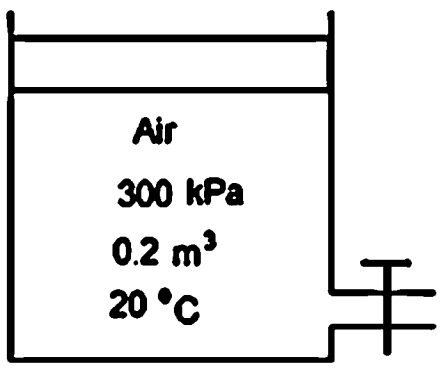
$$E_{in} - E_{out} = E_{sys}$$
$$W_{in} - m_e \times h_e = m_2 \times u_2 - m_1 \times u_1$$
$$W_{in} = m_e \times h_e + m_2 \times u_2 - m_1 \times u_1$$

Substitute the respective values in the above equation,

$$W_{in} = 12.568 \times 138.66 + 8.379 \times 98.9 - 20.947 \times 98.9$$
$$= 1742.679 + 828.683 - 2071.658$$
$$= 499.704 \text{ Btu}$$

Therefore, the work done on the tank is $\boxed{499.704 \text{ Btu}}$

Question: 6.123P



A vertical piston–cylinder device initially contains 0.2 m3 of air at 20°C. The mass of the piston is such that it maintains a constant pressure of 300 kPa inside. Now a valve connected to the cylinder is opened, and air is allowed to escape until the volume inside the cylinder is decreased by one-half. Heat transfer takes place during the process so that the temperature of the air in the cylinder remains constant. Determine (a) the amount of air that has left the cylinder and (b) the amount of heat transfer.

Step 1 of 5

From tables, gas constant of air is

$$R = 0.287 \text{ kJ/kg°K}$$

Draw the figure representing the given system,

Step 2 of 5

Initial mass of air in the cylinder is given by the gas equation

$$m_1 = \frac{P_1 \times V_1}{R \times T_1}$$

where P_1 is the initial pressure, T_1 is the initial temperature and V_1 is the initial volume of air in the cylinder

Substitute 300 kPa for P_1, 0.2 m³ for V_1, 20°C for T_1 and the respective values in the above equation,

$$\begin{aligned} m_1 &= \frac{300 \times 0.2}{0.287 \times (20+273)} \\ &= \frac{300 \times 0.2}{0.287 \times 293} \\ &= \frac{60}{84.091} \\ &= 0.7134 \text{ kg} \end{aligned}$$

Step 3 of 5

The final volume is half of the initial volume and so

$$V_2 = \frac{V_1}{2}$$

Final mass of air in the cylinder is given by the gas equation

$$m_2 = \frac{P_2 \times V_2}{R \times T_2}$$

where P_2 is the final pressure, T_2 is the final temperature and V_2 is the final volume of air in the cylinder

Substitute 300 kPa for P_2, 0.2 m³ for V_1, 20°C for T_1 and the respective values in the above equation,

$$\begin{aligned} m_2 &= \frac{P_2}{R \times T_2} \times \frac{V_1}{2} \\ &= \frac{300}{0.287 \times (20+273)} \times \frac{0.2}{2} \\ &= \frac{300 \times 0.1}{0.287 \times 293} \\ &= 0.3567 \text{ kg} \end{aligned}$$

Step 4 of 5

(a)

Apply the mass balance to the given system,

$$\begin{aligned} m_{in} - m_{out} &= \Delta m_{sys} \\ 0 - m_e &= m_2 - m_1 \\ -m_e &= m_2 - m_1 \\ m_e &= m_1 - m_2 \\ &= 0.7134 - 0.3567 \\ &= 0.3657 \text{ kg} \end{aligned}$$

Step 5 of 5

As the there is no temperature of air in the cylinder the enthalpies will be same and so

$$h_1 = h_2 = h_e$$

(b)

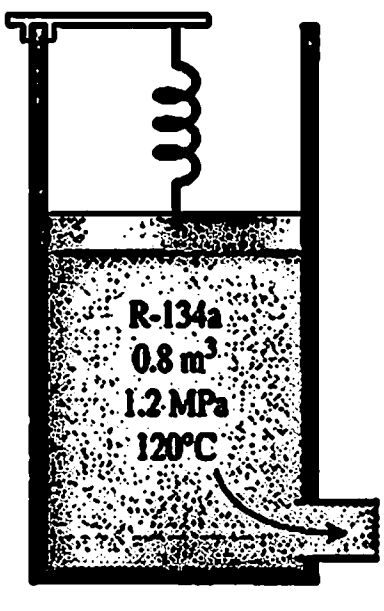
Apply the energy balance to the given system,

$$\begin{aligned} E_{in} - E_{out} &= \Delta E_{sys} \\ Q_{in} - m_e \times h_e &= m_2 \times h_2 - m_1 \times h_1 \\ Q_{in} &= m_e \times h_e + m_2 \times h_2 - m_1 \times h_1 \\ Q_{in} &= m_e \times h_1 + m_2 \times h_1 - m_1 \times h_1 \\ &= (m_e + m_2 - m_1) \times h_1 \\ &= (0.7134 + 0.3657 - 0.3657) \times h_1 \\ &= 0 \times h_1 \\ &= 0 \end{aligned}$$

Therefore, the amount of air left in the cylinder is $\boxed{m_e = 0.3657 \text{ kg}}$ and the heat transferred into the cylinder is $\boxed{Q_{in} = 0}$

Question: 6.124P pg 1

An insulated vertical piston–cylinder device initially contains 0.8 m3 of refrigerant-134a at 1.2 MPa and 120°C. A linear spring at this point applies full force to the piston. A valve connected to the cylinder is now opened, and refrigerant is allowed to escape. The spring unwinds as the piston moves down, and the pressure and volume drop to 0.6 MPa and 0.5 m3 at the end of the process. Determine (a) the amount of refrigerant that has escaped and (b) the final temperature of the refrigerant.



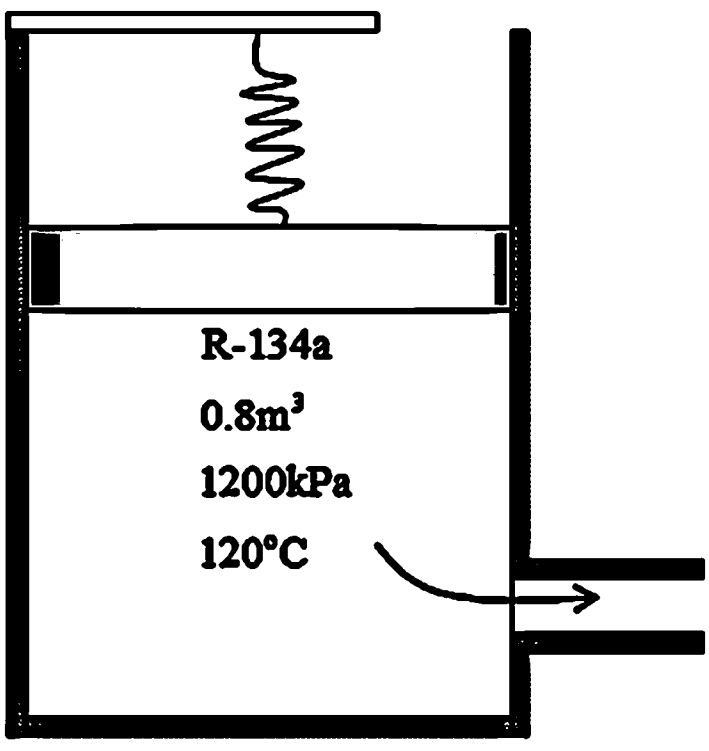


FIGURE P6–124

Step 1 of 12

Draw the Schematic figure of the piston cylinder.

Step 2 of 12

Obtain the properties of R-134a at a Pressure of 1200 kPa and temperature $120°C$ from the table A-13 "saturated refrigerant -134 a".

Specific volume at state-1 is $v_1 = 0.02423 m^3/kg$,

Specific internal energy at state-1is $u_1 = 325.03 kJ/kg$

Specific enthalpy at state-1is $h_1 = 354.11 kJ/kg$

Step 3 of 12

Calculate the initial mass of the refrigerant inside the cylinder.

$$m_1 = \frac{V_1}{v_1}$$

Here, the initial volume of the cylinder is V_1 and the Specific volume at state-1 is v_1 .

Substitute $0.8 m^3$ for V_1 and $0.02423 m^3/kg$ for v_1 .

$$m_1 = \frac{V_1}{v_1}$$
$$= \frac{0.8(m^3)}{0.02423(m^3/kg)}$$
$$= 33.02 kg$$

Step 4 of 12

Calculate the final mass of the refrigerant inside the cylinder,

$$m_2 = \frac{V_2}{v_2}$$

Here, the final volume of the cylinder is V_2 and the Specific volume at state-2 is v_2 .

Substitute $0.5 m^3$ for .

$$m_2 = \frac{V_2}{v_2}$$
$$= \frac{0.5}{v_2}$$

Apply mass balance to the system.

For a steady flow device,

$$\dot{m}_{in} - \dot{m}_{out} = \Delta m_{system}$$
$$m_e = m_1 - m_2$$

Substitute 33.02 kg for m_2 and $\frac{0.5}{v_2}$ for m_1 .

$$m_e = m_2 - m_1$$
$$= \left(33.02 - \frac{0.5}{v_2}\right) \quad \text{..... (1)}$$

Step 5 of 12

Calculate the boundary work during the process assuming average pressure as shown below:

Step 5 of 12

Calculate the boundary work during the process assuming average pressure as shown below:

$$W_{b,in} = \frac{P_1 + P_2}{2}(V_1 - V_2)$$

Here, the initial pressure inside the cylinder is P_1 and the final pressure inside the cylinder is P_2.

Substitute $1200\,\text{kPa}$ for P_1, $600\,\text{kPa}$ for P_2, $0.8\,\text{m}^3$ for V_1 and $0.5\,\text{m}^3$ for V_2,

$$\begin{aligned} W_{b,in} &= \frac{P_1 + P_2}{2}(V_1 - V_2) \\ &= \frac{(1200+600)}{2}(\text{kPa}) \times (0.8-0.5)(\text{m}^3) \\ &= 270\,\text{kJ} \end{aligned}$$

Step 6 of 12

The enthalpy of fluid at the exit is assumed to be the average of initial and final enthalpies of the refrigerant in the cylinder. Therefore,

$$h_e = \frac{h_1 + h_2}{2}$$

Substitute $354.11\,\text{kJ/kg}$ for h_1 .

$$h_e = \frac{(354.11 + h_2)}{2}(\text{kJ/kg})$$

Step 7 of 12

Apply energy balance to the system.

$$E_{in} - E_{out} = \Delta E_{system}$$

$$W_{b,in} - m_e h_e = m_2 u_2 - m_1 u_1$$

Substitute 270kJ for $W_{b,in}$, $\left(33.02 - \frac{0.5}{v_2}\right)$ for m_e , $\frac{(354.11 + h_2)}{2}$ for h_e , $\left(\frac{0.5}{v_2}\right)$ for m_2 ,

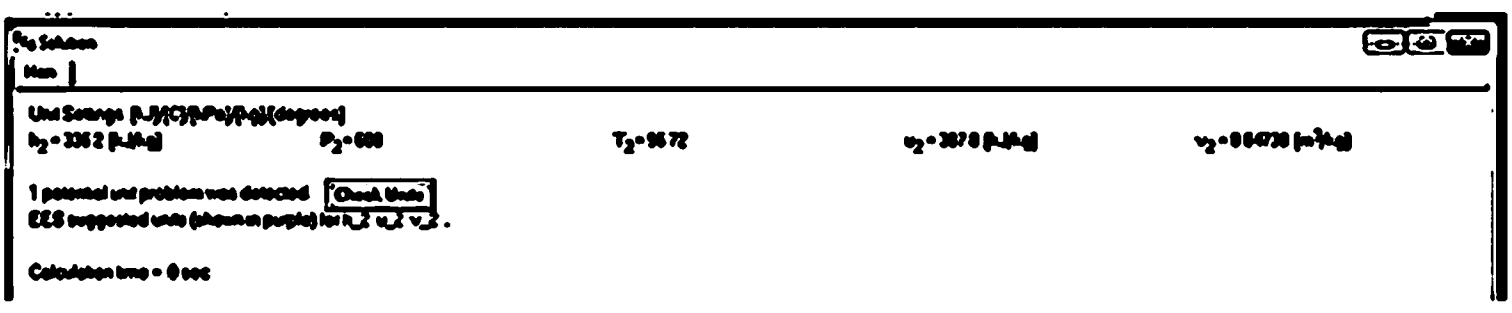
$325.03\,\text{kJ/kg}$ for u_1 , and 33.02 kg for m_1 .

$$270 - \left(33.02 - \frac{0.5}{v_2}\right)\left[\frac{(354.11 + h_2)}{2}\right] = \left(\frac{0.5}{v_2}\right)u_2 - 33.02 \times 325.03 \quad \ldots\ldots (3)$$

Final state properties of the refrigerant R-134a h_2, u_2 and v_2 are all functions of final pressure (known) and temperature (unknown).

The solution may be obtained by a trial-error approach by trying different final state temperatures or by using EES software until equation (3) is satisfied.

Step 8 of 12



Write the equations in EES software as shown below.

Equations Window

```
h_2=Enthalpy(R134a,T=T_2,P=P_2)
u_2=IntEnergy(R134a,T=T_2,P=P_2)
v_2=Volume(R134a,T=T_2,P=P_2)
270-((33.02-(0.5/v_2)))*((354.11+h_2)/2)=((0.5/v_2)*u_2)-(33.02*325.03)
P_2=0.6*1000
```

Step 9 of 12

The results obtained by solving the above equation are shown below:

Step 10 of 12

The properties at the final state are:

The temperature at final state is $T_2 = 96.72°\text{C}$

The enthalpy at final state is $h_2 = 336.20\ \text{kJ/kg}$

The internal energy at final state is $u_2 = 307.8\ \text{kJ/kg}$

The specific volume at final state is $v_2 = 0.04738\ \text{m}^3/\text{kg}$

Step 11 of 12

(a)

Calculate the amount of refrigerant that has escaped.

$$m_e = \left(33.02 - \frac{0.5}{v_2}\right)$$

Substitute $0.04739\ \text{m}^3/\text{kg}$ for v_2 in equation (1).

$$\begin{aligned} m_e &= \left(33.02 - \frac{0.5}{0.047438}\right) \\ &= 22.46\ \text{kg} \end{aligned}$$

Therefore, the amount of refrigerant escaped is $\boxed{22.46\ \text{kg}}$

Step 12 of 12

(b)

The final temperature of the refrigerant is $\boxed{96.72°\text{C}}$.

Step 12 of 12

(b)

The final temperature of the refrigerant is $\boxed{96.72^{\circ}C}$.

Question: 6.125P pg 1

A piston-cylinder device initially contains 0.6 kg of steam with a volume of 0.1 m3. The mass of the piston is such that it maintains a constant pressure of 800 kPa. The cylinder is connected through a valve to a supply line that carries steam at 5 MPa and 500°C. Now the valve is opened and steam is allowed to flow slowly into the cylinder until the volume of the cylinder doubles and the temperature in the cylinder reaches 250°C, at which point the valve is closed. Determine (a) the mass of steam that has entered and (b) the amount of heat transfer.

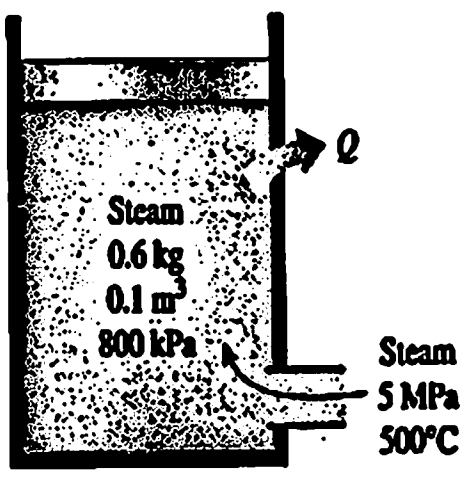


FIGURE P6–125

Step 1 of 10

Initial specific volume of steam in the cylinder is,

$v_1 = \frac{V_1}{m_1}$ Here, the initial volume and initial mass of steam in the cylinder respectively are V_1 and m_1.

Step 2 of 10

Substitute, $0.1\ m^3$ for V_1 and, 0.6 kg for m_1 in the equation,

$$\begin{aligned} v_1 &= \frac{V_1}{m_1} \\ &= \frac{0.1}{0.6} \\ &= 0.1667\ m^3 \end{aligned}$$

Step 3 of 10

Initial specific volume is also given by

$$\begin{aligned} v_1 &= v_{f1} + x_1 \times v_{fg1} \\ &= v_{f1} + x_1 \times (v_{g1} - v_{f1}) \end{aligned}$$

Here, the saturated liquid and saturated vapor specific volumes at that pressure and x_1 is the initial quality of steam are v_{f1} and v_{g1}.

From saturated water pressure table, at initial pressure of steam 800 kPa. Substitute, $0.1667\ m^3$ for v_1, $0.001115\ m^3$ for v_{f1} and, $0.24035\ m^3$ for v_{g1} in the equation,

$$\begin{aligned} v_1 &= v_{f1} + x_1 \times (v_{g1} - v_{f1}) \\ 0.1667 &= 0.001115 + x_1 \times (0.24035 - 0.001115) \\ 0.1667 &= 0.001115 + x_1 \times 0.239235 \\ x_1 &= \frac{0.1667 - 0.001115}{0.239235} \\ &= \frac{0.165585}{0.239235} \\ &= 0.6921 \end{aligned}$$

Step 4 of 10

Initial internal energy is, $u_1 = u_{f1} + x_1 \times u_{fg1}$ Here, the saturated liquid and vaporization specific volumes at that pressure are u_{f1} and u_{fg1}.

Step 5 of 10

From saturated water pressure table, at initial pressure of steam 800 kPa. Substitute, $710.97\ kJ/kg$ for u_{f1}, $1856.1\ kJ/kg$ for u_{fg1} and, 0.6921 for x_1 in the equation,

$$\begin{aligned} u_1 &= u_{f1} + x_1 \times u_{fg1} \\ &= 710.97 + 0.6921 \times 1856.1 \\ &= 710.97 + 1284.607 \\ &= 1995.577\ kJ/kg \end{aligned}$$

Step 6 of 10

The final volume in the cylinder is double the initial volume

$V_2 = 2 \times V_1$

Here, the initial volume and initial mass of steam in the cylinder respectively are V_1 and m_1.

Substitute, $0.1\ m^3$ for V_1 and, 0.6 kg for m_1 in the equation,

$$\begin{aligned} V_2 &= 2 \times V_1 \\ &= 2 \times 0.1 \\ &= 0.2\ m^3 \end{aligned}$$

Step 7 of 10

Final mass of steam in the cylinder is

$m_2 = \frac{V_2}{v_2}$

Here, specific volume at stage 2 is v_2.

Since the cylinder pressure is constant from superheated water table, at pressure $800\ kPa$ and, temperature $T_2 = 250\ °C$, specific volume and internal energy are $0.29321\ m^3/kg$

Substitute, $0.29321\ m^3/kg$ for v_2 and, $0.2\ m^3$ for V_2 in the equation,

$$\begin{aligned} m_2 &= \frac{V_2}{v_2} \\ &= \frac{0.2}{0.29321} \end{aligned}$$

$$m_2 = \frac{V_2}{v_2}$$
$$= \frac{0.2}{0.29321}$$
$$= 0.6821\,\text{kg}$$

Mass of steam entered the cylinder is

$$m_f = m_2 - m_1$$

Here, mass of steam entered in the cylinder at stage 1 is m_1 and, mass of steam entered in the cylinder at stage 2 is m_2

Substitute, 0.6 kg for m_1 and, 0.6821 kg for m_2 in the equation,

$$m_f = m_2 - m_1$$
$$= 0.6821 - 0.6$$
$$= 0.0821\,\text{kg}$$

The net mass entered the cylinder is $\boxed{0.0821\,\text{kg}}$.

Step 8 of 10

Work output is given by the formula,

$$W_{out} = P \times (V_2 - V_1)$$

Here, pressure is denoted by *P*, volume at stage 1 is V_1 and, volume at stage 2 is V_2.

Substitute, 800 kPa for *P*, $0.1\,\text{m}^3$ for V_1 and, $0.2\,\text{m}^3$ for V_2 in the equation,

$$W_{out} = P \times (V_2 - V_1)$$
$$= 800 \times (0.2 - 0.1)$$
$$= 800 \times 0.1$$
$$= 80\,\text{kJ}$$

Step 9 of 10

Energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$
$$Q_{in} + m_f \times h_f - W_{out} = m_2 \times u_2 - m_1 \times u_1$$
$$Q_{in} = m_2 \times u_2 - m_1 \times u_1 - m_f \times h_f + W_{out}$$

Here, mass of the steam at stage 1 is m_1 , internal energy of the steam at stage 1 is u_1 , mass of the steam at stage 2 is m_2 , internal energy of the steam at stage 2 is u_2, net mass of steam entered m_f , enthalpy of steam is denoted as h_f and, work output be W_{out}.

Since the cylinder pressure is constant from superheated water table, at pressure $800\,\text{kPa}$ and, temperature $T_2 = 250\,^\circ\text{C}$, internal energy is obtained as 2715.9 kJ/kg. From superheated water table, at pressure in the pipe $P_f = 5\,\text{MPa}$ and temperature in the pipe $T_f = 500\,^\circ\text{C}$, enthalpy of steam is 3434.7 kJ/kg.

Step 10 of 10

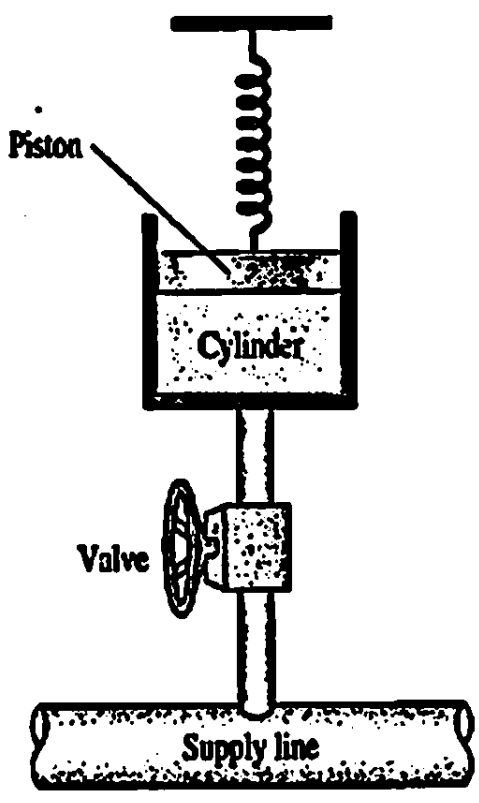
Substitute, 0.6821 kg for m_2, 2715.9 kJ/kg for u_2, 0.6 kg for m_1, 1995.577 kg for u_1, 0.0821 kg for m_f, 3434.7 kJ/kg for h_f and, 80 kJ for W_{out} in the equation,

$$Q_{in} = m_2 \times u_2 - m_1 \times u_1 - m_f \times h_f + W_{out}$$
$$= 0.6821 \times 2715.9 - 0.6 \times 1995.577 - 0.0821 \times 3434.7 + 80$$
$$= 1852.515 - 1197.346 - 281.989 + 80$$
$$= 453.18\,\text{kJ}$$

Therefore, mass of steam that entered is $\boxed{m_f = 0.0821\,\text{kg}}$ and the heat input to the cylinder is $\boxed{Q_{in} = 453.18\,\text{kJ}}$

Question: 6.126P

An adiabatic piston-cylinder device equipped with a spring maintains the pressure inside at 300 kPa when the volume is 0, and 3000 kPa when the volume is 5 m3. The device is connected to a steam line maintained at 1500 kPa and 200°C, and initially the volume is 0. Determine the final temperature (and quality if appropriate) when valve is opened and steam in the line is allowed to enter the cylinder until the pressure inside matches that in the line. Also determine the total work produced during this adiabatic filling process.



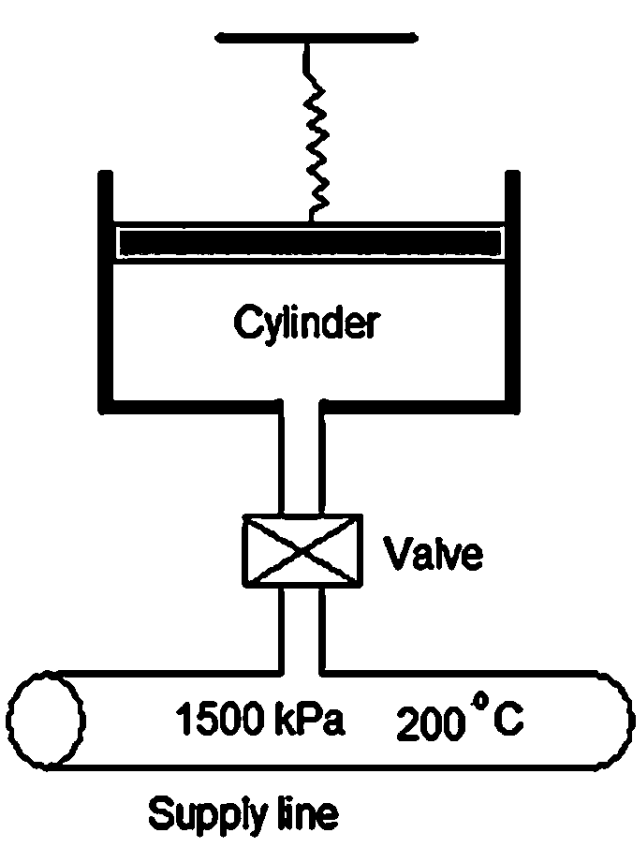


FIGURE P6–126

Step 1 of 5

A piston-cylinder device equipped with a spring:

Step 2 of 5

At pressure $300\ \text{kPa}$, volume in the cylinder is $0\ \text{m}^3$ and at pressure $3000\ \text{kPa}$, volume in the cylinder is $5\ \text{m}^3$. So for the pressure difference of $P_{diff} = 2700\ \text{kPa}$ (i.e., $3000-300$) the difference in the volume of cylinder will be

$$V_{diff} = 5-0$$
$$= 5\ \text{m}^3$$

Step 3 of 5

Find the final vapor volume using the relation between pressure and volume is $P_2 - P_1 = \frac{P_{diff}}{V_{diff}} \times (V_2 - V_1)$

Where P_1 and P_2 are the initial and final pressures in the cylinder and V_1 & V_2 are the initial and final volumes of the cylinder Substitute 1500 kPa for P_2, 300 kPa for P_1, $5\ \text{m}^3$ for V_{diff}, and $2700\ \text{kPa}$ for P_{diff}

$$1500-300 = \frac{2700}{5} \times (V_2 - 0)$$

in the above equation

$$1200 = 540 \times V_2$$
$$V_2 = \frac{1200}{540}$$
$$= 2.22\ \text{m}^3$$

Step 4 of 5

Find the work needed to compress the spring:

$$W = \int_{V_1}^{V_2} P \times dV$$
$$= \int_0^{V_2} \left(\frac{2700}{5} \times V + 300 \right) \times dV$$
$$= \left(\frac{2700}{5 \times 2} \times V^2 + 300 \times V \right)_0^{V_2}$$
$$= \left(\frac{2700}{5 \times 2} \times V_2^2 + 300 \times V_2 \right)$$
$$= 270 \times 2.22^2 + 300 \times 2.222$$
$$= 2000\ \text{kJ}$$

Therefore, the work needed to compress the spring is $\boxed{2000\ \text{kJ}}$.

Step 5 of 5

As the cylinder is evacuated initially ($m_1 = 0$) the final mass of air is equal to the inlet mass of air

$$m_2 = m_i$$

From ideal gas specific heats table, gas constant, specific heat at constant pressure and specific heat at constant volume of air respectively are

$R = 0.287\ \text{kJ/kg°K}$ $c_p = 1.005\ \text{kJ/kg°K}$ $c_v = 0.718\ \text{kJ/kg°K}$ From the table, super-heated water

The enthalpy of steam at the inlet for $P = 1500\ \text{kPa}$ and $T = 200°\text{C}$ is $h_i = 2796.0$

Apply Energy balance to the given system:

$$E_{in} - E_{out} = \Delta E_{sys}$$
$$m_i \times h_i - W = m_2 \times u_2$$
$$W = m_i \times h_i - m_2 \times u_2$$
$$= m_2 (h_i - u_2)$$
$$= \frac{V_2}{v_2}(h_i - u_2)$$
$$2000 = \frac{2.222}{v_2}(2796.0 - u_2)$$

Now we need to find the temperature from tables such that the internal energy and specific volume satisfies the relation obtained above. By trial and error method, the value of temperature is found to be around

$\boxed{T_2 = 233.2\,°\text{C}}$

The properties at this temperature are

$T_2 = 233.2°\text{C}$

$u_2 = 2664.8\ \text{kJ/kg}$

$v_2 = 0.1458\ \text{m}^3/\text{kg}$

Therefore, the temperature of the cylinder is $\boxed{233.2\ °\text{C}}$

Question: 6.127P

Repeat Prob. 6–126 when the line is filled with air that is maintained at 2000 kPa and 327°C.

Step 1 of 5

Given

Initial pressure, $P_1 = 300$ kPa

Initial volume, $V_1 = 0\ \text{m}^3$

Final pressure, $P_2 = 3000$ kPa

Final volume, $V_2 = 5\ \text{m}^3$

Supply line pressure, $P_i = 2000$ kPa

Supply line temperature, $T_i = 327°\text{C}$

$$T_i = 600\ \text{K}$$

From properties of air table,

Gas constant, $R = 0.287$ kJ/kg.K

Specific heat at constant pressure, $c_p = 1.005$ kJ/kg.K

Specific heat at constant volume, $c_v = 0.718$ kJ/kg.K

Step 2 of 5

Assuming the pressure of spring to be linear, we can write

$$(P-300)5 = (3000-300)V_2$$

$$(P-300)5 = 2700 \times V_2$$

$$P = (540 \times V_2) + 300$$

Also, $(3000-300)V_2 = (2000-300)5$

$$V_2 = \frac{(1700)5}{(2700)}$$

$$V_2 = 3.148\ \text{m}^3$$

Step 3 of 5

The work needed to compress the spring by the air is

$$W_{out} = \int PdV$$

$$W_{out} = \int_0^{V_2} \left[(540 \times V_2) + 300\right] dV$$

$$W_{out} = 540\frac{V_2^2}{2} + 300V_2$$

$$W_{out} = 540\frac{(3.148)^2}{2} + 300(3.148)$$

$$W_{out} = 3620\ \text{kJ}$$

Step 4 of 5

Considering the piston-cylinder system, $q = 0$ as the gas is filled adiabatically. Also, the kinetic and potential energies of the fluid stream are negligible so $ke = 0, pe = 0$

Applying mass balance for this system,

$$\dot{m}_{in} = \dot{m}_{out}$$

$$\dot{m}_i + \dot{m}_1 = \dot{m}_2$$

As the initial volume is zero, the initial mass is also zero,

$$\dot{m}_i = \dot{m}_2$$

Applying energy balance for this system,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_{in}h_{in} - W_{out} = \dot{m}_{out}u_{out}$$

$$\dot{m}_i h_i - W_{out} = \dot{m}_2 u_2$$

$$W_{out} = \dot{m}_i h_i - \dot{m}_2 u_2$$

$$W_{out} = \dot{m}_2 (h_i - u_2)$$

Step 5 of 5

Substituting the values, we get

$$W_{out} = \dot{m}_2 (h_i - u_2)$$

But $h = c_p T$ and $u = c_v T$. Hence

$$W_{out} = \dot{m}_2 (c_p T_i - c_v T_2)$$

$$W_{out} = \frac{P_2 V_2}{RT_2}(c_p T_i - c_v T_2)$$

$$3620 = \frac{2000 \times 3.148}{0.287 \times T_2}\left[(1.005 \times 600) - (0.718 \times T_2)\right]$$

$$(0.165 \times T_2) = 603 - (0.718 \times T_2)$$

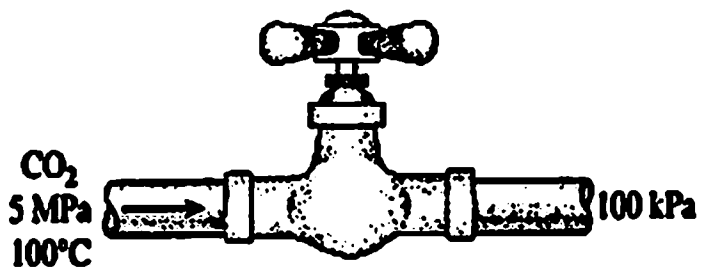
$$(0.883 \times T_2) = 603$$

$$T_2 = 682.899\ \text{K}$$

Therefore the final temperature is $\boxed{T_2 = 682.899\ \text{K}}$

Question: 6.128P

Carbon dioxide gas enters a throttling valve at 5 MPa and 100°C and leaves at 100 kPa. Determine the temperature change during this process if CO2 is assumed to be (a) an ideal gas and (b) a real gas. Real gas properties of CO2 may be obtained from EES.



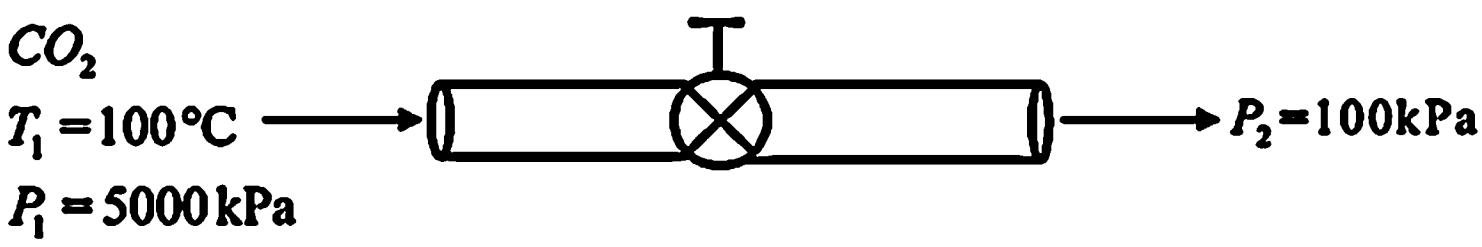


FIGURE P6–128

Step 1 of 3

Schematic diagram of the throttle valve is shown below.

Here, inlet temperature of Carbon dioxide is T_1, inlet pressure of the gas is P_1

and exit pressure of the gas is P_2

Step 2 of 3

Apply the continuity of mass relation

$$m_1 = m_2$$
$$= m$$

Assume the throttle valve as control volume;

Write the energy balance for a steady flow system

Rate of net Energy transfer = Rate of change in the energy of the system

$$E_{in} - E_{out} = \Delta E_{system}$$

For steady state condition, Apply energy conservation law (energy stored within the system is zero).

$$E_{in} = E_{out}$$
$$m\left(h_1 + V_1^2/2\right)_{in} = m\left(h_2 + V_2^2/2\right)_{out}$$

Here, h_1, h_2 are the enthalpies at inlet ant outlet respectively.

$$0 = m\left(h_1 - h_2 + 0\right)$$
$$h_1 = h_2$$

(a)

For an ideal gas, consider the equation for change in enthalpy

$$h_1 - h_1 = c_p\left(T_2 - T_1\right)$$
$$0 = c_p\left(T_2 - T_1\right)$$
$$T_2 = T_1$$

Therefore, for an ideal gas during throttling process the change in temperature is equal to zero.

Step 3 of 3

(b)

For a real gas, using EES software at a pressure $P_1 = 5000\,kPa$ and a temperature $T_1 = 100\,°C$ for CO_2 , obtain the value of enthalpy.

Enthalpy at inlet, $h_1 = 34.77\,kJ/kg$.

For a real gas, using EES software at a pressure $P_2 = 100\,kPa$ and exit enthalpy $h_2 = h_1 = 34.77\,kJ/kg$ for CO_2 , obtain the value of the exit temperature.

Exit temperature, $T_2 = 66\,°C$

Calculate the temperature change during the throttling process:

$$\Delta T = T_1 - T_2$$
$$= 100 - 66$$
$$= 34°C$$

Therefore, when Carbon dioxide is a real gas, the temperature decreases by $\boxed{34\,°C}$

Question: 6.129P

Helium steadily enters a pipe with a mass flow rate of 8 kg/s at 427°C and 100 kPa and leaves the pipe at 27°C. The pressure during the process is constant at 100 kPa. (*a*) Determine the heat transfer for the process, in kW. (*b*) Determine the volume flow rate of the helium at the pipe exit, in m3/s.

Step 1 of 4

Given

Inlet pressure of Helium, $P_1 = 100$ kPa

Inlet temperature of Helium, $T_1 = 427°C$

$T_1 = 700K$

The mass flow rate of Helium, $\dot{m} = 8$ kg/s

Exit pressure of Helium, $P_2 = 100$ kPa

Exit temperature of Helium, $T_2 = 27°C$

$T_2 = 300K$

Step 2 of 4

(a)

From the properties table of helium, at room temperature,

Gas constant, $R = 2.0769$ kJ/kg.K

Specific heat at constant pressure, $c_v = 3.1156$ kJ/kg.K

Specific heat at constant pressure, $c_p = 5.1926$ kJ/kg.K

From the energy balance equation for the conservation of energy,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

$$\dot{Q} = \dot{m}_{out}(h_{out} - h_{in})$$

Step 3 of 4

But enthalpy, $h = C_p T$. Therefore,

$$\dot{Q} = \dot{m}_{out} C_p (T_{out} - T_{in})$$

$$\dot{Q} = \dot{m} C_p (T_2 - T_1)$$

$$\dot{Q} = 8 \times 5.1926(700 - 300)$$

$$\dot{Q} = 16616.32 \text{ kW}$$

Hence heat transfer for the process is $\boxed{\dot{Q} = 16616.32 \text{ kW}}$

Step 4 of 4

(b)

The specific volume at end, $v_2 = \dfrac{RT_2}{P_2}$

$$v_2 = \frac{2.0769(300)}{100}$$

$$v_2 = 6.2307 \text{ m}^3/\text{kg}$$

The volume flow rate at the end is $\dot{V}_2 = \dot{m} v_2$

$$\dot{V}_2 = 8 \times 6.2307$$

$$\dot{V}_2 = 49.63 \text{ m}^3/\text{s}$$

The volume flow rate at the exit $\boxed{\dot{V}_2 = 49.63 \text{ m}^3/\text{s}}$

Question:

6.130P

Underground water is being pumped into a pool whose cross section is 6 m × 9 m while water is discharged through a 7-cm-diameter orifice at a constant average velocity of 4 m/s. If the water level in the pool rises at a rate of 2.5 cm/min, determine the rate at which water is supplied to the pool, in m3/s.

Step 1 of 3

Given

Cross section area of the of pool, $A_{pool} = 6\text{ m} \times 9\text{ m}$

$$A_{pool} = 54\text{ m}^2$$

Diameter of the orifice, $d = 7\text{ cm}$

$$d = 0.07\text{ m}$$

Velocity of the water in the orifice, $V_e = 4\text{ m/s}$

Change in level of the water in the pool, $\dot{V}_L = 2.5\text{ cm/min}$

$$\dot{V}_L = 4.1667 \times 10^{-4}\text{ m/s}$$

Step 2 of 3

Area of orifice, $A_e = \dfrac{\pi d^2}{4}$

$$A_e = \frac{\pi \times 0.07^2}{4}$$

$$A_e = 3.85 \times 10^{-3}\text{ m}^2$$

Volume flow rate at exit, $\dot{V}_e = A_e V_e$

$$\dot{V}_e = \left(3.85 \times 10^{-3}\right) \times (4)$$

$$\dot{V}_e = 0.0154\text{ m}^3/\text{s}$$

Step 3 of 3

The amount of water collected in the pool,

$$\dot{V}_{pool} = A_{pool} V_L$$

$$\dot{V}_{pool} = 54 \times \left(4.1667 \times 10^{-4}\right)$$

$$\dot{V}_{pool} = 0.0225\text{ m}^3/\text{s}$$

Therefore the rate at which water supplied to the pool is sum of volume flow rate of water discharge and water collected.

$$\dot{V}_{total} = \dot{V}_{pool} + \dot{V}_e$$

$$\dot{V}_{total} = 0.0225 + 0.0154$$

$$\dot{V}_{total} = 0.0379\text{ m}^3/\text{s}$$

The rate of discharge of water, $\boxed{\dot{V}_{total} = 0.0379\text{ m}^3/\text{s}}$

Question: 6.131P

Air at 4.18 kg/m3 enters a nozzle that has an inlet-to-exit area ratio of 2:1 with a velocity of 120 m/s and leaves with a velocity of 380 m/s. Determine the density of air at the exit.

Step 1 of 2

Density of air at nozzle inlet,

$$\rho_1 = 4.18\ \text{kg/m}^3$$

There is only one entry and exit and so the mass flow rate is constant

$$m_1 = m_2$$

$$\rho_1 \times A_1 \times C_1 = \rho_2 \times A_2 \times C_2$$

where ρ is the density of air, A is the area of cross-section, C is the velocity of air, variables with suffix 1 are inlet parameters and variables with suffix 2 are exit parameters.

Step 2 of 2

Calculate the density of air at nozzle exit,

$$\rho_2 = \rho_1 \times \frac{A_1}{A_2} \times \frac{C_1}{C_2}$$

The ratio of area of cross-section inlet to exit is 2,

$$\rho_2 = 4.18 \times 2 \times \frac{120}{380}$$

$$= 4.18 \times 2 \times 0.3158$$

$$= 2.64\ \text{kg/m}^3$$

Therefore, the density of air at the nozzle exit is $\boxed{2.64\ \text{kg/m}^3}$

Question: 6.132P

An air compressor compresses 15 L/s of air at 120 kPa and 20°C to 800 kPa and 300°C while consuming 6.2 kW of power. How much of this power is being used to increase the pressure of the air versus the power needed to move the fluid through the compressor?

Step 1 of 4

Given

Pressure of air at inlet of compressor, $P_1 = 120\ \text{kPa}$

Temperature of air at inlet of compressor, $T_1 = 20°\text{C}$

$$T_1 = 293\ \text{K}$$

The volume flow rate at the inlet, $\dot{V} = 15\ \text{L/s}$

$$\dot{V} = 0.015\ \text{m}^3/\text{s}$$

Pressure of air at exit of compressor, $P_2 = 800\ \text{kPa}$

Temperature of air at exit of compressor, $T_2 = 300°\text{C}$

$$T_2 = 573\ \text{K}$$

Power consumed by the compressor, $\dot{W}_{in} = 6.2\ \text{kW}$

Step 2 of 4

From properties table of air, gas constant of air is $R = 0.287\ \text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$

The specific volume at inlet, $v_1 = \dfrac{RT_1}{P_1}$

$$v_1 = \frac{0.287(293)}{120}$$

$$v_1 = 0.7\ \text{m}^3/\text{kg}$$

The mass flow rate, $\dot{m} = \dfrac{\dot{V}}{v_1}$

$$\dot{m} = \frac{0.015}{0.7}$$

$$\dot{m} = 0.0214\ \text{kg/s}$$

Step 3 of 4

Flow work in compressor, $\dot{W}_{flow} = \dot{m}(P_2 v_2 - P_1 v_1)$

$$\dot{W}_{flow} = \dot{m}(RT_2 - RT_1)$$

$$\dot{W}_{flow} = \dot{m}R(T_2 - T_1)$$

$$\dot{W}_{flow} = 0.0214 \times 0.287 \times (573 - 293)$$

$$\dot{W}_{flow} = 1.72\ \text{kW}$$

Therefore the flow power $\boxed{\dot{W}_{flow} = 1.72\ \text{kW}}$

Step 4 of 4

The power used to increases the pressure in air is

$$\dot{W}_p = \dot{W}_{in} - \dot{W}_f$$

$$\dot{W}_p = 6.2 - 1.72$$

$$\dot{W}_p = 4.48\ \text{kW}$$

Hence the power used to increases the pressure in air is $\boxed{\dot{W}_p = 4.48\ \text{kW}}$

Question: 6.133P

A steam turbine operates with 1.6 MPa and 350°C steam at its inlet and saturated vapor at 30°C at its exit. The mass flow rate of the steam is 16 kg/s, and the turbine produces 9000 kW of power. Determine the rate at which heat is lost through the casing of this turbine.

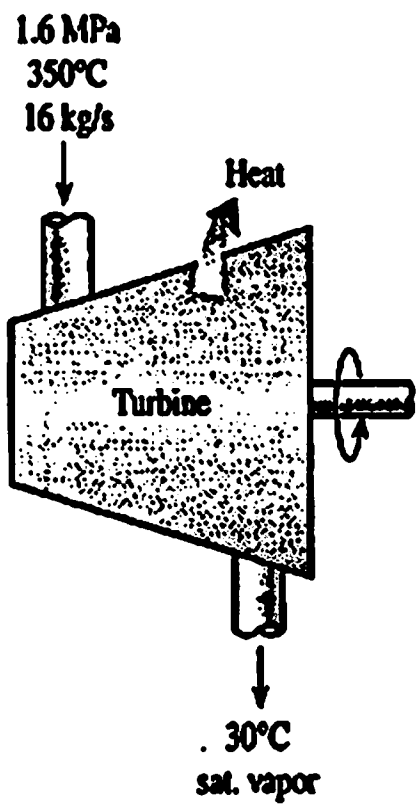

FIGURE P6–133

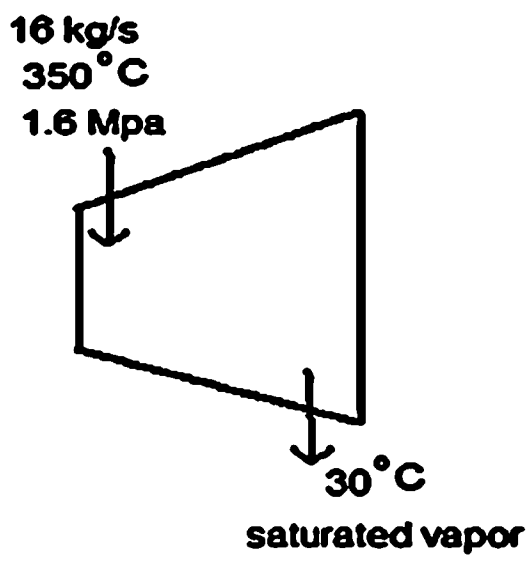
Step 1 of 4

From the table of superheated steam

At turbine inlet pressure $P_1 = 1.6\ \text{MPa}$ and turbine inlet temperature $T_1 = 350\ ^\circ\text{C}$ specific enthalpy of steam is

$$h_1 = 3146\ \text{kJ/kg}$$



From table of saturated water

At turbine exit temperature $T_2 = 30\ ^\circ\text{C}$ and saturated vapor condition specific enthalpy of steam is

$$h_2 = h_g = 2555.6\ \text{kJ/kg}$$

Step 2 of 4

Schematic diagram of turbine system:

Step 3 of 4

The energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ and so

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$m_1 \times h_1 = m_2 \times h_2 + W_{out} + Q_{out}$$

where Q_{out} is heat loss from the turbine and W_{out} is the work done by the turbine.

m_1 is the mass flow rate of steam at inlet and m_2 is the mass flow rate of steam at outlet

As there is only one entry and exit to the turbine, the mass flow rate is constant

$$m_1 = m_2 = m$$

$$m \times h_1 = m \times h_2 + W_{out} + Q_{out}$$

$$Q_{out} = m \times h_1 - m \times h_2 - W_{out}$$

$$Q_{out} = m \times (h_1 - h_2) - W_{out}$$

Step 4 of 4

Substituting 16kg/s for m, 3146kJ/kg for h_1, 2555.6 kJ/kg for h_2, 9000kW for W_{out}

$$Q_{out} = 16 \times (3146 - 2555.6) - 9000$$

$$= 16 \times 590.4 - 9000$$

$$= 9446.4 - 9000$$

$$= 446.4\ \text{kW}$$

Therefore, the rate of heat loss from the turbine is $\boxed{446.4\ \text{kW}}$

Question: 6.134P

Nitrogen gas flows through a long, constant-diameter adiabatic pipe. It enters at 100 psia and 120°F and leaves at 50 psia and 70°F. Calculate the velocity of the nitrogen at the pipe's inlet and outlet.

Step 1 of 7

From table of specific heats of common gases "
For nitrogen
Specific heat of nitrogen is $c_p = 0.248\ \text{Btu/lbm} \cdot \text{R}$
As there is one entry and exit for the pipe, the mass flow rate will be same. So,

$$m_1 = m_2$$
$$\frac{A_1 \times C_1}{v_1} = \frac{A_2 \times C_2}{v_2}$$
$$C_2 = \frac{A_1}{A_2} \times \frac{v_2}{v_1} \times C_1$$

Here,
Mass flow rate of nitrogen at inlet of pipe is m_1
Mass flow rate of nitrogen at inlet of pipe is m_2
Cross sectional area of the section at inlet pipe is A_1
Cross sectional area of the section at exit pipe is A_2
The velocities of nitrogen at entry is C_1
The velocities of nitrogen at exit is C_2
Specific volume of nitrogen at inlet of the pipe is v_1
Specific volume of nitrogen at exit of the pipe is v_2

Step 2 of 7

From the ideal gas equation, ratio of specific volumes is given by the ratio of temperature and pressure

$$C_2 = \frac{A_1}{A_2} \times \frac{T_2}{T_1} \times \frac{P_1}{P_2} \times C_1$$

Here,
Temperature of the nitrogen at inlet of pipe is T_1
Temperature of the nitrogen at exit of pipe is T_2
As the diameter of the pipe is constant, ratio of area of cross-section of the pipe will be unity.

$$C_2 = 1 \times \frac{T_2}{T_1} \times \frac{P_1}{P_2} \times C_1$$
$$C_2 = \frac{T_2}{T_1} \times \frac{P_1}{P_2} \times C_1 \qquad \text{..... (1)}$$

Step 3 of 7

Write the energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$m_1\left(h_1 + \frac{C_1^2}{2}\right) = m_2\left(h_2 + \frac{C_2^2}{2}\right)$$

As $m_1 = m_2$ the above equation becomes,

$$h_1 + \frac{C_1^2}{2} = h_2 + \frac{C_2^2}{2}$$
$$\frac{C_2^2}{2} - \frac{C_1^2}{2} = h_1 - h_2$$
$$\frac{C_2^2 - C_1^2}{2} = c_p \times T_1 - c_p \times T_2$$
$$\frac{C_2^2 - C_1^2}{2} = c_p \times (T_1 - T_2)$$

Step 4 of 7

Substituting equation (1) in the above equation,

$$\frac{\left(\frac{T_2}{T_1} \times \frac{P_1}{P_2} \times C_1\right)^2 - C_1^2}{2} = c_p \times (T_1 - T_2)$$
$$\left(\frac{T_2}{T_1} \times \frac{P_1}{P_2}\right)^2 \times C_1^2 - C_1^2 = 2 \times c_p \times (T_1 - T_2)$$
$$\left[\left(\frac{T_2}{T_1} \times \frac{P_1}{P_2}\right)^2 - 1\right] \times C_1^2 = 2 \times c_p \times (T_1 - T_2)$$
$$C_1^2 = \frac{2 \times c_p \times (T_1 - T_2)}{\left(\frac{T_2}{T_1} \times \frac{P_1}{P_2}\right)^2 - 1}$$

Step 5 of 7

Substituting $0.248\ \text{Btu/lbm} \cdot \text{R}$ for c_p, $120°\text{F}$ for T_1, $70°\text{F}$ for T_2, $100\ \text{psia}$ for P_1, $50\ \text{psia}$ for P_2

$$C_1^2 = \frac{2 \times 0.248 \times (120 - 70)}{\left[\frac{(70 + 460)}{(120 + 460)} \times \frac{100}{50}\right]^2 - 1}$$

In order to convert Btu/lbm into ft^2/s^2 we have to multiply numerator of RHS with 25037

$$C_1^2 = \frac{2 \times 0.248 \times (120 - 70) \times 25037}{\left[\frac{530}{580} \times \frac{100}{50}\right]^2 - 1}$$
$$C_1^2 = \frac{2 \times 0.248 \times 50 \times 25037}{[0.9138 \times 2]^2 - 1}$$

Step 6 of 7

$$C_1^2 = \frac{620917.6}{2.34}$$
$$C_1^2 = \frac{620917.6}{2.34}$$
$$C_1^2 = 265349.4$$
$$C_1 = \sqrt{265349.4}$$

Hence, the velocities of nitrogen at entry is $\boxed{515.12\ \text{ft/s}}$

Step 7 of 7

From equation (1) we get,

$$C_2 = \frac{T_2}{T_1} \times \frac{P_1}{P_2} \times C_1$$
$$= \frac{530}{580} \times \frac{100}{50} \times 515.12$$
$$= 0.9138 \times 2 \times 515.12$$
$$= 941.43\ \text{ft/s}$$

Hence, the velocities of nitrogen at exit is $\boxed{941.43\ \text{ft/s}}$

Question: 6.135P

A 110-V electric hot-water heater warms 0.1 L/s of water from 18 to 30°C. Calculate the current in amperes that must be supplied to this heater.

Step 1 of 3

Given

Inlet temperature of water, $T_1 = 18°C$

The volume flow rate of water, $\dot{V} = 0.1\ L/s$

$\dot{V} = 0.0001\ m^3/s$

Exit temperature of water, $T_2 = 30°C$

Voltage supplied to heater, $V = 110\ V$

Specific heat of water, $c_p = 4.18\ kJ/kg°C$

Step 2 of 3

From the mass balance equation for the conservation of mass,

$$\dot{m}_{in} = \dot{m}_{out}$$

Mass, $\dot{m} = \rho \dot{V}$

$$\dot{m} = 1000 \times (0.0001)$$

$$\dot{m} = 0.1\ kg/s$$

From the energy balance equation for the conservation of energy,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{W}_{in} + \dot{m}_{in} h_{in} = \dot{m}_{out} h_{out}$$

$$\dot{W}_{in} = \dot{m}(h_{out} - h_{in})$$

Step 3 of 3

But $h = c_p T$ and $\dot{W}_{in} = VI$ hence

$$VI = \dot{m} c_p (T_{out} - T_{in})$$

$$I = \frac{\dot{m} c_p}{V}(T_{out} - T_{in})$$

$$I = \frac{0.1 \times 4.8}{100}(30 - 18)$$

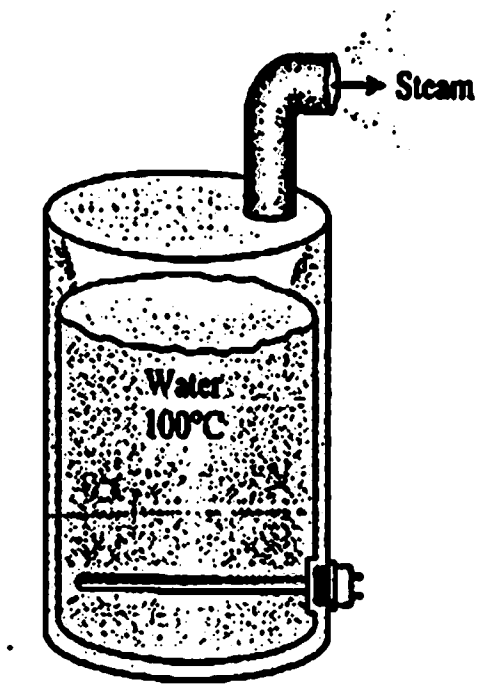
$$I = \frac{0.1 \times (4.18 \times 1000)}{110}(30 - 18)$$

$$I = 45.6\ A$$

The current supplied to the heater in amperes, $\boxed{I = 45.6\ A}$

Question: 6.136P

Water is boiled at 100°C electrically by a 3-kW resistance wire. Determine the rate of evaporation of water.



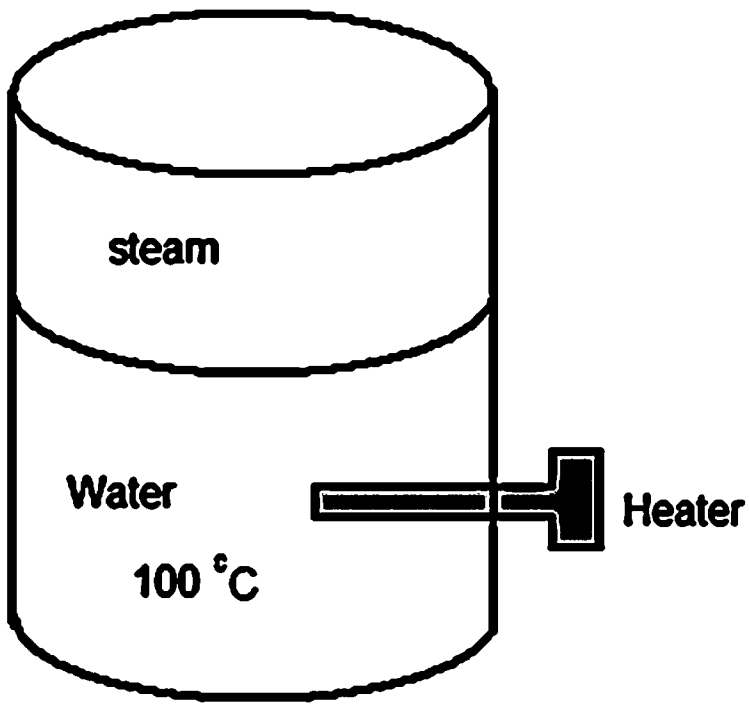


FIGURE P6–136

Step 1 of 3

From the table of Saturation water table "
At boiling temperature of water $T = 100\ ^\circ C$
Latent heat vaporization is $h_{fg} = 2256.4\ kJ/kg^\circ \cdot K$

Step 2 of 3

Schematic diagram water heated in tank system:

Step 3 of 3

Calculate the rate of water evaporated is

$$W_{boiling} = h_{fg} \times m_{evap}$$

Where m_{evap} mass of water evaporated.

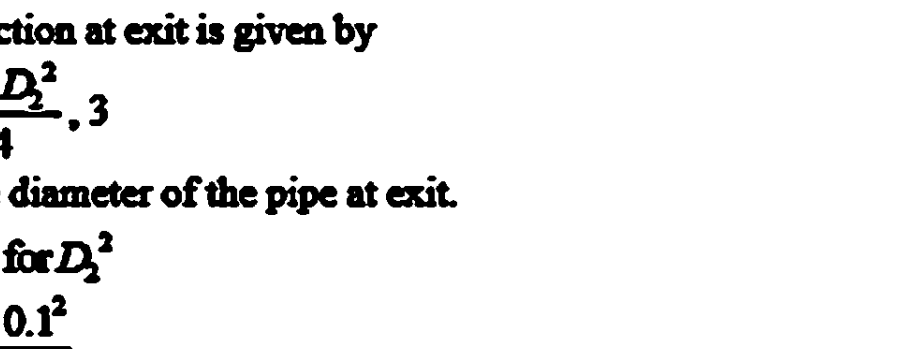
$$m_{evap} = \frac{W_{boiling}}{h_{fg}}$$

Substitute 3kW for W, 2256.4kJ/kg for h_{fg}

$$m_{evap} = \frac{3}{2256.4}$$
$$= 0.001329\ kg/s$$

Therefore, rate of evaporation of water is $\boxed{0.001329\ kg/s}$

Question: 6.137P



Steam enters a long, insulated pipe at 1400 kPa, 350°C, and 10 m/s, and exits at 1000 kPa. The diameter of the pipe is 0.15 m at the inlet, and 0.1 m at the exit. Calculate the mass flow rate of the steam and its speed at the pipe outlet.

Step 1 of 8

From table of properties of steam,
at entrance pressure $P_1 = 1400\ \text{kPa}$ and entrance temperature $T_1 = 350\ ^\circ\text{C}$ properties of steam are
Specific volume is $v_1 = 0.20029\ \text{m}^3/\text{kg}$
Enthalpy is $h_1 = 3150.1\ \text{kJ/kg}$

Step 2 of 8

Schematic diagram flow system:

Step 3 of 8

Area of cross-section at entrance is given by

$$A_1 = \frac{\pi \times D_1^2}{4},$$

Where D_1 is the diameter of the pipe at entrance
Substitute $0.15\,\text{m}$ for D^2

$$A_1 = \frac{\pi \times 0.15^2}{4}$$
$$= \frac{\pi \times 0.0225}{4}$$
$$= \frac{0.0707}{4}$$
$$= 0.017675\ \text{m}^2$$

Step 4 of 8

Area of cross-section at exit is given by

$$A_2 = \frac{\pi \times D_2^2}{4}, 3$$

Where D_2 is the diameter of the pipe at exit.
Substitute $0.1\,\text{m}$ for D_2^2

$$A_2 = \frac{\pi \times 0.1^2}{4}$$
$$= \frac{\pi \times 0.01}{4}$$
$$= \frac{0.0314}{4}$$
$$= 0.00785\ \text{m}^2$$

Step 5 of 8

Write the energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$m_{in} h_1 = m_{out} h_2$$

There is only one entrance and one exit. So, mass flow rate of steam is constant $m_{in} = m_{out}$ and so the equation becomes

$$h_1 = h_2$$

Step 6 of 8

From table of properties of steam ,
At pressure $P_2 = 1000\ \text{kPa}$ and enthalpy $h_2 = 3150.1\ \text{kJ/kg}$,
Specific volume of steam is interpolated as

$$\frac{v_2 - 0.25799}{0.28250 - 0.25799} = \frac{3150.1 - 3051.6}{3158.2 - 3051.6}$$
$$\frac{v_2 - 0.25799}{0.02451} = \frac{98.5}{106.6}$$
$$v_2 = 0.924 \times 0.02451 + 0.25799$$
$$v_2 = 0.02265 + 0.25799$$
$$v_2 = 0.28064\ \text{m}^3/\text{kg}$$

Step 7 of 8

Calculate mass flow rate is

$$m = \frac{A_1 \times C_1}{v_1}$$

Where C_1 is the velocity and v_1 is the specific volume at entrance of the pipe

$$m = \frac{0.017675 \times 10}{0.20029}$$
$$= \frac{0.17675}{0.20029}$$
$$= 0.88247\ \text{kg/s}$$

Hence, mass flow rate is $\boxed{0.88247\ \text{kg/s}}$

Step 8 of 8

Calculate exit velocity is

$$C_2 = \frac{v_2 \times m}{A_2}$$

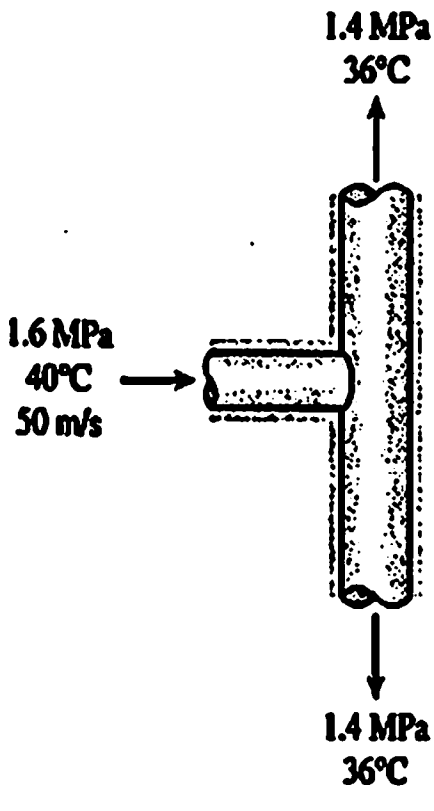
Substitute $0.28064\,\text{kg/m}^3$ for v_2, $0.88247\,\text{kg/s}$ for m, $0.00785\ \text{m}^2$ for A_2

$$C_2 = \frac{0.28064 \times 0.88247}{0.00785}$$
$$= \frac{0.24765}{0.00785}$$
$$= 31.547\ \text{m/s}$$

Therefore, the mass flow rate of steam at exit velocity is $\boxed{31.547\ \text{m/s}}$

Question: 6.138P pg 1

The air flow in a compressed air line is divided into two equal streams by a T-fitting in the line. The compressed air enters this 2.5-cm diameter fitting at 1.6 MPa and 40°C with a velocity of 50 m/s. Each outlet has the same diameter as the inlet, and the air at these outlets has a pressure of 1.4 MPa and a temperature of 36°C. Determine the velocity of the air at the outlets and the rate of change of flow energy (flow power) across the T-fitting.



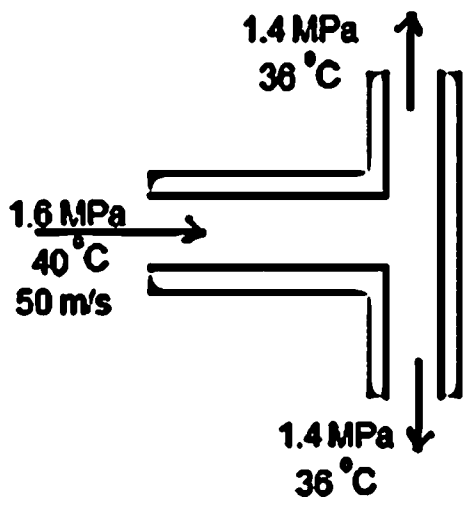


FIGURE P6–138

Step 1 of 8

Schematic diagram of mixing chamber:

Step 2 of 8

From table of properties of common gases
For gas constant of air is

$$R = 0.287 \text{ kJ/kg} \cdot ^\circ\text{K}$$

Specific volume at inlet of line is given by

$$v_1 = \frac{R \times T_1}{P_1},$$

Where T_1 is the temperature and P_1 is the pressure at inlet of line
Substitute $0.287 \text{ kJ/kg} \cdot ^\circ\text{K}$ for R, 313K for T_1, 1600 kPA for P_1

$$v_1 = \frac{0.287 \times (313)}{1600}$$
$$= \frac{0.287 \times 313}{1600}$$
$$= \frac{89.831}{1600}$$
$$= 0.05614 \text{ m}^3/\text{kg}$$

Step 3 of 8

Let us assume that air is divided evenly after the T-junction.
Specific volume at both the exits of line are given by

$$v_2 = v_3 = \frac{R \times T_2}{P_2},$$

Where T_2 is the temperature and P_2 is the pressure at exit of line
Substitute $0.287 \text{ kJ/kg} \cdot ^\circ\text{K}$ for R, 309K for T_2, 1400 kPA for P_1

$$v_2 = \frac{0.287 \times (36+273)}{1400}$$
$$= \frac{0.287 \times 309}{1400}$$
$$= \frac{88.683}{1400}$$
$$v_2 = v_3 = 0.06334 \text{ m}^3/\text{kg}$$

Step 4 of 8

As the diameters of line at inlet and exits is same, area of cross-section will also be same

$$A = \frac{\pi \times D^2}{4},$$

where D is the diameter of the pipe
Substitute 0.025m for D

$$A = \frac{\pi \times 0.025^2}{4}$$
$$= \frac{\pi \times 0.000625}{4}$$
$$= \frac{0.001963}{4}$$
$$= 0.00049075 \text{ m}^2$$

Step 5 of 8

As there is one inlet and two exits, mass flow rate at inlet is double the mass flow rate at exits

$$m_1 = 2m_2$$
$$\frac{A_1 \times C_1}{v_1} = 2\frac{A_2 \times C_2}{v_2},$$

Where C is the velocity and v is the specific volume

$$C_2 = \frac{A_1 \times C_1 \times v_2}{2 \times v_1 \times A_2}$$

$\frac{A_1 \times C_1}{v_1} = 2\frac{A_2 \times C_2}{v_2}$.

Where C is the velocity and v is the specific volume

$$C_2 = \frac{A_1 \times C_1 \times v_2}{2 \times v_1 \times A_2}$$

$$= \frac{C_1 \times v_2}{2 \times v_1}$$

Substitute 50 m/s for C_1, $0.06334\ m^3/kg$ for v_2, $0.05614\ m^3/kg$ for v_1

$$C_2 = \frac{50 \times 0.06334}{2 \times 0.05614}$$

$$= \frac{3.167}{0.11228}$$

$$= 28.206\ m/s$$

Hence, velocity at outlet is $\boxed{28.206\ m/s}$

Step 6 of 8

Calculate Mass flow rate at inlet is

$$m_1 = \frac{A \times C_1}{v_1}$$

Substitute $0.00049075\ m^2$ for A, 50 m/s for C, $0.05614\ m^3/kg$ for v_1

$$m_1 = \frac{0.00049075 \times 50}{0.05614}$$

$$= \frac{0.0245375}{0.05614}$$

$$= 0.43708\ kg/s$$

Step 7 of 8

Mass flow rates at exit is given by

$$m_2 = \frac{A \times C_2}{v_2}$$

Substitute $0.00049075\ m^2$ for A, 28.206 m/s for C_2, $0.06334\ m^3/kg$ for v_2

$$m_2 = \frac{0.00049075 \times 28.206}{0.06334}$$

$$= \frac{0.01384}{0.06334}$$

$$= 0.21854\ kg/s$$

Step 8 of 8

Calculate Change in work flow energy is

$$W_{flow} = 2 \times E_{out} - E_{in}$$

$$= 2 \times m_2 \times P_2 \times v_2 - m_1 \times P_1 \times v_1$$

$$= 38.758 - 39.2603$$

$$= -0.5023\ kW$$

Hence, the decrease in energy is $\boxed{0.5023\ kW}$

Question: 6.139P

Air enters a pipe at 65°C and 200 kPa and leaves at 60°C and 175 kPa. It is estimated that heat is lost from the pipe in the amount of 3.3 kJ per kg of air flowing in the pipe. The diameter ratio for the pipe is D1/D2 = 1.4. Using constant specific heats for air, determine the inlet and exit velocities of the air.

Step 1 of 4

Obtain properties of air from properties of gases table,

Gas constant is $R = 0.287\ \text{kJ/kg}\cdot\text{K}$

Specific heat is $c_p = 1.005\ \text{kJ/kg}\cdot\text{K}$

Apply mass balance by using the equation.

$$m_{in} - m_{out} = \Delta m_{sys}$$

Here, m_{in} is mass flow of air at inlet, m_{out} is mass flow of air at exit and Δm_{sys} is change in mass of air in the system.

For steady flow, $\Delta m_{sys} = 0$

$$m_{in} - m_{out} = 0$$
$$m_{in} = m_{out}$$
$$\rho_1 \times A_1 \times V_1 = \rho_2 \times A_2 \times V_2$$
$$\frac{P_1}{R \times T_1} \times \frac{\pi}{4} D_1^2 \times V_1 = \frac{P_2}{R \times T_2} \times \frac{\pi}{4} D_2^2 \times V_2$$

Here, P is pressure, T is temperature, D is diameter, V is velocity, ρ is density and R is gas constant. Parameters with suffix 1 are parameters at inlet and parameters with suffix 2 are parameters at exit.

Step 2 of 4

Rearrange the terms and simplify the equation.

$$\frac{P_1}{T_1} \times D_1^2 \times V_1 = \frac{P_2}{T_2} \times D_2^2 \times V_2$$
$$\frac{V_2}{V_1} = \frac{P_1}{P_2} \times \frac{T_2}{T_1} \times \frac{D_1^2}{D_2^2}$$
$$\frac{V_2}{V_1} = \frac{P_1}{P_2} \times \frac{T_2}{T_1} \times \left(\frac{D_1}{D_2}\right)^2$$

Substitute $200\,\text{kPa}$ for P_1, $175\,\text{kPa}$ for P_2, $(60+273 = 333\,\text{K})$ for T_2, $(65+273 = 338\,\text{K})$ for T_1, and 1.8 for $\frac{D_1}{D_2}$.

$$\frac{V_2}{V_1} = \frac{200}{175} \times \frac{(60+273)}{(65+273)} \times (1.4)^2$$
$$= \frac{200}{175} \times \frac{333}{338} \times 1.96$$
$$= 1.1428 \times 0.985 \times 1.96$$
$$= 2.206$$

$$V_2 = 2.206 \times V_1 \quad \text{..... (1)}$$

Step 3 of 4

Apply Energy balance to the system by using the equation,

$$E_{in} - E_{out} = \Delta E_{sys}$$

For steady flow, $\Delta E_{sys} = 0$

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} + q_{out}$$
$$c_p \times T_1 + \frac{V_1^2}{2} = c_p \times T_2 + \frac{V_2^2}{2} + q_{out}$$

Here, c_p specific heat of air, and q_{out} is the heat loss from pipe.

$$c_p \times T_1 + \frac{V_1^2}{2} = c_p \times T_2 + \frac{V_2^2}{2} + q_{out}$$

Step 4 of 4

Substitute $1.005 \times 10^3\ \text{J/kg}\cdot\text{K}$ for c_p, $338\,\text{K}$ for T_1, $3.3 \times 10^3\ \text{J/kg}$ for q_{out} and 333 K for T_2.

$$1.005 \times 10^3 \times 338 + \frac{V_1^2}{2} = 1.005 \times 10^3 \times 333 + \frac{V_2^2}{2} + 3.3 \times 10^3$$
$$\frac{V_2^2}{2} - \frac{V_1^2}{2} = 1.725 \times 10^3$$
$$V_2^2 - V_1^2 = 3.45 \times 10^3$$

Substitute $2.206 \times V_1$ for V_2 obtained from equation (1).

$$(2.206 \times V_1)^2 - V_1^2 = 3.45 \times 10^3$$
$$4.8664 \times V_1^2 - V_1^2 = 3.45 \times 10^3$$
$$3.8664 V_1^2 = 3.45 \times 10^3$$
$$V_1 = 29.87\ \text{m/s}$$

Therefore, the velocity of air at inlet is **29.87 m/s**.

Find the velocity of air at exit by using equation (1)

$$V_2 = 2.206 \times V_1$$
$$= 2.206 \times 29.87$$
$$= 65.893\ \text{m/s}$$

Hence, velocity of air at exit is **65.893 m/s**.

Question: 6.140P

Steam enters a nozzle with a low velocity at 150°C and 200 kPa, and leaves as a saturated vapor at 75 kPa. There is a heat transfer from the nozzle to the surroundings in the amount of 26 kJ for every kilogram of steam flowing through the nozzle. Determine (a) the exit velocity of the steam and (b) the mass flow rate of the steam at the nozzle entrance if the nozzle exit area is 0.001 m2.

Step 1 of 5

From superheated water tables take the properties of steam at nozzle inlet pressure $P_1 = 200\ \text{kPa}$ and nozzle inlet temperature $T_1 = 150°\text{C}$.

Specific enthalpy of steam is $h_1 = 2769.1\ \text{kJ/kg}$

From saturated water tables at nozzle exit pressure $P_2 = 75\ \text{kPa}$ and saturated vapor condition

Specific volume $v_2 = v_g = 2.2172\ \text{m}^3/\text{kg}$

Specific enthalpy of steam $h_2 = h_g = 2662.4\ \text{kJ/kg}$

As there is only one entry, one exit for nozzle, mass flow rate of steam will be same

$$\dot{m}_1 = \dot{m}_2 = \dot{m}$$

Step 2 of 5

(a)

Apply the steady state energy balance

$$E_{in} - E_{out} = \Delta E_{sys}$$

For steady flow process, $\Delta E_{sys} = 0$ and so

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$\dot{m} \times \left(h_1 + \frac{V_1^2}{2} \right) = \dot{m} \times \left(h_2 + \frac{V_2^2}{2} \right) + Q_{out}$$

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} + q_{out}$$

Here V_1 and V_2 are the inlet and exit velocities of steam and q_{out} is the specific heat lost from nozzle.

Step 3 of 5

Neglect the inlet velocity of the nozzle, the energy equation becomes,

$$h_1 = h_2 + \frac{V_2^2}{2} + q_{out}$$

Write the exit velocity by rearranging the terms in the above equation,

$$\frac{V_2^2}{2} = h_1 - h_2 - q_{out}$$

$$V_2^2 = 2 \times (h_1 - h_2 - q_{out})$$

$$V_2 = \sqrt{2 \times (h_1 - h_2 - q_{out})}$$

In order to convert m^2/s^2 into kJ/kg we have to multiply RHS with 1000

$$V_2 = \sqrt{2 \times 1000 \times (h_1 - h_2 - q_{out})}$$

$$= \sqrt{2000 \times (h_1 - h_2 - q_{out})}$$

Step 4 of 5

Substitute $26\ \text{kJ/kg}$ for q_{out}.

$$V_2 = \sqrt{2000 \times (2769.1 - 2662.4 - 26)}$$

$$= \sqrt{2000 \times 80.7}$$

$$= \sqrt{161400}$$

$$= 401.75\ \text{m/s}$$

Therefore, exit velocity of the steam from the nozzle is $\boxed{401.75\ \text{m/s}}$

Step 5 of 5

(b)

Find mass flow rate of steam by using the equation,

$$\dot{m} = \frac{A_2 \times V_2}{v_2}$$

Here A_2 is cross-section area of nozzle at exit

Substitute $0.001\ \text{m}^2$ for A_2

$$\dot{m} = \frac{0.001 \times 401.75}{2.2172}$$

$$= \frac{0.40175}{2.2172}$$

$$= 0.18119\ \text{kg/s}$$

Therefore, the mass flow rate of steam is $\boxed{0.18119\ \text{kg/s}}$

Question: 6.141P

In a gas-fired boiler, water is boiled at 150°C by hot gases flowing through a stainless steel pipe submerged in water. If the rate of heat transfer from the hot gases to water is 74 kJ/s, determine the rate of evaporation of water.

Step 1 of 1

From table properties of water,

At temperature $T = 150\ ^\circ C$

Specific enthalpy of evaporation is

$$h_{fg} = 2113.8\ kJ/kg^\circ K$$

Rate of heat transfer is given by

$$Q_{boiling} = h_{fg} \times m_{evap}$$

Where m_{evap} mass of water evaporated.

Calculate the rate at which water is evaporated is

$$m_{evap} = \frac{Q_{boiling}}{h_{fg}}$$

Substitute $75\ kJ/s$ for $Q_{boiling}$, $2113.8 kJ/kg$ for h_{fg}

$$m_{evap} = \frac{74}{2113.8}$$
$$= 0.0355\ kg/s$$

Therefore, the rate of evaporation of water is $\boxed{0.0355\ kg/s}$

Question:

6.142P

Cold water enters a steam generator at 20°C and leaves as saturated vapor at 200°C. Determine the fraction of heat used in the steam generator to preheat the liquid water from 20°C to the saturation temperature of 200°C.

Step 1 of 3

Given

Inlet temperature of cold water, $T_i = 20°C$

Exit temperature of water, $T_{ex} = 200°C$

Specific heat of water, $c_p = 4.18\ kJ/kg°C$

Step 2 of 3

The amount of heat required to raise the temperature of unit mass of water

$$q_{heat} = c_p \Delta T$$

$$q_{heat} = (4.18)(200 - 20)$$

Question:

Cold water enters a steam generator at 20°C and leaves as saturated vapor at 200°C. Determine the fraction of heat used in the steam generator to preheat the liquid water from 20°C to the saturation temperature of 200°C.

Step 1 of 3

Given

Inlet temperature of cold water, $T_i = 20°C$

Exit temperature of water, $T_{ex} = 200°C$

Specific heat of water, $c_p = 4.18\ kJ/kg°C$

Step 2 of 3

The amount of heat required to raise the temperature of unit mass of water

Question: 6.143P

Cold water enters a steam generator at 20°C and leaves as saturated vapor at the boiler pressure. At what pressure will the amount of heat needed to preheat the water to saturation temperature be equal to the heat needed to vaporize the liquid at the boiler pressure?

Step 1 of 4

From table properties of steam,

At temperature of cold water $T_1 = 20\ ^\circ\text{C}$ specific enthalpy of saturated liquid is

$$h_{f1} = 83.915\ \text{kJ/kg°K}$$

Given that, amount of heat needed to preheat the water is equal to heat needed to vaporize the liquid

$$q_{preheat} = q_{boiling}$$

$$h_{f2} - h_{f1} = h_{fg2}$$

Here,

Enthalpy of water is h

$$h_{f2} - 83.915 = h_{fg2}$$

$$h_{f2} - h_{fg2} = 83.915$$

Step 2 of 4

The difference between specific heat of saturate liquid and specific heat of vaporization is calculated by trial and error are

at $T = 310\ ^\circ\text{C}$,

$$h_f - h_{fg} = 1402 - 1325.9$$

$$h_f - h_{fg} = 76.1\ \text{kJ/kg°K}$$

at $T = 315\ ^\circ\text{C}$,

$$h_f - h_{fg} = 1431.6 - 1283.4$$

$$h_f - h_{fg} = 148.2\ \text{kJ/kg°K}$$

Step 3 of 4

By taking the difference of specific heats into consideration, the temperature of water at exit is interpolated as

$$\frac{T_2 - 310}{315 - 310} = \frac{83.915 - 76.1}{148.2 - 76.1}$$

$$\frac{T_2 - 310}{5} = \frac{7.815}{72.1}$$

$$\frac{T_2 - 310}{5} = 0.1084$$

$$T_2 = 0.1084 \times 5 + 310$$

$$h_{f2} - h_{fg2} = 83.915$$

Step 2 of 4

The difference between specific heat of saturate liquid and specific heat of vaporization is calculated by trial and error are

at $T = 310\ ^\circ\text{C}$,

$$h_f - h_{fg} = 1402 - 1325.9$$

$$h_f - h_{fg} = 76.1\ \text{kJ/kg°K}$$

at $T = 315\ ^\circ\text{C}$,

$$h_f - h_{fg} = 1431.6 - 1283.4$$

$$h_f - h_{fg} = 148.2\ \text{kJ/kg°K}$$

Step 3 of 4

By taking the difference of specific heats into consideration, the temperature of water at exit is interpolated as

$$\frac{T_2 - 310}{315 - 310} = \frac{83.915 - 76.1}{148.2 - 76.1}$$

$$\frac{T_2 - 310}{5} = \frac{7.815}{72.1}$$

Question:

6.144P

An ideal gas expands in an adiabatic turbine from 1200 K and 900 kPa to 700 K. Determine the turbine inlet volume flow rate of the gas, in m3/s, required to produce turbine work output at the rate of 350 kW. The average values of the specific heats for this gas over the temperature range and the gas constant are cp = 1.13 kJ/kg•K, cv = 0.83 kJ/kg•K, and R = 0.30 kJ/kg•K.

Step 1 of 3

Given

Inlet pressure of water, $P_1 = 900\ \text{kPa}$

Inlet temperature of water, $T_1 = 1200\ \text{K}$

Exit temperature of water, $T_2 = 700\ \text{K}$

Power produced by the turbine $\dot{W}_{out} = 350\ \text{kW}$

Gas constant, $R = 0.3\ \text{kJ/kg.K}$

Specific heat at constant volume, $c_v = 0.83\ \text{kJ/kg.K}$

Specific heat at constant volume, $c_p = 1.13\ \text{kJ/kg.K}$

Step 2 of 3

Energy from the turbine is $\dot{W}_{out} = \dot{m}(h_1 - h_2)$

$$\dot{W}_{out} = \dot{m}c_p(T_1 - T_2)$$

Hence mass flow rate, $\dot{m} = \dfrac{\dot{W}_{out}}{c_p(T_1 - T_2)}$

$$\dot{m} = \frac{350}{1.13 \times (1200 - 700)}$$

$$\dot{m} = 0.6195\ \text{kg/s}$$

Step 3 of 3

But mass flow rate, $\dot{m} = \dfrac{\dot{V}}{v_1}$

Also from ideal gas equation, $P_1 v_1 = RT_1$

Hence from both the relations,

$$\dot{V} = \frac{\dot{m}RT_1}{P_1}$$

$$\dot{V} = \frac{0.6195 \times 0.3 \times 1200}{900}$$

$$\dot{V} = 0.2478\ \text{m}^3/\text{s}$$

Therefore the volume flow rate is $\boxed{\dot{V} = 0.2478\ \text{m}^3/\text{s}}$

Question: 6.145P

Chickens with an average mass of 2.2 kg and average specific heat of 3.54 kJ/kg•°C are to be cooled by chilled water that enters a continuous-flow-type immersion chiller at 0.5°C. Chickens are dropped into the chiller at a uniform temperature of 15 °C at a rate of 500 chickens per hour and are cooled to an average temperature of 3°C before they are taken out. The chiller gains heat from the surroundings at a rate of 200 kJ/h. Determine (a) the rate of heat removal from the chickens, in kW, and (b) the mass flow rate of water, in kg/s, if the temperature rise of water is not to exceed 2°C.

Step 1 of 3

The mass flow rate of chicken is given by

$$\dot{m}_{chicken} = n \times m_{chicken}$$

Here, $m_{chicken}$ is the average mass of each chicken and n is the number of chickens dropped in the chiller

Substitute 500 Chicken/h for $m_{chicken}$ and 2.2 kg/Chicken for n.

$$\begin{aligned}\dot{m}_{chicken} &= 500 \times 2.2 \\ &= 1100 \text{ kg/h} \\ &= \frac{1100}{3600} \text{ kg/s} \\ &= 0.3056 \text{ kg/s}\end{aligned}$$

Rate of heat gain from surroundings is given as

$$\begin{aligned}Q_{surr} &= 200 \text{kJ/h} \\ &= \frac{200}{3600} \text{kJ/h} \\ &= 0.056 \text{ kJ/s}\end{aligned}$$

Step 2 of 3

The energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$\begin{aligned}E_{in} - E_{out} &= 0 \\ E_{in} &= E_{out} \\ \dot{m}_{chicken} \times h_1 &= Q_{chicken} + \dot{m}_{chicken} \times h_2 \\ Q_{chicken} &= \dot{m}_{chicken} \times h_1 - \dot{m}_{chicken} \times h_2 \\ Q_{chicken} &= \dot{m}_{chicken} \times (h_1 - h_2) \\ Q_{chicken} &= \dot{m}_{chicken} \times c_p \times (T_1 - T_2)\end{aligned}$$

Here, T_1 & T_2 are the initial and final temperatures of Chicken respectively and c_p is the specific heat of Chicken.

Substitute 3°C for T_1, 15°C for T_2 and 3.54 kJ/kg°C for c_p.

$$\begin{aligned}&= \frac{1100}{3600} \text{ kg/s} \\ &= 0.3056 \text{ kg/s}\end{aligned}$$

Rate of heat gain from surroundings is given as

$$\begin{aligned}Q_{surr} &= 200 \text{kJ/h} \\ &= \frac{200}{3600} \text{kJ/h} \\ &= 0.056 \text{ kJ/s}\end{aligned}$$

Step 2 of 3

The energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$\begin{aligned}E_{in} - E_{out} &= 0 \\ E_{in} &= E_{out} \\ \dot{m}_{chicken} \times h_1 &= Q_{chicken} + \dot{m}_{chicken} \times h_2 \\ Q_{chicken} &= \dot{m}_{chicken} \times h_1 - \dot{m}_{chicken} \times h_2 \\ Q_{chicken} &= \dot{m}_{chicken} \times (h_1 - h_2) \\ Q_{chicken} &= \dot{m}_{chicken} \times c_p \times (T_1 - T_2)\end{aligned}$$

Here, T_1 & T_2 are the initial and final temperatures of Chicken respectively and c_p is the specific heat of Chicken.

Substitute 3°C for T_1, 15°C for T_2 and 3.54 kJ/kg°C for c_p.

$$\begin{aligned}&= \frac{8.36}{} \text{ kg/s} \\ &= 1.559 \text{kg/s}\end{aligned}$$

Therefore, the rate of heat removal from chicken is $\boxed{12.98 \text{ kW}}$ and the mass flow rate of water is to be at least $\boxed{1.559 \text{ kg/s}}$

$$\begin{aligned}&= \frac{8.36}{} \text{ kg/s} \\ &= 1.559 \text{kg/s}\end{aligned}$$

Therefore, the rate of heat removal from chicken is $\boxed{12.98 \text{ kW}}$ and the mass flow rate of water is to be at least $\boxed{1.559 \text{ kg/s}}$

Question: 6.146P

Repeat Prob. 6–145 assuming heat gain of the chiller is negligible.

Step 1 of 3

The mass flow rate of chicken is given by

$$\dot{m}_{chicken} = n \times m_{chicken}$$

Here, $m_{chicken}$ is the average mass of each chicken and n is the number of chickens dropped in the chiller

Substitute 500 Chicken/h for $m_{chicken}$ and 2.2 kg/Chicken for n.

$$\begin{aligned}\dot{m}_{chicken} &= 500 \times 2.2 \\ &= 1100 \text{ kg/h} \\ &= \frac{1100}{3600} \text{ kg/s} \\ &= 0.3056 \text{ kg/s}\end{aligned}$$

Step 2 of 3

The energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$\begin{aligned}E_{in} - E_{out} &= 0 \\ E_{in} &= E_{out} \\ \dot{m}_{chicken} \times h_1 &= Q_{chicken} + \dot{m}_{chicken} \times h_2 \\ Q_{chicken} &= \dot{m}_{chicken} \times h_1 - \dot{m}_{chicken} \times h_2 \\ Q_{chicken} &= \dot{m}_{chicken} \times (h_1 - h_2) \\ Q_{chicken} &= \dot{m}_{chicken} \times c_p \times (T_1 - T_2)\end{aligned}$$

Here, $T_1 \& T_2$ are the initial and final temperatures of Chicken respectively and c_p is the specific heat of Chicken.

Substitute $3°C$ for T_1, $15°C$ for T_2 and 3.54 kJ/kg°C for c_p.

$$\begin{aligned}Q_{chicken} &= 0.3056 \times 3.54 \times (15 - 3) \\ &= 0.3056 \times 3.54 \times 12 \\ &= 12.98 \text{ kW}\end{aligned}$$

The rate of heat removal by the chicken $\boxed{12.98 \text{ kW}}$

Step 3 of 3

Total heat gained by water in the chiller is given by

$$\begin{aligned}Q_{water} &= Q_{chicken} + Q_{surr} \\ &= 12.98 + 0 \\ &= 12.98 \text{ kW}\end{aligned}$$

Total heat gained by water is also given by

$$Q_{water} = \dot{m}_{water} \times c_p \times \Delta T_{water}$$

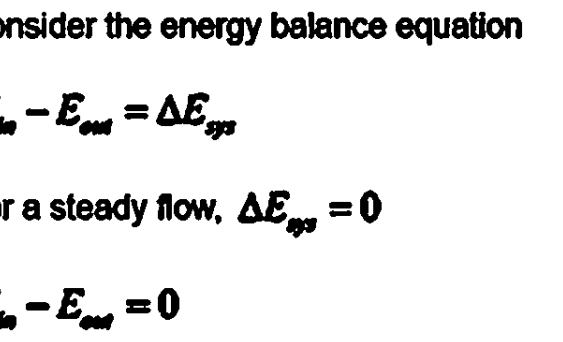
Here, the maximum change in temperature of water is ΔT_{water}, the mass flow rate of water is $\dot{m}_{water}$ and the specific heat of water is c_p

From specific heat of water table the given value is $c_p = 4.18$ kJ/kg°C

Substitute 2°C for ΔT_{water} and 12.98 kW for Q_{water}.

The mass flow rate of water is given by

$$\begin{aligned}\dot{m}_{water} &= \frac{Q_{water}}{c_p \times \Delta T_{water}} \\ &= \frac{12.98}{4.18 \times 2} \\ &= \frac{12.98}{8.36} \\ &= 1.553 \text{kg/s}\end{aligned}$$



Therefore, the rate of heat removal from chicken is $\boxed{12.98 \text{ kW}}$ and the mass flow rate of water is to be at least $\boxed{1.553 \text{ kg/s}}$

Question: 6.147P

A refrigeration system is being designed to cool eggs (ρ = 67.4 lbm/ft3 and cp = 0.80 Btu/lbm•°F) with an average mass of 0.14 lbm from an initial temperature of 90°F to a final average temperature of 50°F by air at 34°F at a rate of 10,000 eggs per hour. Determine (*a*) the rate of heat removal from the eggs, in Btu/h and (b) the required volume flow rate of air, in ft3/h, if the temperature rise of air is not to exceed 10°F.

Step 1 of 5

Process of air cooling egg is shown below.

Step 2 of 5

Obtain the properties of air from the tables: Molar mass, gas constant, and critical – point properties and Ideal – gas specific heats of various common gases

Specific heat, $c_{p,air} = 0.24$ Btu/lbm°F

Gas constant, $R = 0.3704$ psia $\cdot$ ft^3/lbm $\cdot$ R

Calculate the mass flow rate of egg using the following equation

$$\dot{m}_{egg} = n \times m_{avg}$$

Here, n is the number of eggs cooled per hour and m_{avg} is the average mass of egg

Substitute 10000 eggs/h for n and 0.14 lbm for m_{avg}

$$\begin{aligned}\dot{m}_{egg} &= 10000 \times 0.14 \\ &= 1400 \text{ lbm/h}\end{aligned}$$

Step 3 of 5

Consider the energy balance equation

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady flow, $\Delta E_{sys} = 0$

$$\begin{aligned}E_{in} - E_{out} &= 0 \\ E_{in} &= E_{out}\end{aligned}$$

$$\begin{aligned}\dot{m}_{egg} \times h_1 &= Q_{egg} + \dot{m}_{egg} \times h_2 \\ Q_{egg} &= \dot{m}_{egg} \times h_2 - \dot{m}_{egg} \times h_1 \\ &= \dot{m}_{egg} \times (h_2 - h_1) \\ &= \dot{m}_{egg} \times c_{p,egg} \times (T_1 - T_2)\end{aligned}$$

Here, $c_{p,egg}$ is the specific heat of egg. The initial and final temperatures of eggs are denoted by T_1 and T_2 respectively.

Substitute 0.80 Btu/lbm $\cdot$ °F for $c_{p,egg}$, 90°F for T_1 and 50°F for T_2

$$\begin{aligned}Q_{egg} &= 1400 \times 0.8 \times (90 - 50) \\ &= 1400 \times 0.8 \times 40 \\ &= 44800 \text{ Btu/h}\end{aligned}$$

Therefore the rate heat removal of eggs is **44800 Btu/h**

Step 4 of 5

The heat released from eggs (Q_{egg}) is used to heat the refrigerated air (Q_{air}).

$$\begin{aligned}Q_{air} &= Q_{egg} \\ &= 44800 \text{ Btu/h}\end{aligned}$$

Calculate the mass flow rate of air using the following equation

$$\dot{m}_{air} = \frac{Q_{air}}{c_{p,air} \times \Delta T_{air}}$$

Here, ΔT_{air} is the permissible temperature rise of air

Substitute 10°F for ΔT_{air}

$$\begin{aligned}\dot{m}_{air} &= \frac{44800}{0.24 \times 10} \\ &= \frac{44800}{2.4} \\ &= 18666.67 \text{ lbm/h}\end{aligned}$$

Step 5 of 5

Calculate the density of air using the following equation

$$\rho_{air} = \frac{P}{R \times T_{air}}$$

Here, P is atmospheric pressure and T_{air} is the temperature of the air

Substitute 14.7 lbf/in^2 for P and $(34 + 460)$R for T_{air}

$$\begin{aligned}\rho_{air} &= \frac{14.7}{0.3704 \times (34 + 460)} \\ &= \frac{14.7}{0.3704 \times 494} \\ &= \frac{14.7}{182.9776} \\ &= 0.0803 \text{ lbm/ft}^3\end{aligned}$$

Calculate the volume flow rate of air using the following equation

$$\begin{aligned}\dot{V}_{air} &= \frac{\dot{m}_{air}}{\rho_{air}} \\ &= \frac{18666.67}{0.0803} \\ &= 232461.644 \text{ ft}^3\text{/h}\end{aligned}$$

Therefore, the volumetric flow rate of air is **232461.644 ft^3/h**

Question: 6.148P

A glass bottle washing facility uses a well-agitated hot-water bath at 55°C that is placed on the ground. The bottles enter at a rate of 800 per minute at an ambient temperature of 20°C and leave at the water temperature. Each bottle has a mass of 150 g and removes 0.2 g of water as it leaves the bath wet. Make-up water is supplied at 15°C. Disregarding any heat losses from the outer surfaces of the bath, determine the rate at which (a) water and (b) heat must be supplied to maintain steady operation.

Step 1 of 6

From properties of liquids table, specific heat of water is $c_{p,water} = 4.18\ \text{kJ/kg°C}$ From properties of solids table, specific heat of glass is $c_{p,glass} = 0.8\ \text{kJ/kg°C}$

Step 2 of 6

Mass flow rate of glass bottles through the water bath is given by below equation

$$\dot{m}_{bottle} = m_{bottle} \times Flow_{bottle}$$

Where m_{bottle} is the mass of bottle and $Flow_{bottle}$ is the flow rate of bottle

Substitute $150\,\text{kg}$ for m_{bottle}, $800\,\text{bottles/min}$ for $Flow_{bottle}$

$$\begin{aligned}\dot{m}_{bottle} &= \dot{m}_{bottle} \times Flow_{bottle}\\ &= 150 \times 800\\ &= 120000\ \text{g/min}\\ &= \frac{120000}{1000 \times 60}\ \text{kg/s}\\ &= \frac{120000}{60000}\\ &= 2\ \text{kg/s}\end{aligned}$$

Step 3 of 6

Energy balance of the bottle flow is given by below equation

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady flow, $\Delta E_{sys} = 0$

$$\begin{aligned}&E_{in} - E_{out} = 0\\ &E_{in} = E_{out}\\ &Q_{bottle} + \dot{m}_{bottle} \times h_1 = \dot{m}_{bottle} \times h_2\\ &Q_{bottle} = \dot{m}_{bottle} \times h_2 - \dot{m}_{bottle} \times h_1\\ &\quad = \dot{m}_{bottle} \times (h_2 - h_1)\\ &\quad = \dot{m}_{bottle} \times c_{p,glass} \times (T_2 - T_1)\end{aligned}$$

Where T_1 and T_2 are the ambient and hot water temperatures

Calculate the rate of heat transfer from the bottle

$$\begin{aligned}Q_{bottle} &= 2 \times 0.8 \times (55 - 20)\\ &= 2 \times 0.8 \times 35\\ &= 56\ \text{kW}\end{aligned}$$

Step 4 of 6

Calculate the Amount of water removed by bottle

$$\begin{aligned}\dot{m}_{water,rem} &= Flow_{bottle} \times \text{water removed per bottle}\\ &= 800 \times 0.2\\ &= 160\ \text{g/min}\\ &= \frac{160}{1000 \times 60}\ \text{kg/s}\\ &= \frac{160}{60000}\ \text{kg/s}\\ &= 2.667 \times 10^{-3}\ \text{kg/s}\end{aligned}$$

Therefore the rate at which water must be supplied to maintain steady operation is $\boxed{2.667 \times 10^{-3}\ \text{kg/s}}$

Step 5 of 6

Calculate the rate of heat removal by the water

$$Q_{water,rem} = \dot{m}_{water,rem} \times c_{p,water} \times \Delta T$$

Substitute $2.667 \times 10^{-3}\ \text{kg/s}$ for $\dot{m}_{water,rem}$, $4.18\,\text{kJ/kg} \cdot \text{K}$ for $c_{p,water}$

$$\begin{aligned}Q_{water,rem} &= \dot{m}_{water,rem} \times c_{p,water} \times \Delta T\\ &= 2.667 \times 10^{-3} \times 4.18 \times (55 - 15)\\ &= 2.667 \times 10^{-3} \times 4.18 \times 40\\ &= 0.446\ \text{kW}\end{aligned}$$

Step 6 of 6

Calculate the total amount of heat removed by bottles

$$\begin{aligned}Q_{tot,rem} &= Q_{bottle} + Q_{water,rem}\\ &= 56 + 0.446\\ &= 56.446\ \text{kW}\end{aligned}$$

Therefore, the rate at which heat must be supplied to maintain steady operation is $\boxed{56.446\ \text{kW}}$

Question: 6.149P

Long aluminum wires of diameter 5 mm (ρ = 2702 kg/m3 and cp = 0.896 kJ/kg•°C) are extruded at a temperature of 350°C and are cooled to 50°C in atmospheric air at 25°C. If the wire is extruded at a velocity of 8 m/min, determine the rate of heat transfer from the wire to the extrusion room.

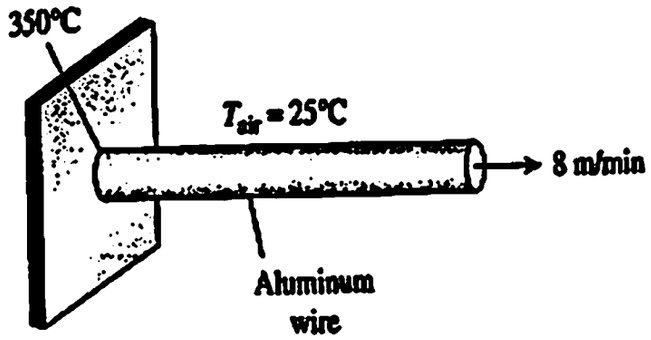


FIGURE P6–149

Step 1 of 3

Given

Diameter of aluminum wire, $d = 5$ mm

Base temperature of wire, $T_1 = 350°C$

Final temperature $T_2 = 50°C$

Velocity of extruded wire, $V = 8$ m/min

The temperature of atmospheric air, $T_{atm} = 25°C$

Density of Aluminum, $\rho = 2702\ kg/m^3$

Specific heat of Aluminum at constant pressure, $c_p = 0.896$ kJ/kg°C

Step 2 of 3

From mass balance, $\dot{m}_{in} = \dot{m}_{out}$

Hence mass flow rate, $\dot{m} = \rho AV$

$$\dot{m} = \rho \times \frac{\pi d^2}{4} \times V$$

$$\dot{m} = 2702 \times \frac{\pi (0.005)^2}{4} \times \left(\frac{8}{60}\right)$$

$$\dot{m} = 0.007\ kg/s$$

Step 3 of 3

The energy balance equation for this process,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}h_1 = \dot{Q}_{out} + \dot{m}h_2$$

$$\dot{Q}_{out} = \dot{m}(h_1 - h_2)$$

But $h = c_p T$. So,

$$\dot{Q}_{out} = \dot{m}c_p(T_1 - T_2)$$

$$\dot{Q}_{out} = 0.007 \times 0.896 \times (350 - 50)$$

$$\dot{Q}_{out} = 1.88\ kW$$

Therefore the rate of heat transfer to the air from wire is $\boxed{\dot{Q}_{out} = 1.88\ kW}$

Question: 6.150P

Repeat Prob. 6–149 for a copper wire (ρ = 8950 kg/m3and cp = 0.383 kJ/kg•°C).

Step 1 of 3

Given

Diameter of copper wire, $d = 5\,\text{mm}$

Base temperature of wire, $T_1 = 350°\text{C}$

Final temperature $T_2 = 50°\text{C}$

Velocity of extruded wire, $V = 8\,\text{m/min}$

The temperature of atmospheric air, $T_{atm} = 25°\text{C}$

Density of copper, $\rho = 8950\,\text{kg/m}^3$

Specific heat of copper at constant pressure, $c_p = 0.383\,\text{kJ/kg°C}$

Step 2 of 3

From mass balance, $\dot{m}_{in} = \dot{m}_{out}$

Hence mass flow rate, $\dot{m} = \rho A V$

$$\dot{m} = \rho \times \frac{\pi d^2}{4} \times V$$

$$\dot{m} = 8950 \times \frac{\pi (0.005)^2}{4} \times \left(\frac{8}{60}\right)$$

$$\dot{m} = 0.0234\,\text{kg/s}$$

Step 3 of 3

The energy balance equation for this process,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}h_1 = \dot{Q}_{out} + \dot{m}h_2$$

$$\dot{Q}_{out} = \dot{m}(h_1 - h_2)$$

But $h = c_p T$. So,

$$\dot{Q}_{out} = \dot{m}c_p(T_1 - T_2)$$

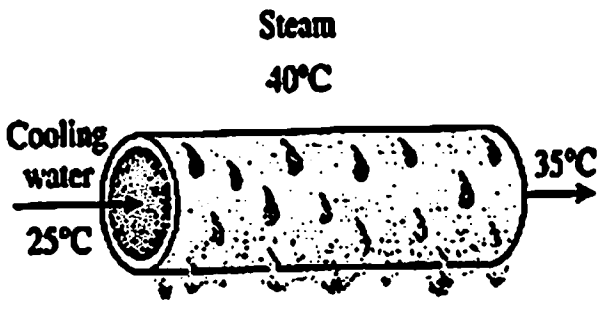
$$\dot{Q}_{out} = 0.0234 \times 0.383 \times (350 - 50)$$

$$\dot{Q}_{out} = 2.688\ \text{kW}$$

Therefore the rate of heat transfer to the air from wire is $\boxed{\dot{Q}_{out} = 2.688\ \text{kW}}$

Question: 6.151P

Steam at 40°C condenses on the outside of a 5-m-long, 3-cm-diameter thin horizontal copper tube by cooling water that enters the tube at 25°C at an average velocity of 2 m/s and leaves at 35°C. Determine the rate of condensation of steam.



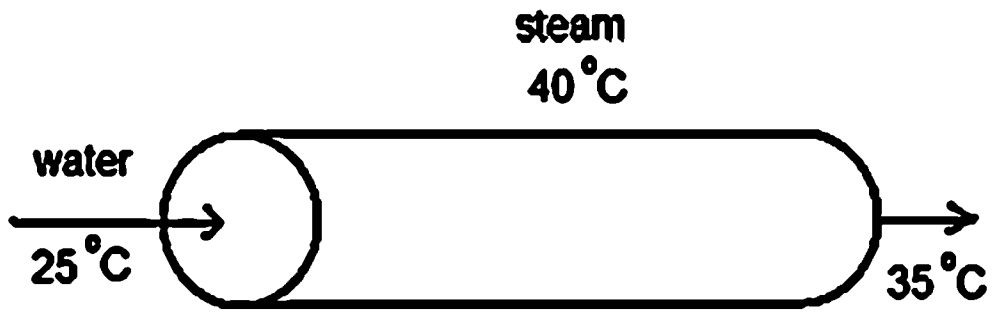


FIGURE P6–151

Step 1 of 4

Schematic Diagram of water flow through a pipe.

Step 2 of 4

The mass flow rate of the extruded wire is given by

$$\dot{m} = \rho \times A \times C$$
$$= \rho \times \frac{\pi \times d^2}{4} \times C$$

Here, A is the area of cross-section of the tube, C is the velocity of water, d is the diameter of cross-section of the tube and ρ is the density of water.

From the properties tables the density of water is $\rho = 997\ \text{kg/m}^3$ and the specific heat $c_p = 4.18\ \text{kJ/kg°C}$

Substitute 0.03 m for d, $997\ \text{kg/m}^3$ for ρ and 2m/min for C.

$$\dot{m} = 997 \times \frac{\pi \times 0.03^2}{4} \times 2$$
$$= 997 \times \frac{2.827 \times 10^{-3}}{4} \times 2$$
$$= 997 \times 7.0675 \times 10^{-4} \times 2$$
$$= 1.409\ \text{kg/s}$$

Step 3 of 4

The energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$Q_{water} + \dot{m} \times h_1 = \dot{m} \times h_2$$
$$Q_{water} = \dot{m} \times h_2 - \dot{m} \times h_1$$
$$Q_{water} = \dot{m} \times (h_2 - h_1)$$
$$Q_{water} = \dot{m} \times c_p \times (T_2 - T_1)$$

Considering the ideal conditions, heat gained by water is equal to heat lost by steam (heat of condensation) and so

$$Q_{cond} = \dot{m} \times c_p \times (T_2 - T_1)$$

Here, T_1 & T_2 are the initial and final temperatures of copper respectively and c_p is the specific heat of copper.

Substitute 25°C for T_1, 35°C for T_2 and 4.18kJ/kg°C for c_p.

$$Q_{cond} = 1.409 \times 4.18 \times (35 - 25)$$
$$= 1.409 \times 4.18 \times 10$$
$$= 58.896\ \text{kW}$$

Step 4 of 4

Heat of condensation is also given by

$$Q_{cond} = \dot{m}_{cond} \times h_{fg}$$

Here, $\dot{m}_{cond}$ is the mass of steam condensed and h_{fg} is the specific enthalpy of vaporization of steam.

From tables specific enthalpy of vaporization of steam is given as $h_{fg} = 2406\ \text{kJ/kg}$

$$Q_{cond} = \dot{m}_{cond} \times h_{fg}$$
$$58.896 = \dot{m}_{cond} \times 2406$$
$$\dot{m}_{cond} = \frac{58.896}{2406}$$
$$= 0.0245\ \text{kg/s}$$

Therefore, the rate of condensation of steam is $\boxed{0.0245\text{kg/s}}$

Question: 6.152P

Steam at 60 psia and 350°F is mixed with water at 40°F and 60 psia steadily in an adiabatic device. Steam enters the device at a rate of 0.05 lbm/s, while the water enters at 1 lbm/s. Determine the temperature of the mixture leaving this device when the outlet pressure is 60 psia.

Step 1 of 3

Apply the energy balance is

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$m_1 \times h_1 + m_2 \times h_2 = m_3 \times h_3$$

Here, mass and enthalpy of steam is m_1 and h_1. Mass and enthalpy of water is m_2 and h_2.

Mass and enthalpy of the mixture m_3 and h_3

Step 2 of 3

Apply mass balance and find the mass of mixture

$$\begin{aligned} m_3 &= m_1 + m_2 \\ &= 0.05 + 1 \\ &= 1.05 \text{ lbm/s} \end{aligned}$$

From table, properties of water obtain the enthalpies of steam and water

For pressure $P_1 = 60$ psia and entrance temperature $T_1 = 350°F$

Enthalpy $h_1 = 1208.3$ Btu/lbm

For $P_2 = 60$ psia and $T_2 = 40°F$.

Enthalpy $h_2 \cong h_f$
$= 8.032$ Btu/lbm

Step 3 of 3

Find the enthalpy mixture coming out using the below relation

$$\begin{aligned} h_3 &= \frac{m_1 h_1 + m_2 h_2}{m_3} \\ &= \frac{0.05 \times 1208.3 + 1 \times 8.032}{1.05} \\ &= 65.19 \text{ Btu/lbm} \end{aligned}$$

Therefore, the exit pressure is 60 psia and enthalpy is 65.19 Btu/lbm

Using the above pressure and enthalpy determine the final mixture temperature from the table saturated water –temperature table

For pressure $P_3 = 60$ psia and enthalpy $h_3 = 65.19$ Btu/lbm

Final temperature of the mixture is $T_3 = 97.2$ °F
$\cong T_f (h = 65.19$ Btu/lbm$)$

Therefore, temperature of the mixture leaving the device is **97.2 °F**

Question: 6.153P

The average atmospheric pressure in Spokane, Washington (elevation = 2350 ft), is 13.5 psia, and the average winter temperature is 36.5°F. The pressurization test of a 9-ft-high, 4500-ft2 older home revealed that the seasonal average infiltration rate of the house is 2.2 air changes per hour (ACH). That is, the entire air in the house is replaced completely 2.2 times per hour by the outdoor air. It is suggested that the infiltration rate of the house can be reduced by half to 1.1 ACH by winterizing the doors and the windows. If the house is heated by natural gas whose unit cost is $1.24/therm and the heating season can be taken to be six months, determine how much the home owner will save from the heating costs per year by this winterization project. Assume the house is maintained at 72°F at all times and the efficiency of the furnace is 0.92. Also assume the latent heat load during the heating season to be negligible.

Step 1 of 5

Given

Average pressure of atmospheric air, $P_{amb} = 13.5$ psia

Average temperature in winter, $T_{amb} = 36.5°F$

$$T_{amb} = 496.5 \text{ R}$$

Height of the home, $h = 9$ ft

Area of the house, $A = 4500 \text{ ft}^2$

Temperature maintained in the house, $T_{in} = 72°C$

$$T_{in} = 532 \text{ R}$$

Unit cost of natural gas is $ 1.24/therm

Thermal efficiency of the furnace, $\eta = 0.92$

Step 2 of 5

From properties table of air,

Gas constant of air is $R = 0.3704$ psia.ft^3/lbm.R

Specific heat of air is $c = 0.24$ Btu/lbm.°F

The density of outdoor air, from the gas equation $P_0 = \rho_0 R T_0$ psia

$$\rho_0 = \frac{P_0}{RT_0} \text{ lbm/ft}^3$$

$$= \frac{13.5}{(0.3704)(496.5)}$$

$$= 0.0734 \text{ lbm/ft}^3$$

The volume of the house

$$V = Ah$$

$$= (4500)(9)$$

$$= 40500 \text{ ft}^3$$

Step 3 of 5

From mass balance, $\dot{m}_{in} = \dot{m}_{out}$

$$\dot{m} = \rho \dot{V}$$

$$= 1000 \times 20 \times 10^{-3}$$

$$= 20 \text{ kg/s}$$

From energy balance equation,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_{in} = \dot{m}_{out} h_{out} - \dot{m}_{in} h_{in}$$

$$= \dot{m}(h_2 - h_1)$$

$$= \rho \dot{V} c_p (T_2 - T_1)$$

Step 4 of 5

Therefore by substituting the values, we get

$$\dot{Q}_{in} = \rho [V \times ACH] c_p (T_2 - T_1)$$

$$= 0.0734 \times \left[40500(2.2 - 1.1)\right](0.24)(532 - 496.5)$$

$$= 27{,}860 \text{ Btu/h } \frac{1 \text{ therm}}{100{,}000 \text{ Btu}}$$

$$= 0.2786 \text{ therm/h}$$

Step 5 of 5

Energy saved is given by,

$$\dot{E}_{saved} = \frac{\dot{Q}_{in}}{\eta_{furnace}}$$

$$= \frac{0.2789}{0.92}$$

$$= 0.3028 \text{ therm/h}$$

Considering the heating season as 6 months, and the unit cost for natural gas as $ 1.24/therm,

$$\text{Money saved} = (\text{Energy saved})(\text{Unit cost of energy})(\text{time period})$$

$$= \left(0.3028 \frac{\text{therm}}{\text{h}}\right)(\$1.24 \text{ /therm})(6 \times 30 \times 24)$$

$$= \$ 1622 \text{ per year}$$

Hence the total money saved per year is $\boxed{\$ 1622}$

Question: 6.154P

Determine the rate of sensible heat loss from a building due to infiltration if the outdoor air at −5°C and 90 kPa enters the building at a rate of 35 L/s when the indoors is maintained at 20°C.

Step 1 of 2

From properties table of air,

Gas constant of air is $R = 0.287\ \text{kPa}\cdot\text{m}^3/\text{kg}$

Specific heat of air is $c_p = 1.005\ \text{kJ/kg}\cdot{}^\circ\text{C}$

Find density of outdoor air, from the gas equation

$$P_o = \rho_0 R T_0 \text{ psia}$$

$$\rho_0 = \frac{P_0}{RT_0} \text{ lbm/ft}^3$$

Here, Average pressure of atmospheric air, P_0 , Average temperature in winter, T_0

Substitute $P_0 = 90\ \text{kPa}$, $T_0 = 268\ \text{K}$ and $R = 0.287\ \text{kPa}\cdot\text{m}^3/\text{kg}$ in the above equation

$$\begin{aligned}\rho_0 &= \frac{P_0}{RT_0} \text{ lbm/ft}^3 \\ &= \frac{90\ \text{kPa}}{(0.287)(268\ \text{K})} \\ &= 1.17\ \text{kg/m}^3\end{aligned}$$

Step 2 of 2

Apply the energy balance equation,

$$E_{in} = E_{out}$$

$$\begin{aligned}Q_{in} &= m_{out}h_{out} - m_{in}h_{in} \\ &= m(h_2 - h_1) \\ &= mc_p(T_2 - T_1)\end{aligned}$$

Find reduction in the sensible infiltration heat lost due to infiltration:

$$\begin{aligned}Q_{in} &= \rho_0 V_{air} c_p (T_2 - T_1) \\ &= 1.17\times[0.035](1.005)(20-(-5)) \\ &= 1.029\ \text{kW}\end{aligned}$$

Therefore, sensible heat will be lost due to infiltration is $\boxed{1.029\ \text{kJ/s}}$.

Question: 6.155P

Consider a large classroom on a hot summer day with 150 students, each dissipating 60 W of sensible heat. All the lights, with 6.0 kW of rated power, are kept on. The room has no external walls, and thus heat gain through the walls and the roof is negligible. Chilled air is available at 15°C, and the temperature of the return air is not to exceed 25°C. Determine the required flow rate of air, in kg/s, that needs to be supplied to the room to keep the average temperature of the room constant.

Step 1 of 4

The rate of heat generation by the people in the classroom

$$Q_{gen} = q_{gen} \times n$$

Here, q_{gen} is the heat generated by each student and n is the number of students in the classroom.

Substitute 60 W/persons for q_{gen} and 150 for n.

$$\begin{aligned} Q_{gen} &= 60 \times 150 \\ &= 9000 \text{ W} \\ &= 9 \text{ kW} \end{aligned}$$

Step 2 of 4

The total heat generated in the classroom is given by

$$Q_{tot} = Q_{gen} + Q_{light}$$

Here, Q_{gen} is the rate of heat generation by the people in the classroom and Q_{light} is the rate of heat generation by the light.

Substitute 9 kW for Q_{gen} and 6 kW for Q_{light}.

$$\begin{aligned} Q_{tot} &= Q_{gen} + Q_{light} \\ Q_{tot} &= 9 + 6 \\ Q_{tot} &= 15 \text{ kW} \end{aligned}$$

Step 3 of 4

The energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$\begin{aligned} E_{in} - E_{out} &= 0 \\ E_{in} &= E_{out} \\ Q_{in} + \dot{m} \times h_1 &= \dot{m} \times h_2 \\ Q_{in} &= \dot{m} \times h_2 - \dot{m} \times h_1 \\ Q_{in} &= \dot{m} \times (h_2 - h_1) \\ Q_{in} &= \dot{m} \times c_p \times (T_2 - T_1) \end{aligned}$$

Heat input to classroom is from students and lighting and so the heat input is same as total heat generated

$$Q_{out} = \dot{m} \times c_p \times (T_2 - T_1)$$

Step 4 of 4

Mass flow rate of air is given by

$$\dot{m} = \frac{Q_{tot}}{c_p \times (T_2 - T_1)}$$

Here, T_1 & T_2 are the initial and final temperatures of air respectively and c_p is the specific heat ratio.

From specific heat tables at air is $c_p = 1.005$ kJ/kg°C

Substitute 15°C for T_1 and 25°C for T_2.

$$\begin{aligned} \dot{m} &= \frac{Q_{tot}}{c_p \times (T_2 - T_1)} \\ &= \frac{15}{1.005 \times (25 - 15)} \\ &= \frac{15}{1.005 \times 10} \\ &= \frac{15}{10.05} \\ &= 1.492 \text{ kg/s} \end{aligned}$$

Therefore, the mass flow rate of air is $\boxed{1.492 \text{kg/s}}$

Question: 6.156P

A fan is powered by a 0.5-hp motor and delivers air at a rate of 85 m3/min. Determine the highest value for the average velocity of air mobilized by the fan. Take the density of air to be 1.18 kg/m3.

Step 1 of 3

Since mass crosses the system boundary during the process, consider the fan-motor assembly is control volume

Since there is only one inlet and one exit, and thus

$$\dot{m}_1 = \dot{m}_2 = \dot{m}$$

When all of the entire electrical energy drawn by the motor is converted to kinetic energy and the friction between the air layers is zero then the velocity of air leaving the fan will be high. In this best possible case, no energy will be converted to thermal energy, and thus there is no change in temperature change

$T_1 = T_2$ Since temperature remains constant, enthalpy remains constant $h_1 = h_2$

Step 2 of 3

Find mass flow rate of air is

$$\begin{aligned}\dot{m} &= \rho \dot{V} \\ &= 1.18(\text{kg/m}^3) \times 85(\text{m}^3/\text{min}) \\ &= 100.3\,\text{kg/min} \\ &= 1.67\,\text{kg/s}\end{aligned}$$

Apply energy balance for this steady-flow system:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} = 0$$

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{W}_{e,in} + \dot{m}_1 h_1 = \dot{m}_2 \left(h_2 + \frac{V_2^2}{2} \right)$$

$$\dot{W}_{e,in} + \dot{m} h_1 = \dot{m} \left(h_2 + \frac{V_2^2}{2} \right)$$

$$\dot{W}_{e,in} + \dot{m} h_1 = \dot{m} \left(h_1 + \frac{V_2^2}{2} \right)$$

$$\dot{W}_{e,in} = \dot{m} \frac{V_2^2}{2}$$

$$V_2 = \sqrt{\frac{2\dot{W}_{e,in}}{\dot{m}}}$$

Step 3 of 3

Substitute the known values in above equation

$$\begin{aligned}V_2 &= \sqrt{\frac{2\dot{W}_{e,in}}{\dot{m}}} \\ &= \sqrt{\frac{2 \times 0.5\,\text{hp}}{1.67\,\text{kg/s}} \times \left(\frac{745.7\,\text{W}}{1\,\text{hp}} \right) \times \left(\frac{1\,\text{kg-m}^2/\text{s}^3}{\text{W}} \right)} \\ &= 21.13\,\text{m/s}\end{aligned}$$

Therefore the average velocity of air is $\boxed{V_2 = 21.13\,\text{m/s}}$

Question: 6.157P

An air-conditioning system requires airflow at the main supply duct at a rate of 130 m3/min. The average velocity of air in the circular duct is not to exceed 8 m/s to avoid excessive vibration and pressure drops. Assuming the fan converts 80 percent of the electrical energy it consumes into kinetic energy of air, determine the size of the electric motor needed to drive the fan and the diameter of the main duct. Take the density of air to be 1.20 kg/m3.

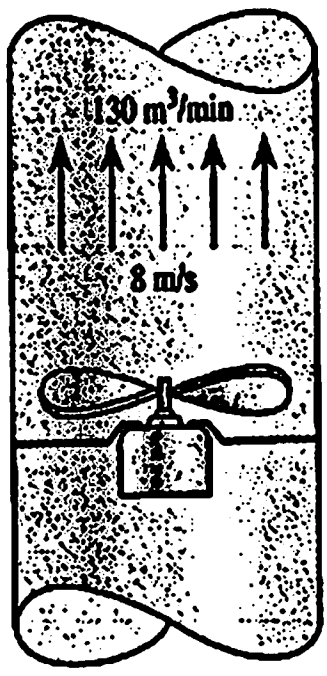

FIGURE P6–157

Step 1 of 3

Given

Volume flow rate of air, $\dot{V} = 130\ \text{m}^3/\text{min}$

The average velocity of air $V_2 = 8\ \text{m/s}$

The efficiency of fan is 80%

From properties table, Gas constant $R = 0.287\ \text{kJ/kg.K}$

Specific heat at constant pressure, $c_p = 1.005\ \text{kJ/kg.K}$

density of air, $\rho = 1.2\ \text{kg/m}^3$

Step 2 of 3

The mass flow rate is expressed as

$$\dot{m} = \rho\dot{V}$$
$$= (1.2)(130/60)$$
$$= 2.6\ \text{kg/s}$$

The energy balance equation for a steady state process is

$$\dot{W} = \dot{Q} - \dot{m}\left(h_1 - h_2 + \frac{V_1^2 - V_2^2}{2} + g(z_1 - z_2)\right)$$

Neglecting potential energy change, enthalpy change and heat losses,

$$\eta\dot{W} = \dot{Q} - \dot{m}\left(h_1 - h_2 + \frac{V_1^2 - V_2^2}{2} + g(z_1 - z_2)\right)$$

$$\eta\dot{W} = 0 - 2.6\left(\frac{0^2 - 8^2}{2} \times \frac{1\ \text{kJ/kg}}{1000\ \text{m}^2/\text{s}^2}\right)$$

$$(0.8)\dot{W} = -(0.0832)\ \text{kW}$$

Thus $\dot{W}_{\text{motor}} = 0.104\ \text{kW}$

The electric power consumed by the motor is $\boxed{\dot{W}_{\text{motor}} = 0.104\ \text{kW}}$

Step 3 of 3

From volumetric flow relation,

$$\dot{V} = VA$$

$$\dot{V} = V \times \frac{\pi D^2}{4}$$

Thus the diameter of the main duct is

$$D = \sqrt{\frac{4\dot{V}}{\pi V}}$$
$$= \sqrt{\frac{4(130/60)}{\pi(8)}}$$
$$= \sqrt{0.3448}$$
$$= 0.587\ \text{m}$$

Hence the duct diameter is $\boxed{D = 0.587\ \text{m}}$

Question: 6.158P

An adiabatic air compressor is to be powered by a direct-coupled adiabatic steam turbine that is also driving a generator. Steam enters the turbine at 12.5 MPa and 500°C at rate of 25 kg/s and exits at 10 kPa and a quality of 0.92. Air enters the compressor at 98 kPa and 295 K at a rate of 10 kg/s and exits at 1 MPa and 620 K. Determine the net power delivered to the generator by the turbine.

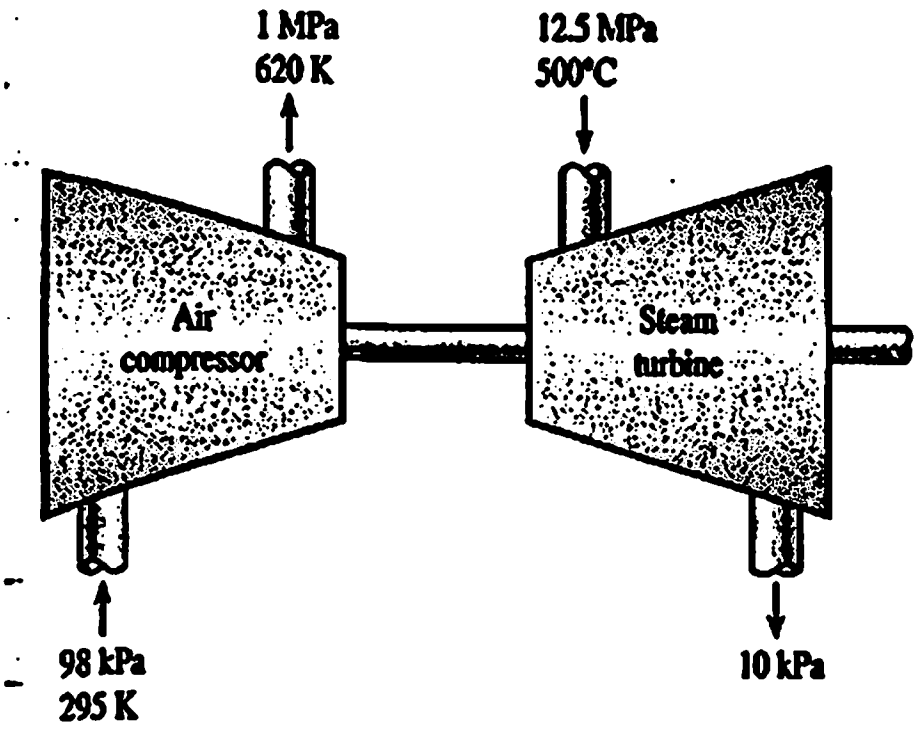

FIGURE P6–158

Step 1 of 4

Take the properties at turbine inlet pressure $P_1 = 12.5$ MPa and turbine inlet temperature $T_1 = 500$ °C from superheated water tables,

Specific enthalpy of steam $h_1 = 3343.6$ kJ/kg

Take the properties of water from saturated water tables at turbine exit pressure $P_2 = 10$ kPa

Specific enthalpy of saturated liquid $h_{f2} = 191.81$kJ/kg

Specific enthalpy of evaporation $h_{fg2} = 2392.1$kJ/kg

Find specific enthalpy of steam by using the equation,

$$h_2 = h_{f2} + x_2 \times h_{fg2}$$

Here, turbine exit quality $x_2 = 0.92$

$$h_2 = 191.81 + 0.92 \times 2392.1$$
$$= 191.81 + 2200.732$$
$$= 2392.542 \text{ kJ/kg}$$

Step 2 of 4

From ideal gas properties of air table at compressor inlet temperature $T_3 = 295$ K specific enthalpy of air is

$$h_3 = 295.17 \text{ kJ/kg}$$

Similarly at compressor exit temperature $T_4 = 620$ K specific enthalpy of air is

$$h_4 = 628.07 \text{ kJ/kg}$$

As there is only one entry and one exit for turbine, mass flow rate will be same

$$\dot{m}_1 = \dot{m}_2 = \dot{m}_{steam}$$
$$\dot{m}_{steam} = 25 \text{ kg/s}$$

As there is only one entry and one exit for compressor, mass flow rate will be same

$$\dot{m}_3 = \dot{m}_4 = \dot{m}_{air}$$
$$\dot{m}_{air} = 10 \text{ kg/s}$$

Step 3 of 4

Find the work done by turbine by using the equation,

$$\dot{W}_{tur} = \dot{m}_{steam} \times (h_1 - h_2)$$
$$= 25 \times (3343.6 - 2392.542)$$
$$= 25 \times 951.058$$
$$= 23776.45 \text{ kW}$$

Find the work required to run the compressor by using the equation,

$$\dot{W}_{comp} = \dot{m}_{air} \times (h_4 - h_3)$$
$$= 10 \times (628.07 - 295.17)$$
$$= 10 \times 332.9$$
$$= 3329 \text{ kW}$$

Step 4 of 4

Since work done by turbine is used for running compressor and generator

$$\dot{W}_{tur} = \dot{W}_{comp} + \dot{W}_{gen}$$
$$\dot{W}_{gen} = \dot{W}_{tur} - \dot{W}_{comp}$$
$$= 23776.45 - 3329$$
$$= 20447.45 \text{ kW}$$

Therefore, the net power delivered to generator is **20447.45 kW**

Question: 6.159P

Determine the power input for a compressor that compresses helium from 150 kPa and 20°C to 400 kPa and 200°C. Helium enters this compressor through a 0.1-m2 pipe at a velocity of 15 m/s.

Step 1 of 4

From ideal gas properties take the properties of helium

Specific heat at constant pressure $c_p = 5.1926\ \text{kJ/kg}\cdot\text{K}$

Gas constant of Helium $R = 2.0769\ \text{kJ/kg}\cdot\text{K}$

Step 2 of 4

As there is only one entry and one exit for compressor, mass flow rate will be same

$$\dot{m}_1 = \dot{m}_2 = \dot{m}$$

Calculate the specific volume of helium at inlet of compressor by using the equation,

$$v_1 = \frac{R \times T_1}{P_1}$$

Here T_1 and P_1 are inlet temperature and pressure respectively

Substitute $20°\text{C} = 293\text{K}$ for T_1 and 150 kPa for P_1

$$\begin{aligned} v_1 &= \frac{2.0769 \times (20+273)}{150} \\ &= \frac{2.0769 \times 293}{150} \\ &= \frac{608.5317}{150} \\ &= 4.0569\ \text{m}^3/\text{kg} \end{aligned}$$

Step 3 of 4

Find the mass flow rate of helium by using the expression

$$\dot{m} = \frac{A_1 \times V_1}{v_1}$$

Here A_1 is the area of cross-section and V_1 is the inlet velocity of compressor.

Substitute $15\ \text{m/s}$ for V_1

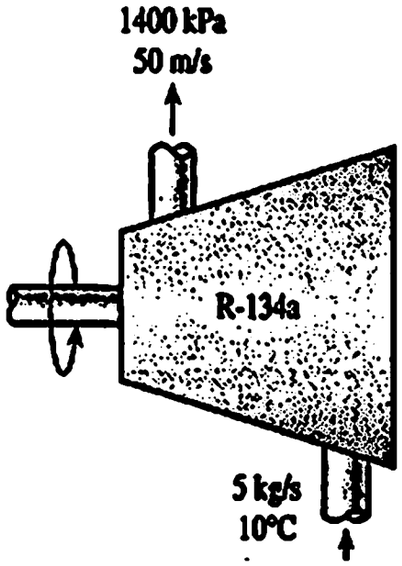
$$\begin{aligned} \dot{m} &= \frac{0.1 \times 15}{4.0569} \\ &= \frac{1.5}{4.0569} \\ &= 0.3697\ \text{kg/s} \end{aligned}$$

Step 4 of 4

Apply the energy balance equation to the steady flow system,

$$E_{in} - E_{out} = \Delta E_{sys}$$

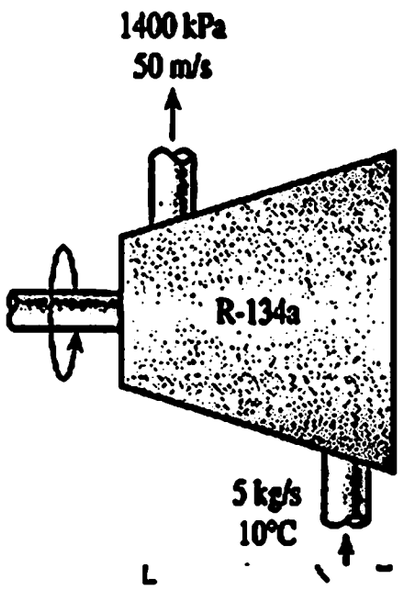
For steady process, $\Delta E_{sys} = 0$ and so



$$\begin{aligned} E_{in} - E_{out} &= 0 \\ E_{in} &= E_{out} \\ W_{in} + \dot{m} \times h_1 &= \dot{m} \times h_2 \\ W_{in} &= \dot{m} \times h_2 - \dot{m} \times h_1 \\ W_{in} &= \dot{m} \times (h_2 - h_1) \\ &= \dot{m} \times c_p \times (T_2 - T_1) \\ &= 0.3697 \times 5.1926 \times (200 - 20) \\ &= 0.3697 \times 5.1926 \times 180 \\ &= 345.55\ \text{kW} \end{aligned}$$

Therefore, the power required to run the compressor is $\boxed{345.55\ \text{kW}}$

Question:



6.160P

Refrigerant 134a enters a compressor with a mass flow rate of 5 kg/s and a negligible velocity. The refrigerant enters the compressor as a saturated vapor at 10°C and leaves the compressor at 1400 kPa with an enthalpy of 281.39 kJ/kg and a velocity of 50 m/s. The rate of work done on the refrigerant is measured to be 132.4 kW. If the elevation change between the compressor inlet and exit is negligible, determine the rate of heat transfer associated with this process, in kW.

Question:

Refrigerant 134a enters a compressor with a mass flow rate of 5 kg/s and a negligible velocity. The refrigerant enters the compressor as a saturated vapor at 10°C and leaves the compressor at 1400 kPa with an enthalpy of 281.39 kJ/kg and a velocity of 50 m/s. The rate of work done on the refrigerant is measured to be 132.4 kW. If the elevation change between the compressor inlet and exit is negligible, determine the rate of heat transfer associated with this process, in kW.

$$= 5\left[(256.16 - 281.39) - \left(\frac{50^2}{2000}\right)\right] + (132.4)$$

$$= 0$$

The heat transfer in the process is $\boxed{\dot{Q}_{out} = 0}$

Therefore it is an adiabatic process.

Question:

6.161P

Submarines change their depth by adding or removing air from rigid ballast tanks, thereby displacing seawater in the tanks. Consider a submarine that has a 700 m3 air-ballast tank originally partially filled with 100 m3 of air at 1500 kPa and 15°C. For the submarine to surface, air at 1500 kPa and 20°C is pumped into the ballast tank, until it is entirely filled with air. The tank is filled so quickly that the process is adiabatic and the seawater leaves the tank at 15°C. Determine the final temperature and mass of the air in the ballast tank.

Step 1 of 4

Obtain properties of air from properties of air table.

Gas constant of air is $R = 0.287\ \text{kPa} \cdot \text{m}^3/\text{kg}$

Specific heat of air is $c_p = 1.005\ \text{kJ/kg} \cdot °\text{C}$

Apply the conservation of mass principle to the air.

$$\frac{dm_a}{dt} = \dot{m}_{in} - \dot{m}_{out}$$

Question:

Submarines change their depth by adding or removing air from rigid ballast tanks, thereby displacing seawater in the tanks. Consider a submarine that has a 700 m3 air-ballast tank originally partially filled with 100 m3 of air at 1500 kPa and 15°C. For the submarine to surface, air at 1500 kPa and 20°C is pumped into the ballast tank, until it is entirely filled with air. The tank is filled so quickly that the process is adiabatic and the seawater leaves the tank at 15°C. Determine the final temperature and mass of the air in the ballast tank.

Step 1 of 4

Obtain properties of air from properties of air table.

Gas constant of air is $R = 0.287\ \text{kPa} \cdot \text{m}^3/\text{kg}$

Specific heat of air is $c_p = 1.005\ \text{kJ/kg} \cdot °\text{C}$

Apply the conservation of mass principle to the air.

$$\frac{dm_a}{dt} = \dot{m}_{in} - \dot{m}_{out}$$

Step 2 of 4

Apply steady flow energy equation to the system

$$0 = \frac{d(mu)_a}{dt} + \frac{d(mu)_w}{dt} + h_w \dot{m}_{out} - h_a \dot{m}_{in} \quad \cdots\cdots (3)$$

Here, enthalpies of mass water and air are h_w and h_a respectively and u_a and u_w are specific internal energies of air and water respectively.

Substitute equation (1) and (2) in equation (3).

$$0 = \frac{d(mu)_a}{dt} + \frac{d(mu)_w}{dt} - h_w \frac{dm_w}{dt} - h_a \frac{dm_a}{dt}$$

$$d(mu)_a + d(mu)_w = h_w dm_w + h_a dm_a$$

Integrate the equation.

$$\int \left(d(mu)_a + d(mu)_w \right) = h_w \int dm_w + h_a \int dm_a$$

$$\left[(mu)_2 - (mu)_1 \right]_a + \left[(mu)_2 - (mu)_1 \right]_w = h_w (m_2 - m_1)_w + h_a (m_2 - m_1)_a$$

Here, mass of water at state 2 is zero, $m_{2,w} = 0$

Step 3 of 4

Substitute mass of air by using ideal gas equation as $\frac{Pv}{RT}$ for m_a and $c_v T$ for u_a and $c_p T$ for h_a

$$\frac{Pv_2}{RT_2} c_v T_2 - \frac{Pv_1}{RT_1} c_v T_1 + \left(0 - m_{w,1} c_w T_w \right) = \left(0 - m_{w1} c_w T_w \right) + c_p T_{in} \left(\frac{Pv_2}{RT_2} - \frac{Pv_1}{RT_1} \right)$$

$$\frac{Pv_2}{RT_2} c_v T_2 - \frac{Pv_1}{RT_1} c_v T_1 = c_p T_{in} \left(\frac{Pv_2}{RT_2} - \frac{Pv_1}{RT_1} \right)$$

$$c_v \left(\frac{v_2}{T_2} T_2 - \frac{v_1}{T_1} T_1 \right) = c_p T_{in} \left(\frac{v_2}{T_2} - \frac{v_1}{T_1} \right)$$

$$\frac{c_v}{c_p} (v_2 - v_1) = T_{in} \left(\frac{v_2}{T_2} - \frac{v_1}{T_1} \right)$$

$$\frac{1}{kT_{in}} (v_2 - v_1) + \frac{v_1}{T_1} = \frac{v_2}{T_2}$$

$$T_2 = \frac{v_2}{\frac{1}{kT_{in}} (v_2 - v_1) + \frac{v_1}{T_1}} \quad \cdots\cdots (4)$$

Here, k is specific heat ratio and T_{in} is temperature of air entering into the ballast tank

Step 4 of 4

Substitute $700\,\text{m}^3$ for v_2 , $100\,\text{m}^3$ for v_1 , $(15°\text{C} = 288\,\text{K})$ for T_1 , $(20°\text{C} = 293\,\text{K})$ for T_{in} and 1.4 for k in equation (4)

$$T_2 = \frac{v_2}{\frac{v_1}{T_1} + \frac{1}{kT_{in}} (v_2 - v_1)}$$

$$= \frac{700}{\frac{100}{288} + \frac{1}{1.4 \times 293} (700 - 100)}$$

$$= 386.75\ \text{K}$$

The final temperature of the air in the ballast tank is $\boxed{386.75\ \text{K}}$.

Find the final mass of air present in the ballast tank

$$m_{2a} = \frac{Pv_2}{RT_2}$$

Here, P is final pressure of air in the tank and v_2 is final volume of air in the ballast tank.

Substitute 1500 kPa for P, $700\,\text{m}^3$ for v_2 and 386.75 K for T_2

$$m_{2a} = \frac{1500 \times 700}{(0.287)(386.75)}$$

$$= 9{,}459.693\ \text{kg}$$

Therefore, the final mass of air present in the ballast tank is $\boxed{9{,}459.693\ \text{kg}}$

k in equation (4)

Question: 6.162P

In the preceding problem, presume that air is added to the tank in such a way that the temperature and pressure of the air in the tank remain constant. Determine the final mass of the air in the ballast tank under this condition. Also determine the total heat transfer while the tank is being filled in this manner.

Step 1 of 2

Find the initial mass of the air,

$$m_1 = \frac{P_1 V_1}{R T_1}$$

Here,

The pressure, temperature and volume at state-1 is P_1, T_1 and V_1 respectively

Substitute $1500\,\text{kPa}$ for P_1, $100\,\text{m}^3$ for V_1, $0.287\,\text{kJ/kg}\cdot\text{K}$ and $288.15\,\text{K}$ for T_1,

$$m_1 = \frac{P_1 V_1}{R T_1}$$

Question:

In the preceding problem, presume that air is added to the tank in such a way that the temperature and pressure of the air in the tank remain constant. Determine the final mass of the air in the ballast tank under this condition. Also determine the total heat transfer while the tank is being filled in this manner.

Step 1 of 2

Find the initial mass of the air,

$$m_1 = \frac{P_1 V_1}{R T_1}$$

Here,

The pressure, temperature and volume at state-1 is P_1, T_1 and V_1 respectively

Substitute $1500\,\text{kPa}$ for P_1, $100\,\text{m}^3$ for V_1, $0.287\,\text{kJ/kg}\cdot\text{K}$ and $288.15\,\text{K}$ for T_1,

$$\begin{aligned} m_1 &= \frac{P_1 V_1}{R T_1} \\ &= \frac{1500\times 100}{0.287\times 288.15} \\ &= 1814\,\text{kg} \end{aligned}$$

Find the initial mass of the water,

$$m_w = \frac{V_w}{v_1}$$

Here,

The initial volume of the water is V_w

The initial specific volume of the water is v_1

Substitute $600\,\text{m}^3$ for V_w and $0.001\,\text{m}^3/\text{kg}$ for v_1,

$$\begin{aligned} m_w &= \frac{V_w}{v_1} \\ &= \frac{600}{0.001} \\ &= 600000\,\text{kg} \end{aligned}$$

Step 2 of 2

Find the final mass of the air,

$$m_2 = \frac{P_2 V_2}{R T_2}$$

Here,

The pressure, temperature and volume at state-2 is P_2, T_2 and V_2 respectively

Substitute $1500\,\text{kPa}$ for P_2, $700\,\text{m}^3$ for V_2, $0.287\,\text{kJ/kg}\cdot\text{K}$ and $288.15\,\text{K}$ for T_1,

$$m_2 = \frac{P_2 V_2}{R T_2}$$

$$1500 \times 700$$

$600000\,\text{kg}$ for m_w and $62.98\,\text{kJ/kg}$ for h_w,

$$\begin{aligned} Q_{in} &= m_2 c_v T - (m_1 c_v T + m_w h_w) + m_w h_w - (m_2 - m_1) c_p T \\ &= (12696\times 0.718\times 288.15) - (1814\times 0.718\times 288.15 + 600000\times 62.98) \\ &\quad + (600000\times 62.98) - (12696\times 1.005\times 288.15) \\ &= 0\,\text{kJ} \end{aligned}$$

Therefore, the process is adiabatic.

Question: 6.163P

A steel cylinder initially contains nitrogen gas at 200 kPa and 25°C. The cylinder is connected to a supply line containing nitrogen at 800 kPa and 25 °C. A valve is opened, allowing nitrogen to flow into the cylinder until the pressure reaches 800 kPa. The cylinder internal volume is 0.1 m3, its mass (cylinder only) is 50 kg, and its specific heat is 0.43 kJ/kg•K. Find the final mass of nitrogen in the tank and the final temperature of the nitrogen assuming constant specific heats at room temperature for nitrogen, and assuming (a) no heat transfer from the nitrogen to the tank, and (b) rapid heat transfer between the nitrogen and tank such that the cylinder and nitrogen remain in thermal equilibrium during the process (with negligible heat transfer from the cylinder to its external surroundings.)

Step 1 of 5

Calculate the Final mass by using the following equation

$$m_2 = \frac{P_2 \times V}{T_2 \times R}$$

Here, Final pressure of the air P_2 Final temperature of the air T_2

Question:

A steel cylinder initially contains nitrogen gas at 200 kPa and 25°C. The cylinder is connected to a supply line containing nitrogen at 800 kPa and 25 °C. A valve is opened, allowing nitrogen to flow into the cylinder until the pressure reaches 800 kPa. The cylinder internal volume is 0.1 m3, its mass (cylinder only) is 50 kg, and its specific heat is 0.43 kJ/kg•K. Find the final mass of nitrogen in the tank and the final temperature of the nitrogen assuming constant specific heats at room temperature for nitrogen, and assuming (a) no heat transfer from the nitrogen to the tank, and (b) rapid heat transfer between the nitrogen and tank such that the cylinder and nitrogen remain in thermal equilibrium during the process (with negligible heat transfer from the cylinder to its external surroundings.)

Step 1 of 5

Calculate the Final mass by using the following equation

$$m_2 = \frac{P_2 \times V}{T_2 \times R}$$

Here, Final pressure of the air P_2 Final temperature of the air T_2

Substitute, $800\ \text{kPa}$ for P_2, $0.1\ \text{m}^3$ for V and $0.287\ \text{kJ/kg}\cdot\text{K}$ for R

$$m_2 = \frac{800 \times 0.1}{T_2 \times 0.287} = \frac{278.7}{T_2}$$

Step 2 of 5

Calculate the mass of air by using the mass balance

$$m_{in} - m_{out} = \Delta m_{sys}$$

$$m_s - 0 = m_2 - m_1$$

Here, Initial mass in the tank is m_1, Final mass in the tank is m_2, mass entered in the tank is m_s

Substitute, $11.946\ \text{kg}$ for m_2 and $2.362\ \text{kg}$ for m_1

$$m_s = m_2 - m_1$$

Calculate heat transfer by using the following energy balance

$$E_{in} - E_{out} = E_{sys}$$

For a steady process, $E_{sys} = 0$ and so

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$m_s h_s = m_2 u_2 - m_1 u_1$$

$$m_s h_s = m_2 c_v T_2 - m_1 c_v T_1$$

Step 3 of 5

(a) No heat transfer from nitrogen to the tank

From the mass balance equation

$$(m_2 - m_1) c_p T_s = m_2 c_v T_2 - m_1 c_v T_1$$

Rearrange the above equation to find the final temperature

$$T_2 = \frac{(m_2 - m_1) c_p T_s + m_1 c_v T_1}{m_2 c_v}$$

Substitute the corresponding values in the above equation

$$T_2 = \frac{\left(\frac{278.7}{T_2} - 0.2261\right)(1.039 \times 298) + (0.2261 \times 0.743 \times 298)}{\frac{278.7}{T_2} \times 0.743}$$

Step 4 of 5

Solve the above equation using Equation solver and find the values of final temperature

$$T_2 = 380.1\ \text{K} = 107.1°\text{C}$$

Therefore, the final temperature of the system $\boxed{107.1°\text{C}}$

Find the final mass of the system as below

$$m_2 = \frac{800 \times 0.1}{T_2 \times 0.287} = \frac{278.7}{380.1} = 0.733\ \text{kg}$$

Therefore, the final mass of the system is $\boxed{0.733\ \text{kg}}$

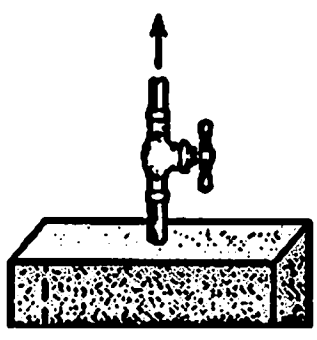
(b) Rapid heat transfer between nitrogen and tank

Apply the energy balance to the system

$$E_{in} - E_{out} = E_{sys}$$

$$(m_2 - m_1) c_p T_s = (m_{air,2} c_v T_2 + m_{cy} c_{cy} T_2) - (m_{air,1} c_v T_1 + m_{cy} c_{cy} T_1)$$

Therefore, the final mass of the system is $\boxed{0.9226\ \text{kg}}$



Question: 6.164P pg 1

A tank with an internal volume of 1 m3 contains air at 800 kPa and 25°C. A valve on the tank is opened allowing air to escape and the pressure inside quickly drops to 150 kPa, at which point the valve is closed. Assume there is negligible heat transfer from the tank to the air left in the tank.

(*a*) Using the approximation he ≈ constant = he,avg = 0.5(*h*1 + h2), calculate the mass withdrawn during the process.

(*b*) Consider the same process but broken into two parts. That is, consider an intermediate state at P2 = 400 kPa, calculate the mass removed during the process from *P*1, = 800 kPa to P2 and then the mass removed during the process from P2 to *P*3 = 150 kPa, using the type of approximation used in part (a), and add the two to get the total mass removed.

(*c*) Calculate the mass removed if the variation of he is accounted for.

Question:

A tank with an internal volume of 1 m3 contains air at 800 kPa and 25°C. A valve on the tank is opened allowing air to escape and the pressure inside quickly drops to 150 kPa, at which point the valve is closed. Assume there is negligible heat transfer from the tank to the air left in the tank.

(*a*) Using the approximation he ≈ constant = he,avg = 0.5(*h*1 + h2), calculate the mass withdrawn during the process.

(*b*) Consider the same process but broken into two parts. That is, consider an intermediate state at P2 = 400 kPa, calculate the mass removed during the process from *P*1, = 800 kPa to P2 and then the mass removed during the process from P2 to *P*3 = 150 kPa, using the type of approximation used in part (a), and add the two to get the total mass removed.

(*c*) Calculate the mass removed if the variation of he is accounted for.

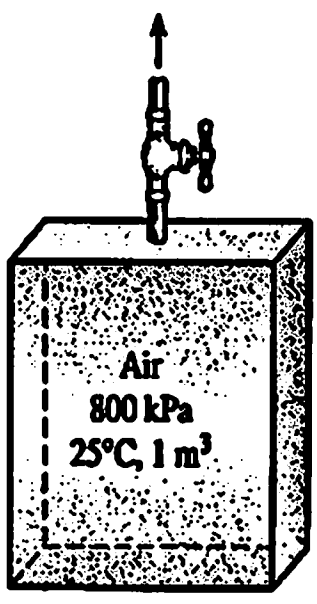


FIGURE P6–164

Step 1 of 12

(a)

Calculate the initial mass in the tank using the ideal gas equation:

$$p_1V_1 = m_1RT_1$$

$$m_1 = \frac{p_1V_1}{RT_1}$$

Here, p is the pressure, T is the temperature, R is the gas constant, V is the volume, and m is the mass.

Substitute $800(10^3)$ Pa for p_1, $1\ \text{m}^3$ for V_1, $(25+273)$ K for T_1, and $287\ \text{J/kg}\cdot\text{K}$ for R.

$$m_1 = \frac{[800(10^3)](1)}{(287)(25+273)}$$
$$= 9.35\ \text{kg}$$

Step 2 of 12

Calculate the final mass in the tank using the ideal gas equation:

$$p_2V_2 = m_2RT_2$$

$$m_2 = \frac{p_2V_2}{RT_2}$$

Substitute $150(10^3)$ Pa for p_2, $1\ \text{m}^3$ for V_2, and $287\ \text{J/kg}\cdot\text{K}$ for R.

$$m_2 = \frac{[150(10^3)](1)}{(287)T_2} \quad \text{..... (1)}$$
$$= \frac{522.64}{T_2}$$

Step 3 of 12

Apply mass balance equation.

$$m_e = m_1 - m_2 \quad \text{..... (2)}$$

Here, m_e is the mass exiting the tank.

[illegible] 2.73 kg [illegible]

Calculate the mass withdrawn from the tank using equation (2).

$$m_e = m_1 - m_2$$
$$= 9.35 - 2.73$$
$$= 6.62\ \text{kg}$$

Therefore, the mass of air extracted is $\boxed{6.62\ \text{kg}}$.

$= 9.35 - 2.73$

$= 6.62 \text{ kg}$

Therefore, the mass of air extracted is $\boxed{6.62 \text{ kg}}$.

Step 4 of 12

(b)

Stage 1 to a: Consider the pressure drop from 800 kPa to 400 kPa.

Calculate the mass during the intermediate stage (m_2) using the ideal gas equation:

$$p_2 V_2 = m_2 R T_2$$

$$m_2 = \frac{p_2 V_2}{R T_2}$$

Here, suffix *a* indicates intermediate stage.

Substitute $400(10^3)$ Pa for p_2, 1 m^3 for V_2, and $287 \text{ J/kg} \cdot \text{K}$ for R.

$$p_2 V_2 = m_2 R T_2$$

$= 2.15 \text{ kg}$

Calculate the mass withdrawn from the tank using equation (2).

$$m_e = m_1 - m_2$$

$= 9.35 - 2.73$

$= 6.62 \text{ kg}$

Therefore, the mass of air extracted is $\boxed{6.62 \text{ kg}}$.

Step 4 of 12

(b)

Stage 1 to a: Consider the pressure drop from 800 kPa to 400 kPa.

Calculate the mass during the intermediate stage (m_2) using the ideal gas equation:

$$p_2 V_2 = m_2 R T_2$$

$$m_2 = \frac{p_2 V_2}{R T_2}$$

Here, suffix *a* indicates intermediate stage.

Substitute $400(10^3)$ Pa for p_2, 1 m^3 for V_2, and $287 \text{ J/kg} \cdot \text{K}$ for R.

$$p_2 V_2 = m_2 R T_2$$

$$m_a = \frac{400(10^3)(1)}{(287) T_2}$$

$$= \frac{1394}{T_2}$$

Step 5 of 12

Apply energy equation for the stage 1-a.

$$\Delta E = E_{in} - E_{out}$$

$$0 - m_e h_e = m_2 u_2 - m_1 u_1$$

$$m_e h_e + m_2 u_2 - m_1 u_1 = 0$$

$$\left[(m_1 - m_2) c_p \left(\frac{T_1 + T_2}{2}\right)\right] + (m_2 c_v T_2) - (m_1 c_v T_1) = 0$$

Substitute 9.35 kg for m_1, $1.005 \text{ kJ/kg} \cdot \text{K}$ for c_p, $0.718 \text{ kJ/kg} \cdot \text{K}$ for c_v, and $(25 + 273)$ K.

$$\left[\left(9.35 - \frac{1394}{T_2}\right)(1.005)\left(\frac{298 + T_2}{2}\right)\right] + \left(\frac{1394}{T_2}(0.718) T_2\right) - (9.35)(0.718)(298) = 0$$

$$T_2 = 245.12 \text{ K}$$

Step 6 of 12

Calculate the mass at the intermediate stage.

$$m_2 = \frac{1394}{T_2}$$

$$= \frac{1394}{245.12}$$

$$= 5.687 \text{ kg}$$

Calculate the mass of air extracted during the stage 1-2 (m_{1-2}) using the following relation:

$$m_{1-2} = m_1 - m_2$$

$= 9.35 - 5.687$

$= 3.66 \text{ kg}$

Step 7 of 12

Stage 2 to 3: Consider the pressure drop from 400 kPa to 150 kPa.

Apply energy equation for the stage 2-3.

$$\Delta E = E_{in} - E_{out}$$

$$0 - m_e h_e = m_3 u_3 - m_2 u_2$$

$$m_e h_e + m_3 u_3 - m_2 u_2 = 0$$

$$\left[(m_2 - m_3) c_p \left(\frac{T_3 + T_2}{2}\right)\right] + (m_3 c_v T_3) - (m_2 c_v T_2) = 0$$

Substitute $\frac{522.64}{T_3}$ for m_3, $1.005 \text{ kJ/kg} \cdot \text{K}$ for c_p, $0.718 \text{ kJ/kg} \cdot \text{K}$ for c_v, and $(25 + 273)$ K.

$$\left[\left[\left(5.687 - \frac{522.64}{T_3}\right)(1.005)\left(\frac{245.12 + T_3}{2}\right)\right] + \left(\frac{522.64}{T_3}(0.718) T_3\right)\right] - 0$$

Substitute $\frac{522.64}{T_3}$ for m_3, $1.005\ \text{kJ/kg·K}$ for c_p, $0.718\ \text{kJ/kg·K}$ for c_v, and $(25+273)\ \text{K}$.

$$\left[\left[\left(5.687-\frac{522.64}{T_3}\right)(1.005)\left(\frac{245.12+T_3}{2}\right)\right]+\left(\frac{522.64}{T_3}(0.718)T_3\right)\right]=0$$
$$-(5.687)(0.718)(245.12)$$

$$T_3=186.47\ \text{K}$$

Step 8 of 12

Calculate the mass m_3 using the following relation:

$$m_3=\frac{522.64}{T_3}$$
$$=\frac{522.64}{186.47}$$
$$=2.80\ \text{kg}$$

Calculate the mass extracted during stage 2-3 using the following relation:

$$m_{2-3}=m_2-m_3$$
$$=5.687-2.80$$
$$=2.887\ \text{kg}$$

Calculate the total mass extracted during the process:

$$m_e=m_{1-2}+m_{2-3}$$
$$=3.66+2.887$$
$$=6.547\ \text{kg}$$

Therefore, the mass of air extracted is $\boxed{6.547\ \text{kg}}$.

Step 9 of 12

(c)

Consider the differential form of mass flow rate

$$\dot{m}_e=\frac{dm}{dt}$$

Apply the relation for the ideal gas equation:

$$pV=mRT$$
$$m=\frac{pV}{RT}$$

Differentiate the equation with respect to time.

$$pV=mRT$$
$$\frac{dm}{dt}=\frac{d}{dt}\left(\frac{pV}{RT}\right)$$
$$=\frac{V}{R}\frac{d(p/T)}{dt}$$

Step 10 of 12

The volume of the tank is constant through the process. Calculate the change in energy during the process as follows:

The change in internal energy (du) in the tank is equal to the rate of enthalpy exiting the tank (h_e).

$$\frac{d(mu)}{dt}=-h_e\dot{m}_e$$
$$c_v\frac{d(mT)}{dt}=c_pT\frac{dm}{dt}$$

Substitute $\frac{V}{R}\frac{d(p/T)}{dt}$ for $\frac{dm}{dt}$.

$$c_v\frac{v}{R}\frac{d\left[(P/T)(T)\right]}{dt}=c_p\left(\frac{dP}{dt}-\frac{P}{T}\frac{dT}{dt}\right)$$
$$c_v\frac{v}{R}\frac{dP}{dt}=c_p\left(\frac{dP}{dt}-\frac{P}{T}\frac{dT}{dt}\right)$$
$$(c_p-c_v)\frac{dP}{P}=c_p\frac{dT}{T}$$
$$\frac{(c_p-c_v)}{c_p}\frac{dP}{P}=\frac{dT}{T}$$
$$\left(1-\frac{c_v}{c_p}\right)\frac{dP}{P}=\frac{dT}{T}$$
$$\left(1-\frac{1}{\gamma}\right)\frac{dP}{P}=\frac{dT}{T}$$
$$\left(\frac{\gamma-1}{\gamma}\right)\frac{dP}{P}=\frac{dT}{T}$$

Step 11 of 12

Integrate the above equation.

$$\frac{(\gamma-1)}{\gamma}\int_{P_1}^{P_2}\left(\frac{dP}{P}\right)=\int_{T_1}^{T_2}\left(\frac{dT}{T}\right)$$
$$\frac{(\gamma-1)}{\gamma}\left[\ln(p_2)-\ln(p_1)\right]=\ln(T_2)-\ln(T_1)$$
$$\frac{(\gamma-1)}{\gamma}\ln\left(\frac{p_2}{p_1}\right)=\ln\left(\frac{T_2}{T_1}\right)$$
$$\ln\left(\frac{p_2}{p_1}\right)^{\frac{(\gamma-1)}{\gamma}}=\ln\left(\frac{T_2}{T_1}\right)$$
$$\left(\frac{T_2}{T_1}\right)=\left(\frac{p_2}{p_1}\right)^{\frac{(\gamma-1)}{\gamma}}$$

$$\ln\left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}} = \ln\left(\frac{T_2}{T_1}\right)$$

$$\left(\frac{T_2}{T_1}\right) = \left(\frac{p_2}{p_1}\right)^{\frac{(\gamma-1)}{\gamma}}$$

Substitute 298 K for T_1, 800 kPa for p_1, 150 kPa for p_2 and 1.4 for γ.

$$\left(\frac{T_2}{298}\right) = \left(\frac{150}{800}\right)^{\frac{(1.4-1)}{1.4}}$$

$$T_2 = 184.7 \text{ K}$$

$$m_e = m_1 - m_2$$
$$= 9.35 - 2.830$$
$$= 6.52 \text{ kg}$$

Therefore, the mass removed from the tank if the variation in h_e is accounted, is **6.52 kg**.

Question: 6.165P

A liquid R-134a bottle has an internal volume of 0.001 m3. Initially it contains 0.4 kg of R-134a (saturated mixture) at 26°C. A valve is opened and R-134a vapor only (no liquid) is allowed to escape slowly such that temperature remains constant until the mass of R-134a remaining is 0.1 kg. Find the heat transfer necessary with the surroundings to maintain the temperature and pressure of the R-134a constant.

Step 1 of 6

Assuming container as the control volume since mass crosses the boundary.

Applying mass balance for a steady flow device,

$$\dot{m}_{in} - \dot{m}_{out} = \Delta m_{system} \quad \text{..... (1)}$$

Since there is no mass of R-134a is entering into the system

$$\dot{m}_{in} = 0$$

Then equation (1) becomes

$$0 - m_e = m_2 - m_1$$
$$m_e = m_1 - m_2$$

Here, initial mass of the refrigerant inside the container, $m_1 = 0.4\,\text{kg}$, Final mass of the refrigerant inside the container, $m_2 = 0.1\,\text{kg}$

Step 2 of 6

Applying energy balance to the control volume

$$\dot{E}_{in} - \dot{E}_{out} = \Delta E_{system}$$
$$Q_{in} - m_e h_e = m_2 u_2 - m_1 u_1$$

$$Q_{in} = m_2 u_2 - m_1 u_1 + m_e h_e$$
$$= m_2 u_2 - m_1 u_1 + m_e h_e$$
$$= m_2 u_2 - m_1 u_1 + (m_1 - m_2) h_e$$

The specific volume at the initial state can be determined as

$$v_1 = \frac{V}{m_1}$$
$$= \frac{0.001(\text{m}^3)}{0.4(\text{kg})}$$
$$= 0.0025\,\text{m}^3/\text{kg}$$

Here, Volume of the tank, $V = 0.001\,\text{m}^3$.

Step 3 of 6

At Temperature inside the container, $T_1 = 26°\text{C}$ from saturated R-134a refrigerant tables

$$v_f = 0.0008313\,\text{m}^3/\text{kg}$$
$$v_g = 0.029976\,\text{m}^3/\text{kg}$$
$$u_f = 87.26\,\text{kJ/kg}$$
$$u_{fg} = 156.87\,\text{kJ/kg}$$

Step 4 of 6

Then specific volume at state1 is

$$v_1 = v_f + x_1 v_{fg}$$
$$v_1 = v_f + x_1 (v_g - v_f)$$

$$x_1 = \frac{v_1 - v_f}{v_g - v_f}$$
$$= \frac{0.0025 - 0.0008313}{0.029976 - 0.0008313}$$
$$= 0.05726$$

Internal energy at state 1 is

$$u_1 = u_f + x_1 u_{fg}$$
$$= 87.26 + 0.05726 \times 156.87$$
$$= 96.24\,\text{kJ/kg}$$

Step 5 of 6

Since saturated vapor escapes slowly by maintaining the temperature remains constant

Therefore from the saturated R-134a tables, enthalpy of saturated vapor refrigerant leaving the bottle is

$$h_e = h_{g@26°\text{C}} = 264.68\,\text{kJ/kg}$$

The final specific volume in the container is

$$v_2 = \frac{V}{m_2}$$
$$= \frac{0.001(\text{m}^3)}{0.1(\text{kg})}$$
$$= 0.01\,\text{m}^3/\text{kg}$$

From saturated R-134a tables at $T_2 = T_1 = 26°\text{C}$

$$v_2 = v_f + x_2 (v_g - v_f)$$

$$x_2 = \frac{v_1 - v_f}{v_g - v_f}$$
$$= \frac{0.01 - 0.0008313}{0.029976 - 0.0008313}$$
$$= 0.3146$$

Step 6 of 6

Internal energy at state 2 is

$$u_2 = u_f + x_2 u_{fg}$$
$$= 87.26 + 0.3146 \times 156.87$$
$$= 136.61\,\text{kJ/kg}$$

Substituting the known values in the energy equation

$$Q_{in} = m_2 u_2 - m_1 u_1 + (m_1 - m_2) h_e$$
$$= 0.1 \times 136.61 - 0.4 \times 96.24 + (0.4 - 0.1) \times 264.68$$
$$= 54.569\,\text{kJ}$$

Therefore heat transfer with the surroundings is $\boxed{54.569\,\text{kJ}}$

Question: 6.166P

Steam enters a turbine steadily at 7 MPa and 600°C with a velocity of 60 m/s and leaves at 25 kPa with a quality of 95 percent. A heat loss of 20 kJ/kg occurs during the process. The inlet area of the turbine is 150 cm2, and the exit area is 1400 cm2. Determine (a)the mass flow rate of the steam, (b) the exit velocity, and (*c*) the power output.

Step 1 of 5

From the properties of superheated water,

At state-1

At temperature $T_1 = 600°C$ and pressure $P_1 = 7\,MPa$

The specific volume is $v_1 = 0.05567\,m^3/kg$

The specific enthalpy is $h_1 = 3650.6\,kJ/kg$

From the properties of saturated water

At state-2

At pressure $P_2 = 25\,kPa$

$v_f = 0.00102\,m^3/kg$ and $v_{fg} = 6.20238\,m^3/kg$

$h_f = 271.96\,kJ/kg$ and $h_{fg} = 2345.5\,kJ/kg$

Step 2 of 5

Find the enthalpy at state-2,

$$h_2 = h_f + x_2 h_{fg}$$

Substitute $271.96\,kJ/kg$ for h_f, 0.95 for x_2 and $2345.5\,kJ/kg$ for h_{fg},

$$\begin{aligned} h_2 &= h_f + x_2 h_{fg} \\ &= 271.96 + (0.95)(2345.5) \\ &= 2500.2\,kJ/kg \end{aligned}$$

Find the specific volume at state-2,

$$v_2 = v_f + x_2 v_{fg}$$

Substitute $0.00102\,m^3/kg$ for v_f, 0.95 for x_2 and $6.20238\,m^3/kg$ for v_{fg},

$$\begin{aligned} v_2 &= v_f + x_2 v_{fg} \\ &= 0.00102 + (0.95)(6.20238) \\ &= 5.8933\,m^3/kg \end{aligned}$$

Step 3 of 5

a)

Calculate the mass flow rate of the steam,

$$\dot{m} = \frac{V_1 A_1}{v_1}$$

Here,

The velocity of steam at state-1 is V_1

The inlet area of the turbine is A_1

Substitute $60\,m/s$ for V_1, $0.015\,m^2$ for A_2 and $0.05567\,m^3/kg$ for v_1,

$$\begin{aligned} \dot{m} &= \frac{V_1 A_1}{v_1} \\ &= \frac{60 \times 0.015}{0.05567} \\ &= 16.17\,kg/s \end{aligned}$$

Therefore, the mass flow rate of the steam is $\boxed{16.17\,kg/s}$

Step 4 of 5

b)

Calculate the exit velocity of the steam,

$$\dot{m} = \frac{V_2 A_2}{v_2}$$

Here,

The velocity of steam at state-2 is V_2

The inlet area of the turbine is A_2

Substitute $16.17\,kg/s$ for $\dot{m}$, $0.14\,m^2$ for A_2 and $5.8933\,m^3/kg$ for v_2,

$$\begin{aligned} 16.17 &= \frac{V_2 \times 0.14}{5.8933} \\ &= 680.6\,m/s \end{aligned}$$

Step 5 of 5

c)

Calculate the power output by using the energy balance equation,

$$\dot{W}_{out} = -\dot{Q}_{out} - \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}\right)$$

Substitute $16.17\,kg/s$ for $\dot{m}$, $20\,kJ/kg$ for $\dot{Q}_{out}$, $3650.6\,kJ/kg$ for h_1,

$2500.2\,kJ/kg$ for h_2, $680.6\,m/s$ for V_2 and $60\,m/s$ for V_1

$$\begin{aligned} \dot{W}_{out} &= -(16.17 \times 20) - 16.17\left(2500.2 - 2650.6 + \frac{680.6^2 - 60^2}{2}\right) \\ &= 14560\,kW \end{aligned}$$

Therefore, the power output of the turbine is $\boxed{14560\,kW}$

Question: 6.167P

Reconsider Prob. 6–166. Using EES (or other) software, investigate the effects of turbine exit area and turbine exit pressure on the exit velocity and power output of the turbine. Let the exit pressure vary from 10 to 50 kPa (with the same quality), and the exit area to vary from 1000 to 3000 cm2. Plot the exit velocity and the power outlet against the exit pressure for the exit areas of 1000, 2000, and 3000 cm2, and discuss the results.

Step 1 of 3

Open the EES software, then click file on menu bar and select the new file on menu bar.

Then write the program in equation window.

Equations Window

```
Fluid$='Steam_IAPWS'
A[1]=150 [cm^2]

Step 3 of 3

Select the plot on menu bar, then click x-y plot .Dialog box will appeared, then select variables to draw graph, then click ok button.

The graph will appeared

By plotting the graph between Power and P[2]:

Question: 6.168P

In large gas-turbine power plants, air is preheated by the exhaust gases in a heat exchanger called the regeneratorbefore it enters the combustion chamber. Air enters the regenerator at 1 MPa and 550 K at a mass flow rate of 800 kg/min. Heat is transferred to the air at a rate of 3200 kJ/s. Exhaust gases enter the regenerator at 140 kPa and 800 K and leave at 130 kPa and 600 K. Treating the exhaust gases as air, determine (a) the exit temperature of the air and (b) the mass flow rate of exhaust gases.

Step 1 of 6

From properties of air table, gas constant of air is

$$R = 0.287 \text{ kJ/kg-K}$$

From ideal gas properties of air at inlet temperature $T_1 = 550 \text{ K}$, specific enthalpy of air is

$$h_1 = 555.74 \text{ kJ/kg}$$

Let us assume that the properties of exhaust gases are taken as properties of air.

From ideal gas properties of air at exhaust gas inlet temperature $T_3 = 800 \text{ K}$, specific enthalpy of gas is

$$h_3 = 821.95 \text{ kJ/kg}$$

Similarly at exhaust gas exit temperature $T_4 = 600 \text{ K}$, specific enthalpy of gas is

$$h_4 = 607.02 \text{ kJ/kg}$$

Step 2 of 6

(a)

As there is only one entry, one exit for air and as air and exhaust gases are not mixing anywhere, mass flow rate of air will be same

$$\dot{m}_1 = \dot{m}_2 = \dot{m}_{air}$$

Apply the energy balance to the steady flow system,

$$E_{in} - E_{out} = \Delta E_{sys}$$

Here, E_{in}, E_{out} are rate of net energy transfer and ΔE_{sys} is rate of change in internal, kinetic and potential energies.

For steady process, $\Delta E_{sys} = 0$ is zero and so

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$Q_{in} + \dot{m}_{air} \times h_1 = \dot{m}_{air} \times h_2$$
$$Q_{in} = \dot{m}_{air} \times h_2 - \dot{m}_{air} \times h_1$$

Step 3 of 6

Then find the amount of heat transferred to air by using the expression,

$$Q_{in} = \dot{m}_{air} \times (h_2 - h_1)$$

Substitute 3200kJ/s for Q_{in} and $\frac{800}{60}$ kg/s for $\dot{m}_{air}$

$$3200 = \frac{800}{60} \times (h_2 - 555.74)$$
$$3200 = 13.33 \times (h_2 - 555.74)$$
$$h_2 = \frac{3200}{13.33} + 555.74$$
$$h_2 = 240.06 + 555.74$$
$$= 795.8 \text{ kJ/kg}$$

Step 4 of 6

From ideal gas properties of air table, find exit temperature of air by using interpolation

$$\frac{T_2 - 760}{780 - 760} = \frac{795.8 - 778.18}{800.03 - 778.18}$$
$$\frac{T_2 - 760}{20} = \frac{17.62}{21.85}$$
$$\frac{T_2 - 760}{20} = 0.8064$$
$$T_2 = 0.8064 \times 20 + 760$$
$$T_2 = 776.128 \text{ K}$$

Therefore, exit temperature of air is $\boxed{776.128 \text{K}}$

Step 5 of 6

(b)

As there is only one entry, one exit for air and as air exhaust gases are not mixing anywhere, mass flow rate of exhaust gas will be same

$$\dot{m}_3 = \dot{m}_4 = \dot{m}_{gas}$$

Assume exhaust gases behaves as an ideal gas, apply the energy balance of exhaust gas

$$E_{in} - E_{out} = \Delta E_{sys}$$

For steady process, $\Delta E_{sys} = 0$ and so

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$\dot{m}_{gas} \times h_3 = Q_{out} + \dot{m}_{gas} \times h_4$$
$$Q_{out} = \dot{m}_{gas} \times h_3 - \dot{m}_{gas} \times h_4$$
$$Q_{out} = \dot{m}_{gas} \times (h_3 - h_4)$$
$$\dot{m}_{gas} = \frac{Q_{out}}{(h_3 - h_4)}$$

Step 6 of 6

The amount of heat rejected from exhaust gases is equal to the heat addition to air then the above expression becomes,

$$\dot{m}_{gas} = \frac{Q_{in}}{(h_3 - h_4)}$$
$$= \frac{3200}{(821.95 - 607.02)}$$
$$= \frac{3200}{214.93}$$
$$= 14.89 \text{kg/s}$$

Therefore, the mass flow rate of exhaust gases is $\boxed{14.89 \text{ kg/s}}$

Question: 6.169P

It is proposed to have a water heater that consists of an insulated pipe of 5-cm diameter and an electric resistor inside. Cold water at 20°C enters the heating section steadily at a rate of 30 L/min. If water is to be heated to 55 °C, determine (a) the power rating of the resistance heater and (b) the average velocity of the water in the pipe.

Step 1 of 6

From saturated water tables at average temperature of water $T = 25\ ^\circ\text{C}$, the properties of water is

Density of water is $\rho = 997\ \text{kg/m}^3$

Specific heat of water at constant pressure $c_p = 4.18\ \text{kJ/kg}\cdot\text{K}$

Step 2 of 6

As there is only one entry, one exit for water, mass flow rate of water will be same

$$\dot{m}_1 = \dot{m}_2 = \dot{m}$$

Find the mass flow rate of water by using the equation,

$$\dot{m} = \rho \times \dot{V}_1$$

Here ρ is the density of water and $\dot{V}_1$ is volume flow rate of water at inlet

Substitute $30\ \text{L/min} = \frac{0.03}{60}\ \text{m}^3/\text{s}$ for $\dot{V}_1$

$$\dot{m} = 997 \times \frac{0.03}{60}$$
$$= 997 \times 0.0005$$
$$= 0.4985\ \text{kg/s}$$

Step 3 of 6

Find the energy balance of steady flow system

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady process, $\Delta E_{sys} = 0$ is zero and so

$$E_{in} - E_{out} = 0$$
$$E_{in} = E_{out}$$
$$W_{in} + \dot{m} \times h_1 = \dot{m} \times h_2$$
$$W_{in} = \dot{m} \times h_2 - \dot{m} \times h_1$$

Step 4 of 6

(a)

Find the power rating of the resistance heater from energy equation,

$$W_{in} = \dot{m} \times (h_2 - h_1)$$
$$W_{in} = \dot{m} \times c_p \times (T_2 - T_1)$$

Here T_1 and T_2 are inlet and exit temperatures of water respectively

Substitute 55°C for T_2 and 20°C for T_1

$$W_{in} = 0.4985 \times 4.18 \times (55 - 20)$$
$$= 0.4985 \times 4.18 \times 35$$
$$= 72.93\ \text{kW}$$

Therefore, power rating of the resistance heater is $\boxed{72.9306\ \text{kW}}$

Step 5 of 6

(b)

Find cross-section area of the pipe by using the equation,

$$A = \pi \times \frac{D^2}{4}$$

Here D is the diameter of cross-section of the pipe

Substitute 0.05 m for D

$$A = \pi \times \frac{0.05^2}{4}$$
$$= \pi \times \frac{0.0025}{4}$$
$$= \pi \times 0.000625$$
$$= 0.0019635\ \text{m}^2$$

Step 6 of 6

Now find velocity of water by using volume flow rate of water,

$$V_1 = \frac{\dot{V}_1}{A}$$
$$= \frac{0.03/60}{0.0019635}$$
$$= \frac{0.0005}{0.0019635}$$
$$= 0.2546\ \text{m/s}$$

Therefore, the velocity of water in the pipe is $\boxed{0.2546\ \text{m/s}}$

Question: 6.170P

An insulated vertical piston-cylinder device initially contains 0.11 m3 of air at 150 kPa and 22°C. At this state, a linear spring touches the piston but exerts no force on it. The cylinder is connected by a valve to a line that supplies air at 700 kPa and 22°C. The valve is opened, and air from the high-pressure line is allowed to enter the cylinder. The valve is turned off when the pressure inside the cylinder reaches 600 kPa. If the enclosed volume inside the cylinder doubles during this process, determine (*a*) the mass of air that entered the cylinder, and (b) the final temperature of the air inside the cylinder.

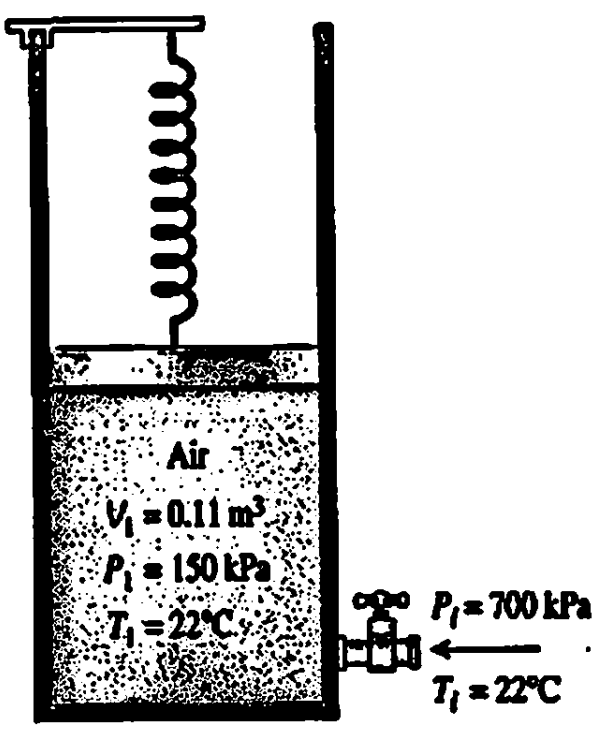

FIGURE P6–170

Step 1 of 6

Apply mass balance equation to the piston cylinder arrangement.

$$m_i + m_1 = m_e + m_2$$

Here, m_i is mass of air entering into the cylinder, m_1 is mass of air in the cylinder at initial state, m_2 is mass of air in the cylinder at final state and m_e is mass of air leaving from the cylinder.

Since there is no mass of air leaving from the cylinder,

$$m_e = 0$$

The mass balance equation becomes.

$$m_i + m_1 = m_e + m_2$$
$$m_i + m_1 = 0 + m_2$$

$$m_i = m_2 - m_1 \quad \text{..... (1)}$$

Step 2 of 6

Apply energy balance equation to the arrangement.

$$m_i h_i + m_1 u_1 = m_e h_e + m_2 u_2 + W_{b,out}$$

Here, *u* is internal energy and *h* is enthalpy.

Since there is no mass of air leaving from the system $m_e = 0$, then energy equation becomes.

$$m_i h_i + m_1 u_1 = 0 \times h_e + m_2 u_2 + W_{b,out}$$
$$m_i h_i = m_2 u_2 - m_1 u_1 + W_{b,out}$$

Substitute $m_2 - m_1$ for m_i .

$$(m_2 - m_1) h_i = m_2 u_2 - m_1 u_1 + W_{b,out}$$

$$(m_2 - m_1) c_p T_i = m_2 c_v T_2 - m_1 c_v T_1 + W_{b,out} \quad \text{..... (2)}$$

Here, c_p is specific heat at constant pressure, c_v is specific heat at constant volume and *T* is temperature.

Step 3 of 6

Find the mass of air at initial state by using ideal gas equation,

$$P_1 V_1 = m_1 R T_1$$
$$m_1 = \frac{P_1 V_1}{R T_1}$$

Here, T_1 is initial temperature, V_1 is initial volume of the cylinder and *R* is gas constant.

Substitute 150 kPa for P_1 , $0.11\,m^3$ for V_1 and $0.287\,kJ/kg \cdot K$ for *R*

$$m_1 = \frac{150 \times 0.11}{0.287 \times 295}$$
$$= 0.1948\,kg$$

Find the mass of air at final state by using ideal gas equation,

$$P_2 V_2 = m_2 R T_2$$
$$m_2 = \frac{P_2 V_2}{R T_2}$$

Here, T_2 is final temperature V_2 is final volume of the cylinder and *R* is gas constant.

Substitute 600 kPa for P_2 , $0.22\,m^3$ for V_1 and $0.287\,kJ/kg \cdot K$ for *R*

$$m_2 = \frac{600 \times 0.22}{0.287 \times T_2}$$
$$= \frac{459.93}{T_2}$$

Step 4 of 6

Find the boundary work due to the linear spring by using the following equation:

$$W_{b,out} = \frac{1}{2}(P_1 + P_2)(V_2 - V_1)$$

Substitute 150 kPa for P_1 , 600 kPa for P_2 , $0.11\,m^3$ for V_1 and $0.22\,m^3$ for V_2

$$W_{b,out} = \frac{1}{2}(150 + 600)(0.22 - 0.11)$$
$$= 41.25\,kJ/kg$$

Step 5 of 6

Substitute $\frac{459.93}{T_2}$ for m_2 , 0.1948 kg for m_1 , 295 K for T_1 , 295 K for T_i , $1.005\,kJ/kg \cdot K$ for c_p , $0.718\,kJ/kg \cdot K$ for c_v and 41.25 kJ/kg for $W_{b,out}$ in equation (2)

$$(m_2 - m_1) c_p T_i = m_2 c_v T_2 - m_1 c_v T_1 + W_{b,out}$$
$$\left(\frac{459.93}{T_2} - 0.1948\right) \times 1.005 \times 295 = \frac{459.93}{T_2} \times 0.718 \times T_2 - 0.1948 \times 0.718 \times 295 + 41.25$$
$$\left(\frac{459.93}{T_2} - 0.1948\right) 296.475 = 330.229 - 0.0105$$
$$T_2 = 351.46\,K$$

Therefore, the final temperature of air in the tank is $\boxed{351.46\,K}$

Step 6 of 6

Find the mass of air entering into the tank by using equation (1),

$$m_i = m_2 - m_1$$
$$= \frac{459.93}{T_2} - m_1$$

Substitute 351.46 K for T_2 and 0.1948 kg for m_1

$$m_i = \frac{459.93}{351.46} - 0.1948$$
$$= 1.1138\,kg$$

Therefore, mass of air entering into the tank is $\boxed{1.1138\,kg}$

Question: 6.171P

A piston-cylinder device initially contains 2 kg of l refrigerant-134a at 800 kPa and 80°C. At this state, the piston is touching on a pair of stops at the top. The mass of the piston is such that a 500-kPa pressure is required to move it. A valve at the bottom of the tank is opened, andR-134a is withdrawn from the cylinder. After a while, the piston is observed to move and the valve is closed when half of the refrigerant is withdrawn from the tank and the temperature in the tank drops to 20°C. Determine (*a*) the j work done and (b) the heat transfer.

Step 1 of 4

From the table, saturated refrigeration table of R-134a at various states obtain the following values

At initial pressure $P_1 = 800\,\text{kPa}$, and initial temperature $T_1 = 80°\text{C}$

At initial state

Specific volume $v_1 = 0.32659\ \text{m}^3/\text{kg}$.

Internal energy $u_1 = 290.84\ \text{kJ/kg}$

Enthalpy $h_1 = 316.97\ \text{kJ/kg}$

At final pressure $P_2 = 500\,\text{kPa}$, and final temperature $T_2 = 20°\text{C}$

At final state

Specific volume $v_2 = 0.042115\ \text{m}^3/\text{kg}$.

Internal energy $u_2 = 242.40\ \text{kJ/kg}$

Enthalpy $h_2 = 263.46\ \text{kJ/kg}$

Step 2 of 4

Find the volume of refrigerant at initial state

$$\begin{aligned} V_1 &= m_1 \times v_1 \\ &= 2\ \text{kg} \times 0.32659\ \text{m}^3/\text{kg} \\ &= 0.06532\,\text{m}^3 \end{aligned}$$

Find the volume of refrigerant at final state

$$\begin{aligned} V_2 &= m_2 \times v_2 \\ &= 0.5m_1 \times v_2 \\ &= 0.5 \times 2\,\text{kg} \times 0.042115\ \text{m}/\text{kg} \\ &= 0.04212\ \text{m}^3 \end{aligned}$$

Find the mass left in the cylinder from the mass balance relation

$$\begin{aligned} m_e &= m_1 - m_2 \\ &= 2 - 1 \\ &= 1\ \text{kg} \end{aligned}$$

Step 3 of 4

Find the enthalpy of the refrigerant withdrawn from the cylinder

$$\begin{aligned} h_e &= \left(\frac{h_1 + h_2}{2}\right) \\ &= \left(\frac{316.97 + 263.46}{2}\right) \\ &= 290.21\ \text{kJ/kg} \end{aligned}$$

Find the boundary work for the piston movement

$$\begin{aligned} W_{b,in} &= P_2(V_1 - V_2) \\ &= (500\text{kPa})(0.06532 - 0.04212)\text{m}^3 \\ &= 11.6\ \text{kJ} \end{aligned}$$

Therefore, the boundary work for the piston movement $\boxed{11.6\ \text{kJ}}$

Step 4 of 4

Find the heat transferred from the system as below

Substitute the $11.6\ \text{kJ}$ for $W_{b,in}$ in the equation (2)

$$W_{b,in} - Q_{out} - m_e h_e = m_2 u_2 - m_1 u_1$$

$$11.6\,\text{kJ} - Q_{out} - (1\,\text{kg})(290.21\,\text{kJ/kg}) = (1\ \text{kg})(242.40\ \text{kJ/kg})\ (2\ \text{kg})(290.84\ \text{kJ/kg})$$

$$Q_{out} = 60.7\,\text{kJ}$$

Therefore, the heat transferred from the system is $\boxed{60.7\,\text{kJ}}$

Question: 6.172P

The pump of a water distribution system is powered by a 6-kW electric motor whose efficiency is 95 percent. The water flow rate through the pump is 18 L/s. The diameters of the inlet and outlet pipes are the same, and the elevation difference across the pump is negligible. If the pressures at the inlet and outlet of the pump are measured to be 100 kPa and 300 kPa (absolute), respectively, determine (*a*) the mechanical efficiency of the pump and (b) the temperature rise of water as it flows through the pump due to the mechanical inefficiency.

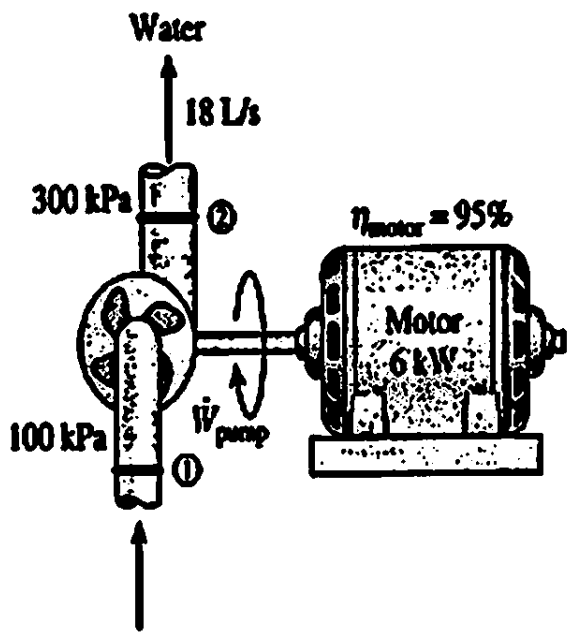

FIGURE P6–172

Step 1 of 3

(a)

Find the mass flow rate of water through the pump by using the equation,

$$\dot{m} = \rho \dot{V}$$

Here, ρ is the density of the water, and $\dot{V}$ is the volume flow rate.

Substitute 1000 kg / m^3 for ρ , and 18 L/s for $\dot{V}$.

$$\begin{aligned}\dot{m} &= 1000\frac{\text{kg}}{\text{m}^3}\times 18\frac{\text{L}}{\text{s}}\times 10^{-3}\frac{\text{m}^3}{\text{L}}\\ &= 18\,\text{kg/s}\end{aligned}$$

Find the mechanical (shaft) power it delivers to the pump is

$$\dot{W}_{\text{pump, shaft}} = \eta_{\text{motor}}\dot{W}_{\text{electric}}$$

Here η_{motor} is the efficiency of the motor, and $\dot{W}_{\text{electric}}$ is the electrical power.

Substitute 0.95 for η_{motor} , and 6 kW for $\dot{W}_{\text{electric}}$

$$\begin{aligned}\dot{W}_{\text{pump, shaft}} &= 0.95\times 6\\ &= 5.7\,\text{kW}\end{aligned}$$

Step 2 of 3

Find the mechanical energy of the fluid when pumping,

$$\begin{aligned}\Delta\dot{E}_{\text{mech,fluid}} &= \dot{E}_{\text{mech, out}} - \dot{E}_{\text{mech, in}}\\ &= \dot{m}\left(\frac{P_2}{\rho}+\frac{V_2^2}{2}+gz_2\right)-\dot{m}\left(\frac{P_1}{\rho}+\frac{V_1^2}{2}+gz_1\right)\end{aligned}$$

Substitute z_1 for z_2 and V_1 for V_2 in the above equation

$$\begin{aligned}\Delta\dot{E}_{\text{mech,fluid}} &= \dot{m}\left(\frac{P_2}{\rho}+\frac{V_1^2}{2}+gz_1\right)-\dot{m}\left(\frac{P_1}{\rho}+\frac{V_1^2}{2}+gz_1\right)\\ &= \dot{m}\left(\frac{P_2-P_1}{\rho}\right)\end{aligned}$$

Here, P_1 is the pressure at state 1 and P_2 is the pressure at state 2.

Substitute $18\,\text{kg/s}$ for $\dot{m}$, $300\,\text{kPa}$ for P_2 , $100\,\text{kPa}$ for P_1, and $1000\,\text{kg/m}^3$ for ρ .

$$\begin{aligned}\Delta\dot{E}_{\text{mech,fluid}} &= 18\left(\frac{300-100}{1000}\right)\times\left(\frac{1\,\text{kJ}}{\text{kPa}\cdot\text{m}^3}\right)\\ &= 3.6\,\text{kW}\end{aligned}$$

Find the mechanical efficiency of the pump by using the equation

$$\eta_{\text{pump}} = \frac{\Delta\dot{E}_{\text{mech,fluid}}}{\dot{W}_{\text{pump, shaft}}}$$

Substitute $3.6\,\text{kW}$ for $\Delta\dot{E}_{\text{mech,fluid}}$, and $5.7\,\text{kW}$ for $\dot{W}_{\text{pump, shaft}}$.

$$\begin{aligned}\eta_{\text{pump}} &= \frac{3.6}{5.7}\\ &= 0.6316\\ &= 63.16\%\end{aligned}$$

Therefore, the mechanical efficiency of the pump $\boxed{63.16\%}$

Step 3 of 3

(b)

Find the energy lost by the pump in the form of heat due to frictional effects,

$$\dot{E}_{\text{mech,loss}} = \dot{W}_{\text{pump,shaft}} - \Delta\dot{E}_{\text{mech,fluid}}$$

Substitute $3.6\,\text{kW}$ for $\Delta\dot{E}_{\text{mech,fluid}}$, and $5.7\,\text{kW}$ for $\dot{W}_{\text{pump, shaft}}$ in the equation

$$\begin{aligned}\dot{E}_{\text{mech,loss}} &= 5.7-3.6\\ &= 2.1\,\text{kW}\end{aligned}$$

Find the temperature rise of water,

$$\begin{aligned}\dot{E}_{\text{mech,loss}} &= \dot{m}(u_2-u_1)\\ &= \dot{m}c\Delta T\\ \Delta T &= \frac{\dot{E}_{\text{mech,loss}}}{\dot{m}c}\end{aligned}$$

Here, c is the specific heat constant.

Substitute 2.1 kW for $\dot{E}_{\text{mech,loss}}$, 16 kg/s for $\dot{m}$, and $4.18\,\text{kJ/kg}\cdot\text{K}$ for c .

$$\begin{aligned}\Delta T &= \frac{2.1\,\text{kW}}{18\,\text{kg/s}\times 4.18\,\text{kJ/kg}\cdot\text{K}}\\ &= 0.0279°\text{C}\end{aligned}$$

Therefore, the temperature rise of water is $\boxed{0.0279°\text{C}}$

Question: 6.173P pg 1

A pressure cooker is a pot that cooks food much faster than ordinary pots by maintaining a higher pressure and temperature during cooking. The pressure inside the pot is controlled by a pressure regulator (the petcock) that keeps the pressure at a constant level by periodically allowing some steam to escape, thus preventing any excess pressure buildup, pressure cookers, in general, maintain a gage pressure of 2 atm (or 3 atm absolute) inside. Therefore, pressure cookers cook at a temperature of about 133°C instead of 100°C, cutting the cooking time by as much as 70 percent while minimizing the loss of nutrients. The newer pressure cookers use a spring valve with several pressure settings rather than a weight on the cover.

A certain pressure cooker has a volume of 6 L and an operating pressure of 75 kPa gage. Initially, it contains 1 kg of water. Heat is supplied to the pressure cooker at a rate of 500 W for 30 min after the operating pressure is reached. Assuming an atmospheric pressure of 100 kPa, determine (a) the temperature at which cooking takes place and (b)the amount of water left in the pressure cooker at the end of the process.

Step 1 of 8

(a)

Convert the pressure inside the cooker from gage pressure to absolute pressure by using the relation,

$$P_{abs} = P_{gage} + P_{atm}$$

Here, P_{atm} is atmospheric pressure.

Substitute 75 kPa for P_{gage} and 100 kPa for P_{atm}

$$\begin{aligned} P_{abs} &= 75+100 \\ &= 175\,\text{kPa} \end{aligned}$$

Obtain the temperature corresponding to the saturation pressure $P_{abs} = 175\,\text{kPa}$ from saturated water tables,

$$T_{sat} = 116.04°\text{C}$$

Since saturation conditions exist in the cooker, therefore, the cooking temperature is $\boxed{116.04°\text{C}}$

Step 2 of 8

(b)

Apply mass balance equation to the system,

$$m_1 + m_i = m_2 + m_e$$

Here, m_1 is mass of water at initial state, m_2 is mass of water at final state, m_i is mas of fluid entering and m_e is mass of fluid exiting from the system.

Since there is no mass of fluid entering into the system,

$$m_i = 0$$

Then

$$\begin{aligned} m_1 + 0 &= m_2 + m_e \\ m_e &= m_1 - m_2 \end{aligned}$$

Step 3 of 8

Apply energy balance equation to the system,

$$m_1 u_1 + m_i h_i + Q_{in} = m_2 u_2 + m_e h_e$$

Since $m_i = 0$

$$m_1 u_1 + Q_{in} = m_2 u_2 + m_e h_e \quad \text{..... (1)}$$

Here, u indicates specific internal energy, h is specific enthalpy of the fluid and Q_{in} is the amount of heat addition.

Substitute $m_2 - m_1$ for m_e in equation (1)

$$\begin{aligned} m_1 u_1 + Q_{in} &= m_2 u_2 + m_e h_e \\ m_1 u_1 + Q_{in} &= m_2 u_2 + (m_1 - m_2) h_e \end{aligned}$$

Find the amount of heat transfer in kJ by using the equation,

$$Q_{in} = \dot{Q}_{in} \Delta t$$

Here, $\dot{Q}_{in}$ is rate of heat transfer and Δt is the time taken for heat transfer.

Substitute 500 W for $\dot{Q}_{in}$ and $30\,\text{min}$ for Δt

$$\begin{aligned} Q_{in} &= 500\frac{\text{J}}{\text{sec}} \times 30\,\text{min}\frac{60\,\text{sec}}{\text{min}} \\ &= 900000\,\text{J} \\ &= 900\,\text{kJ} \end{aligned}$$

Step 4 of 8

Find the enthalpy of saturated vapour at pressure 175 kPa from saturated water tables,

$$h_e = h_g = 2700.2\,\text{kJ/kg}$$

Calculate the specific volume at state 1

$$v_1 = \frac{V}{m_1}$$

Here, V is volume of pressure cooker and m_1 is mass of water

Substitute $0.006\,\text{m}^3$ for V and 1 kg for m_1

$$\begin{aligned} v_1 &= \frac{0.006}{1} \\ &= 0.006\,\text{m}^3/\text{kg} \end{aligned}$$

Step 5 of 8

Find the quality at state 1 by using the equation,

Step 5 of 8

Find the quality at state 1 by using the equation,

$$v_1 = v_f + x_1\left(v_g - v_f\right)$$

Note down the properties of saturated specific volumes at 175 kPa from saturated water tables,

Specific volume of saturated liquid, $v_f = 0.001057\,\mathrm{m^3/kg}$

Specific volume of saturated vapour, $v_g = 1.0037\,\mathrm{m^3/kg}$

Substitute $0.006\,\mathrm{m^3/kg}$ for v_1 , $0.001057\,\mathrm{m^3/kg}$ for v_f and $1.0037\,\mathrm{m^3/kg}$ for v_g

$$v_1 = v_f + x_1\left(v_g - v_f\right)$$
$$0.006 = 0.001057 + x_1\left(1.0037 - 0.001057\right)$$
$$x_1 = 0.00492$$

Step 6 of 8

Find the specific internal energy at state 1 by using the equation,

$$u_1 = u_{f@175\mathrm{kPa}} + x_1 u_{fg@175\mathrm{kPa}}$$
$$= 486.82 + 0.004929 \times 2037.7$$
$$= 496.863\,\mathrm{kJ/kg}$$

Find the final mass by using the equation,

$$m_2 = \frac{V}{v_2}$$

Find the internal energy at state 2 by using the equation,

$$u_2 = u_{f@175\mathrm{kPa}} + x_2 u_{fg@175\mathrm{kPa}}$$
$$= 486.82 + x_2 \times 2037.7$$

Find the specific volume at state 2 by using the equation,

$$v_2 = v_{f@175\mathrm{kPa}} + x_2\left(v_{g@175\mathrm{kPa}} - v_{f@175\mathrm{kPa}}\right)$$
$$= 0.001 + x_2 \times 1.003$$

Step 7 of 8

Substitute $\frac{V}{v_2}$ for m_2 and $u_f + x_2 u_{fg}$ for u_2 in equation (1)

$$m_1 u_1 + Q_{in} = m_2 u_2 + \left(m_1 - m_2\right) h_e$$
$$m_1 u_1 + Q_{in} = \frac{V}{v_2} u_2 + \left(m_1 - \frac{V}{v_2}\right) h_e$$
$$Q_{in} = \left(m_1 - \frac{V}{v_2}\right) h_e + \frac{V}{v_2} u_2 - m_1 u_1$$

Substitute 1 kg for m_1 , $0.006\,\mathrm{m^3}$ for V, $2700.2\,\mathrm{kJ/kg}$ for h_e , 496.863 kJ/kg for u_1 and 900 kJ for Q_{in}

$$900 = \left[\left(1 - \frac{0.006}{0.001 + x_2\left(1.004 - 0.001\right)}\right)2700.2 + \left(\frac{0.006}{0.001 + x_2\left(1.004 - 0.001\right)} \times \left(486.82 + x_2 2037.7\right)\right) - 1 \times 496.863\right]$$

$$900 = 2700.2 - \frac{16.2012}{0.001 + 1.003x_2} + \frac{0.006 \times \left(486.82 + 2037.7x_2\right)}{0.001 + 1.003x_2} - 496.863$$

Solve the variable x_2

$$x_2 = 0.009$$

Step 8 of 8

Now find the specific volume at state 2 by using the dryness fraction,

$$v_2 = v_{f@175\mathrm{kPa}} + x_2\left(v_{g@175\mathrm{kPa}} - v_{f@175\mathrm{kPa}}\right)$$
$$= 0.001 + x_2 \times 1.003$$
$$= 0.001 + 0.009 \times 1.003$$
$$= 0.010027\,\mathrm{m^3/kg}$$

Find the mass of water at state 2 by using the equation,

$$m_2 = \frac{V}{v_2}$$

Substitute $0.006\,\mathrm{m^3}$ for V and $0.010027\,\mathrm{m^3/kg}$ for v_2

$$m_2 = \frac{0.006}{0.010027}$$
$$= 0.598\,\mathrm{kg}$$

Therefore, mass of water at state 2 is $\boxed{0.598\,\mathrm{kg}}$

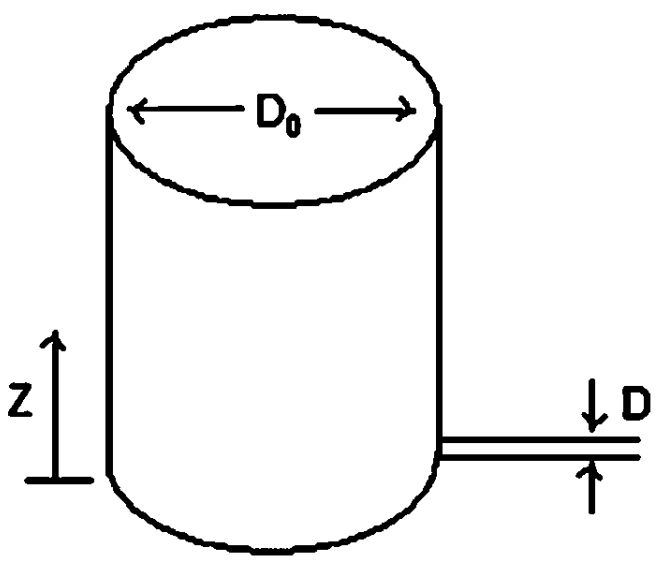
Question: 6.174P

A D0 = 10-m-diameter tank is initially filled with water 2 m above the center of a D = 10-cm-diameter valve near the bottom. The tank surface is open to the atmosphere, and the tank drains through a L = 100-m-long pipe connected to the valve. The friction factor of the pipe is given to be f = 0.015, and the discharge velocity is expressed as $V = \sqrt{\frac{2gz}{1.5 + fL/D}}$ where z is the water height above the center of the valve.

Determine (a) the initial discharge velocity from the tank and (b) the time required to empty the tank. The tank can be considered to be empty when the water level drops to the center of the valve.

Step 1 of 8

Discharge velocity is given by below equation $V = \sqrt{\frac{2 \times g \times z}{1.5 + \frac{f \times L}{D}}}$ where g is the acceleration due to gravity, z is the water level in the tank, above the center of the valve, f of the friction factor of the pipe, L is the length of the pipe and D is the diameter of the valve. Substitute $g = 9.81\ m/s^2$, $f = 0.015$, $L =$



$$V = \sqrt{\frac{2 \times 9.81 \times z}{1.5 + \frac{0.015 \times 100}{0.1}}}$$

$$= \sqrt{\frac{19.62 \times z}{1.5 + \frac{1.5}{0.1}}} \qquad = \sqrt{1.189 \times z}$$

$$= \sqrt{\frac{19.62 \times z}{1.5 + 15}}$$

$$= \sqrt{\frac{19.62 \times z}{16.5}}$$

Step 2 of 8

Step 3 of 8

Substituting the value of z in the above equation we get initial discharge from the tank

$$V_1 = \sqrt{1.189 \times 2}$$

$$= \sqrt{2.378}$$

$$\boxed{V_1 = 1.542\ m/s}$$

Therefore the initial discharge from the tank is $\boxed{V_1 = 1.542\ m/s}$

Step 4 of 8

Volume flow rate of the water from the tank is given by below equation

$$\dot{V} = A_{pipe} \times V_2$$

$$= \pi \times \frac{D^2}{4} \times \sqrt{1.189 \times z}$$

Differentiating the above equation with respect to time we get the below equation

$$d\dot{V} = \pi \times \frac{D^2}{4} \times \sqrt{1.189 \times z} \times dt \quad \text{..... (1)}$$

Step 5 of 8

From conversation of mass, volume flow rate is equal to decrease in volume of the tank

$$d\dot{V} = A_{tank} \times (-dz)$$

$$= A_{tank} \times (-dz)$$

$$= -\pi \times \frac{D_0^2}{4} \times dz \quad \text{..... (2)}$$

where D_0 is the diameter of the tank

Step 6 of 8

From equation (1) and equation (2)

$$\pi \times \frac{D^2}{4} \times \sqrt{1.189 \times z} \times dt = -\pi \times \frac{D_0^2}{4} \times dz$$

$$\frac{D^2}{4} \times \sqrt{1.189 \times z} \times dt = -\times \frac{D_0^2}{4} \times dz$$

$$dt = \frac{-\times \frac{D_0^2}{4} \times dz}{\frac{D^2}{4} \times \sqrt{1.189 \times z}}$$

$$= \frac{-\times \frac{D_0^2}{4} \times dz}{\frac{D^2}{4} \times \sqrt{1.189 \times z}}$$

$$= \frac{-\times D_0^2 \times dz}{D^2 \times \sqrt{1.189} \times \sqrt{z}}$$

$$= \frac{-\times D_0^2 \times dz}{D^2 \times 1.0904} \times (z)^{-\frac{1}{2}}$$

Step 7 of 8

Differentiating the above equation within limit $z = 0$ to $z = z_1$ we get the below equation

$$t = \frac{-\times D_0^2}{D^2 \times 1.0904} \times \left[\frac{z^{\frac{1}{2}+1}}{-\frac{1}{2}+1} \right]_{z_1}^{0}$$

$$= \frac{-2 \times D_0^2}{D^2 \times 1.0904} \times \left[z^{\frac{1}{2}} \right]_{z_1}^{0}$$

$$= \frac{-2 \times D_0^2}{D^2 \times 1.0904} \times \left[0^{\frac{1}{2}} - z_1^{\frac{1}{2}} \right]$$

$$= \frac{2 \times D_0^2}{D^2 \times 1.0904} \times \sqrt{z_1}$$

Step 8 of 8

Time taken to empty the tank is

$$t = \frac{2 \times 10^2}{0.1^2 \times 1.0904} \times \sqrt{2}$$

$$= \frac{2 \times 100}{0.01 \times 1.0904} \times 1.414$$

$$= \frac{200}{0.010904} \times 1.414$$

$$= 18341.893 \times 1.414$$

$$= 25935.437\ s$$

$$\boxed{t = 7.204\ h}$$

Therefore the time taken to empty the tank is $\boxed{t = 7.204\ h}$

CHAPTER 07
SOLUTIONS

Question: 7.001P

Describe an imaginary process that satisfies the first law but violates the second law of thermodynamics.

Step 1 of 2

Assuming in a cyclic process, transferring 15kJ of heat to the system and obtaining 15kJ of work output

If you apply the first law to this cyclic process and according to first law the algebraic sum of work transfers is proportional to the algebraic sum of heat transfers

Therefore

$Q = W$

$15\text{kJ} = 15\text{kJ}$

From the above statement the first law satisfies

Step 2 of 2

Again applying second law to this cyclic process and according to Kelvin Planck statement it is impossible to convert all the heat energy to useful work output. There is some heat rejection from the system.

Here in this cyclic process heat rejection is zero so it violates the second law of thermodynamics

Question: 7.002P

Describe an imaginary process that satisfies the second law but violates the first law of thermodynamics.

Step 1 of 1

First last of thermodynamics, just discusses the changes that a system is undergoing and the processes involved in it. It explains conservation of energy for a system undergoing changes or processes.

Second law of thermodynamics helps in defining the process and also the direction of the processes. It tells about the possibility of a process or the restriction of a process. It states that the entropy of a system always increases.

For this to occur the energy contained by a body has to diminish without converting to work or internal energy. So imagine a machine which works with less than 100% efficiency, this means there are losses but they don't show up anywhere. But the energy is obtained from a higher energy source to lower.

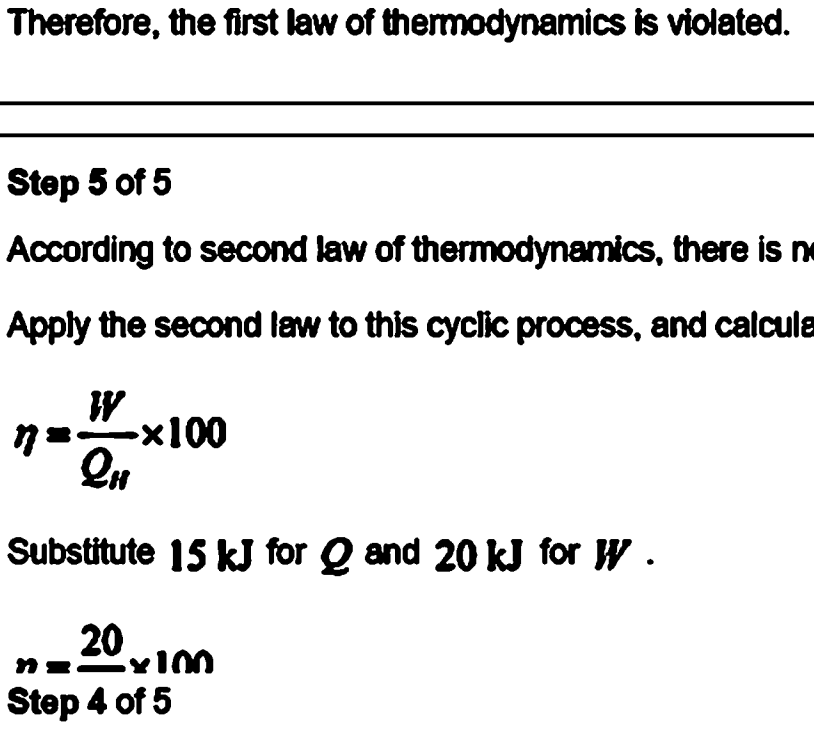
First law is violated since the energy conversion dint apply but the direction of work is applied so second law is satisfied.

Question: 7.003P

Describe an imaginary process that violates both the first and the second laws of thermodynamics.

Step 1 of 5

First last of thermodynamics, just discusses the changes that a system is undergoing. The processes involved in it. It just deals with conservation of energy for a system undergoing changes or processes.



It accounts for the energy balance involving work interactions, heat interactions, etc.

It does not deal, with the possibility of the process, the direction of the process etc.

Second law of thermodynamics helps in defining the process and also the direction of the processes. It tells about the possibility of a process or the restriction of a process. It helps in analyzing the performance of processes, cycles, devices etc.

Step 2 of 5

For example, consider a device taking heat from a reservoir and producing work.

Step 3 of 5

Write an expression for the first law of thermodynamics, upon energy balance for the system.

$$Q = W_{net}$$

Here, Q is the rate of heat transfer, and W_{net} is the net amount of Work done.

It does not deal with the information about the possibility of the process or cycle. It only deals with the energy balance.

Step 4 of 5

Consider a system that transfer $15\ \text{kJ}$ of heat to the air and obtaining $20\ \text{kJ}$ of work, caused by expanding the gas and moving a piston.

Apply the first law to this cyclic process.

$$Q = W$$

Substitute $15\ \text{kJ}$ for Q and $20\ \text{kJ}$ for W .

$$15\,\text{kJ} \neq 20\text{kJ}$$

Observe the above statement, and it indicates that the cyclic process is violating the first law of thermodynamics.

Therefore, the first law of thermodynamics is violated.

Step 5 of 5

According to second law of thermodynamics, there is no heat engine which is 100% efficient.

Apply the second law to this cyclic process, and calculate the efficiency of cyclic process.

$$\eta = \frac{W}{Q_H} \times 100$$

Substitute $15\ \text{kJ}$ for Q and $20\ \text{kJ}$ for W .

$$\eta = \frac{20}{} \times 100$$

Step 4 of 5

Consider a system that transfer $15\ \text{kJ}$ of heat to the air and obtaining $20\ \text{kJ}$ of work, caused by expanding the gas and moving a piston.

Apply the first law to this cyclic process.

$$Q = W$$

Question: 7.004P

An experimentalist claims to have raised the temperature of a small amount of water to 150°C by transferring heat from high-pressure steam at 120°C. Is this a reasonable claim? Why? Assume no refrigerator or heat pump is used in the process.

Step 1 of 1

Here high pressure steam at temperature is at 120°C which is at low temperature and it transfers energy to high temperature and it is at 150°C but as you know that the energy flows from high energy to low energy but not from low energy to high energy.
Therefore transferring of energy from low temperature to high temperature is not possible and this is not a reasonable claim.

Question: 7.005P

What is a thermal energy reservoir? Give some examples.

Step 1 of 1

A thermal reservoir is a hypothetical body with a relatively large thermal energy capacity that can supply or absorb finite amounts of heat without undergoing any change in temperature. Such a body is called a thermal energy reservoir.
Some examples are oceans, lakes, rivers and a large block of copper and so on

Question: 7.006P

Consider the process of baking potatoes in a conventional oven. Can the hot air in the oven be treated as a thermal energy reservoir? Explain.

Step 1 of 1

When the heat is added to the potatoes but the temperature remains constant in the oven and it can be treated as a thermal energy reservoir.

Question: 7.007P

Consider the energy generated by a TV set. What is a suitable choice for a thermal energy reservoir?

Step 1 of 1

The atmospheric air surrounding the TV set acts as the thermal energy reservoir.

Question: 7.008P

Is it possible for a heat engine to operate without rejecting any waste heat to a low-temperature reservoir? Explain.

Step 1 of 1

It is not possible for a heat engine to operate without rejecting any waste heat to a low temperature reservoir.

As per Kelvin-Planck statement of the second law of thermodynamics it states that "It is impossible for any device that operates on a cycle to receive heat from a single reservoir and produce a net amount of work."

Question: 7.009P

What are the characteristics of all heat engines?

Step 1 of 1

Heat engines differ considerably from one another, but all can be characterized by the following:

1. They receive heat from a high-temperature source (solar energy, furnace etc.).
2. They convert part of this heat to work.
3. They reject the remaining waste heat to a low-temperature sink (the atmosphere, rivers, etc.).
4. Heat engines are cyclic devices

Question: 7.010P

Baseboard heaters are basically electric resistance heaters and are frequently used in space heating. A home owner claims that her 5-year-old baseboard heaters have a conversion efficiency of 100 percent. Is this claim in violation of any thermodynamic laws? Explain.

Step 1 of 1

According to second law of thermodynamics there is no system which is 100% efficient
so the claim is false i.e. the total amount of work cannot be converted into heat
So it is the violation of second law of thermodynamics

Question: 7.011P

What is the Kelvin-Planck expression of the second law of thermodynamics?

Step 1 of 1

Kelvin-Planck statement of the second law of thermodynamics states that "It is impossible for any device that operates on a cycle to receive heat from a single thermal reservoir and produce a net amount of work."

Question: 7.012P

Does a heat engine that has a thermal efficiency of 100 percent necessarily violate (*a*) the first law and (*b*) the second law of thermodynamics? Explain.

Step 1 of 1

(a) From first law of thermodynamics it states that work and heat are mutually convertible to one another and it is possible to have 100% efficient engine
So it does not violate the first law of thermodynamics
(b) As per second law of thermodynamics it is not possible for a heat engine to have 100% efficient. So it violates the second law of thermodynamics

Question: 7.013P

In the absence of any friction and other irreversibilities, can a heat engine have an efficiency of 100 percent? Explain.

Step 1 of 1

A heat engine having an efficiency of 100 percent violates Kelvin-Planck statement of the second law of thermodynamics which states that:

"It is impossible for any device that operates on a cycle to receive heat from a single reservoir and produce a net amount of work."

This means that the operation of a heat engine requires a low-temperature sink as well as a high-temperature source. Therefore, thermal efficiency of any heat engine cannot be 100 percent.

Also, due to the absence of friction or other dissipative effects a heat engine cannot have 100 percent efficiency, which is a limitation that applies to both the idealized and the actual heat engines.

Therefore, it is not possible for a heat engine to have 100 percent efficiency even during the absence of friction and other irreversibilities.

Question: 7.014P

Are the efficiencies of all the work-producing devices, including the hydroelectric power plants, limited by the Kelvin-Planck statement of the second law? Explain.

Step 1 of 1

Kelvin-Planck statement is valid only for heat engines undergoing a cyclic process that transfers heat from high temperature to low temperature and producing some useful work output.

Question: 7.015P

Consider a pan of water being heated (*a*) by placing it on an electric range and (*b*) by placing a heating element in the water. Which method is a more efficient way of heating water? Explain.

Step 1 of 1

Method (b) is desirable by placing a heating element in the water since the electrical heating element will be in direct contact with the water so the heat losses to the surrounding air will be less compared to the other

So the desired effect can be achieved with less power input compared to the method (a)

Question: 7.016P

A heat engine has a heat input of 3 × 104 Btu/h and a thermal efficiency of 40 percent. Calculate the power it will produce, in hp.

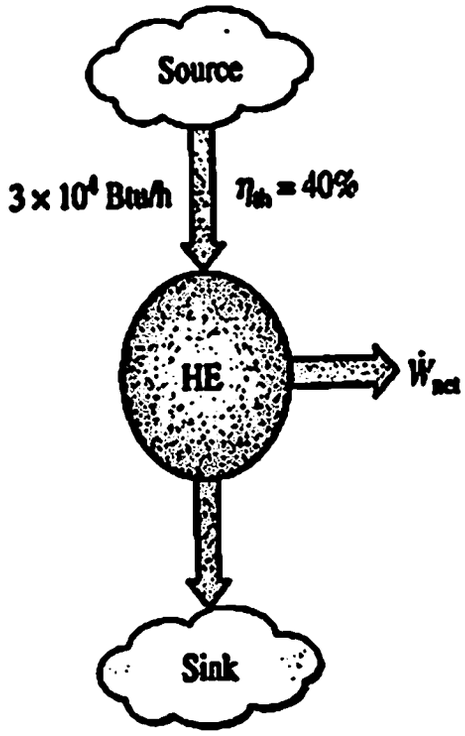


FIGURE P7–16E

Step 1 of 2

Given

The heat input to the heat engine, $\dot{Q}_H = 3\times10^4$ Btu/h

The thermal efficiency of the engine, $\eta_{HE} = 40\%$

Step 2 of 2

The thermal efficiency of a heat engine is defined as $\eta_{HE} = \dfrac{\dot{W}_{net}}{\dot{Q}_H}$

Where $\dot{W}_{net}$ the work net is transferred to the heat engine,

$\dot{Q}_H$ is the heat transfer between the device and high temperature reservoir.

Substituting the values, we get

$$\dot{W}_{net} = \eta_{HE} \times \dot{Q}_H$$
$$= (0.4)\left(3\times10^4\right) \text{ Btu/h}$$
$$= \frac{(0.4)\left(3\times10^4\right)}{2544.5} \text{ hp}$$
$$= 4.716 \text{ hp}$$

Hence the net work done is $\boxed{\dot{W}_{net} = 4.716 \text{ hp}}$

Question: 7.017P

The thermal efficiency of a general heat engine is 40 percent, and it produces 30 hp. At what rate is heat transferred to this engine, in kJ/s?

Step 1 of 2

Given

The power output from the heat engine $\dot{W}_{net} = 30$ hp

The thermal efficiency of the engine, $\eta_{HE} = 40\%$

Step 2 of 2

The thermal efficiency of a heat engine is defined as $\eta_{HE} = \frac{\dot{W}_{net}}{\dot{Q}_H}$

Where $\dot{W}_{net}$ the work net is transferred to the heat engine,

$\dot{Q}_H$ is the heat transfer between the device and high temperature reservoir.

Substituting the values, we get

$$\begin{aligned}\dot{Q}_H &= \frac{\dot{W}_{net}}{\eta_{HE}} \\ &= \frac{30}{0.4}\ \text{hp} \\ &= \frac{30 \times 0.745}{0.4}\ \text{kJ/s} \\ &= 55.875\ \text{kJ/s}\end{aligned}$$

Hence the net work done is $\boxed{\dot{W}_{net} = 55.875\ \text{kJ/s}}$

Question: 7.018P

A 600-MW steam power plant, which is cooled by a nearby river, has a thermal efficiency of 40 percent. Determine the rate of heat transfer to the river water. Will the actual heat transfer rate be higher or lower than this value? Why?

Step 1 of 4

Given

The capacity of the steam power plant is $W_{net} = 600\,\text{MW}$

The thermal efficiency of the plant $\eta_{th} = 40\%$

Step 2 of 4

The thermal efficiency of a heat engine is defined as

$$\eta_{th} = \frac{W_{net}}{Q_H}$$

Where

W_{net} is the net work output

Q_H is the amount of heat transfer from the high temperature reservoir

$$0.4 = \frac{600}{Q_H}$$

$$Q_H = 1500\ \text{MW}$$

Step 3 of 4

By applying first law to the cyclic system

$$\Sigma Q = \Sigma W$$

$$W_{net} = Q_H - Q_L$$

$$Q_L = Q_H - W_{net}$$

$$Q_L = 1500 - 600$$

$$\boxed{Q_L = 900\ \text{MW}}$$

Step 4 of 4

The actual amount of heat rejected to the river water will be less than the obtained value because there will be heat losses in the piping or the heat loss to the surroundings etc.

Question: 7.019P

A heat engine that pumps water out of an underground mine accepts 700 kJ of heat and produces 250 kJ of work. How much heat does it reject, in kJ?

Step 1 of 1

Given

The heat input, $Q_H = 700\ \text{kJ}$

Net work, $W_{net} = 250\ \text{kJ}$

From thermodynamic relation, $W_{net} = Q_H - Q_L$

Therefore the heat rejected is $Q_L = Q_H - W_{net}$

$$Q_L = 700 - 250$$

$$= 450\ \text{kJ}$$

Hence the total heat rejected is $\boxed{Q_L = 450\ \text{kJ}}$

Question:

7.020P

A heat engine with a thermal efficiency of 40 percent rejects 1000 kJ/kg of heat. How much heat does it receive?

Step 1 of 3

Given

Thermal efficiency of heat engine is $\eta = 40\%$

Amount of heat rejection $q_L = 1000\,\text{kJ/kg}$

Step 2 of 3

For heat engines, the desired output is the net work output, and the required input is the amount of heat supplied to the working fluid. Then the thermal efficiency of a heat engine can be expressed as

$$\text{Thermal efficiency} = \frac{\text{Net work output}}{\text{Total heat input}}$$

Question:

A heat engine with a thermal efficiency of 40 percent rejects 1000 kJ/kg of heat. How much heat does it receive?

Step 1 of 3

Given

Thermal efficiency of heat engine is $\eta = 40\%$

Amount of heat rejection $q_L = 1000\,\text{kJ/kg}$

Step 2 of 3

$q_H =$ [illegible] kJ/kg

Question: 7.021P

A steam power plant with a power output of 150 MW consumes coal at a rate of 60 tons/h. If the heating value of the coal is 30,000 kJ/kg, determine the overall efficiency of this plant.

Step 1 of 3

Given

Power output $\dot{W}_{net} = 150\ \text{MW}$
Heating value of the coal $HV = 30,000\ \text{kJ/kg}$

Mass flow rate of coal $\dot{m}_{coal} = 60\ \text{tons/h}$

$$\dot{m}_{coal} = 60 \times 1000 \times \frac{1}{3600}\ \text{kg/s}$$

Step 2 of 3

The rate of heat supplied to the power plant

$$\dot{Q}_{in} = \dot{m}_{coal} \times HV$$

$$\dot{Q}_{in} = 60 \times 1000 \times \frac{1}{3600} \times 30,000$$

$$\dot{Q}_{in} = 500000\ \text{kW}$$

$$\dot{Q}_{in} = 500\ \text{MW}$$

Step 3 of 3

The overall efficiency of the plant is

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}}$$

$$\eta_{th} = \frac{150}{500}$$

$$= 0.3$$

$$\boxed{\eta_{th} = 30\%}$$

7.022P

Question:

An automobile engine consumes fuel at a rate of 22 L/h and delivers 55 kW of power to the wheels. If the fuel has a heating value of 44,000 kJ/kg and a density of 0.8 g/cm3, determine the efficiency of this engine.

Step 1 of 3

Given

Power output, $\dot{W}_{net} = 55\ \text{kW}$

Heating value, $HV = 44{,}000\ \text{kJ/kg}$

Volume flow rate of fuel, $\dot{V}_{fuel} = 22\ \text{L/h}$

Density of fuel, $\rho = 0.8\ \text{g/cm}^3$

Step 2 of 3

The mass flow rate of fuel is expressed as

$$\dot{m}_{fuel} = \dot{V}_{fuel} \times \rho$$

Question:

An automobile engine consumes fuel at a rate of 22 L/h and delivers 55 kW of power to the wheels. If the fuel has a heating value of 44,000 kJ/kg and a density of 0.8 g/cm3, determine the efficiency of this engine.

Step 1 of 3

Given

Power output, $\dot{W}_{net} = 55\ \text{kW}$

Heating value, $HV = 44{,}000\ \text{kJ/kg}$

Volume flow rate of fuel, $\dot{V}_{fuel} = 22\ \text{L/h}$

Density of fuel, $\rho = 0.8\ \text{g/cm}^3$

7.023P

Question:

In 2001, the United States produced 51 percent of its electricity in the amount of 1.878 × 1012 kWh from coal-fired power plants. Taking the average thermal efficiency to be 34 percent, determine the amount of thermal energy rejected by the coal-fired power plants in the United States that year.

Step 1 of 3

Given

The amount of power output by means of coal fired power plants is

$\dot{W}_{net} = 1.878 \times 10^{12}\ \text{kWh}$

Average thermal efficiency is $\eta = 34\%$

Step 2 of 3

The overall efficiency of the plant is

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{}}$$

Question:

In 2001, the United States produced 51 percent of its electricity in the amount of 1.878 × 1012 kWh from coal-fired power plants. Taking the average thermal efficiency to be 34 percent, determine the amount of thermal energy rejected by the coal-fired power plants in the United States that year.

Step 1 of 3

Given

The amount of power output by means of coal fired power plants is

$\dot{W}_{net} = 1.878 \times 10^{12}\ \text{kWh}$

Question: 7.024P

The Department of Energy projects that between the years 1995 and 2010, the United States will need to build new power plants to generate an additional 150,000 MW of electricity to meet the increasing demand for electric power. One possibility is to build coal-fired power plants, which cost $1300 per kW to construct and have an effi- ciency of 40 percent. Another possibility is to use the clean-burning Integrated Gasification Combined Cycle (IGCC) plants where the coal is subjected to heat and pressure to gasify it while removing sulfur and particulate matter from it. The gaseous coal is then burned in a gas turbine, and part of the waste heat from the exhaust gases is recovered to generate steam for the steam turbine. Currently the construction of IGCC plants costs about $ 1500 per kW but their efficiency is about 48 percent. The average heating value of the coal is about 28,000,000 kJ per ton (that is, 28,000,000 kJ of heat is released when 1 ton of coal is burned). If the IGCC plant is to recover its cost dif- ference from fuel savings in five years, determine what the price of coal should be in $ per ton.

Step 1 of 5

Given

The construction cost for coal power plant is $1300/kW

Efficiency of coal based power plant, $\eta_{coal} = 0.4$

The construction cost for IGCC plant, $1500/kW

Efficiency of IGCC plant, $\eta_{IGCC} = 0.48$

The heating value of coal, $HV = 28{,}000{,}000$ kJ/ton

Step 2 of 5

The amount of electricity generated by a 150,000 MW plant that produces of electricity in 5 years is

$$E_{elec} = (150{,}000\times10^3\ \text{kW})\times(5\times365\times24)$$
$$= 6.57\times10^{12}\ \text{kWh}$$

The efficiency of any power plant is defined as

$$\eta = \frac{E_{elec}}{Q_{in}}$$
$$= \frac{E_{elec}}{\dot{m}_{fuel}\times HV}$$

Hence the mass of fuel is $\dot{m}_{fuel} = \frac{E_{elec}}{\eta\times HV}$

Step 3 of 5

For coal power plant,

$$\dot{m}_{coal} = \frac{E_{elec}}{\eta_{coal}\times HV}$$
$$= \frac{6.57\times10^{12}}{0.4\times\left(28\times10^6\ \text{kJ/ton}\right)}\left(\frac{3600\ \text{kJ}}{1\ \text{kWh}}\right)$$
$$= 2.112\times10^9\ \text{tons}$$

For IGCC power plant,

$$\dot{m}_{IGCC} = \frac{E_{elec}}{\eta_{IGCC}\times HV}$$
$$= \frac{6.57\times10^{12}}{0.48\times\left(28\times10^6\ \text{kJ/ton}\right)}\left(\frac{3600\ \text{kJ}}{1\ \text{kWh}}\right)$$
$$= 1.759\times10^9\ \text{tons}$$

The mass difference between plants is

$$\Delta m = m_{coal} - m_{IGCC}$$
$$= \left(2.112\times10^9\right) - \left(1.759\times10^9\right)$$
$$= 0.352\times10^9\ \text{tons}$$

Step 4 of 5

The construction cost difference between two plants

Construction cost for coal power plant is

$$\text{Cost}_{coal} = (150{,}000\times10^3\ \text{kW})\times\$1300/\text{kW}$$
$$= \$1.95\times10^{11}$$

Construction cost for IGCC power plant is

$$\text{Cost}_{IGCC} = (150{,}000\times10^3\ \text{kW})\times\$1500/\text{kW}$$
$$= \$2.25\times10^{11}$$

Cost difference between two power plants is

$$\Delta\text{cost} = \$(2.25-1.95)\times10^{11}$$
$$= \$0.3\times10^{11}$$

Step 5 of 5

The unit cost of coal per ton used in the power plant is

$$\text{unit cost} = \frac{\Delta\text{cost}}{\Delta m_{coal}}$$
$$= \frac{0.3\times10^{11}}{0.352\times10^9}$$
$$= \$85.2/\text{ton}$$

So IGCC power plant is cost effective if the coal price is $85.2 per ton

Question:

Reconsider Prob. 7–24. Using EES (or other) software, investigate the price of coal for varying simple payback periods, plant construction costs, and operating efficiency.

Step 1 of 7

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click table on menu bar, select the new parameter table.

And run the table for now values.

Then click ok.

Now again select the plot command on menu bar .then select the required variables from the list, then click okay.

Step 2 of 7

Equation window:

```
"Given"
W_dot=15E7 [kW]
Cost_coal=1300 [$/kW]
eta_coal=0.40
Cost_IGCC=1500 [$/kW]
eta_IGCC=0.48
HV_coal=28000 [kJ/kg]
"PaybackYears=5 [yr]"

"Analysis"
time=PaybackYears*Convert(yr, h)
ConstCost_coal=W_dot*Cost_coal
ConstCost_IGCC=W_dot*Cost_IGCC
ConstCostDif=ConstCost_IGCC-ConstCost_coal
W_e=W_dot*time
m_coal_coal=W_e/(eta_coal*HV_coal)*Convert(kWh, kJ)
m_coal_IGCC=W_e/(eta_IGCC*HV_coal)*Convert(kWh, kJ)
DELTAm_coal=m_coal_coal-m_coal_IGCC
UnitCost_coal=ConstCostDif/DELTAm_coal*1000
```

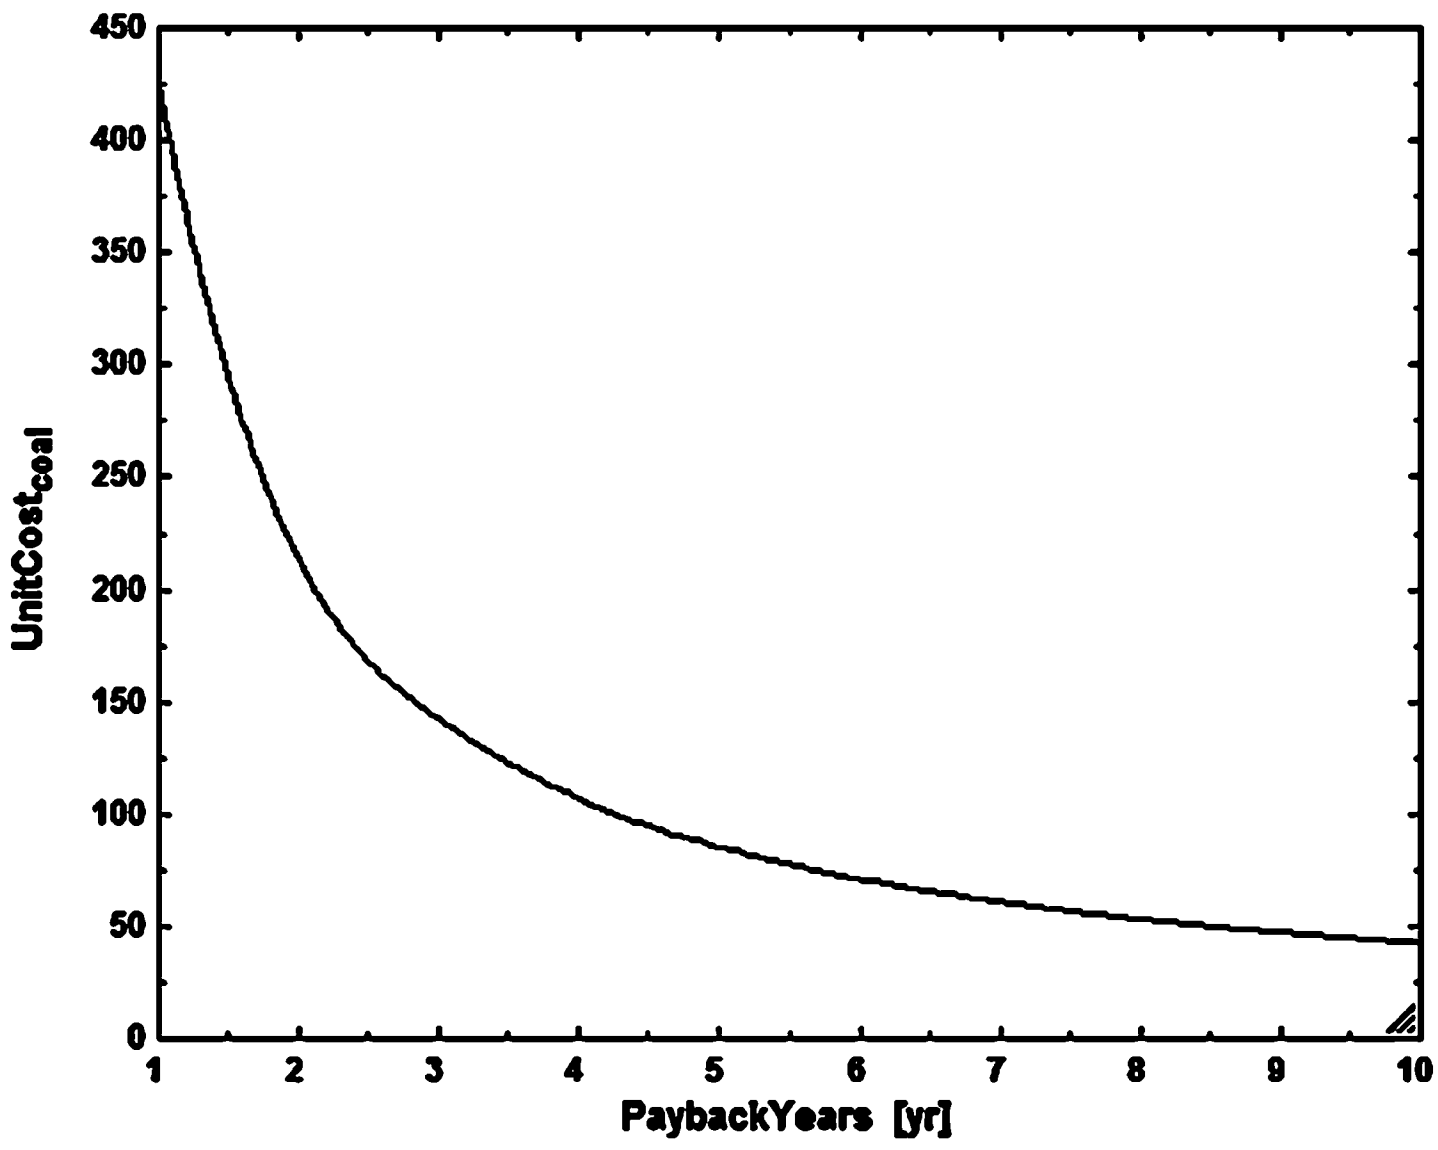
Step 3 of 7

Table for unit cost of coal as a function of payback periods:

1..10	1 PaybackYears [yr]	2 $UnitCost_{coal}$
Run 1	1	426.2
Run 2	2	213.1
Run 3	3	142.1
Run 4	4	106.5
Run 5	5	85.24
Run 6	6	71.03
Run 7	7	60.88
Run 8	8	53.27
Run 9	9	47.35
Run 10	10	42.62

Step 4 of 7

Graph between the unit cost of coal and payback periods:



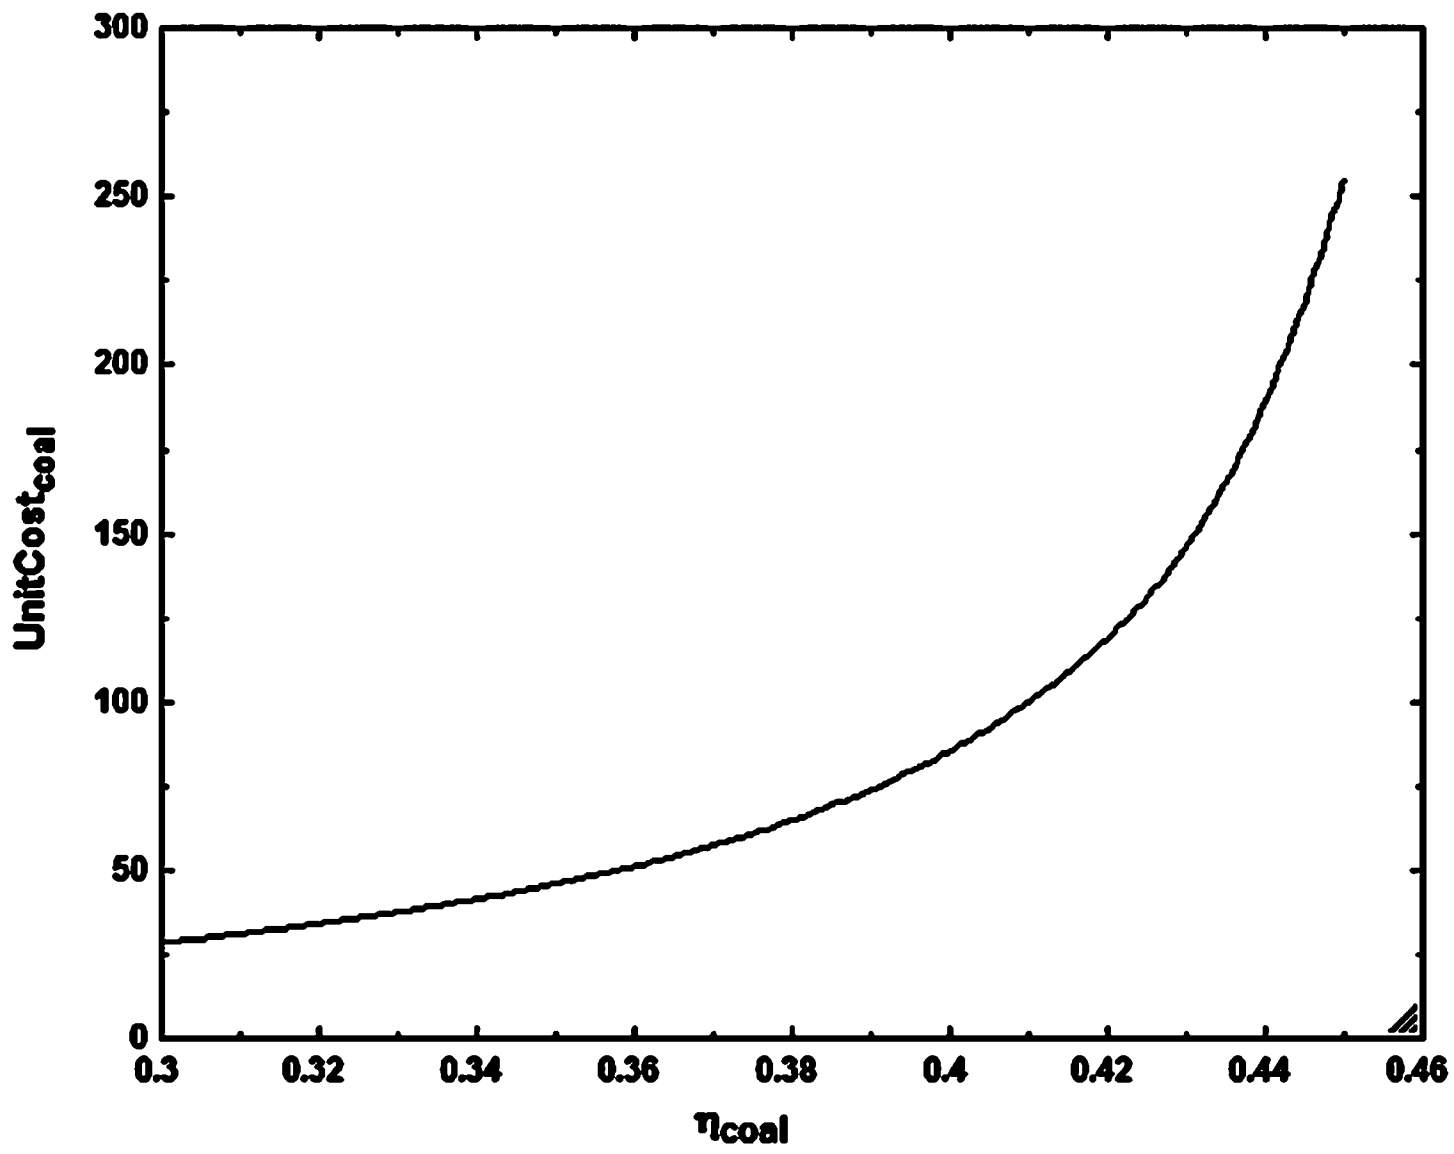


Table for unit cost of coal as a function of efficiency of coal

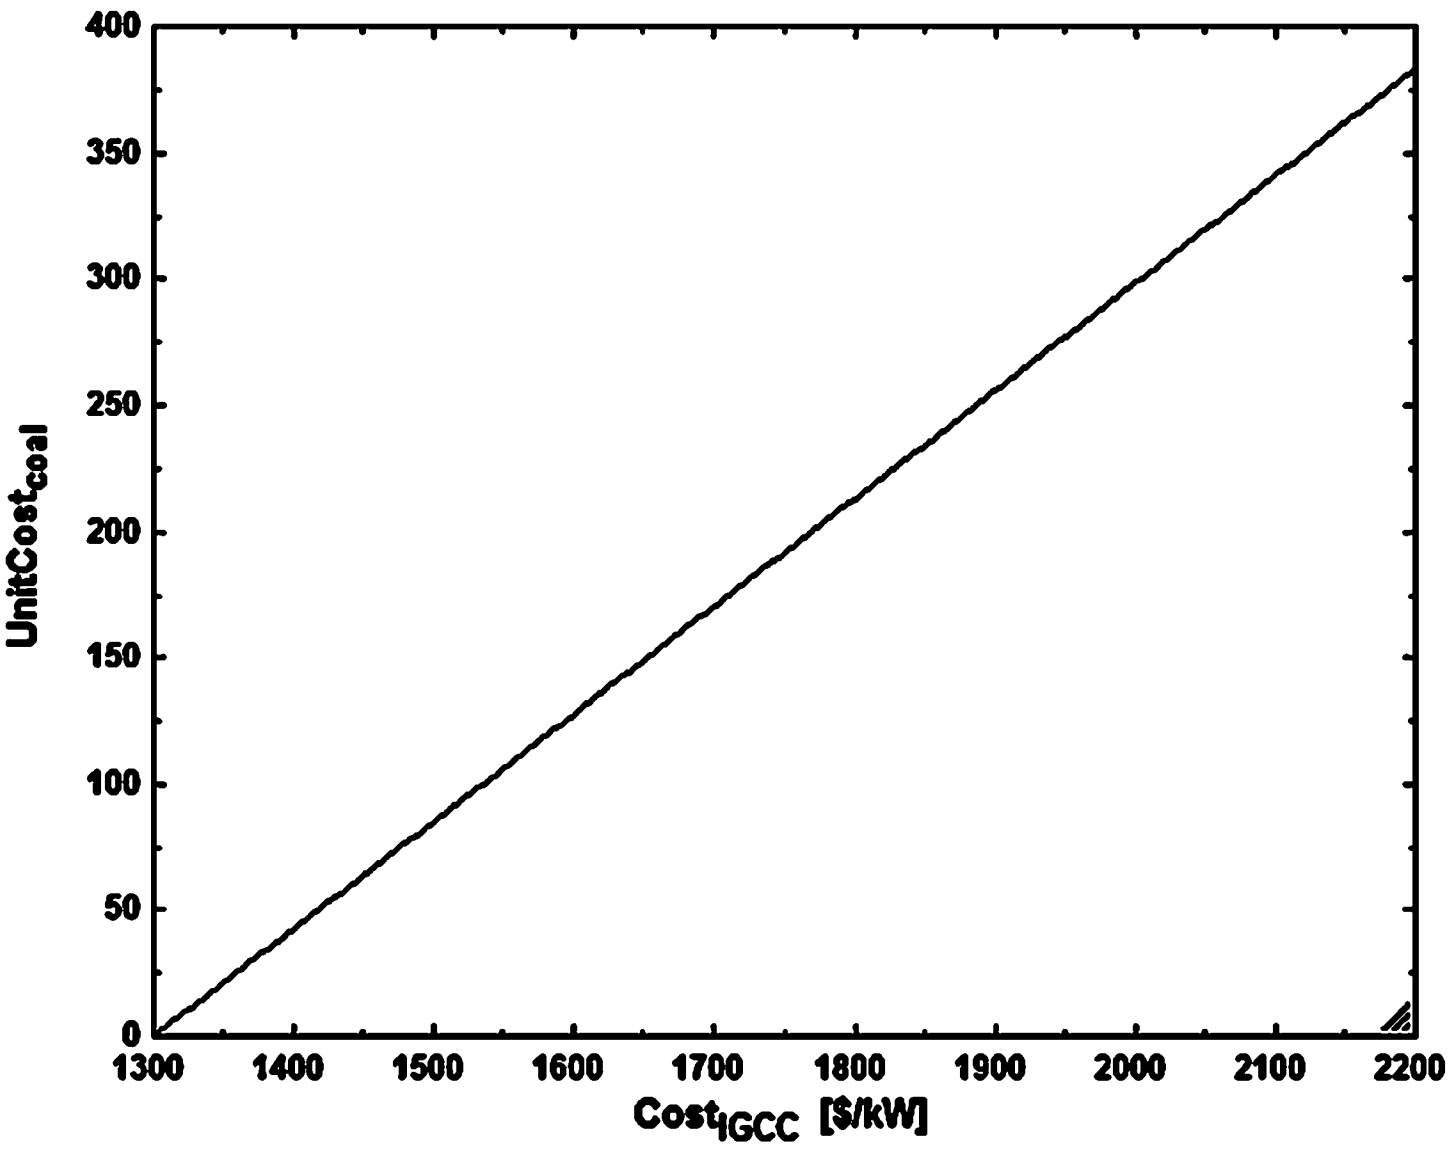
1..10	1 η_{coal}	2 $UnitCost_{coal}$
Run 1	0.3	28.41
Run 2	0.3167	33.05
Run 3	0.3333	38.74
Run 4	0.35	45.9
Run 5	0.3667	55.15
Run 6	0.3833	67.6
Run 7	0.4	85.24
Run 8	0.4167	112.2

Run 5	0.3667	59.15
Run 6	0.3833	67.6
Run 7	0.4	85.24
Run 8	0.4167	112.2
Run 9	0.4333	158.3
Run 10	0.45	255.7

Step 5 of 7

Graph between the unit cost of coal and efficiency of coal:



Step 6 of 7

Table for unit cost of coal as a function of constructive coal:

1..10	1 Cost_IGCC [$/kW]	2 UnitCost_coal
Run 1	1300	0
Run 2	1400	42.62
Run 3	1500	85.24
Run 4	1600	127.9
Run 5	1700	170.5
Run 6	1800	213.1
Run 7	1900	255.7
Run 8	2000	298.3
Run 9	2100	340.9
Run 10	2200	383.6

Step 7 of 7

Graph between the unit cost of coal and constrictive cost :

Question: 7.026P

Repeat Prob. 7–24 for a simple payback period of three years instead of five years.

Step 1 of 5

Given
The construction cost for coal power plant is \$1300/kW
Efficiency of coal based power plant, $\eta_{coal} = 0.4$
The construction cost for IGCC plant is \$1500/kW
Efficiency of IGCC plant, $\eta_{IGCC} = 0.48$
The heating value of coal, $HV = 28{,}000{,}000$ kJ/ton

Step 2 of 5

The amount of electricity generated by any of the plant for 3 years in order to produced 150,000 MW of electricity is

$$E_{elec} = (150{,}000 \times 10^3 \text{ kW}) \times (3 \times 365 \times 24)$$
$$= 3.942 \times 10^{12} \text{ kWh}$$

The mass required for this energy is $\dot{m}_{fuel} = \frac{Q_{in}}{HV}$

The efficiency of any power plant is defined as $\eta = \frac{E_{elec}}{Q_{in}}$

Combining both the expression, we get $\dot{m}_{fuel} = \frac{E_{elec}}{\eta \times HV}$

Step 3 of 5

For coal power plant,

$$\dot{m}_{coal} = \frac{E_{elec}}{\eta_{coal} \times HV}$$
$$= \frac{(3.942 \times 10^{12})}{(0.4) \times (28 \times 10^6)} \left(\frac{3600 \text{ kJ}}{1 \text{ kWh}}\right)$$
$$= 1.267 \times 10^9 \text{ tons}$$

For IGCC power plant,

$$\dot{m}_{IGCC} = \frac{E_{elec}}{\eta_{IGCC} \times HV}$$
$$= \frac{(3.942 \times 10^{12})}{(0.48) \times (28 \times 10^6)} \left(\frac{3600 \text{ kJ}}{1 \text{ kWh}}\right)$$
$$= 1.055 \times 10^9 \text{ tons}$$

The mass difference between plants is

$$\Delta m = m_{coal} - m_{IGCC}$$
$$= (1.267 \times 10^9) - (1.055 \times 10^9)$$
$$= 0.211 \times 10^9$$

Step 4 of 5

The construction cost difference between two plants
Construction cost for coal power plant is

$$\text{Cost}_{coal} = (150{,}000 \times 10^3 \text{ kW}) \times (\$1300/\text{kW})$$
$$= \$1.95 \times 10^{11}$$

Construction cost for IGCC power plant is

$$\text{Cost}_{IGCC} = (150{,}000 \times 10^3 \text{ kW}) \times (\$1500/\text{kW})$$
$$= \$2.25 \times 10^{11}$$

Cost difference between two power plants is

$$\Delta\text{cost} = \$(2.25 - 1.95) \times 10^{11}$$
$$= \$0.3 \times 10^{11}$$

Step 5 of 5

The unit cost of coal per ton used in the power plant is

$$\text{unit cost} = \frac{\Delta\text{cost}}{\Delta m}$$
$$= \frac{0.3 \times 10^{11}}{0.211 \times 10^9}$$
$$= \$142.2/\text{ton}$$

So IGCC power plant is cost effective if the coal price is \$142.2/ton

Question: 7.027P

Solar energy stored in large bodies of water, called solar pounds, is being used to generate electricity. If such a solar power plant has an efficiency of 4 percent and a net power output of 350 kW, determine the average value of the required solar energy collection rate, in Btu/h.

Step 1 of 3

Given

Efficiency of solar power plant $\eta = 4\% = 0.04$

Net power output $\dot{W}_{net} = 350\,\text{kW}$

Step 2 of 3

The rate of solar energy collection rate can be determined from the thermal efficiency relation

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}}$$

$$\dot{Q}_{in} = \frac{\dot{W}_{net}}{\eta_{th}}$$

$$\dot{Q}_{in} = \frac{350}{0.04}$$

$$\dot{Q}_{in} = 8750\ \text{kW}$$

Step 3 of 3

We know $1\,\text{Btu} = 1.055\,\text{kJ}$

$$\dot{Q}_{in} = 8750\,\frac{\text{kJ}}{\text{s}}\left(\frac{1\,\text{Btu}}{1.055\,\text{kJ}}\right)\left(\frac{3600\,\text{s}}{1\,\text{h}}\right)$$

$$\boxed{\dot{Q}_{in} = 29.8\times10^{6}\ \text{Btu/h}}$$

Question: 7.028P

A coal-burning steam power plant produces a net power of 300 MW with an overall thermal efficiency of 321 percent. The actual gravimetric air-fuel ratio in the furnace is calculated to be 12 kg air/kg fuel. The heating value of the coal is 28,000 kJ/kg. Determine (*a*) the amount of coal consumed during a 24-hour period and (*b*) the rate of air flowing through the furnace.

Step 1 of 5

Given data:

Net power produced by the plant, $\dot{W}_{net} = 300\ \text{MW}$

Thermal efficiency, $\eta_{th} = 32\%$

The air fuel ratio is, $A/F = 12\ \text{kg air/kg fuel}$

Heating value of coal $HV = 28,000\ \text{kJ/kg}$

Step 2 of 5

(a) The coal consumed in a 24 hour period

The amount of heat input to the power plant is calculated by

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}}$$

$$\dot{Q}_{in} = \frac{300}{0.32}$$

$$\dot{Q}_{in} = 937.5\ \text{MW}$$

$$\dot{Q}_{in} = 937.5 \times 1000\ \text{kW}$$

Step 3 of 5

The rate of heat supplied to the power plant is also expressed as

$$\dot{Q}_{in} = \dot{m}_f \times HV$$

Here the fuel is coal

Therefore, $\dot{m}_{coal} = \frac{\dot{Q}_{in}}{HV}$

$$= \frac{937.5 \times 1000\ \text{kJ/s}}{28000\ \text{kJ/kg}}$$

$$= 33.48\ \text{kg/s}$$

Step 4 of 5

The coal consumed in a 24 hour period

$$m_{coal} = 33.48 \times 24 \times 3600$$

$$= 2.89 \times 10^6\ \text{kg}$$

∴ The amount of coal consumed is, $\boxed{m_{coal} = 2.89 \times 10^6\ \text{kg}}$

Step 5 of 5

(b) The amount of air flowing through the furnace

$$A/F = \frac{\dot{m}_{air}}{\dot{m}_{fuel}}$$

$$\dot{m}_{air} = A/F \times \dot{m}_{fuel}$$

$$\dot{m}_{air} = 12 \times 33.48$$

$$\dot{m}_{air} = 401.76\ \text{kg/s}$$

∴ The mass of air flowing, $\boxed{\dot{m}_{air} = 401.76\ \text{kg/s}}$

Question: 7.029P

What is the difference between a refrigerator and a heat pump?

Step 1 of 1

Both the refrigerator and the heat pumps carry the heat from low temperature reservoir or the sink to the high temperature reservoir or source. The main purpose of the refrigerator is to chill or cool or freeze the substance, by maintaining very low temperature in the freezer. It absorbs the heat from the evaporator and throws it to the atmosphere which is at high temperature.

The objective of a heat pump, however, is to maintain a heated space at a high temperature. The main purpose of the heat pump is to heat the room.

Question: 7.030P

What is the difference between a refrigerator and an air conditioner?

Step 1 of 1

Air conditioners are basically refrigerators whose refrigerated space is a room or a building instead of the food compartment. A window air conditioning unit cools a room by absorbing heat from the room air and discharging it to the outside.
A refrigerator cools the space where food or other materials are placed.

Question: 7.031P

In a refrigerator, heat is transferred from a lower-temperature medium (the refrigerated space) to a higher-temperature one (the kitchen air). Is this a violation of the second law of thermodynamics? Explain.

Step 1 of 1

According to clausius statement it is impossible to transfer heat from low temperature to high temperature without an input of work. So in refrigerator heat is transferred from low temperature to high temperature by consuming some work input.
Therefore refrigerator does not violate the second law of thermodynamics.

Question: 7.032P

A heat pump is a device that absorbs energy from the cold outdoor air and transfers it to the warmer indoors. Is this a violation of the second law of thermodynamics? Explain.

Step 1 of 1

According to clausius statement it is impossible to transfer heat from low temperature to high temperature without an input of work. So in heat pump heat is transferred from low temperature to high temperature by consuming some work input.
Therefore heat pump does not violate the second law of thermodynamics.

Question: 7.033P

Define the coefficient of performance of a refrigerator in words. Can it be greater than unity?

Step 1 of 1

The COP (coefficient of performance) of refrigerator is defined as the ratio of amount of heat removed from the refrigerated space to the work input.

$$COP_R = \frac{Q_L}{W_{net,in}}$$

COP of refrigerator is greater than one

Question: 7.034P

Define the coefficient of performance of a heat pump in words. Can it be greater than unity?

Step 1 of 1

The COP (coefficient of performance) of heat pump is defined as the ratio of amount of heat supplied to the work input.

$$COP_{HP} = \frac{Q_H}{W_{net,in}}$$

COP of heat pump is greater than one.

Question: 7.035P

A heat pump that is used to heat a house has a COP of 2.5. That is, the heat pump delivers 2.5 kWh of energy to the house for each 1 kWh of electricity it consumes. Is this a violation of the first law of thermodynamics? Explain.

Step 1 of 2

Given

COP of heat pump $COP_{HP} = 2.5$

Heat supplied to the house $Q_H = 2.5\text{kWh}$

Work input to the heat pump $W_{net,in} = 1\text{kWh}$

Step 2 of 2

COP of heat pump is

$$COP_{HP} = \frac{Q_H}{W_{net,in}}$$

$$COP_{HP} = \frac{2.5}{1}$$

$$COP_{HP} = 2.5$$

Therefore the given COP satisfies

Here heat transfer takes place from low energy to high energy but the energy is neither created nor destroyed. So it does not violate the first law of thermodynamics

Question: 7.036P

A refrigerator has a COP of 1.5. That is, the refrigerator removes 1.5 kWh of energy from the refrigerated space for each 1 kWh of electricity it consumes. Is this a violation of the first law of thermodynamics? Explain.

Step 1 of 3

Given

COP of refrigerator $COP_R = 1.5$

The amount of heat removed from the refrigerated space $\dot{Q}_L = 1.5\text{kWh}$

Work input to the refrigerator $\dot{W}_{net,in} = 1\text{kWh}$

Step 2 of 3

COP of refrigerator is

$$COP_R = \frac{Q_L}{W_{net,in}}$$

$$COP_R = \frac{1.5}{1}$$

$$COP_R = 1.5$$

Therefore the given COP satisfies

Step 3 of 3

Here heat transfer takes place from low energy to high energy but the energy is neither created nor destroyed. So it does not violate the first law of thermodynamics

Question: 7.037P

What is the Clausius expression of the second law of thermodynamics?

Step 1 of 2

The Clausius statement.

It is not possible to construct a thermodynamic system undergoing a cyclic process undergoes the heat transfer from a lower temperature body to a higher temperature body without any work interaction.

Step 2 of 2

The Clausius expression.

$$\oint \frac{\delta Q}{T} \leq 0$$

Here, δQ is the energy flow into the system and T is the absolute temperature.

For a cyclic reversible process.

$$\oint \frac{\delta Q}{T} = 0$$

For a cyclic irreversible process.

$$\oint \frac{\delta Q}{T} < 0$$

Question: 7.038P

Show that the Kelvin-Planck and the Clausius expressions of the second law are equivalent.

Step 1 of 1

The Kelvin-Planck and Clausius expressions of the second law of thermodynamics are equivalent in their consequences which means that if any device violates one statement then consequently the other statement is also violated.

Consider two devices *A* and *B* which are working between a high-temperature reservoir and a low-temperature reservoir. Let device *A* be a heat engine and is assumed to transfer heat $(Q_H)_A$ completely into work $(W_{net})_A$ by which it has 100% efficiency, thus violating Kelvin-Planck statement. Then the amount of heat transfer by device *A* is equal to the net work by the device *A*. Mathematically it is given by the relation as follows:

$$(Q_H)_A = (W_{net})_A$$

Consider device *B* to be a refrigerator which removes heat $(Q_L)_B$ from the low-temperature reservoir and also receives work $(W_{net})_A$ from device *A* and rejects the total energy of $(W_{net})_A$ and $(Q_L)_B$ to the high-temperature reservoir.

Heat rejected by device *C*, which is the combination of devices A and B, to the high-temperature reservoir equals

$$\begin{aligned}\left((Q_L)_B + (W_{net})_A\right) - (Q_H)_A &= \left((Q_L)_B + (W_{net})_A\right) - (W_{net})_A \\ &= (Q_L)_B\end{aligned}$$

Thus device *C* extracts $(Q_L)_B$ amount of heat from the low-temperature reservoir and rejects it to the high-temperature reservoir which results in violation of the Clausius statement. Similarly if any device violates Kelvin-Planck statement Clausius statement is also violated.

Therefore, the Kelvin-Planck and the Clausius expressions of the second law are equivalent.

Question: 7.039P

A residential heat pump has a coefficient of performance of 2.4. How much heating effect, in Btu/h, will result when 5 hp is supplied to this heat pump?

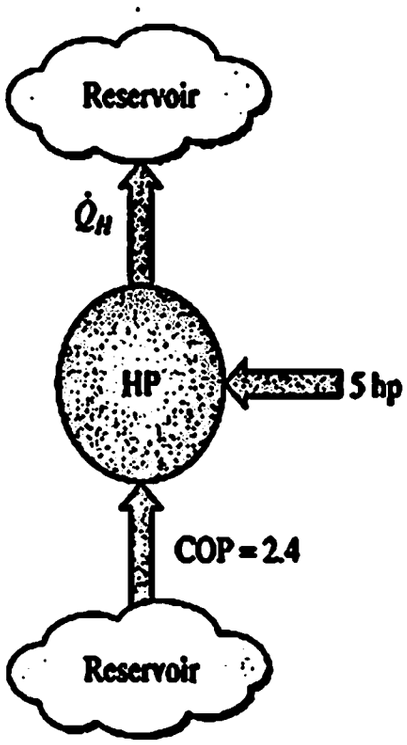


FIGURE P7–39E

Step 1 of 2

Given

The coefficient of performance of the heat pump is COP = 2.4

The power input to the heat pump $\dot{W}_{net} = 5$ hp

Step 2 of 2

The measure of performance of a heat pump is also expressed in terms of the coefficient of performance defined as

$$COP_{HP} = \frac{\text{Desired effect}}{\text{Work input}}$$

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

Therefore the amount of heating effect is

$$\dot{Q}_H = COP_{HP} \times \dot{W}_{net}$$
$$= 2.4 \times 5$$
$$\dot{Q}_H = 12 \text{ hp}$$

We know 1 hp = 2544.5 Btu/h

$$\dot{Q}_H = 12 \times 2544.5 \text{ Btu/h}$$

$$\boxed{\dot{Q}_H = 30534 \text{ Btu/h}}$$

Question: 7.040P

An air conditioner produces a 2-kW cooling effect while rejecting 2.5 kW of heat. What is its COP?

Step 1 of 3

Given

The cooling effect is $\dot{Q}_L = 2\,\text{kW}$

The amount of heat rejected $\dot{Q}_H = 2.5\,\text{kW}$

Step 2 of 3

Applying first law of thermodynamics for this system

$$\dot{W}_{net} = \dot{Q}_H - \dot{Q}_L$$

$$\dot{W}_{net} = 2.5 - 2$$

$$\dot{W}_{net} = 0.5\,\text{kW}$$

Step 3 of 3

The coefficient of performance of refrigerator is defined as desired effect (to remove heat (Q_L) from the refrigerated space) to the work input

$$COP_R = \frac{\text{Desired effect}}{\text{work input}}$$

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

$$COP_R = \frac{2}{0.5}$$

$$\boxed{COP_R = 4}$$

Question: 7.041P

A refrigerator used to cool a computer requires 3 kW of electrical power and has a COP of 1.4. Calculate the cooling effect of this refrigerator, in kW.

Step 1 of 2

Given

The COP of refrigerator $COP_R = 1.4$

The amount of power input $\dot{W}_{net} = 3\ \text{kW}$

Step 2 of 2

The coefficient of performance of refrigerator is defined as desired effect (to remove heat (Q_L) from the refrigerated space) to the work input

$$COP_R = \frac{\text{Desired effect}}{\text{work input}}$$

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

Therefore the cooling effect of the refrigerator is

$$\dot{Q}_L = COP_R \times \dot{W}_{net}$$

$$\dot{Q}_L = 1.4 \times 3$$

$$\boxed{\dot{Q}_L = 4.2\ \text{kW}}$$

Question: 7.042P

A food department is kept at −12°C by a refrigerator in an environment at 30°C. The total heat gain to the food department is estimated to be 3300 kJ/h and the heat rejection in the condenser is 4800 kJ/h. Determine the power input to the compressor, in kW and the COP of the refrigerator.

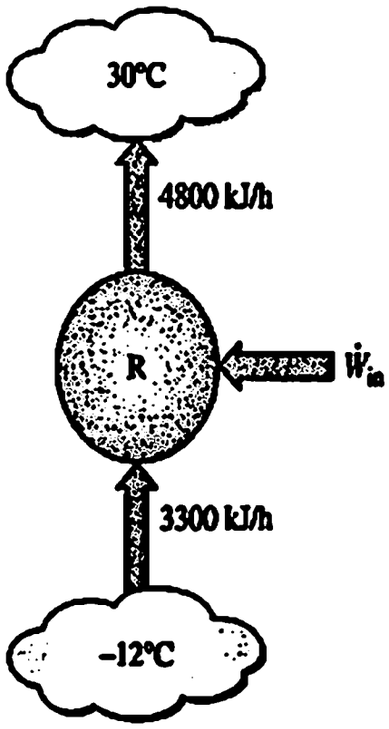

FIGURE P7–42

Step 1 of 3

Given

The cooling effect is $\dot{Q}_L = 3300$ kJ/h

The amount of heat rejected $\dot{Q}_H = 4800$ kJ/h

Step 2 of 3

Applying first law of thermodynamics for this system

$$\dot{W}_{net} = \dot{Q}_H - \dot{Q}_L$$
$$= 4800 - 3300 = 1500 \text{ kJ/h}$$
$$\dot{W}_{net} = 1500 \text{kJ/h}$$

Step 3 of 3

The coefficient of performance of refrigerator is defined as desired effect (to remove heat (Q_L) from the refrigerated space) to the work input

$$COP_R = \frac{\text{Desired effect}}{\text{work input}}$$

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

$$COP_R = \frac{3300}{1500}$$

$$\boxed{COP_R = 2.2}$$

Question: 7.043P

A household refrigerator with a COP of 1.2 removes heat from the refrigerated space at a rate of 60 kJ/min. Determine (*a*) the electric power consumed by the refrigerator and (*b*) the rate of heat transfer to the kitchen air.

Step 1 of 3

Given data:

Coefficient of performance $COP = 1.2$

Heat removed from refrigerant $\dot{Q}_L = 60$ kJ/min

Step 2 of 3

a)

The electric power consumed by the refrigerator

The COP of a refrigerator is given by

$$COP = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

$$1.2 = \frac{60}{\dot{W}_{net}}$$

$$\dot{W}_{net} = \frac{60}{1.2}$$

$$\dot{W}_{net} = 50 \text{ kJ/min}$$

$$\dot{W}_{net} = \frac{50}{60} \text{kJ/s}$$

$$\dot{W}_{net} = 0.833 \text{kJ/s} (\text{or}) \text{kW}$$

∴ The electric power consumed is $\boxed{\dot{W}_{net} = 0.833 \text{kW}}$

Step 3 of 3

b)

The rate of heat transfer to the kitchen is calculated from

$$\dot{W}_{net} = \dot{Q}_H - \dot{Q}_L$$

$$\dot{Q}_H = \dot{Q}_L + \dot{W}_{net}$$

$$\dot{Q}_H = (60+50) \text{ kJ/min}$$

$$\dot{Q}_H = 110 \text{ kJ/min}$$

∴ The heat transfer to the kitchen is $\boxed{\dot{Q}_H = 110 \text{ kJ/min}}$

Question: 7.044P

A commercial heat pump removes 10,000 Btu/h from the source, rejects 15,090 Btu/h to the sink, and requires 2 hp of power. What is this heat pump's coefficient of performance?

Step 1 of 2

Given data:

Heat pump absorbs heat at a rate of $\dot{Q}_L = 10000\,\text{Btu/h}$

Heat pump removes heat at a rate of $\dot{Q}_H = 15090\,\text{Btu/h}$

Power input to the heat pump, $W_{net,in} = 2\,\text{hp}$

Conversion factor $1\text{hp} = 2545.458\ \text{Btu/h}$

Step 2 of 2

The measure of performance of a heat pump is also expressed in terms of the coefficient of performance COP_{HP}, defined as

$$COP_{HP} = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_{HP} = \frac{\dot{Q}_H}{W_{net,in}}$$

$$COP_{HP} = \frac{15{,}090}{2 \times 2545.458}$$

$$COP_{HP} = 2.964$$

∴ The coefficient of performance of the heat pumps is $\boxed{COP_{HP} = 2.964}$

Question: 7.045P

A refrigerator used for cooling food in a grocery store is to produce a 25,000 kJ/h cooling effect, and it has a coefficient of performance of 1.60. How many kilowatts of power will this refrigerator require to operate?

Step 1 of 2

Given

The COP of refrigerator $COP_R = 1.6$

Cooling effect produced $\dot{Q}_L = 25,000$ kJ/h

Step 2 of 2

The coefficient of performance of refrigerator is defined as desired effect (to remove heat (Q_L) from the refrigerated space) to the work input

$$COP_R = \frac{\text{Desired effect}}{\text{work input}}$$

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

Therefore the amount of power required to the refrigerator is

$$\dot{W}_{net} = \frac{\dot{Q}_L}{COP_R}$$

$$= \frac{25000}{1.6}$$

$$\dot{W}_{net} = 15625 \text{ kJ/h}$$

$$\dot{W}_{net} = 15625 \times \frac{1}{3600}$$

$$\boxed{\dot{W}_{net} = 4.34 \text{ kW}}$$

Question: 7.046P

A household refrigerator that has a power input of 450 W and a COP of 2.5 is to cool five large watermelons, 10 kg each, to 8°C. If the watermelons are initially at 20°C, determine how long it will take for the refrigerator to cool them. The watermelons can be treated as water whose specific heat is 4.2 kJ/kg·°C. Is your answer realistic or optimistic? Explain.

Step 1 of 5

Given data:

The power input to the refrigerator, $W_{net} = 450\ \text{W}$

The COP of the refrigerator, $COP_R = 2.5$

Low temperature, $T_L = 8°\text{C}$

High temperature, $T_H = 20°\text{C}$

Mass of each watermelon, $m = 10\ \text{kg}$

Specific heat, $c = 4.2\ \text{kJ/kg°C}$

Step 2 of 5

The amount of heat removed from 5 watermelons is

$$Q_L = mc\Delta T\ \text{kJ}$$

$$Q_L = 5\times10\times4.2(20-8)\ \text{kJ}$$

$$Q_L = 2520\ \text{kJ}$$

Step 3 of 5

We know that

$$COP_R = \frac{\dot{Q}_L}{W_{net}}$$

$$2.5 = \frac{\dot{Q}_L}{450}$$

$$\dot{Q}_L = 1125\ \text{W}$$

$$\dot{Q}_L = 1.125\ \text{kW}$$

Step 4 of 5

Therefore, the time required to cool the watermelons is

$$t = \frac{Q_L}{\dot{Q}_L}$$

$$= \frac{2520}{1.125}$$

$$= 2240\ s$$

$$\therefore \boxed{t = 2240\ s}$$

Step 5 of 5

This answer seems to be not realistic since the refrigerated space will gain some heat during this process from the surrounding air, the refrigerator may take even more time to cool the watermelons.

Question: 7.047P

Bananas are to be cooled from 24 to 13°C at a rate of 215 kg/h by a refrigeration system. The power input to the refrigerator is 1.4 kW. Determine the rate of cooling, in kJ/min, and the COP of the refrigerator. The specific heat of banana above freezing is 3.35 kJ/kg·°C.

Step 1 of 3

Calculate the amount of heat removed from banana,

$$\dot{Q}_L = \dot{m}c_p\Delta T$$
$$= \dot{m}c_p(T_2 - T_1)$$

Here,

Initial temperature of banana, T_1

Final temperature of banana, T_2

The mass flow rate of refrigerant air, $\dot{m}$

The specific heat of banana, c_p

Substitute 24°C for T_1, 13°C for T_2, 215 kg/h for $\dot{m}$, 1.4 kW for $\dot{W}_{in}$, 3.35 kJ/kg·°C for c_p

$$\dot{Q}_L = 215\ \text{kg/h}\left(\frac{1\text{h}}{3600\text{s}}\right)\times 3.35\times(24-13)$$
$$= 2.2\ \text{kW}$$

Step 2 of 3

Calculate the rate of cooling in kJ/min,

$$\dot{Q}_L = 2.2\ \text{kW}\times\frac{1\text{J/s}}{1\text{W}}$$
$$= 2.2\ \text{kJ/s}\times\frac{60\text{s}}{\text{min}}$$
$$= 132\ \text{kJ/min}$$

Therefore, the rate of cooling is $\boxed{132\ \text{kJ/min}}$

Step 3 of 3

The coefficient of performance of refrigerator is defined as desired effect (to remove heat ($\dot{Q}_L$) from the refrigerated space) to the work input.

$$(\text{COP})_{\text{Refrigerator}} = \frac{\text{Desired effect}}{\text{work input}}$$
$$= \frac{\dot{Q}_L}{\dot{W}_{in}}$$

Here,

The Power input to the refrigerator, $\dot{W}_{in}$

Substitute 2.2 kW for $\dot{Q}_L$, 1.4 kW for $\dot{W}_{in}$,

$$(\text{COP})_{\text{Refrigerator}} = \frac{2.2}{1.4}$$
$$= 1.57$$

Therefore, the coefficient of performance of refrigerator is $\boxed{1.57}$

Question: 7.048P

A refrigerator is used to cool water from 23 to 5°C in a continuous manner. The heat rejected in the condenser is 570 kJ/min and the power is 2.65 kW. Determine the rate at which water is cooled, in L/min and the COP of the refrigerator. The specific heat of water is 4.18 kJ/kg·°C and its density is 1 kg/L.

Step 1 of 5

Given

Initial temperature of water $T_1 = 23°C$

Final temperature of water $T_2 = 5°C$

The amount of heat rejected is $\dot{Q}_H = 570$ kJ/min

$$\dot{Q}_H = \frac{570}{60} \text{ kJ/sec}$$

The power input to the refrigerator is $\dot{W}_{in} = 2.65$ kW

The specific heat of water is $c_p = 4.18$ kJ/kg.°C

Density of water is $\rho = 1$ kg/L

Step 2 of 5

The cooling effect can be determined from energy balance as

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{in}$$

$$\dot{Q}_L = (570/60) - 2.65$$

$$\dot{Q}_L = 6.85 \text{ kW}$$

Step 3 of 5

The mass flow rate of water can be determined from the amount of cooling effect produced by the water

$$\dot{Q}_L = \dot{m} c_p \Delta T \text{ kJ/s}$$

Therefore the mass flow rate is

$$\dot{m} = \frac{6.85}{(4.18)(23-5)}$$

$$\dot{m} = 0.091 \text{ kJ/s}$$

Step 4 of 5

The volume flow rate in L/min is

$$\dot{V} = \frac{\dot{m}}{\rho} \text{ L/min}$$

$$\dot{V} = \frac{0.091 \text{ kg/s}}{1 \text{ kg/L}} \left(\frac{60 \text{ s}}{1 \text{ min}} \right) \text{ L/min}$$

$$\boxed{\dot{V} = 5.46 \text{ L/min}}$$

Step 5 of 5

The coefficient of performance of refrigerator is defined as desired effect (to remove heat (Q_L) from the refrigerated space) to the work input

$$COP_R = \frac{\text{Desired effect}}{\text{work input}}$$

We know that

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{in}}$$

$$COP_R = \frac{6.85}{2.65}$$

$$\boxed{COP_R = 2.58}$$

Question: 7.049P

A heat pump is used to maintain a house at a constant temperature of 23°C. The house is losing heat to the outside air through the walls and the windows at a rate of 60,000 kJ/h while the energy generated within the house from people, lights, and appliances amounts to 4000 kJ/h. For a COP of 2.5, determine the required power input to the heat pump.

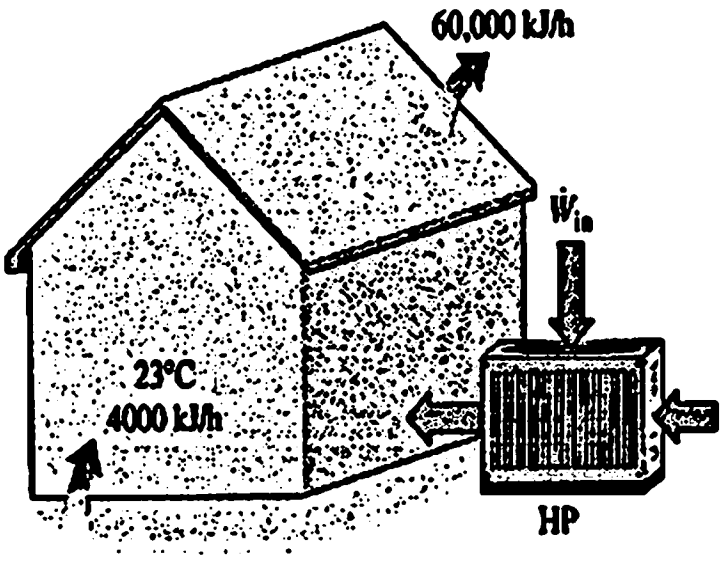

FIGURE P7–49

Step 1 of 3

Given data:

High temperature, $T_H = 23°C$

Heat loss from the house, $\dot{Q}_L = 60,000$ kJ/h

Heat absorbed by appliance, $\dot{Q}_{App} = 4000$ kJ/h

The coefficient of performance of heat pump, $COP_{HP} = 2.5$

Step 2 of 3

The total heat load by the heat pump is the difference between heat loss by the house and heat absorbed by the appliances

$$\dot{Q}_H = \dot{Q}_L - \dot{Q}_{App}$$

$$\dot{Q}_H = 60,000 - 4000$$

$$\dot{Q}_H = 56000 \text{ kJ/h}$$

Step 3 of 3

The measure of performance of a heat pump is also expressed in terms of the coefficient of performance COP_{HP} and it is defined as

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

Therefore, the power input to the heat pump is

$$\dot{W}_{net} = \frac{\dot{Q}_H}{COP_{HP}}$$

$$\dot{W}_{net} = \frac{56000}{2.5 \times 3600}$$

$$\dot{W}_{net} = 6.22 \text{ kJ/s}$$

∴ The power input to the heat pump, $\boxed{\dot{W}_{net} = 6.22 \text{ kW}}$

Question: 7.050P

Water enters an ice machine at 55°F and leaves as ice at 25°F. If the COP of the ice machine is 2.4 during this operation, determine the required power input for an ice production rate of 28 lbm/h. (169 Btu of energy needs to be removed from each lbm of water at 55°F to turn it into ice at 25°F.)

Step 1 of 3

Given data:

COP of refrigerator, $COP_R = 2.4$

Low temperature, $T_L = 25°F$

High temperature, $T_H = 55°F$

Mass of ice produced, $\dot{m}_{ice} = 28$ lbm/h

Conversion factor, 1hp = 2545.458 Btu/h

Step 2 of 3

The cooling effect of the ice machine is defined as

$\dot{Q}_L = \dot{m}_{ice} \times 169$

$\dot{Q}_L = 28 \times 169$

$\dot{Q}_L = 4732$ Btu/h

We know that

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net,in}}$$

$$2.4 = \frac{4732}{\dot{W}_{net,in}}$$

$\dot{W}_{net,in} = 1971.67$ Btu/h

Step 3 of 3

The power input for ice production is calculated in hp

$$\dot{W}_{net,in} = \frac{1971.67}{2545.458}$$

$\dot{W}_{net,in} = 0.7745$ hp

∴ The power input is, $\boxed{\dot{W}_{net,in} = 0.7745 \text{ hp}}$

Question: 7.051P

Consider an office room that is being cooled adequately by a 12,000 Btu/h window air conditioner. Now it is decided to convert this room into a computer room by installing several computers, terminals, and printers with a total rated power of 8.4 kW. The facility has several 7000 Btu/h air conditioners in storage that can be installed to meet the additional cooling requirements. Assuming a usage factor of 0.4 (i.e., only 40 percent of the rated power will be consumed at any given time) and additional occupancy of seven people, each generating heat at a rate of 100 W, determine how many of these air conditioners need to be installed to the room.

Step 1 of 5

Given

The cooling effect of window a/c $\dot{Q}_L = 12{,}000$ Btu/h

Power input of the computer and other related parts $\dot{W}_{in} = 8.4\,\text{kW}$

Number of people in the room N=7

Each person is generating heat at a rate of $\dot{Q}_p = 100\,\text{W}$

The cooling capacity of a/c $\dot{Q}_L = 7{,}000$ Btu/h

Usage factor 0.4

Step 2 of 5

The amount of heat dissipated by the computers

$$\dot{Q}_{comp} = \text{usage factor} \times \dot{W}_{in}$$

$$\dot{Q}_{comp} = 0.4 \times 8.4$$

$$\dot{Q}_{comp} = 3.36\,\text{kW}$$

Since we know

$1\,\text{W} = 3.412$ Btu/h

$$\dot{Q}_{comp} = 3.36 \times 1000 \times 3.412$$

$$\dot{Q}_{comp} = 11464.32 \text{ Btu/h}$$

Step 3 of 5

The total amount of heat generated by people in the room'

$$\dot{Q}_{people} = 7 \times 100$$

$$= 700\,\text{W}$$

$$\dot{Q}_{people} = 700 \times 3.412$$

$$\dot{Q}_{people} = 2388.4 \text{ Btu/h}$$

Step 4 of 5

Therefore the total heat generated in the room

$$\dot{Q}_{total} = \dot{Q}_{comp} + \dot{Q}_{people}$$

$$\dot{Q}_{total} = 11464.32 + 2388.4$$

$$\dot{Q}_{total} = 13852.7 \text{ Btu/h}$$

Step 5 of 5

The number of conditioners required for adequate cooling of the room is

$$n = \frac{\text{cooling load}}{\text{cooling capacity}}$$

$$n = \frac{13852.7}{7000}$$

$$n = 1.978 \approx 2$$

Therefore 2 air conditioners are required for the room

Question: 7.052P

Consider a building whose annual air-conditioning load is estimated to be 120,000 kWh in an area where the unit cost of electricity is \$0.10/kWh. Two air conditioners are considered for the building. Air conditioner A has a seasonal average COP of 3.2 and costs \$5500 to purchase and install. Air conditioner B has a seasonal average COP of 5.0 and costs \$7000 to purchase and install. All else being equal, determine which air conditioner is a better buy.

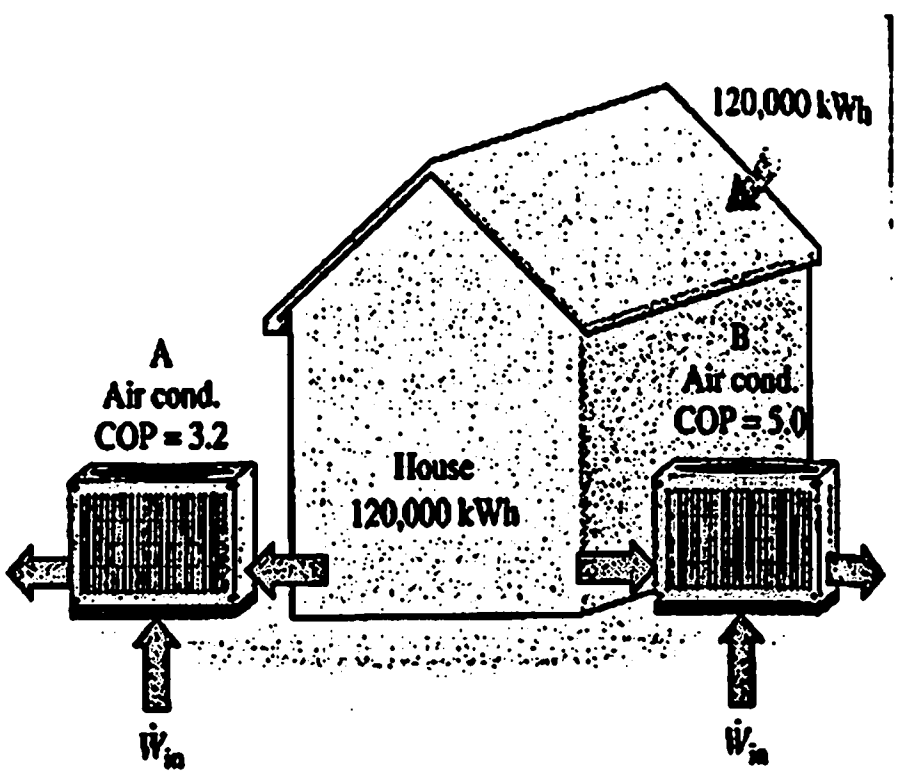

FIGURE P7–52

Step 1 of 4

Calculate the required power input to the Air conditioner *A*.

$$COP = \frac{N}{W}$$

Here, *COP* is the Coefficient Of Performance, *N* is the cooling load, and *W* is the work input.

Substitute 3.2 for COP_A, and $120000\ \text{kWh}$ for *N*.

$$COP_A = \frac{N}{W_A}$$

$$W_A = \frac{120000}{3.2}$$

$$= 37500\ \text{kWh}$$

Calculate the annual cost to the air conditioner *A*.

$$C_A = W_A \times c_u$$

Here, c_u is the unit cost of electricity.

Substitute $\$0.10/\text{kWh}$ for c_u, and $37500\ \text{kWh}$ for W_A.

$$C_A = W_A \times c_u$$

$$= 37500 \times 0.1$$

$$= \$3750$$

Step 2 of 4

Calculate the required power input to the Air conditioner *B*.

$$COP_B = \frac{N}{W_B}$$

Substitute 5 for COP_B, and $120000\ \text{kWh}$ for *N*.

$$COP_B = \frac{N}{W_B}$$

$$W_B = \frac{120000}{5}$$

$$= 24000\ \text{kWh}$$

Calculate the annual cost to the air conditioner *B*.

$$C_B = W_B \times c_u$$

Substitute $\$0.10/\text{kWh}$ for c_u, and $24000\ \text{kWh}$ for W_B.

$$C_B = W_B \times c_u$$

$$= 24000 \times 0.1$$

$$= \$2400$$

Step 3 of 4

Find the total cost of the air conditioner *A* per year:

$$T = C + I$$

Here, *T* is the total cost, *C* is annual service charges, and *I* is installation charges.

Substitute $\$3750$ for C_A, and $\$5500$ for I_A.

$$T_A = C_A + I_A$$

$$= 3750 + 5500$$

$$= \$9250$$

Step 4 of 4

Find the total cost of the air conditioner *B* per year:

$$T = C + I$$

Substitute $\$2400$ for C_B, and $\$7000$ for I_B.

$$T_B = C_B + I_B$$

$$= 2400 + 7000$$

$$= \$9400$$

Since, the total cost for air conditioner *A* is smaller than that of *B*, therefore the air conditioner *A* is better to buy.

Question: 7.053P

A house that was heated by electric resistance heaters consumed 1200 kWh of electric energy in a winter month. If this house were heated instead by a heat pump that has an average COP of 2.4, determine how much money the home owner would have saved that month. Assume a price of 8.50/kWh for electricity.

Step 1 of 3

Given data:

Heat transferred by the electric heater, $\dot{Q}_H = 1200\ \text{kWh}$

Average coefficient of performance, $COP_H = 2.4$

Step 2 of 3

The power consumed by the electrical heater is defined as

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$\dot{W}_{net} = \frac{\dot{Q}_H}{COP_{HP}}$$

$$= \frac{1200}{2.4}$$

$$= 500\ \text{kWh}$$

Step 3 of 3

The heat transfer from the low temperature reservoir is

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{net}$$

$$\dot{Q}_L = 1200 - 500$$

$$\dot{Q}_L = 700\ \text{kWh}$$

The amount of money saved is $Q_L \times 0.085$

Therefore amount of money saved is

$0.085 \times 700 = 59.5\$$

$\therefore$ The home owner can save $\boxed{59.5\$}$

Question: 7.054P

Refrigerant-134a enters the condenser of a residential heat pump at 800 kPa and 35°C at a rate of 0.018 kg/s and leaves at 800 kPa as a saturated liquid. If the compressor consumes 1.2 kW of power, determine (*a*) the COP of the heat pump and (*b*) the rate of heat absorption from the outside air.

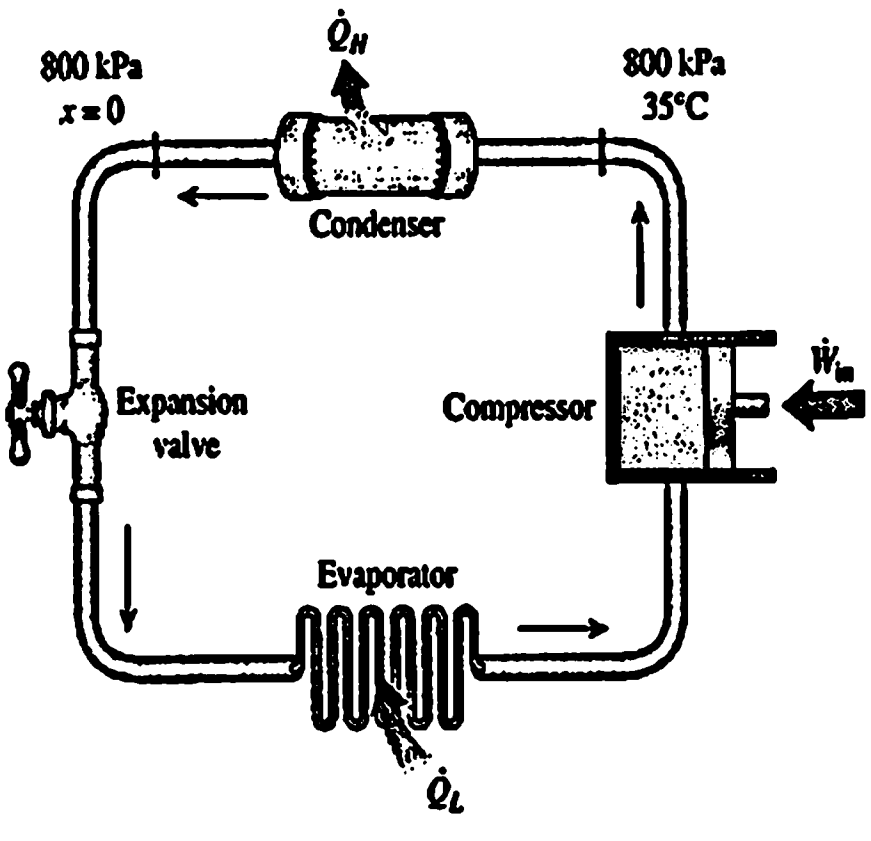

FIGURE P7–54

Step 1 of 6

Given data:

Inlet pressure of the condenser, $P_1 = 800\ \text{kPa}$

Inlet temperature of the condenser, $T_1 = 35°\text{C}$

Flow rate of the refrigerant, $\dot{m} = 0.018\ \text{kg/s}$

Exit pressure, $P_2 = 800\ \text{kPa}$

Quality of refrigerant at exit of condenser, $x_2 = 0$

Power input to the compressor, $\dot{W}_{net} = 1.2\ \text{kW}$

Step 2 of 6

From superheated refrigerant -134a tables

Taking enthalpy at $P_1 = 800\ \text{kPa}$ & $T_1 = 35°\text{C}$,

By interpolating the values

$$h_1 = 267.29 + (276.45 - 267.29)\left[\frac{35 - 31.31}{40 - 31.31}\right]$$

$$h_1 = 271.17\ \text{kJ/kg}$$

Step 3 of 6

From saturated refrigerant -134a tables

Taking enthalpy at $P_2 = 800\ \text{kPa}$ and $x_2 = 0$ is,

By interpolating the values

$$h_2 = h_f = 93.58 + (96.48 - 93.58)\left[\frac{800 - 770.64}{815.89 - 770.64}\right]$$

$$h_2 = h_f = 95.46\ \text{kJ/kg}$$

Step 4 of 6

(a) The COP of heat pump:

The heat rejected in the condenser is expressed as

$$\dot{Q}_H = \dot{m}(h_1 - h_2)\text{kW}$$

$$\dot{Q}_H = 0.018(271.17 - 95.46)\text{kW}$$

$$\dot{Q}_H = 3.16\ \text{kW}$$

Step 5 of 6

The measure of performance of a heat pump is also expressed in terms of the coefficient of performance COP_{HP} and it is defined as

$$\text{COP}_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$\text{COP}_{HP} = \frac{3.16}{1.2}$$

$$\text{COP}_{HP} = 2.633$$

∴ The COP of heat pump $\boxed{\text{COP}_{HP} = 2.633}$

Step 6 of 6

(b) The rate of heat absorption from the outside air is expressed as

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{net}$$

$$\dot{Q}_L = 3.16 - 1.2$$

$$\dot{Q}_L = 1.96\ \text{kW}$$

∴ The rate of heat absorption is $\boxed{\dot{Q}_L = 1.96\ \text{kW}}$

Question: 7.055P

Show that processes that use work for mixing are irreversible by considering an adiabatic system whose contents are stirred by turning a paddle wheel inside the system (e.g., stirring a cake mix with an electric mixer).

Step 1 of 1

Adiabatic stirring processes are irreversible .Because of the changing of the temperature which cause the energy stored within the system can not be spontaneously released in a manor to cause the mass of the system to turn the paddle wheel in the opposite direction to do work on the surroundings. So that work for mixing are irreversible process.

Question: 7.056P

Show that processes involving rapid chemical reactions are irreversible by considering the combustion of a natural gas (e.g., methane) and air mixture in a rigid container.

Step 1 of 1

The chemical reactions are almost irreversible.
The reaction which involved combustion of natural gas and air mixture in a rigid container, results in formation of carbon dioxide, water and some releases heat energy.
It is not possible to convert them into back.

Question: 7.057P

A cold canned drink is left in a warmer room where its temperature rises as a result of heat transfer. Is this a reversible process? Explain.

Step 1 of 1

The process is a irreversible process
The temperature gain by the cold canned drink occurs in an infinitesimally temperature difference which is difficult to reverse the process.

The heat transfer through a differential temperature difference dT can be considered to be reversible. There is a smaller heat transfer when there is a small temperature difference between two bodies. Any significant heat transfer through a small temperature difference requires a very large surface area and a very long time. Therefore, even though approaching reversible heat transfer is desirable from a thermodynamic point of view, it is not practical and not economically feasible.

Question: 7.058P

A block slides down an inclined plane with friction and no restraining force. Is this process reversible or irreversible? Justify your answer.

Step 1 of 1

When a block slides down an inclined plane with friction and no restraining force then the process is irreversible because in a reversible process both the system and the surroundings are returned to their initial states at the end of the reverse process. And in this case the process is irreversible we can explain it into two ways

(a)

Due to friction, the block and plane gets warm up. In order to attain equilibrium temperature, the heat is transferred to the surroundings. This causes change in state of surroundings which is permanent and cannot be restored to its initial state. Therefore, the process is irreversible.

(b)

The potential energy of the block gradually decreases and stored in some form of energy in the surroundings. The potential energy can be restored by lifting the block to its original state however, the state of surroundings cannot be changed. Hence, the process is irreversible.

Question: 7.059P

Why are engineers interested in reversible processes even though they can never be achieved?

Step 1 of 1

Because reversible processes can be approached in reality, and they form the limiting cases. Engineers are interested in reversible processes because Work producing devices such as turbines that operate on reversible processes deliver the most work, and work consuming devices such as compressors that operate on reversible processes consume the least work.

We know the second law efficiency is the degree of approximation to the actual processes to the corresponding reversible processes. This enables us to compare the performance of different devices that are designed to do the same task on the basis of their efficiencies. The better the design, the lower the irreversibilities and the higher the second-law efficiency

Question: 7.060P

Why does a nonquasi-equilibrium compression process require a larger work input than the corresponding quasi-equilibrium one?

Step 1 of 1

We know quasi equilibrium process is a reversible process, and the compressors consume least work or in non quasi equilibrium compression process it consumes larger work input

When the compression process is non-quasi equilibrium, the molecules on the piston face cannot escape fast enough, forming a high pressure region in front of the piston. It requires more work to move the piston against this high pressure region.

Question: 7.061P

Why does a nonquasi-equilibrium expansion process deliver less work than the corresponding quasi-equilibrium one?

Step 1 of 1

We know quasi equilibrium process is a reversible process, and work producing devices such as turbines deliver the most work or in non quasi equilibrium expansion process delivers less work output

And when an expansion process is non-quasi equilibrium, the molecules before the piston face cannot follow the piston fast enough, forming a low pressure region behind the piston. The lower pressure that pushes the piston produces less work.

Question: 7.062P

How do you distinguish between internal and external irreversibilities?

Step 1 of 1

A process is called internally irreversible if irreversibilities occur within the boundaries of the system during the process. During an internally reversible process, a system proceeds through a series of equilibrium states, and when the process is reversed, the system passes through exactly the same equilibrium states while returning to its initial state. That is, the paths of the forward and reverse processes coincide for an internally reversible process. The quasi-equilibrium process is an example of an internally reversible process.

A process is called externally irreversible if irreversibilities occur outside the system boundaries during the process. Heat transfer between a reservoir and a system is an externally reversible process if the outer surface of the system is at the temperature of the reservoir.

Question: 7.063P

Is a reversible expansion or compression process necessarily quasi-equilibrium? Is a quasi-equilibrium expansion or compression process necessarily reversible? Explain.

Step 1 of 2

A reversible process is a process that can be reversed without leaving any trace on the surroundings. That is, both the system and the surroundings are returned to their initial states at the end of the reverse process. This is possible only if the net heat and net work exchange between the system and the surroundings is zero Reversible processes actually do not occur in nature. They are merely idealizations of actual processes. So a reversible expansion or compression process cannot involve unrestrained expansion or sudden compression, and thus it is quasi-equilibrium.

Step 2 of 2

Quasi-equilibrium is the quasi-balanced state of a thermodynamic system near to thermodynamic equilibrium in some sense or degree. A process is called quasi-static when it follows a succession of equilibrium states; the surroundings may be irreversibly altered during the process so that after a return path, the system ends up in a final state which differs from its initial state.

A quasi-equilibrium expansion or compression process, on the other hand, may involve external irreversibility's (such as heat transfer through a finite temperature difference), and thus is not necessarily reversible.

Question: 7.064P

What are the four processes that make up the Carnot cycle?

Step 1 of 1

The four reversible processes that make up the Carnot cycle are as follows:

(1) Reversible Isothermal expansion. (Process 1-2, T_H = constant)

(2) Reversible Adiabatic expansion. (Process 2-3)

(3) Reversible Isothermal compression. (Process 3-4, T_L = constant)

(4) Reversible Adiabatic compression. (Process 4-1)

Question: 7.065P

What are the two statements known as the Carnot principles?

Step 1 of 1

Two conclusions pertain to the thermal efficiency of reversible and irreversible (i.e., actual) heat engines and they are known as the Carnot principles
Expressed as follows:
1. The efficiency of an irreversible heat engine is always less than the efficiency of a reversible one operating between the same two reservoirs.
2. The efficiencies of all reversible heat engines operating between the same two reservoirs are the same.

Question: 7.066P

Somebody claims to have developed a new reversible heat-engine cycle that has a higher theoretical efficiency than the Carnot cycle operating between the same temperature limits. How do you evaluate this claim?

Step 1 of 1

According to Carnot principle the efficiencies of all reversible heat engines operating between the same two reservoirs are the same so, the claim is false, since the Carnot theorem says that no heat engine cycle can have a higher thermal efficiency than the Carnot heat engine operating between the same temperature limits.

Question: 7.067P

Somebody claims to have developed a new reversible heat-engine cycle that has the same theoretical efficiency as the Carnot cycle operating between the same temperature limits. Is this a reasonable claim?

Step 1 of 1

According to Carnot principle the efficiencies of all reversible heat engines operating between the same two reservoirs are the same so, the claim is true

Question: 7.068P

Is it possible to develop (*a*) an actual and (*b*) a reversible heat-engine cycle that is more efficient than a Carnot cycle operating between the same temperature limits? Explain.

Step 1 of 2

(a) Impossible

No actual heat engine operating at same temperatures limits produces more efficiency than Carnot heat engine.

Step 2 of 2

(b) Impossible

No reversible heat engine operating at same temperatures limits produces more efficiency than Carnot heat engine.

A reversible heat engine operating at same temperatures limits produces efficiency which is equal to Carnot engine.

Question: 7.069P

Is there any way to increase the efficiency of a Carnot heat engine other than by increasing *TH* or decreasing *TL*?

Step 1 of 1

No, since the thermal efficiency of actual heat engines can be maximized by supplying heat to the engine at the highest possible temperature and rejecting heat from the engine at the lowest possible temperature so, the efficiency of Carnot heat engine is function of T_L and T_H

That is $\eta_{th-rev} = 1 - \frac{T_L}{T_H}$

Question: 7.070P

Consider two actual power plants operating with solar energy. Energy is supplied to one plant from a solar pond at 80°C and to the other from concentrating collectors that raise the water temperature to 600°C. Which of these power plants will have a higher efficiency? Explain.

Step 1 of 1

From the definition of thermal efficiency of a power plant, the thermal efficiency of actual heat engines cycles can be maximized by supplying heat to the engine at the highest possible temperature and rejecting heat from the engine at the lowest possible temperature so, the one which higher source temperature will have higher efficiency

$$\eta_{th-rev} = 1 - \frac{T_L}{T_H}$$

So the concentrating collectors which have 600°C source temperature have higher thermal efficiency.

Question: 7.071P

A heat engine operates between two thermal-energy reservoirs at 1260 R and 510 R. What is the maximum work the engine can produce per unit of heat that the engine receives from the source?

Step 1 of 1

The thermal efficiency η of a heat engine is equal to the ratio between maximum work, W_{max} obtained from the engine to the amount of heat supplied Q_H to the engine.

$$\eta = \frac{W_{max}}{Q_H} \qquad \text{..... (1)}$$

The maximum amount of work is obtained from the heat engine when the cycle is in reversible cycle. The thermal efficiency of reversible cycle is given by the following expression:

$$\eta = \frac{T_1 - T_2}{T_1} \qquad \text{..... (2)}$$

Here, T_1 is temperature of high temperature reservoir and T_2 is temperature of low temperature reservoir.

Equate equations (1) and (2).

$$\eta = \frac{W_{max}}{Q_H} = \frac{T_1 - T_2}{T_1}$$

$$\frac{W_{max}}{Q_H} = \frac{T_1 - T_2}{T_1}$$

Substitute 1260 R for T_1 and 510 R for T_2.

$$\frac{W_{max}}{Q_H} = \frac{1260 - 510}{1260}$$

$$= 0.595$$

Therefore, the maximum work obtained from the heat engine to the amount of heat supplied is $\boxed{0.595}$.

Question: 7.072P

From a work-production perspective, which is more valuable: (*a*) thermal energy reservoirs at 675 K and 325 K or (*b*) thermal energy reservoirs at 625 K and 275 K?

Step 1 of 2

a)

Source temperature, $T_H = 675\ \text{K}$

Sink temperature, $T_L = 325\ \text{K}$

The Carnot efficiency is given by

$$\eta_{th-rev} = 1 - \frac{T_L}{T_H}$$

$$\eta_{th-rev} = 1 - \frac{325}{675}$$

$$\eta_{th-rev} = 0.518$$

$$\eta_{th-rev} = 51.8\%$$

Step 2 of 2

(b)

Source temperature, $T_H = 625\ \text{K}$

Sink temperature, $T_L = 275\ \text{K}$

The Carnot efficiency is given by

$$\eta_{th-rev} = 1 - \frac{T_L}{T_H}$$

$$\eta_{th-rev} = 1 - \frac{275}{625}$$

$$\eta_{th-rev} = 0.56$$

$$\eta_{th-rev} = 56\%$$

The second produces more power, since it has higher thermal efficiency.

Question: 7.073P

A heat engine operates between a source at 477°C and a sink at 25°C. If heat is supplied to the heat engine at a steady rate of 65,000 kJ/min, determine the maximum power output of this heat engine.

Step 1 of 4

Given

Temperature of source $T_H = 477°C$

Temperature of sink $T_L = 25°C$

Heat supplied to the heat engine is $\dot{Q}_H = 65000 \ \frac{kJ}{min}$

Step 2 of 4

Temperature of source

$T_H = 477°C$

$= 477 + 273$

$= 750K$

Temperature of sink

$T_L = 25°C$

$= 25 + 273$

$= 298K$

Step 3 of 4

The maximum efficiency of any plant is the Carnot efficiency,

The Carnot efficiency $\eta_{th-rev} = 1 - \frac{T_L}{T_H}$

$$\eta_{th-rev} = 1 - \frac{298}{750}$$

$$= 0.602$$

$$\eta_{carnot} = 60\%$$

Step 4 of 4

Therefore maximum power output determined from the definition of thermal efficiency to be

$$\dot{W}_{net} = \eta_{carnot} \dot{Q}_H$$

$$\dot{W}_{net} = (0.60)\left(\frac{65000}{60}\right) \frac{kJ}{s}$$

$$\dot{W}_{net} = 650 \text{ kW}$$

$$\boxed{\dot{W}_{net} = 650 \text{ kW}}$$

Question: 7.074P

Reconsider Prob. 7–73. Using EES (or other) software, study the effects of the temperatures of the heat source and the heat sink on the power produced and the cycle thermal efficiency. Let the source temperature vary from 300 to 1000°C, and the sink temperature to vary from 0 to 50°C. Plot the power produced and the cycle efficiency against the source temperature for sink temperatures of 0°C, 25°C, and 50°C, and discuss the results.

Step 1 of 5

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click table on menu bar, select the new parameter table.

And run the table for now values.

Then click ok.

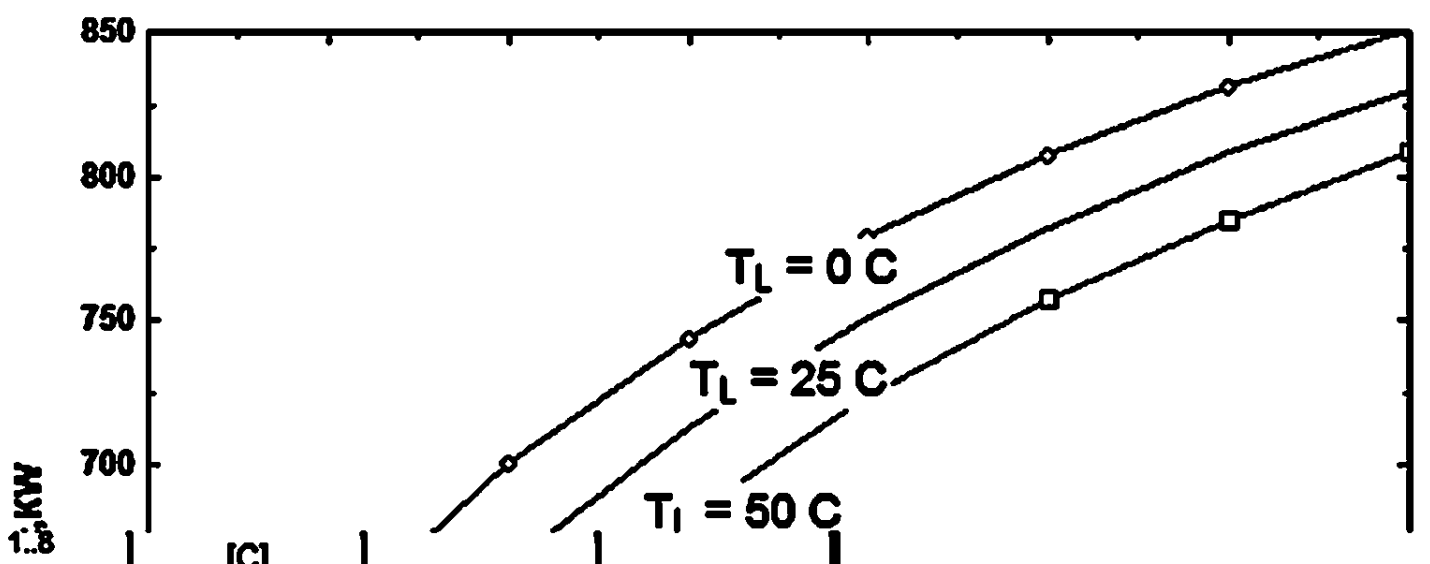
Now again select the plot command on menu bar .then select the required variables from the list, then click okay.

Step 2 of 5

Equation window:

```
"T_H = 477 [C] "
T_L =50 [C]   [ Parameter to be varied 0,25 and 50 C]
Q_dot_H = 65000 [kJ/min]

"First Law applied to the heat engine"
Q_dot_H - Q_dot_L- W_dot_net = 0
W_dot_net_KW=W_dot_net*convert(kJ/min,kW)
"Cycle Thermal Efficiency - Temperatures must be absolute"
eta_th = 1 - (T_L + 273)/(T_H + 273)
"Definition of cycle efficiency"
eta_th=W_dot_net / Q_dot_H
```

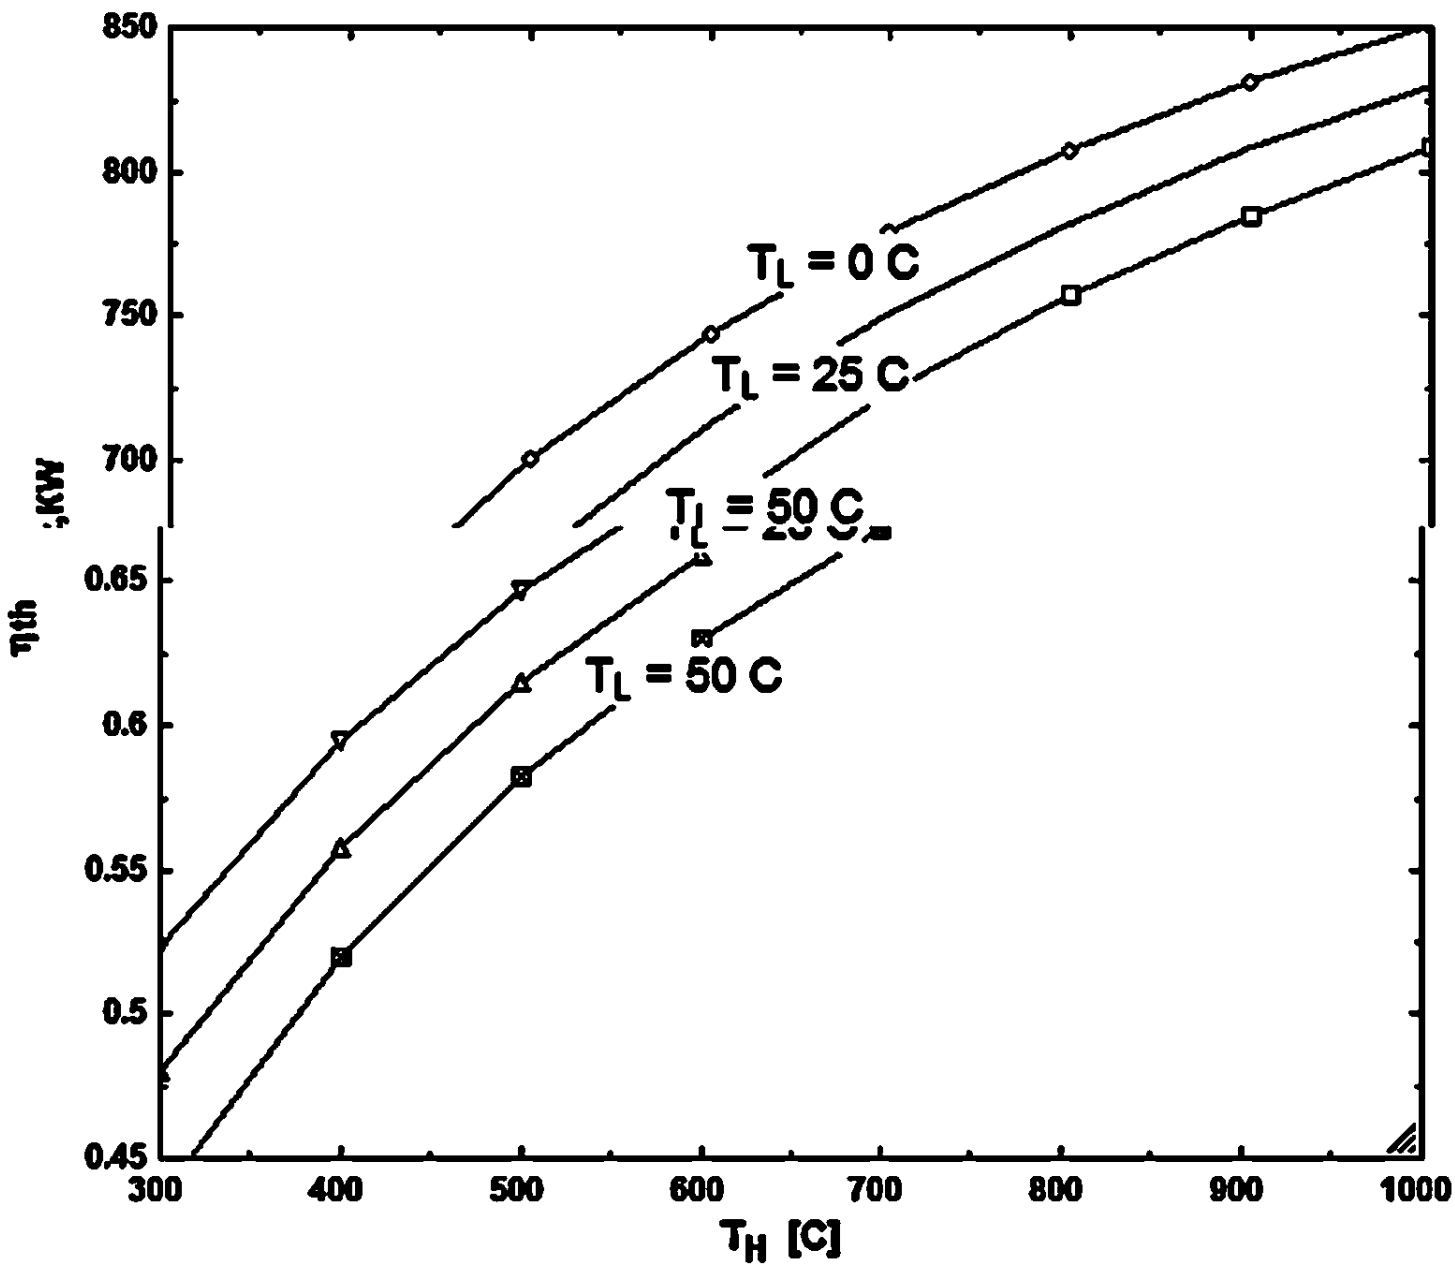


Step 3 of 5

Table for varies parameter as function of source temperature::

$\triangleright_{1..8}$	1 T_H [C]	2 $\dot{W}_{netKW}$	3 η_{th}
Run 1	300	472.7	0.4363
Run 2	400	563.4	0.5201
Run 3	500	630.7	0.5821
Run 4	600	682.5	0.63
Run 5	700	723.7	0.668
Run 6	800	757.2	0.699
Run 7	900	785	0.7246
Run 8	1000	808.5	0.7463

Step 4 of 5



Graph between the Source temperature and Work input::

	[C]		
Run 1	300	472.7	0.4363
Run 2	400	563.4	0.5201
Run 3	500	630.7	0.5821
Run 4	600	682.5	0.63
Run 5	700	723.7	0.668
Run 6	800	757.2	0.699
Run 7	900	785	0.7246
Run 8	1000	808.5	0.7463

Step 4 of 5

Graph between the Source temperature and Work input::

Question: 7.075P

A heat engine is operating on a Carnot cycle and has a thermal efficiency of 75 percent. The waste heat from this engine is rejected to a nearby lake at 60°F at a rate of 800 Btu/min. Determine (*a*) the power output of the engine and (*b*) the temperature of the source.

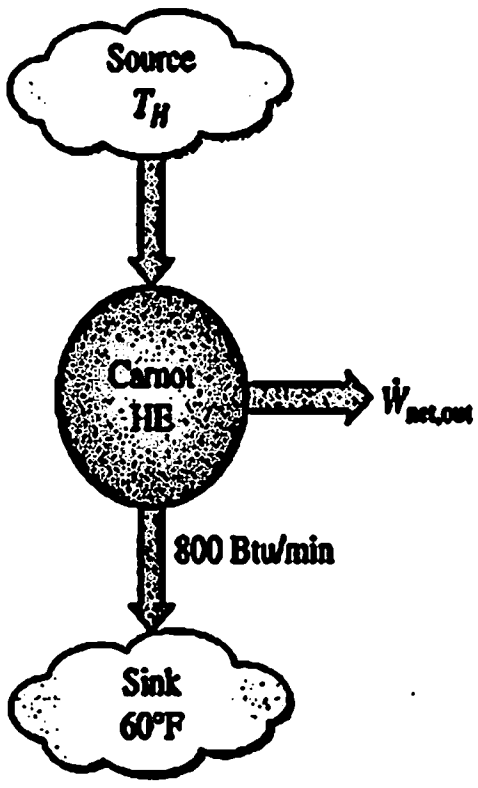


FIGURE P7–75E

Step 1 of 4

Given

Thermal efficiency of Carnot cycle heat engine $\eta_{th} = 75\%$

Temperature of sink $T_L = 60°F$

Heat rejected to lake at a rate of $\dot{Q}_L = 800$ Btu/min

Step 2 of 4

(a)

The power output of the engine

The maximum efficiency of any heat engine is the Carnot cycle engine efficiency

Carnot efficiency

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H}$$

$$\eta = \frac{\dot{Q}_H - \dot{Q}_L}{\dot{Q}_H}$$

$$\eta = 1 - \frac{\dot{Q}_L}{\dot{Q}_H}$$

$$0.75 = 1 - \frac{800}{\dot{Q}_H}$$

$$\dot{Q}_H = \frac{800}{1 - 0.75}$$

$$\dot{Q}_H = 3200 \text{ Btu/min}$$

Step 3 of 4

Therefore maximum power output determined from the definition of thermal efficiency

$$\dot{W}_{net} = \eta_{carnot} \dot{Q}_H$$

$$\dot{W}_{net} = (0.75)(3200)$$

$$\dot{W}_{net} = 2400 \text{ Btu/min} \qquad (1 \text{ Btu/min} = 0.02356 \text{ hp})$$

$$\dot{W}_{net} = 2400 \times 0.02356$$

$$\boxed{\dot{W}_{net} = 56.544 \text{ hp}}$$

Step 4 of 4

(b) The temperature of the source

We know the Carnot efficiency of the heat engine cycle is

$$\eta = 1 - \frac{T_L}{T_H}$$

$$0.75 = 1 - \frac{60 + 460}{T_H}$$

$$\frac{520}{T_H} = 0.25$$

$$T_H = 2080\text{R}$$

Temperature of the source

$$\boxed{T_H = 2080\text{R}}$$

Question: 7.076P

An inventor claims to have devised a cyclical engine for use in space vehicles that operates with a nuclear-fuel-generated energy source whose temperature is 1000 R and a sink at 550 R that radiates waste heat to deep space. He also claims that this engine produces 5 hp while rejecting heat at a rate of 15,000 Btu/h. Is this claim valid?

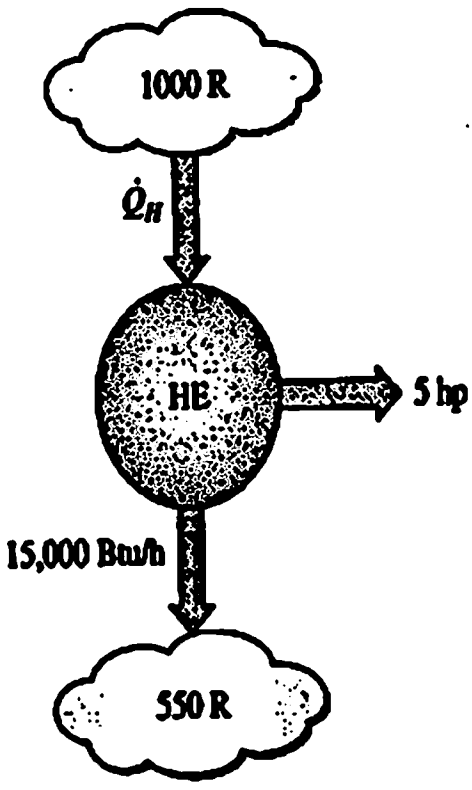

FIGURE P7–76E

Step 1 of 5

Given

Temperature of source $T_H = 1000\text{R}$

Temperature of sink $T_L = 550\text{R}$

Power produced $\dot{W}_{net} = 5\text{ hp}$

Heat rejected from the engine $\dot{Q}_L = 15,000\text{ Btu/h}$

Step 2 of 5

The thermal efficiency of reversible engine is

$$\eta_{rev} = 1 - \frac{T_L}{T_H}$$

$$\eta_{rev} = 1 - \frac{550}{1000}$$

$$= 0.45$$

$$\eta_{rev} = 45\%$$

Step 3 of 5

From first law of thermodynamics

Heat rejected is expressed as

$$\dot{Q}_H = \dot{W}_{net} + \dot{Q}_L$$

$$\dot{Q}_H = 5 \times 2545 + 15,000 \qquad \text{(Since 1 hp} = 2545\text{ Btu/h)}$$

$$\dot{Q}_H = 27725\text{ Btu/h}$$

Step 4 of 5

Thermal efficiency of any heat engine is expressed as

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H}$$

$$\eta = \frac{5 \times 2545}{27725}$$

$$\eta = 0.4589$$

$$\eta = 45.89\%$$

Step 5 of 5

We know efficiency of Carnot cycle engine should be more than efficiency of any heat engine working under same thermal energy reservoirs

And the efficiency of given heat engine is greater than the Carnot efficiency of the given heat engine cycle. So the claim is invalid.

Question: 7.077P

A heat engine receives heat from a heat source at 1200°C and has a thermal efficiency of 40 percent. The heat engine does maximum work equal to 500 kJ. Determine the heat supplied to the heat engine by the heat source, the heat rejected to the heat sink, and the temperature of the heat sink.

Step 1 of 4

Given

Temperature of source $T_H = 1200°C$

Work done by heat engine $\dot{W}_{net} = 500$ kJ

The thermal efficiency of the heat engine $\eta_{th} = 0.4$

Step 2 of 4

Temperature of source

$T_H = 1200°C$

$= 1200 + 273$

$= 1473K$

The maximum efficiency of any plant is the Carnot efficiency,

The Carnot efficiency $\eta_{th-rev} = 1 - \frac{\dot{Q}_L}{\dot{Q}_H}$

$$= \frac{\dot{W}_{net}}{\dot{Q}_H}$$

The heat supplied to heat engine is obtained as

$$\dot{Q}_H = \frac{\dot{W}_{net}}{\eta_{th}}$$

$$\dot{Q}_H = \frac{500}{0.4}$$

$$\boxed{\dot{Q}_H = 1250 \text{ kJ}}$$

Step 3 of 4

From first law of thermodynamics

Heat rejected is expressed as

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{net}$$

$$\dot{Q}_L = 1250 - 500$$

$$\boxed{\dot{Q}_L = 750 \text{ kJ}}$$

Step 4 of 4

The heat rejected to heat temperature can be determined from thermal energy relation

The thermal efficiency $\eta_{th} = 1 - \frac{T_L}{T_H}$

$$0.4 = 1 - \frac{T_L}{1473}$$

$$T_L = 883.8K$$

$$\boxed{T_L = 883.8K}$$

Question: 7.078P

A heat engine operating on the Carnot cycle has a measured work output of 900 kJ and heat rejection of 150 kJ to a heat reservoir at 27°C. Determine the heat supplied to the heat engine by the heat source, in kJ, and the temperature of the heat source, in °C.

Step 1 of 3

Given

Temperature of sink $T_L = 27°C$

Work done by heat engine $\dot{W}_{net} = 900$ kJ

The amount of heat rejected is $\dot{Q}_L = 150$ kJ

Step 2 of 3

Temperature of sink $T_L = 27°C$

$= 27 + 273$

$= 300K$

The maximum efficiency of any plant is the Carnot efficiency,

The Carnot efficiency $\eta_{th-rev} = 1 - \frac{\dot{Q}_L}{\dot{Q}_H} = \frac{\dot{W}_{net}}{\dot{Q}_H}$

From first law of thermodynamics

Heat rejected is expressed as

$$\dot{Q}_H = \dot{W}_{net} + \dot{Q}_L$$

$$\dot{Q}_H = 900 + 150$$

$$\boxed{\dot{Q}_H = 1050 \text{ kJ}}$$

Step 3 of 3

The heat rejected to heat temperature can be determined from thermal energy relation

The thermal efficiency $\eta_{th-rev} = 1 - \frac{T_L}{T_H} = \frac{\dot{W}_{net}}{\dot{Q}_H}$

$$1 - \frac{300}{T_H} = \frac{900}{1050}$$

$$T_H = 2100K$$

$$= 2100 - 273$$

$$T_H = 1827°C$$

$$\boxed{T_H = 1827°C}$$

Question: 7.079P

A heat engine is operating on a Carnot cycle and has a thermal efficiency of 75 percent. The waste heat from this engine is rejected to a nearby lake at 15°C at a rate of 14 kW. Determine the power output of the engine and the temperature of the source, in °C.

Step 1 of 4

Given

Temperature of sink $T_L = 15°C = 15+273 = 288K$

The amount of heat rejected is $\dot{Q}_L = 14$ kW

The thermal efficiency of the heat engine $\eta_{th} = 0.75$

Step 2 of 4

Temperature of sink $T_L = 15°C$

$= 15 + 273$

$= 288K$

The maximum efficiency of any plant is the Carnot efficiency,

The Carnot efficiency $\eta_{th-rev} = 1 - \frac{\dot{Q}_L}{\dot{Q}_H} = \frac{\dot{W}_{net}}{\dot{Q}_H}$

The heat supplied to heat engine is obtained as

$$0.75 = 1 - \frac{14}{\dot{Q}_H}$$

$$\dot{Q}_H = 56 \text{ kW}$$

Step 3 of 4

Therefore the power output delivered by the heat engine is

$$\dot{W}_{net} = \eta_{th} \dot{Q}_H$$

$$\dot{W}_{net} = (0.75)(56)$$

$$\boxed{\dot{W}_{net} = 42 \text{ kW}}$$

Step 4 of 4

The heat rejected to heat temperature can be determined from thermal energy relation

The thermal efficiency $\eta_{th-rev} = 1 - \frac{T_L}{T_H} = \frac{\dot{W}_{net}}{\dot{Q}_H}$

$$0.75 = 1 - \frac{288}{T_H}$$

$$T_H = 1152K$$

$$= 1152 - 273$$

$$T_H = 879°C$$

$$\boxed{T_H = 879°C}$$

Question: 7.080P

A geothermal power plant uses geothermal water extracted at 150°C at a rate of 210 kg/s as the heat source and produces 8000 kW of net power. The geothermal water leaves the plant at 90°C. If the environment temperature is 25 °C, determine (*a*) the actual thermal efficiency, (*b*) the maximum possible thermal efficiency, and (*c*) the actual rate of heat rejection from this power plant.

Step 1 of 5

Given

Mass flow rate of geothermal water $\dot{m}_w = 210\ \frac{\text{kg}}{\text{s}}$

Temperature of source $T_H = 150°\text{C}$

Power produces in the thermal plant $\dot{W}_{net} = 8000\ \text{kW}$

The exit temperature of the plant $T_{H_2} = 90°\text{C}$

Temperature of sink $T_L = 25°\text{C}$

Step 2 of 5

(a) The actual thermal efficiency

Using saturated liquid properties of water

At high temperature $T_H = 150°\text{C}$

$$h_1 = h_f = 632.18\ \frac{\text{kJ}}{\text{kg}}$$

At source temperature $T_{H_2} = 90°\text{C}$

$$h_{water} = h_f = 377.04\ \frac{\text{kJ}}{\text{kg}}$$

At low temperature $T_L = 25°\text{C}$

$$h_{sink} = h_f = 104.83\ \frac{\text{kJ}}{\text{kg}}$$

The rate of heat input to the plant is expressed as

$$\dot{Q}_{in} = \dot{m}_w (h_1 - h_2)\ \text{kW}$$

$$\dot{Q}_{in} = 210(632.18 - 377.04)\ \text{kW}$$

$$\dot{Q}_{in} = 53,580\ \text{kW}$$

Step 3 of 5

The thermal efficiency $\eta_{th} = 1 - \frac{\dot{Q}_L}{\dot{Q}_H} = \frac{\dot{W}_{net}}{\dot{Q}_H}$

$$\eta_{th} = 1 - \frac{8000}{53,580}$$

$$\eta_{th} = 0.149$$

$$\boxed{\eta_{th} = 14.9\%}$$

Step 4 of 5

(b) The maximum possible thermal efficiency

The Carnot efficiency $\eta_{th-rev} = 1 - \frac{T_L}{T_H}$

$$\eta_{th-rev} = 1 - \frac{25+273}{150+273}$$

$$\eta_{th-rev} = 0.296$$

$$\boxed{\eta_{max} = 29.6\%}$$

Step 5 of 5

(c) The actual heat rejected to the system

$$\dot{Q}_{out} = \dot{Q}_{in} - \dot{W}_{net}$$

$$\dot{Q}_{out} = 53,580 - 8000\ \text{kW}$$

$$\boxed{\dot{Q}_{out} = 45,580\ \text{kW}}$$

Question: 7.081P

It is claimed that the efficiency of a completely reversible heat engine can be doubled by doubling the temperature of the energy source. Justify the validity of this claim.

Step 1 of 2

Let

Temperature of the heat source is T_H

Temperature of the heat sink is T_L

The thermal efficiency of completely reversible engine is expressed as

The Carnot efficiency

$$\eta_{rev} = \frac{T_H - T_L}{T_H}$$

$$\eta_{rev} = 1 - \frac{T_L}{T_H}$$

Step 2 of 2

Now the temperature of the source is doubled then temperature of heat source is $2T_H$

$$\eta' = \frac{2T_H - T_L}{2T_H}$$

$$\eta' = 1 - \frac{T_L}{2T_H}$$

We know efficiency of Carnot cycle engine should be more than efficiency of any heat engine working under same thermal energy reservoirs

Since thermal efficiency is less than the thermal efficiency of reversible heat engine

So the claim is not valid

Question: 7.082P

How can we increase the COP of a Carnot refrigerator?

Step 1 of 1

A refrigerator or a heat pump that operates on the reversed Carnot cycle is called a Carnot refrigerator.

The coefficient of performance of any refrigerator is expressed as

$$\mathrm{COP}_{\mathrm{Ref}} = \frac{1}{Q_H/Q_L - 1}$$

$$\mathrm{COP}_{\mathrm{Ref}} = \frac{1}{T_H/T_L - 1}$$

$$\mathrm{COP}_{\mathrm{Ref}} = \frac{T_L}{T_H - T_L}$$

From the above relation by reducing the value of T_H, or by increasing the value of T_L, the COP of a Carnot refrigerator can be increased.

Question: 7.083P

A homeowner buys a new refrigerator and a new air conditioner. Which one of these devices would you expect to have a higher COP? Why?

Step 1 of 1

The air conditioner operates at lower temperatures differences than a refrigerator, the smaller the difference between the temperatures limits the higher the COP will, so the air conditioner should have higher COP.

The power input to a refrigerator/air conditioner will be a minimum when the refrigerator/air conditioner operates in a reversible manner. The coefficient of performance of a reversible refrigerator/air conditioner depends on the temperature limits in the cycle only

i.e.

$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_R = \frac{T_L}{T_H - T_L}$$

Question: 7.084P

A homeowner buys a new refrigerator with no freezer compartment and a deep freezer for the new kitchen.

Which of these devices would you expect to have a lower COP? Why?

Step 1 of 1

The power input to a refrigerator/air conditioner will be a minimum when the refrigerator/air conditioner operates in a reversible manner. The coefficient of performance of a reversible refrigerator/air conditioner depends on the temperature limits in the cycle only

i.e.
$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_R = \frac{T_L}{T_H - T_L}$$

Here the freezer operates at higher temperature differences, so the COP of the freezer will be lower compared to refrigerator.

Question: 7.085P

In an effort to conserve energy in a heat-engine cycle, somebody suggests incorporating a refrigerator that will absorb some of the waste energy *QL* and transfer it to the energy source of the heat engine. Is this a smart idea? Explain.

Step 1 of 1

No it is a wrong idea. In actual cycle due to irreversibilities the work consumed by the refrigerator will always be greater than work produced by the heat engine, which leads to decrease in the thermal efficiency of the power plant.
For a reversible cycle the power consumed by the refrigerator will be almost equal to power produced.

Question: 7.086P

It is well established that the thermal efficiency of a heat engine increases as the temperature T_L at which heat is rejected from the heat engine decreases. In an effort to increase the efficiency of a power plant, somebody suggests refrigerating the cooling water before it enters the condenser, where heat rejection takes place. Would you be in favor of this idea? Why?

Step 1 of 1

No it is a wrong idea. Here maintaining the refrigerator will be more cost than sending normal water in to the condenser. In actual cycle the work consumed by the refrigerator will always be greater than work produced by the heat engine due to irreversibilities which is leads to decrease in the thermal efficiency of the power plant.

Question: 7.087P

It is well known that the thermal efficiency of heat engines increases as the temperature of the energy source increases. In an attempt to improve the efficiency of a power plant, somebody suggests transferring heat from the available energy source to a higher-temperature medium by a heat pump before energy is supplied to the power plant. What do you think of this suggestion? Explain.

Step 1 of 1

No it is a wrong idea. Here maintaining a heat pump will be a costly thing, better to use a normal boiler for heating the higher temperature body.
In actual cycle due to irreversibilities the work consumed by the heat pump will always be greater than work produced by the heat engine which is leads to decrease in the thermal efficiency of the power plant.

Question: 7.088P

Determine the minimum work per unit of heat transfer from the source that is required to drive a refrigerator with thermal-energy reservoirs at 273 K and 303 K.

Step 1 of 3

Given data:

Temperature of source, $T_H = 303\text{K}$

Temperature of sink, $T_L = 273\text{K}$

Step 2 of 3

The minimum work per unit heat transfer of a refrigerator is expressed as

$$W_{net} = Q_H - Q_L$$

The maximum coefficient of performance of the reversible refrigerator is given by

$$\text{COP} = \frac{T_L}{T_H - T_L}$$

The COP is also given by

$$\text{COP} = \frac{Q_L}{Q_H - Q_L} = \frac{Q_L}{W_{net}}$$

Step 3 of 3

Therefore we can write,

$$\frac{Q_L}{W_{net}} = \frac{T_L}{T_H - T_L}$$

The minimum work per unit of heat transfer from the source that is

$$\frac{W_{net}}{Q_L} = \frac{T_H - T_L}{T_L}$$

$$\frac{W_{net}}{Q_L} = \frac{303 - 273}{273}$$

$$\frac{W_{net}}{Q_L} = 0.1098$$

$\therefore$ The minimum work required to drive a refrigerator is $\boxed{\frac{W_{net}}{Q_L} = 0.1098}$

Question: 7.089P

An inventor claims to have developed a heat pump that produces a 200-kW heating effect for a 293 K heated zone while only using 75 kW of power and a heat source at 273 K. Justify the validity of this claim.

Step 1 of 3

Given data:

The power produced by the heat pump is, $\dot{W}_{net} = 75\,\text{kW}$

The heat effect of the heat pump is, $\dot{Q}_H = 200\,\text{kW}$

The temperature of sink, $T_L = 273\text{K}$

The temperature of source, $T_H = 293\text{K}$

Step 2 of 3

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$\begin{aligned} COP_{HP} &= \frac{T_H}{T_H - T_L} \\ &= \frac{\dot{Q}_H}{\dot{W}_{net}} \\ &= \frac{200}{75} \\ &= 2.667 \end{aligned}$$

The actual COP of heat pump is $COP_{HP} = 2.667$

Step 3 of 3

The maximum COP for a reversible heat pump

$$\begin{aligned} COP_{HP_rev} &= \frac{T_H}{T_H - T_L} \\ &= \frac{293}{293 - 273} \\ &= 14.65 \end{aligned}$$

The reversible COP of heat pump is $COP_{HP} = 14.65$

Therefore the actual COP is less than the maximum COP of the heat pump so the claim is valid

Question: 7.090P

A heat pump operates on a Carnot heat pump cycle with a COP of 8.7. It keeps a space at 26°C by consuming 4.25 kW of power. Determine the temperature of the reservoir from which the heat is absorbed and the heating load provided by the heat pump.

Step 1 of 3

Given data:

The COP of the heat pump is $COP = 8.7$

The power input to the heat pump $\dot{W}_{net} = 4.25\ \text{kW}$

Temperature of the source $T_H = 26°\text{C}$

$= 26 + 273$

$= 299\text{K}$

Step 2 of 3

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

From the above relation the temperature of the low temperature reservoir is

$$8.7 = \frac{299}{299 - T_L}$$

$$299 - T_L = \frac{299}{8.7}$$

$$T_L = 299 - 34.367$$

$$T_L = 264.6\text{K}$$

∴ The low temperature is $\boxed{T_L = 264.6\text{K}}$

Step 3 of 3

The heating load effect of the heat pump

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$8.7 = \frac{\dot{Q}_H}{4.25}$$

$$\dot{Q}_H = 36.975\ \text{kW}$$

∴ The required heating load is $\boxed{\dot{Q}_H = 36.975\ \text{kW}}$

Question: 7.091P

A refrigerator is to remove heat from the cooled space at a rate of 300 kJ/min to maintain its temperature at −8°C. If the air surrounding the refrigerator is at 25°C, determine the minimum power input required for this refrigerator.

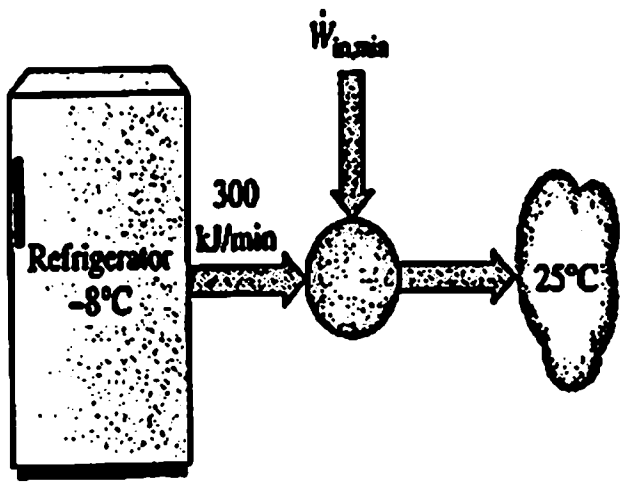

FIGURE P7-91

Step 1 of 4

Given

Surrounding air temperature $T_H = 25°C$

$= 25+273$

$T_H = 298K$

Refrigerated space temperature $T_L = -8°C$

$= -8+273$

$T_L = 265K$

Rate of cooling effect $\dot{Q}_L = 300$ kJ/min

$\dot{Q}_L = 5$ kW

Step 2 of 4

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends on the temperature limits in the cycle only

$$COP_{Ref} = \frac{T_L}{T_H - T_L}$$

$$= \frac{265}{298-265}$$

$$COP_{Ref} = 8.0303$$

Step 3 of 4

The coefficient of performance of any refrigerator is also expressed as

$$COP_{Ref} = \frac{Q_L}{Q_H - Q_L}$$

$$8.0303 = \frac{5}{\dot{Q}_H - 5}$$

$$\dot{Q}_H - 5 = 0.6226$$

$$\dot{Q}_H = 5.6226\text{kW}$$

Step 4 of 4

Power input required for this refrigerator is

$$\dot{W}_{net} = \dot{Q}_H - \dot{Q}_L$$

$$= 5.6226 - 5$$

$$\boxed{\dot{W}_{net} = 0.6226\text{kW}}$$

Question: 7.092P

An inventor claims to have developed a refrigeration system that removes heat from the closed region at −12°C and transfers it to the surrounding air at 25°C while maintaining a COP of 6.5. Is this claim reasonable? Why?

Step 1 of 3

Given

Temperature of source $T_H = 25°C$

$= 25+273$

$T_L = 298K$

Temperature of sink $T_L = -12°C$

$= -12+273$

$T_L = 261K$

COP of refrigeration system is $COP = 6.5$

Step 2 of 3

The maximum coefficient of performance of any refrigerator is expressed as

$$COP_{rev} = \frac{T_L}{T_H - T_L}$$

$$COP_{rev} = \frac{261}{298-261}$$

$$COP_{rev} = 7.05$$

Step 3 of 3

We know that reversible refrigeration system is having maximum COP and in the problem COP claimed by the inventor is less than the maximum COP.

So the inventor claim is valid.

Question: 7.093P

An air-conditioning system is used to maintain a house at 70°F when the temperature outside is 100°F. The house is gaining heat through the walls and the windows at a rate of 800 Btu/min, and the heat generation rate within the house from people, lights, and appliances amounts to 100 Btu/min. Determine the minimum power input required for this air-conditioning system.

Step 1 of 3

Conversion factor $(\text{Fahrenheit})°\text{F}$ to $(\text{Rankine})\text{R}$

$$1°\text{F} = 460\,\text{R}$$

Convert the source temperature of the air-conditioner $(\text{Fahrenheit})°\text{F}$ to $(\text{Rankine})\text{R}$ by using the above conversion factor

$$\begin{aligned} T_H &= 100°\text{F} \\ &= 100 + 460 \\ &= 560\,\text{R} \end{aligned}$$

Convert the sink temperature of the air-conditioner $(\text{Fahrenheit})°\text{F}$ to $(\text{Rankine})\text{R}$ by using the above conversion factor

$$\begin{aligned} T_L &= 70°\text{F} \\ &= 70 + 460 \\ &= 530\,\text{R} \end{aligned}$$

Step 2 of 3

Consider the equation for coefficient of performance of refrigerator

$$\begin{aligned} \text{COP}_{\text{Ref}} &= \frac{\text{Desired output}}{\text{Required input}} \\ &= \frac{\dot{Q}_{out}}{\dot{W}_{net}} \qquad \text{..... (1)} \\ &= \frac{\dot{Q}_L + \dot{Q}_W}{\dot{W}_{net}} \end{aligned}$$

Here, the rate of heat gained through the wall is $\dot{Q}_W$ and the heat generation from people and lights and appliances is $\dot{Q}_L$

Consider the equation for coefficient of performance of refrigerator in terms of temperatures

$$\text{COP}_{\text{Ref}} = \frac{T_L}{T_H - T_L}$$

Substitute $530\,\text{R}$ for T_L and $560\,\text{R}$ for T_H in the equation

$$\begin{aligned} \text{COP}_{\text{Ref}} &= \frac{530}{560 - 530} \\ &= 17.66 \end{aligned}$$

Step 3 of 3

Substitute 17.66 for COP_{Ref}, $800\ \text{Btu/min}$ for $\dot{Q}_W$ and $100\ \text{Btu/min}$ for $\dot{Q}_L$ in the equation (1)

$$17.66 = \frac{100 + 800}{\dot{W}_{net}}$$

$$\dot{W}_{net} = 50.94\ \text{Btu/min}$$

Conversion factor for power Btu/min to 1hp

$$1\text{hp} = 42.53\ \text{Btu/min}$$

Convert the units of power Btu/min to 1hp by using the above conversion factor

$$\begin{aligned} \dot{W}_{net} &= \frac{50.94\ \text{Btu/min}}{42.53} \times \frac{\text{hp}}{\text{Btu/min}} \\ &= 1.197\ \text{hp} \end{aligned}$$

Therefore, the minimum power input is $\boxed{1.197\ \text{hp}}$

Question: 7.094P

A heat pump is used to maintain a house at 22°C by extracting heat from the outside air on a day when the outside air temperature is 2°C. The house is estimated to lose heat at a rate of 110,000 kJ/h, and the heat pump consumes 5 kW of electric power when running. Is this heat pump powerful enough to do the job?

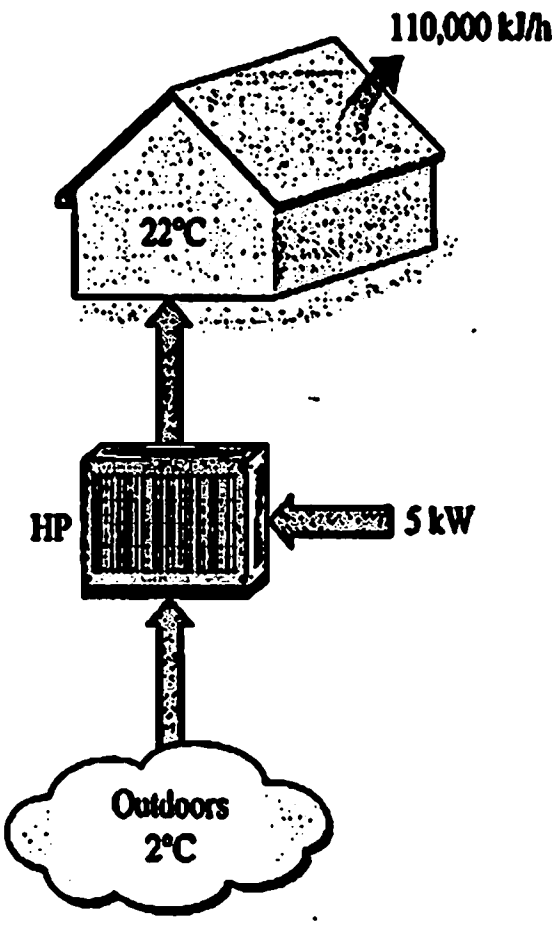

FIGURE P7–94

Step 1 of 3

Given data:

Temperature of source, $T_H = 22°C$

$= 22+273$

$= 295K$

Temperature of sink, $T_L = 2°C$

$= 2+273$

$= 275K$

The rate at which heat is lost is, $\dot{Q}_H = 110,000$ kJ/h

The power consumed by the heat pump, $\dot{W}_{net} = 5$ kW

Step 2 of 3

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

$$COP_{HP} = \frac{295}{295-275}$$

$$COP_{HP} = 14.75$$

Step 3 of 3

The minimum work per unit heat transfer of a heat pump is expressed as

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$14.75 = \frac{110,000}{\dot{W}_{net}}$$

$$\dot{W}_{net} = \frac{110000}{3600 \times 14.75}$$

$$\dot{W}_{net} = 2.07 \text{ kW}$$

The power consumed is 5 kW which is more than $\dot{W}_{net} = 2.07$ kW so this heat pump powerful enough to do the job.

Question: 7.095P

A completely reversible refrigerator operates between thermal energy reservoirs at 450 R and 540 R. How many kilowatts of power are required for this device to produce a 15,000-Btu/h cooling effect?

Step 1 of 3

Given data:

Temperature of source, $T_H = 540\text{R}$

Temperature of sink, $T_L = 450\text{R}$

The cooling effect, $\dot{Q}_L = 15{,}000\ \text{Btu/h}$

Step 2 of 3

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends on the temperature limits in the cycle only

$$\text{COP}_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

Step 3 of 3

A refrigerator or a heat pump that operates on the reversed Carnot cycle is called a Carnot refrigerator.

We know that network output, $W_{net} = Q_H - Q_L$

The coefficient of performance of any refrigerator is expressed as

$$\text{COP}_{Ref} = \frac{Q_L}{Q_H - Q_L}$$

$$\text{COP}_{Ref} = \frac{1}{Q_H / Q_L - 1}$$

Where $\frac{Q_H}{Q_L} = \frac{T_H}{T_L}$

$$\text{COP}_{Ref} = \frac{1}{T_H / T_L - 1}$$

$$\frac{450}{540 - 450} = \frac{15000}{\dot{W}_{net}}$$

$$\dot{W}_{net} = 3000\ \text{Btu/h}$$

We know that, $1\ \text{kW} = 3412\ \text{Btu/h}$

$$\dot{W}_{net} = 0.879\ \text{kW}$$

Therefore the minimum power input is $\boxed{\dot{W}_{net} = 0.879\ \text{kW}}$

Question: 7.096P

A refrigerator operating on the reversed Carnot cycle has a measured work input of 200 kW and heat rejection of 2000 kW to a heat reservoir at 27°C. Determine the cooling load supplied to the refrigerator, in kW, and the temperature of the heat source, in °C.

Step 1 of 4

Given data:

The source temperature of the refrigerator is $T_H = 27°C$

$= 27 + 273$

$= 300K$

The work input to the refrigerator is, $\dot{W}_{net} = 200\ kW$

The hear supplied to the refrigerator is, $\dot{Q}_H = 2000\ kW$

Step 2 of 4

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends on the temperature limits in the cycle only

$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

$$COP_R = \frac{1}{T_H / T_L - 1}$$

Step 3 of 4

A refrigerator or a heat pump that operates on the reversed Carnot cycle is called a Carnot refrigerator.

We know that $\dot{W}_{net} = \dot{Q}_H - \dot{Q}_L$

Therefore the cooling effect of the refrigerator is

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{net}$$

$$\dot{Q}_L = 2000 - 200$$

$$\dot{Q}_L = 1800\ kW$$

∴ The cooling effect of the refrigerator is $\boxed{\dot{Q}_L = 1800\ kW}$

Step 4 of 4

The temperature of heat sink is determined by from the definition of COP

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

$$COP_R = \frac{1}{T_H / T_L - 1}$$

$$\frac{1800}{200} = \frac{T_L}{300 - T_L}$$

$$T_L = 270K$$

∴ The temperature is $\boxed{T_L = -3°C}$

Question: 7.097P

An 18,000 Btu/h split air conditioner running at full load is used to keep a room at 22°C in an environment at 33°C. The power input to the compressor is 3.4 kW. Determine (*a*) the rate of heat rejected in the condenser, in kJ/h, (*b*) the COP of the air conditioner, and (*c*) the rate of cooling, in Btu/h, if the air conditioner operated as a Carnot refrigerator for the same power input.

Step 1 of 4

Given data:

The cooling load to the refrigerator is, $\dot{Q}_L = 18000$ Btu/h

The power input to the refrigerator is, $\dot{W}_{in} = 3.4$ kW

The source temperature of the refrigerator is, $T_H = 33+273$
$= 306$K

The sink temperature of the refrigerator is, $T_L = 22+273$
$= 295$K

Conversion factor, 1 Btu = 1.055 kJ

Step 2 of 4

(a) The rate of heat rejected

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends on the temperature limits in the cycle only

$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{in}}$$

$$\dot{Q}_H = \dot{W}_{in} + \dot{Q}_L$$

Therefore the rate of heat rejected is

$$\dot{Q}_H = 3.4 \text{ kW}\left(\frac{3600 \text{ kJ/h}}{1 \text{ kW}}\right) + 18000 \text{ Btu/h}\left(\frac{1.055 \text{ kJ}}{\text{Btu}}\right)$$

$$\dot{Q}_H = 31,230 \text{ kJ/h}$$

∴ The rate of heat rejected is $\boxed{\dot{Q}_H = 31,230 \text{ kJ/h}}$

Step 3 of 4

(b) The COP is expressed as

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

$$COP_R = \frac{18000 \text{ Btu/h}}{3.4 \text{ Btu/h}\,(3600/1.055)}$$

$$COP_R = 1.55$$

∴ The COP of refrigerator is, $\boxed{COP_R = 1.55}$

Step 4 of 4

(c) The rate of cooling of the refrigerator if the cycle operates in as Carnot refrigerator

$$COP_{Carnot} = \frac{T_L}{T_H - T_L}$$

$$COP_{Carnot} = \frac{295}{306-295}$$

$$COP_{Carnot} = 26.818$$

Therefore the cooling effect

$$\dot{Q}_L = COP_{Carnot} \times \dot{W}_{net}$$

$$\dot{Q}_L = 26.818 \times \left(3.4\,(3600/1.055)\right) \text{ Btu/h}$$

$$\dot{Q}_L = 311,140 \text{ Btu/h}$$

∴ The cooling effect is $\boxed{\dot{Q}_L = 311,140 \text{ Btu/h}}$

Question: 7.098P

A Carnot refrigerator absorbs heat from a space at 15°C at a rate of 16,000 kJ/h and rejects heat to a reservoir at 36°C. Determine the COP of the refrigerator, the power input, in kW, and the rate of heat rejected to high-temperature reservoir, in kJ/h.

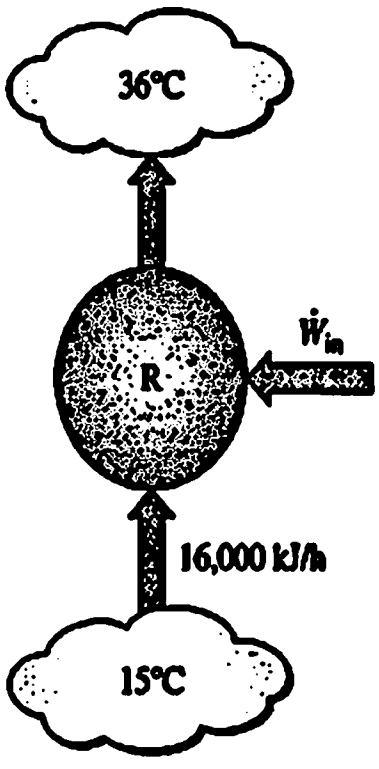

FIGURE P7–98

Step 1 of 4

Given data:

The source temperature of the refrigerator, $T_H = 36 + 273$

$= 309\text{K}$

The sink temperature of the refrigerator, $T_L = 15 + 273$

$= 288\text{K}$

The cooling effect of the refrigerator, $\dot{Q}_L = 16{,}000\ \text{kJ/h}$

Step 2 of 4

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends on the temperature limits in the cycle only

$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_{Carnot} = \frac{T_L}{T_H - T_L}$$

$$COP_{Carnot} = \frac{288}{309 - 288}$$

$$COP_{Carnot} = 13.71$$

Step 3 of 4

The power input to the refrigerator is

$$COP_{R_net} = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

$$\dot{W}_{net} = \frac{16000}{13.71}$$

$$\dot{W}_{net} = 1167\left(\frac{1\text{h}}{3600}\right)\text{kJ/s}$$

$$\dot{W}_{net} = 0.324\ \text{kW}$$

∴ The power input is $\boxed{\dot{W}_{net} = 0.324\ \text{kW}}$

Step 4 of 4

The rate of heat rejected to the high temperature reservoir is

We know that $\dot{Q}_H = \dot{W}_{net} + \dot{Q}_L$

Therefore the rate of heat rejected is

$$\dot{Q}_H = 16000\ \text{kJ/h} + 1167\ \text{kJ/h}$$

$$\dot{Q}_H = 17{,}167\ \text{kJ/h}$$

∴ The rate of heat rejected $\boxed{\dot{Q}_H = 17{,}167\ \text{kJ/h}}$

Question: 7.099P

The performance of a heat pump degrades (i.e., its COP decreases) as the temperature of the heat source decreases. This makes using heat pumps at locations with severe weather conditions unattractive. Consider a house that is heated and maintained at 20°C by a heat pump during the winter. What is the maximum COP for this heat pump if heat is extracted from the outdoor air at (*a*) 10°C, (*b*) -5°C, and (*c*) -30°C?

Step 1 of 4

Given data:

Temperature of source, $T_H = 20°C$

$= 20 + 273$

$= 293K$

Step 2 of 4

(a) Temperature of the heat extracted is, $T_L = 10°C$

$= 10 + 273$

$= 283K$

The maximum COP is calculated from the reversible Carnot COP

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

$$COP_{HP} = \frac{293}{293 - 283}$$

$$COP_{HP} = 29.3$$

∴ The maximum COP of the heat pump is $\boxed{COP_{HP} = 29.3}$

Step 3 of 4

(b) Temperature of the heat extracted is, $T_L = -5°C$

$= -5 + 273$

$= 268K$

The maximum COP is calculated from the reversible Carnot COP

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

$$COP_{HP} = \frac{293}{293 - 268}$$

∴ The maximum COP is $\boxed{COP_{HP} = 11.72}$

Step 4 of 4

(c) Temperature of the heat extracted is, $T_L = -30°C$

$= -30 + 273$

$= 243K$

The maximum COP is calculated from the reversible Carnot COP

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP} = \frac{293}{293 - 243}$$

$$COP_{HP} = 5.86$$

∴ The maximum COP is $\boxed{COP_{HP} = 5.86}$

Question: 7.100P

A heat pump is to be used for heating a house in the winter. The house is to be maintained at 78°F at all times. When the temperature outdoors drops to 25°F, the heat losses from the house are estimated to be 55,000 Btu/h. Determine the minimum power required to run this heat pump if heat is extracted from *(a)*the outdoor air at 25°F and *(b)*the well water at 50°F.

Step 1 of 5

Given data:

Temperature of source, $T_H = 78°F$

$= 78+460$

$= 538R$

The rate at which heat is lost is $\dot{Q}_H = 55,000\ \text{Btu/h}$

Step 2 of 5

a)

Temperature of the heat extracted is, $T_L = 25°F$

$= 25+460$

$= 485R$

The maximum COP is calculated from the reversible Carnot COP

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$\text{COP}_{HP} = \frac{T_H}{T_H - T_L}$$

$$\text{COP}_{HP} = \frac{538}{538-485}$$

$$\text{COP}_{HP} = 10.15$$

Step 3 of 5

The minimum work per unit heat transfer of a heat pump is expressed as

$$\text{COP}_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$\frac{55,000}{\dot{W}_{net}} = 10.15$$

$$\dot{W}_{net} = \frac{5418.2}{2545\ \text{Btu/h}}(1\text{hp}) \qquad (\because 1\ \text{hp} = 2545\ \text{Btu/h})$$

∴ The minimum power required is $\boxed{\dot{W}_{net} = 2.12\ \text{hp}}$

Step 4 of 5

(b) Temperature of the heat extracted is, $T_L = 50°F$

$= 50+460$

$= 510R$

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$\text{COP}_{HP} = \frac{T_H}{T_H - T_L}$$

$$\text{COP}_{HP} = \frac{538}{538-510}$$

$$\text{COP}_{HP} = 19.21$$

Step 5 of 5

The minimum work per unit heat transfer of a heat pump is expressed as

$$\text{COP}_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$\frac{55,000}{\dot{W}_{net}} = 19.21$$

$$\dot{W}_{net} = 2863\ \text{Btu/h}$$

$$\dot{W}_{net} = \frac{2863}{2545\ \text{Btu/h}}(1\text{hp}) \qquad (\because 1\ \text{hp} = 2545\ \text{Btu/h})$$

∴ The minimum power required is $\boxed{\dot{W}_{net} = 1.124\ \text{hp}}$

Question:

7.101P

A Carnot heat pump is to be used to heat a house and maintain it at 25°C in winter. On a day when the average outdoor temperature remains at about 2°C, the house is estimated to lose heat at a rate of 55,000 kJ/h. If the heat pump consumes 6.6 kW of power while operating, determine (*a*) how long the heat pump ran on that day; (*b*) the total heating costs, assuming an average price of 8.5e7kWh for electricity; and (*c*) the heating cost for the same day if resistance heating is used instead of a heat pump.

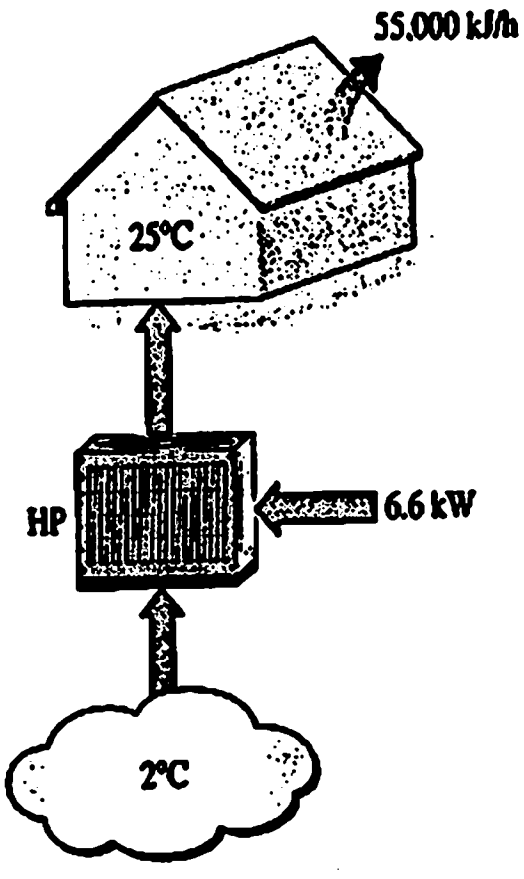

FIGURE P7–101

Step 1 of 6

Loading solution. Please wait ...

Step 2 of 6

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

$$COP_{HP_rev} = \frac{298}{298-275}$$

$$COP_{HP} = 12.96$$

Step 3 of 6

Amount of heat loss in a day is

$$Q_H = \dot{Q}_H \times 24$$
$$= 55000 \times 24$$
$$= 1{,}320{,}000 \text{ kJ}$$

The minimum work per unit heat transfer of a heat pump is expressed as

$$COP_{HP} = \frac{Q_H}{W_{net}}$$

$$\frac{1{,}320{,}000}{W_{net}} = 12.96$$

$$W_{net} = 101{,}852 \text{ kJ}$$

Step 4 of 6

(a) The period of time that the heat pump ran a day is

$$t = \frac{W_{net}}{\dot{W}_{net}}$$
$$= \frac{101{,}852}{6.6}$$
$$= 15{,}432 \text{ sec}$$
$$= \frac{15{,}432}{3600} h$$

∴ The time required is, $\boxed{t = 4.29 \text{ h}}$

Step 5 of 6

(b) The total heating cost per day

$$\text{Cost} = W \times 8.5\text{cent} \times t$$
$$= 6.6 \times 0.085 \times 4.29$$
$$= \$2.41$$

Therefore the total heating cost is, $\boxed{\text{Cost} = \$2.41}$

Step 6 of 6

(c) The heat cost of the same day

$$Q_H \times 0.085\$/\text{kwh} = 1{,}320{,}000 \times 0.085 \frac{1\text{h}}{3600\text{s}}$$
$$= \$31.2$$

Therefore the heating cost is $\boxed{\$31.2}$

Question:

7.102P

A Carnot heat engine receives heat from a reservoir at 900°C at a rate of 800 kJ/min and rejects the waste heat to the ambient air at 27°C. The entire work output of the heat engine is used to drive a refrigerator that removes heat from the refrigerated space at −5°C and transfers it to the same ambient air at 27°C. Determine (*a*) the maximum rate of heat removal from the refrigerated space and (*b*) the total rate of heat rejection to the ambient air.

Step 1 of 8

Loading solution. Please wait ...

Step 2 of 8

(a) The highest thermal efficiency a heat engine operating between two specified temperature limits can have is the Carnot efficiency,

The thermal efficiency, $\eta_{th} = 1 - \frac{T_L}{T_H}$

$$\eta_{th} = 1 - \frac{300}{1173}$$

$$\eta_{th} = 0.744$$

Step 3 of 8

The maximum power output of a heat engine is expressed as

$$\dot{W}_{net} = \eta_{th}\dot{Q}_H$$

$$= 0.744(800)$$

$$= 595.4 \text{ kJ/min}$$

The power output from the heat engine will be power input to the refrigerant

Step 4 of 8

The rate at which heat rejected in the heat engine is

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{net}$$

$$= 800 - 595.4$$

$$= 204.6 \text{ kJ/min}$$

Step 5 of 8

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends upon the temperature limits in the cycle only

$$\text{COP}_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$\text{COP}_{Ref_max} = \frac{1}{T_H/T_L - 1}$$

$$\text{COP}_{Ref_max} = \frac{268}{300 - 268}$$

$$\text{COP}_{Ref_max} = 8.375$$

Step 6 of 8

Therefore the rate of heat removal from the refrigerant is expressed as

$$\dot{Q}_{ref} = \text{COP} \times \dot{W}_{net}$$

$$= 8.375 \times 595.4$$

$$= 4986.4 \text{ kJ/min}$$

∴ The rate of heat removal, $\boxed{\dot{Q}_{ref} = 4986.4 \text{ kJ/min}}$

Step 7 of 8

(b) The total heat rejected to ambient

For refrigerator, heat rejected is expressed as

$$\dot{Q}_{H,ref} = \dot{W}_{net} + \dot{Q}_L$$

$$\dot{Q}_{H,ref} = 595.4 + 4986.4$$

$$\dot{Q}_{H,ref} = 5581.8 \text{ kJ/min}$$

Step 8 of 8

Therefore the total heat rejected to ambient is

$$\dot{Q}_{total} = \dot{Q}_L + \dot{Q}_{H,ref}$$

$$\dot{Q}_{total} = 5581.8 + 204.6$$

$$\dot{Q}_{total} = 5786.4 \text{ kJ/min}$$

∴ The total heat rejection is, $\boxed{Q_{total} = 5786.4 \text{ kJ/min}}$

Question: 7.103P

A Carnot heat engine receives heat from a reservoir at 1700°F at a rate of 700 Btu/min and rejects the waste heat to the ambient air at 80°F. The entire work output of the heat engine is used to drive a refrigerator that removes heat from the refrigerated space at 20°F and transfers it to the same ambient air at 80°F. Determine (*a*) the maximum rate of heat removal from the refrigerated space and (*b*) the total rate of heat rejection to the ambient air.

Step 1 of 4

Given data:-

The temperature of source

$$T_H = 1700^\circ F$$
$$= 1700 + 460$$
$$= 2160R$$

The ambient air temperature

$$T_L = 80^\circ F + 460$$
$$= 540R$$

The amount of heat received $\dot{Q}_H = 700$ Btu/min

The amount of heat removed for the refrigerator

$$T_L = 20^\circ F$$
$$= 20 + 460$$
$$= 480R$$

Step 2 of 4

(a) The highest thermal efficiency a heat engine operating between two specified temperature limits can have is the Carnot efficiency,

The thermal efficiency

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$
$$= 1 - \frac{540}{2160}$$
$$= 0.75$$

The maximum power output of a heat engine is expressed as

$$\dot{W}_{net} = \eta_{th} \dot{Q}_H$$
$$= 0.75(700)$$
$$= 525 \text{ Btu/min}$$

The power output from the heat engine will be power input to the refrigerant

Step 3 of 4

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends upon the temperature limits in the cycle only

i.e.

$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_{Ref} = \frac{1}{T_H / T_L - 1}$$

$$COP_{Ref_max} = \frac{480}{540 - 480}$$

$$COP_{Ref_max} = 8$$

Therefore the rate of heat removal from the refrigerant is expressed as

$$\dot{Q}_{ref} = COP \dot{W}_{net}$$
$$= 8 \times 525$$
$$= 4200 \text{ Btu/min}$$

$$\boxed{\dot{Q}_{ref} = 4200 \text{ Btu/min}}$$

Step 4 of 4

(b) The total heat rejected to ambient

For refrigerator, heat rejected is expressed as

$$\dot{Q}_H = \dot{W}_{net} + \dot{Q}_L$$
$$= 525 + 4200$$

$$\dot{Q}_{H_ref} = 4725 \text{ Btu/min}$$

For heat engine

$$\dot{Q}_L = Q_H - \dot{W}_{net}$$
$$= 700 - 525$$
$$= 175 \text{ Btu/min}$$

Therefore the total heat rejected to ambient is

$$Q_{total} = Q_H + Q_{Href}$$

$$Q_{total} = 4725 + 175$$

$$\boxed{Q_{total} = 4900 \text{ Btu/min}}$$

Question: 7.104P

The structure of a house is such that it loses heat at a rate of 3800 kJ/h per °C difference between the indoors and outdoors. A heat pump that requires a power input of 4 kW is used to maintain this house at 24°C. Determine the lowest outdoor temperature for which the heat pump can meet the heating requirements of this house.

Step 1 of 3

Find the total amount of heat lost by the house.

$$Q_L = \dot{Q}_L (T_H - T_L)$$

Here, $\dot{Q}_L$ is the heat loss per unit degree, T_H is the temperature inside the house (higher in value), and T_L is the temperature outside the house (lower in value).

Substitute, $3800\ \text{kJ/h°K}$ for Q_L, and $(24°C+273)°K$ for T_H.

$$\begin{aligned} Q_L &= 3800\ \frac{\text{kJ}}{\text{h°K}}\left[(24°C+273)°K - T_L\right] \\ &= 3800\ \frac{\text{kJ}}{3600\text{s-°K}}\left[297 - T_L\right]°K \\ &= 1.0556\left[297 - T_L\right]\text{kW} \end{aligned}$$

Step 2 of 3

Find the coefficient of performance of the heat pump based on the heat and work.

$$COP_{HP} = \frac{Q_L}{W_{in}}$$

Here, W_{in} is the work input to the heat pump.

Substitute, $1.0556(297 - T_L)\text{kW}$ for Q_L, and 4 kW for W_{in}.

$$\begin{aligned} COP_{HP} &= \frac{1.0556(297 - T_L)\text{kW}}{4\ \text{kW}} \\ &= 0.26388(297 - T_L) \end{aligned}$$

Step 3 of 3

Find the coefficient of performance of the heat pump based on the temperature.

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

Substitute, $(24°C+273)°K$ for T_H, and $0.26388(297 - T_L)$ for COP_{HP}.

$$0.26388(297 - T_L) = \frac{(24°C+273)°K}{(24°C+273)°K - T_L}$$

$$0.26388(297 - T_L) = \frac{297}{(297 - T_L)}$$

$$(297 - T_L)^2 = \frac{297}{0.26388}$$

$$(297 - T_L) = \sqrt{\frac{297}{0.26388}}$$

$$\begin{aligned} T_L &= 297 - \sqrt{\frac{297}{0.26388}} \\ &= 297 - 33.548 \\ &= 263.452°K \\ &= -9.548°C \end{aligned}$$

Therefore, the lowest outdoor temperature for which the heat pump can meet the heating requirements of this house is at $\boxed{-9.548°C}$.

Question:

7.105P

An air-conditioner with refrigerant-134a as the working fluid is used to keep a room at 23°C by rejecting the waste heat to the outdoor air at 37°C. The room gains heat through the walls and the windows at a rate of 250 kJ/min while the heat generated by the computer, TV, and lights amounts to 900 W. The refrigerant enters the compressor at 400 kPa as a saturated vapor at a rate of 100 L/min and leaves at 1200 kPa and 70°C. Determine (*a*) the actual COP, (*b*) the maximum COP, and (*c*) the minimum volume flow rate of the refrigerant at the compressor inlet for the same compressor inlet and exit conditions.

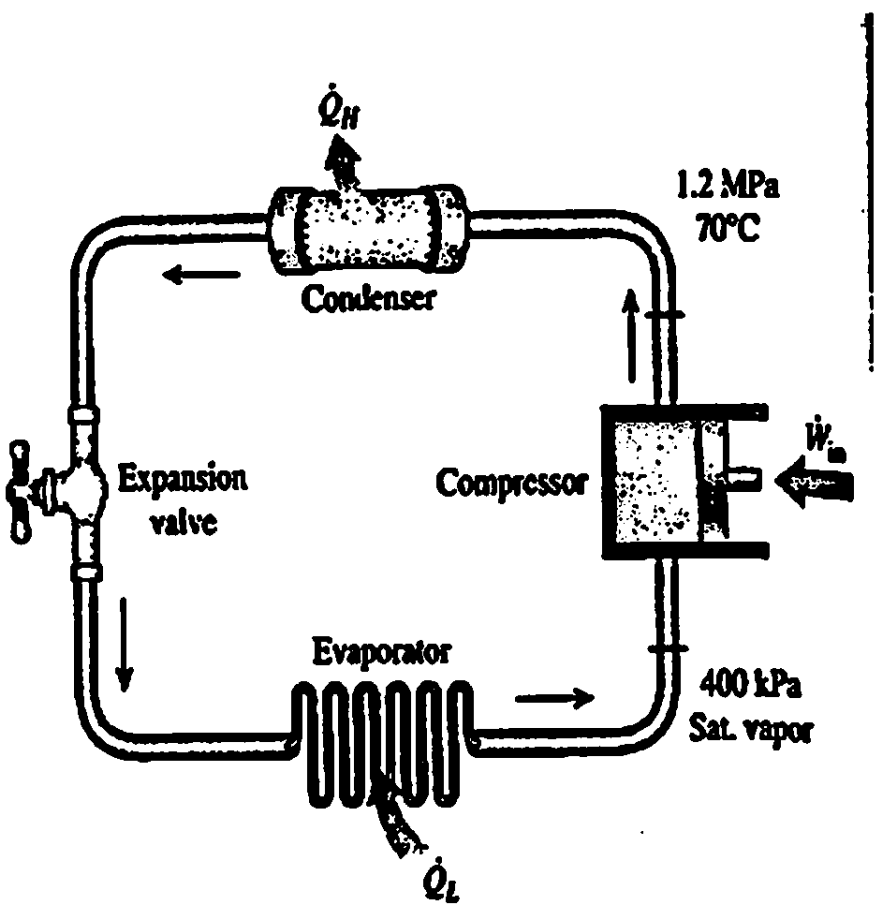

FIGURE P7–105

Step 1 of 8

Loading solution. Please wait ...

Step 2 of 8

From the saturated refrigerant R-134a temperature tables

The enthalpy at $P_1 = 400\ \text{kPa}, x_1 = 1$ is $h_1 = h_g = 255.55\ \text{kJ/kg}$

Specific volume, $v_1 = 0.051201\ \text{m}^3/\text{kg}$

From the superheated refrigerant R-134a tables

At $P_2 = 1.2\ \text{MPa}$ and $T_1 = 70°\text{C}$

Taking enthalpy is, $h_2 = 300.61\ \text{kJ/kg}$

Step 3 of 8

a) The mass flow rate of refrigerant

$$\dot{m}_R = \frac{\dot{V}_1}{v_1}\ \text{kg/s}$$

$$\dot{m}_R = \frac{100\ \text{L/min}\left(\frac{1\ \text{m}^3}{1000\ \text{L}}\right)\left(\frac{1\ \text{min}}{60\text{s}}\right)}{0.0512}\ \text{kg/s}$$

$$\dot{m}_R = 0.03255\ \text{kg/s}$$

Step 4 of 8

The power consumption of the compressor is

$$\dot{W}_{in} = \dot{m}_R(h_2 - h_1)\text{kW}$$

$$\dot{W}_{in} = (0.03255)(300.61 - 255.55)\text{kW}$$

$$\dot{W}_{in} = 1.4667\text{kW}$$

Step 5 of 8

The heating load by the air conditioner

$$\dot{Q}_L = \dot{Q}_{room} + \dot{Q}_{eq}$$

$$\dot{Q}_L = 250\left(\frac{1\text{min}}{60s}\right) + 0.9$$

$$\dot{Q}_L = 5.067\ \text{kW}$$

We know that

$$COP_R = \frac{\dot{Q}_L}{W_{net}}$$

$$COP_R = \frac{5.067}{1.4667}$$

$$COP_R = 3.455$$

Therefore the COP of the refrigerator is $\boxed{COP_R = 3.455}$.

Step 6 of 8

b) The COP of the reversible refrigerator is expressed as

$$COP_{Rev} = \frac{T_L}{T_H - T_L}$$

$$COP_R = \frac{23+273}{37-23}$$

$$COP_{Rev} = 21.143$$

Therefore the COP of a reversible engine is $\boxed{COP_{Rev} = 21.143}$.

Step 7 of 8

c) The minimum volume flow rate of the compressor is expressed as

$$\dot{V}_{min} = \dot{m}_{min} \times v_1\ \text{m}^3/s$$

The minimum mass flow rate is obtained by

$$\dot{m}_r = \frac{\dot{W}_{min}}{(h_2 - h_1)}\ \text{kg/s}$$

Where

$$\dot{W}_{min} = \frac{Q_L}{COP_{Rev}}$$

$$\dot{W}_{min} = \frac{5.067}{21.14}$$

$$\dot{W}_{min} = 0.24\ \text{kW}$$

Step 8 of 8

Therefore

$$\dot{m}_{min} = \frac{0.24}{(300.61 - 255.55)}\ \text{kg/s}$$

$$\dot{m}_{min} = 0.00532\ \text{kg/s}$$

The minimum volume flow rate is

$$\dot{V}_{min} = 0.00532 \times 0.0512\ \text{m}^3/s$$

$$\dot{V}_{min} = 2.723 \times 10^{-4} \times 60 \times 1000\ \text{L/min}$$

$$\dot{V}_{min} = 16.36\ \text{L/min}$$

Therefore the minimum volume flow rate $\boxed{\dot{V}_{min} = 16.36\ \text{L/min}}$.

Question: 7.106P

Calculate and plot the COP of a completely reversible refrigerator as a function of the temperature of the sink up to 500 K with the temperature of the source fixed at 250 K.

Step 1 of 4

Given

Temperature of source T_H varies from 300K to 500K

Temperature of sink fixed at $T_L = 250K$

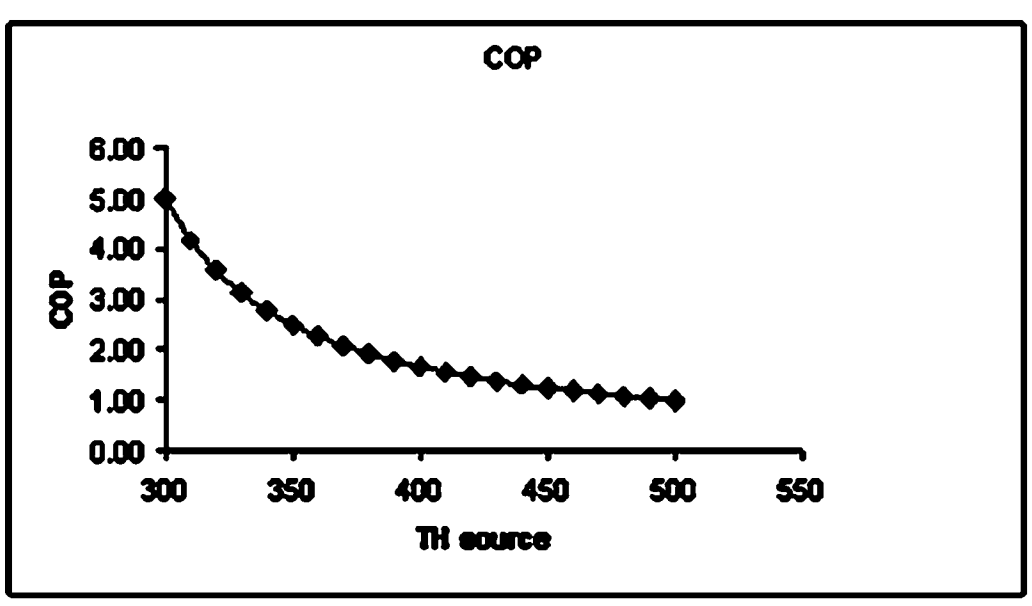
Step 2 of 4

The power input to a refrigerator will be a minimum when the refrigerator operates in a reversible manner. The coefficient of performance of a reversible refrigerator depends upon the temperature limits in the cycle only

$$COP_R = \frac{\text{Desired output}}{\text{work input}}$$

$$= \frac{T_L}{T_H - T_L}$$

$$COP_R = \frac{250}{T_H - 250}$$



Step 3 of 4

Calculating COP of the reversible refrigerator by varying the temperature of the source (T_H) between 300K to 500K tabulated as follows

TH	COP
300	5.00
310	4.17
320	3.57
330	3.13
340	2.78
350	2.50
360	2.27
370	2.08
380	1.92
390	1.79
400	1.67
410	1.56
420	1.47
430	1.39
440	1.32
450	1.25
460	1.19
470	1.14
480	1.09
490	1.04
500	1

Step 4 of 4

Plotting the graph between COP of the refrigerator and source temperature

Question: 7.107P

Derive an expression for the COP of a completely I reversible refrigerator in terms of the thermal energy reservoir temperatures, *TL* and *TH*.

Step 1 of 2

Let the thermal energy reservoirs is T_L and T_H

The efficiency of a refrigerator is expressed in terms of the coefficient of performance (COP), denoted by COP_R. A refrigerator or a heat pump that operates on the reversed Carnot cycle is called a Carnot refrigerator.

$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

$$COP_R = \frac{\dot{Q}_L}{W_{net}}$$

Step 2 of 2

The objective of a refrigerator is to remove heat (Q_L) from the refrigerated space. To accomplish this objective, it requires a work input of W_{net}

$$W_{net} = Q_H - Q_L$$

The coefficient of performance of any refrigerator is expressed as

$$COP_R = \frac{Q_L}{Q_H - Q_L}$$

$$COP_R = \frac{1}{Q_H/Q_L - 1}$$

For a reversible cycle the $\frac{Q_H}{Q_L}$ ratio can be replaced by $\frac{T_H}{T_L}$

$$COP_R = \frac{1}{T_H/T_L - 1}$$

From the above relation, by reducing the value of T_H, or by increasing the value of T_L, the COP of a Carnot refrigerator can be increased.

Question: 7.108P

A heat engine operates with a source at 1280 K and a sink at 290 K. What is the maximum work per unit of heat that the engine can remove from the source?

Step 1 of 3

Given

Source temperature $T_H = 1280\text{K}$

Sink temperature $T_L = 290\text{K}$

Step 2 of 3

The Carnot cycle efficiency is the highest possible efficiency of a heat engine

So the efficiency of Carnot cycle is

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$\eta_{th} = 1 - \frac{290}{1280}$$

$$\eta_{th} = 0.773$$

Step 3 of 3

We know thermal efficiency of an engine is

$$\eta_{th} = \frac{W}{Q_H}$$

Where W is the maximum work output from the engine

Q_H is the heat removed from the source

Therefore the work per unit of heat that the engine can remove from the source is

$$\frac{W}{Q_H} = \eta_{th} = 0.773$$

$$\boxed{\frac{W}{Q_H} = 0.773}$$

Question: 7.109P

A heat engine receives heat from a heat source at 1200°C and rejects heat to a heat sink at 50°C. The heat engine does maximum work equal to 500 kJ. Determine the heat supplied to the heat engine by the heat source and the heat rejected to the heat sink.

Step 1 of 4

Given

Temperature of source $T_H = 1200^0\text{C}$

$= 1200 + 273$

$T_H = 1473\text{K}$

Temperature of sink $T_L = 50^0\text{C}$

$= 50 + 273$

$T_L = 323\text{K}$

The maximum work output from the heat engine is $W_{max} = 500\text{ kJ}$

Step 2 of 4

We know the Carnot efficiency is the highest possible efficiency of a heat engine

Efficiency of Carnot heat engine is

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$\eta_{th} = 1 - \frac{323}{1473}$$

$$\eta_{th} = 0.7807$$

Step 3 of 4

Thermal efficiency of Carnot heat engine can also be written as

$$\eta_{th} = \frac{W_{max}}{Q_H}$$

The amount of heat supplied to the heat engine by the heat source

$$Q_H = \frac{W_{max}}{\eta_{th}}$$

$$Q_H = \frac{500}{0.7807}$$

$$\boxed{Q_H = 640.45\text{ kJ}}$$

Step 4 of 4

Similarly the amount of heat rejected to the heat sink can be calculated by applying first law of thermodynamics to the heat engine

$$Q_H - Q_L = W_{max}$$

$$Q_L = Q_H - W_{max}$$

$$= 640.45 - 500$$

$$\boxed{Q_L = 140.45\text{ kJ}}$$

Question: 7.110P

A heat pump creates a heating effect of 32,000 Btu/h for a space maintained at 530 R while using 1.8 kW of electrical power. What is the minimum temperature of the source that satisfies the second law of thermodynamics?

Step 1 of 4

Given

Temperature of source $T_H = 530\text{R}$

The heating effect is $\dot{Q}_H = 32{,}000\ \text{Btu/h}$

The minimum power required is $\dot{W}_{net} = 1.8\ \text{kW}$

Step 2 of 4

The minimum power required is

$\dot{W}_{net} = 1.8\ \text{kW}$

Since $1\ \text{kW} = 3412.14\ \text{Btu/h}$

$\dot{W}_{net} = 1.8 \times 3412.14$

$\dot{W}_{net} = 6141.852\ \text{Btu/h}$

Step 3 of 4

The COP of a reversible heat pump can be calculated as

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$= \frac{32000}{6141.852}$$

$$COP_{HP} = 5.21$$

Step 4 of 4

The COP of a reversible heat pump can also be calculated as

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

$$5.21 = \frac{530}{530 - T_L}$$

$$T_L = 428.272\text{R}$$

Therefore the minimum temperature of the heat source is

$$\boxed{T_L = 428.272\text{R}}$$

Question: 7.111P

A heat pump with a COP of 2.4 is used to heat a house. When running, the heat pump consumes 8 kW of electric power. If the house is losing heat to the outside at an average rate of 40,000 kJ/h and the temperature of the house is 3°C when the heat pump is turned on, determine how long it will take for the temperature in the house to rise to 22°C. Assume the house is well sealed (i.e., no air leaks) and take the entire mass within the house (air, furniture, etc.) to be equivalent to 2000 kg of air.

Step 1 of 2

Calculate the amount of heat lost in the room.

$$\mathrm{COP}_{HP} = \frac{\dot{Q}_H}{\dot{W}_{in}}$$

$$\dot{Q}_H = \mathrm{COP}_{HP} \times \dot{W}_{in}$$

Here, COP_{HP} is the Coefficient of performance of heat pump, and $\dot{W}_{in}$ is the work input to the compressor.

Substitute 2.4 for COP_{HP} and 8 kW for $\dot{W}_{in}$.

$$\dot{Q}_H = 2.4(8)$$
$$= 19.2 \text{ kW}$$

Convert heat loss to surroundings in kW.

$$\dot{Q}_{loss} = 40000 \text{ kJ/h}$$
$$= 400000 \times \frac{1}{3600} \text{ kW}$$
$$= 11.11 \text{ kW}$$

Step 2 of 2

Considering the house as a system.

Apply the energy balance of the system.

$$E_{in} - E_{out} = \Delta E_{system}$$

Neglect the kinetic and potential energy changes.

Write the equation for internal energy.

$$\Delta U = m(u_2 - u_1)$$
$$= mc_v(T_2 - T_1)$$

Therefore,

$$\left(\dot{Q}_H - \dot{Q}_{loss}\right)\text{kJ/s} = mc_v(T_2 - T_1)\text{ kJ}$$
$$\left(\dot{Q}_H - \dot{Q}_{loss}\right)t = mc_v(T_2 - T_1)$$

Substitute 19.2 kW for $\dot{Q}_H$, 11.11 kW for $\dot{Q}_{loss}$, 2000 kg for m, 0.718 kJ/kg·K for c_v , 22°C for T_2 , and 3°C for T_1 .

$$\left(19.2 - \frac{40,000}{3600}\right)t = 2000(0.718)(22-3)$$
$$8.09t = 27284$$
$$t = \frac{27284}{8.09}$$
$$\Delta t = 3372.55 \text{ s}$$
$$= 3372.5 \times \frac{1}{3600}$$
$$= 0.936 \text{ h}$$

Therefore, the time taken to rise the temperature is $\boxed{\Delta t = 0.936 \text{ h}}$.

Question: 7.112P

A refrigeration system uses water-cooled condenser for rejecting the waste heat. The system absorbs heat from a space at 25°F at a rate of 24,000 Btu/h. Water enters the condenser at 58°F at a rate of 1.45 lbm/s. The COP of the system is estimated to be 1.77. Determine (*a*) the power input to the system, in kW, (*b*) the temperature of the water at the exit of the condenser, in °F and (*c*) the maximum possible COP of the system. The specific heat of water is 1.0 Btu/bm·°F.

Step 1 of 4

Given data:

The cooling load of the refrigerator is $\dot{Q}_L = 24{,}000 \text{ Btu/h}$.

The COP of the Refrigerator is $COP = 1.77$.

The temperature of sink $T_L = 25°\text{F}$

$= 25 + 460$

$T_L = 485\text{R}$.

Temperature of the water entering into the condenser $T_1 = 58°\text{F}$

$= 58 + 460$

$T_1 = 518\text{R}$.

The mass flow rate of water $\dot{m} = 1.45 \text{ lbm/s}$.

Specific heat of water $c_p = 1 \text{ Btu/lbm.°F}$.

Step 2 of 4

(a) The power input to the system

The efficiency of a refrigerator is expressed in terms of the coefficient of performance (COP), denoted by COP_R. The objective of a refrigerator is to remove heat (Q_L) from the refrigerated space. To accomplish this objective, it requires a work input of $\dot{W}_{net}$

$$COP_R = \frac{\text{Desired effect}}{\text{work input}}$$

$$COP_R = \frac{\dot{Q}_L}{\dot{W}_{net}}$$

Therefore power input is

$$\dot{W}_{net} = \frac{\dot{Q}_L}{COP_R}$$
$$= \frac{24000}{1.77}$$
$$= 13559.3 \text{ Btu/h}$$
$$= \frac{13559.3 \text{ Btu}}{3600 \text{ s}} \frac{1.055 \text{ kJ}}{\text{Btu}}$$

$$\boxed{\dot{W}_{net} = 3.974 \text{ kW}}$$

Therefore power input to the system is $\dot{W}_{net} = 3.974 \text{ kW}$

Step 3 of 4

(b) The exit temperature of water from the condenser

The heat rejected in the condenser

$$\dot{Q}_H = \dot{m} c_p (T_2 - T_1)$$

By applying first law of thermodynamics to the system

$$\dot{Q}_H = \dot{W}_{net} + \dot{Q}_L$$

Therefore the rate of heat rejection is

$$\dot{Q}_H = 13559.3 + 24000$$

$$\dot{Q}_H = 37559.3 \text{ Btu/h}$$

By substituting the known values in the equation

$$\dot{Q}_H = \dot{m} c_p (T_2 - T_1)$$
$$\frac{37559.3}{3600} = 1.45 \times (1) \times (T_2 - 58)$$
$$T_2 = 65.195°\text{F}$$

Therefore the exit temperature of water in the condenser is

$$\boxed{T_2 = 65.2°\text{F}}$$

Step 4 of 4

(c) The maximum possible COP of the refrigerator

$$COP_{rev} = \frac{T_L}{T_H - T_L}$$

Taking the average temperature of water as source temperature

$$T_H = \frac{T_1 + T_2}{2}$$
$$= \frac{58 + 65.2}{2}$$
$$T_H = 61.6°\text{F}$$

Therefore the maximum COP of the refrigerator

$$COP_{rev} = \frac{485}{61.6 - 25}$$
$$COP_{rev} = 13.25$$

Therefore the maximum possible COP of the system is $\boxed{COP_{rev} = 13.25}$

$$= \frac{58 + 65.2}{2}$$
$$T_H = 61.6°\text{F}$$

Therefore the maximum COP of the refrigerator

$$COP_{rev} = \frac{485}{61.6 - 25}$$
$$COP_{rev} = 13.25$$

Therefore the maximum possible COP of the system is $\boxed{COP_{rev} = 13.25}$

7.113P

Question:

Consider a Carnot heat-engine cycle executed in a closed system using 0.01 kg of refrigerant-134a as the working fluid. The cycle has a thermal efficiency of 15 percent, and the refrigerant-134a changes from saturated liquid to saturated vapor at 50°C during the heat addition process. Determine the net work output of this engine per cycle.

Step 1 of 3

Given data:

Mass of refrigerator $m = 0.01\,\text{kg}$

The thermal efficiency of cycle, $\eta_{th} = 15\%$

The saturated temperature is $T_{sat} = 50°C$

Refrigerant R-134a

Step 2 of 3

From saturated refrigerant R-134a table at $T_{sat} = 50°C$

Question:

Consider a Carnot heat-engine cycle executed in a closed system using 0.01 kg of refrigerant-134a as the working fluid. The cycle has a thermal efficiency of 15 percent, and the refrigerant-134a changes from saturated liquid to saturated vapor at 50°C during the heat addition process. Determine the net work output of this engine per cycle.

Step 1 of 3

Given data:

Mass of refrigerator $m = 0.01\,\text{kg}$

The thermal efficiency of cycle, $\eta_{th} = 15\%$

7.114P

Question:

A heat pump with a COP of 2.8 is used to heat an air-tight house. When running, the heat pump consumes 5 kW of power. If the temperature in the house is 7°C when the heat pump is turned on, how long will it take for the heat pump to raise the temperature of the house to 22°C? Is this answer realistic or optimistic? Explain. Assume the entire mass within the house (air, furniture, etc.) is equivalent to 1500 kg of air.

Step 1 of 4

Given data:

COP of heat pump, $\text{COP} = 2.8$

The power consumed, $\dot{W}_{net} = 5\ \text{kW}$

The initial temperature of house, $T_1 = 7°\text{C}$

The final temperature of house, $T_2 = 22°\text{C}$

The total mass in the house, $m = 1500\ \text{kg}$

Step 2 of 4

The specific heat at constant volume for air $c_v = 0.718\ \text{kJ/kg}\cdot°\text{C}$

The amount of heat lost in the room is

$$\text{COP}_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$

$$\dot{Q}_H = 2.8(5)$$

$$\dot{Q}_H = 14\ \text{kW}$$

Step 3 of 4

The total amount of heat to be supplied to the house

$$Q_{in} = mc_v\Delta T\ \text{kJ}$$

$$Q_{in} = 1500(0.718)(22-7)\ \text{kJ}$$

$$Q_{in} = 16{,}155\ \text{kJ}$$

Step 4 of 4

The heat pump supplies 14 kW of heat into the house per second.

The time required to supply that heat is

$$\Delta t = \frac{16{,}155}{14}$$

$$= 1153.928\ s$$

$$= \frac{1153.928}{60}\text{min}$$

$$= 19.23\ \text{min}$$

$\therefore$ Time taken to heat the pump, $\boxed{\Delta t = 19.23\ \text{min}}$

Question: 7.115P

Consider a Carnot heat-engine cycle executed in a closed system using 0.025 kg of steam as the working fluid. It is known that the maximum absolute temperature in the cycle is twice the minimum absolute temperature, and the net work output of the cycle is 60 kJ. If the steam changes from saturated vapor to saturated liquid during heat rejection, determine the temperature of the steam during the heat rejection process.

Step 1 of 2

The maximum absolute temperature (T_H) in the cycle is twice the minimum absolute temperature (T_L) in the cycle $T_H = 0.5T_L$.

Find the efficiency of the Carnot cycle heat engine.

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$\eta_{th} = 1 - \frac{T_L}{0.5T_L}$$

$$\eta_{th} = 0.5$$

Here, T_H is the maximum absolute temperature and T_L is the minimum absolute temperature.

The efficiency of the Carnot heat engine can also be written as:

$$\eta_{th} = \frac{W_{net}}{Q_H}$$

$$0.5 = \frac{60}{Q_H}$$

$$Q_H = 120\,\text{kJ}$$

Here, W_{net} is the net work done and Q_H is the heat supplied.

Apply the first law of thermodynamics to the system

$$W_{net} = Q_H - Q_L$$

$$60 = 120 - Q_L$$

$$Q_L = 60\,\text{kJ}$$

Step 2 of 2

The amount of heat rejection per kg of steam is

$$q_L = \frac{Q_L}{m}$$

$$= \frac{60}{0.025}$$

$$q_L = 2400\ \text{kJ/kg}$$

For 1 kg of conversion of saturated vapor to saturated liquid it takes 2400 kJ/kg of heat

i.e. enthalpy of vaporization

$$q_L = h_{fg} = 2400\ \text{kJ/kg}$$

At $h_{fg} = 2400\ \text{kJ/kg}$ from saturated water tables

$$T_L = 40 + (45 - 40)\left(\frac{2400 - 2406.0}{2394.0 - 2406.0}\right)$$

$$T_L = 42.5^\circ\text{C}$$

Therefore the temperature of the steam during the heat rejection process is $\boxed{T_L = 42.5^\circ\text{C}}$

Question: 7.116P

Reconsider Prob. 7–115. Using EES (or other) software, investigate the effect of the net work output on the required temperature of the steam during the heat rejection process. Let the work output vary from 40 to 60 kJ.

Step 1 of 4

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click table on menu bar, select the new parameter table.

And run the table for now values.

Then click ok.

Now again select the plot command on menu bar .then select the required variables from the list, then click okay.

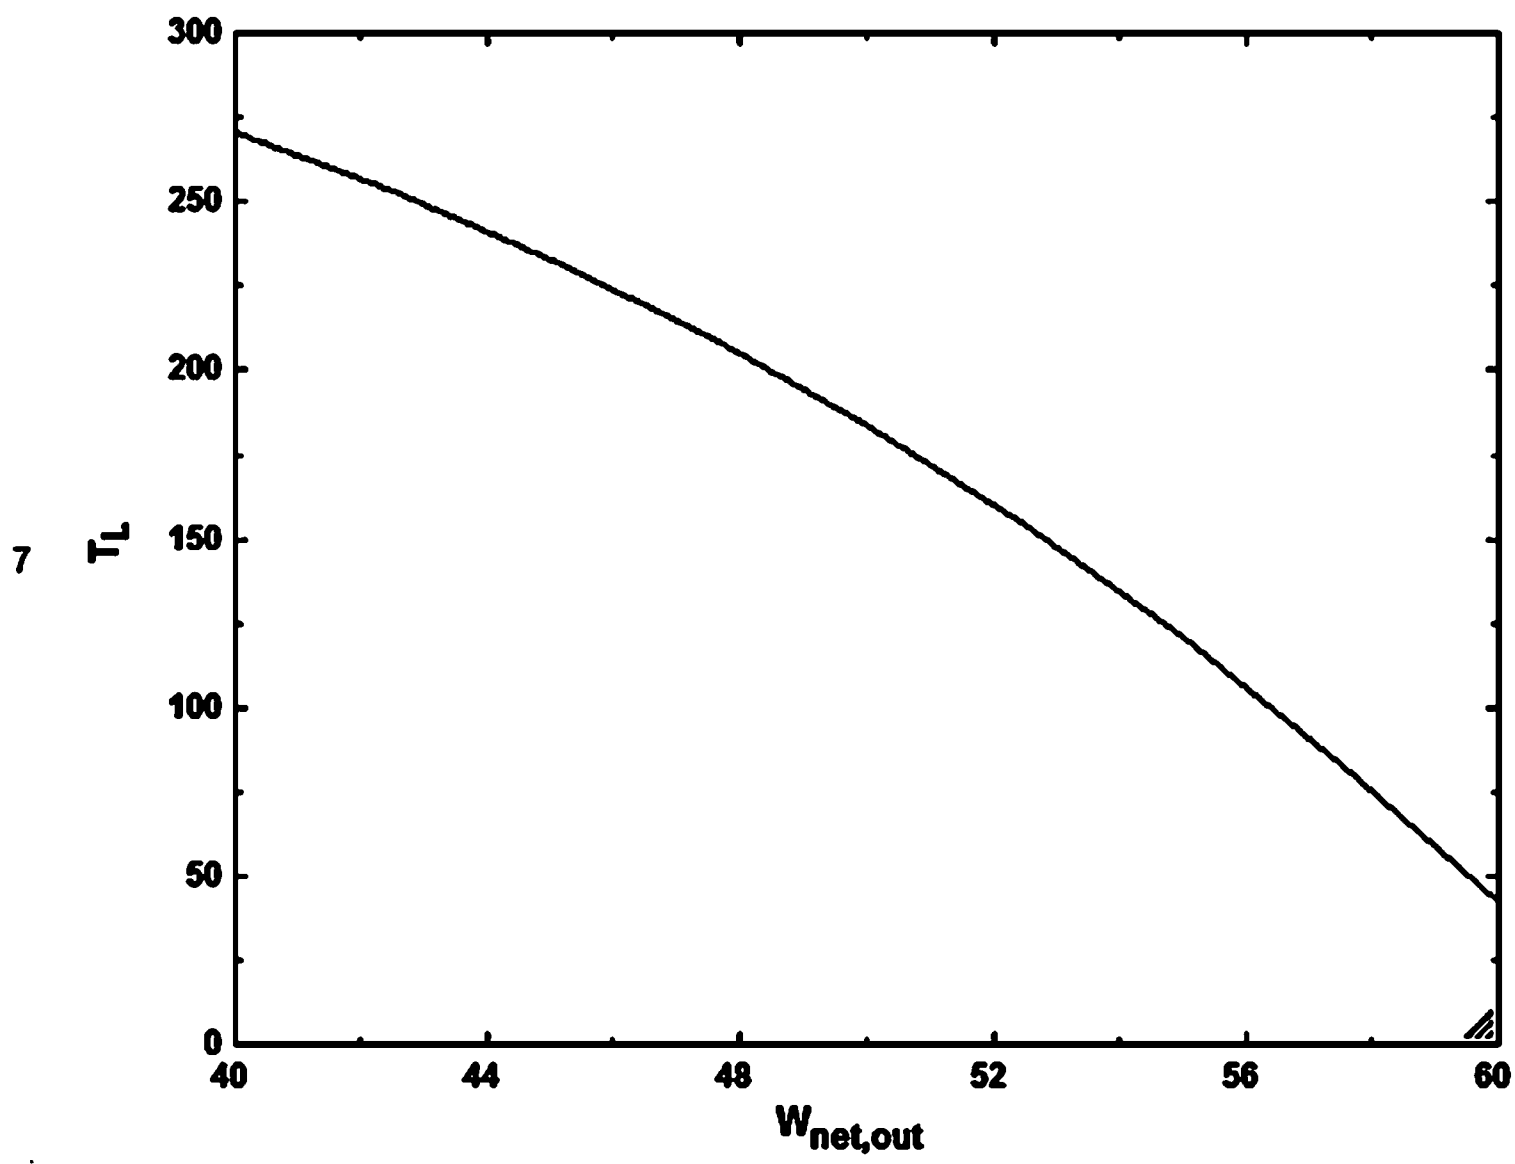
Step 2 of 4

Equation window:

```
"Given"
m=0.025 [kg]
RatioT=0.5 "RatioT=T_L/T_H"
"W_net_out=60 [kJ]"

"Properties"
FluidS= 'steam_iapws'
h_f=enthalpy(FluidS, T=T_L, x=0)
h_g=enthalpy(FluidS, T=T_L, x=1)
h_fg=h_g-h_f

"Analysis"
eta_th=1-RatioT
eta_th=W_net_out/Q_H
Q_L=Q_H-W_net_out
Q_L=m*h_fg
```



Step 3 of 4

Table for sink temperature as a function of Work input:

1..9	1 $W_{net,out}$	2 T_L
Run 1	40	270.8
Run 2	42.5	252.9
Run 3	45	232.8
Run 4	47.5	209.9
Run 5	50	184
Run 6	52.5	154.5
Run 7	55	120.9
Run 8	57.5	83.18
Run 9	60	42.49

Step 4 of 4

Graph between Sink temperatures Vs. Work input:

Question: 7.117P

Consider a Carnot refrigeration cycle executed in a closed system in the saturated liquid–vapor mixture region using 0.96 kg of refrigerant-134a as the working fluid. It is known that the maximum absolute temperature in the cycle is 1.2 times the minimum absolute temperature, and the net work input to the cycle is 22 kJ. If the refrigerant changes from saturated vapor to saturated liquid during the heat rejection process, determine the minimum pressure in the cycle.

Step 1 of 6

Given data:

The mass of refrigerant R-134a, $m = 0.96\ \text{kg}$

The maximum temperature, $T_H = 1.2T_L$

The net work input to the cycle, $\dot{W}_{net} = 22\ \text{kJ}$

Step 2 of 6

The maximum coefficient of performance of any refrigerator is expressed as

$$\text{COP}_{Ref} = \frac{T_L}{T_H - T_L}$$

The we can also written as $\text{COP}_{Ref} = \frac{\dot{Q}_L}{\dot{W}_{net}}$

$$\text{Here COP}_{Ref} = \frac{T_L}{1.2T_L - T_L} = \frac{\dot{Q}_L}{22}$$

$$\frac{T_L}{1.2T_L - T_L} = \frac{\dot{Q}_L}{22}$$

$$\frac{1}{0.2} = \frac{\dot{Q}_L}{22}$$

$$\dot{Q}_L = 110\ \text{kJ}$$

Step 3 of 6

The refrigerant effect is, $\dot{Q}_L = 110\ \text{kJ}$

The heat rejected in the conversion is

$$\dot{Q}_H = \dot{W}_{net} + \dot{Q}_L$$

$$Q_H = 22 + 110$$

$$Q_H = 132\ \text{kJ}$$

Step 4 of 6

Per unit kg of steam

Heat lost in this process,

$$q_{out} = \frac{Q_H}{m}$$

$$= \frac{132}{0.96}$$

$$= 137.5\ \text{kJ/kg}$$

For 1 kg of conversion of saturated vapor to saturated liquid it takes 137.5 kJ/kg of heat

i.e. Enthalpy of vaporization $h_{fg} = 137.5\ \text{kJ/kg}$

Step 5 of 6

The temperature corresponds to $h_{fg} = 137.5\ \text{kJ/kg}$ from saturated refrigerant R-134a tables

Using method of interpolation

$$T_H = 60 + (65 - 60)\left[\frac{137.5 - 139.10}{132.02 - 139.10}\right]$$

$$T_H = 61.129°\text{C}$$

Therefore the lower temperature reservoir is

$$T_L = \frac{T_H}{1.2}$$

$$= \frac{61.129 + 273}{1.2}$$

$$= 278.44\text{K} - 273$$

$$= 5.44°\text{C}$$

Step 6 of 6

The saturated pressure at minimum temperature is

At $T_L = 5.44°\text{C}$ the minimum pressure is lays between

$T_1 = 4°\text{C}$, the $P_{sat_1} = 337.9\ \text{kPa}$

$T_2 = 6°\text{C}$, the $P_{sat_2} = 362.23\ \text{kPa}$

By interpolation method

$$\frac{P_{sat} - P_1}{P_2 - P_1} = \frac{T_{sat} - T_1}{T_2 - T_1}$$

$$\frac{P_{sat} - 337.9}{363.23 - 337.9} = \frac{5.44 - 4}{6 - 4}$$

$$P_{sat} = 355.4\ \text{kPa}$$

∴ The minimum pressure is $\boxed{P_{sat} = 355.4\ \text{kPa}}$

Question: 7.118P

Reconsider Prob. 7–117. Using EES (or other) software, investigate the effect of the net work input on the minimum pressure. Let the work input vary from 10 to 30 kJ. Plot the minimum pressure in the refrigeration cycle as a function of net work input, and discuss the results.

Step 1 of 4

Solve the solution by entering the following code in 'Equations window' of EES software.

EES Limited Academic Version: C:\EES (LIMITED ACADEMIC)\HELLO.TXT - [Equations Window]

File Edit Search Options Calculate Tables Plots Windows Help Thermal-Fluid Sciences

```
m_R134a=0.96 "Here, m_R134a is the mass of R134a"
THtoTLRatio=1.2 "Here, TH is the higher temperature and TL is the lower temperature"
COP_R=1/(THtoTLRatio-1) "Here, COP_R is the COP of regrigerator"
Q_L=W_in*COP_R "Here, Q_L is the heat rejected and W_in is the work input"
Q_L+W_in=Q_H "Here, Q_H is the heat added"
Q_H=(m_R134a)*(h_fg) "Here, h_fg is the specific enthalpy of R134a at wet region"
h_fg=Enthalpy(R134a,T=T_H,x=1)-Enthalpy(R134a,T=T_H,x=0) "Here, x is the dryness fraction"
T_H=(THtoTLRatio)*T_L
P_min=Pressure(R134a,T=T_L,x=0)
```

Step 2 of 4

Obtain the parametric table for the code entered in the Equations window' of EES software.

Parametric Table

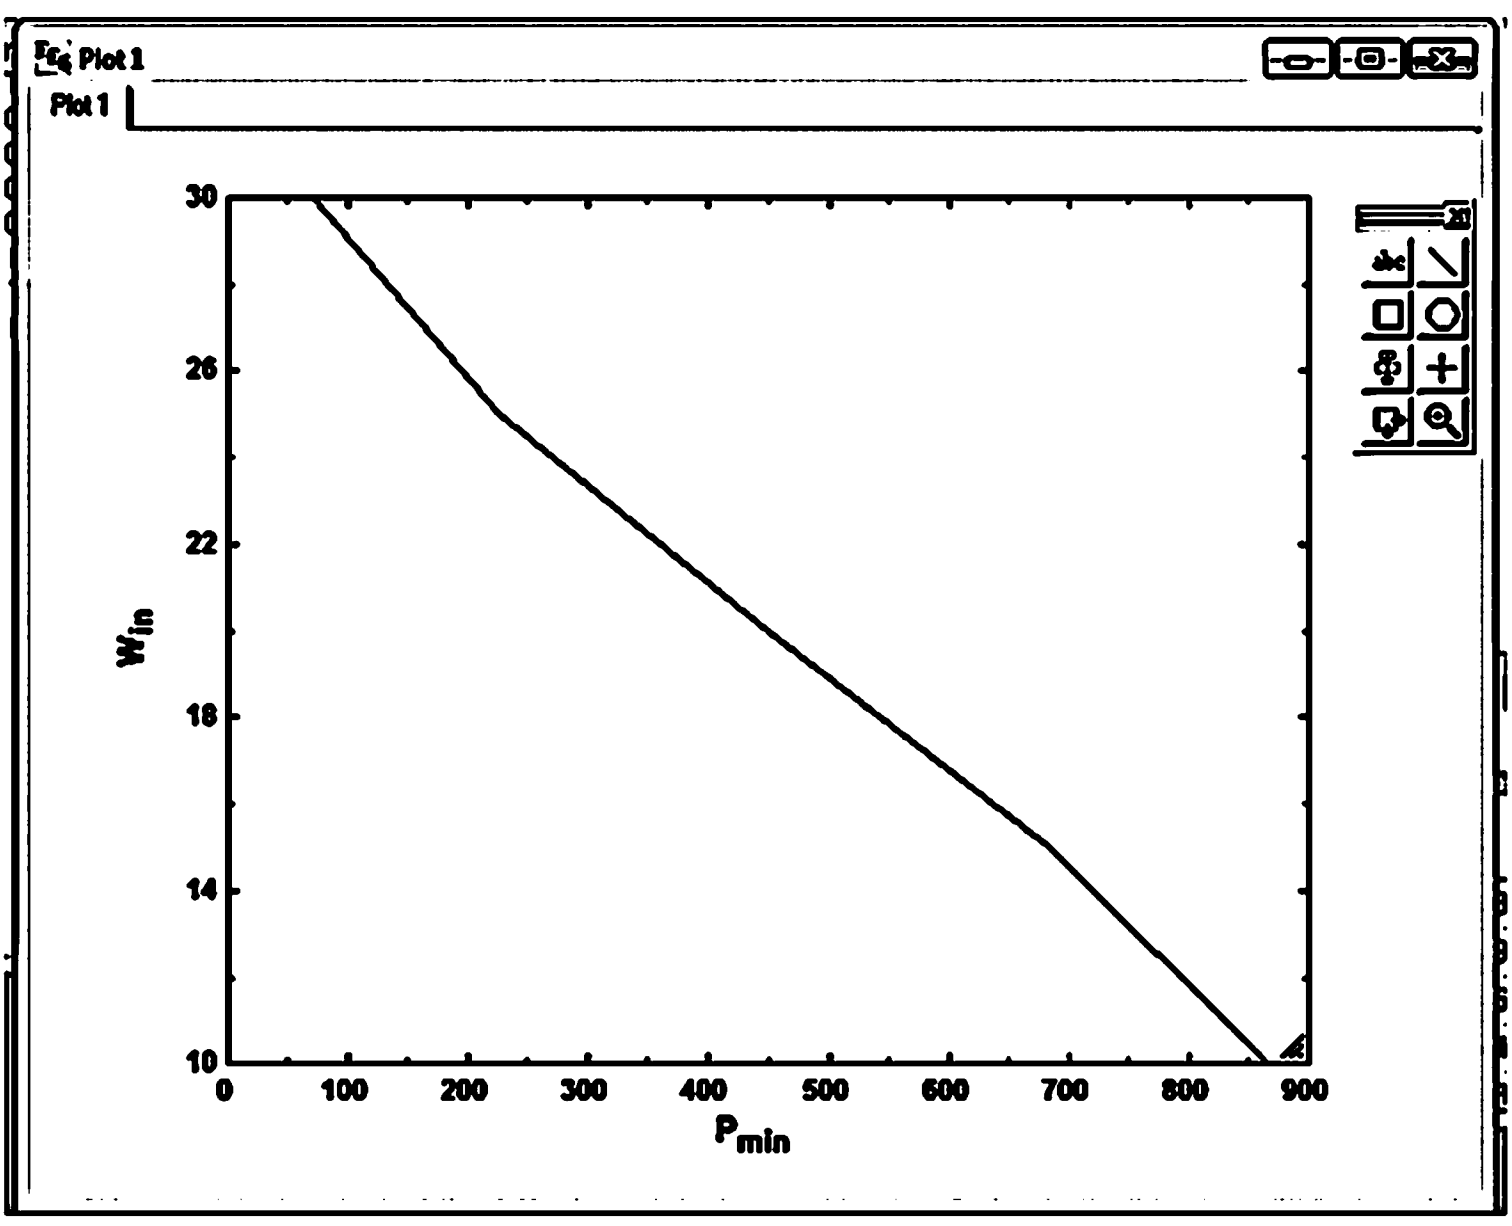


Table 1

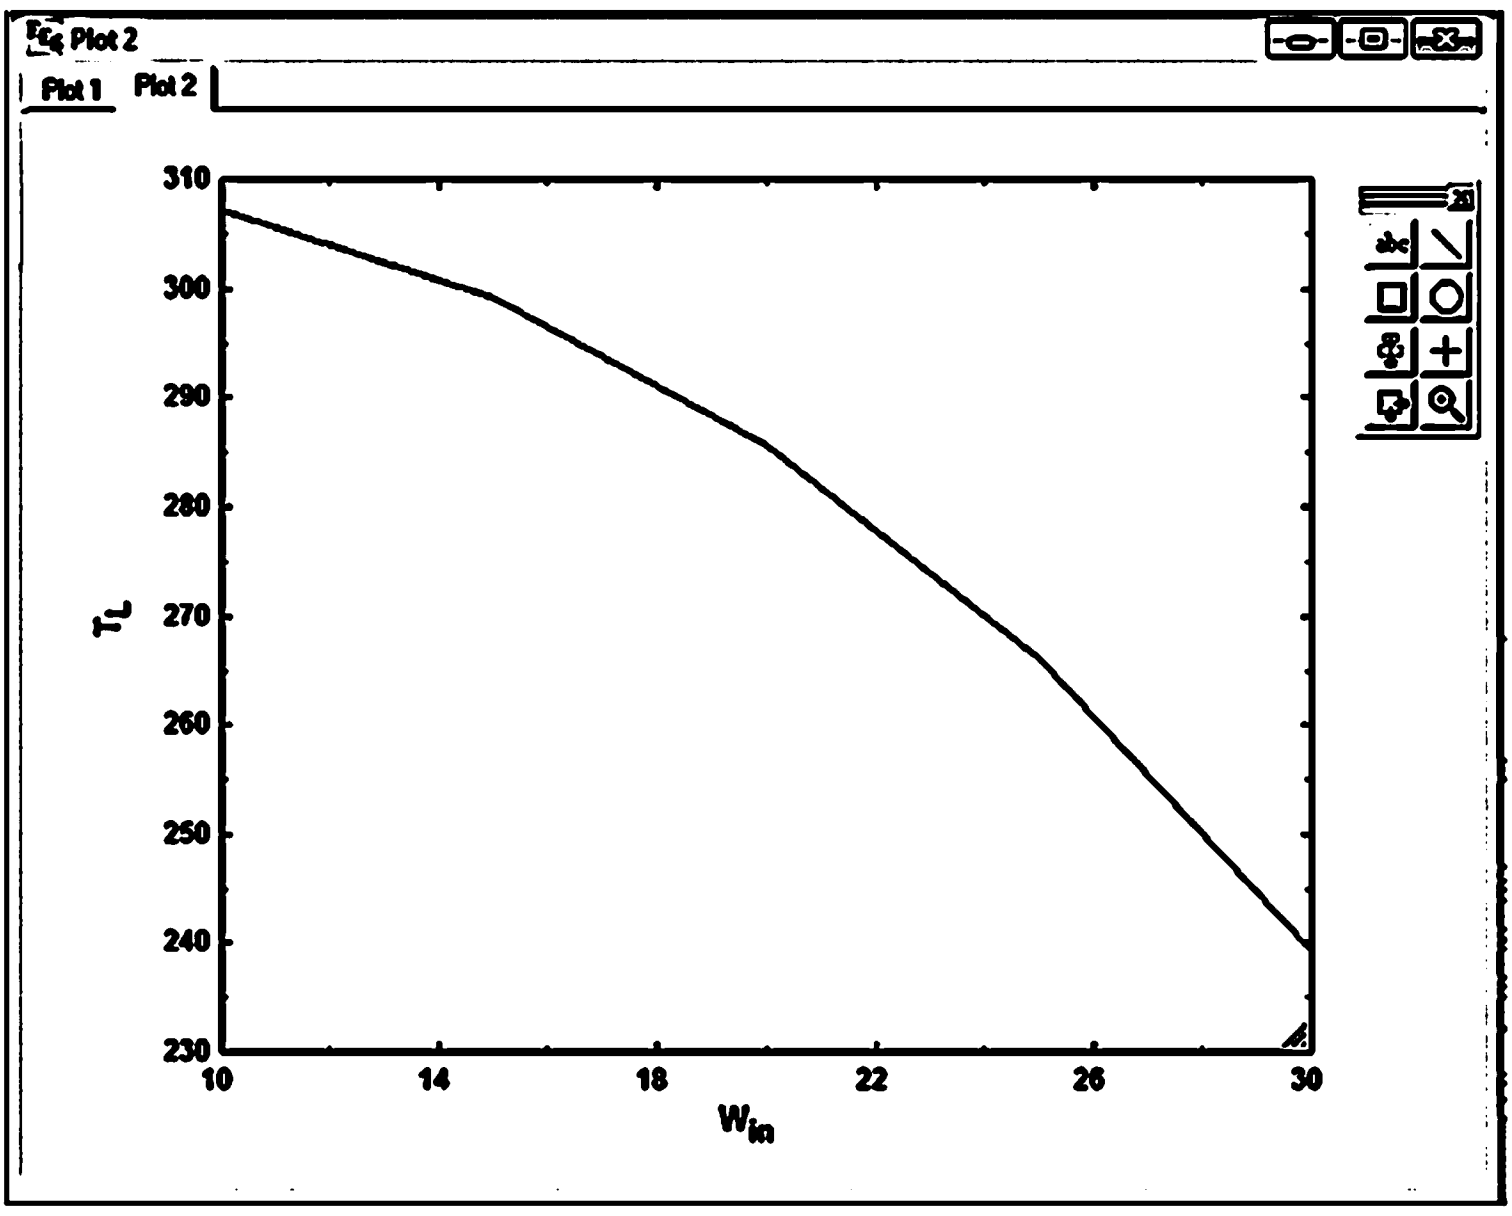
1..5	1 P_{min}	2 T_H	3 T_L	4 W_{in}
Run 1	866	368.7	307.3	10
Run 2	683.4	358.8	299	15
Run 3	450.3	342.7	285.6	20
Run 4	225.3	319.3	266.1	25
Run 5	70.01	287.1	239.3	30

Here, T_H values must be kept in limits at "Variable info" for execution of the EES source file.



Step 3 of 4

Obtain the plot for minimum pressure and work input from the EES software.

Step 4 of 4

Obtain the plot for lower temperature and work input from the EES software.

Question: 7.119P

Consider two Carnot heat engines operating in series. The first engine receives heat from the reservoir at 1800 K and rejects the waste heat to another reservoir at temperature *T*. The second engine receives this energy rejected by the first one, converts some of it to work, and rejects the rest to a reservoir at 300 K. If the thermal efficiencies of both engines are the same, determine the temperature *T*.

Step 1 of 3

Given data:

HE-1:

Source temperature, $T_H = 1800\,\text{K}$

Sink temperature, $T_L = T$

HE-2:

Source temperature, $T_H = T$

Sink temperature, $T_L = 300\,\text{K}$

Step 2 of 3

The thermal efficiency of Carnot heat engine is given by

$$\eta_{th} = \frac{T_H - T_L}{T_H}$$

For HE-1:

$$\eta_{th_1} = \frac{T_H - T}{T_H}$$

For HE-2:

$$\eta_{th_2} = \frac{T - T_L}{T}$$

Step 3 of 3

Given that the both heat engines having same thermal efficiency

$$\eta_{th_1} = \eta_{th_2}$$

$$\frac{T_H - T}{T_H} = \frac{T - T_L}{T}$$

$$T_H \times T - T^2 = T_H \times T - T_L T_H$$

$$T^2 = T_L T_H$$

$$T = \sqrt{T_L T_H}$$

$$T = \sqrt{1800 \times 300}$$

$$T = 734.84\,\text{K}$$

The intermittent temperature is $\boxed{T = 734.84\,\text{K}}$

Question: 7.120P

Calculate and plot the thermal efficiency of a completely reversible heat engine as a function of the source temperature up to 2000 R with the sink temperature fixed at 500 R.

Step 1 of 3

Given data:

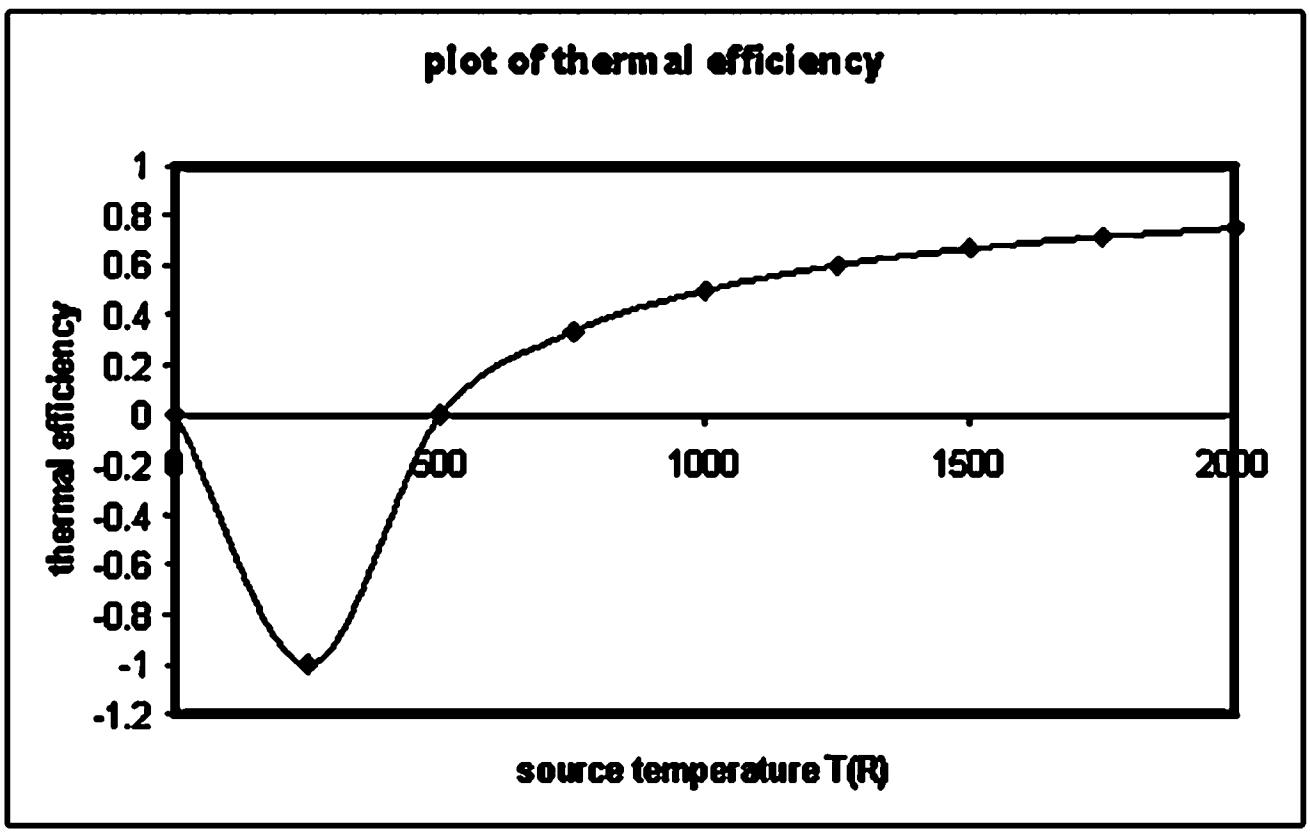
The temperature of source, $T_H = 0 - 2000\text{R}$

The temperature of sink, $T_L = 500\text{R}$

Step 2 of 3

The thermal efficiency of Carnot engine is expressed as

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$



$$\eta_{th} = 1 - \frac{500}{T_H}$$

Finding efficiency of heat engine with the increment of source temperature is 250R

Source T(R)	Thermal efficiency
0	#DIV/0!
250	-1.00
500	0.00
750	0.33
1000	0.50
1250	0.60
1500	0.67
1750	0.71
2000	0.75

Step 3 of 3

Graph between source temperature and thermal efficiency

Question:

7.121P

A Carnot heat engine receives heat at 900 K and rejects the waste heat to the environment at 300 K. The entire work output of the heat engine is used to drive a Carnot refrigerator that removes heat from the cooled space at −15°C at a rate of 250 kJ/min and rejects it to the same environment at 300 K. Determine (*a*) the rate of heat supplied to the heat engine and (*b*) the total rate of heat rejection to the environment.

Step 1 of 6

Given data:

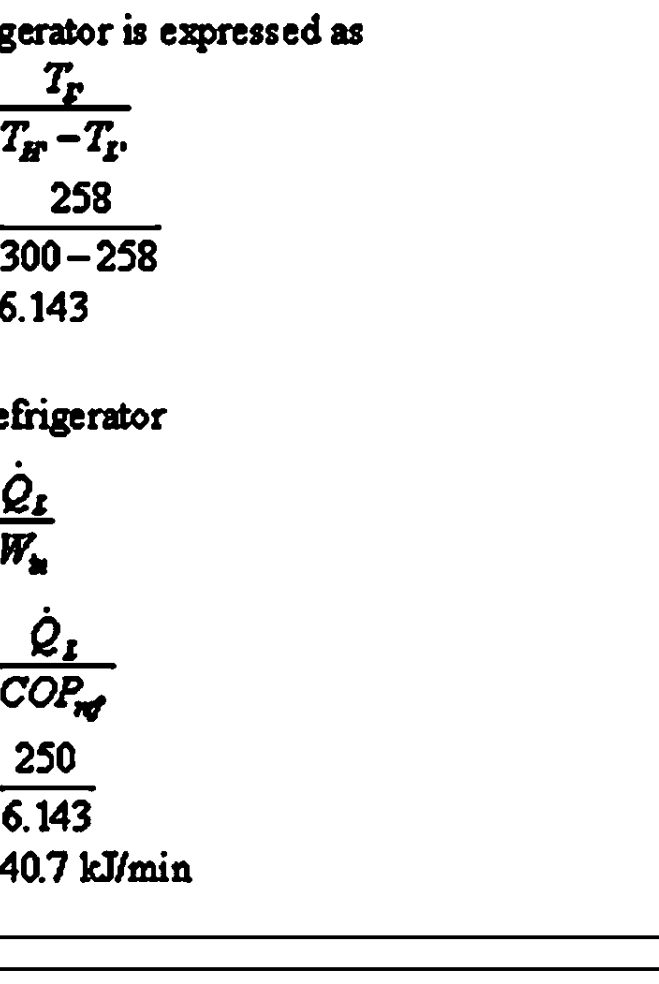
For the heat engine

Temperature of source $T_H = 900\text{K}$

Temperature of sink $T_L = 300\text{K}$

For the refrigerator

Temperature of source $T_{H'} = 300\text{K}$



Temperature of sink

$T_{L'} = -15^0\text{C}$

$T_{L'} = 258\text{K}$

The heat removed from the refrigerator $\dot{Q}_{L'} = 250\ \text{kJ/min}$

Step 2 of 6

Where

Q_H Is the heat absorbed from the source to the heat engine

Q_L is the heat rejected from the heat engine to the sink

$Q_{H'}$ Is the heat absorbed from the source to the refrigerator

$Q_{L'}$ Is the heat rejected from the refrigerator to the sink

W_{in} Is the power input to the refrigerator

W_{out} Is the power output from the heat engine

Step 3 of 6

(a)

The COP of Carnot refrigerator is expressed as

$$COP_{ref} = \frac{T_{L'}}{T_{H'} - T_{L'}}$$

$$= \frac{258}{300 - 258}$$

$$COP_{ref} = 6.143$$

The power input to the refrigerator

$$COP_{ref} = \frac{\dot{Q}_L}{W_{in}}$$

$$W_{in} = \frac{\dot{Q}_L}{COP_{ref}}$$

$$= \frac{250}{6.143}$$

$$W_{in} = 40.7\ \text{kJ/min}$$

Step 4 of 6

The power input to the refrigerator is equal to power output from the heat engine

$$W_{in} = W_{out}$$

The thermal efficiency of the Carnot heat engine is expressed as

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$= 1 - \frac{300}{900}$$

$$\eta_{th} = 0.667$$

The rate of heat supplied to the heat engine is

$$\eta_{th} = \frac{W_{out}}{\dot{Q}_H}$$

$$0.667 = \frac{40.7}{\dot{Q}_H}$$

$$\dot{Q}_H = 61.1\ \text{kJ/min}$$

Therefore heat supplied to the heat engine is

$$\boxed{\dot{Q}_H = 61.1\ \text{kJ/min}}$$

Step 5 of 6

(b)

The total heat rejection will be sum of the heat rejected by the heat engine and heat rejected by the refrigerant

$$\dot{Q}_{total} = \dot{Q}_L + \dot{Q}_{H'}$$

For heat engine the heat rejection is

$$\dot{Q}_L = \dot{Q}_H - W_{out}$$

$$\dot{Q}_L = 61.1 - 40.7$$

$$\dot{Q}_L = 20.4\ \text{kJ/min}$$

Step 6 of 6

For refrigerator the heat rejection is

$$\dot{Q}_{L'} - \dot{Q}_{H'} = -W_{in}$$

$$\dot{Q}_{H'} = W_{in} + \dot{Q}_{L'}$$

$$= 250 + 40.7$$

$$\dot{Q}_{H'} = 290.7\ \text{kJ/min}$$

The total heat rejection is

$$\dot{Q}_{total} = \dot{Q}_L + \dot{Q}_{H'}$$

$$\dot{Q}_{total} = 290.7 + 20.4$$

$$\boxed{\dot{Q}_{total} = 311.1\ \text{kJ/min}}$$

Therefore the total heat rejection to the environment is $\dot{Q}_{total} = 311.1\ \text{kJ/min}$

Question:

Reconsider Prob. 7–121. Using EES (or other) software, investigate the effects of the heat engine source temperature, the environment temperature, and the cooled space temperature on the required heat supply to the heat engine and the total rate of heat rejection to the environment. Let the source temperature vary from 500 to 1000 K, the environment temperature vary from 275 to 325 K, and the cooled space temperature vary from −20 to 0°C. Plot the required heat supply against the source temperature for the cooled space temperature of −15°C and environment temperatures of 275, 300, and 325 K, and discuss the results.

Step 1 of 7

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click table on menu bar, select the new parameter table.

And run the table for now values.

Then click ok.

Now again select the plot command on menu bar .then select the required variables from the list, then click okay.

Step 2 of 7

Equation window:

```
Q_dot_L_R = 250 [kJ/min]
T_surr = 325 [K]
"T_H = 900 [K]"
T_L_C = -15 [C]
T_L =T_L_C+ 273

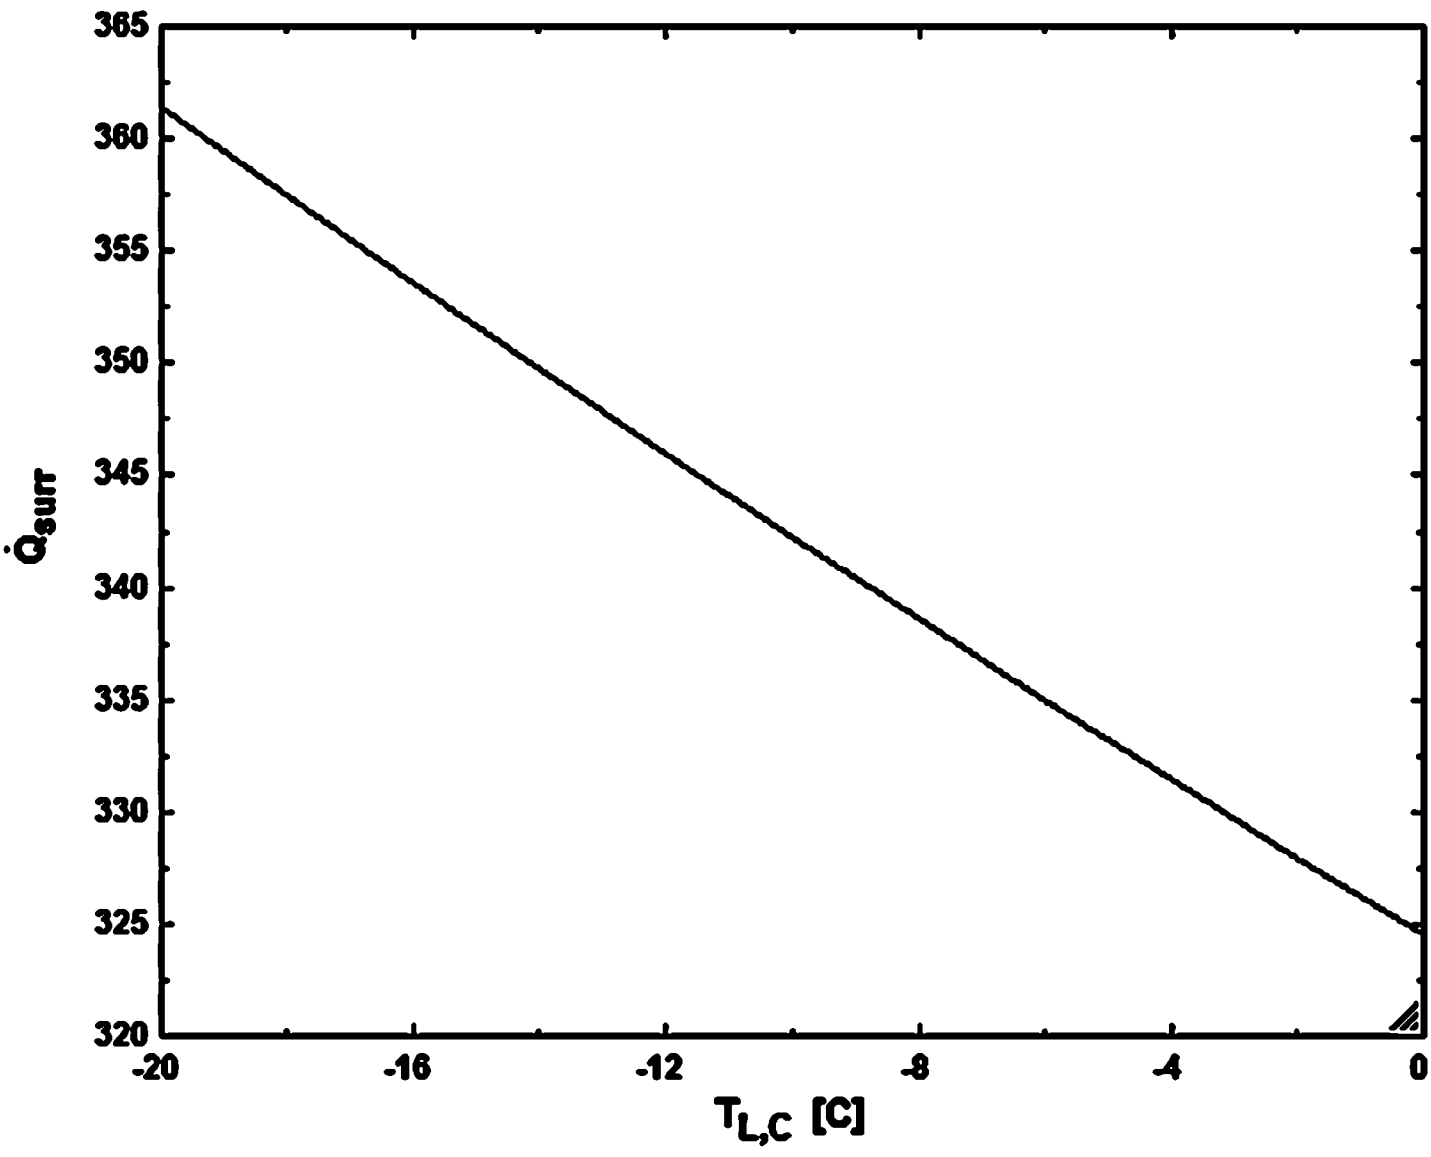
Graph between the Heat engine and sink temperature :



Step 6 of 7

Graph between the sink temperature and Work input :

Step 7 of 7

Graph between the heat surrounding and sink temperature :

Question:

7.123P

A heat engine operates between two reservoirs at 800 and 20°C. One-half of the work output of the heat engine is used to drive a Carnot heat pump that removes heat from the cold surroundings at 2°C and transfers it to a house maintained at 22°C. If the house is losing heat at a rate of 62,000 kJ/h, determine the minimum rate of heat supply to the heat engine required to keep the house at 22°C.

Step 1 of 6

Given data:

For heat engine:

Temperature of source, $T_H = 800°C$

$= 800 + 273$

$= 1073K$

Temperature of sink, $T_L = 20°C$

$= 20 + 273$

$= 293K$

For a heat pump:

Temperature of source, $T_H = 22°C$

$= 22 + 273$

$= 295K$

Temperature of sink, $T_L = 2°C$

$= 20 + 273$

$= 275K$

The work output of a heat engine is used to drive heat pump, $\frac{1}{2}W_{net_HE} = W_{in_HP}$

The heat rejected by the house, $\dot{Q}_H = 62{,}000$ kJ/h

Step 2 of 6

The COP of heat pump is expressed as

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

$$COP_{HP} = \frac{295}{295 - 275}$$

$$COP_{HP} = 14.75$$

Step 3 of 6

The power input to the heat pump

$$COP_{HP} = \frac{\dot{Q}_H}{W_{net}}$$

$$W_{in} = \frac{62000}{14.75}$$

$$W_{in} = 4203.38 \text{ kJ/h}$$

Step 4 of 6

The work output of a heat engine is used to drive heat pump, $\frac{1}{2}W_{net_HE} = W_{in_HP}$

Therefore the power output from the heat engine

$W_{net} = 2 \times W_{in}$

$= 2 \times 4203.38$

$= 8406.76$ kJ/h

Step 5 of 6

The thermal efficiency of a heat engine is expressed as

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$\eta_{th} = 1 - \frac{293}{1073}$$

$$\eta_{th} = 0.7269$$

Step 6 of 6

The minimum rate of heat supplied to the heat engine is expressed as

$$\eta_{th} = \frac{W_{net}}{\dot{Q}_{HP}}$$

$$0.7269 = \frac{8406.76}{\dot{Q}_{HP}}$$

$$\dot{Q}_{HP} = 11{,}565.2 \text{ kJ/h}$$

∴ The minimum rate of heat supplied is $\boxed{\dot{Q}_{HP} = 11{,}565.2 \text{ kJ/h}}$

Question: 7.124P

An inventor claims to have developed a refrigerator that maintains the refrigerated space at 35°F while operating in a room where the temperature is 75°F and that has a COP of 13.5. Is this claim reasonable?

Step 1 of 4

Given

Temperature of source $T_H = 75°C$

Temperature of sink $T_L = 35°C$

COP of the refrigerator is 13.5

Step 2 of 4

Temperature of source

$T_H = 75°C$

$= 75 + 460$

$= 535K$

Temperature of sink

$T_L = 35°C$

$= 35 + 460$

$= 495K$

Step 3 of 4

The efficiency of a refrigerator is expressed in terms of the coefficient of performance (COP), denoted by COP_R. The objective of a refrigerator is to remove heat (Q_L) from the refrigerated space. To accomplish this objective, it requires a work input of W_{net}

$$COP_R = \frac{\text{Desired output}}{\text{Required input}}$$

Step 4 of 4

For a reversible refrigerator has the maximum COP, which is expressed as

$$COP_R = \frac{T_L}{T_H - T_L}$$

$$COP_R = \frac{495}{535 - 495}$$

$$COP_R = 12.375$$

Here

$$COP_R = 12.375 < 13.4$$

The maximum possible COP of this temperature limits is 12.375, but the inventor claims 13.4, So his claim is not reasonable.

Question: 7.125P

Consider a Carnot heat-pump cycle executed in a steady-flow system in the saturated liquid–vapor mixture region using refrigerant-134a flowing at a rate of 0.22 kg/s as the working fluid. It is known that the maximum absolute temperature in the cycle is 1.2 times the minimum absolute temperature, and the net power input to the cycle is 5 kW. If the refrigerant changes from saturated vapor to saturated liquid during the heat rejection process, determine the ratio of the maximum to minimum pressures in the cycle.

Step 1 of 8

Given

Mass flow rate of refrigerant $\dot{m} = 0.22$ kg/s.

The temperature $T_H = 1.2T_L$.

The net power input to the cycle $P = 5$ kW.

Step 2 of 8

The COP of the heat pump is

$$COP_{HP} = \frac{T_H}{T_H - T_L}$$

$$COP_{HP} = \frac{T_H}{T_H - \frac{1}{1.2}T_H}$$

$$= 6$$

Step 3 of 8

The heat rejected to the heat pump

$$COP_{HP} = \frac{\dot{Q}_H}{W_{net}}$$

$$\dot{Q}_H = 6 \times 5$$

$$= 30 \text{ kW}$$

Step 4 of 8

Per unit kg of mass

Heat lost in this process

$$q_H = \frac{\dot{Q}_H}{\dot{m}}$$

$$= \frac{30}{0.22}$$

$$= 136.4 \text{ kJ/kg}$$

Step 5 of 8

For 1 kg of conversion of saturated vapor to saturated liquid it takes 136.4 kJ/kg of heat

I.e. Enthalpy of vaporization $h_{fg} = 136.4$ kJ/kg

The temperature corresponds to $h_{fg} = 136.4$ kJ/kg

From saturated refrigerant 134a Temperature table

At $h_{fg} = 136.4$ kJ/kg

By using the method of interpolation

$$T_H = 60 + \frac{(136.4 - 139.10)(65 - 60)}{((132.02 - 139.10))}$$

$$T_H = 61.903^\circ C$$

$$= 62^\circ C$$

Step 6 of 8

From saturated refrigerant 134a Temperature table

Pressure at $T_H = 62^\circ C$

By interpolation

$$\frac{P_{sat} - P_1}{P_2 - P_1} = \frac{T_{sat} - T_1}{T_2 - T_1}$$

$$\frac{P_{sat} - 1682.8}{1891 - 1682.8} = \frac{62 - 60}{65 - 60}$$

$$P_H = 1821.6 \text{ kPa}$$

Step 7 of 8

Therefore the lower temperature reservoir is

$$T_L = \frac{T_H}{1.2}$$

$$= \frac{62 + 273}{1.2}$$

$$= 279.167\text{K} - 273$$

$$= 6.167^\circ C$$

Step 8 of 8

From saturated refrigerant 134a Temperature table

At $T_L = 6.167^\circ C$

The minimum pressure is

The saturated pressure at minimum temperature is

$$P_L = 363 \text{ kPa}$$

Therefore the ratio of maximum to minimum pressure is

$$\frac{P_H}{P_L} = \frac{1821.6}{363}$$

$$= 5.02$$

$$\boxed{\frac{P_H}{P_L} = 5.02}$$

Question: 7.126P

Replacing incandescent lights with energy-efficient fluorescent lights can reduce the lighting energy consumption to one-fourth of what it was before. The energy consumed by the lamps is eventually converted to heat, and thus switching to energy-efficient lighting also reduces the cooling load in summer but increases the heating load in winter. Consider a building that is heated by a natural gas furnace with an efficiency of 80 percent and cooled by an air conditioner with a COP of 3.5. If electricity costs \$0.08/kWh and natural gas costs \$1.40/therm (1 therm = 105,500 kJ), determine if efficient lighting will increase or decrease the total energy cost of the building (*a*) in summer and (*b*) in winter.

Step 1 of 4

Given data:
The thermal efficiency of furnace, $\eta = 0.8$
The COP of refrigerant, COP = 3.5
Unit cost of electricity for refrigerant, \$0.08/kWh
Unit cost of natural gas for furnace, \$1.40/therm
1 therm = 105,500 kJ

Step 2 of 4

(a) In summer the usage of lightening in the house will be lesser than the winter, so therefore total cost of energy used of the household will be decreased.

Step 3 of 4

(b) In winter the usage of lightening will be higher based on cost of electricity.
For a natural gas furnace

$$\text{Unit cost} = \frac{\$1.40}{\eta_{th}}\left(\frac{1\text{ therm}}{105{,}500}\right)$$

$$= \frac{\$1.40}{0.8}\left(\frac{1\text{ therm}}{105{,}500}\right)$$

$$= \$1.66\times10^{-5}/\text{kJ}$$

For 1 kWh heat supplied the cost for furnace is $= \$1.66\times10^{-5}/\text{kJ}\times3600$

$= \$\,0.06/\text{kWh}$

Step 4 of 4

So for heat supplied for natural gas furnace is \$ 0.06/kWh which is less than \$ 0.08/kWh cost of electricity for refrigerator.
Thus the energy efficient lighting will reduce the total energy cost of this building both in summer and in winter.

Question: 7.127P

A heat pump supplies heat energy to a house at the rate of 140,000 kJ/h when the house is maintained at 25°C. Over a period of one month, the heat pump operates for 100 hours to transfer energy from a heat source outside the house to inside the house. Consider a heat pump receiving heat from two different outside energy sources. In one application the heat pump receives heat from the outside air at 0°C. In a second application the heat pump receives heat from a lake having a water temperature of 10°C. If electricity costs \$0.085/kWh, determine the maximum money saved by using the lake water rather than the outside air as the outside energy source.

Step 1 of 9

Given

The temperature of house $T_H = 25°C$.

The temperature of the outside air $T_L = 0°C$.

The heat energy supplied $\dot{Q}_H = 140{,}000$ kJ/h .

Operating hours of heat pump $t = 100$ hrs .

The cost of electricity is \$0.085/kWh.

In second case heat pump receives from water at $T_{L_B} = 10°C$.

Step 2 of 9

The temperature of house

$$T_H = 25°C$$
$$= 25 + 273$$
$$= 298K$$

The temperature of the outside air

$$T_L = 0°C$$
$$= 273K$$

In second case heat pump receives from water at

$$T_{L_B} = 10°C$$
$$= 10 + 273$$
$$= 283K$$

Step 3 of 9

CASE A:

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP_A} = \frac{T_H}{T_H - T_L}$$
$$COP_{HP_A} = \frac{298}{298 - 273}$$
$$COP_{HP_A} = 11.92$$

Step 4 of 9

The minimum work per unit heat transfer of a heat pump is expressed as

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$
$$\dot{W}_{net} = \frac{\dot{Q}_H}{COP_{HP}}$$
$$\dot{W}_{net} = \frac{\left(\frac{140{,}000}{3600}\right)}{11.92}$$
$$\dot{W}_{net} = 3.262 \text{ kW}$$

Step 5 of 9

The cost for electricity if the heat pump takes outside air

$$Cost = \dot{W}_{net} \times 100 \text{ h} \times \$0.085 / \text{kWh}$$
$$Cost = 3.262 \times 100 \text{ h} \times \$0.085 / \text{kWh}$$
$$Cost = \$27.73$$

Step 6 of 9

CASE B:

The heat pump receives heat from lake water

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$COP_{HP_B} = \frac{T_H}{T_H - T_L}$$
$$COP_{HP_B} = \frac{298}{298 - 283}$$
$$COP_{HP_B} = 19.867$$

Step 7 of 9

The minimum work per unit heat transfer of a heat pump is expressed as

$$COP_{HP} = \frac{\dot{Q}_H}{\dot{W}_{net}}$$
$$\dot{W}_{net} = \frac{\dot{Q}_H}{COP_{HP}}$$
$$\dot{W}_{net} = \frac{\left(\frac{140{,}000}{3600}\right)}{19.867}$$
$$\dot{W}_{net} = 1.957 \text{ kW}$$

Step 8 of 9

The cost for electricity if the heat pump takes outside air

$$Cost = \dot{W}_{net} \times 100 \text{ h} \times \$0.085 / \text{kWh}$$
$$Cost = 1.957 \times 100 \text{ h} \times \$0.085 / \text{kWh}$$
$$Cost_B = \$16.64$$

Step 9 of 9

Therefore money saved is

$$\$ = Cost_A - Cost_B$$
$$= \$27.73 - \$16.64$$
$$= \$11.1$$
$$\boxed{\$ = \$11.1}$$

If the heat pump uses lake water it can save \$11.1 for a month.

Question: 7.128P

The cargo space of a refrigerated truck whose inner dimensions are 12 m × 2.3 m × 3.5 m is to be precooled from 25°C to an average temperature of 5°C. The construction of the truck is such that a transmission heat gain occurs at a rate of 80 W/°C. If the ambient temperature is 25°C, determine how long it will take for a system with a refrigeration capacity of 8 kW to precool this truck.

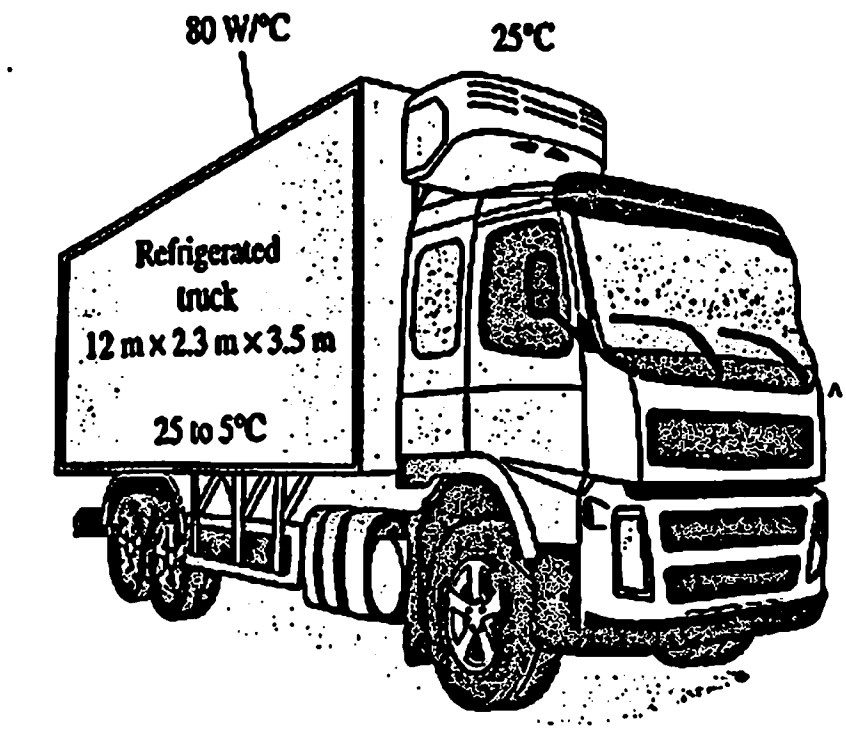


FIGURE P7–128

Step 1 of 6

Given data:

The total volume of the truck, $V = 12 \times 2.3 \times 3.5\ \text{m}^3$

$= 96.6\ \text{m}^3$

The temperature of the ambient air is, $T_1 = 25°\text{C}$

The cooled temperature of the air, $T_2 = 5°\text{C}$

The transmission heat gain into the refrigerator is, 80 W/°C

The cooling capacity of refrigerator is, $\dot{Q}_{ref} = 8\ \text{kW}$

Step 2 of 6

From the properties of air tables at 25^0C is

Specific heat, $c_p = 1.005\ \text{kJ/kg}$

Density of air, $\rho = 1.2\ \text{kg/m}^3$

Step 3 of 6

The amount of heat removed from the truck as the air gets cooled is

$Q_{air} = mc_p\Delta T\ \text{kJ}$

Where m is mass of air in kg

$m = \rho V_{air}\ \text{kg}$

$m = (1.2)(96.6)\ \text{kg}$

$m = 115.9\ \text{kg}$

Step 4 of 6

Therefore the heat removed is

$Q_{air} = mc_p\Delta T\ \text{kJ}$

$Q_{air} = (115.9)(1.005)(25-5)\ \text{kJ}$

$Q_{air} = 2329.99\ \text{kJ}$

Step 5 of 6

The average rate of heat transmission in the truck due to pre-cooling is

$\dot{Q}_{tran} = UA\Delta T\ \text{kW}$

Where U is heat transmission rate 80 W/°C,

Average temperature is $\frac{25+5}{2} = 15°\text{C}$

$\dot{Q}_{tran} = 80(25-15)\ \text{W}$

$\dot{Q}_{tran} = 800\ \text{W}$

$\dot{Q}_{tran} = 0.8\ \text{kW}$

Step 6 of 6

The time taken for refrigerator to cool this truck is

$\dot{Q}_{ref} = \dot{Q}_{tran} + \frac{Q_{air}}{\Delta t}$

$\Delta t = \frac{Q_{air}}{\dot{Q}_{ref} - \dot{Q}_{tran}}\ \text{sec}$

$\Delta t = \frac{2329.99}{8-0.8}$

$\Delta t = 323.6\ \text{s}$

$\Delta t = \frac{323.6}{60}\ \text{min}$

$\Delta t = 5.39\ \text{min}$

Therefore the time taken is $\boxed{\Delta t = 5.39\ \text{min}}$

Question: 7.129P

A refrigeration system is to cool bread loaves with an average mass of 350 g from 30 to −10°C at a rate of 1200 loaves per hour by refrigerated air at −30°C. Taking the average specific and latent heats of bread to be 2.93 kJ/kg·°C and 109.3 kJ/kg, respectively, determine (*a*) the rate of heat removal from the breads, in kJ/h; (*b*) the required volume flow rate of air, in m3/h, if the temperature rise of air is not to exceed 8°C; and (*c*) the size of the compressor of the refrigeration system, in kW, for a COP of 1.2 for the refrigeration system.

Step 1 of 8

Given

The average mass of refrigerant $m = 350\ \text{g} = 0.35\ \text{kg}$.

The higher temperature of the refrigerator $T_2 = 30°\text{C}$.

The lower temperature of the refrigerator $T_1 = -10°\text{C}$.

The temperature of the refrigerant air $T_{air} = -30°\text{C}$.

1200 loves of bread is cooled per hour.

The average specific heat of bread $c = 2.93\ \text{kJ/kg°C}$.

Latent heat $h = 109.3\ \text{kJ/kg}$.

Step 2 of 8

From the ideal gas specific heat of various common gases

The average specific heat of air $c_{p_air} = 1.005\ \text{kJ/kg°C}$

(a) The rate of heat removal from the bread

The mass flow rate of bread

$$\dot{m}_{bread} = \text{no of bread loafs cooled} \times (0.45\ \text{kg/bread})$$

$$\dot{m}_{bread} = 1200 \times (0.35\ \text{kg/bread})$$

$$= 420\ \text{kg/h}$$

$$= \frac{420}{3600}$$

$$= 0.1166\ \text{kg/s}$$

Step 3 of 8

The amount of heat removed from bread is

$$\dot{Q}_{bread} = \dot{m}_{bread} c_p (T_2 - T_1)\ \text{kg/h}$$

$$\dot{Q}_{bread} = 420(2.93)(30 - (-10))\ \text{kg/h}$$

$$\dot{Q}_{bread} = 49,224\ \text{kg/h}$$

Step 4 of 8

The heat produced due to freezing is

$$\dot{Q}_{freezing} = \dot{m}_{bread} h_{latent}\ \text{kJ/h}$$

$$\dot{Q}_{freezing} = (420)(109.3)\ \text{kJ/h}$$

$$\dot{Q}_{freezing} = 45,906\ \text{kJ/h}$$

Step 5 of 8

The total heat removed from the bread

$$\dot{Q}_{total} = \dot{Q}_{bread} + \dot{Q}_{freeze}$$

$$\dot{Q}_{total} = 49224 + 45,906\ \text{kJ/h}$$

$$\boxed{\dot{Q}_{total} = 95,130\ \text{kJ/h}}$$

Step 6 of 8

(b) The volume flow rate, if exceeding 8°C

$$\dot{V}_{air} = \frac{\dot{m}_{air}}{\rho_{air}}\ \text{m}^3\text{/h}$$

The density of air can be determined by ideal gas equation

$$\rho_{air} = \frac{P}{RT}$$

$$= \frac{101.325}{(0.287)(-30 + 273)}$$

$$= 1.45\ \text{kg/m}^3$$

Step 7 of 8

The mass flow rate of air is determined by

$$\dot{Q}_{air} = \dot{m}_{air} c_p \Delta T\ \text{kg/h}$$

The heat released by bread will be absorbed by the refrigerant air

$$95,130 = \dot{m}_{air}(1.005)(8)\ \text{kg/h}$$

$$\dot{m}_{air} = 11,832\ \text{kg/h}$$

The volume flow rate is

$$\dot{V}_{air} = \frac{11,832}{1.45}\ \text{m}^3\text{/h}$$

$$\boxed{\dot{V}_{air} = 8160\ \text{m}^3\text{/h}}$$

Step 8 of 8

(c) The size of the compressor is nothing but the power capacity of the compressor

For a COP of 1.2

We know that

$$COP = \frac{\dot{Q}_{ref}}{\dot{W}_{ref}}$$

$$\dot{W}_{ref} = \frac{\dot{Q}_{ref}}{COP}$$

$$= \frac{95,130}{1.2}$$

$$\dot{W}_{ref} = \frac{79275}{3600}\left(\frac{\text{kJ}}{s}\right)$$

$$\boxed{\dot{W}_{ref} = 22.02\ \text{kW}}$$

Question:

7.130P

The drinking water needs of a production facility with 20 employees is to be met by a bubbler type water fountain. The refrigerated water fountain is to cool water from 22 to 8°C and supply cold water at a rate of 0.4 L per hour per person. Heat is transferred to the reservoir from the surroundings at 25°C at a rate of 45 W. If the COP of the refrigeration system is 2.9, determine the size of the compressor, in W, that will be suitable for the refrigeration system of this water cooler.

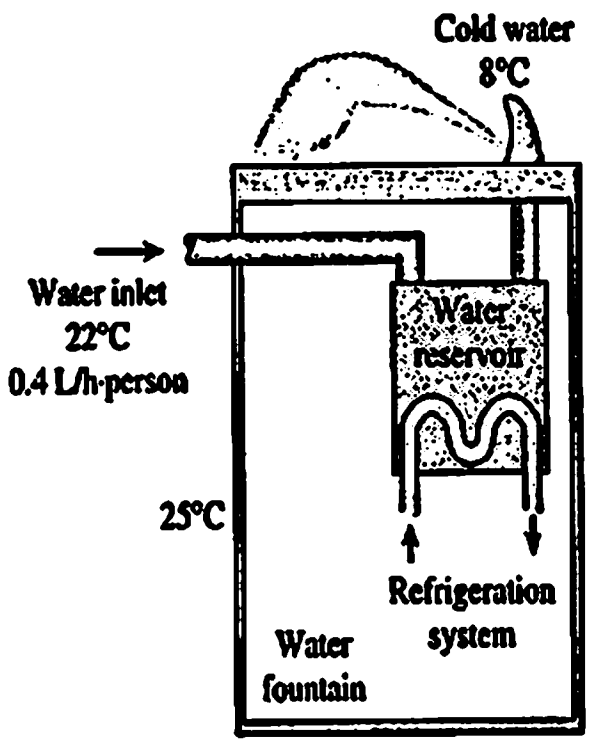

FIGURE P7–130

Step 1 of 5

Given data:
The number of employees in the room = 20
The initial temperature 0f the water, $T_1 = 22°C$
The final temperature of the water, $T_2 = 8°C$
The volume flow rate of the cold water, $\dot{V} = 0.4$ L/h
The amount of heat transferred from the surroundings, $\dot{Q}_{surr} = 45$ W
The COP of the refrigerator system is 2.9

Step 2 of 5

From properties of water tables,
Taking the specific heat of water $c = 4.18$ kJ/kg°C,
The density of water $\rho = 1000$ kg/m^3
The amount of heat removed from water
$\dot{Q}_{water} = \dot{m}c(T_2 - T_1)$ kW

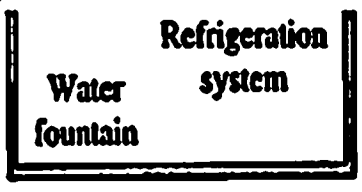

FIGURE P7–130

Step 1 of 5

Given data:
The number of employees in the room = 20
The initial temperature 0f the water, $T_1 = 22°C$
The final temperature of the water, $T_2 = 8°C$
The volume flow rate of the cold water, $\dot{V} = 0.4$ L/h
The amount of heat transferred from the surroundings, $\dot{Q}_{surr} = 45$ W
The COP of the refrigerator system is 2.9

Step 2 of 5

From properties of water tables,
Taking the specific heat of water $c = 4.18$ kJ/kg°C,
The density of water $\rho = 1000$ kg/m^3
The amount of heat removed from water
$\dot{Q}_{water} = \dot{m}c(T_2 - T_1)$ kW

For a COP of 2.9
We know that

$$COP = \frac{\dot{Q}_{ref}}{\dot{W}_{ref}}$$

$$\dot{W}_{ref} = \frac{\dot{Q}_{total}}{COP}$$
$$= \frac{0.175}{2.9}$$
$$= 0.0603 \text{ kW}$$
$$= 60.3 \text{ W}$$

$$\boxed{\dot{W}_{ref} = 60.3 \text{ W}}$$

The power needed to the run the compressor may be greater than 60.3 W to meet the requirement

Question:

7.131P

The "Energy Guide" label on a washing machine indicates that the washer will use $33 worth of hot water if the water is heated by a gas water heater at a natural gas rate , of $1.21/therm. If the water is heated from 60 to 130°F, determine how many gallons of hot water an average family uses per week. Disregard the electricity consumed by the washer, and take the efficiency of the gas water heater to be 58 percent.

Step 1 of 5

Given data:

The thermal efficiency of the gas heater $\eta_{th} = 58\%$

The amount of electricity consumed in a year is $ 33

The amount of natural gas consumed in a year is $1.21/therm

The initial temperature of the water, $T_1 = 60°F$

The final temperature of the water, $T_2 = 130°F$

Step 2 of 5

From the properties of common liquids, solids, and foods tables taking properties of water

The density of water at room temperatures is, $\rho = 62.11 \text{lbm/ft}^3$

Specific heat, $c = 1 \text{ Btu/lbm} \cdot °F$

The amount of electricity consumed to heat water in a year is

$$= \frac{\text{Total Cost}}{\text{Unit Cost}}$$

$$= \frac{\$\ 33/\text{year}}{\$\ 1.21/\text{therm}}$$

$$= 27.2727 \text{ Therm/year}$$

Step 3 of 5

The energy transferred to water is

$$\dot{E}_{in} = \eta \times \text{Total energy}$$

$$\dot{E}_{in} = 0.58(27.2727) \text{ therm/year}$$

For a week

$$\dot{E}_{in} = 0.58(27.2727) \text{ therm/year}\left(\frac{100{,}000 \text{ Btu}}{1 \text{ therm}}\right)\left(\frac{1 \text{ Year}}{52 \text{ weeks}}\right)$$

$$\dot{E}_{in} = 30{,}419.58 \text{Btu/week}$$

Step 4 of 5

The energy transferred is expressed as

$$\dot{E}_{in} = \dot{m}c(T_2 - T_1)\text{Btu}$$

Where m is the mass flow rate of hot water supplied to the heater

Therefore

$$\dot{m} = \frac{\dot{E}_{in}}{c(T_2 - T_1)}\text{Btu}$$

$$\dot{m} = \frac{30{,}419.58}{1 \times (130 - 60)}\text{Btu/week}$$

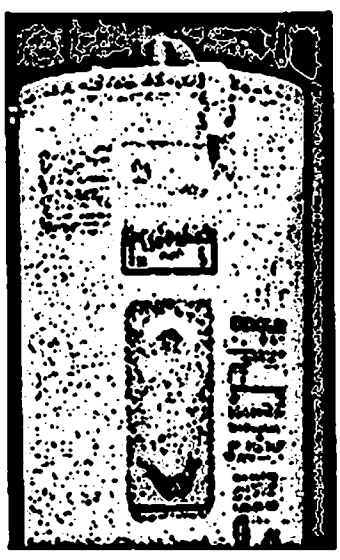
$$\dot{m} = 434.56 \text{ Btu/week}$$

Step 5 of 5

The amount of flow supplied is the volume flow rate of hot water

$$\dot{V}_{hot} = \frac{\dot{m}\ \text{lbm/week}}{\rho\ \text{lbm/ft}^3} \quad (7.48 \text{ gallons} = 1 \text{ ft}^3)$$

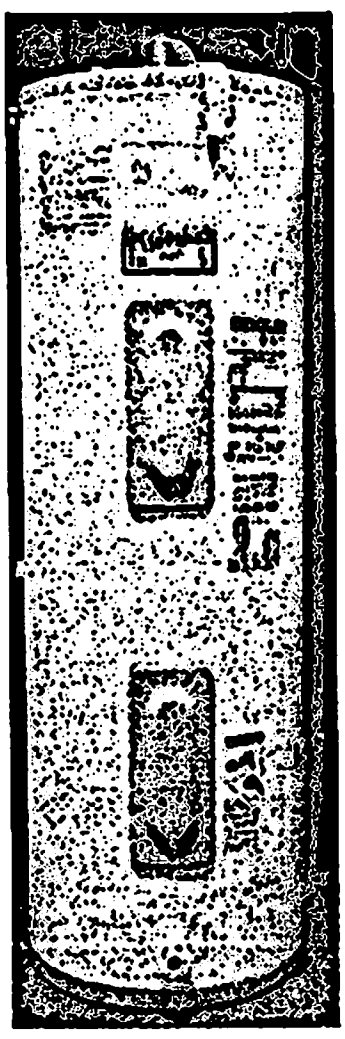
$$\dot{V}_{hot} = \frac{434.56}{62.1}\left(\frac{7.48 \text{ gal}}{1 \text{ ft}^3}\right)$$



$$\boxed{\dot{V}_{hot} = 52.34 \text{ gal/week}}$$

On an average 52 gallons of hot water is used for washing cloths in a week

Question:



7.132P

A typical electric water heater has an efficiency of 95 percent and costs $250 a year to operate at a unit cost of electricity of $0.08/kWh. A typical heat pump-powered water heater has a COP of 3.3 but costs about $800 more to install. Determine how many years it will take for the heat pump water heater to pay for its cost differential from the energy it saves.

Question:

A typical electric water heater has an efficiency of 95 percent and costs $250 a year to operate at a unit cost of electricity of $0.08/kWh. A typical heat pump-powered water heater has a COP of 3.3 but costs about $800 more to install. Determine how many years it will take for the heat pump water heater to pay for its cost differential from the energy it saves.

Water heater

Jill Braaten, photographer.

FIGURE P7–132

Step 1 of 6

Loading solution. Please wait ...

Step 2 of 6

From the properties of common liquids, solids and foods
For water

Specific heat of water $c = 4.18 \frac{kJ}{kg \cdot {}^{\circ}C}$,

The density of water $\rho = 1000 \frac{kg}{m^3}$

The amount of electricity consumed by the water heater in a year is

$$= \frac{\text{Total Cost}}{\text{Unit Cost}}$$

$$= \frac{\$\,250}{\$\,0.08}$$

$$= 3125 \frac{kWh}{year}$$

Step 3 of 6

The energy transferred to water is

$$\dot{E}_{in} = \eta \times \text{Total energy}$$

$$\dot{E}_{in} = 0.95 \times 3125 \frac{kWh}{year}$$

$$\dot{E}_{in} = 2968.75 \frac{kWh}{year}$$

Step 4 of 6

The energy consumed by the heat pump in a year is expressed as

$$= \frac{\text{Energy observed by water}}{\text{COP}}$$

$$= \frac{2968.75}{3.3}$$

So if we use a heat pump, it will take approx 7.7 years to repay the amount.

Question: 7.133P

Reconsider Prob. 7–132. Using EES (or other) software, investigate the effect of the heat pump COP on the yearly operation costs and the number of years required to break even. Let the COP vary from 2 to 5. Plot the payback period against the COP and discuss the results.

We don't have the solution to this problem yet.

Question: 7.134P

A homeowner is trying to decide between a high-efficiency natural gas furnace with an efficiency of 97 percent and a ground-source heat pump with a COP of 3.5. The unit costs of electricity and natural gas are \$0.092/kWh and \$1.42/therm (1 therm = 105,500 kJ). Determine which system will have a lower energy cost.

Step 1 of 3

Given data:
The thermal efficiency of furnace, $\eta = 97\%$
The heat pump, COP = 3.5
Unit cost of electricity for heat pump, \$0.092/kWh
Unit cost of natural gas for furnace, \$1.42/therm
1 therm = 105,500 kJ

Step 2 of 3

For a natural gas furnace

$$\text{Unit cost} = \frac{\$1.42}{0.97}\left(\frac{1\,\text{therm}}{105{,}500}\right)$$
$$= \$1.3876\times10^{-5}/\text{kJ}$$

Step 3 of 3

For heat pump

$$\text{Unit cost} = \frac{\$0.092}{3.5}\left(\frac{1\,\text{kWh}}{3600}\right)$$
$$= \$0.73\times10^{-5}/\text{kJ}$$

So the system have a lower energy cost is the heat pump

Question: 7.135P

Cold water at 10°C enters a water heater at the rate of 0.02 m3/min and leaves the water heater at 50°C. The water heater receives heat from a heat pump that receives heat from a heat source at 0°C.

(a) Assuming the water to be an incompressible liquid that does not change phase during heat addition, determine the rate of heat supplied to the water, in kJ/s.

(b) Assuming the water heater acts as a heat sink having an average temperature of 30°C, determine the minimum power supplied to the heat pump, in kW.

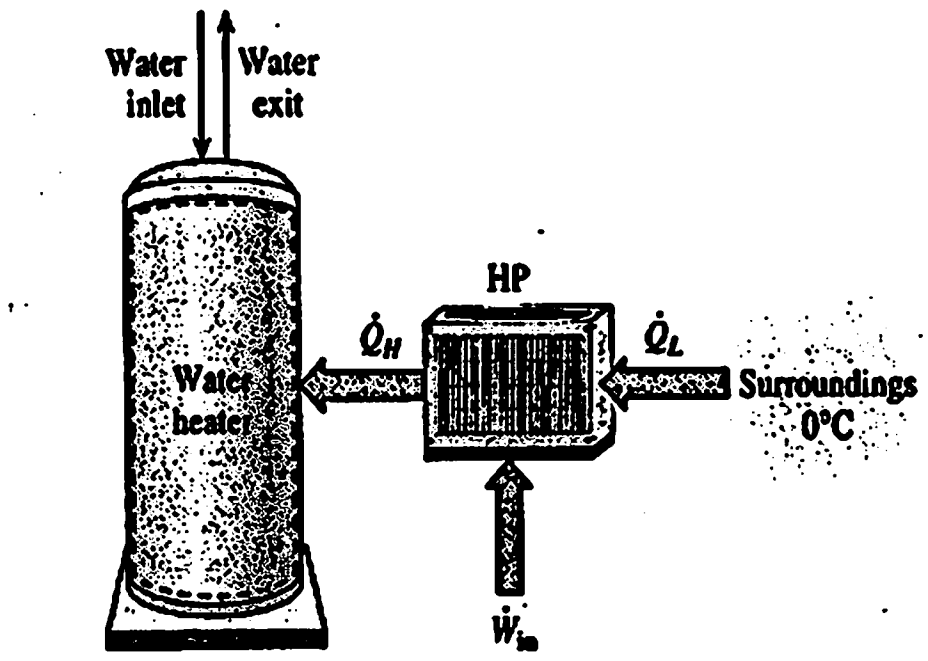

FIGURE P7–135

Step 1 of 5

Given data:

Initial temperature of water, $T_1 = 10°C$

$= 10 + 273$

$= 283K$

Final temperature of water, $T_2 = 50°C$

$= 50 + 273$

$= 323K$

The volume flow rate of cold water, $\dot{V} = 0.02\ m^3/min$

The temperature of the sink for heat pump is $T_L = 0°C$

$= 0 + 273$

$= 273K$

Step 2 of 5

(a) The amount of heat supplied to the water is determined from the energy balance

$\dot{Q}_H = \dot{m} c_p (T_2 - T_1)$ kW

Taking properties of water from properties of common liquids tables

The specific heat of water, $c = 4.18$ kJ/kg°C

The density of water, $\rho = 1000\ kg/m^3$

Where the mass of cold water is expressed as

$\dot{m}_{water} = \rho \dot{V}$ kg/s

$$\dot{m}_{water} = \left(1000 kg/m^3\right)\left(0.02 m^3/min\right)\left(\frac{1}{60\ s}\right) kg/s$$

$\dot{m}_{water} = 0.334$ kg/s

Step 3 of 5

Therefore the heat supplied to water is

$\dot{Q}_H = (0.334)(4.18)(323 - 283)$ kJ/s

$\dot{Q}_H = 55.84$ kJ/s

∴ The rate of heat supplied $\boxed{\dot{Q}_H = 55.84 \text{ kJ/s}}$

Step 4 of 5

(b) The power supplied to heat pump

The temperature of heat source of a heat pump $T_H = 30°C$

$= 30 + 273$

$= 303K$

The COP of a reversible heat pump is expressed as

$$COP_{max} = \frac{T_H}{T_H - T_L}$$

$$COP_{max} = \frac{303}{303 - 273}$$

$COP_{max} = 10.1$

Step 5 of 5

The minimum power input to the heat pump

$$COP_{max} = \frac{\dot{Q}_H}{\dot{W}_{in}}$$

$$\dot{W}_{in} = \frac{55.84}{10.1}$$

$\dot{W}_{in} = 5.528$ kW

∴ The power input is $\boxed{\dot{W}_{in} = 5.528 \text{ kW}}$

Question: 7.136P

A heat pump receives heat from a lake that has an average winter time temperature of 6°C and supplies heat into a house having an average temperature of 27°C.

(*a*) If the house loses heat to the atmosphere at the rate of 64,000 kJ/h, determine the minimum power supplied to the heat pump, in kW.

(*b*) A heat exchanger is used to transfer the energy from the lake water to the heat pump. If the lake water temperature decreases by 5°C as it flows through the lake water-to-heat pump heat exchanger, determine the minimum mass flow rate of lake water, in kg/s. Neglect the effect of the lake water pump.

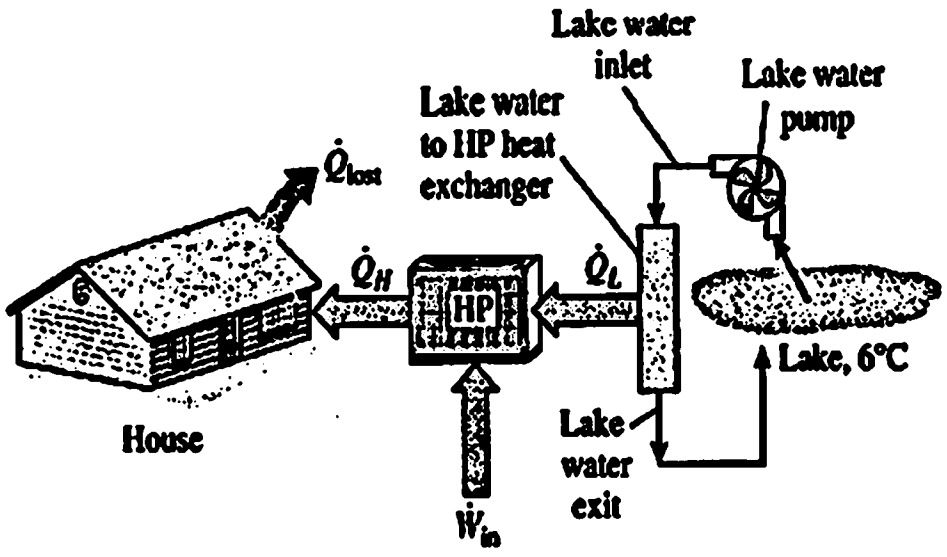

FIGURE P7–136

Step 1 of 6

Given data:

The temperature of heat source of a heat pump $T_H = 27°C$

$= 27 + 273$

The temperature of sink of a heat pump is, $T_L = 6°C$

$= 6 + 273$

$= 279K$

Step 2 of 6

(a) The power supplied to heat pump

The heat lost to the atmosphere, $\dot{Q}_H = 64{,}000$ kJ/h

The COP of a reversible heat pump is expressed as

$$COP_{max} = \frac{T_H}{T_H - T_L}$$

$$COP_{max} = \frac{300}{300 - 279}$$

$$COP_{max} = 14.3$$

Step 3 of 6

The minimum power input to the heat pump

$$COP_{max} = \frac{\dot{Q}_H}{\dot{W}_{in}}$$

$$\dot{W}_{in} = \frac{64000/3600}{14.3}$$

$$\dot{W}_{in} = 1.243 \text{ kW}$$

∴ The minimum power supplied, $\boxed{\dot{W}_{in} = 1.243 \text{ kW}}$

Step 4 of 6

(b)The minimum mass flow rate of lake

The rate of heat absorbed by the lake is

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{in}$$

$$\dot{Q}_L = 64000 \text{ kJ/h} - 1.243 \text{ kJ/s}$$

$$\dot{Q}_L = 64000\left(\frac{1 \text{ h}}{3600 \text{ s}}\right) \text{kJ/s} - 1.243 \text{ kJ/s}$$

$$\dot{Q}_L = 16.53 \text{ kJ/s}$$

Step 5 of 6

The amount of heat supplied to the water is determined from the energy balance

$$\dot{Q}_L = \dot{m}c(T_2 - T_1) \text{ kW}$$

From the properties of common liquids, solids, and foods tables taking properties of water

The specific heat of water, $c = 4.18$ kJ/kg°C

The density of water, $\rho = 1000$ kg/m^3

Given the change in temperature of the lake water is 5°C

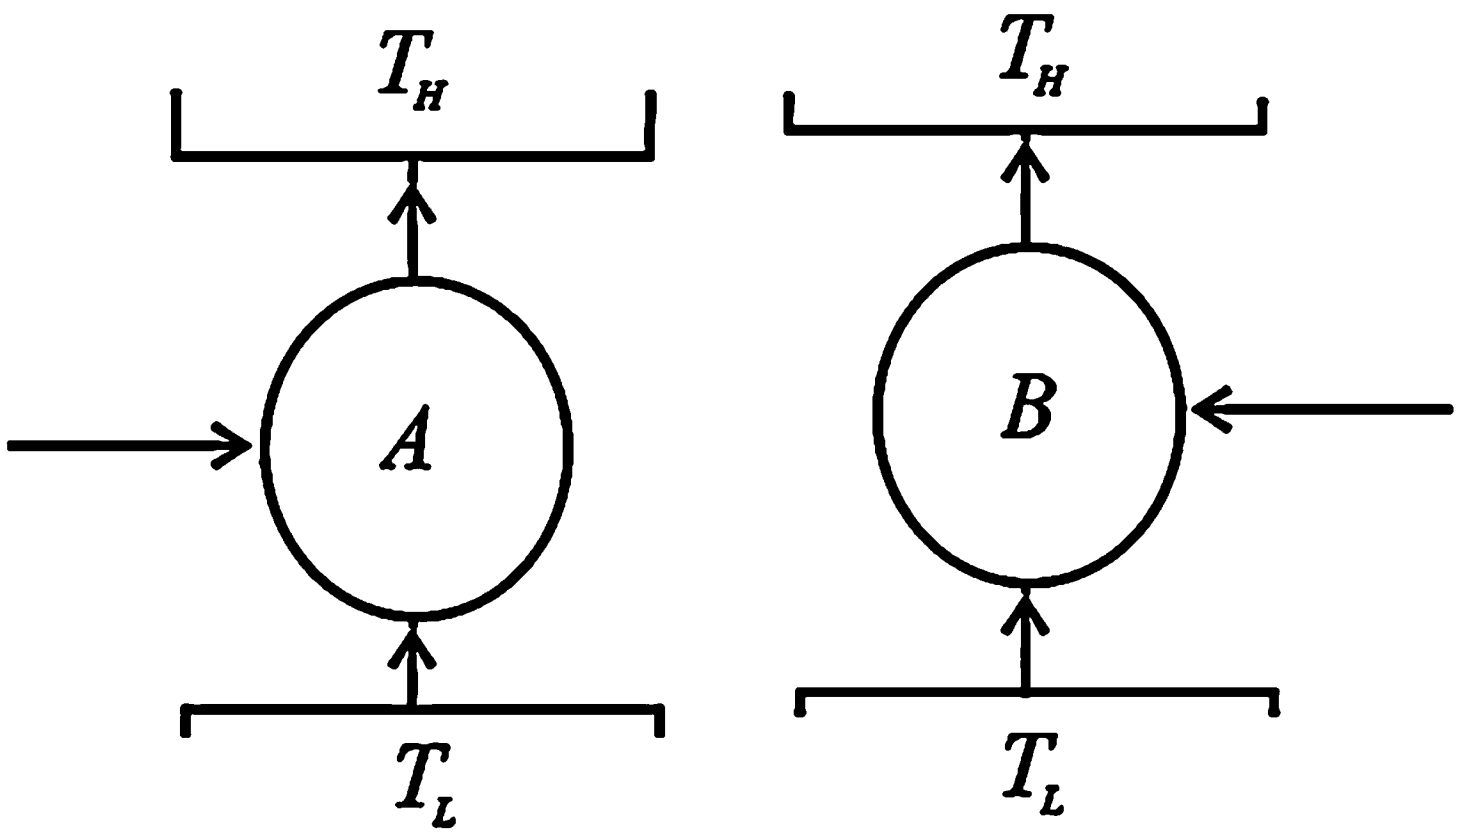
Step 6 of 6

Where the $\dot{m}$ is the mass flow rate of lake water

$$16.53 = \dot{m}(4.18)(5) \text{ kW}$$

$$\dot{m} = \frac{16.53}{(4.18)(5)} \text{ kg/s}$$

$$\dot{m} = 0.791 \text{ kg/s}$$



∴ The minimum mass flow rate of lake water, $\boxed{\dot{m} = 0.791 \text{ kg/s}}$

Question: 7.137P

Prove that a refrigerator's COP cannot exceed that of a completely reversible refrigerator that shares the same thermal energy reservoirs.

Step 1 of 4

Consider two refrigerators A and B with completely reversible and irreversible characteristics respectively.

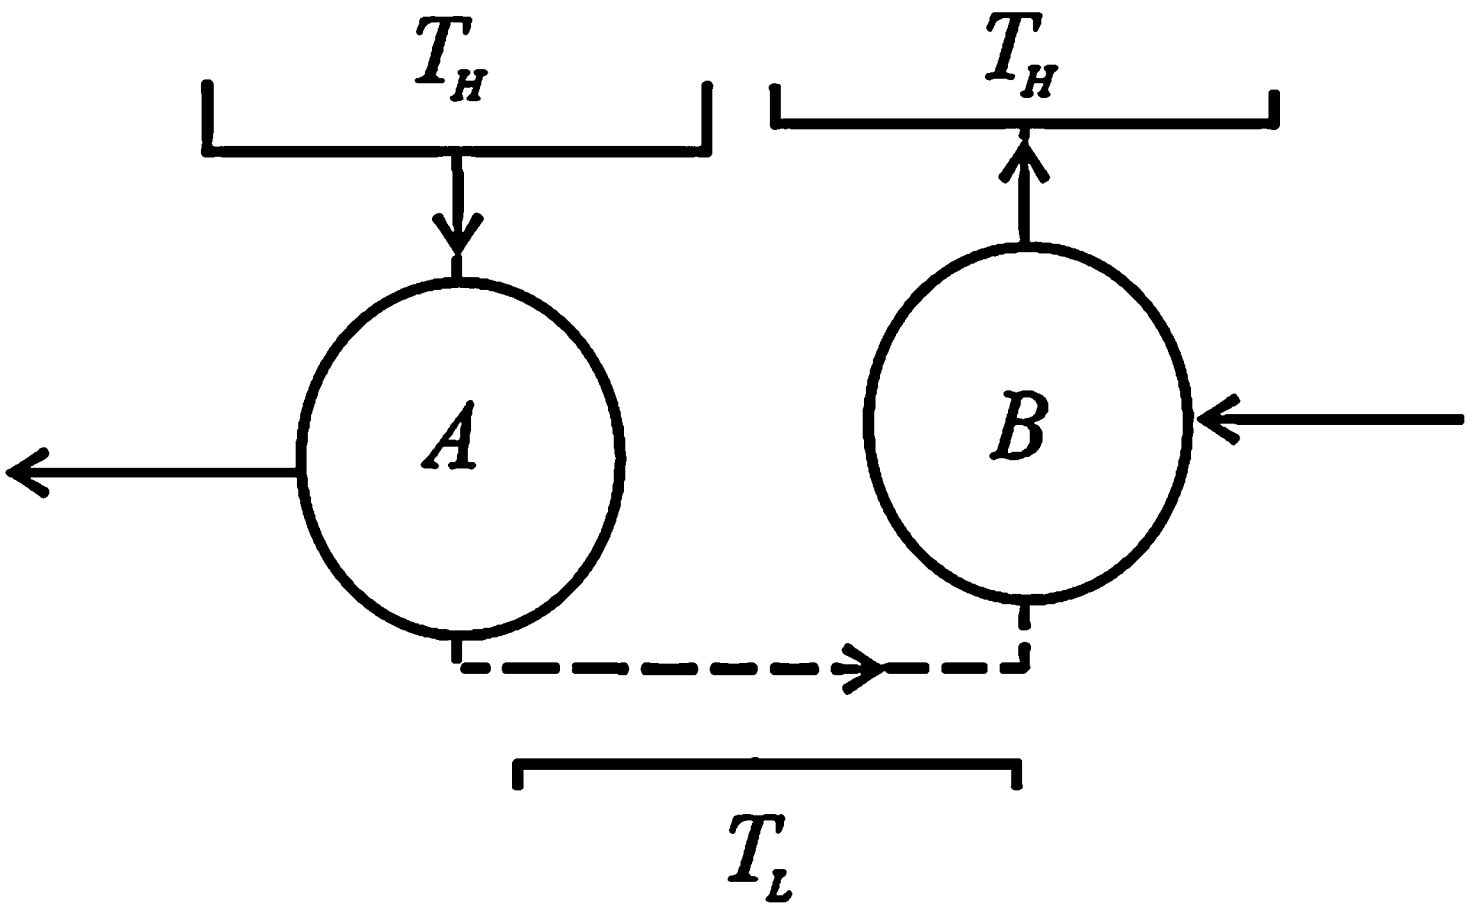
Assume the COP of the general refrigerator B is greater than that of a completely reversible refrigerator A.
i.e. $COP_B > COP_A$

Step 2 of 4

From the definition of COP of a refrigerator, we get

$$\frac{Q_L}{W_B} > \frac{Q_L}{W_A}$$

$$W_B < W_A$$



Hence, the work required to drive refrigerator B is less than needed to drive reversible refrigerator A.

Also note that from the first law, assuming the same cooling effect Q_L, the heat rejected by the refrigerators is equal to

$$Q_{H_B} < Q_{H_A}$$

Step 3 of 4

Since A is a completely reversible refrigerator, we can reverse it without changing the magnitude of the heat and work transfers. The heat Q_L, which is rejected by the reversed refrigerator A can now be routed directly to refrigerator B as shown below

Thus, no heat is to be exchanged with the T_L reservoir. The magnitude of the heat supplied to the reversed refrigerator A, Q_{H_A} has been shown to be larger than that rejected by refrigerator B.

Step 4 of 4

Upon observation, there is then a net heat transfer from the T_H reservoir to the combined device whose magnitude is given by $Q_{H_B} - Q_{H_A}$. Similarly, there is a net work production by the combined device whose magnitude is given by $W_B - W_A$

The combined cyclic device then exchanges heat with a reservoir at a single temperature and produces work which is clearly a violation of the Kelvin-Planck statement of the second law.

Therefore the assumption of $COP_B > COP_A$ is wrong. A refrigerator's COP cannot exceed the COP of a completely reversible refrigerator when operating between the same temperature limits.

Question: 7.138P

Prove that the COP of all completely reversible refrigerators must be the same when the reservoir temperatures are the same.

Step 1 of 2

Initially consider the COP of the general refrigerator *A* is lesser than that of the refrigerator *B*.

$$\mathrm{COP}_A < \mathrm{COP}_B \quad \text{..... (1)}$$

Write the relation for COP of refrigerator *A*.

$$\mathrm{COP}_A = \frac{Q_L}{W_A}$$

Here, Q_L is the heat rejected and W_A is the work done by the refrigerator *A*.

Write the relation for COP of refrigerator *B*.

$$\mathrm{COP}_B = \frac{Q_L}{W_B}$$

Here, W_B is the work done by the refrigerator *B*.

Substitute COP's of refrigerators *A* and *B* in equation (1).

$$\frac{Q_L}{W_A} < \frac{Q_L}{W_B}$$

$$W_A > W_B$$

Thus, the work required to drive refrigerator *B* needs more to drive reversible refrigerator *A*.

Step 2 of 2

Obtain the relation by using the first law of thermodynamics to both the refrigerators.

$$Q_{H_A} > Q_{H_B}$$

The magnitude of heat transfer and the magnitude of work transfer because refrigerator *A* is a completely reversible refrigerator.

The heat rejected by the reversed refrigerator *A*, Q_L is routed directly to refrigerator *B*. In this process no heat is exchanged with the reservoir at temperature T_L is the net effect and the magnitude of the heat supplied to the reversed refrigerator *A*, Q_{H_A} is larger than heat rejected by refrigerator *B* which results in a net heat transfer of magnitude $Q_{H_A} - Q_{H_B}$ from the reservoir at a temperature T_H to the combined device.

Similarly, net-work of magnitude $W_A - W_B$ is produced by the combined device. Now the combined cyclic device exchanges heat with a reservoir at a single temperature and produces work violating the Kelvin-Planck statement of the second law.

This clearly states that the assumption of $\mathrm{COP}_A < \mathrm{COP}_B$ is wrong and the assumption is correct only when the reservoir temperatures are the same.

Therefore, the COP of all completely reversible refrigerators will be the same.

Question: 7.139P

Derive an expression for the COP of a completely reversible heat pump in terms of the thermal energy reservoir temperatures, *TL*and *TH*.

Step 1 of 4

Let the higher thermal reservoir is T_H

The lower thermal reservoir is T_L

Step 2 of 4

The COP of a heat pump is expressed as

$$\text{COP}_{HP} = \frac{\text{Desired output}}{\text{input}}$$

$$\text{COP}_{HP} = \frac{Q_H}{W_{net,in}}$$

From first law of thermodynamics we know that

$$W_{net} = Q_H - Q_L$$

Substituting in above relation

$$\text{COP}_{HP} = \frac{Q_H}{Q_H - Q_L}$$

$$\text{COP}_{HP} = \frac{1}{1 - Q_L / Q_H}$$

Step 3 of 4

From seconding of thermodynamics, for a reversible heat pump the temperatures are expressed as

$$\frac{Q_H}{Q_L} = \frac{T_H}{T_L}$$

Substituting in the COP expression

$$\text{COP}_{HP} = \frac{1}{1 - T_L / T_H}$$

$$\text{COP}_{HP} = \frac{T_H}{T_H - T_L}$$

Step 4 of 4

The COP of a reversible heat pump depends on the temperature limits in the cycle only, and is determined from

$$\text{COP}_{HP} = \frac{T_H}{T_H - T_L}$$

∴ The expression for COP $\boxed{\text{COP}_{HP} = \frac{T_H}{T_H - T_L}}$

Question:

7.140P

A Carnot heat engine is operating between a source at *TH* and a sink at *TL*. If it is desired to double the thermal efficiency of this engine, what should the new source temperature be? Assume the sink temperature is held constant.

Step 1 of 1

The Carnot heat engine operating between source temperature T_H and sink T_L has thermal efficiency

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

The thermal efficiency gets doubled with sink temperature remaining constant

$$\eta_{th_new} = 1 - \frac{T_L}{T_{H_new}}$$

$$\eta_{th_new} = 2\eta_{th}$$

$$1 - \frac{T_L}{T_{H_new}} = 2\left(1 - \frac{T_L}{T_H}\right)$$

$$1 - \frac{T_L}{T_{H_new}} = 2 - 2\frac{T_L}{T_H}$$

$$2\frac{T_L}{T_H} - \frac{T_L}{T_{H_new}} = 1$$

$$\frac{2T_L\left(T_{H_new}\right) - T_L T_H}{T_H T_{H_new}} = 1$$

$$\frac{T_{H_new}\left(2T_L - \dfrac{T_L T_H}{T_{H_new}}\right)}{T_H T_{H_new}} = 1$$

$$\frac{\left(2T_L - \dfrac{T_L T_H}{T_{H_new}}\right)}{T_H} = 1$$

$$2T_L - T_H = \frac{T_L T_H}{T_{H_new}}$$

$$T_{H_new} = \frac{T_L T_H}{2T_L - T_H}$$

∴ The new source temperature is $\boxed{T_{H_new} = \dfrac{T_L T_H}{2T_L - T_H}}$

CHAPTER 08

SOLUTIONS

Question: 8.001P

Does the cyclic integral of work have to be zero (i.e., does a system have to produce as much work as it consumes to complete a cycle)? Explain.

Step 1 of 1

No, the cyclic integral of work need not be zero. For a cycle the system can produce less or more amount of work than it receives. The difference is the network output.

So, the cyclic integral of *work* is not zero. Otherwise, heat engines that work on a cycle such as steam power plants would produce zero net-work.

Question: 8.002P

A system undergoes a process between two fixed states first in a reversible manner and then in an irreversible manner. For which case is the entropy change greater? Why?

Step 1 of 1

Entropy is a property. Like all other properties it has fixed values at fixed states. Therefore, the Entropy change between two specified states is same no matter what path is. It can be reversible or irreversible. So, in this case the entropy change will be same in both the cases.

Question: 8.003P

Is the value of the integral $\int_1^2 \delta Q/T$ the same for all processes between states 1 and 2? Explain.

Step 1 of 1

No.

Reason: Depending upon the process the integral value may vary for an irreversible process. If it is a reversible process the integral value will be same for all the states.

Note that the integral of dQ/T gives us the value of entropy change only if the integration is carried out along an internally reversible path between the two states. The Entropy change between two specified states is same no matter what path is.

The integral of dQ/T along an irreversible path is not a property, and in general, different values will be obtained when the integration is carried out along different irreversible paths.

Question: 8.004P

To determine the entropy change for an irreversible process between states 1 and 2, should the integral $\int_1^2 \delta Q/T$ be performed along the actual process path or an imaginary reversible path? Explain.

Step 1 of 1

The integral value of $\delta Q/T$ gives the value of entropy change if the integration is carried out along an internally reversible path between two states. The integral value of $\delta Q/T$ along an irreversible path is not a property. So, different values will be obtained when integration is carried out on different irreversible paths. Therefore, even for irreversible process entropy change should be determined by carrying out this integration along some convenient imaginary internally reversible path between the specified states.

Question: 8.005P

Is an isothermal process necessarily internally reversible? Explain your answer with an example.

Step 1 of 1

No.

Reason: An isothermal process need not be internally reversible. It can be irreversible also. Consider a cylinder containing water. It is receiving 100KJ of heat and at the same time its losing same amount of heat to the external environment. This is an irreversible isothermal process

Question: 8.006P

How do the values of the integral $\int_1^2 \delta Q/T$ compare for a reversible and irreversible process between the same end states?

Step 1 of 1

For the same states the value of the given integral is always greater for reversible process.

Explanation: The integral of dQ/T gives us the value of entropy change only if the integration is carried out along an internally reversible path between the two states.

The relation can be expressed as $dS \geq \frac{\delta Q}{T}$.

Where, the equality holds for an internally reversible process and the inequality for an irreversible process. We may conclude from these equations that the entropy change of a closed system during an irreversible process is greater than the integral of dQ/T evaluated for that process.

Question: 8.007P

The entropy of a hot baked potato decreases as it cools. Is this a violation of the increase of entropy principle? Explain.

Step 1 of 1

No.

Reason: This is not a violation of the increase of entropy principle. As the potato cools, the air surrounding gains heat and its entropy increase even more. This makes the total entropy change positive.

Question: 8.008P

Is it possible to create entropy? Is it possible to destroy it?

Step 1 of 1

The entropy can be created but it cannot be destroyed.
Explanation: The property entropy is a measure of molecular disorder or randomness of a system, and the second law of thermodynamics states that entropy can be created but it cannot be destroyed.

Question: 8.009P

When a system is adiabatic, what can be said about the entropy change of the substance in the system?

Step 1 of 1

$\Delta S \geq 0$

If the system goes through a reversible process, the entropy of the system remains same as there is not heat transfer. If it is an irreversible process the entropy must increase. In other words, it never decreases. In the absence of any heat transfer, entropy change is due to irreversibility's only, and their effect is always to increase entropy

Question: 8.010P

Work is entropy free, and sometimes the claim is made that work will not change the entropy of a fluid passing through an adiabatic steady-flow system with a single inlet and outlet. Is this a valid claim?

Step 1 of 1

Only those processes that are reversible adiabatic, will keep the entropy unaltered. So the claim that work will not change the entropy of a fluid passing through a reversible adiabatic steady flow system is true. But in real, no process is reversible and hence the entropy of a fluid will always increase.

Question: 8.011P

A piston-cylinder device contains helium gas. During a reversible, isothermal process, the entropy of the helium will (*never* , *sometimes* , *always*) increase.

Step 1 of 1

Entropy of a reversible adiabatic process is constant. But for reversible isothermal process, the entropy may increase sometimes. This is because isothermal process can exchange heat with surroundings.

Question: 8.012P

A piston-cylinder device contains nitrogen gas. During a reversible, adiabatic process, the entropy of the nitrogen will (*never* , *sometimes* , *always*) increase.

Step 1 of 1

As it is a reversible adiabatic process the entropy will never increase.

$\Rightarrow \Delta S = 0$

Question: 8.013P

A piston-cylinder device contains superheated steam. During an actual adiabatic process, the entropy of the steam will (*never* , *sometimes* , *always*) increase.

Step 1 of 1

The entropy always increases as actual processes are never reversible. They are always irreversible.

$\Rightarrow \Delta S > 0$

Question:

8.014P

The entropy of steam will (*increase* , *decrease* , *remain the same*) as it flows through an actual adiabatic turbine.

Step 1 of 1

The entropy of this system always increases as actual processes are never reversible.

$\Rightarrow \Delta S > 0$

Question: 8.015P

The entropy of the working fluid of the ideal Carnot cycle (*increases, decreases, remains the same*) during the isothermal heat addition process.

Step 1 of 1

The heat is adding here but the temperature remains same (isothermal process) so, the entropy increases.

Question: 8.016P

The entropy of the working fluid of the ideal Carnot cycle (*increases, decreases, remains the same*) during the isothermal heat rejection process.

Step 1 of 1

The heat is rejected here but the temperature remains same so, the entropy decreases

Question: 8.017P

During a heat transfer process, the entropy of a system (*always* , *sometimes* , *never*) increases.

Step 1 of 1

The direction of entropy transfer is the same as the direction of heat transfer since the thermodynamic temperature T is always a positive quantity.

The heat transfer into the system increases the entropy, whereas the heat transfer out of the system decreases the entropy.

Hence, the entropy of a system increases some times.

Question: 8.018P

Steam is accelerated as it flows through an actual adiabatic nozzle. The entropy of the steam at the nozzle exit will be (*greater than* , *equal to* , *less than*) the entropy at the nozzle inlet.

Step 1 of 1

As it is irreversible adiabatic process, entropy will increase. So the entropy at the nozzle exit is greater than that of inlet.

Question: 8.019P

Is it possible for the entropy change of a closed system to be zero during an irreversible process? Explain.

Step 1 of 1

Yes

Reason: It can be zero. Consider a system losing heat. The entropy should decrease as its losing heat. But, if the decrease in the entropy is same the increase due to the irreversibility's then the total increase in entropy can be zero.

Question: 8.020P

What three different mechanisms can cause the entropy of a control volume to change?

Step 1 of 1

The three different mechanisms that cause the entropy of a control volume to change are

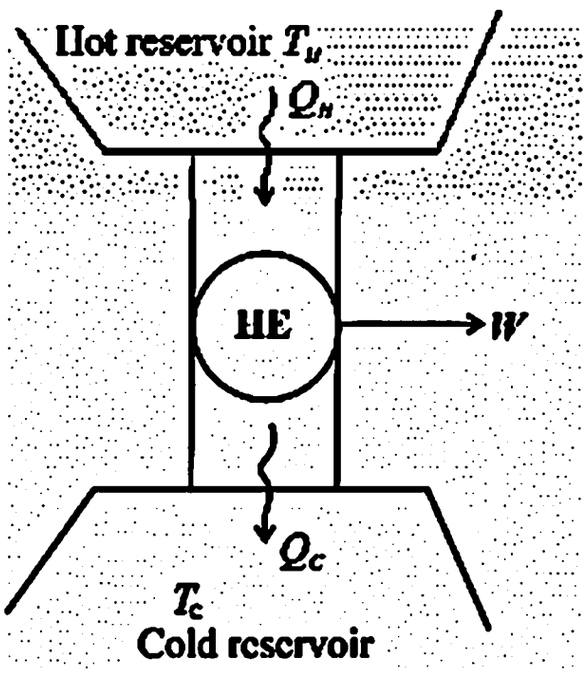
- Heat transfer
- Irreversibilities
- Entropy transport with mass

Question:

8.021P

A completely reversible heat engine operates with a source at 1500 R and a sink at 500 R. If the entropy of the sink increases by 10 Btu/R, how much will the entropy of the source decrease? How much heat, in Btu, is transferred from the source?

Step 1 of 3



Given

Source temperature is, $T_{source} = T_H = 1500\ \text{R}$

Sink temperature is, $T_{sink} = T_C = 500\ \text{R}$

Entropy of the sink increases by $\Delta S_{sink} = 10\ \text{Btu/R}$

Step 2 of 3

Step 3 of 3

As it is given that the heat engine is reversible, the entropy generation will be zero. So,

$S_{gen} = \Delta S_{source} + \Delta S_{sink}$

$0 = \Delta S_{source} + \Delta S_{sink}$

$\Delta S_{source} = -\ \Delta S_{sink}$

$\Delta S_{source} = -\ 10\ \text{Btu/R}$

The entropy change in the source can be given by

$$\Delta S_{source} = \frac{Q_{source}}{T_{source}}$$

Therefore the heat transfer from the source is given by

$Q_{source} = \Delta S_{source} \times T_{source}$

$Q_{source} = -10 \times 1500$

$\boxed{Q_{source} = -15000\ \text{Btu}}$

Therefore the heat transfer from the source is 15000 Btu

Question: 8.022P

An energy-source at 1000 K transfers heat to a completely reversible heat engine. This engine transfers heat to a sink at 300 K. How much heat must be transferred from the energy-source to increase the entropy of the energy-sink by 20 kJ/K?

Step 1 of 5

Given data:

Source temperature of the heat engine, $T_1 = 1000\ \text{K}$

Sink temperature of the heat engine, $T_2 = 300\ \text{K}$

Increased entropy for sink, $20\ \text{kJ/K}$

Step 2 of 5

Let

The Heat transferred for sink be Q_1

The Heat transferred for sink be Q_2

Change of entropy be Δs

Reversible process, the change of entropy becomes zero, $\Delta s = 0$

For reversible process,

$$\frac{Q_1}{T_1} + \frac{Q_2}{T_2} = \Delta s \quad \text{..... (1)}$$

Since heat transferred for sink be increased by $20\ \text{kJ/K}$, so equation (1), can be re written as

$$\frac{Q_1}{T_1} + \frac{Q_2 + 20}{T_2} = 0 \quad \text{..... (2)}$$

Step 3 of 5

Substituting T_1 and T_2 in equation (2), we get

$$\frac{Q_1}{1000} + \frac{Q_2 + 20}{300} = 0$$

$$300Q_1 + 1000Q_2 + 2000 = 0 \quad \text{..... (3)}$$

As we know that,

$$\frac{Q_1}{Q_2} = \frac{T_1}{T_2}$$

$$Q_1 = \frac{T_1}{T_2} \times Q_2$$

$$Q_1 = \frac{1000}{300} Q_2$$

$$Q_1 = 3.333 Q_2 \quad \text{..... (4)}$$

Step 4 of 5

Substituting Q_1 in equation (3), we get

$$300 \times 3.33 Q_2 + 1000 Q_2 + 20000 = 0$$

$$1999 Q_2 = -20000$$

$$Q_2 = \frac{-20000}{1999}$$

$$= -10.005\ \text{kJ}$$

Step 5 of 5

Substituting Q_2 value in equation (4), we get

$$Q_1 = 3.333(-10.005)$$

$$= -33.34\ \text{kJ}$$

Here negative sign indicates that heat rejections of the system.

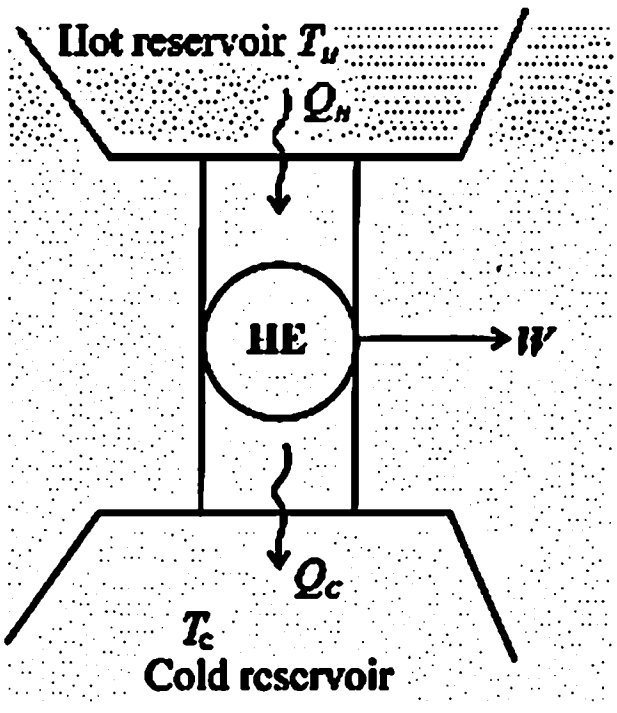
Hence, the energy required to increased entropy, $\boxed{Q_1 = -33.34\ \text{kJ}}$

Question: 8.023P

A heat engine accepts 200,000 Btu of heat from a source at 1500 R and rejects 100,000 Btu of heat to a sink at 600 R. Calculate the entropy change of all the components of this engine and determine if it is completely reversible. How much total work does it produce?

Step 1 of 5

Given



Heat released from the source is, $Q_{source} = 200000\ \text{Btu}$

Source temperature is, $T_{source} = T_H = 1500\ \text{R}$

Sink temperature is, $T_{sink} = T_C = 600\ \text{R}$

Heat rejected to sink from heat engine is, $Q_{sink} = 100000\ \text{Btu}$

Step 2 of 5

Step 3 of 5

Work done by heat engine is given by

$W = Q_{source} - Q_{sink}$

$W = 200000 - 100000$

$\boxed{W = 100000\ \text{Btu}}$

Step 4 of 5

The entropy change of source is given by

$$\Delta S_{source} = \frac{Q_{source}}{T_{source}}$$

As heat is coming out of the source it is taken as negative,

$$\Delta S_{source} = \frac{-200000}{1500}$$

$\Delta S_{source} = -133.33\ \text{Btu/R}$

Similarly, the entropy change of sink is given by

$$\Delta S_{sink} = \frac{Q_{sink}}{T_{sink}}$$

$$\Delta S_{sink} = \frac{100000}{600}$$

$\Delta S_{sink} = 166.67\ \text{Btu/R}$

Step 5 of 5

The entropy generation can be given by

$S_{gen} = \Delta S_{source} + \Delta S_{sink}$

$S_{gen} = -133.33 + 166.67$

$S_{gen} = 33.34\ \text{Btu/R}$

Since $S_{gen} \neq 0$ the heat engine is not reversible.

Therefore the work done by the heat engine is 100000 Btu and the heat engine is not reversible.

Question: 8.024P

Air is compressed by a 30-kW compressor from $P1$, to $P2$. The air temperature is maintained constant at 25°C during this process as a result of heat transfer to the surrounding medium at 17°C. Determine the rate of entropy change of the air. State the assumptions made in solving this problem.

Step 1 of 4

Given

Compressor power input $\dot{W}_{in} = 30\ \text{kW}$

Temperature of air in the compressor $T = 25°\text{C} = 298\ \text{K}$

Temperature of the surroundings $T_{sur} = 17°\text{C} = 290\ \text{K}$

Step 2 of 4

Let us assume,

The process is steady

Kinetic and potential energies are negligible

The process is reversible

Energy balance is given by

$$E_{in} - E_{out} = \frac{dE_{sys}}{dt}$$

As the process is steady, the right hand side in the above equation becomes zero. So,

$E_{in} - E_{out} = 0$

$E_{in} = E_{out}$ ..... (1)

Step 3 of 4

The energy input to the compressor is in terms of work. Therefore,

$E_{in} = \dot{W}_{in}$

$E_{in} = 30\ \text{kW}$

As the process is isothermal, the energy output to the compressor is in terms of heat. Therefore,

$E_{out} = \dot{Q}_{out}$

Substituting the values E_{in} and E_{out} in equation (1) we get,

$30\ \text{kW} = \dot{Q}_{out}$

$\dot{Q}_{out} = 30\ \text{kW}$

Step 4 of 4

As the process is reversible, the change in entropy is given by

$$\Delta\dot{S} = -\frac{\dot{Q}_{out}}{T}$$

$$\Delta\dot{S} = -\frac{30}{298}$$

$$\boxed{\Delta\dot{S} = -\ 0.1007\ \text{kW/K}}$$

Therefore the rate of entropy change of the air decreases by 0.1007 kW/K

Question: 8.025P

Heat in the amount of 100 kJ is transferred directly from a hot reservoir at 1200 K to a cold reservoir at 600 K. Calculate the entropy change of the two reservoirs and determine if the increase of entropy principle is satisfied.

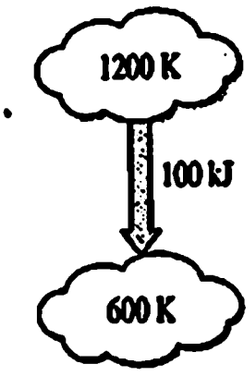


FIGURE P8–25

Step 1 of 4

Given:

Temperature at hot reservoir, $T_H = 1200\ \text{K}$

Temperature at cold reservoir, $T_L = 600\ \text{K}$

Amount of heat transferred, $Q = 100\ \text{kJ}$

Step 2 of 4

Entropy change at hot reservoir, $\Delta S_H = \dfrac{Q_H}{T_H}$

$$\Delta S_H = \frac{-100}{1200}$$

$$\Delta S_H = -0.083333\ \frac{\text{kJ}}{\text{k}}$$

Step 3 of 4

Entropy change at cold reservoir, $\Delta S_L = \dfrac{Q_L}{T_L}$

$$\Rightarrow \Delta S_L = \frac{100}{600}$$

$$\Rightarrow \Delta S_L = 0.166666\ \frac{\text{kJ}}{\text{k}}$$

Step 4 of 4

Total entropy change,

$$\Delta S = \Delta S_H + \Delta S_L$$

$$\Rightarrow \Delta S = -0.083333 + 0.166666$$

$$\Rightarrow \boxed{\Delta S = 0.083333\ \frac{\text{kJ}}{\text{k}}}$$

ΔS is not less than zero, so it satisfies the increase of entropy principle.

Question: 8.-26ASSUME-H

In the previous problem, assume that the heat is transferred from the cold reservoir to the hot reservoir contrary to the Clausius statement of the second law. Prove that this violates the increase of entropy principle—as it must according to Clausius.

Step 1 of 4

Given:

Temperature at hot reservoir, $T_H = 1200\ \text{K}$

Temperature at cold reservoir, $T_L = 600\ \text{K}$

Amount of heat transferred, $Q = 100\ \text{kJ}$

Given that the heat is transferred from the cold reservoir to the hot reservoir.

Step 2 of 4

Entropy change at hot reservoir, $\Delta S_H = \frac{Q_H}{T_H}$

$$\Rightarrow \Delta S_H = \frac{100}{1200}$$

$$\Rightarrow \Delta S_H = 0.083333\ \frac{\text{kJ}}{\text{k}}$$

Step 3 of 4

Entropy change at cold reservoir, $\Delta S_L = \frac{Q_L}{T_L}$

$$\Rightarrow \Delta S_L = \frac{-100}{600}$$

$$\Rightarrow \Delta S_L = -0.166666\ \frac{\text{kJ}}{\text{k}}$$

Step 4 of 4

Total entropy change,

$$\Delta S = \Delta S_H + \Delta S_L$$

$$\Rightarrow \Delta S = 0.083333 - 0.166666$$

$$\Rightarrow \boxed{\Delta S = -0.083333\ \frac{\text{kJ}}{\text{k}}}$$

ΔS is less than zero, so it violates the increase of entropy principle.

Question: 8.027P

A completely reversible heat pump produces heat at rate of 300 kW to warm a house maintained at 24°C. The exterior air, which is at 7°C, serves as the source. Calculate the rate of entropy change of the two reservoirs and determine if this heat pump satisfies the second law according to the increase of entropy principle.

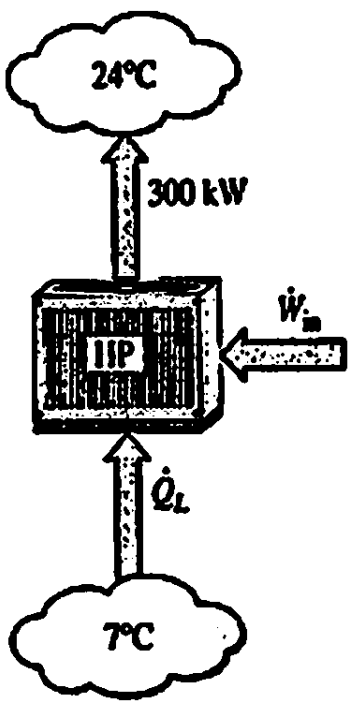

FIGURE P8–27

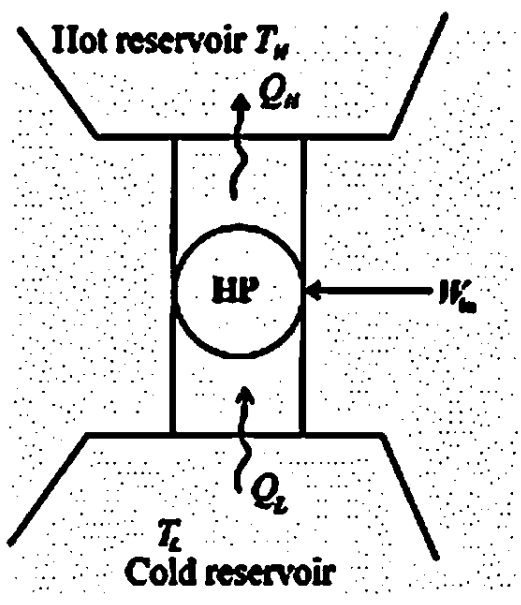
Step 1 of 5



Given

Temperature of warm house (source) is, $T_H = 24°C = 297\ K$

Temperature of exterior air (sink) is, $T_L = 7°C = 280\ K$

Heat produced by heat pump is, $Q_H = 300\ kW$

Step 2 of 5

Step 3 of 5

The coefficient of performance of heat pump is given by

$$(C.O.P)_{HP} = \frac{Q_H}{W_{in}}$$

By applying first law to the heat pump

$$-W_{in} = -Q_H + Q_L$$

$$W_{in} = Q_H - Q_L$$

So C.O.P of heat pump can be written as

$$(C.O.P)_{HP} = \frac{Q_H}{Q_H - Q_L} \quad \ldots\ldots (1)$$

The coefficient of performance of heat pump is also given by

$$(C.O.P)_{HP} = \frac{T_H}{T_H - T_L} \quad \ldots\ldots (2)$$

Equating equations (1) and (2) we get,

$$\frac{Q_H}{Q_H - Q_L} = \frac{T_H}{T_H - T_L}$$

$$\frac{300}{300 - Q_L} = \frac{297}{297 - 280}$$

$$\frac{300}{300 - Q_L} = \frac{297}{17}$$

$$\frac{300 - Q_L}{300} = \frac{17}{297}$$

$$300 - Q_L = 300 \times \frac{17}{297}$$

$$300 - Q_L = \frac{5100}{297}$$

$$300 - Q_L = 17.17$$

$$Q_L = 300 - 17.17$$

$$Q_L = 282.83\ kW$$

Step 4 of 5

The change in entropy of source is given by

$$\Delta S_H = \frac{Q_H}{T_H}$$

$$\Delta S_H = \frac{300}{297}$$

$$\boxed{\Delta S_H = 1.01\ kW/K}$$

The change in entropy of sink is given by

$$\Delta S_L = \frac{Q_L}{T_L}$$

As heat rejected from the sink therefore Q_L is negative

$$\Delta S_L = \frac{-282.83}{280}$$

$$\boxed{\Delta S_L = -1.01\ kW/K}$$

Step 5 of 5

The entropy generation is given by

$$S_{gen} = \Delta S_H + \Delta S_L$$

$$S_{gen} = 1.01 + (-1.01)$$

$$S_{gen} = 1.01 - 1.01$$

$$\boxed{S_{gen} = 0}$$

Therefore the entropy of source is increased by 1.01 kW/K , the entropy of sink is decreased by 1.01 kW/K . As the entropy generation is zero it satisfies the second law according to increase of entropy principle.

Question: 8.028P

During the isothermal heat rejection process of a Carnot cycle, the working fluid experiences an entropy change of -0.7 Btu/R. If the temperature of the heat sink is 95°F, determine (a) the amount of heat transfer, (*b*) the entropy change of the sink, and (c) the total entropy change for this process.

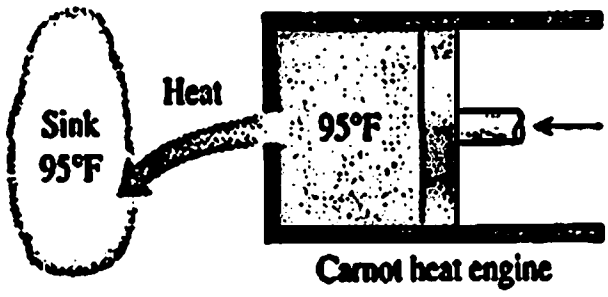


FIGURE P8–28E

Step 1 of 4

Given:

For a carnot cycle, the process is isothermal heat rejection.

Temperature at sink and fluid, $T_{sink} = T_{fluid} = 95°\,\text{F}$

$$\Rightarrow T_{sink} = T_{fluid} = 555\,\text{R}$$

Entropy change at fluid, $\Delta \dot{S}_{fluid} = -0.7\ \text{Btu/R}$

Step 2 of 4

(a) Amount of heat transfer:

Heat transferred from the working fluid,

$$Q_{fluid} = T_{fluid} \times \Delta S_{fluid}$$

$$\Rightarrow Q_{fluid} = 555 \times -0.7$$

$$\Rightarrow Q_{fluid} = -388.5\ \text{Btu}$$

Heat transferred from the working fluid is equal to heat transferred to sink.

So, $Q_{sink} = 388.5\ \text{Btu}$

Amount of heat transfer, $\boxed{Q = 388.5\ \text{Btu}}$

Step 3 of 4

(b) Entropy change of the sink:

Entropy change of the sink,

$$\Delta S_{sink} = \frac{Q_{sink}}{T_{sink}}$$

$$\Rightarrow \Delta S_{sink} = \frac{388.5}{555}$$

$$\Rightarrow \boxed{\Delta S_{sink} = 0.7\ \frac{\text{Btu}}{\text{R}}}$$

Step 4 of 4

(c) Total entropy change during the process:

Total entropy change during the process,

$$\Delta S_{total} = \Delta S_{sink} + \Delta S_{fluid}$$

$$\Rightarrow \Delta S_{total} = 0.7 - 0.7$$

$$\Rightarrow \boxed{\Delta S_{total} = 0\ \frac{\text{Btu}}{\text{R}}}$$

Question: 8.029P

Refrigerant-134a enters the coils of the evaporator of a refrigeration system as a saturated liquid-vapor mixture at a pressure of 160 kPa. The refrigerant absorbs 180 kJ of heat from the cooled space, which is maintained at -5°C, and leaves as saturated vapor at the same pressure. Determine (*a*) the entropy change of the refrigerant, (*b*) the entropy change of the cooled space, and (*c*) the total entropy change for this process.

Step 1 of 5

Given:

For Refrigerant-134a,

Pressure of saturated liquid-vapor mixture, $P = 160\ \text{kPa}$

Temperature of cold space, $T_{space} = -5^{\circ}\ \text{C}$

$$\Rightarrow T_{cold} = 268\ \text{K}$$

Heat absorbed from sold space, $Q_{absorbed} = 180\ \text{kJ}$

Step 2 of 5

From saturated For Refrigerant-134a pressure Table

Temperature of saturated liquid-vapor mixture, $T_{mixture} = -15.60^{\circ}\ \text{C}$

$$\Rightarrow T_{mixture} = 257.4\ \text{K}$$

Step 3 of 5

(a) Entropy change of the refrigerant:

Entropy change of the refrigerant, $\Delta S_{refrigerant} = \dfrac{Q_{absorbed}}{T_{mixture}}$

$$\Rightarrow \Delta S_{refrigerant} = \frac{180}{257.4}$$

$$\Rightarrow \boxed{\Delta S_{refrigerant} = 0.7\ \frac{\text{kJ}}{\text{K}}}$$

Step 4 of 5

(b) Entropy change of the cooled space:

Entropy change of the cooled space, $\Delta S_{space} = \dfrac{Q_{absorbed}}{T_{space}}$

$$\Rightarrow \Delta S_{space} = -\frac{180}{268}$$

$$\Rightarrow \boxed{\Delta S_{space} = -0.6716\ \frac{\text{kJ}}{\text{K}}}$$

Step 5 of 5

(c) Total entropy change for this process:

Total entropy change for this process,

$$\Delta S_{total} = \Delta S_{space} + \Delta S_{refrigerant}$$

$$\Rightarrow \Delta S_{total} = -0.6716 + 0.7$$

$$\Rightarrow \boxed{\Delta S_{total} = 0.0284\ \frac{\text{kJ}}{\text{K}}}$$

Question: 8.030P

Is a process that is internally reversible and adiabatic necessarily isentropic? Explain.

Step 1 of 1

YES.

Reason: The entropy of a fixed mass does not change during a process that is internally reversible and adiabatic. A process during which the entropy remains constant is called an isentropic process.

Question: 8.031P

2-lbm of water at 300 psia fill a weighted piston-cylinder device whose volume is 2.5 ft3 . The water is then heated at constant pressure until the temperature reaches 500°F. Determine the resulting change in the water's total entropy.

Step 1 of 5

Given: For water,
Mass, $m = 2$ lbm
Pressure, $P = 300$ psia
Volume, $V = 2.5\ \text{ft}^3$
Final temperature, $T_2 = 500^\circ\text{F}$

Step 2 of 5

Initial specific volume, $v_1 = \dfrac{V}{m}$

$$\Rightarrow v_1 = \frac{2.5}{2}$$

$$\Rightarrow v_1 = 1.25\ \frac{\text{ft}^3}{\text{lbm}}$$

From saturated water –pressure Table, at $P = 300$ psia

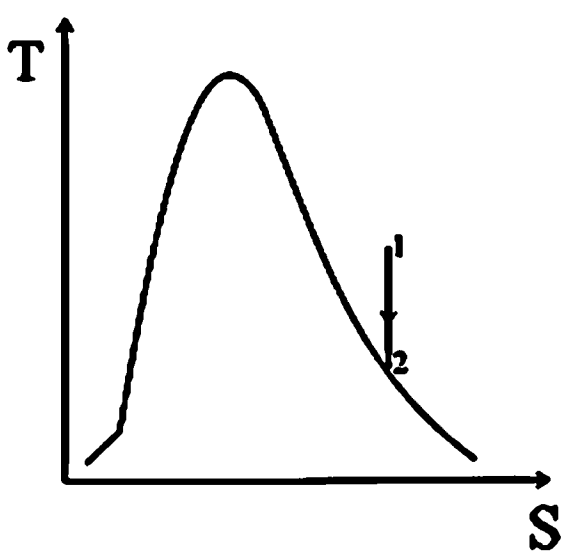
Initial quality, $x_1 = \dfrac{v_1 - v_f}{v_{fg}}$

$$\Rightarrow x_1 = \frac{v_1 - v_f}{v_g - v_f}$$

$$\Rightarrow x_1 = \frac{1.25 - 0.01890}{1.5435 - 0.01890}$$

$$\Rightarrow x_1 = 0.80749$$

Initial entropy, $s_1 = s_f + x_1 s_{fg}$



$$\Rightarrow s_1 = 0.58818 + 0.80749 \times 0.92289$$

$$\Rightarrow s_1 = 1.333404\ \frac{\text{Btu}}{\text{lbm} \cdot \text{R}}$$

Step 3 of 5

At final state:
From super heated water tables
The final temperature $T_2 = 500^\circ$ F,
The final pressure $P_2 = 300$ psia
The final entropy $s_2 = 1.5706\ \dfrac{\text{Btu}}{\text{lbm.R}}$

Step 4 of 5

Step 5 of 5

Total entropy change,

$$\Delta S = m(s_2 - s_1)$$

$$\Rightarrow \Delta S = 2 \times (1.5706 - 1.333404)$$

$$\Rightarrow \boxed{\Delta S = 0.4744\ \frac{\text{Btu}}{\text{R}}}$$

Question: 8.032P

A well-insulated rigid tank contains 5 kg of a saturated liquid-vapor mixture of water at 150 kPa. Initially, three-quarters of the mass is in the liquid phase. An electric resistance heater placed in the tank is now turned on and kept on until all the liquid in the tank is vaporized. Determine the entropy change of the steam during this process.

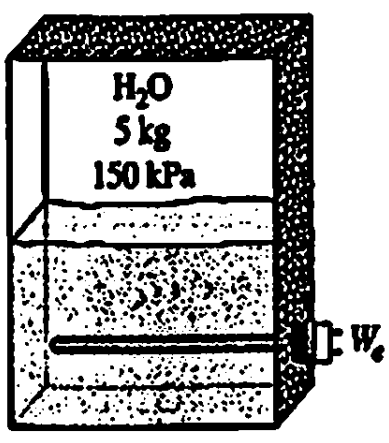


FIGURE P8–32

Step 1 of 8

Given data:

Mass of mixture in the tank is, $m = 5\,kg$.

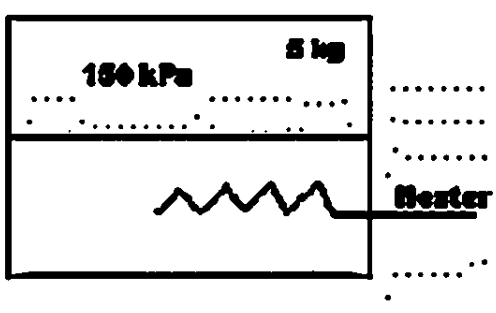
Pressure in the tank is, $P = 150\,kPa$.

Step 2 of 8

From the saturated water pressure table,

At pressure $P = 150\,kPa$

Entropy of saturated liquid is $s_{f1} = 1.4337\,kJ/kg \cdot K$



Entropy of evaporation is $s_{fg1} = 5.7894\,kJ/kg \cdot K$

Specific volume of saturated liquid is $v_{f1} = 0.001053\,m^3/kg$

Specific volume of saturated vapor is $v_{g1} = 1.1594\,m^3/kg$

Step 3 of 8

Consider the diagram:

Step 4 of 8

As it is given initially three-fourth of mass is liquid phase, the mass of water is

$$m_w = \frac{3}{4}$$
$$= 0.75$$

Therefore mass of vapor is

$$m_v = 1 - m_w$$
$$= 1 - 0.75$$
$$= 0.25$$

Dryness fraction is the fraction of vapor in the mixture $x_1 = m_v$

So the dryness of the mixture initially is given by $x_1 = 0.25$

Step 5 of 8

Initial specific volume of mixture is given by

$$v_1 = v_{f1} + x_1 \times v_{fg1}$$
$$= v_{f1} + x_1 \times (v_{g1} - v_{f1})$$
$$= 0.001053 + 0.25 \times (1.1594 - 0.001053)$$
$$= 0.001053 + 0.25 \times 1.158347$$
$$= 0.001053 + 0.289587$$
$$= 0.29064\,m^3/kg$$

Step 6 of 8

Initial specific entropy of mixture is given by

$$s_1 = s_{f1} + x_1 \times s_{fg1}$$

As the pressure is constant the equation can be written as

$$s_1 = s_f + x_1 \times s_{fg}$$
$$= 1.4337 + 0.25 \times 5.7894$$
$$= 1.4337 + 1.4474$$
$$= 2.8811\,kJ/kg \cdot K$$

Step 7 of 8

The final state is saturated vapor, and as the tank is closed, the final specific volume of mixture will be same as initial.

$$v_2 = v_1$$

Therefore, $v_2 = 0.29064\,m^3/kg$

From the saturated water pressure table,

At specific volume $v_2 = 0.29064\,m^3/kg$,

The specific entropy is interpolated as

$$\frac{0.29260 - v_2}{0.29260 - 0.27278} = \frac{6.7322 - s_2}{6.7322 - 6.7071}$$
$$\frac{0.29260 - 0.29064}{0.29260 - 0.27278} = \frac{6.7322 - s_2}{6.7322 - 6.7071}$$
$$\frac{0.00196}{0.01982} = \frac{6.7322 - s_2}{0.0251}$$
$$0.0989 = \frac{6.7322 - s_2}{0.0251}$$
$$s_2 = 6.7322 - (0.0989 \times 0.0251)$$
$$s_2 = 6.7322 - 0.00248$$
$$s_2 = 6.7322 - 0.00248$$
$$s_2 = 6.72972\,kJ/kg°K$$

Step 8 of 8

The change in entropy is given by

$$\Delta s = m \times (s_2 - s_1)$$
$$= 5 \times (6.72972 - 2.8811)$$
$$= 5 \times 3.84862$$
$$\boxed{\Delta s = 19.2431\,kJ/K}$$

Therefore change in entropy water mixture is 19.2431 kJ/K .

Question: 8.033P

A rigid tank is divided into two equal parts by a partition. One part of the tank contains 2.5 kg of compressed liquid water at 400 kPa and 60°C while the other part is evacuated. The partition is now removed, and the water expands to fill the entire tank. Determine the entropy change of water during this process, if the final pressure in the tank is 40 kPa.

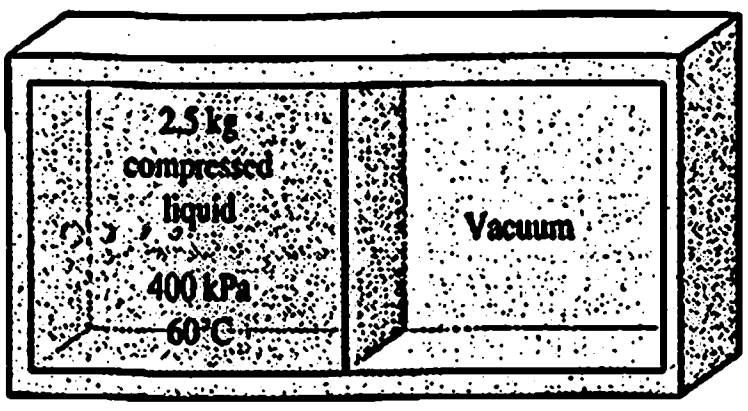


FIGURE P8–33

Step 1 of 6

Given data:

Mass of water in the tank is, $m = 2.5$ kg

Initial pressure of liquid is, $P_1 = 400$ kPa

Initial temperature of liquid is, $T_1 = 60\ ^\circ\text{C} = 333$ K

Final pressure of liquid is, $P_2 = 40$ kPa

Step 2 of 6

As initial temperature of liquid is lesser than the saturated temperature at pressure $P_1 = 400$ kPa,

We take the properties at saturated liquid at temperature $T_1 = 60\ ^\circ\text{C}$

From the table of 'saturated water –temperature table',

At temperature $T_1 = 60\ ^\circ\text{C}$ and saturated liquid condition,

Properties of water are

$v_1 = v_f = 0.001017\ \text{m}^3/\text{kg}$

$s_1 = s_f = 0.8313\ \text{kJ/kg°K}$

From the table of 'saturated water –pressure table',

At pressure $P_2 = 40$ kPa, properties of water are

$v_{f2} = 0.001026\ \text{m}^3/\text{kg}$

$v_{fg2} = 3.9933\ \text{m}^3/\text{kg}$

$s_{f2} = 1.0261\ \text{kJ/kg°K}$

$s_{fg2} = 6.6430\ \text{kJ/kg°K}$

Step 3 of 6

As both the parts of the tank have equal volume, after expansion volume will be doubled.

Final pressure of adiabatic process is given by

$$v_2 = 2 \times v_1$$
$$= 2 \times 0.001017$$
$$= 0.002034\ \text{m}^3/\text{kg}$$

Step 4 of 6

Final volume is also given by

$$v_2 = v_{f2} + x_2 v_{fg2}$$
$$0.002034 = 0.001026 + x_2 \times 3.9933$$
$$x_2 = \frac{0.002034 - 0.001026}{3.9933}$$
$$= \frac{0.001008}{3.9933}$$
$$= 0.0002524$$

Step 5 of 6

Final entropy is given by

$$s_2 = s_{f2} + x_2 \times s_{fg2}$$
$$= 1.0261 + 0.0002524 \times 6.6430$$
$$= 1.0261 + 0.00168$$
$$= 1.02778\ \text{kJ/kg°K}$$

Step 6 of 6

Entropy change in the process is given by

$$\Delta S = m \times (s_2 - s_1)$$
$$= 2.5 \times (1.02778 - 0.8313)$$
$$= 2.5 \times 0.19648$$
$$= 0.4912\ \text{kJ/°K}$$

$\boxed{\Delta S = 0.4912\ \text{kJ/°K}}$

Therefore the entropy change in the process is 0.4912 kJ/°K.

Question: 8.034P

Reconsider Prob. 8-33. Using EES (or other) software, evaluate and plot the entropy generated as a function of surrounding temperature, and determine the values of the surrounding temperatures that are valid for this problem. Let the surrounding temperature vary from 0 to 100°C. Discuss your results.

Step 1 of 8

Given data:

Mass of water in the tank is, $m = 2.5$ kg

Initial pressure of liquid is, $P_1 = 400$ kPa

Initial temperature of liquid is, $T_1 = 60\ ^\circ\text{C} = 333$ K

Final pressure of liquid is, $P_2 = 40$ kPa

Step 2 of 8

Give all the inputs in the EES software as given below

T1 =60 [C]

P1 =400 [kPa]

m = 2.5 [kg]

P2 =40 [kPa]

Step 3 of 8

For calculating other parameters we should give other equations as below

V1 =m *sv1

sv1 =volume(steam_iapws,P=P1,T=T1)

u1 =intenergy(steam_iapws,P=P1,T=T1)

s1 =entropy(steam_iapws,P=P1,T=T1)

V2 =2*V1

sv2 =V2/ m

u2 =intenergy(steam_iapws,P=P2,v=sv2)

s2 =entropy(steam_iapws,v=sv2,P=P2)

For energy balance we give

Ein-Eout =Ediff

Ediff =m *(u2-u1)

Ein =0

Eout =Qout

For entropy generation we give

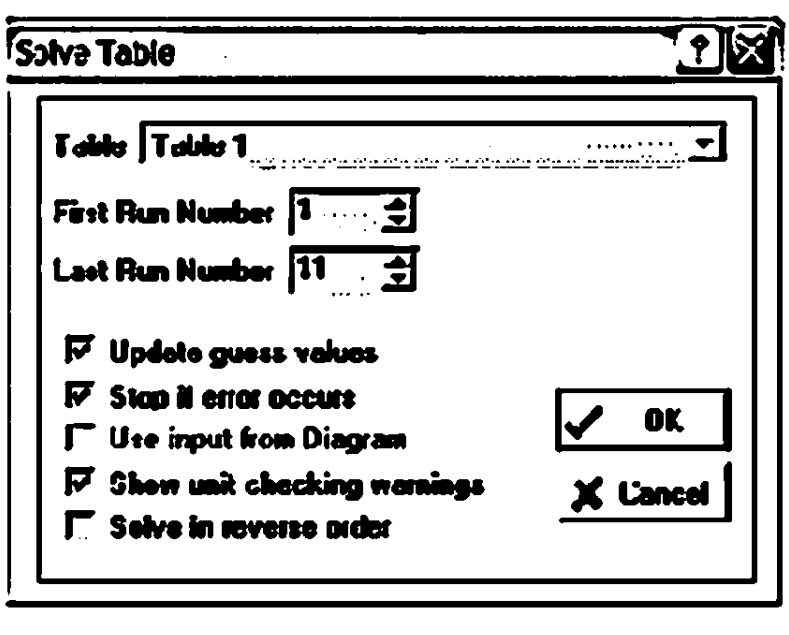
Sgen =Ssys+Qout/(T0+273)

Ssys =m*(s2-s1)

Step 4 of 8

After writing these sets of equations, we should create a parametric table from

Tables → new parametric



Fill all the values of T0.

Table 1

	1 T0 [C]	2 Sgen [kJ/K]
1..11		
Run 1	0	
Run 2	10	
Run 3	20	
Run 4	30	
Run 5	40	
Run 6	50	
Run 7	60	
Run 8	70	
Run 9	80	
Run 10	90	
Run 11	100	

Step 5 of 8

Now solve the table for respective Sgen values by pressing F3.

Step 6 of 8

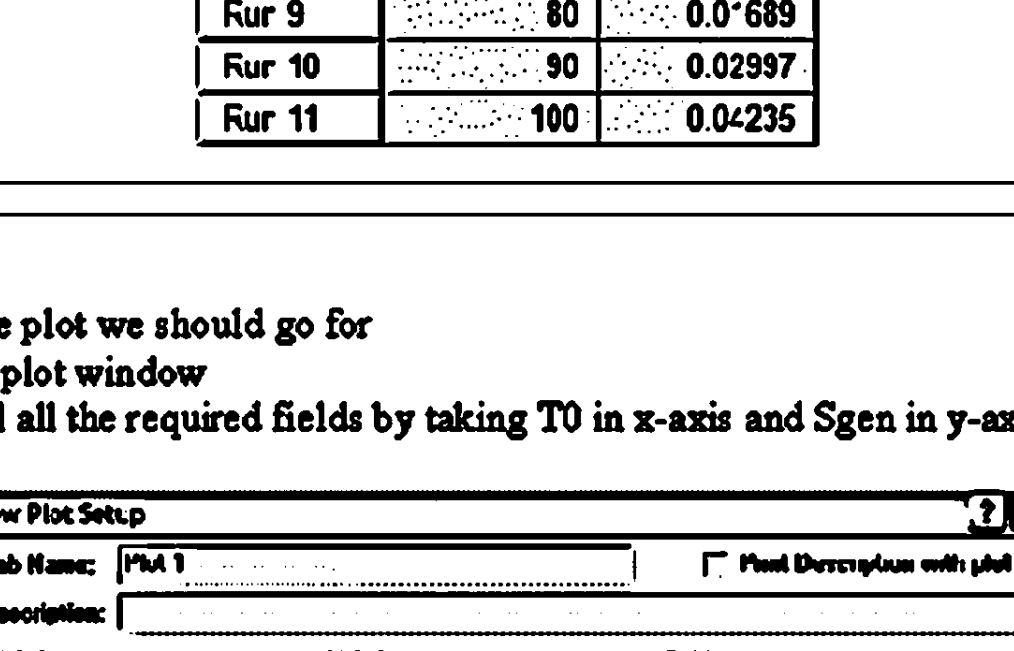
Then we get

Table 1

	1 T0 [C]	2 Sgen [kJ/K]
1..11		
Run 1	0	-0.0222
Run 2	10	-0.0105
Run 3	20	-0.08033
Run 4	30	-0.06145
Run 5	40	-0.04370
Run 6	50	-0.0272
Run 7	60	-0.0162
Run 8	70	0.003079
Run 9	80	0.01689
Run 10	90	0.02997
Run 11	100	0.04235

Step 7 of 8

For getting the plot we should go for



Plots → New plot window

We should fill all the required fields by taking T0 in x-axis and Sgen in y-axis.

Step 8 of 8

After that we get the plot as

Question: 8.035P

A piston-cylinder device contains 2 lbm of refrigerant-134a at 120 psia and 100°F. The refrigerant is now cooled at constant pressure until it exists as a liquid at 50°F. Determine the entropy change of the refrigerant during this process.

Step 1 of 4

Given: For R-134a,

Mass, $m = 2$ lbm

Initial pressure, $P_1 = 120$ psia

Initial temperature, $T_1 = 100°\text{F}$

Final temperature, $T_2 = 50°\text{F}$

The refrigerant is cooled at constant pressure.

Step 2 of 4

Super heated refrigerant -134aTables,

At $T_1 = 100°\text{F}$, $P_1 = 120$ psia

Initial Entropy, $s_1 = 0.22362 \dfrac{\text{Btu}}{\text{lbm.R}}$

Step 3 of 4

saturated refrigerant -134a temperature Tables

At $T_1 = 50°\text{F}$, satuarated liquid

Final Entropy, $s_2 = 0.06039 \dfrac{\text{Btu}}{\text{lbm.R}}$

Step 4 of 4

Entropy change,

$$\Delta S = m \times (s_2 - s_1)$$

$$\Rightarrow \Delta S = 2 \times (0.06039 - 0.22362)$$

$$\Rightarrow \boxed{\Delta S = -0.32646 \text{ Btu/R}}$$

Question: 8.036P

An insulated piston-cylinder device contains 5 L of saturated liquid water at a constant pressure of 150 kPa. An electric resistance heater inside the cylinder is now turned on, and 2200 kJ of energy is transferred to the steam. Determine the entropy change of the water during this process.

Step 1 of 6

Given data

Energy transferred to the steam $E_{in} = 2200\text{kJ}$

Pressure of Saturated liquid water $P_1 = 150\text{kPa}$

Volume of saturated liquid water $V = 5\,\text{L}$

$$= 5\times10^{-3}\text{m}^3$$

Step 2 of 6

From the saturated water-Pressure

At $P_1 = 150\text{kPa}$

Specific volume $v_1 = v_f$

$$= 0.001053\text{m}^3/\text{kg}$$

Enthalpy $h_1 = h_f$

$$= 467.13\text{kJ/kg}$$

Entropy $s_1 = s_f$

$$= 1.4337\text{kJ/kg}\cdot\text{K}$$

Mass of sat liquid

$$m = \frac{V}{v_1}$$

$$m = \frac{0.005\text{m}^3}{0.001053\text{m}^3/\text{kg}}$$

$$= 4.75\text{kg}$$

Step 3 of 6

From first law of thermodynamics, energy balance for this closed system at constant pressure

$$E_{in} + mh_1 = mh_2$$

$$h_2 = h_1 + \frac{E_{in}}{m}$$

$$= 467.13\left(\frac{\text{kJ}}{\text{kg}}\right) + \frac{2200\text{kJ}}{4.75\text{kg}}$$

$$= 930.29\text{kJ/kg}$$

Step 4 of 6

From the saturated water-Pressure

At $P_1 = 150\text{kPa}$

Enthalpy of evaporation $h_{fg} = 2226\text{kJ/kg}$

Enthalpy of evaporation $s_{fg} = 5.7894\text{kJ/kg}\cdot\text{K}$

We know that

$$h_2 = h_f + x_2\left(h_{fg}\right)$$

Quality at stage 2

$$x_2 = \frac{h_2 - hf}{h_{fg}}$$

$$x_2 = \frac{(930.29 - 467.13)}{2226}$$

$$= 0.208$$

Step 5 of 6

Entropy at state (2)

$$s_2 = s_f + x_2 s_{fg}$$

$$= 1.4337 + (0.208)(5.7894)$$

$$= 2.6382\text{kJ/kg}$$

Step 6 of 6

Entropy change of water during this process

$$\Delta s = m(s_2 - s_1)$$

$$= (4.75\text{kg})(2.6382 - 1.4337)\text{kJ/kg}\cdot\text{K}$$

$$= 5.72\text{kJ/K}$$

$$\boxed{\Delta s = 5.72\text{kJ/K}}$$

Question: 8.037P

Calculate the change in the specific entropy of water as it is cooled at a constant pressure of 300 kPa from a saturated vapor to asaturated liquid by using aGibbs equation ($Tds = dh - vdP$) . Use the steam tables to verify your result.

Step 1 of 2

Obtain the properties of water at pressure $P = 300$ kPa from saturated water tables:

Saturation temperature, $T = T_{sat} = 133.52°C = 406.67$ K

Specific enthalpy of saturated liquid, $h_f = 561.43$ kJ/kg

Specific enthalpy of saturated vapor, $h_g = 2724.9$kJ/kg

Write the Gibbs equation.

$$T \times ds = dh - v \times dP$$

$$ds = \frac{1}{T}(dh - v \times dP)$$

Here, T is temperature, dP is change in pressure, dh is change in enthalpy, and ds is change in entropy.

As pressure is constant the change in pressure is zero.

$$dP = 0$$

Substitute this value in Gibb's equation.

$$ds = \frac{1}{T}(dh - v \times 0)$$

$$= \frac{1}{T}dh$$

$$= \frac{1}{T} \times (h_2 - h_1)$$

Here, h_2 is enthalpy of saturated vapor and h_1 is specific enthalpy of saturated liquid.

Substitute the values and calculate ds.

$$ds = \frac{1}{T} \times (h_g - h_f)$$

$$= \frac{1}{406.7} \times (2724.9 - 561.43)$$

$$= 5.319 \text{kJ/kg} \cdot \text{K}$$

Therefore, the change in entropy by using Gibb's equation is $\boxed{5.319 \text{ kJ/kg} \cdot \text{K}}$.

Step 2 of 2

Obtain the properties of water at pressure $P = 300$ kPa from saturated water tables.

Specific entropy of saturated liquid, $s_f = 1.6717 \text{kJ/kg} \cdot \text{K}$

As pressure is constant the change in pressure is zero.

$$dP = 0$$

Substitute this value in Gibb's equation.

$$ds = \frac{1}{T}(dh - v \times 0)$$

$$= \frac{1}{T}dh$$

$$= \frac{1}{T} \times (h_2 - h_1)$$

Here, h_2 is enthalpy of saturated vapor and h_1 is specific enthalpy of saturated liquid.

Substitute the values and calculate ds.

$$ds = \frac{1}{T} \times (h_g - h_f)$$

Question: 8.038P

Saturated R-134a vapor enters a compressor at 0°F. At compressor exit, the specific entropy is the same as that at the inlet, and the pressure is 60 psia. Determine the R-l34a exit temperature and the change in the enthalpy of R-134a.

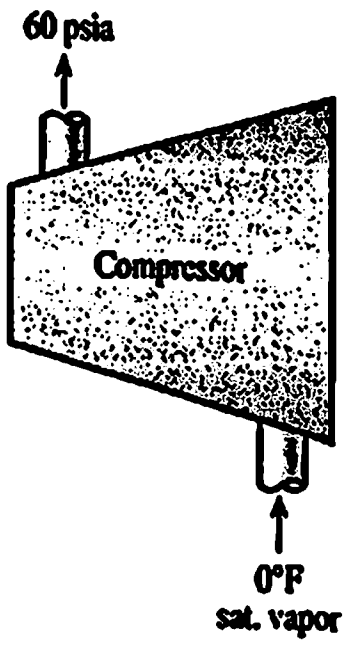


FIGURE P8–38E

Step 1 of 6

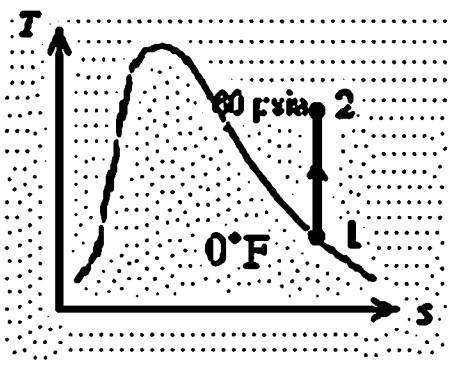
Given data:

Temperature at compressor inlet is, $T_1 = 0\ ^\circ F$.

Pressure at compressor exit is, $P_2 = 60$ psia.

Step 2 of 6

From the Saturated refrigerant 134a-Temperature table



At temperature $T_1 = 0\ ^\circ F$ and saturated vapor state,

$h_1 = h_g = 103.08$ Btu/lbm

$s_1 = s_g = 0.22539$ Btu/lbm · R

Step 3 of 6

Let us draw the T-s diagram:

Step 4 of 6

Given the final state is superheated vapor and the final specific entropy of steam is constant. So,

$s_2 = s_1$

Therefore, $s_2 = 0.22539$ Btu/lbm.R

From the superheated refrigerant 134a-Temperature table

At pressure $P_2 = 60$ psia and specific entropy $s_2 = 0.22539$ Btu/lbm.R ,

The temperature is interpolated as

$$\frac{s_2 - 0.22127}{0.22570 - 0.22127} = \frac{T_2 - 49.84}{60 - 49.84}$$

$$\frac{0.22539 - 0.22127}{0.22570 - 0.22127} = \frac{T_2 - 49.84}{60 - 49.84}$$

$$\frac{0.00412}{0.00443} = \frac{T_2 - 49.84}{10.16}$$

$$0.93 = \frac{T_2 - 49.84}{10.16}$$

$T_2 = (10.16 \times 0.93) + 49.84$

$T_2 = 9.4488 + 49.84$

Therefore the exit temperature is $\boxed{T_2 = 59.2888\ ^\circ F}$

Step 5 of 6

From the superheated refrigerant 134a-Temperature table,

At pressure $P_2 = 60$ psia and specific entropy $s_2 = 0.22539$ Btu/lbm.R ,

The enthalpy is interpolated as

$$\frac{s_2 - 0.22127}{0.22570 - 0.22127} = \frac{h_2 - 110.11}{112.39 - 110.11}$$

$$\frac{0.22539 - 0.22127}{0.22570 - 0.22127} = \frac{h_2 - 110.11}{112.39 - 110.11}$$

$$\frac{0.00412}{0.00443} = \frac{h_2 - 110.11}{2.28}$$

$$0.93 = \frac{h_2 - 110.11}{2.28}$$

$h_2 = (2.28 \times 0.93) + 110.11$

$h_2 = 2.1204 + 110.11$

$h_2 = 112.2304$ Btu/lbm

Step 6 of 6

The change in enthalpy is given by

$\Delta h = h_2 - h_1$

$= 112.2304 - 103.08$

$= 9.1504$ Btu/lbm

Therefore exit temperature is $\boxed{59.2888\ ^\circ F}$ and change in enthalpy is $\boxed{\Delta h = 9.1504\ \text{Btu/lbm}}$.

Question: 8.039P

Water vapor enters a turbine at 6 MPa and 400°C, and leaves the turbine at 100 kPa with the same specific entropy as that at the inlet. Calculate the difference between the specific enthalpy of the water at the turbine inlet and exit.

Step 1 of 5

Given

Inlet pressure of turbine is, $P_1 = 6\ \text{MPa} = 6000\ \text{kPa}$

Inlet temperature of turbine is, $T_1 = 400\ ^\circ\text{C} = 673\ \text{K}$

Exit pressure of turbine is, $P_2 = 100\ \text{kPa}$

Specific entropy at inlet and exit of turbine is same.

Step 2 of 5

From superheated water tables at pressure $P_1 = 6\ \text{MPa}$ and temperature $T_1 = 400\ ^\circ\text{C}$ the enthalpy and entropy values respectively are

$h_1 = 3178.3\ \text{kJ/kg}$ And

$s_1 = 6.5432\ \text{kJ/kg.K}$

From saturated water tables at pressure $P_2 = 100\ \text{kPa}$ enthalpy and entropy of saturated liquid and enthalpy and entropy of vaporization respectively are

$h_{f2} = 417.51\ \text{kJ/kg}$

$h_{fg2} = 2257.5\ \text{kJ/kg}$

$s_{f2} = 1.3028\ \text{kJ/kg.K}$

$s_{fg2} = 6.0562\ \text{kJ/kg.K}$

Step 3 of 5

As it is given that specific entropy at inlet and exit of turbine is same we can write it as

$s_1 = s_2$

$s_1 = s_{f2} + x_2 \times s_{fg2}$

$x_2 \times s_{fg2} = s_1 - s_{f2}$

$$x_2 = \frac{s_1 - s_{f2}}{s_{fg2}}$$

$$x_2 = \frac{6.5432 - 1.3028}{6.0562}$$

$$x_2 = \frac{5.2404}{6.0562}$$

$x_2 = 0.8653$

Step 4 of 5

The enthalpy at turbine exit is given by

$h_2 = h_{f2} + x_2 \times h_{fg2}$

$h_2 = 417.51 + 0.8653 \times 2257.5$

$h_2 = 417.51 + 1953.415$

$h_2 = 2370.925\ \text{kJ/kg}$

Step 5 of 5

The difference in specific enthalpies of water at turbine inlet and exit is given by

$dh = h_1 - h_2$

$dh = 3178.3 - 2370.925$

$\boxed{dh = 807.375\ \text{kJ/kg}}$

Therefore the difference in specific enthalpies of water at turbine inlet and exit is

$dh = 807.375\ \text{kJ/kg}$

Question: 8.040P

1-kg of R-134a initially at 600 kPa and 25°C undergoes a process during which the entropy is kept constant until the pressure drops to 100 kPa. Determine the final temperature of the R-134a and the final specific internal energy.

Step 1 of 3

Obtain the entropy at state 1 from superheated refrigerant-134a tables at initial pressure $P_1 = 600\ \text{kPa}$ and initial temperature $T_1 = 25°\text{C}$ by using interpolation.

$$\frac{s_1 - 0.9218}{0.9499 - 0.9218} = \frac{25 - 21.55}{30 - 21.55}$$

$$\frac{s_1 - 0.9218}{0.0281} = \frac{3.45}{8.45}$$

$$\frac{s_1 - 0.9218}{0.0281} = 0.4083$$

$$s_1 = (0.4083 \times 0.0281) + 0.9218$$

$$= 0.01147 + 0.9218$$

$$= 0.93327\ \text{kJ/kg·K}$$

Step 2 of 3

Entropy remains constant during the process 1-2. So, the final entropy is equal to the initial entropy.

$$s_2 = s_1$$

$$s_2 = 0.93327\ \text{kJ/kg·K}$$

At the final pressure , $P_2 = 100\ \text{kPa}$, from saturated R-134a tables, the following values are obtained:

Specific entropy of saturated liquid $s_{f2} = 0.07188\ \text{kJ/kg·K}$

Specific entropy of liquid vapor mixture $s_{fg2} = 0.87995\ \text{kJ/kg·K}$

Specific entropy of saturated vapor $s_{g2} = 0.95183\ \text{kJ/kg·K}$

Specific internal energy of saturated liquid $u_{f2} = 17.21\ \text{kJ/kg}$

Specific internal energy of liquid vapor mixture $u_{fg2} = 197.98\ \text{kJ/kg}$

Saturation temperature $T_{sat} = -26.37°\text{C}$

The final entropy is in between s_f and s_g.

$$s_f < s_2 < s_g$$

Therefore, the final state is liquid-vapor mixture.

Then the final temperature will be same as the saturated temperature.

$$T_2 = T_{sat@100\text{kPa}} = -26.37°\text{C}$$

Therefore, the final temperature of R-134a is $\boxed{-26.37°\text{C}}$.

Step 3 of 3

Find the dryness fraction at final state 2 by using the entropy expression.

$$s_2 = s_{f2} + x_2 \times s_{fg2}$$

$$x_2 = \frac{s_2 - s_{f2}}{s_{fg2}}$$

$$= \frac{0.93327 - 0.07188}{0.87995}$$

$$= \frac{0.86139}{0.87995}$$

$$= 0.9789$$

Find the final internal energy by using the following expression:

$$u_2 = u_{f2} + x_2 \times u_{fg2}$$

$$= 17.21 + (0.9789 \times 197.98)$$

$$= 17.21 + 193.803$$

$$= 211.013\ \text{kJ/kg}$$

Therefore, the final internal energy u_2 is $\boxed{211.013\ \text{kJ/kg}}$.

Question: 8.041P

Refrigerant-134a is expanded isentropically from 800 kPa and 60°C at the inlet of a steady-flow turbine to 100 kPa at the outlet. The outlet area is 1 m2 , and the inlet area is 0.5 m2 . Calculate the inlet and outlet velocities when the mass flow rate is 0.5 kg/s.

Step 1 of 6

Given data:

Mass of R-134a used is, $m = 1\ kg$

Inlet pressure is, $P_1 = 800\ kPa$

Inlet temperature is, $T_1 = 60\ °C = 333\ K$

Exit Pressure is, $P_2 = 100\ kPa$

Outlet area is, $A_2 = 1\ m^2$

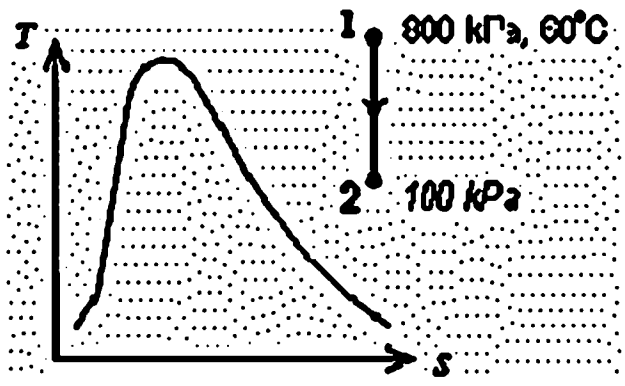
Inlet area is, $A_1 = 0.5\ m^2$

Mass flow rate is, $m = 0.5\ kg/s$

Step 2 of 6

From the superheated refrigerant-134a

At pressure $P_1 = 800\ kPa$ and temperature $T_1 = 60\ °C$,



Specific volume and entropy of refrigerant respectively are

$v_1 = 0.029973\ m^3/kg$

$s_1 = 1.011\ kJ/kg \cdot K$

Step 3 of 6

Let us draw the T-s Diagram:

Step 4 of 6

Given entropy is constant. So, the final entropy is given by

$s_2 = s_1$

Therefore, $s_2 = 1.011\ kkJ/kg \cdot K$

From the superheated refrigerant-134a

At pressure $P_2 = 100\ kPa$ and entropy $s_2 = 1.011\ kJ/kg°K$,

The specific volume is interpolated as

$$\frac{v_2 - 0.20743}{0.2163 - 0.20743} = \frac{1.011 - 1.003}{1.0332 - 1.003}$$

$$\frac{v_2 - 0.20743}{0.00887} = \frac{0.008}{0.0302}$$

$$\frac{v_2 - 0.20743}{0.00887} = 0.2649$$

$$v_2 = 0.20743 + (0.2649 \times 0.00887)$$

$$= 0.20743 + 0.00235$$

$$= 0.20978\ m^3/kg$$

Step 5 of 6

The inlet velocity is given by

$$c_1 = \frac{m \times v_1}{A_1}$$

$$= \frac{0.5 \times 0.029973}{0.5}$$

$$= \frac{0.0149865}{0.5}$$

$$= 0.029973\ m/s$$

$\boxed{c_1 = 0.029973\ m/s}$

Step 6 of 6

The exit velocity is given by

$$c_2 = \frac{m \times v_2}{A_2}$$

$$= \frac{0.5 \times 0.20978}{1.0}$$

$$= \frac{0.10489}{1.0}$$

$$= 0.10489\ m/s$$

$\boxed{c_2 = 0.10489\ m/s}$

Therefore inlet velocity is $\boxed{c_1 = 0.029973\ m/s}$ and exit velocity is $\boxed{c_2 = 0.10489\ m/s}$.

Question: 8.042P

A heavily insulated piston-cylinder device contains 0.02 m3 of steam at 300 kPa and 200°C. Steam is now compressed in a reversible manner to a pressure of 1.2 MPa. Determine the work done on the steam during this process.

Step 1 of 5

Given data:

Volume of steam is, $v = 0.02\ m^3$.

Initial pressure is, $P_1 = 300\ kPa$.

Initial temperature is, $T_1 = 200\ ^\circ C = 473\ K$.

Final pressure is, $P_2 = 1.2\ MPa = 1200\ kPa$.

Step 2 of 5

From the superheated water,

At pressure $P_1 = 300\ kPa$ and temperature $T_1 = 200\ ^\circ C$,

Specific volume, internal energy and entropy of steam respectively are

$v_1 = 0.71643\ m^3/kg$

$u_1 = 2651\ kJ/kg$

$s_1 = 7.3132\ kJ/kg \cdot K$

Step 3 of 5

As the cylinder is insulated, the process is isentropic. So, the final entropy is given by

$s_2 = s_1$

Therefore, $s_2 = 7.3132\ kJ/kg \cdot K$

From the superheated water

At pressure $P_2 = 1.2\ MPa$ and entropy $s_2 = 7.3132\ kJ/kg \cdot K$,

The internal energy is interpolated as

$$\frac{u_2 - 2872.7}{2955.5 - 2872.7} = \frac{7.3132 - 7.2139}{7.3793 - 7.2139}$$

$$\frac{u_2 - 2872.7}{82.8} = \frac{0.0993}{0.1654}$$

$$u_2 = 2872.7 + (0.6004 \times 82.8)$$

$$= 2872.7 + 49.7131$$

$$= 2922.4131\ kJ/kg$$

Step 4 of 5

The mass of steam is given by

$$m = \frac{v}{v_1}$$

$$= \frac{0.02}{0.71643}$$

$$= 0.0279\ kg$$

Step 5 of 5

As the cylinder is closed, we will consider internal energy for calculating the work done.

The work done is given by

$$W = m \times (u_2 - u_1)$$

$$= 0.0279 \times (2922.4131 - 2651)$$

$$= 0.0279 \times 271.4131$$

$$= 7.5724\ kJ$$

$\boxed{W = 7.5724\ kJ}$

Therefore the work done on the steam is $\boxed{W = 7.5724\ kJ}$.

Question: 8.043P

Reconsider Prob. 8-42. Using EES (or other) software, evaluate and plot the work done on the steam as a function of final pressure as the pressure varies from 300 kPato 1.2 MPa.

Step 1 of 8

Given data:

Volume of steam is, $v = 0.02\ m^3$

Initial pressure is, $P_1 = 300\ kPa$

Initial temperature is, $T_1 = 200\ °C = 473\ K$

Final pressure varies, $P_2 = 300$ to $1200\ kPa$

Step 2 of 8

Give all the inputs in the EES software as given below

T1 =200 [C]

P1 =300 [kPa]

Vsys =0.02 [m^3]

Step 3 of 8

For calculating other parameters we should give other equations as

u1 =intenergy(steam_iapws,P=P1,T=T1)

v1 =volume(steam_iapws,P=P1,T=T1)

s1 =entropy(steam_iapws,P=P1,T=T1)

Vsys=m_sys*v1

s2 =s1

u2 =intenergy(steam_iapws,P=P2,s=s2)

Ein − Eout = Esys

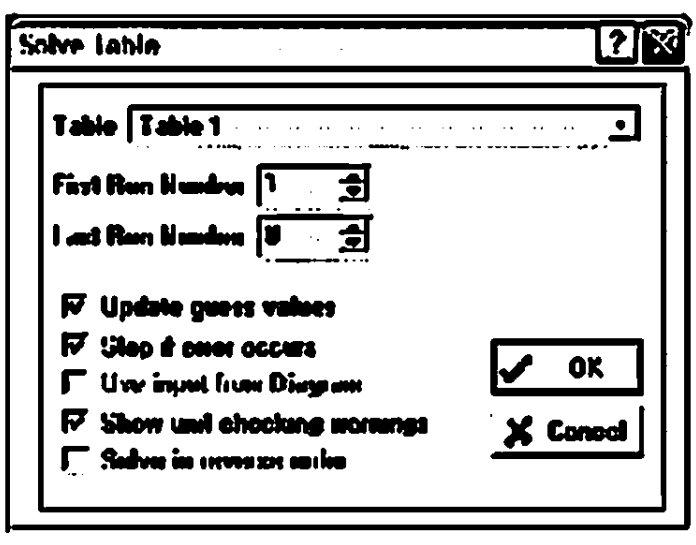
Esys =m_sys*(u2−u1)

Ein =Win

Eout =0

Step 4 of 8

After writing these sets of equations, we should create a parametric table from



Tables → new parametric

Fill all the values of P2.

	1	2
	P2 [kPa]	Win [kJ]
Run 1	300	
Run 2	400	
Run 3	500	
Run 4	600	
Run 5	700	
Run 6	800	
Run 7	900	
Run 8	1000	

Step 5 of 8

Now solve the table for respective Win values by pressing F3.

Step 6 of 8

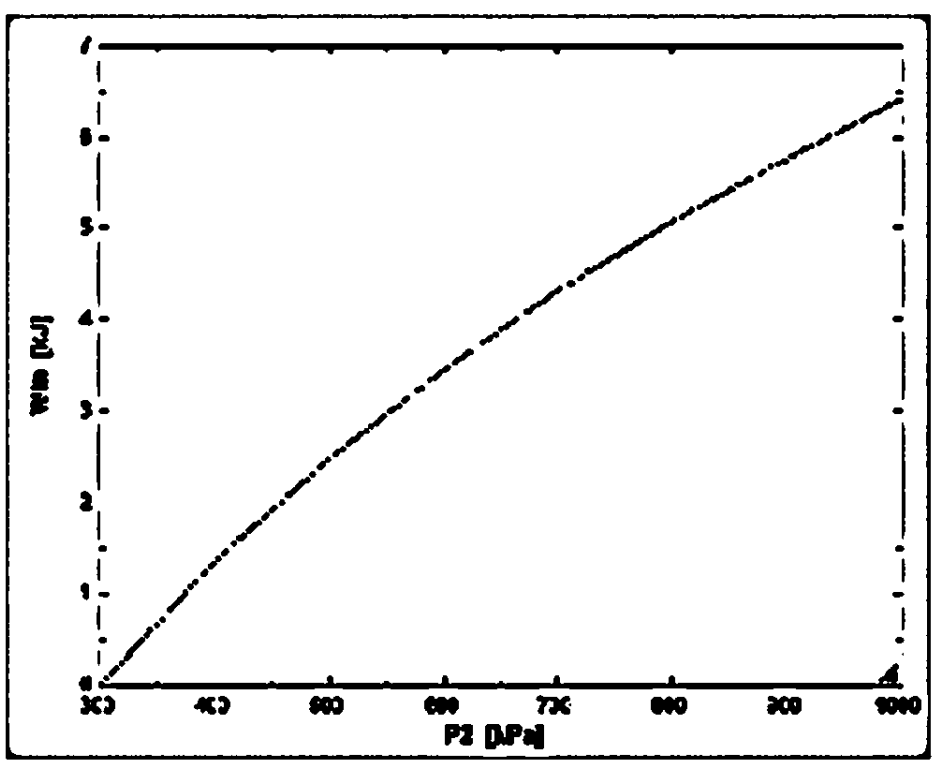
Then we get

Table 1

	1	2
	P2 [kPa]	Win [kJ]
Run 1	300	0
Run 2	400	1.363
Run 3	500	2.494
Run 4	600	3.462
Run 5	700	4.314
Run 6	800	5.073
Run 7	900	5.773
Run 8	1000	6.411

Step 7 of 8

For getting the plot we should go for



Plots → New plot window

We should fill all the required fields by taking P2 in x-axis and Win in y-axis.

Step 8 of 8

After that we get the plot as

Question: 8.044P

A piston-cylinder device contains 1.2 kg of saturated water vapor at 200°C. Heat is now transferred to steam, and steam expands reversibly and isothermally to a final pressure of 800 kPa. Determine the heat transferred and the work done during this process.

Step 1 of 4

Given data

Mass of saturate water vapor $m = 1.2\text{kg}$

Temperature of saturated vapor $T_1 = 200°\text{C}$

Final pressure $P = 800\text{kPa}$

Step 2 of 4

From the Saturated water –Temperature

At $T_1 = 200°\text{C}$

Saturated water vapor

Internal energy of saturated vapor $u_1 = u_g$

$= 2594.2\text{kJ/kg}$

Entropy of saturated vapor $s_1 = s_g$

$= 6.4302\text{kJ/kg}\cdot\text{K}$

Since process isothermally,

At $T_2 = 200°\text{C}$

$P_2 = 800\text{kPa}$

Internal energy of steam $u_2 = 2631.1\text{kJ/kg}$

Entropy of steam $s_2 = 6.8177\text{kJ/kg}\cdot\text{K}$

Step 3 of 4

Heat transfer for this reversible isothermal process

$$Q = T\Delta s$$
$$= Tm(s_2 - s_1)$$
$$= (200+273)(\text{K})(1.2(\text{kg}))(6.8177 - 6.4302)(\text{kJ/kg}\cdot\text{K})$$
$$= 219.94\text{kJ}$$

$$\boxed{Q = 219.94\text{kJ}}$$

Step 4 of 4

From energy balance for closed system

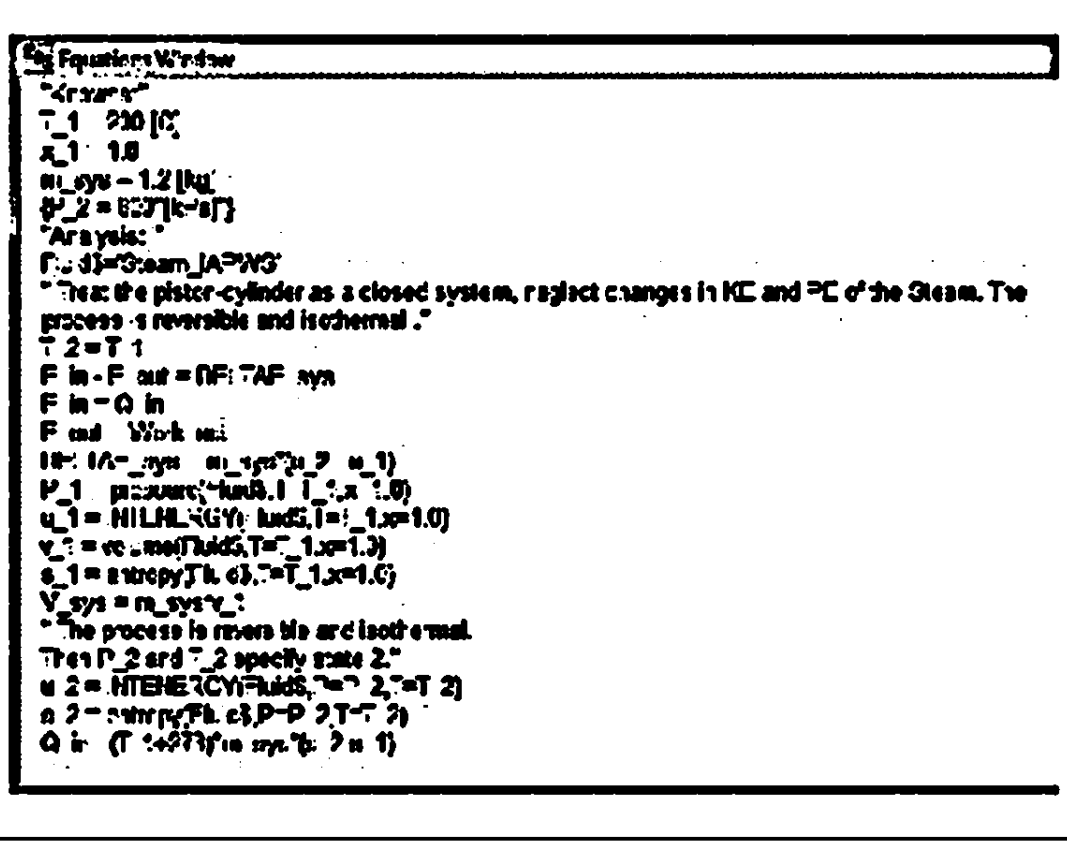
$$E_{in} - E_{out} = \Delta E_{system}$$
$$Q_{in} - w_{out} = \Delta U$$
$$w_{out} = Q_{in} - \Delta U$$
$$= Q_{in} - m(u_2 - u_1)$$

Work done during this process

$$w_{out} = (219.94) - (1.2)(\text{kg})(2631 - 2599)(\text{kJ/kg})$$
$$= 175.54\text{kJ}$$

$$\boxed{w_{out} = 175.54\text{kJ}}$$

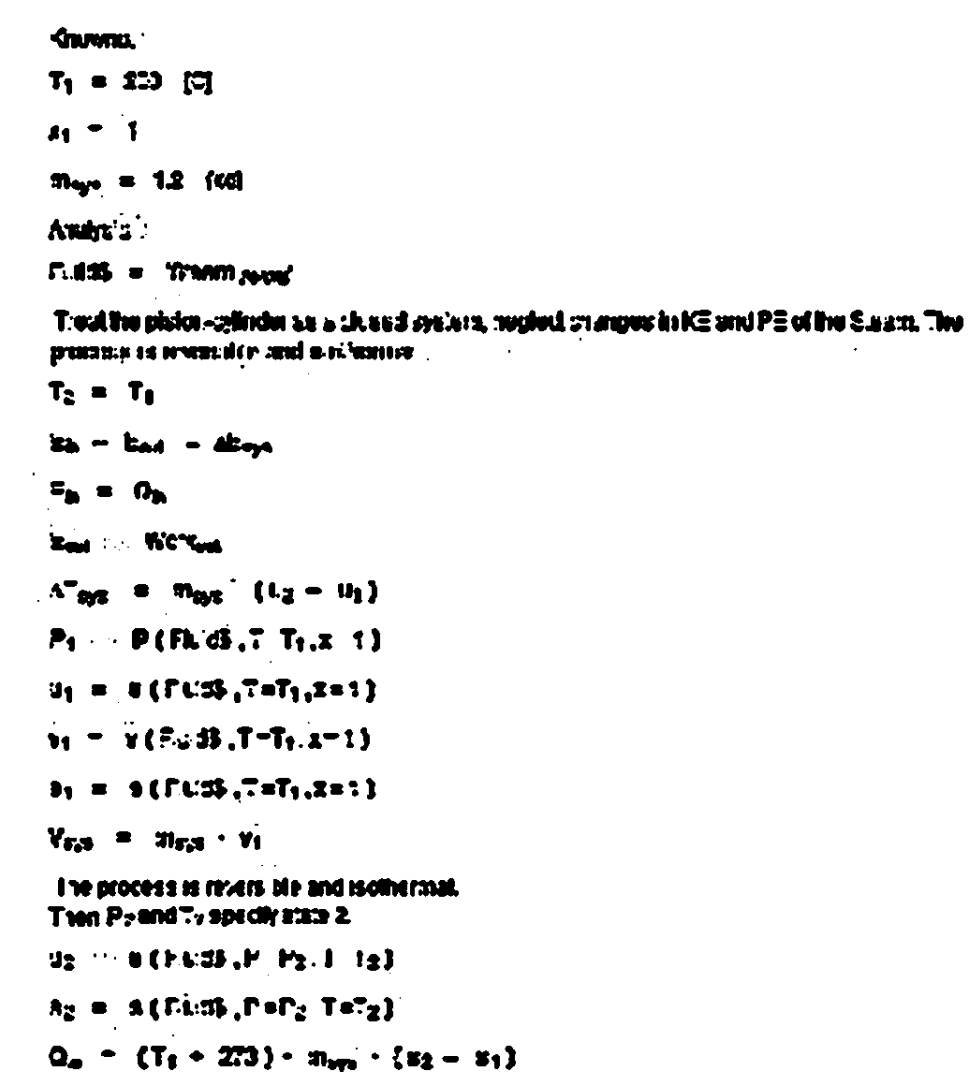
Question: 8.045P



Reconsider Prob. 8-44. Using EES (or other) software, evaluate and plot the heat transferred to the steam and the work done as a function of final pressure as the pressure varies from the initial value to the final value of 800 kPa.

Step 1 of 6

The procedure for developing solution by using EES software:
Open the new equations window EES software and type all the information which is used to solve the problem
For developing table:
1) Click on table followed by new parametric table and add the variables, which are varying variable and required answer variable, then one table will form with that variables
2) Click on the variable which is varying and enter initial value and final value.
3) For getting the required answer variable values corresponding to the varying variable values click on the green color button and then the table will form with required answers
For developing graph:
1) Click on plot followed by new plot window followed by x-y plot.
2) Select the x-axis variable and y-axis variable and then press ok, then the graph will form with the given values.

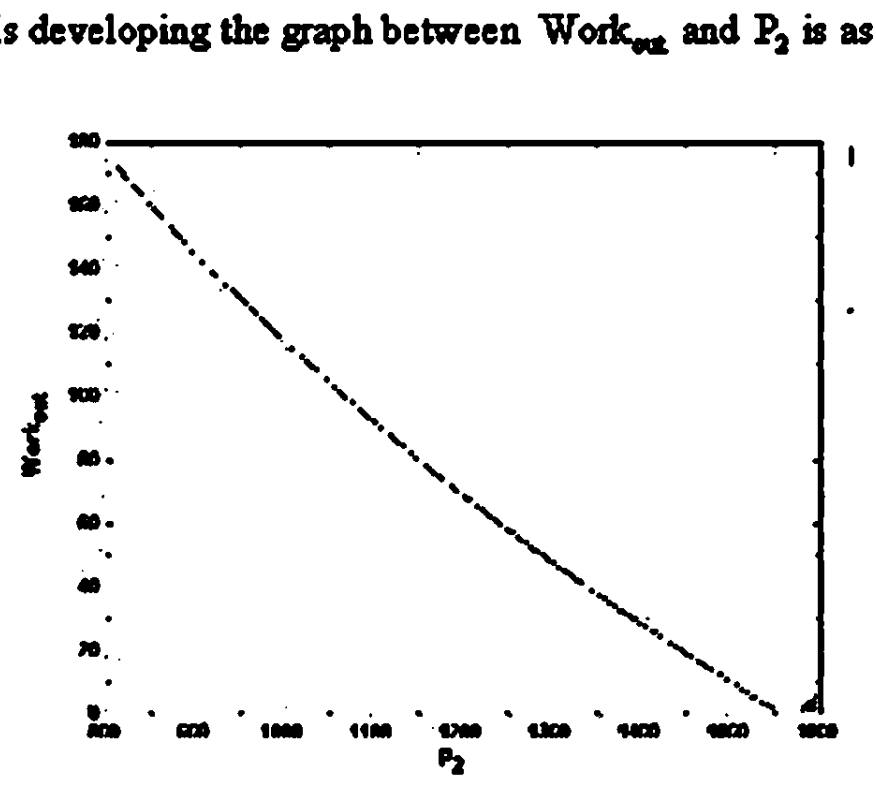


Step 2 of 6

The equations which are using in EES software for developing the solution are given in equations window is as shown below

Step 3 of 6

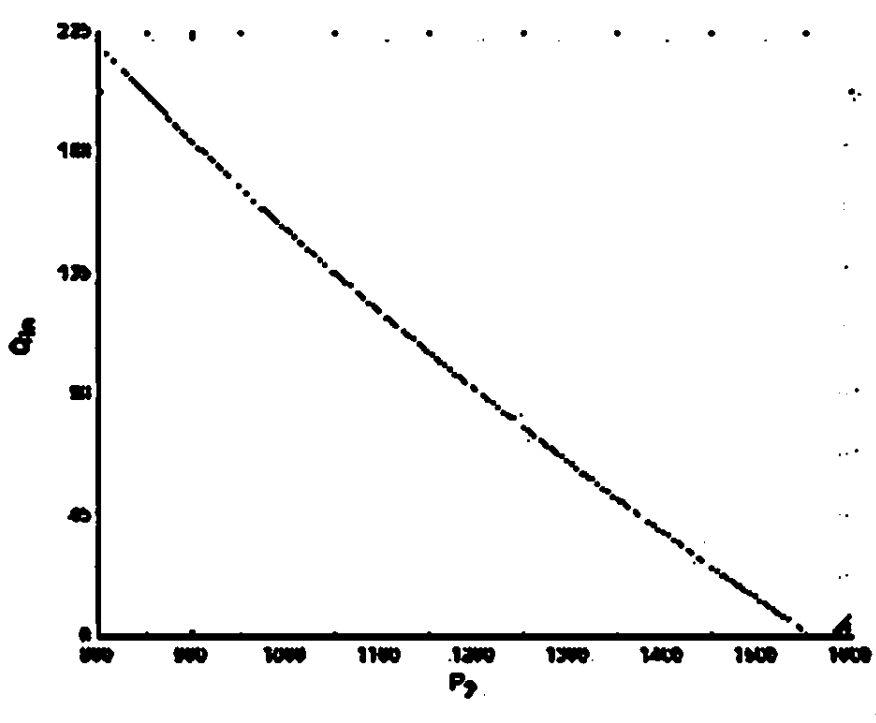
The EES software will convert the equations in equations window to equations in formatting window is as shown below



Step 4 of 6

The EES software is developing the table for Q_{in} and $Work_{out}$ corresponding to the P_2 values is as shown below

▷ 1..9	1 P_2	2 Q_{in}	3 $Work_{out}$
Run 1	800	219.9	175.7
Run 2	894.1	185.8	146.5
Run 3	988.3	154.4	120.1
Run 4	1082	125.2	96.11
Run 5	1177	97.83	74.08
Run 6	1271	71.91	53.71
Run 7	1365	47.2	34.75
Run 8	1459	23.45	17.02
Run 9	1553	0.4645	0.3319



Step 5 of 6

The EES software is developing the graph between $Work_{out}$ and P_2 is as shown below

Step 6 of 6

The EES software is developing the graph between Q_{in} and P_2 is as shown below

Question: 8.046P

Refrigerant-134a at 240 kPa and 20°C undergoes an isothermal process in a closed system until its quality is 20 percent. On per unit mass basis, determine how much work and heat transfer are required.

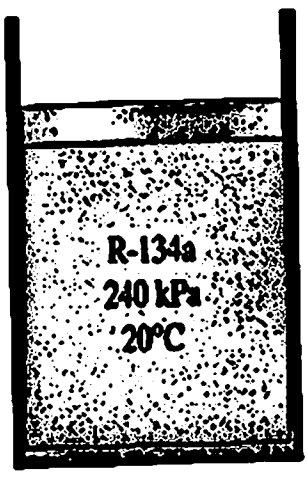


FIGURE P8–46

Step 1 of 5

Given data:

Inlet pressure of the refrigerant-143a, $P_1 = 240$ kPa

Inlet temperature of the refrigerant-143a,

$T_1 = 20°C$

$= 20 + 273$ K

$= 293$ K

Quality of refrigerant-143a at state 2,

$x_2 = 20\%$

$= 0.2$

Step 2 of 5

From the refrigerant-143a table,

At temperature, $T_1 = 20°C$ and pressure, $P_1 = 240$ kPa, we have

Internal energy at state 1, $u_1 = 246.74$ kJ/kg

Entropy at state 1, $s_1 = 1.0134$ kJ/kg·K

Since the process is an isothermal, so temperature remains constant, $T_1 = T_2 = 20°C$

From the refrigerant-143a table,

At temperature, $T_2 = 20°C$ and $x_2 = 0.2$, we have

Internal energy at saturated liquid, $u_f = 78.86$ kJ/kg

Internal energy during evaporation, $u_{fg} = 162.16$ kJ/kg

Entropy at saturated liquid, $s_f = 0.30063$ kJ/kg·K

Entropy during evaporation, $s_{fg} = 0.62172$ kJ/kg·K

Step 3 of 5

Internal energy at state 2,

$u_2 = u_f + x_2 u_{fg}$

$= 78.86 + (0.2 \times 162.16)$

$= 111.292$ kJ/kg

Entropy at state 2,

$s_2 = s_f + x_2 s_{fg}$

$= 0.30063 + (0.2 \times 0.62172)$

$= 0.4249$ kJ/kg·K

Step 4 of 5

Heat transferred into the system, we have

$Q_{in} = T_1(s_2 - s_1)$

$= 293(0.4249 - 1.0134)$

$= -172.43$ kJ/kg

Here the negative sign indicates that heat flow out to the system, Q_{out}

$Q_{out} = 172.43$ kJ/kg

Hence heat transferred from the system, $\boxed{Q_{out} = 172.43 \text{ kJ/kg}}$

Step 5 of 5

From the energy balance equation, we have

$E_{in} = E_{out}$

The equation can be rewritten as

$w_{in} = Q_{out} + u_2 - u_1$

$= 172.43 + (111.292 - 246.74)$

$= 36.98$ kJ/kg

Hence, work required for the system is $\boxed{w_{in} = 36.98 \text{ kJ/kg}}$

Question: 8.047P

Determine the heat transfer, in kJ/kg, for the reversible process 1-3 shown in Fig. P8-47.

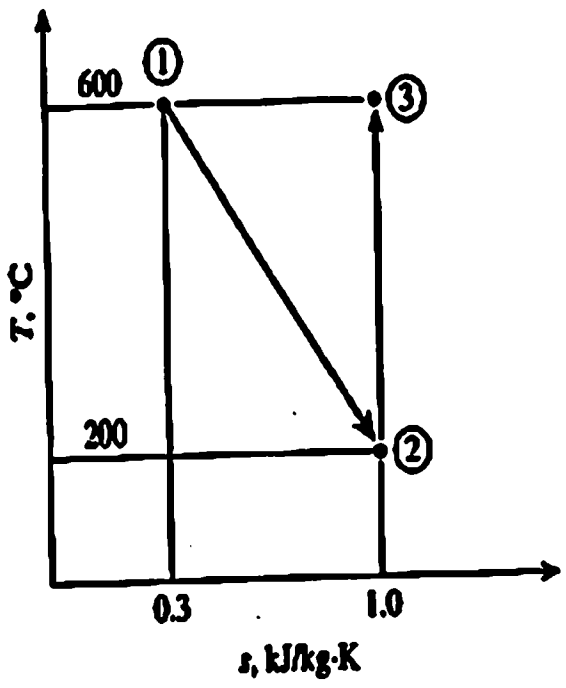

FIGURE P8–47

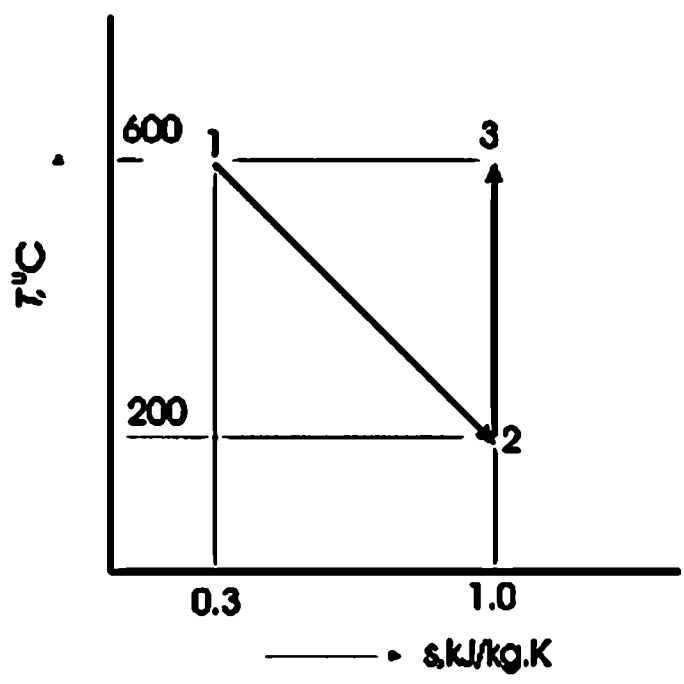
Step 1 of 5

Given

Temperature at point 1 is, $T_1 = 600°C = 873\ K$

Temperature at point 2 is, $T_2 = 200°C = 473\ K$



Temperature at point 3 is, $T_3 = 600°C = 873\ K$

Entropy at point 1 is, $s_1 = 0.3\ kJ/kg.K$

Entropy at point 2 is, $s_2 = 1.0\ kJ/kg.K$

Entropy at point 3 is, $s_3 = 1.0\ kJ/kg.K$

Step 2 of 5

Step 3 of 5

The heat transfer in any process is given by the area under the curve in a T-s diagram
So the heat transfer in the process 1-2 is given by

$$q_{1\text{-}2} = \int_1^2 T\,ds$$

$$q_{1\text{-}2} = T(s_2 - s_1)$$

In the process 1-2 the temperature is not constant and assuming that it is linear variation then we can take the temperature as average temperature. Therefore the above equation reduces to

$$q_{1\text{-}2} = \frac{T_1 + T_2}{2} \times (s_2 - s_1)$$

$$q_{1\text{-}2} = \frac{873 + 473}{2} \times (1.0 - 0.3)$$

$$q_{1\text{-}2} = \frac{1346}{2} \times (0.7)$$

$$q_{1\text{-}2} = 673 \times 0.7$$

$$q_{1\text{-}2} = 471.1\ kJ/kg$$

Step 4 of 5

The heat transfer in the process 2-3 is given by

$$q_{2\text{-}3} = \int_2^3 T\,ds$$

$$q_{2\text{-}3} = T(s_3 - s_2)$$

As the process 2-3 is a vertical line in the T-s diagram, there will not be any change in entropy. So, the above equation reduces to

$$q_{2\text{-}3} = T \times 0$$

$$q_{2\text{-}3} = 0$$

Step 5 of 5

The total heat transfer in the process 1-3 is given by

$$q_{1\text{-}3} = q_{1\text{-}2} + q_{2\text{-}3}$$

$$q_{1\text{-}3} = 471.1 + 0$$

$$\boxed{q_{1\text{-}3} = 471.1\ kJ/kg}$$

Therefore heat transfer for the reversible process 1-3 is 471.1 kJ/kg

Question: 8.048P

Calculate the heat transfer, in Btu/lbm, for the reversible process 1-3 shown in Fig. P8–18E.

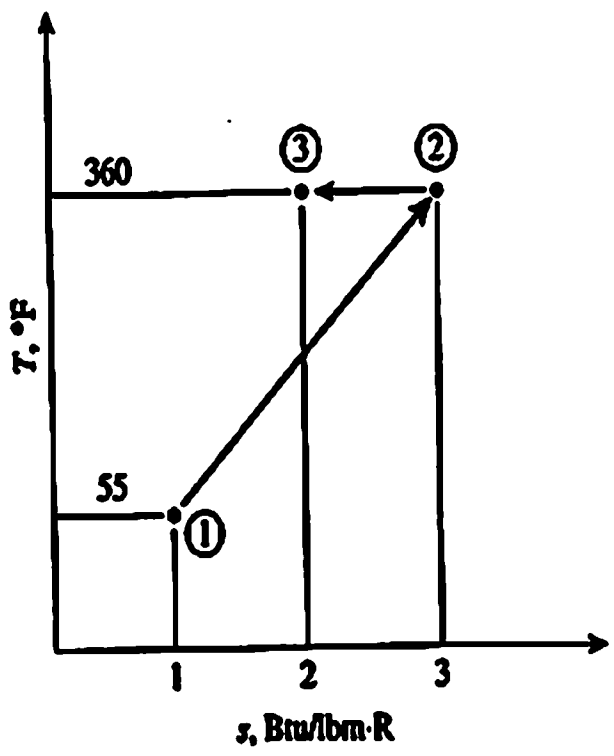


FIGURE P8–48E

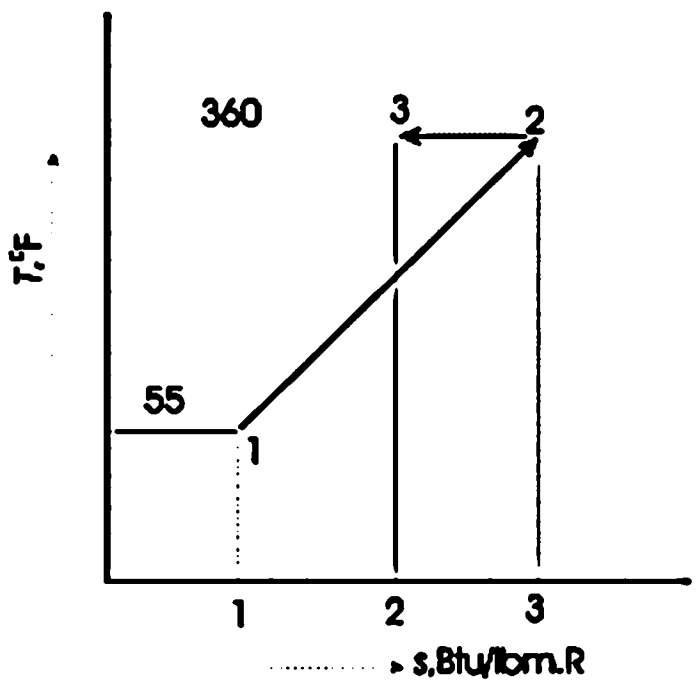
Step 1 of 5

Given

Temperature at state 1 is, $T_1 = 55°F = 514.67\ R$

Temperature at state 2 is, $T_2 = 360°F = 819.67\ R$



Temperature at state 3 is, $T_3 = 360°F = 819.67\ R$

Entropy at state 1 is, $s_1 = 1\ Btu/lbm\text{-}R$

Entropy at state 2 is, $s_2 = 3\ Btu/lbm\text{-}R$

Entropy at state 3 is, $s_3 = 2\ Btu/lbm\text{-}R$

Step 2 of 5

Step 3 of 5

The heat transfer in a process is given by the area under the curve in a T-s diagram.
So the heat transfer in the process 1-2 is given by

$$q_{1\text{-}2} = \int_1^2 T\,ds$$

$$q_{1\text{-}2} = T(s_2 - s_1)$$

In the process 1-2 the temperature is not constant and assuming that it is linear variation then we can take the temperature as average temperature. Therefore the above equation reduces to

$$q_{1\text{-}2} = \frac{T_1 + T_2}{2} \times (s_2 - s_1)$$

$$q_{1\text{-}2} = \frac{514.67 + 819.67}{2} \times (3 - 1)$$

$$q_{1\text{-}2} = \frac{1334.34}{2} \times 2$$

$$q_{1\text{-}2} = 1334.34\ Btu/lbm$$

Step 4 of 5

The heat transfer in the process 2-3 is given by

$$q_{2\text{-}3} = \int_2^3 T\,ds$$

As the process 2-3 is a horizontal line in the T-s diagram there will not be any change in temperature. So, the above equation reduces to

$$q_{2\text{-}3} = T_2(s_3 - s_2)$$

$$= 819.67 \times (2 - 3)$$

$$= 819.67 \times (-1)$$

$$q_{2\text{-}3} = -819.67\ Btu/lbm$$

Step 5 of 5

The total heat transfer in the process 1-3 is given by

$$q_{1\text{-}3} = q_{1\text{-}2} + q_{2\text{-}3}$$

$$q_{1\text{-}3} = 1334.34 + (-819.67)$$

$$q_{1\text{-}3} = 1334.34 - 819.67$$

$$\boxed{q_{1\text{-}3} = 514.67\ Btu/lbm}$$

Therefore heat transfer in the process 1-3 is 514.67 Btu/lbm

Question: 8.049P

Calculate the heat transfer, in kJ/kg, for the reversible steady-flow process 1-3 shown in Fig. P8-49

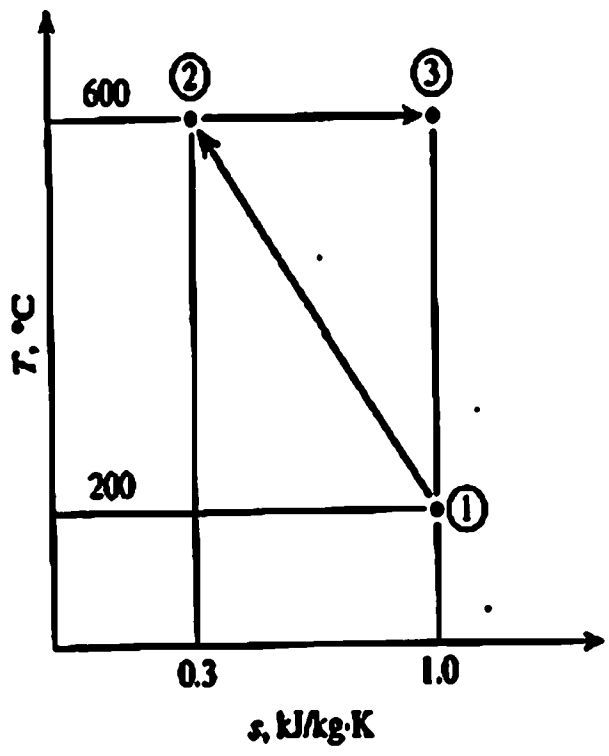


FIGURE P8–49

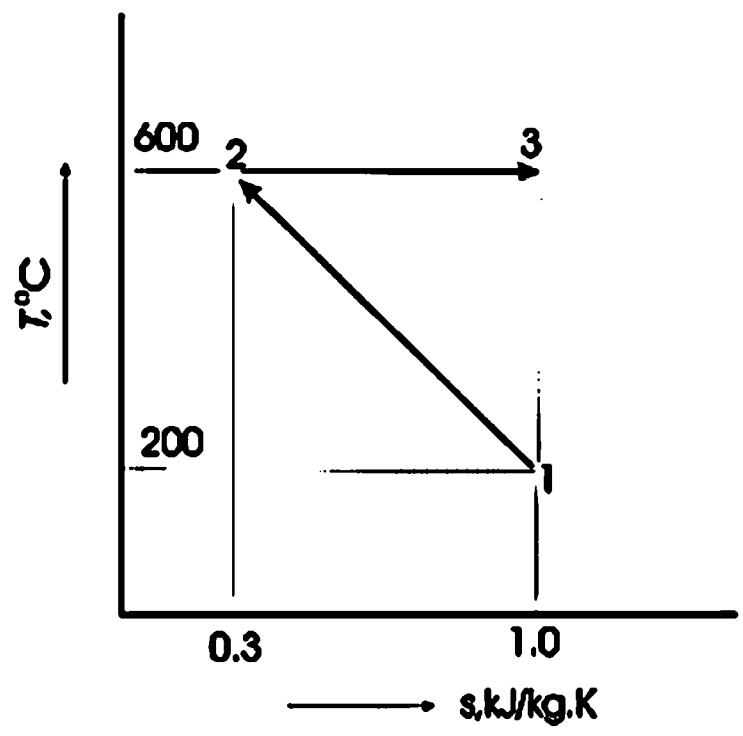
Step 1 of 5

Given

Temperature at point 1 is, $T_1 = 200^\circ C = 473\,K$

Temperature at point 2 is, $T_2 = 600^\circ C = 873\,K$



Temperature at point 3 is, $T_3 = 600^\circ C = 873\,K$

Entropy at point 1 is, $s_1 = 1.0\,kJ/kg.K$

Entropy at point 2 is, $s_2 = 0.3\,kJ/kg.K$

Entropy at point 3 is, $s_3 = 1.0\,kJ/kg.K$

Step 2 of 5

Step 3 of 5

The heat transfer in a process is given by the area under the curve in a T-s diagram.
So the heat transfer in the process 1-2 is given by

$$q_{1\text{-}2} = \int_1^2 T\,ds$$

$$q_{1\text{-}2} = T(s_2 - s_1)$$

In the process 1-2 the temperature is not constant and assuming that it is linear variation then we can take the temperature as average temperature. Therefore the above equation reduces to

$$q_{1\text{-}2} = \frac{T_1 + T_2}{2} \times (s_2 - s_1)$$

$$q_{1\text{-}2} = \frac{473+873}{2} \times (0.3 - 1.0)$$

$$q_{1\text{-}2} = \frac{1346}{2} \times (-0.7)$$

$$q_{1\text{-}2} = 673 \times (-0.7)$$

$$q_{1\text{-}2} = -471.1\,kJ/kg$$

Step 4 of 5

The heat transfer in the process 2-3 is given by

$$q_{2\text{-}3} = \int_2^3 T\,ds$$

$$q_{2\text{-}3} = T(s_3 - s_2)$$

As the process 2-3 is a horizontal line in the T-s diagram, there will not be any change in temperature. So, the above equation reduces to

$$q_{2\text{-}3} = T_2(s_3 - s_2)$$

$$q_{2\text{-}3} = 873 \times (1.0 - 0.3)$$

$$q_{2\text{-}3} = 873 \times 0.7$$

$$q_{2\text{-}3} = 611.1\,kJ/kg$$

Step 5 of 5

The total heat transfer in the process 1-3 is given by

$$q_{1\text{-}3} = q_{1\text{-}2} + q_{2\text{-}3}$$

$$q_{1\text{-}3} = -471.1 + 611.1$$

$$\boxed{q_{1\text{-}3} = 140\,kJ/kg}$$

Therefore heat transfer in the process 1-3 is 140 kJ/kg

Question: 8.050P

Steam is expanded in an isentropic turbine with a single inlet and outlet. At the inlet, the steam is at 2 MPa and 360°C The steam pressure at the outlet is 100 kPa. Calculate I the work produced by this turbine, in kJ/kg.

Step 1 of 5

Given

Inlet pressure of the steam is $P_1 = 2\ \text{MPa}$

Inlet temperature of the steam is $T_1 = 360\ \text{C}$

Outlet pressure of the steam is $P_2 = 100\ \text{kPa}$

Step 2 of 5

From Saturated water tables, at $P_1 = 2\ \text{MPa}$

At 350 C, $h = 3137.7\ \text{kJ/kg}$

At 400 C, $h = 3248.4\ \text{kJ/kg}$

Using interpolation technique,

$$h_1 = h_{at\ 350} + \frac{h_{at\ 400} - h_{at\ 350}}{400 - 350}(360 - 350)$$

$$h_1 = 3137.7 + \frac{3248.4 - 3137.7}{400 - 350}(360 - 350)$$

$$h_1 = 3137.7 + \frac{110.7}{50}(10)$$

$$h_1 = 3137.7 + 22.14$$

$$h_1 = 3159.84\ \text{kJ/kg}$$

Step 3 of 5

From Superheated steam tables, at $P_1 = 2\ \text{MPa}$

At 350 C, $s = 6.9583\ \text{kJ/kgK}$

At 400 C, $s = 7.1292\ \text{kJ/kgK}$

Using interpolation technique,

$$s_1 = s_{at\ 350} + \frac{s_{at\ 400} - s_{at\ 350}}{400 - 350}(360 - 350)$$

$$s_1 = 6.9583 + \frac{7.1292 - 6.9583}{400 - 350}(360 - 350)$$

$$s_1 = 6.9583 + \frac{0.1709}{50}(10)$$

$$s_1 = 6.9583 + 0.03418$$

$$s_1 = 6.99248\ \text{kJ/kgK}$$

Step 4 of 5

As the process is isentropic, $s_2 = s_1$

$s_2 = 6.99248\ \text{kJ/kgK}$

Now at pressure $P_2 = 100\ \text{kPa}$ from saturated steam tables

Entropy of saturated liquid $s_f = 1.3028\ \text{kJ/kgK}$

Entropy of evaporation $s_{fg} = 6.0562\ \text{kJ/kgK}$

Enthalpy of saturated liquid $h_f = 417.51\ \text{kJ/kg}$

Enthalpy of evaporation $h_{fg} = 2257.5\ \text{kJ/kg}$

Step 5 of 5

Quality at sate 2, $x_2 = \frac{s_2 - s_f}{s_{fg}}$

$$x_2 = \frac{6.99248 - 1.3028}{6.0562}$$

$$x_2 = 0.9395$$

Enthalpy at sate 2, $h_2 = h_f + x_2 h_{fg}$

$$h_2 = 417.51 + (0.9395)2257.5$$

$$h_2 = 2538.4\ \text{kJ/kg}$$

Work output per unit mass is

$$w_{out} = (h_1 - h_2)$$

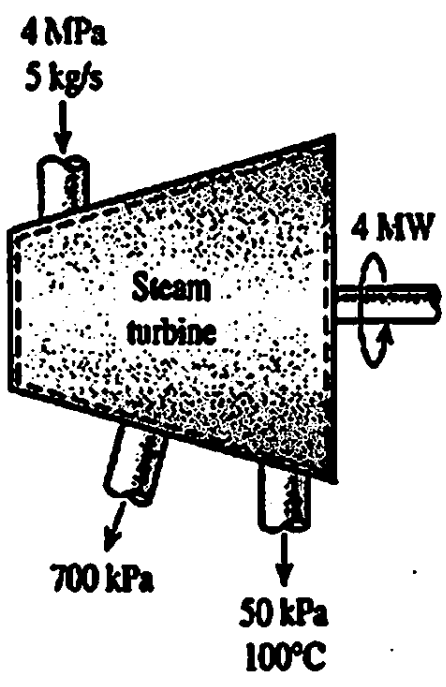
$$w_{out} = 3159.84 - 2538.4$$

$$w_{out} = 621.4\ \text{kJ/kg}$$

Work produced by turbine $\boxed{w_{out} = 621.4\ \text{kJ/kg}}$

Question: 8.051P

An isentropic steam turbine processes 5 kg/s of steam at 4 MPa, which is exhausted at 50 kPa and 100°C. Five percent of this flow is diverted for feedwater heating at 700 kPa. Determine the power produced by this turbine, in kW.



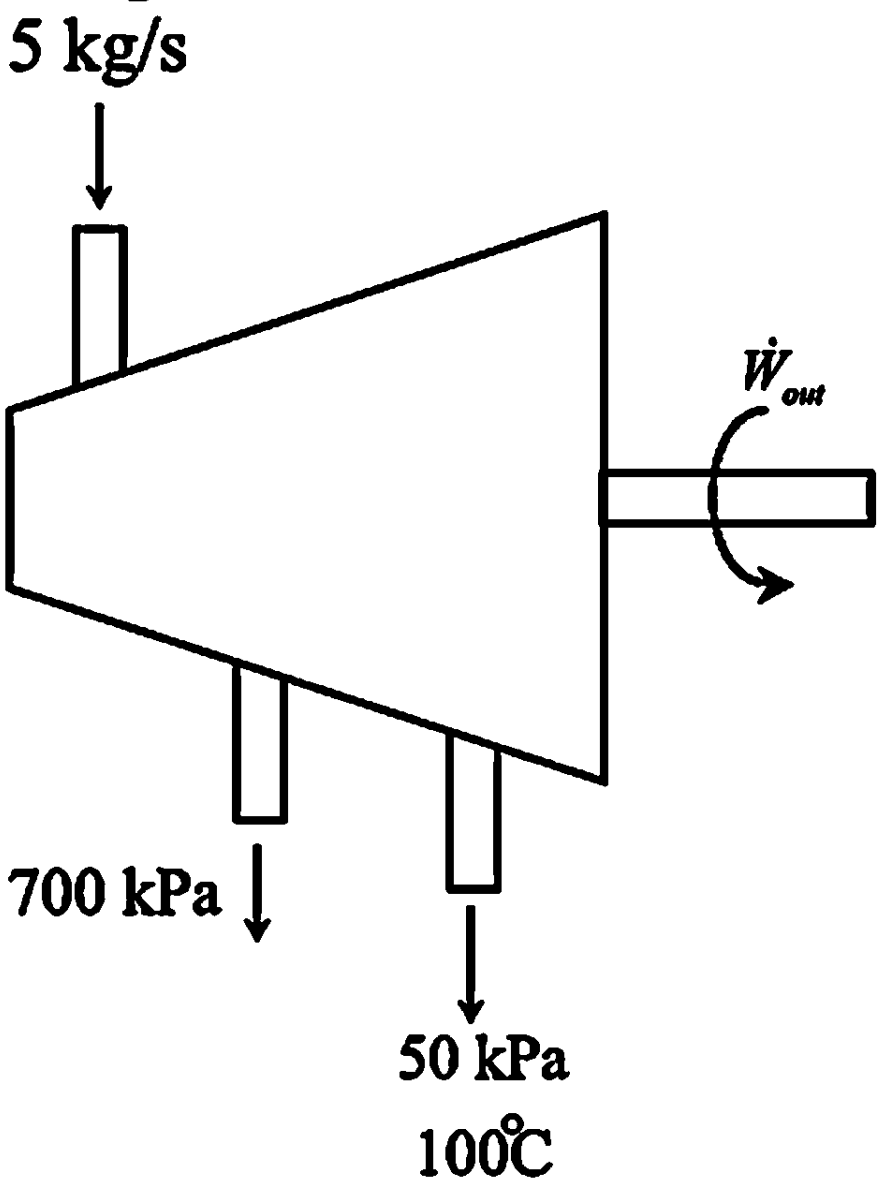


FIGURE P8–51

Step 1 of 7

Draw the schematic of the steam turbine.

Step 2 of 7

Calculate the mass of steam diverted to the feed water heater.

$$\dot{m}_2 = \frac{5}{100} \times \dot{m}_1 \text{ kg/s}$$

Here, $\dot{m}_1$ is the mass flow rate of steam into the turbine and $\dot{m}_2$ is the mass flow rate of diverted steam.

Substitute 5 kg/s for $\dot{m}_1$.

$$\begin{aligned}\dot{m}_2 &= 0.05\,\dot{m}_1 \text{ kg/s} \\ &= 0.05 \times 5 \text{ kg/s} \\ &= 0.25 \text{ kg/s}\end{aligned}$$

Step 3 of 7

Apply conservation of mass of mass to the turbine.

$$\dot{m}_1 = \dot{m}_2 + \dot{m}_3 \quad \text{..... (1)}$$

Here, $\dot{m}_3$ is the mass of steam leaving the turbine.

Substitute 5 kg/s for $\dot{m}_1$ and 0.25 kg/s for $\dot{m}_2$.

$$\begin{aligned}5 &= 0.25 + \dot{m}_3 \\ \dot{m}_3 &= 4.75 \text{ kg/s}\end{aligned}$$

Step 4 of 7

Obtain the properties of steam at a temperature of $100°C$ and at pressure 50 kPa from the table A-6 "super-heated water".

The enthalpy, $h_3 = 2682.4 \text{ kJ/kg}$

The entropy, $s_3 = 7.6953 \text{ kJ/kg·K}$

Step 5 of 7

As the expansion is isentropic,

$$s_1 = s_3$$

Obtain the properties of steam at a pressure of 4MPa and entropy of 7.6953 kJ/kg·K , by using the interpolation from the table A-6 "super-heated water".

$$\begin{aligned}h_1 &= 3906.3 + (4142.3 - 3906.3) \times \left(\frac{7.6953 - 7.6214}{7.8523 - 7.6214}\right) \\ &= 3981.8322 \text{ kJ/kg}\end{aligned}$$

Step 6 of 7

Obtain the properties of steam at a pressure of 700 kPa and entropy of 7.6953 kJ/kg·K , by using the interpolation from the table A-6 "super-heated water".

At pressure $P = 0.6 \text{ MPa}$, the enthalpy be is

$$\begin{aligned}(h_2)_1 &= 3166.1 + \frac{(7.6953 - 7.5481)(3270.8 - 3166.1)}{(7.7097 - 7.5481)} \\ &= 3261.47 \text{ kJ/kg}\end{aligned}$$

At pressure $P = 0.8 \text{ MPa}$, the enthalpy is

$$\begin{aligned}(h_2)_2 &= 3267.7 + \frac{(7.6953 - 7.5735)(3481.3 - 3267.7)}{(7.8692 - 7.5735)} \\ &= 3355.6826 \text{ kJ/kg}\end{aligned}$$

Obtain the value of enthalpy at 700 kPa by using double interpolation method.

$$\begin{aligned}h_2 &= 3261.47 + \frac{(0.7 - 0.6)(3355.6826 - 3261.47)}{(0.8 - 0.6)} \\ &= 3308.576 \text{ kJ/kg}\end{aligned}$$

Step 7 of 7

Apply energy balance to the turbine.

$$E_{in} = E_{out}$$

$$\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3 + \dot{W}_{out}$$

$$\dot{W}_{out} = \dot{m}_1 h_1 - \dot{m}_2 h_2 - \dot{m}_3 h_3$$

Substitute 5 kg/s for $\dot{m}_1$, 0.25 kg/s for $\dot{m}_2$, 4.75 kg/s for $\dot{m}_3$, 3981.8322 kJ/kg for h_1 , 3308.576 kJ/kg for 3308.576 kJ/kg and 2682.4 kJ/kg for h_3 .

$$\begin{aligned}\dot{W}_{out} &= 5 \times (3981.8322) - 0.25 \times 3308.576 - 4.75 \times 2682.4 \\ &= 6340.617 \text{ kW}\end{aligned}$$

Hence, the power produced in the turbine is $\boxed{6340.617 \text{ kW}}$.

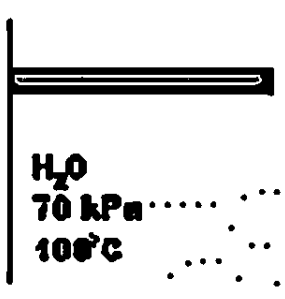
Question: 8.052P

Water at 70 kPa and 100°C is compressed is entropically in a closed system to 4 MPa. Determine the final temperature of the water and the work required, in kJ/kg, for this compression.

FIGURE P8–52

Step 1 of 7

Given Data:



Initial pressure is, $P_1 = 70$ kPa.

Initial temperature is, $T_1 = 100\ °C = 373$ K.

Final pressure is, $P_2 = 4$ MPa $= 4000$ kPa.

Step 2 of 7

Let us draw the diagram:

Step 3 of 7

We should interpolate between 50 kPa and 100 kPa

From the superheated water,

at pressure $P_1 = 70$ kPa and temperature $T_1 = 100\ °C$,

Entropy of steam is interpolated as

$$\frac{s_1 - 7.6953}{7.3611 - 7.6953} = \frac{70 - 50}{100 - 50}$$

$$\frac{s_1 - 7.6953}{-0.3342} = \frac{20}{50}$$

$$\frac{s_1 - 7.6953}{-0.3342} = 0.4$$

$$s_1 = (0.4 \times -0.3342) + 7.6953$$

$$= -0.13368 + 7.6953$$

$$= 7.56162\ \text{kJ/kg} \cdot \text{K}$$

Step 4 of 7

From the superheated water,

At pressure $P_1 = 70$ kPa and temperature $T_1 = 100\ °C$,

internal energy of steam is interpolated as

$$\frac{u_1 - 2511.5}{2506.2 - 2511.5} = \frac{70 - 50}{100 - 50}$$

$$\frac{u_1 - 2511.5}{-5.3} = \frac{20}{50}$$

$$\frac{u_1 - 2511.5}{-5.3} = 0.4$$

$$u_1 = (-5.3 \times 0.4) + 2511.5$$

$$= -2.12 + 2511.5$$

$$= 2509.38\ \text{kJ/kg}$$

Step 5 of 7

As the cylinder is insulated, the process is isentropic. So, the final entropy is given by

$s_2 = s_1$

Therefore, $s_2 = 7.56162\ \text{kJ/kg} \cdot \text{K}$

From the superheated water,

At pressure $P_2 = 4$ MPa and entropy $s_2 = 7.56162$ kJ/kg°K, the temperature is interpolated as

$$\frac{T_2 - 600}{700 - 600} = \frac{7.56162 - 7.3706}{7.6214 - 7.3706}$$

$$\frac{T_2 - 600}{100} = \frac{0.19102}{0.2508}$$

$$\frac{T_2 - 600}{100} = 0.7616$$

$$T_2 = 600 + (0.7616 \times 100)$$

$$T_2 = 600 + 76.16$$

$$= 676.16°C$$

$\boxed{T_2 = 676.16\ °C}$

Step 6 of 7

From the superheated water,

at pressure $P_2 = 4$ MPa and entropy $s_2 = 7.56162\ \text{kJ/kg} \cdot \text{K}$,

The internal energy is interpolated as

$$\frac{u_2 - 3279.4}{3462.4 - 3279.4} = \frac{7.56162 - 7.3706}{7.6214 - 7.3706}$$

$$\frac{u_2 - 3279.4}{183} = \frac{0.19102}{0.2508}$$

$$\frac{u_2 - 3279.4}{183} = 0.7616$$

$$u_2 = 3279.4 + (0.7616 \times 183)$$

$$= 3279.4 + 139.3728$$

$$= 3418.7728\ \text{kJ/kg}$$

Step 7 of 7

As the system is closed system, we will consider internal energy for calculating the work done. The work done is given by

$w = u_2 - u_1$

$w = 3418.7728 - 2509.38$

$\boxed{w = 909.3928\ \text{kJ}}$

Therefore the final temperature is $\boxed{T_2 = 676.16\ °C}$ and the work done is

$\boxed{w = 909.3928\ \text{kJ}}$.

Question: 8.053P

0.5-kg of R-134a is expanded isentropically from 600 kPa and 30°C to 140 kPa. Determine the total heat transfer and work production for this expansion.

Step 1 of 5

Given

Mass of R-134a used is, $m = 0.5\ \text{kg}$.

Initial pressure is, $P_1 = 600\ \text{kPa}$.

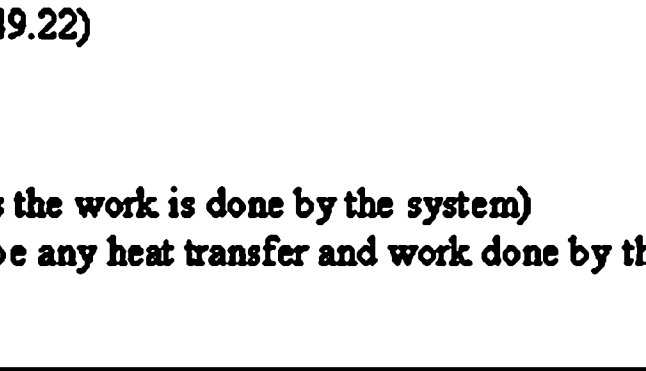
Initial temperature is, $T_1 = 30\ ^\circ\text{C} = 303\ \text{K}$.

Final Pressure is, $P_2 = 140\ \text{kPa}$.

Step 2 of 5

From the superheated refrigerant 134a,

At pressure $P_1 = 600\ \text{kPa}$ and temperature $T_1 = 30\ ^\circ\text{C}$,



internal energy and entropy of refrigerant respectively are

$u_1 = 249.22\ \text{kJ/kg}$

$s_1 = 0.9499\ \text{kJ/kg} \cdot \text{K}$

Step 3 of 5

Let us draw the T-s diagram:

Step 4 of 5

Given the process is isentropic. Therefore there will not be any heat transfer.

$$\boxed{Q = 0}$$

As the process is isentropic (constant entropy), the final entropy is given by

$s_2 = s_1$

Therefore, $s_2 = 0.9499\ \text{kJ/kg} \cdot \text{K}$

From the superheated refrigerant 134a,

at pressure $P_2 = 140\ \text{kPa}$ and entropy $s_2 = 0.9499\ \text{kJ/kg} \cdot \text{K}$,

the internal energy is interpolated as

$$\frac{u_2 - 219.54}{225.91 - 219.54} = \frac{0.9499 - 0.9446}{0.9724 - 0.9446}$$

$$\frac{u_2 - 219.54}{6.37} = \frac{0.0053}{0.0278}$$

$$\frac{u_2 - 219.54}{6.37} = 0.1906$$

$$u_2 = (6.37 \times 0.1906) + 219.54$$

$$= 1.2141 + 219.54$$

$$= 220.7541\ \text{kJ/kg}$$

Step 5 of 5

The work done on the system is given by

$$W = m \times (u_2 - u_1)$$

$$= 0.5 \times (220.7541 - 249.22)$$

$$= 0.5 \times (-28.4659)$$

$$= -14.233\ \text{kJ}$$

(Negative value indicates the work is done by the system)

Therefore there will not be any heat transfer and work done by the system is

$$\boxed{W = -14.233\ \text{kJ}}$$

Question: 8.054P

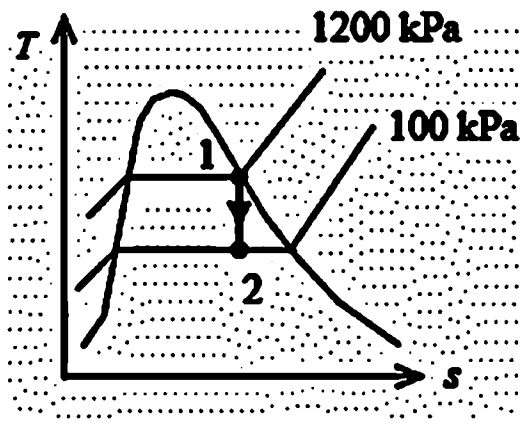
Refrigerant-134a enters a steady-flow, adiabatic turbine as a saturated vapor at 1200 kPa and expands to 100 kPa. The power produced by the turbine is found to be 100 kW when the process is also reversible.

(*a*) Sketch the *T*-*s* diagram with respect to the saturation lines for this process.

(*b*) Determine the volume flow rate of the refrigerant-134a at the turbine exit, in m3 /s.

Step 1 of 8

Given Data:



Inlet pressure is, $P_1 = 1200$ kPa.

Exit pressure is, $P_2 = 100$ kPa.

Power produced by the turbine is, $W_{tur} = 100$ kW.

Step 2 of 8

(a) Let us draw the T-s diagram:

Step 3 of 8

(b)

From The Saturated Refrigerant 134a,

At pressure $P_1 = 1200$ kPa and saturated vapor condition,

Enthalpy and entropy of refrigerant respectively are

$h_1 = h_g = 273.87$ kJ/kg

$s_1 = s_g = 0.91303$ kJ/kg · K

Step 4 of 8

From The Saturated Refrigerant 134a,

at pressure $P_2 = 100$ kPa saturated properties of refrigerant are as follows

Entropy of saturated liquid is $s_{f2} = 0.07188$ kJ/kg · K

Entropy of evaporation is $s_{fg2} = 0.87995$ kJ/kg · K

Enthalpy of saturated liquid is $h_{f2} = 17.28$ kJ/kg

Enthalpy of evaporation is $h_{fg2} = 217.16$ kJ/kg

Specific volume of saturated liquid is $v_{f2} = 0.0007259$ m^3/kg

Specific volume of saturated vapor is $v_{g2} = 0.19254$ m^3/kg

Step 5 of 8

Given entropy is constant. So, the final entropy is given by

$s_2 = s_1$

Therefore, $s_2 = 0.91303$ kJ/kg · K

The entropy is also given by

$s_2 = s_{f2} + x_2 \times s_{fg2}$

$0.91303 = 0.07188 + x_2 \times 0.87995$

$$x_2 = \frac{0.91303 - 0.07188}{0.87995}$$

$$= \frac{0.84115}{0.87995}$$

$$= 0.956$$

Step 6 of 8

Exit enthalpy is given by

$h_2 = h_{f2} + x_2 \times h_{fg2}$

$= 17.28 + 0.956 \times 217.16$

$= 17.28 + 207.60496$

$= 224.88496$ kJ/kg

Step 7 of 8

Exit specific volume is given by

$v_2 = v_{f2} + x_2 \times v_{fg2}$

$= v_{f2} + x_2 \times (v_{g2} - v_{f2})$

$= 0.0007259 + 0.956 \times (0.19254 - 0.0007259)$

$= 0.0007259 + 0.956 \times 0.1918141$

$= 0.0007259 + 0.18337428$

$= 0.1841002$ m^3/kg

Step 8 of 8

The turbine work is given by

$W_{tur} = m \times (h_1 - h_2)$

$100 = m \times (273.87 - 224.88496)$

$100 = m \times 48.98504$

$$m = \frac{100}{48.98504}$$

$m = 2.041$ kg/s

The volume flow rate is given by

$Q = m \times v_2$

$= 2.041 \times 0.1841002$

$= 0.3757$ m^3/s

Therefore volume flow rate is $\boxed{Q = 0.3757 \text{ m}^3/\text{s}}$

Question: 8.055P

Two kilograms of saturated water vapor at 600 kPa are contained in a piston-cylinder device. The water expands adiabatically until the pressure is 100 kPa and is said to produce 700 kJ of work output.

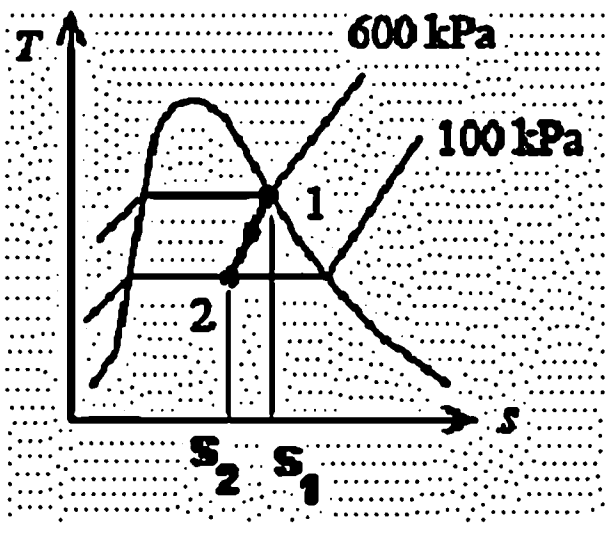
(*a*) Determine the entropy change of the water, in kJ/kg-K.

(*b*) Is this process realistic? Using the *T-s* diagram for the process and the concepts of second law, support your answer.

Step 1 of 9

Given

Mass of water in the device is, $m = 2\ kg$.



Initial pressure is, $P_1 = 600\ kPa$.

Final pressure is, $P_2 = 100\ kPa$.

Power produced by the device is, $W_{dev} = 700\ kJ$.

Step 2 of 9

Let us draw the T-s diagram:

Step 3 of 9

(a)

From the saturated water pressure table,

At pressure $P_1 = 600\ kPa$ and saturated vapor condition,

Internal energy and entropy of steam respectively are

$u_1 = u_g = 2566.8\ kJ/kg$

$s_1 = s_g = 6.7593\ kJ/kg \cdot K$

Step 4 of 9

Work output is given by

$$W_{dev} = m \times (u_1 - u_2)$$

$$u_2 = u_1 - \frac{W_{dev}}{m}$$

$$u_2 = 2566.8 - \frac{700}{2}$$

$$u_2 = 2566.8 - 350$$

$$u_2 = 2216.8\ kJ/kg$$

Step 5 of 9

From the saturated water pressure table,

At pressure $P_2 = 100\ kPa$ saturated properties of refrigerant are as follows

Entropy of saturated liquid is $s_{f2} = 1.3028 kJ/kg \cdot K$

Entropy of evaporation is $s_{fg2} = 6.0562\ kJ/kg \cdot K$

Internal energy of saturated liquid is $u_{f2} = 417.4\ kJ/kg$

Internal energy of evaporation is $u_{fg2} = 2088.2\ kJ/kg$

Step 6 of 9

The internal energy is also given by

$$u_2 = u_{f2} + x_2 \times u_{fg2}$$

$$2216.8 = 417.4 + x_2 \times 2088.2$$

$$x_2 = \frac{2216.8 - 417.4}{2088.2}$$

$$= \frac{1799.4}{2088.2}$$

$$= 0.8617$$

Step 7 of 9

Exit entropy is given by

$$s_2 = s_{f2} + x_2 \times s_{fg2}$$

$$= 1.3028 + 0.8617 \times 6.0562$$

$$= 1.3028 + 5.2186$$

$$= 6.5214\ kJ/kg \cdot K$$

Step 8 of 9

The entropy change is given by

$$\Delta s = s_2 - s_1$$

$$= 6.5214 - 6.7593$$

$$= -0.2379 kJ/kg \cdot K$$

$$\boxed{\Delta s = -0.2379\ kJ/kg^{\circ}K}$$

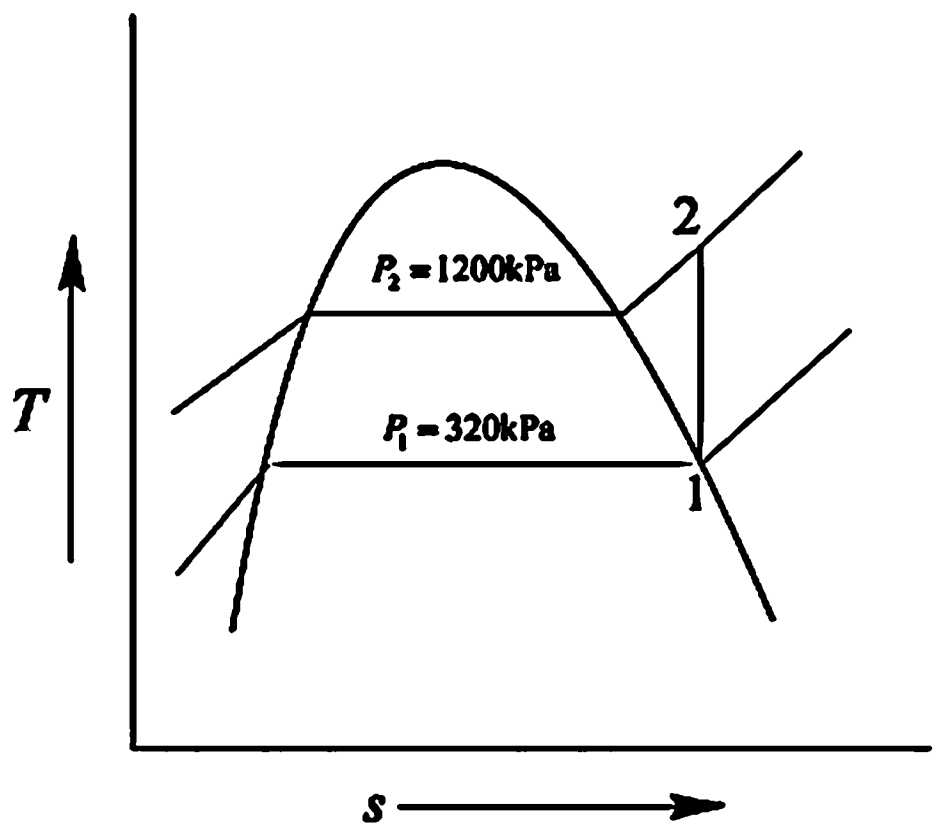
(Negative sign indicates that the entropy decreases)

Step 9 of 9

(b) Generally the entropy of an adiabatic process should remain constant. The process is not realistic as the entropy of the steam decreases.

Question: 8.056P

Refrigerant-134a enters a steady-flow adiabatic compressor as a saturated vapor at 320 kPa and is compressed to 1200 kPa. The minimum power supplied to the compressor is found to be 100 kW.



(*a*) Sketch the *T*-*s* diagram with respect to the saturation lines for this process.

(*b*) Determine the volume flow rate of the refrigerant-134a at the compressor inlet, in m3 /s.

Step 1 of 4

(a)

Represent the compression process 1-2 on *T*-*s* diagram as shown below:

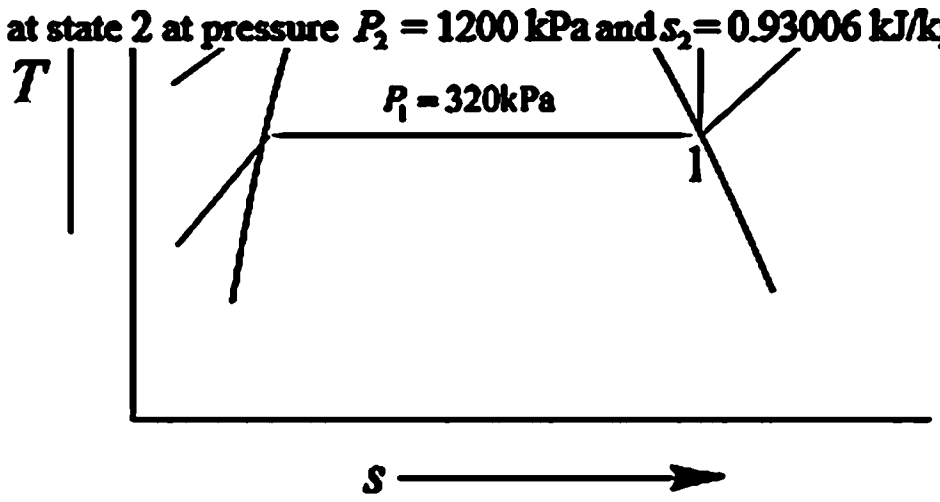
Step 2 of 4

(b)

Obtain the properties from saturated refrigerant 134a tables at pressure $P_1 = 320\ \text{kPa}$

Specific enthalpy of saturated vapor $h_1 = h_g = 251.88\ \text{kJ/kg}$

Specific entropy of saturated vapor $s_1 = s_g = 0.93006\ \text{kJ/kg·K}$



Specific volume of saturated vapor $v_1 = v_g = 0.063604\ \text{m}^3/\text{kg}$

Entropy remains constant during the process 1-2. Find the enthalpy at state 2 by using the condition,

$s_2 = s_1$

$s_2 = 0.93006\ \text{kJ/kg·K}$

Obtain enthalpy at state 2 at pressure $P_2 = 1200\ \text{kPa}$ and $s_2 = 0.93006\ \text{kJ/kg·K}$ from

Step 2 of 4

(b)

Obtain the properties from saturated refrigerant 134a tables at pressure $P_1 = 320\ \text{kPa}$

Specific enthalpy of saturated vapor $h_1 = h_g = 251.88\ \text{kJ/kg}$

Specific entropy of saturated vapor $s_1 = s_g = 0.93006\ \text{kJ/kg·K}$

Specific volume of saturated vapor $v_1 = v_g = 0.063604\ \text{m}^3/\text{kg}$

Entropy remains constant during the process 1-2. Find the enthalpy at state 2 by using the condition,

$s_2 = s_1$

$s_2 = 0.93006\ \text{kJ/kg·K}$

Obtain enthalpy at state 2 at pressure $P_2 = 1200\ \text{kPa}$ and $s_2 = 0.93006\ \text{kJ/kg·K}$ from

$= 0.23137\ \text{m}^3/\text{s}$

Therefore, volume flow rate of the refrigerant at the inlet of the compressor is

$\boxed{0.23137\ \text{m}^3/\text{s}}$

Question: 8.057P

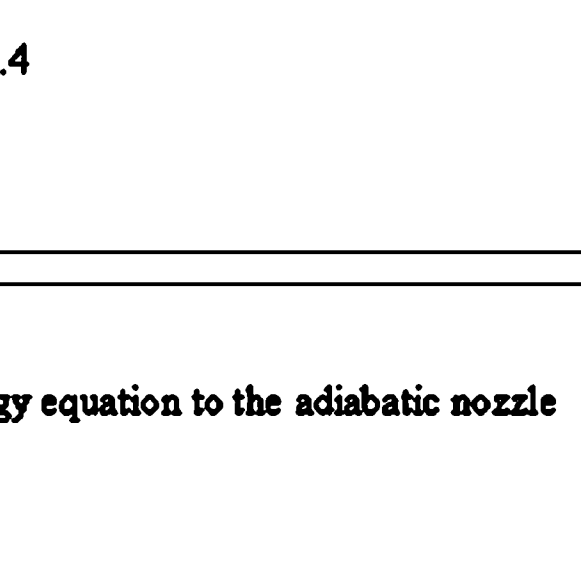
Steam enters a steady-flow adiabatic nozzle with a low inlet velocity as a saturated vapor at 6 MPa and expands to 1.2 MPa.

(*a*) Under the conditions that the exit velocity is to be the maximum possible value, sketch the *T-s* diagram with respect to the saturation lines for this process.

(*b*) Determine the maximum exit velocity of the steam, in m/s.

Step 1 of 5

Given



Saturated vapor enters the nozzle at pressure $P_1 = 6\ \text{MPa} = 6000\ \text{kPa}$

Pressure at nozzle exit is, $P_2 = 1.2\ \text{MPa} = 1200\ \text{kPa}$

Step 2 of 5

(a)

For the maximum possible exit velocity $h_1 - h_2$ should be maximum, for which the process to be isentropic.

Step 3 of 5

(b)

From saturated water tables at pressure $P_1 = 6\ \text{MPa}$

$h_1 = h_g = 2784.6\ \text{kJ/kg}$

$s_1 = s_g = 5.8902\ \text{kJ/kg.K}$

From saturated water tables at pressure $P_2 = 1.2\ \text{MPa}$

$h_{f2} = 798.33\ \text{kJ/kg}$

$h_{fg2} = 1985.4\ \text{kJ/kg}$

$s_{f2} = 2.2159\ \text{kJ/kg.K}$

$s_{fg2} = 4.3058\ \text{kJ/kg.K}$

Step 4 of 5

Since the process is isentropic the exit specific entropy can be calculated as

$s_2 = s_1$

$s_{f2} + x_2 \times s_{fg2} = s_1$

$2.2159 + x_2 \times 4.3058 = 5.8902$

$$x_2 = \frac{5.8902 - 2.2159}{4.3058}$$

$x_2 = 0.853$

Specific enthalpy at the exit can be calculated as

$h_2 = h_{f2} + x_2 \times h_{fg2}$

$h_2 = 798.33 + 0.8533 \times 1985.4$

$h_2 = 798.33 + 1694.14$

$h_2 = 2492.47\ \text{kJ/kg}$

Step 5 of 5

Applying steady flow energy equation to the adiabatic nozzle

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2}$$

$$h_1 - h_2 + \frac{V_1^2}{2} = \frac{V_2^2}{2}$$

Since inlet velocity is very low $V_1 = 0$

$$(2784.6 - 2492.47) \times 10^3 + 0 = \frac{V_2^2}{2}$$

$V_2 = 764.369\ \text{m/s}$

Therefore the maximum exit velocity of the steam is $\boxed{V_2 = 764.369\ \text{m/s}}$

Question: 8.058P

A rigid, 20-L steam cooker is arranged with a pressure relief valve set to release vapor and maintain the pressure once the pressure inside the cooker reaches 150 kPa. Initially, this cooker is filled with water at 175 kPa with a quality of 10 percent. Heat is now added until the quality inside the cooker is 40 percent. Determine the minimum entropy change of the thermal energy reservoir supplying this heat.

Step 1 of 7

Obtain the properties of water from table A-15 "properties of saturated water" at pressure of $175\ \text{kPa}$.

Specific volume of saturated liquid $v_{f1} = 0.0010057\ \text{m}^3/\text{kg}$

Specific volume of saturated vapor $v_{g1} = 1.0037\ \text{m}^3/\text{kg}$

Specific entropy of saturated liquid $s_{f1} = 1.4850\ \text{kJ/kg}\cdot\text{K}$

Specific entropy of liquid vapor mixture $s_{fg1} = 5.6865\ \text{kJ/kg}\cdot\text{K}$

Step 2 of 7

Find the initial specific volume at the initial condition.

$$v_1 = v_{f1} + x_1 \times \left(v_{g1} - v_{f1}\right)$$

Substitute $0.0010057\ \text{m}^3/\text{kg}$ for v_{f1}, $1.0037\ \text{m}^3/\text{kg}$ for v_{g1} and 0.1 for x.

$$\begin{aligned} v_1 &= 0.001057 + 0.1 \times (1.0037 - 0.001057) \\ &= 0.10132\ \text{m}^3/\text{kg} \end{aligned}$$

Find the initial specific entropy by using the equation,

$$s_1 = s_{f1} + x_1 \times s_{fg1}$$

Substitute $1.4850\ \text{kJ/kg}\cdot\text{K}$ for s_{f1}, $5.6865\ \text{kJ/kg}\cdot\text{K}$ for s_{fg1}.

$$\begin{aligned} s_1 &= 1.485 + 0.1 \times 5.6865 \\ &= 2.05365\ \text{kJ/kg}\cdot\text{K} \end{aligned}$$

Step 3 of 7

Obtain the properties of water from table A-15 "properties of saturated water" at pressure of $150\ \text{kPa}$.

Specific volume of saturated liquid $v_{f2} = 0.0010053\ \text{m}^3/\text{kg}$

Specific volume of saturated vapor $v_{g2} = 1.1594\ \text{m}^3/\text{kg}$

Specific entropy of saturated liquid $s_{f2} = 1.4337\ \text{kJ/kg}\cdot\text{K}$

Specific entropy of liquid vapor mixture $s_{fg2} = 5.7894\ \text{kJ/kg}\cdot\text{K}$

Specific entropy of saturated vapor $s_{g2} = 7.2231\ \text{kJ/kg}\cdot\text{K}$

Step 4 of 7

Find the final specific volume at the final condition.

$$v_2 = v_{f2} + x_2 \times \left(v_{g2} - v_{f2}\right)$$

Substitute $0.0010053\ \text{m}^3/\text{kg}$ for v_{f2}, $1.1594\ \text{m}^3/\text{kg}$ for v_{g2} and 0.4 for x as the final quality is 40%.

$$\begin{aligned} v_2 &= 0.001053 + 0.4 \times (1.1594 - 0.001053) \\ &= 0.4643\ \text{m}^3/\text{kg} \end{aligned}$$

Find the final specific entropy by using the equation,

$$s_2 = s_{f2} + x_2 \times s_{fg2}$$

Substitute $1.4337\ \text{kJ/kg}\cdot\text{K}$ for s_{f2}, $5.7894\ \text{kJ/kg}\cdot\text{K}$ for s_{fg2} and 0.4 for x_2.

$$\begin{aligned} s_2 &= 1.4337 + 0.4 \times 5.7894 \\ &= 3.74946\ \text{kJ/kg}\cdot\text{K} \end{aligned}$$

Step 5 of 7

Find the initial mass of water by using the expression,

$$m_1 = \frac{V}{v_1}$$

Here, V is volume of steam cooker

Substitute $20\times10^{-3}\ \text{m}^3$ for V and $0.10132\ \text{m}^3/\text{kg}$ for v_1.

$$\begin{aligned} m_1 &= \frac{0.02}{0.10132} \\ &= 0.1974\ \text{kg} \end{aligned}$$

Calculate the final mass using the relation,

$$m_2 = \frac{V}{v_2}$$

Substitute $20\times10^{-3}\ \text{m}^3$ for V and $0.4643\ \text{m}^3/\text{kg}$ for v_2.

$$\begin{aligned} m_2 &= \frac{0.02}{0.46439} \\ &= 0.0431\ \text{kg} \end{aligned}$$

Step 6 of 7

Apply conservation of mass equation to the system,

$$\frac{dm}{dt} = \sum_{in} m - \sum_{out} m$$

Since there is no mass of water entering into the system, $\sum_{in} m = 0$

$$\frac{dm}{dt} = 0 - \sum_{out} m$$

$$\frac{dm}{dt} = -m_{out}$$

Apply Entropy balance by using the equation,

$$\frac{dS_{surr}}{dt} + \frac{d(ms)}{dt} + s \times m_{out} \geq 0$$

$$\frac{dS_{surr}}{dt} + \frac{d(ms)}{dt} - s\frac{dm}{dt} \geq 0$$

Multiply with dt and integrate the above equation.

$$\Delta S_{surr} + m_2 s_2 - m_1 s_1 - s_{out}\left(m_2 - m_1\right) \geq 0$$

Here, s_{out} is specific entropy of saturated vapor coming out from the steam cooker at pressure $p_2 = 150\ \text{kPa}$

Step 7 of 7

Obtain the properties of water from table A-15 "properties of saturated water" at pressure of $150\ \text{kPa}$.

Specific entropy of saturated vapor $s_{g2} = 7.2231\ \text{kJ/kg}\cdot\text{K}$

Substitute $0.0431\ \text{kg}$ for m_2, $0.1974\ \text{kg}$ for m_1, $3.74946\ \text{kJ/kg}\cdot\text{K}$ for s_2 and $7.2231\ \text{kJ/kg}\cdot\text{K}$ for s_{out}.

$$\begin{aligned} &\Delta S_{surr} + m_2 s_2 - m_1 s_1 - s_{out}\left(m_2 - m_1\right) \geq 0 \\ &\Delta S_{surr} + (0.0431\times3.74946) - (0.1974\times2.05365) - 7.2231\times(0.0431 - 0.1974) \geq 0 \\ &\Delta S_{surr} + 0.1616 - 0.4054 - 7.2231\times(-0.1543) \geq 0 \\ &\Delta S_{surr} + 0.1616 - 0.4054 + 1.1145 \geq 0 \\ &\Delta S_{surr} + 0.8707 \geq 0 \\ &\Delta S_{surr} \geq -0.8707\ \text{kJ/K} \end{aligned}$$

Therefore, the minimum entropy change required is $\boxed{-0.8707\ \text{kJ/K}}$

Question: 8.-59WATER-ST

In the preceding problem, the water is stirred at the same time that it is being heated. Determine the minimum entropy change of the heat-supplying source if 100 kJ of work is done on the water as it is being heated.

Step 1 of 11

Given data:

Volume of the cooker is, $V = 20\ \text{L}$

$= 0.02\ \text{m}^3$

Initial pressure in the cooker is, $P_1 = 175\ \text{kPa}$

Initial quality of steam in the cooker is, $x_1 = 10\ \%$

$= 0.1$

Final quality of steam in the cooker is, $x_2 = 40\ \%$

$= 0.4$

Pressure maintained in the cooker is, $P_2 = 150\ \text{kPa}$

Work done on water is, $W = 100\ \text{kJ}$

Step 2 of 11

From Saturated water pressure table

At pressure $P_1 = 175\ \text{kPa}$ the properties of steam are

$v_{f1} = 0.001057\ \text{m}^3/\text{kg}$

$v_{g1} = 1.0037\ \text{m}^3/\text{kg}$

$s_{f1} = 1.485\ \text{kJ/kg°K}$

$s_{fg1} = 5.6865\ \text{kJ/kg°K}$

From Saturated water pressure table

At pressure $P_2 = 150\ \text{kPa}$ the properties of steam are

$v_{f2} = 0.001053\ \text{m}^3/\text{kg}$

$v_{g2} = 1.1594\ \text{m}^3/\text{kg}$

$s_{f2} = 1.4337\ \text{kJ/kg°K}$

$s_{fg2} = 5.7894\ \text{kJ/kg°K}$

Step 3 of 11

Initial specific volume is given by

$v_1 = v_{f1} + x_1 \times v_{fg1}$

$v_1 = v_{f1} + x_1 \times (v_{g1} - v_{f1})$

$v_1 = 0.001057 + 0.1 \times (1.0037 - 0.001057)$

$v_1 = 0.001057 + 0.1 \times 1.002643$

$v_1 = 0.001057 + 0.1002643$

$v_1 = 0.10132\ \text{m}^3/\text{kg}$

Step 4 of 11

Initial specific entropy is given by

$s_1 = s_{f1} + x_1 \times s_{fg1}$

$s_1 = 1.485 + 0.1 \times 5.6865$

$s_1 = 1.485 + 0.56865$

$s_1 = 2.05365\ \text{kJ/kg°K}$

Step 5 of 11

Final specific volume is given by

$v_2 = v_{f2} + x_2 \times v_{fg2}$

$v_2 = v_{f2} + x_2 \times (v_{g2} - v_{f2})$

$v_2 = 0.001053 + 0.4 \times (1.1594 - 0.001053)$

$v_2 = 0.001053 + 0.4 \times 1.158347$

$v_2 = 0.001053 + 0.46334$

$v_2 = 0.46439\ \text{kJ/kg°K}$

Step 6 of 11

Final specific entropy is given by

$s_2 = s_{f2} + x_2 \times s_{fg2}$

$s_2 = 1.4337 + 0.4 \times 5.7894$

$s_2 = 1.4337 + 2.31576$

$s_2 = 3.74946\ \text{kJ/kg°K}$

Step 7 of 11

Initial mass is given by

$$m_1 = \frac{V}{v_1}$$

$$m_1 = \frac{0.02}{0.10132}$$

$m_1 = 0.1974\ \text{kg}$

Final mass is given by

$$m_2 = \frac{V}{v_2}$$

$$m_2 = \frac{0.02}{0.46439}$$

$m_2 = 0.0431\ \text{kg}$

Step 8 of 11

According to conversation of mass principle,

$$\frac{dm}{dt} = \sum_{in} m - \sum_{out} m$$

As no mass is coming in, $\sum_{in} m = 0$

$$\frac{dm}{dt} = 0 - \sum_{out} m$$

$$\frac{dm}{dt} = -m_{out}$$

Step 9 of 11

Work done on water cannot be added to entropy balance as work done has no effect on entropy.

So, entropy balance is given by

$$\frac{dS_{sur}}{dt} + \frac{d(ms)}{dt} + s \times m_{out} \geq 0$$

$$\frac{dS_{sur}}{dt} + \frac{d(ms)}{dt} - s\frac{dm}{dt} \geq 0$$

Multiplying by dt and integrating we get

$\Delta S_{sur} + m_2 s_2 - m_1 s_1 - s_{out}(m_2 - m_1) \geq 0$

Step 10 of 11

Entropy of water vapor coming out is given by

$s_{out} = s_g$ at final pressure (i.e., 150 kPa)

$s_{out} = 7.2231\ \text{kJ/kg°K}$

Step 11 of 11

$\Delta S_{sur} + m_2 s_2 - m_1 s_1 - s_{out}(m_2 - m_1) \geq 0$

$\Delta S_{sur} + (0.0431 \times 3.74946) - (0.1974 \times 2.05365) - 7.2231 \times (0.0431 - 0.1974) \geq 0$

$\Delta S_{sur} + 0.1616 - 0.4054 - 7.2231 \times (-0.1543) \geq 0$

$\Delta S_{sur} + 0.1616 - 0.4054 + 1.1145 \geq 0$

$\Delta S_{sur} + 0.8707 \geq 0$

$\Delta S_{sur} \geq -0.8707\ \text{kJ/kg}$

Therefore the minimum entropy change required is $\boxed{-0.8707\ \text{kJ/kg}}$

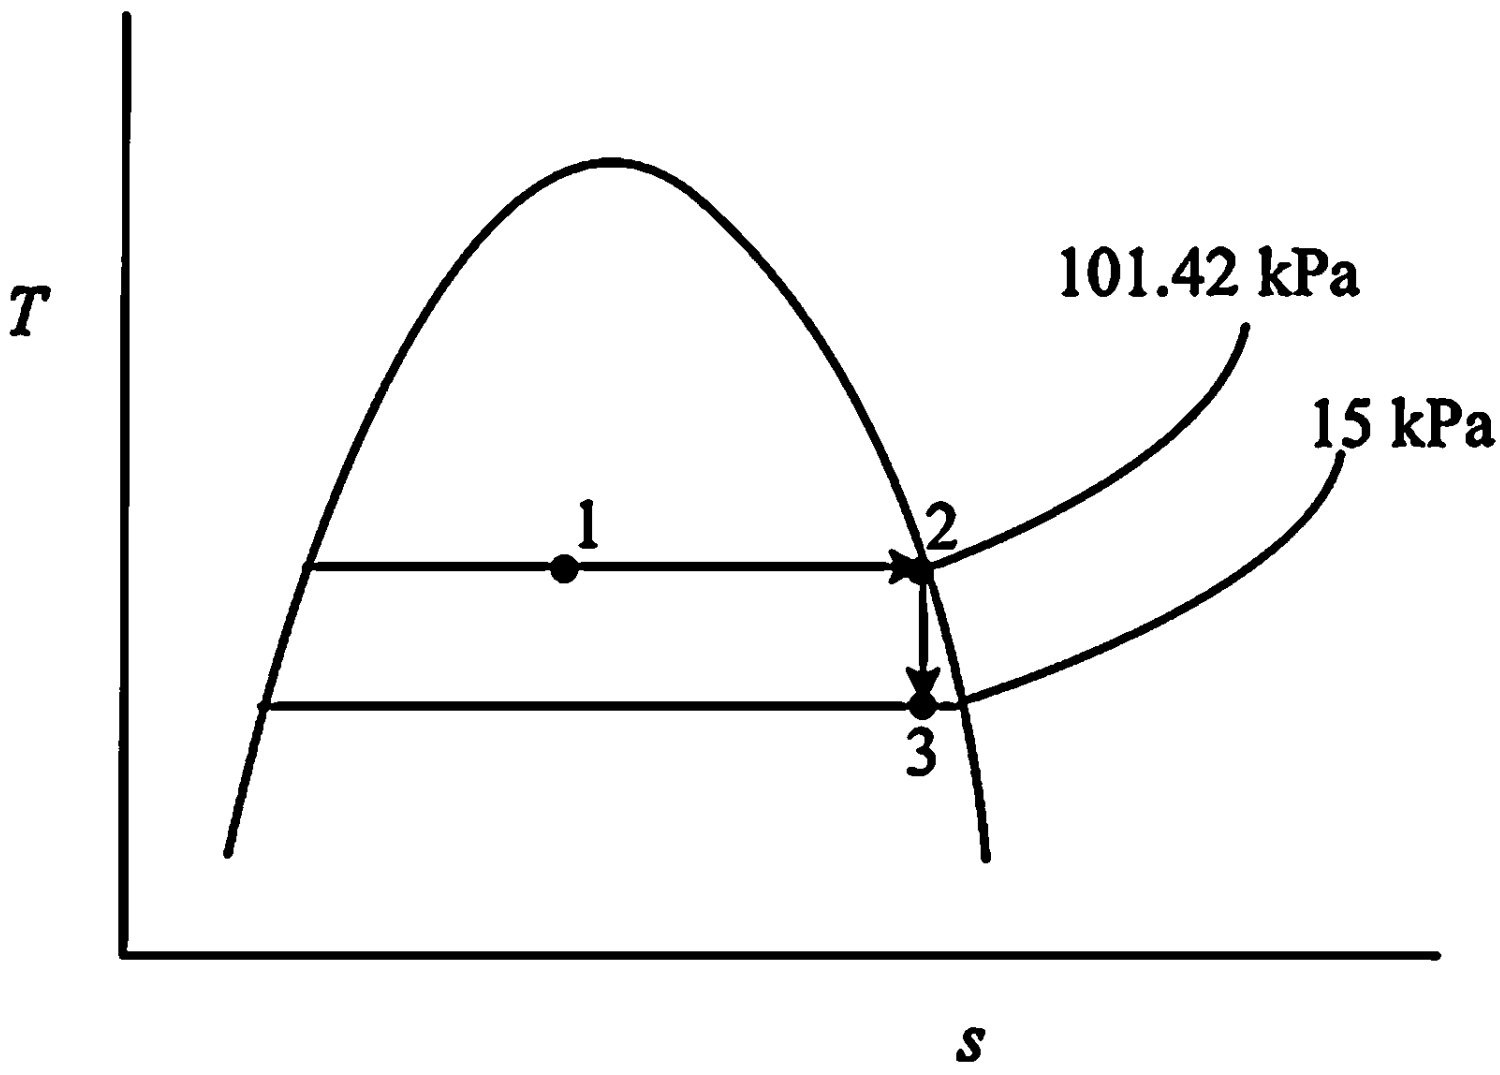
Question: 8.060P

A piston-cylinder device contains 5 kg of steam at 100°C with a quality of 50 percent. This steam undergoes two processes as follows:

1-2 Heat is transferred to the steam in a reversible manner while the temperature is held constant until the steam exists as a saturated vapor.

2-3 The steam expands in an adiabatic, reversible process until the pressure is 15 kPa.

(*a*) Sketch these processes with respect to the saturation lines on a single *T-s* diagram.



(*b*) Determine the heat transferred to the steam in process 1-2, in kJ.

(*c*) Determine the work done by the steam in process 2-3, in kJ.

Step 1 of 5

(a)

Consider the *T-s* diagram of the processes underwent by the steam.

Step 2 of 5

(b)

Obtain the properties of steam at state 1 from the table A.4, "Saturated water-Temperature table" at a temperature of $100°C$.

Specific enthalpy of saturated liquid, $h_f = 419.17\,kJ/kg$

Specific enthalpy of saturated vapor, $h_g = 2675.6\,kJ/kg$

Determine the enthalpy of the steam at a temperature of $100°C$ and a quality of 0.5.

$$h_1 = h_f + x_1\left(h_g - h_f\right)$$

Substitute $419.17\,kJ/kg$ for h_f , and $2675.6\,kJ/kg$ for h_g .

$$h_1 = 419.17 + 0.5(2675.6 - 419.17)$$
$$= 1547.385\,kJ/kg$$

Step 3 of 5

Obtain the properties of saturated vapor at state 2 from the table A.4, "Saturated water-Temperature table" at a temperature of $100°C$.

Specific enthalpy of saturated vapor, $h_2 = h_g = 2675.6\,kJ/kg$

Internal energy of saturated vapor, $u_2 = u_g = 2506\,kJ/kg$

Specific entropy of saturated vapor, $s_2 = s_g = 7.3542\,kJ/kg \cdot K$

As the process 2-3 is isentropic,

$$s_2 = s_3 = 7.3542\,kJ/kg \cdot K$$

Obtain the properties of the steam at state 3 from the EES software at a pressure of 15 kPa and an entropy of $7.3542\,kJ/kg \cdot K$.

$$u_3 = 2247.9\,kJ/kg$$

Step 4 of 5

Determine the heat transferred to the steam in process 1-2.

$$Q_{12} = m\left(h_2 - h_1\right)$$

Substitute 5 kg for m , $2675.6\,kJ/kg$ for h_2 , and $1547.385\,kJ/kg$ for h_1 .

$$Q_{12} = 5(2675.6 - 1547.385)$$
$$= 5641.075\ kJ$$

Hence the transferred to the steam in process 1-2 is, $\boxed{5641.075\ kJ}$

Step 5 of 5

(c)

Determine the work done by the steam in the process 2-3.

$$W_{23} = m\left(u_2 - u_3\right)$$

Substitute 5 kg for m , $2506\,kJ/kg$ for u_2 , and $2247.9\,kJ/kg$ for u_3 .

$$W_{23} = 5(2506 - 2247.9)$$
$$= 1290.5\ kJ$$

Hence work done by the steam in the process 2-3 is, $\boxed{1290.5\ kJ}$.

Question: 8.061P

A 0.8-ft3 well-insulated rigid can initially contains refrigerant-134a at 140 psia and 50°F. Now a crack develops in the can, and the refrigerant starts to leak out slowly, Assuming the refrigerant remaining in the can has undergone a reversible, adiabatic process, determine the final mass in the can when the pressure drops to 30 psia.

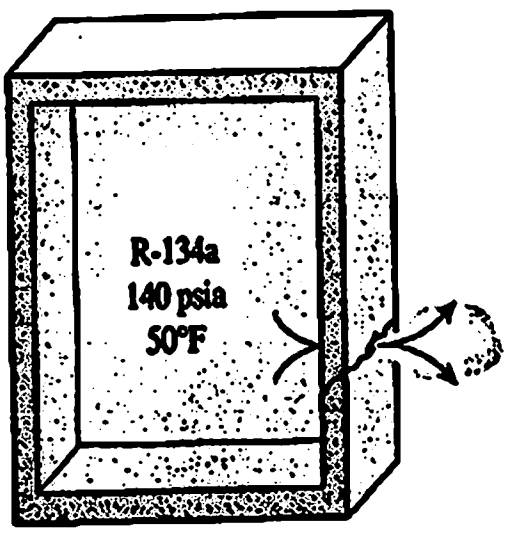


FIGURE P8–61E

Step 1 of 6

Given

Volume of the tank is, $V = 0.8\ ft^3$

Initial pressure of R-134a $P_1 = 140$ psia

Initial temperature $T_1 = 50°F$

Final pressure is, $P_2 = 30$ psia

Step 2 of 6

From saturated R-134a tables at pressure $P_1 = 140$ psia

Saturation temperature is $T_{sat} = 100.51°F$.

Since $T_1 < 100.51°F$

The refrigerant will be in sub cooled region.

We will consider the values at saturated condition at 50°F

From saturated R-134a tables at pressure $T_1 = 50°F$

Entropy of refrigerant is

$s_1 = s_f = 0.06039$ Btu/lbm.R

Step 3 of 6

From saturated R-134a tables at pressure $P_2 = 30$ psia saturated properties of refrigerant are as follows

Entropy of saturated liquid is $s_{f2} = 0.03793$ Btu/lbm.R

Entropy of evaporation is $s_{fg2} = 0.18589$ Btu/lbm.R

Specific volume of saturated liquid is $v_{f2} = 0.01209\ ft^3/lbm$

Specific volume of saturated vapor is $v_{g2} = 1.5492\ ft^3/lbm$

Step 4 of 6

Since the process is reversible adiabatic process entropy remains constant.

$s_2 = s_1$

Therefore, $s_2 = 0.06039$ Btu/lbm.R

The entropy is also given by

$s_2 = s_{f2} + x_2 \times s_{fg2}$

$0.06039 = 0.03793 + x_2 \times 0.18589$

$$x_2 = \frac{0.06039 - 0.03793}{0.18589}$$

$$x_2 = \frac{0.02246}{0.18589}$$

$x_2 = 0.1208$

Step 5 of 6

Final specific volume is given by

$v_2 = v_{f2} + x_2 \times v_{fg2}$

$v_2 = v_{f2} + x_2 \times (v_{g2} - v_{f2})$

$v_2 = 0.01209 + 0.1208 \times (1.5492 - 0.01209)$

$v_2 = 0.01209 + 0.1208 \times .1.53711$

$v_2 = 0.01209 + 0.18568$

$v_2 = 0.19777\ ft^3/lbm$

Step 6 of 6

The final mass is given by

$$m = \frac{V}{v_2}$$

$$m = \frac{0.8}{0.19777}$$

$\boxed{m = 4.045\ lbm}$

Therefore final mass in the can is 4.045 lbm

Question: 8.062P

An electric windshield defroster is used to remove 0.25-in of ice from a windshield. The properties of the ice are *T* sat = 32°F, *uif* = *hif* = 144 Btu/lbm, and *V* = 0.01602 ft3 /lbm. Determine the electrical energy required per square foot of windshield surface area to melt this ice and remove it as liquid water at 32°F. What is the minimum temperature at which the defroster may be operated? Assume that no heat is transferred from the defroster or ice to the surroundings.

Step 1 of 7

Given

Thickness of ice is, $t = 0.25$ in

$= 0.0208$ ft

Saturation temperature is, $T_{sat} = 32°F$

Initial internal energy is, $u_{if} = 144$ Btu/lbm

Specific volume is, $v = 0.01602\ ft^3/lbm$

Temperature of liquid water is, $T_{min} = 32°F$

Step 2 of 7

Mass of ice is given by

$$m_i = \frac{V}{v}$$

Volume is given by product of thickness and area $V = tA$

$$m_i = \frac{tA}{v}$$

Step 3 of 7

According to conversation of mass principle,

$$\frac{dm_{cv}}{dt} = \sum_{in} m - \sum_{out} m$$

As no mass is coming in, $\sum_{in} m = 0$

$$\frac{dm_{cv}}{dt} = 0 - \sum_{out} m$$

$$\frac{dm_{cv}}{dt} = -m_{out} \qquad \ldots\ldots (1)$$

Step 4 of 7

Work done according to first law of thermodynamics is given by

$$W_{out} = -\frac{d(mu)_{cv}}{dt} - m_{out}h_{out}$$

Substituting equation (1) in the above equation we get

$$W_{out} = -\frac{d(mu)_{cv}}{dt} - \left[-\frac{dm_{cv}}{dt}\right]h_{out}$$

$$W_{out} = \left[\frac{dm_{cv}}{dt}\right]h_{out} - \frac{d(mu)_{cv}}{dt}$$

Multiplying above equation by 'dt' and integrating we get

$$W_{out} = h_{out} \times (-m)_i + (mu)_i$$

$$W_{out} = -h_{out} \times m_i + m_i u_i$$

Step 5 of 7

$$W_{out} = -h_{out} \times \frac{tA}{v} + \frac{tA}{v}u_i$$

$$W_{out} = \frac{tA}{v}(u_i - h_{out})$$

$$\frac{W_{out}}{A} = \frac{t}{v}(u_i - h_{out})$$

Step 6 of 7

As non flow process, $h_{out} = u_f$

$$\frac{W_{out}}{A} = \frac{t}{v}(u_i - u_f)$$

$$\frac{W_{out}}{A} = \frac{t}{v} \times (-u_{if})$$

$$\frac{W_{out}}{A} = \frac{0.0208}{0.01602} \times (-144)$$

$$\frac{W_{out}}{A} = 1.298 \times (-144)$$

$$\frac{W_{out}}{A} = -186.91\ Btu/ft^2$$

So the energy input should be

$$\boxed{W_{in} = 186.91\ Btu/ft^2}$$

Step 7 of 7

According to Clausius statement of second law of thermodynamics the temperature of the defroster cannot be lower than the temperature of the ice being melted. So,

$$\boxed{T_{min} = T_{min} = 32°F}$$

Therefore the energy input should be $186.91\ Btu/ft^2$ and the minimum temperature of the defroster should be 32°F .

Question: 8.063P

Consider two solid blocks, one hot and the other cold, brought into contact in an adiabatic container. After a while, thermal equilibrium is established in the container as a result of heat transfer. The first law requires that the amount of energy lost by the hot solid be equal to the amount of energy gained by the cold one. Does the second law require that the decrease in entropy of the hot solid be equal to the increase in entropy of the cold one?

Step 1 of 1

According to first law, amount of energy lost by hot object is the amount of energy gained by cold object and hence it is called as law of conservation of energy.

But there is no principle like conservation of entropy therefore entropy is not at all a conserved property.

Hence the decrease in entropy of hot solid cannot be equal to total entropy change for a process.

Question: 8.064P

A 75-kg copper block initially at 110°C is dropped into an insulated tank that contains 160 L of water at 15°C. Determine the final equilibrium temperature and the total entropy change for this process.

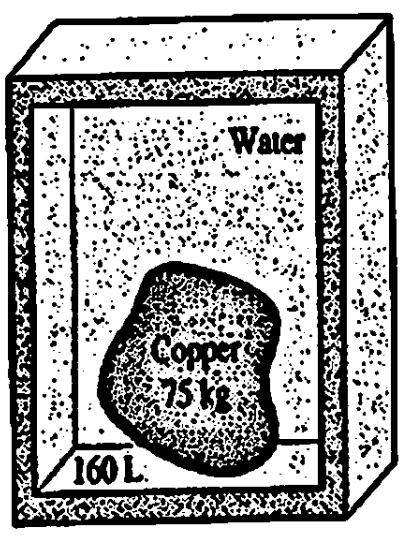

FIGURE P8–64

Step 1 of 6

From properties of common liquids solids table,

The specific heat of water at $25°C$, $c_{pw} = 4.18\ kJ/kg \cdot K$

Density of water at $25°C$, $\rho = 997\ kg/m^3$

The specific heat of copper at $27°C$, $c_{pcu} = 0.386\ kJ/kg \cdot K$

Calculate the mass of water,

$$m_w = \rho \times V$$

Here,

Volume of water in the tank is, V

Density of water in the tank, ρ

Substitute $997\ kg/m^3$ for ρ, $160\ L$ or $0.16\ m^3$ for V,

$$m_w = 997 \times 0.16$$
$$= 159.52\ kg$$

Step 2 of 6

As tank is closed, the internal energy will be constant.

$$\Delta U = 0$$
$$\Delta U_{cu} + \Delta U_w = 0$$
$$m_{cu} \times c_{pcu} \times (T_2 - T_{1cu}) + m_w \times c_{pw} \times (T_2 - T_{1w}) = 0$$

Here,

Mass of copper block, m_{cu}

Initial temperature is, T_{1cu}

Final temperature is, T_{1w}

Final equilibrium temperature, T_2

Step 3 of 6

Substitute $0.386\ kJ/kg \cdot K$ for c_{pcu}, $159.52\ kg$ for m_w, $4.18\ kJ/kg \cdot K$ for c_{pw}, $5\ kg$ for m_{cu},

$110°C$ or $383\ K$ for T_{1cu}, $15°C$ or $288\ K$ for T_{1w}, in the above equation,

$$75 \times 0.386 \times (T_2 - 383) + 159.52 \times 4.18 \times (T_2 - 288) = 0$$
$$28.95 \times (T_2 - 383) + 666.7936 \times (T_2 - 288) = 0$$
$$28.95 \times (T_2 - 383) = 666.7936 \times (288 - T_2)$$
$$28.95\ T_2 - 11087.85 = 192036.5568 - 666.7936\ T_2$$
$$28.95\ T_2 + 666.7936\ T_2 = 192036.5568 + 11087.85$$
$$695.7436\ T_2 = 203124.4068$$
$$T_2 = \frac{203124.4068}{695.7436}$$
$$= 291.95\ K$$
$$= 18.95°C$$

Therefore the final equilibrium temperature is $\boxed{T_2 = 18.95°C}$

Step 4 of 6

Calculate the change in entropy of copper block,

$$\Delta S_{cu} = m_{cu} \times c_{pcu} \times \ln\left(\frac{T_2}{T_{1cu}}\right)$$

Substitute $0.386\ kJ/kg \cdot K$ for c_{pcu}, $5\ kg$ for m_{cu}, $18.95°C$ for T_2, $110°C$ or $383\ K$ for T_{1cu} in the above equation,

$$\Delta S_{cu} = 75 \times 0.386 \times \ln\left(\frac{291.95}{383}\right)$$
$$= 75 \times 0.386 \times \ln(0.7623)$$
$$= 75 \times 0.386 \times (-0.2714)$$
$$= -7.85703\ kJ/K$$

Step 5 of 6

Calculate the change in entropy of water is given by

$$\Delta S_w = m_w \times c_{pw} \times \ln\left(\frac{T_2}{T_{1w}}\right)$$

Substitute $159.52\ kg$ for m_w, $4.18\ kJ/kg \cdot K$ for c_{pw}, $15°C$ or $288\ K$ for T_{1w}, $18.95°C$ for T_2 in the above equation,

$$\Delta S_w = 159.52 \times 4.18 \times \ln\left(\frac{291.95}{288}\right)$$
$$= 159.52 \times 4.18 \times \ln(1.0137)$$
$$= 159.52 \times 4.18 \times 0.0136$$
$$= 9.0684\ kJ/K$$

Step 6 of 6

The total change in entropy is given by

$$\Delta S_{total} = \Delta s_w + \Delta s_{cu}$$

Substitute $9.0684\ kJ/K$ for Δs_w, $-7.85703\ kJ/K$ for Δs_{cu},

$$\Delta S_{total} = 9.0684 - 7.85703$$
$$= 1.21137\ kJ/K$$

Therefore, the total change in entropy is $\boxed{1.21137\ kJ/K}$

Question: 8.065P

Ten grams of computer chips with a specific heat of 0.3 kJ/kg·K are initially at 20°C. These chips are cooled by placement in 5 grams of saturated liquid R-134a at -40°C. Presuming that the pressure remains constant while the chips are being cooled, determine the entropy change of (*a*) the chips, (*b*) the R-134a, and (*c*) the entire system. Is this process possible? Why?

Step 1 of 5

(a)

Write the equation for the change of entropy in the chips.

$$\Delta S_{chips} = m_c c \ln\left(\frac{T_2}{T_1}\right)$$

Here, ΔS_{chips} is the change in entropy in the chips, m_c is the mass of the chips, c is the specific heat of chips, T_2 is temperature at state (2), and T_1 is temperature at state (1).

Substitute $10\text{gm} = 0.01\text{kg}$ for m_c, $0.3\ \text{KJ/kgK}$ for c, $20°\text{C}=293\text{K}$ for T_1, and $-40°\text{C}=233\text{K}$ for T_2.

$$\Delta S_{chips} = 0.01\times 0.3\times \ln\left(\frac{233}{293}\right)$$
$$= -6.874\times 10^{-4}\ \text{kJ/K}$$

Thus, the change of entropy in the chips, $\boxed{\Delta S_{chips} = -6.874\times 10^{-4}\ \text{kJ/K}}$.

Step 2 of 5

(b)

Calculate the heat transferred from the chips to saturated liquid.

$$Q_{chips} = m_c c(T_1 - T_2)$$

Here, Q_{chips} is the heat transferred from the chips to saturated liquid.

Substitute $10\text{gm} = 0.01\text{kg}$ for m_c, $0.3\ \text{KJ/kgK}$ for c, $20°\text{C}=293\text{K}$ for T_1, and $-40°\text{C}=233\text{K}$ for T_2.

$$Q_{chips} = 0.01\times 0.3(293-233)$$
$$= 0.18\ \text{kJ}$$

Step 3 of 5

When the chips are kept in saturated liquid "R-134a," some of the liquid is evaporated due to this heat transfer and remaining liquid is in saturated state.

From the properties of R-134a at temperature $T_2 = -40°\text{C}$

Specific internal energy during evaporation, $u_{fg_2} = 207.37\ \text{kJ/kg}$

Heat transfer during the vaporization, $Q_{\text{R-134a}} = m_{g_2} u_{fg_2}$

Consider heat balance equation and calculate the mass of liquid is evaporated.

$$Q_{\text{R-134a}} = Q_{chips}$$
$$Q_{\text{R-134a}} = 0.18\ \text{kJ}$$
$$0.18 = m_{g_2}\times 207.4$$
$$m_{g_2} = \frac{0.18}{207.4}$$
$$= 8.678\times 10^{-4}\ \text{kg}$$

Mass of the saturated vapor, $m_{g_2} = 8.678\times 10^{-4}\ \text{kg}$

Step 4 of 5

Calculate the mass of the saturated liquid after heat transfer by considering law of conservation of mass.

$$m_{f_2} = m - m_{g_2}$$

Substitute $0.005\ \text{kg}$ for m and $8.678\times 10^{-4}\ \text{kg}$ for m_{g_2}.

$$m_{f_2} = 0.005 - 8.6788\times 10^{-4}$$
$$= 4.132\times 10^{-3}\ \text{kg}$$

Step 5 of 5

Calculate the change of entropy of R-134a,

$$\Delta S_{\text{R-134a}} = \left(m_{g_2} s_{g_2} + m_{f_2} s_{f_2}\right) - m_{f_1} s_{f_1} \quad \text{..... (1)}$$

Obtain the properties from the table "properties of R-134a," recorded at temperature, $T_2 = -40°\text{C}$.

Specific entropy at saturated liquid, $s_{f_2} = s_{f_1} = 0\ \text{kJ/kg·K}$

Specific entropy during evaporation, $s_{fg_2} = 0.96866\ \text{kJ/kg·K}$

Specific entropy at saturated vapor, $s_{g_2} = 0.96866\ \text{kJ/kg·K}$

Specific entropy at saturated liquid, $s_{f_1} = 0\ \text{kJ/kg·K}$

Substitute $4.132\times 10^{-3}\ \text{kg}$ for m_{f_2}, $8.678\times 10^{-4}\ \text{kg}$ for m_{g_2}, and 0.005 for m in equation (1).

$$\Delta S_{\text{R-134a}} = 8.768\times 10^{-4}\times 0.96866 + 4.132\times 10^{-3}\times 0 - 0.005\times 0$$
$$= 8.768\times 10^{-4}\times 0.96866$$
$$= 8.4932\times 10^{-4}\ \text{kJ/kg·K}$$

Thus, the change of entropy of R-134a, $\boxed{\Delta S_{\text{R-134a}} = 8.4932\times 10^{-4}\ \text{kJ/K}}$

(c)

Calculate the total change of entropy,

$$\Delta S = \Delta S_{chips} + \Delta S_{\text{R-134a}}$$

Substitute $8.4932\times 10^{-4}\ \text{kJ/K}$ for $\Delta S_{\text{R-134a}}$ and $-6.874\times 10^{-4}\ \text{kJ/K}$ for ΔS_{chips}.

$$\Delta S = -6.874\times 10^{-4} + 8.4932\times 10^{-4}$$
$$= 1.619\times 10^{-4}\ \text{kJ/kg·K}$$

Thus, total change of entropy is $\boxed{\Delta S = 1.619\times 10^{-4}\ \text{kJ/kg·K}}$.

The process is possible since the total change of entropy value is positive.

Question: 8.066P

A 25-kg iron block initially at 350°C is quenched inan insulated tank that contains 100 kg of water at 18°C. Assuming the water that vaporizes during the process condenses back in the tank, determine the total entropy change j during this process.

Step 1 of 4

Given

Mass of water $m_w = 100$ kg

Temperature of water $T_w = 18°C$

Mass of Iron $m_I = 25$ kg

Temperature of iron $T_I = 350°C$

Step 2 of 4

Specific heat of water at room temperature,

$$c_p = 4.18 \text{ kJ/kg°C}$$

Specific heat of iron at room temperature

$$c_p = 0.45 \text{ kJ/kg°C}$$

From first law of thermodynamics, for closed system

Net energy transfer = change in internal energy.

$$Q - w = \Delta U$$

$$\Delta U = 0$$

$$(\Delta U)_{\text{water}} + (\Delta U)_{\text{Iron}} = 0$$

$$m_w c_p (T_2 - T_w) + m_I c_p (T_2 - T_I) = 0$$

Substituting the values,

$$[100 \times 4.18(T_2 - 18)] + [25 \times 0.45(T_2 - 350)] = 0$$

$$418(T_2 - 18) + (11.25)(T_2 - 350) = 0$$

$$(418 + 11.25)T_2 - (418 \times 18) + (11.25 \times 350) = 0$$

$$419.25 \times T_2 = 11461.5$$

$$T_2 = 26.7°C$$

Step 3 of 4

Entropy change of Iron

$$\Delta s_I = m_I c_{\text{avg}} \ln\left(\frac{T_2}{T_I}\right)$$

$$\Delta s_I = (25 \times 0.45) \times \ln\left(\frac{26.7 + 273}{350 + 273}\right)$$

$$\Delta s_I = -8.23 \text{ kJ/kg}$$

Entropy change of water

$$\Delta s_{\text{water}} = m_w c_{\text{avg}} \ln\left(\frac{T_2}{T_w}\right)$$

$$\Delta s_{\text{water}} = (100 \times 4.18) \times \ln\left(\frac{26.7 + 273}{18 + 273}\right)$$

$$\Delta s_{\text{water}} = 418 \ln\left(\frac{299.7}{291}\right)$$

$$\Delta s_{\text{water}} = 12.31 \text{ kJ/kg}$$

Step 4 of 4

Total entropy change during this process is

$$\Delta s_{\text{total}} = \Delta s_{\text{iron}} + \Delta s_{\text{water}}$$

$$\Delta s_{\text{total}} = -8.232 + 12.314$$

$$\Delta s_{\text{total}} = 4.08 \text{ kJ/kg}$$

Hence total entropy change is $\boxed{\Delta s_{\text{total}} = 4.08 \text{ kJ/kg}}$

Question: 8.067P

A 30-kg aluminum block initially at 140°C is broughtinto contact with a 40-kg block of iron at 60°C in an insulated enclosure. Determine the final equilibrium temperature and the total entropy change for this process.

Step 1 of 3

Obtain the properties of specific heat from "properties of common liquids, solids and foods" at temperature 400 K.

Specific heat of aluminum, $c_{Al} = 0.949\ \text{kJ/kg-K}$

Specific heat of iron, $c_{Fe} = 0.45\ \text{kJ/kg-K}$

Apply energy balance to the given system.

$$E_{in} - E_{out} = \Delta E_{sys}$$

Since there is no amount of energy entering or leaving from the system, $E_{in} = E_{out} = 0$.

$$E_{in} - E_{out} = \Delta E_{sys}$$

$$0 = \Delta U$$

$$\Delta U_{Al} + \Delta U_{Fe} = 0$$

$$\left\{m_{Al} c_{Al} \left(T_{Al,2} - T_{Al,1}\right)\right\} + \left\{m_{Fe} c_{Fe} \left(T_{Fe,2} - T_{Fe,1}\right)\right\} = 0 \qquad \text{..... (1)}$$

Here, m_{Al} is the mass of Aluminum block, m_{Fe} is the mass of iron, $T_{Al,2}$ is the final temperature of aluminum block, $T_{Al,1}$ is the initial temperature of aluminum block, $T_{Fe,2}$ is the final temperature of iron, and $T_{Fe,1}$ is the initial temperature of iron.

Step 2 of 3

The final temperature is same for both the blocks.

$$T_{Al,2} = T_{Fe,2} = T_2$$

Then, rewrite the equation (1) as follows:

$$\left\{m_{Al} c_{Al} \left(T_2 - T_{Al,1}\right)\right\} + \left\{m_{Fe} c_{Fe} \left(T_2 - T_{Fe,1}\right)\right\} = 0$$

Substitute 30 kg for m_{Al}, 40 kg for m_{Fe}, 140°C for $T_{Al,1}$, and 60°C for $T_{Fe,1}$.

$$\left\{30 \times 0.949 \times (T_2 - 140)\right\} + \left\{40 \times 0.45 \times (T_2 - 60)\right\} = 0$$

$$\left\{28.47(T_2 - 140)\right\} + \left\{18(T_2 - 60)\right\} = 0$$

$$46.47 T_2 - 5065.8 = 0$$

$$T_2 = 109.012°\text{C}$$

Therefore, final equilibrium temperature of aluminum and iron block is $\boxed{109.012°\text{C}}$.

Step 3 of 3

Find the entropy change in iron block by using the following equation:

$$\Delta S_{Fe} = m_{Fe} c_{Fe} \ln\left(\frac{T_2}{T_{Fe,1}}\right)$$

$$= 40 \times 0.45 \times \ln\left(\frac{109.012 + 273}{60 + 273}\right)$$

$$= 40.45 \times 0.1373$$

$$= 2.4714\ \text{kJ/K}$$

Similarly, find the entropy change in aluminum block by using the following equation:

$$\Delta S_{Al} = m_{Al} c_{p,Al} \ln\left(\frac{T_2}{T_{Al,1}}\right)$$

$$= 30 \times 0.949 \times \ln\left(\frac{109.012 + 273}{140 + 273}\right)$$

$$= 28.47 \times (-0.0779)$$

$$= -2.2178\ \text{kJ/K}$$

Then find the total entropy change by using the following equation:

$$\Delta S_{total} = \Delta S_{Al} + \Delta S_{Fe}$$

$$= -2.2178 + 2.4714$$

$$= 0.253\ \text{kJ/K}$$

Therefore, the total entropy change during the process is $\boxed{0.253\ \text{kJ/K}}$.

Question: 8.068P pg 1

Reconsider Prob. 8-67. Using EES (or other) software, study the effect of the mass of the iron block on the final equilibrium temperature and the total I entropy change for the process. Let the mass of the iron vary I from 10 to 100 kg. Plot the equilibrium temperature and the total entropy change as a function of iron mass, and discuss 5 the results.

Step 1 of 10

Given data:

Mass of aluminum block is, $m_a = 30\ \text{kg}$

Initial temperature of aluminum block is, $T_{a1} = 140\ ^\circ\text{C} = 413\ \text{K}$

Mass of iron block varies, $m_{fe} = 10$ to $100\ \text{kg}$

Initial temperature of iron block is, $T_{fe1} = 60\ ^\circ\text{C} = 333\ \text{K}$

Step 2 of 10

Give all the inputs in the EES software as given below

T1_fe =60 [C]

T1_al =140 [C]

P1 =140 [kPa]

m_al =30 [kg]

c_al =0.949 [kJ/kg-K]

c_fe =0.45 [kJ/kg-K]

Step 3 of 10

For calculating other parameters we should give other equations as

T2_fe =T2

T2_al =T2

Ein – Eout =Esys

Ein=0

Eout =0

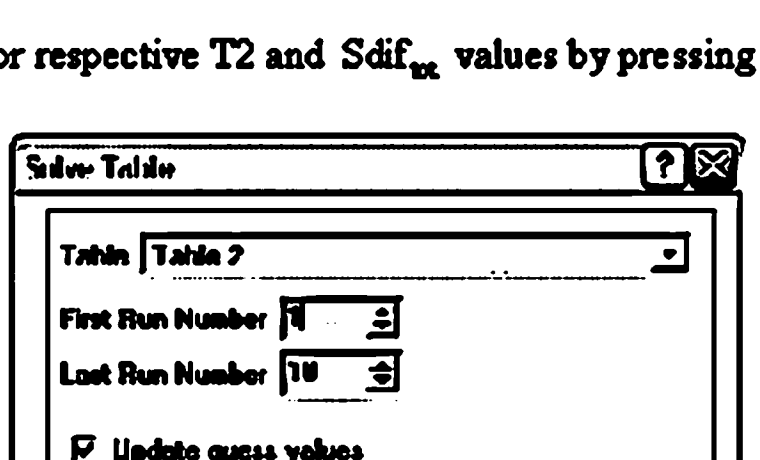
Esys =m_fe*c_fe*(T2_fe – T1_fe)+m_al*c_al*(T2_al – T1_al)

Sdif_fe =m_fe*c_fe*ln((T2_fe+273)/(T1_fe+273))

Sdif_al =m_al*c_al*ln((T2_al+273)/(T1_al+273))

Sdif_tot =Sdif_fe+Sdif_al

Step 4 of 10



After writing these sets of equations, we should create a parametric table from Tables → new parametric

Fill all the values of m_{fe}.

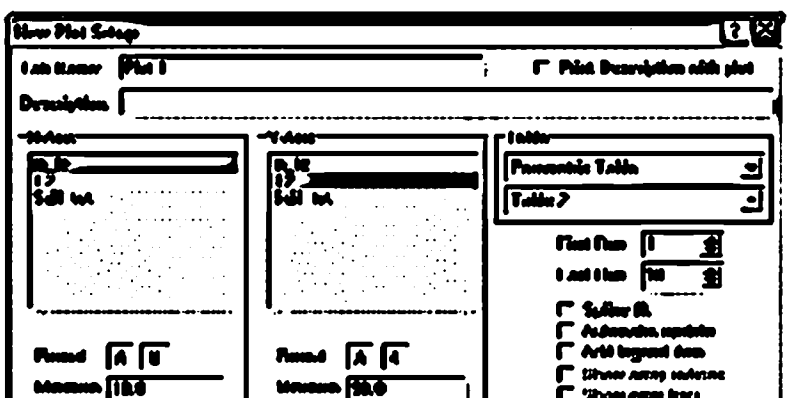
▷ 1..10	1 m_{fe}	2 I2	3 $Sdif_{tot}$
Run 1	10		
Run 2	20		
Run 3	30		
Run 4	40		
Run 5	50		
Run 6	60		
Run 7	70		
Run 8	80		
Run 9	90		
Run 10	100		

Step 5 of 10

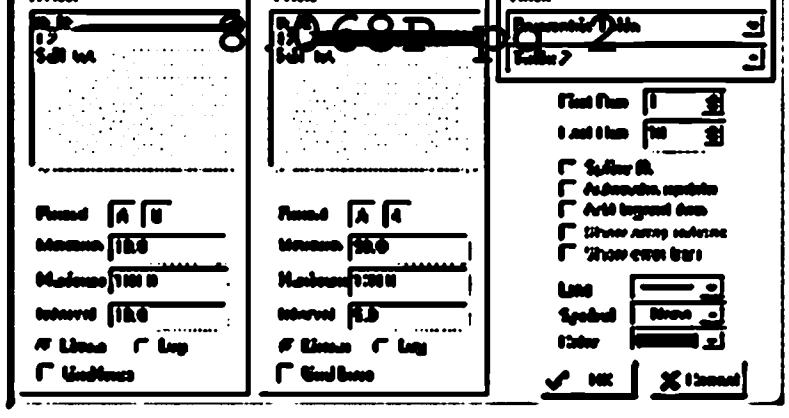
Now solve the table for respective T2 and $Sdif_{tot}$ values by pressing F3.

Step 6 of 10

Then we get



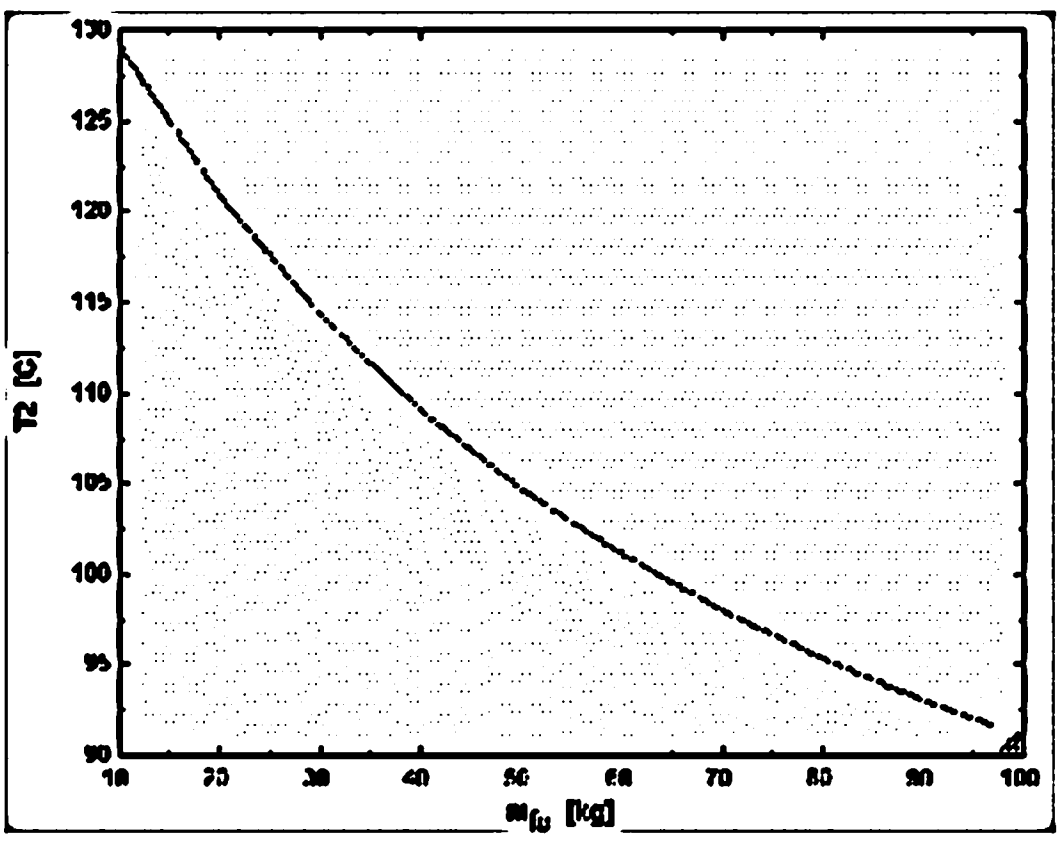
▷ 1..10	1 m_{fe}	2 T2 [C]	3 $Sdif_{tot}$ [kJ/K]
Run 1	10	129.1	0.08547
Run 2	20	120.8	0.1525
Run 3	30	114.3	0.2066
Run 4	40	109	0.2511
Run 5	50	104.7	0.2883
Run 6	60	101.1	0.32
Run 7	70	97.98	0.3472
Run 8	80	95.33	0.3709
Run 9	90	93.02	0.3916
Run 10	100	91	0.41



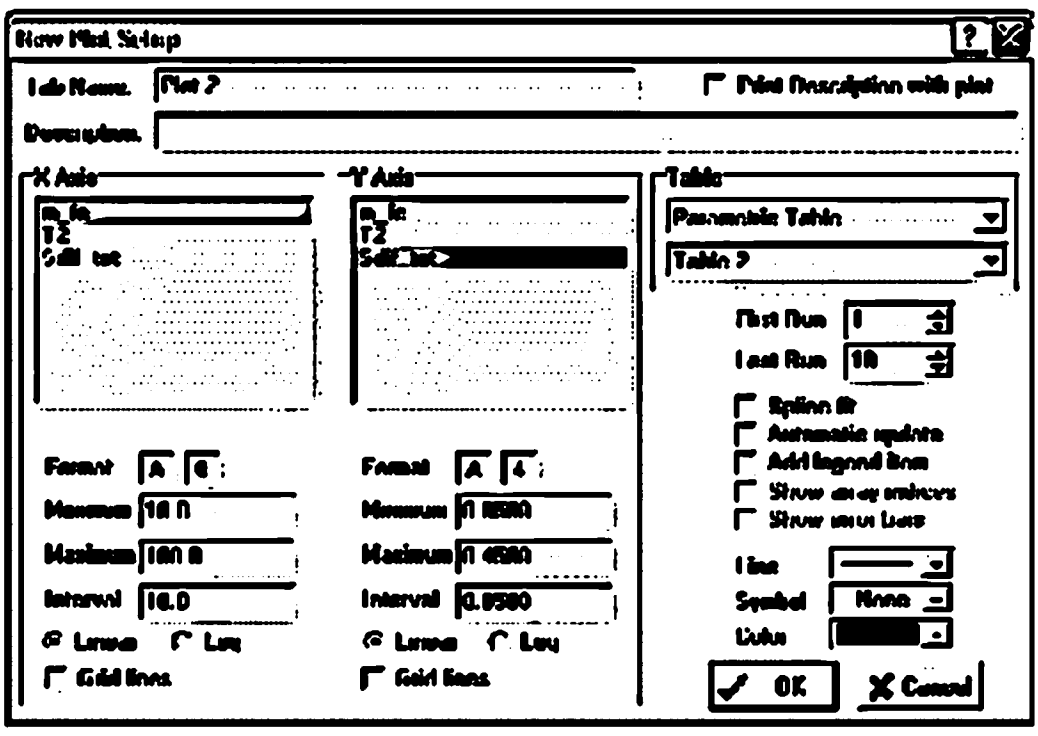
Step 7 of 10

For getting the plot we should go for

Plots → New plot window

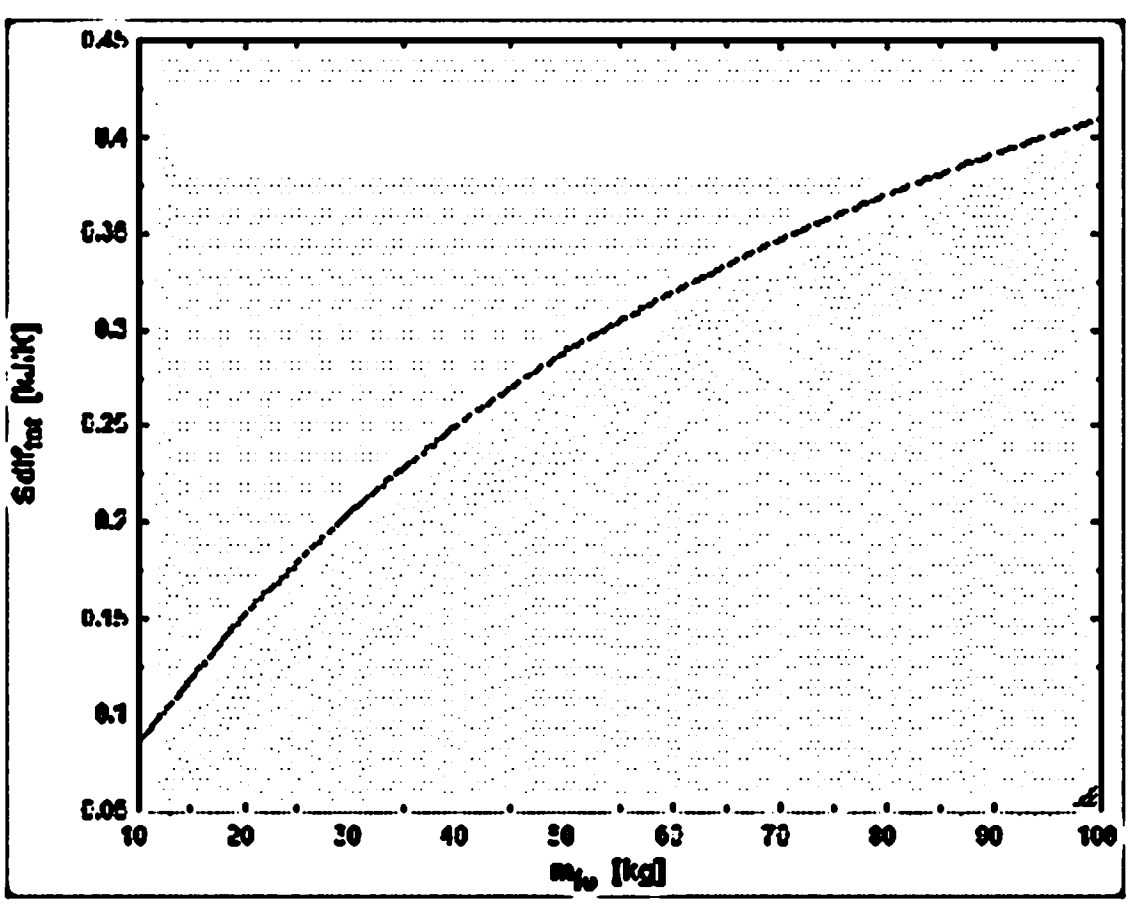


We should fill all the required fields by taking m_{fe} in x-axis and T2 in y-axis.



Step 8 of 10

After that we get the plot as



Step 9 of 10

For getting the plot we should go for
Plots → New plot window
We should fill all the required fields by taking m_{fu} in x-axis and $Sdif_{tot}$ in y-axis.

Step 10 of 10

After that we get the plot as

Question: 8.069P

A 50-kg iron block and a 20-kg copper block, both initially at 80°C, are dropped into a large lake at 15°C. Thermal equilibrium is established after a while as a result of heat transfer between the blocks and the lake water. Determine the total entropy change for this process.

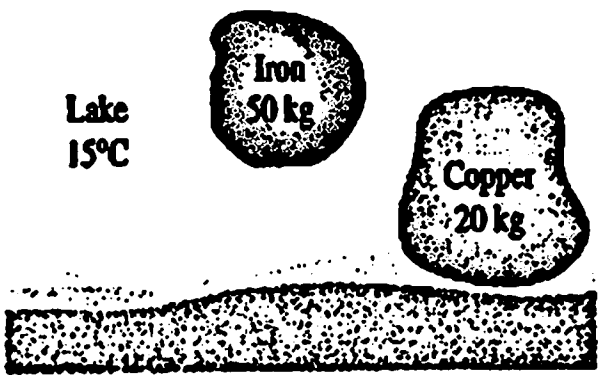


FIGURE P8–69

Step 1 of 4

Given data

Mass of Iron block $m_I = 50$ kg

Mass of copper block $m_{cu} = 20$ kg

Temperature of Iron block $T_I = 80°C$

Temperature of copper block $T_{cu} = 80°C$

Temperature of lake water $T_l = 15°C$

Step 2 of 4

Specific heat of iron at room temperature, $c_p = 0.45$ kJ/kgK

Specific heat of copper at room temperature, $c_p = 0.386$ kJ/kgK

Entropy change of iron during this process

$$\Delta s_{iron} = m_I c_{avg} \times \ln\left(\frac{T_l}{T_I}\right)$$

$$= (50\text{ kg})(0.45\text{kJ/kgK})\ln\left(\frac{15+273}{80+273}\right)$$

$$= -4.579\text{ kJ/K}$$

Entropy change of copper during this process

$$\Delta s_{copper} = m_{cu} c_{avg} \ln\left(\frac{T_l}{T_{cu}}\right)$$

$$= (20\text{ kg})(0.386\text{ kJ/kgK}) \times \ln\left(\frac{15+273}{80+273}\right)$$

$$= -1.571\text{ kJ/K}$$

Step 3 of 4

Energy balance from first law of thermodynamics

Energy in − energy out = change in internal energy

$$Q_{in} - Q_{out} = \Delta U$$

$$0 - Q_{out} = \Delta U$$

$$-Q_{out} = \Delta U_{iron} + \Delta U_{copper}$$

$$Q_{out} = m_I c_{avg}(T_I - T_l) + m_{cu} c_{avg}(T_{cu} - T_l)$$

$$Q_{out} = [50 \times 0.45(80-15)] + [20 \times 0.386 \times (80-15)]$$

$$Q_{out} = 1462.5 + 501.8$$

$$Q_{out} = 1964.3\text{ kJ}$$

Step 4 of 4

Entropy change of lake water, $\Delta s_{lake} = \dfrac{Q_{lake}}{T_{lake}}$

$$\Delta s_{lake} = \frac{Q_{out}}{T_{lake}}$$

$$\Delta s_{lake} = \frac{1964.3}{15+273}$$

$$\Delta s_{lake} = 6.8205\text{ kJ/K}$$

Total entropy change for this process,

$$\Delta s_{total} = \Delta s_{iron} + \Delta s_{copper} + \Delta s_{lake}$$

$$\Delta s_{total} = -4.579 - 1.571 + 6.8205$$

$$\Delta s_{total} = 0.6705\text{ kJ/K}$$

Hence total entropy change for the process is $\boxed{\Delta s_{total} = 0.6705\text{ kJ/K}}$

Question: 8.070P pg 1

An adiabatic pump is to be used to compress saturated liquid water at 10 kPa to a pressure to 15 MPa in a reversible manner. Determine the work input using (*a*) entropy data from the compressed liquid table, (*b*) inlet specific volume and pressure values, (*c*) average specific volume and pressure values. Also, determine the errors involved in parts (*b*) and (*c*).

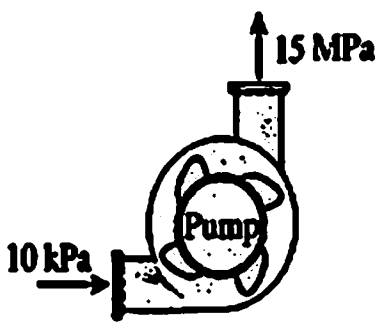

FIGURE P8–70

Step 1 of 8

Obtain the properties of saturated liquid water at pressure 10 kPa from the table A.5, "Saturated water-Pressure table".

Specific enthalpy, $h_1 = 191.8 \text{ kJ/kg}$

Specific entropy, $s_1 = 0.6492 \text{ kJ/kgK}$

Specific volume, $v_1 = 0.00101 \text{ m}^3/\text{kg}$

As the process is isentropic, $s_2 = s_1$

$s_2 = s_1 = 0.649 \text{ kJ/kgK}$

Step 2 of 8

Obtain the Specific enthalpy values from the table A.7 , "Compressed liquid water" at the pressure 15 MPa.

$h = 180.77 \text{ kJ/kg}$ at $s = 0.5666 \text{ kJ/kgK}$

$h = 263.74 \text{ kJ/kg}$ at $s = 0.8234 \text{ kJ/kgK}$

Calculate the enthalpy at state 2 using the interpolation,

$$h_2 = h_{at\ s=0.5666} + \left(\frac{h_{at\ s=0.8234} - h_{at\ s=0.5666}}{0.8234 - 0.5666}\right)(0.649 - 0.5666)$$

$$h_2 = 180.77 + \left(\frac{263.74 - 180.77}{0.8234 - 0.5666}\right)(0.649 - 0.5666)$$

$$h_2 = 180.77 + \left(\frac{82.97}{0.2568}\right)(0.0824)$$

$$h_2 = 207.323 \text{ kJ/kg}$$

Step 3 of 8

Obtain the Specific volume values from the table A.7 , "Compressed liquid water" at the pressure 15 MPa.

$v = 0.0010013 \text{ m}^3/\text{kg}$ for $s = 0.5666 \text{ kJ/kgK}$

$v = 0.0010105 \text{ m}^3/\text{kg}$ for $s = 0.8234 \text{ kJ/kgK}$

Calculate the specific volume at state 2 using the interpolation,

$$v_2 = v_{at\ s=0.5666} + \left(\frac{v_{at\ s=0.8234} - v_{at\ s=0.5666}}{0.8234 - 0.5666}\right)(0.649 - 0.5666)$$

$$v_2 = 0.0010013 + \left(\frac{0.0010105 - 0.0010013}{0.8234 - 0.5666}\right)(0.649 - 0.5666)$$

$$v_2 = 0.0010013 + \left(\frac{9.2 \times 10^{-6}}{0.2568}\right)(0.0824)$$

$$v_2 = 0.0010042 \text{ m}^3/\text{kg}$$

Step 4 of 8

(a)

Determine the work input to the pump using the data from the compressed liquid water tables.

$w_{pump} = h_2 - h_1$

Substitute 207.323 kJ/kg for h_2 , and 191.8 kJ/kg for h_1 .

$w_{pump} = 207.323 - 191.8$

$w_{pump} = 15.523 \text{ kJ/kg}$

Hence work input to the pump is, $\boxed{w_{pump} = 15.513 \text{ kJ/kg}}$.

Step 5 of 8

(b)

Determine the work input to the compressor using inlet specific volume and pressure values.

$w_{pump} = v_1(P_2 - P_1)$

Substitute $0.001010 \text{ m}^3/\text{kg}$ for v_1 , 15000 kPa for P_2 , and 10 kPa for P_1 .

$w_{pump} = 0.00101 \times (15{,}000 - 10)$

$w_{pump} = 15.14 \text{ kJ/kg}$

Hence, the work input to the pump is, $\boxed{15.14 \text{ kJ/kg}}$.

Step 6 of 8

Hence, the work input to the pump is, 15.14 kJ/kg . pg 2

Step 6 of 8

(c)

Calculate the average specific volume.

$$v_{avg} = \frac{v_1 + v_2}{2}$$

Substitute $0.001010\,m^3/kg$ for v_1 , and $0.001004\,m^3/kg$ for v_2 .

$$v_{avg} = \frac{0.001010 + 0.001004}{2}$$
$$= 0.001007\,m^3/kg$$

Step 7 of 8

Determine the work input to the compressor using average specific volume and pressure values.

$$w_{pump} = v_{avg}(P_2 - P_1)$$

Substitute $0.001007\,m^3/kg$ for v_{avg} , 15000 kPa for P_2 , and $10\,kPa$ for P_1 .

$$w_{pump} = 0.001007(15{,}000 - 10)$$

$$w_{pump} = 15.096\ kJ/kg$$

Hence, the work input to the pump is, **15.096 kJ/kg** .

Step 8 of 8

Determine the error involved in part (b).

$$\%Error$$

$$\%Error = \left(\frac{15.14 - 15.513}{15.14}\right) \times 100$$

$$\%Error = 2.13\%$$

Hence, the error involved in part (b) is, **2.13%** .

Determine the error involved in part (c).

$$\%Error = \left(\frac{15.096 - 15.09}{15.096}\right) \times 100$$

$$\%Error = 0.04\%$$

Hence, the error involved in part (b) is, **0.04%** .

Question: 8.071P

Some properties of ideal gases such as internal energy and enthalpy vary with temperature only [that is, $u = u(T)$ and $h = h(T)$]. Is this also the case for entropy?

Step 1 of 1

Unlike internal energy and enthalpy, the entropy of an ideal gas varies with specific volume or pressure as well as the temperature.

The variation of entropy with pressure is accounted for by the last term in the following equation.

$$s_2 - s_1 = c_p \ln\left(\frac{T_2}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right)$$

Question: 8.072P

Can the entropy of an ideal gas change during an isothermal process?

Step 1 of 1

The entropy of an ideal gas changes during isothermal process.
The entropy of an ideal gas depends on pressure as well as the temperature. So during isothermal process, the entropy of ideal varies with pressure as follows.

$$s_2 - s_1 = -R \ln\left(\frac{P_2}{P_1}\right)$$

Question: 8.073P

An ideal gas undergoes a process between two specified temperatures, first at constant pressure and then at constant volume. For which case will the ideal gas experience a larger entropy change? Explain.

Step 1 of 2

At constant pressure $P_1 = P_2$,

Entropy change, $s_2 - s_1 = c_p \ln\left(\frac{T_2}{T_1}\right) - R\ln\left(\frac{P_1}{P_1}\right)$

$$\Rightarrow s_2 - s_1 = c_p \ln\left(\frac{T_2}{T_1}\right) \text{---(1)}$$

At constant volume $v_1 = v_2$,

Entropy change, $s_2 - s_1 = c_v \ln\left(\frac{T_2}{T_1}\right) + R\ln\left(\frac{v_1}{v_1}\right)$

$$\Rightarrow s_2 - s_1 = c_v \ln\left(\frac{T_2}{T_1}\right) \text{----(2)}$$

Step 2 of 2

From (1) and (2), Entropy change for these two cases varies with C_p and C_v.

But, C_p is greater than C_v. So, Entropy change will be larger at constant pressure case.

Question: 8.074P

Prove that the two relations for entropy change of ideal gases under the constant-specific-heat assumption (Eqs. 8-33 and 8-34) are equivalent.

Step 1 of 2

Given:

$$s_2 - s_1 = c_{v,avg} \ln\left(\frac{T_2}{T_1}\right) + R \ln\left(\frac{v_2}{v_1}\right) \text{--------(1)}$$

$$\Rightarrow s_2 - s_1 = c_{p,avg} \ln\left(\frac{T_2}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right) \text{--------(2)}$$

We need to prove that these two relations for entropy change of ideal under the constant-specific-heat assumptions are equivalent.

Step 2 of 2

For ideal gas, $\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1}$

$$\Rightarrow \frac{v_2}{v_1} = \frac{T_2 P_1}{T_1 P_2} \text{---------(3)}$$

And $c_{p,avg} - c_{v,avg} = R$ --------(4)

From (1), (2), and (3),

$$\Rightarrow s_2 - s_1 = c_{v,avg} \ln\left(\frac{T_2}{T_1}\right) + R \ln\left(\frac{T_2 P_1}{T_1 P_2}\right)$$

$$\Rightarrow s_2 - s_1 = c_{v,avg} \ln\left(\frac{T_2}{T_1}\right) + R \ln\left(\frac{T_2}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right)$$

$$\Rightarrow s_2 - s_1 = \left(c_{v,avg} + R\right) \ln\left(\frac{T_2}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right)$$

$$\Rightarrow s_2 - s_1 = c_{p,avg} \ln\left(\frac{T_2}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right)$$, here we get equation (4)

So, these two relations for entropy change of ideal under the constant-specific-heat assumptions are equivalent.

Question: 8.075P

Starting with the second $T\,ds$ relation (Eq. 8-26), obtain Eq. 8-34 for the entropy change of ideal gases under the constant-specific-heat assumption.

Step 1 of 2

Given:

The differential change of entropy $ds = \frac{dh}{T} - \frac{v\,dP}{T}$ -------(1)

The entropy change under the constant specific heat,

$$\Rightarrow s_2 - s_1 = c_{p,avg} \ln\left(\frac{T_2}{T_1}\right) - R\ln\left(\frac{P_2}{P_1}\right) \text{-------(2)}$$

Step 2 of 2

For ideal gas, $P \times v = R \times T$

$$\Rightarrow v = \frac{R \times T}{P} \text{-----(3)}$$

And $dh = C_p \times dT$ -------(4)

From (1), (3), and (4),

$$\Rightarrow ds = \frac{dh}{T} - \frac{v\,dP}{T}$$

$$\Rightarrow ds = c_p \frac{dT}{T} - R\frac{dP}{P}$$

On integrating both sides,

$$\Rightarrow [s]_{s_1}^{s_2} = c_p [\ln T]_{T_1}^{T_2} - R[\ln P]_{P_1}^{P_2}$$

$$\Rightarrow \boxed{s_2 - s_1 = c_p \ln\left(\frac{T_2}{T_1}\right) - R\ln\left(\frac{P_2}{P_1}\right)}$$, here we get equation (2)

Question: 8.076P

Starting with Eq. 8-34, obtain Eq. 8-43.

Step 1 of 2

Given:

The entropy change under the constant specific heat,

$$s_2 - s_1 = c_{p,avg} \ln\left(\frac{T_2}{T_1}\right) - R\ln\left(\frac{P_2}{P_1}\right) \text{-------(1)}$$

The first isentropic relation for ideal gases

$$\left(\frac{T_2}{T_1}\right)_{s=\text{constant}} = \left(\frac{P_2}{P_1}\right)^{\frac{(k-1)}{k}} \text{--------(2)}$$

Step 2 of 2

For ideal gas, $C_p - C_v = R$ -------(3)

$$\text{And } k = \frac{c_p}{c_v} \text{-----(4)}$$

From (1), (3), and (4), and at constant entropy

$$0 = c_p \ln\left(\frac{T_2}{T_1}\right) - R\ln\left(\frac{P_2}{P_1}\right)$$

$$\Rightarrow \ln\left(\frac{T_2}{T_1}\right) = \frac{R}{c_p}\ln\left(\frac{P_2}{P_1}\right)$$

$$\Rightarrow \frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{R}{c_p}}$$

$$\Rightarrow \frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{c_p - c_v}{c_p}}$$

$$\Rightarrow \frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\Rightarrow \boxed{\left(\frac{T_2}{T_1}\right)_{s=\text{constant}} = \left(\frac{P_2}{P_1}\right)^{(k-1)/k}}$$, here we get equation (2)

Question: 8.077P

Which of the two gases—helium or nitrogen—experiences the greatest entropy change as its state is changed from 2000 kPa and 427°C to 200 kPa and 27°C?

Step 1 of 5

Given:

The initial Temperatures, $T_1 = 427°C = 700K$

The final Temperatures, $T_2 = 27°C = 300K$

The initial Pressures, $P_1 = 2000\ kPa$

The final pressure, $P_2 = 200\ kPa$

Step 2 of 5

Average temperature, $T = \frac{T_1 + T_2}{2}$

$$\Rightarrow T = \frac{700 + 300}{2}$$

$$\Rightarrow T = 500K$$

For Helium

From ideal gas specific heats of various common gases at various temperatures table,

Specific Heat at constant pressure, $c_p = 5.1926\ \frac{kJ}{kg \cdot K}$

Gas constant, $R = 2.0769\ \frac{kJ}{kg \cdot K}$

Step 3 of 5

For Nitrogen

From ideal gas specific heats of various common gases at various temperatures table,

Specific Heat at constant pressure at the average temperature, $c_p = 1.056\ \frac{kJ}{kg \cdot K}$

Gas constant, $R = 0.2968\ \frac{kJ}{kg \cdot K}$

Step 4 of 5

For Helium:

Entropy change, $\Delta s_{He} = \left[c_p \ln\left(\frac{T_2}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right) \right]_{He}$

$$\Rightarrow \Delta s_{He} = 5.1926 \times \ln\left(\frac{27+273}{427+273}\right) - 2.0769 \times \ln\left(\frac{200}{2000}\right)$$

$$\Rightarrow \Delta s_{He} = 0.38256\ \frac{kJ}{kg \cdot K} \text{------(1)(greatest entropy change)}$$

Step 5 of 5

For Nitrogen:

Entropy change, $\Delta s_{Nitrogen} = \left[c_p \ln\left(\frac{T_2}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right) \right]_{Nitrogen}$

$$\Rightarrow \Delta s_{Nitrogen} = 1.056 \times \ln\left(\frac{27+273}{427+273}\right) - 0.2968 \times \ln\left(\frac{200}{2000}\right)$$

$$\Rightarrow \Delta s_{Nitrogen} = -0.21134\ \frac{kJ}{kg \cdot K} \text{------(2)}$$

From (1) and (2), Helium experiences the greatest entropy change.

Question: 8.078P

Air is expanded from 2000 kPa and 500°C to 100 kPa and 50°C. Assuming constant specific heats, determine the change in the specific entropy of air.

Step 1 of 2

Given

Initial pressure of air is, $P_1 = 2000\ \text{kPa}$

Initial temperature of air is, $T_1 = 500\ ^\circ\text{C} = 773\ \text{K}$

Final pressure of air is, $P_2 = 100\ \text{kPa}$

Final temperature of air is, $T_2 = 50\ ^\circ\text{C} = 323\ \text{K}$

Step 2 of 2

The change in specific entropies of an ideal gas is given by

$$s_2 - s_1 = c_p \times \ln\left(\frac{T_2}{T_1}\right) - R \times \ln\left(\frac{P_2}{P_1}\right)$$

From ideal gas specific heats of gases table properties of air are

$(c_p)_{air} = 1.005\ \text{kJ/kg.K}$

$(R)_{air} = 0.287\ \text{kJ/kg.K}$

$$s_2 - s_1 = 1.005 \times \ln\left(\frac{323}{773}\right) - 0.287 \times \ln\left(\frac{100}{2000}\right)$$

$$s_2 - s_1 = 1.005 \times \ln(0.4178) - 0.287 \times \ln(0.05)$$

$$s_2 - s_1 = 1.005 \times (-0.873) - 0.287 \times (-2.996)$$

$$s_2 - s_1 = -0.8774 + 0.8598$$

$$\boxed{s_2 - s_1 = -0.0176\ \text{kJ/kg.K}}$$

Therefore the change in the specific entropy of air is $-0.0176\ \text{kJ/kg.K}$

Question: 8.079P

What is the difference between the entropies of air at 15 psia and 70°F and air at 40 psia and 250°F per unit mass basis.

Step 1 of 2

Given

Initial pressure of air is, $P_1 = 15$ psia

Initial temperature of air is, $T_1 = 70°F = 529.67$ R

Final pressure of air is, $P_2 = 40$ psia

Final temperature of air is, $T_2 = 250°F = 709.67$ R

Step 2 of 2

From ideal gas specific heat of air table

$(c_p)_{air} = 0.24$ Btu/lbm.R

$(R)_{air} = 0.06855$ Btu/lbm.R

As air is an ideal gas the change in specific entropy can be calculated as

$$s_2 - s_1 = c_p \times \ln\left(\frac{T_2}{T_1}\right) - R \times \ln\left(\frac{P_2}{P_1}\right)$$

$$s_2 - s_1 = 0.24 \times \ln\left(\frac{709.67}{529.67}\right) - 0.06855 \times \ln\left(\frac{40}{15}\right)$$

$$s_2 - s_1 = 0.24 \times \ln(1.3398) - 0.06855 \times \ln(2.667)$$

$$s_2 - s_1 = 0.24 \times 0.2925 - 0.06855 \times 0.981$$

$$s_2 - s_1 = 0.0702 - 0.0672$$

$$\boxed{s_2 - s_1 = 0.003 \text{ Btu/lbm.R}}$$

Therefore the specific entropy of air increases by 0.003 Btu/lbm.R.

Question: 8.080P

Nitrogen at 900 kPa and 300°C is expanded adiabati-cally in a closed system to 100 kPa. Determine the minimum nitrogen temperature after the expansion.

Step 1 of 3

Given

Initial pressure of Nitrogen is, $P_1 = 900\ \text{kPa}$

Initial temperature Nitrogen is, $T_1 = 300\ ^\circ\text{C} = 573\ \text{K}$

Final pressure of Nitrogen is, $P_2 = 100\ \text{kPa}$

Step 2 of 3

Since the process is adiabatic process the ratio of temperatures is given by

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{\gamma-1}{\gamma}}$$

Where γ is ratio of specific heats

Assuming the average temperature of 450K and at this temperature from ideal gas specific heats of gases for Nitrogen

$\gamma = 1.395$

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{1.395-1}{1.395}}$$

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{0.395}{1.395}}$$

$$T_2 = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{0.395}{1.395}}$$

$$T_2 = 573 \times \left(\frac{100}{900}\right)^{\frac{0.395}{1.395}}$$

$$T_2 = 307.579\ \text{K}$$

$$\boxed{T_2 = 34.579^\circ\text{C}}$$

Step 3 of 3

Average temperature

$$T_{avg} = \frac{T_1 + T_2}{2}$$

$$= \frac{573 + 307.579}{2}$$

$$T_{avg} = 440.289\ \text{K}$$

The obtained value of average temperature of Nitrogen is approximately equal to the assumed value so our assumption is correct

Therefore the minimum nitrogen temperature after the expansion is $T_2 = 34.579^\circ\text{C}$

Question: 8.081P

Air at 15 psia and 70°F is compressed adiabatically in a closed system to 200 psia. What is the minimum temperature of the air following this compression?

Step 1 of 2

Given

Initial pressure of closed system is, $P_1 = 15$ psia

Initial temperature of closed system is, $T_1 = 70°F = 529.67$ R

Final pressure of closed system is, $P_2 = 200$ psia

Step 2 of 2

The minimum temperature of the air in the compression process is obtained when the compression process is reversible adiabatic then the final temperature of the air can be calculated by using the relation

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{\gamma-1}{\gamma}},$$

Where

γ = ratio of specific heats of air

$\gamma = 1.4$

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{1.4-1}{1.4}}$$

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{0.4}{1.4}}$$

$$\frac{T_1}{T_1} = \left(\frac{P_2}{P_1}\right)^{0.2857}$$

$$T_2 = T_1 \times \left(\frac{P_2}{P_1}\right)^{0.2857}$$

$$T_2 = 529.67 \times \left(\frac{200}{15}\right)^{0.2857}$$

$$T_2 = 529.67 \times (13.33)^{0.2857}$$

$$T_2 = 529.67 \times 2.096$$

$$T_2 = 1110.188 \text{ R}$$

$$T_2 = 650.518°F$$

Therefore the temperature after the compression is 650.518°F.

Question: 8.082P

An insulated piston-cylinder device initially contains 300 L of air at 120 kPa and 17°C. Air is now heated for 15 min by a 200-W resistance heater placed inside the cylinder. The pressure of air is maintained constant during this process. Determine the entropy change of air, assuming (*a*) constant specific heats and (*b*) variable specific heats.

Step 1 of 3

Calculate the Mass of air by using the following equation:

$$m = \frac{P_1 V_1}{R T_1}$$

Here, initial pressure is P_1 ,initial volume is V_1 , gas constant is R, initial temperature is T_1 .

Substitute $120\ \text{kPa}$ for P_1 , $290\ \text{K}$ for T_1 , $0.3\ \text{m}^3$ for V_1 , $0.287\ \text{kJ/kg}\cdot\text{K}$ for R.

$$\begin{aligned} m &= \frac{120\times 0.3}{0.287\times 290} \\ &= \frac{36}{83.23} \\ &= 0.4325\,\text{kg} \end{aligned}$$

Calculate Electrical work done by using the following equation:

$$W = \dot{W} \times \Delta t$$

Here, Power of resistance is $\dot{W}$, time is Δt .

Substitute, $200\ \text{W}$ for $\dot{W}$, $15\ \text{min}$ for Δt :

$$\begin{aligned} W &= 200\times 15\times 60 \\ &= 180\,\text{kJ} \end{aligned}$$

Step 2 of 3

(a)

Assume constant specific heats.

Assume average temperature as room temperature 300 K.

From ideal gas specific heats of various gas table,

For air, the Specific heat at constant pressure is $c_p = 1.005\ \text{kJ/kg}\cdot\text{K}$.

Calculate the final temperature by using the following equation:

$$W = mc_p(T_2 - T_1)$$

$$T_2 = T_1 + \frac{W}{mc_p}$$

Substitute, $1.005\ \text{kJ/kg}\cdot\text{K}$ for c_p , $290\ \text{K}$ for T_1, $0.4325\,\text{kg}$ for m , $180\,\text{kJ}$ for W :

$$\begin{aligned} T_2 &= 290 + \left(\frac{180}{0.4325\times 1.005}\right) \\ &= 290 + 414.114 \\ &= 704.11\,\text{K} \end{aligned}$$

Calculate the Entropy change by using the following equation.

$$\begin{aligned} \Delta s_{sys} &= m\times(s_2 - s_1) \\ &= m\left(c_p \ln\frac{T_2}{T_1} - R\ln\frac{P_2}{P_1}\right) \end{aligned}$$

Since, pressure is constant, $P_1 = P_2$.

$$\Delta s_{sys} = mc_p \ln\frac{T_2}{T_1}$$

Substitute, $0.4325\,\text{kg}$ for m , $1.029\ \text{kJ/kg}\cdot\text{K}$ for c_p , $290\ \text{K}$ for T_1 and 694.45K for T_2 :

$$\begin{aligned} \Delta s_{sys} &= 0.43254\times 1.029\times \ln\left(\frac{704.11}{290}\right) \\ &= 0.43254\times 1.029\times 0.887 \\ &= 0.3948\,\text{kJ/K} \end{aligned}$$

Therefore, the Entropy change of air for constant specific heat, Δs_{sys} is $\boxed{0.3948\,\text{kJ/K}}$.

(b)

Assume variable specific heats.

Calculate the Work done by using the following equation:

$$W = m(h_2 - h_1)$$

$$h_2 = h_1 + \frac{W}{m}$$

Here, enthalpy at initial state is h_1 , enthalpy at final state is h_2

From ideal gas properties of air table at $T_1 = 290\ \text{K}$,

The enthalpy is $h_1 = 290.16\ \text{kJ/kg}$

The entropy is $s_1^\circ = 1.66802\ \text{kJ/kg}\cdot\text{K}$

Substitute, $290.16\ \text{kJ/kg}$ for h_1 , $180\,\text{kJ}$ for W , $0.4325\,\text{kg}$ for m :

$$\begin{aligned} h_2 &= 290.16 + \frac{180}{0.43254} \\ &= 290.16 + 416.146 \\ &= 706.306\,\text{kJ/kg} \end{aligned}$$

Step 3 of 3

From ideal gas properties of air, calculate entropy at $h_2 = 706.306\,\text{kJ/kg}$ by interpolating the entropy values at $h = 702.52\,\text{kJ/kg}$ and $h = 713.27\,\text{kJ/kg}$:

$$\begin{aligned} s_2^\circ &= s^0_{h=702.52\text{kJ/kg}} + \left(s^\circ_{h=713.27\text{kJ/kg}} - s^0_{h=702.52\text{kJ/kg}}\right)\left(\frac{706.306-702.52}{713.27-702.52}\right) \\ &= 2.55731 + (2.57277 - 2.55731)(0.35355) \\ &= 2.55731 + 0.00546 \\ &= 2.5627\ \text{kJ/kg}\cdot\text{K} \end{aligned}$$

Calculate the Entropy change by using the following equation:

$$\begin{aligned} \Delta s_{sys} &= m\left(s_2^\circ - s_1^0 + R\ln\frac{P_2}{P_1}\right) \\ &= \Delta s_{sys} = m\left(s_2^0 - s_1^\circ\right) \qquad (P_2 = P_1) \end{aligned}$$

Substitute, $0.4325\,\text{kg}$ for m , $2.5627\ \text{kJ/kg}\cdot\text{K}$ for s_2°, $1.66802\ \text{kJ/kg}\cdot\text{K}$ for s_1° :

$$\begin{aligned} \Delta s_{sys} &= 0.43254\times(2.5628 - 1.66802) \\ &= 0.387\,\text{kJ/K} \end{aligned}$$

Therefore, the Entropy change of air for variable specific heat, Δs_{sys} is $\boxed{0.387\,\text{kJ/K}}$.

Question: 8.083P

A piston-cylinder device contains 0.75 kg of nitrogen gas at 140 kPa and 37°C. The gas is now compressed slowly in a polytropic process during which $PV^{1.3}$ = constant. The process ends when the volume is reduced by one-half. Determine the entropy change of nitrogen during this process.

Step 1 of 3

Given

Mass of nitrogen is, $m = 0.75\,\text{kg}$

Initial pressure of nitrogen is, $P_1 = 140\,\text{kPa}$

Initial temperature of nitrogen is, $T_1 = 37°\text{C} = 310\,\text{K}$

Polytropic index is, $n = 1.3$

Step 2 of 3

The final volume is half of the initial volume. So,

$$v_2 = \frac{v_1}{2}$$

$$v_1 = 2 \times v_2$$

In polytropic process the relation between temperature and volume is

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{n-1}$$

$$T_2 = T_1 \times \left(\frac{v_1}{v_2}\right)^{n-1}$$

$$T_2 = 310 \times \left(\frac{2 \times v_2}{v_2}\right)^{1.3-1}$$

$$T_2 = 310 \times 2^{0.3}$$

$$T_2 = 310 \times 1.2311$$

$$T_2 = 381.641\,\text{K}$$

Step 3 of 3

From properties of ideal gases table the specific heat (at constant volume) and gas constant values of nitrogen are respectively

$c_v = 0.743\,\text{kJ/kg.K}$

$R = 0.2968\,\text{kJ/kg.K}$

The change in entropy is given by

$$\Delta S = m \times \left[c_v \times \ln\left(\frac{T_2}{T_1}\right) + R \times \ln\left(\frac{v_2}{v_1}\right)\right]$$

$$\Delta S = 0.75 \times \left[0.743 \times \ln\left(\frac{381.641}{310}\right) + 0.2968 \times \ln\left(\frac{v_2}{2 \times v_2}\right)\right]$$

$$\Delta S = 0.75 \times \left[0.743 \times \ln(1.2311) + 0.2968 \times \ln(0.5)\right]$$

$$\Delta S = 0.75 \times \left[0.743 \times 0.2079 + 0.2968 \times (-0.693)\right]$$

$$\Delta S = 0.75 \times \left[0.1545 - 0.2057\right]$$

$$\Delta S = 0.75 \times \left[-0.0512\right]$$

$$\boxed{\Delta S = -0.0384\,\text{kJ/K}}$$

Therefore the entropy of nitrogen decreases by 0.0384 kJ/K.

Question: 8.084P

Reconsider Prob. 8-83. Using EES (or other) software, investigate the effect of varying the polytropic exponent from 1 to 1.4 on the entropy change of the nitrogen. Show the processes on a common P- *V* diagram.

Step 1 of 8

Given

Mass of nitrogen is, $m = 0.75\ \text{kg}$

Initial pressure of nitrogen is, $P_1 = 140\ \text{kPa}$

Initial temperature of nitrogen is, $T_1 = 37\ ^\circ\text{C} = 310\ \text{K}$

Polytrophic index varies, $n = 1$ to 1.4

Step 2 of 8

Give all the inputs in the EES software as given below

T1 =310 [K]

P1 =140 [kPa]

m =0.75 [kg]

RatioV =0.5

c_v =0.743 [kJ/kg-K]

R =0.297 [kJ/kg-K]

Step 3 of 8

For calculating other parameters we should give other equations as

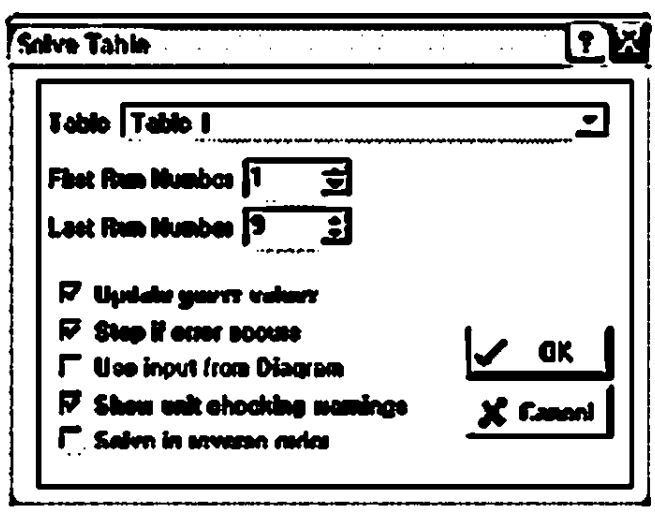
T2 =T1*(1/RatioV)^(n-1)

DELTAS =m *(c_v *ln(T2/T1)+R *ln (RatioV))

P1*V1 = m *R *T1

Step 4 of 8

After writing these sets of equations, we should create a parametric table from



Tables → new parametric

Fill all the values of n.

	n	
Run 1	1	
Run 2	1.05	
Run 3	1.1	
Run 4	1.15	
Run 5	1.2	
Run 6	1.25	
Run 7	1.3	
Run 8	1.35	
Run 9	1.4	

Step 5 of 8

Now solve the table for respective DELTAS values by pressing F3.

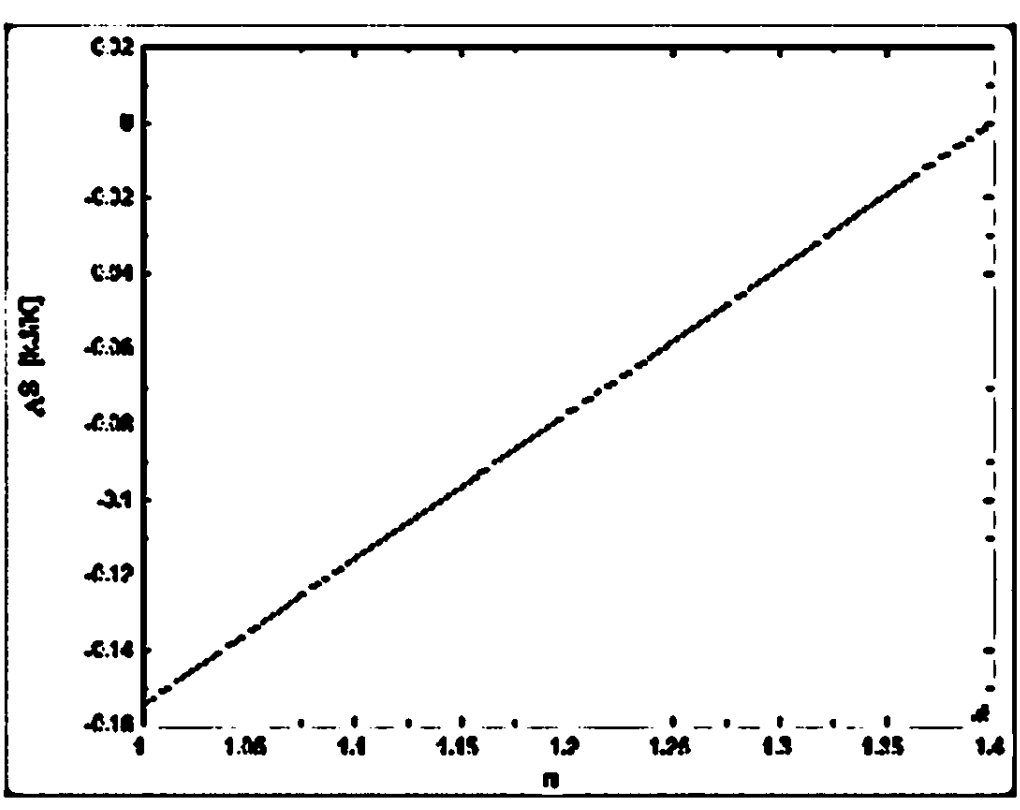
Step 6 of 8

Then we get

	n	ΔS [kJ/K]
Run 1	1	-0.1544
Run 2	1.05	-0.1361
Run 3	1.1	-0.1159
Run 4	1.15	-0.09646
Run 5	1.2	-0.07715
Run 6	1.25	-0.05783
Run 7	1.3	-0.03852
Run 8	1.35	-0.01921
Run 9	1.4	0.000104

Step 7 of 8

For getting the plot we should go for



Plots → New plot window

We should fill all the required fields by taking n in x-axis and DELTAS in y-axis.

Step 8 of 8

After that we get the plot as

Question: 8.085P

A mass of 15 lbm of helium undergoes a process from an initial state of 50 ft3 /lbm and 80°F to a final state of 10 ft3 /lbm and 200°F Determine the entropy change of helium during this process, assuming (*a*) the process is reversible and (*b*) the process is irreversible.

Step 1 of 2

Given:

Initial temperature, $T_1 = 80°\text{F}$

$\Rightarrow T_1 = 540\ \text{R}$

Initial volume, $V_1 = 50\ \text{ft}^3/\text{lbm}$

Final temperature, $T_2 = 200°\text{F}$

$\Rightarrow T_2 = 660\ \text{R}$

Final volume, $V_2 = 10\ \text{ft}^3/\text{lbm}$

Mass of helium, $m = 15\ \text{lbm}$

Gas constant of helium, $R = 0.4961\ \text{Btu/lbm.R}$

Constant volume specific heat of helium, $c_v = 0.753\ \text{Btu/lbm.R}$

Step 2 of 2

(a) and (b):

The entropy change will be the same for both reversible and irreversible cases.

Entropy change, $\Delta s_{He} = m \times \left(c_v \ln \frac{T_2}{T_1} + R \ln \frac{V_2}{V_1} \right)$

$$\Rightarrow \Delta s_{He} = 15 \times \left(0.753 \times \ln\left(\frac{660}{540}\right) + 0.4961 \times \ln\left(\frac{10}{50}\right) \right)$$

$$\Rightarrow \boxed{\Delta s_{He} = -9.7101\ \text{Btu/R}}$$

Question: 8.086P

1-kg of air at 200 kPa and 127°C is contained in a piston-cylinder device. Air is now allowed to expand in a reversible, isothermal process until its pressure is 100 kPa. Determine the amount of heat transferred to the air during this expansion.

Step 1 of 3

Given

Mass of air is, $m = 1.0\ \text{kg}$

Initial pressure of air is, $P_1 = 200\ \text{kPa}$

Temperature of air is, $T = 127°\text{C} = 400\ \text{K}$

Final pressure of air is, $P_2 = 100\ \text{kPa}$

Step 2 of 3

From properties of gases gas constant of air is

$R = 0.287\ \text{kJ/kg.K}$

Applying first law of thermodynamics to the piston cylinder device

$dQ = dU + dW$

As work is done by the device, the equation can be written as

$dQ = dU + W_{out}$

$dQ = m(u_2 - u_1) + W_{out}$

As the process is isothermal process, there is no change in internal energy then the first term on right hand side will be zero.

$dQ = 0 + W_{out}$

$dQ = W_{out}$ ..... (1)

Step 3 of 3

The work done in an isothermal process is given by

$$W_{out} = mRT \times \ln\left(\frac{P_1}{P_2}\right)$$

$$W_{out} = 1 \times 0.287 \times 400 \times \ln\left(\frac{200}{100}\right)$$

$W_{out} = 0.287 \times 400 \times \ln 2$

$W_{out} = 0.287 \times 400 \times 0.693$

$W_{out} = 79.5564\ \text{kJ}$ ..... (2)

Substituting value obtained from equation (2) in equation (1) we get

$\boxed{dQ = 79.5564\ \text{kJ}}$

Therefore the heat transferred during expansion of air is 79.5564 kJ

Question: 8.087P

Argon is expanded in an isentropic turbine from 2 MPa and 500°C to 200 kPa. Determine the outlet temperature and the work produced by this turbine per unit mass of argon.

Step 1 of 3

Given

Inlet pressure of argon is, $P_1 = 2\ \text{MPa} = 2000\ \text{kPa}$

Inlet temperature of argon is, $T_1 = 500°\text{C} = 773\ \text{K}$

Exit pressure of argon is, $P_2 = 200\ \text{kPa}$

Step 2 of 3

From ideal gas specific heat of gases specific heat and index values of argon respectively are

$c_p = 0.2081\ \text{kJ/kg.K}$

$k = 1.667$

Since the process is isentropic. The temperature and pressure in an isentropic process can be related as below

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = 773 \times \left(\frac{200}{2000}\right)^{\frac{1.667-1}{1.667}}$$

$$T_2 = 773 \times \left(\frac{200}{2000}\right)^{\frac{0.667}{1.667}}$$

$$T_2 = 773 \times (0.1)^{0.4}$$

$$T_2 = 773 \times 0.3981$$

$$T_2 = 307.73\ \text{K}$$

$$\boxed{T_2 = 34.73°\text{C}}$$

Therefore outlet temperature of the argon is $T_2 = 34.73°\text{C}$

Step 3 of 3

The work done by the turbine is given by

$$w_{tur} = h_1 - h_2$$

$$w_{tur} = c_p(T_1 - T_2)$$

$$w_{tur} = 0.2081 \times (773 - 307.73)$$

$$w_{tur} = 0.2081 \times 465.27$$

$$\boxed{w_{tur} = 96.8223\ \text{kJ/kg}}$$

Therefore the work produced by the turbine per unit mass of argon is $96.8223\ \text{kJ/kg}$

Question: 8.088P

Air is compressed in an isentropic compressor from 15 psia and 70°F to 200 psia. Determine the outlet temperature and the work consumed by this compressor per unit mass of air.

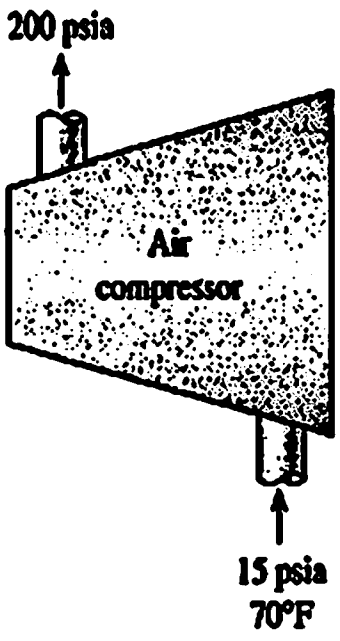


FIGURE P8–88E

Step 1 of 2

Obtain properties of air at an average temperature of $400°F$ from table A-2E, "ideal gas specific heat of gases" in the text book.

Specific heat at constant pressure, $c_p = 0.245$ Btu/lbm.R

Specific heat ratio, $k = 1.389$

Find the temperature at the exit of the compressor by using the following isentropic relation:

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Here, P_1 is compressor inlet pressure, P_2 is compressor exit pressure, T_1 is compressor inlet temperature, and T_2 is compressor exit temperature.

Substitute $(70+459.67)$R for T_1, 15 psia for P_1, 200 psia for P_2, and 1.389 for *k*.

$$T_2 = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = (70+459.67) \times \left(\frac{200}{15}\right)^{\frac{1.389-1}{1.389}}$$

$$T_2 = 1094.089\,\text{R}$$

Therefore, the outlet temperature of air is $\boxed{1094.089\ \text{R}}$.

Step 2 of 2

Find the work done on the compressor by using the following equation:

$$w_{com} = h_1 - h_2$$
$$w_{com} = c_p(T_1 - T_2)$$

Substitute 0.245 Btu/lbm.R for c_p, $(70+459.67)$R for T_1, and 1094.089 R for T_2.

$$w_{com} = 0.245 \times (529.67 - 1094.089)$$
$$= -138.282\,\text{Btu/lbm}$$

Negative sign indicates work is done on the system.

Therefore, the work consumed by the compressor per unit mass of air is $\boxed{138.282\ \text{Btu/lbm}}$.

Question: 8.089P

An insulated rigid tank is divided into two equal parts by a partition. Initially, one part contains 5 kmol of an ideal gas at 250 kPa and 40°C, and the other side is evacuated. The partition is now removed, and the gas fills the entire tank. Determine the total entropy change during this process.

Step 1 of 3

Given

Number of moles in first part of the tank is, $N = 5\ \text{kmol}$

Initial pressure in first part of the tank is, $P_1 = 250\ \text{kPa}$

Initial temperature in first part of the tank is, $T_1 = 40°C = 313\ \text{K}$

Step 2 of 3

As there is no heat addition and also the tank is insulated, the change in internal energy is zero.

$$\Delta U = 0$$

$$mc_v(T_1 - T_2) = 0$$

$$T_1 - T_2 = 0$$

$$T_1 = T_2$$

As the gas is made to fill the second part of the tank then the final volume will be double (since both the parts are of equal volume) the initial volume.

$$v_2 = 2 \times v_1$$

We know universal gas constant is,

$$\overline{R} = 8.314\ \text{kJ/kmol.K}$$

Step 3 of 3

The entropy change during the process is given by

$$\Delta S = N \times \left[c_v \times \ln\left(\frac{T_2}{T_1}\right) + \overline{R} \times \ln\left(\frac{v_2}{v_1}\right) \right]$$

$$\Delta S = N \times \left[c_v \times \ln\left(\frac{T_1}{T_1}\right) + \overline{R} \times \ln\left(\frac{v_2}{v_1}\right) \right]$$

$$\Delta S = N \times \left[c_v \times \ln(1) + \overline{R} \times \ln\left(\frac{v_2}{v_1}\right) \right]$$

$$\Delta S = N \times \left[c_v \times 0 + \overline{R} \times \ln\left(\frac{v_2}{v_1}\right) \right]$$

$$\Delta S = N \times \left[0 + \overline{R} \times \ln\left(\frac{v_2}{v_1}\right) \right]$$

$$\Delta S = N \times \overline{R} \times \ln\left(\frac{v_2}{v_1}\right)$$

$$\Delta S = 5 \times 8.314 \times \ln\left(\frac{2 \times v_1}{v_1}\right)$$

$$\Delta S = 5 \times 8.314 \times \ln(2)$$

$$\Delta S = 5 \times 8.314 \times 0.693$$

$$\boxed{\Delta S = 28.808\ \text{kJ/K}}$$

Therefore the total entropy change during this process is 28.808 kJ/K

Question: 8.090P

Air is compressed in a piston-cylinder device from 90 kPa and 22°C to 900 kPa in a reversible, adiabatic process. Determine the final temperature and the work done during this process, assuming (*a*) constant specific heats and (*b*) variable specific heats for air.

Step 1 of 6

Given data:

Initial pressure of air is, $P_1 = 90\ \text{kPa}$

Initial temperature of air is, $T_1 = 22°\text{C}$

$= 295\ \text{K}$

Final pressure of air is, $P_2 = 900\ \text{kPa}$

Step 2 of 6

Assuming an average temperature of $T_{avg} = 425\ \text{K}$

From ideal gas specific heats of various common liquids

By taking average of 400 K & 450 K

$$k = \frac{1.395 + 1.391}{2}$$

$$k = \frac{2.786}{2}$$

$$k = 1.393$$

$$c_v = \frac{0.726 + 0.733}{2}$$

$$c_v = \frac{1.459}{2}$$

$$c_v = 0.7295\ \text{kJ/kg}\cdot\text{K}$$

The gas constant, $R = 0.287\ \text{kJ/kg}\cdot\text{K}$

Step 3 of 6

(a) For an isentropic process, the final temperature is given by

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = 295\times\left(\frac{900}{90}\right)^{\frac{1.393-1}{1.393}}$$

$$T_2 = 295\times(10)^{\frac{0.393}{1.393}}$$

$$T_2 = 295\times 1.915$$

$$\boxed{T_2 = 564.9\ \text{K}}$$

The final temperature, $T_2 = 564.9\ \text{K}$

Step 4 of 6

Now we know that

Work done by constant specific heat

$$w_{in} = c_v\times(T_2 - T_1)$$

$$w_{in} = 0.7295\times(564.9 - 295)$$

$$w_{in} = 0.7295\times 269.9$$

$$\boxed{w_{in} = 196.89\ \text{kJ/kg}}$$

The work done, $w_{in} = 196.89\ \text{kJ/kg}$

Step 5 of 6

(b) From ideal gas properties of air

At temperature, $T_1 = 295\ \text{K}$

Relative pressure, $P_{r1} = 1.3068$

Internal energy, $u_1 = 210.49\ \text{kJ/kg}$

We know that

Final relative pressure

$$P_{r2} = P_{r1}\left(\frac{P_2}{P_1}\right)$$

$$P_{r2} = 1.3068\times\left(\frac{900}{90}\right)$$

$$P_{r2} = 1.3068\times 10$$

$$P_{r2} = 13.068$$

Now from ideal gas properties of air

Final temperature is interpolated as

$$\left(\frac{T_2 - 560}{570 - 560}\right) = \left(\frac{13.068 - 12.66}{13.50 - 12.66}\right)$$

$$\left(\frac{T_2 - 560}{10}\right) = \left(\frac{0.408}{0.84}\right)$$

$$\left(\frac{T_2 - 560}{10}\right) = 0.4857$$

$$T_2 - 560 = 0.4857\times 10$$

$$T_2 = 4.857 + 560$$

$$\boxed{T_2 = 564.9\ \text{K}}$$

The final temperature, $T_2 = 564.9\ \text{K}$

Step 6 of 6

Now from ideal gas properties of air

Final internal energy is interpolated as

$$\left(\frac{u_2 - 404.42}{411.97 - 404.42}\right) = \left(\frac{13.068 - 12.66}{13.50 - 12.66}\right)$$

$$\left(\frac{u_2 - 404.42}{7.55}\right) = \left(\frac{0.408}{0.84}\right)$$

$$\left(\frac{u_2 - 404.42}{7.55}\right) = 0.4857$$

$$u_2 - 404.42 = 0.4857\times 7.55$$

$$u_2 = 3.667 + 404.42$$

$$u_2 = 408.087\ \text{kJ/kg}$$

Work input by variable specific heats is given by

$$w_{in} = u_2 - u_1$$

$$w_{in} = 408.087 - 210.49$$

$$\boxed{w_{in} = 197.6\ \text{kJ/kg}}$$

The work done, $w_{in} = 197.6\ \text{kJ/kg}$

Question: 8.091P

 Reconsider Prob. 8-90. Using EES (or other) software, evaluate and plot the work done and final temperature during the compression process as functions of the final pressure for the two cases as the final pressure varies from 100 to 1200 kPa.

We don't have the solution to this problem yet.

Ask an expert

Question: 8.092P

An insulated rigid tank contains 4 kg of argon gas at 450 kPa and 30°C. A valve is now opened, and argon is allowed to escape until the pressure inside drops to 200 kPa. Assuming the argon remaining inside the tank has undergone a reversible, adiabatic process, determine the final mass in the tank.

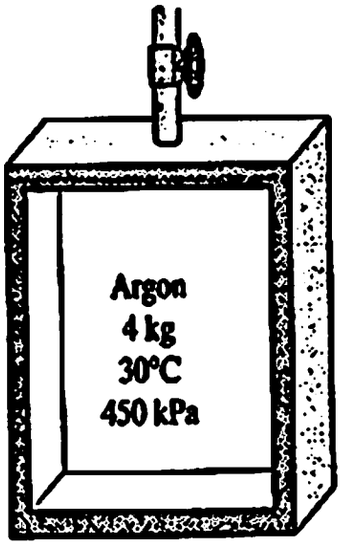

FIGURE P8–92

Step 1 of 2

Given:

Initial temperature, $T_1 = 30°C$

$$\Rightarrow T_1 = 303\ K$$

Initial Pressures, $P_1 = 450\ kPa$

Final pressure, $P_2 = 200\ kPa$

Specific heat ratio of argon, $k = 1.667$

Initial mass, $m = 4\ kg$

Step 2 of 2

Final temperature, $T_2 = T_1\left(\frac{P_2}{P_1}\right)^{(k-1)/k}$

$$\Rightarrow T_2 = 303\times\left(\frac{200}{450}\right)^{(1.667-1)/1.667}$$

$$\Rightarrow T_2 = 219.04K$$

From ideal gas equation, $PV = mRT$

$$\Rightarrow \frac{P_1V}{P_2V} = \frac{m_1RT_1}{m_2RT_2}$$

Final mass, $m_2 = \frac{P_2T_1}{P_1T_2}\times m_1$

$$\Rightarrow m_2 = \frac{200\times 303}{450\times 219}\times 4$$

$$\Rightarrow \boxed{m_2 = 2.46\ kg}$$

Question:

Reconsider Prob. 8-92. Using EES (or other) software, investigate the effect of the final pressure on the final mass in the tank as the pressure varies from 450 to 150 kPa, and plot the results.

Step 1 of 5

Mass of the argon, $m = 4\,\text{kg}$

Initial temperature of the argon gas, $T_1 = 30°\text{C} = 303°\text{F}$

Initial pressure of the argon gas, $P_1 = 450\,\text{kPa}$

Final pressure of the argon gas, $P_2 = 200\,\text{kPa}$

Step 2 of 5

This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below,

Equations Window

```
"Given data"
T_1=30 [C]
P_1=450 [kPa]
"P_2=200 [kPa]"
m_1=4 [kg]

cp_1=Cp(Argon,T=T_1,P=P_1)
cv_1=Cv(Argon,T=T_1,P=P_1)
k=cp_1/cv_1

"For an isentropic process"
T_2/T_1=(P_2/P_1)^((k-1)/k)

"Ideal gas equation P*V=m*R*T"
P_1*V=m_1*R#*T_1
P_2*V=m_2*R#*T_2
```

Step 3 of 5

To check weather the program typed is in correct mathematical format or not go to "Options > Function info" a window opens as show below ,

Formatted Equations

Given data

$T_1 = 30 \;\; [C]$

$P_1 = 450 \;\; [kPa]$

$P_2 = 200 \;\; [kPa]$

$m_1 = 4 \;\; [kg]$

$cp_1 = Cp('Argon', T = T_1, P = P_1)$

$cv_1 = Cv('Argon', T = T_1, P = P_1)$

$$k = \frac{cp_1}{cv_1}$$

For an isentropic process

$$\frac{T_2}{T_1} = \left[\frac{P_2}{P_1}\right]^{\left[\frac{k-1}{k}\right]}$$

Ideal gas equation P*V=m*R*T

$P_1 \cdot V = m_1 \cdot 8.314 \;\; [kJ/kmol\text{-}K] \cdot T_1$

$P_2 \cdot V = m_2 \cdot 8.314 \;\; [kJ/kmol\text{-}K] \cdot T_2$

Step 4 of 5

Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

New Parametric Table

No. of Runs: 11 Table: Table 1

Variables in equations: cp_1, cv_1, k, m_1, P_1, T_1, T_2, V

Add ->

<- Remove

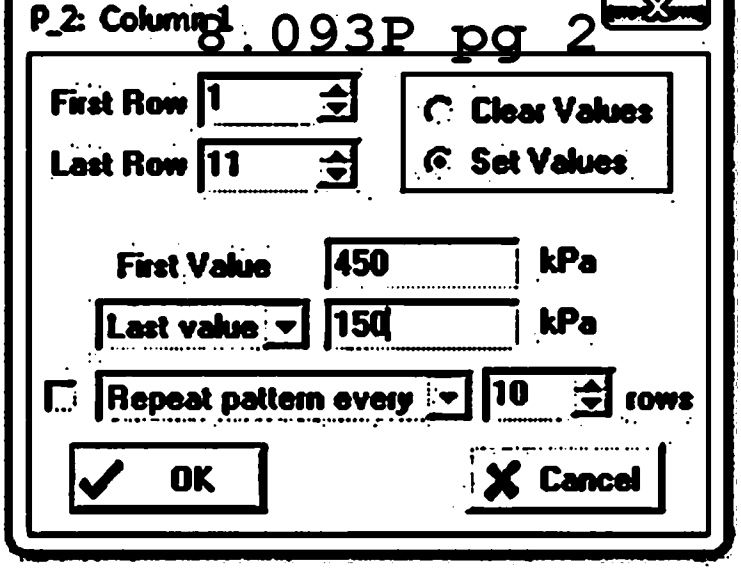
Variables in table: P_2, m_2

Show Array Variables

OK Cancel

Step 5 of 5

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,



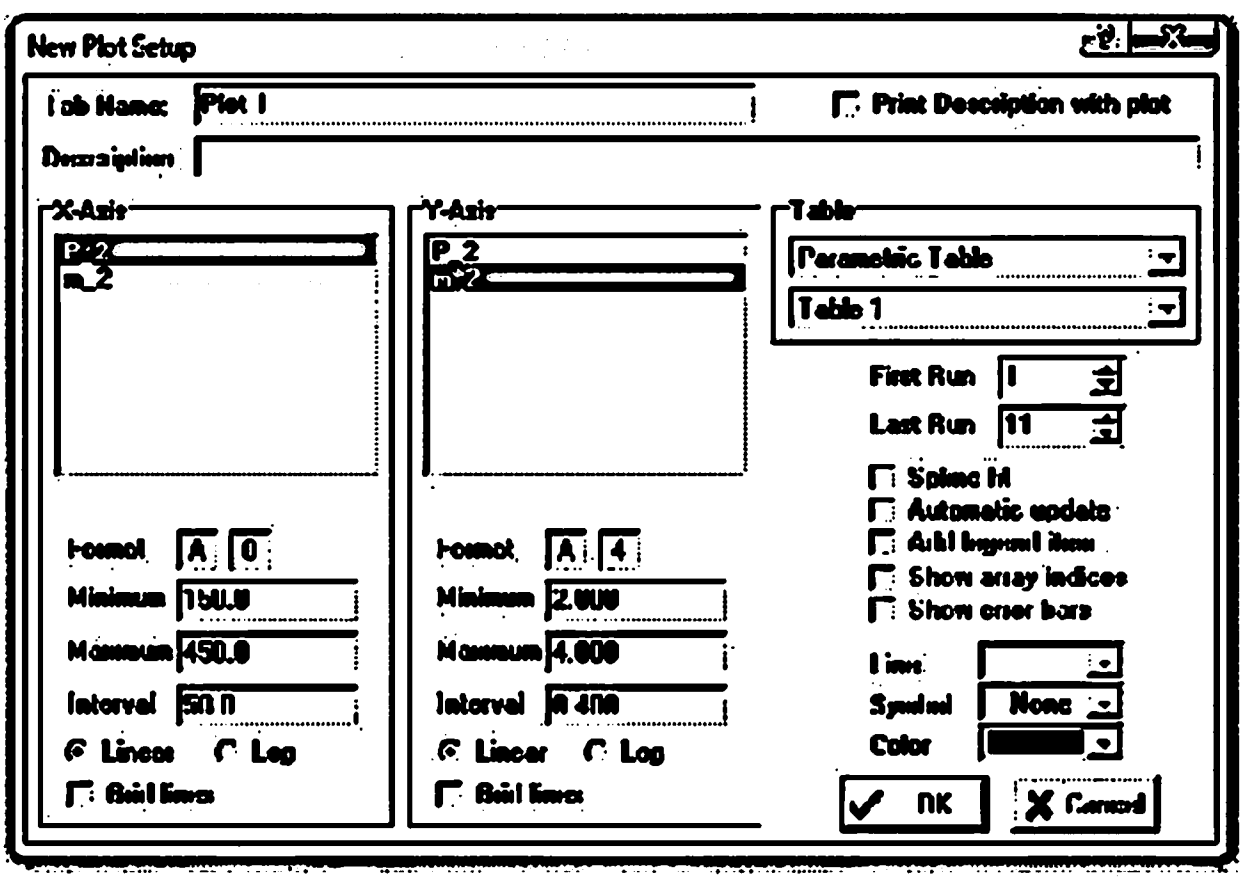
P_2: Column 1

First Row 1

Last Row 11

Clear Values

Set Values



Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Parametric Table

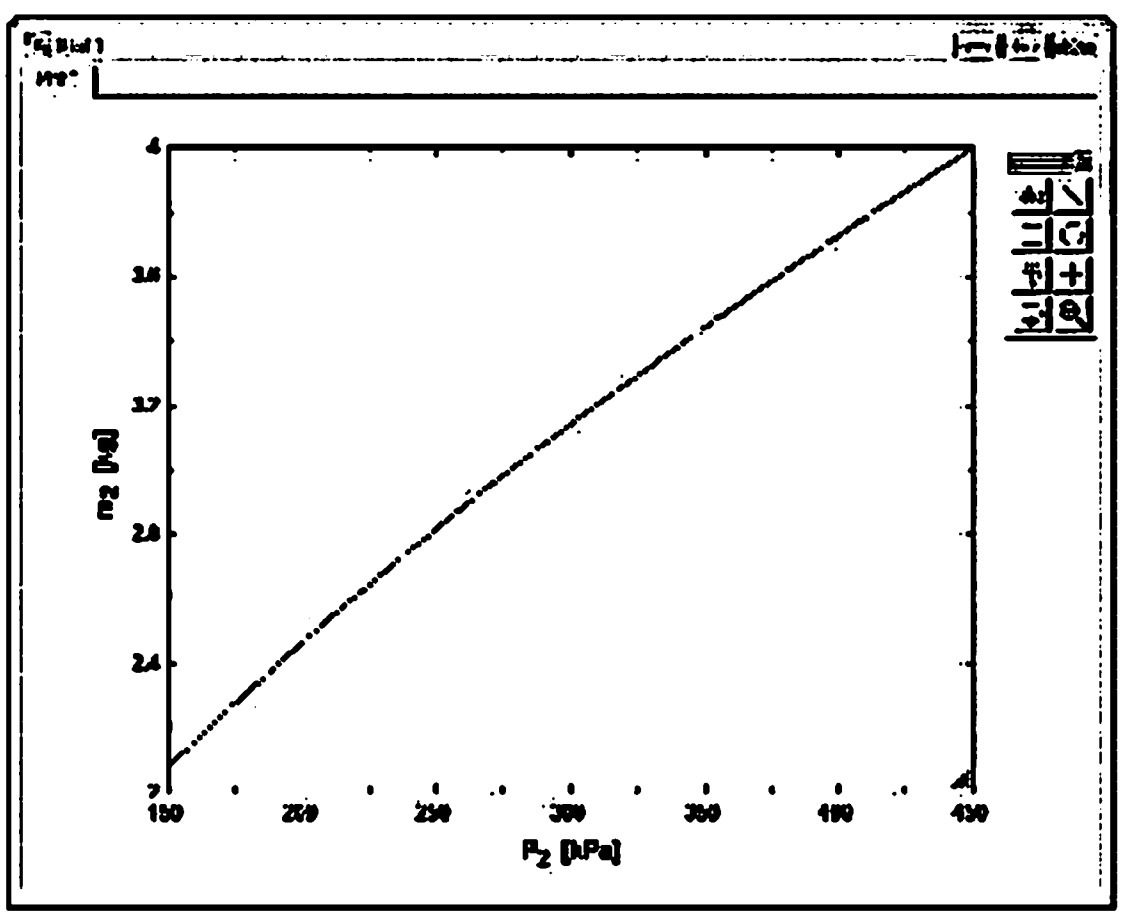


Table 1

1..11	P_2 [kPa]	m_2 [kg]
Run 1	450	4
Run 2	420	3.839
Run 3	390	3.673
Run 4	360	3.502
Run 5	330	3.325
Run 6	300	3.142
Run 7	270	2.951
Run 8	240	2.751
Run 9	210	2.541
Run 10	180	2.318
Run 11	150	2.079

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

By clicking on OK the graph will be generated as shown,

Question: 8.094P

Air enters an adiabatic nozzle at 60 psia, 540°F, and 200 ft/s and exits at 12 psia. Assuming air to be an ideal gas with variable specific heats and disregarding any irreversibilities, determine the exit velocity of the air.

Step 1 of 3

Given:

Initial temperature, $T_1 = 540^\circ F \Rightarrow T_1 = 1000\ \text{R}$

Inlet Pressures, $P_1 = 60\ \text{psia}$

Exit pressure $P_2 = 12\ \text{psia}$

Inlet velocity, $V_1 = 200\ \text{ft/s}$

Initial mass, $m = 4\ \text{kg}$

Step 2 of 3

From ideal gas properties of air table, at $T_1 = 1000\ \text{R}$

Initial relative pressure, $P_{r_1} = 12.3$

Initial enthalpy, $h_1 = 240.98\text{Btu/lbm}$

Initial relative pressure, $P_{r_2} = \dfrac{P_2}{P_1} P_{r_1}$

$$\Rightarrow P_{r_2} = \frac{12}{60} \times 12.3$$

$$\Rightarrow P_{r_2} = 2.46$$

From ideal gas properties of air Table, at $P_{r_2} = 2.46$

Final temperature, $T_2 = 635.9R$

Final enthalpy, $h_2 = 152.11\text{Btu/lbm}$

Step 3 of 3

Apply energy balance for this steady-flow system,

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} = 0$$

$$\Rightarrow \dot{E}_{in} = \dot{E}_{out}$$

$$\Rightarrow \dot{m} \times \left(h_1 + \frac{V_1^2}{2} \right) = \dot{m} \times \left(h_2 + \frac{V_2^2}{2} \right)$$

$$\Rightarrow h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} = 0$$

Exit velocity of the air, $V_2 = \sqrt{2(h_1 - h_2) + V_1^2}$

$$\Rightarrow V_2 = \sqrt{2(240.98 - 152.11)\left(\frac{25,037}{1} \right) + 200^2}$$

$$\Rightarrow V_2 = \sqrt{4450076.38 + 40000}$$

$$\Rightarrow \boxed{V_2 = 2118.98\text{ft/s}}$$

Question: 8.095P

Air is expanded in an adiabatic nozzle during a polytropic process with $n = 1.3$. It enters the nozzle at 700 kPa and 100°C with a velocity of 30 m/s and exits at a pressure of 200 kPa. Calculate the air temperature and velocity at the nozzle exit.

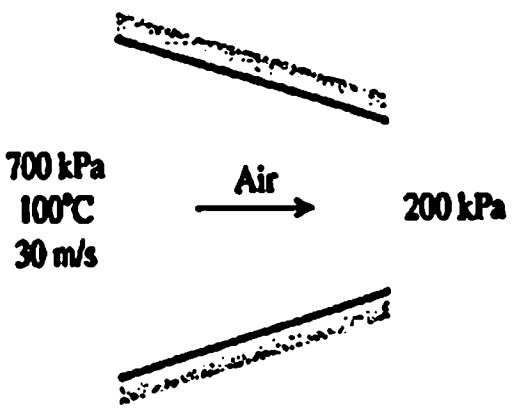

FIGURE P8–95

Step 1 of 2

Calculate the air temperature at the exit of the nozzle.

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}$$

Here, the temperature at the inlet is T_1, pressure at the inlet is P_1, temperature at outlet is T_2, pressure at outlet is P_2 and n is polytropic constant.

Substitute $373\ \text{K}$ for T_1, $700\ \text{kPa}$ for P_1, 1.3 for n, and $200\ \text{kPa}$ for P_2.

$$T_2 = (373)\left(\frac{200}{700}\right)^{\frac{1.3-1}{1.3}}$$
$$= 279.35\ \text{K}$$

Therefore, the temperature of air at the exit of the nozzle is, $\boxed{279.35\ \text{K}}$.

Step 2 of 2

Apply the energy balance for the steady flow system.

$$\dot{E}_{in} = \dot{E}_{out}$$
$$(\text{H}+\text{KE})_1 = (\text{H}+\text{KE})_2$$

$$\dot{m}\left(h_1 + \frac{V_1^2}{2}\right) = \dot{m}\left(h_2 + \frac{V_2^2}{2}\right)$$
$$\frac{V_2^2}{2} = \frac{V_1^2}{2} + (h_1 - h_2)$$
$$V_2 = \sqrt{V_1^2 + 2(h_1 - h_2)}$$
$$V_2 = \sqrt{V_1^2 + 2(c_p T_1 - c_p T_2)}$$

Here, the velocity at the inlet is V_1, mass flow rate is $\dot{m}$, and specific heat at constant pressure is c_p.

Substitute $1.005\ \text{kJ/kg K}$ for c_p, 373 K for T_1, $279.35\ \text{K}$ for T_2, and $30\ \text{m/s}$ for V_1.

$$V_2 = \sqrt{(30)^2 + \left[2\times 1.005\times(373-279.35)\left(\frac{1000\ \text{m}^2/\text{s}^2}{1\ \text{kJ/kg}}\right)\right]}$$
$$= 434.89\ \text{m/s}$$

Therefore, the velocity of air at the exit is, $\boxed{434.89\ \text{m/s}}$

Question: 8.096P

Repeat Prob. 8-95 for the polytropic exponent of $n = 1.1$.

Step 1 of 6

Given

Polytropic index is, $n = 1.1$

Pressure at nozzle inlet is, $P_1 = 700\ \text{kPa}$

Temperature at nozzle inlet is, $T_1 = 100\ ^\circ\text{C}$

$= 373\ \text{K}$

Velocity at nozzle inlet is, $V_1 = 30\ \text{m/s}$

Pressure at nozzle exit is, $P_2 = 200\ \text{kPa}$

Step 2 of 6

From the ideal gas specific heats of various common gases

For specific heat of air is,

$c_p = 1.005\ \text{kJ/kg°K}$

The temperature ratio of polytropic process is given by

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}$$

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}$$

$$T_2 = 373\times\left(\frac{200}{700}\right)^{\frac{1.1-1}{1.1}}$$

$$T_2 = 373\times(0.2857)^{\frac{0.1}{1.1}}$$

$$T_2 = 373\times(0.2857)^{0.09}$$

$$T_2 = 373\times 0.8934$$

$$\boxed{T_2 = 333.24\ \text{K}}$$

Step 3 of 6

The energy balance for a steady-flow system is given by

$E_{in} - E_{out} = \Delta E_{sys}$

For a steady flow system the change in energy is zero. $E_{sys} = 0$

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$m_1\left[h_1 + \left(\frac{V_1^2}{2}\right)\right] = m_2\left[h_2 + \left(\frac{V_2^2}{2}\right)\right]$$

Step 4 of 6

As only one inlet and exit are there the mass flow rate will be same $m_1 = m_2 = m$

$$m\left[h_1 + \left(\frac{V_1^2}{2}\right)\right] = m\left[h_2 + \left(\frac{V_2^2}{2}\right)\right]$$

$$h_1 + \left(\frac{V_1^2}{2}\right) = h_2 + \left(\frac{V_2^2}{2}\right)$$

$$\left(\frac{V_2^2}{2}\right) = h_1 - h_2 + \left(\frac{V_1^2}{2}\right)$$

$$V_2^2 = 2\times\left[h_1 - h_2 + \left(\frac{V_1^2}{2}\right)\right]$$

$$V_2^2 = \left[2\times(h_1 - h_2) + V_1^2\right]$$

Step 5 of 6

In order to change enthalpy value from kJ/kg°K to m^2/s^2 we get

$$V_2^2 = \left[2000\times(h_1 - h_2) + V_1^2\right]$$

$$V_2 = \sqrt{2000\times(h_1 - h_2) + V_1^2}$$

$$V_2 = \sqrt{2000\times c_p\times(T_1 - T_2) + V_1^2}$$

Step 6 of 6

$$V_2 = \sqrt{2000\times c_p\times(T_1 - T_2) + V_1^2}$$

$$V_2 = \sqrt{2000\times 1.005\times(373 - 333.24) + 30^2}$$

$$V_2 = \sqrt{2000\times 1.005\times 39.76 + 900}$$

$$V_2 = \sqrt{79917.6 + 900}$$

$$V_2 = \sqrt{80817.6}$$

$$\boxed{V_2 = 284.28\ \text{m/s}}$$

Therefore the exit temperature is 333.24 K and the exit velocity is 284.28 m/s

Question: 8.097P

Air at 427°C and 600 kPa is contained in a piston-cylinder device. The air expands adiabatically until the pressure is 100 kPa. Determine the mass of air needed to produce maximum work of 1000 kJ. Assume air has constant specific heats evaluated at 300 K.

Step 1 of 3

Given

Initial pressure of air is, $P_1 = 600\ \text{kPa}$

Initial temperature of air is, $T_1 = 427°\text{C} = 700\ \text{K}$

Final pressure of air is, $P_2 = 100\ \text{kPa}$

Work produced by the device is $w_{dev} = 1000\ \text{kJ}$

Step 2 of 3

From ideal gas specific heats of gases specific heat and index values of air at temperature 300 K respectively are

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Since the process is isentropic. The temperature and pressure in an isentropic process can be related as below

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = 700 \times \left(\frac{100}{600}\right)^{\frac{0.4}{1.4}}$$

$$T_2 = 700 \times (0.1666)^{\frac{0.4}{1.4}}$$

$$T_2 = 700 \times 0.599$$

$$T_2 = 419.3\ \text{K}$$

Step 3 of 3

The work done by the device is given by

$$w_{dev} = m(u_1 - u_2)$$

$$w_{dev} = mc_v(T_1 - T_2)$$

$$m = \frac{w_{dev}}{c_v(T_1 - T_2)}$$

$$m = \frac{1000}{0.718 \times (700 - 419.3)}$$

$$m = \frac{1000}{0.718 \times 280.7}$$

$$m = \frac{1000}{201.5426}$$

$$\boxed{m = 4.9617\ \text{kg}}$$

Therefore the mass of air needed to produce maximum work of 1000 kJ is

$m = 4.9617\ \text{kg}$

Question: 8.098P

Helium enters a steady-flow adiabatic compressor at0.6 kg/s, 100 kPa, and 27°C with a low inlet velocity and compressed to 600 kPa.

(*a*) Determine the exit temperature to make the work input and kinetic energy at the compressor exit have the minimum values.

(*b*) If the rate of work input into the compressor is measured to be a minimum with a value of 1000 kW, determine the compressor exit velocity, in m/s.

Step 1 of 8

Given data:

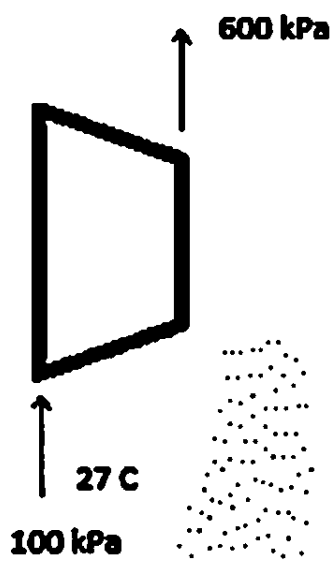
Mass flow rate is, $\dot{m} = 0.6\,kg/s$

Pressure at compressor inlet is, $P_1 = 100\,kPa$

Temperature at compressor inlet is, $T_1 = 27\,^{\circ}C = 300\,K$

Pressure at compressor exit is, $P_2 = 600\,kPa$

Work input is, $W_{in} = 1000\,kW$



Step 2 of 8

From table A-2(a), properties of helium are,

$c_p = 5.1926\,kJ/kg^{\circ}K$

$k = 1.667$

Step 3 of 8

Step 4 of 8

(a) The temperature ratio of polytropic process is given by

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = 300\times\left(\frac{600}{100}\right)^{\frac{1.667-1}{1.667}}$$

$$T_2 = 300\times(6)^{\frac{0.667}{1.667}}$$

$$T_2 = 300\times(6)^{0.4}$$

$$T_2 = 300\times 2.0476$$

$$\boxed{T_2 = 614.3\,K}$$

Step 5 of 8

(b) The energy balance for a steady-flow system is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For a steady flow system the change in energy is zero. $E_{sys} = 0$

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$m_1\left[h_1 + \left(\frac{V_1^2}{2}\right)\right] + W_{in} = m_2\left[h_2 + \left(\frac{V_2^2}{2}\right)\right]$$

Step 6 of 8

As only one inlet and exit are there the mass flow rate will be same $m_1 = m_2 = m$

$$m\left[h_1 + \left(\frac{V_1^2}{2}\right)\right] + W_{in} = m\left[h_2 + \left(\frac{V_2^2}{2}\right)\right]$$

$$h_1 + \left(\frac{V_1^2}{2}\right) + \frac{W_{in}}{m} = h_2 + \left(\frac{V_2^2}{2}\right)$$

$$\left(\frac{V_2^2}{2}\right) = h_1 - h_2 + \left(\frac{V_1^2}{2}\right) + \frac{W_{in}}{m}$$

$$V_2^2 = 2\times\left[h_1 - h_2 + \left(\frac{V_1^2}{2}\right) + \frac{W_{in}}{m}\right]$$

Step 7 of 8

As inlet velocity is very low, it should be negligible,

$$V_2^2 = 2\times\left[h_1 - h_2 + \frac{W_{in}}{m}\right]$$

$$V_2^2 = \left[2\times(h_1 - h_2) + \frac{2\times W_{in}}{m}\right]$$

In order to change enthalpy value from kJ/kg°K to m^2/s^2 we get

$$V_2^2 = 1000\times\left[2\times(h_1 - h_2) + \frac{2\times W_{in}}{m}\right]$$

$$V_2 = \sqrt{1000\times\left[2\times(h_1 - h_2) + \frac{2\times W_{in}}{m}\right]}$$

$$V_2 = \sqrt{1000\times\left[2\times c_p\times(T_1 - T_2) + \frac{2\times W_{in}}{m}\right]}$$

Step 8 of 8

$$V_2 = \sqrt{1000\times\left[2\times 5.1926\times(300 - 614.3) + \frac{2\times 1000}{0.6}\right]}$$

$$V_2 = \sqrt{1000\times\left[2\times 5.1926\times(-314.3) + 3333.33\right]}$$

$$V_2 = \sqrt{1000\times\left[-3264.07 + 3333.33\right]}$$

$$V_2 = \sqrt{1000\times 69.26}$$

$$V_2 = \sqrt{69260}$$

$$\boxed{V_2 = 263.17\,m/s}$$

Therefore the exit temperature is 614.3 K and the exit velocity is 263.17 m/s

Question: 8.099P

5-kg of air at 427°C and 600 kPa are contained in piston-cylinder device. The air expands adiabatically until the pressure is 100 kPa and produces 600 kJ of work output. Assume air has constant specific heats evaluated at 300 K.

(*a*) Determine the entropy change of the air, in kJ/kg-K I

(*b*) Since the process is adiabatic, is the process realistic? Using concepts of the second law, support your answer.

Step 1 of 5

Given

Mass of air is, $m = 5\ \text{kg}$

Initial pressure of air is, $P_1 = 600\ \text{kPa}$

Initial temperature of air is, $T_1 = 427\ ^\circ\text{C} = 700\ \text{K}$

Final pressure of air is, $P_2 = 100\ \text{kPa}$

Work done by the device is, $W_{dev} = 600\ \text{kJ}$

Step 2 of 5

From ideal gas specific heats of air at temperature 300 K are

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

The gas constant of air is

$R = 0.287\ \text{kJ/kg.K}$

Step 3 of 5

(a)

From first law of thermodynamics,

$dQ = dU + dW$

As work is done by the device, the equation can be written as

$dQ = dU + W_{dev}$

$dQ = m(u_2 - u_1) + W_{dev}$

As the process is adiabatic process, first term on right hand side will be zero.

$0 = m(u_2 - u_1) + W_{dev}$

$W_{dev} = m(u_1 - u_2)$

$W_{dev} = mc_v(T_1 - T_2)$

$$T_1 - T_2 = \frac{W_{dev}}{m \times c_v}$$

$$T_2 = T_1 - \frac{W_{dev}}{m \times c_v}$$

$$T_2 = 700 - \frac{600}{5 \times 0.718}$$

$$T_2 = 700 - \frac{600}{3.59}$$

$T_2 = 700 - 167.13$

$T_2 = 532.87\ \text{K}$

Step 4 of 5

The entropy change is given by

$$\Delta s = c_v \times \ln\left(\frac{T_2}{T_1}\right) - R \times \ln\left(\frac{P_2}{P_1}\right)$$

$$\Delta s = 1.005 \times \ln\left(\frac{532.87}{700}\right) - 0.287 \times \ln\left(\frac{100}{600}\right)$$

$\Delta s = 1.005 \times \ln(0.761) - 0.287 \times \ln(0.167)$

$\Delta s = 1.005 \times (-0.273) - 0.287 \times (-1.789)$

$\Delta s = -0.274365 - (-0.5134)$

$\Delta s = -0.274365 + 0.5134$

$\boxed{\Delta s = 0.239\ \text{kJ/kg.K}}$

Therefore the entropy change of the air is $\Delta s = 0.239\ \text{kJ/kg.K}$

Step 5 of 5

(b)

As the change in entropy is not zero (positive in this case) the process is irreversible.

Therefore the process is realistic as it is not reversible.

Question: 8.100P

A constant-volume tank contains 5 kg of air at 100 kPa and 327°C. The air is cooled to the surroundings temperature of 27°C. Assume constant specific heats at 300 K. (a) Determine the entropy change of the air in the tank during the process, in kJ/K, (*b*) determine the net entropy change of the universe due to this process, in kJ/K, and (*c*) sketch the processes for the air in the tank and the surroundings on a single *T-s* diagram. Besure to label the initial and final states for both processes.

Step 1 of 5

Given

Mass of air in the tank $m = 5\ \text{kg}$

Temperature of air in the tank $T_1 = 327°\text{C}$

$= 600°\text{K}$

Pressure of air in the tank $p_1 = 100\ \text{kPa}$

Temperature of surroundings $T_2 = 27°\text{C}$

$= 300°\text{K}$

Step 2 of 5

(a)

Entropy change of air in the tank, $\Delta s_{air} = mc_v \ln \frac{T_2}{T_1}$

Specific heat of air, $c_v = 0.718\ \text{kJ/kg K}$

$$\Delta s_{air} = (5\ \text{kg})(0.718\ \text{kJ/kg K})\ln\left(\frac{300\text{K}}{600\text{K}}\right)$$

$$\Delta s_{air} = -2.488\ \text{kJ/K}$$

Entropy change of the air in the tank during the process $\boxed{\Delta s_{air} = -2.488\ \text{kJ/K}}$

Step 3 of 5

(b)

From energy balance

$$Q_{out} = mc_v(T_2 - T_1)$$

$$Q_{out} = (5\ \text{kg})(0.718\ \text{kJ/kg K})(327 - 27)\text{K}$$

$$Q_{out} = 1077\ \text{kJ}$$

Entropy change of the surroundings

$$\Delta s_{surr} = \frac{Q_{out}}{T_{surr}}$$

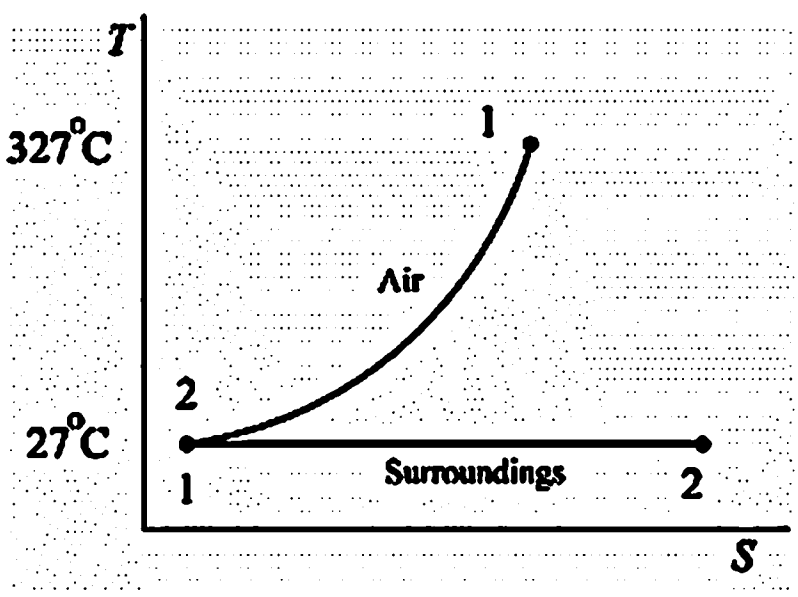
$$\Delta s_{surr} = \frac{1077\text{kJ}}{300\ \text{K}}$$

$$\Delta s_{surr} = 3.59\ \text{kJ/K}$$

Step 4 of 5

Net entropy change of the universe due to this process

$$\Delta s_{total} = \Delta s_{air} + \Delta s_{surr}$$



$$\Delta s_{total} = -2.488 + 3.59$$

$$\Delta s_{total} = 1.10\ \text{kJ/K}$$

Entropy change of the universe due to this process, $\boxed{\Delta s_{total} = 1.10\ \text{kJ/K}}$

Step 5 of 5

(c) Air in the tank and surroundings on a single T-s diagram

Question: 8.101P pg 1

A container filled with 45 kg of liquid water at 95°C is placed in a 90-m3 room that is initially at 12°C. Thermal equilibrium is established after a while as a result of heat ? transfer between the water and the air in the room. Using constant specific heats, determine (*a*) the final equilibrium temperature, (*b*) the amount of heat transfer between the water and the air in the room, and (*c*) the entropy generation.Assume the room is well sealed and heavily insulated.

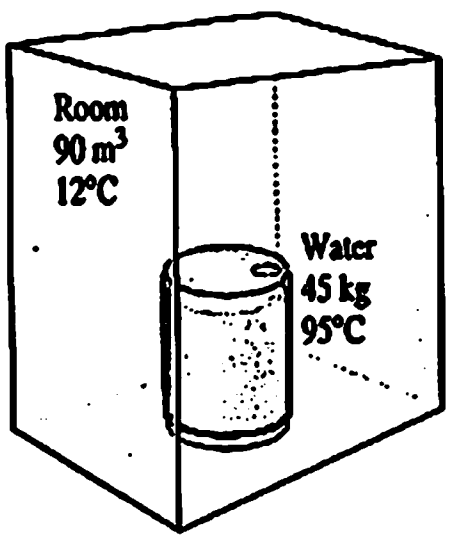


FIGURE P8–101

Step 1 of 7

Obtain the following properties of air from table A-2, "Ideal-gas specific heats of various common gases" in the textbook.

Gas constant for air, $R = 0.287\ \text{kJ/kg.K}$

Specific heat of air at constant pressure, $c_p = 1.005\ \text{kJ/kg.K}$

Specific heat of air at constant volume, $c_v = 0.718\ \text{kJ/kg.K}$

Obtain the specific heat of water from table, "Properties of common liquids, solids, and foods" from the textbook.

$c_{pw} = 4.18\ \text{kJ/kg.K}$

Calculate the mass of air in the room using the following relation.

$$m_{air} = \frac{PV}{RT_1}$$

Here, P is the pressure in the room (atmospheric pressure), V is the volume of the room, R is the gas constant, and T_1 initial room temperature.

Substitute $101.325\,\text{kPa}$ for P, $90\ \text{m}^3$ for V, $0.287\ \text{kJ/kg.K}$ for R, and $12°\text{C}$ for T_1.

$$m_{air} = \frac{(101.325)(90)}{(0.287)(12+273)}$$
$$= 111.5\ \text{kg}$$

Step 2 of 7

(a)

Calculate the final equilibrium temperature by applying energy balance considering the room as the system.

$$E_{in} - E_{out} = \Delta E_{system}$$
$$m_w c_{pw}(T_2 - T_w) + m_{air} c_v (T_2 - T_1) = 0$$

Here, m_w is the mass of water, and T_w is the initial temperature of water.

Substitute 45 kg for m_w, $95°\text{C}$ for T_w, $111.5\ \text{kg}$ for m_{air}, $4.18\ \text{kJ/kg.K}$ for c_{pw}, $0.718\ \text{kJ/kg.K}$ for c_v, and $12°\text{C}$ for T_1.

$$45(4.18)(T_2 - 95) + (111.5)(0.718)(T_2 - 12) = 0$$
$$188.1T_2 - 17869.5 + 80.057T_2 - 960.684 = 0$$
$$268.157T_2 = 18830.184$$
$$T_2 = 70.22°\text{C}$$

Therefore the final equilibrium temperature is $\boxed{T_2 = 70.22°\text{C}}$.

Step 3 of 7

(b)

Calculate the amount of heat transferred from water to air as

$$Q = m_{air} c_v (T_2 - T_1)$$

Substitute $111.5\ \text{kg}$ for m_{air}, $0.718\ \text{kJ/kg.K}$ for c_v, $70.22°\text{C}$ for T_2, and $12°\text{C}$ for T_1.

$$Q = 111.5(0.718)(70.22 - 12)$$
$$= 4660.918\ \text{kJ}$$

Hence, the amount of heat transfer between water and air is $\boxed{Q = 4660.918\ \text{kJ}}$.

Step 4 of 7

(c)

Calculate the entropy change for water.

$$\Delta s_w = m_w c_{pw} \ln \frac{T_2}{T_w}$$

Substitute 45 kg for m_w, $95°\text{C}$ for T_w, $4.18\ \text{kJ/kg.K}$ for c_{pw}, and $70.22°\text{C}$ for T_2.

$$\Delta s_w = 45(4.18) \ln \frac{70.22+273}{95+273}$$
$$\Delta s_w = -13.11\ \text{kJ/K}$$

Step 5 of 7

Calculate the final pressure of air in the room using the ideal gas equation.

$$P_2 = \frac{mRT_2}{}$$

Step 5 of 7

Calculate the final pressure of air in the room using the ideal gas equation.

$$P_2 = \frac{mRT_2}{V}$$

Substitute $90\ \text{m}^3$ for V, $0.287\ \text{kJ/kg.K}$ for R, $70.22°\text{C}$ for T_2, and 111.5 kg for m.

$$P_2 = \frac{111.5 \times 0.287 \times (70.22 + 273)}{90}$$
$$= 122.035\,\text{kPa}$$

Step 6 of 7

Calculate the entropy change for air.

$$s_2 - s_1 = c_p \ln\frac{T_2}{T_1} - R\ln\frac{P_2}{P_1}$$

Substitute $0.718\ \text{kJ/kg.K}$ for c_v, $70.22°\text{C}$ for T_1, $12°\text{C}$ for T_1, $1.005\ \text{kJ/kg.K}$ for c_p, 101.3 kPa for P_1, and $122.035\,\text{kPa}$ for P_2.

$$\Delta S_{air} = m_a\left(c_p \ln\frac{T_2}{T_1} - R\ln\frac{P_2}{P_1}\right)$$
$$= (111.5)\left((1.005)\ln\frac{70.22+273}{12+273} - (0.287)\ln\frac{122.035}{101.3}\right)$$
$$\Delta S_{air} = 14.87\ \text{kJ/K}$$

Step 7 of 7

Write the entropy balance for whole system (insulated room) considering both water and air.

$$\Delta s_{system} = \int\frac{\delta Q}{T} + s_{gen}$$
$$(\Delta s_{air} + \Delta s_{water}) = \int\frac{\delta Q}{T} + s_{gen}$$

As the room is heavily insulated and well-sealed, there is no heat transfer between the system and surroundings, and the amount of entropy generation is equal to the sum of entropy change of water and air.

$$s_{gen} = (\Delta s_{air} + \Delta s_{water})$$

Substitute $-13.11\ \text{kJ/K}$ for Δs_w, and $14.87\ \text{kJ/K}$ for ΔS_{air}.

$$S_{gen} = -13.1 + 14.88$$
$$S_{gen} = 1.78\ \text{kJ/K}$$

Hence, the amount of entropy generation during the process is $\boxed{S_{gen} = 1.78\ \text{kJ/K}}$.

Question: 8.102P pg 1

An ideal gas at 100 kPa and 15°C enters a steady-flow compressor. The gas is compressed to 600 kPa, and jq percent of the mass that entered the compressor is removed for some other use. The remaining 90 percent of the inlet gas is compressed to 800 kPa before leaving the compressor. The entire compression process is assumed to be reversible and adiabatic. The power supplied to the compressor is measured to be 32 kW. If the ideal gas has constant specific heats such that *cv* = 0.8 kJ/kg-K and *cp* = 1.1 kJ/kg-K, (*a*) sketch the compression process on a *T-s* diagram, (*b*) determine the temperature of the gas at the two compressor exits, in K, and (c) determine the mass flow rate of the gas into the compressor, in kg/s.

Step 1 of 6

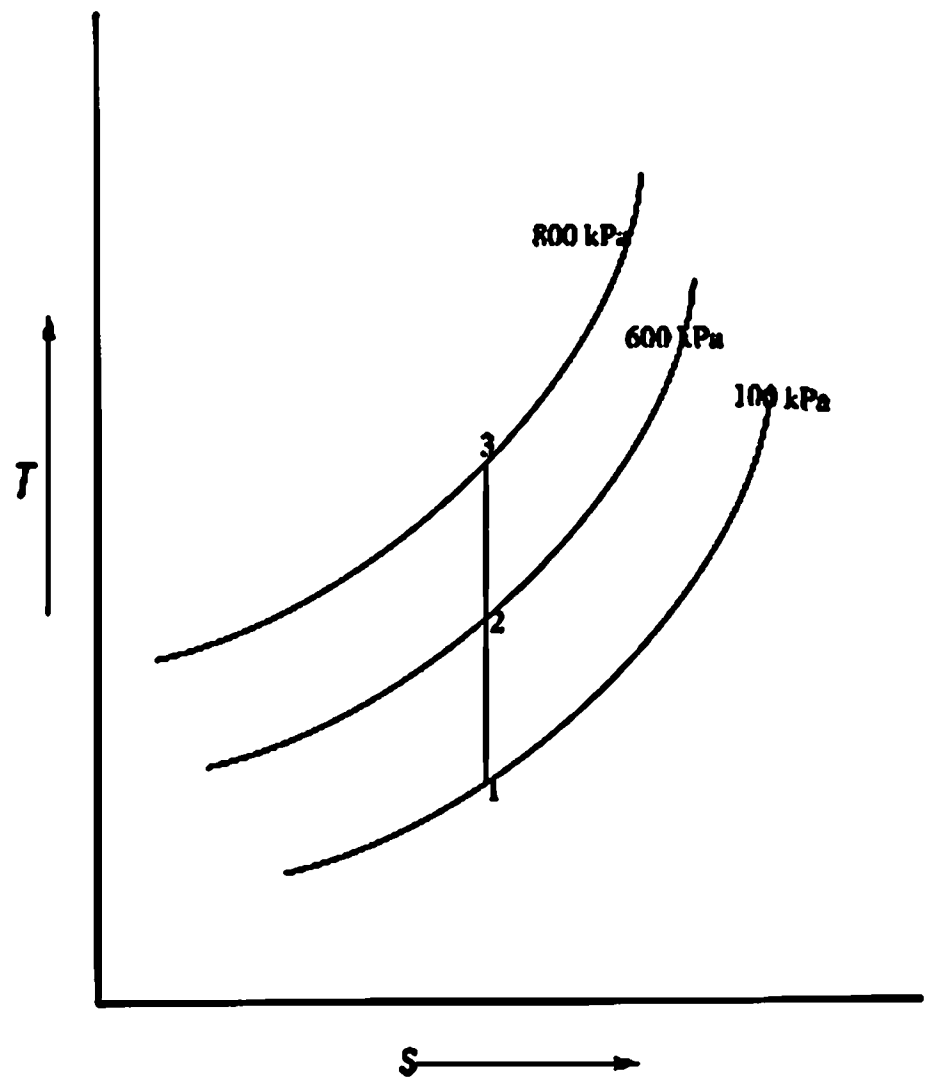
Given

Pressure of the gas at compressor inlet is, $P_1 = 100\ \text{kPa}$

Temperature of the gas at compressor inlet is, $T_1 = 15°\text{C} = 288\ \text{K}$

Intermediate pressure is, $P_2 = 600\ \text{kPa}$

Exit pressure is, $P_3 = 800\ \text{kPa}$



Power supplied to the compressor is, $W_{in} = 32\ \text{kW}$

Specific heat at constant volume is, $c_v = 0.8\ \text{kJ/kg.K}$

Specific heat at constant pressure is, $c_p = 1.1\ \text{kJ/kg.K}$

Step 2 of 6

(a)

Step 3 of 6

(b)

The ratio of specific heats can be calculated as

$$k = \frac{c_p}{c_v}$$

$$k = \frac{1.1}{0.8}$$

$$k = 1.375$$

As given, the process is assumed to be isentropic (reversible and adiabatic). So, the ratio of temperatures of intermediate and inlet is given by

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_2 = 288 \times \left(\frac{600}{100}\right)^{\frac{1.375-1}{1.375}}$$

$$T_2 = 288 \times (6)^{\frac{0.375}{1.375}}$$

$$T_2 = 288 \times (6)^{0.2727}$$

$$T_2 = 288 \times 1.63$$

$$\boxed{T_2 = 469.44\ \text{K}}$$

Therefore the intermediate temperatures is given by $T_2 = 469.44\ \text{K}$

Step 4 of 6

As given, the process is assumed to be isentropic (reversible and adiabatic). So, the ratio of temperatures of exit and inlet is given by

$$\frac{T_3}{T_1} = \left(\frac{P_3}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_3 = T_1 \times \left(\frac{P_3}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_3 = 288 \times \left(\frac{800}{100}\right)^{\frac{1.375-1}{1.375}}$$

$$T_3 = 288 \times (8)^{\frac{0.375}{1.375}}$$

$$T_3 = 288 \times (8)^{0.2727}$$

$$T_3 = 288 \times 1.763$$

$$\boxed{T_3 = 507.744\ \text{K}}$$

Therefore the exit temperatures is given by $T_3 = 507.744\ \text{K}$

Step 5 of 6

(c)

Let the mass entered the compressor be, m_1

Mass removed at intermediate stage is,

$m_2 = 10\ \%$ of m_1

$$m_2 = \frac{10}{\quad} \times m_1$$

(c)

Let the mass entered the compressor be, m_1

Mass removed at intermediate stage is,

$m_2 = 10\%$ of m_1

$$m_2 = \frac{10}{100} \times m_1$$

$$m_2 = 0.1 \times m_1$$

The remaining mass entered into the compressor is,

$m_3 = 90\%$ of m_1

$$m_3 = \frac{90}{100} \times m_1$$

$$m_3 = 0.9 \times m_1$$

By applying energy balance to the system

$$E_{in} - E_{out} = \frac{dE_{sys}}{dt}$$

The process is steady and so the right hand side in the above equation becomes zero. So,

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out} \qquad \ldots\ldots (1)$$

Work input is given to the compressor the energy transfer inlet is given by

$$E_{in} = m_1 \times h_1 + W_{in}$$

$$E_{in} = m_1 \times c_p \times T_1 + W_{in} \qquad \ldots\ldots (2)$$

The energy transfer out is given by

$$E_{out} = m_2 \times h_2 + m_3 \times h_3$$

$$E_{out} = m_2 \times c_p \times T_2 + m_3 \times c_p \times T_3 \qquad \ldots\ldots (3)$$

Step 6 of 6

Substituting the equations (2) and (3) in equation (1), we get

$$E_{in} = E_{out}$$

$$m_1 \times c_p \times T_1 + W_{in} = m_2 \times c_p \times T_2 + m_3 \times c_p \times T_3$$

Substituting the values of m_2 and m_3, then the above equation becomes

$$m_1 \times c_p \times T_1 + W_{in} = 0.1\, m_1 \times c_p \times T_2 + 0.9 m_1 \times c_p \times T_3$$

$$W_{in} = 0.1\, m_1 \times c_p \times T_2 + 0.9 m_1 \times c_p \times T_3 - m_1 \times c_p \times T_1$$

$$W_{in} = m_1 \times c_p \times (0.1T_2 + 0.9T_3 - T_1)$$

$$m_1 = \frac{W_{in}}{c_p \times (0.1T_2 + 0.9T_3 - T_1)}$$

Substituting the known values we get,

$$m_1 = \frac{32}{1.1 \times (0.1 \times 469.44 + 0.9 \times 507.744 - 288)}$$

$$m_1 = \frac{32}{1.1 \times (46.944 + 456.969 - 288)}$$

$$m_1 = \frac{32}{1.1 \times 215.913}$$

$$m_1 = \frac{32}{237.504}$$

$$\boxed{m_1 = 0.1347 \text{ kg/s}}$$

Therefore the mass flow rate of the gas into the compressor is $m_1 = 0.1347$ kg/s.

Question: 8.103P

The well-insulated container shown in Fig. P8-103E is initially evacuated. The supply line contains air that is maintained at 200 psia and 100°F. The valve is opened until the pressure in the container is the same as the pressure in the supply line. Determine the minimum temperature in the container when the valve is closed.

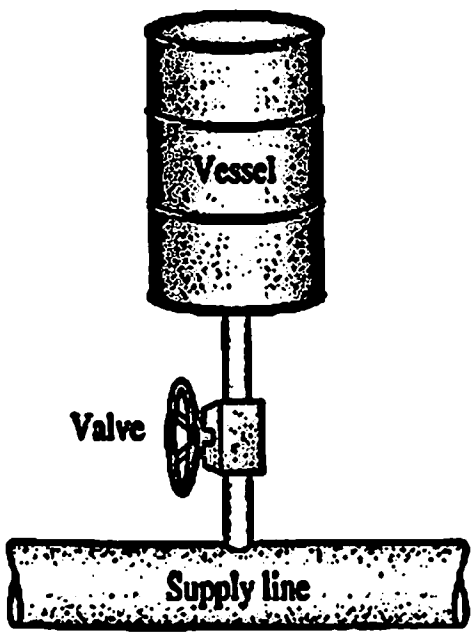


FIGURE P8–103E

Step 1 of 3

Given

Pressure of air in the supply line $p_1 = 200$ psia

Temperature of air in the supply line $T_1 = 100°F$

Pressure in the container be p_2

The valve is opened so $p_2 = p_1$

Step 2 of 3

From the entropy relation, $s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{p_2}{p_1}$ ---- (1)

But entropy either increases or remains constant so, $s_2 - s_1 \geq 0$

Hence for minimum temperature, eq (1) becomes

$$c_p \ln \frac{T_2}{T_1} - R \ln \frac{p_2}{p_1} = 0$$

$$c_p \ln \frac{T_2}{T_1} = T \ln \frac{p_2}{p_1}$$

$$c_p \ln \frac{T_2}{T_1} = T \ln \frac{p_1}{p_1}$$

$$c_p \ln \frac{T_2}{T_1} = R \ln (1)$$

$$c_p \ln \frac{T_2}{T_1} = 0$$

Step 3 of 3

But c_p cannot be zero hence

$$\ln \frac{T_2}{T_1} = 0$$

$$\ln \left(\frac{T_2}{T_1} \right) = \ln (1)$$

$$\frac{T_2}{T_1} = 1$$

$$T_2 = T_1$$

$$T_2 = 100°F$$

Minimum temperature in the container is $\boxed{T_2 = 100°F}$

Question: 8.104P

In large compressors, the gas is frequently cooled while being compressed to reduce the power consumed by the compressor. Explain how cooling the gas during a compression process reduces the power consumption.

Step 1 of 4

2760-07-108 SA: 9079

Step 2 of 4

The larger the specific volume the larger the reversible work produced or consumed by the steady-flow device. This conclusion is equally valid for actual steady-flow devices. Therefore, every effort should be made to keep the specific volume of a fluid as small as possible during a compression process to minimize the work input.

Step 3 of 4

Cooling a gas during compression will reduce its specific volume. So, cooling the gas during a compression process reduces the power consumption.

Step 4 of 4

Question: 8.105P

The turbines in steam power plants operate essentially under adiabatic conditions. A plant engineer suggests to end this practice. She proposes to run cooling water through the outer surface of the casing to cool the steam as it flows through the turbine. This way, she reasons, the entropy of the steam will decrease, the performance of the turbine will improve, and as a result the work output of the turbine will increase. How would you evaluate this proposal?

Step 1 of 1

The larger the specific volume the larger the reversible work produced or consumed by the steady-flow device. This conclusion is equally valid for actual steady-flow devices. Therefore, every effort should be made to keep the specific volume of a fluid as large as possible during an expansion process to maximize the work output.

Cooling a gas during expansion will reduce its specific volume. So, cooling the gas during an expansion process reduces the work output. So, it is not a good proposal.

Question: 8.106P

It is well known that the power consumed by a compressor can be reduced by cooling the gas during compression. Inspired by this, somebody proposes to cool the liquid as it flows through a pump, in order to reduce the power consumption of the pump. Would you support this proposal? Explain.

Step 1 of 1

The larger the specific volume the larger the reversible work produced or consumed by the steady-flow device. This conclusion is equally valid for actual steady-flow devices. Therefore, every effort should be made to keep the specific volume of a fluid as small as possible during a compression process to minimize the work input.

But, cooling a liquid during compression will not reduce its specific volume significantly. So, cooling a liquid during a compression process will not reduce the work input. So, it is not a good proposal.

Question: 8.107P

Air is compressed isothermally from 13 psia and 90°F to 80 psia in a reversible steady-flow device. Calculate the work required, in Btu/lbm, for this compression.

Step 1 of 2

Given

Inlet pressure is, $P_1 = 13$ psia

Isothermal temperature is, $T = 90°F = 549.67$ R

Exit pressure is, $P_2 = 80$ psia

Process is isothermal compression process

Step 2 of 2

From properties of molar mass, gas constant and critical properties table the gas constant of air is

$R = 0.06855$ Btu/lbm.R

Work done during the isothermal compression process is

$$W_{in} = \int_1^2 v dP$$

$$= \int_1^2 \frac{RT}{P} dP$$

$$= RT \times \int_1^2 \frac{1}{P} dP$$

$$W_{in} = RT \times \int_1^2 \frac{1}{P} dP$$

$$W_{in} = RT \times \left[\ln (P)\right]_1^2$$

$$= RT \times \left[\ln P_2 - \ln P_1\right]$$

$$= RT \times \ln\left(\frac{P_2}{P_1}\right)$$

$$W_{in} = 0.06855 \times 549.67 \times \ln\left(\frac{80}{13}\right)$$

$$= 0.06855 \times 549.67 \times \ln(6.154)$$

$$W_{in} = 0.06855 \times 549.67 \times 1.817$$

$$\boxed{W_{in} = 68.464 \text{ Btu/lbm}}$$

Therefore the required work input for this compression process is 68.464 Btu/lbm

Question: 8.108P

Saturated water vapor at 150°C is compressed in a reversible steady-flow device to 1000 kPa while its specific volume remains constant. Determine the work required, in kJ/kg.

Step 1 of 5

2760-07-112 SA: 9079

Step 2 of 5

Given:

Initial conditions:

Temperature, $T_1 = 150^\circ C \Rightarrow T_1 = 423\ \text{K}$

Initially it is saturated vapor

From Table A- 4, at $T_1 = 150^\circ C$ and $x_1 = 1$

Pressure, $P_1 = 476.16\ \text{kPa}$

Specific volume, $V_1 = 0.39248\ \text{m}^3/\text{kg}$

Initial conditions:

Pressure, $P_2 = 1000\ \text{kPa}$

Specific volume remains constant $\Rightarrow V_2 = 0.39248\ \text{m}^3/\text{kg}$

Step 3 of 5

Step 4 of 5

Work required, $W = \int_1^2 V dP$

$\Rightarrow W = V \times (P_2 - P_1)$

$\Rightarrow W = 0.39248 \times (1000 - 476.16)$

$\Rightarrow \boxed{W = 205.597\ kJ/kg}$

Step 5 of 5

Question: 8.109P

Calculate the work produced, in Btu/lbm, for the reversible steady-flow process 1-3 shown in Fig. P8-109E.

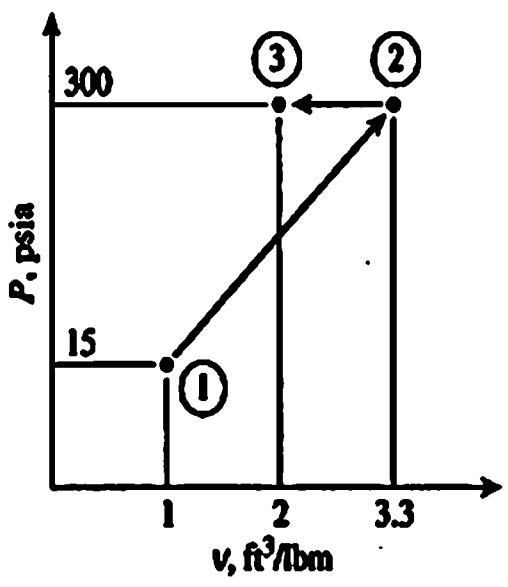

FIGURE P8–109E

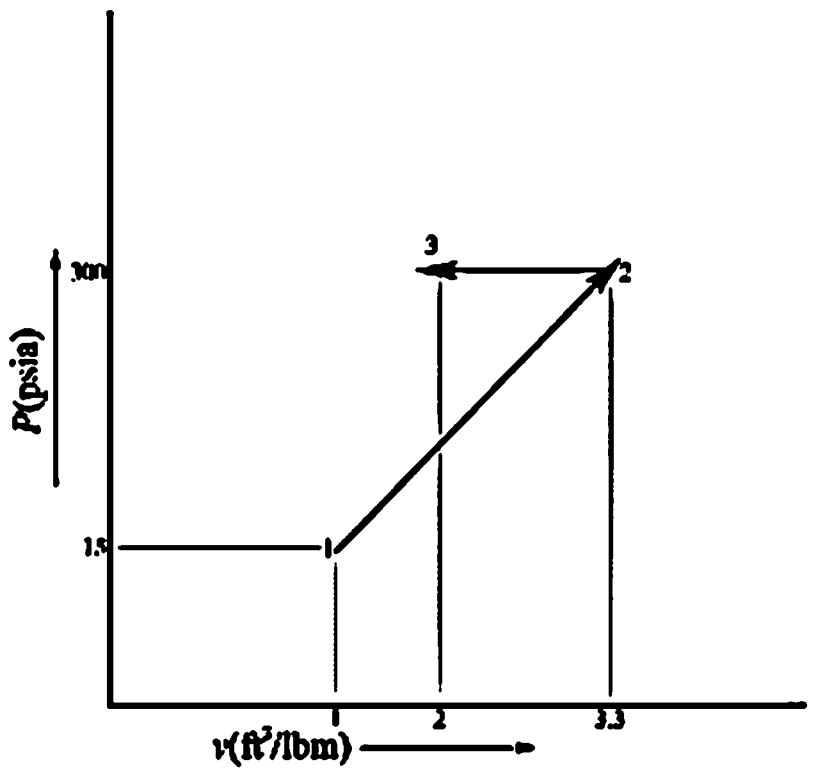
Step 1 of 4

Given

Pressure at state 1 is, $P_1 = 15$ psia

Pressure at state 2 is, $P_2 = 300$ psia



Pressure at state 3 is, $P_3 = 300$ psia

Volume at state 1 is, $v_1 = 1.0\ \text{ft}^3/\text{lbm}$

Volume at state 2 is, $v_2 = 3.3\ \text{ft}^3/\text{lbm}$

Volume at state 3 is, $v_3 = 2.0\ \text{ft}^3/\text{lbm}$

Step 2 of 4

Step 3 of 4

The total work done is given by

$$W_{tot} = W_{1\text{-}2} + W_{2\text{-}3}$$

Work done in a steady flow process is given by

$$W_{sb} = \int_a^b v dP$$

Therefore the equation reduces to

$$W_{tot} = \int_1^2 v dP + \int_2^3 v dP$$

As pressure is constant in process 2-3, change in pressure in that process will be zero

$$W_{tot} = \int_1^2 v dP + \int_2^3 v \times 0$$

$$W_{tot} = \int_1^2 v dP + 0$$

$$W_{tot} = \int_1^2 v dP$$

$$W_{tot} = v \times \int_1^2 dP$$

$$W_{tot} = v \times [P]_1^2$$

$$W_{tot} = v \times [P_2 - P_1]$$

Step 4 of 4

Volume can be taken as average volume. So,

$$W_{tot} = \frac{v_1 + v_2}{2} \times (P_2 - P_1)$$

$$W_{tot} = \frac{1 + 3.3}{2} \times (300 - 15)$$

$$W_{tot} = \frac{4.3}{2} \times 285$$

$$W_{tot} = 2.15 \times 285$$

$$W_{tot} = 612.75\ \text{psia.ft}^3/\text{lbm}$$

We know that

$1\ \text{Btu} = 5.404\ \text{psia.ft}^3$.

So we can write as

$$1\ \text{psia.ft}^3 = \frac{1}{5.404}\ \text{Btu}$$

Then

$$W_{tot} = 612.75 \times \frac{1}{5.404}\ \text{Btu/lbm}$$

$$\boxed{W_{tot} = 113.388\ \text{Btu/lbm}}$$

Therefore the total work done in the reversible steady flow process 1-3 is

$W_{tot} = 113.388\ \text{Btu/lbm}$.

Question:

8.110P

Calculate the work produced, in kJ/kg, for the reversible isothermal, steady-flow process 1-3 shown in Fig. P8-110 when the working fluid is an ideal gas.

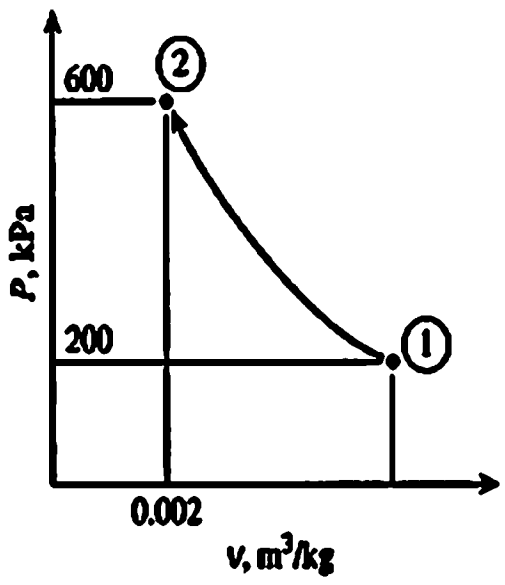


FIGURE P8–110

Question:

Calculate the work produced, in kJ/kg, for the reversible isothermal, steady-flow process 1-3 shown in Fig. P8-110 when the working fluid is an ideal gas.

FIGURE P8–110

Step 2 of 4

The work produced in a process is given by the area under the $P-v$ diagram. So the work produced in the process 1-2 is given by

$$w_{1\text{-}2} = -\int_1^2 v\,dP$$

For an ideal gas, the volume is given by

$$v = \frac{RT}{P}$$

Therefore work produced can be written as

$$w_{1\text{-}2} = -\int_1^2 \frac{RT}{P}\,dP$$

$$w_{1\text{-}2} = -RT\int_1^2 \frac{dP}{P}$$

$$w_{1\text{-}2} = -RT\times\ln\left(\frac{P_2}{P_1}\right)$$

$$w_{1\text{-}2} = -P_2v_2\times\ln\left(\frac{P_2}{P_1}\right)$$

Step 4 of 4

Substituting the known values in the above equation

$$w_{1\text{-}2} = -600\times0.002\times\ln\left(\frac{600}{200}\right)$$

$$w_{1\text{-}2} = -600\times0.002\times\ln(3)$$

$$w_{1\text{-}2} = -1.2\times\ln(3)$$

$$w_{1\text{-}2} = -1.2\times1.0986$$

$$\boxed{w_{1\text{-}2} = -1.31832\ \text{kJ/kg}}$$

The work produced is negative, therefore work is given to the system in the process 1-2 is

$$w_{1\text{-}2} = 1.31832\ \text{kJ/kg}$$

Question: 8.111P

Liquid water enters a 25-kW pump at 100-kPa pressure at a rate of 5 kg/s. Determine the highest pressure the liquid water can have at the exit of the pump. Neglect the kinetic and potential energy changes of water, and take the specific volume of water to be 0.001 m3 /kg.

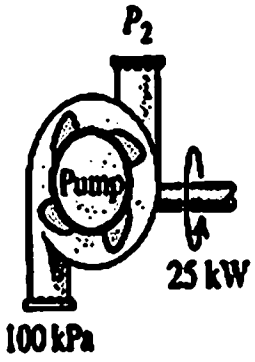

FIGURE P8–111

Step 1 of 2

Given:

Initial Pressure $P_1 = 100$ kPa

Question:

Liquid water enters a 25-kW pump at 100-kPa pressure at a rate of 5 kg/s. Determine the highest pressure the liquid water can have at the exit of the pump. Neglect the kinetic and potential energy changes of water, and take the specific volume of water to be 0.001 m3 /kg.

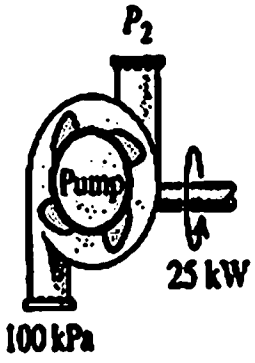

FIGURE P8–111

Question: 8.112P

Consider a steam power plant that operates between the pressure limits of 5 MPa and 10 kPa. Steam enters the pump as saturated liquid and leaves the turbine as saturated vapor. Determine the ratio of the work delivered by the turbine to the work consumed by the pump. Assume the entire cycle to be reversible and the heat losses from the pump and the turbine to be negligible.

Step 1 of 4

Given data:

Lower pressure limit is, $P_1 = P_4 = 10\ \text{kPa}$

Higher pressure limit is, $P_2 = P_3 = 5\ \text{MPa}$

$= 5000\ \text{kPa}$

Inlet to pump is saturated liquid steam

Exit to turbine is saturated vapor steam

Step 2 of 4

From properties of saturated water

At pressure $P_4 = 10\ \text{kPa}$

$$h_4 = h_g = 2583.9\ \text{kJ/kg}$$

$$s_4 = s_g = 8.1488\ \text{kJ/kg}\cdot\text{K}$$

Specific volume, $v_1 = v_f = 0.001010\ \text{m}^3/\text{kg}$

As no heat loss in pump and turbine, compression and expansion are adiabatic process.

As the processes are reversible also, they are isentropic process

Therefore,

$$s_3 = s_4 = 8.1488\ \text{kJ/kg}\cdot\text{K}$$

As $s_3 = 8.1488\ \text{kJ/kg°K}$ is greater than the saturated entropy at pressure $P_3 = 5\ \text{MPa}$, the steam at that condition is superheated state.

From properties of saturated water

At pressure $P_3 = 5\ \text{MPa}$

The enthalpy at that state is interpolated as

$$\left(\frac{h_3 - 4380.2}{4628.3 - 4380.2}\right) = \left(\frac{8.1488 - 7.9619}{8.1648 - 7.9619}\right)$$

$$\left(\frac{h_3 - 4380.2}{248.1}\right) = \left(\frac{0.1869}{0.2029}\right)$$

$$\left(\frac{h_3 - 4380.2}{248.1}\right) = 0.9211$$

$$h_3 = (0.9211 \times 248.1) + 4380.2$$

$$h_3 = 228.53 + 4380.2$$

$$h_3 = 4608.73\ \text{kJ/kg}$$

Step 3 of 4

We know that

Work done by isentropic turbine

$$w_{tur} = (h_3 - h_4)$$

$$w_{tur} = (4608.73 - 2583.9)$$

$$w_{tur} = 2024.83\ \text{kJ/kg}$$

Work done on isentropic pump is given by

$$w_{pump} = \int_1^2 v dP + \Delta KE + \Delta PE$$

As given, the kinetic and potential energies are neglected.

$$w_{pump} = \int_1^2 v dP$$

$$w_{pump} = v\int_1^2 1 \times dP$$

$$w_{pump} = v[P]_1^2$$

$$w_{pump} = v(P_2 - P_2)$$

$$w_{pump} = 0.001010 \times (5000 - 10)$$

$$w_{pump} = 0.001010 \times 4990$$

$$w_{pump} = 5.0399\ \text{kJ/kg}$$

Step 4 of 4

Now we know that

The ratio of turbine work to the pump work

Step 3 of 4

We know that

Work done by isentropic turbine

$$w_{tur} = (h_3 - h_4)$$

$$w_{tur} = (4608.73 - 2583.9)$$

$$w_{tur} = 2024.83\ \text{kJ/kg}$$

Work done on isentropic pump is given by

$$w_{pump} = \int_1^2 v dP + \Delta KE + \Delta PE$$

As given, the kinetic and potential energies are neglected.

Question: 8.113P

Reconsider Prob. 8-112. Using EES (or other) software, investigate the effect of the quality of the steam at the turbine exit on the net work output. Vary the quality from 0.5 to 1.0, and plot the net work output as a function of this quality.

We don't have the solution to this problem yet.

Question: 8.114P

Liquid water at 120 kPa enters a 7-kW pump where its pressure is raised to 5 MPa. If the elevation difference between the exit and the inlet levels is 10 m, determine the highest mass flow rate of liquid water this pump can handle. Neglect the kinetic energy change of water, and take the specific volume of water to be 0.001 m3 /kg.

Step 1 of 2

Given:

Pressures, $P_1 = 120\ \text{kPa}$ and $P_2 = 5\ \text{MPa}$

Power, $\dot{W} = 7\ \text{kW}$

Elevation difference, $\Delta z = 10\ \text{m}$

Mass flow rate, $= \dot{m}$

So, potential energy changes may be significant.

Specific volume of water, $V = 0.001\ \text{m}^3/\text{kg}$

Step 2 of 2

$$\text{Power, } \dot{W} = \int_1^2 \dot{m} \times V \times dP + \dot{m} \times g \times \Delta z$$

$$\Rightarrow \dot{W} = \dot{m} \times V (P_2 - P_1) + \dot{m} \times g \times \Delta z$$

$$\Rightarrow 7 = \dot{m} \times 0.001(5000 - 120) + \dot{m} \times 9.8 \times 10 \times \left(\frac{1\ \text{kJ/kg}}{1000\ \text{m}^2/\text{s}^2} \right)$$

$$\Rightarrow 7 = \dot{m} \times 4.88 + \dot{m} \times 0.098$$

$$\Rightarrow 7 = \dot{m} \times 4.978$$

$$\Rightarrow \dot{m} = \frac{7}{4.978}$$

So, Mass flow rate, $\boxed{\dot{m} = 1.4062\ \text{kJ/s}}$

Question: 8.115P

Describe the ideal process for an (*a*) adiabatic turbine, (*b*) adiabatic compressor, and (c) adiabatic nozzle, and define the isentropic efficiency for each device.

Step 1 of 4

There is some heat transfer between these devices and the surrounding medium is unavoidable, many steady-flow devices are intended to operate under adiabatic conditions. Therefore, the ideal process for these devices should be an adiabatic or isentropic process. Furthermore, an ideal process should involve no irreversibilities since the effect of irreversibilities is always to downgrade the performance of engineering devices. Thus, the ideal process that can serve as a suitable model for adiabatic steady-flow devices is the isentropic process.

Step 2 of 4

(a) Isentropic efficiency of adiabatic turbine,

$$\eta_{turbine} = \frac{\text{Actual turbine work}}{\text{Isentropic turbine work}}$$

Step 3 of 4

(b) Isentropic efficiency of adiabatic compressor,

$$\eta_{compressor} = \frac{\text{Isentropic compressor work}}{\text{Actual compressor work}}$$

Step 4 of 4

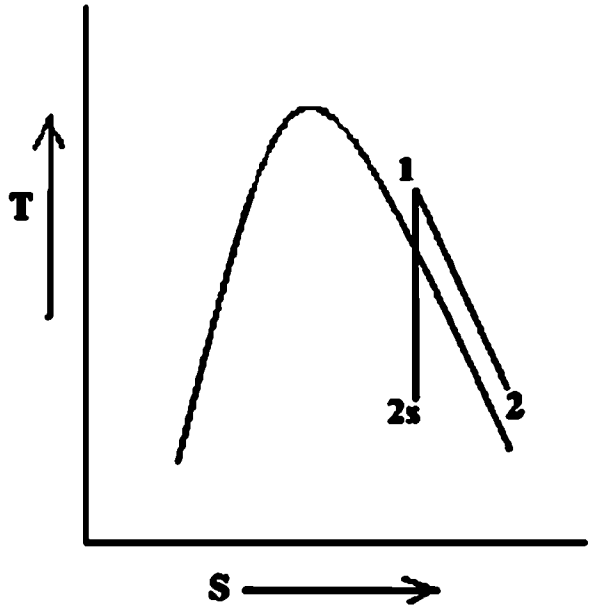
(c) Isentropic efficiency of adiabatic nozzle,

$$\eta_{nozzle} = \frac{\text{Actual Kinetic energy at nozzle exit}}{\text{Isentropic Kinetic energy at nozzle exit}}$$

Question: 8.116P

Is the isentropic process a suitable model for compressors that are cooled intentionally? Explain.

Step 1 of 1



Isentropic process is not the ideal process for compressors that are cooled intentionally
Sometimes, compressors are cooled intentionally by utilizing fins or a water jacket placed around the casing to reduce the work input requirements. In this case, the isentropic process is not suitable as the model process since the device is no longer adiabatic. A realistic model process for compressors that are intentionally cooled during the compression process is the reversible isothermal process.

Question: 8.117P

On a *T-s* diagram, does the actual exit state (state 2) of an adiabatic turbine have to be on the right-hand side of the isentropic exit state (state 2 *s*)? Why?

Step 1 of 1

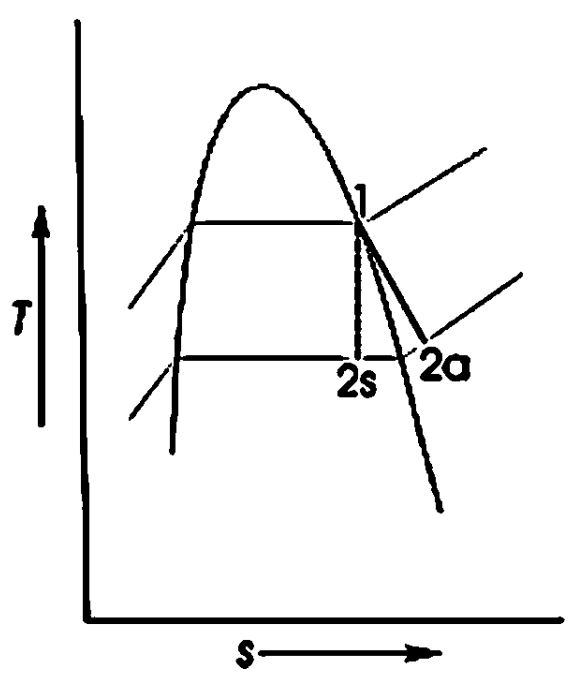
In actual process the entropy of the exit state increases due to irrversibilities. That is the reason the actual exit state will be the right hand side of the isentropic exit state
In the diagram below process 1-2s is isentropic expansion
Process 1-2 is actual process

Question: 8.118P

Steam at 100 psia and 650°F is expanded adiabatically in a closed system to 10 psia. Determine the work produced, in Btu/lbm, and the final temperature of steam for an isentropic expansion efficiency of 80 percent.

Step 1 of 7

Given



Initial pressure is, $P_1 = 100$ psia

Initial temperature is, $T_1 = 650°F = 1109.67$ R

Final pressure is, $P_2 = 10$ psia

Isentropic efficiency is, $\eta_{isen} = 80\% = 0.8$

Step 2 of 7

Step 3 of 7

As the process is occurring in closed system (non-flow process) we have to take internal energy instead of enthalpy.

From superheated water tables at pressure $P_1 = 100$ psia and $T_1 = 650°F$ by using interpolation

$$u_1 = 1214.4 + (1253.0 - 1214.4)\left(\frac{650 - 600}{700 - 600}\right)$$

$$u_1 = 1233.7 \text{ Btu/lbm}$$

$$s_1 = 1.7586 + (1.8037 - 1.7586)\left(\frac{650 - 600}{700 - 600}\right)$$

$$s_1 = 1.78115 \text{ Btu/lbm.R}$$

Step 4 of 7

From saturated water tables at pressure $P_2 = 10$ psia

Internal energy of saturated liquid is $u_{f2} = 161.22$ Btu/lbm

Internal energy of evaporation is $u_{fg2} = 910.75$ Btu/lbm

Entropy of saturated liquid is $s_{f2} = 0.28362$ Btu/lbm.R

Entropy of evaporation is $s_{fg2} = 1.50391$ Btu/lbm.R

For an isentropic process 1-2s entropy remains constant so,

$s_{2s} = s_1$

We know

$s_{2s} = s_{f2} + x_{2s} \times s_{fg2}$

Then

$s_{f2} + x_{2s} \times s_{fg2} = s_1$

$$x_{2s} = \frac{s_1 - s_{f2}}{s_{fg2}}$$

$$x_{2s} = \frac{1.78115 - 0.28362}{1.50391}$$

$$x_{2s} = \frac{1.49753}{1.50391}$$

$$x_{2s} = 0.99575$$

The internal energy at the end of isentropic process is given by

$u_{2s} = u_{f2} + x_{2s} \times u_{fg2}$

$u_{2s} = 161.22 + 0.99575 \times 910.75$

$u_{2s} = 161.22 + 906.879$

$u_{2s} = 1068.099$ Btu/lbm

Step 5 of 7

The work done in the isentropic process 1-2s is given by

$w_s = u_1 - u_{2s}$

$w_s = 1233.7 - 1068.099$

$w_s = 165.601$ Btu/lbm

The isentropic efficiency is given by

$$\eta_{isen} = \frac{\text{Actual work done by the turbine}}{\text{Isentropic work done by the turbine}}$$

$$\eta_{isen} = \frac{w_a}{w_s}$$

$w_a = \eta_{isen} \times w_s$

$w_a = 0.8 \times 165.601$

$\boxed{w_a = 132.4808 \text{ Btu/lbm}}$

Step 6 of 7

The actual work is also given by

$w_a = u_1 - u_{2a}$

So the actual final internal energy is given by

$u_{2a} = u_1 - w_a$

$u_{2a} = 1233.7 - 132.4808$

$u_{2a} = 1101.2192$ Btu/lbm

Step 7 of 7

At $P_2 = 10$ psia and $u_{2a} = 1101.2192$ Btu/lbm from superheated water tables by using interpolation

$$T_{2a} = 240 + (280 - 240)\left(\frac{1101.2192 - 1089.1}{1103.4 - 1089.1}\right)$$

$\boxed{T_{2a} = 273.89°F}$

Therefore work produced is $w_a = 132.128$ Btu/lbm and the actual final temperature of steam is $T_{2a} = 273.89°F$

Question: 8.119P

Steam at 3 MPa and 400°C is expanded to 30 kpa in an adiabatic turbine with an isentropic efficiency of 92 percent. Determine the power produced by this turbine, in kW, when the mass flow rate is 2 kg/s.

Step 1 of 8

Given:

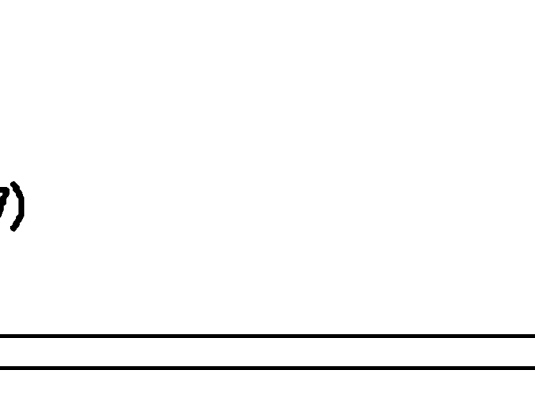
Mass flow rate, $\dot{m} = 2\ \text{kg/s}$

Initial pressure, $P_1 = 3\ \text{MPa}$

Initial temperature, $T_1 = 400^0\text{C}$

Final pressure, $P_{2s} = 30\ \text{kPa}$

Isentropic efficiency of the turbine, $\eta = 92\%$



Step 2 of 8

At $P_1 = 3\ \text{MPa}$ and $T_1 = 400^0\text{C}$ from superheated water tables

Entropy, $s_1 = 6.9235\ \text{kJ/kg.K}$

Enthalpy, $h_1 = 3231.7\ \text{kJ/kg}$

Step 3 of 8

Step 4 of 8

At $P_{2s} = 30\ \text{kPa}$ from saturated water tables

$s_f = 0.9441\ \text{kJ/kg.K}$

$s_{fg} = 6.8234\ \text{kJ/kg.K}$

$h_f = 289.27\ \text{kJ/kg}$

$h_{fg} = 2335.3\ \text{kJ/kg}$

Step 5 of 8

Process 1-2s is isentropic expansion

$$s_1 = s_{2s}$$

$$s_{2s} = s_f + x_{2s}s_{fg}$$

$$x_{2s} = \frac{s_{2s} - s_f}{s_{fg}}$$

$$x_{2s} = \frac{6.9235 - 0.9441}{6.8234}$$

$$x_{2s} = 0.87631$$

Step 6 of 8

$$h_{2s} = h_f + x_{2s}h_{fg}$$

$$h_{2s} = 289.27 + 0.87631 \times 2335.3$$

$$h_{2s} = 2335.717\ \text{kJ/kg}$$

Step 7 of 8

Isentropic power output

$$\dot{W}_{ise} = \dot{m}(h_1 - h_{2s})$$

$$\dot{W}_{ise} = 2 \times (3231.7 - 2335.717)$$

$$\dot{W}_{ise} = 1791.966\ \text{kW}$$

Step 8 of 8

Isentropic efficiency of the turbine

$$\eta_T = \frac{\dot{W}_{act}}{\dot{W}_{ise}}$$

$$\dot{W}_{act} = \eta_T \times \dot{W}_{ise}$$

$$\dot{W}_{act} = 0.92 \times 1791.966$$

$$\boxed{\dot{W}_{act} = 1648.608\ \text{kW}}$$

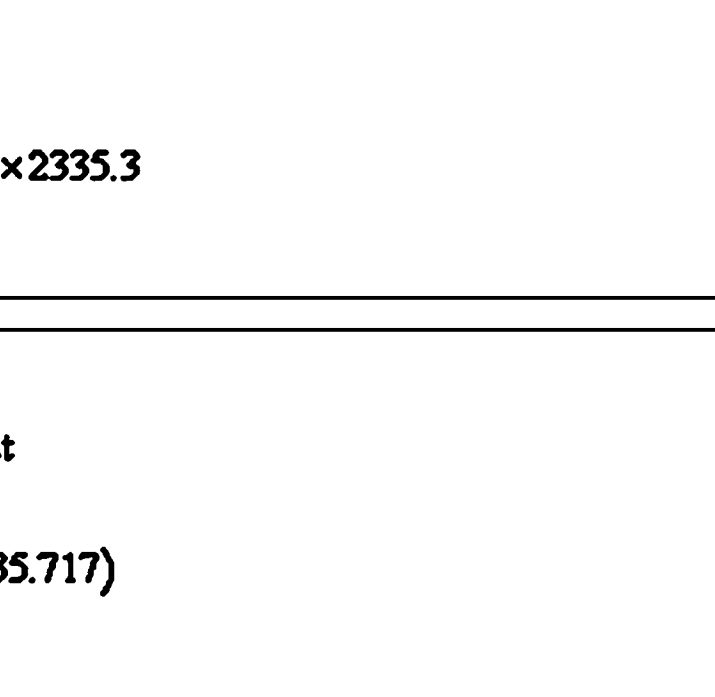
Question: 8.120P

Repeat Prob. 8-119 for a turbine efficiency of 85 percent.

Step 1 of 5

Given:

Mass flow rate, $\dot{m} = 2\ \text{kg/s}$



Initial pressure, $P_1 = 3\ \text{MPa}$

Initial temperature, $T_1 = 400^0\text{C}$

Final pressure, $P_{2s} = 30\ \text{kPa}$

Isentropic efficiency of the turbine, $\eta = 85\%$

Step 2 of 5

Step 3 of 5

At $P_1 = 3\ \text{MPa}$ and $T_1 = 400^0\text{C}$ from superheated water tables

Entropy, $s_1 = 6.9235\ \text{kJ/kg.K}$

Enthalpy, $h_1 = 3231.7\ \text{kJ/kg}$

At $P_{2s} = 30\ \text{kPa}$ from saturated water tables

$s_f = 0.9441\ \text{kJ/kg.K}$

$s_{fg} = 6.8234\ \text{kJ/kg.K}$

$h_f = 289.27\ \text{kJ/kg}$

$h_{fg} = 2335.3\ \text{kJ/kg}$

Step 4 of 5

Process 1-2s is isentropic expansion in the turbine

$$s_1 = s_{2s}$$

$$s_{2s} = s_f + x_{2s} s_{fg}$$

$$x_{2s} = \frac{s_{2s} - s_f}{s_{fg}}$$

$$x_{2s} = \frac{6.9235 - 0.9441}{6.8234}$$

$$x_{2s} = 0.87631$$

$$h_{2s} = h_f + x_{2s} h_{fg}$$

$$h_{2s} = 289.27 + 0.87631 \times 2335.3$$

$$h_{2s} = 2335.717\ \text{kJ/kg}$$

Step 5 of 5

Isentropic power output

$$\dot{W}_{ise} = \dot{m}(h_1 - h_{2s})$$

$$= 2 \times (3231.7 - 2335.717)$$

$$\dot{W}_{ise} = 1791.966\ \text{kW}$$

Isentropic efficiency of the turbine

$$\eta_T = \frac{\dot{W}_{act}}{\dot{W}_{ise}}$$

$$\dot{W}_{act} = \eta_T \times \dot{W}_{ise}$$

$$\dot{W}_{act} = 0.85 \times 1791.966$$

$$\boxed{\dot{W}_{act} = 1523.171\ \text{kW}}$$

Therefore power produced by the turbine is $\dot{W}_{act} = 1523.171\ \text{kW}$

Question: 8.121P

Steam enters an adiabatic turbine at 7 MPa. 600°C, and 80 m/s and leaves at 50 kPa, 150°C, and 140 m/s. If the power output of the turbine is 6 MW, determine (*a*) the mass flow rate of the steam flowing through the turbine and (*b*) the isentropic efficiency of the turbine.

Step 1 of 6

Obtain the properties of steam at inlet and out let from "Properties of superheated water" in the textbook.

At pressure, $P_1 = 7\ \text{MPa}$ and temperature, $T_1 = 600°\text{C}$, we have

Enthalpy of water, $h_1 = 3650.6\ \text{kJ/kg}$

Entropy of water, $s_1 = 7.0910\ \text{kJ/kg}\cdot\text{K}$

At pressure, $P_2 = 50\ \text{kPa}$ and temperature, $T_2 = 150°\text{C}$, we have

Actual enthalpy of water, $h_2 = 2780.2\ \text{kJ/kg}$

Step 2 of 6

Apply energy balance to the entire system.

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} + W \quad \text{..... (1)}$$

Here, V_1, V_2 are velocities at inlet and exit.

Substitute $3650.6\,\text{kJ/kg}$ for h_1, $2780.2\,\text{kJ/kg}$ for h_2, $80\,\text{m/s}$ for V_1, and $140\,\text{m/s}$ for V_2.

$$3650.6\frac{\text{kJ}}{\text{kg}}\times 1000\frac{\text{J}}{\text{kJ}} + \frac{(80)^2}{2} = 2780.2\frac{\text{kJ}}{\text{kg}}\times 1000\frac{\text{J}}{\text{kJ}} + \frac{(140)^2}{2} + W$$

$$W = 863800\ \text{J/kg}$$

Step 3 of 6

a)

Write the expression for power output of the turbine.

$$\dot{W} = \dot{m}W$$

Here $\dot{m}$ is the mass flow rate of steam.

Substitute $6599\,\text{J/kg}$ for W and $6\,\text{MW}$ for $\dot{W}$.

$$\dot{W} = \dot{m}W$$

$$6\,\text{MW}\times 10^6\frac{\text{W}}{\text{MW}} = \dot{m}\times 863800$$

$$\dot{m} = 6.94\,\text{kg/s}$$

Therefore, the mass flow rate of steam is $\boxed{6.94\,\text{kg/s}}$.

Step 4 of 6

b)

Let Dryness fraction at state 2 be x_{2s}, Enthalpy at state 2 be h_{2s}, The pressure at exit be $P_2 = P_{2s} = 50\ \text{kPa}$.

For Isentropic process entropy remains constant.

Obtain the properties of steam from "Table A-5 Properties of saturated water pressure table" in the textbook.

At $P_2 = P_{2s} = 50\ \text{kPa}$, $s_1 = s_{2s} = 7.0910\ \text{kJ/kg}\cdot\text{K}$, we have

Entropy at saturated liquid, $s_f = 1.0912\ \text{kJ/kg}\cdot\text{K}$

Entropy during evaporation, $s_{fg} = 6.5019\ \text{kJ/kg}\cdot\text{K}$

Enthalpy at saturated liquid, $h_f = 340.54\ \text{kJ/kg}$

Enthalpy during evaporation, $h_{fg} = 2304.7\ \text{kJ/kg}$

Step 5 of 6

Write the relation for entropies.

$$s_{2s} = h_f + x_{2s}h_{fg}$$

$$x_{2s} = \frac{s_{2s} - h_f}{h_{fg}} = \frac{7.0910 - 1.0912}{6.5019} = 0.9227$$

Find the enthalpy at state 2.

$$h_{2s} = h_f + x_{2s}h_{fg}$$

Substitute $340.54\,\text{kJ/kg}$ for h_f, 0.9277 for x_{2s}, and $2304.7\,\text{kJ/kg}$ for h_{fg}.

$$h_{2s} = 340.54 + 0.9227\times 2304.7 = 2467.08\ \text{kJ/kg}$$

Step 6 of 6

Find the isentropic work.

Substitute $3650.6\,\text{kJ/kg}$ for h_1, $2467.08\,\text{kJ/kg}$ for h_2, $80\,\text{m/s}$ for V_1, and $140\,\text{m/s}$ for V_2.

$$3650.6\frac{\text{kJ}}{\text{kg}}\times 1000\frac{\text{J}}{\text{kJ}} + \frac{(80)^2}{2} = 2467.08\frac{\text{kJ}}{\text{kg}}\times 1000\frac{\text{J}}{\text{kJ}} + \frac{(140)^2}{2} + W_{isen}$$

$$W_{isen} = 1176920\ \text{J/kg}$$

Find the isentropic efficiency.

$$\eta = \frac{\dot{W}}{\dot{m}W_{isen}}$$

Substitute $1176920\,\text{J/kg}$ for W_{isen}, $6\,\text{MW}$ for $\dot{W}$, and $6.94\,\text{kg/s}$ for $\dot{m}$.

$$\eta = \frac{6\,\text{MW}\times 10^6\frac{\text{W}}{\text{MW}}}{6.94\times 1176920} = 0.7345 = 73.45\%$$

Therefore, the isentropic efficiency of the turbine is $\boxed{73.45\%}$.

Question: 8.122P

Combustion gases enter an adiabatic gas turbine at 1540°F and 120 psia and leave at 60 psia with a low velocity. Treating the combustion gases as air and assuming an isentropic efficiency of 82 percent, determine the work output of the turbine.

Step 1 of 4

Given

Air temperature at inlet of turbine $T_1 = 1540°F$

$= 2000°R$

Pressure of air at inlet of turbine $P_1 = 120$ psia

Pressure of air at outlet of turbine $P_2 = 60$ psia

Isentropic efficiency of the turbine $\eta_T = 0.82$

Step 2 of 4

Ratio of specific heats for air, $k = 1.4$

For an isentropic process,

$$\frac{T_2}{T_1} = \left(\frac{p_2}{p_1}\right)^{k-1/k}$$

$$\frac{T_2}{(2000\ \text{R})} = \left(\frac{60\ \text{psia}}{120\ \text{psia}}\right)^{\frac{1.4-1}{1.4}}$$

$$T_2 = (2000\ \text{R}) \times 0.82$$

$$T_2 = 1640°R$$

Step 3 of 4

From air tables,

At 2000 R

Enthalpy of air at inlet, $h_1 = 504.71$ Btu/lbm

At 1640 R

Enthalpy of air at outlet $h_2 = 417.3$ Btu/lbm

Isentropic specific work of the turbine is

$$w_{s,out} = (h_1 - h_2)$$

$$w_{s,out} = (504.71 - 417.3)$$

$$w_{s,out} = 87.41\ \text{Btu/lbm}$$

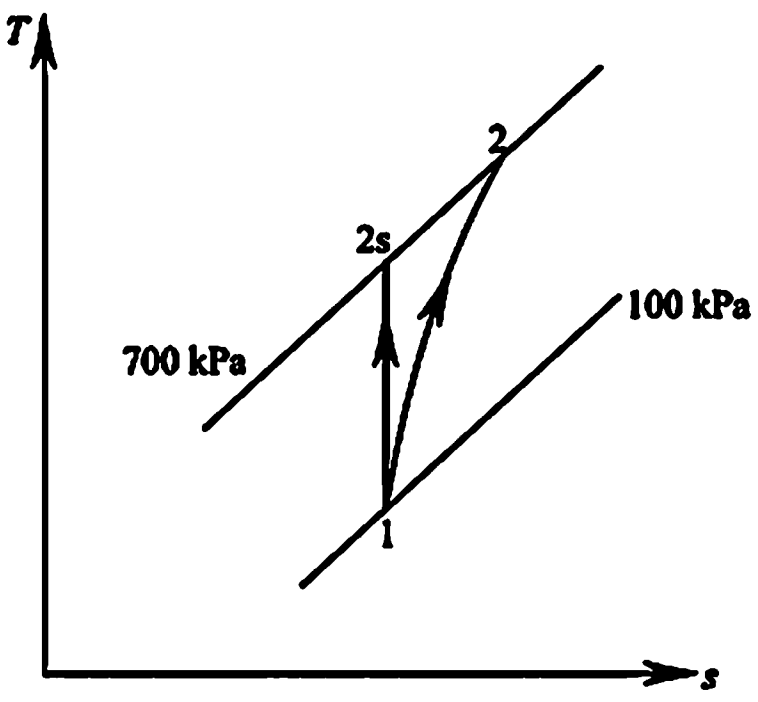
Step 4 of 4

Work output of the turbine,

$$w_{out} = \eta_T w_{s,out}$$

$$w_{out} = 0.82 \times 87.41\ \text{Btu/lbm}$$

$$w_{out} = 71.7\ \text{Btu/lbm}$$



Hence actual work output of the turbine, $\boxed{w_{out} = 71.7\ \text{Btu/lbm}}$

Question: 8.123P

Air at 100 kPa and 20°C is compressed to 700 kPa steadily and adiabatically at a rate of 2 kg/s. Determine the power required to compress this air if the isentropic compression efficiency is 95 percent.

Step 1 of 4

Draw the $T-s$ diagram.

Step 2 of 4

Obtain the specific heat ratio and specific heat constant for air from the "ideal gas specific heats of various common gases table".

At $T_{avg} = 400\,\text{K}$,

$k = 1.395$

$c_p = 1.013\ \text{kJ/kg}\cdot\text{K}$

Find the exit isentropic temperature using the following relation:

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Here, T_1 is the temperature at state 1, P_1 is the pressure at state 1 and P_2 is the pressure at state 2.

Substitute 1.395 for k, 100 kPa for P_1, 700 kPa for P_2 and $293\,\text{K}$ for T_1.

$$\begin{aligned} T_{2s} &= 293\left(\frac{700}{100}\right)^{\frac{1.395-1}{1.395}} \\ &= 293(7)^{\frac{0.395}{1.395}} \\ &= 508.347\ \text{K} \end{aligned}$$

Step 3 of 4

Find the isentropic work input using the following formula:

$$\dot{W}_{s,in} = \dot{m}c_p(T_{2s} - T_1)$$

Here, $\dot{m}$ is the mass flow rate.

Substitute 2 kg/s for $\dot{m}$, $293\,\text{K}$ for T_1, $1.013\ \text{kJ/kg}\cdot\text{K}$ for c_p, and $508.347\ \text{K}$ for T_{2s}.

$$\begin{aligned} \dot{W}_{s,in} &= 2\times 1.013\times(508.347-293) \\ &= 436.293\ \text{kW} \end{aligned}$$

Step 4 of 4

Find the power required to compress the air using the following formula:

$$\dot{W} = \frac{\dot{W}_{s,in}}{\eta_s}$$

Here, η_s is the isentropic efficiency.

Substitute $436.293\ \text{kW}$ for $\dot{W}_{s,in}$ and 0.95 for η_s.

$$\begin{aligned} \dot{W} &= \frac{436.293}{0.95} \\ &= 459.26\,\text{kW} \end{aligned}$$

Therefore, the power required to compress the air is $\boxed{459.26\ \text{kW}}$.

Question: 8.124P

Steam at 4 MPa and 350°C is expanded in an adiabatic turbine to 120 kPa. What is the isentropic efficiency of this turbine if the steam is exhausted as a saturated vapor?

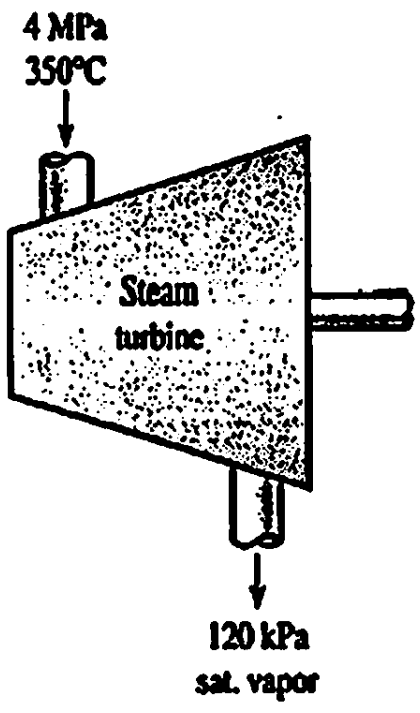


FIGURE P8–124

Step 1 of 6

Given data:

Pressure at turbine inlet is, $P_1 = 4\ \text{MPa} = 4000\ \text{kPa}$.

Temperature at turbine inlet is, $T_1 = 350°\text{C} = 623\ \text{K}$.

Pressure at turbine exit is, $P_2 = 120\ \text{kPa}$.

Exit state of steam is saturated vapor

Step 2 of 6

From superheated water,

At pressure $P_1 = 4\ \text{MPa}$ and temperature $T_1 = 350°\text{C}$

the enthalpy and entropy values are

$h_1 = 3093.3\ \text{kJ/kg}$

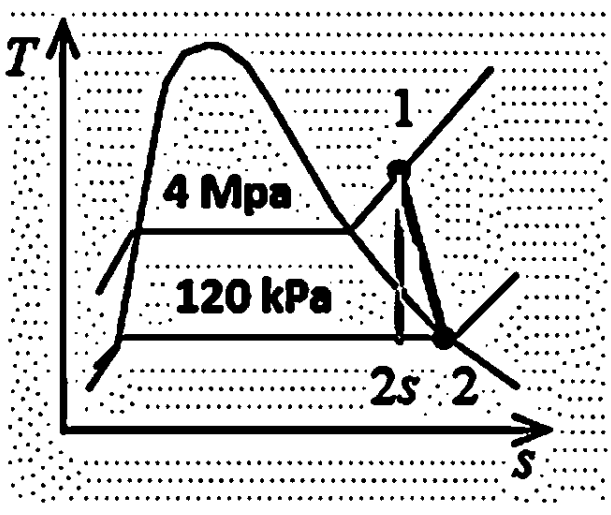
$s_1 = 6.5843\ \text{kJ/kg} \cdot \text{K}$

From Saturated water,

At pressure $P_2 = 120\ \text{kPa}$

Saturated properties of steam are as follows

Enthalpy of saturated liquid is $h_{f2} = 439.46\ \text{kJ/kg}$



Enthalpy of evaporation is $h_{fg2} = 2243.07\ \text{kJ/kg}$

Entropy of saturated liquid is $s_{f2} = 1.3601\ \text{kJ/kg} \cdot \text{K}$

Entropy of evaporation is $s_{fg2} = 5.936\ \text{kJ/kg} \cdot \text{K}$

Step 3 of 6

Let us draw the T-s diagram:

Step 4 of 6

Actual exit state of steam is saturated vapor.

From Saturated water,

At pressure $P_2 = 120\ \text{kPa}$ and

Saturated vapor condition the actual exit enthalpy is

$h_2 = 2683.1\ \text{kJ/kg}$

If the process is isentropic, the exit specific entropy is given by

$$s_{2s} = s_1$$

$$s_{f2} + x_{2s} \times s_{fg2} = s_1$$

$$1.3601 + x_{2s} \times 5.936 = 6.5843$$

$$x_{2s} \times 5.936 = 6.5843 - 1.3601$$

$$x_{2s} = \frac{6.5843 - 1.3601}{5.936}$$

$$= \frac{5.2242}{5.936}$$

$$= 0.88$$

Therefore isentropic exit dryness fraction is $x_{2s} = 0.88$

Step 5 of 6

The isentropic exit specific enthalpy is given by

$$h_{2s} = h_{f2} + x_{2s} \times h_{fg2}$$

$$= 439.46 + 0.88 \times 2243.07$$

$$= 439.46 + 1973.9$$

$$= 2413.36\ \text{kJ/kg}$$

Step 6 of 6

The isentropic efficiency of turbine is given by

$$\eta_{turb} = \frac{\text{Actual work done by the turbine}}{\text{Isentropic work done by the turbine}}$$

$$= \frac{m \times (h_1 - h_2)}{m \times (h_1 - h_{2s})}$$

$$= \frac{h_1 - h_2}{h_1 - h_{2s}}$$

$$= \frac{3093.3 - 2683.1}{3093.3 - 2413.36}$$

$$= \frac{410.2}{679.94}$$

$$= 0.6033$$

$$= 60.33\%$$

Therefore isentropic efficiency of turbine is $\boxed{\eta_{turb} = 60.33\%}$.

Question: 8.125P

Air is expanded from 2 MPa and 327°C to 100 kPa in an adiabatic turbine. Determine the isentropic efficiency of this turbine if the air is exhausted at 0°C.

Step 1 of 5

Given data:

Inlet pressure to the turbine is, $P_1 = 2\ \text{MPa} = 2000\ \text{kPa}$.

Exit pressure to the turbine is, $P_2 = 100\ \text{kPa}$.

Inlet temperature to the turbine is, $T_1 = 327°\text{C} = 600\ \text{K}$.

Exit temperature the turbine is $T_2 = 0°\text{C} = 273\ \text{K}$.

Step 2 of 5

Let us draw the T-s diagram:

Step 3 of 5

As the process is isentropic, the ratio of temperatures of exit and inlet is given by

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}},$$

From Ideal Gas Specific Heats of Various Common Gases

At temp $= 400\text{K}$

Where $k = 1.395$,

Therefore the isentropic exit temperature of a turbine is given by

$$T_{2s} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{\gamma-1}{\gamma}}$$

$$= 600\left(\frac{100}{2000}\right)^{\frac{1.395-1}{1.395}}$$

$$= 600(0.05)^{\frac{0.395}{1.395}}$$

$$= 600(0.05)^{0.28315}$$

$$= 600(0.428)$$

$$= 256.8\ \text{K}$$

Step 4 of 5

The isentropic efficiency of turbine is given by

$$\eta_{isen} = \frac{\text{Actual work done by the turbine}}{\text{Isentropic work done by the turbine}}$$

$$= \frac{m(h_1 - h_2)}{m(h_1 - h_{2s})}$$

$$= \frac{h_1 - h_2}{h_1 - h_{2s}}$$

$$= \frac{c_p \times (T_1 - T_2)}{c_p \times (T_1 - T_{2s})}$$

$$= \frac{T_1 - T_2}{T_1 - T_{2s}}$$

Step 5 of 5

Substituting the values,

$$\eta_{isen} = \frac{600 - 273}{600 - 256.8}$$

$$= \frac{327}{343.2}$$

$$= 0.953$$

$$= 95.3$$

Therefore the isentropic efficiency of turbine is $\boxed{\eta_{isen} = 0.953 = 95.3\,\%}$.

Question: 8.126P

A refrigeration unit compresses saturated R-134a vapor at 20°C to 1000 kPa. How much power is required to compress 0.5 kg/s of R-134a with a compressor efficiency of 85 percent?

Step 1 of 2

Determine the enthalpy at two states to calculate the compression work

From the saturated R-134a tables, at $20°C$

The enthalpy of the saturated vapor is $h_1 = 261.59 \text{ kJ/kg}$

The entropy of the saturated vapor is $s_1 = 0.9223 \text{ kJ/kg} \cdot \text{K}$

Consider isentropic compression

$$\begin{aligned} s_2 &= s_1 \\ &= 0.9223 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Now find the enthalpy at the exit if the process is isentropic (property of R-134a at pressure of 1 MPa and enthalpy of 0.9223 $\text{kJ/kg} \cdot \text{K}$)

$$h_{2s} = 273.11 \text{ kJ/kg}$$

Step 2 of 2

The power input to the isentropic compression.

$$W_{s,in} = \dot{m}(h_{2s} - h_1)$$

Substitute 0.5 kg/s for $\dot{m}$, 273.11 kJ/kg for h_{2s} , and 261.59 kJ/kg for h_1

$$\begin{aligned} W_{s,in} &= \dot{m}(h_{2s} - h_1) \\ &= 0.5(273.11 - 261.59) \\ &= 0.5 \times 11.52 \\ &= 5.76 \text{ kW} \end{aligned}$$

The work input to the compression process operating with 85 percent efficiency is

$$W_{in} = \frac{W_{s,in}}{\eta}$$

Substitute 0.85 for η , and 5.76 kW for $W_{s,in}$

$$\begin{aligned} W_{in} &= \frac{W_{s,in}}{\eta} \\ &= \frac{5.76}{0.85} \\ &= 6.776 \text{ kW} \end{aligned}$$

Thus the work input to the compression process is $\boxed{6.776 \text{ kW}}$

Question: 8.127P

Refrigerant-134a enters an adiabatic compressor as saturated vapor at 100 kPa at a rate of 0.7 m3 /min and exits at 1-MPa pressure. If the isentropic efficiency of the compressor is 87 percent, determine (*a*) the temperature of the refrigerant at the exit of the compressor and (*b*) the power input, in kW. Also, show the process on a *T-s* diagram with respect to saturation lines.

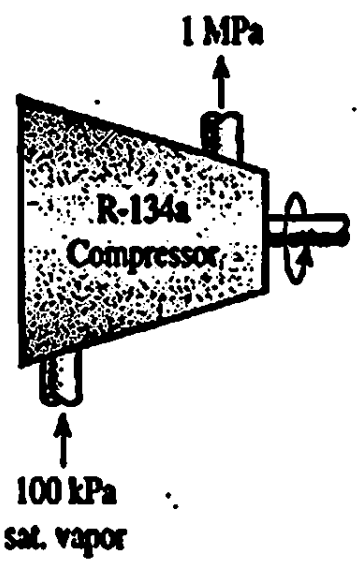


FIGURE P8–127

Step 1 of 6

Obtain the properties of saturated refrigerant 134a from table A-12 (Saturated refrigerant 134a-pressure table) in the text book, at pressure $P_1 = 100\,\text{kPa}$.

Specific volume of saturated vapour is $v_1 = v_g = 0.19254\ \text{m}^3/\text{kg}$.

Specific enthalpy of saturated vapour is $h_1 = h_g = 234.44\ \text{kJ/kg}$.

Specific entropy of saturated vapour is $s_1 = s_g = 0.95183\ \text{kJ/kg-K}$.

Since, the process is an adiabatic process, entropy will be constant. $s_2 = s_1 = 0.95183\ \text{kJ/kg-K}$

Obtain the enthalpy at state-2s from table A-13 (Superheated refrigerant R-134a) in the text book, at pressure $P_2 = 1\,\text{MPa}$ and entropy $s_2 = 0.95183\ \text{kJ/kg-K}$ by using interpolation.

$$\frac{h_{2s}-271.71}{282.74-271.71}=\frac{0.95183-0.9179}{0.9525-0.9179}$$
$$\frac{h_{2s}-271.71}{11.03}=0.9806$$
$$h_{2s}=(0.9806)(11.03)+271.71$$
$$=282.526\ \text{kJ/kg}$$

Step 2 of 6

Calculate the actual enthalpy at state-2 using the isentropic efficiency of compressor.

$$\eta_{isen}=\frac{h_{2s}-h_1}{h_{2a}-h_1}$$

Substitute $282.526\ \text{kJ/kg}$ for h_{2s} , $234.44\ \text{kJ/kg}$ for h_1 , and 0.87 for η_{isen} .

$$0.87=\frac{282.526-234.44}{h_{2a}-234.44}$$
$$0.87=\frac{48.086}{h_{2a}-234.44}$$
$$h_{2a}=\frac{48.086}{0.87}+234.44$$
$$=289.71\ \text{kJ/kg}$$

Step 3 of 6

a)

Obtain the enthalpy at state-2s from table A-13 (Superheated refrigerant R-134a) in the text book, at pressure $P_2 = 1\,\text{MPa}$ and entropy $h_{2a} = 289.71\ \text{kJ/kg}$ by using interpolation.

$$\frac{T_{2a}-50}{60-50}=\frac{289.71-282.74}{293.38-282.74}$$
$$\frac{T_{2a}-50}{10}=0.6551$$
$$T_{2a}=(0.6551)(10)+50$$
$$=56.551°\text{C}$$

Therefore, the temperature of the refrigerant at the exit of the compressor is $\boxed{56.551°\text{C}}$.

Step 4 of 6

b)

Calculate the power input to compressor.

$$W_{act}=\dot{m}(h_{2a}-h_1) \quad \text{..... (1)}$$

Here, $\dot{m}$ is the mass flow rate.

Calculate the mass flow rate.

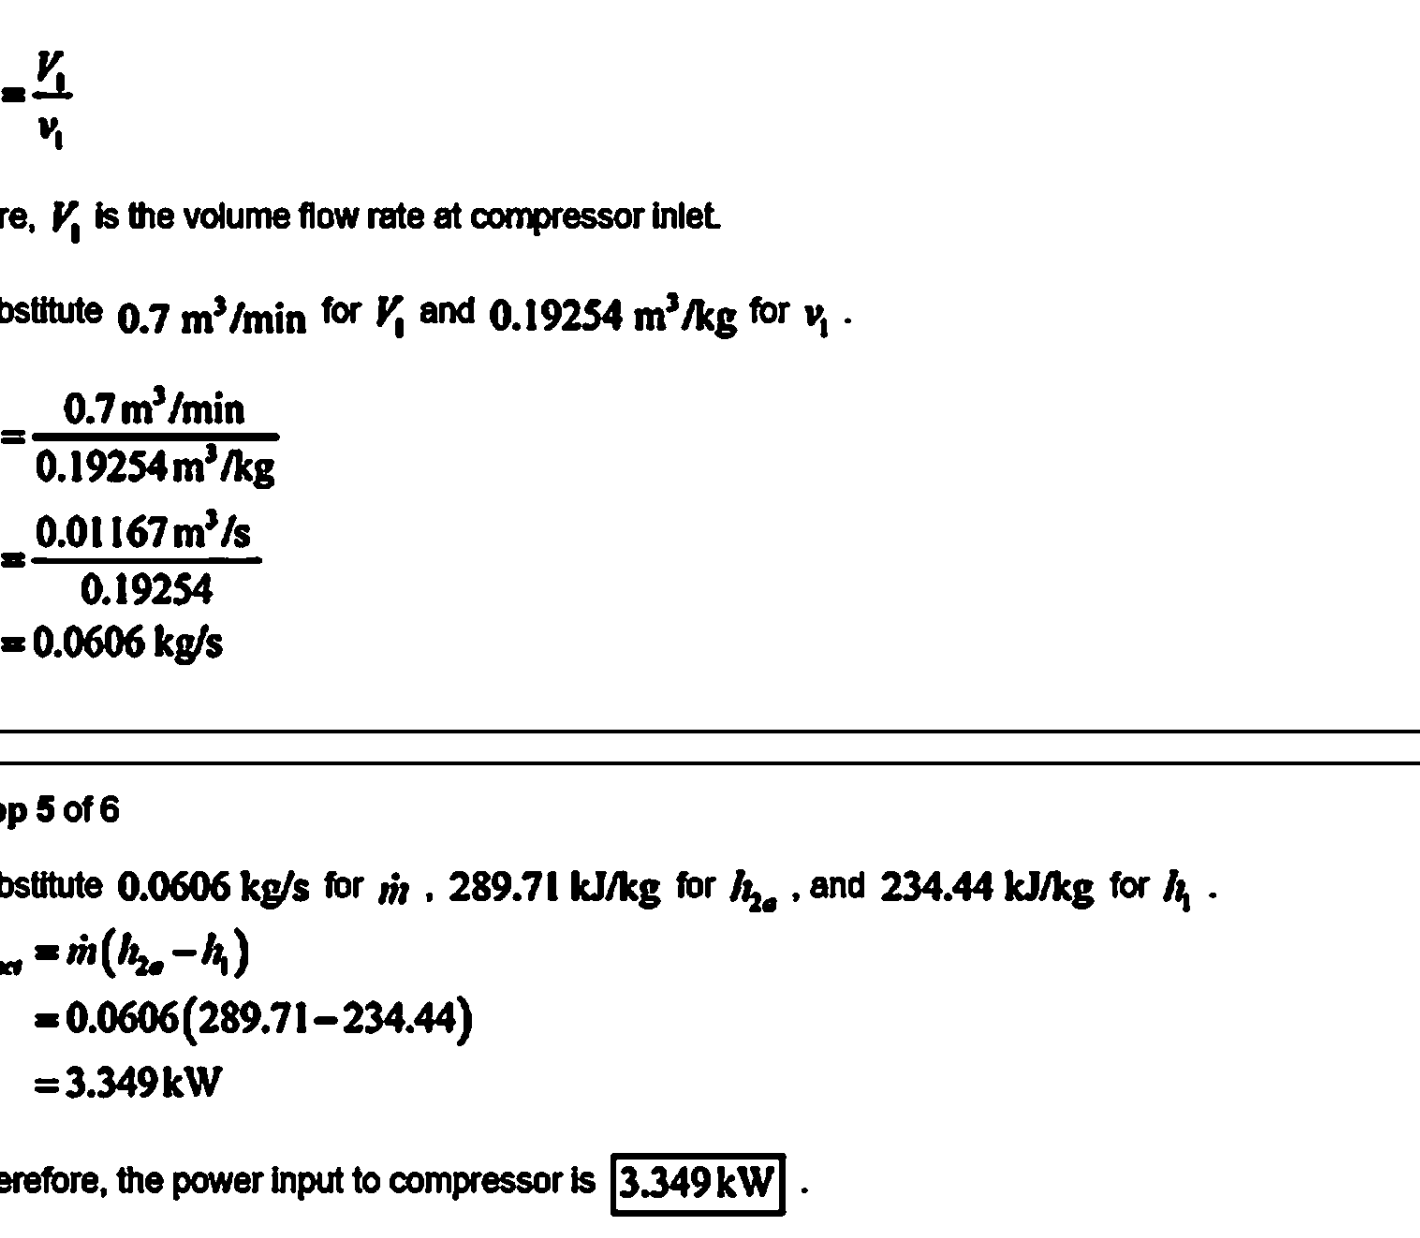
$$\dot{m}=\frac{V_1}{v_1}$$

Here, V_1 is the volume flow rate at compressor inlet.

Substitute $0.7\ \text{m}^3/\text{min}$ for V_1 and $0.19254\ \text{m}^3/\text{kg}$ for v_1 .

$$\dot{m}=\frac{0.7\,\text{m}^3/\text{min}}{0.19254\,\text{m}^3/\text{kg}}$$
$$=\frac{0.01167\,\text{m}^3/\text{s}}{0.19254}$$
$$=0.0606\ \text{kg/s}$$

Step 5 of 6



Substitute $0.0606\ \text{kg/s}$ for $\dot{m}$, $289.71\ \text{kJ/kg}$ for h_{2a} , and $234.44\ \text{kJ/kg}$ for h_1 .

$$W_{act}=\dot{m}(h_{2a}-h_1)$$
$$=0.0606(289.71-234.44)$$
$$=3.349\,\text{kW}$$

Therefore, the power input to compressor is $\boxed{3.349\,\text{kW}}$.

Step 6 of 6

Draw the T-s diagram.

Question: 8.128INCLUD-C

Reconsider Prob. 8-127. Using EES (or other) software, redo the problem by including the effects of the kinetic energy of the flow by assuming an inlet-to-exit area ratio of 1.5 for the compressor when the compressor exit pipe inside diameter is 2 cm.

We don't have the solution to this problem yet.

Ask an expert

Question: 8.129P

Air enters an adiabatic compressor at 100 kPa and 17°C at a rate of 2.4 m3 /s, and it exits at 257°C. The compressor has an isentropic efficiency of 84 percent. Neglecting the changes in kinetic and potential energies, determine (a) the exit pressure of air and (*b*) the power required to drive the compressor.

Step 1 of 6

Draw the schematic figure of the compressor.

Step 2 of 6

Convert the units of inlet temperature from Celsius to Kelvin.

$$\begin{aligned} T_1 &= 17°C \\ &= (17°C + 273)\ K \\ &= 290\ K \end{aligned}$$

Convert the units of inlet temperature from Celsius to Kelvin.

$$\begin{aligned} T_2 &= 257°C \\ &= (257°C + 273)\ K \\ &= 530\ K \end{aligned}$$

Obtain the properties of air at the inlet temperature of $290\ K$ from Table A-17, "Ideal-gas properties of air," from the text book.

Enthalpy, $h_1 = 290.16\ kJ/kg$

Reduced pressure, $P_{r1} = 1.2311$

Obtain the properties of air at the exit temperature of $530\ K$ from Table A-17, "Ideal-gas properties of air," from the text book.

Enthalpy, $h_{2s} = 533.98\ kJ/kg$

Step 3 of 6

Write the relation or the isentropic efficiency of the compressor.

$$\eta_C = \frac{h_{2s} - h_1}{h_{2a} - h_1}$$

Here, h_{2s} is the isentropic enthalpy.

Substitute 0.84 for η_C , $290.16\ kJ/kg$ for h_1 , and $533.98\ kJ/kg$ for h_{2a} .

$$\begin{aligned} 0.84 &= \frac{h_{2s} - 290.16}{533.98 - 290.16} \\ h_{2s} &= 494.9688\ kJ/kg \end{aligned}$$

Obtain the reduced pressure corresponding to an enthalpy of $494.9688\ kJ/kg$ from Table A-17, "Ideal-gas properties of air," from the text book by interpolation.

$$\begin{aligned} \frac{503.02 - 494.9688}{503.02 - 492.74} &= \frac{8.411 - P_{r2}}{8.411 - 7.824} \\ P_{r2} &= 7.951 \end{aligned}$$

Step 4 of 6

(a)

Calculate the exit pressure of the air by using the following adiabatic relation:

$$\frac{P_2}{P_1} = \frac{P_{r2}}{P_{r1}}$$

Here, P_1 is the inlet pressure.

Substitute $100\ kPa$ for P_1 , 7.951 for P_{r2} , and 1.2311 for P_{r1} .

$$\begin{aligned} \frac{P_2}{100} &= \frac{7.951}{1.2311} \\ P_2 &= 645.87\ kPa \end{aligned}$$

Therefore, the exit pressure of the air is $\boxed{645.87\ kPa}$.

Step 5 of 6

(b)

Write the energy balance equation for a steady flow system.

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system}$$

Here, $\dot{E}_{in} - \dot{E}_{out}$ is the rate of net energy transfer by heat, work, and mass and $\Delta \dot{E}_{system}$ is the rate of change in internal, kinetic, potential, energies.

Neglect the heat, kinetic and potential energies and rewrite the equation.

$$\dot{W}_{a,in} = \dot{m}(h_{2a} - h_1) \quad \text{..... (1)}$$

Here, $\dot{W}_{a,in}$ is the power input to the compressor and $\dot{m}$ is the mass flow rate.

Step 6 of 6

Calculate the mass flow rate by using the following ideal gas equation:

$$\dot{m} = \frac{P_1 \dot{V}_1}{R T_1}$$

Here, $\dot{V}_1$ is the volumetric flow rate and R is the gas constant for air.

Substitute $100\ kPa$ for P_1 , $2.4\ m^3/s$ for $\dot{V}_1$, $0.287\ kPa \cdot m^3/kg$ for R , and $290\ K$ for T_1 .

$$\begin{aligned} \dot{m} &= \frac{100 \times 2.4}{0.287 \times 290} \\ &= 2.884\ kg/s \end{aligned}$$

Substitute $2.884\ kg/s$ for $\dot{m}$, $533.98\ kJ/kg$ for h_{2a} , and $290.16\ kJ/kg$ for h_1 in equation (1) to calculate the power input to the compressor.

$$\begin{aligned} \dot{W}_{a,in} &= \dot{m}(h_{2a} - h_1) \\ &= 2.884(533.98 - 290.16) \\ &= 703.2\ kJ/s \times \left(\frac{1\ kW}{1\ kJ/s}\right) \\ &= 703.2\ kW \end{aligned}$$

Therefore, the power input to the compressor is $\boxed{703.2\ kW}$.

Question: 8.130P

Air is compressed by an adiabatic compressor from 95 kPa and 27°C to 600 kPa and 277°C. Assuming variable specific heats and neglecting the changes in kinetic and potential energies, determine (*a*) the isentropic efficiency of the compressor and (*b*) the exit temperature of air if the process were reversible.

Step 1 of 5

Obtain the properties from ideal-gas properties of air table,

At initial temperature, $T_1 = 300\ \text{K}$

Enthalpy of air at inlet, $h_1 = 300.19\ \text{kJ/kg}$

Relative pressure, $p_{r_1} = 1.386$

At actual temperature, $T_{2a} = 500\ \text{K}$

Actual enthalpy of air at outlet, $h_{2a} = 555.74\ \text{kJ/kg}$

Step 2 of 5

Calculate the enthalpy of air at the end of isentropic compression.

Consider the following isentropic relation as shown below,

$$p_{r_2} = \left(\frac{p_2}{p_1}\right) p_{r_1}$$

Substitute $95\ \text{kPa}$ for p_1 and $600\ \text{kPa}$ for p_2.

$$p_{r_2} = \left(\frac{600}{95}\right)(1.386)$$
$$= 8.754$$

Step 3 of 5

From ideal-gas properties of air table, the value of isentropic enthalpy (h_{2s}) corresponding to relative pressure (p_{r_2}) can be obtained by the use of interpolation technique.

Now, obtain the properties from ideal-gas properties of air table,

At $p_r = 8.411$, $h = 503.02\ \text{kJ/kg}$

At $p_r = 9.031$, $h = 513.32\ \text{kJ/kg}$

The value of h_{2s} lies between the above two values of h

$$h_{2s} = h_{at\ 8.411} + \left(\frac{h_{at\ 9.031} - h_{at\ 8.411}}{9.031 - 8.411}\right)(8.754 - 8.411)$$
$$= 503.02 + \left(\frac{513.32 - 503.02}{0.62}\right)(0.343)$$
$$= 503.02 + 5.7$$
$$= 508.72\ \text{kJ/kg}$$

Therefore, the isentropic enthalpy is, $h_{2s} = 508.72\ \text{kJ/kg}$

Step 4 of 5

(a)

Calculate the isentropic efficiency of the compressor by using the following equation,

$$\eta_c = \frac{\text{Isentropic work input}}{\text{Actual work input}}$$
$$= \frac{h_{2s} - h_1}{h_{2a} - h_1}$$
$$= \frac{508.72 - 300.19}{555.74 - 300.19}$$
$$= 0.816$$

Therefore, the isentropic efficiency of the compressor is, **81.6 percent**

Step 5 of 5

(b)

Calculate the exit temperature of air in the isentropic process.

From the ideal-gas properties of air table, the exit temperature of air (T_{2s}) in an isentropic process corresponding to relative pressure (p_{r_2}) can be obtained by the use of interpolation technique.

Now, obtain the properties from ideal-gas properties of air table,

At $p_r = 8.411$, $T = 500\ \text{K}$

At $p_r = 9.031$, $T = 510\ \text{K}$

$$T_{2s} = T_{at\ 8.411} + \left(\frac{T_{at\ 9.031} - T_{at\ 8.411}}{9.031 - 8.411}\right)(8.754 - 8.411)$$
$$= 500 + \left(\frac{510 - 500}{0.62}\right)(0.343)$$
$$= 500 + 5.53$$
$$= 505.53\ \text{K}$$

Therefore, the exit temperature of air in an isentropic process is, **505.53 K**

Question: 8.131P

Argon gas enters an adiabatic compressor at 20 psia and 90°F with a velocity of 60 ft/s, and it exits at 200 psia and 240 ft/s. If the isentropic efficiency of the compressor is 80 percent, determine (*a*) the exit temperature of the argon and (*b*) the work input to the compressor.

Step 1 of 5

Given data

Pressure of argon at compressor inlet, $P_1 = 20\,\text{psia}$

Temperature of argon at compressor inlet, $T_1 = 90°\text{F}$

$= 550°\text{R}$

Velocity of argon at compressor inlet, $V_1 = 60\,\text{ft/s}$

Pressure of argon at outlet of compressor, $P_2 = 200\,\text{psia}$

Velocity of argon at compressor outlet, $V_2 = 240\,\text{ft/s}$

Isentropic efficiency of compressor $\eta_C = 0.80$

Step 2 of 5

a) Let T_{2a} be the exit temperature of the argon

From the properties of ideal gas specific heats of various common gases

The specific heat of argon, $c_p = 0.1253\,\text{Btu/lbm}\cdot\text{R}$

Ratio of specific heats, $k = 1.667$

For an isentropic process,

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = (550)\left(\frac{200}{20}\right)^{\frac{0.667}{1.667}}$$

$$T_{2s} = 1381.92°\text{R}$$

Step 3 of 5

Now using the change in actual kinetic energy

$$\Delta ke = \frac{V_2^2 - V_1^2}{2}$$

$$\Delta ke = \frac{(240)^2 - (60)^2}{2}$$

$$\Delta ke = 27000\,\text{ft}^2/s^2$$

$$\Delta ke = 27000\left(\frac{\text{ft}^2}{s^2}\right)\left(\frac{1\,\text{Btu/lbm}}{25037\,\text{ft}^2/s^2}\right)$$

$$\Delta ke = 1.078\ \text{Btu/lbm}$$

Step 4 of 5

The isentropic efficiency of a compressor,

$$\eta_C = \frac{(h_{2s} - h_1) + \Delta ke}{(h_{2a} - h_1) + \Delta ke}$$

$$\eta_C = \frac{c_p(T_{2s} - T_1) + \Delta ke}{c_p(T_{2a} - T_1) + \Delta ke}$$

$$0.80 = \frac{0.1253(1381.92 - 550) + 1.078}{0.1253(T_{2a} - 550) + 1.078}$$

$$0.1253(T_{2a} - 550) + 1.078 = 131.65$$

$$(T_{2a} - 550) = 1042.1$$

$$\boxed{T_{2a} = 1592.1°\text{R}}$$

Therefore the exit temperature of the argon, $T_{2a} = 1592.1°\text{R}$

Step 5 of 5

b) Let w_{in} be the work input of the compressor

Energy balance for steady flow system,

$$W_{in} + \dot{m}\left(h_1 + \frac{V_1^2}{2}\right) = \dot{m}\left(h_2 + \frac{V_2^2}{2}\right)$$

$$W_{in} = \dot{m}\left(h_2 + \frac{V_2^2}{2}\right) - \dot{m}\left(h_1 + \frac{V_1^2}{2}\right)$$

$$W_{in} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}\right)$$

$$\frac{W_{in}}{\dot{m}} = \left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}\right)$$

$$w_{in} = \left(c_p T_2 - c_p T_1 + \frac{V_2^2 - V_1^2}{2}\right)$$

$$w_{in} = \{(0.1253 \times 1592.1) - (0.1253 \times 550) + 1.078\}$$

$$\boxed{w_{in} = 131.65\,\text{Btu/lbm}}$$

Therefore the work input of the compressor $w_{in} = 131.65\,\text{Btu/lbm}$

Question: 8.132P

Air enters an adiabatic nozzle at 45 psia and 940°F with low velocity and exits at 650 ft/s. If the isentropic efficiency of the nozzle is 85 percent, determine the exit temperature and pressure of the air.

Step 1 of 5

Apply mass balance equation to the nozzle

$$m_{in} = m_{out}$$

$$m_1 = m_2$$

Here, m_{in} or m_1 is mass of air entering into the nozzle and m_{out} or m_2 is mass of air exiting from the nozzle.

Apply energy balance to the adiabatic nozzle,

$$m_1\left(h_1 + \frac{V_1^2}{2}\right) = m_2\left(h_2 + \frac{V_2^2}{2}\right)$$

Since $m_1 = m_2$ from the mass balance equation,

$$\left(h_1 + \frac{V_1^2}{2}\right) = \left(h_2 + \frac{V_2^2}{2}\right)$$

Here, V_1 and V_2 are the inlet and exit velocities of the nozzle.

Neglect the velocity of air at inlet, since air enters the adiabatic nozzle at very low velocity, $V_1 = 0$

Then energy equation becomes,

$$(h_1 + 0) = \left(h_2 + \frac{V_2^2}{2}\right)$$

$$h_2 = h_1 - \frac{V_2^2}{2} \qquad \text{..... (1)}$$

Step 2 of 5

Obtain the properties of air, at temperature $T_1 = 940°\text{F} = 1400\text{R}$ from ideal gas properties of air table.

The enthalpy and relative pressure are

$$h_1 = 342.9\ \text{Btu/lbm}$$

$$P_{r1} = 42.88$$

Substitute 650 ft/s for V_2 in equation (1)

$$h_2 = h_1 - \frac{V_2^2}{2}$$

$$= 342.9\text{Btu/lbm} - \frac{650^2\ \text{ft}^2/\text{s}^2}{2} \times \frac{1\text{Btu/lbm}}{25037\ \text{ft}^2/\text{s}^2}$$

$$= 334.462\text{Btu/lbm}$$

Step 3 of 5

Find the exit temperature at $h_2 = 334.462\text{Btu/lbm}$ from ideal gas properties of air table by using interpolation,

$$T_2 = 1360 + (1400 - 1360)\left(\frac{334.462 - 332.48}{342.9 - 332.48}\right)$$

$$= 1360 + 40 \times 0.19$$

$$= 1367.6\text{R}$$

$$T_2 = 1367.6 - 460\text{R}$$

$$= 907.6°\text{F}$$

Therefore, exit temperature of air from the nozzle is $\boxed{907.6°\text{F}}$

Step 4 of 5

Find the isentropic exit enthalpy, h_{2s} by using isentropic efficiency of the nozzle by using the equation,

$$\eta_{isen} = \frac{h_2 - h_1}{h_{2s} - h_1}$$

Substitute 0.85 for η_{isen}

$$0.85 = \frac{334.462 - 342.9}{h_{2s} - 342.9}$$

$$0.85 = \frac{-8.438}{h_{2s} - 342.9}$$

$$h_{2s} - 342.9 = -9.927$$

$$h_{2s} = 332.973\ \text{Btu/lbm}$$

Step 5 of 5

Find the relative exit pressure at $h_{2s} = 332.973\text{Btu/lbm}$ from ideal gas properties of air,

$$P_{r2} = 38.41 + (42.88 - 38.14)\left(\frac{332.973 - 332.48}{342.9 - 332.48}\right)$$

$$= 38.634$$

Find the exit pressure of air by using the relation between relative and normal pressures

$$\frac{P_{r2}}{P_{r1}} = \frac{P_2}{P_1}$$

$$P_2 = \frac{P_{r2}}{P_{r1}} \times P_1$$

$$= \frac{38.634}{42.88} \times 45$$

$$= (0.9)(45)$$

$$= 40.54\ \text{psia}$$

Therefore, the exit pressure of air from adiabatic nozzle is $\boxed{40.54\ \text{psia}}$

Question: 8.133P pg 1

Reconsider Prob. 8-132E. Using EES (or other) software, study the effect of varying the nozzle isentropic efficiency from 0.8 to 1.0 on both the exit temperature and pressure of the air, and plot the results.

Step 1 of 10

Given data:

Inlet pressure to the nozzle is, $P_1 = 45$ psia

Inlet temperature to the nozzle is, $T_1 = 940°F = 1489.67$ R

Exit velocity is, $C_2 = 650$ ft/s

Nozzle efficiency varies, $\eta_{isen} = 0.8$ to 1

Question:

Reconsider Prob. 8-132E. Using EES (or other) software, study the effect of varying the nozzle isentropic efficiency from 0.8 to 1.0 on both the exit temperature and pressure of the air, and plot the results.

Step 1 of 10

Given data:

Inlet pressure to the nozzle is, $P_1 = 45$ psia

Inlet temperature to the nozzle is, $T_1 = 940°F = 1489.67$ R

Exit velocity is, $C_2 = 650$ ft/s

Nozzle efficiency varies, $\eta_{isen} = 0.8$ to 1

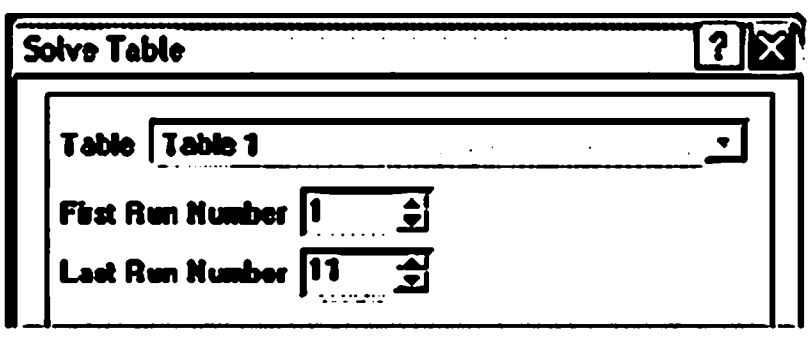
Step 2 of 10

Give all the inputs in the EES software as given below

T1 =940 [F]

Step 2 of 10

Give all the inputs in the EES software as given below



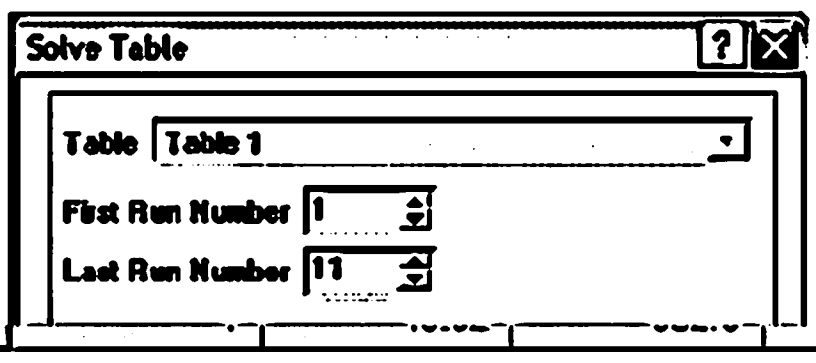
T1 =940 [F]

Fill all the values of η_{isen}.

▷	1 η_{isen}	2 P2 [psia]	3 T2 [F]	4 $T2_s$ [F]
Run 1	0.8			
Run 2	0.82			
Run 3	0.84			
Run 4	0.86			
Run 5	0.88			
Run 6	0.9			
Run 7	0.92			
Run 8	0.94			
Run 9	0.96			
Run 10	0.98			
Run 11	1			

Step 5 of 10

Now solve the table for respective P2 and T2 values by pressing F3.



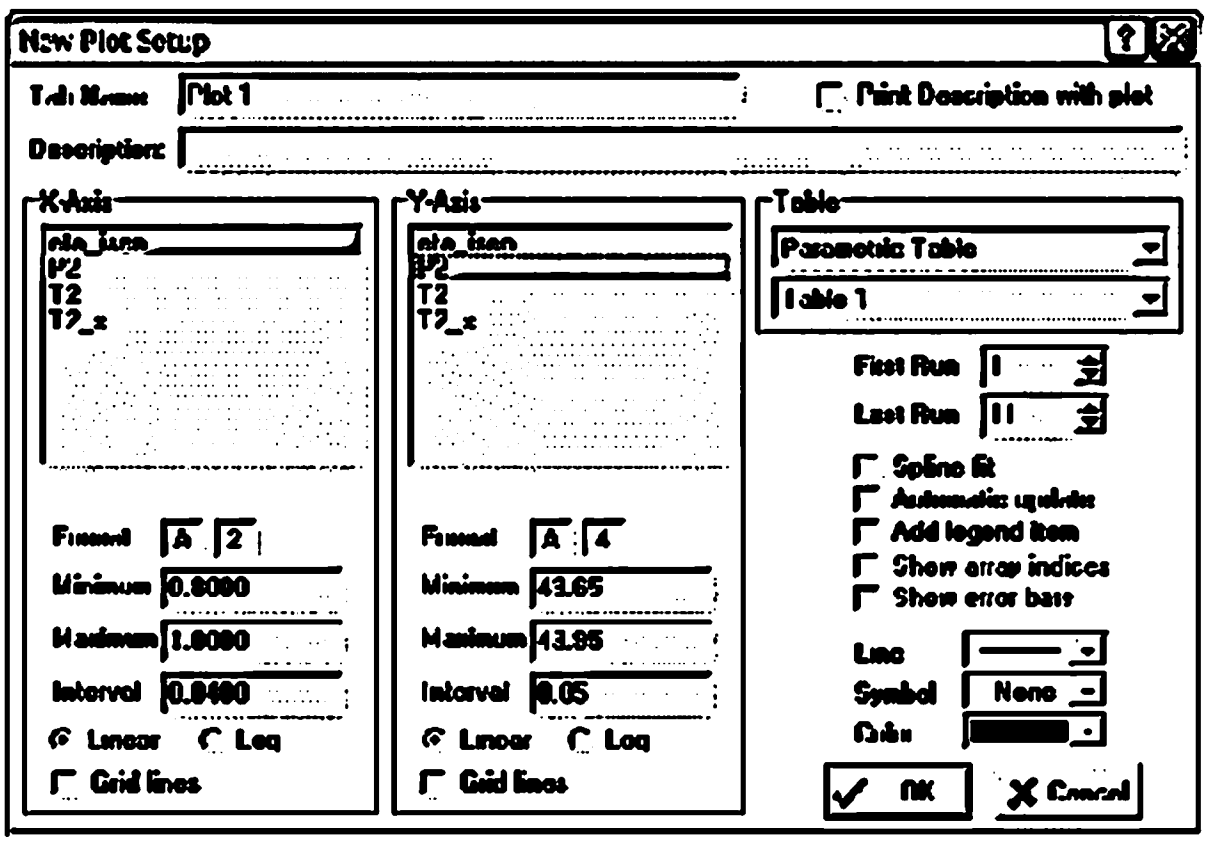
Fill all the values of η_{isen}.

▷	1 η_{isen}	2 P2 [psia]	3 T2 [F]	4 $T2_s$ [F]
Run 1	0.8			
Run 2	0.82			
Run 3	0.84			
Run 4	0.86			
Run 5	0.88			
Run 6	0.9			
Run 7	0.92			
Run 8	0.94			
Run 9	0.96			
Run 10	0.98			
Run 11	1			

Step 5 of 10

Now solve the table for respective P2 and T2 values by pressing F3.

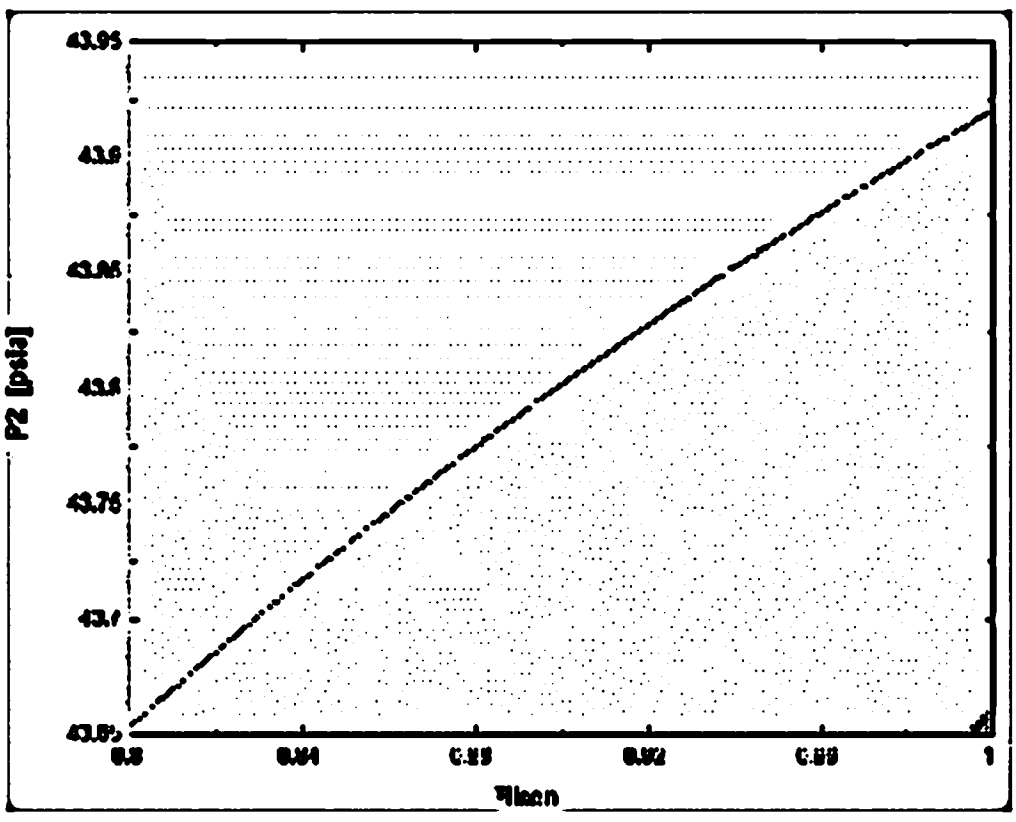
Step 7 of 10



For getting the plot we should go for

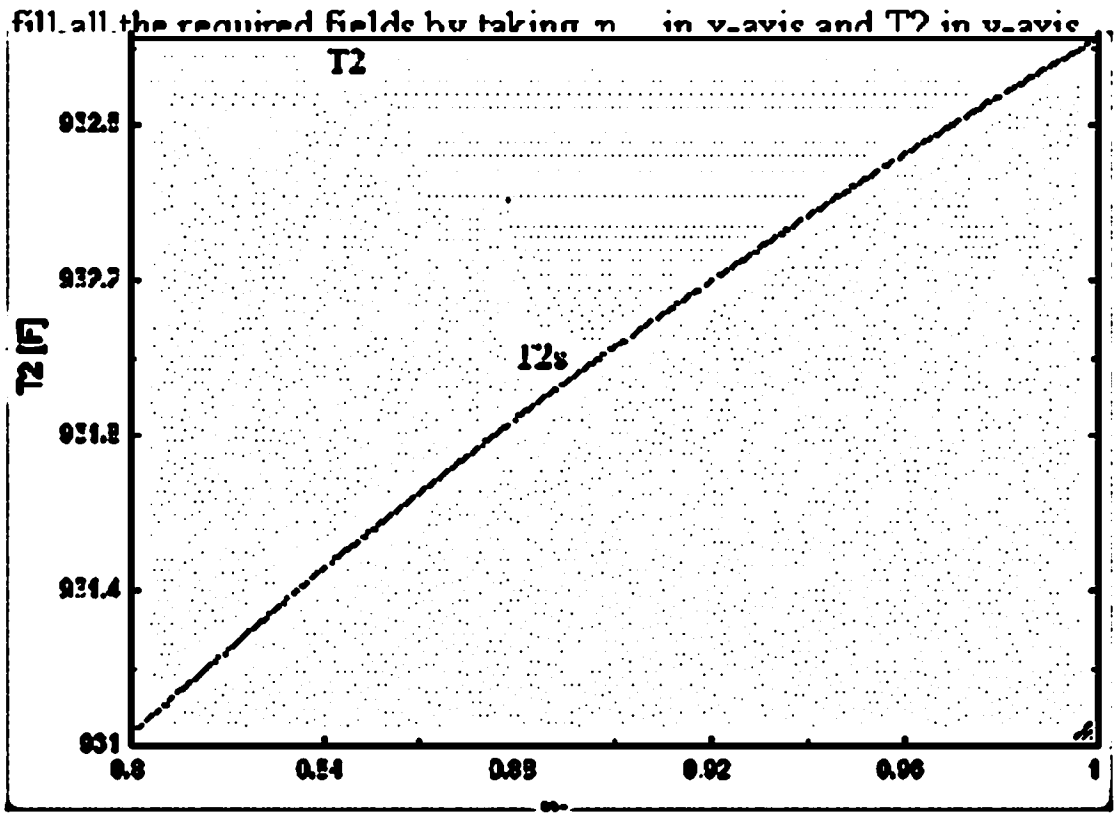
Plots → New plot window

We should fill all the required fields by taking η_{isen} in x-axis and P2 in y-axis.



Step 7 of 10

For getting the plot we should go for
Plots → New plot window
We should fill all the required fields by taking η_{ksm} in x-axis and P2 in y-axis.



Step 8 of 10

After that we get the plot as

Step 9 of 10

For getting the plot we should go for
Plots → New plot window
We should fill all the required fields by taking η_{ksm} in x-axis and T2 in y-axis

Step 9 of 10

For getting the plot we should go for
Plots → New plot window
We should fill all the required fields by taking η_{ksm} in x-axis and T2 in y-axis

Question:

8.134P

The exhaust nozzle of a jet engine expands air at 300 kPa and 180°C adiabatically to 100 kPa. Determine the air velocity at the exit when the inlet velocity is low and the nozzle isentropic efficiency is 96 percent.

Step 1 of 3

Find the exit temperature of air in case of isentropic process by using isentropic relation during the process 1-2s.

$$\frac{T_{2s}}{T_1}=\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s}=T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Here, T_1 is temperature of air at nozzle inlet, P_1 is pressure of air at nozzle inlet, P_2 is pressure of air at nozzle exit T_{2s} is isentropic temperature of air at nozzle exit and k is isentropic index of air.

Question:

The exhaust nozzle of a jet engine expands air at 300 kPa and 180°C adiabatically to 100 kPa. Determine the air velocity at the exit when the inlet velocity is low and the nozzle isentropic efficiency is 96 percent.

Step 1 of 3

Find the exit temperature of air in case of isentropic process by using isentropic relation during the process 1-2s.

$$\frac{T_{2s}}{T_1}=\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s}=T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Here, T_1 is temperature of air at nozzle inlet, P_1 is pressure of air at nozzle inlet, P_2 is pressure of air at nozzle exit T_{2s} is isentropic temperature of air at nozzle exit and k is isentropic index of air.

Find the isentropic kinetic energy change by using the equation,

$$(\Delta kE)_{\text{isentropic}}=c_p(T_1-T_{2s})$$

Here, c_p is specific heat of air at constant pressure.

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p

$$\begin{aligned}(\Delta kE)_{\text{isentropic}}&=(1.005\ \text{kJ/kg}\cdot\text{K})(453-331.221)\\&=122.387\,\text{kJ/kg}\end{aligned}$$

Find the actual kinetic energy change by using the efficiency of the nozzle,

$$\eta_N=\frac{(\Delta kE)_{\text{actual}}}{(\Delta kE)_{\text{isentropic}}}$$

$$(\Delta kE)_{\text{actual}}=\eta_N(\Delta kE)_{\text{isentropic}}$$

Substitute 0.96 for η_N

$$\begin{aligned}(\Delta kE)_{\text{actual}}&=0.96\times122.387\\&=117.491\,\text{kJ/kg}\end{aligned}$$

Find the actual velocity of air at nozzle exit by using the expression,

$$(\Delta kE)_{\text{actual}}=\frac{V_2^2-V_1^2}{2}$$

Find the isentropic kinetic energy change by using the equation,

$$(\Delta kE)_{\text{isentropic}}=c_p(T_1-T_{2s})$$

Here, c_p is specific heat of air at constant pressure.

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p

$$\begin{aligned}(\Delta kE)_{\text{isentropic}}&=(1.005\ \text{kJ/kg}\cdot\text{K})(453-331.221)\\&=122.387\,\text{kJ/kg}\end{aligned}$$

Find the actual kinetic energy change by using the efficiency of the nozzle,

$$\eta_N=\frac{(\Delta kE)_{\text{actual}}}{(\Delta kE)_{\text{isentropic}}}$$

$$(\Delta kE)_{\text{actual}}=\eta_N(\Delta kE)_{\text{isentropic}}$$

Substitute 0.96 for η_N

$$\begin{aligned}(\Delta kE)_{\text{actual}}&=0.96\times122.387\\&=117.491\,\text{kJ/kg}\end{aligned}$$

Question: 8.135P

An adiabatic diffuser at the inlet of a jet engine increases the pressure of the air that enters the diffuser at 13 psia and 30°F to 20 psia. What will the air velocity at the diffuser exit be if the diffuser isentropic efficiency defined as the ratio of the actual kinetic energy change to the isentropic kinetic energy change is 82 percent and the diffuser inlet velocity is 1000 ft/s?

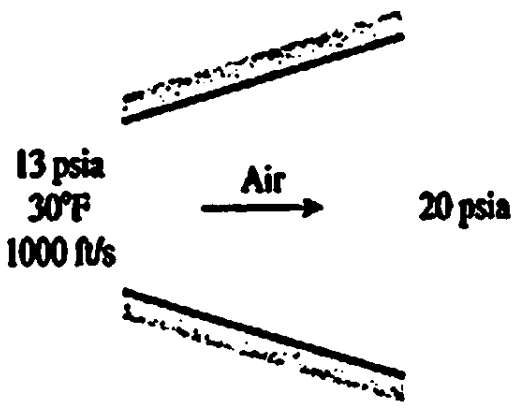


FIGURE P8–135E

Step 1 of 4

Obtain the properties of air from ideal gas properties of gases,

Specific heat ratio $k = 1.4$

Specific heat at constant pressure $c_p = 0.24\ \text{Btu/lbm} \cdot \text{R}$

Find the isentropic exit temperature of the diffuser by using isentropic relation,

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{(k-1)/k}$$

Here, T_1 is the initial temperature of the air, T_{2s} is the final isentropic temperature, P_1 is the initial pressure of air, P_2 is final pressure of air and k is specific heat ratio of air.

Substitute 13 psia for P_1, 20 psia for P_2 and $\left[30°\text{F} = (460+30)°\text{R}\right]$ for T_1

$$\frac{T_2}{(30+460)} = \left(\frac{20}{13}\right)^{(1.4-1)/1.4}$$

$$\frac{T_2}{490} = 1.1306$$

$$T_{2s} = 553.99\ \text{R}$$

Step 2 of 4

Apply the energy balance for this steady-flow system

Obtain the properties of air from ideal gas properties of gases,

Specific heat ratio $k = 1.4$

Specific heat at constant pressure $c_p = 0.24\ \text{Btu/lbm} \cdot \text{R}$

Find the isentropic exit temperature of the diffuser by using isentropic relation,

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{(k-1)/k}$$

Here, T_1 is the initial temperature of the air, T_{2s} is the final isentropic temperature, P_1 is the initial pressure of air, P_2 is final pressure of air and k is specific heat ratio of air.

Substitute 13 psia for P_1, 20 psia for P_2 and $\left[30°\text{F} = (460+30)°\text{R}\right]$ for T_1

$$\frac{T_2}{(30+460)} = \left(\frac{20}{13}\right)^{(1.4-1)/1.4}$$

$$\frac{T_2}{490} = 1.1306$$

$$T_{2s} = 553.99\ \text{R}$$

Step 2 of 4

Apply the energy balance for this steady-flow system

Their actual enthalpy drop is

$$c_p(T_1 - T_2) = \eta c_p(T_1 - T_{2s})$$

Step 4 of 4

Substitute enthalpy drop in the energy balance equation,

$$c_p(T_1 - T_2) = \frac{V_2^2 - V_1^2}{2}$$

$$\eta c_p(T_1 - T_{2s}) = \frac{V_2^2 - V_1^2}{2}$$

Here, V_1 is diffuser inlet velocity, V_2 is diffuser exit velocity

Substitute 0.82 for η, 1000 ft/s for V_1

$$0.82(0.24)(490 - 553.99) = \left(\frac{V_2^2 - 1000^2}{2}\right)\frac{\text{ft}^2}{\text{s}^2}\left(\frac{1\ \text{Btu/lbm}}{25037\ \text{ft}^2/\text{s}^2}\right)$$

$$-12.593 \times 25037 = \frac{V_2^2 - 1000^2}{2}$$

$$V_2^2 = 369418.118$$

$$V_2 = 607.79\ \text{ft/s}$$

Therefore, exit velocity of the diffuser is **607.79 ft/s**

Question: 8.136P

Refrigerant-134a is expanded adiabatically from 100 psia and 100°F to a saturated vapor at 10 psia. Determine the entropy generation for this process, in Btu/lbm R.

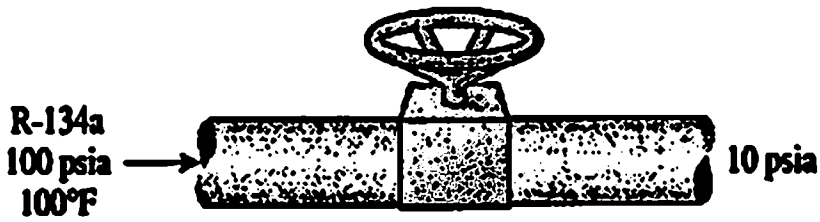

FIGURE P8–136E

Step 1 of 2

Given

Initial pressure in the pipe is, $P_1 = 100$ psia

Initial temperature in the pipe is, $T_1 = 100°F = 559.67$ R

Final pressure in the pipe is, $P_2 = 10$ psia

Step 2 of 2

From superheated R-134a tables at pressure $P_1 = 100$ psia and temperature $T_1 = 100°F$, the superheated entropy is

$s_1 = 0.229$ Btu/lbm.R

At pressure $P_2 = 10$ psia from saturated R-134a tables the entropy of saturated vapor is

$s_2 = s_g = 0.22948$ Btu/lbm.R

By applying entropy balance

$S_{in} - S_{out} + S_{gen} = \Delta S$

Let us assume the process is steady. So, $\Delta S = 0$

$m_1 s_1 - m_2 s_2 + S_{gen} = 0$

$S_{gen} = m_2 s_2 - m_1 s_1$

As there is no flow outside the mass flow rate will be same. $m_2 = m_1$

$S_{gen} = m_1 s_2 - m_1 s_1$

$S_{gen} = m_1 (s_2 - s_1)$

$s_{gen} = s_2 - s_1$

$s_{gen} = 0.22948 - 0.229$

$\boxed{s_{gen} = 0.00048 \text{ Btu/lbm.R}}$

Therefore the entropy generated is 0.00048 Btu/lbm.R .

Question: 8.137P

Oxygen enters an insulated 12-cm-diameter pipe with a velocity of 70 m/s. At the pipe entrance, the oxygen is at 240 kPa and 20°C; and, at the exit, it is at 200 kPa and 18°C. Calculate the rate at which entropy is generated in the pipe.

Step 1 of 4

Given

Diameter of the pipe $D = 12\,\text{cm} = 0.12\,\text{m}$

Velocity at inlet of the pipe $V_1 = 70\,\text{m/s}$

Pressure of O_2 at inlet of the pipe $P_1 = 240\,\text{kPa}$

Temperature of O_2 at inlet $T_1 = 20°\text{C}$

$$= (20 + 273)\,K$$

$$T_1 = 293\,\text{K}$$

Pressure of O_2 at exit of the pipe $P_2 = 200\,\text{kPa}$

Temperature of O_2 at exit of pipe $T_2 = 18°\,\text{C}$

$$= (18 + 273)\,\text{K}$$

$$T_2 = 291\,\text{K}$$

Step 2 of 4

Properties of oxygen are

$R = 0.2598\,\text{kJ/kg K}$

$C_p = 0.918\,\text{kJ/kg K}$

Specific volume of O_2 at inlet

$$v_1 = \frac{RT_1}{P_1}$$

$$v_1 = \frac{(0.2598)\times(293)}{240}$$

$$v_1 = 0.3172\,\text{m}^3/\text{kg}$$

Step 3 of 4

Mass flow rate of oxygen

$$\dot{m} = \frac{A_1 V_1}{v_1}$$

Where area of the pipe

$$A_1 = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.12)^2$$

$$A_1 = 0.0113\,\text{m}^2$$

Then

$$\dot{m} = \frac{A_1 V_1}{v_1}$$

$$= \frac{(0.0113)\times(70)}{(0.3172)}$$

$$\dot{m} = 2.4936\,\text{kg/s}$$

Step 4 of 4

Rate of entropy generation in the pipe

$$\dot{S}_{gen} = \dot{m}(s_2 - s_1)$$

$$\dot{S}_{gen} = \dot{m}\left(C_p \ln\frac{T_2}{T_1} - R\ln\frac{P_2}{P_1}\right)$$

$$= (2.496)\left[0.918\ln\frac{291}{293} - 0.2598\ln\frac{200}{240}\right]$$

$$= 2.496\times 0.041079$$

$$\boxed{\dot{S}_{gen} = 0.10253\,\text{kW/K}}$$

Question: 8.138P

Nitrogen is compressed by an adiabatic compressor from 100 kPa and 25°C to 800 kPa and 307°C. Calculate the entropy generation for this process, in kJ/kg-K.

Step 1 of 3

Given

Inlet pressure to the compressor is, $P_1 = 100\ \text{kPa}$

Inlet temperature to the compressor is, $T_1 = 25°\text{C} = 298\ \text{K}$

Exit pressure to the compressor is, $P_2 = 800\ \text{kPa}$

Exit temperature to the compressor is, $T_2 = 307°\text{C} = 580\ \text{K}$

Step 2 of 3

The average temperature is,

$$T_{av} = \frac{T_1 + T_2}{2}$$

$$T_{av} = \frac{298 + 580}{2}$$

$$T_{av} = \frac{878}{2}$$

$$T_{av} = 439\ \text{K}$$

From ideal gas specific heats of nitrogen at temperature $T_{av} = 439\ \text{K}$,

The specific heat of nitrogen is

$c_p = 1.048\ \text{kJ/kg.K}$

The gas constant of nitrogen is

$R = 0.2968\ \text{kJ/kg.K}$

Step 3 of 3

The entropy balance is given by

$$S_{in} - S_{out} + S_{gen} = \Delta S$$

Let assume the process is steady. So, $\Delta S = 0$

$$m_1 s_1 - m_2 s_2 + S_{gen} = 0$$

$$S_{gen} = m_2 s_2 - m_1 s_1$$

As there is no flow outside the mass flow rate will be same. $m_2 = m_1$

$$S_{gen} = m_1 s_2 - m_1 s_1$$

$$S_{gen} = m_1 (s_2 - s_1)$$

$$s_{gen} = s_2 - s_1$$

$$s_{gen} = c_p \times \ln\left(\frac{T_2}{T_1}\right) - R \times \ln\left(\frac{P_2}{P_1}\right)$$

$$s_{gen} = 1.048 \times \ln\left(\frac{580}{298}\right) - 0.2968 \times \ln\left(\frac{800}{100}\right)$$

$$s_{gen} = 1.048 \times \ln(1.946) - 0.2968 \times \ln(8)$$

$$s_{gen} = 1.048 \times (0.6659) - 0.2968 \times (2.079)$$

$$s_{gen} = 0.6978 - 0.617$$

$$\boxed{s_{gen} = 0.0808\ \text{kJ/kg.K}}$$

Therefore the entropy generation for this process is 0.0808 kJ/kg.K.

Question: 8.139P

Consider a family of four, with each person taking a 5-min shower every morning. The average flow rate through the shower head is 12 L/min. City water at 15°C is heated to 55°C in an electric water heater and tempered to 42°C by cold water at the T-elbow of the shower before being routed to the shower head. Determine the amount of entropy generated by this family per year as a result of taking daily showers.

Step 1 of 5

Members in the family, $n = 4$

Time taking for shower,

Average flow rate through the shower head, $\dot{V} = 12\,\text{L/min}$

Initial temperature f the water, $T_i = 15°\text{C}$

Final temperature of the water, $T_o = 55°\text{C}$

Temperature of the cold water for temper, $T_c = 42°\text{C}$

Step 2 of 5

Calculate the mass flow rate of the water,

$$\dot{m} = \rho\dot{V}$$

Here,

The density of water is ρ

The average flow rate through the shower head is $\dot{V}$

Substitute $12\,\text{L/min}$ for $\dot{V}$ and $1000\,\text{kg/m}^3$ for ρ,

$$\begin{aligned}\dot{m} &= \rho\dot{V}\\ &= 1000\,\text{kg/m}^3 \times 12\,L/\text{min}\\ &= 1000\,\text{kg}/10^3\,\text{L} \times 12\,L/\text{min}\\ &= 12\,\text{kg/min}\end{aligned}$$

Step 3 of 5

From the mass balance equation,

$$\dot{m}_{\text{cold}} + \dot{m}_{\text{hot}} = \dot{m}_{\text{mixed}}$$

The entropy balance equation for the steady floe system,

$$\dot{m}_1 s_1 + \dot{m}_2 s_2 - \dot{m}_3 s_3 + S_{\text{gen}} = 0$$

Therefore,

$$S_{\text{gen}} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2$$

And $s_1 = s_2$

Step 4 of 5

Calculate the entropy generation,

$$\begin{aligned}S_{\text{gen}} &= \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2\\ &= \dot{m}_3 s_3 - (\dot{m}_1 + \dot{m}_2) s_1\\ &= (\dot{m}_1 + \dot{m}_2) s_3 - (\dot{m}_1 + \dot{m}_2) s_1\\ &= (\dot{m}_1 + \dot{m}_2)(s_3 - s_1)\\ &= -\dot{m}_3 c_p \ln\left(\frac{T_C}{T_i}\right)\end{aligned}$$

Here,

The mass flow rate of the water is $\dot{m} = \dot{m}_3$

Initial temperature of the water is T_i

The temperature of the cold water is T_C

The specific heat of the water is c_p

Substitute $12\,\text{kg/min}$ for $\dot{m}_3$, $4.18\,\text{kJ/kg}\cdot\text{K}$ for c_p, $278\,\text{K}$ for T_i and $315\,\text{K}$ for T_C, .

$$\begin{aligned}S_{\text{gen}} &= \dot{m}_3 c_p \ln\left(\frac{T_C}{T_i}\right)\\ &= 12 \times 4.18 \times \ln\left(\frac{315}{288}\right)\\ &= 4.495\,\text{kJ/min}\cdot\text{K}\end{aligned}$$

Step 5 of 5

Now calculate the total amount of entropy generated per year,

$$S_{\text{gen}} = \dot{S}_{\text{gen}}(t) n \times N$$

Here,

The number of members in the family is n

The number of days per year is N

Time taking for shower is t

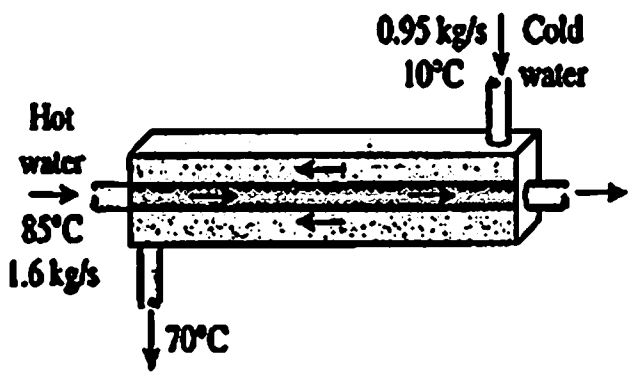
Now substitute $5\,\text{min}$ for t, 4 for n, $365\,\text{days}$ for N and $4.495\,\text{kJ/min}\cdot\text{K}$ for $\dot{S}_{\text{gen}}$,

$$\begin{aligned}S_{\text{gen}} &= \dot{S}_{\text{gen}}(t) n \times N\\ &= 4.495 \times 5 \times 4 \times 365\\ &= 32813.10\ \text{kJ/K/year}\end{aligned}$$

Therefore, the total amount of entropy generated per year is $\boxed{32813.10\ \text{kJ/K/year}}$

Question: 8.140P

Cold water (cp = 4.18 kJ/kg·°C) leading to a shower enters a well-insulated, thin-walled, double-pipe, counter-flow heat exchanger at 10°C at a rate of 0.95 kg/s and is heated to 70°C by hot water (cp = 4.19 kJ/kg·°C) that enters at 85 °C at a rate of 1.6 kg/s. Determine (*a*) the rate of heat transfer and (*b*) the rate of entropy generation in the heat exchanger.



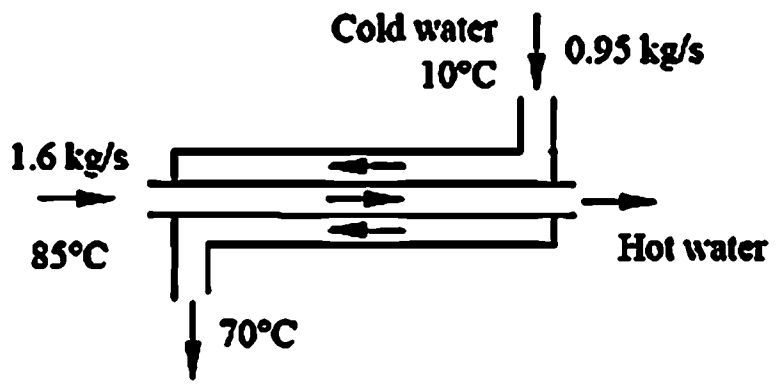


FIGURE P8–140

Step 1 of 5

Draw the double pipe, counter flow heat exchanger of hot water and cold water flowing through pipes as shown below:

Step 2 of 5

(a)

The amount of heat lost from hot water is equal to the amount of heat gained to cold water.

$$\dot{Q}_c = \dot{Q}_h$$

Calculate the amount of heat gained to cold water by using the inlet and exit temperatures of water,

$$\dot{Q}_c = \dot{m}_c \times c_{p,c} \times (T_{c2} - T_{c1})$$

Here, $\dot{m}_c$ is mass flow rate of cold water, $c_{p,c}$ is specific heat of cold water, T_{c2} is exit temperature of cold water and T_{c1} is inlet temperature of cold water.

Substitute 0.95kg/s for $\dot{m}_c$, 4.18kJ/kg·°C for $c_{p,c}$, 70°C for T_{c2} and 10°C for T_{c1}

$$\dot{Q}_c = 0.95 \times 4.18 \times (70 - 10)$$
$$= 238.26\text{kW}$$

Therefore, the rate of heat transfer is $\boxed{238.26\text{ kW}}$

Step 3 of 5

(b)

Find the heat transfer per kg of cold water,

$$q_c = \frac{\dot{Q}_c}{\dot{m}_c}$$
$$= \frac{238.26}{0.95}$$
$$= 250.8\text{kJ/kg}$$

Step 4 of 5

Find the exit temperature of hot water by using the expression,

$$\dot{Q}_h = \dot{m}_h\, c_{p,h} \times (T_{h1} - T_{h2})$$

Here, $\dot{m}_h$ is mass flow rate of hot water, $c_{p,h}$ is specific heat of hot water, T_{h2} is exit temperature of hot water and T_{h1} is inlet temperature of hot water.

Substitute 1.6kg/s for $\dot{m}_h$, 4.19kJ/kg·°C for $c_{p,h}$ and 85°C for T_{h1}

$$238.26 = 1.6 \times 4.19 \times (85 - T_{h2})$$
$$T_{h2} = 49.46°\text{C}$$

Step 5 of 5

Find the entropy generation in the heat exchanger by using the equation,

$$S_{gen} = \dot{m}_c (s_{c2} - s_{c1}) + \dot{m}_h (s_{h2} - s_{h1})$$
$$S_{gen} = \dot{m}_c \times c_{p,c} \times \ln\left(\frac{T_{c2}}{T_{c1}}\right) + \dot{m}_h \times c_{p,h} \times \ln\left(\frac{T_{h2}}{T_{h1}}\right)$$
$$= 0.95 \times 4.18 \times \ln\left(\frac{70+273}{10+273}\right) + 1.6 \times 4.19 \times \ln\left(\frac{49.46+273}{85+273}\right)$$
$$= 0.95 \times 4.18 \times \ln(1.212) + 1.6 \times 4.19 \times \ln(0.9007)$$
$$= 0.95 \times 4.18 \times (0.192) + 1.6 \times 4.19 \times (-0.1045)$$
$$= 0.7624 - 0.7005$$
$$= 0.0619\text{kW/K}$$

Therefore, the entropy generation in the heat exchanger is $\boxed{0.0619\text{ kW/K}}$

Question: 8.141P

Air (*cp* = 1.005 kf/kg·°C) is to be preheated by hot exhaust gases in a cross-flow heat exchanger before it enters the furnace. Air enters the heat exchanger at 95 kPa and 20°C at a rate of 1.6 m3 /s. The combustion gases (*cp* = 1.10 kJ/kg·°C) enter at 180°C at a rate of 2.2 kg/s and leave at 95 °C. Determine (*a*) the rate of heat transfer to the air, (*b*) the outlet temperature of the air, and (*c*) the rate of entropy generation.

Step 1 of 3

(a) Let $\dot{Q}$ be the rate of Heat transfer

Calculate the rate of Heat transfer by using energy balance equation,

$$\dot{Q} = \dot{m}_h \times c_p \times (T_1 - T_2)$$

Here,

The mass flow rate of hot gas is $\dot{m}_h$

The specific heat of gases is c_p

The inlet temperature of hot gas is T_1

The outlet temperature of hot gas is T_2

Substitute $2.2\,\text{kg/s}$ for $\dot{m}_h$, $1.10\ \text{kJ/kg°C}$ for c_p, $453\,\text{K}$ for T_1 and $368\,\text{K}$ for T_2,

$$\begin{aligned}\dot{Q} &= \dot{m}_h \times c_p \times (T_1 - T_2)\\ &= (2.2\times 1.1)\times(180-95)\\ &= 205.7\,\text{kW}\end{aligned}$$

Therefore, the rate of heat transfer is $\boxed{205.7\,\text{kW}}$

Step 2 of 3

b) Let T_{out} be the outlet temperature of the air

Calculate the mass flow rate,

$$P\dot{V} = \dot{m}RT_{in}$$

Here,

The pressure of air is P

The volume flow rate is $\dot{V}$

The temperature of air is T_{in}

Substitute $95\,\text{kPa}$ for P, $1.6\,\text{m}^3/\text{s}$ for $\dot{V}$, $287\,\text{J/kg}\cdot\text{K}$ for R and $293\ \text{K}$ for T_{in},

$$\begin{aligned}P\dot{V} &= \dot{m}RT_{in}\\ (95\times 10^3 \times 1.6) &= \dot{m}(287\times 293)\\ \dot{m} &= 1.808\,\text{kg/s}\end{aligned}$$

Calculate outlet temperature of the air,

Applying for the air

$$\dot{Q} = \dot{m}\times c_p \times (T_{out} - T_{in})$$

Substitute $205.7\,\text{kW}$ for $\dot{Q}$, $1.808\,\text{kg/s}$ for $\dot{m}$ and $20°\text{C}$ for T_{in},

$$\begin{aligned}\dot{Q} &= \dot{m}\times c_p \times (T_{out} - T_{in})\\ 205.7 &= (1.808\times 1.005)\times(T_{out} - 20)\\ (T_{out} - 20) &= 113.21\\ T_{out} &= 133.21°\text{C}\end{aligned}$$

Therefore the outlet temperature of air is $\boxed{133.21°\text{C}}$

Step 3 of 3

c) Let S_{gen} be the entropy generation

Calculate the entropy generation,

$$S_{gen} = \dot{m}_h(s_2 - s_1) + \dot{m}(s_4 - s_3)$$

$$S_{gen} = \dot{m}_h \times c_p \times \ln\left(\frac{T_2}{T_1}\right) + \dot{m}\times c_p \times \ln\left(\frac{T_{out}}{T_{in}}\right)$$

$$S_{gen} = (2.2\times 1.1)\times \ln\left(\frac{368}{453}\right) + (1.808\times 1.005)\times \ln\left(\frac{133.21+273}{293}\right)$$

$$S_{gen} = (-0.503) + 0.594$$

$$S_{gen} = 0.091\,\text{kW/K}$$

Therefore the entropy generation is $\boxed{0.091\,\text{kW/K}}$

Question: 8.142P

A well-insulated, shell-and-tube heat exchanger is used to heat water (cp = 4.18 kJ/kg·°C) in the tubes from 20 to 70°C at a rate of 4.5 kg/s. Heat is supplied by hot oil (cp = 2.30 kJ/kg·°C) that enters the shell side at 170°C at a rate of 10 kg/s. Disregarding any heat loss from the heat exchanger, determine (*a*) the exit temperature of the oil and (*b*) the rate of entropy generation in the heat exchanger.

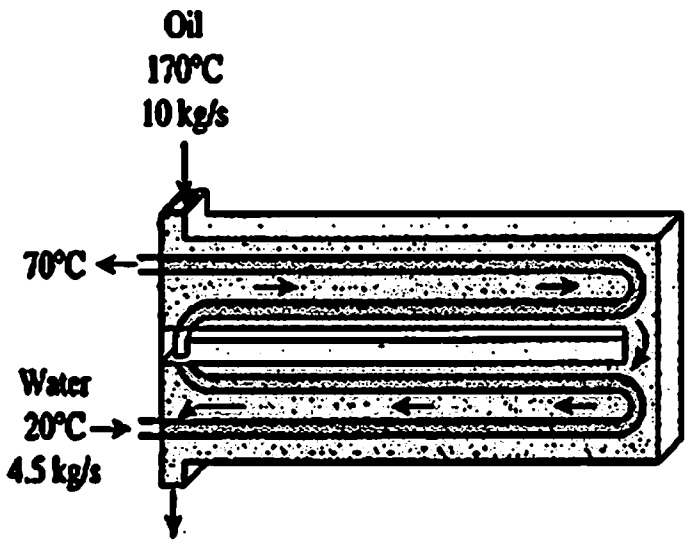

FIGURE P8–142

Step 1 of 3

(a) Let $\dot{Q}$ be the rate of Heat transfer

Calculate the rate of Heat transfer by using energy balance equation,

$$\dot{Q} = \dot{m}_w \times c_p \times (T_1 - T_2)$$

Here,

The mass flow rate of hot gas is $\dot{m}_w$

The specific heat of gases is c_p

The inlet temperature of hot gas is T_{out}

The outlet temperature of hot gas is T_{in}

Substitute $4.5\,\text{kg/s}$ for $\dot{m}_w$, $4.18\ \text{kJ/kg°C}$ for c_p, $70°\text{C}$ for T_{out} and $20°\text{CK}$ for T_{out},

$$\begin{aligned}\dot{Q} &= \dot{m}_w \times c_p \times (T_{out} - T_{in}) \\ &= (4.5 \times 4.18) \times (70 - 20) \\ &= 940.5\,\text{kW}\end{aligned}$$

Therefore, the rate of heat transfer is $\boxed{940.5\,\text{kW}}$

Step 2 of 3

b) Let T_2 be the exit temperature of the oil

Calculate outlet temperature of the air,

Applying for the air

$$\dot{Q} = \dot{m}_{oil} \times c_p \times (T_1 - T_2)$$

Substitute $940.5\,\text{kW}$ for $\dot{Q}$, $10\,\text{kg/s}$ for $\dot{m}_{oil}$ and $170°\text{C}$ for T_1,

$$\begin{aligned}\dot{Q} &= \dot{m}_{oil} \times c_p \times (T_1 - T_2) \\ 940.5 &= (10 \times 2.3) \times (170 - T_2) \\ (170 - T_2) &= 40.89 \\ T_2 &= 129.11°\text{C}\end{aligned}$$

Therefore the exit temperature of air is $\boxed{129.11°\text{C}}$

Step 3 of 3

c) Let S_{gen} be the entropy generation

Calculate the entropy generation,

$$S_{gen} = \dot{m}_w (s_2 - s_1) + \dot{m}_{oil} (s_4 - s_3)$$

$$S_{gen} = \dot{m}_w \times c_p \times \ln\left(\frac{T_{out}}{T_{in}}\right) + \dot{m}_{oil} \times c_p \times \ln\left(\frac{T_2}{T_1}\right)$$

$$S_{gen} = (4.5 \times 4.18) \times \ln\left(\frac{343}{293}\right) + (10 \times 2.3) \times \ln\left(\frac{129.11 + 273}{443}\right)$$

$$S_{gen} = 2.96 + (-2.23)$$

$$S_{gen} = 0.73\,\text{kW/K}$$

Therefore the entropy generation, $\boxed{0.73\,\text{kW/K}}$

Question: 8.143P

Refrigerant-134a is throttled from 1200 kPa and 40°C to 200 kPa. Heat is lost from the refrigerant in the amount of 0.5 kJ/kg to the surroundings at 25°C. Determine (*a*) the exit temperature of the refrigerant and (*b*) the entropy generation during this process.

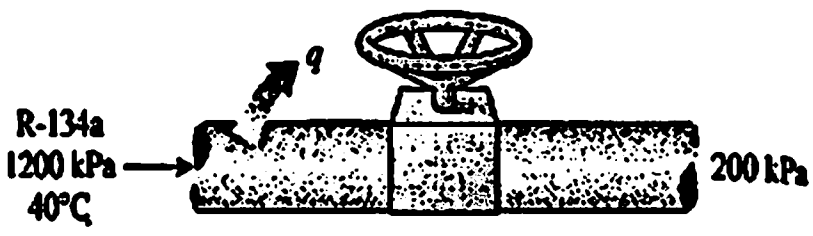

FIGURE P8–143

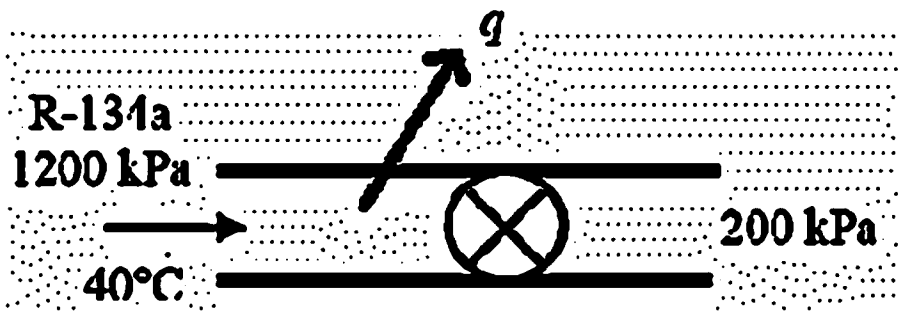
Step 1 of 6

Given data:

Initial pressure is, $P_1 = 1200\ \text{kPa}$

Initial temperature is, $T_1 = 40\ ^\circ\text{C}$

$= 313\ \text{K}$



Final pressure is, $P_2 = 200\ \text{kPa}$

Heat lost by refrigerant is, $q_{out} = 0.5\ \text{kJ/kg}$

Surrounding temperature is, $T_{sur} = 25\ ^\circ\text{C}$

$= 298\ \text{K}$

Step 2 of 6

Step 3 of 6

a) As saturation temperature ($T_{sat} = 46.29\ ^\circ\text{C}$) at pressure $P_1 = 1200\ \text{kPa}$ is greater than initial temperature ($T_1 = 40\ ^\circ\text{C}$), we will consider the properties of saturation liquid condition at temperature ($T_1 = 40\ ^\circ\text{C}$)

From the saturated refrigerant 134a temperature table

At temperature $T_1 = 40\ ^\circ\text{C}$ the properties of saturated liquid R-134a are

$h_1 = 108.26\ \text{kJ/kg}$

$s_1 = 0.39486\ \text{kJ/kg°K}$

Step 4 of 6

As the process is throttling the enthalpy does not change.

$h_2 = h_1 = 108.26\ \text{kJ/kg}$

At pressure $P_2 = 200\ \text{kPa}$ saturation enthalpy is $h_{sat} = 244.46\ \text{kJ/kg}$ ($> h_2$) and so the final temperature is same as the saturation temperature at pressure $P_2 = 200\ \text{kPa}$.

The final temperature is $\boxed{T_2 = T_{sat@200kPa} = -10.09\ ^\circ\text{C}}$

Step 5 of 6

b) As the enthalpy is constant, the final entropy can be calculated by

$s_2 = \frac{h_2}{T_2}$ (Here enthalpy is also considered as its units is same as energy unit)

$s_2 = \frac{108.26}{-10.09+273}$

$s_2 = \frac{108.26}{262.91}$

$s_2 = 0.4118\ \text{kJ/kg°K}$

Step 6 of 6

The entropy generation in the process is given by

$s_{gen} = \Delta s_{ref} + \Delta s_{sur}$

$s_{gen} = s_2 - s_1 + \frac{q_{out}}{T_{sur}}$

$s_{gen} = 0.4118 - 0.39486 + \frac{0.5}{298}$

$s_{gen} = 0.4118 - 0.39486 + 0.00168$

$\boxed{s_{gen} = 0.018618\ \text{kJ/kg°K}}$

Therefore the final temperature is $-10.09\ ^\circ\text{C}$ and the entropy generation is $0.018618\ \text{kJ/kg°K}$

Question: 8.144P

In an ice-making plant, water at 0°C is frozen at 1 atmospheric pressure by evaporating saturated R- 134a liquid at -16°C. The refrigerant leaves this evaporator as a saturated vapor, and the plant is sized to produce ice at 0°C at a rate of 2500 kg/h. Determine the rate of entropy generation in § this plant.

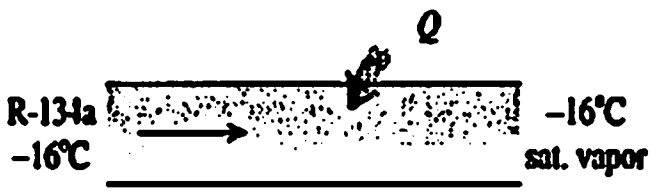


FIGURE P8–144

Step 1 of 3

Given

Inlet and exit temperature of the refrigerant is, $T_1 = T_2 = -16°C = 257\ K$

Temperature of ice is, $T_i = 0°C = 273\ K$

Inlet condition is saturated liquid.

Exit condition is saturated vapor.

Rate of ice produced is, $m_i = 2500\ kg/h = 0.6944\ kg/s$

Step 2 of 3

From saturated R-134a tables at temperature $T_1 = -16°C$

Enthalpy of evaporation is $h_{fg} = 210.18\ kJ/kg$

Entropy of evaporation is $s_{fg} = 0.81729\ kJ/kg°K$

From properties of common liquids, solids table latent heat of fusion of water is $h_f = 333.7\ kJ/kg$

Heat taken out of the plant during freezing (using heat of fusion) is given by

$Q_{out} = m_i \times h_f$

$Q_{out} = 0.69444 \times 333.7$

$Q_{out} = 231.734\ kW$

Mass flow rate of the refrigerant is given by

$$m_R = \frac{Q_{out}}{h_{fg}}$$

$$m_R = \frac{231.734}{210.18}$$

$m_R = 1.1025\ kg/s$

Step 3 of 3

The entropy balance is given by

$S_{in} - S_{out} + S_{gen} = \Delta S$

Let us assume the process is steady. So, $\Delta S = 0$

$$m_1 s_1 - m_2 s_2 + \frac{Q_{out}}{T_i} + S_{gen} = 0$$

$$S_{gen} = m_2 s_2 - m_1 s_1 - \frac{Q_{out}}{T_i}$$

$$S_{gen} = m_R (s_2 - s_1) - \frac{Q_{out}}{T_i}$$

$$S_{gen} = m_R (s_g - s_f) - \frac{Q_{out}}{T_i}$$

$$S_{gen} = m_R \times s_{fg} - \frac{Q_{out}}{T_i}$$

Substituting the known values in the above equation

$$S_{gen} = 1.1025 \times 0.81729 - \frac{231.734}{273}$$

$S_{gen} = 0.90106 - 0.8488$

$\boxed{s_{gen} = 0.05226\ kW/K}$

Therefore the entropy generated is 0.05226 kW/K.

Question: 8.145P

Water at 20 psia and 50° Fenters a mixing chamber at a rate of 300 lbm/min where it is mixed steadily with I steam entering at 20 psia and 240° F.The mixture leaves the chamber at 20 psia and 130°F, and heat is lost to the surrounding air at 70°F at a rate of 180 Btu/min. Neglecting the changes in kinetic and potential energies, determine the rate of entropy generation during this process?

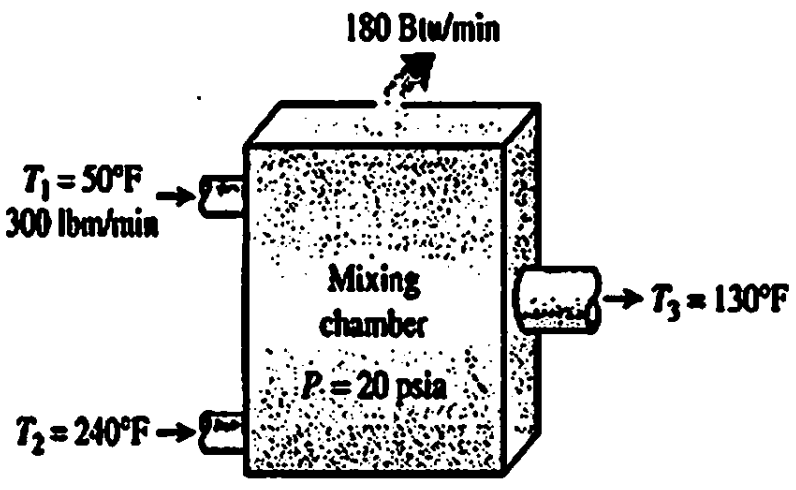

FIGURE P8–145E

Step 1 of 5

Given

Inlet pressure of water is, $P_1 = 20$ psia

Inlet temperature of water is, $T_1 = 50°F$

Mass flow rate of water is, $m_1 = 300$ lbm/min $= 5$ lbm/s

Inlet pressure of steam is, $P_2 = 20$ psia

Inlet temperature of steam is, $T_2 = 240°F$

Exit pressure of mixture is, $P_3 = 20$ psia

Exit temperature of mixture is, $T_3 = 130°F$

Surrounding temperature is, $T_0 = 70°F = 529.67°R$

Rate of heat loss is, $Q_{out} = 180$ Btu/min $= 3$ Btu/s

Step 2 of 5

At $P_1 = 20$ psia from saturated water tables

$T_{sat} = 227.92°F$

The inlet and exit temperatures are less than saturated temperature so we can take the values at saturated liquid condition of that temperature.

From saturated water tables at temperature $T_1 = 50°F$ the enthalpy and entropy of steam are as follows

$h_1 = h_f = 18.07$ Btu/lbm

$s_1 = s_f = 0.03609$ Btu/lbm.R

From saturated water tables at temperature $T_3 = 130°F$, the enthalpy and entropy of steam are as follows

$h_3 = h_f = 97.99$ Btu/lbm

$s_3 = s_f = 0.18174$ Btu/lbm.R

At pressure $P_2 = 20$ psia and temperature $T_2 = 240°F$, the enthalpy and entropy of steam are as follows

$h_2 = 1162.3$ Btu/lbm

$s_2 = 1.7406$ Btu/lbm.R

Step 3 of 5

Applying mass balance

$m_1 + m_2 = m_3$

Applying energy balance

$E_{in} - E_{out} = \Delta E$

As the process is steady, $\Delta E = 0$

$E_{in} - E_{out} = 0$

$E_{in} = E_{out}$

$m_1 h_1 + m_2 h_2 = m_3 h_3 + Q_{out}$

$m_1 h_1 + m_2 h_2 = (m_1 + m_2) h_3 + Q_{out}$

$m_1 h_1 + m_2 h_2 = m_1 h_3 + m_2 h_3 + Q_{out}$

$m_2 h_2 - m_2 h_3 = m_1 h_3 - m_1 h_1 + Q_{out}$

$m_2 (h_2 - h_3) = m_1 (h_3 - h_1) + Q_{out}$

Step 4 of 5

Mass flow rate of steam is given by

$$m_2 = \frac{m_1 (h_3 - h_1) + Q_{out}}{h_2 - h_3}$$

$$m_2 = \frac{5 \times (97.99 - 18.07) + 3}{1162.3 - 97.99}$$

$$m_2 = \frac{5 \times 79.92 + 3}{1064.31}$$

$$m_2 = \frac{399.6 + 3}{1064.31}$$

$$m_2 = \frac{402.6}{1064.31}$$

$m_2 = 0.3783$ lbm/s

Step 5 of 5

The entropy balance is given by

$S_{in} - S_{out} + S_{gen} = \Delta S$

Let us assume the process is steady. So, $\Delta S = 0$

$S_{in} - S_{out} + S_{gen} = 0$

$$m_1 s_1 + m_2 s_2 - m_3 s_3 - \frac{Q_{out}}{T_0} + S_{gen} = 0$$

$$S_{gen} = m_3 s_3 - m_2 s_2 - m_1 s_1 + \frac{Q_{out}}{T_0}$$

$$S_{gen} = (m_1 + m_2) s_3 - m_2 s_2 - m_1 s_1 + \frac{Q_{out}}{T_0}$$

$$S_{gen} = [(5 + 0.3783) \times 0.18174] - [0.3783 \times 1.7406] - [5 \times 0.03609] + \frac{3}{529.67}$$

$$S_{gen} = [5.3783 \times 0.18174] - [0.3783 \times 1.7406] - [5 \times 0.03609] + \frac{3}{529.67}$$

$$S_{gen} = 0.97745 - 0.6585 - 0.18045 + 0.0057$$

$$\boxed{S_{gen} = 0.1442 \text{ Btu/s.R}}$$

Therefore the rate of entropy generation during this process is 0.1442 Btu/s.R .

Question: 8.146P

Steam is to be condensed on the shell side of a heat exchanger at 120°F. Cooling water enters the tubes at 60°F at a rate of 92 lbm/s and leaves at 73° F.Assuming the heat exchanger to be well-insulated, determine (*a*) the rate of heat transfer in the heat exchanger and (*b*) the rate of entropy generation in the heat exchanger.

Step 1 of 3

(a) Let $\dot{Q}$ be the rate of Heat transfer

From the properties of common liquids, solids and foods

Specific heat of water, $c_p = 1.01\ \text{Btu/lbm} \cdot \text{R}$

From the energy balance equation

Calculate the rate of heat transfer

$$\dot{Q} = \dot{m}_w \times c_p \times (T_1 - T_2)$$

Here,

The mass flow rate of hot gas is $\dot{m}_h$

The specific heat of gases is c_p

The inlet temperature of cooling water is T_1

The outlet temperature of cooling water is T_2

Substitute $92\ \text{lbm/s}$ for $\dot{m}_w$, $1.01\ \text{Btu/lbm} \cdot \text{R}$ for c_p, $520°\text{R}$ for T_1 and $533°\text{R}$ for T_2,

$$\begin{aligned}\dot{Q} &= \dot{m}_w \times c_p \times (T_2 - T_1) \\ &= (92 \times 1.01) \times (73 - 60) \\ &= 1207.96\ \text{Btu/s}\end{aligned}$$

Therefore, the rate of heat transfer, $\boxed{1207.96\ \text{Btu/s}}$

Step 2 of 3

b) Let S_{gen} be the outlet temperature of the air

From the properties of saturated water

At $T_{in} = 120°\text{F}$

The enthalpy, $h_{fg} = 1025.2\ \text{Btu/lbm}$

The entropy, $s_{fg} = 1.76856\ \text{Btu/lbm} \cdot \text{R}$

From the energy balance equation

Applying for the air

$$\dot{Q} = \dot{m}_s (h_{fg})$$

$$1207.96 = \dot{m}_s (1025.2)$$

$$\dot{m}_s = 1.178\ \text{lbm/s}$$

Step 3 of 3

Calculate the entropy generation,

$$\begin{aligned}S_{gen} &= \dot{m}_w (s_2 - s_1) + \dot{m}_s (s_4 - s_3) \\ &= \dot{m}_w \times c_p \times \ln\left(\frac{T_2}{T_1}\right) + \dot{m}_s \times (-s_{fg})\end{aligned}$$

Substitute $92\ \text{lbm/s}$ for $\dot{m}_w$, $1.01\ \text{Btu/lbm} \cdot \text{R}$ for c_p, $520°\text{R}$ for T_1, $533°\text{R}$ for T_2 and $1.178\ \text{lbm/s}$ for $\dot{m}_s$,

$$\begin{aligned}S_{gen} &= \dot{m}_w \times c_p \times \ln\left(\frac{T_2}{T_1}\right) + \dot{m}_s \times (-s_{fg}) \\ &= (92 \times 1.01) \times \ln\left(\frac{533}{520}\right) + (1.178)(-1.76856) \\ &= (92 \times 1.01) \times \ln\left(\frac{533}{520}\right) + (1.178)(-1.76856) \\ &= 2.294 + (-2.083) \\ &= 0.211\ \text{Btu/s} \cdot \text{R}\end{aligned}$$

Therefore the entropy generation, $\boxed{0.211\ \text{Btu/s} \cdot \text{R}}$

Question: 8.147P

In a dairy plant, milk at 4°C is pasteurized continuously at 72°C at a rate of 12 L/s for 24 hours a day and 365 days a year. The milk is heated to the pasteurizing temperature by hot water heated in a natural-gas-fired boiler that has an efficiency of 82 percent. The pasteurized milk is then cooled by cold water at 18°C before it is finally refrigerated back to 4°C. To save energy and money, the plant installs a regenerator that has an effectiveness of 82 percent. If the cost of natural gas is $1.04/therm (1 therm = 105,500 kJ), determine how much energy and money the regenerator will save this company per year and the annual reduction in entropy generation.

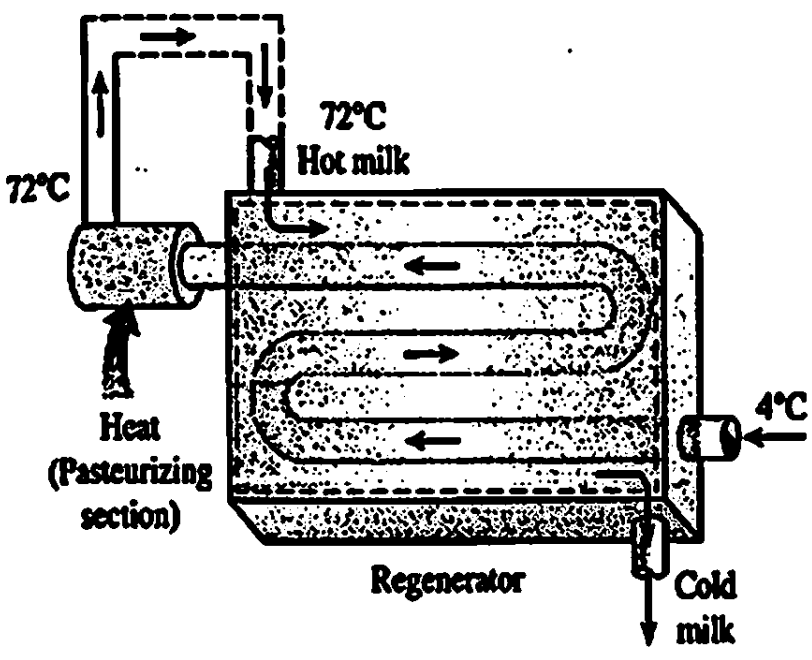

FIGURE P8–147

Step 1 of 4

From the properties of the milk,

Specific heat, $c_p = 3.79\,\text{kJ/kg}\cdot\text{K}$

Consider the density of the milk $\rho = 1\,\text{kg/L}$

Calculate the mass flow rate of the milk,

$$\begin{aligned}\dot{m}_{\text{milk}} &= \rho \dot{V}_{\text{milk}} \\ &= 1\,\text{kg/L} \times 12\,\text{L/sec} \\ &= 12\,\text{kg/sec}\end{aligned}$$

For the pasteurizing section, the energy balance for steady flow system,

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} = 0$$

Therefore,

$$E_{\text{in}} = E_{\text{out}}$$
$$Q_{\text{in}} + \dot{m}h_1 = \dot{m}h_2$$

Calculate the rate of heat transfer,

$$\begin{aligned}Q_{\text{in}} &= \dot{m}(h_2 - h_1) \\ &= \dot{m}c_p(T_2 - T_1) \\ &= 12 \times 3.79 \times (72 - 4) \\ &= 3092.64\,\text{kJ/sec}\end{aligned}$$

Step 2 of 4

Effectiveness of the regenerator, $\varepsilon_{\text{reg}} = 82\%$

Therefore, energy saved,

$$\begin{aligned}\dot{Q}_{\text{saved}} &= \varepsilon \dot{Q}_{\text{in}} \\ &= 0.28 \times 3092.64 \\ &= 2535.965\,\text{kJ/s}\end{aligned}$$

Efficiency of the boiler, $\eta_{\text{eff}} = 82\%$

So, the fuel saving,

$$\begin{aligned}\text{F}_{\text{saved}} &= \frac{\dot{Q}_{\text{saved}}}{\eta_{\text{boiler}}} \\ &= \frac{2535.965}{0.82} \\ &= 3092.64\,\text{kJ/sec} \\ &= \frac{3092.64}{105500} \\ &= 0.02931\,\text{therm/sec}\end{aligned}$$

Step 3 of 4

Annual fuel saved,

$$\begin{aligned}\text{F}_{\text{annual saved}} &= 0.02931 \times (24 \times 3600) \times 365 \\ &= 924450.19\,\text{therm/year}\end{aligned}$$

Therefore, the fuel saved due to the regenerator per year is $\boxed{924450.19\,\text{therm/year}}$

Annual money saved,

$$\begin{aligned}\text{m}_{\text{annual saved}} &= F_{\text{annual saved}} \times C \\ &= 924450.19 \times 1.04 \\ &= \$961400/\text{yr}\end{aligned}$$

Therefore, the money saved due to the regenerator per year is $\boxed{\$961400/\text{yr}}$

Step 4 of 4

From the rate form of the entropy balance on an extended system,

$$\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} = \Delta \dot{S}_{\text{system}} = 0$$
$$\dot{S}_{\text{gen}} = \dot{S}_{\text{out}} - \dot{S}_{\text{in}}$$

So,

The reduction in the entropy transfer to water,

$$\begin{aligned}\dot{S}_{\text{gen,reduction}} &= \frac{\dot{Q}_{\text{out}}}{T_{\text{sp}}} \\ &= \frac{\dot{Q}_{\text{saved}}}{T_{\text{sp}}} \\ &= \frac{2536}{18 + 273} \\ &= 8.714\,\text{kW/K}\end{aligned}$$

So, reduction in the entropy transfer to water in a year,

$$\begin{aligned}\dot{S}_{\text{gen,reduction}} &= 8.714\,\text{kW/K} \times (24 \times 3600) \times 365 \\ &= 2.74 \times 10^5\,\text{kW/K/year}\end{aligned}$$

Therefore, the annual reduction is $\boxed{2.74 \times 10^5\,\text{kW/K/year}}$

Question: 8.148P

Stainless-steel ball bearings (ρ = 8085 kg/m3 and cp = 0.480 kJ/kg·°C) having a diameter of 1.8 cm are to be quenched in water at a rate of 1100 per minute. The balls leave the oven at a uniform temperature of 900°C and are exposed to air at 20°C for a while before they are dropped into the water. If the temperature of the balls drops to 850°C prior to quenching, determine (*a*) the rate of heat transfer from the balls to the air and (*b*) the rate of entropy generation due to heat loss from the balls to the air.

Step 1 of 7

Given

Diameter of each ball is, $D = 1.8\ \text{cm}$
$= 0.018\ \text{m}$

No. of balls quenched is, $n_{ball} = 1100\ \text{balls/min}$

Initial temperature of balls is, $T_1 = 900\ ^\circ\text{C}$
$= 1173\ \text{K}$

Final temperature of balls is, $T_2 = 850\ ^\circ\text{C}$
$= 1123\ \text{K}$

Surrounding temperature is, $T_{surr} = 20\ ^\circ\text{C}$
$= 293\ \text{K}$

Density of stainless-steel is, $\rho = 8085\ \text{kg/m}^3$

Specific heat of stainless-steel is, $c_p = 0.48\ \text{kJ/kg°K}$

Step 2 of 7

Mass of balls is given by

$$m = \rho \times V$$

$$m = \rho \times \frac{\pi D^3}{6}$$

$$m = 8085 \times \frac{\pi (0.018)^3}{6}$$

$$m = 8085 \times \frac{3.14 \times 5.832 \times 10^{-6}}{6}$$

$$m = 0.0247\ \text{kg}$$

Step 3 of 7

The of heat transfer per ball is given by

$$Q_{out/ball} = m c_p (T_1 - T_2)$$

$$Q_{out/ball} = 0.0247 \times 0.48 \times (1173 - 1123)$$

$$Q_{out/ball} = 0.0247 \times 0.48 \times 50$$

$$Q_{out/ball} = 0.5928\ \text{kJ}$$

Step 4 of 7

Total heat transfer is given by

$$Q_{out} = Q_{out/ball} \times n_{ball}$$

$$Q_{out} = 0.5928 \times 1100$$

$$\boxed{Q_{out} = 652.08\ \text{kJ/min} = 10.868\ \text{kW}}$$

Step 5 of 7

Entropy change in system is given by

$$\Delta s_{sys} = m \times c_p \times \ln\left(\frac{T_2}{T_1}\right)$$

$$\Delta s_{sys} = 0.0247 \times 0.48 \times \ln\left(\frac{1123}{1173}\right)$$

$$\Delta s_{sys} = 0.0247 \times 0.48 \times \ln(0.9574)$$

$$\Delta s_{sys} = 0.0247 \times 0.48 \times (-0.0435)$$

$$\Delta s_{sys} = -0.00051574\ \text{kJ/K}$$

Step 6 of 7

The entropy generation per ball is given by

$$\delta_{gen/ball} = \frac{Q_{out/ball}}{T_{surr}} + \Delta s_{sys}$$

$$\delta_{gen/ball} = \frac{0.5928}{293} + (-0.00051574)$$

$$\delta_{gen/ball} = 0.002023 - 0.00051574$$

$$\delta_{gen/ball} = 0.00151\ \text{kJ/K}$$

Step 7 of 7

The entropy generation is given by

$$\delta_{gen} = \delta_{gen/ball} \times n_{ball}$$

$$\delta_{gen} = 0.00151 \times 1100$$

$$\boxed{s_{gen} = 1.661\ \text{kJ/min.K} = 0.0277\ \text{kW/K}}$$

The rate of heat transfer from balls to air is 10.868 kW and the entropy generated is 0.0277 kW/K

Question: 8.149P

An ordinary egg can be approximated as a 5.5-cm-diameter sphere. The egg is initially at a uniform temperature of 8°C and is dropped into boiling water at 97°C. Taking the properties of the egg to be ρ = 1020 kg/m3 and cp = 3.32 kJ/kg·°C, determine (*a*) how much heat is transferred to the egg by the time the average temperature of the egg rises to 70°C and (*b*) the amount of entropy generation associated with this heat transfer process.

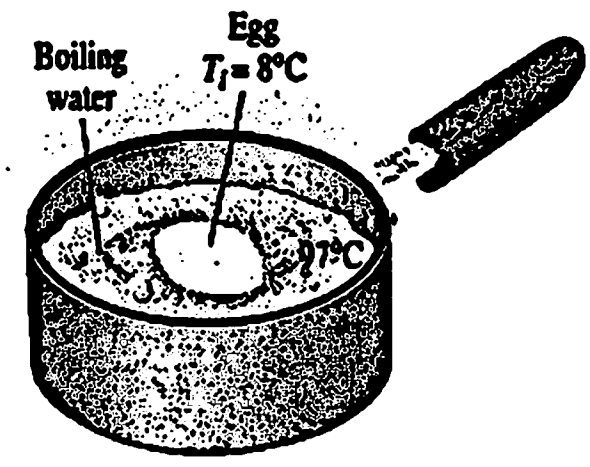

FIGURE P8–149

Step 1 of 4

Given data:

The diameter of egg, $d = 5.5\text{cm}$

The initial temperature of egg, $T_1 = 8°\text{C}$

$= 281\text{K}$

The temperature of boiled water, $T_2 = 97°\text{C}$

$= 370\text{K}$

The density of egg, $\rho = 1020\text{kg/m}^3$

The specific heat of egg, $c_p = 3.32\ \text{kJ/kg°C}$

Step 2 of 4

(a) The average temperature of egg, $T_{avg} = 70°\text{C}$

Let $\dot{Q}$ be the rate of Heat transfer

By using the relation

$m = \rho v$

$$m = \left(1020 \times \frac{\pi d^3}{6}\right)$$

$$m = \left\{1020 \times \frac{\pi \times \left(5.5 \times 10^{-2}\right)^3}{6}\right\}$$

$m = 0.08886\text{kg}$

Step 3 of 4

From the energy balance equation

Applying for the egg

$$Q = m \times c_p \times \left(T_{avg} - T_1\right)$$

$$= (0.08886 \times 3.32) \times (70 - 8)$$

$$= 18.29\text{kJ}$$

Therefore, the heat transfer, $\boxed{Q = 18.29\text{kJ}}$

Step 4 of 4

b) Let S_{gen} be the outlet temperature of the air

Now from the entropy balance equation

$$S_{gen} = (mS_2 - mS_1) - \frac{Q}{T_2}$$

$$S_{gen} = mc_p \ln\left(\frac{T_{avg}}{T_1}\right) - \frac{Q}{T_2}$$

$$S_{gen} = (0.08886 \times 3.32) \ln\left(\frac{70+273}{281}\right) - \left(\frac{18.29}{370}\right)$$

$$S_{gen} = 0.0588 - 0.04945$$

$$\boxed{S_{gen} = 0.00935\text{kJ/K}}$$

Therefore the entropy generation, $S_{gen} = 0.00935\text{kJ/K}$

Question: 8.150P

Long cylindrical steel rods (ρ = 7833 kg/m3 and cp = 0.465 kJ/kg·°C) of 10-cm diameter are heat treated by drawing them at a velocity of 3 m/min through a 7-m-long oven maintained at 900°C. If the rods enter the oven at 30°C and leave at 700°C, determine (*a*) the rate of heat transfer to the rods in the oven and (*b*) the rate of entropy generation associated with this heat transfer process.

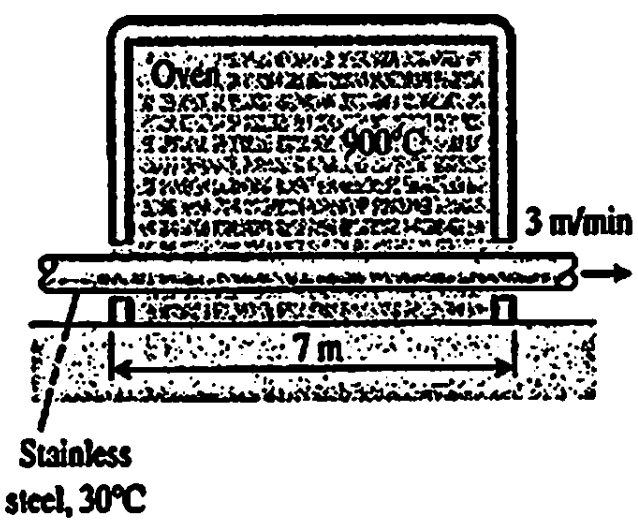

FIGURE P8–150

Step 1 of 4

(a)

Find the volume of the rod using the following equation:

$$V = L\left(\frac{\pi D^2}{4}\right)$$

Here, D is the diameter of the rod and L is the length of the rod.

The rod enters and exits the oven with the same velocity. A 3 m long section is heated in 1 minute.

Substitute $0.1\ \text{m}$ for D and $3\ \text{m}$ for L.

$$V = (3)\left(\frac{\pi(0.1)^2}{4}\right)$$
$$= 0.02356\,\text{m}^3$$

Find the mass of the steel rod (m) using the following equation

$$m = \rho V$$

Here density of the steel rod is ρ

Substitute $0.02356\ \text{m}^3$ for V and $7833\ \text{kg/m}^3$ for ρ.

$$m = \left(7833\ \text{kg/m}^3\right) \times \left(0.02356\ \text{m}^3\right)$$
$$= 184.5455\ \text{kg}$$

Step 2 of 4

Find the heat transfer to the rod in oven.

$$Q_{\text{in}} = \Delta U$$
$$= mc_p(T_2 - T_1)$$

..... (1)

Here, c_p specific heat of steel rod, T_1 is the initial temperature and T_2 is the leaving temperature of the oven.

Substitute $184.5455\ \text{kg}$ for m, $0.465\ \text{kJ/kg°C}$ for c_p, $700°\text{C}$ for T_2, and $30°\text{C}$ for T_1.

$$Q_{\text{in}} = (184.5455\ \text{kg})(0.465\ \text{kJ/kg°C})(700-30)°\text{C}$$
$$= 57495.144\ \text{kJ}$$

Find the rate of heat transfer to the rod in oven.

$$\dot{Q}_{\text{in}} = \frac{Q_{\text{in}}}{t}$$

Here, t is the time.

Substitute $57495.144\ \text{kJ}$ for Q_{in} and 1 min for t.

$$\dot{Q}_{\text{in}} = \frac{57495.144\,\text{kJ}}{1\,\text{min} \times 60\,\frac{\text{s}}{\text{min}}}$$
$$= 958.25\,\text{kJ/s}$$
$$= 958.25\,\text{kW}$$

Therefore, the rate of heat transferred to the rod is $\boxed{958.25\ \text{kW}}$.

Step 3 of 4

(b)

Find the change in net entropy transfer using the following equation:

$$(S_{\text{in}} - S_{\text{out}}) = \frac{Q_{\text{in}}}{T_b}$$

Here, T_b is the temperature of the oven.

Substitute $57495.144\ \text{kJ}$ for Q_{in} and $900°\text{C}$ for T_b.

$$(S_{\text{in}} - S_{\text{out}}) = \frac{57495.144\ \text{kJ}}{(900°\text{C}+273)\,\frac{\text{K}}{°\text{C}}}$$
$$= 49.0155\,\text{kJ/K}$$

Find the entropy change in the system using the following equation:

$$\Delta S_{\text{system}} = mc_p \ln\frac{T_2}{T_1}$$

Substitute $184.5455\ \text{kg}$ for m, $0.465\ \text{kJ/kg°C}$ for c_p, $700°\text{C}$ for T_2, and $30°\text{C}$ for T_1.

$$\Delta S_{\text{system}} = (184.5455)(0.465)\ln\left(\frac{700+273}{30+273}\right)$$
$$= 100.115\,\text{kJ/K}$$

Step 4 of 4

Find the generated entropy change using the entropy balance equation.

$$S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$$
$$S_{\text{gen}} = -(S_{\text{in}} - S_{\text{out}}) + \Delta S_{\text{system}}$$

Substitute $49.0155\,\text{kJ/K}$ for $(S_{\text{in}} - S_{\text{out}})$ and $100.115\,\text{kJ/K}$ for ΔS_{system}.

$$S_{\text{gen}} = -49.0155 + 100.115$$
$$= 51.0995\,\text{kJ/K}$$

Find the rate of entropy generation.

$$\dot{s}_{\text{gen}} = \frac{S_{\text{gen}}}{t}$$

Substitute $51.0995\,\text{kJ/K}$ for Q_{in} and 1 min for t.

$$\dot{s}_{\text{gen}} = \frac{51.0995\,\text{kJ/K}}{1\,\text{min} \times 60\,\frac{\text{s}}{\text{min}}}$$
$$= 0.8517\,\text{kW/K}$$

Therefore, the rate of entropy generation is $\boxed{0.8517\ \text{kW/K}}$.

Question: 8.151P

The inner and outer surfaces of a 3-m × 8-m brick wall of thickness 20 cm are maintained at temperatures of 20°C and 2°C, respectively. If the rate of heat transfer through the wall is 1550 W, determine the rate of entropy generation within the wall.

Step 1 of 2

Given data:

Temperature on leading side of wall is, $T_1 = 20°C = 293\ K$.

Temperature on lagging side of wall is, $T_2 = 2°C = 275\ K$.

Heat transfer through the wall is, $Q = 1550\ W$.

Step 2 of 2

The entropy balance is given by

$$S_{in} - S_{out} + S_{gen} = \Delta S$$

Let assume the process is steady. So, $\Delta S = 0$

$$S_{in} - S_{out} + S_{gen} = 0$$

$$\frac{Q_1}{T_1} - \frac{Q_2}{T_2} + S_{gen} = 0$$

As all the heat taken by wall is transferred to the other side, $Q_1 = Q_2 = Q$

$$\frac{Q}{T_1} - \frac{Q}{T_2} + S_{gen} = 0$$

$$S_{gen} = \frac{Q}{T_2} - \frac{Q}{T_1}$$

$$= \frac{1550}{275} - \frac{1550}{293}$$

$$= 5.636 - 5.29$$

$$= 0.346\ W/K$$

Therefore the entropy generated is $\boxed{s_{gen} = 0.346\ W/K}$.

Question: 8.152P

For heat transfer purposes, a standing man can be modeled as a 30-cm-diameter, 170-cm-long vertical cylinder with both the top and bottom surfaces insulated and with the side surface at an average temperature of 34°C. If the rate of heat loss from this man to the environment at 20°C is 336 W, determine the rate of entropy transfer from the body of this person accompanying heat transfer, in W/K.

Step 1 of 2

Given data

Rate of heat loss from man to environment $Q = 336\,\text{W}$

Surface temperature of the man $T = 34^\circ\text{C}$

$$= (34 + 273)\,\text{K}$$

$$T = 307\,\text{K}$$

Step 2 of 2

Rate of entropy transfer from the body of the man accompanying heat transfer is

$$\dot{S} = \frac{Q}{T}$$

$$= \frac{336}{307}$$

$$\dot{S} = 1.0944\,\text{W/K}$$

$$\boxed{\dot{S} = 1.0944\,\text{W/K}}$$

Question: 8.153P

A 1000-W iron is left on the ironing board with its base exposed to the air at 20°C. If the surface temperature is 400°C, determine the rate of entropy generation during this process in steady operation. How much of this entropy generation occurs within the iron?

Step 1 of 3

Given

Heating capacity of iron box $\dot{Q} = 1000\,\text{W}$

Temperature of air $T_{air} = 20°\text{C}$

$= (20+273)\,\text{K}$

$T_{air} = 293\,\text{K}$

Surface temperature of the iron box $T_{iron} = 400°\text{C}$

$= (400+273)\,\text{K}$

$T_{iron} = 673\,\text{K}$

Step 2 of 3

From the entropy balance on the system,

The rate of total entropy generation during this process in steady operation

$$\dot{S}_{gen,total} = \frac{\dot{Q}}{T_{air}}$$

$$= \frac{1000}{293}$$

$$= 3.413\,\text{W/K}$$

$$\boxed{\dot{S}_{gen,total} = 3.413\,\text{W/K}}$$

Step 3 of 3

Rate of entropy generation within the iron

$$\dot{S}_{gen,iron} = \frac{\dot{Q}}{T_{iron}}$$

$$= \frac{1000}{673}$$

$$= 1.486\,\text{W/K}$$

$$\boxed{\dot{S}_{gen,iron} = 1.486\,\text{W/K}}$$

Question: 8.154P

A frictionless piston-cylinder device contains saturated liquid water at 40-psia pressure. Now 600 Btu of heat is transferred to water from a source at 1000°F, and part of the liquid vaporizes at constant pressure. Determine the total entropy generated during this process, in Btu/R.

Step 1 of 5

Given data:

Initial pressure in the device, $P_1 = 40$ psia.

Temperature of source is, $T_{src} = 1000\ ^\circ F = 1459.67$ R.

Heat transfer to the device is, $Q = 600$ Btu.

Step 2 of 5

From the saturated water pressure table,

At pressure $P_1 = 40$ psia

the saturated temperature is

$T_{sat} = T_{dev} = 267.22\ ^\circ F$

$= 726.89$ R

Heat is transferred to the device from the source. So the heat transfer will take as positive in case of device and negative in case of source. Therefore

$Q_{dev} = 600$ Btu And

$Q_{src} = -600$ Btu

Step 3 of 5

The entropy change in the device is given by

$$\Delta S_{dev} = \frac{Q_{dev}}{T_{dev}}$$

$$= \frac{600}{726.89}$$

$$= 0.8254 \text{ Btu/R}$$

Step 4 of 5

The entropy change in the source is given by

$$\Delta S_{src} = \frac{Q_{src}}{T_{src}}$$

$$= \frac{-600}{1459.67}$$

$$= -0.411 \text{ Btu/R}$$

$T_{sat} = T_{dev} = 267.22\ ^\circ F$

$= 726.89$ R

Heat is transferred to the device from the source. So the heat transfer will take as positive in case of device and negative in case of source. Therefore

$Q_{dev} = 600$ Btu And

$Q_{src} = -600$ Btu

Step 3 of 5

The entropy change in the device is given by

$$\Delta S_{dev} = \frac{Q_{dev}}{T_{dev}}$$

$$= \frac{600}{726.89}$$

$$= 0.8254 \text{ Btu/R}$$

Question: 8.155P

Steam enters a diffuser at 20 psia and 240°F with a velocity of 900 ft/s and exits as saturated vapor at 240°F and 100 ft/s. The exit area of the diffuser is 1 ft2 . Determine (*a*) the mass flow rate of the steam and (*b*) the rate of entropy generation during this process. Assume an ambient temperature of 77°F.

Step 1 of 4

Obtain the values for the following:

The pressure at the entrance P_1 of the diffuser is $20\,\text{psia}$.

The temperature at the entrance T_1 of the diffuser is $240°\text{F}$.

From the properties table of super-heated water-temperature table the value for the above points is follows.

For the pressure P_1 and the temperature T_1;

The enthalpy at the entrance of the diffuser h_1 is $1162.3\,\text{Btu/lbm}$.

The entropy at the entrance of the diffuser s_1 is $1.7406\,\text{Btu/lbm}\cdot\text{R}$.

From the properties of saturated water tables,

At $T_2 = 240°\text{F}$;

The enthalpy at the exit h_2 of the diffuser is $1160.5\,\text{Btu/lbm}$.

The entropy at the exit of the diffuser s_2 is $1.7141\,\text{Btu/lbm}\cdot\text{R}$.

The specific volume v_2 at the exit is $16.316\,\text{ft}^3/\text{lbm}$.

Step 2 of 4

a)

Calculate the mass flow rate of the steam through the diffuser:

$$\dot{m} = \frac{A_2 V_2}{v_2}$$

Here, A_2 is the exit area, V_2 is the exit velocity of the steam and v_2 is the specific volume.

Substitute $1\,\text{ft}^2$ for A_2, $100\,\text{ft/sec}$ for V_2 and $16.316\,\text{ft}^3/\text{lbm}$ for v_2.

$$= \frac{1\times 100}{16.316}$$
$$= 6.1289\,\text{lbm/sec}$$

Therefore, mass flow rate $\dot{m}$ of the steam through the diffuser, $\boxed{6.1289\,\text{lbm/sec}}$

Step 3 of 4

b)

Calculate the heat transfer at the outlet:

From the entropy balance equation on an extended system,

$$S_{in} - S_{out} + S_{gen} = \Delta S_{system}$$
$$= 0$$

Hence the above equation becomes as follows.

$$\dot{m}s_1 - \dot{m}s_2 - \frac{\dot{Q}_{out}}{T_\infty} + \dot{S}_{gen} = 0$$

From the energy balance equation for the steady flow,

$$E_{in} - E_{out} = \Delta E_{system} = 0$$

Therefore, $E_{in} = E_{out}$

$$\dot{m}\left(h_1 + \frac{V_1^2}{2}\right) - \dot{Q}_{out} = \dot{m}\left(h_2 + \frac{V_2^2}{2}\right)$$

$= 6.1289\,\text{lbm/sec}$

Therefore, mass flow rate $\dot{m}$ of the steam through the diffuser, $\boxed{6.1289\,\text{lbm/sec}}$

Step 3 of 4

b)

Calculate the heat transfer at the outlet:

From the entropy balance equation on an extended system,

$$S_{in} - S_{out} + S_{gen} = \Delta S_{system}$$
$$= 0$$

Hence the above equation becomes as follows.

$$\dot{m}s_1 - \dot{m}s_2 - \frac{\dot{Q}_{out}}{T_\infty} + \dot{S}_{gen} = 0$$

From the energy balance equation for the steady flow,

$$E_{in} - E_{out} = \Delta E_{system} = 0$$

Therefore, $E_{in} = E_{out}$

$$\dot{m}\left(h_1 + \frac{V_1^2}{2}\right) - \dot{Q}_{out} = \dot{m}\left(h_2 + \frac{V_2^2}{2}\right)$$

$$= (6.1289)\left(\text{lbm/sec}\right)\left[(1162.3 - 1160.5)\left(\text{Btu/lbm}\right) + \left(\frac{900^2}{2} - \frac{100^2}{2}\right)\left(\frac{1}{25037}\right)\left(\text{Btu/lbm}\right)\right]$$
$$= 6.1289\left(\text{lbm/sec}\right)\left[(1.8 + 15.976)\left(\text{Btu/lbm}\right)\right]$$
$$= 108.94\,\text{Btu/sec}$$

Calculate the rate of entropy generation during the process:

$$\dot{m}s_1 - \dot{m}s_2 - \frac{\dot{Q}_{out}}{T_\infty} + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{m}(s_2 - s_1) + \frac{\dot{Q}_{out}}{T_\infty}$$

Here, $\dot{S}_{gen}$ is the rate of entropy generation is the mass flow rate $\dot{m}$, s_2 is the entropy at the inlet, s_1 is the entropy at the outlet, $\dot{Q}_{out}$ is the heat transfer at the outlet and T_∞ is the total temperature.

Substitute $6.1289\,\text{lbm/sec}$ for $\dot{m}$, $1.7406\,\text{Btu/lbm}\cdot\text{R}$ for s_1, $1.7141\,\text{Btu/lbm}\cdot\text{R}$ for s_2 and $108.94\,\text{Btu/sec}$ for $\dot{Q}_{out}$.

$$= 6.1289(1.7141 - 1.7406) + \frac{108.95}{77 + 460}$$
$$= 0.0404\,\text{Btu/sec}\cdot\text{R}$$

Therefore, the rate of entropy generation $\dot{S}_{gen}$ during the process is $\boxed{0.0404\,\text{Btu/sec}\cdot\text{R}}$.

$$= (6.1289)\left(\text{lbm/sec}\right)\left[(1162.3 - 1160.5)\left(\text{Btu/lbm}\right) + \left(\frac{900^2}{2} - \frac{100^2}{2}\right)\left(\frac{1}{25037}\right)\left(\text{Btu/lbm}\right)\right]$$
$$= 6.1289\left(\text{lbm/sec}\right)\left[(1.8 + 15.976)\left(\text{Btu/lbm}\right)\right]$$

Question: 8.156P

Steam enters an adiabatic nozzle at 2.5 MPa and 450°C with a velocity of 55 m/s and exits at 1 MPa and 390 m/s. If the nozzle has an inlet area of 6 cm2 , determine (*a*) the exit temperature and (*b*) the rate of entropy generation for this process.

Step 1 of 5

Given data:

Pressure at nozzle inlet is, $P_1 = 2.5\ \text{MPa}$

$= 2500\ \text{kPa}$

Temperature at nozzle inlet is, $T_1 = 450°\text{C}$

$= 723\ \text{K}$

Velocity at nozzle inlet is, $C_1 = 55\ \text{m/s}$

Pressure at nozzle exit is, $P_2 = 1\ \text{MPa}$

$= 1000\ \text{kPa}$

Velocity at nozzle exit is, $C_2 = 390\ \text{m/s}$

Area at nozzle inlet is, $A_1 = 6\ \text{cm}^2$

Question:

Steam enters an adiabatic nozzle at 2.5 MPa and 450°C with a velocity of 55 m/s and exits at 1 MPa and 390 m/s. If the nozzle has an inlet area of 6 cm2 , determine (*a*) the exit temperature and (*b*) the rate of entropy generation for this process.

Step 1 of 5

Given data:

Pressure at nozzle inlet is, $P_1 = 2.5\ \text{MPa}$

$= 2500\ \text{kPa}$

Temperature at nozzle inlet is, $T_1 = 450°\text{C}$

$= 723\ \text{K}$

Velocity at nozzle inlet is, $C_1 = 55\ \text{m/s}$

Pressure at nozzle exit is, $P_2 = 1\ \text{MPa}$

$= 1000\ \text{kPa}$

Velocity at nozzle exit is, $C_2 = 390\ \text{m/s}$

Area at nozzle inlet is, $A_1 = 6\ \text{cm}^2$

For converting m^2/s^2 to kJ/kg we have to divide by 1000. So,

$$h_2 = h_1 + \left(\frac{C_1^2 - C_2^2}{2000}\right)$$

$$h_2 = 3351.6 + \left(\frac{55^2 - 390^2}{2000}\right)$$

$$h_2 = 3351.6 + \left(\frac{3025 - 152100}{2000}\right)$$

$$h_2 = 3351.6 + \left(\frac{-149075}{2000}\right)$$

$$h_2 = 3351.6 - 74.538$$

$$h_2 = 3277.062\ \text{kJ/kg}$$

Step 3 of 5

a) From properties of superheated steam

At pressure $P_2 = 1\ \text{MPa}$

Final temperature is interpolated as

$$\left(\frac{T_2 - 400}{500 - 400}\right) = \left(\frac{3277.062 - 3264.5}{3479.1 - 3264.5}\right)$$

$$\left(\frac{T_2 - 400}{100}\right) = \left(\frac{12.562}{214.6}\right)$$

$$\left(\frac{T_2 - 400}{100}\right) = 0.0585$$

$$T_2 = (0.0585 \times 100) + 400$$

$$T_2 = 5.85 + 400$$

$$\boxed{T_2 = 405.85°\text{C}}$$

Therefore, the final temperature, $T_2 = 405.85°\text{C}$

Step 4 of 5

b) From properties of superheated steam

At pressure $P_2 = 1\ \text{MPa}$

Final entropy is interpolated as

$$\left(\frac{s_2 - 7.4670}{7.7642 - 7.4670}\right) = \left(\frac{3277.062 - 3264.5}{3479.1 - 3264.5}\right)$$

$$\left(\frac{s_2 - 7.4670}{0.2972}\right) = \left(\frac{12.562}{214.6}\right)$$

$$\left(\frac{s_2 - 7.4670}{0.2972}\right) = 0.0585$$

$$s_2 = (0.0585 \times 0.2972) + 7.4670$$

$$s_2 = 0.0174 + 7.4670$$

$$s_2 = 7.4844\ \text{kJ/kg} \cdot \text{K}$$

$$\left(\frac{T_2 - 400}{100}\right) = 0.0585$$

$$T_2 = (0.0585 \times 100) + 400$$

$$T_2 = 5.85 + 400$$

$$\boxed{T_2 = 405.85°\text{C}}$$

Therefore, the final temperature, $T_2 = 405.85°\text{C}$

Step 4 of 5

b) From properties of superheated steam

At pressure $P_2 = 1\ \text{MPa}$

Final entropy is interpolated as

$$\left(\frac{s_2 - 7.4670}{7.7642 - 7.4670}\right) = \left(\frac{3277.062 - 3264.5}{3479.1 - 3264.5}\right)$$

$$\left(\frac{s_2 - 7.4670}{0.2972}\right) = \left(\frac{12.562}{214.6}\right)$$

$$\left(\frac{s_2 - 7.4670}{0.2972}\right) = 0.0585$$

$$s_2 = (0.0585 \times 0.2972) + 7.4670$$

$$s_2 = 0.0174 + 7.4670$$

$$s_2 = 7.4844\ \text{kJ/kg} \cdot \text{K}$$

Question: 8.157P

Steam expands in a turbine steadily at a rate of 40,000 kg/h, entering at 8 MPa and 500°C and leaving at 40 kPa as saturated vapor. If the power generated by the turbine is 8.2 MW, determine the rate of entropy generation for this process. Assume the surrounding medium is at 25°C.

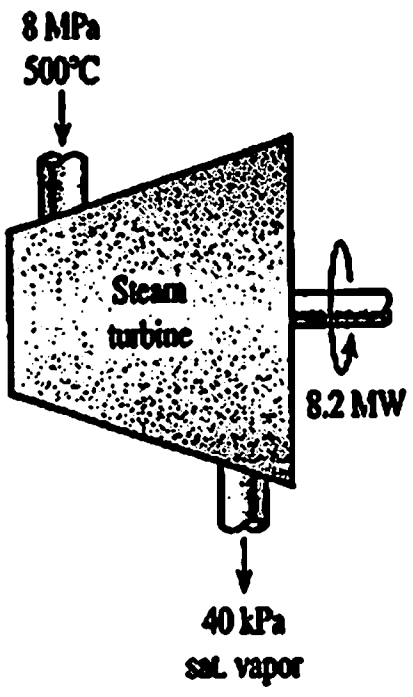

FIGURE P8–157

Step 1 of 5

Given data:

Mass flow rate is

$m = 40{,}000\ kg/h$

$= 40{,}000\ kg/h \times 3600 h/s$

$= 11.11\ kg/s$

Inlet pressure to the turbine is, $P_1 = 8\ MPa = 8000\ kPa$.

Inlet temperature to the turbine is, $T_1 = 500\ °C = 773\ K$.

Exit pressure to the turbine is, $P_2 = 40\ kPa$.

Surrounding temperature is, $T_0 = 25\ °C = 298\ K$.

Power produced by the turbine is, $W_{out} = 8.2\ MW = 8200\ kW$.

Step 2 of 5

From the superheated water

At pressure $P_1 = 8\ MPa$ and temperature $T_1 = 500\ °C$,

the enthalpy and entropy respectively are

$h_1 = 3399.5\ kJ/kg$

$s_1 = 6.7266\ kJ/kg \cdot K$

From the superheated water

At pressure $P_2 = 40\ kPa$ and saturated vapor condition

the enthalpy and entropy respectively are

$h_2 = h_g = 2636.1\ kJ/kg$

$s_2 = s_g = 7.6691\ kJ/kg \cdot K$

Step 3 of 5

The energy balance is given by

$E_{in} - E_{out} = \Delta E_{sys}$

Let assume the process is steady. So, $\Delta E_{sys} = 0$

$E_{in} - E_{out} = 0$

$E_{in} = E_{out}$

$m \times h_1 = Q_{out} + W_{out} + m \times h_2$

$Q_{out} = m \times h_1 - W_{out} - m \times h_2$

Step 4 of 5

The rate of heat transfer is given by

$Q_{out} = m(h_1 - h_2) - W_{out}$

$= 11.11(3399.5 - 2636.1) - 8200$

$= 11.11(763.4) - 8200$

$= 8481.374 - 8200$

$= 281.374\ kW$

Step 5 of 5

The entropy balance is given by

$S_{in} - S_{out} + S_{gen} = \Delta S_{sys}$

Let assume the process is steady. So, $\Delta S_{sys} = 0$

$S_{in} - S_{out} + S_{gen} = 0$

$m \times s_1 - m \times s_2 - \frac{Q_{out}}{T_0} + S_{gen} = 0$

$S_{gen} = m \times s_2 - m \times s_1 + \frac{Q_{out}}{T_0}$

$= m \times (s_2 - s_1) + \frac{Q_{out}}{T_0}$

$= 11.11 \times (7.6691 - 6.7266) + \frac{281.374}{298}$

$= 11.11 \times 0.9425 + 0.9442$

$= 10.4712 + 0.9442$

$= 11.4154 kW/K$

Therefore the entropy generated is $\boxed{s_{gen} = 11.4154\ kW/K}$.

Question: 8.158P

Air enters a compressor at ambient conditions of 15 psia and 60°F with a low velocity and exits at 150 psia, 620°F, and 350 ft/s. The compressor is cooled by the ambient air at 60°F at a rate of 1500 Btu/min. The power input to the compressor is 400 hp. Determine (*a*) the mass flow rate of air and (*b*) the rate of entropy generation.

Step 1 of 7

Given data:

The ambient conditions of air at the entrance,

$p_1 = 15\,\text{psia}$

$T_1 = 60°\text{F}$

The ambient conditions of air at the exit,

$p_2 = 150\,\text{psia}$

$T_2 = 620°\text{F}$

Velocity of ambient air at exit, $V_2 = 350\,\text{ft/s}$

The ambient temperature of air, when the compressor is cooled, $T = 60°\text{F}$

The rate of ambient air, $\dot{Q}_{out} = 1500\,\text{Btu/min}$

Step 2 of 7

(a)Calculation of mass flow rate of air through the compressor:

The mass flow rate of air can be calculated by using energy balance equation as follows:

The energy balance for the given steady flow system can be expressed as,

$\dot{E}_{in} = \dot{E}_{out}$

Since, potential energy changes is zero,

$$\dot{W}_{in} + \dot{m}\left(h_1 + \frac{V_1^2}{2}\right) = \dot{Q}_{out} + \dot{m}\left(h_2 + \frac{V_2^2}{2}\right)$$

$$\dot{W}_{in} - \dot{Q}_{out} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}\right) \qquad \text{..... (1)}$$

Step 3 of 7

From ideal gas properties of air tables,

At $T_1 = 60°\text{F} = 520\,\text{R}$,

The specific enthalpy is, $h_1 = 124.27\,\text{Btu/lbm}$

The specific entropy is, $s_1^0 = 0.59173\,\text{Btu/lbm}\cdot\text{R}$

At $T_2 = 620°\text{F} = 1080\,\text{R}$,

The specific enthalpy is, $h_2 = 260.97\,\text{Btu/lbm}$

The specific entropy is, $s_2^0 = 0.76964\,\text{Btu/lbm}\cdot\text{R}$

Step 4 of 7

By substituting these known values in equation (1), we get

$$\dot{W}_{in} - \dot{Q}_{out} = \dot{m}\left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}\right)$$

$$(400\,\text{hp})\left(\frac{0.7068\,\text{Btu/s}}{1\,\text{hp}}\right) - \left(\frac{1500\,\text{Btu}}{60\,\text{s}}\right) = \dot{m}\left[\begin{array}{l}(260.97 - 124.27) \\ \quad + \dfrac{(350\,\text{ft/s})^2}{2}\left(\dfrac{1\,\text{Btu/lbm}}{25{,}037\,\text{ft}^2/\text{s}^2}\right)\end{array}\right]$$

$$\dot{m} = \frac{257.72}{136.7}$$

$$= 1.8851\,\text{lbm/s}$$

Therefore, the mass flow rate of air through the compressor is, $\boxed{\dot{m} = 1.885\,\text{lbm/s}}$

Step 5 of 7

(b)Calculation of total rate of entropy generation:

Since, there is no heat transfer to the surroundings.

Therefore, the entropy balance for the given system is,

$$\dot{m}s_1 - \dot{m}s_2 - \frac{\dot{Q}_{out}}{T_{b,surr}} + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{m}(s_2 - s_1) + \frac{\dot{Q}_{out}}{T_{b,surr}} \qquad \text{..... (2)}$$

Where, $\dot{m}(s_2 - s_1) = \dot{m}\left(s_2^0 - s_1^0 - R\ln\frac{p_2}{p_1}\right)$

Step 6 of 7

The gas constant of air, $R = 0.06855\,\text{Btu/lbm}\cdot\text{R}$

By substituting the known values in the above equation, we get

$$\dot{m}(s_2 - s_1) = 1.852\left(0.76964 - 0.59173 - \left(0.06855\ln\frac{150}{15}\right)\right)$$

$$= 1.852 \times 0.02006$$

$$= 0.0371\,\text{Btu/s}\cdot\text{R}$$

Step 7 of 7

By substituting the above value in equation (2), we get

$$\dot{S}_{gen} = \dot{m}(s_2 - s_1) + \frac{\dot{Q}_{out}}{T_{b,surr}}$$

$$= 0.0372 + \frac{(1500/60)}{520}$$

$$= 0.0372 + 0.048$$

$$= 0.08527\,\text{Btu/s}\cdot\text{R}$$

Therefore, the total rate of entropy generation, $\boxed{\dot{S}_{gen} = 0.08527\,\text{Btu/s}\cdot\text{R}}$

Question: 8.159P

A hot-water stream at 70°C enters an adiabatic mixing chamber with a mass flow rate of 3.6 kg/s, where it is mixed with a stream of cold water at 20°C. If the mixture leaves the chamber at 42°C, determine (*a*) the mass flow rate of the cold water and (*b*) the rate of entropy generation during this adiabatic mixing process. Assume all the streams are at a pressure of 200 kPa.

Step 1 of 5

Given data:

The temperature of hot water stream, $T_1 = 70°C$

The temperature of cold water, $T_2 = 20°C$

Temperature of mixture, $T_3 = 42°C$

Mass flow rate of hot water, $\dot{m}_1 = 3.6\,kg/s$

The pressure for all streams, $p = 200kPa$

Step 2 of 5

(a)Calculation of mass flow rate of cold stream:

The mass flow rate of cold stream can be calculated by using mass and energy balance equations as follow:

The mass balance for the given steady flow system can be expressed as,

$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$ ..... (1)

The energy balance for the given steady flow system can be expressed as,

$\dot{E}_{in} = \dot{E}_{out}$

$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$ ..... (2)

From equations (1), (2) we get,

$\dot{m}_1 h_1 + \dot{m}_2 h_2 = (\dot{m}_1 + \dot{m}_2) h_3$

$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_1 h_3 + \dot{m}_2 h_3$

$\dot{m}_2 (h_2 - h_3) = \dot{m}_1 (h_3 - h_1)$

$\dot{m}_2 = \dfrac{(h_3 - h_1)}{(h_2 - h_3)} \dot{m}_1$ ..... (3)

Step 3 of 5

From saturated water pressure tables at $p = 200kPa$, the temperature is, $T_{sat} = 120.21°C$

Since, the given temperatures of the three streams are less than the saturated temperature; the three streams can be approximated to saturated liquid state.

From the properties of saturated water temperature tables,

At $T_1 = 70°C$

The specific enthalpy of the saturated liquid, $h_1 = h_f = 293.07\,kJ/kg$

The specific entropy of the saturated liquid, $s_1 = s_f = 0.955kJ/kg \cdot K$

At $T_2 = 20°C$

The specific enthalpy of the saturated liquid, $h_2 = h_{f2} = 83.91kJ/kg$

The specific entropy of the saturated liquid, $s_2 = s_{f2} = 0.2965kJ/kg \cdot K$

At $T_3 = 42°C$

The specific enthalpy of the saturated liquid, $h_3 = h_{f3} = 175.90kJ/kg$

The specific entropy of the saturated liquid, $s_3 = s_{f3} = 0.599\,kJ/kg \cdot K$

Step 4 of 5

By substituting these known values in equation (3), we get

$$\dot{m}_2 = \frac{(h_3 - h_1)}{(h_2 - h_3)} \dot{m}_1$$

$$= \left(\frac{175.90 - 293.07}{83.91 - 175.90}\right) \times 3.6$$

$$= \left(\frac{-117.17}{-91.99}\right) \times 3.6$$

$$= 1.2737 \times 3.6$$

$$= 4.5854\ kg/s$$

And,

$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$

$\dot{m}_3 = 3.6 + 4.586$

$\dot{m}_3 = 8.186 kg/s$

Therefore, the mass flow rate of cold water is, $\boxed{\dot{m}_2 = 4.5854\ kg/s}$

Step 5 of 5

(b)Calculation of total rate of entropy generation:

Since the mixing chamber is adiabatic, there is no heat transfer to the surroundings.

Therefore, the entropy balance for the given system is,

$\dot{m}_1 s_1 + \dot{m}_2 s_2 - \dot{m}_3 s_3 + \dot{S}_{gen} = 0$

$\dot{S}_{gen} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2$

By substituting the known values in the above equation, we get

$$\dot{S}_{gen} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2$$

$$= (8.186 \times 0.599) - (3.6 \times 0.955) - (4.586 \times 0.2965)$$

$$= 0.105665 kW/K$$

Therefore, the total rate of entropy generation, $\boxed{\dot{S}_{gen} = 0.105665 kW/K}$

Question: 8.160P

Liquid water at 200 kPa and 20°C is heated in a chamber by mixing it with superheated steam at 200 kPa and 150°C. Liquid water enters the mixing chamber at a rate of 2.5 kg/s, and the chamber is estimated to lose heat to the surrounding air at 25°C at a rate of 1200 kJ/min. If the mixture leaves the mixing chamber at 200 kPa and 60°C, determine (*a*) the mass flow rate of the superheated steam and (*b*) the rate of entropy generation during this mixing process.

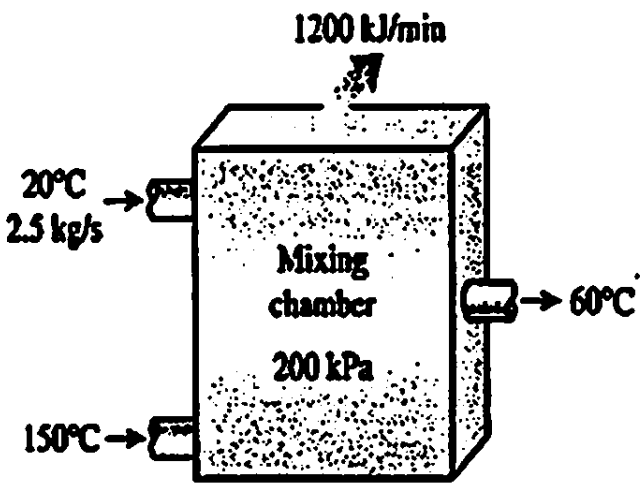

FIGURE P8–160

Step 1 of 6

Given data:

The pressure and temperature of liquid water,

$p_1 = 200\text{kPa}$

$T_1 = 20°\text{C}$

The pressure and temperature of super heated steam,

$p_2 = 200\text{kPa}$

$T_2 = 150°\text{C}$

The pressure and Temperature of mixture after leaving the mixing chamber,

$p_3 = 200\text{kPa}$

$T_3 = 60°\text{C}$

Mass flow rate of liquid water, $\dot{m}_1 = 2.5\text{kg/s}$

The rate of heat transfer, $\dot{Q} = 1200\text{kJ/min}$

The surrounding temperature, $T_{b,surr} = 25°\text{C}$

Step 2 of 6

(a)Calculation of mass flow rate steam:

The mass flow rate of steam can be calculated by using mass and energy balance equations as follow:

The mass balance for the given steady flow system can be expressed as,

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3 \qquad \text{..... (1)}$$

The energy balance for the given steady flow system can be expressed as,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{Q}_{out} + \dot{m}_3 h_3 \qquad \text{..... (2)}$$

From equations (1), (2) we get,

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{Q}_{out} + (\dot{m}_1 + \dot{m}_2) h_3$$

$$\dot{Q}_{out} = \dot{m}_1 h_1 + \dot{m}_2 h_2 - (\dot{m}_1 + \dot{m}_2) h_3$$

$$\dot{Q}_{out} = \dot{m}_1 (h_1 - h_3) + \dot{m}_2 (h_2 - h_3)$$

$$\dot{m}_2 (h_2 - h_3) = \dot{Q}_{out} - \dot{m}_1 (h_1 - h_3)$$

$$\dot{m}_2 = \frac{\dot{Q}_{out} - \dot{m}_1 (h_1 - h_3)}{(h_2 - h_3)} \qquad \text{..... (3)}$$

Step 3 of 6

From saturated water pressure tables at $p = 200\text{kPa}$, the temperature is, $T_{sat} = 120.21°\text{C}$

Since, the liquid water and exit temperatures of the streams are less than the saturated temperature; this both streams can be approximated to saturated liquid state.

From the properties of saturated water temperature tables,

At $T_1 = 20°\text{C}$

The specific enthalpy of the saturated liquid, $h_1 = h_f = 83.91\text{kJ/kg}$

The specific entropy of the saturated liquid, $s_1 = s_f = 0.2965\text{kJ/kg}\cdot\text{K}$

At $T_3 = 60°\text{C}$

The specific enthalpy of the saturated liquid, $h_3 = h_{f3} = 251.18\text{kJ/kg}$

The specific entropy of the saturated liquid, $s_3 = s_{f3} = 0.8313\text{kJ/kg}\cdot\text{K}$

From super heated water tables at $p_2 = 200\text{kPa}$ and $T_2 = 150°\text{C}$ the properties are

The specific enthalpy of the super heated liquid, $h_2 = 2769.1\text{kJ/kg}$

The specific entropy of the super heated liquid, $s_2 = 7.2810\text{kJ/kg}\cdot\text{K}$

Step 4 of 6

By substituting these known values in equation (3), we get

$$\dot{m}_2 = \frac{\dot{Q}_{out} - \dot{m}_1 (h_1 - h_3)}{(h_2 - h_3)}$$

$$\dot{m}_2 = \frac{(1200/60\text{kJ/s}) - (2.5\text{kg/s})(83.91 - 251.18)\text{kJ/kg}}{(2769.1 - 251.18)\text{kJ/kg}}$$

$$= \frac{438.175}{2517.92}$$

$$= 0.174\text{kg/s}$$

And,

$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$

$\dot{m}_3 = 2.5 + 0.174$

$\dot{m}_3 = 2.674\text{kg/s}$

Therefore, the mass flow rate of steam is, $\boxed{\dot{m}_2 = 0.174\text{ kg/s}}$

Step 5 of 6

(b)Calculation of total rate of entropy generation:

Entropy generation can be calculated by using entropy balance,

Therefore, the entropy balance for the given system is,

$$\dot{m}_1 s_1 + \dot{m}_2 s_2 - \dot{m}_3 s_3 - \frac{\dot{Q}_{out}}{T_{b,surr}} + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2 + \frac{\dot{Q}_{out}}{T_{b,surr}}$$

Step 6 of 6

By substituting the known values in the above equation, we get

$$\dot{S}_{gen} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2 + \frac{\dot{Q}_{out}}{T_{b,surr}}$$

$$= (2.674 \times 0.8313) - (2.5 \times 0.2965) - (0.174 \times 7.2810) + \left(\frac{1200/60}{298}\right)$$

$$= 0.283\text{kW/K}$$

Therefore, the total rate of entropy generation, $\boxed{\dot{S}_{gen} = 0.283\text{kW/K}}$

Question:

A 0.18-m3 rigid tank is filled with saturated liquid water at 120°C. A valve at the bottom of the tank is now opened, and one-half of the total mass is withdrawn from the tank in the liquid form. Heat is transferred to water from asource at 230°C so that the temperature in the tank remains constant. Determine (*a*) the amount of heat transfer and (*b*) the total entropy generation for this process.

Step 1 of 8

Since, the mass inside the rigid tank is crossing the boundaries of the tank. The system is considered as open system.

Apply mass balance equation to the rigid tank.

$$m_i + m_1 = m_e + m_2 \quad \text{..... (1)}$$

Here, m_i is the mass of the water entering the tank, m_1 is the initial mass in the tank, m_e is the mass withdrawn from the tank, and m_2 is the final mass in the tank.

Step 2 of 8

Calculate the initial mass in the tank using the equation,

$$m_1 = \frac{V}{v_1}$$

Here, V is volume of the tank, and v_1 is specific volume of water.

Use saturated water - Temperature tables to determine the specific volume of water at saturated liquid state at a temperature of $120°C$.

$$v_1 = 0.001060 \ \text{m}^3/\text{kg}$$

Substitute $0.001060 \ \text{m}^3/\text{kg}$ for v_1 , and $0.18 \ \text{m}^3$ for V.

$$m_1 = \frac{0.18}{0.001060}$$
$$= 169.81 \ \text{kg}$$

Step 3 of 8

Calculate the mass of water withdrawn from the tank using the equation,

$$m_e = \frac{m_1}{2}$$

Substitute 169.81 kg for m_1 .

$$m_e = \frac{169.81}{2}$$
$$= 84.91 \ \text{kg}$$

Calculate the final mass of water in the tank by substituting 0 for m_i , 169.81 for m_1 , and 84.91 kg for m_e in equation (1).

$$m_i + m_1 = m_e + m_2$$
$$0 + 169.81 = 84.91 + m_2$$
$$m_2 = 84.91 \ \text{kg}$$

Step 4 of 8

Calculate the final specific volume of water in the tank using the equation,

$$v_2 = \frac{V}{m_2}$$

Substitute $0.18 \ \text{m}^3$ for V, and 84.91 kg for m_2 .

$$v_2 = \frac{0.18}{84.91}$$
$$= 2.1199 \times 10^{-3} \ \text{m}^3/\text{kg}$$

Step 5 of 8

Calculate the dryness fraction of water in the tank at the final state using the equation,

$$v_2 = v_f + x(v_g - v_f)$$

Here, x is the dryness fraction, v_f is the specific volume of water at saturated liquid state, and v_g is the specific volume of water at saturated vapor state.

Use saturated water - Temperature tables to determine the corresponding values of water at a temperature of $120°C$.

Specific volume at saturated liquid state, $v_f = 0.001060 \ \text{m}^3/\text{kg}$.

Specific volume at saturated vapor state, $v_g = 0.89133 \ \text{m}^3/\text{kg}$.

Substitute $2.1199 \times 10^{-3} \ \text{m}^3/\text{kg}$ for v_2 , $0.001060 \ \text{m}^3/\text{kg}$ for v_f , and $0.89133 \ \text{m}^3/\text{kg}$ for v_g .

$$2.1199 \times 10^{-3} = 0.001060 + x(0.89133 - 0.001060)$$
$$0.89027x = 1.0599 \times 10^{-3}$$
$$x = 0.001191$$

Step 6 of 8

Calculate the internal energy of water in tank at the final stage using the equation,

$$u_2 = u_f + x u_{fg}$$

Here, u_f is the internal energy of water at saturated liquid state, and u_{fg} is the internal energy for evaporate of water.

Use saturated water - Temperature tables to determine the corresponding values of water at a temperature of $120°C$.

Internal energy at saturated liquid state, $u_f = 503.60 \ \text{kJ/kg}$.

evaporate of water.

Use saturated water - Temperature tables to determine the corresponding values of water at a temperature of $120°C$.

Internal energy at saturated liquid state, $u_f = 503.60 \text{ kJ/kg}$.

Internal energy for evaporate of water, $u_{fg} = 2025.3 \text{ kJ/kg}$.

Substitute 0.001191 for x, 503.60 kJ/kg for u_f , and 2025.3 kJ/kg for u_{fg} .

$$u_2 = 503.60 + 0.001191 \times 2025.3$$
$$= 506.01 \text{ kJ/kg}$$

(a)

Calculate the heat supplied to the tank by applying energy balance equation for the tank.

$$m_i h_i + m_1 u_1 + Q_{in} = m_e h_e + m_2 u_2$$

Here, Q_{in} is the heat supplied to the tank.

Use saturated water - Temperature tables to determine the corresponding values of water at a temperature of $120°C$.

Enthalpy at saturated liquid state, $h_e = 503.81 \text{ kJ/kg}$.

Internal energy at saturated liquid state, $u_1 = 503.60 \text{ kJ/kg}$.

Substitute 0 for m_i , 169.81 kg for m_1 , 503.60 kJ/kg for u_1 , 84.91 kg for m_e , 503.81 kJ/kg for h_e , 84.91 kg for m_2 , and 506.01 kJ/kg for u_2 .

$$0 + 169.81 \times 503.60 + Q_{in} = 84.91 \times 503.81 + 84.91 \times 506.01$$
$$Q_{in} = 227.50 \text{ kJ}$$

Therefore, the heat supplied to the tank is $\boxed{227.50 \text{ kJ}}$.

Step 7 of 8

(b)

Calculate the entropy of water in tank at the final stage using the equation,

$$s_2 = s_f + x s_{fg}$$

Here, s_f is the entropy of water at saturated liquid state, and s_{fg} is the entropy for evaporate of water.

Use saturated water - Temperature tables to determine the corresponding values of water at a temperature of $120°C$.

Entropy at saturated liquid state, $s_f = 1.5279 \text{ kJ/kg·K}$.

Entropy for evaporate of water, $s_{fg} = 5.6013 \text{ kJ/kg·K}$.

Substitute 0.001191 for x, 1.5279 kJ/kg·K for s_f , and 5.6013 kJ/kg·K for s_{fg} .

$$s_2 = 1.5279 + 0.001191 \times 5.6013$$
$$= 1.5346 \text{ kJ/kg·K}$$

Step 8 of 8

Calculate the entropy generated during the process by applying entropy balance equation.

$$m_i s_i + m_1 s_1 + S_{gen} + \frac{Q_{in}}{T_{source}} = m_e s_e + m_2 s_2$$

Here, T_{source} is the temperature of the source, and S_{gen} is the entropy generated during the process.

Use saturated water - Temperature tables to determine the corresponding values of water at a temperature of $120°C$.

Entropy at saturated liquid state, $s_1 = s_e = 1.5279 \text{ kJ/kg·K}$.

Substitute 0 for m_i , 169.81 kg for m_1 , 1.5279 kJ/kg·K for s_1 , 227.50 kJ for Q_{in} , $(230+273) \text{ K}$ for T_{source} , 84.91 kg for m_e , 1.5279 kJ/kg·K for s_e , 84.91 kg for m_2 , and 1.5346 kJ/kg·K for s_2 .

$$0 + 169.81 \times 1.5279 + S_{gen} + \frac{227.50}{230+273} = 84.91 \times 1.5279 + 84.91 \times 1.5346$$
$$S_{gen} = 0.1319 \text{ kJ/K}$$

Therefore, the entropy generated during the process is $\boxed{0.1319 \text{ kJ/K}}$.

Question: 8.162P

An iron block of unknown mass at 185°F is dropped into an insulated tank that contains 0.8 ft3 of water at 70°F. At the same time, a paddle wheel driven by a 200-W motor is activated to stir the water. Thermal equilibrium is established after 10 min with a final temperature of 75°F. Determine (*a*) the mass of the iron block and (*b*) the entropy generated during this process.

Step 1 of 4

(a) Calculation of mass of the iron block:

The mass of iron block can be calculated by using energy balance equation as follows: The energy balance

$$\dot{E}_{in} - \dot{E}_{out} = \Delta E_{system}$$

for the given steady flow system can be expressed as, $W_{pw,in} = \Delta U$

$$W_{pw,in} = \Delta U_{iron} + \Delta U_{water}$$

$W_{pw,in} = \left[mc(T_2 - T_1)\right]_{iron} + \left[mc(T_2 - T_1)\right]_{water}$ ..... (1) Since, density of water at room temperature,

$$m_{water} = \rho V$$

$\rho = 62.1\,\text{lbm/ft}^3$ Calculate the mass of water, $= 62.1 \times 0.8$

$$= 49.68\,\text{lbm}$$

Step 2 of 4

Calculate the work done driven by the paddle wheel after 10 min,

$$W_{pw} = \dot{W}_{pw}\Delta t$$

$$= (0.2\,\text{kJ/s})\left(\frac{1\text{Btu}}{1.055\text{kJ}}\right)(10 \times 60\text{s})$$

$$= 113.7\,\text{Btu}$$

And, from properties of liquid and solids table,

Specific heat of iron is, $c_{pi} = 0.107\,\text{Btu/lbm °F}$

Specific heat of water is, $c_{pw} = 1.00\,\text{Btu/lbm °F}$

Substitute the known values in equation (1),

$$113.7 = \left[m_{iron} \times 0.107 \times (75 - 185)\right] + \left[49.7 \times 1.00 \times (75 - 70)\right]$$

$$m_{iron} = \frac{113.7 - 248.5}{-11.77}$$

$$m_{iron} = 11.52\,\text{lbm}$$

Therefore, the mass of iron block is, $\boxed{11.52\,\text{lbm}}$

Step 3 of 4

(b) Calculation of total rate of entropy generation:

Entropy generation can be calculated by using entropy balance,

Therefore, the entropy balance for the given system is,

$$S_{gen,total} = \Delta S_{system}$$

$S_{gen,total} = \Delta S_{iron} + \Delta S_{water}$ ..... (2)

Where,

$$\Delta S_{iron} = mc_{pi} \ln\left(\frac{T_2}{T_1}\right)$$

$$= 11.4 \times 0.107 \times \ln\left(\frac{535}{645}\right)$$

$$= -0.2208\,\text{Btu/R}$$

$$\Delta S_{water} = m_w c_{pw} \ln\left(\frac{T_2}{T_1}\right)$$

$$= 49.6 \times 1.0 \times \ln\left(\frac{535}{530}\right)$$

$$= 0.465\,\text{Btu/R}$$

Step 4 of 4

Substitute $-0.2208\,\text{Btu/R}$ for ΔS_{iron} and $0.465\,\text{Btu/R}$ for ΔS_{water} in equation (2)

$$S_{gen,total} = \Delta S_{iron} + \Delta S_{water}$$

$$= -0.2208 + 0.465$$

$$= 0.244\,\text{Btu/R}$$

Therefore, the total rate of entropy generation, $\boxed{0.244\,\text{Btu/R}}$

Question: 8.163P

A rigid tank contains 7.5 kg of saturated water mixture at 400 kPa. A valve at the bottom of the tank is now opened, and liquid is withdrawn from the tank. Heat is transferred to the steam such that the pressure inside the tank remains constant. The valve is closed when no liquid is left in the lank. If it is estimated that a total of 5 kJ of heat is transferred to the tank, determine (*a*) the quality of steam in the tank at the initial state, (*b*) the amount of mass that has escaped, and (*c*) the entropy generation during this process if heat is supplied to the tank from a source at 500T.

Step 1 of 5

Mass of the saturated water in the tank, $m_1 = 7.5\text{kg}$

Pressure of the saturated water, $p = 400\text{kPa}$

Total heat transferred to the tank, $Q = 5\text{kJ}$

Step 2 of 5

For the saturated vapor at pressure $P = 400\text{kPa}$

Properties of the saturated vapor,

Internal energy, $u_g = 2553.1\text{kJ/kg}$

Specific volume, $v_g = 0.46242\text{m}^3/\text{kg}$

Entropy, $s_g = 6.8955\text{kJ/kg}\cdot\text{K}$

For the escaped saturated water at pressure $P_e = 400\text{kPa}$

Properties of the saturated water,

Internal energy, $h_e = 604.66\text{kJ/kg}$

Entropy, $s_e = 1.7765\text{kJ/kg}\cdot\text{K}$

Step 3 of 5

Let the mass of the saturated vapor be m_2

So,

$$m_1 v_1 = m_2 v_2$$

$$m_2 = \frac{m_1 v_1}{v_2}$$

$$= \frac{7.5 v_1}{0.46242}$$

$$m_2 = 16.219 v_1 \quad \text{..... (1)}$$

By the mass balance equation,

Mass of escaped gas, $m_e = m_1 - m_2$

By the energy balance equation,

$$Q_{in} - m_e h_e = m_2 u_2 - m_1 u_1$$

$$5 - (7.5 - 16.219 v_1)(604.66) = 16.219 v_1 (2553.1) - 7.5 u_1 \quad \text{..... (2)}$$

By the entropy balance,

$$\frac{Q_{in}}{T} - m_e s_e + S_{gen} = m_2 s_2 - m_1 s_1$$

Substituting equation (1) in above expression,

$$\frac{Q_{in}}{T} - (7.5 - 16.219 v_1)(1.7765) + S_{gen} = (16.219 v_1) 6.8955 - 7.5 s_1$$

$$\frac{5}{500+273} - (7.5 - 16.219 v_1)(1.7765) + S_{gen} = (16.219 v_1) 6.8955 - 7.5 s_1 \quad \text{..... (3)}$$

Step 4 of 5

Solving the above equations by EES software

$x_1 = 0.866$

Hence, properties of the water at initial state are,

Pressure, $P_1 = 400\text{kPa}$ and $x_1 = 0.866$

Internal energy, $u_1 = 2293.2\text{kJ/kg}$

Specific volume, $v_1 = 0.40089\text{m}^3/\text{kg}$

Entropy, $s_1 = 6.2129\text{kJ/kg}\cdot\text{K}$

Substituting the values in equation (1) and (3)

$$m_e = 7.5 - 16.219(0.40089)$$

$$= 0.998\text{kg}$$

Therefore, amount of mass that has escaped is $\boxed{m_e = 0.998\text{kg}}$

Step 5 of 5

(c) The entropy generation,

From the equation (3)

$$\frac{5}{500+273} - (7.5 - 16.219 v_1)(1.7765) + S_{gen} = (16.219 v_1) 6.8955 - 7.5 s_1$$

$$\frac{5}{500+273} - (7.5 - 16.219(0.40089))(1.7765) + S_{gen} = \left\{ \begin{matrix} (16.219(0.40089))6.8955 \\ -7.5(6.2129) \end{matrix} \right\}$$

$$S_{gen} = -1.761968 + 1.7664$$

$$= 4.43 \times 10^{-3}\text{kJ/K}$$

Therefore, the entropy generation during the process is $\boxed{S_{gen} = 4.43 \times 10^{-3}\text{kJ/K}}$

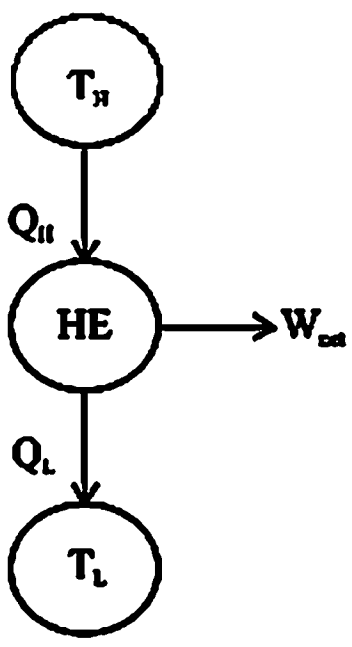
Question:

8.164P

A heat engine whose thermal efficiency is 40 percent uses a hot reservoir at 1300 R and a cold reservoir at 500 R. Calculate the entropy change of the two reservoirs when 1 Btu of heat is transferred from the hot reservoir to the engine. Does this engine satisfy the increase of entropy principle? If the thermal efficiency of the heat engine is increased to 70 percent, will the increase of entropy principle still be satisfied?

Step 1 of 6

Given data



Temperature of hot reservoir $T_H = 1300\text{R}$

Temperature of cold reservoir $T_L = 500\text{R}$

Heat transferred from hot reservoir $Q_H = 1\text{Btu}$

Thermal efficiency $\eta = 0.4$

Step 2 of 6

Step 3 of 6

Thermal efficiency

$$\eta = 1 - \frac{Q_L}{Q_H}$$

$$0.4 = 1 - \frac{Q_L}{1}$$

$$Q_L = 0.6\text{Btu}$$

Heat transferred to cold reservoir

$$Q_L = 0.6\text{Btu}$$

Step 4 of 6

Entropy change of two reservoirs

$$\Delta S_{total} = \Delta S_H + \Delta S_L$$

$$= \frac{Q_H}{T_H} + \frac{Q_L}{T_L}$$

$$= \frac{-1}{1300} + \frac{0.6}{500}$$

$$\boxed{\Delta S_{total} = 0.000431\text{Btu/R}}$$

When thermal efficiency of the heat engine is $\eta = 40\%$ total entropy increases

So this engine satisfies the increase of entropy principle

Step 5 of 6

When thermal efficiency of engine is $\eta = 70\%$

$$\eta = 1 - \frac{Q_L}{Q_H}$$

$$0.7 = 1 - \frac{Q_L}{1}$$

$$Q_L = 0.3\text{Btu}$$

Heat transferred to cold reservoir

$$Q_L = 0.3\text{Btu}$$

Step 6 of 6

Total entropy change of two reservoirs

$$\Delta S_{total} = \Delta S_H + \Delta S_L$$

$$= \frac{Q_H}{T_H} + \frac{Q_L}{T_L}$$

$$= \frac{-1}{1300} + \frac{0.3}{500}$$

$$= -0.000169\text{Btu/R}$$

$$\boxed{\Delta S_{total} = -0.000169\text{Btu/R}}$$

When thermal efficiency of the heat engine is $\eta = 70\%$ total entropy decreases

So the engine does not satisfies the increase of entropy principle therefore the engine is impossible

Question: 8.165P pg 1

A refrigerator with a coefficient of performance of 4 transfers heat from a cold region at -20°C to a hot region at 30°C. Calculate the total entropy change of the regions when 1 kJ of heat is transferred from the cold region. Is the second law satisfied? Will this refrigerator still satisfy the second law if its coefficient of performance is 6?

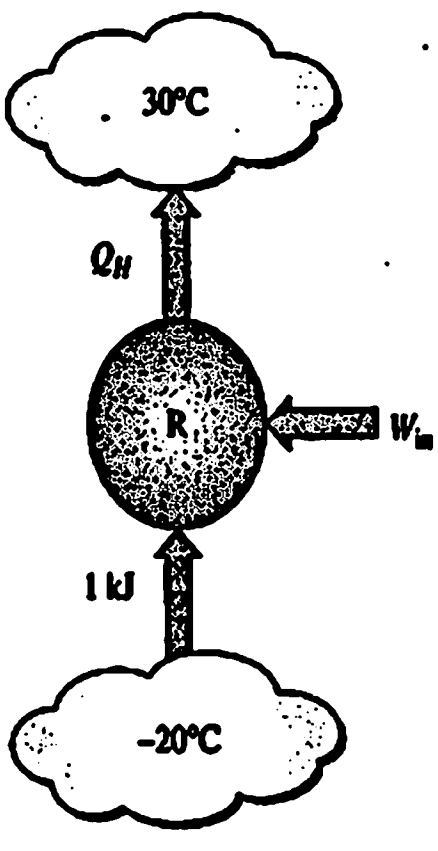


FIGURE P8–165

Step 1 of 6

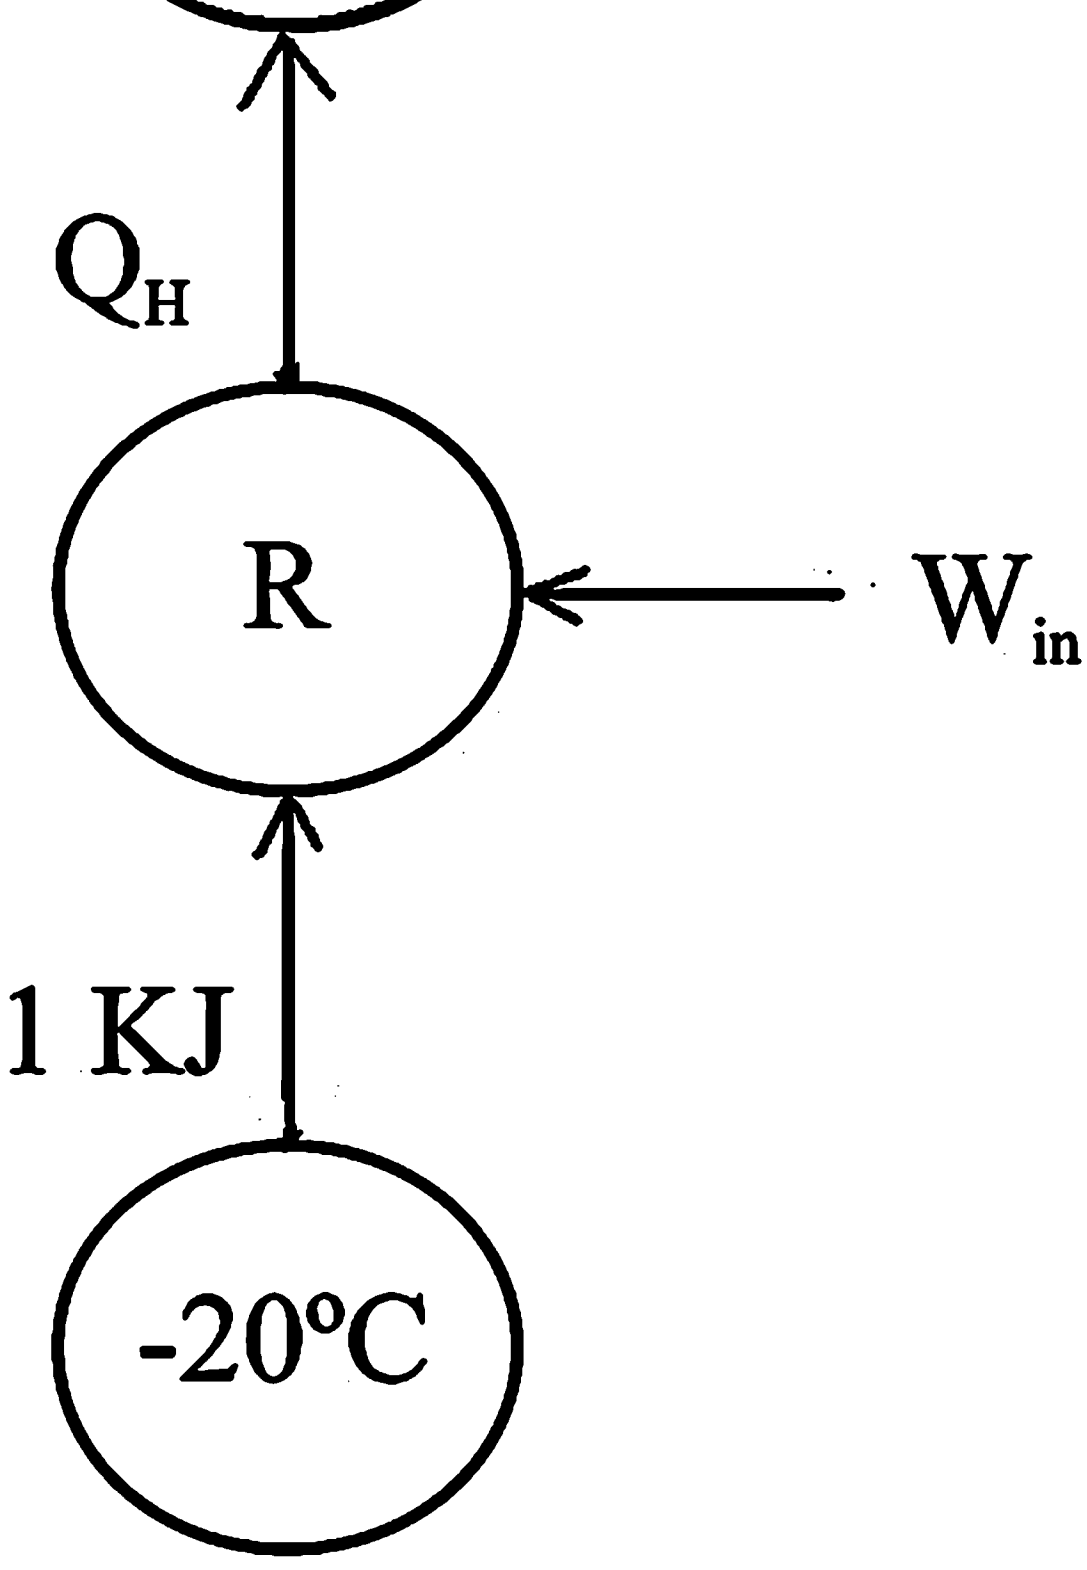
Given

Coefficient of performance of refrigerator $COP_R = 4$

Temperature of cold region $T_L = -20°C$

$= (-20 + 273)K$

$T_L = 253K$



Temperature of hot region $T_H = 30°C$

$= (30 + 273)K$

$T_H = 303K$

Heat transferred from the cold region $Q_L = 1kJ$

Step 2 of 6

Step 3 of 6

Coefficient of the performance of the refrigerator is

$$COP_R = \frac{Q_L}{Q_H - Q_L}$$

$$4 = \frac{1}{Q_H - 1}$$

$$Q_H - 1 = 0.25$$

$$Q_H = 1.25kJ$$

Heat transferred to the hot region

$$Q_H = 1.25kJ$$

$Q_H = 1.25\,\text{kJ}$

Heat transferred to the hot region

$$Q_H = 1.25\,\text{kJ}$$

Step 4 of 6

Entropy change of the process

$$\Delta S_{total} = \Delta S_H + \Delta S_L$$

$$= \frac{Q_H}{T_H} + \frac{Q_L}{T_L}$$

$$= \frac{1.25}{303} + \frac{(-1)}{253}$$

$$\boxed{\Delta S_{total} = 0.000173\,\text{kJ/K}}$$

When $COP = 4$ the total entropy increases so the process is possible

Step 5 of 6

When $COP = 6$

$$COP_R = \frac{Q_L}{Q_H - Q_L}$$

$$6 = \frac{1}{Q_H - 1}$$

$$Q_H - 1 = 0.1666$$

$$Q_H = 1.1666\,\text{kJ}$$

Heat transferred to the hot region

$$Q_H = 1.1666\,\text{kJ}$$

Step 6 of 6

Total entropy change

$$\Delta S_{total} = \Delta S_H + \Delta S_L$$

$$= \frac{Q_H}{T_H} + \frac{Q_L}{T_L}$$

$$= \frac{1.1666}{303} + \frac{(-1)}{253}$$

$$= -0.0001024\,\text{kJ/K}$$

$$\boxed{\Delta S_{total} = -0.0001024\,\text{kJ/K}}$$

Since total entropy is negative when $COP = 6$, so this process is impossible.

Question: 8.166P

Calculate the rate of entropy change of all the components of a refrigerator that uses 10 kW of power, rejects 14 kW of heat, and has a high-temperature energy reservoir at 400 K and a low-temperature energy reservoir at 200 K. What is the rate of cooling produced by this refrigerator? Is this refrigerator completely reversible?

Step 1 of 4

Given data:

Power given to the refrigerator is, $W_{in} = 10\,kW$.

Rate of heat rejection at source is $Q_H = 14\,kW$.

Temperature of source is, $T_H = 400\,K$.

Temperature of sink is, $T_L = 200\,K$.

Step 2 of 4

The work input to the refrigerator is given by

$$W_{in} = Q_H - Q_L$$

Therefore the rate of heat addition at sink is given by

$$Q_L = Q_H - W_{in}$$
$$= 14 - 10$$
$$= 4\,kW$$

$$\boxed{Q_L = 4\,kW}$$

The entropy change at sink is given by

$$\Delta S_L = \frac{Q_L}{T_L}$$

$$\Delta S_L = \frac{-4}{200}$$

(as heat is taken out of the sink, negative sign is taken)

$$\Delta S_L = -0.02\,kW/k$$

Step 3 of 4

The entropy change at source is given by

$$\Delta S_H = \frac{Q_H}{T_H}$$

$$\Delta S_H = \frac{14}{400}$$ (as heat is given to the source, positive sign is taken)

$$\Delta S_H = 0.035\,kW/K$$

Step 4 of 4

The total entropy change is given by

$$\Delta S_{tot} = \Delta S_H + \Delta S_L + \Delta S_{dev}$$
$$= 0.035 - 0.02 + 0$$
$$= 0.015\,kW/K$$

Therefore the rate of cooling produced by the refrigerator is 4 kW.

As the entropy is increased, the refrigerator is real and irreversible.

Question: 8.167P

What is the minimum internal energy that R-134a can achieve as it is compressed adiabatically from 200 kPa and 85 percent quality to 800 kPa in a closed system?

Step 1 of 5

Given data:

Inlet pressure of the refrigerant is, $P_1 = 200$ kPa.

Inlet quality of the refrigerant is, $x_1 = 85\% = 0.85$.

Exit pressure of the refrigerant is, $P_2 = 800$ kPa.

Step 2 of 5

From saturated refrigerant 134a Pressure table

At pressure $P_1 = 200$ kPa ,

the saturated properties of steam are

Entropy of saturated liquid is $s_{f1} = 0.15457\ \text{kJ/kg} \cdot \text{K}$

Entropy of evaporation is $s_{fg1} = 0.78316\ \text{kJ/kg} \cdot \text{K}$

From saturated refrigerant 134a Pressure table,

At pressure $P_2 = 800$ kPa

Saturated properties of steam are as follows

Internal energy of saturated liquid is $u_{f2} = 94.79\ \text{kJ/kg}$

Internal energy of evaporation is $u_{fg2} = 152.0\ \text{kJ/kg}$

Entropy of saturated liquid is $s_{f2} = 0.35404\ \text{kJ/kg} \cdot \text{K}$

Entropy of evaporation is $s_{fg2} = 0.56431\ \text{kJ/kg} \cdot \text{K}$

Step 3 of 5

The inlet entropy is given by

$$s_1 = s_{f1} + x_1 \times s_{fg1}$$
$$= 0.15457 + 0.85 \times 0.78316$$
$$= 0.15457 + 0.66569$$
$$= 0.82026\ \text{kJ/kg} \cdot \text{K}$$

Step 4 of 5

As the process is adiabatic, $s_2 = s_1$

Therefore, $s_2 = 0.82026\ \text{kJ/kg} \cdot \text{K}$

The exit entropy is also given by

$$s_2 = s_{f2} + x_2 \times s_{fg2}$$
$$0.82026 = 0.35404 + x_2 \times 0.56431$$
$$x_2 = \frac{0.82026 - 0.35404}{0.56431}$$
$$= \frac{0.46622}{0.56431}$$
$$= 0.8262$$

Step 5 of 5

The exit internal energy is also given by

$$u_2 = u_{f2} + x_2 u_{fg2}$$
$$= 94.79 + (0.8262)(152)$$
$$= 94.79 + 125.5824$$
$$= 220.3724\ \text{kJ/kg}$$

Therefore the exit internal energy is $\boxed{u_2 = 220.3724\ \text{kJ/kg}}$.

Question: 8.168P

Is it possible to cool and condense R-134a to a saturated liquid from 1000 kPa and 180°C in a closed system undergoing an isobaric, reversible process while exchanging heat with an isothermal energy reservoir at 100°C?

Step 1 of 5

Given

Constant pressure is, $P_1 = P_2 = 1000$ kPa

Initial temperature is, $T_1 = 180$ °C

$= 453$ K

Reservoir temperature is, $T_{res} = 100$ °C

$= 373$ K

Step 2 of 5

From the properties of superheated refrigerant 134a,

at pressure $P_1 = 1000$ kPa and temperature $T_1 = 180$ °C properties of R-134a are

$h_1 = 421.36$ kJ/kg

$s_1 = 1.3124$ kJ/kg°K

From the properties of saturated refrigerant 134a,

at pressure $P_2 = 1000$ kPa and saturation liquid condition properties of R-134a are

$h_2 = h_f = 107.32$ kJ/kg

$s_2 = s_f = 0.39189$ kJ/kg°K

Step 3 of 5

The energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

$$-Q_{out} - W_{out} = \Delta U$$

$$-Q_{out} = \Delta U + W_{out}$$

$$-Q_{out} = \Delta H$$

$$-Q_{out} = m(h_2 - h_1)$$

$$Q_{out} = m(h_1 - h_2)$$

$$q_{out} = h_1 - h_2$$

$$q_{out} = 421.36 - 107.32$$

$$q_{out} = 314.04 \text{ kJ/kg}$$

Step 4 of 5

Entropy change of reservoir is given by

$$\Delta s_{res} = \Delta s_{surr} = \frac{q_{out}}{T_{res}}$$

$$\Delta s_{surr} = \frac{314.04}{373}$$

$$\Delta s_{surr} = 0.8419 \text{ kJ/kg°K}$$

Step 5 of 5

The total entropy change is given by

$$\Delta s_{tot} = \Delta s_{R134a} + \Delta s_{surr}$$

$$\Delta s_{tot} = s_2 - s_1 + \Delta s_{surr}$$

$$\Delta s_{tot} = 0.39189 - 1.3124 + 0.8419$$

$$\Delta s_{tot} = -0.0786 \text{ kJ/kg°K}$$

$\boxed{\Delta s_{tot} < 0}$

As the entropy change is negative the process is impossible.

Question: 8.169P

It has been suggested that air at 100 kPa and 25°C can be cooled by first compressing it adiabatically in a closed system to 1000 kPa and then expanding it adiabatically back to 100 kPa. Is this possible?

Step 1 of 4

Given data:

Initial pressure of air is, $P_1 = 100\ kPa$.

Initial temperature of air is, $T_1 = 25\ °C = 298\ K$.

Intermediate pressure of air is, $P_2 = 1000\ kPa$.

Final pressure of air is, $P_3 = 100\ kPa$.

Step 2 of 4

Air is first compressed adiabatically from $P_1 = 100\ kPa$ to $P_2 = 1000\ kPa$

As air is compressed the temperature will be increasing.

$T_2 > T_1$

Air is then expanded adiabatically to the final (same as initial) pressure.

Now it is to be determined if air can be cooled by this process.

Step 3 of 4

The entropy change is given by

$$\Delta s = c_p \times \ln\left(\frac{T_3}{T_1}\right) - R \times \ln\left(\frac{P_3}{P_1}\right)$$

As $P_3 = P_1 = 100\ kPa$, the equation reduces to

$$\Delta s = c_p \times \ln\left(\frac{T_3}{T_1}\right) - R \times \ln\left(\frac{P_1}{P_1}\right)$$

$$\Delta s = c_p \times \ln\left(\frac{T_3}{T_1}\right) - R \times \ln(1)$$

$$\Delta s = c_p \times \ln\left(\frac{T_3}{T_1}\right) - R \times 0$$

$$\Delta s = c_p \times \ln\left(\frac{T_3}{T_1}\right) - 0$$

$$\Delta s = c_p \times \ln\left(\frac{T_3}{T_1}\right)$$

Step 4 of 4

As the process is adiabatic, there will not be any heat transfer and so entropy generation will be equal to entropy change.

As entropy generation should not be negative, the entropy change can be

$\Delta s \geq 0$

$$c_p \times \ln\left(\frac{T_3}{T_1}\right) \geq 0$$

$$\ln\left(\frac{T_3}{T_1}\right) \geq \frac{0}{c_p}$$

$$\ln\left(\frac{T_3}{T_1}\right) \geq 0$$

$$\frac{T_3}{T_1} \geq e^0$$

$$\frac{T_3}{T_1} \geq 1$$

$$\boxed{T_3 \geq T_1}$$

By this process the final temperature will be positive or at least equal to the initial temperature and so it is not possible to cool air using this process.

Question: 8.170P

Can 1 lbm of air in a closed system at 20 psia and 100°F be compressed adiabatically to 120 psia and a volume of 3 ft3 ?

Step 1 of 4

Given data:

Mass of air is $m = 1$ lbm

Initial pressure of air is, $P_1 = 20$ psia

Initial temperature of air is, $T_1 = 100\ ^\circ\text{F}$

$= 559.67\ \text{R}$

Final pressure of air is, $P_2 = 120$ psia

Volume of air is, $V = 3\ \text{ft}^3$

Step 2 of 4

From properties of molar mass, gas constant and critical point

For air $R = 0.3704\ \text{psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$

Similarly, from ideal gas specific heats of various common gases

For air $c_p = 0.240\ \text{Btu/lbm} \cdot \text{R}$ and $k = 1.4$

We know that

Air is an ideal gas.

The ideal gas equation is given by

$$P_1 \times v_1 = m \times R \times T_1$$

$$v_1 = \frac{m \times R \times T_1}{P_1}$$

$$v_1 = \frac{1 \times 0.3704 \times 559.67}{20}$$

$$v_1 = \frac{207.3}{20}$$

$$v_1 = 10.365\ \text{ft}^3/\text{lbm}$$

Step 3 of 4

Now we know that

The ratio of specific volumes in an isentropic process is given by,

$$\frac{v_2}{v_1} = \left(\frac{P_1}{P_2}\right)^{\frac{1}{k}}$$

$$v_2 = v_1\left(\frac{P_1}{P_2}\right)^{\frac{1}{k}}$$

$$v_2 = 10.365 \times \left(\frac{20}{120}\right)^{\frac{1}{1.4}}$$

$$v_2 = 10.365 \times 0.2781$$

$$v_2 = 2.88\ \text{ft}^3/\text{lbm}$$

Step 4 of 4

Now we know that

The minimum final volume is given by

$$V_2 = m \times v_2$$

$$V_2 = 1 \times 2.8742$$

$$V_2 = 2.8742\ \text{ft}^3/\text{lbm}$$

$$\boxed{V_2 < V}$$

As minimum final volume ($2.8742\ \text{ft}^3/\text{lbm}$) is less than the volume ($3\ \text{ft}^3/\text{lbm}$) given, it is possible to compress the air in the given condition.

Question: 8.171P

A 100-lbm block of a solid material whose specific heat is 0.5 Btu/lbm·R is at 70°R It is heated with 10 lbm of saturated water vapor that has a constant pressure of 14.7 psia. Determine the final temperature of the block and water, and the entropy change of (*a*) the block, (*b*) the water, and (*c*) the entire system. Is this process possible? Why?

Step 1 of 8

Given data:

The mass of solid block, $m = 100\,\text{lbm}$

The specific heat of the solid material, $c = 0.5\,\text{Btu/lbm}\cdot\text{R}$

The initial temperature of the solid block, $T_1 = 70°\text{F}$

The mass of saturated water, $m_w = 10\,\text{lbm}$

The pressure of saturated water vapor, $p = 14.7\,\text{psia}$

Step 2 of 8

Determination of final temperature of the water and solid block:

Since the block is heated, some of the water vapor will be condensed.

From saturated water tables, at $p = 14.7\,\text{psia}$

The saturation temperature is, $T_2 = 212°\text{F}$

Therefore the final temperature of the water and the solid block is, $\boxed{T_2 = 212°\text{F}}$

Step 3 of 8

The heat gained by the block,

$$Q_{block} = mc(T_2 - T_1)$$
$$= 100 \times 0.5 \times (212 - 70)$$
$$= 7100\,\text{Btu}$$

The water properties at initial state can determined as follows:

Since, at initial state the water is in saturated vapor state, the quality of water vapor is,

$x_1 = 1$

From properties of saturated water pressure tables, at $p = 14.7\,\text{psia}$

The specific enthalpy of saturated vapor, $h_g = h_1 = 1150.3\,\text{Btu/lbm}$

The specific entropy of saturated vapor, $s_g = s_1 = 1.7566\,\text{Btu/lbm}\cdot\text{R}$

Step 4 of 8

The water properties at final state can be determined as follows:

The enthalpy is,

$$h_2 = h_1 - \frac{Q_{water}}{m_w}$$
$$= 1150.3 - \left(\frac{7100}{10}\right)$$
$$= 440.3\,\text{Btu/lbm}$$

Now the quality of water at this state is,

$h_2 = h_{f2} + x_2 h_{fg2}$

From properties of saturated water pressure tables, at $p = 14.7\,\text{psia}$

The specific enthalpy of saturated liquid, $h_{f2} = 180.16\,\text{Btu/lbm}$

The specific enthalpy of saturated water mixture, $h_{fg2} = 970.12\,\text{Btu/lbm}$

The specific entropy of saturated liquid, $s_{f2} = 0.31215\,\text{Btu/lbm}\cdot\text{R}$

The specific entropy of saturated water mixture, $s_{fg2} = 1.44441\,\text{Btu/lbm}\cdot\text{R}$

Step 5 of 8

Therefore,

$h_2 = h_{f2} + x_2 h_{fg2}$

$440.3 = 180.16 + (x_2 \times 970.12)$

$$x_2 = \frac{440.3 - 180.16}{970.12}$$

$x_2 = 0.2681$

And,

$$s_2 = s_{f2} + x_2 s_{fg2}$$
$$= (0.31215) + (0.2681 \times 1.44441)$$
$$= 0.31215 + 0.3873$$
$$= 0.69947$$

Step 6 of 8

(a)Calculation of entropy change of water:

The entropy change of water is,

$$\Delta S_{water} = m_w (s_2 - s_1)$$
$$= 10 \times (0.69947 - 1.7566)$$
$$= -10.571\,\text{Btu/R}$$

Therefore the entropy change of water, $\boxed{\Delta S_{water} = -10.571\,\text{Btu/R}}$

Step 7 of 8

(b)Calculation of the entropy change of block:

The entropy change of block is,

$$\Delta S_{block} = mc \ln \frac{T_2}{T_1}$$
$$= 100 \times 0.5 \times \ln\left(\frac{212 + 460}{70 + 460}\right)$$
$$= 11.869\,\text{Btu/R}$$

Therefore, the entropy change of block, $\boxed{\Delta S_{block} = 11.869\,\text{Btu/R}}$

Step 8 of 8

(c) Calculation of entropy change of entire system:

The total entropy change is,

$$\Delta S_{total} = \Delta S_{water} + \Delta S_{block}$$
$$= -10.57 + 11.87$$
$$= 1.299\,\text{Btu/R}$$

Therefore, the entropy change of entire system, $\boxed{\Delta S_{total} = 1.299\,\text{Btu/R}}$

Since, the entropy change for the entire system is positive, this process is possible.

Question: 8.172P

One kilogram of air is in a piston-cylinder apparatus that can only exchange heat with a reservoir at 300 K. Initially this air is at 100 kPa and 27°C. Someone claims that the air can be compressed to 250 kPa and 27°C. Determine if this claim is valid by performing a second-law analysis of the claimed process.

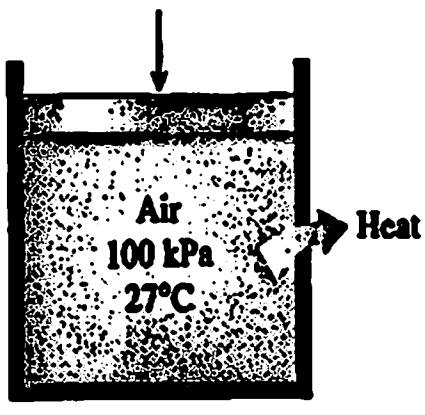


FIGURE P8–172

Step 1 of 5

Given data:

The mass of air, $m = 1\text{kg}$

Temperature of reservoir, $T_R = 300\text{K}$

Initial pressure of air, $p_1 = 100\text{kPa}$

Final pressure of air, $p_2 = 250\text{kPa}$

Initial and final temperature of air is, $T_1 = T_2 = 27°\text{C}$

Step 2 of 5

In order to determine which process is possible, let us calculate the total entropy as follows:

Entropy change of air during isothermal process is,

$$\Delta s_{air} = c_p \ln\frac{T_2}{T_1} - R\ln\frac{P_2}{P_1} \qquad \text{..... (1)}$$

Entropy change of reservoir is,

$$\Delta s_R = \frac{q_R}{T_R} \qquad \text{..... (2)}$$

Step 3 of 5

From the properties of ideal gas specific heat properties,

Specific heat of air is, $c_p = 1.005\text{kJ/kg}\cdot\text{K}$

And, we know that, gas constant, $R = 0.287\text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$

By substituting these known values in equation (1), we get,

$$\Delta s_{air} = c_p \ln\frac{T_2}{T_1} - R\ln\frac{P_2}{P_1}$$

$$= \left[1.005\times\ln\left(\frac{27}{27}\right)\right] - \left[0.287\times\ln\left(\frac{250}{100}\right)\right]$$

$$= 0 - 0.2629$$

$$= -0.2629\text{kJ/kg}\cdot\text{K}$$

Step 4 of 5

To calculate the rate of heat transfer, let us consider the energy balance,

$$W_{in} - Q_{out} = \Delta U$$

$$W_{in} - Q_{out} = mc_p(T_2 - T_1)$$

$$W_{in} - Q_{out} = 0 \qquad (\because T_1 = T_2)$$

$$W_{in} = Q_{out}$$

$$w_{in} = q_{out}$$

We know that,

$$w_{in} = RT\ln\frac{P_2}{P_1}$$

$$= 0.287\times300\times\ln\left(\frac{250}{100}\right)$$

$$= 78.89\text{kJ/kg}$$

Therefore, $w_{in} = q_{out} = 78.89\text{kJ/kg}$

Step 5 of 5

By substituting this rate of heat transfer value in equation (2), we get

$$\Delta s_R = \frac{q_R}{T_R}$$

$$= \frac{78.89}{300}$$

$$= 0.2629\text{ kJ/kg}\cdot\text{K}$$

Now, the total entropy is,

$$\Delta s_{total} = \Delta s_{air} + \Delta s_R$$

$$= -0.2629 + 0.2629$$

$$= 0\text{kJ/kg}\cdot\text{K}$$

Since, the total entropy is zero; second law of reversible process is possible.

Question: 8.173P

A rigid tank contains 3.2 kg of water at 140°C and 400 kPa. Now 48 kJ of shaft work is done on the system and the final temperature in the tank is 80°C. If the entropy change of water is zero and the surroundings are at 15°C, determine (a) the final pressure in the tank, (*b*) the amount of heat transfer between the tank and the surroundings, and (c) the entropy generation during this process.

Step 1 of 7

Given

Mass of water in the tank is, $m = 3.2\,\text{kg}$

Initial temperature of water is, $T_1 = 140°\text{C}$

Initial pressure of water is, $P_1 = 400\,\text{kPa}$

Work done on the system is, $W_{in} = 48\,\text{kJ}$

Final temperature of water is, $T_2 = 80°\text{C}$

Surrounding temperature is, $T_{sur} = 15°\text{C} = 288\,\text{K}$

Step 2 of 7

At pressure $P_1 = 400\,\text{kPa}$ from saturated water tables

The saturated temperature is $T_{sat} = 143.61°\text{C}$

And $T_{sat} > T_1$

So we will consider saturated liquid properties at initial temperature

At temperature $T_1 = 140°\text{C}$ and saturated liquid condition, properties of water are

$u_1 = u_f = 588.77\,\text{kJ/kg}$

$s_1 = s_f = 1.7392\,\text{kJ/kg}\cdot\text{K}$

Step 3 of 7

From saturated water tables at temperature $T_2 = 80°\text{C}$ properties of water are

$u_{f2} = 334.97\,\text{kJ/kg}$

$u_{fg2} = 2146.6\,\text{kJ/kg}$

$s_{f2} = 1.0756\,\text{kJ/kg}\cdot\text{K}$

$s_{fg2} = 6.5355\,\text{kJ/kg}\cdot\text{K}$

As given there will not be any change in entropy of water.

$s_1 = s_2$

$s_1 = s_{f2} + x_2 \times s_{fg2}$

$1.7392 = 1.0756 + x_2 \times 6.5355$

$$x_2 = \frac{1.7392 - 1.0756}{6.5355}$$

$x_2 = 0.1015$

Step 4 of 7

Therefore the final internal energy is given by

$u_2 = u_{f2} + x_2 \times u_{fg2}$

$u_2 = 334.97 + 0.1015 \times 2146.6$

$u_2 = 334.97 + 217.88$

$u_2 = 552.85\,\text{kJ/kg}$

Step 5 of 7

(a) At state 2 the state is in wet condition the pressure will be the saturation pressure at exit temperature.

From saturated water tables at $T_2 = 80°\text{C}$

$P_2 = P_{sat} = 47.416\,\text{kPa}$

$\boxed{P_2 = 47.416\,\text{kPa}}$

Step 6 of 7

(b) Applying energy balance to the system

$Q_{out} = W_{in} - m(u_2 - u_1)$

$Q_{out} = 48 - 3.2(552.85 - 588.77)$

$Q_{out} = 48 - 3.2(-35.92)$

$Q_{out} = 48 + 114.944$

$\boxed{Q_{out} = 162.944\,\text{kJ}}$

Step 7 of 7

(c) As entropy change of water is zero, the entropy generation will be only due to the change in surroundings entropy

$$S_{gen} = S_{sur} = \frac{Q_{out}}{T_{sur}}$$

$$S_{gen} = \frac{162.944}{288}$$

$\boxed{S_{gen} = 0.5657\,\text{kJ/K}}$

Therefore

The final pressure in the tank is 47.416 kPa

The amount of heat transfer between the tank and the surroundings is 162.944 kJ

The entropy generation is 0.5657 kJ/K

Question: 8.174P pg 1

A horizontal cylinder is separated into two compartments by an adiabatic, frictionless piston. One side contains 0.2 m3 of nitrogen and the other side contains 0.1 kg of helium, both initially at 20°C and 95 kPa. The sides of the cylinder and the helium end are insulated. Now heat is added to the nitrogen side from a reservoir at 500°C until the pressure of the helium rises to 120 kPa. Determine (*a*) the final temperature of the helium, (*b*) the final volume of the nitrogen, (*c*) the heat transferred to the nitrogen, and (*d*) the entropy generation during this process.

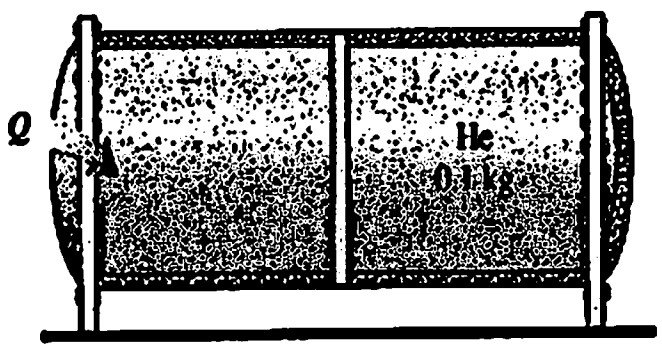

FIGURE P8–174

Step 1 of 6

Obtain the properties of Helium and Nitrogen from "ideal gas specific heats of gases" table,

Gas constant of Helium $R_{He} = 2.0769\,\text{kJ/kg}\cdot\text{K}$

Gas constant of Nitrogen $R_{N_2} = 0.2968\,\text{kJ/kg}\cdot\text{K}$

Specific heat ratio of Helium $k_{He} = 1.667$

Specific heat ratio of Nitrogen $k_{N_2} = 1.400$

Specific heat of Helium at constant volume $c_{v,He} = 3.1156\,\text{kJ/kg}\cdot\text{K}$

Specific heat of Nitrogen at constant volume $c_{v,N_2} = 0.743\,\text{kJ/kg}\cdot\text{K}$

Specific heat of Nitrogen at constant pressure $c_{p,N_2} = 1.039\,\text{kJ/kg}\cdot\text{K}$

Step 2 of 6

(a)

Find the final temperature of helium by applying isentropic relation to the process

$$\frac{T_{2,He}}{T_{1,He}} = \left(\frac{P_{2,He}}{P_{1,He}}\right)^{\frac{k-1}{k}}$$

Here, $T_{1,He}$ and $T_{2,He}$ are the initial and final temperatures of Helium, $P_{1,He}$ and $P_{2,He}$ are the initial and final pressures of Helium

Substitute $(20°\text{C} = 293\,\text{K})$ for $T_{1,He}$, $95\,\text{kPa}$ for $P_{1,He}$ and $120\,\text{kPa}$ for $P_{2,He}$

$$\frac{T_{2,He}}{293} = \left(\frac{120}{95}\right)^{\frac{1.667-1}{1.667}}$$

$$\frac{T_{2,He}}{293} = 1.097$$

$$T_{2,He} = 321.4\,\text{K}$$

Therefore, the final temperature of Helium is $\boxed{321.4\,\text{K}}$

Step 3 of 6

(b)

Find the initial volume of helium by using ideal gas equation

$$P_{1,He}V_{1,He} = m_{1,He}RT_{1,He}$$

Here, $m_{1,He}$ is mass of Helium

Substitute 0.1 kg for m_{He}

$$95 \times V_{1,He} = 0.1 \times 2.0769 \times 293$$

$$V_{1,He} = 0.64\,\text{m}^3$$

Similarly find the final volume of helium by using the equation,

$$V_{2,He} = \frac{m_{He}RT_{2,He}}{P_{2,He}}$$

$$= \frac{0.1 \times 2.0769 \times 321.4}{120}$$

$$= 0.5562\,\text{m}^3$$

Step 4 of 6

Now find the final volume of nitrogen by applying balancing equation,

$$V_{1,N_2} + V_{1,He} = V_{2,N_2} + V_{2,He}$$

$$V_{2,N_2} = V_{1,N_2} + V_{1,He} - V_{2,He}$$

Here, V_{1,N_2} is initial volume of Nitrogen

Substitute $0.2\,\text{m}^3$ for V_{1,N_2}

$$V_{2,N_2} = 0.2 + 0.64 - 0.5562$$

$$= 0.2838\,\text{m}^3$$

Therefore, final volume of Nitrogen is $\boxed{0.2838\,\text{m}^3}$

Step 5 of 6

(c)

Find the Mass of nitrogen by using ideal gas equation,

$$m_{N_2} = \frac{P_{1,N_2}V_{1,N_2}}{R_{N_2}T_{1,N_2}}$$

Find the Mass of nitrogen by using ideal gas equation,

$$\begin{aligned} m_{N_2} &= \frac{P_{1,N_2} V_{1,N_2}}{R_{N_2} T_{1,N_2}} \\ &= \frac{95 \times 0.2}{0.2968 \times 293} \\ &= 0.21848 \text{ kg} \end{aligned}$$

Find final temperature of nitrogen

$$\begin{aligned} T_{2,N_2} &= \frac{P_{2,N_2} V_{2,N_2}}{m_{N_2} R_{N_2}} \\ &= \frac{120 \times 0.2838}{0.21848 \times 0.2968} \\ &= 525.19 \text{ K} \end{aligned}$$

Apply energy balance to the system,

$$\begin{aligned} Q_{in} &= \Delta U_{N_2} + \Delta U_{He} \\ &= \left[mc_v (T_2 - T_1)\right]_{N_2} + \left[mc_v (T_2 - T_1)\right]_{He} \\ &= (0.21848)(0.743)(525.19 - 293) + (0.1)(3.1156)(321.4 - 293) \\ &= 37.69 + 8.848 \\ &= 46.538 \text{ kJ} \end{aligned}$$

Therefore, heat transferred to the Nitrogen is **46.538 kJ**

Step 6 of 6

(d)

Find the entropy generation during this process by using the equation,

$$S_{gen} = \Delta S_{N_2} + \Delta S_{He} + \Delta S_{surr}$$

Here, $\Delta S_{He} = 0$

Since the process is isentropic process in Helium

$$S_{gen} = m_{N_2}\left[c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}\right]_{N_2} + \left[\frac{-Q_{in}}{T_{Surr}}\right]$$

Here, T_{Surr} is temperature of the reservoir from which heat is added to the Nitrogen side.

Substitute $500°C$ for T_{Surr}

$$\begin{aligned} S_{gen} &= (0.21848)\left[(1.039)\ln \frac{525.19}{293} - (0.2968)\ln \frac{120}{95}\right] + \left(\frac{-46.538}{(500+273)}\right) \\ &= 0.21848[0.6063 - 0.06933] - 0.0602 \\ &= 0.05711 \text{ kJ/K} \end{aligned}$$

Therefore, entropy generation during the process is **0.05711 kJ/K**

Question: 8.175P

A 0.8-m3 rigid tank contains carbon dioxide (CO2) gas at 250 K and 100 kPa. A 500-W electric resistance heater placed in the tank is now turned on and kept on for 40 min after which the pressure of CO2 is measured to be 175 kPa. Assuming the surroundings to be at 300 K and using constant specific heats, determine (*a*) the final temperature of CO2 , (*b*) the net amount of heat transfer from the tank, and (*c*) the entropy generation during this process.

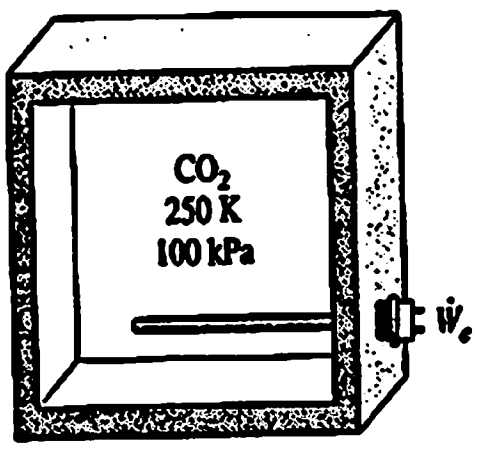

FIGURE P8–175

Step 1 of 5

Given data:

The volume of the tank, $V = 0.8\,\mathrm{m}^3$

The initial temperature of CO_2, $T_1 = 250\,\mathrm{K}$

The initial pressure of CO_2, $P_1 = 100\,\mathrm{kPa}$

The final pressure of CO_2, $P_2 = 175\,\mathrm{kPa}$

Time duration, $\Delta t = 40\,\mathrm{min}$

The power of electrical resistance heater, $\dot{E}_{e,in} = 500\,\mathrm{W}$

The surrounding temperature, $T_\infty = 300\,\mathrm{K}$

Step 2 of 5

(a)Calculation of final temperature of CO_2:

In order to calculate the final temperature, let us calculate mass of CO_2:

The mass of CO_2, $m = \dfrac{P_1 V}{R T_1}$ ..... (1)

Let us assume, the average temperature of CO_2, $T_{avg} = 350\,\mathrm{K}$

From specific heat properties of selected gases table, the properties of CO_2,

Gas constant, $R = 0.1889\,\mathrm{kPa \cdot m^3/kg \cdot K}$

Specific heat of pressure, $c_p = 0.895\,\mathrm{kJ/kg \cdot K}$

Specific heat of temperature, $c_v = 0.706\,\mathrm{kJ/kg \cdot K}$

Step 3 of 5

By substituting these known values in equation (1), we get

$$m = \frac{P_1 V}{R T_1}$$
$$= \frac{(100 \times 0.8)}{(0.1889 \times 250)}$$
$$= 1.694\,\mathrm{kg}$$

Now, the final temperature of CO_2 is,

$$T_2 = \frac{P_2 V}{mR}$$
$$= \frac{(175 \times 0.8)}{(1.694 \times 0.1889)}$$
$$= 437.5\,\mathrm{K}$$

Therefore, the final temperature of CO_2, $\boxed{T_2 = 437.5\,\mathrm{K}}$

Step 4 of 5

(b)Calculation of rate of heat transfer:

The rate of heat transfer can be calculated by using energy balance as follows:

$$Q_{out} = \dot{E}_{e,in}\Delta t - mc_v(T_2 - T_1)$$
$$= [0.5 \times (40 \times 60)] - [1.694 \times 0.706 \times (437.5 - 250)]$$
$$= 1200 - 224.24$$
$$= 975.75\,\mathrm{kJ}$$

Therefore, The rate of heat transfer, $\boxed{Q_{out} = 975.75\,\mathrm{kJ}}$

Step 5 of 5

(c)Calculation of entropy generation:

The entropy generation can be calculated by using,

$$S_{gen} = \Delta S_{CO_2} + \Delta S_{surr}$$
$$= m\left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}\right) + \frac{Q_{out}}{T_{surr}}$$

By substituting the known values in the above equation, we get

$$S_{gen} = m\left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}\right) + \frac{Q_{out}}{T_{surr}}$$
$$= \left[1.694 \times \left[\left(0.895 \times \ln \frac{437.5}{250}\right) - \left(0.1889 \times \ln \frac{175}{100}\right)\right]\right] + \left(\frac{975.8}{300}\right)$$
$$= [1.694 \times (0.5 - 0.1057)] + 3.25$$
$$= 3.917\,\mathrm{kJ/K}$$

Therefore, the entropy generation, $\boxed{S_{gen} = 3.917\,\mathrm{kJ/K}}$

Question: 8.176P

Helium gas is throttled steadily from 300 kPa and 50°C. Heat is lost from the helium in the amount of 1.75 kJ/kg to the surroundings at 25°C and 100 kPa. If the entropy of the helium increases by 0.25 kJ/kg·K in the valve, determine (*a*) the exit pressure and temperature and (*b*) the entropy generation during this process.

Step 1 of 5

Given data:

Initial pressure is, $P_1 = 300\ kPa$

Initial temperature is, $T_1 = 50\ °C = 323\ K$

Surrounding pressure is, $P_{sur} = 100\ kPa$

Surrounding temperature is, $T_{sur} = 25\ °C = 298\ K$

Heat lost by helium is, $q_{out} = 1.75\ kJ/kg$

Entropy change in helium is, $\Delta s_{He} = 0.25\ kJ/kg°K$

Step 2 of 5

From the ideal gas specific heats of various common gases

For helium

$c_p = 5.1926\ kJ/kg°K$

$R = 2.0769\ kJ/kg°K$

Step 3 of 5

(a) The heat lost by helium is given by

$$q_{out} = c_p(T_1 - T_2)$$

Therefore the final temperature is given by

$$T_2 = T_1 - \frac{q_{out}}{c_p}$$

$$T_2 = 323 - \frac{1.75}{5.1926}$$

$$T_2 = 323 - 0.337$$

$$\boxed{T_2 = 322.63\ K = 49.63\ °C}$$

Step 4 of 5

Entropy change in helium is given by

$$\Delta s_{He} = c_p \times \ln\left(\frac{T_2}{T_1}\right) - R \times \ln\left(\frac{P_2}{P_1}\right)$$

$$0.25 = 5.1926 \times \ln\left(\frac{322.63}{323}\right) - 2.0769 \times \ln\left(\frac{P_2}{300}\right)$$

$$0.25 = 5.1926 \times \ln(0.9989) - 2.0769 \times \ln\left(\frac{P_2}{300}\right)$$

$$0.25 = 5.1926 \times (-0.0011) - 2.0769 \times \ln\left(\frac{P_2}{300}\right)$$

$$0.25 = -0.005712 - 2.0769 \times \ln\left(\frac{P_2}{300}\right)$$

$$0.25 + 0.005712 = -2.0769 \times \ln\left(\frac{P_2}{300}\right)$$

$$0.255712 = -2.0769 \times \ln\left(\frac{P_2}{300}\right)$$

$$\ln\left(\frac{P_2}{300}\right) = -\frac{0.255712}{2.0769}$$

$$\ln\left(\frac{P_2}{300}\right) = -0.123$$

$$\frac{P_2}{300} = e^{-0.123}$$

$$\frac{P_2}{300} = 0.8843$$

$$P_2 = 0.8843 \times 300$$

$$\boxed{P_2 = 265.29\ kPa}$$

Step 5 of 5

The entropy generation is given by

$$\Delta s_{gen} = \Delta s_{He} + \Delta s_{sur}$$

$$\Delta s_{gen} = \Delta s_{He} + \frac{q_{out}}{T_{sur}}$$

$$\Delta s_{gen} = 0.25 + \frac{1.75}{298}$$

$$\Delta s_{gen} = 0.25 + 0.00587$$

$$\boxed{\Delta s_{gen} = 0.25587\ kJ/kg°K}$$

Therefore the final temperature is 49.63 °C , the final pressure is 265.29 kPa and the entropy generation is 0.25587 kJ/kg°K

Question: 8.177P

Refrigerant-134a enters a compressor as a saturated vapor at 200 kPa at a rate of 0.03 m3 /s and leaves at 700 kPa. The power input to the compressor is 10 kW. If the surroundings at 20°C experience an entropy increase of 0.008 kW/K, determine (*a*) the rate of heat loss from the compressor, (*b*) the exit temperature of the refrigerant, and (c) the rate of entropy generation.

Step 1 of 3

(a)

Calculate the rate of heat loss by using the equation of Entropy increases by surrounding.

$$\Delta S_{surr} = \frac{q_{out}}{T_{surr}}$$

Here, temperature of the surroundings is T_{surr} , Entropy increase by surrounding is ΔS_{surr} , the rate of heat loss is q_{out} .

Substitute $(20°C + 273 = 293\ K)$ for T_{surr} , $0.008\ kW/K$ for ΔS_{surr} .

Calculate the rate of heat loss from the compressor.

$$q_{out} = 293 \times 0.008$$
$$= 2.344\ kW$$

Therefore, rate of heat loss from the compressor is $\boxed{2.344\ kW}$

Step 2 of 3

(b)

From the properties of saturated refrigerant – 134a pressure tables, at $P_1 = 200\ kPa$,

$x_1 = 1(\text{Saturated vapor})$

Specific volume of $134a$, $v_1 = 0.0998\ m^3/kg$

Enthalpy of $R-134a$, $h_1 = 244.46\ kJ/kg$

Entropy of $R-134a$, $s_1 = 0.937\ kJ/kgK$

Calculate the Mass flow rate of refrigerant by using the following equation:

$$\dot{m} = \frac{\dot{V}_1}{v_1}$$

Here, $\dot{V}_1$ is the volume flow rate.

Substitute $0.03\ m^3/s$ for $\dot{V}_1$, $0.0998\ m^3/kg$ for v_1

$$\dot{m} = \frac{0.03}{0.0998}$$
$$= 0.3\ kg/s$$

Step 3 of 3

From the energy balance on compressor, write the following:

$$W_{in} - q_{out} = \dot{m}(h_2 - h_1)$$

Here, the power input to the compressor is W_{in}

Substitute, 10 kW for W_{in} , $0.3\ kg/s$ for $\dot{m}$, $2.344\ kW$ for q_{out} , $269.99\ kJ/kg$ for h_2

$$10 - 2.344 = 0.3 \times (h_2 - 244.46)$$
$$h_2 = 269.99\ kJ/kg$$

From properties of super-heated refrigerant -134a tables, calculate the entropy and temperature at $P_2 = 700\ kPa$, $h_2 = 269.99\ kJ/kg$ by interpolating the entropy and temperature at $h_2 = 268.45\ kJ/kg$ and $h_2 = 278.57\ kJ/kg$.

$$s_2 = s_{h_2=268.45\ kJ/kg} + \left(s_{h_2=278.57\ kJ/kg} - s_{h_2=268.45\ kJ/kg}\right)\left(\frac{269.99-268.45}{278.57-268.45}\right)$$
$$= 0.9313 + (0.9641 - 0.9313)(0.1521)$$
$$= 0.9313 + 0.00451737$$
$$= 0.93581\ kJ/kg \cdot K$$

$$T_2 = T_{h_2=268.45\ kJ/kg} + \left(T_{h_2=278.57\ kJ/kg} - T_{h_2=268.45\ kJ/kg}\right)\left(\frac{269.99-268.45}{278.57-268.45}\right)$$
$$= 30 + (40 - 30)(0.1521)$$
$$= 30 + 1.521$$
$$= 31.521°C$$

Enthalpy, $h_2 = 269.94\ kJ/kg$.

Entropy, $s_2 = 0.936\ kJ/kgK$

Therefore, the Final temperature of refrigerant, T_2 is $\boxed{31.5°C}$.

(c)

Calculate the Rate of entropy generation by using the following equation:

$$\dot{S}_{gen} = \dot{\Delta}S_{R-134a} + \dot{\Delta}S_{surr}$$
$$= \dot{m}(s_2 - s_1) + \dot{\Delta}S_{surr}$$

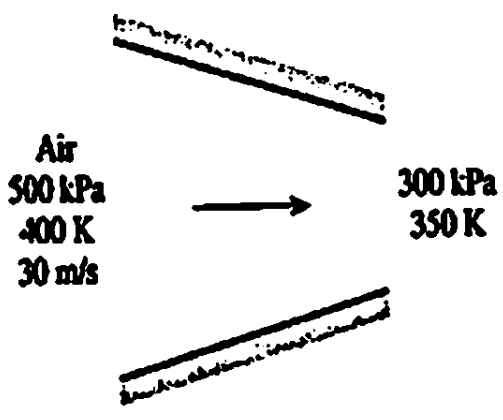
Substitute, $0.3\ kg/s$ for $\dot{m}$, $0.936\ kJ/kgK$ for s_2 , $0.937\ kJ/kgK$ for s_1 , $0.008\ kW/K$ for ΔS_{surr} .

$$\dot{S}_{gen} = 0.3 \times (0.936 - 0.937) + 0.008$$
$$= 0.0077\ kW/K$$

Therefore, the Entropy generation, $\dot{S}_{gen}$ is $\boxed{0.0075\ kW/K}$.

Question: 8.178P

Air at 500 kPa and 400 K enters an adiabatic nozzle at a velocity of 30 m/s and leaves at 300 kPa and 350 K. Using variable specific heats, determine (*a*) the isentropic efficiency, (*b*) the exit velocity, and (*c*) the entropy generation.



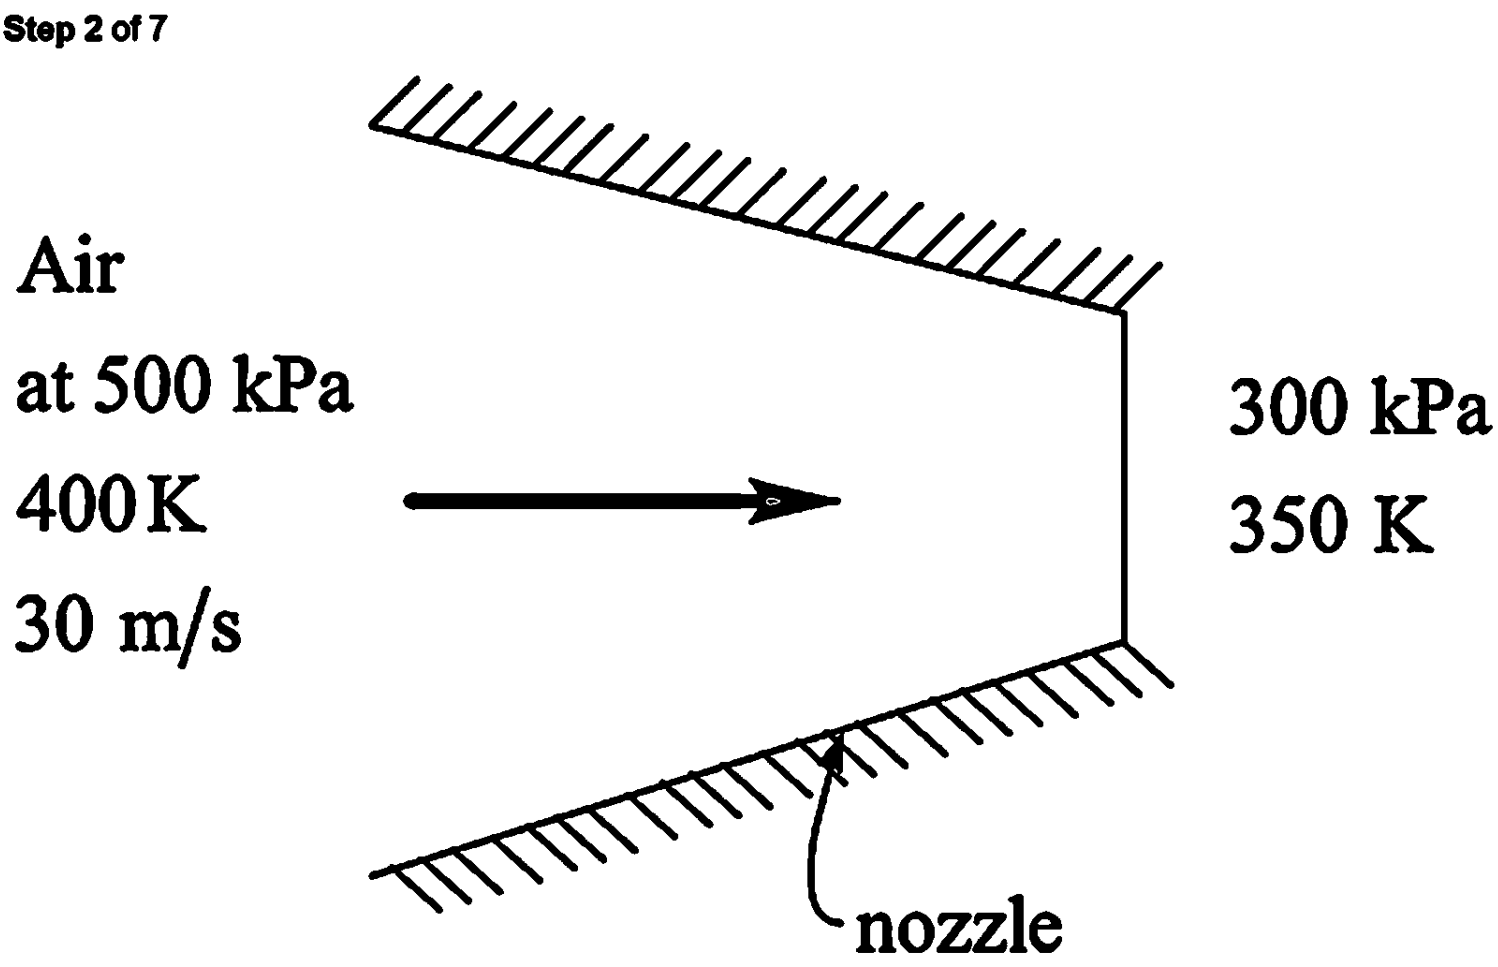


FIGURE P8–178

Step 1 of 7

Flow through the nozzle is as shown below.

Step 2 of 7

Step 3 of 7

The gas constant of air $R = 0.2870\ \text{kJ/kg}\cdot\text{K}$

From the ideal-gas properties of the air table, at inlet temperature $T_1 = 400\ \text{K}$

$h_1 = 400.98\ \text{kJ/kg}$

$s_1^\circ = 1.99194\ \text{kJ/kg}\cdot\text{K}$

$P_{r1} = 3.806$

Similarly From the ideal-gas properties of the air table, at outlet temperature $T_2 = 350\ \text{K}$

$h_2 = 350.49\ \text{kJ/kg}$

$s_2^\circ = 1.85708\ \text{kJ/kg}\cdot\text{K}$

Using the isentropic relation to process 1-2

$$P_{r2} = \frac{P_2}{P_1}(P_{r1})$$
$$= \frac{300}{500}(3.806)$$
$$= 2.2836$$

At $P_{r2} = 2.2836$ from the ideal-gas properties of the air table, at outlet temperature $T_2 = 350\ \text{K}$ the enthalpy is $h_{2s} = 346.31\ \text{kJ/kg}$

Step 4 of 7

From the energy balance equation the actual velocity at the exit is given by

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2}$$

$$400.98(\text{kJ/kg}) + \frac{(30\ \text{m/s})^2}{2}\left(\frac{1\ \text{kJ/kg}}{1000\ \text{m}^2/\text{s}^2}\right) = 350.49(\text{kJ/kg}) + \frac{V_2^2}{2}\left(\frac{1\ \text{kJ/kg}}{1000\ \text{m}^2/\text{s}^2}\right)$$

$$400.98 + 0.45 = 350.49 + \frac{V_2^2}{2}\left(\frac{1}{1000}\right)$$

$$50.94 = \frac{V_2^2}{2}\left(\frac{1}{1000}\right)$$

$$V_2^2 = 101880$$

$$V_2 = 319.186\ \text{m/s}$$

Step 5 of 7

Using the energy balance equation for the isentropic process the velocity at the exit is given by

$$h_1 + \frac{V_1^2}{2} = h_{2s} + \frac{V_{2s}^2}{2}$$

$$400.98(\text{kJ/kg}) + \frac{(30\ \text{m/s})^2}{2}\left(\frac{1\ \text{kJ/kg}}{1000\ \text{m}^2/\text{s}^2}\right) = 346.31\ (\text{kJ/kg}) + \frac{V_{2s}^2}{2}\left(\frac{1\ \text{kJ/kg}}{1000\ \text{m}^2/\text{s}^2}\right)$$

$$400.98 + 0.45 = 346.31 + \frac{V_{2s}^2}{2}\left(\frac{1}{1000}\right)$$

$$55.12 = \frac{V_{2s}^2}{2}\left(\frac{1}{1000}\right)$$

$$V_{2s}^2 = 110240$$

$$V_{2s} = 332.024\ \text{m/s}$$

Step 6 of 7

a)

The isentropic efficiency of the nozzle is given by

$$\eta_{nozz} = \frac{V_2^2}{V_{2s}^2}$$
$$= \frac{(319.186)^2}{(332.024)^2}$$
$$= 0.9242$$

Therefore, the isentropic efficiency of the nozzle is $\boxed{\eta = 92.42\%}$

b)

The actual velocity at the exit is $\boxed{V_2 = 319.186\ \text{m/s}}$

Step 7 of 7

c)

The entropy generation for variable specific heat treatment process is given by

$$s_{gen} = s_2^\circ - s_1^0 - R\ln\frac{P_2}{P_1}$$
$$= 1.85708 - 1.99194 - 0.2870\ln\frac{300}{500}$$
$$= 0.0117\ \text{kJ/kg}\cdot\text{K}$$

Therefore, the entropy generation for variable specific heat treatment process is $\boxed{s_{gen} = 0.0117\ \text{kJ/kg}\cdot\text{K}}$

Question: 8.179P pg 1

An insulated tank containing 0.2 m3 of saturated water vapor at 350 kPa is connected to an initially evacuated, insulated piston-cylinder device. The mass of the piston is such that a pressure of 200 kPa is required to raise it. Now the valve is opened slightly, and part of the steam flows to the cylinder, raising the piston. This process continues until the pressure in the tank drops to 200 kPa. Assuming the steam that remains in the tank to have undergone a reversible adiabatic process, determine the final temperature (*a*) in the rigid tank and (*b*) in the cylinder.

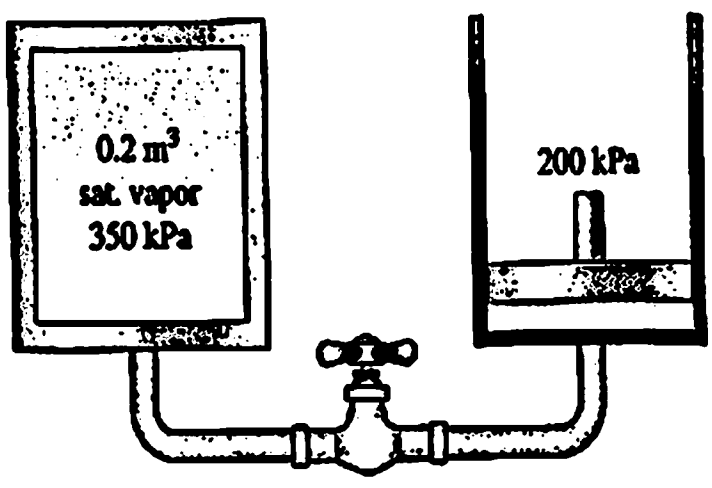

FIGURE P8–179

Step 1 of 8

(a)

The initial pressure inside the tank is 350 kPa.

Use saturated water - Pressure tables to determine the corresponding values of steam at a pressure of 350 kPa.

Specific volume at saturated vapor state, $v_{1,\text{tank}} = 0.52422 \text{ m}^3/\text{kg}$.

Internal energy at saturated vapor state, $u_{1,\text{tank}} = 2548.5 \text{ kJ/kg}$.

Entropy at saturated vapor state, $s_{1,\text{tank}} = 6.9402 \text{ kJ/kg}\cdot\text{K}$.

Step 2 of 8

The final pressure inside the tank is 200 kPa.

Use saturated water - Pressure tables to determine the corresponding values of steam at a pressure of 200 kPa.

Saturated temperature, $T_2 = 120.21°\text{C}$

Specific volume at saturated liquid state, $v_f = 0.001061 \text{ m}^3/\text{kg}$.

Specific volume at saturated vapor state, $v_g = 0.88578 \text{ m}^3/\text{kg}$.

Internal energy at saturated liquid state, $u_f = 504.50 \text{ kJ/kg}$.

Internal energy for evaporate of water, $u_{fg} = 2024.6 \text{ kJ/kg}$.

Entropy at saturated liquid state, $s_f = 1.5302 \text{ kJ/kg}\cdot\text{K}$.

Entropy for evaporate of water, $s_{fg} = 5.5968 \text{ kJ/kg}\cdot\text{K}$.

Therefore, the final temperature of steam inside the rigid tank is $\boxed{120.21°\text{C}}$.

Step 3 of 8

Steam has undergone reversible adiabatic process. Therefore, entropy of steam remains constant.

$$\begin{aligned} s_{1,\text{tank}} &= s_{2,\text{tank}} \\ &= s_f + x s_{fg} \end{aligned}$$

Here, $s_{2,\text{tank}}$ is the entropy of steam inside the rigid tank at state 2, and x is the dryness fraction of steam at state 2.

Substitute $6.9402 \text{ kJ/kg}\cdot\text{K}$ for $s_{1,\text{tank}}$, $1.5302 \text{ kJ/kg}\cdot\text{K}$ for s_f , $5.5968 \text{ kJ/kg}\cdot\text{K}$ and for s_{fg} .

$$\begin{aligned} 6.9402 &= 1.5302 + x \times 5.5968 \\ 5.5968x &= 5.41 \\ x &= 0.9666 \end{aligned}$$

Step 4 of 8

Calculate the initial mass of steam in the rigid tank using the equation,

$$m_{1,\text{tank}} = \frac{V}{v_{1,\text{tank}}}$$

Here, V is the volume of the rigid tank.

Substitute 0.2 m^3 for V, and $0.52422 \text{ m}^3/\text{kg}$ for $v_{1,\text{tank}}$.

$$\begin{aligned} m_{1,\text{tank}} &= \frac{0.2}{0.52422} \\ &= 0.3815 \text{ kg} \end{aligned}$$

Step 5 of 8

Calculate the final specific volume of steam in the rigid tank using the equation,

$$v_{2,\text{tank}} = v_f + x\left(v_g - v_f\right)$$

Substitute $0.001061 \text{ m}^3/\text{kg}$ for v_f , $0.88578 \text{ m}^3/\text{kg}$ for v_g .

$$\begin{aligned} v_{2,\text{tank}} &= 0.001061 + 0.9666\left(0.88578 - 0.001061\right) \\ &= 0.85623 \text{ m}^3/\text{kg} \end{aligned}$$

Step 6 of 8

Calculate the final mass of steam in the rigid tank using the equation,

$$m_{2,\text{tank}} = \frac{V}{v_{2,\text{tank}}}$$

Step 6 of 8

Calculate the final mass of steam in the rigid tank using the equation,

$$m_{2,\,\text{tank}} = \frac{V}{v_{2,\,\text{tank}}}$$

Substitute $0.2\ \text{m}^3$ for V, and $0.85623\ \text{m}^3/\text{kg}$ for $v_{2,\,\text{tank}}$.

$$\begin{aligned} m_{2,\,\text{tank}} &= \frac{0.2}{0.85623} \\ &= 0.2336\ \text{kg} \end{aligned}$$

Step 7 of 8

(b)

Calculate the mass of steam left the rigid tank using the equation,

$$m_{\text{cylinder}} = m_{1,\,\text{tank}} - m_{2,\,\text{tank}}$$

Substitute 0.3815 kg for $m_{1,\,\text{tank}}$, and 0.2336 kg for $m_{2,\,\text{tank}}$.

$$\begin{aligned} m_{\text{cylinder}} &= 0.3815 - 0.2336 \\ &= 0.1479\ \text{kg} \end{aligned}$$

Apply energy balance equation for the whole system (Consider rigid tank, and piston-cylinder device as system).

$$m_{1,\,\text{tank}} u_{1,\,\text{tank}} = m_{2,\,\text{tank}} u_{2,\,\text{tank}} + m_{\text{cylinder}} h_{\text{cylinder}} \quad \cdots\cdots (1)$$

Calculate the final internal energy of steam inside rigid tank using the equation,

$$u_{2,\,\text{tank}} = u_f + x u_{fg}$$

Substitute $504.50\ \text{kJ/kg}$ for u_f, 0.9666 for x, and $2024.6\ \text{kJ/kg}$ for u_{fg}.

$$\begin{aligned} u_{2,\,\text{tank}} &= 504.50 + 0.9666 \times 2024.6 \\ &= 2461.48\ \text{kJ/kg} \end{aligned}$$

Substitute 0.3815 kg for $m_{1,\,\text{tank}}$, $2548.5\ \text{kJ/kg}$ for $u_{1,\,\text{tank}}$, 0.2336 kg for $m_{2,\,\text{tank}}$, $2461.48\ \text{kJ/kg}$ for $u_{2,\,\text{tank}}$, and 0.1479 kg for m_{cylinder} in equation (1).

$$\begin{aligned} m_{1,\,\text{tank}} u_{1,\,\text{tank}} &= m_{2,\,\text{tank}} u_{2,\,\text{tank}} + m_{\text{cylinder}} h_{\text{cylinder}} \\ 0.3815 \times 2548.5 &= 0.2336 \times 2461.48 + 0.1479 \times h_{\text{cylinder}} \\ 0.1479 \times h_{\text{cylinder}} &= 397.2510 \\ h_{\text{cylinder}} &= 2685.94\ \text{kJ/kg} \end{aligned}$$

Step 8 of 8

Use saturated water - Pressure tables to determine the corresponding values of steam at a pressure of 200 kPa.

Enthalpy at saturated liquid state, $h_f = 504.71\ \text{kJ/kg}$.

Enthalpy at saturated vapor state, $h_g = 2706.3\ \text{kJ/kg}$.

Since, $h_f < h_{\text{cylinder}} < h_g$. The steam insider the piston-cylinder device is at a pressure of 200 kPa.

Use saturated water - Pressure tables to determine the corresponding values of steam at a pressure of 200 kPa.

Saturated temperature, $T_{\text{cylinder}} = 120.21°\text{C}$

Therefore, the temperature of steam inside the piston-cylinder device is $\boxed{120.21°\text{C}}$.

Question: 8.180P

3-kg of helium gas at 100 kPa and 27°C are adiabatically compressed to 900 kPa. If the isentropic compression efficiency is 80 percent, determine the required work input *M* and the final temperature of helium.

Step 1 of 4

Given data:

Mass of helium compressed is $m = 3\ \text{kg}$

Initial pressure is, $P_1 = 100\ \text{kPa}$

Initial temperature is, $T_1 = 27°\text{C}$

$= 300\ \text{K}$

Final pressure is, $P_2 = 900\ \text{kPa}$

The isentropic efficiency is, $\eta_{isen} = 80\ \%$

$= 0.8$

Step 2 of 4

From ideal gas specific heats of various common gases

For helium, $c_v = 3.1156\ \text{kJ/kg°K}$ and $k = 1.667$

We know that

The temperature ratio is given by

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = 300 \times \left(\frac{900}{100}\right)^{\frac{1.667-1}{1.667}}$$

$$T_{2s} = 300 \times (9)^{\frac{0.667}{1.667}}$$

$$T_{2s} = 300 \times (9)^{0.4}$$

$$T_{2s} = 300 \times 2.408$$

$$T_{2s} = 722.4\ \text{K}$$

Step 3 of 4

Now we know that

The adiabatic work done is given by

$$W_{in,s} = m \times c_v \times (T_{2s} - T_1)$$

$$W_{in,s} = 3 \times 3.1156 \times (722.4 - 300)$$

$$W_{in,s} = 3 \times 3.1156 \times 422.4$$

$$W_{in,s} = 3948.088\ \text{kJ}$$

Now we know that

The isentropic efficiency of compressor is given by

$$\eta_{isen} = \frac{W_{in,s}}{W_{in,act}}$$

$$W_{in,act} = \frac{W_{in,s}}{\eta_{isen}}$$

$$W_{in,act} = \frac{3948.088}{0.8}$$

$$\boxed{W_{in,act} = 4935.11\ \text{kJ}}$$

Step 4 of 4

We know that

The actual work done is also given by

$$W_{in,act} = m \times c_v \times (T_2 - T_1)$$

$$T_2 - T_1 = \frac{W_{in,act}}{m \times c_v}$$

$$T_2 = T_1 + \frac{W_{in,act}}{m \times c_v}$$

$$T_2 = 300 + \frac{4935.11}{3 \times 3.1156}$$

$$T_2 = 300 + \frac{4935.11}{9.3468}$$

$$T_2 = 300 + 527.99$$

$$T_2 = 827.99\ \text{K}$$

$$\boxed{T_2 = 554.99°\text{C}}$$

Therefore the actual work done, $W_{in,act} = 4935.11\ \text{kJ}$

The actual final temperature, $T_2 = 554.99°\text{C}$

Question: 8.181P

Refrigerant-134a at 600 kPa and 100°C undergoes areversible, isothermal expansion to 200 kPa in a steady-flowdevice with one inlet and one outlet. Determine the powerproduced by this device and the rate of heat transfer when theflow rate through the device is 1 kg/s.

Step 1 of 3

Given data:

Mass of helium compressed is $\dot{m} = 1$ kg/s

Pressure at inlet of the device is, $P_1 = 600$ kPa

Temperature at inlet of the device is, $T_1 = 100°C$

$= 373$ K

Pressure at exit of the device is, $P_2 = 200$ kPa

Step 2 of 3

From properties of superheated refrigerant-134a

At pressure $P_1 = 600$ kPa and temperature $T_1 = 100°C$

$h_1 = 339.47$ kJ/kg

$s_1 = 1.1536$ kJ/kg°K

As the process is isothermal, temperature at inlet and exit will be same.

$T_2 = T_1 = 100°C$

Similarly, from properties of superheated refrigerant-134a

At pressure $P_2 = 200$ kPa and temperature $T_2 = 100°C$

$h_2 = 343.6$ kJ/kg

$s_2 = 1.2512$ kJ/kg°K

We know that

From entropy equation the heat input is given by

$$Q_{in} = m\int_1^2 T\, ds$$

$$Q_{in} = m \times T\ (s_2 - s_1)$$

$$Q_{in} = 1 \times 373 \times (1.2512 - 1.1536)$$

$$Q_{in} = 1 \times 373 \times 0.0976$$

$$\boxed{Q_{in} = 36.405 \text{ kW}}$$

Step 3 of 3

Now we know that

The energy balance given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

As the flow is steady, $\Delta E_{sys} = 0$.

Therefore,

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$Q_{in} + \dot{m}h_1 = W_{out} + \dot{m}h_2$$

$$W_{out} = Q_{in} + \dot{m}h_1 - \dot{m}h_2$$

$$W_{out} = 36.405 + (1 \times 339.47) - (1 \times 343.6)$$

$$W_{out} = 36.405 + 339.47 - 343.6$$

$$\boxed{W_{out} = 32.275 \text{ kW}}$$

Therefore the heat transfer, $Q_{in} = 36.405$ kW

The work done, $W_{out} = 32.275$ kW

Question: 8.182P

An inventor claims to have invented an adiabatic steady-flow device with a single inlet-outlet that produces 100 kW when expanding 1 kg/s of air from 900 kPa and 300°C to 100 kPa. Is this claim valid?

Step 1 of 3

Given data:

Mass of air is $m = 1\ \text{kg/s}$

Work done by the device is, $W_{out,act} = 100\ \text{kW}$

Pressure at inlet of the device is, $P_1 = 900\ \text{kPa}$

Temperature at inlet of the device is, $T_1 = 300\ ^\circ\text{C}$

$= 573\ \text{K}$

Pressure at exit of the device is, $P_2 = 100\ \text{kPa}$

Step 2 of 3

From ideal gas specific heats of various common gases

$T_{avg} = 400\ \text{K}$ (Assumed)

$c_p = 1.013\ \text{kJ/kg°K}$

$k = 1.395$

We know that

The temperature ratio is given by

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = 573 \times \left(\frac{100}{900}\right)^{\frac{1.395-1}{1.395}}$$

$$T_{2s} = 573 \times (0.111)^{\frac{0.395}{1.395}}$$

$$T_{2s} = 573 \times (0.111)^{0.283}$$

$$T_{2s} = 573 \times 0.5368$$

$$T_{2s} = 307.586\ \text{K}$$

Step 3 of 3

Now we that

The energy balance given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

As the flow is steady, $\Delta E_{sys} = 0$. So,

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$mh_1 = W_{out} + mh_2$$

Therefore the isentropic work done is given by

$$W_{out,s} = mh_1 - mh_{2s}$$

$$W_{out,s} = m(h_1 - h_{2s})$$

$$W_{out,s} = m \times c_p \times (T_1 - T_{2s})$$

$$W_{out,s} = 1 \times 1.013 \times (573 - 307.586)$$

$$W_{out,s} = 1 \times 1.013 \times 265.414$$

$$W_{out,s} = 268.864\ \text{kW}$$

$$\boxed{W_{out,s} > W_{out,act}}$$

As actual work done is less than isentropic work done (max, possible work done), the claim is valid

Question: 8.183P

You are to expand a gas adiabatically from 3 MPa and 300°C to 80 kPa in a piston-cylinder device. Which of the two choices - air with an isentropic expansion efficiency of 90 percent or neon with an isentropic expansion efficiency of 80 percent - will produce the most work?

Step 1 of 4

Given

Mass of helium compressed is $m = 3\ \text{kg}$

Initial pressure is, $P_1 = 3\ \text{MPa}$

$= 3000\ \text{kPa}$

Initial temperature is, $T_1 = 300°\text{C}$

$= 573\ \text{K}$

Final pressure is, $P_2 = 80\ \text{kPa}$

The isentropic efficiency while using air is, $\eta_{isen,a} = 0.9$

The isentropic efficiency while using neon is, $\eta_{isen,n} = 0.8$

Step 2 of 4

From ideal gas specific heats of various common gases

For air

$c_{v,a} = 0.718\ \text{kJ/kg°K}$

$k_a = 1.4$

Similarly, from ideal gas specific heats of various common gases

For neon

$c_{v,n} = 0.6179\ \text{kJ/kg°K}$

$k_n = 1.667$

Now we know that

The temperature ratio is given by

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s,a} = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k_a-1}{k_a}}$$

$$T_{2s,a} = 573 \times \left(\frac{80}{3000}\right)^{\frac{1.4-1}{1.4}}$$

$$T_{2s,a} = 573 \times (0.0266)^{\frac{0.4}{1.4}}$$

$$T_{2s,a} = 573 \times (0.0266)^{0.2857}$$

$$T_{2s,a} = 573 \times 0.3548$$

$$T_{2s,a} = 203.3\ \text{K}$$

Step 3 of 4

Now we know that

The adiabatic work done by air is given by

$$w_{s,a} = c_{v,a} \times (T_1 - T_{2s,a})$$

$$w_{s,a} = 0.718 \times (573 - 203.3)$$

$$w_{s,a} = 0.718 \times 369.7$$

$$w_{s,a} = 265.445\ \text{kJ/kg}$$

The actual work done by air is given by

$$w_{act,a} = \eta_{isen,a} \times w_{s,a}$$

$$w_{act,a} = 0.9 \times 265.445$$

$$w_{act,a} = 238.9\ \text{kJ/kg}$$

Similarly, we know that

The adiabatic final temperature of neon is given by

$$T_{2s,n} = T_1 \times \left(\frac{P_2}{P_1}\right)^{\frac{k_n-1}{k_n}}$$

$$T_{2s,n} = 573 \times \left(\frac{80}{3000}\right)^{\frac{1.667-1}{1.667}}$$

$$T_{2s,n} = 573 \times (0.0266)^{\frac{0.667}{1.667}}$$

$$T_{2s,n} = 573 \times (0.0266)^{0.4}$$

$$T_{2s,n} = 573 \times 0.2344$$

$$T_{2s,n} = 134.31\ \text{K}$$

Step 4 of 4

The adiabatic work done by neon is given by

$$w_{s,n} = c_{v,n} \times (T_1 - T_{2s,n})$$

$$w_{s,n} = 0.6179 \times (573 - 134.31)$$

$$w_{s,n} = 0.6179 \times 438.69$$

$$w_{s,n} = 271.067\ \text{kJ/kg}$$

The actual work done by air is neon by

$$w_{act,n} = \eta_{isen,n} \times w_{s,n}$$

$$w_{act,n} = 0.8 \times 271.067$$

$$w_{act,n} = 216.854\ \text{kJ/kg}$$

$$\boxed{w_{act,n} < w_{act,a}}$$

Therefore the actual work done by air is greater than the actual work done by neon.

Question: 8.184P

An adiabatic capillary tube is used in some refrigeration systems to drop the pressure of the refrigerant from the condenser level to the evaporator level. R-134a enters the capillary tube as a saturated liquid at 50°C, and leaves at -12°C. Determine the rate of entropy generation in the capillary tube for a mass flow rate of 0.2 kg/s.

FIGURE P8–184

Step 1 of 4

Apply the entropy balance on the heat exchanger,

$$\dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} = \Delta \dot{S}_{system}$$

$$\dot{S}_{gen} = \dot{m}(s_2 - s_1) \quad \text{..... (1)}$$

Step 2 of 4

From the properties table of the refrigerant R-134a,

Calculate the entropy and enthalpy at $T_1 = 50°C$, $x_1 = 0$ by interpolating the enthalpy and entropy values at $T = 48°C$ and $T = 52°C$

$$h_1 = h_{T=48°C} + (h_{T=52°C} - h_{T=48°C})\left(\frac{50-48}{52-48}\right)$$
$$= 120.39 + (126.59 - 120.39)(0.5)$$
$$= 120.39 + 3.1$$
$$= 123.49 \text{ kJ/kg}$$

$$s_1 = s_{T=48°C}^{\bullet} + (s_{T=52°C}^{\bullet} - s_{T=48°C}^{\bullet})\left(\frac{50-48}{52-48}\right)$$
$$= 0.43242 + (0.45126 - 0.43242)(0.5)$$
$$= 0.43242 + 0.00942$$
$$= 0.44184 \text{ kJ/kg} \cdot \text{K}$$

Step 3 of 4

From the properties table of the refrigerant R-134a,

At $T_1 = -12°C$,

$h_{fg} = 207.38$ kJ/kg.K,

$h_f = 35.92$ kJ/kg.K

$s_f = 0.14504$ kJ/kg·K

$s_{fg} = 0.79406$ kJ/kg·K

A capillary device has a constant enthalpy process $h_1 = h_2$,

$$h_2 = h_1$$
$$= h_f + x_2 h_{fg}$$

From the above equation calculate the Quality at final state as follows:

$$x_2 = \frac{h_2 - h_f}{f_{fg}}$$

Substitute, 123.49 kJ/kg·K for h_1, 0.44184 kJ/kg·K for s_1, 207.38 kJ/kg.K for h_{fg}, 35.92 kJ/kg.K for h_f

$$x_2 = \frac{123.5 - 35.92}{207.38}$$
$$= \frac{87.58}{207.38}$$
$$= 0.4223$$

Step 4 of 4

Calculate Entropy at final state by using the following equation:

$$s_2 = s_f + x_2 s_{fg}$$

Substitute, 0.14504 kJ/kg·K for s_f, 0.79406 kJ/kg·K for s_{fg}

$$s_2 = 0.14504 + (0.4233)(0.794)$$
$$= 0.14504 + 0.3361$$
$$= 0.4811 \text{ kJ/kg} \cdot \text{K}$$

Substitute, in the above entropy relation in equation (1), we have

$$\dot{S}_{gen} = 0.2(0.4811 - 0.44184)$$
$$= 0.2 \times 0.03926$$
$$= 0.00785 \text{ kW/K}$$

Therefore, the rate of entropy generation in capillary tube, $\dot{S}_{gen}$ is $\boxed{0.00785 \text{ kW/K}}$

Question: 8.185P

Air is compressed steadily by a compressor from 100 kPa and 17°C to 700 kPa at a rate of 5 kg/min. Determine the minimum power input required if the process is adiabatic and (*b*) isothermal. Assume air to be an ideal gas with variable specific heats, and neglect the changes in kinetic and potential energies.

Step 1 of 8

Given data:

Pressure at compressor inlet is, $P_1 = 100\ \text{kPa}$

Temperature at compressor inlet is, $T_1 = 17\ ^\circ\text{C} = 290\ \text{K}$

Pressure at compressor exit is, $P_2 = 700\ \text{kPa}$

Mass flow rate of air is, $m = 5\ \text{kg/min} = 0.083\ \text{kg/s}$

Step 2 of 8

From table of ideal gas specific heats of various common gases '

Gas constant of air is

$R = 0.287\ \text{kJ/kg°K}$

From table of 'ideal gas properties of air'

At temperature $T_1 = 290\ \text{K}$ properties of air are

$P_{r1} = 1.2311$

$h_1 = 290.16\ \text{kJ/kg}$

Step 3 of 8

(a) Final pressure of adiabatic process is given by

$$P_{r2} = P_{r1} \times \left(\frac{P_2}{P_1}\right)$$

$$= 1.2311 \times \left(\frac{700}{100}\right)$$

$$= 1.2311 \times 7$$

$$= 8.6177$$

Step 4 of 8

From table of 'ideal gas properties of air'

At pressure ratio $P_{r2} = 8.6177$, final temperature is interpolated as

$$\frac{T_2 - 500}{510 - 500} = \frac{8.6177 - 8.411}{9.031 - 8.411}$$

$$\frac{T_2 - 500}{10} = \frac{0.2067}{0.62}$$

$$\frac{T_2 - 500}{10} = 0.333$$

$$T_2 = 0.333 \times 10 + 500$$

$$= 3.33 + 500$$

$$= 503.3\ \text{K}$$

Step 5 of 8

From table of 'ideal gas properties of air'

At pressure ratio $P_{r2} = 8.6177$, final enthalpy is interpolated as

$$\frac{h_2 - 503.02}{513.32 - 503.02} = \frac{8.6177 - 8.411}{9.031 - 8.411}$$

$$\frac{h_2 - 503.02}{10.3} = \frac{0.2067}{0.62}$$

$$\frac{h_2 - 503.02}{10.3} = 0.333$$

$$h_2 = 0.333 \times 10.3 + 503.02$$

$$= 3.43 + 503.02$$

$$= 506.45\ \text{kJ/kg}$$

Step 6 of 8

Power input is given by

$$W_{in} = m \times (h_2 - h_1)$$

$$= 0.083 \times (506.45 - 290.16)$$

$$= 0.083 \times 216.29$$

$$= 17.952\ \text{kW}$$

$$\boxed{W_{in} = 17.952\ \text{kW}}$$

Step 7 of 8

(b) Energy balance is given by

$$E_{in} - E_{out} = \Delta E_{sys}$$

For steady process, $\Delta E_{sys} = 0$

$$E_{in} - E_{out} = 0$$

$$E_{in} = E_{out}$$

$$W_{in} + mh_1 = Q_{out} + mh_2$$

$$W_{in} = Q_{out} + mh_2 - mh_1$$

$$W_{in} = Q_{out} + m(h_2 - h_1)$$

For ideal gas enthalpy is a function of temperature. As the process is isothermal, change in enthalpy is zero.

$$W_{in} = Q_{out} + 0$$

$$= Q_{out}$$

$$= m \times T \times (s_1 - s_2)$$

$$= -m \times T \times (s_2 - s_1)$$

Step 8 of 8

$$W_{in} = -m \times T \times \left[\left(s_t^0 - s_1^0\right) - R \times \ln\left(\frac{P_2}{P_1}\right)\right]$$

As the process is isothermal, change in entropy is zero.

$$W_{in} = -m \times T \times \left[0 - R \times \ln\left(\frac{P_2}{P_1}\right)\right]$$

$$= -m \times T \times \left[-R \times \ln\left(\frac{P_2}{P_1}\right)\right]$$

$$= m \times T \times R \times \ln\left(\frac{P_2}{P_1}\right)$$

$$= 0.083 \times 290 \times 0.287 \times \ln\left(\frac{700}{100}\right)$$

$$= 0.083 \times 290 \times 0.287 \times \ln 7$$

$$= 0.083 \times 290 \times 0.287 \times 1.946$$

$$= 13.443\text{kW}$$

$$\boxed{W_{in} = 13.443\ \text{kW}}$$

The power input in an adiabatic process is 17.952 kW and the power input in an isothermal process is 13.443 kW

Question: 8.186P

Refrigerant-134a at 100 kPa and - 20°C is compressed by an adiabatic 1.3-kW compressor to an exit state of 800 kPa and 60°C. Neglecting the changes in kinetic and potential energies, determine (*a*) the isentropic efficiency of the compressor, (*b*) the volume flow rate of the refrigerant at the compressor inlet, in L/min, and (*c*) the maximum volume flow rate at the inlet conditions that this adiabatic 0.7-kW compressor can handle without violating the second law.

Step 1 of 8

Given data:

Pressure at compressor inlet is, $P_1 = 100\ \text{kPa}$

Temperature at compressor inlet is, $T_1 = -20\ ^\circ\text{C} = 253\ \text{K}$

Pressure at compressor exit is, $P_2 = 800\ \text{kPa}$

Temperature at compressor exit is, $T_2 = 60\ ^\circ\text{C} = 333\ \text{K}$

Power input to compressor is, $W_{in} = 1.3\ \text{kW}$

Step 2 of 8

From table of superheated refrigerant 134a,

At pressure $P_1 = 100\ \text{kPa}$ and temperature $T_1 = -20\ ^\circ\text{C}$

Properties of refrigerant are

$v_1 = 0.19841\ \text{m}^3/\text{kg}$

$h_1 = 239.5\ \text{kJ/kg}$

$s_1 = 0.9721\ \text{kJ/kg°K}$

From table of superheated refrigerant 134a,

at pressure $P_2 = 800\ \text{kPa}$ and temperature $T_2 = 60\ ^\circ\text{C}$

Properties of refrigerant are

$h_{2a} = 296.81\ \text{kJ/kg}$

Step 3 of 8

From table of superheated refrigerant 134a,

at pressure $P_2 = 800\ \text{kPa}$ and entropy $s_{2s} = s_1 = 0.9721\ \text{kJ/kg°K}$

Enthalpy of refrigerant is interpolated as

$$\frac{h_{2s} - 276.45}{286.69 - 276.45} = \frac{0.9721 - 0.9480}{0.9802 - 0.9480}$$

$$\frac{h_{2s} - 276.45}{10.24} = \frac{0.0241}{0.0322}$$

$$\frac{h_{2s} - 276.45}{10.24} = 0.7484$$

$$h_{2s} = 0.7484 \times 10.24 + 276.45$$

$$= 7.66 + 276.45$$

$$= 284.11\ \text{kJ/kg}$$

Step 4 of 8

(a) Isentropic efficiency of compressor is given by

$$\eta_c = \frac{h_{2s} - h_1}{h_{2a} - h_1}$$

$$= \frac{284.11 - 239.5}{296.81 - 239.5}$$

$$= \frac{44.61}{57.31}$$

$$= 0.7784$$

$$= 77.84\%$$

$$\boxed{\eta_c = 0.7784 = 77.84\ \%}$$

Step 5 of 8

Actual work input is given by

$$W_{in} = m_a \times (h_{2a} - h_1)$$

Actual mass flow rate of compressor is given by

$$m_a = \frac{W_{in}}{h_{2a} - h_1}$$

$$= \frac{1.3}{296.81 - 239.5}$$

$$= \frac{1.3}{57.31}$$

$$= 0.0227\ \text{kg/s}$$

Step 6 of 8

(b) Volume flow rate at compressor inlet is given by

$$V_1 = m_a \times v_1$$

$$= 0.0227 \times 0.19841$$

$$= 0.0045\ \text{m}^3/\text{s}$$

$$= 270\ \text{L/min}$$

$$\boxed{V_1 = 0.0045\ \text{m}^3/\text{s} = 270\ \text{L/min}}$$

Step 7 of 8

Adiabatic work input is given by

$$W_{in} = m_s \times (h_{2s} - h_1)$$

Adiabatic mass flow rate of compressor is given by

$$m_s = \frac{W_{in}}{h_{2s} - h_1}$$

Given for calculating maximum volume flow rate, $W_{in} = 0.7\ \text{kW}$

$$m_s = \frac{0.7}{284.11 - 239.5}$$

$$= \frac{0.7}{44.61}$$

$$= 0.0157\ \text{kg/s}$$

Step 8 of 8

(c) Maximum volume flow rate at compressor inlet is given by

$$V_{max} = m_s \times v_1$$

$$V_{max} = 0.0157 \times 0.19841$$

$$= 0.00311\ \text{m}^3/\text{s}$$

$$= 186.6\ \text{L/min}$$

$$\boxed{V_{max} = 0.00311\ \text{m}^3/\text{s} = 186.6\ \text{L/min}}$$

The isentropic efficiency of compressor is 77.84 % , the volume flow rate is 270 L/min and the maximum flow rate for the compressor with work input $W_{in} = 0.7\ \text{kW}$ is 186.6 L/min

Question: 8.187P pg 1

An adiabatic air compressor is to be powered by a direct-coupled adiabatic steam turbine that is also driving a generator. Steam enters the turbine at 12.5 MPa and 500°C at a rate of 25 kg/s and exits at 10 kPa and a quality of 0.92. Air enters the compressor at 98 kPa and 295 K at a rate of 10 kg/s and exits at 1 MPa and 620 K. Determine (*a*) the net power delivered to the generator by the turbine and (*b*) the rate of entropy generation within the turbine and the compressor during this process.

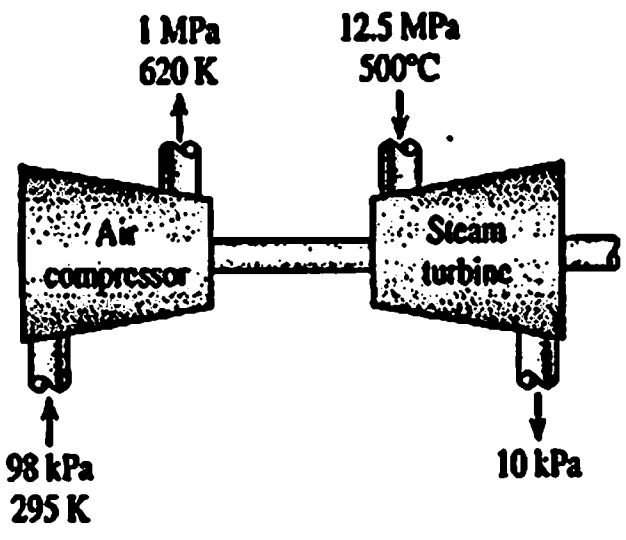

FIGURE P8–187

Step 1 of 9

Given data:

Air entering the compressor at a pressure, $P_1 = 98\ \text{kPa}$

Air entering the compressor at a temperature, $T_1 = 295\ \text{K}$

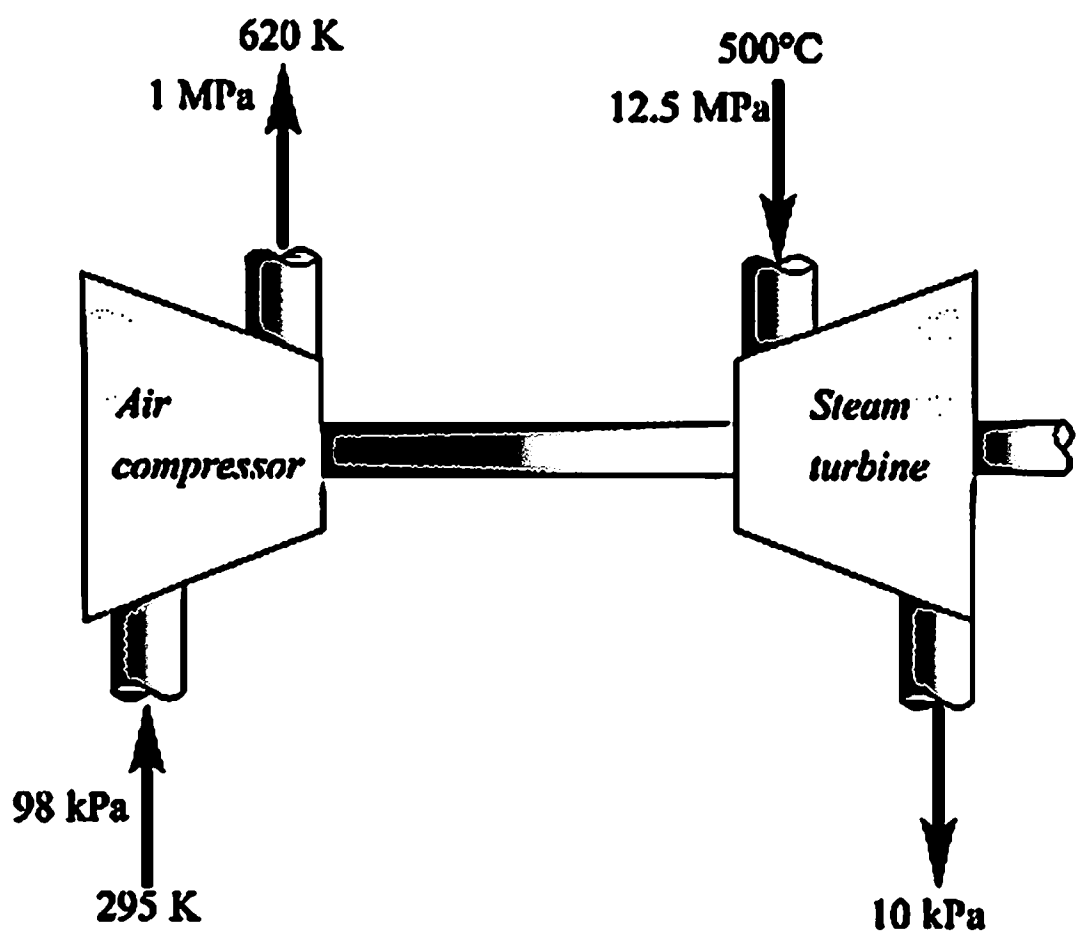
Mass flow rate of the air in the compressor, $m_1 = 10\ \text{kg/s}$

Compressed air leaving the compressor at a pressure, $P_2 = 1\ \text{MPa}$

Exit temperature of the compressed air, $T_2 = 620\ \text{K}$

Steam entering the turbine at a pressure, $P_3 = 12.5\ \text{MPa}$

Steam entering the turbine at a temperature, $T_3 = 500\ ^\circ\text{C}$



Mass flow rate of the steam, $m_3 = 25\ \text{kg/s}$

Steam exits the turbine at a pressure, $P_4 = 10\ \text{kPa}$

Quality of steam is $x = 0.92$

Step 2 of 9

An adiabatic air compressor double coupled to the turbine is as shown below:

Step 3 of 9

From the ideal-gas properties of air at temperature $T_1 = 295\ \text{K}$, the following values are taken

Enthalpy $h_1 = 295.17\ \text{kJ/kg}$

Entropy $s_1^0 = 1.68515\ \text{kJ/kg}\cdot\text{K}$

Similarly at temperature $T_2 = 620\ \text{K}$, the following values are taken

Enthalpy $h_2 = 628.07\ \text{kJ/kg}$

Entropy $s_2^0 = 2.44356\ \text{kJ/kg}\cdot\text{K}$

In the turbine steam entering at a pressure, $P_3 = 12.5\ \text{MPa}$ maintaining temperature, $T_3 = 500\ ^\circ\text{C}$ the steam is in superheated state at this temperature. Therefore from the superheated water tables at $P_3 = 12.5\ \text{MPa}$ and at temperature $T_3 = 500\ ^\circ\text{C}$ the following values are taken

Enthalpy $h_3 = 3343.6\ \text{kJ/kg}$

Entropy $s_3 = 6.4651\ \text{kJ/kg}\cdot\text{K}$

Step 4 of 9

Similarly at pressure $P_4 = 10\ \text{kPa}$ the steam is in saturated liquid state, therefore from the saturated water tables at $P_4 = 10\ \text{kPa}$ the following values are taken

Enthalpy of Saturated liquid $h_f = 191.81\ \text{kJ/kg}$

Enthalpy of Evaporated liquid $h_{fg} = 2392.1\ \text{kJ/kg}$

Similarly Entropy of Saturated liquid $s_f = 0.6492\ \text{kJ/kg}\cdot\text{K}$

Entropy of Evaporated liquid $s_{fg} = 7.4996\ \text{kJ/kg}\cdot\text{K}$

The enthalpy at state 4 is given by

$$h_4 = h_f + xh_{fg}$$
$$= 191.81 + (0.92)(2392.1)$$
$$= 2392.54\ \text{kJ/kg}$$

The entropy at state 4 is given by

$$s_4 = s_f + xs_{fg}$$
$$= 0.6492 + (0.92)(7.4996)$$
$$= 7.5488\ \text{kJ/kg}\cdot\text{K}$$

Step 5 of 9

Net energy transfer by heat, work and mass is equal to change in the internal, kinetic, potential energies

The energy balance for steady-flow system is

$$E_{in} - E_{out} = \Delta E_{system} = 0\ (steady)$$

Work done on the compressor at the inlet of the system is given by

$$\dot{W}_{comp,in} + \dot{m}_{air} h_1 = \dot{m}_{air} h_2$$

energies

The energy balance for steady-flow system is

$$E_{in} - E_{out} = \Delta E_{system} = 0 (steady)$$

Work done on the compressor at the inlet of the system is given by

$$\dot{W}_{comp,in} + \dot{m}_{air} h_1 = \dot{m}_{air} h_2$$

$$\dot{W}_{comp,in} = \dot{m}_{air} (h_2 - h_1)$$

$$= 10(628.07 - 295.17)$$

$$= 3328.3 \text{ kW}$$

Step 6 of 9

The work done by the turbine at the outlet of the system is given by

$$E_{in} - E_{out} = 0$$

$$\dot{m}_{steam} h_3 = \dot{W}_{turb,out} + \dot{m}_{steam} h_4$$

$$\dot{W}_{turb,out} = \dot{m}_{steam} (h_3 - h_4)$$

$$= 25(3343.6 - 2392.5)$$

$$= 23777.5 \text{ kW}$$

Step 7 of 9

a)

The net power delivered to the generator by the turbine is given by

$$\dot{W}_{net} = \dot{W}_{turb,out} - \dot{W}_{turb,in}$$

$$= 23777.5 - 3328.3$$

$$= 20449.2 \text{ kW}$$

Therefore, the net power delivered to the generator by the turbine is $\boxed{\dot{W}_{net} = 20449.2 \text{ kW}}$

Step 8 of 9

b)

The rate of entropy generation of air in the compressor is given by

$$\dot{S}_{gen(comp)} = \dot{m}_{air} (s_2 - s_1)$$

$$= \dot{m}_{air} \left(s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right)$$

$$= 10 \left(2.44356 - 1.68515 - 0.2871 \ln \frac{1000}{98} \right)$$

$$= 10(2.44356 - 1.68515 - 0.667)$$

$$= 0.92 \text{ kW/K}$$

Step 9 of 9

Similarly the rate of entropy generation of steam in the turbine is

$$\dot{S}_{gen(turb)} = \dot{m}_{steam} (s_4 - s_3)$$

$$= (25)(7.5488 - 6.4651)$$

$$= 27.09 \text{ kW/K}$$

The rate of entropy generation within the turbine and compressor during this process

$$\dot{S}_{gen} = \dot{S}_{gen(comp)} + \dot{S}_{gen(turb)}$$

$$= 0.92 + 27.09$$

$$= 28.012 \text{ kW/K}$$

Therefore, the rate of entropy generation within the turbine and compressor during this process is

$$\boxed{\dot{S}_{gen} = 28.012 \text{ kW/K}}$$

Question: 8.188P

Reconsider Prob. 8-187. Using EES (or other) software, determine the isentropic efficiencies for the compressor and turbine. Then use EES to study how varying the compressor efficiency over the range 0.6 to 0.8 and the turbine efficiency over the range 0.7 to 0.95 affect the net work for the cycle and the entropy generated for the process. Plot the net work as a function of the compressor efficiency for turbine efficiencies of 0.7, 0.8, and 0.9, and discuss your results.

Step 1 of 8

(a)

The initial pressure inside the tank is 500 kPa.

Obtain the properties of saturated water vapor at pressure is 500 kPa from the Table A-5 "saturated water-pressure table" from the text book.

Specific volume at saturated vapor state, $v_{1,\text{tank}} = 0.37483\ \text{m}^3/\text{kg}$.

Internal energy at saturated vapor state, $u_{1,\text{tank}} = 2560.7\ \text{kJ/kg}$.

Entropy at saturated vapor state, $s_{1,\text{tank}} = 6.8207\ \text{kJ/kg}\cdot\text{K}$.

Step 2 of 8

The final pressure inside the tank is 150 kPa.

Obtain the properties of saturated water at pressure is 150 kPa from the Table A-5 "saturated water-pressure table" from the text book.

Saturated temperature, $T_2 = 111.35°\text{C}$

Specific volume at saturated liquid state, $v_f = 0.001053\ \text{m}^3/\text{kg}$.

Specific volume at saturated vapor state, $v_g = 1.1594\ \text{m}^3/\text{kg}$.

Internal energy at saturated liquid state, $u_f = 466.97\ \text{kJ/kg}$.

Internal energy for evaporate of water, $u_{fg} = 2052.3\ \text{kJ/kg}$.

Entropy at saturated liquid state, $s_f = 1.4337\ \text{kJ/kg}\cdot\text{K}$.

Entropy for evaporate of water, $s_{fg} = 5.7894\ \text{kJ/kg}\cdot\text{K}$.

Therefore, the final temperature of the steam inside the rigid tank is, $\boxed{111.35°\text{C}}$.

Step 3 of 8

Steam has undergone reversible adiabatic process. Therefore, entropy of steam remains constant.

$$\begin{aligned} s_{1,\text{tank}} &= s_{2,\text{tank}} \\ &= s_f + x s_{fg} \end{aligned}$$

Here, $s_{2,\text{tank}}$ is the entropy of the steam inside the rigid tank at state 2, and x is the dryness fraction of steam at state 2.

Substitute $6.8207\ \text{kJ/kg}\cdot\text{K}$ for $s_{1,\text{tank}}$, $1.4337\ \text{kJ/kg}\cdot\text{K}$ for s_f , $5.7894\ \text{kJ/kg}\cdot\text{K}$ and for s_{fg} .

$$6.8207 = 1.4337 + x \times 5.7894$$
$$x = 0.9304$$

Step 4 of 8

Calculate the initial mass of steam in the rigid tank using the equation,

$$m_{1,\text{tank}} = \frac{V}{v_{1,\text{tank}}}$$

Here, V is the volume of the rigid tank.

Substitute $0.4\ \text{m}^3$ for V, and $0.37483\ \text{m}^3/\text{kg}$ for $v_{1,\text{tank}}$.

$$\begin{aligned} m_{1,\text{tank}} &= \frac{0.4}{0.37483} \\ &= 1.067\ \text{kg} \end{aligned}$$

Step 5 of 8

Calculate the final specific volume of steam in the rigid tank using the equation,

$$v_{2,\text{tank}} = v_f + x\left(v_g - v_f\right)$$

Substitute $0.001053\ \text{m}^3/\text{kg}$ for v_f , $1.1594\ \text{m}^3/\text{kg}$ for v_g .

$$\begin{aligned} v_{2,\text{tank}} &= 0.001053 + 0.9304(1.1594 - 0.001053) \\ &= 1.079\ \text{m}^3/\text{kg} \end{aligned}$$

Calculate the final mass of steam in the rigid tank using the equation,

$$m_{2,\text{tank}} = \frac{V}{v_{2,\text{tank}}}$$

Substitute $0.4\ \text{m}^3$ for V, and $1.079\ \text{m}^3/\text{kg}$ for $v_{2,\text{tank}}$.

$$\begin{aligned} m_{2,\text{tank}} &= \frac{0.4}{1.079} \\ &= 0.371\ \text{kg} \end{aligned}$$

Step 6 of 8

(b)

Calculate the mass of steam left the rigid tank using the equation,

$$m_{\text{cylinder}} = m_{1,\text{tank}} - m_{2,\text{tank}}$$

Substitute $1.067\ \text{kg}$ for $m_{1,\text{tank}}$, and $0.371\ \text{kg}$ for $m_{2,\text{tank}}$.

$$\begin{aligned} m_{\text{cylinder}} &= 1.067 - 0.371 \\ &= 0.696\ \text{kg} \end{aligned}$$

Apply energy balance equation for the whole system (Consider rigid tank, and piston-cylinder device as system).

$$m_{1,\text{tank}} u_{1,\text{tank}} = m_{2,\text{tank}} u_{2,\text{tank}} + m_{\text{cylinder}} h_{\text{cylinder}} \quad \cdots\cdots (1)$$

Step 7 of 8

Calculate the final internal energy of steam inside rigid tank using the equation,

$$u_{2,\text{tank}} = u_f + x u_{fg}$$

Substitute $466.97\ \text{kJ/kg}$ for u_f , 0.9304 for x, and $2052.3\ \text{kJ/kg}$ for u_{fg} .

$$\begin{aligned} u_{2,\text{tank}} &= 466.97 + 0.9304 \times 2052.3 \\ &= 2376.43\ \text{kJ/kg} \end{aligned}$$

Substitute $1.067\ \text{kg}$ for $m_{1,\text{tank}}$, $2560.7\ \text{kJ/kg}$ for $u_{1,\text{tank}}$, $0.371\ \text{kg}$ for $m_{2,\text{tank}}$, $2376.43\ \text{kJ/kg}$ for $u_{2,\text{tank}}$, and $0.696\ \text{kg}$ for m_{cylinder} in equation (1).

$$m_{1,\text{tank}} u_{1,\text{tank}} = m_{2,\text{tank}} u_{2,\text{tank}} + m_{\text{cylinder}} h_{\text{cylinder}}$$
$$1.067 \times 2560.7 = 0.371 \times 2376.43 + 0.696 \times h_{\text{cylinder}}$$
$$h_{\text{cylinder}} = 2658.924\ \text{kJ/kg}$$

Step 8 of 8

Obtain the properties of saturated water at pressure is 150 kPa from the Table A-5 "saturated water-pressure table" from the text book.

Enthalpy at saturated liquid state, $h_f = 467.13\ \text{kJ/kg}$.

Enthalpy at saturated vapor state, $h_g = 2693.1\ \text{kJ/kg}$.

Since, $h_f < h_{\text{cylinder}} < h_g$. The steam inside the piston-cylinder device is at a pressure of 150 kPa.

Obtain the saturated temperature the water at pressure is 150 kPa from the Table A-5 "saturated water-pressure table" from the text book.

Saturated temperature, $T_{\text{cylinder}} = 111.35°\text{C}$

Therefore, the temperature of the steam inside the piston-cylinder device is, $\boxed{111.35°\text{C}}$.

Question: 8.189P

The explosion of a hot water tank in a school in Spencer, Oklahoma, in 1982 killed 7 people while injuring 33 others. Although the number of such explosions has decreased dramatically since the development of the ASME Pressure Vessel Code, which requires the tanks to be designed to withstand four times the normal operating pressures, they still occur as a result of the failure of the pressure relief valves and thermostats. When a tank filled with a high-pressure and high-temperature liquid ruptures, the sudden drop of the pressure of the liquid to the atmospheric level causes part of the liquid to flash into vapor, and thus to experience a huge rise in its volume. The resulting pressure wave that propagates rapidly can cause considerable damage.

Considering that the pressurized liquid in the tank eventually reaches equilibrium with its surroundings shortly after the explosion, the work that a pressurized liquid would do if allowed to expand reversibly and adiabatically to the pressure of the surroundings can be viewed as the *explosive energy* of the pressurized liquid. Because of the very short time period of the explosion and the apparent calm afterward, the explosion process can be considered to be adiabatic with no changes in kinetic and potential energies and no mixing with the air.

Consider a 80-L hot-water tank that has a working pressure of 0.5 MPa. As a result of some malfunction, the pressure in the tank rises to 2 MPa, at which point the tank explodes. Taking the atmospheric pressure to be 100 kPa and assuming the liquid in the tank to be saturated at the time of explosion, determine the total explosion energy of the tank in terms of the TNT equivalence. (The explosion energy of TNT is about 3250 kJ/kg, and 5 kg of TNT can cause total destruction of unreinforced structures within about a 7-m radius.)

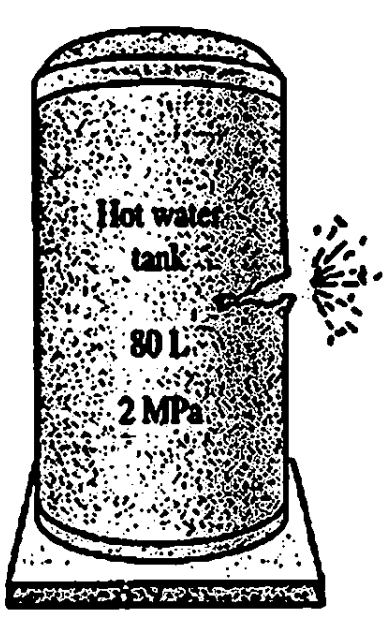


FIGURE P8–189

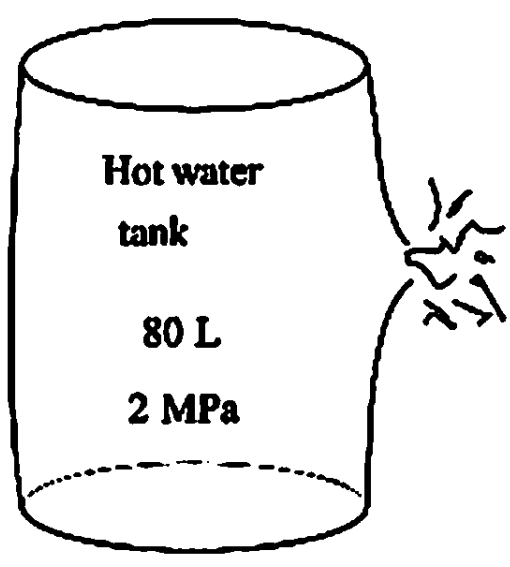
Step 1 of 6

Given data:

Volume of the water in the tank, $V = 80$ L

Pressure in the hot water tank rises $P_1 = 2$ MPa



Atmospheric pressure $P_2 = 100$ kPa

The explosion energy of TNT $E_{ex} = 3250$ kJ/kg

Kinetic and potential energy effects can be neglected

Step 2 of 6

The explosion of the hot water tank due to the rise in pressure is as shown below.

Step 3 of 6

From the saturated water-pressure tables, at pressure $P_1 = 2$ MPa the following values are taken

Specific volume, $v_1 = 0.001177\ m^3/kg$

Internal energy, $u_1 = 906.12$ kJ/kg

Entropy, $s_1 = 2.4467$ kJ/kg·K

Similarly at pressure $P_2 = 100$ kPa the following values are taken

Specific volume, $v_f = 0.001043\ m^3/kg$

$u_f = 417.40$ kJ/kg

$u_{fg} = 2088.2$ kJ/kg

$s_f = 1.3028$ kJ/kg·K

$s_{fg} = 6.0562$ kJ/kg·K

Step 4 of 6

Since the system that undergoes a reversible adiabatic process, the relation between the entropies in terms of the dryness fraction of the saturated liquid is given by

$$s_1 = s_2$$

$$s_2 = s_f + x_2 s_{fg}$$

$$x_2 = \frac{s_2 - s_f}{s_{fg}}$$

$$= \frac{2.4467 - 1.3028}{6.0562}$$

$$= 0.1889$$

The internal energy at the exit in saturated state is given by

$$u_2 = u_f + x_2 u_{fg}$$

$$= 417.40 + (0.1889)(2088.2)$$

$$= 811.86 \text{ kJ/kg}$$

Step 5 of 6

The work done during the explosion of the tank is given by

$$W_{out} = \text{Energy at TNT} \times \text{mass of TNT}$$

$$= E_{ex} \times m_{TNT}$$

$$= 3250 \times m_{TNT}$$

The mass of the water is given by

$$m = \frac{V}{v_1}$$

$$= \frac{0.08}{0.001177}$$

$$= 67.97 \text{ kg}$$

Step 6 of 6

The explosion process is considered as adiabatic and with negligible kinetic, potential energies. The net energy transfer by work is equal to change in the internal energy.

$$E_{in} - E_{out} = \Delta E_{system}$$

$$-W_{out} = \Delta U$$

$$W_{out} = m(u_1 - u_2)$$

$$= 67.99 \times (906.12 - 811.83)$$

$$E_{ex} m_{TNT} = 6410 \text{ kJ}$$

$$m_{TNT} = \frac{6410 \text{ kJ}}{3250 \text{ kJ/kg}}$$

$$= 1.9723 \text{ kg of TNT}$$

Therefore, the total explosion of the tank in terms of the TNT equivalence is

$$\boxed{m_{TNT} = 1.9723 \text{ kg of TNT}}$$

Question: 8.190P

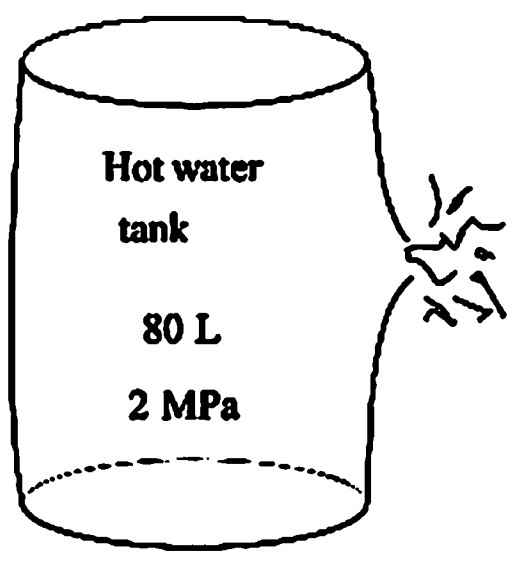
Using the arguments in the Prob. 8-189, determine the total explosion energy of a 0.35-L canned drink that explodes at a pressure of 1.2 MPa. To how many kg of TNT is this explosion energy equivalent?

Step 1 of 6

Given data:

Volume of the water in the tank, $V = 0.35$ L

Pressure in the hot water tank rises $P_1 = 1.2$ MPa



Atmospheric pressure $P_2 = 100$ kPa

The explosion energy of TNT $E_{ex} = 3250$ kJ/kg

Kinetic and potential energy effects can be neglected

Step 2 of 6

The explosion of the hot water tank due to the rise in pressure is as shown below.

Step 3 of 6

From the saturated water-pressure tables, at pressure $P_1 = 1.2$ MPa the following values are taken

Specific volume, $v_1 = 0.001138\ \text{m}^3/\text{kg}$

Internal energy, $u_1 = 796.96$ kJ/kg

Entropy, $s_1 = 2.2159$ kJ/kg·K

Similarly now at pressure $P_2 = 100$ kPa the following values are taken

$v_f = 0.001043\ \text{m}^3/\text{kg}$

$u_f = 417.40$ kJ/kg

$u_{fg} = 2088.2$ kJ/kg

$s_f = 1.3028$ kJ/kg·K

$s_{fg} = 6.0562$ kJ/kg·K

Step 4 of 6

Since the system that undergoes a reversible adiabatic process, the relation between the entropies in terms of the dryness fraction of the saturated liquid is given by

$$s_1 = s_2$$

$$s_2 = s_f + x_2 s_{fg}$$

$$x_2 = \frac{s_2 - s_f}{s_{fg}}$$

$$= \frac{2.2159 - 1.3028}{6.0562}$$

$$= 0.15077$$

The internal energy at the exit in saturated state is given by

$$u_2 = u_f + x_2 u_{fg}$$

$$= 417.40 + (0.10577)(2088.2)$$

$$= 732.24\ \text{kJ/kg}$$

Step 5 of 6

The work done during the explosion of the tank is given by

$$W_{out} = \text{Energy at TNT} \times \text{mass of TNT}$$

$$= E_{ex} \times m_{TNT}$$

$$= 3250 \times m_{TNT}$$

The mass of the water is given by

$$m = \frac{V}{v_1}$$

$$= \frac{0.00035}{0.001138}$$

$$= 0.3075\ \text{kg}$$

Step 6 of 6

The explosion process is considered as adiabatic and negligible kinetic and potential energies. The net energy transfer by work is equal to change in the internal energy

$$E_{in} - E_{out} = \Delta E_{system}$$

$$-W_{out} = \Delta U$$

$$W_{out} = m(u_1 - u_2)$$

$$= 0.3075 \times (796.96 - 732.24)$$

$$E_{ex} m_{TNT} = 19.905\ \text{kJ}$$

$$m_{TNT} = \frac{19.905\ \text{kJ}}{3250\ \text{kJ/kg}}$$

$$= 6.125 \times 10^{-3}\ \text{kg of TNT}$$

Therefore, the total explosion of the tank in the terms of the TNT equivalence is

$$\boxed{m_{TNT} = 6.125 \times 10^{-3}\ \text{kg of TNT}}$$

Question: 8.191P

Air is expanded in an adiabatic turbine of 85 percent isentropic efficiency from an inlet state of 2200 kPa and 300°C to an outlet pressure of 200 kPa. Calculate the outlet temperature of air and the work produced by this turbine per unit mass of air.

Step 1 of 6

Given

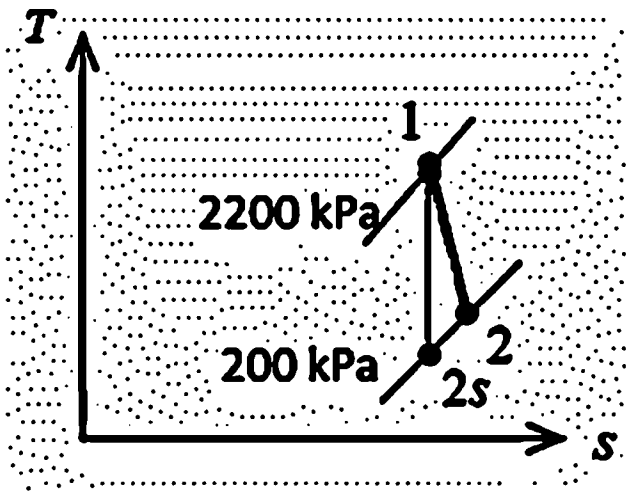
Isentropic efficiency of the turbine is, $\eta = 85\% = 0.85$

Inlet temperature of air is, $T_1 = 300°C = 573\ K$

Inlet pressure of air is, $P_1 = 2200\ kPa$

Exit pressure of air is, $P_2 = 200\ kPa$

Step 2 of 6



As air is an ideal gas from ideal gas specific heats of gases the properties of air at an average temperature $T_{avg} = 400\ K$ are

$C_p = 1.013\ kJ/kg \cdot K$

$k = 1.395$

Step 3 of 6

The T-s diagram of the expansion in the turbine is as follows

1-2s is isentropic expansion in the turbine
1-2 is actual expansion in the turbine

Step 4 of 6

During the isentropic expansion of the turbine we know

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Therefore the isentropic exit temperature is given by

$$T_{2s} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = 573 \times \left(\frac{200}{2200}\right)^{\frac{1.395-1}{1.395}}$$

$$T_{2s} = 573 \times (0.09)^{\frac{0.395}{1.395}}$$

$$T_{2s} = 289.76\ K$$

Step 5 of 6

Isentropic efficiency of turbine is given by

$$\eta = \frac{w_a}{w_{is}}$$

Therefore the actual work done is given by

$$w_a = w_s \times \eta$$

$$= \eta \times C_p (T_1 - T_{2s})$$

$$= 0.85 \times 1.013 \times (573 - 289.76)$$

$$\boxed{w_a = 243.883 kJ/kg}$$

Step 6 of 6

The actual work done is also given by

$$w_a = C_p (T_1 - T_2)$$

Therefore the actual exit temperature is given by

$$T_2 = T_1 - \frac{w_a}{C_p}$$

$$= 573 - \frac{243.883}{1.013}$$

$$= 573 - 240.75$$

$$T_{2a} = 332.25\ K$$

$$\boxed{T_{2a} = 59.25°C}$$

Therefore actual work done by the turbine is 243.883 kJ/kg and the actual exit temperature is 59.25°C

Question: 8.192P

Air is expanded in an adiabatic turbine of 90 percent isentropic efficiency from an inlet state of 2200 kPa and 300°C to an outlet pressure of 200 kPa. Calculate the outlet temperature of air, the work produced by this turbine, and the entropy generation.

Step 1 of 8

Given

Isentropic efficiency of turbine is, $\eta = 90\% = 0.9$

Inlet temperature of air is, $T_1 = 300°C = 573\ K$

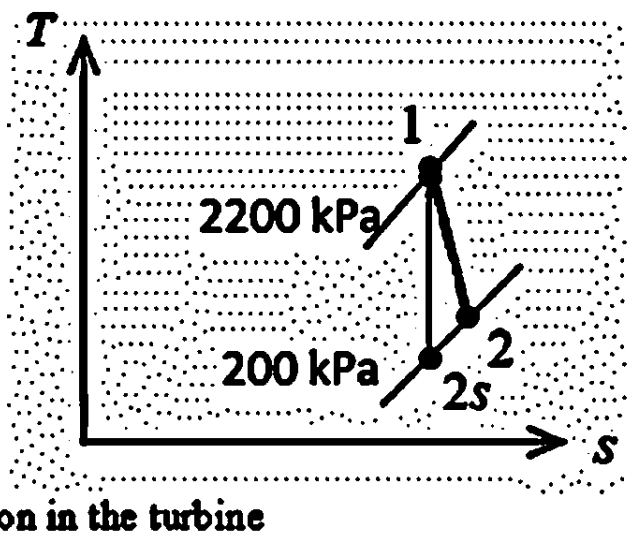
Inlet pressure of air is, $P_1 = 2200\ kPa$

Exit pressure of air is, $P_2 = 200\ kPa$

Step 2 of 8

As air is an ideal gas from ideal gas specific heats of gases the properties of air at an average temperature $T_{avg} = 400\ K$ are

$C_p = 1.013\ kJ/kg \cdot K$



$k = 1.395$

And the gas constant of air is

$R = 0.287\ kJ/kg \cdot K$

Step 3 of 8

The T-s diagram of the expansion in the turbine is as follows

1-2s is isentropic expansion in the turbine

1-2 is actual expansion in the turbine

Step 4 of 8

During the isentropic expansion of the turbine we know

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Therefore the isentropic exit temperature is given by

$$T_{2s} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$T_{2s} = 573 \times \left(\frac{200}{2200}\right)^{\frac{1.395-1}{1.395}}$$

$$T_{2s} = 573 \times (0.09)^{\frac{0.395}{1.395}}$$

$$T_{2s} = 289.76\ K$$

Step 5 of 8

Isentropic efficiency of turbine is given by

$$\eta = \frac{w_a}{w_{bs}}$$

Therefore the actual work done is given by

$$w_a = w_s \times \eta$$

$$= \eta \times C_p (T_1 - T_{2s})$$

$$= 0.9 \times 1.013 \times (573 - 289.76)$$

$$\boxed{w_a = 258.229\ kJ/kg}$$

Step 6 of 8

The actual work done is also given by

$$w_a = C_p (T_1 - T_2)$$

Therefore the actual exit temperature is given by

$$T_2 = T_1 - \frac{w_a}{C_p}$$

$$= 573 - \frac{258.229}{1.013}$$

$$= 573 - 254.915$$

$$\boxed{T_2 = 318.085\ K}$$

Step 7 of 8

The entropy balance is given by

$$S_{in} - S_{out} + S_{gen} = \Delta S_{sys}$$

Considering the process to be steady, the entropy of system can be neglected. $\Delta S_{sys} = 0$

$$S_{in} - S_{out} + S_{gen} = 0$$

$$S_{gen} = S_{out} - S_{in}$$

$$s_{gen} = s_{out} - s_{in}$$

$$s_{gen} = s_2 - s_1$$

$$s_{gen} = C_p \times \ln\left(\frac{T_2}{T_1}\right) - R \times \ln\left(\frac{P_2}{P_1}\right)$$

$$s_{gen} = 1.013 \times \ln\left(\frac{318.085}{573}\right) - 0.287 \times \ln\left(\frac{200}{2200}\right)$$

$$s_{gen} = -0.596 - (-0.68819)$$

$$\boxed{s_{gen} = 0.09219\ kJ/kg \cdot K}$$

Step 8 of 8

Therefore actual work done by the turbine is 258.229 kJ/kg ,

The actual exit temperature is 318.085K

And the entropy generation is 0.09219 kJ/kg · K

Question: 8.193P pg 1

To control the power output of an isentropic steam turbine, a throttle valve is placed in the steam line supplying the turbine inlet, as shown in the figure. Steam at 6 MPa and 400°C is supplied to the throttle inlet, and the turbine exhaust pressure is set at 70 kPa. Compare the work produced by this steam turbine, in kJ/kg, when the throttle valve is completely open (so that there is no pressure loss) and when it is partially closed so that the pressure at the turbine inlet is 3 MPa.

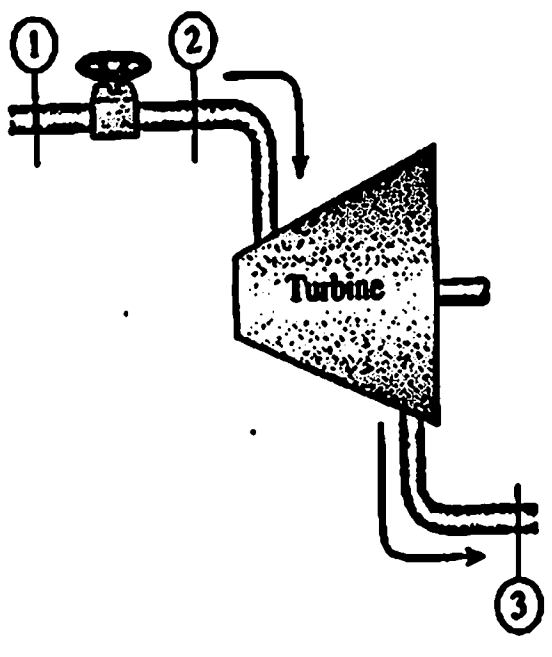


FIGURE P8–193

Step 1 of 13

Given data:

Temperature at throttle inlet is, $T_1 = 400\,^{\circ}\text{C} = 673\,\text{K}$

Pressure at throttle inlet is, $P_1 = 6\,\text{MPa} = 6000\,\text{kPa}$

Pressure at turbine inlet is, $P_2 = 3\,\text{MPa} = 3000\,\text{kPa}$

Pressure at turbine exit is, $P_3 = 70\,\text{kPa}$

Step 2 of 13

From table of 'superheated water',

At pressure $P_1 = 6\,\text{MPa}$ and temperature $T_1 = 400\,^{\circ}\text{C}$ the properties of steam are

$h_1 = 3178.3\,\text{kJ/kg}$

$s_1 = 6.5432\,\text{kJ/kg°K}$

From table of saturated water,

At pressure $P_2 = 3\,\text{MPa}$ the properties of steam are

$h_{f2} = 1008.3\,\text{kJ/kg}$

$h_{fg2} = 1794.9\,\text{kJ/kg}$

$s_{f2} = 2.6454\,\text{kJ/kg°K}$

$s_{fg2} = 3.5402\,\text{kJ/kg°K}$

Step 3 of 13

From table of 'saturated water,

At pressure $P_3 = 70\,\text{kPa}$ the properties of steam are interpolated between

50 kPa & 75 kPa

$$\frac{h_{f3} - 340.54}{384.44 - 340.54} = \frac{70 - 50}{75 - 50}$$

$$\frac{h_{f3} - 340.54}{43.9} = \frac{20}{25}$$

$$\frac{h_{f3} - 340.54}{43.9} = 0.8$$

$$h_{f3} = 0.8 \times 43.9 + 340.54$$

$$= 35.12 + 340.54$$

$$= 375.66\,\text{kJ/kg}$$

Step 4 of 13

$$\frac{h_{fg3} - 2304.7}{2278 - 2304.7} = \frac{70 - 50}{75 - 50}$$

$$\frac{h_{fg3} - 2304.7}{-26.7} = \frac{20}{25}$$

$$\frac{h_{fg3} - 2304.7}{-26.7} = 0.8$$

$$h_{fg3} = -0.8 \times 26.7 + 2304.7$$

$$= -21.36 + 2304.7$$

$$= 2283.34\,\text{kJ/kg}$$

Step 5 of 13

By using the method of interpolation

$$\frac{s_{f3} - 1.0912}{1.2132 - 1.0912} = \frac{70 - 50}{75 - 50}$$

$$\frac{s_{f3} - 1.0912}{0.122} = \frac{20}{25}$$

$$\frac{s_{f3} - 1.0912}{0.122} = 0.8$$

$$s_{f3} = 0.8 \times 0.122 + 1.0912$$

$$= 0.0976 + 1.0912$$

$$= 1.1888\,\text{kJ/kg°K}$$

Step 6 of 13

Similarly,

$$\frac{s_{fg3} - 6.5019}{6.2426 - 6.5019} = \frac{70 - 50}{75 - 50}$$

$$\frac{s_{fg3} - 6.5019}{-0.2593} = \frac{20}{25}$$

$$\frac{s_{fg3} - 6.5019}{-0.2593} = 0.8$$

$$s_{fg3} = -0.8 \times 0.2593 + 6.5019$$

$$= -0.2074 + 6.5019$$

$$= 6.2945\,\text{kJ/kg°K}$$

8.193P pg 2

$$-0.2593$$

$$s_{fg3} = -0.8 \times 0.2593 + 6.5019$$
$$= -0.2074 + 6.5019$$
$$= 6.2945 \text{ kJ/kg°K}$$

Step 7 of 13

For an isentropic process,

$s_3 = s_1$

$s_3 = 6.54323 \text{ kJ/kg°K}$

The entropy at turbine exit is also is given by

$$s_3 = s_{f3} + x_3 \times s_{fg3}$$
$$6.54323 = 1.1888 + x_3 \times 6.2945$$
$$x_3 = \frac{6.54323 - 1.1888}{6.2945}$$
$$= \frac{5.35443}{6.2945}$$
$$= 0.8507$$

Step 8 of 13

The enthalpy at turbine exit is also is given by

$$h_3 = h_{f3} + x_3 \times h_{fg3}$$
$$= 375.66 + 0.8507 \times 2283.34$$
$$= 375.66 + 1942.44$$
$$= 2318.1 \text{ kJ/kg}$$

Step 9 of 13

The work produced when throttle is open fully is given by

$$w_{open} = h_1 - h_3$$
$$w_{open} = 3178.3 - 2318.1$$
$$\boxed{w_{open} = 860.2 \text{ kJ/kg}}$$

Step 10 of 13

As throttling is an isenthalpic process,

$h_2 = h_1$

$h_2 = 3178.3 \text{ kJ/kg}$

From table of superheated water ,

At pressure $P_2 = 3$ MPa and enthalpy $h_2 = 3178.3$ kJ/kg , entropy is interpolated as

$$\frac{s_2 - 6.745}{6.9235 - 6.745} = \frac{3178.3 - 3116.1}{3231.7 - 3116.1}$$
$$\frac{s_2 - 6.745}{0.1785} = \frac{62.2}{115.6}$$
$$\frac{s_2 - 6.745}{0.1785} = 0.538$$
$$= 0.538 \times 0.1785 + 6.745$$
$$= 0.096 + 6.745$$
$$s_2 = 6.841 \text{ kJ/kg°K}$$

Step 11 of 13

For an isentropic process,

$s_3 = s_2$

$s_3 = 6.841 \text{ kJ/kg°K}$

The entropy at turbine exit is also is given by

$$s_3 = s_{f3} + x_3 \times s_{fg3}$$
$$6.841 = 1.1888 + x_3 \times 6.2945$$
$$x_3 = \frac{6.841 - 1.1888}{6.2945}$$
$$= \frac{5.6522}{6.2945}$$
$$= 0.898$$

Step 12 of 13

The enthalpy at turbine exit is also is given by

$$h_3 = h_{f3} + x_3 \times h_{fg3}$$
$$= 375.66 + 0.898 \times 2283.34$$
$$= 375.66 + 2050.44$$
$$= 2426.1 \text{ kJ/kg}$$

Step 13 of 13

The work produced when throttle is partial closed is given by

$$w_{par} = h_1 - h_3$$
$$w_{par} = 3178.3 - 2426.1$$
$$\boxed{w_{par} = 752.2 \text{ kJ/kg}}$$

Therefore actual work produced by turbine when throttle fully open is greater than when throttle partially closed.

Question: 8.194P pg 1

Oxygen tanks are filled by compressing the oxygen gas, as shown in the figure. An initially evacuated 1-m3 tank is to be filled to 13,000 kPa while the temperature of the oxygen in the tank remains constant at 20°C with this system. An isentropic compressor is used. The oxygen enters this compressor with a constant pressure and temperature of 150 kPa and 20°C. Determine the total work required by the compressor and the total heat transfer from the oxygen tank.

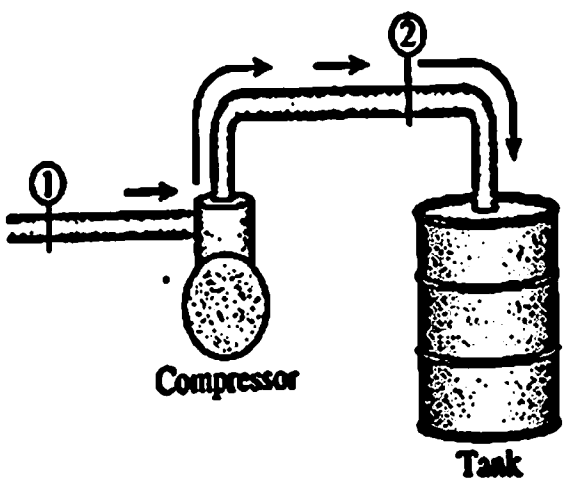

FIGURE P8–194

Step 1 of 9

Given data:

Volume of tank is, $V = 1\ \text{m}^3$

Final pressure in the tank is, $P_2 = 13000\ \text{kPa}$

Temperature in the tank is, $T_2 = 20\ ^\circ\text{C} = 293\ \text{K}$

Initial pressure at compressor inlet is, $P_1 = 150\ \text{kPa K}$

Temperature at compressor inlet is, $T_1 = 20\ ^\circ\text{C} = 293\ \text{K}$

Step 2 of 9

From table of 'ideal gas specific heats of various common gases'

Properties of oxygen are

$R = 0.2598\ \text{kJ/kg°K}$

$c_p = 0.918\ \text{kJ/kg°K}$

$c_v = 0.658\ \text{kJ/kg°K}$

$k = 1.395$

Step 3 of 9

Mass of the control volume is given by

$$m_{cv} = \frac{PV}{RT}$$

Initial mass at of tank is given by

$$m_{in} = \frac{d\left(m_{cv}\right)}{dt}$$

$$= \frac{d\left(\frac{PV}{RT}\right)}{dt}$$

$$= \frac{V}{RT} \times \frac{dP}{dt}$$

Step 4 of 9

Final mass at of tank is given by

$$m_2 = \frac{P_2 \times V}{R \times T_2}$$

$$= \frac{13000 \times 1}{0.2598 \times 293}$$

$$= \frac{13000}{76.1214}$$

$$= 170.78\ \text{kg}$$

Step 5 of 9

According to first law of thermodynamics

$$Q = \frac{d(\text{mu})}{dt} - \text{m}_{\text{in}} \times \text{h}_{\text{in}}$$

$$= \text{c}_\text{v} \times \text{T} \times \frac{\text{dm}}{\text{dt}} - \text{m}_{\text{in}} \times \text{c}_\text{p} \times \text{T}_2$$

For isentropic process, the final temperature is given by $T_2 = T_1\left(\frac{P}{P_1}\right)^{\frac{k-1}{k}}$. So,

$$Q = c_v \times T \times \frac{dm}{dt} - m_{in} \times c_p \times T_1\left(\frac{P}{P_1}\right)^{\frac{k-1}{k}}$$

$$= \left[c_v \times T \times \frac{dm}{dt}\right] - \left[\frac{V}{RT} \times \frac{dP}{dt} \times c_p \times T_1\left(\frac{P}{P_1}\right)^{\frac{k-1}{k}}\right]$$

Step 6 of 9

Integrating from initial to end of compression we get

$$Q_{in} = \left[c_v \times T \times \int_1^2 dm\right] - \left[\frac{V}{RT} \times c_p \times T_1\left(\frac{1}{P_1}\right)^{\frac{k-1}{k}} \times \int_1^2 P^{\frac{k-1}{k}} dP\right]$$

$$Q_{in} = \left[c_v \times T \times (m_2 - m_1)\right] - \left[\frac{V}{RT} \times c_p \times T_1\left(\frac{1}{P_1}\right)^{\frac{k-1}{k}} \times \frac{k}{2k-1} \times P_2^{\frac{k-1}{k}} \times P_2\right]$$

As initial tank is evacuated, $\text{m}_1 = 0$

$$Q_{in} = \left[c_v \times T \times (m_2 - 0)\right] - \left[\frac{V}{RT} \times c_p \times T_1\left(\frac{1}{P_1}\right)^{\frac{k-1}{k}} \times \frac{k}{2k-1} \times P_2^{\frac{k-1}{k}} \times P_2\right]$$

$$Q_{in} = \left[c_v \times T \times m_2\right] - \left[c_p \times T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} \times \frac{k}{2k-1} \times \frac{P_2 V}{RT}\right]$$

Step 7 of 9

Step 7 of 9

$$Q_{in} = [c_v \times T \times m_2] - \left[c_p \times T_1 \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} \times \frac{k}{2k-1} \times m_2\right]$$

$$= [0.658 \times 293 \times 170.78] - \left[0.918 \times 293 \times \left(\frac{13000}{150}\right)^{\frac{1.395-1}{1.395}} \times \frac{1.395}{2 \times 1.395 - 1} \times 170.78\right]$$

$$= [0.658 \times 293 \times 170.78] - \left[0.918 \times 293 \times (86.67)^{\frac{0.395}{1.395}} \times \frac{1.395}{2.79-1} \times 170.78\right]$$

$$= [32925.36] - \left[0.918 \times 293 \times (86.67)^{0.2831} \times \frac{1.395}{1.79} \times 170.78\right]$$

$$= [32925.36] - [0.918 \times 293 \times 3.537 \times 0.7793 \times 170.78]$$

$$= [32925.36] - [126615.55]$$

$$\boxed{Q_{in} = -93690.19 \text{ kJ}}$$

Step 8 of 9

Applying first law to the whole system,

$$Q_{in} + W_{in} = \frac{d(mu)}{dt} - m_{in} \times h_{in}$$

$$Q_{in} + W_{in} = (m_2 u_2 - m_1 u_1) - m_2 \times h_1$$

As initial tank is evacuated, $m_1 = 0$

$$Q_{in} + W_{in} = (m_2 u_2 - 0) - m_2 \times h_1$$

$$Q_{in} + W_{in} = m_2 u_2 - m_2 \times h_1$$

$$W_{in} = -Q_{in} + m_2 u_2 - m_2 \times h_1$$

$$= -Q_{in} + m_2 \times (u_2 - h_1)$$

$$= -Q_{in} + m_2 \times (c_v \times T_2 - c_p \times T_1)$$

Step 9 of 9

As the temperature is constant $T_2 = T_1 = T$

$$W_{in} = -Q_{in} + m_2 \times (c_v \times T - c_p \times T)$$

$$= -Q_{in} + m_2 \times T \times (c_v - c_p)$$

$$= -(-93690.19) + 170.78 \times 293 \times (0.658 - 0.918)$$

$$= 93690.19 + 170.78 \times 293 \times (-0.26)$$

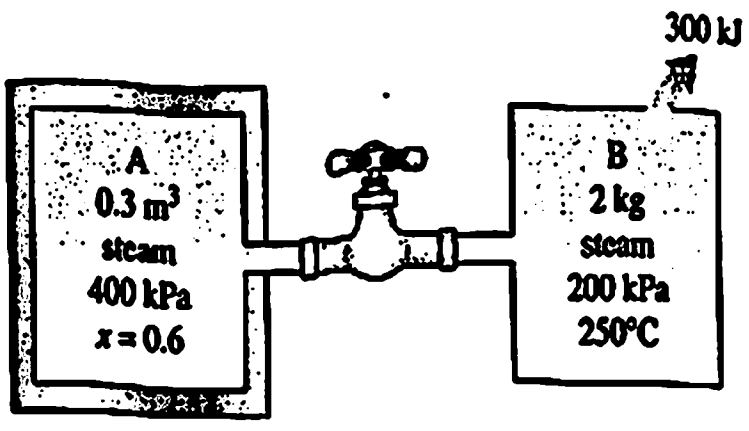
$$= 93690.19 - 13010.02$$

$$\boxed{W_{in} = 80680.17 \text{ kJ}}$$

Therefore total work input is 80680.17 kJ and total heat lost is 93690.19 kJ

Question: 8.195P pg 1

Two rigid tanks are connected by a valve. Tank A is insulated and contains 0.3 m3 of steam at 400 kPa and 60 percent quality. Tank B is uninsulated and contains 2 kg of steam at 200 kPa and 250°C. The valve is now opened, and steam flows from tank A to tank B until the pressure in tank A drops to 200 kPa. During this process 300 kJ of heat is transferred from tank B to the surroundings at 17°C. Assuming the steam remaining inside tank A to have undergone a reversible adiabatic process, determine (a) the final temperature in each tank and (*b*) the entropy generated during this process.



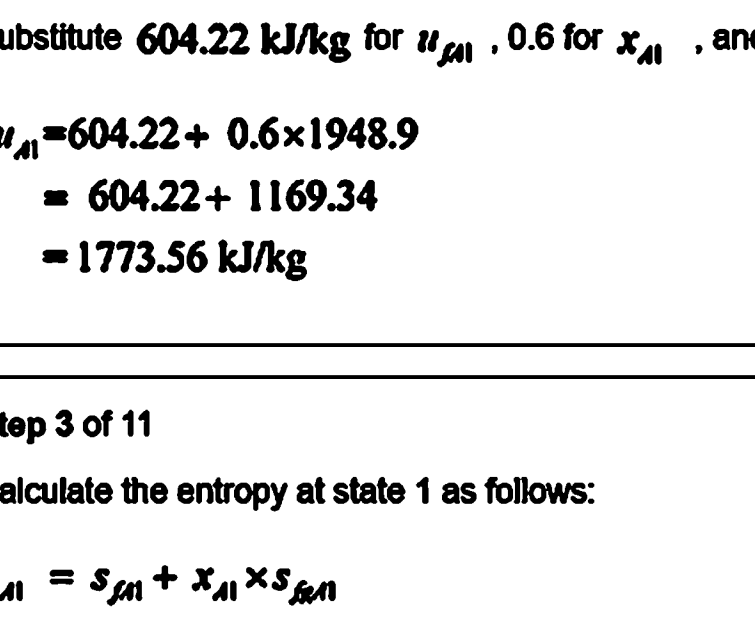


FIGURE P8–195

Step 1 of 11

Draw the schematic diagram of rigid tanks connected system:

Step 2 of 11

Obtain the properties from the table A-5, "Saturated water - pressure table" in textbook.

At pressure $P_{A1} = 400\ \text{kPa}$ and quality $x_{A1} = 0.6$ the properties of steam are

$$u_{fA1} = 604.22\ \text{kJ/kg}$$
$$u_{fgA1} = 1948.9\ \text{kJ/kg}$$
$$s_{fA1} = 1.7765\ \text{kJ/kg}\cdot\text{K}$$
$$s_{fgA1} = 5.1191\ \text{kJ/kg}\cdot\text{K}$$
$$v_{fA1} = 0.001084\ \text{m}^3\text{/kg}$$
$$v_{gA1} = 0.46242\ \text{m}^3\text{/kg}$$

Calculate the internal energy at state 1 as follows:

$$u_{A1} = u_{fA1} + x_{A1} \times u_{fgA1}$$

Substitute $604.22\ \text{kJ/kg}$ for u_{fA1}, 0.6 for x_{A1}, and $1948.9\ \text{kJ/kg}$ for u_{fgA1}.

$$u_{A1} = 604.22 + 0.6 \times 1948.9$$
$$= 604.22 + 1169.34$$
$$= 1773.56\ \text{kJ/kg}$$

Step 3 of 11

Calculate the entropy at state 1 as follows:

$$s_{A1} = s_{fA1} + x_{A1} \times s_{fgA1}$$

Substitute $1.7765\ \text{kJ/kg}\cdot\text{K}$ for s_{fA1} and $5.1191\ \text{kJ/kg}\cdot\text{K}$ for s_{fgA1}.

$$s_{A1} = 1.7765 + 0.6 \times 5.1191$$
$$= 1.7765 + 3.0715$$
$$= 4.848\ \text{kJ/kg°K}$$

Calculate the specific volume at state 1 as follows:

$$v_{A1} = v_{fA1} + x_{A1} \times v_{fgA1}$$
$$= v_{fA1} + x_{A1} \times (v_{gA1} - v_{fA1})$$

Substitute $0.001084\ \text{m}^3\text{/kg}$ for v_{fA1}, 0.6 for x_{A1}, and $0.46242\ \text{m}^3\text{/kg}$ for v_{gA1}.

$$v_{A1} = 0.001084 + 0.6 \times (0.46242 - 0.001084)$$
$$= 0.001084 + 0.6 \times 0.461336$$
$$= 0.001084 + 0.276802$$
$$= 0.277886\ \text{m}^3\text{/kg}$$

Step 4 of 11

For a reversible adiabatic process entropy remains constant.

$$s_{A2} = s_{A1} = 4.848\ \text{kJ/kg°K}$$

As saturated vapor entropy is greater than $s_{A2} = 4.848\ \text{kJ/kg°K}$, final temperature of tank A is given by saturated temperature at pressure $P_{A2} = 200\ \text{kPa}$.

Therefore, from table of saturated water pressure table', final temperature of tank A is

$$\boxed{T_{A2} = 120.21\ °\text{C}}.$$

Final entropy of tank A is also given by

$$s_{A2} = s_{fA2} + x_{A2} \times s_{fgA2}$$
$$4.848 = 1.5302 + x_{A2} \times 5.5968$$
$$x_{A2} = \frac{4.848 - 1.5302}{5.5968}$$
$$= \frac{3.3178}{5.5968}$$
$$= 0.5928$$

Obtain the properties from the table A-5, "Saturated water - pressure table" in textbook.

At pressure $P_{A1} = 200\ \text{kPa}$ and quality $x_{A1} = 0.5928$ the properties of steam are

$= 0.5928$

Obtain the properties from the table A-5, "Saturated water - pressure table" in textbook.

At pressure $P_{A1} = 200\ \text{kPa}$ and quality $x_{A1} = 0.5928$ the properties of steam are

$v_{fA2} = 0.001061\ \text{m}^3/\text{kg}$

$v_{gA2} = 0.88578\ \text{m}^3/\text{kg}$

$u_{fA2} = 504.5\ \text{kJ/kg}$

$u_{fgA2} = 2024.6\ \text{kJ/kg}$

Step 5 of 11

Final volume of tank A is given by

$$\begin{aligned} v_{A2} &= v_{fA2} + x_{A2} \times v_{fgA2} \\ &= v_{fA2} + x_{A2} \times \left(v_{gA2} - v_{fA2}\right) \end{aligned}$$

Substitute $0.001061\ \text{m}^3/\text{kg}$ for v_{fA2}, $0.88578\ \text{m}^3/\text{kg}$ for v_{gA2}, and 0.5928 for x_{A2}.

$$\begin{aligned} v_{A2} &= 0.001061 + 0.5928 \times (0.88578 - 0.001061) \\ &= 0.001061 + 0.5928 \times 0.884719 \\ &= 0.001061 + 0.524461 \\ &= 0.5255\ \text{m}^3/\text{kg} \end{aligned}$$

Step 6 of 11

Final volume of tank A is given by

$$\begin{aligned} u_{A2} &= u_{fA2} + x_{A2} \times u_{fgA2} \\ &= 504.5 + 0.5928 \times 2024.6 \\ &= 504.5 + 1200.18 \\ &= 1704.68\ \text{kJ/kg} \end{aligned}$$

Obtain the properties from the table A-6, "Superheated water" in the textbook.

At pressure $P_{B1} = 200\ \text{kPa}$ and temperature $T_{B1} = 250\ ^\circ\text{C}$.

Properties of steam are

$u_{B1} = 2731.4\ \text{kJ/kg}$

$s_{B1} = 7.7100\ \text{kJ/kg} \cdot \text{K}$

$v_{B1} = 1.1989\ \text{m}^3/\text{kg}$

Calculate the initial mass in tank A as follows:

$$m_{A1} = \frac{V_A}{v_{A1}}$$

Here, V_A is the volume of the tank *A*.

Substitute $0.3\ \text{m}^3$ for V_A and $0.277886\ \text{m}^3/\text{kg}$ for v_{A1}.

$$\begin{aligned} m_{A1} &= \frac{0.3}{0.277886} \\ &= 1.0796\ \text{kg} \end{aligned}$$

Step 7 of 11

Calculate the final mass of the tank as follows:

$$m_{A2} = \frac{V_A}{v_{A2}}$$

Substitute $0.3\ \text{m}^3$ for V_A and $0.5255\ \text{m}^3/\text{kg}$ for v_{A2}.

$$\begin{aligned} m_{A2} &= \frac{0.3}{0.5255} \\ &= 0.5709\ \text{kg} \end{aligned}$$

Calculate the mass of steam out from tank A as follows:

$$m_{Aout} = m_{A1} - m_{A2}$$

Substitute 1.0796 kg for m_{A1} and $0.5709\ \text{kg}$ for m_{A2}.

$$\begin{aligned} m_{Aout} &= 1.0796 - 0.5709 \\ &= 0.5087\ \text{kg} \end{aligned}$$

Final mass of steam in tank B is given by

$$m_{B2} = m_{B1} + m_{Bin}$$

As steam is moved from tank A to tank B, $m_{Aout} = m_{Bin}$

$$\begin{aligned} m_{B2} &= m_{B1} + m_{Aout} \\ &= 2 + 0.5087 \\ &= 2.5087\ \text{kg} \end{aligned}$$

Step 8 of 11

Final specific volume of steam in tank B as follows:

$$\begin{aligned} v_{B2} &= \frac{V_B}{m_{B2}} \\ &= \frac{m_{B1} \times v_{B1}}{m_{B2}} \end{aligned}$$

Here, m_{B1} is the initial mass of tank *B*.

Substitute 2 kg for m_{B1}, $1.1989\ \text{m}^3/\text{kg}$ for v_{B1}, and $2.5087\ \text{kg}$ for m_{B2}.

$$\begin{aligned} v_{B2} &= \frac{2 \times 1.1989}{2.5087} \\ &= \frac{2.3978}{} \end{aligned}$$

Substitute 2 kg for m_{B1}, 1.1989 m^3/kg for v_{B1}, and 2.5087 kg for m_{B2}.

$$v_{B2} = \frac{2 \times 1.1989}{2.5087}$$
$$= \frac{2.3978}{2.5087}$$
$$= 0.9558 \text{ m}^3/\text{kg}$$

Energy balance is given by

$$E_{in} - E_{in} = \Delta E_{sys}$$
$$0 - Q_{out} = \Delta U$$

Step 9 of 11

Re-write the equation as follows:

$$-Q_{out} = \left(m_{A2}u_{A2} - m_{A1}u_{A1}\right) + \left(m_{B2}u_{B2} - m_{B1}u_{B1}\right)$$

Here, Q_{out} is the heat transferred from *B* to surroundings.

Substitute 300 kJ for Q_{out}, 0.5709 kg for m_{A2}, 1704.68 kg for u_{A2}, 1.7096 kg for m_{A1}, 1773.02 kJ/kg for u_{A1}, 2.5087 kg for m_{B2}, 2 kg for m_{B1}, and 2731.4 kJ/kg for u_{B1}.

$$-300 = \left(0.5709 \times 1704.68 - 1.0796 \times 1773.02\right) + \left(2.5087 \times u_{B2} - 2 \times 2731.4\right)$$
$$-300 = -940.95 + 2.5087 \times u_{B2} - 5462.8$$
$$u_{B2} = \frac{940.95 - 300 + 5462.8}{2.5087}$$
$$= \frac{6103.75}{2.5087}$$
$$= 2433.03 \text{ kJ/kg}$$

Step 10 of 11

From table of saturated water temperature table,

At specific volume $v_{B2} = 0.9558 \text{ m}^3/\text{kg}$ and $u_{B2} = 2433.03 \text{ kJ/kg}$ is interpolated as

$$\frac{T_{B2} - 115}{120 - 115} = \frac{0.9558 - 1.0360}{0.89133 - 1.0360}$$
$$\frac{T_{B2} - 115}{5} = \frac{-0.0802}{-0.14467}$$
$$\frac{T_{B2} - 115}{5} = 0.5544$$
$$T_{B2} = 0.5544 \times 5 + 115$$
$$= 2.772 + 115$$

Therefore, the final temperature of tank B is $\boxed{T_{B2} = 117.772\ ^\circ\text{C}}$.

Step 11 of 11

(b)

Final the quality of the steam as follows:

$$u_{B2} = u_{fB2@200kpa} + x_{B2} \times u_{fgB22@200kpa}$$

Substitute 2433.03 kJ/kg for u_{B2}, 504.5 kJ/kg for $u_{fB2@200kpa}$, and 2024.6 kJ/kg for $u_{fgB22@200kpa}$.

$$2433.03 = 504.5 + x_{B2} \times 2024.6$$
$$x_{B2} = \frac{2433.03 - 504.5}{2024.6}$$
$$= \frac{1928.53}{2024.6}$$
$$= 0.9525$$

Find the final entropy as follows:

$$s_{B2} = s_{fB2} + x_{B2} \times s_{fgB2}$$

Substitute 1.5302 kJ/kg·K for s_{fB2}, 0.953 for x_{B2}, and 5.5968 kJ/kg for s_{fgB2}.

$$s_{B2} = 1.5302 + 0.953 \times 5.5968$$
$$= 1.5302 + 5.3310$$
$$= 6.8612 \text{ kJ/kg°K}$$

Write the equation for entropy balance as follows:

$$S_{in} - S_{in} + S_{gen} = \Delta S_{sys}$$
$$-\frac{Q_{out}}{T_{surr}} + S_{gen} = \Delta S_A + \Delta S_B$$
$$S_{gen} = \Delta S_A + \Delta S_B + \frac{Q_{out}}{T_{surr}}$$
$$S_{gen} = \left(m_{A2}s_{A2} - m_{A1}s_{A1}\right) + \left(m_{B2}s_{B2} - m_{B1}s_{B1}\right) + \frac{Q_{out}}{T_{surr}}$$

Substitute 0.5709 kg for m_{A2}, 1.7096 kg for m_{A1}, 4.848 kJ/kg·K for s_{A2}, 4.848 kJ/kg·K for s_{A1}, 6.8612 kJ/kg·K for s_{B2}, 7.71 kJ/kg·K for s_{B1}, 300 kJ for Q_{out}, and 290 K for T_{surr}.

$$S_{gen} = \left(0.5709 \times 4.848 - 1.0796 \times 4.848\right) + \left(2.5087 \times 6.8612 - 2 \times 7.7100\right) + \frac{300}{290}$$
$$S_{gen} = \left(2.768 - 5.234\right) + \left(17.213 - 15.420\right) + 1.034$$
$$S_{gen} = -2.466 + 1.793 + 1.034$$

Therefore, the entropy generated during this process is $\boxed{0.361 \text{ kJ/·K}}$

Question: 8.196P

Heat is transferred steadily to boiling water in the pan through its flat bottom at a rate of 500 W. If the temperatures of the inner and outer surfaces of the bottom of the tank are 104 and 105°C, respectively, determine the rate of entropy generation within bottom of the pan, in W/K.

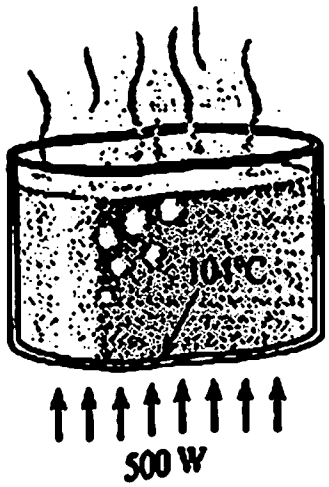

FIGURE P8–196

Step 1 of 2

Given data

Rate of heat transfer to boiling water from the bottom of the pan $Q = 500\,\text{W}$

Temperature of the inner surface of the bottom of the tank $T_{inner} = 104°\text{C}$

Temperature of the outer surface of the bottom of the tank $T_{outer} = 105°\text{C}$

Step 2 of 2

From entropy balance for this steady system is

$$\dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{S}_{out} - \dot{S}_{in}$$

$$\dot{S}_{gen} = -\frac{Q}{T_{outer}} + \frac{Q}{T_{inner}}$$

$$= -\frac{500}{(105+273)} + \frac{500}{(104+273)}$$

$$= -\frac{500}{378} + \frac{500}{377}$$

$$\dot{S}_{gen} = 0.00351\,\text{W/K}$$

Rate of entropy generation within bottom of the pan is

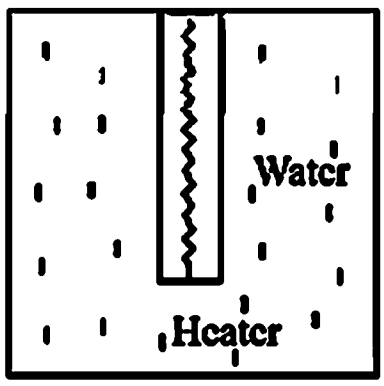
$$\boxed{\dot{S}_{gen} = 0.00351\,\text{W/K}}$$

Question: 8.197P

A 1200-W electric resistance heating element whose diameter is 0.5 cm is immersed in 40 kg of water initially at 20°C. Assuming the water container is well-insulated, determine how long it will take for this heater to raise the water temperature to 50°C. Also, determine the entropy generated during this process, in kJ/K.

Step 1 of 4

Given data



Mass of water $m = 40\,\text{kg}$

Heating capacity of the heater $Q = 1200\,\text{W}$

Initial temperature of water $T_1 = 20°\text{C}$

Final temperature of water $T_2 = 50°\text{C}$

Step 2 of 4

Step 3 of 4

Assume specific heat of water is

$c = 4.18\,\text{kJ/kg}\,°\text{C}$

Energy balance for this closed system

$(Q)t = mc\Delta T$

$Q \cdot t = mc(T_2 - T_1)$

$(1200) \times t = (40) \times 4.18 \times 10^3 \times (50 - 20)$

$(1200) \times t = 5016000$

$t = 4180\,s$

$= \left(\frac{4180}{3600}\right)$

$t = 1.16\,\text{h}$

Time taken to reach the final temperature of 50° C is

$\boxed{t = 1.16\,\text{h}}$

Step 4 of 4

Entropy generated during this process

$\Delta S = mC \ln \frac{T_2}{T_1}$

$= (40)(4.18) \ln \left[\frac{(50+273)}{(20+273)}\right]$

$\Delta S = 16.3\,\text{kJ/K}$

Entropy generated during this process $\boxed{\Delta S = 16.3\,\text{kJ/K}}$

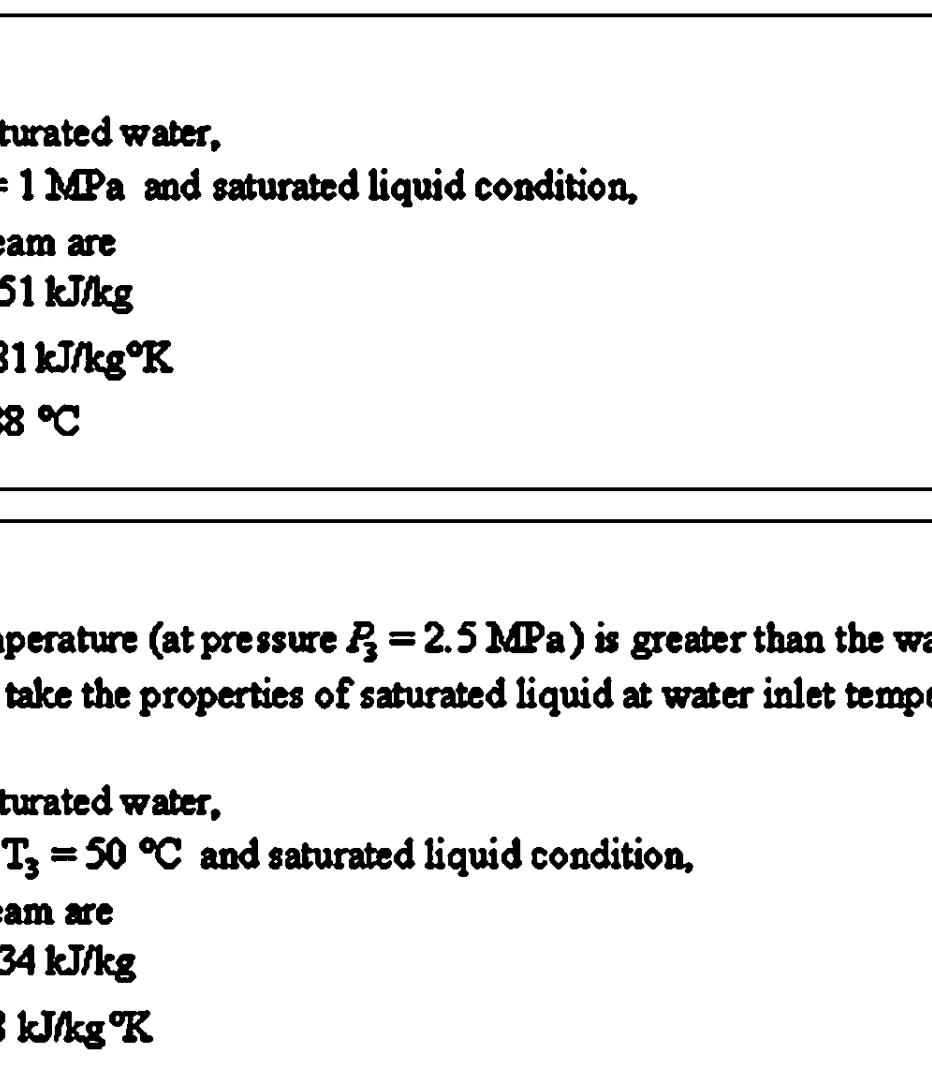
Question: 8.198P

In large steam power plants, the feedwater is frequently heated in closed feedwater heaters, which are basically heat exchangers, by steam extracted from the turbine at some stage. Steam enters the feedwater heater at 1 MPa and 200°C and leaves as saturated liquid at the same pressure. Feedwater enters the heater at 2.5 MPa and 50°C and leaves 10°C below the exit temperature of the steam. Neglecting any heat lossesfrom the outer surfaces of the heater, determine (*a*) the ratio of the mass flow rates of the extracted steam and the feedwater heater and (*b*) the total entropy change for this process per unit mass of the feedwater.

Step 1 of 9

Given data:

Pressure at steam inlet is, $P_1 = 1\,\text{MPa} = 1000\,\text{kPa}$



Temperature at steam inlet is, $T_1 = 200\,^\circ\text{C} = 473\,\text{K}$

Pressure at water inlet is, $P_3 = 2.5\,\text{MPa} = 2500\,\text{kPa}$

Temperature at water inlet is, $T_3 = 50\,^\circ\text{C} = 323\,\text{K}$

Temperature at water exit is, $T_4 = T_2 - 10$

Step 2 of 9

Step 3 of 9

From table of superheated water' ,

At pressure $P_1 = 1\,\text{MPa}$ and Temperature $T_1 = 200\,^\circ\text{C}$, properties of steam are

$h_1 = 2828.3\,\text{kJ/kg}$

$s_1 = 6.6956\,\text{kJ/kg°K}$

Step 4 of 9

From table of saturated water,

At pressure $P_2 = 1\,\text{MPa}$ and saturated liquid condition,

Properties of steam are

$h_2 = h_f = 762.51\,\text{kJ/kg}$

$s_2 = s_f = 2.1381\,\text{kJ/kg°K}$

$T_2 = T_{sat} = 179.88\,^\circ\text{C}$

Step 5 of 9

As saturated temperature (at pressure $P_3 = 2.5\,\text{MPa}$) is greater than the water inlet temperature, we take the properties of saturated liquid at water inlet temperature ($T_3 = 50\,^\circ\text{C}$)

From table of saturated water,

At temperature $T_3 = 50\,^\circ\text{C}$ and saturated liquid condition,

properties of steam are

$h_3 = h_f = 209.34\,\text{kJ/kg}$

$s_3 = s_f = 0.7038\,\text{kJ/kg°K}$

Step 6 of 9

Then,

$T_4 = T_2 - 10$

$T_4 = 179.88 - 10$

$= 169.88\,^\circ\text{C}$

As saturated temperature (at pressure $P_4 = 2.5\,\text{MPa}$) is greater than the water inlet temperature, we take the properties of saturated liquid at water inlet temperature ($T_4 = 169.88\,^\circ\text{C}$)

From table of saturated water,

At temperature $T_4 = 169.88\,^\circ\text{C} = 170\,^\circ\text{C}$ and saturated liquid condition,

Properties of steam are

$h_4 = h_f = 719.08\,\text{kJ/kg}$

$s_4 = s_f = 2.0417\,\text{kJ/kg°K}$

Step 7 of 9

As there is no mass loss,

$m_1 = m_2 = m_s$

$m_3 = m_4 = m_w$

Heat loss by steam is same as heat gained by water. So,

$$m_s(h_2 - h_1) = m_w(h_3 - h_4)$$

$$\frac{m_s}{m_w} = \frac{h_3 - h_4}{h_2 - h_1}$$

$$= \frac{209.34 - 719.08}{762.51 - 2828.3}$$

$$= \frac{-509.74}{-2065.79}$$

$$\boxed{\frac{m_s}{m_w} = 0.2468}$$

Step 8 of 9

Entropy balance is given by

$$S_{in} - S_{in} + S_{gen} = \Delta S_{sys}$$

For steady process $\Delta S_{sys} = 0$

$$S_{in} - S_{in} + S_{gen} = \Delta S_{sys}$$

$$m_1 s_1 - m_2 s_2 + m_3 s_3 - m_4 s_4 + S_{gen} = 0$$

$$m_s s_1 - m_s s_2 + m_w s_3 - m_w s_4 + S_{gen} = 0$$

$$m_s(s_1 - s_2) + m_w(s_3 - s_4) + S_{gen} = 0$$

Step 9 of 9

Entropy generation is

$$S_{gen} = m_s(s_2 - s_1) + m_w(s_4 - s_3)$$

$$\frac{S_{gen}}{m_w} = \frac{m_s}{m_w}(s_2 - s_1) + (s_4 - s_3)$$

$$\frac{S_{gen}}{m_w} = 0.2468 \times (2.1381 - 6.6956) + (2.0417 - 0.7038)$$

$$\frac{S_{gen}}{m_w} = 0.2468 \times (-4.5575) + 1.3379$$

$$\frac{S_{gen}}{m_w} = -1.1248 + 1.3379$$

$$\boxed{\frac{S_{gen}}{m_w} = 0.2131\,\text{kJ/°K/kg of feed water}}$$

Therefore ratio of mass flow rates is 0.2468 and entropy generation is 0.2131 kJ/°K/kg of feed water

Question: 8.199P

Reconsider Prob. 8-198. Using EES (or other) software, investigate the effect of the state of the steam at the inlet of the feedwater heater. Assume the entropy of the extraction steam is constant at the value for 1 MPa, 200°C and decrease the extraction steam pressure from 1 MPa to 100 kPa. Plot both the ratio of the mass flow rates of the extracted steam and the feedwater heater and the total entropy change for this process per unit mass of the feedwater as functions of the extraction pressure.

We don't have the solution to this problem yet.

Question: 8.200P

A 5-ft3 rigid tank initially contains refrigerant-134a at 80 psia and 100 percent quality. The tank is connected by a valve to a supply line that carries refrigerant-134a at 160 psia and 80°F. The valve is now opened, allowing the refrigerant to enter the tank, and is closed when it is observed that the tank contains only saturated liquid at 120 psia. Determine (*a*) the mass of the refrigerant that entered the tank, (*b*) the amount of heat transfer with the surroundings at 100°F, and (*c*) the entropy generated during this process.

Step 1 of 9

Given data:

Volume of the tank is, $V = 5\ \text{ft}^3$

Initial pressure in the tank is, $P_1 = 80$ psia

Initial quality in the tank is, $x_1 = 100\%$

Final pressure in the tank is, $P_2 = 120$ psia

Final quality in the tank is, $x_2 = 0\%$

Pressure of supply line is, $P_{in} = 160$ psia

Temperature of supply line is, $T_{in} = 80\ ^\circ\text{F} = 540\ \text{R}$

Surrounding temperature is, $T_{surr} = 100\ ^\circ\text{F} = 560\ \text{R}$

Step 2 of 9

From table A-12E, at pressure $P_1 = 80$ psia and saturated vapor condition, properties of R-134a are

$v_1 = v_g = 0.5975\ \text{ft}^3/\text{lbm}$

$u_1 = u_g = 103.35\ \text{Btu/lbm}$

$s_1 = s_g = 0.2204\ \text{Btu/lbm}^\circ\text{R}$

Step 3 of 9

From table A-12E, at pressure $P_2 = 120$ psia and saturated liquid condition, properties of R-134a are

$v_2 = v_f = 0.01360\ \text{ft}^3/\text{lbm}$

$u_2 = u_f = 41.485\ \text{Btu/lbm}$

$s_2 = s_f = 0.08589\ \text{Btu/lbm}^\circ\text{R}$

Step 4 of 9

As saturated temperature (at pressure $P_{in} = 160$ psia) is greater than the water temperature, we take the properties of saturated liquid at water temperature ($T_{in} = 80\ ^\circ\text{F}$)

From table A-11E, at temperature $T_{in} = 80\ ^\circ\text{F}$ and saturated liquid condition, properties of steam are

$h_{in} = h_f = 38.169\ \text{Btu/lbm}$

$s_{in} = s_f = 0.07934\ \text{Btu/lbm}^\circ\text{R}$

Step 5 of 9

Initial mass in the tank is given by

$$m_1 = \frac{V}{v_1}$$

$$= \frac{5}{0.5975}$$

$$= 8.368\ \text{ft}$$

Step 6 of 9

Final mass in the tank is given by

$$m_2 = \frac{V}{v_2}$$

$$= \frac{5}{0.0136}$$

$$= 367.647\ \text{ft}$$

Step 7 of 9

(a) Mass entered in the tank is given by,

$$m_{in} = m_2 - m_1$$

$$= 367.647 - 8.638$$

$$\boxed{m_{in} = 359.009\ \text{ft}}$$

Step 8 of 9

(b) Energy balance is given by

$$E_{in} - E_{out} = \Delta S_{sys}$$

As there is no energy is going out, $E_{out} = 0$

$$E_{in} - 0 = \Delta S_{sys}$$

$$E_{in} = \Delta S_{sys}$$

$$Q_{in} + m_{in} \times h_{in} = m_2 \times u_2 - m_1 \times u_1$$

$$Q_{in} = m_2 \times u_2 - m_1 \times u_1 - m_{in} \times h_{in}$$

$$Q_{in} = 367.647 \times 41.485 - 8.368 \times 103.35 - 359.009 \times 38.169$$

$$Q_{in} = 15251.84 - 864.83 - 13703.01$$

$$\boxed{Q_{in} = 684\ \text{Btu}}$$

Step 9 of 9

(c) Entropy balance is given by

$$S_{in} - S_{out} + S_{gen} = \Delta S_{sys}$$

$$\frac{Q_{in}}{T_{surr}} - m_{in} \times s_{in} + S_{gen} = m_2 \times s_2 - m_1 \times s_1$$

$$S_{gen} = m_2 \times s_2 - m_1 \times s_1 - \frac{Q_{in}}{T_{surr}} + m_{in} \times s_{in}$$

$$S_{gen} = 367.647 \times 0.08589 - 8.368 \times 0.2204 - \frac{684}{560} + 359.009 \times 0.07934$$

$$S_{gen} = 31.58 - 1.84 - 1.22 + 28.28$$

$$\boxed{S_{gen} = 56.8\ \text{Btu/lbm.R}}$$

The mass input to the tank is 359.009 ft , heat transfer to the surroundings is 684 Btu and the entropy generation is 56.8 Btu/lbm.R

Question: 8.201P

A passive solar house that is losing heat to the outdoors at 3°C at an average rate of 50,000 kJ/h is maintained at 22°C at all times during a winter night for 10 h. The house is to be heated by 50 glass containers, each containing 20 L of water that is heated to 80°C during the day by absorbing solar energy. A thermostat controlled 15 kW backup electric resistance heater turns on whenever necessary to keep the house at 22°C. Determine how long the electric heating system was on that night and the amount of entropy generated during the night.

Step 1 of 4

Given data:

The quantity of heat rate losing per hour, $Q_{out} = 50000\ \text{kJ/h}$

Temperature of the water, maintained in the house during all times of winter, $T_2 = 22°\text{C}$

Each volume of the water containing in glass containers, $V = 20\ \text{L}$

Work done by the electric resistance, $\dot{W}_{in} = 15\ \text{kW}$

Water is initially at temperature, $T_1 = 80°\text{C}$

Surrounding temperature of the house,

$T_{surr} = 3°\text{C}$

$= 276\ \text{K}$

Step 2 of 4

From the properties of common liquids, solids, and foods table,

The density of water, $\rho = 1\ \text{kg/L}$

Specific weight of the water at room temperature, $c = 4.18\ \text{kJ/kg}\cdot°\text{C}$

Mass of the water containing in the 50 glass containers is given by

$m = \rho V$

$= 1\ \text{kg/L} \times (50 \times 20\ \text{L})$

$= 1000\ \text{kg}$

Step 3 of 4

The amount of time taken by the electric system is determined from the energy balance equation of the solar house is given by

Net energy transfer by heat, work and mass is equal to change in the internal, kinetic, potential energies

$$E_{in} - E_{out} = \Delta E_{system}$$

$$(\dot{W}_{in})\Delta t - Q_{out} = \Delta U$$

$$= (\Delta U)_{water} + (\Delta U)_{air}$$

$$= (\Delta U)_{water} + 0$$

$$(\dot{W}_{in})\Delta t - Q_{out} = mc(T_2 - T_1)$$

$$(15\text{kJ/s})\Delta t - (50000\ \text{kJ/h})(10\ \text{h}) = 1000\ \text{kg} \times 4.18\ \text{kJ/kg}\cdot°\text{C}(22°\text{C} - 80°\text{C})$$

$$(15\text{kJ/s})\Delta t = -242440 + 500000$$

$$\Delta t = \frac{257560}{15}$$

$$= 17170.67\ \text{s}$$

$$= \frac{17170.67}{3600}$$

$$= 4.769\ \text{h}$$

Therefore the electric heating system was on that night for a period of time is $\boxed{\Delta t = 4.77\ \text{h}}$

Step 4 of 4

The entropy generated during this process is determined by applying the entropy balance on the house during the night at all times of the winter. The entropy generated for the house on the during the night is given by

$$\dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} = \Delta S_{system}$$

$$\dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} = \Delta S_{water} + \Delta S_{air}$$

$$-\frac{Q_{out}}{T_{surr}} + \dot{S}_{gen} = \left(mc\ln\frac{T_2}{T_1}\right)_{water} + 0$$

$$\dot{S}_{gen} = \left(mc\ln\frac{T_2}{T_1}\right)_{water} + \frac{Q_{out}}{T_{surr}}$$

$$= \left(1000\text{kg} \times 4.18\ \text{kJ/kg}\cdot°\text{C} \times \ln\frac{295\ \text{K}}{353\ \text{K}}\right) + \frac{(50000\ \text{kJ/h})(10\ \text{h})}{276\ \text{K}}$$

$$= -750.28 + 1811.59$$

$$= 1061.31\ \text{kJ/K}$$

Therefore, the amount of entropy generated for the house during night is $\boxed{\dot{S}_{gen} = 1061.31\ \text{kJ/K}}$

CHAPTER 09
SOLUTIONS

Question: 9.001P

How does the thermal efficiency of an ideal cycle, in general, compare to that of a Carnot cycle operating between the same temperature limits?

Step 1 of 1

The Carnot cycle have the maximum thermal efficiency of all heat engines operating between the same temperature limits.

An ideal cycle is a cycle that delivers work without the loss of heat.

It is impossible to construct a cycle with 100% efficiency as there are always losses involved as per the second law of thermodynamics. The Carnot cycle is regarded as the ideal cycle in thermodynamics and as such, the efficiencies of an ideal cycle and the Carnot cycle are the same.

Question: 9.002P

What does the area enclosed by the cycle represent on a *P-V* diagram? How about on a *T-s* diagram?

Step 1 of 1

On both P-v and T-s diagram, the area enclosed by the process curve represents the net work of the cycle.

Question: 9.003P

What are the air-standard assumptions?

Step 1 of 1

The air standard assumptions are:

(1) The working fluid is air, which continuously circulates in a closed loop and always behaves as an ideal gas.

(2) All the processes that make up the cycle are internally reversible.

(3)The combustion process is replaced by a heat-addition process from an external source.

(4) The exhaust process is replaced by a heat-rejection process that restores the working fluid to its initial state.

Question: 9.004P

What is the difference between air-standard assumptions and the cold-air-standard assumptions?

Step 1 of 1

The air standard assumptions are

a) The working fluid is air, which continuously circulates in a closed loop and always behaves as an ideal gas.
b) All the processes that make up the cycle are internally reversible.
c) The combustion process is replaced by a heat addition process from an external source.
d) The exhaust process is replaced by a heat rejection process that restores the working fluid to its initial state.

Cycles for which the air standard assumptions are applicable are known as air standard cycle

To simplify the analysis even more is that air has constant specific heats whose values are determined at room temperature. When this assumption is utilized, the air standard assumptions are called the cold air standard assumptions.

Question: 9.005P

What is the difference between the clearance volume and the displacement volume of reciprocating engines?

Step 1 of 1

The minimum volume formed in the cylinder when the piston is at TDC is called the clearance volume.

The volume displaced by the piston as it moves between TDC and BDC is called the displacement volume.

Question: 9.006P

Define the compression ratio for reciprocating engines.

Step 1 of 1

The ratio of the maximum volume formed in the cylinder to the minimum (clearance) volume is called the compression ratio r of the engine.

$$r = \frac{V_{max}}{V_{min}}$$

$$r = \frac{V_{BDC}}{V_{TDC}}$$

Question: 9.007P

How is the mean effective pressure for reciprocating engines defined?

Step 1 of 1

It is a fictitious pressure that, if it acted on the piston during the entire power stroke, would produce the same amount of net work as that produced during the actual cycle.

$W_{net} = \text{MEP} \times \text{displacement volume}$

$$\text{MEP} = \frac{W_{net}}{V_{max} - V_{min}}$$

Question: 9.008P

Can the mean effective pressure of an automobile engine in operation be less than the atmospheric pressure?

Step 1 of 1

2760-9-10P SA: 2981

Yes, the MEP can be less than the atmospheric pressure.

Question: 9.009P

As a car gets older, will its compression ratio change? How about the mean effective pressure?

Step 1 of 2

Assuming there is no accumulation of carbon deposits on piston face the compression ratio remains same. If there is a carbon deposit on the face of the piston, the compression ratio of the engine increases.

Step 2 of 2

The mean effective pressure is mainly a function of swept volume of the cylinder which may increase due to wear and tear in the cylinder and piston. Consider the equation for the mean effective pressure.

$$MEP = \frac{W_{net}}{V_1 - V_2}$$

Here, V_1 is the swept volume and V_2 is the clearance volume.

From the above equation it is clear that the mean effective pressure reduces due to change in volume of the cylinder.

Therefore, as the car gets older, the compression remains same or increases and the mean effective pressure will reduce.

.

Question: 9.010P

What is the difference between spark-ignition and I compression-ignition engines?

Step 1 of 1

In spark ignition engines the fuel air mixture is compressed to a temperature that is below the auto ignition temperature of the fuel, and the combustion takes place by the ignition of fuel and air mixture using a spark plug. SI engines are usually petrol engines.
In a compression ignition engine, the air is compressed to high temperature that is above the auto ignition temperature of the fuel, and combustion starts on contact as the fuel is injected into this hot air. CI engines are usually diesel engines.
Therefore, the spark plug and carburetor are replaced by a fuel injector in diesel engines.

Question: 9.011P

Define the following terms related to reciprocating engines: stroke, bore, top dead center, and clearance volume.

Step 1 of 1

Stroke: The distance between the top dead center (TDC) and the bottom bead center (BDC) is the largest distance that the piston can travel in one direction, and it is called the stroke

Bore: The diameter of the piston is called the bore

Top dead center: The position of the cylinder when it is at the top part near to the valves or ports.

Clearance volume: the minimum volume formed in the cylinder when the piston is at TDC is called the clearance volume.

Question: 9.012P

What is the maximum possible thermal efficiency of a gas power cycle when using thermal energy reservoirs at 1 940°F and 40°F?

Step 1 of 4

Given,

The higher temperature limit, $T_H = 940^0\text{F}$

The lower temperature limit, $T_L = 40^0\text{F}$

The conversion from Degrees Fahrenheit to Degree Kelvin is

$$T(K) = \frac{5}{9}\left[T(^\circ\text{F}) - 32\right] + 273$$

Hence higher temperature limit in K is,

$$T_H = \frac{5}{9}[940 - 32] + 273$$

$$T_H = 504.444 + 273$$

$$T_H = 777.444^\circ\text{C}$$

Hence lower temperature limit,

$$T_H = \frac{5}{9}[40 - 32] + 273$$

$$T_H = 4.444 + 273$$

$$T_H = 277.444^\circ\text{C}$$

Step 2 of 4

The heat input to a cycle is $q_{in} = T_H (ds)_H$

And heat output from a cycle is $q_{out} = T_L (ds)_L$

As the carnot cycle operates with two isentropic processes and two isothermal processes,

The change in entropy remains constant for both heat transfer processes so $(ds)_H = (ds)_L$

Hence $q_{in} = T_H (ds)$ and

$$q_{out} = T_L (ds)$$

Step 3 of 4

Carnot Efficiency is given by

$$\eta_{carnot} = \frac{w_{net}}{q_{in}}$$

$$\eta_{carnot} = \frac{q_{in} - q_{out}}{q_{in}}$$

$$\eta_{carnot} = 1 - \frac{q_{out}}{q_{in}}$$

$$\eta_{carnot} = 1 - \frac{T_L (ds)}{T_H (ds)}$$

Step 4 of 4

Substituting the values of temperatures, we get

$$\eta_{carnot} = \left(1 - \frac{T_L}{T_H}\right) \times 100$$

$$\eta_{carnot} = \left(1 - \frac{277.444}{777.444}\right) \times 100$$

$$\eta_{carnot} = (1 - 0.3568) \times 100$$

$$\eta_{carnot} = 64.3\ \%$$

Hence efficiency of carnot cycle is $\boxed{\eta_{carnot} = 64.3\ \%}$

Question:

An air-standard cycle with constant specific heats is .1 executed in a closed piston-cylinder system and is composed of the following three processes:

1-2 Isentropic compression with a compression ratio $r = 6$, $T1$,=27°C, and $P1 = 100$ kPa

2-3 Constant pressure heat addition

3-1 Constant volume heat rejection

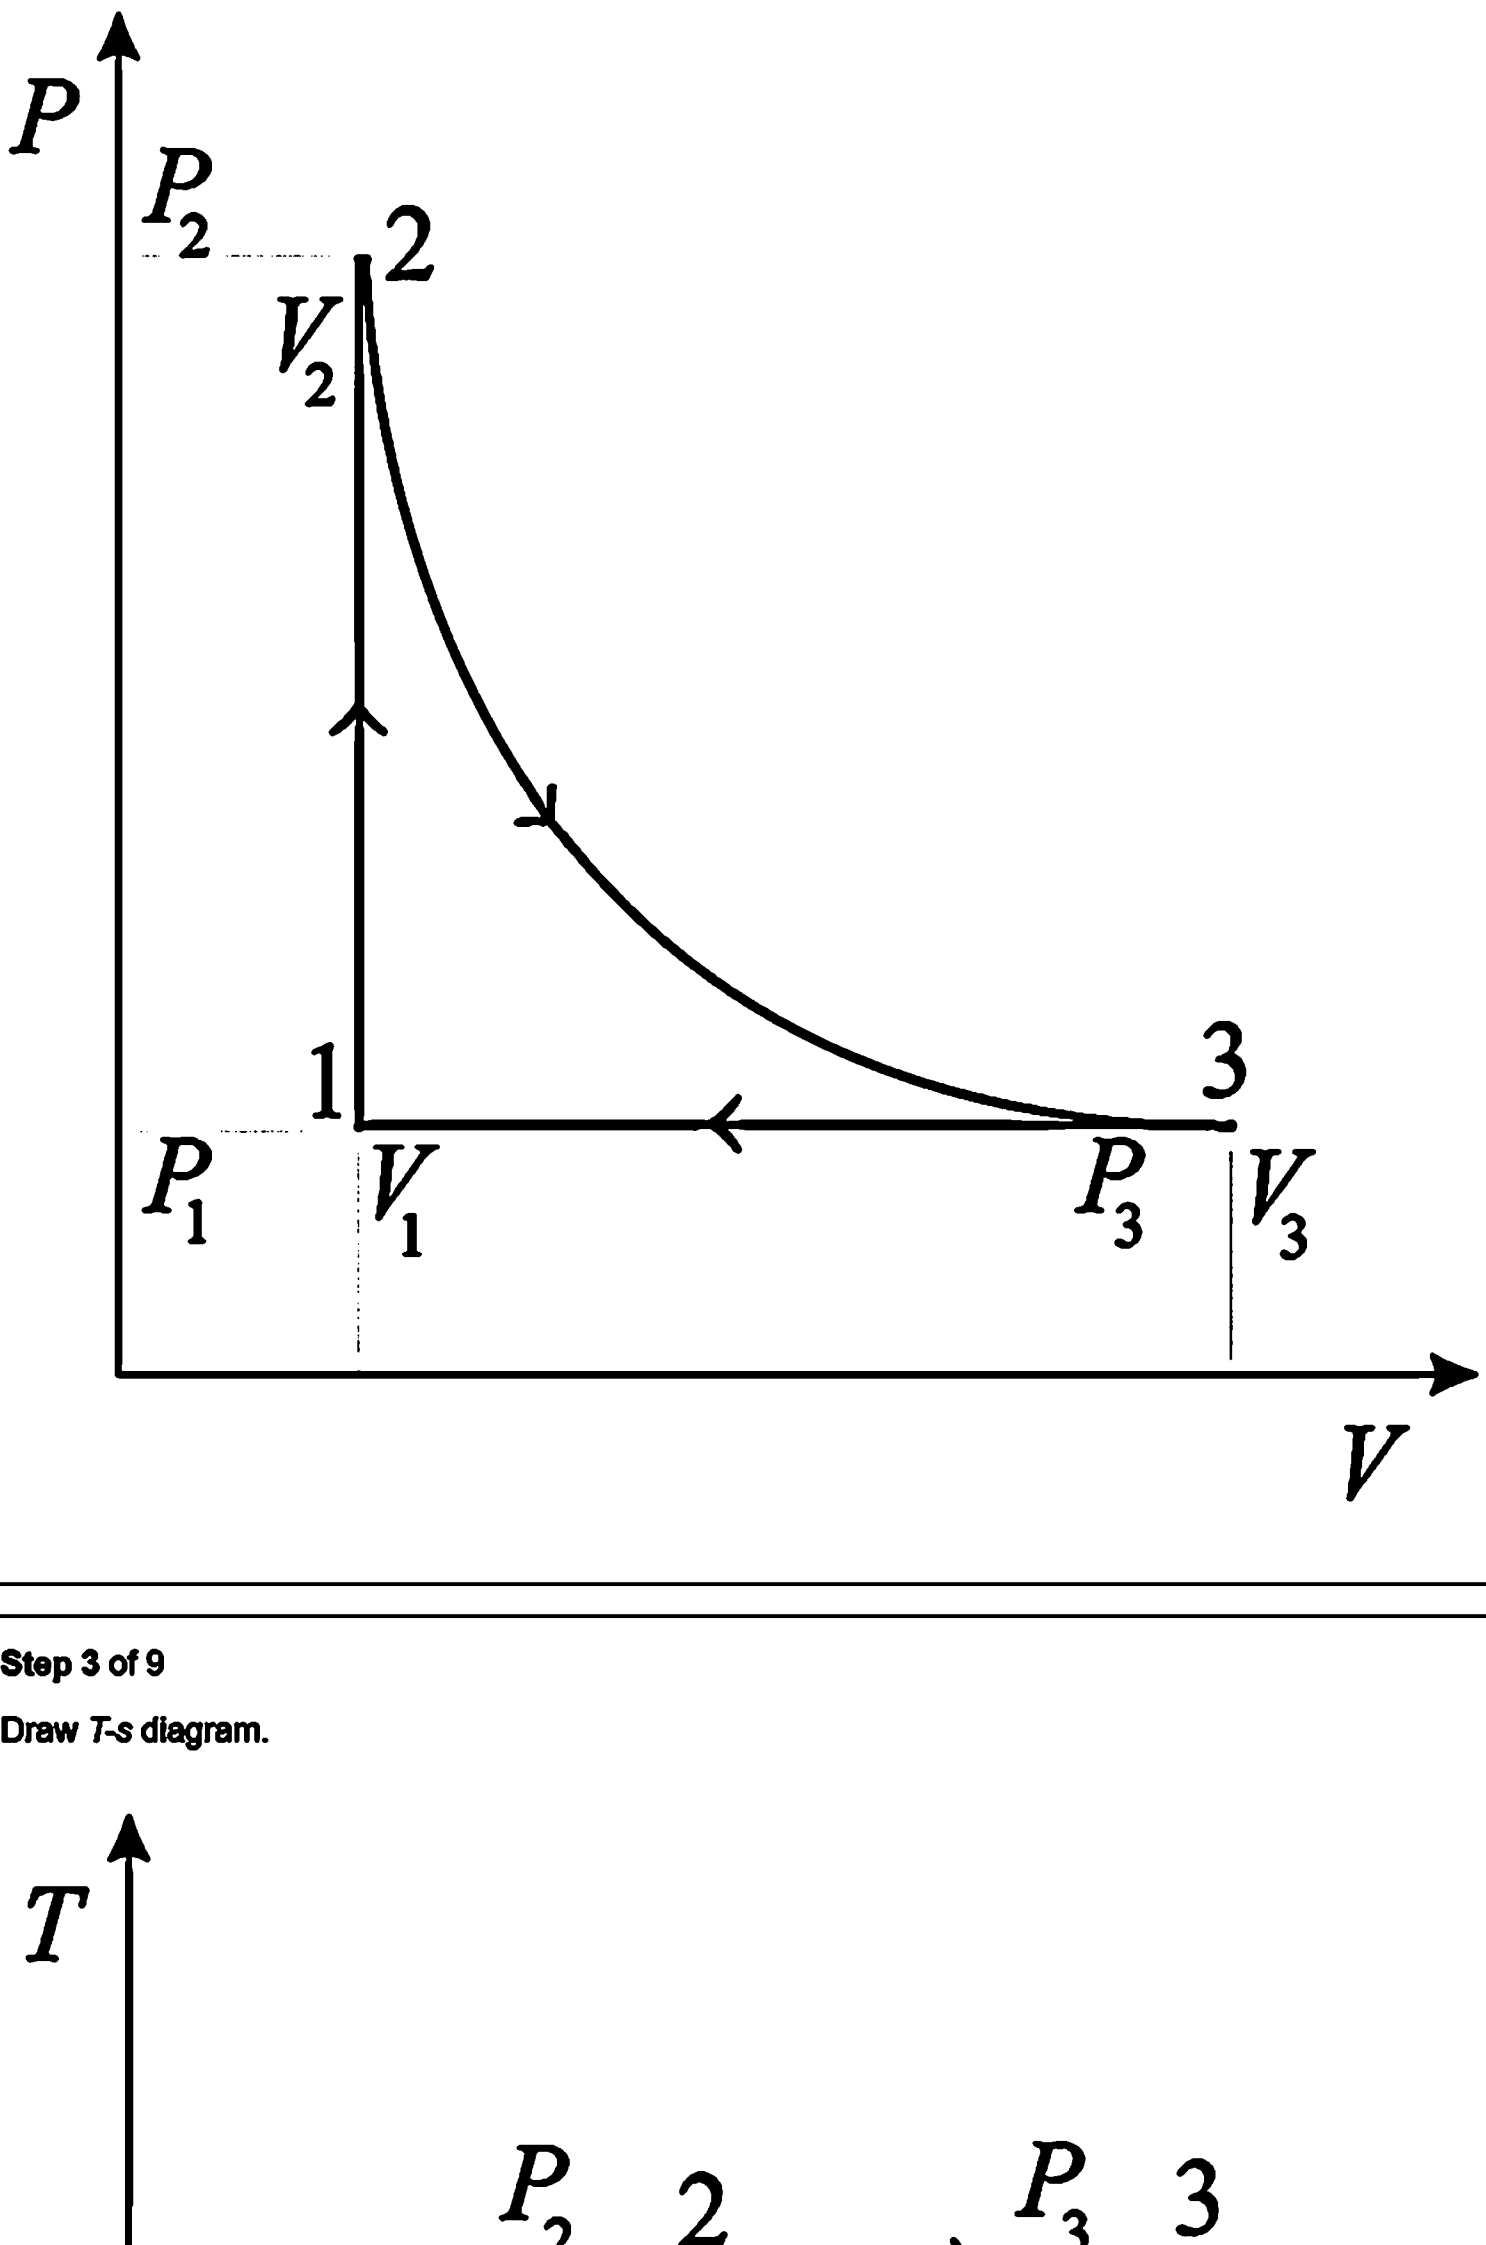
Assume air has constant properties with cv= 0.718 kJ/kg.K, cp = 1.005 kJ/kg·K. R =0.287 kj/kg.K, and k= 1.4.

(*a*) Sketch the *P-v* and *T-s* diagrams for this cycle.

(*b*) Determine the back work ratio for this cycle.

Step 1 of 9

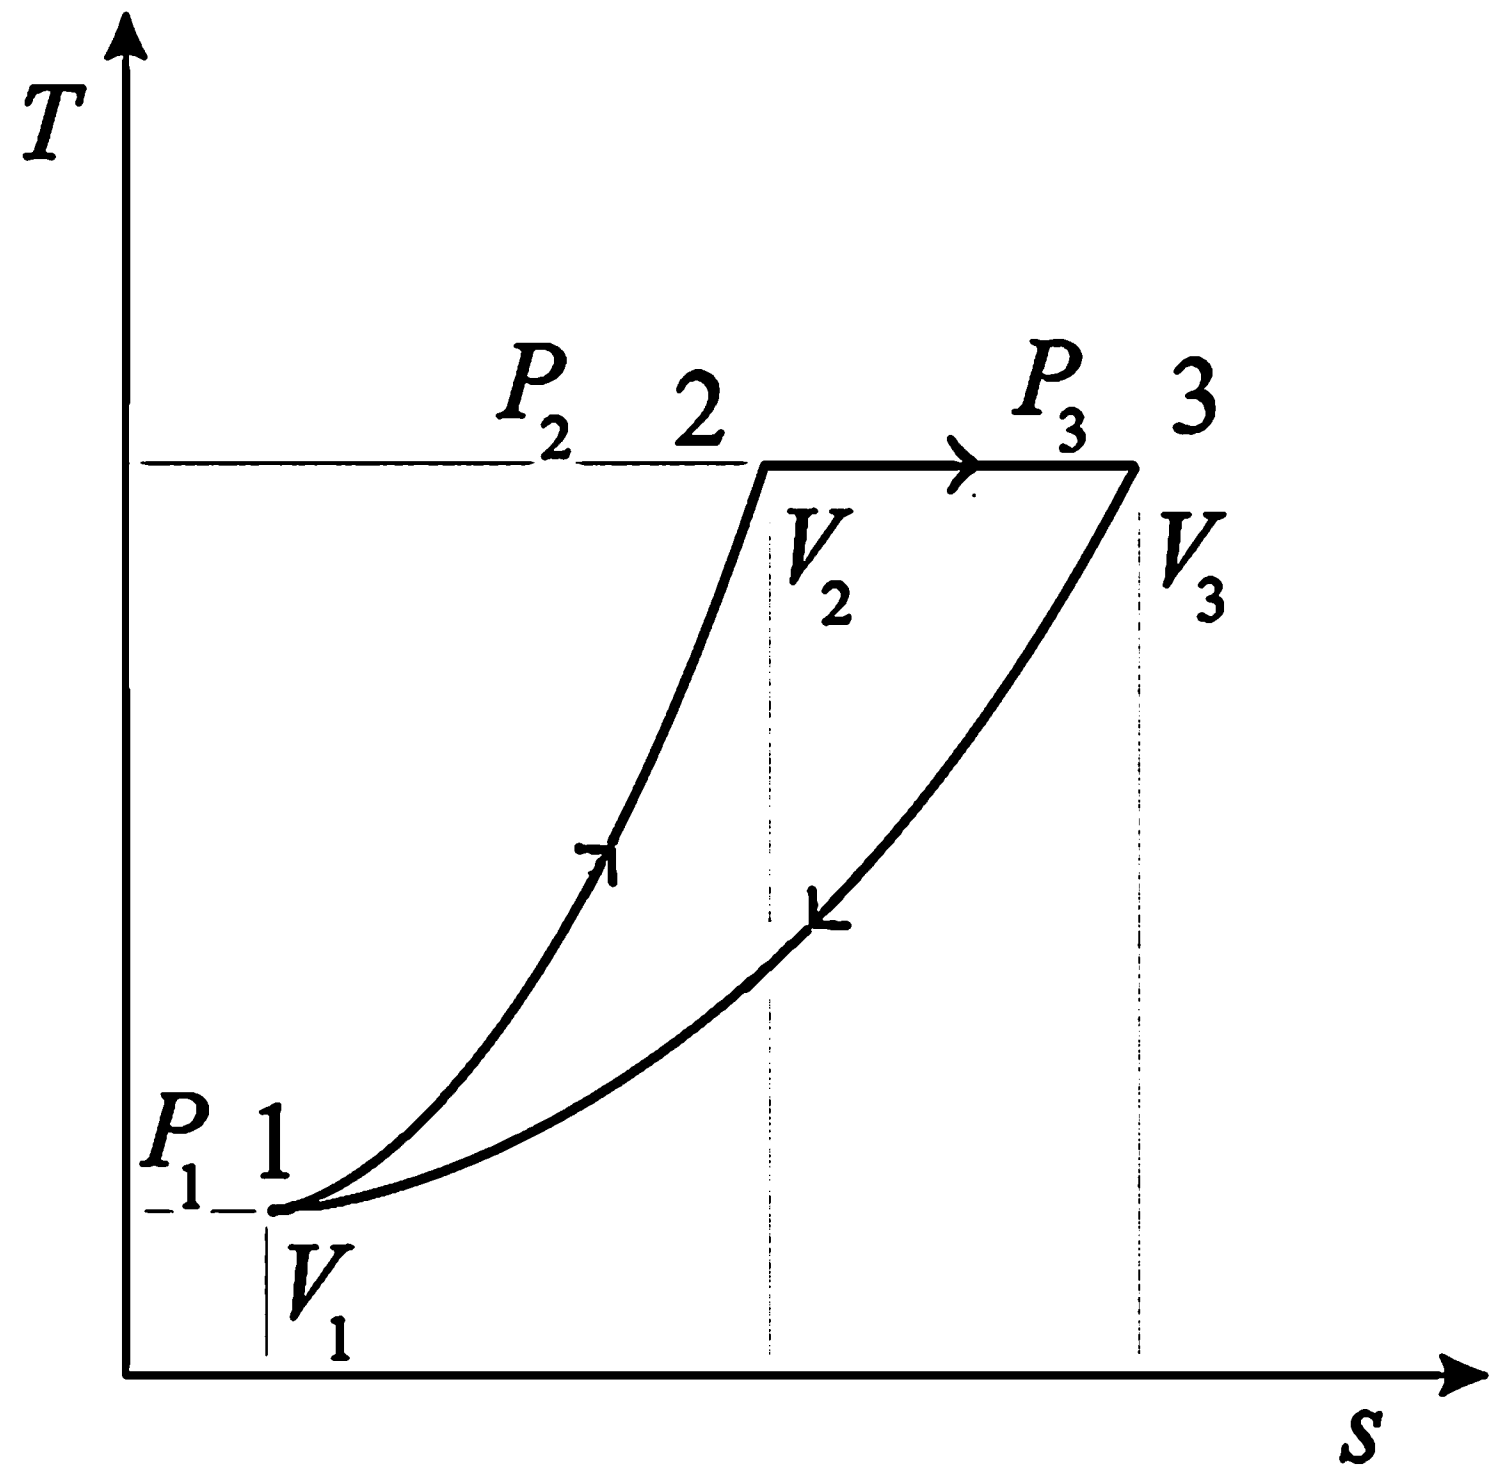
(a)



The process 1-2 is of constant volume. Hence the process can be represented as a vertical line in *P-V* diagram and as a curve on *T-s* diagram.

The process 2-3 is a isothermal process. Hence the process can be represented as a parabolic curve on *P-V* diagram and as a horizontal line in *T-s* diagram.

The process 3-1 is of constant pressure. Hence the process can be represented as a horizontal line in *P-V* diagram and as a curve in *T-s* diagram.



Step 2 of 9

Draw *P-V* diagram.

Step 3 of 9

Draw *T-s* diagram.

Step 4 of 9

(b)

Process 1-2 is Constant volume heat addition.

Find the temperature at state 2 using the ideal gas relations.

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

$$T_2 = T_1 \frac{P_2}{P_1}$$

Find the temperature at state 2 using the ideal gas relations.

$$\frac{P_1}{T_1}=\frac{P_2}{T_2}$$

$$T_2=T_1\frac{P_2}{P_1}$$

Here, T_1 is the temperature at state 1, P_1 is the pressure at state 1 and P_2 is the pressure at state 2.

Substitute 300 K for T_1, 100 kPa for P_1 and 700 kPa for P_2.

$$T_2=300\times\frac{700}{100}$$
$$=2100\ \text{K}$$

Step 5 of 9

For constant volume process, ${}_1W_2=0$.

Find the Heat transfer in 1-2 process using first law of thermodynamics.

$${}_1Q_2={}_1U_2+{}_1W_2$$
$${}_1Q_2=c_v(T_2-T_1)+{}_1W_2$$

Here, c_v is the specific heat constant at constant volume.

Substitute $0.718\,\text{kJ/kg}\cdot\text{K}$ for c_v, 0 for ${}_1W_2$, 300 K for T_1, and $2100\ \text{K}$ for T_2.

$${}_1Q_2=0.718\times(2100-300)$$
$$=1292.4\ \text{kJ/kg}$$

Step 6 of 9

Process 2-3 is Isothermal Expansion.
Find the pressure at state 3 using the ideal gas relation.

$$P_2V_2=P_3V_3$$

$$P_3=\frac{P_2V_2}{V_3}$$

Here, V_2 is the volume at state 2 and V_3 is the volume at state 3.

Substitute $7V_2$ for V_3 and 700 kPa for P_2.

$$P_3=\frac{700\times V_2}{7V_2}$$
$$=100\ \text{kPa}$$

Step 7 of 9

Find the work done in 2-3 process.

$${}_2W_3=P_2V_2\ln\left(\frac{V_3}{V_2}\right)$$
$$=RT_2\ln\left(\frac{V_3}{V_2}\right)$$

Here, R is the universal gas constant.

Substitute $7V_2$ for V_3, $2100\ \text{K}$ for T_2, $0.287\,\text{kJ/kg}\cdot\text{K}$ for R, and 700 kPa for P_2.

$${}_2W_3=0.287\times2100\times\ln\left(\frac{7V_2}{V_2}\right)$$
$$=1172.8\ \text{kJ/kg}$$

For Isothermal Expansion, ${}_1U_2=0$.

Find the Heat transfer in 2-3 process using first law of thermodynamics.

${}_2Q_3={}_2U_3+{}_2W_3$ Substitute 0 for ${}_1U_2$ and $1172.8\ \text{kJ/kg}$ for ${}_2W_3$.

$${}_2Q_3=0+1172.8$$
$$=1172.8\ \text{kJ/kg}$$

Step 8 of 9

Process 3-1 is constant pressure heat rejection.

Find the temperature at state 3 using the ideal gas relations.

$$\frac{T_3}{T_1}=\frac{V_3}{V_1}$$

$$T_3=T_1\left(\frac{V_3}{V_1}\right)$$

Substitute 300 K for T_1 and $7V_1$ for V_3.

$$T_3=300\times\frac{7V_1}{V_1}$$
$$=2100\ \text{K}$$

Find the work done in 3-1 process.

$${}_1W_3=P_3(V_1-V_3)$$
$$=R(T_1-T_3)$$

Substitute 300 K for T_1, $2100\ \text{K}$ for T_3 and $0.287\,\text{kJ/kg}\cdot\text{K}$ for R.

$${}_1W_3=0.287\times(300-2100)$$
$$=-516.6\ \text{kJ/kg}$$

Step 9 of 9

Find the back work ratio.

$$r_{bw}=\frac{\text{Comperssion work}}{}$$

Step 9 of 9

Find the back work ratio.

$$r_{bw} = \frac{\text{Comperssion work}}{\text{Expansion work}}$$
$$= \frac{W_{3-1}}{W_{2-3}}$$

Substitute $516.6\ \text{kJ/kg}$ for W_{3-1} and $1172.8\ \text{kJ/kg}$ for ${}_2W_3$.

$$r_{bw} = \frac{516.6}{1172.8}$$
$$= 0.44$$

Therefore, the back work ratio is $\boxed{0.44}$.

(c)

Find the thermal efficiency.

$$\eta_{th} = \frac{W_{net}}{Q_{in}}$$
$$= \frac{{}_2W_3 - {}_3W_1}{{}_1Q_2 + {}_2Q_3}$$

Substitute $1292.4\ \text{kJ/kg}$ for ${}_1Q_2$, $1172.8\ \text{kJ/kg}$ for ${}_2Q_3$, $516.6\ \text{kJ/kg}$ for W_{3-1} and $1172.8\ \text{kJ/kg}$ for ${}_2W_3$.

$$\eta_{th} = \frac{1172.8 - 516.6}{1292.4 + 1172.8}$$
$$= 0.266$$
$$= 26.6\%$$

Therefore, the thermal Efficiency of the cycle is $\boxed{26.6\%}$

Question:

An air-standard cycle is executed within a closed I piston-cylinder system and consists of three processes as follows:

1-2 *V*= *constant* heat addition from 100 kPa and 27°C to 700 kPa

2-3 Isothermal expansion until *V*3 = 7*V*2

3-1 *P* = *constant* heat rejection to the initial state

Assume air has constant properties with *cv*=0.718 kJ/kg·K, *cp*= 1.005 kJ/kg·K, *R* =0.287 kJ/kg·K, and *k* = 1.4.

Sketch the *P-v* and *T-s* diagrams for the cycle.

(b) Determine the ratio of the compression work to the expansion work (the back work ratio).

(c) Determine the cycle thermal efficiency.

Step 1 of 9

Given,

Temperature of air before compression $T_1 = 27^0\,\mathrm{C}$

$$T_1 = 300\,\mathrm{K}$$

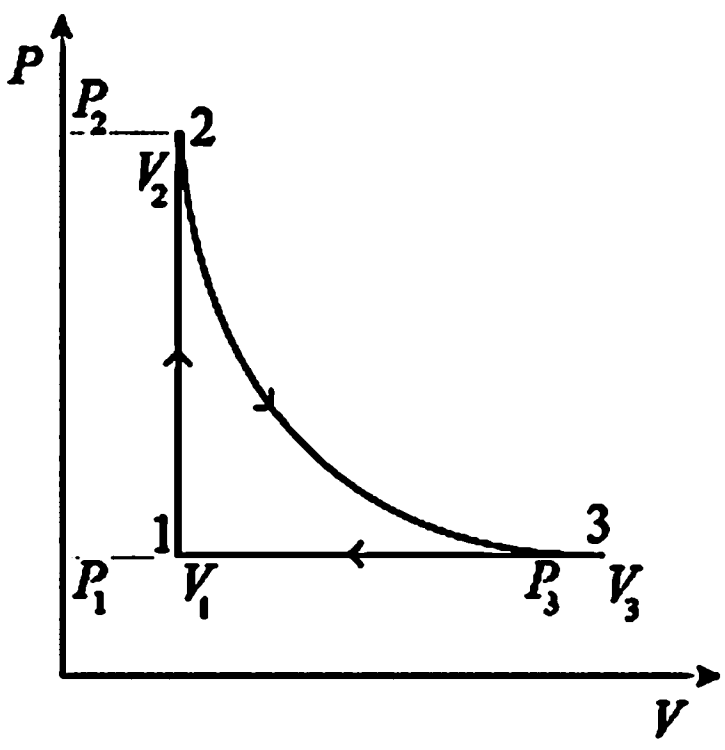
Pressure of air before compression $P_1 = 100\ \mathrm{kPa}$

Pressure of air after compression $P_2 = 700\ \mathrm{kPa}$

Volume relation, $V_3 = 7V_2$

Step 2 of 9

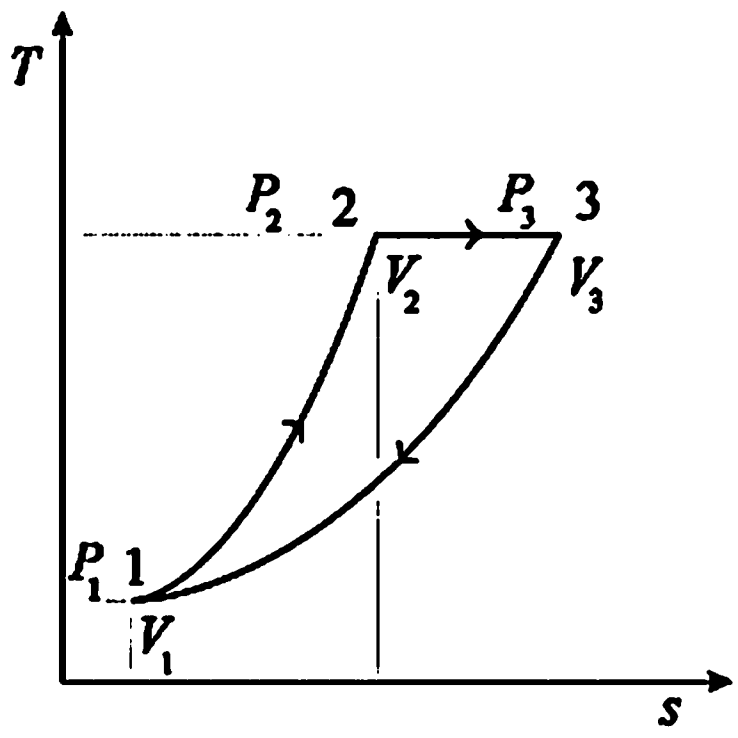
(a)



The process from 1-2 is of constant volume. Hence the process can be represented as a vertical line in *P-V* diagram and as a curve on *T-s* diagram.

The process from 2-3 is a isothermal process. Hence the process can be represented as a parabolic curve on *P-V* diagram and as a horizontal line in *T-s* diagram.

The process from 3-1 is of constant pressure. Hence the process can be represented as a horizontal line in *P-V* diagram and as a curve in *T-s* diagram.



Step 3 of 9

P-V diagram:

Step 4 of 9

T-s diagram:

Step 5 of 9

(b)

Process 1-2 is of constant volume hence it follows, the relation, $\frac{P_1}{T_1} = \frac{P_2}{T_2}$

$$T_2 = T_1\frac{P_2}{P_1}$$

$$T_2 = 300\times\frac{700}{100}$$

$$T_2 = 2100\ \mathrm{K}$$

In a constant volume process, $dV = 0$. So ${}_1W_2 = 0$. From energy balance, ${}_1Q_2 = {}_1U_2 + {}_1W_2$

$${}_1Q_2 = {}_1U_2 + 0$$

$${}_1Q_2 = c_v(dT)$$

$${}_1Q_2 = c_v(T_2 - T_1)$$

$${}_1Q_2 = 0.718\times(2100-300)$$

$${}_1Q_2 = 1292.4\ \mathrm{kJ/kg}$$

Step 6 of 9

Process 2-3 is Isothermal Expansion. Hence it follows, $P_2V_2 = P_3V_3$

$$P_3 = \frac{P_2V_2}{V_3}$$

$$P_3 = \frac{700\times V_2}{7V_2}$$

$$P_3 = 100\ \mathrm{kPa}$$

Work done is ${}_2W_3 = P_2V_2\ln\left(\frac{V_3}{V_2}\right)$

$${}_2W_3 = RT_2\times\ln\left(\frac{7V_2}{V_2}\right)$$

$P_3 = 100$ kPa

Work done is $${}_2W_3 = P_2V_2 \ln\left(\frac{V_3}{V_2}\right)$$

$${}_2W_3 = RT_2 \times \ln\left(\frac{7V_2}{V_2}\right)$$

$${}_2W_3 = 0.287 \times 2100 \times \ln\left(\frac{7V_2}{V_2}\right)$$

Step 7 of 9

$${}_2W_3 = 1172.8 \text{ kJ/kg}$$

In an isothermal process, $dT = 0$. So ${}_1U_2 = 0$. From energy balance, ${}_2Q_3 = {}_2U_3 + {}_2W_3$

$${}_2Q_3 = 0 + {}_2W_3$$

$${}_2Q_3 = {}_2W_3$$

$${}_2Q_3 = 1172.8 \text{ kJ/kg}$$

Process 3-1 is of constant pressure. Hence

$${}_1W_3 = P_3(V_1 - V_3)$$

$${}_1W_3 = R(T_1 - T_3)$$

$${}_1W_3 = 0.287 \times (300 - 2100)$$

$${}_1W_3 = -516.6 \text{ kJ/kg}$$

Step 8 of 9

$$\textit{Back work ratio} = \frac{\textit{Comperssion work}}{\textit{Expansion work}}$$

$$\textit{Back work ratio} = \frac{W_{3\text{-}1}}{W_{2\text{-}3}}$$

$$\textit{Back work ratio} = \frac{516.6}{1172.8}$$

$$\textit{Back work ratio} = 0.44$$

Hence back work ratio is $\boxed{\textit{Back work ratio} = 0.44}$

Step 9 of 9

(c)

Thermal efficiency, $\eta_{th} = \frac{W_{net}}{Q_{in}}$

$$\eta_{th} = \frac{{}_2W_3 - {}_3W_1}{{}_1Q_2 + {}_2Q_3}$$

$$\eta_{th} = \frac{1172.8 - 516.6}{1292.4 + 1172.8}$$

$$\eta_{th} = 0.266$$

$$\eta_{th} = 26.6\%$$

Thermal Efficiency of the cycle is $\boxed{\eta_{th} = 26.6\%}$

Question:

An air-standard cycle with variable specific heats is executed in a closed system and is composed of the following four processes:

1–2 Isentropic compression from 100 kPa and 22°C to 600 kPa

2-3 *V - constant* heat addition to 1500 K

3-4 Isentropic expansion to 100 kPa

4-4 *P=constant* heat rejection to initial state

(a) Show the cycle on *P-V* and *T-s* diagrams.

(b) Calculate the net work output per unit mass.

(c) Determine the thermal efficiency.

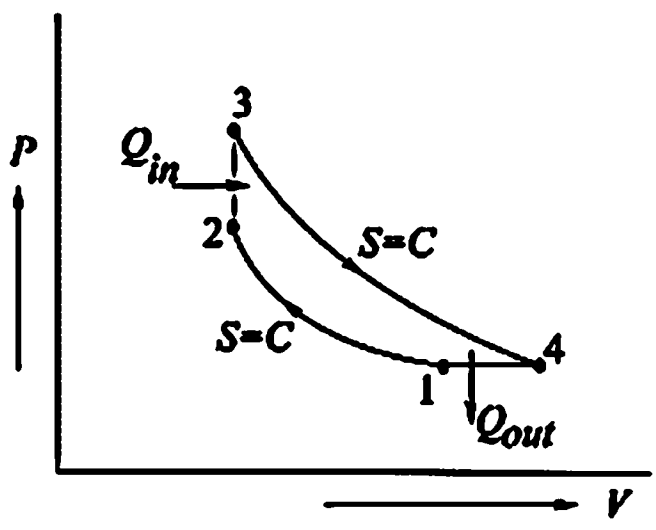
Step 1 of 12

Given data:

Temperature before compression of the given system, $T_1 = 22°C$

Pressure before compression of the given system, $p_1 = 100\,kPa$

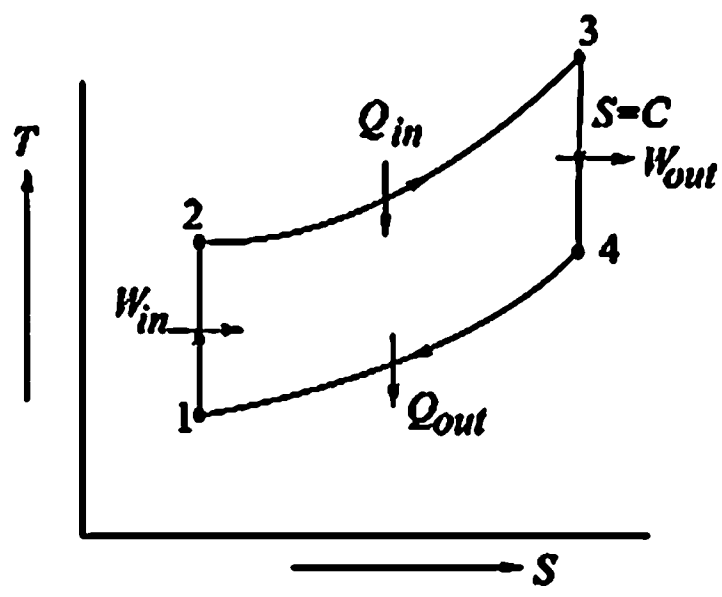
Pressure after compression of the given system, $P_2 = 600\,kPa$



Temperature after heat addition, $T_3 = 1500\,K$

Pressure after expansion of the given system, $p_4 = 100\,kPa$

Step 2 of 12



(a)

PV- diagram of the given system:

Step 3 of 12

TS- diagram for the given system:

Step 4 of 12

(b)

Since we are considering variable specific heats the specific heats at constant pressure and constant volume will be different at different temperatures.

At $T_1 = 22°C = 295\,K$ from ideal gas properties of air, we have

$h_1 = 295.17\ kJ/kg$

$u_1 = 210.49\ kJ/kg$

$P_{r1} = 1.3068$

Step 5 of 12

For the isentropic compression process 1-2, we have

$$\frac{P_{r2}}{P_{r1}} = \frac{P_2}{P_1}$$

$$\frac{P_{r2}}{1.3068} = \frac{600}{100}$$

$$P_{r2} = 7.8408$$

Step 6 of 12

At $P_{r2} = 7.8408$ $P_{r_1} = 11.088$ from ideal gas properties of air by using interpolation

$$\frac{T_2 - 490}{500 - 490} = \frac{7.8408 - 7.824}{8.411 - 7.824}$$

$$T_2 = 490.286\,K$$

Similarly,

$$\frac{u_2 - 344.7}{352.08 - 344.7} = \frac{7.8408 - 7.824}{8.411 - 7.824}$$

$$u_2 = 344.91\,kJ/kg$$

Step 7 of 12

For the process constant volume heat addition 2-3, we have

$$\frac{P_2}{P_3} = \frac{T_2}{T_3}$$

$$P_3 = P_2 \frac{T_3}{T_2}$$

$$= (600)\frac{1500}{490.286}$$

$$P_3 = 1835.66\ kPa$$

At $T_3 = 1500K$ from ideal gas properties of air, we have

$h_3 = 1635.97\ kJ/kg$

$u_3 = 1205.41\ kJ/kg$

$P_{r3} = 601.9$

$h_3 = 1635.97$ kJ/kg

$u_3 = 1205.41$ kJ/kg

$P_{r3} = 601.9$

Step 8 of 12

For the isentropic expansion process 3-4, we have

$$\frac{P_{r4}}{P_{r3}} = \frac{P_4}{P_3}$$

$$P_{r4} = \frac{P_4}{P_3} P_{r3}$$

$$= \frac{100}{1835.66} \times 601.9$$

$$P_{r4} = 32.789$$

At $P_{r4} = 32.789$ from ideal gas properties of air, we have

$$\frac{h_4 - 734.82}{745.62 - 734.82} = \frac{32.789 - 32.02}{33.72 - 32.02}$$

$h_4 = 739.71$ kJ/kg

Step 9 of 12

Process 2-3 is constant volume heat addition

$$q_{in} = u_3 - u_2$$

$$= 1205.41 - 344.91$$

$$= 860.5$$

$q_{in} = 860.5$ kJ/kg

Step 10 of 12

Process 4-1 is heat rejection at constant pressure

$$q_{out} = h_4 - h_1$$

$$= 739.71 - 295.17$$

$$= 444.54$$

$q_{out} = 444.54$ kJ/kg

Step 11 of 12

Net work output of the given system per unit mass,

$$w_{net} = q_{in} - q_{out}$$

$$= 860.5 - 444.54$$

$$= 415.96 \text{ kJ/kg}$$

Therefore, Net work output of the given system per unit mass, $\boxed{w_{net} = 415.96 \text{ kJ/kg}}$

Step 12 of 12

(c)

Thermal efficiency of the given system,

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$= \frac{415.96}{860.5}$$

$$= 0.4834$$

Therefore, thermal efficiency of the given system, $\boxed{\eta_{th} = 48.34\%}$

Question:

Reconsider Prob. 9–15. Using EES (or other) software, study the effect of varying the temperature after the constant-volume heat addition from 1500 K to 2500 K. Plot the net work output and thermal efficiency as a function of the maximum temperature of the cycle. Plot the *T-s* and *P-V* diagrams for the cycle when the maximum temperature of the cycle is 1500 K.

Step 1 of 7

Given data:

Inlet pressure $P_1 = 100\,\text{kPa}$

Inlet temperature, $T_1 = 22°\text{C}$

Pressure at state 2, $P_2 = 600\,\text{kPa}$

Maximum temperature of the cycle, $T_3 = 1500\,\text{K}$

Step 2 of 7

Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

```
"Input Data"
T[1]=295 [K]
P[1]=100 [kPa]
P[2] = 600 [kPa]
"T[3]=1500 [K]"

"Analysis"
"Process 1-2 is isentropic compression"
s[1]=entropy(air,T=T[1],P=P[1])
s[2]=s[1]
T[2]=temperature(air, s=s[2], P=P[2])
P[2]*v[2]/T[2]=P[1]*v[1]/T[1]
P[1]*v[1]=R*T[1]
R=0.287 [kJ/kg-K]
P[4] = 100 [kPa]
```

Step 3 of 7

```
"Conservation of energy for process 1 to 2"
q_12 -w_12 = DELTAu_12
q_12 =0 "isentropic process"
DELTAu_12=intenergy(air,T=T[2])-intenergy(air,T=T[1])

"Process 2-3 is constant volume heat addition"
s[3]=entropy(air, T=T[3], P=P[3])
{P[3]*v[3]/T[3]=P[2]*v[2]/T[2]}
P[3]*v[3]=R*T[3]
v[3]=v[2]
```

Step 4 of 7

```
"Conservation of energy for process 2 to 3"
q_23 -w_23 = DELTAu_23
w_23 =0 "constant volume process"
DELTAu_23=intenergy(air,T=T[3])-intenergy(air,T=T[2])

"Process 3-4 is isentropic expansion"
s[4]=entropy(air,T=T[4],P=P[4])
s[4]=s[3]
P[4]*v[4]/T[4]=P[3]*v[3]/T[3]
{P[4]*v[4]=0.287*T[4]}

"Conservation of energy for process 3 to 4"
q_34 -w_34 = DELTAu_34
q_34 =0"isentropic process"
DELTAu_34=intenergy(air,T=T[4])-intenergy(air,T=T[3])
```

Step 5 of 7

```
"Process 4-1 is constant pressure heat rejection"
{P[4]*v[4]/T[4]=P[1]*v[1]/T[1]}
"Conservation of energy for process 4 to 1"
q_41 -w_41 = DELTAu_41
w_41 =P[1]*(v[1]-v[4]) "constant pressure process"
DELTAu_41=intenergy(air,T=T[1])-intenergy(air,T=T[4])
q_in_total=q_23
w_net = w_12+w_23+w_34+w_41
Eta_th=w_net/q_in_total*100 "Thermal efficiency, in percent"
```

Step 6 of 7

After writing the program in equation window select table on menu bar and click new parameter table. Now the dialog box will be appeared on the screen and then select the efficiency, head loss and work done by the pump. Finally click ADD, then click OK button.

The following results are displayed:

EES Limited Academic Version: C:\EES (LIMITED ACADEMIC)\HELLO.DTT - [Param

Step 7 of 7

Select the plot on menu bar, then click x-y plot .Dialog box will be appeared and select variables to draw graph, then click OK button.

By plotting the graph between pressure and volume:

By plotting the graph between temperature and entropy:

Question:

An air-standard cycle is executed in a closed system with 0.004 kg of air and consists of the following three processes:

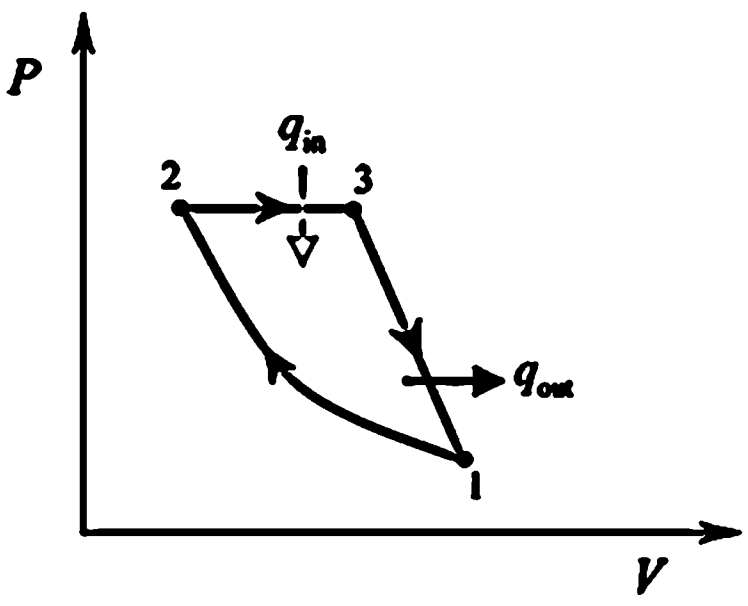
1-2 Isentropic compression from 100 kPa and 27°C to 1 MPa

2-3 *P - constant* heat addition in the amount of 2.76 kJ

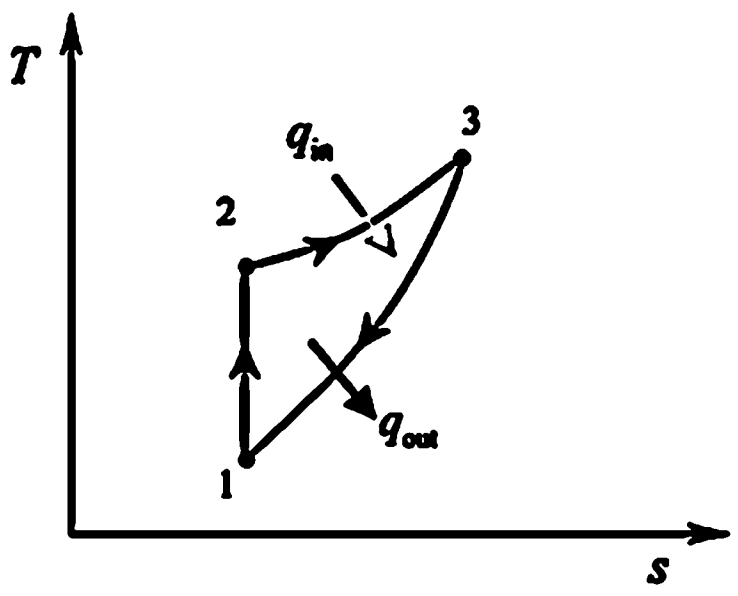
3-3*P* = *c*1*V* + *c*2 heat rejection to initial state (*c*1, and *c*2 are constants)

(a) Show the cycle on *P-v* and *T-s* diagrams.

(b) Calculate the heat rejected.



(c) Determine the thermal efficiency.



Assume constant specific heats at room temperature.

Step 1 of 8

(a)

Draw $P-V$ and $T-S$ diagrams of an air-standard cycle as follows:

Step 2 of 8

The process $1-2$ is an isentropic compression process.

Hence, the process is represented as a curve on the $P-V$ diagram and as a vertical line on $T-S$ diagram.

The process $2-3$ is of constant pressure heat addition process.

Hence, the process is represented as a horizontal line on the $P-V$ diagram and as a curve on $T-S$ diagram.

The process $3-1$ is a heat rejection process which follows the law, $P=c_1V+c_2$

Hence, the process is represented as a straight line on the $P-V$ diagram and as a curve on $T-S$ diagram.

Step 3 of 8

(b)

Obtain the properties of air from the **Table A-2a**.

At room temperature,

Gas constant, $R=0.287\,\text{kJ/kg}\cdot\text{K}$

Specific heats at constant pressure, $c_p=1.005\,\text{kJ/kg}\cdot\text{K}$

Specific heats at constant volume, $c_v=0.718\,\text{kJ/kg}\cdot\text{K}$

Ratio of specific heats (or) Specific heat ratio, $k=1.4$

Step 4 of 8

Consider the process $1-2\left(\text{Isentropic Compression process}\right)$:

Calculate the temperature at the end of compression in an isentropic compression process by using the following equation,

$$\frac{T_2}{T_1}=\left(\frac{P_2}{P_1}\right)^{\left(\frac{k-1}{k}\right)}$$

$$T_2=T_1\left(\frac{P_2}{P_1}\right)^{\left(\frac{k-1}{k}\right)}$$

Here, the temperature of air before compression is T_1, the volume of air before compression is V_1, the volume of air after compression is V_2, the temperature of air at the end of compression is T_2, and the specific heat ratio is k.

Substitute 300 K for T_1, 1000 kPa for P_2, 100 kPa for P_1, and 1.4 for k.

$$\begin{aligned}T_2&=T_1\left(\frac{P_2}{P_1}\right)^{\left(\frac{k-1}{k}\right)}\\&=300\left(\frac{1000}{100}\right)^{\left(\frac{1.4-1}{1.4}\right)}\\&=579.20\text{ K}\end{aligned}$$

Step 5 of 8

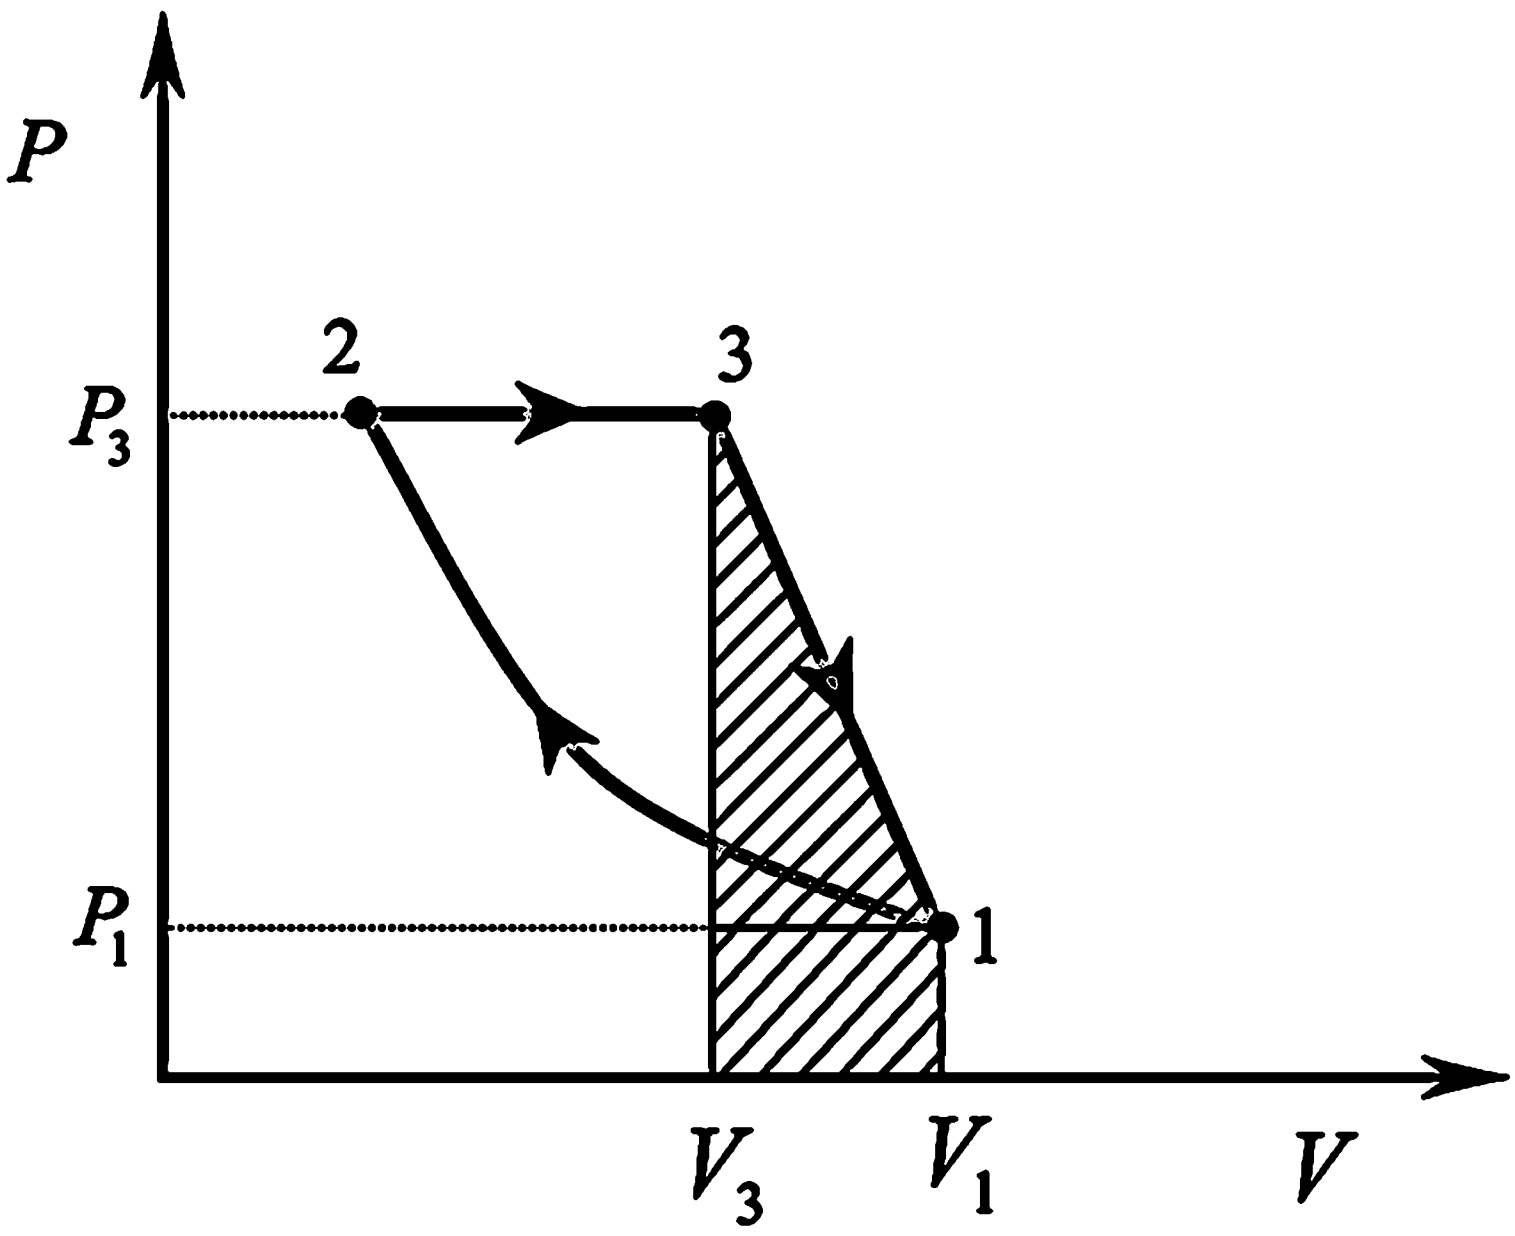
Write an expression for the heat input to the system during the constant pressure heat addition process $2-3$.

$$Q_{in,2\text{-}3}=mc_p\left(T_3-T_2\right)$$

Here, the mass of air is m, the temperature of air at the end of heat addition process is T_3 and the specific heat at constant pressure is c_p.

Substitute 0.004 kg for m, $1.005\text{ kJ/kg}\cdot\text{K}$ for c_p, 2.76 kJ for $Q_{in,2\text{-}3}$, and 579.20 K for T_2.

$$\begin{aligned}2.76&=0.004\times1.005\left(T_3-579.20\right)\\T_3-579.20&=686.56\\T_3&=1265.76\text{ K}\end{aligned}$$



Substitute 0.004 kg for m, 1.005 kJ/kg·K for c_p, 2.76 kJ for $Q_{in,2-3}$, and 579.20 K for T_2.

$$2.76 = 0.004 \times 1.005 (T_3 - 579.20)$$

$$T_3 - 579.20 = 686.56$$

$$T_3 = 1265.76 \text{ K}$$

Draw the shaded region representing the work done during the process 3-1.

The process 3-1 is a straight line on the $P-V$ diagram. Thus, the area under the process curve 3-1 represents the work done during the process.

Step 6 of 8

Calculate the work done during the process 3-1.

$$W_{3-1} = \left[P_1(V_1 - V_3)\right] + \left[\frac{1}{2}(V_1 - V_3)(P_3 - P_1)\right]$$

$$= (V_1 - V_3)\left[P_1 + \left(\frac{P_3 - P_1}{2}\right)\right]$$

$$= (V_1 - V_3)\left[\frac{P_1 + P_3}{2}\right]$$

$$= \left[mR\left(\frac{T_1}{P_1} - \frac{T_3}{P_3}\right)\right]\left[\frac{P_1 + P_3}{2}\right] \qquad (\because PV = mRT)$$

Substitute 0.004 kg for m, 0.287 kJ/kg·K for R, 300 K for T_1, 1265.76 K for T_3, 1000 kPa for P_3, and 100 kPa for P_1.

$$W_{3-1} = \left[0.004 \times 0.287\left(\frac{300}{100} - \frac{1265.76}{1000}\right)\right]\left[\frac{100 + 1000}{2}\right]$$

$$= 1.0949 \text{ kJ}$$

Step 7 of 8

Write the energy balance equation for the process 3-1.

$$E_{in} - E_{out} = \Delta E_{system}$$

$$-Q_{out,3-1} - W_{3-1} = m(u_1 - u_3)$$

$$Q_{out,3-1} = -mc_v(T_1 - T_3) - W_{3-1}$$

Here, the specific heat at constant volume is c_v and the heat rejected during the process $3-1$ is $Q_{out,3-1}$.

Substitute 0.004 kg for m, 0.718 kJ/kg·K for c_v, 300 K for T_1, 1265.76 K for T_3, and 1.0949 kJ for W_{3-1}.

$$Q_{out,3-1} = -\left[0.004 \times 0.718(300 - 1265.76)\right] - 1.0949$$

$$= -\left[-2.7736\right] - 1.0949$$

$$= 1.6787 \text{ kJ}$$

Therefore, the heat rejected during the process $3-1$ is $\boxed{1.6787 \text{ kJ}}$.

Step 8 of 8

(c)

Calculate the thermal efficiency of the system by using the following equation,

$$\eta = \frac{Q_{in,2-3} - Q_{out,3-1}}{Q_{in,2-3}}$$

$$= 1 - \frac{Q_{out,3-1}}{Q_{in,2-3}}$$

Substitute 1.6787 kJ for $Q_{out,3-1}$ and 2.76 kJ for $Q_{in,2-3}$.

$$\eta = 1 - \frac{1.6787}{2.76}$$

$$= 0.3917$$

$$= 39.17\%$$

Therefore, thermal efficiency of the system is $\boxed{39.17\%}$.

Question:

An air-standard cycle with variable specific heats is executed in a closed system and is composed of the following four processes:

1–2 *V*= *constant* heat addition from 14.7 psia and 80°F in

the amount of 300 Btu/lbm

2-3 *P* = *constant* heat addition to 3200 R

3-4 Isentropic expansion to 14.7 psia

4-1 *P* = *constant* heat rejection to initial state

(*a*) Show the cycle on *P-V* and *T-s* diagrams.

(*b*) Calculate the total heat input per unit mass.

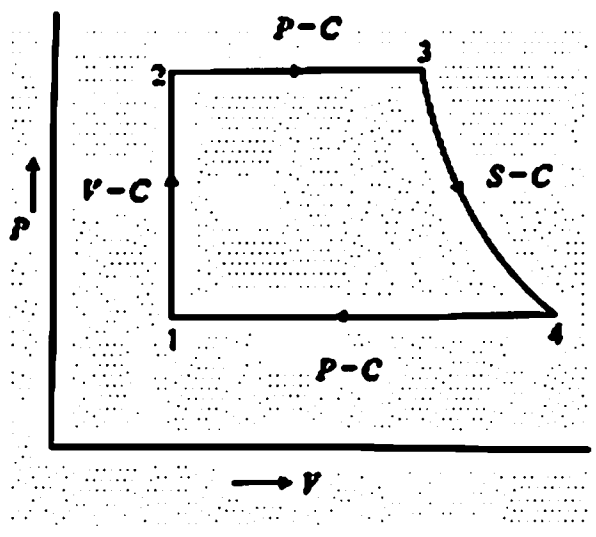
(*c*) Determine the thermal efficiency.

Step 1 of 14

Given

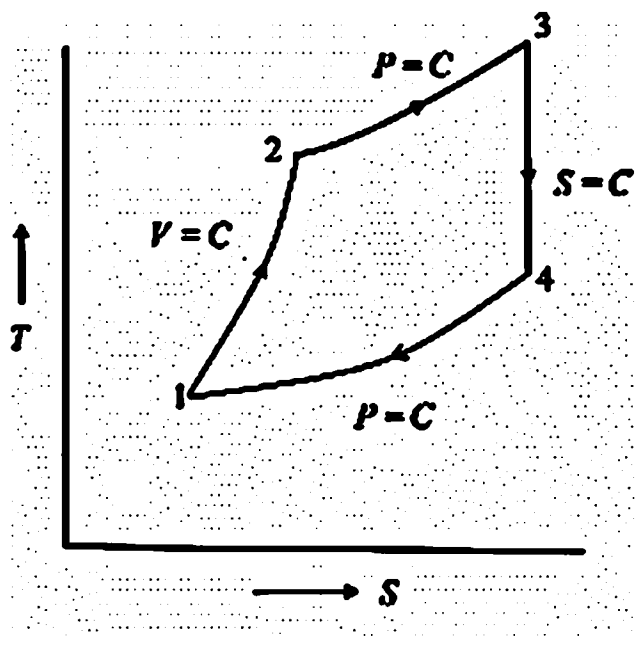
Pressure at state 1 $p_1 = 14.7\,\text{psia}$

Temperature at state 1 $T_1 = 80^0\text{F} = 540\text{R}$



Heat addition during the process 1-2 is $q_{in1\text{-}2} = 300\,\text{Btu/lbm}$

Temperature at state 3 $T_3 = 3200\text{R}$



Pressure at state 4 $p_4 = 14.7\,\text{psia}$

Step 2 of 14

(a)

Step 3 of 14

Step 4 of 14

(b)

Since we are considering variable specific heats the specific heat at constant pressure and specific heat at constant volume will be different at different temperatures.

At $T_1 = 540\text{R}$ from ideal gas properties of air

$h_1 = 129.06\,\text{Btu/lbm}$

$u_1 = 92.04\,\text{Btu/lbm}$

$P_{r1} = 1.386$

Step 5 of 14

Process 1-2 is constant volume heat addition

$q_{in1\text{-}2} = u_2 - u_1$

$300 = u_2 - 92.04$

$u_2 = 392.04\,\text{Btu/lbm}$

Step 6 of 14

At $u_2 = 392.04\,\text{Btu/lbm}$ from ideal gas properties of air

$$T_2 = 2100 + (2150 - 2100)\left(\frac{392.04 - 388.60}{399.17 - 388.60}\right)$$

$T_2 = 2116.27\text{R}$

$$h_2 = 532.55 + (546.54 - 532.55)\left(\frac{392.04 - 388.60}{399.17 - 388.60}\right)$$

$h_2 = 537.103\,\text{Btu/lbm}$

Step 7 of 14

Process 1-2 is constant volume process so

$$\frac{P_2}{P_1} = \frac{T_2}{T_1}$$

$$P_2 = P_1 \times \frac{T_2}{T_1}$$

$$P_2 = 14.7 \times \frac{2116.27}{540}$$

$P_2 = 57.609\,\text{psia}$

Step 8 of 14

At $T_3 = 3200\text{R}$ from ideal gas properties of air

$h_3 = 849.48\,\text{Btu/lbm}$

Step 8 of 14

At $T_3 = 3200\text{R}$ from ideal gas properties of air

$h_3 = 849.48\ \text{Btu/lbm}$

$P_{r3} = 1242$

Step 9 of 14

Process 3-4 is isentropic process

$$\frac{P_{r4}}{P_{r3}} = \frac{P_4}{P_3}$$

$$\frac{P_{r4}}{1242} = \frac{14.7}{57.609} \qquad (\text{Since } p_2 = p_3)$$

$$P_{r4} = 0.255 \times 1242$$

$$P_{r4} = 316.71$$

Step 10 of 14

At $P_{r4} = 316.71$ from ideal gas properties of air

$$h_4 = 588.82 + (603.00 - 588.82)\left(\frac{316.71 - 308.1}{336.8 - 308.1}\right)$$

$$h_4 = 593.074\ \text{Btu/lbm}$$

Step 11 of 14

The heat input in process 2-3

$$q_{in2\text{-}3} = h_3 - h_2$$

$$q_{in2\text{-}3} = 849.48 - 537.103$$

$$q_{in2\text{-}3} = 312.377\ \text{Btu/lbm}$$

Step 12 of 14

The total heat input

$$q_{in} = q_{in1\text{-}2} + q_{in2\text{-}3}$$

$$= 300 + 312.377$$

$$\boxed{q_{in} = 612.377\ \text{Btu/lbm}}$$

Step 13 of 14

(c)

The heat output in process 4-1

$$q_{out4\text{-}1} = h_4 - h_1$$

$$= 593.074 - 129.06$$

$$q_{out4\text{-}1} = 464.014\ \text{Btu/lbm}$$

Step 14 of 14

The thermal efficiency of the cycle

$$\eta_{th} = \frac{q_{in} - q_{out}}{q_{in}}$$

$$= \frac{612.377 - 464.014}{612.377}$$

$$= 0.2422$$

$$\boxed{\eta_{th} = 24.22\%}$$

Question: 9.019P

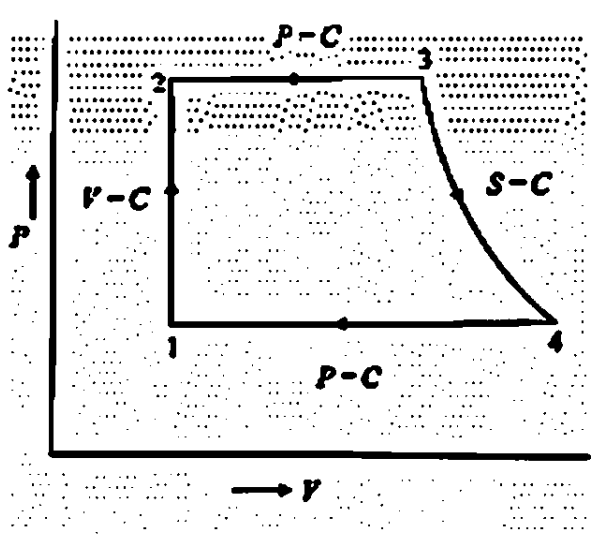
Repeat Prob. 9-18E using constant specific heats at room temperature.

Step 1 of 11

Given

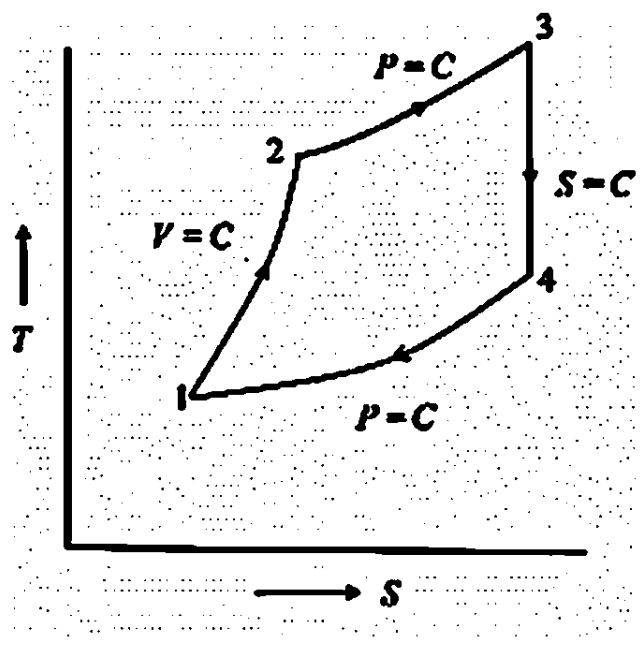
Pressure at state 1 $p_1 = 14.7 \text{psia}$

Temperature at state 1 $T_1 = 80^0\text{F} = 540\text{R}$



Heat addition during the process 1-2 is $q_{in1-2} = 300 \text{Btu/lbm}$

Temperature at state 3 $T_3 = 3200\text{R}$



Pressure at state 4 $p_4 = 14.7 \text{psia}$

Step 2 of 11

(a)

Step 3 of 11

Step 4 of 11

(b)

Considering constant specific heats at room temperature

From table ideal gas specific heats of various common gases

$c_p = 0.24 \text{ Btu/lbm.R}$

$c_v = 0.171 \text{ Btu/lbm.R}$

$k = 1.4$

Step 5 of 11

Process 1-2 is constant volume heat addition

$q_{in1-2} = u_2 - u_1$

$q_{in1-2} = c_v (T_2 - T_1)$

$300 = (0.171)(T_2 - 540)$

$T_2 = 2294.38 \text{ R}$

Step 6 of 11

Process 1-2 is constant volume process

By using ideal gas relation

$$\frac{P_2}{P_1} = \frac{T_2}{T_1}$$

$$P_2 = P_1 \times \frac{T_2}{T_1}$$

$$P_2 = 14.7 \times \frac{2294.38}{540}$$

$P_2 = 62.45 \text{ psia}$

Step 7 of 11

Process 2-3 is constant pressure heat addition

$q_{in2-3} = h_3 - h_2$

$q_{in2-3} = c_p (T_3 - T_2)$

$q_{in2-3} = (0.24)(3200\text{-}2294.38)$

$q_{in2-3} = 217.34 \text{ Btu/lbm}$

Step 8 of 11

The total heat input

$q_{in} = q_{in1-2} + q_{in2-3}$

$= 300 + 217.34$

$\boxed{q_{in} = 517.34 \text{ Btu/lbm}}$

Step 9 of 11

(c)

Process 3-4 is isentropic expansion

Therefore

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{3200} = \left(\frac{14.7}{62.45}\right)^{\frac{1.4-1}{1.4}} \qquad (\text{Since } P_4 = P_3)$$

$T_4 = 2116.70\text{R}$

Step 10 of 11

The heat output in process 4-1

$q_{out4-1} = h_4 - h_1$

$= c_p (T_4 - T_1)$

$= (0.24)(2116.70 - 540)$

$q_{out4-1} = 378.408 \text{ Btu/lbm}$

Step 11 of 11

The thermal efficiency

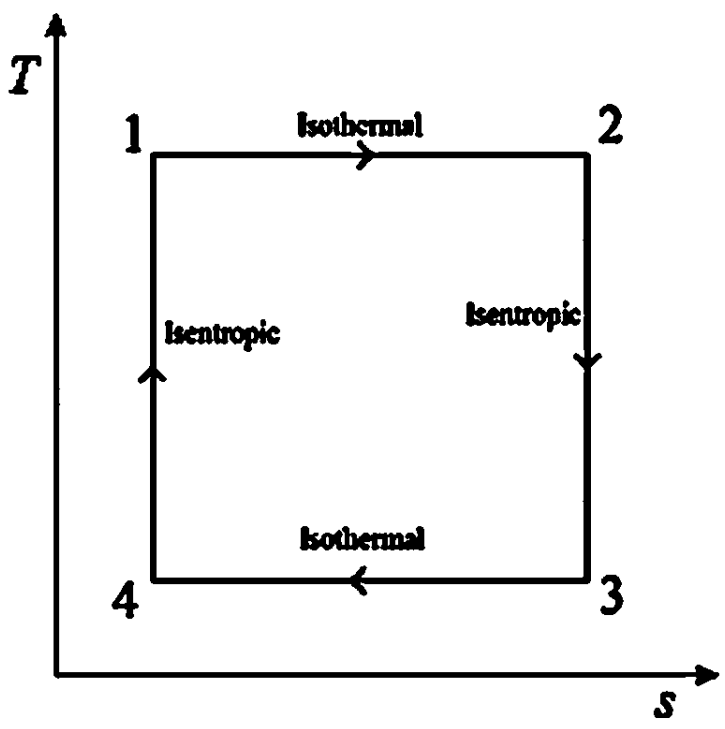
$$\eta_{th} = \frac{q_{in} - q_{out}}{q_{in}}$$

$$= \frac{517.34 - 378.408}{517.34}$$

$= 0.2685$

$\boxed{\eta_{th} = 26.85\%}$

Question: 9.020P



Consider a Carnot cycle executed in a closed system with 0.6 kg of air. The temperature limits of the cycle are 300 and 1100 K, and the minimum and maximum pressures that occur during the cycle are 20 and 3000 kPa. Assuming constant specific heats, determine the net work output per cycle.

Step 1 of 7

All four processes that comprise the Carnot cycle are reversible, and thus the area under each process curve represents the heat transfer for that process. Heat is transferred to the system during 1-2 and rejected during process 3-4 through isothermal processes and expansion, compression of medium is done in isentropic processes. Therefore, the representation of carnot cycle in T-S diagram is a rectangle

Step 2 of 7

***T-s* diagram for Carnot cycle:**

Step 3 of 7

For process 2-3 is isentropic,

$$P_2 = P_3\left(\frac{T_2}{T_3}\right)^{(k/1-k)}$$

$$P_2 = P_{min}\left(\frac{T_2}{T_3}\right)^{(k/1-k)}$$

Here, P_2 is the pressure at state point 2 and P_3 is the pressure at state point 3 , P_{min} is the pressure at minimum pressure and T_3 and T_2 are the temperature at sate point 2 and 3 respectively.

Substitute 20kPa for P_{min} , 1100K for T_2 and 300K for T_3

$$P_2 = 20\left(\frac{1100}{300}\right)^{(1.4/1-1.4)}$$

$$= 1887.9 \text{ kPa}$$

Step 4 of 7

From energy balance, $dQ = dU + dW$ but $dQ = mTds$ Hence

$$mTds = mc_v dT + mPdV$$

$$ds = \frac{c_v dT}{T} + \frac{PdV}{T}$$

$$ds = \frac{c_v dT}{T} + \frac{RdV}{V}$$

$$ds = c_v \ln\left(\frac{T_2}{T_1}\right) + R\ln\left(\frac{V_2}{V_1}\right)$$

$$ds = c_v \ln\left(\frac{T_2}{T_1}\right) + R\ln\left(\frac{V_2}{V_1}\right)$$

Step 5 of 7

For isothermal process, $T_2 = T_1$

And for isothermal process, $P_1V_1 = P_2V_2$

Write the relation for entropy change,

$$ds = c_v \ln\left(\frac{T_1}{T_1}\right) - R\ln\left(\frac{P_2}{P_1}\right)$$

$$= -R\ln\left(\frac{P_2}{P_1}\right)$$

$$= -0.287 \times \ln\left(\frac{1887.9}{3000}\right)$$

$$= -0.1329 \text{ kJ/kg}\cdot\text{K}$$

Step 6 of 7

Calculate the heat required for evaporation process

$$Q_{sup} = mT_H ds$$

Here, T_H is the source temperature and m is the mass flow rate through a processes

Substitute 0.6kg for m, 1100K for T_H and 0.132 kJ/kg·K for ds

$$Q_{sup} = 0.6 \times 1100 \times 0.132$$

$$= 87.12 \text{ kJ}$$

Calculate the Efficiency of carnot cycle

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

Substitute 300K for T_L

$$\eta_{th} = 1 - \frac{300}{1100}$$

$$= 0.7273$$

Step 7 of 7

Calculate the Net work in cycle,

$$W_{net} = \eta_{th} \times Q_{sup}$$

$$= 0.7273 \times 87.12 \text{ kJ}$$

$$= 63.36 \text{ kJ}$$

Hence net work output of the cycle is $\boxed{63.36 \text{ kJ}}$

Question: 9.021P

Consider a Carnot cycle executed in a closed system with air as the working fluid. The maximum pressure in the cycle is 800 kPa while the maximum temperature is 750 K. If the entropy increase during the isothermal heat rejection process is 0.25 kJ/kg-K and the net work output is 100 kJ/kg, determine (*a*) the minimum pressure in the cycle, (*b*) the heat rejection from the cycle, and (*c*) the thermal efficiency of the cycle, (*d*) If an actual heat engine cycle operates between the same temperature limits and produces 5200 kW of power for an air flow rate of 90 kg/s, determine the second law efficiency of this cycle.

Step 1 of 10

Given

Maximum temperature $T_1 = T_2 = 750K$

Maximum pressure $P_1 = 800$ kPa

Ideal net work output $w_{carnot} = 100$ kJ/kg

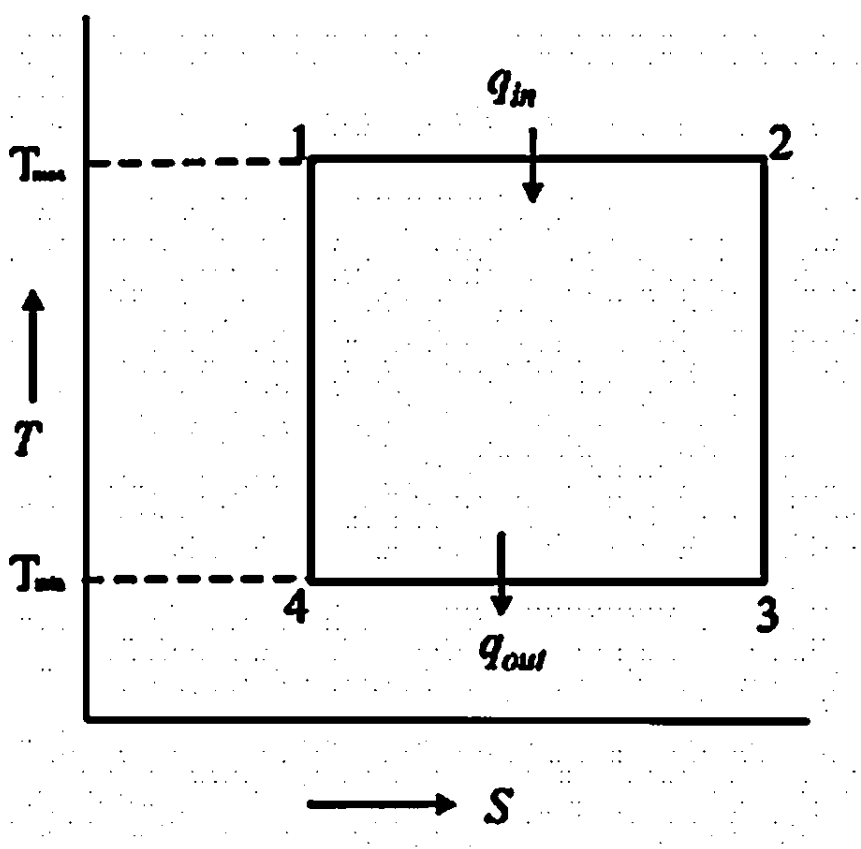
Entropy change during the isothermal heat rejection is $\Delta s_{3-4} = 0.25$ kJ/kg

Actual work output $W_{actual} = 5200$kW

Step 2 of 10

Considering constant specific heats

At room temperature from table ideal gas specific heats of various common gases



Gas constant $R = 0.287$ kJ/kg.K

$c_p = 1.005$ kJ/kg.K

$c_v = 0.718$ kJ/kg.K

$k = 1.4$

Step 3 of 10

Step 4 of 10

A Carnot cycle consists of 4 processes executing a cycle they are

Process 1-2 is constant temperature heat addition.

Process 2-3 is isentropic expansion.

Process 3-4 is constant temperature heat rejection.

Process 4-1 is isentropic compression.

Step 5 of 10

(a) The minimum pressure in the cycle

The work net is expressed as

$$w_{carnot} = q_{in} - q_{out}$$

$$= T_{max}\Delta s - T_{min}\Delta s$$

$$w_{carnot} = (T_{max} - T_{min})\Delta s$$

$$100 = (750 - T_{min})0.25$$

$$T_{min} = T_3 = T_4 = 350K$$

Step 6 of 10

Change in entropy we can write it as

$$s_2 - s_1 = c_p \ln\frac{T_2}{T_1} - R\ln\frac{P_2}{P_1}$$

$$0.25 = 0 - (0.287)\ln\frac{P_2}{800} \qquad (\text{Since } T_2 = T_1)$$

$$-0.871 = \ln\frac{P_2}{800}$$

$$P_2 = 334.8 \text{ kPa}$$

Step 7 of 10

Process 2-3 is isentropic expansion

$$\frac{T_2}{T_3} = \left(\frac{P_2}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{750}{350} = \left(\frac{334.8}{P_3}\right)^{\frac{1.4-1}{1.4}}$$

$$\boxed{P_3 = 23.24 \text{ kPa}}$$

Step 8 of 10

(b) Heat rejection from the cycle is

$$q_{out} = T_{min}\Delta s$$

$$= 350(0.25)$$

$$\boxed{q_{out} = 87.5 \text{ kJ/kg}}$$

Step 9 of 10

(c) The thermal efficiency of a Carnot cycle is defined as

$$\eta = 1 - \frac{T_{min}}{T_{max}}$$

$$= 1 - \frac{350}{750}$$

$$= 0.533333$$

$$\boxed{\eta = 53.34\%}$$

Step 10 of 10

(d) The second law of efficiency is defined as

$$\eta_{II} = \frac{W_{actual}}{W_{carnot}}$$

$$\eta_{II} = \frac{W_{actual}}{\dot{m}w_{carnot}}$$

$$\eta_{II} = \frac{5200}{90(100)}$$

$$= 0.5777$$

$$\boxed{\eta_{II} = 57.77\%}$$

Question: 9.022P

An ideal gas Carnot cycle uses air as the working fluid, receives heat from a heat reservoir at 1027°C, is repeated 1500 times per minute, and has a compression ratio of 12. The compression ratio is defined as the volume ratio during the compression process. Determine the maximum temperature of the low-temperature heat reservoir, the cycle's thermal efficiency, and the amount of heat that must be supplied per cycle if this device is to produce 500 kW of power.

Step 1 of 7

Given

High temperature reservoir $T_H = 1027^0\text{C}$

$$= 1027 + 273$$

$$T_H = 1300\text{K}$$

The compression ratio $r = \frac{v_1}{v_2} = 12$

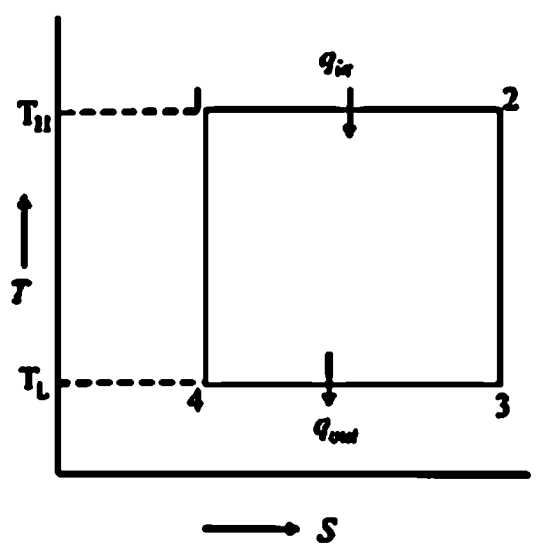
Power output $\dot{W}_{net} = 500\ \text{kW}$

Number of cycles per minute $N = 1500\ \text{cycles/min}$

Step 2 of 7

Considering constant specific heats at room temperature

Taking properties of air at room temperature from table ideal gas specific heats of various common gases



$R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 7

Step 4 of 7

We know that

$$\frac{T_2}{T_1} = \frac{T_H}{T_L} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_H}{T_L} = (r)^{k-1}$$

$$T_L = \frac{T_H}{r^{k-1}}$$

$$T_L = \frac{1300}{12^{1.4-1}}$$

$$\boxed{T_L = 481.139\text{K}}$$

Step 5 of 7

Efficiency of Carnot cycle is

$$\eta = 1 - \frac{T_L}{T_H}$$

$$\eta = 1 - \frac{481.139}{1300}$$

$$= 0.629$$

$$\boxed{\eta = 62.9\%}$$

Step 6 of 7

Work output per cycle

$$W_{net} = \frac{\dot{W}_{net}}{N}$$

$$= 500 \times \frac{1}{1500/60}$$

$$W_{net} = 20\text{kJ/cycle}$$

Step 7 of 7

The amount of heat supplied is

$$\eta = \frac{W_{net}}{Q_{in}}$$

$$Q_{in} = \frac{W_{net}}{\eta}$$

$$= \frac{20}{0.629}$$

$$\boxed{Q_{in} = 31.79\ \text{kJ/cycle}}$$

Question: 9.023P

How is the rpm (revolutions per minute) of an actual four-stroke gasoline engine related to the number of thermodynamic cycles? What would your answer be for a two-stroke engine?

Step 1 of 1

While calculating the performance of the four stroke engine the rpm is taken twice the actual value, since the actual engine gives one power stroke for every two revolutions or four strokes of the piston cylinder arrangement

In two stroke engine it gives one power stroke for one revolution or two strokes of the piston cylinder arrangement. So for two stroke engine rpm is equal to the number of thermodynamic cycles.

Question: 9.024P

How do the efficiencies of the ideal Otto cycle and the Carnot cycle compare for the same temperature limits? Explain.

Step 1 of 1

In Carnot cycle there are two isothermal processes and two isentropic processes whereas in Otto cycle two constant volume processes and two isentropic processes.
Otto cycle is not totally reversible, however, since they involve heat transfer through a finite temperature difference during the non isothermal heat addition and heat rejection processes, which are irreversible. Therefore the thermal efficiency of an Otto cycle will be less than that of a Carnot engine operating between the same temperature limits

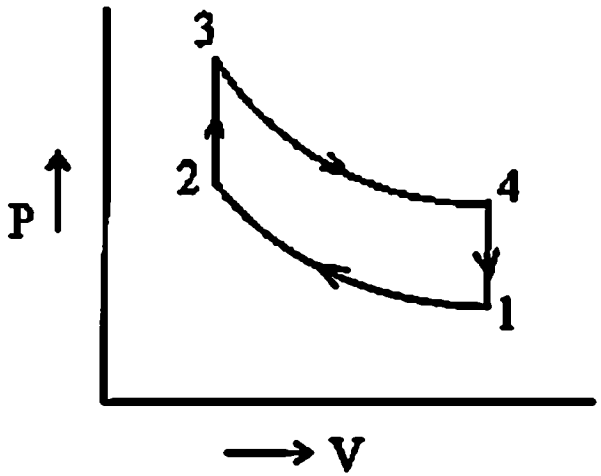
$\eta_{Otto} < \eta_{carnot}$

Question: 9.025P

What four processes make up the ideal Otto cycle?

Step 1 of 2

An ideal Otto cycle consists of four internally reversible processes:



1-2 isentropic compression

2-3 Constant-volume heat addition

3-4 isentropic expansion

4-1 Constant-volume heat rejection

Step 2 of 2

Question: 9.026P

Are the processes that make up the Otto cycle analyzed as closed-system or steady-flow processes? Why?

Step 1 of 1

All the processes in Otto cycle are analyzed as closed system because there is no mass transfer from the system boundary in any one of the processes.

Question: 9.027P

How does the thermal efficiency of an ideal Otto cycle change with the compression ratio of the engine and the specific heat ratio of the working fluid?

Step 1 of 1

The ideal efficiency of an Otto cycle is defined as

$$\eta_{otto} = 1 - \frac{1}{r^{k-1}}$$

Where

r Is compression ratio

k Is specific heat ratio

The efficiency of an Otto cycle depends on the compression ratio and ratio of gas constant. As compression ratio increases efficiency increases and specific heat ratio increases the efficiency of Otto cycle increases

Question: 9.028P

Why are high compression ratios not used in spark-ignition engines?

Step 1 of 1

The increase in thermal efficiency with the compression ratio is not as pronounced at high compression ratios. Also when high compression ratios are used, the temperature of the air fuel mixture rises above the auto ignition temperature of the fuel during the combustion process, causing an early and rapid burn of the fuel. This premature ignition of the fuel, called auto ignition, produces an audible noise, which is called engine knock. So high compression ratios are not desirable, since they lead to engine knock

Question: 9.029P

An ideal Otto cycle with a specified compression ratio is executed using (*a*) air. (*b*) argon, and (*c*) ethane as the working fluid. For which case will the thermal efficiency be the highest? Why?

Step 1 of 1

The thermal efficiency of an Otto cycle is defined as

$$\eta_{otto} = 1 - \frac{1}{r^{k-1}}$$

We know as specific heat ratio, k increases thermal efficiency increases

Specific heat for air $k = 1.4$

Specific heat ratio for argon $k = 1.667$

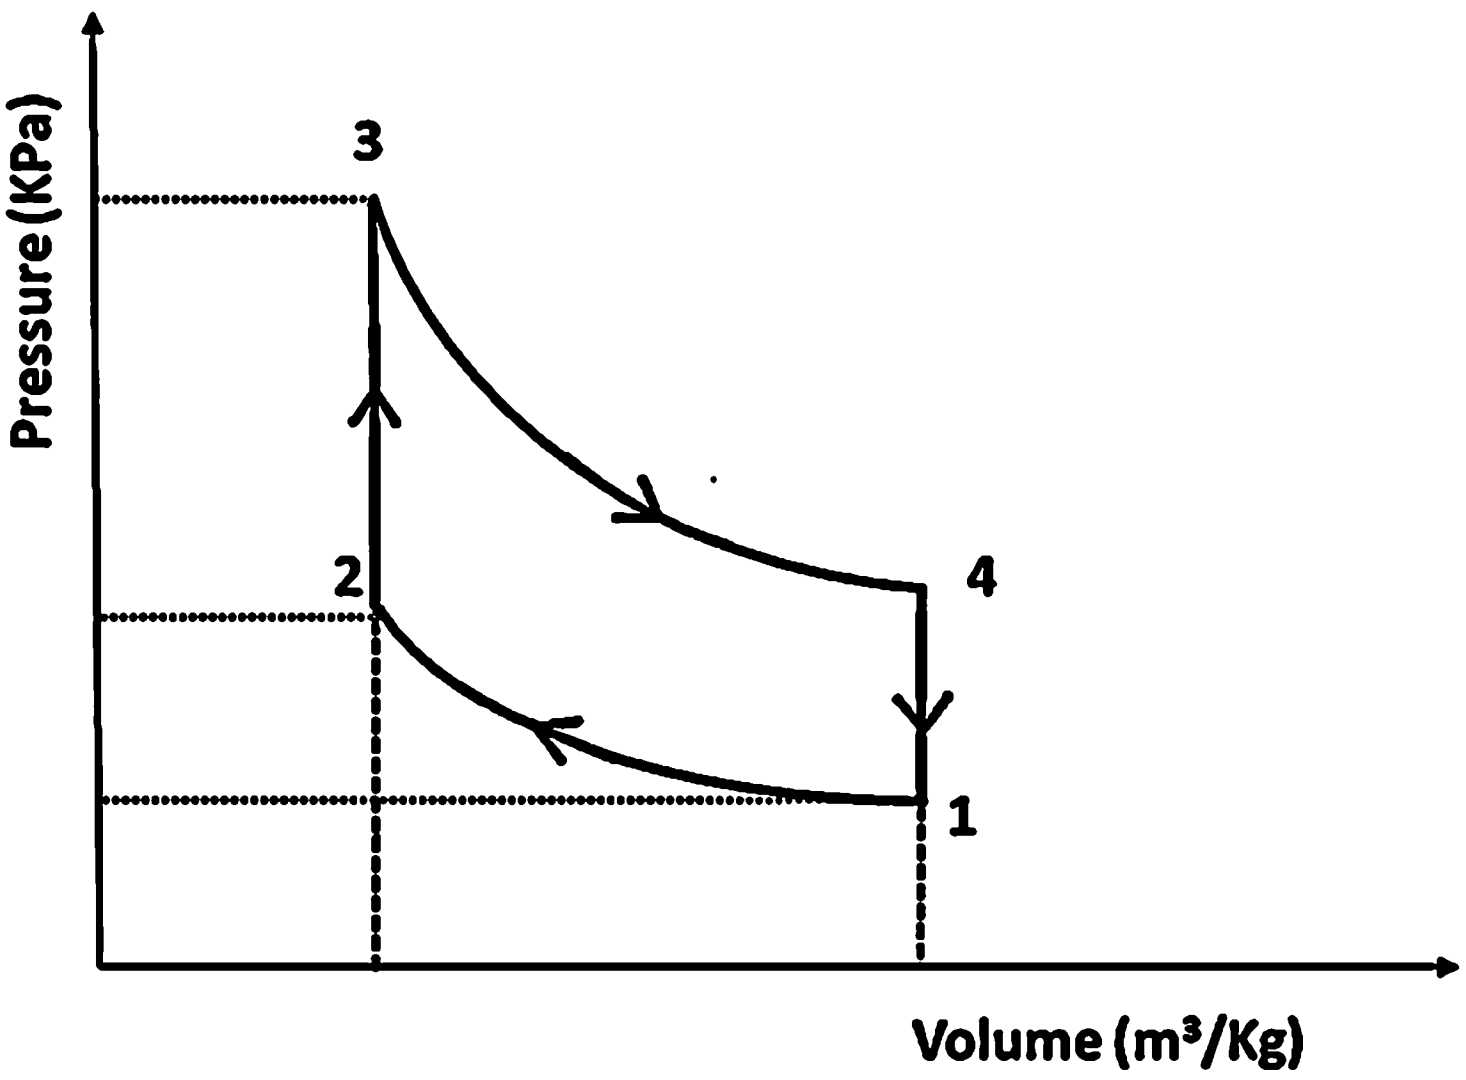
Specific heat ratio for ethane $k = 1.2$

Since specific heat ratio for argon is more compared to the air and ethane the thermal efficiency of Otto cycle using argon is high.

Question: 9.030P

What is the difference between fuel-injected gasoline engines and diesel engines?

Step 1 of 1



In a fuel-injected gasoline engine the ignition is done by a spark, where as in the diesel engine there in no requirement of spark.

Question: 9.031P

An ideal Otto cycle has a compression ratio of 10.5, takes in air at 90 kPa and 40°C, and is repeated 2500 times per minute. Using constant specific heats at room temperature, determine the thermal efficiency of this cycle and the rate of heat input if the cycle is to produce 90 kW of power.

Step 1 of 4

Draw the *P-V* diagram:

Step 2 of 4

Process 1-2 is an isentropic Compression process, hence $P_2V_2^{\gamma} = P_1V_1^{\gamma}$

From ideal gas equation, $\frac{P_2V_2}{T_2} = \frac{P_1V_1}{T_1}$.

Here, Pressures are P_1 , P_2; temperatures are T_1 , T_2 and volumes are V_1 and V_2 .

Substitute $P_1 = \frac{P_2V_2}{T_2} \times \frac{T_1}{V_1}$ in the equation

$$T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$$

$$T_2 = \frac{T_1V_1^{\gamma-1}}{V_2^{\gamma-1}}$$

$$= T_1\left(\frac{V_1}{V_2}\right)^{\gamma-1}$$

$$T_2 = T_1(r)^{\gamma-1}$$

Here, Compression ratio of the Otto cycle is $r = 10.5$

Substitute 1.4 for γ and 10.5 for r in the equation

$$T_2 = (313)(10.5)^{1.4-1}$$

$$= 801.715 \text{ K}$$

Step 3 of 4

Thermal efficiency of the cycle is

$$\eta_{th} = 1 - \frac{T_1}{T_2}$$

Substitute 801.715 K for T_2 and $(313\text{K} = 40°\text{C})$ for T_1 in the equation

$$\eta_{th} = 1 - \frac{313}{801.715}$$

$$= 1 - 0.39$$

$$= 0.61$$

Step 4 of 4

Find the heat added to the cycle by using the following equation

$$W_{net} = \eta_{th} \times Q_{in}$$

$$Q_{in} = \frac{W_{net}}{\eta_{th}}$$

Here, Power output is W_{net}

Substitute 90 kW for W_{net} 0.61 for η_{th} in the equation

$$Q_{in} = \frac{90 \text{ kW}}{0.61}$$

$$= 147.54 \text{ kW}$$

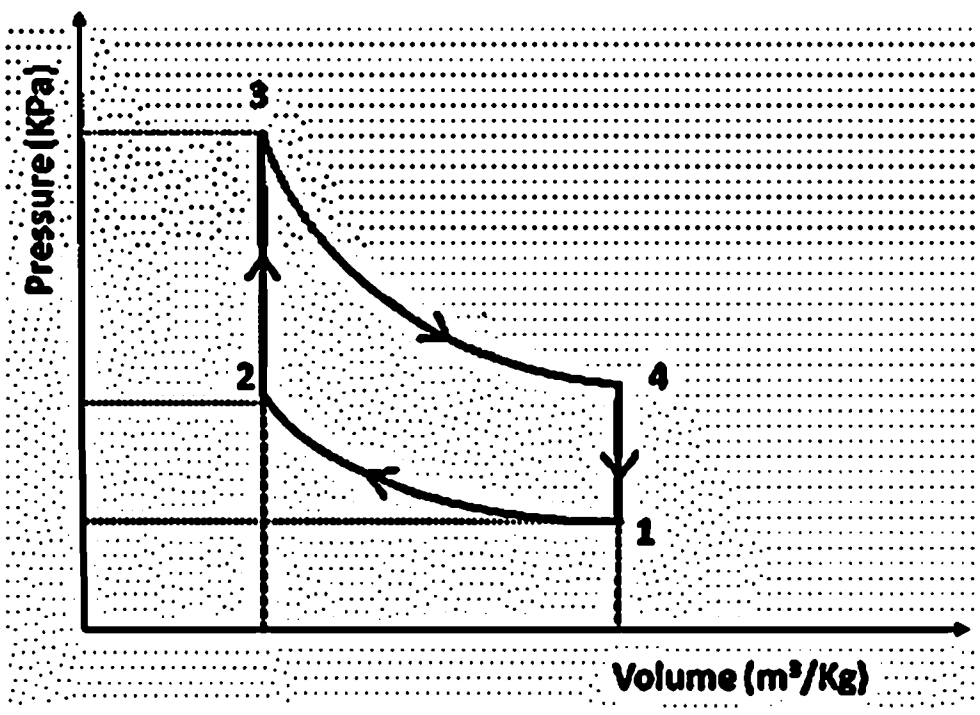
Therefore, the heat added to the cycle is $\boxed{147.54 \text{ kW}}$

Question: 9.032P

Repeat Prob. 9–31 for a compression ratio of 8.5.

Step 1 of 5

Given,



Compression ratio of the Otto cycle is $r = 8.5$

Temperature of air before compression, $T_1 = 40°C$

Pressure of air before compression, $P_1 = 90\ \text{kPa}$

Power output, $W_{net} = 90\ \text{kW}$

Step 2 of 5

Step 3 of 5

Process 1-2 is an isentropic Compression process, hence $P_2V_2^k = P_1V_1^k$

But from ideal gas equation, $\frac{P_2V_2}{T_2} = \frac{P_1V_1}{T_1}$.

$$T_1V_1^{k-1} = T_2V_2^{k-1}$$

$$T_2 = \frac{T_1V_1^{k-1}}{V_2^{k-1}}$$

$$T_2 = T_1\left(\frac{V_1}{V_2}\right)^{k-1}$$

$$T_2 = T_1(r)^{k-1}$$

$$T_2 = (313)(8.5)^{1.4-1}$$

$$T_2 = 736.736\ \text{K}$$

Step 4 of 5

Thermal efficiency of the cycle is

$$\eta_{th} = 1 - \frac{T_1}{T_2}$$

$$\eta_{th} = 1 - \frac{313}{736.736}$$

$$\eta_{th} = 1 - 0.425$$

$$\eta_{th} = 0.575$$

Step 5 of 5

Work output of the cycle is

$$W_{net} = \eta_{th} \times Q_{in}$$

$$Q_{in} = \frac{W_{net}}{\eta_{th}}$$

$$Q_{in} = \frac{90\ \text{kW}}{0.575}$$

$$Q_{in} = 156.52\ \text{kW}$$

Hence heat added to the cycle is $\boxed{Q_{in} = 156.52\ \text{kW}}$

Question:

Someone has suggested that the air-standard Otto cycle is more accurate if the two isentropic processes are replaced with polytropic processes with a polytropic exponent n= 1.3. Consider such a cycle when the compression ratio is 8, $P1$ =95 kPa, $T1$, = 15°C, and the maximum cycle temperature is 1200T. Determine the heat transferred to and rejected from this cycle, as well as the cycle's thermal efficiency. Use constant specific heats at room temperature.

Step 1 of 5

From the properties of air (Table A-2a):

Universal gas constant, $R = 0.287\,\text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$

Specific heat constants,

$$c_p = 1.005\,\text{kJ/kg}\cdot\text{K}$$
$$c_v = 0.718\,\text{kJ/kg}\cdot\text{K}$$

Calculate the temperature at stage 2:

The process 1-2 and 3-4 are replaced with polytropic compression and expression processes respectively.

For the polytrophic compression process $1-2$

$$\frac{T_1}{T_2} = \left(\frac{V_2}{V_1}\right)^{n-1}$$
$$= \left(\frac{1}{r}\right)^{n-1}$$

Here r is the Compression ratio, n is the polytrophic index and T_1 , T_2 are temperatures at stage1,stage 2 respectively.

Substitute 8 for r and 288 K for T_1 and 1.3 for n in above relation.

Therefore,

$$\frac{288}{T_2} = \left(\frac{1}{8}\right)^{1.3-1}$$
$$T_2 = 288\times(8)^{1.3-1}$$
$$= 537.43\,\text{K}$$

Therefore, temperature at state 2 is $T_2 = 537.43\,\text{K}$

Step 2 of 5

Calculate the temperature at stage 4:

The process 3-4 is a polytrophic expansion process,

$$\frac{T_4}{T_3} = \left(\frac{V_3}{V_4}\right)^{n-1}$$
$$T_4 = T_3\left(\frac{V_2}{V_1}\right)^{n-1}$$
$$= T_3\left(\frac{1}{r}\right)^{n-1}$$

Substitute 8 for r and 1473 K for T_3 and 1.3 for n in above relation.

$$T_4 = 1473\left(\frac{1}{8}\right)^{1.3-1}$$
$$= 789.36\,\text{K}$$

Step 3 of 5

Calculate specific work done in the 1-2 process:

$$w_{1-2} = \frac{RT_1}{n-1}\left(\left(\frac{v_1}{v_2}\right)^{n-1} - 1\right)$$
$$= \frac{RT_1}{n-1}\left((r)^{n-1} - 1\right)$$

Substitute $R = 0.287\,\text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $T_1 = 288\,\text{K}$, $n = 1.3$ and $r = 8$ in above formula,

$$w_{1-2} = \frac{0.287\times288}{1.3-1}\left((8)^{1.3-1} - 1\right)$$
$$= 238.62\,\text{kJ/kg}$$

Calculate specific work done in the 3-4 process:

$$w_{3-4} = -\frac{RT_3}{n-1}\left(\left(\frac{v_3}{v_4}\right)^{n-1} - 1\right)$$
$$= -\frac{RT_3}{n-1}\left(\left(\frac{1}{r}\right)^{n-1} - 1\right)$$

Substitute $R = 0.287\,\text{kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $T_3 = 1473\,\text{K}$, $n = 1.3$ and $r = 8$ in above formula,

$$w_{3-4} = -\frac{0.287\times1473}{1.3-1}\left(\left(\frac{1}{8}\right)^{1.3-1} - 1\right)$$
$$= 654\,\text{kJ/kg}$$

Step 4 of 5

Calculate specific heat in 1-2 process by using first law of thermodynamics:

$$q_{1-2} = w_{1-2} - c_v(T_2 - T_1)$$

Substitute $238.62\,\text{kJ/kg}$ for w_{1-2} , $0.718\,\text{kJ/kg}\cdot\text{K}$ for c_v ,537.43 K for T_2 and 288 K for T_1 in above relation.

$$q_{1-2} = 238.62 - 0.718(537.4 - 288)$$
$$= 59.55\,\text{kJ/kg}$$

Calculate specific heat in 2-3 process

relation.

$$q_{1-2} = 238.62 - 0.718(537.4 - 288)$$
$$= 59.55\,\text{kJ/kg}$$

Calculate specific heat in 2-3 process,

$$q_{2-3} = c_v(T_3 - T_2)$$
$$= 0.718(1473 - 537.43)$$
$$= 671.74\,\text{kJ/kg}$$

Calculate specific heat in 2-3 process by using first law of thermodynamics:

$$q_{3-4} = w_{3-4} - c_v(T_3 - T_4)$$

Substitute 654 for w_{3-4} , $0.718\,\text{kJ/kg}\cdot\text{K}$ for c_v ,1473 K for T_3 and 789.36 K for T_4 in above relation.

$$q_{3-4} = 654 - 0.718(1473 - 789.36)$$
$$= 163.15\,\text{kJ/kg}$$

Calculate specific heat in 4-1 process,

$$q_{4-1} = c_v(T_4 - T_1)$$
$$= 0.718(789.36 - 288)$$
$$= 359.98\,\text{kJ/kg}$$

Step 5 of 5

Calculate heat addition to the cycle,

$$q_{in} = q_{2-3} + q_{3-4}$$

Substitute 671.74 kJ/kg for q_{2-3} and 163.15 kJ/kg for q_{3-4} in above relation.

$$q_{in} = 671.74 + 163.15$$
$$= 834.89\,\text{kJ/kg}$$

Therefore, heat transfer to cycle is $\boxed{835\,\text{kJ/kg}}$.

Calculate heat rejection from the cycle,

$$q_{out} = q_{1-2} + q_{4-1}$$

Substitute 59.53 kJ/kg for q_{1-2} and 359.98 kJ/kg for q_{4-1} in above relation.

$$q_{out} = 59.53 + 359.98$$
$$= 419.51\,\text{kJ/kg}$$

Therefore, heat rejection from cycle is $\boxed{419.5\,\text{kJ/kg}}$

Calculate efficiency of the cycle is given by

$$\eta_{thermal} = \frac{q_{in} - q_{out}}{q_{in}}$$

Substitute 834.89 kJ/kg for q_{in} and 419.51 kJ/kg for q_{out} in above relation.

$$\eta_{thermal} = \frac{834.89 - 419.51}{834.89}$$
$$= 0.4976$$
$$= 49.76\%$$

Therefore, efficiency of the Otto cycle is $\boxed{49.8\%}$

Question: 9.034P

How do the results of Prob. 9–33 change when isentropic processes are used in place of the polytropic processes?

Step 1 of 5

Given data:

For the Otto cycle

Temperature at state 1, $T_1 = 15°C = 288K$

Pressure at state 1, $P_1 = 95kPa$

Compression ratio, $r = 8$

Maximum temperature in the cycle, $T_3 = 1200°C = 1473K$

Polytropic exponent, $n = 1.3$

Step 2 of 5

Compression ratio, $r = \frac{V_1}{V_2}$

For the isentropic compression process 1-2

Therefore,

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{r-1}$$

$$T_2 = T_1\left(\frac{V_1}{V_2}\right)^{r-1}$$

$$= 288 \times (8)^{1.4-1}$$

$$= 661.65K$$

Therefore, temperature at state 2, $T_2 = 661.65K$

Step 3 of 5

The process 3-4 is an isentropic expansion process.

$$\frac{T_4}{T_3} = \left(\frac{V_3}{V_4}\right)^{r-1}$$

$$T_4 = T_3\left(\frac{V_2}{V_1}\right)^{r-1}$$

$$= 1473\left(\frac{1}{8}\right)^{1.4-1}$$

$$= 641.16K$$

Step 4 of 5

Specific heat of the air, $c_v = 0.718kJ/kg$

Heat added in the process 2-3,

$$Q_{added} = c_v(T_3 - T_2)$$

$$= 0.718(1473 - 661.65)$$

$$= 582.54kJ/kg$$

Heat added in the cycle, $\boxed{Q_{added} = 582.54kJ/kg}$

Heat rejected in the process 2-3,

$$Q_{rejected} = c_v(T_4 - T_1)$$

$$= 0.718(641.16 - 288)$$

$$= 253.56kJ/kg$$

Therefore, Heat rejected in the cycle is $\boxed{Q_{rejected} = 253.56kJ/kg}$

Step 5 of 5

Efficiency of the cycle,

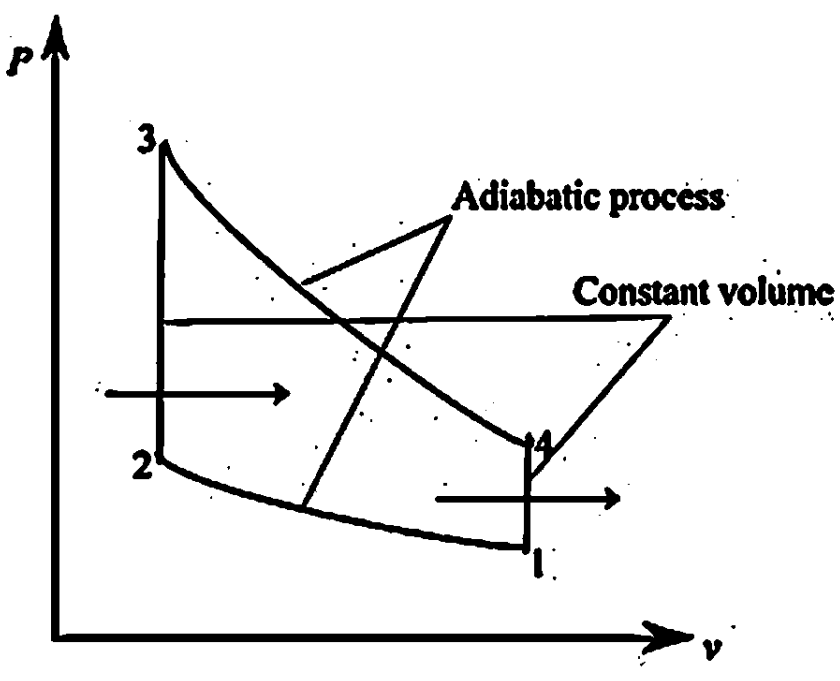
$$\eta_{thermal} = \frac{Q_{in} - Q_{out}}{Q_{in}}$$

$$= \frac{582.54 - 253.56}{582.54}$$

$$= 0.564$$

$$= 56.47\%$$

Therefore, Efficiency of the Otto cycle is $\boxed{\eta_{thermal} = 56.47\%}$



The thermal efficiency of engine will increase with the isentropic processes than the polytropic processes in the cycle.

Question: 9.035P

A six-cylinder, four-stroke, spark-ignition engine, operating on the ideal Otto cycle takes in air at 14 psia and 65°F, and is limited to a maximum cycle temperature of 1600°F. Each cylinder has a bore of 3.5 in. and each piston has a stroke of 3.9 in. The minimum enclosed volume is 14 percent of the maximum enclosed volume. How much power will this engine produce when operated at 2500 rpm? Use constant specific heats at room temperature.

Step 1 of 5

Draw the *P-v* diagram of the Otto-cycle:

Step 2 of 5

Considering constant specific heats at room temperature

Gas constant $R = 0.3704\,\text{psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$

$c_p = 0.240\,\text{Btu/lbm}\cdot\text{R}$

$c_v = 0.171\,\text{Btu/lbm}\cdot\text{R}$

$k = 1.4$

Calculate compression ratio by using,

From the isentropic compression Process 1-2,

$$r = \frac{V_1}{V_2}$$

Here V_1 is the maximum volume and V_2 is the minimum volume

Substitute 14% of V_1 for V_2 in above relation

$$r = \frac{V_1}{0.14V_1}$$
$$= 7.1429$$

Step 3 of 5

Calculate temperature at state 2 by using

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{k-1}$$
$$T_2 = T_1 r^{k-1}$$

Here k is the index and T_1 is the temperature at state 1

Substitute 1.4 for k, $65°\text{F} = 524.67°\text{R}$ for T_1 and 7.1429 for r in above relation

$$T_2 = 524.67\left(7.1429^{1.4-1}\right)$$
$$= 1151.95°\text{R}$$

Calculate temperature at state 4 by using

$$\frac{T_4}{T_3} = \left(\frac{V_3}{V_4}\right)^{k-1}$$
$$T_4 = T_3\left(\frac{1}{r}\right)^{k-1}$$

Here k is the index and T_3 is the temperature at state 3

Substitute 1.4 for k, $2060°\text{R}$ for T_3 and 7.1429 for r in above relation

$$T_4 = 2060\left(\frac{1}{7.1429}\right)^{1.4-1}$$
$$= 938.26°\text{R}$$

Step 4 of 5

Calculate net work done per mass by using

$$w_{net} = c_v(T_3 - T_4) - c_v(T_2 - T_1)$$

Substitute 0.171 Btu/lbm for c_v, $524.67°\text{R}$ for T_1, $1151.95°\text{R}$ for T_2, $2060°\text{R}$ for T_3 and $938.26°\text{R}$ for T_4 in above relation

$$w_{net} = 0.171(2060 - 938.26) - 0.171(1151.95 - 524.67)$$
$$= 191.81754 - 107.26488$$
$$= 84.55\,\text{Btu/lbm}$$

Calculate total mass m by using ,

$$m = n\rho V$$
$$\dot{m} = n \times \frac{P_1}{RT_1} \times \frac{\pi}{4} d^2 L$$

Here n is the number of the cylinders, P_1 is the initial pressure of the given system, T_1 is the initial temperature of the given system, d is the bore of the cylinder, L is the length of the cylinder and N is the operating speed of the engine.

Substitute 6 for n,14 psia for P_1,0.3704 $\text{psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ for R, $\frac{3.5}{12}\text{ft}$ for d, $\frac{3.9}{12}\text{ft}$ for L and $524.67°\text{R}$ for T_1 in above relation

$$m = 6 \times \frac{14}{0.3704 \times 524.67} \times \frac{\pi}{4} \times \left(\frac{3.5}{12}\right)^2 \times \frac{3.9}{12}$$
$$= 0.0093856\,\text{lbm}$$

Calculate network produced per cycle by using

$$W_{net} = mw_{net}$$

Substitute 0.0093856 lbm for m and 84.55 Btu/lbm for w_{net} in above relation

$$W_{net} = 0.0093856 \times 84.55$$
$$= 0.7935\,\text{Btu/cycle}$$

Step 5 of 5

Calculate power produced by using

$$\dot{W}_{net} = \frac{W_{net}N}{N_{rev}}$$

Here N_{rev} is the number of revolutions per cycle

Substitute 0.7935 Btu/cycle for W_{net}, $\frac{2500}{60}\text{rps}$ for N and 2 rev/cycle for N_{rev} in above relation

$$\dot{W}_{net} = \frac{0.7935 \times \frac{2500}{60}}{2}$$
$$= 16.53125\,\text{Btu/s}$$

Convert the power units from Btu/s to hp

$$\dot{W}_{net} = 16.53125\,\text{Btu/s} \times \frac{1}{0.7068}\frac{\text{hp}}{\text{Btu/s}}$$
$$= 23.39\,\text{hp}$$

Therefore, total power generated in the given Otto cycle, **23.4 hp**

Question: 9.036P

A spark-ignition engine has a compression ratio of 8, an isentropic compression efficiency of 85 percent, and an isentropic expansion efficiency of 95 percent. At the beginning of the compression, the air in the cylinder is at 13 psia and 60°F. The maximum gas temperature is found to be 2300°F by measurement. Determine the heat supplied per unit mass, the thermal efficiency, and the mean effective pressure of this engine when modeled with the Otto cycle. Use constant specific heats at room temperature.

Step 1 of 12

Given

Compression ratio $r = \frac{v_1}{v_2} = 8$

Isentropic compression efficiency $\eta_c = 85\%$

Isentropic expansion efficiency $\eta_t = 95\%$

Inlet pressure $P = 13$ psia

Inlet temperature $T_1 = 60°F$

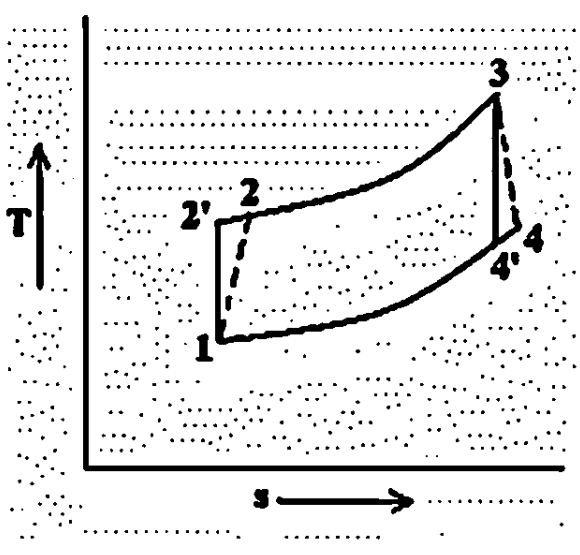
$= 60+460$

$T_1 = 520R$

Maximum temperature $T_3 = 2300°F = 2760R$

Step 2 of 12

Considering constant specific heats at room temperature



Gas constant $R = 0.3704$ psia.ft^3/lbm.R

$c_p = 0.24$ Btu/lbm.R

$c_v = 0.171$ Btu/lbm.R

$k = 1.4$

Step 3 of 12

Step 4 of 12

Process 1-2' is isentropic compression

$$\frac{T_2'}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2'}{520} = (8)^{1.4-1}$$

$$T_2' = 1194.6R$$

Step 5 of 12

Isentropic compression efficiency is

$$\eta_c = \frac{T_2' - T_1}{T_2 - T_1}$$

$$0.85 = \frac{1194.6 - 520}{T_2 - 520}$$

$$T_2 = 1313.647R$$

Step 6 of 12

The heat supplied per unit mass is

$$q_{in} = c_v(T_3 - T_2)$$

$$= (0.171)(2760 - 1313.647)$$

$$\boxed{q_{in} = 247.32 \text{ Btu/lbm}}$$

Step 7 of 12

Process 4'-1 is isentropic expansion

$$\frac{T_4'}{T_3} = \left(\frac{v_3}{v_4'}\right)^{k-1}$$

$$\frac{T_4'}{T_3} = \left(\frac{v_2'}{v_1}\right)^{k-1}$$

$$\frac{T_4'}{2760} = \left(\frac{1}{8}\right)^{1.4-1}$$

$$T_4' = 1201.35R$$

Step 8 of 12

The isentropic expansion efficiency is

$$\eta_{ex} = \frac{T_3 - T_4}{T_3 - T_4'}$$

$$0.95 = \frac{2760 - T_4}{2760 - 1201.35}$$

$$T_4 = 1279.28R$$

Step 9 of 12

Net work of the cycle is

$$w_{net} = w_{3-4} - w_{1-2}$$

$$w_{net} = c_v(T_3 - T_4) - c_v(T_2 - T_1)$$

$$w_{net} = c_v\left[(T_3 - T_4) - (T_2 - T_1)\right]$$

$$= (0.171)\left[(2760 - 1279.28) - (1313.647 - 520)\right]$$

$$w_{net} = 117.48 \text{ Btu/lbm}$$

Step 10 of 12

The thermal efficiency is defined as

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$\eta_{th} = \frac{117.48}{247.32}$$

$$= 0.475$$

$$\boxed{\eta_{th} = 47.5\%}$$

Step 11 of 12

The mean effective pressure of an engine is defined as

$$MEP = \frac{w_{net}}{v_1 - v_2}$$

Where specific volume at inlet is

$$v_1 = \frac{RT_1}{P_1}$$

$$v_1 = \frac{0.3704(520)}{13}$$

$$v_1 = 14.816 \text{ ft}^3/\text{lbm}$$

Step 12 of 12

Compression ratio

$$\frac{v_1}{v_2} = 8$$

$$v_2 = \frac{v_1}{8}$$

$$v_2 = \frac{14.816}{8}$$

$$v_2 = 1.852 \text{ ft}^3/\text{lbm}$$

$$MEP = \frac{w_{net}}{v_1 - v_2}$$

$$MEP = \frac{117.48}{14.816 - 1.852} \times 778 \times \frac{1}{144}$$

$$\boxed{MEP = 48.96 \text{ psia}}$$

Question: 9.037P

The compression ratio of an air-standard Otto cycle is 9.5. Prior to the isentropic compression process, the air is at 100 kPa. 35°C, and 600 cm 3, The temperature at the end of the isentropic expansion process is 800 K. Using specific heat values at room temperature, determine (*a*) the highest temperature and pressure in the cycle; (*b*) the amount of heat transferred in, in kJ; (*c*) the thermal efficiency; and (*d*) the mean effective pressure.

Step 1 of 10

Given

The compression ratio $r = \frac{V_1}{V_2} = 9.5$

Initial pressure $P_1 = 100\ \text{kPa}$

Initial temperature $T_1 = 35°\text{C}$

$= 35 + 273$

$T_1 = 308\text{K}$

Initial volume $V_1 = 600\ \text{cm}^3$

Temperature at the end of expansion process $T_4 = 800\text{K}$

Step 2 of 10

Considering constant specific heats at room temperature

Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 10

(a)

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = (r)^{k-1}$$

$$T_2 = 308(9.5)^{1.4-1}$$

$$T_2 = 757.94\text{K}$$

$$\frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^{k}$$

$$P_2 = 100(9.5)^{1.4}$$

$$P_2 = 2337.83\ \text{kPa}$$

Step 4 of 10

Process 3-4 is an isentropic expansion

$$\frac{T_3}{T_4} = \left(\frac{V_4}{V_3}\right)^{k-1}$$

$$\frac{T_3}{T_4} = (r)^{k-1}$$

$$T_3 = 800(9.5)^{1.4-1}$$

$$T_3 = 1968.69\text{K}$$

The maximum temperature is

$$\boxed{T_3 = 1968.69\text{K}}$$

Step 5 of 10

Process 2-3 is constant volume process

$$\frac{P_3}{P_2} = \frac{T_3}{T_2}$$

$$P_3 = P_2 \times \frac{T_3}{T_2}$$

$$P_3 = 2337.83 \times \left(\frac{1968.69}{757.94}\right)$$

$$P_3 = 6072.33\text{kPa}$$

Therefore maximum pressure

$$\boxed{P_3 = 6072.33\ \text{kPa}}$$

Step 6 of 10

(b) The amount of heat transferred

Mass of air can be calculated as by using ideal gas equation

$$P_1V_1 = mRT_1$$

$$m = \frac{P_1V_1}{RT_1}$$

$$m = \frac{100\left(600\times10^{-6}\right)}{0.287(308)}$$

$$m = 6.78\times10^{-4}\ \text{kg}$$

Step 7 of 10

Therefore the amount of heat transferred from the cycle

$$Q_{in} = mc_v(T_3 - T_2)\ \text{kJ}$$

$$= 6.78\times10^{-4}(0.718)(1968.69 - 757.94)$$

$$\boxed{Q_{in} = 0.589\ \text{kJ}}$$

Step 8 of 10

(c) The thermal efficiency

$$\eta_{th} = 1 - \frac{Q_{out}}{Q_{in}}$$

The amount of heat rejected is expressed as

$$Q_{out} = mc_v(T_4 - T_1)\ \text{kJ}$$

$$= 6.78\times10^{-4}(0.718)(800 - 308)$$

$$Q_{out} = 0.2395\ \text{kJ}$$

Step 9 of 10

Therefore thermal efficiency

$$\eta_{th} = 1 - \frac{0.2395}{0.589}$$

$$= 0.5933$$

$$\boxed{\eta_{th} = 59.33\%}$$

Step 10 of 10

(d) The Mean effective pressure

$$MEP = \frac{W_{net}}{V_1 - V_2}$$

$$MEP = \frac{Q_{in} - Q_{out}}{V_1\left(1 - \frac{V_2}{V_1}\right)}$$

$$MEP = \frac{0.589 - 0.2395}{V_1\left(1 - \frac{1}{r}\right)}$$

$$= \frac{0.3495}{6\times10^{-4}\left(1 - \frac{1}{9.5}\right)}$$

$$\boxed{MEP = 651.029\ \text{kPa}}$$

Question: 9.038P

Repeat Prob. 9–37, but replace the isentropic expansion process by a polytropic expansion process with the polytropic exponent n =1.35.

Step 1 of 11

Given

The compression ratio $r = \frac{V_1}{V_2} = 9.5$

Initial pressure $P_1 = 100\ \text{kPa}$

Initial temperature $T_1 = 35°\text{C}$

$= 35 + 273$

$T_1 = 308\text{K}$

Initial volume $V_1 = 600\ \text{cm}^3$

Temperature at the end of expansion process $T_4 = 800\text{K}$

Polytropic exponent $n = 1.35$

Step 2 of 11

Considering constant specific heats at room temperature

Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 11

(a) The highest temperature in the cycle

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = (r)^{k-1}$$

$$T_2 = 308(9.5)^{1.4-1}$$

$$T_2 = 757.949\text{K}$$

Step 4 of 11

$$\frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^k$$

$$\frac{P_2}{P_1} = (r)^k$$

$$P_2 = P_1(r)^k$$

$$P_2 = 100(9.5)^{1.4}$$

$$P_2 = 2337.8\ \text{kPa}$$

Step 5 of 11

Process 3-4 is a polytropic expansion with index $n = 1.35$

$$\frac{T_3}{T_4} = \left(\frac{V_4}{V_3}\right)^{n-1}$$

$$\frac{T_3}{T_4} = \left(\frac{V_1}{V_2}\right)^{n-1}$$

$$\frac{T_3}{T_4} = (r)^{n-1}$$

$$T_3 = 800(9.5)^{1.35-1}$$

$$\boxed{T_3 = 1759.11\text{K}}$$

Step 6 of 11

Process 2-3 is constant volume process

$$\frac{P_3}{P_2} = \frac{T_3}{T_2}$$

$$P_3 = 2337.8\left(\frac{1759.1}{757.949}\right)$$

$$\boxed{P_3 = 5425.72\ \text{kPa}}$$

Step 7 of 11

b) The amount of heat transferred

The amount of mass of air can be calculated as

$$P_1V_1 = mRT_1$$

$$m = \frac{P_1V_1}{RT_1}$$

$$m = \frac{100\left(600\times10^{-6}\right)}{0.287(308)}$$

$$m = 6.78\times10^{-4}\ \text{kg}$$

Step 8 of 11

The amount of heat transferred is

$$Q_{in} = mc_v(T_3 - T_2)\ \text{kJ}$$

$$= 6.78\times10^{-4}(0.718)(1759.1 - 757.949)$$

$$\boxed{Q_{in} = 0.4873\ \text{kJ}}$$

Step 9 of 11

(c)

The thermal efficiency

$$\eta_{th} = 1 - \frac{Q_{out}}{Q_{in}}$$

The amount of heat rejected is expressed as

$$Q_{out} = mc_v(T_4 - T_1)\ \text{kJ}$$

$$= 6.78\times10^{-4}(0.718)(800 - 308)$$

$$Q_{out} = 0.2395\ \text{kJ}$$

Step 10 of 11

Therefore thermal efficiency

$$\eta_{th} = 1 - \frac{0.2395}{0.4873}$$

$$= 0.5085$$

$$\boxed{\eta_{th} = 50.85\%}$$

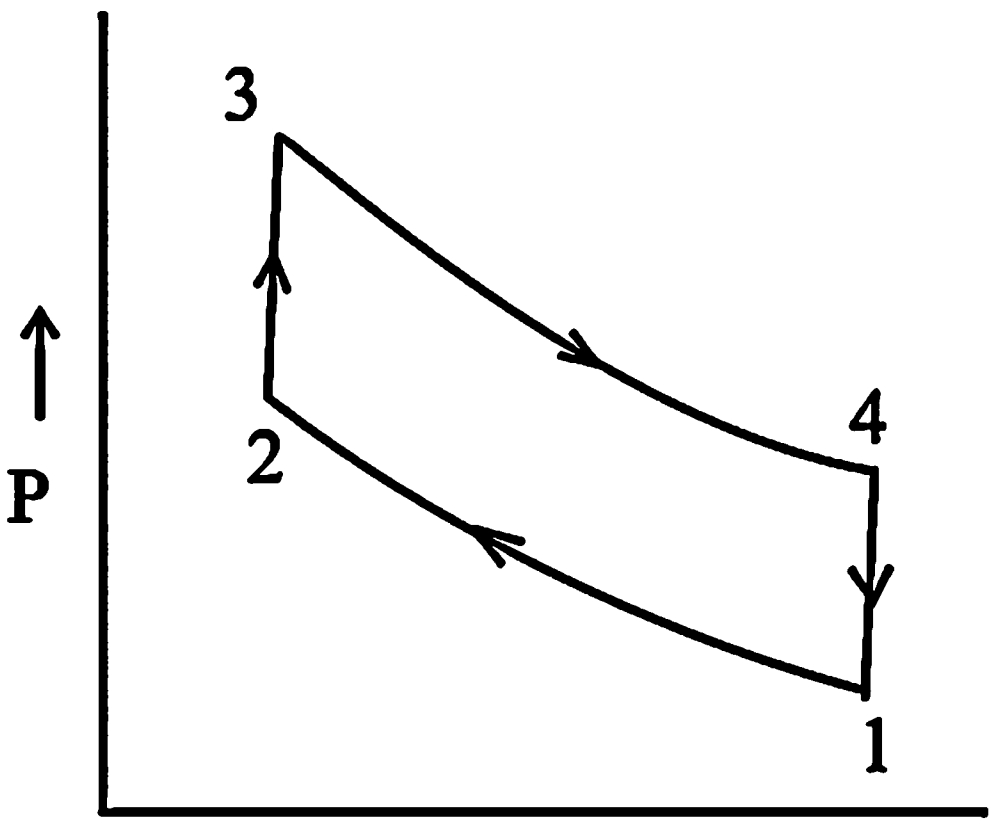
Step 11 of 11

(d) The Mean effective pressure

$$MEP = \frac{W_{net}}{V_1 - V_2}$$

$$MEP = \frac{Q_{in} - Q_{out}}{V_1\left(1 - \frac{V_2}{V_1}\right)}$$

$$MEP = \frac{0.4873 - 0.2395}{6\times10^{-4}\left(1 - \frac{1}{9.5}\right)}$$



$$\boxed{MEP = 461.588\ \text{kPa}}$$

Question:

An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The minimum and maximum temperatures in the cycle are 540 and 2400 R. Accounting for the variation of specific heats with temperature, determine (*a*) the amount of heat transferred to the air during the heat-addition process, (*b*) the thermal efficiency, and (*c*) the thermal efficiency of a Carnot cycle operating between the same temperature limits.

Step 1 of 8

Draw *P-v* diagram of the ideal Otto cycle.

Here, process 1-2 is isentropic compression, process 2-3 is constant volume heat addition, process 3-4 is isentropic expansion, and process 4-1 is constant volume heat rejection.

Step 2 of 8

Obtain properties of air at $T_1 = 540\text{R}$ from table A-17E, "ideal gas properties of air" in the text book.

Specific internal energy, $u_1 = 92.04\ \text{Btu/lbm}$

Relative volume, $v_{r1} = 144.32$

Similarly, obtain properties of air at $T_3 = 2400\text{R}$ from table A-17E, "ideal gas properties of air" in the text book.

Specific internal energy, $u_3 = 452.70\ \text{Btu/lbm}$

Relative volume, $v_{r3} = 2.419$

Step 3 of 8

Apply isentropic relation to the process 1-2.

$$\frac{v_{r2}}{v_{r1}} = \frac{v_2}{v_1}$$

$$v_{r2} = v_{r1} \times \frac{v_2}{v_1}$$

Here, $\frac{v_1}{v_2}$ is compression ratio.

Substitute 8 for $\frac{v_1}{v_2}$

$$v_{r2} = \frac{144.32}{8}$$
$$= 18.04$$

Step 4 of 8

Obtain properties of air at $v_{r2} = 18.04$ from table A-17E, "ideal gas properties of air" in the text book.

Specific internal energy,

$$u_2 = 209.05 + (216.53 - 209.05)\left(\frac{18.04 - 18.51}{16.93 - 18.51}\right)$$
$$= 211.275\ \text{Btu/lbm}$$

Step 5 of 8

Apply isentropic relation to the process 3-4,

$$\frac{v_{r4}}{v_{r3}} = \frac{v_4}{v_3}$$

$$v_{r4} = \frac{v_4}{v_3} v_{r3}$$

$$v_{r4} = \frac{v_1}{v_2} v_{r3}$$

Substitute 8 for $\frac{v_1}{v_2}$ and 2.419 for v_{r3}

$$v_{r4} = 8(2.419)$$
$$= 19.352$$

Obtain properties of air at $v_{r4} = 19.352$ from table A-17E, "ideal gas properties of air" in the text book.

Specific internal energy,

$$u_4 = 201.63 + (209.05 - 201.63)\left(\frac{19.352 - 20.29}{18.51 - 20.29}\right)$$
$$= 205.54\ \text{Btu/lbm}$$

Step 6 of 8

(a)

$= 205.54$ Btu/lbm

Step 6 of 8

(a)

Find the amount of heat addition during the process 2-3.

$$q_{in} = (u_3 - u_2)$$

Substitute 452.70 Btu/lbm for u_3 and 211.275 Btu/lbm for u_2

$$q_{in} = (452.70 - 211.275)$$
$$= 241.425 \text{ Btu/lbm}$$

Therefore, the amount of heat addition is $\boxed{241.425 \text{ Btu/lbm}}$

Step 7 of 8

(b)
Find the amount of heat rejection in the process 4-1.

$$q_{out} = (u_4 - u_1)$$

Substitute 205.54 Btu/lbm for u_4 and 92.04 Btu/lbm for u_1

$$q_{out} = (205.54 - 92.04)$$
$$= 113.5 \text{ Btu/lbm}$$

Find the thermal efficiency by using the following equation:

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

Substitute 241.425 Btu/lbm for q_{in} and 113.5 Btu/lbm for q_{out}

$$\eta_{th} = 1 - \frac{113.5}{241.425}$$
$$= 0.5298$$
$$= 52.98\%$$

Therefore, the thermal efficiency of the cycle is $\boxed{52.98\%}$

Step 8 of 8

(c)

Find the thermal efficiency of a Carnot cycle operating between the same temperature limits by using the following equation:

$$\eta_{carnot} = 1 - \frac{T_L}{T_H}$$
$$= 1 - \frac{T_1}{T_3}$$

Substitute 540 R for T_1 and 2400 R for T_3

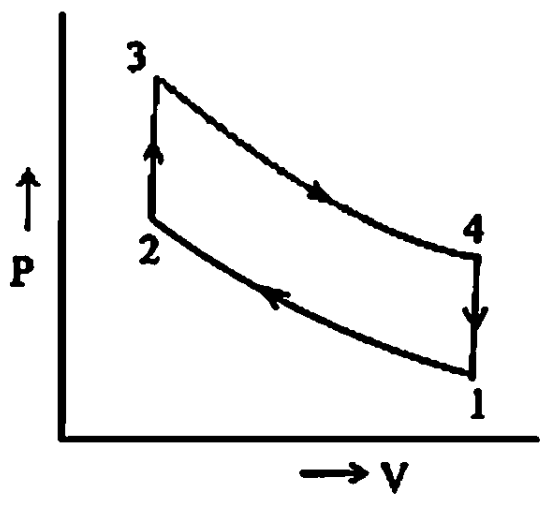
$$\eta_{carnot} = 1 - \frac{540}{2400}$$
$$= 0.775$$
$$= 77.5\%$$

Therefore, the efficiency of eth Carnot cycle is $\boxed{77.5\%}$.

Question: 9.040P

Repeat Prob. 9-39E using argon as the working flujj

Step 1 of 9



Given

The compression ratio $r = \frac{v_1}{v_2} = 8$

Minimum temperature $T_1 = 540\text{R}$

Maximum temperature $T_3 = 2400\text{R}$

Step 2 of 9

Step 3 of 9

Considering constant specific heats at room temperature

From table ideal gas specific heats of common gases for Argon gas

$c_p = 0.1253$ Btu/lbm.R

$c_v = 0.0756$ Btu/lbm.R

$k = 1.667$

Step 4 of 9

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{540} = (8)^{1.667-1}$$

$$T_2 = 2161.497\text{R}$$

Step 5 of 9

Process 3-4 as isentropic expansion

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_4}\right)^{k-1}$$

$$T_4 = T_3\left(\frac{1}{8}\right)^{1.667-1}$$

$$T_4 = 2400 \times \left(\frac{1}{8}\right)^{1.667-1}$$

$$T_4 = 599.58\text{R}$$

Step 6 of 9

(a) Process 2-3 is the constant volume heat addition

$$q_{in} = u_3 - u_2$$

$$= c_v(T_3 - T_2)$$

$$= (0.0756)(2400 - 2161.497)$$

$$\boxed{q_{in} = 18.03\ \text{Btu/lbm}}$$

Step 7 of 9

(b) The thermal efficiency is defined as

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

The amount of heat rejected is expressed as

$$q_{out} = (u_4 - u_1)\ \text{Btu/lbm}$$

$$= c_v(T_4 - T_1)$$

$$= (0.0756)(599.58 - 540)$$

$$q_{out} = 4.5042\ \text{Btu/lbm}$$

Step 8 of 9

Therefore thermal efficiency

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

$$\eta_{th} = 1 - \frac{4.5042}{18.03}$$

$$= 0.75018$$

$$\boxed{\eta_{th} = 75.018\%}$$

Step 9 of 9

(c) The thermal efficiency of a Carnot cycle operating between the same temperature limits is

$$\eta_{carnot} = 1 - \frac{T_L}{T_H}$$

$$\eta_{carnot} = 1 - \frac{T_1}{T_3}$$

$$= 1 - \frac{540}{2400}$$

$$= 0.775$$

$$\boxed{\eta_{Carnot} = 77.5\%}$$

Question:

A four-cylinder, four-stroke. 1.6-L gasoline engine operates on the Otto cycle with a compression ratio of 11.The air is at 100 kPa and 37°C at the beginning of the compression process, and the maximum pressure in the cycle is 8 MPa. The compression and expansion processes may be modeled aspolytropic with a polytropic constant of 1.3. Using constant specific heats at 850 K. determine (*a*) the temperature at the end of the expansion process, (*b*) the net work output and the thermal efficiency, (*c*) the mean effective pressure, (*d*) the engine speed for a net power output of 50 kW. and (*e*) the specific fuel consumption, in g/kWh, defined as the ratio of the mass of the fuel consumed to the network produced. The air-fuel ratio, defined as the amount of air divided by the amount of fuel intake, is 16.

Step 1 of 9

Calculate the temperature at state-2 using the relation.

$$\frac{T_2}{T_1}=\left(\frac{V_1}{V_2}\right)^{n-1}$$

$$T_2=T_1r^{n-1}$$

Here, T_1 is the temperature at state 1, r is the compression ratio, and n is the polytropic index.

Substitute $310\,\mathrm{K}$ for T_1, 11 for r, and 1.3 for n.

$$T_2=310(11)^{1.3-1}$$
$$=636.47\,\mathrm{K}$$

Calculate the pressure at state-2 using the relation.

$$\frac{P_2}{P_1}=\left(\frac{V_1}{V_2}\right)^{n}$$

$$P_2=P_1r^{n}$$

Here, P_1 is the pressure at state 1.

Substitute $100\,\mathrm{kPa}$ for P_1, 11 for r, and 1.3 for n.

$$P_2=100(11)^{1.3}$$
$$=2258.45\,\mathrm{kPa}$$

Step 2 of 9

Consider process 2-3 is constant volume heat addition process.

Calculate the temperature at state-3 using the relation.

$$\frac{T_3}{T_2}=\frac{P_3}{P_2}$$

$$T_3=T_2\left(\frac{P_3}{P_2}\right)$$

Substitute $636.47\,\mathrm{K}$ for T_2, $8000\,\mathrm{kPa}$ for P_3, and $2258.45\,\mathrm{kPa}$ for P_2.

$$T_3=636.47\left(\frac{8\times10^3}{2258.45}\right)$$
$$=2254.53\ \mathrm{K}$$

Calculate the heat addition in process 2-3.

$$Q_{in}=c_v(T_3-T_2)$$

Substitute $0.823\,\mathrm{kJ/kg\text{-}K}$ for c_v, $2254.53\ \mathrm{K}$ for T_3, and $636.47\,\mathrm{K}$ for T_2.

$$Q_{in}=0.823(2254.53-636.47)$$
$$=1331.669\ \mathrm{kJ/kg}$$

Step 3 of 9

(a)

Consider the process 3-4 is polytropic expansion.

Calculate the temperature at the end of the expansion process.

$$\frac{T_4}{T_3}=\left(\frac{V_3}{V_4}\right)^{n-1}$$

$$T_4=T_3\left(\frac{1}{r}\right)^{n-1}$$

Substitute $2254.53\ \mathrm{K}$ for T_3, 11 for r, and 1.3 for n.

$$T_4=2254.53\times\left(\frac{1}{11}\right)^{1.3-1}$$
$$=1098.09\,\mathrm{K}$$

Therefore, the temperature at the end of the expansion process is $\boxed{1098.09\,\mathrm{K}}$.

Step 4 of 9

(b)

Calculate the heat rejected during the process 4-1.

$$Q_{out}=c_v(T_4-T_1)$$

Substitute $0.823\,\mathrm{kJ/kg\text{-}K}$ for c_v, $1098.09\,\mathrm{K}$ for T_4, and $310\,\mathrm{K}$ for T_1.

$$Q_{out}=0.823(1098.09-310)$$
$$=648.59\,\mathrm{kJ/kg}$$

Calculate the net-work output.

$$W_{net}=Q_{in}-Q_{out}$$

Substitute $648.59\,\mathrm{kJ/kg}$ for Q_{out} and $1331.669\ \mathrm{kJ/kg}$ for Q_{in}.

$$W_{net}=1331.669-648.59$$

$W_{net} = Q_{in} - Q_{out}$

Substitute $648.59\,kJ/kg$ for Q_{out} and $1331.669\,kJ/kg$ for Q_{in}.

$$W_{net} = 1331.669 - 648.59$$
$$= 683.08\,kJ/kg$$

Therefore, the net-work output is $\boxed{683.08\,kJ/kg}$.

Step 5 of 9

Calculate the thermal efficiency of the cycle.

$$\eta_{th} = \frac{Q_{in} - Q_{out}}{Q_{in}}$$

Substitute $648.59\,kJ/kg$ for Q_{out} and $1331.669\,kJ/kg$ for Q_{in}.

$$\eta_{th} = \frac{1331.669 - 648.59}{1331.67}$$
$$= 0.513$$
$$= 51.3\%$$

Therefore, the thermal efficiency of the cycle is $\boxed{51.3\%}$.

Step 6 of 9

(c)

Calculate the Mean effective pressure.

$$m.e.p = \frac{W_{net}}{v_1\left(1 - \frac{1}{r}\right)} \quad \text{..... (1)}$$

Here, v_1 is the specific volume at state-1.

Calculate the specific volume at state 1.

$$v_1 = \frac{RT_1}{P_1}$$

Substitute $0.287\,kJ/kg\text{-}K$ for R, $310\,K$ for T_1, and $100\,kPa$ for P_1.

$$v_1 = \frac{0.287 \times 310}{100}$$
$$= 0.8897\,m^3/kg$$

Substitute $683.08\,kJ/kg$ for W_{net}, $0.8897\,m^3/kg$ for v_1, and 11 for r in equation (1).

$$m.e.p = \frac{W_{net}}{v_1\left(1 - \frac{1}{r}\right)}$$
$$= \frac{683.08}{0.8897\left(1 - \frac{1}{11}\right)}$$
$$= 844.54\,kPa$$

Therefore, the mean effective pressure is $\boxed{844.54\,kPa}$.

Step 7 of 9

(d)

Calculate the clearance volume using the compression ratio.

$$r = \frac{v_c + v_s}{v_c}$$

Here, v_s is the swept volume.

Substitute 11 for r and $1.6 \times 10^{-3}\,m^3$ for v_s.

$$11 = \frac{v_c + \left(1.6 \times 10^{-3}\right)}{v_c}$$
$$10v_c = 1.6 \times 10^{-3}$$
$$v_c = 1.6 \times 10^{-4}\,m^3$$

Calculate the total mass of the air in the cylinder.

$$m = \frac{P_1 V_1}{RT_1}$$

Substitute $0.287\,kJ/kg\text{-}K$ for R, $310\,K$ for T_1, $100\,kPa$ for P_1, and $1.6 \times 10^{-4}\,m^3$ for V_1.

$$m = \frac{100 \times 1.6 \times 10^{-4}}{0.287 \times 310}$$
$$= 1.798 \times 10^{-4}\,kg$$

Step 8 of 9

Calculate the engine speed.

$$P = m \times W_{net} \times n$$
$$n = 2\left(\frac{P}{mW_{net}}\right)$$

Substitute $1.798 \times 10^{-4}\,kg$ for m, $683.08\,kJ/kg$ for W_{net}, and $50\,kW$ for P.

$$n = 2 \times \left(\frac{50}{1.798 \times 10^{-4} \times 683.08}\right)$$
$$= 814\,rev/sec$$

Therefore, the speed of the engine is $\boxed{814\,rev/sec}$.

(e)

$= 814\,\text{rev/sec}$

Therefore, the speed of the engine is $\boxed{814\,\text{rev/sec}}$.

(e)

Calculate the specific fuel consumption.

$$sfc = \frac{m_f}{m_1 \times W_{net}} \quad \text{..... (2)}$$

Here, m_f is the mass of the fuel.

Calculate the mass of the fuel using the air-fuel ratio.

$$AF = \frac{m_a}{m_f}$$

$$AF = \frac{m - m_f}{m_f}$$

Substitute 16 for AF and $1.6\times10^{-4}\,\text{kg}$ for m .

$$16 = \frac{1.6\times10^{-4} - m_f}{m_f}$$

$$m_f = \frac{1.6\times10^{-4}}{17}$$

$$= 9.41\times10^{-6}\,\text{kg}$$

Step 9 of 9

Substitute $9.41\times10^{-6}\,\text{kg}$ for m_f , $1.6\times10^{-4}\,\text{kg}$ for m , and $683.08\,\text{kJ/kg}$ for W_{net} in equation (2).

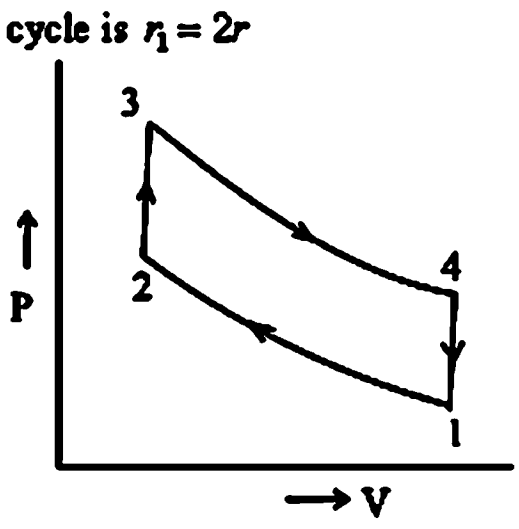
$$sfc = \frac{m_f}{m_1 \times W_{net}}$$

$$= \frac{9.41\times10^{-6}}{1.6\times10^{-4}\times683.08}$$

$$= 8.609\times10^{-5}\,\text{kg/kJ}$$

$$= 309.96\,\text{g/kWh}$$

Therefore, the specific fuel consumption is $\boxed{309.96\,\text{g/kWh}}$.



Question: 9.042P

When we double the compression ratio of an ideal Otto cycle, what happens to the maximum gas temperature and pressure when the state of the air at the beginning of the compression and the amount of heat addition remain the same? Use constant specific heats at room temperature.

Step 1 of 8

Given

Compression ratio of Otto cycle is $r_1 = 2r$

Step 2 of 8

An ideal Otto cycle consists of four internally reversible processes:
1-2 Isentropic compression
2-3 Constant-volume heat addition
3-4 Isentropic expansion
4-1 Constant-volume heat rejection

Step 3 of 8

For a compression ratio r,

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = T_1 r^{k-1}$$

If the compression ratio double then

$$T_2' = T_1'(2r)^{k-1}$$

$$T_2' = 1.32 T_1' r^{k-1}$$

Step 4 of 8

Since the amount of heat addition remains constant
The maximum temperature is expressed as

$$q_{in} = c_v (T_3 - T_2) \text{ kJ/kg}$$

$$T_3 = \frac{q_{in}}{c_v} + T_2$$

When the compression ratio is r the maximum temperature will be

$$T_3 = \frac{q_{in}}{c_v} + T_1 r^{k-1} \text{ ---------- (1)}$$

Step 5 of 8

When the compression ratio is 2r the maximum temperature will be

$$T_3' = \frac{q_{in}}{c_v} + T_2'$$

$$T_3' = \frac{q_{in}}{c_v} + 1.32\left(T_1' r^{k-1}\right) \text{ ---------- (2)}$$

Comparing equations 1 and 2 the maximum temperature increases when the compression ratio increases.

Step 6 of 8

The smallest gas specific volume is obtained at state 3

$$\frac{v_2}{v_1} = \frac{1}{r}$$

$$\frac{v_3}{v_1} = \frac{1}{r} \qquad (\text{Since } v_2 = v_3)$$

$$v_3 = \frac{v_1}{r}$$

When the compression ratio double then

$$v_3' = \frac{v_1'}{2r}$$

Step 7 of 8

By using ideal gas

$$P_3 v_3 = R T_3$$

$$P_3 = \frac{R T_3}{v_3}$$

By substituting T_3 and v_3 then

$$P_3 = \frac{R\left[\frac{q_{in}}{c_v} + \left(T_1 r^{k-1}\right)\right]}{v_1 / r}$$

$$P_3 = \frac{Rr\left[\frac{q_{in}}{c_v} + \left(T_1 r^{k-1}\right)\right]}{v_1} \text{ ---------- (3)}$$

Step 8 of 8

When the compression ratio doubles then the maximum pressure will be

$$P_3' = \frac{R\left[\frac{q_{in}}{c_v} + 1.32\left(T_1' r^{k-1}\right)\right]}{v_1' / 2r}$$

$$P_3' = \frac{R \times 2r\left[\frac{q_{in}}{c_v} + 1.32\left(T_1' r^{k-1}\right)\right]}{v_1'} \text{ ---------- (4)}$$

Comparing 3 and 4 equations as compression ratio increases maximum pressure increases

Question: 9.043P

In a spark-ignition engine, some cooling occurs as the gas is expanded. This may be modeled by using a polytropic process in lieu of the isentropic process. Determine if the polytropic exponent used in this model will be greater than or less than the isentropic exponent.

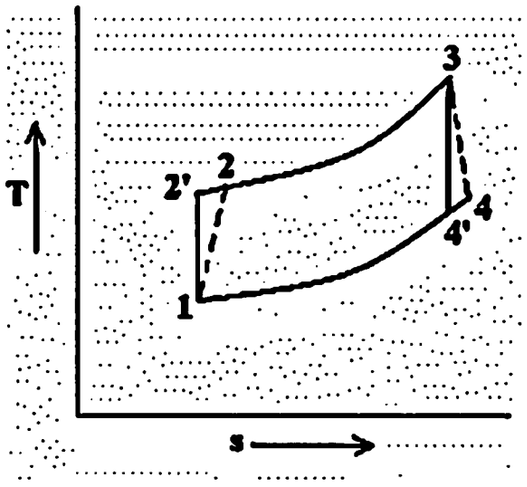
Step 1 of 3

In spark ignition engine, during the expansion process in case of isentropic expansion

$$Pv^k = cons$$

$$\frac{T_{4'}}{T_3} = \left(\frac{P_{4'}}{P_3}\right)^{\frac{k-1}{k}}$$

$$T_{4'} = T_3\left(\frac{P_{4'}}{P_3}\right)^{\frac{k-1}{k}}$$



In case of polytropic expansion

$$Pv^n = const$$

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{n-1}{n}}$$

$$T_4 = T_3\left(\frac{P_4}{P_3}\right)^{\frac{n-1}{n}}$$

Step 2 of 3

Step 3 of 3

From the above figure the exit temperature during the polytropic process is greater than the exit temperature during the isentropic process

$$T_{4\,poly} > T_{4\,ideal}$$

$$T_3\left(\frac{P_4}{P_3}\right)^{\frac{n-1}{n}} > T_3\left(\frac{P_{4'}}{P_3}\right)^{\frac{k-1}{k}} \qquad (\text{Since } P_{4'} = P_4)$$

$$\frac{n-1}{n} > \frac{k-1}{k}$$

$$\frac{1}{n} > \frac{1}{k}$$

From the above statement it is clear that $n \le k$

Question: 9.044P

How does a diesel engine differ from a gasoline engine?

Step 1 of 1

In gasoline engines the air–fuel mixture is compressed to a temperature that is below the auto ignition temperature of the fuel, and the combustion process is initiated by firing a spark plug.

In CI engines (also known as diesel engines), the air is compressed to a temperature that is above the auto ignition temperature of the fuel, and combustion starts on contact as the fuel is injected into this hot air. Therefore, the spark plug and carburetor are replaced by a fuel injector in diesel engines.

Question: 9.045P

How does the ideal Diesel cycle differ from the ideal Otto cycle?

Step 1 of 1

The Diesel cycle differs from the Otto cycle in the heat addition process.
Heat addition takes place at constant volume in the Otto cycle, but in the Diesel cycle heat addition takes place at constant pressure.

Question: 9.046P

For a specified compression ratio, is a diesel or gasoline engine more efficient?

Step 1 of 1

The thermal efficiency of the Otto cycle is given by

$$\eta = 1 - \frac{1}{r^{k-1}}$$

The thermal efficiency of the diesel cycle is given by

$$\eta = 1 - \frac{1}{r^{k-1}}\left[\frac{r_c^k - 1}{k(r_c - 1)}\right]$$

Where

r is compression ratio

r_c is cutoff ratio

Equation for the diesel cycle differs from equation for the Otto cycle only by the term in brackets, which for $r_c > 1$ is greater than unity. Thus, when the compression ratio is the same, the thermal efficiency of the cold air standard diesel cycle would be less than that of the cold air standard Otto cycle

Question: 9.047P

Do diesel or gasoline engines operate at higher compression ratios? Why?

Step 1 of 1

In gasoline engines, a mixture of air and fuel is compressed during the compression stroke, and the compression ratios are limited by the onset of auto ignition or engine knock.

In diesel engines, only air is compressed during the compression stroke, eliminating the possibility of auto ignition. Therefore, diesel engines can be designed to operate at much higher compression ratios, typically between 12 and 24. Fuels that are less refined can be used in diesel engines.

Question: 9.048P

What is the cutoff ratio? How does it affect the thermal efficiency of a Diesel cycle?

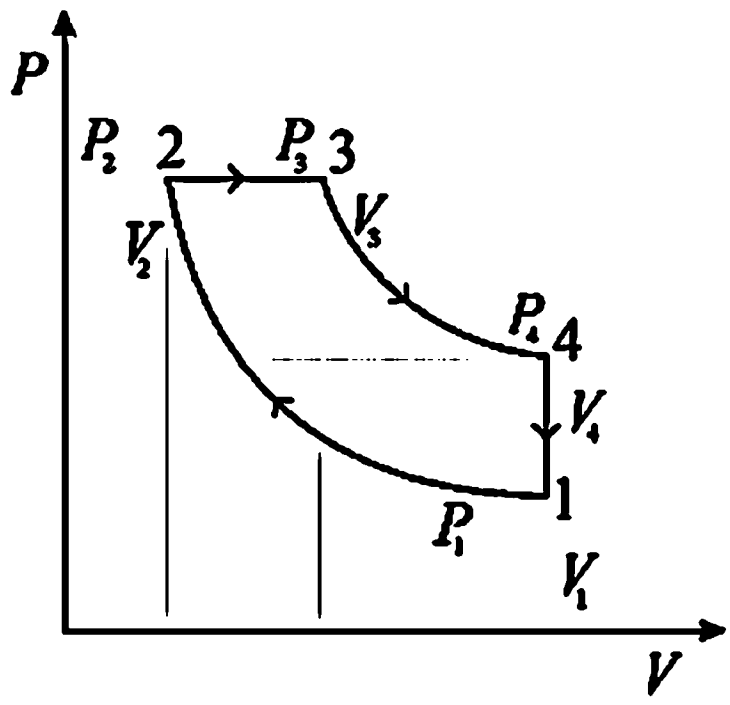
Step 1 of 1

Write the equation for cutoff ratio r_c.

$$r_c = \frac{v_3}{v_2}$$

Write the equation for thermal efficiency of a Diesel engine.

$$\eta_{th} = 1 - \frac{1}{r^{k-1}}\left(\frac{r_c^k - 1}{k(r_c - 1)}\right)$$



Since, in the equation thermal efficiency of the engine increases with decrease in cutoff ratio. In the limiting case the cutoff ratio is equal to 1 where efficiencies of diesel engine and gasoline engine will be identical.

Question: 9.049P

An ideal Diesel cycle has a compression ratio of 20 and a cutoff ratio of 1.3. Determine the maximum temperature of the air and the rate of heat addition to this cycle when it produces 250 kW of power and the state of the air at the beginning of the compression is 90 kPa and 15°C. Use constant specific heats at room temperature.

Step 1 of 5

The *P-V* diagram of ideal diesel cycle shown in figure:

Step 2 of 5

Process 1-2 is an Isentropic Compression.

$$T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$$

$$T_2 = T_1 \times \frac{V_1^{\gamma-1}}{V_2^{\gamma-1}}$$

$$= T_1\left(\frac{V_1}{V_2}\right)^{\gamma-1}$$

Here, T_2 and T_1 is the temperature at state points at 1 and 2 respectively and V_1 and V_2 are the volume at sate points 1 and 2 respectively.

Substitute 288K for T_1 and 20 for $\frac{V_1}{V_2}$

$$T_2 = 288(20)^{1.4-1}$$

$$= 954.56 \text{ K}$$

Step 3 of 5

Write the relation for process 2 and 3

$$T_2V_2 = T_3V_3$$

$$T_3 = T_2 \times \frac{V_3}{V_2}$$

$$= T_2\left(\frac{V_3}{V_2}\right)$$

$$= T_2(r_e)$$

Here, r_e is the expansion processes

Substitute 1.3 for r_e

$$T_3 = 954.56 \times 1.3$$

$$T_3 = 1240.93 \text{ K}$$

Therefore, Maximum temperature in the cycle is $\boxed{1240.93 \text{ K}}$

Step 4 of 5

Calculate the Thermal Efficiency of the Diesel cycle,

$$\eta_{th} = 1 - \frac{1}{r^{\gamma-1}}\left[\frac{r_e^{\gamma} - 1}{\gamma(r_e - 1)}\right]$$

$$= 1 - \frac{1}{20^{1.4-1}}\left[\frac{1.3^{1.4} - 1}{1.4(1.3-1)}\right]$$

$$= 1 - \frac{1.056775}{3.31445}$$

$$= 1 - 0.31884$$

$$= 0.681$$

Step 5 of 5

Calculate the Heat transferred

$$Q_{in} = \frac{W_{net}}{\eta_{th}}$$

Here, W_{net} is the net work done through a processes

Substitute 250 kW for W_{net} and 0.681 for η_{th}

$$Q_{in} = \frac{250}{0.681}$$

$$= 367.11 \text{ kW}$$

Hence heat input to the cycle is $\boxed{367.11 \text{ kW}}$

Question: 9.050P

An ideal Diesel cycle has a maximum cycle temperature of 2300°F and a cutoff ratio of 1.4. The state of the air at the beginning of the compression is $P1$ = 14.4 psia and $T1$= 50°F. This cycle is executed in a four-stroke, eight-cylinder engine with a cylinder bore of 4 in and a piston stroke of 4 in. The minimum volume enclosed in the cylinder is 4.5 percent of the maximum cylinder volume. Determine the power produced by this engine when it is operated at 1800 rpm. Use constant specific heats at room temperature.

Step 1 of 10

Given data:

Cutoff ratio of the given diesel cycle, $r_c = 1.4$

Initial pressure of the given cycle, $P_1 = 14.4\,\text{psi}$

Initial temperature of the given cycle, $T_1 = 50°\text{F} = 509.67°\text{R}$

Maximum Temperature of the given cycle, $T_3 = 2300°\text{F} = 2759.67°\text{R}$

Cylinder bore, $d = 4\,\text{in.}$

Piston stroke, $L = 4\,\text{in.}$

$$\left(\begin{matrix}\text{Minimum volume enclosed in the cylinder is}\\ 5\text{ percent of the maximum cylinder volume}\end{matrix}\right) V_2 = 0.045 \times V_1$$

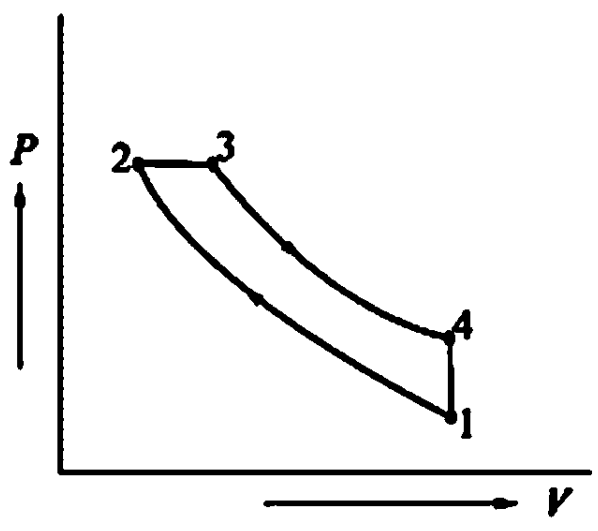
Speed of the operating engine, $N = 1800\,\text{rpm}$

Number of cylinders, $n = 8$

Step 2 of 10

Considering constant specific heats at room temperature

Gas constant $R = 0.3704\,\text{psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$



$c_p = 0.240\,\text{Btu/lbm}\cdot\text{R}$

$c_v = 0.171\,\text{Btu/lbm}\cdot\text{R}$

$k = 1.4$

Step 3 of 10

Representation of the diesel cycle in PV-coordinates:

Step 4 of 10

An ideal Diesel cycle consists of four internally reversible processes:

1-2 isentropic compression

2-3 Constant-pressure heat addition

3-4 isentropic expansion

4-1 Constant-volume heat rejection

Step 5 of 10

The compression ratio is defined as volume before compression to volume after compression

$$r = \frac{V_1}{V_2}$$

$$= \frac{1}{0.045}$$

$$r = 22.2$$

Step 6 of 10

From the isentropic compression Process 1-2, we have

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 509.67\left(22.2^{1.4-1}\right)$$

$$T_2 = 1762°\text{R}$$

Step 7 of 10

Thermal efficiency of a Diesel engine,

$$\eta_{th} = 1 - \frac{1}{r^{k-1}}\left(\frac{r_c^k - 1}{k(r_c - 1)}\right)$$

$$= 1 - \frac{1}{22.2^{1.4-1}}\left(\frac{1.4^{1.4} - 1}{1.4(1.4-1)}\right)$$

$$\eta_{th} = 0.689$$

Step 8 of 10

The heat supplied during the process 2-3:

$$Q_{in} = \dot{m}c_p(T_3 - T_2)$$

Where, total mass flow rate of air

$$\dot{m} = n\rho\dot{V}$$

$$\dot{m} = n \times \frac{p_1}{RT_1} \times \frac{\pi}{4}d^2L \times \frac{N}{2}$$

$$= 8 \times \frac{14.4}{0.3704 \times 509.67} \times \frac{\pi}{4} \times \left(\frac{4}{12}\right)^2 \times \frac{4}{12} \times \frac{1800}{2}$$

$$= 15.975\,\text{lb/min}$$

(Since there are two revolutions per cycle in a four stroke engine $N = \frac{N}{2}$)

Step 9 of 10

Heat supplied of the given cycle,

$$Q_{in} = \dot{m}c_p(T_3 - T_2)$$

$$= 15.975 \times 0.24(2759.67 - 1762)$$

$$= 3825.244\,\text{Btu/min}$$

Step 10 of 10

The efficiency of the given cycle,

$$\eta_{th} = \frac{\dot{W}_{net}}{Q_{in}}$$

$$\dot{W}_{net} = Q_{in} \times \eta_{th}$$

$$\dot{W}_{net} = 3825.224 \times 0.689$$

$$= 2635.59\,\text{Btu/min}$$

Therefore, the net work done of the given cycle, $\boxed{\dot{W}_{net} = 2635.59\,\text{Btu/min}}$

Question:

An air-standard dual cycle has a compression ratio of 14 and a cut off ratio of 1.2. The pressure ratio during the constant-volume heat addition process is 1.5. Determine the thermal efficiency, amount of heat added, the maximum gas pressure and temperature when this cycle is operated at 80 kPa and 20°C at the beginning of the compression. Use constant specific heats at room temperature.

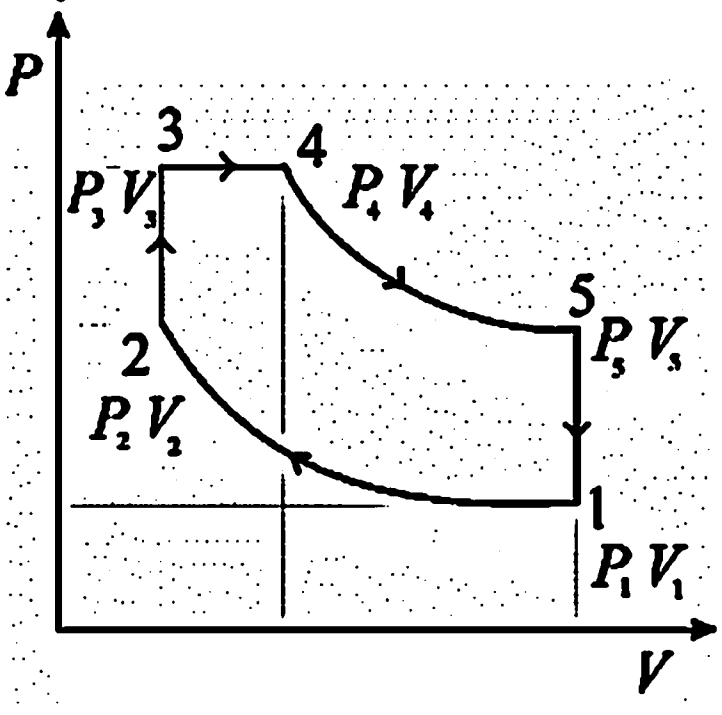
Step 1 of 10

Given,

Compression ratio of the Diesel cycle, $r = 14$

Cutoff ratio, $r_c = 1.2$

Pressure ratio, $r_p = 1.5$



Temperature of air before compression, $T_1 = 20°C$

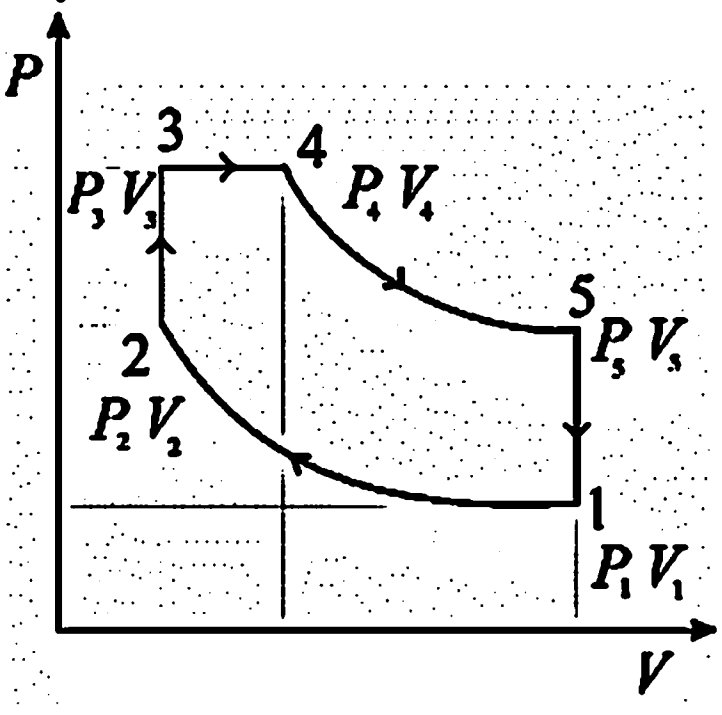
$T_1 = 293\ K$

Pressure of air before compression, $P_1 = 80\ kPa$

Step 2 of 10

The *P-V* diagram of dual cycle:

Step 3 of 10



Process 1-2 is an Isentropic Compression. Hence it follows, $T_1 v_1^{\gamma-1} = T_2 v_2^{\gamma-1}$

$$T_2 = T_1 \times \frac{v_1^{\gamma-1}}{v_2^{\gamma-1}}$$

$$T_2 = T_1 \left(\frac{v_1}{v_2}\right)^{\gamma-1}$$

$$T_2 = T_1 (r)^{\gamma-1}$$

The *P-V* diagram of dual cycle:

Step 3 of 10

Process 1-2 is an Isentropic Compression. Hence it follows, $T_1 v_1^{\gamma-1} = T_2 v_2^{\gamma-1}$

$$T_2 = T_1 \times \frac{v_1^{\gamma-1}}{v_2^{\gamma-1}}$$

$$T_2 = T_1 \left(\frac{v_1}{v_2}\right)^{\gamma-1}$$

$$T_2 = T_1 \left(\frac{r}{r_2}\right)^{\gamma-1}$$

$$T_3 = T_2 (r_p)$$

$$T_3 = 842 \times (1.5)$$

$$T_3 = 1263\ K$$

Pressure at state 3 is $P_3 = r_p \times P_2$

$$P_3 = 1.5 \times 3218.616$$

$$P_3 = 4827.924\ kPa$$

Volume at state 3 is $v_3 = v_2$

$$v_3 = 0.075\ m^3/kg$$

Step 6 of 10

Process 3-4 is of constant pressure. Hence it follows, $\frac{v_3}{T_3} = \frac{v_4}{T_4}$

$$T_4 = T_3 \left(\frac{v_4}{v_3}\right)$$

$$T_4 = T_3 (r_c)$$

$$T_4 = 1263 \times (1.2)$$

$$T_4 = 1515.6\ K$$

Hence the maximum temperature in the cycle is $\boxed{T_4 = 1515.6\ K}$

Step 7 of 10

And pressure at state 4 is $P_4 = P_3$

$$P_4 = 4827.924\ kPa$$

Hence maximum pressure in the cycle is $\boxed{P_4 = 4827.924\ kPa}$

Also $v_4 = r_c \times v_3$

$$v_4 = 1.2 \times 0.075$$

9 051P pg 2

Hence maximum pressure in the cycle is $\boxed{P_4 = 4827.924 \text{ kPa}}$

Also $v_4 = r_c \times v_3$

$v_4 = 1.2 \times 0.075$

$v_4 = 0.09 \text{ m}^3/\text{kg}$

Step 8 of 10

Process 4-5 is an isentropic expansion. Hence it follows, $T_4 v_4^{\gamma-1} = T_5 v_5^{\gamma-1}$

$$T_5 = T_4 \times \frac{v_4^{\gamma-1}}{v_5^{\gamma-1}}$$

$$T_5 = T_4 \left(\frac{v_4}{v_1}\right)^{\gamma-1}$$

$$T_5 = T_4 \left(\frac{v_4}{r \times v_2}\right)^{\gamma-1}$$

$$T_5 = 1515.6 \left(\frac{0.09}{1.05}\right)^{1.4-1}$$

$$T_5 = 567.3 \text{ K}$$

Step 9 of 10

Heat added in process 2-3

$$q_{2-3} = c_v (T_3 - T_2)$$

$$q_{2-3} = 0.718 \times (1263 - 842)$$

$$q_{2-3} = 302.278 \text{ kJ/kg}$$

Heat added in process 3-4

$$q_{3-4} = c_p (T_4 - T_3)$$

$$q_{3-4} = 1.005 \times (1515.6 - 1263)$$

$$q_{3-4} = 253.863 \text{ kJ/kg}$$

Total heat input to cycle is $q_{in} = q_{2-3} + q_{3-4}$

$$q_{in} = 302.278 + 253.863$$

$$q_{in} = 556.141 \text{ kJ/kg}$$

Step 10 of 10

Heat rejected in process 5-1

$$q_{5-1} = c_v (T_5 - T_1)$$

$$q_{4-5} = 0.718 \times (567.3 - 293)$$

$$q_{4-5} = 196.95 \text{ kJ/kg}$$

Amount of heat rejected in the cycle is $q_{out} = q_{4-5}$

$$q_{out} = 196.95 \text{ kJ/kg}$$

Step 9 of 10

Heat added in process 2-3

$$q_{2-3} = c_v (T_3 - T_2)$$

$$q_{2-3} = 0.718 \times (1263 - 842)$$

$$q_{2-3} = 302.278 \text{ kJ/kg}$$

Heat added in process 3-4

$$q_{3-4} = c_p (T_4 - T_3)$$

$$q_{3-4} = 1.005 \times (1515.6 - 1263)$$

$$q_{3-4} = 253.863 \text{ kJ/kg}$$

Total heat input to cycle is $q_{in} = q_{2-3} + q_{3-4}$

Question: 9.052P pg 1

Repeat Prob. 9–51 when the state of the air at the beginning of the compression is 80 kPa and –20°C

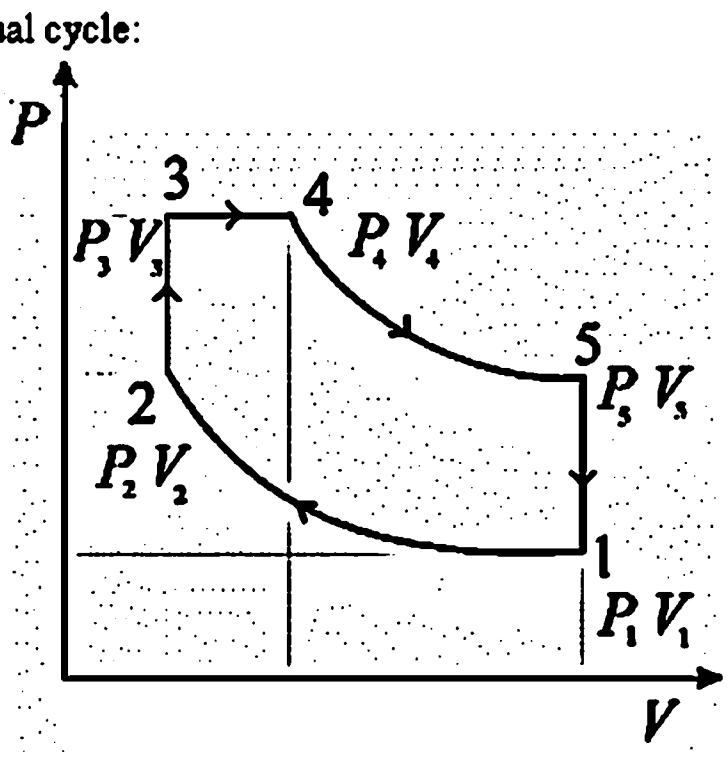
Step 1 of 10

Given,

Compression ratio of the Diesel cycle, $r = 14$

Cutoff ratio, $r_c = 1.2$

Pressure ratio, $r_p = 1.5$



Temperature of air before compression, $T_1 = -20°C$

$T_1 = 253\ K$

Pressure of air before compression, $P_1 = 80\ kPa$

Step 2 of 10

The P-V diagram of dual cycle:

Step 3 of 10

Process 1-2 is an Isentropic Compression. Hence it follows, $T_1 V_1^{\gamma-1} = T_2 V_2^{\gamma-1}$

$$T_2 = T_1 \times \frac{V_1^{\gamma-1}}{V_2^{\gamma-1}}$$

$$T_2 = T_1 \left(\frac{V_1}{V_2}\right)^{\gamma-1}$$

$$T_2 = T_1 (r)^{\gamma-1}$$

$$T_2 = 253(14)^{1.4-1}$$

$$T_2 = 727\ K$$

Step 4 of 10

Pressure at state 2 is $P_2 = P_1 \left(\frac{v_1}{v_2}\right)^{\gamma}$

$$P_2 = 80(14)^{1.4}$$

$$P_2 = 3218.616\ kPa$$

Volume at state 2 is $v_2 = \frac{v_1}{r}$

$$v_2 = \frac{RT_1}{rP_1}$$

$$v_2 = \frac{0.287 \times 273}{14 \times 80}$$

$$v_2 = 0.07\ m^3/kg$$

Step 5 of 10

Process 2-3 is of constant volume. Hence it follows, $\frac{P_2}{T_2} = \frac{P_3}{T_3}$

$$T_3 = T_2 \left(\frac{P_3}{P_2}\right)$$

$$T_3 = T_2 (r_p)$$

$$T_3 = 727 \times (1.5)$$

$$T_3 = 1090.5\ K$$

Pressure at state 3 is $P_3 = r_p \times P_2$

$$P_3 = 1.5 \times 3218.616$$

$$P_3 = 4827.924\ kPa$$

Volume at state 3 is $v_3 = v_2$

$$v_3 = 0.07\ m^3/kg$$

Step 6 of 10

Process 3-4 is of constant pressure. Hence it follows, $\frac{v_3}{T_3} = \frac{v_4}{T_4}$

$$T_4 = T_3 \left(\frac{v_4}{v_3}\right)$$

$$T_4 = T_3 (r_c)$$

$$T_4 = 1090.5 \times (1.2)$$

$$T_4 = 1308.6\ K$$

Hence the maximum temperature in the cycle is $\boxed{T_4 = 1308.6\ K}$

Step 7 of 10

And pressure at state 4 is $P_4 = P_3$

$$P_4 = 4827.924\ kPa$$

Hence maximum pressure in the cycle is $\boxed{P_4 = 4827.924\ kPa}$

Also $v_4 = r_c \times v_3$

$$v_4 = 1.2 \times 0.07$$

$$v_4 = 0.084\ m^3/kg$$

Also $v_4 = r_c \times v_3$

$v_4 = 1.2 \times 0.07$

$v_4 = 0.084 \text{ m}^3/\text{kg}$

Step 8 of 10

Process 4-5 is an isentropic expansion. Hence it follows, $T_4 v_4^{\gamma-1} = T_5 v_5^{\gamma-1}$

$$T_5 = T_4 \times \frac{v_4^{\gamma-1}}{v_5^{\gamma-1}}$$

$$T_5 = T_4 \left(\frac{v_4}{v_1}\right)^{\gamma-1}$$

$$T_5 = T_4 \left(\frac{v_4}{r \times v_2}\right)^{\gamma-1}$$

$$T_5 = 1308.6 \left(\frac{0.084}{0.98}\right)^{1.4-1}$$

$$T_5 = 489.8 \text{ K}$$

Step 9 of 10

Heat added in process 2-3

$$q_{2-3} = c_v (T_3 - T_2)$$

$$q_{2-3} = 0.718 \times (1090.5 - 727)$$

$$q_{2-3} = 260.993 \text{kJ/kg}$$

Heat added in process 3-4

$$q_{3-4} = c_p (T_4 - T_3)$$

$$q_{3-4} = 1.005 \times (1308.6 - 1090.5)$$

$$q_{3-4} = 219.19 \text{ kJ/kg}$$

Total heat input to cycle is $q_{in} = q_{2-3} + q_{3-4}$

$$q_{in} = 260.993 + 219.19$$

$$q_{in} = 480.183 \text{ kJ/kg}$$

Step 10 of 10

Heat rejected in process 5-1

$$q_{5-1} = c_v (T_5 - T_1)$$

$$q_{4-5} = 0.718 \times (489.8 - 253)$$

$$q_{4-5} = 170.02 \text{ kJ/kg}$$

Amount of heat rejected in the cycle is $q_{out} = q_{4-5}$

$$q_{out} = 170.02 \text{ kJ/kg}$$

Efficiency of the cycle is $\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$

$$\eta_{th} = 1 - \frac{170.02}{480.183}$$

$$\eta_{th} = 0.646$$

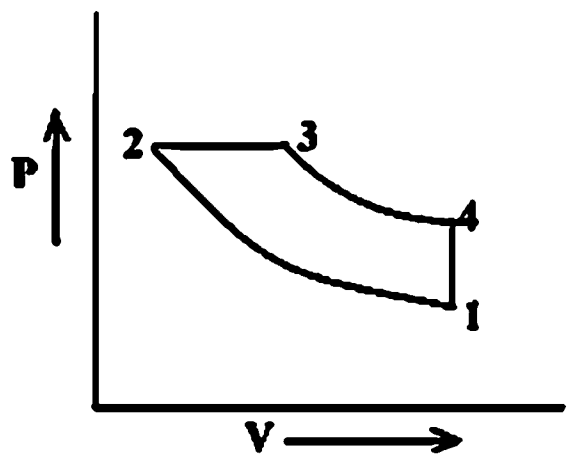
Hence efficiency of the cycle is $\boxed{\eta_{th} = 64.6\%}$

Question:

An air-standard Diesel cycle has a compression ratio of 18.2. Air is at 80°F and 14.7 psia at the beginning of the compression process and at 3000 R at the end of the heat-addition process. Accounting for the variation of specific heats with temperature, determine (*a*) the cutoff ratio, (*b*) the heat rejection per unit mass, and (*c*) the thermal efficiency.

Step 1 of 14

Given



Compression ratio $r = 18.2$

Initial pressure $P_1 = 14.7$ psia

Initial temperature $T_1 = 80°F = 540R$

Maximum temperature is $T_3 = 3000R$

Step 2 of 14

Step 3 of 14

An ideal Diesel cycle consists of four internally reversible processes:

1-2 Isentropic compression

2-3 Constant-pressure heat addition

3-4 Isentropic expansion

4-1 Constant-volume heat rejection

Step 4 of 14

Assuming variation of specific heats with temperature

At $T_1 = 540R$ from ideal gas properties of air

$u_1 = 92.04$ Btu/lbm

$v_{r1} = 144.32$

Step 5 of 14

We know that

$$\frac{v_1}{v_2} = \frac{v_{r1}}{v_{r2}}$$

$$v_{r2} = v_{r1} \times \frac{v_2}{v_1}$$

$$v_{r2} = v_{r1} \times \frac{1}{r}$$

$$v_{r2} = \frac{144.32}{18.2}$$

$$v_{r_2} = 7.929$$

Step 6 of 14

At $v_{r_2} = 7.929$ from ideal gas properties of air

$$h_2 = 395.74 + (409.13 - 395.74)\left(\frac{7.929 - 8.263}{7.556 - 8.263}\right)$$

$$h_2 = 402.065 \text{Btu/lbm}$$

$$T_2 = 1600 + (1650 - 1600)\left(\frac{7.929 - 8.263}{7.556 - 8.263}\right)$$

$$T_2 = 1623.62R$$

Step 7 of 14

At $T_3 = 3000R$ from ideal gas properties of air

$h_3 = 790.68$ Btu/lbm

$v_{r3} = 1.18$

Step 8 of 14

(a)

The cut-off ratio is expressed as

$$r_c = \frac{v_3}{v_2}$$

Process 2-3 is constant pressure heat addition

$$\frac{v_3}{v_2} = \frac{T_3}{T_2}$$

$$r_c = \frac{3000}{1623.62}$$

$$\boxed{r_c = 1.8477}$$

Step 9 of 14

(b)

The heat rejection per unit mass

$q_{out} = u_4 - u_1$ Btu/lbm

Step 10 of 14

Process 3-4 is constant volume heat addition

$$\frac{v_{r4}}{v_{r3}} = \frac{v_4}{v_3}$$

$$\frac{v_{r4}}{v_{r3}} = \frac{v_1}{v_3}$$

Process 3-4 is constant volume heat addition

$$\frac{v_{r4}}{v_{r3}} = \frac{v_4}{v_3}$$

$$\frac{v_{r4}}{v_{r3}} = \frac{v_1}{v_3}$$

$$\frac{v_{r4}}{v_{r3}} = \frac{v_1}{v_2} \times \frac{v_2}{v_3}$$

$$\frac{v_{r4}}{v_{r3}} = r \times \frac{1}{r_c}$$

$$v_{r4} = \frac{r}{r_c} v_{r3}$$

$$v_{r4} = \frac{18.2}{1.8477}(1.18)$$

$$v_{r4} = 11.623$$

Step 11 of 14

At $v_{r4} = 11.623$ from ideal gas properties of air

$$u_4 = 246.93 + (254.66 - 246.93)\left(\frac{11.623 - 12.10}{11.17 - 12.10}\right)$$

$$u_4 = 250.894 \text{ Btu/lbm}$$

Step 12 of 14

Therefore the amount of heat rejection is

$$q_{out} = u_4 - u_1 \text{ Btu/lbm}$$

$$= 250.894 - 92.04$$

$$\boxed{q_{out} = 158.85 \text{ Btu/lbm}}$$

Step 13 of 14

(c)

The thermal efficiency

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

Where q_{in} heat supplied is expressed as

$$q_{in} = h_3 - h_2 \text{ Btu/lbm}$$

$$= 790.68 - 402.065$$

$$q_{in} = 388.615 \text{ Btu/lbm}$$

Step 14 of 14

Therefore thermal efficiency is

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

$$\eta_{th} = 1 - \frac{158.85}{388.615}$$

$$= 0.5912$$

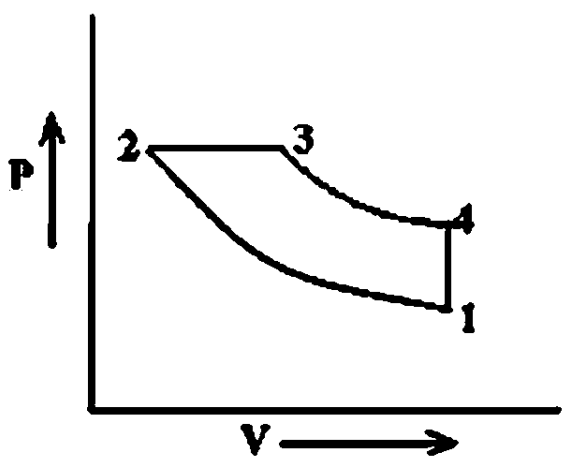
$$\boxed{\eta_{th} = 59.12\%}$$

Question: 9.054P

Repeat Prob. 9-53E using constant specific heats at room temperature.

Step 1 of 10

Given



Compression ratio $r = 18.2$

Initial pressure $P_1 = 14.7$ psia

Initial temperature $T_1 = 80°F = 540R$

Maximum temperature is $T_3 = 3000R$

Step 2 of 10

Step 3 of 10

An ideal Diesel cycle consists of four internally reversible processes:

1-2 Isentropic compression

2-3 Constant-pressure heat addition

3-4 Isentropic expansion

4-1 Constant-volume heat rejection

Step 4 of 10

Considering constant specific heats at room temperature

Gas constant $R = 0.3704$ Btu/lbm.R

$c_p = 0.24$ Btu/lbm.R

$c_v = 0.171$ Btu/lbm.R

$k = 1.4$

Step 5 of 10

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 540\left(18.2^{1.4-1}\right)$$

$$T_2 = 1723.5R$$

Step 6 of 10

(a)

The cut-off ratio is expressed as

$$r_c = \frac{v_3}{v_2}$$

Process 2-3 is constant pressure heat addition

$$\frac{v_3}{v_2} = \frac{T_3}{T_2}$$

$$r_c = \frac{3000}{1723.5}$$

$$\boxed{r_c = 1.74}$$

Step 7 of 10

(b)

The heat rejection per unit mass is expressed as

$$q_{out} = u_4 - u_1$$

$$q_{out} = c_v (T_4 - T_1)$$

Process 4-1 is isentropic expansion

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_4}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_2} \times \frac{v_2}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(r_c \times \frac{1}{r}\right)^{k-1}$$

$$T_4 = (3000)\left(\frac{1.74}{18.2}\right)^{1.4-1}$$

$$T_4 = 1173.038R$$

Step 8 of 10

Therefore heat rejection is

$$q_{out} = c_v (T_4 - T_1)$$

$$= (0.171)(1173.038 - 540)$$

$$\boxed{q_{out} = 108.24 \text{ Btu/lbm}}$$

Step 9 of 10

(c)

The thermal efficiency

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

Heat supplied is expressed as

$$q_{in} = h_3 - h_2$$

$$= c_p (T_3 - T_2)$$

$$= (0.24)(3000\text{-}1723.5)$$

$$q_{in} = 306.36 \text{ Btu/lbm}$$

Step 10 of 10

Therefore the thermal efficiency

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

$$\eta_{th} = 1 - \frac{108.24}{306.36}$$

$$= 0.64669$$

$$\boxed{\eta_{th} = 64.669\%}$$

Question:

An ideal diesel engine has a compression ratio of 20 and uses air as the working fluid. The state of air at the beginning of the compression process is 95 kPa and 20°C. If the maximum temperature in the cycle is not to exceed 2200 K, determine (*a*) the thermal efficiency and (*b*) the mean effective pressure. Assume constant specific heats for air at room temperature.

Step 1 of 12

Given

Compression ratio $r = 20$

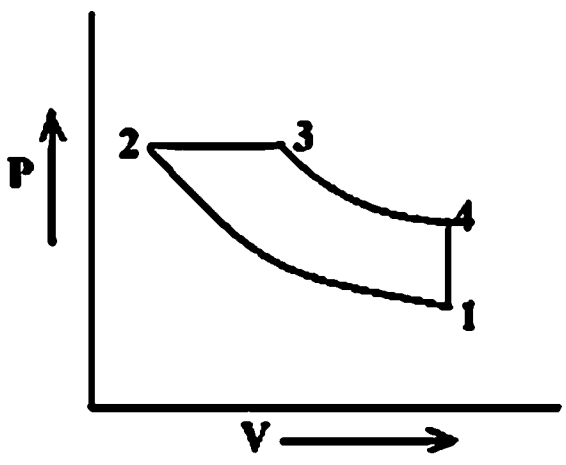
Initial pressure $P_1 = 95\ \text{kPa}$

Initial temperature $T_1 = 20°\text{C} = 293\text{K}$

Maximum Temperature $T_3 = 2200\text{K}$

Step 2 of 12

Considering constant specific heats at room temperature



Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 12

Step 4 of 12

An ideal Diesel cycle consists of four internally reversible processes:

1-2 Isentropic compression

2-3 Constant-pressure heat addition

3-4 Isentropic expansion

4-1 Constant-volume heat rejection

Step 5 of 12

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 293\left(20^{1.4-1}\right)$$

$$T_2 = 971.13\text{K}$$

Step 6 of 12

Process 2-3 is constant pressure heat addition

$$\frac{v_3}{v_2} = \frac{T_3}{T_2}$$

$$r_c = \frac{2200}{971.13}$$

$$r_c = 2.265$$

Step 7 of 12

Process 3-4 is isentropic expansion

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_4}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_2} \times \frac{v_2}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(r_c \times \frac{1}{r}\right)^{k-1}$$

$$T_4 = (2200)\left(\frac{2.265}{20}\right)^{1.4-1}$$

$$T_4 = 920.53\text{K}$$

Step 8 of 12

Heat supplied is expressed as

$$q_{in} = h_3 - h_2$$

$$= c_p\left(T_3 - T_2\right)$$

$$q_{in} = (1.005)(2200\text{-}971.13)$$

$$q_{in} = 1235.014\ \text{kJ/kg}$$

Step 9 of 12

The heat rejected per unit mass is expressed as

$$q_{out} = u_4 - u_1$$

$$= c_v\left(T_4 - T_1\right)$$

$$= 0.718(920.53 - 293)$$

$$q_{out} = 450.566\ \text{kJ/kg}$$

$$= c_v (T_4 - T_1)$$
$$= 0.718(920.53 - 293)$$
$$q_{out} = 450.566 \text{ kJ/kg}$$

Step 10 of 12

(a)

The thermal efficiency

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$
$$= 1 - \frac{450.566}{1235.014}$$
$$= 0.635$$
$$\boxed{\eta_{th} = 63.5\%}$$

Step 11 of 12

(b)

The Mean effective pressure

$$MEP = \frac{w_{net}}{v_1 - v_2}$$

Work net is expressed as

$$w_{net} = q_{in} - q_{out}$$
$$= 1235.014 - 450.566$$
$$w_{net} = 784.44 \text{ kJ/kg}$$

Specific volume

$$v_1 = \frac{RT_1}{P_1}$$
$$v_1 = \frac{0.287 \times 293}{95}$$
$$v_1 = 0.885 \text{m}^3/\text{kg}$$

Step 12 of 12

Then the mean effective pressure

$$MEP = \frac{w_{net}}{v_1 - v_2}$$
$$MEP = \frac{w_{net}}{v_1\left(1 - \frac{1}{r}\right)}$$
$$= \frac{784.44}{(0.885)\left(1 - \frac{1}{20}\right)}$$
$$\boxed{MEP = 933.02 \text{ kPa}}$$

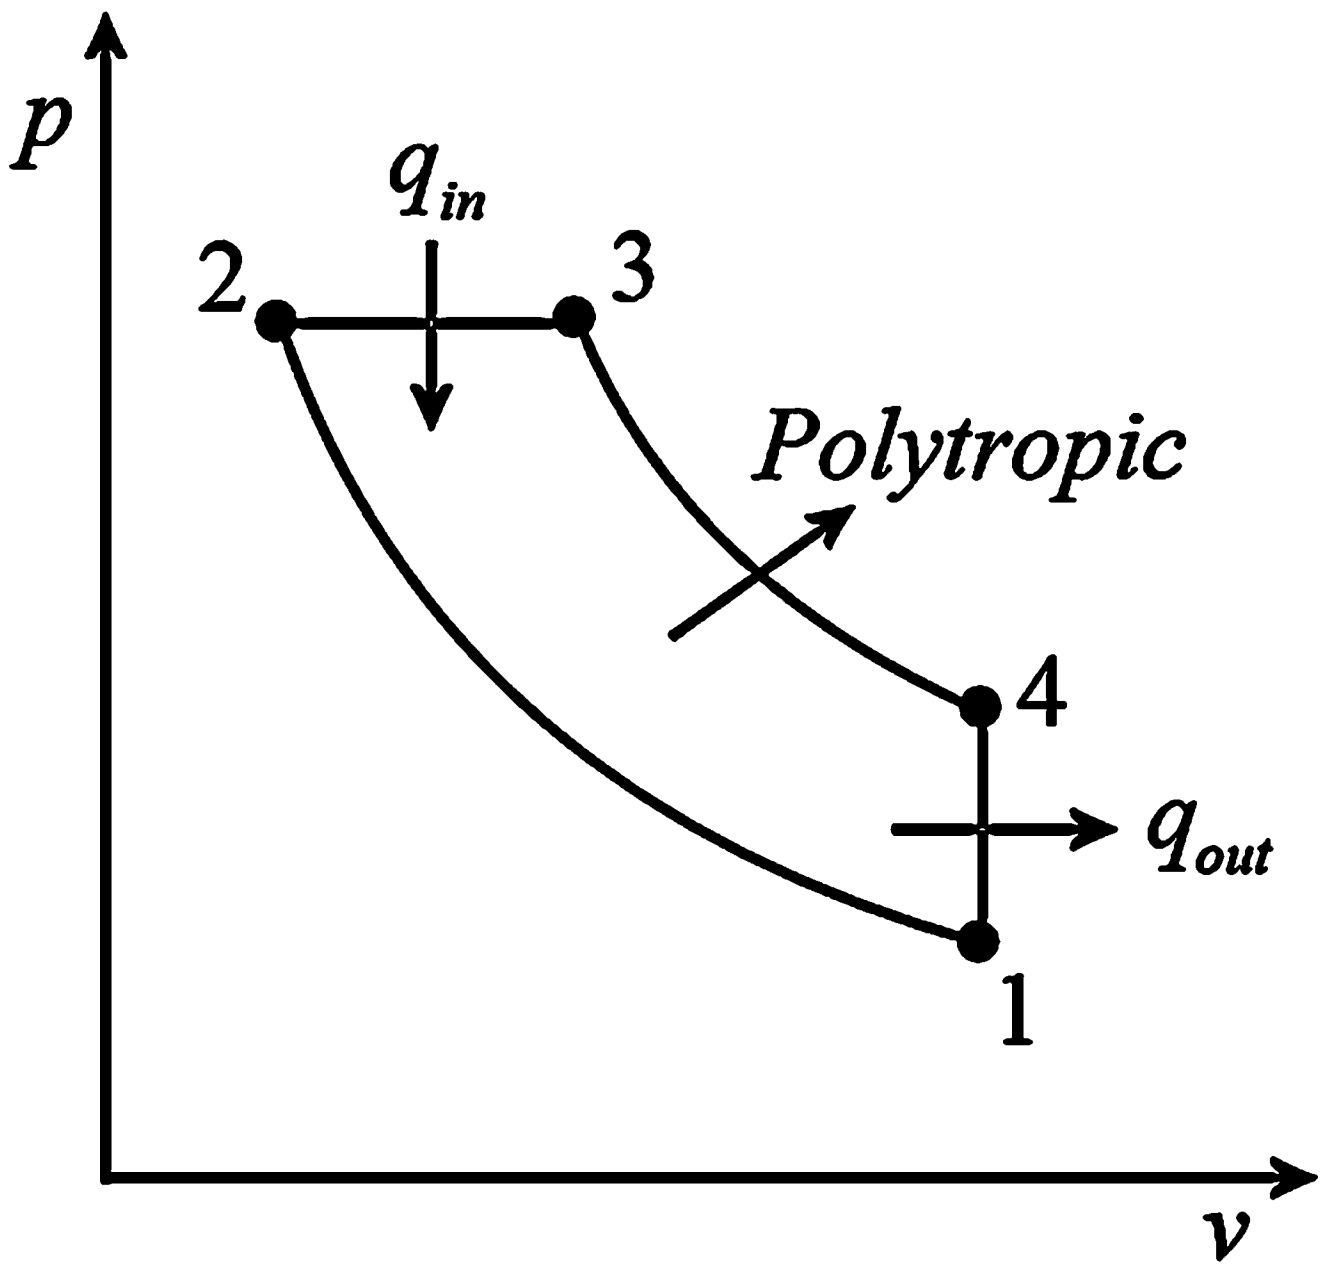
Question:

Repeat Prob. 9–55, but replace the isentropic expansion process by polytropic expansion process with the polytropic exponent n= 1.35.

Step 1 of 11

Considering constant specific heats at room temperature.

Gas constant of air, $R = 0.287\ \text{kJ/kg}\cdot\text{K}$



Specific heat of air at constant pressure, $c_p = 1.005\ \text{kJ/kg}\cdot\text{K}$

Specific heat of air at constant volume, $c_v = 0.718\ \text{kJ/kg}\cdot\text{K}$

Specific heats ratio, $k = 1.4$

Step 2 of 11

Draw the $p-v$ diagram for the diesel cycle.

Step 3 of 11

The Diesel cycle consists of four internally reversible processes:

1-2 isentropic compression

2-3 Constant-pressure heat addition

3-4 Polytropic expansion

4-1 Constant-volume heat rejection

Consider the process 1-2 is isentropic compression:

Using the following equation to determine the temperature at state 2.

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

Here, r is the compression ratio, T_1 is the temperature at state 1.

Substitute 20 for r and $293\ \text{K}$ for T_1.

$$T_2 = 293(20)^{1.4-1}$$
$$= 971.1\ \text{K}$$

Step 4 of 11

Process 2-3 is constant pressure heat addition:

Find the cut-off ratio as follows:

$$\frac{v_3}{v_2} = \frac{T_3}{T_2}$$

Here, v_3 is the volume after the heat addition at constant pressure, v_2 is the volume before the heat addition at constant pressure and T_3 is the temperature after the heat addition.

Substitute $2200\ \text{K}$ for T_3 and $971.1\ \text{K}$ for T_2.

$$\frac{v_3}{v_2} = \frac{2200}{971.1}$$
$$= 2.265$$
$$v_3 = 2.265 v_2$$

Step 5 of 11

Consider the process 3-4 is Polytropic expansion:

Calculate the temperature at state 4 using the following equation:

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_4}\right)^{n-1}$$

$$T_4 = T_3\left(\frac{v_3}{v_4}\right)^{n-1}$$

Since the process 4-1 is constant volume heat rejection, $v_4 = v_1$

$$\frac{T_3}{T_4} = \left(\frac{v_3}{v_4}\right)^{n-1}$$

$$T_4 = T_3\left(\frac{v_3}{v_4}\right)^{n-1}$$

Since the process 4-1 is constant volume heat rejection, $v_4 = v_1$

Substitute $2.265v_2$ for v_3 and v_1 for v_4 .

$$T_4 = T_3\left(\frac{2.265v_2}{v_1}\right)^{n-1}$$

Substitute $\frac{1}{r}$ for $\frac{v_2}{v_1}$.

$$T_4 = T_3\left(\frac{2.265}{r}\right)^{n-1}$$

Substitute $2200\,\text{K}$ for T_3 , 20 for r and 1.35 for n .

$$T_4 = (2200)\left(\frac{2.265}{20}\right)^{1.35-1}$$
$$= 1026\,\text{K}$$

Step 6 of 11

Calculate the heat supplied per unit mass using the following equation.

$$q_{in} = h_3 - h_2$$
$$= c_p(T_3 - T_2)$$

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p , $2200\,\text{K}$ for T_3 and $971.1\,\text{K}$ for T_2 .

$$q_{in} = (1.005)(2200\text{-}971.1)$$
$$= 1235\,\text{kJ/kg}$$

Calculate the heat rejected per unit mass using the following equation.

$$q_{out,41} = u_4 - u_1$$
$$= c_v(T_4 - T_1)$$

Substitute $0.718\,\text{kJ/kg}\cdot\text{K}$ for c_v , $1026\,\text{K}$ for T_4 and $293\,\text{K}$ for T_1 .

$$q_{out,41} = 0.718(1026 - 293)$$
$$= 526.3\,\text{kJ/kg}$$

Note that q_{out} in this case does not represent the entire heat rejected, since some heat is also rejected during the polytropic process.

Step 7 of 11

Calculate the work produced in process 3-4, using the following equation:

$$w_{34} = \frac{R(T_4 - T_3)}{1-n}$$

Substitute $0.287\,\text{kJ/kg}\cdot\text{K}$ for R , $1026\,\text{K}$ for T_4 , $2200\,\text{K}$ for T_3 and 1.35 for n .

$$w_{34} = \frac{(0.287)(1026 - 2200)}{1-1.35}$$
$$= 963\,\text{kJ/kg}$$

Apply the energy balance in process 3-4:

$$E_{in} - E_{out} = \Delta E_{system}$$
$$q_{in,34} - w_{34} = u_4 - u_3$$
$$q_{in,34} = (u_4 - u_3) + w_{34}$$
$$q_{in,34} = c_v(T_4 - T_3) + w_{34}$$

Substitute $963\,\text{kJ/kg}$ for w_{34} , $1026\,\text{K}$ for T_4 , $2200\,\text{K}$ for T_3 and $0.718\,\text{kJ/kg}\cdot\text{K}$ for c_v .

$$q_{in,34} = 0.718(1026 - 2200) + 963$$
$$= 120.1\,\text{kJ/kg}$$

It indicates that $120.1\,\text{kJ/kg}$ of heat is transferred to the combustion gases during the polytropic expansion process. This is unrealistic since the gas at higher temperatures than the surroundings, and a hot gas loses heat during polytropic expansion.

Step 8 of 11

Now calculate the heat rejected during the process 3-4 using the properties of air tables:

Obtain the following values from the table "ideal gas properties of air".

At $2200\,\text{K}$: $u = 1872.4\,\text{kJ/kg}$

At $1026\,\text{K}$: $u = 781.3\,\text{kJ/kg}$

$$q_{out,34} = w_{34} + (u_4 - u_3)$$

Substitute $1872.4\,\text{kJ/kg}$ for u_3 , $781.3\,\text{kJ/kg}$ for u_4 and $963\,\text{kJ/kg}$ for w_{34} .

$$q_{out,34} = 963 + (781.3 - 1872.4)$$
$$= -128.1\,\text{kJ/kg}$$

Which is a heat loss expected.

Calculate the total heat rejected from the cycle as follows:

$$q_{out} = q_{out,41} + q_{out,34}$$

Substitute $128.1\,\text{kJ/kg}$ for $q_{out,34}$ and $526.3\,\text{kJ/kg}$ for $q_{out,41}$.

$$q_{out} = 128.1 + 526.3$$
$$= 654.4\,\text{kJ/kg}$$

Step 9 of 11

$$q_{out} = 128.1 + 526.3$$
$$= 654.4\ \text{kJ/kg}$$

Step 9 of 11

(a)

Calculate the thermal efficiency.

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

Substitute $654.4\ \text{kJ/kg}$ for q_{out} and $1235\ \text{kJ/kg}$ for q_{in}.

$$\eta_{th} = 1 - \frac{654.4}{1235}$$
$$= 0.470$$
$$= 47.0\%$$

Therefore, the thermal efficiency is $\boxed{47.0\%}$.

(b)

Calculate the Mean effective pressure as follows:

$$MEP = \frac{w_{net}}{v_1 - v_2}$$
$$= \frac{w_{net}}{v_1\left(1 - \frac{1}{r}\right)} \quad \text{..... (1)}$$

Step 10 of 11

Find the net work done as follows:

$$w_{net} = q_{in} - q_{out}$$

Substitute $654.4\ \text{kJ/kg}$ for q_{out} and $1235\ \text{kJ/kg}$ for q_{in}.

$$w_{net} = 1235 - 654.4$$
$$= 580.6\ \text{kJ/kg}$$

Calculate the specific volume at state 1 using the following equation:

$$v_1 = \frac{RT_1}{P_1}$$

Substitute $0.287\ \text{kJ/kg}\cdot\text{K}$ for R, $293\ \text{K}$ for T_1 and $95\ \text{kPa}$ for P_1.

$$v_1 = \frac{0.287 \times 293}{95}$$
$$= 0.885\ \text{m}^3/\text{kg}$$

Step 11 of 11

Substitute $0.885\ \text{m}^3/\text{kg}$ for v_1, $580.6\ \text{kJ/kg}$ for w_{net} and 20 for r in equation (1).

$$MEP = \frac{w_{net}}{v_1\left(1 - \frac{1}{r}\right)}$$
$$= \frac{580.6}{(0.885)\left(1 - \frac{1}{20}\right)}$$
$$= 690.57\ \text{kPa}$$

Therefore, the mean effective pressure is $\boxed{690.57\ \text{kPa}}$.

Question: 9.057P

Reconsider Prob. 9–56. Using EES (or other) software, study the effect of varying the compression ratio from 14 to 24. Plot the network output, mean effective pressure, and thermal efficiency as a function of the compression ratio. Plot the *T-s* and *P-V* diagrams for the cycle when the compression ratio is 20.

We don't have the solution to this problem yet.

Question: 9.058P

A four-cylinder two-stroke 2,0-L diesel engine that operates on an ideal Diesel cycle has a compression ratio of 22 and a cutoff ratio of 1.8. Air is at 70°C and 97 kPa at the beginning of the compression process. Using the cold-air-standard assumptions, determine how much power the engine will deliver at 2300 rpm.

Step 1 of 10

Given data:

Compression ratio of the given cycle, $r = 22$

Cutoff ratio of the given cycle, $r_c = 1.8$

Initial pressure of the given cycle, $P_1 = 97\,\text{kPa}$

Initial temperature of the given cycle, $T_1 = 70°\text{C} = 343\text{K}$

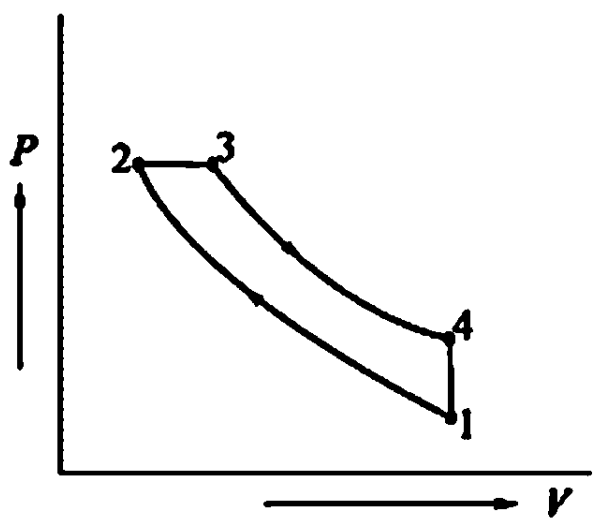
Volume of the cylinder, $V = 2\text{L} = 2\times10^{-3}\,\text{m}^3$

Speed of the engine, $N = 2300\,\text{rpm}$

Step 2 of 10

Considering constant specific heats at room temperature

Gas constant $R = 0.287\,\text{kJ/kg.K}$



$c_p = 1.005\,\text{kJ/kg.K}$

$c_v = 0.718\,\text{kJ/kg.K}$

$k = 1.4$

Step 3 of 10

Representation of the ideal diesel cycle:

Step 4 of 10

An ideal Diesel cycle consists of four internally reversible processes:

1-2 isentropic compression

2-3 Constant-pressure heat addition

3-4 isentropic expansion

4-1 Constant-volume heat rejection

Step 5 of 10

From the isentropic compression process 1-2,

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 343\left(22^{1.4-1}\right)$$

$$= 1181\text{K}$$

Step 6 of 10

For the Process 2-3:

Constant pressure heat addition, we have

$$\frac{T_3}{T_2} = \frac{v_3}{v_2}$$

$$\frac{T_3}{T_2} = r_c$$

$$T_3 = 1181(1.8)$$

$$= 2125.8\text{K}$$

Step 7 of 10

For the Process 3-4:

From isentropic expansion, we have

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_4}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_2}\times\frac{v_2}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(r_c\times\frac{1}{r}\right)^{k-1}$$

$$T_4 = (2125.8)\left(\frac{1.8}{22}\right)^{1.4-1}$$

$$= 781\text{K}$$

Step 8 of 10

Heat supplied for the given diesel cycle,

$$q_{in} = h_3 - h_2$$

$$= c_p(T_3 - T_2)$$

$$q_{in} = (1.005)(2125.8 - 1181)$$

$$= 949.524\,\text{kJ/kg}$$

Step 9 of 10

The heat rejected per unit mass for the given cycle,

$$q_{out} = u_4 - u_1$$

$$= c_v(T_4 - T_1)$$

$$= 0.718(781 - 343)$$

$$= 314.484\text{K}$$

Net work done of the given cycle,

$$w_{net} = q_{in} - q_{out}$$

$$= 949.524 - 314.484$$

$$= 635.04\,\text{kJ/kg}$$

Step 10 of 10

Mass flow rate of air for the given cycle,

$$m = \frac{P_1V}{RT_1}$$

$$m = \frac{97\times2\times10^{-3}}{0.287\times343}$$

$$= 1.97\times10^{-3}\,\text{kg}$$

The power delivered by the cycle,

$$P = m\times N\times w_{net}$$

$$P = 1.97\times10^{-3}\times\frac{2300}{60}\times635.04$$

$$= 47.956\text{kW}$$

Therefore the power developed by the complete cycle, $\boxed{P = 47.956\text{kW}}$

Question: 9.059P

Repeat Prob. 9–58 using nitrogen as the working fluid.

Step 1 of 10

Given data:

Compression ratio of the given cycle, $r = 22$

Cutoff ratio of the given cycle, $r_c = 1.8$

Initial pressure of the given cycle, $P_1 = 97\ \text{kPa}$

Initial temperature of the given cycle, $T_1 = 70^\circ\text{C} = 343\text{K}$

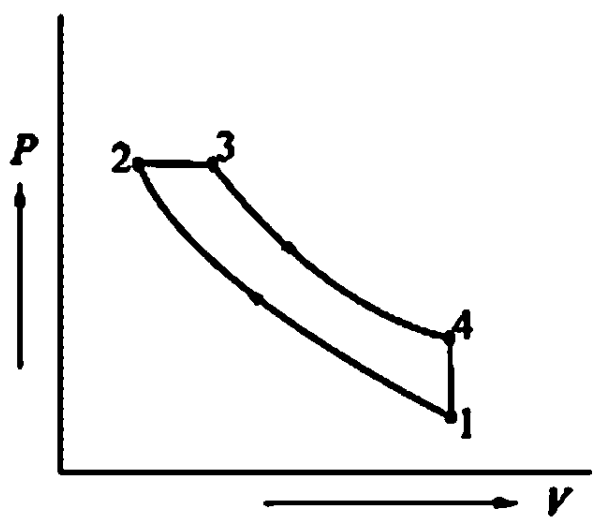
Volume of the cylinder, $V = 2\text{L} = 2\times10^{-3}\text{m}^3$

Speed of the engine, $N = 2300\text{rpm}$

Step 2 of 10

Considering constant specific heats at room temperature for Nitrogen

Gas constant $R = 0.2968\ \text{kJ/kg.K}$



$c_p = 1.039\ \text{kJ/kg.K}$

$c_v = 0.743\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 10

Representation of the ideal diesel cycle:

Step 4 of 10

An ideal Diesel cycle consists of four internally reversible processes:

1-2 isentropic compression

2-3 Constant-pressure heat addition

3-4 isentropic expansion

4-1 Constant-volume heat rejection

Step 5 of 10

From the isentropic compression process 1-2,

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 343\left(22^{1.4-1}\right)$$

$$= 1181\text{K}$$

Step 6 of 10

For the Process 2-3:

Constant pressure heat addition, we have

$$\frac{T_3}{T_2} = \frac{v_3}{v_2}$$

$$\frac{T_3}{T_2} = r_c$$

$$T_3 = 1181(1.8)$$

$$= 2125.8\text{K}$$

Step 7 of 10

For the Process 3-4:

From isentropic expansion, we have

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_4}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_2}\times\frac{v_2}{v_1}\right)^{k-1}$$

$$\frac{T_4}{T_3} = \left(r_c\times\frac{1}{r}\right)^{k-1}$$

$$T_4 = (2125.8)\left(\frac{1.8}{22}\right)^{1.4-1}$$

$$= 781\text{K}$$

Step 8 of 10

Heat supplied for the given diesel cycle,

$$q_{in} = h_3 - h_2$$

$$= c_p(T_3 - T_2)$$

$$q_{in} = (1.039)(2125.8 - 1181)$$

$$= 981.6472\text{kJ/kg}$$

Step 9 of 10

The heat rejected per unit mass for the given cycle,

$$q_{out} = u_4 - u_1$$

$$= c_v(T_4 - T_1)$$

$$= 0.743(781 - 343)$$

$$= 325.434\text{K}$$

Net work done of the given cycle,

$$w_{net} = q_{in} - q_{out}$$

$$= 981.6472 - 325.434$$

$$= 656.2132\text{kJ/kg}$$

Step 10 of 10

Mass flow rate of air for the given cycle,

$$m = \frac{P_1V}{RT_1}$$

$$= \frac{97\times2\times10^{-3}}{0.2968\times343}$$

$$= 1.9\times10^{-3}\text{kg}$$

The power delivered by the cycle,

$$P = m\times N\times w_{net}$$

$$= 1.9\times10^{-3}\times\frac{2300}{60}\times656.2134$$

$$= 47.92\text{kW}$$

Therefore the power developed by the complete cycle, $\boxed{P = 47.92\text{kW}}$

Question: 9.060P pg 1

An air-standard dual cycle has a compression ratio of 18 and a cutoff ratio of 1.1. The pressure ratio during constant-volume heat addition process is 1.1. At the beginning of the compression, $P1$= 90 kPa, $T1$= 18°C, and $V1$= 0.003 m3. How much power will this cycle produce when it is executed 4000 times per minute? Use constant specific heats at room temperature.

Step 1 of 14

Given

$$\text{Compression ratio } r = \frac{v_1}{v_2} = 18$$

$$\text{Cutoff ratios } r_c = \frac{v_4}{v_3} = 1.1$$

$$\text{Pressure ratio } r_p = \frac{p_3}{p_2} = 1.1$$

$$\text{Initial pressure } P_1 = 90\ \text{kPa}$$

$$\text{Initial temperature } T_1 = 18°\text{C}$$

$$= 18 + 273$$

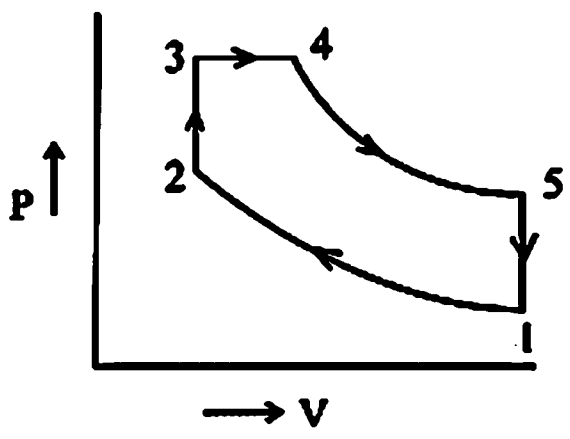
$$T_1 = 291\text{K}$$

$$\text{Initial volume } V_1 = 0.003\ \text{m}^3$$

$$\text{Revolutions per minute } N = 4000\text{RPM}$$

Step 2 of 14

Considering constant specific heats at room temperature for air



Gas constant $R = 0.287$ kJ/kg.K

$c_p = 1.005$ kJ/kg.K

$c_v = 0.718$ kJ/kg.K

$k = 1.4$

Step 3 of 14

Step 4 of 14

An ideal dual cycle consists of five internally reversible processes:

1-2 Isentropic compression

2-3 Constant-volume heat addition

3-4 Constant-pressure heat addition

4-5 Isentropic expansion

5-1 Constant-volume heat rejection

Step 5 of 14

1-2 process is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = 291\left(18^{1.4-1}\right)$$

$$T_2 = 924.7\text{K}$$

Step 6 of 14

$$\frac{P_2}{P_1} = \left(\frac{v_1}{v_2}\right)^k$$

$$\frac{P_2}{P_1} = r^k$$

$$P_2 = 90\left(18^{1.4}\right)$$

$$P_2 = 5147.8\ \text{kPa}$$

Step 7 of 14

Given

$$\frac{P_3}{P_2} = r_p$$

$$P_3 = 1.1(5147.8)$$

$$P_4 = 5662.58\ \text{kPa}$$

Step 8 of 14

Process 2-3 is constant volume heat addition

$$\frac{T_3}{T_2} = \frac{P_3}{P_2}$$

$$\frac{T_3}{T_2} = r_p$$

$$T_3 = 924.7(1.1)$$

$$T_3 = 1017.17\text{K}$$

Step 9 of 14

Process 3-4 is constant pressure heat addition

$$\frac{T_4}{T_3} = \frac{v_4}{v_3}$$

Step 9 of 14

Process 3-4 is constant pressure heat addition

$$\frac{T_4}{T_3}=\frac{v_4}{v_3}$$

$$\frac{T_4}{T_3}=r_c$$

$$T_4=1017.17(1.1)$$

$$T_4=1118.88\text{K}$$

Step 10 of 14

Process 4-5 is isentropic expansion

$$\frac{T_5}{T_4}=\left(\frac{v_4}{v_5}\right)^{k-1}$$

$$\frac{T_5}{T_4}=\left(\frac{v_4}{v_1}\right)^{k-1}$$

$$\frac{T_5}{T_4}=\left(\frac{v_4}{v_3}\times\frac{v_3}{v_1}\right)^{k-1}$$

$$\frac{T_5}{T_4}=\left(\frac{v_4}{v_3}\times\frac{v_2}{v_1}\right)^{k-1}$$

$$\frac{T_5}{T_4}=\left(\frac{r_c}{r}\right)^{k-1}$$

$$T_5=1118.88\left(\frac{1.1}{18}\right)^{1.4-1}$$

$$T_5=365.78\text{K}$$

Step 11 of 14

Heat addition is done partly in constant volume and partly in constant pressure process

$$q_{in}=c_v(T_3-T_2)+c_p(T_4-T_3)$$

$$=(0.718)(1017.17-924.7)+(1.005)(1118.88-1017.17)$$

$$=66.39+102.218$$

$$q_{in}=168.608\text{ kJ/kg}$$

Step 12 of 14

Heat rejection in the process 5-1 is

$$q_{out}=c_v(T_5-T_1)\text{ kJ/kg}$$

$$=(0.718)(365.78-291)$$

$$q_{out}=53.69\text{ kJ/kg}$$

Step 13 of 14

Net work is expressed as

$$w_{net}=q_{in}-q_{out}$$

$$=168.608-53.69$$

$$w_{net}=114.918\text{ kJ/kg}$$

Mass of air

$$m=\frac{P_1V}{RT_1}$$

$$=\frac{90\times0.003}{0.287\times291}$$

$$m=3.232\times10^{-3}\text{kg}$$

Step 14 of 14

The power delivered by the cycle

$$P=m\times N\times w_{net}\text{ kW}$$

$$P=3.232\times10^{-3}\times\frac{4000}{60}\times114.918$$

$$\boxed{P=24.76\text{ kW}}$$

Question:

Repeat Prob. 9–60 if the isentropic compression efficiency is 85 percent and the isentropic expansion efficiency is 90 percent.

Step 1 of 15

Given

Compression ratio $r = \frac{v_1}{v_2} = 18$

Cutoff ratios $r_c = \frac{v_4}{v_3} = 1.1$

Pressure ratio $r_p = \frac{p_3}{p_2} = 1.1$

Initial pressure $P_1 = 90\ \text{kPa}$

Initial temperature $T_1 = 18°\text{C}$

$= 18 + 273$

$T_1 = 291\text{K}$

Initial volume $V_1 = 0.003\ \text{m}^3$

Revolutions per minute $N = 4000\text{RPM}$

Isentropic compressor efficiency $\eta_c = 85\%$

Isentropic expansion efficiency $\eta_e = 90\%$

Step 2 of 15

Considering constant specific heats at room temperature for air

Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 15

Dual cycle consists of five internally reversible processes:

1-2 Compression process

2-3 Constant-volume heat addition

3-4 Constant-pressure heat addition

4-5 Expansion process

5-1 Constant-volume heat rejection

Step 4 of 15

1-2' process is isentropic compression

$$\frac{T_2'}{T_1} = \left(\frac{v_1}{v_2}\right)^{k-1}$$

$$\frac{T_2'}{T_1} = r^{k-1}$$

$$T_2' = 291\left(18^{1.4-1}\right)$$

$$T_2' = 924.7\text{K}$$

Step 5 of 15

Since the isentropic efficiency of the compression is given by

$$\eta_c = \frac{T_2' - T_1}{T_2 - T_1}$$

$$0.85 = \frac{924.7 - 291}{T_2 - 291}$$

$$T_2 = 1036.5\text{K}$$

Step 6 of 15

$$\frac{P_2}{P_1} = \left(\frac{v_1}{v_2}\right)^k$$

$$\frac{P_2}{P_1} = r^k$$

$$P_2 = 90\left(18^{1.4}\right)$$

$$P_2 = 5147.8\ \text{kPa}$$

Step 7 of 15

Given

$$\frac{P_3}{P_2} = r_p$$

$$P_3 = 1.1(5147.8)$$

$$P_4 = 5662.58\ \text{kPa}$$

Step 8 of 15

Process 2-3 is constant volume heat addition

$$\frac{T_3}{T_2} = \frac{P_3}{P_2}$$

$$\frac{T_3}{T_2} = r_p$$

$$T_3 = 1036.5(1.1)$$

$$T_3 = 1140.15\text{K}$$

Step 9 of 15

Process 3-4 is constant pressure heat addition

$$\frac{T_4}{T_3} = \frac{v_4}{v_3}$$

Step 9 of 15

Process 3-4 is constant pressure heat addition

$$\frac{T_4}{T_3}=\frac{v_4}{v_3}$$

$$\frac{T_4}{T_3}=r_c$$

$$T_4=1140.15(1.1)$$

$$T_4=1254.165\text{K}$$

Step 10 of 15

Process 4-5' is isentropic expansion

$$\frac{T_5'}{T_4}=\left(\frac{v_4}{v_5}\right)^{k-1}$$

$$\frac{T_5'}{T_4}=\left(\frac{v_4}{v_1}\right)^{k-1}$$

$$\frac{T_5'}{T_4}=\left(\frac{v_4}{v_3}\times\frac{v_3}{v_1}\right)^{k-1}$$

$$\frac{T_5'}{T_4}=\left(\frac{v_4}{v_3}\times\frac{v_2}{v_1}\right)^{k-1}$$

$$\frac{T_5'}{T_4}=\left(\frac{r_c}{r}\right)^{k-1}$$

$$T_5'=1254.165\left(\frac{1.1}{18}\right)^{1.4-1}$$

$$T_5'=410.0178\text{K}$$

Step 11 of 15

Since the isentropic efficiency of the expansion is given

$$\eta_{ex}=\frac{T_4-T_5}{T_4-T_5'}$$

$$0.90=\frac{1254.165-T_5}{1254.165-410.0178}$$

$$T_5=494.43\text{K}$$

Step 12 of 15

Heat addition is done partly by constant volume and partly by constant pressure process

$$q_{in}=c_v(T_3-T_2)+c_p(T_4-T_3)$$

$$=(0.718)(1140.15-1036.5)+(1.005)(1254.165-1140.15)$$

$$=74.4207+114.58$$

$$q_{in}=189\text{ kJ/kg}$$

Step 13 of 15

Heat rejection takes place in the process 5-1 at constant volume

$$q_{out}=c_v(T_5-T_1)\text{ kJ/kg}$$

$$=(0.718)(494.43-291)$$

$$q_{out}=146.062\text{ kJ/kg}$$

Step 14 of 15

Net work is expressed as

$$w_{net}=q_{in}-q_{out}$$

$$=188.9-146.062$$

$$w_{net}=42.838\text{ kJ/kg}$$

Mass of air

$$m=\frac{P_1V}{RT_1}$$

$$=\frac{90\times0.003}{0.287\times291}$$

$$m=3.232\times10^{-3}\text{kg}$$

Step 15 of 15

The power delivered by the cycle

$$P=m\times N\times w_{net}\text{ kW}$$

$$P=3.232\times10^{-3}\times\frac{4000}{60}\times42.838$$

$$\boxed{P=9.23016\text{ kW}}$$

Question: 9.062P

An ideal dual cycle has a compression ratio of 15 and a cutoff ratio of 1.4. The pressure ratio during constant-volume heat addition process is 1.1. The state of the air at the beginning of the compression is $P1$, = 14.2 psia and $T1$, = 75°F. Calculate the cycle's net specific work, specific heat addition, and thermal efficiency. Use constant specific heats at room temperature.

Step 1 of 11

Given

Compression ratio $r = \frac{V_1}{V_2} = 15$

Cutoff ratio $r_c = \frac{V_4}{V_3} = 1.4$

Pressure ratio $r_p = \frac{p_3}{p_2} = 1.1$

Initial pressure $P_1 = 14.2$ psia

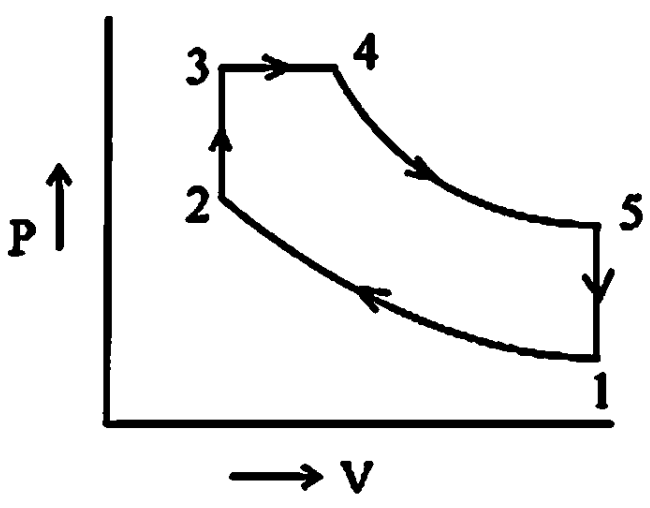
Initial temperature $T_1 = 75°F$

$= 75+460$

$T_1 = 535R$

Step 2 of 11

Considering constant specific heats at room temperature



Gas constant $R = 0.3704$ psia.ft^3/lbm.R

Specific heat at constant pressure $c_p = 0.24$ Btu/lbm.R

Specific heat at constant volume $c_v = 0.171$ Btu/lbm.R

Ratio of specific heats $k = 1.4$

Step 3 of 11

Step 4 of 11

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{k-1}$$

$$\frac{T_2}{535} = 15^{1.4-1}$$

$$T_2 = 1580.48^0 R$$

Step 5 of 11

Process 2-3 is constant-volume heat addition

$$\frac{T_3}{T_2} = \frac{P_3}{P_2}$$

$$\frac{T_3}{1580.48} = 1.1$$

$$T_3 = 1738.528^0 R$$

Step 6 of 11

Process 3-4 is constant pressure heat addition

$$\frac{T_4}{T_3} = \frac{V_4}{V_3}$$

$$\frac{T_4}{1738.528} = 1.4$$

$$T_4 = 2433.93^0 R$$

Step 7 of 11

Process 4-5 is isentropic expansion

$$\frac{T_5}{T_4} = \left(\frac{V_4}{V_5}\right)^{k-1}$$

$$\frac{T_5}{T_4} = \left(\frac{V_4}{V_1}\right)^{k-1}$$

$$\frac{T_5}{T_4} = \left(\frac{V_4}{V_2} \times \frac{V_2}{V_1}\right)^{k-1}$$

$$\frac{T_5}{T_4} = \left(\frac{V_4}{V_3} \times \frac{V_2}{V_1}\right)^{k-1}$$

$$\frac{T_5}{T_4} = \left(r_c \times \frac{1}{r}\right)^{k-1}$$

$$\frac{T_5}{2433.93} = \left(1.4 \times \frac{1}{15}\right)^{1.4-1}$$

$$T_5 = 942.589^0 R$$

Step 8 of 11

Heat addition is done partly by constant volume and constant pressure process

$$q_{in} = c_v(T_3 - T_2) + c_p(T_4 - T_3)$$

$$= (0.171)(1738.528 - 1580.48) + (0.24)(2433.93 - 1738.528)$$

$$= 27.0262 + 166.896$$

$$\boxed{q_{in} = 193.922 \text{ Btu/lbm}}$$

Step 9 of 11

Heat rejection in the process 5-1 takes place at constant volume

$$q_{out} = c_v(T_5 - T_1)$$

$$= (0.171)(942.589 - 535)$$

$$q_{out} = 69.697 \text{ Btu/lbm}$$

Step 10 of 11

Net specific work

$$w_{net} = q_{in} - q_{out}$$

$$= 193.922 - 69.697$$

$$\boxed{w_{net} = 124.225 \text{ Btu/lbm}}$$

Step 11 of 11

The thermal efficiency is defined as

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$= \frac{124.225}{193.922}$$

$$= 0.6405$$

$$\boxed{\eta_{th} = 64.05\%}$$

Question:

A six-cylinder, four-stroke, 3.2-L compression-ignition engine operates on the ideal diesel cycle with a compression ratio of 19. The air is at 95 kPa and 67°C at the beginning of the compression process and the engine speed is 1750 rpm. The engine uses light diesel fuel with a heating value of 42,500 kJ/kg, an air-fuel ratio of 28, and a combustion efficiency of 98 percent. Using constant specific heats at 850 K, determine (*a*) the maximum temperature in the cycle and the cutoff ratio (*b*) the net work output per cycle and the thermal efficiency, (*c*) the mean effective pressure, (*d*) the net power output, and (*e*) the specific fuel consumption, in g/kWh, defined as the ratio of the mass of the fuel consumed to the network produced.

Step 1 of 14

Given data:

Compression ratio, $r = \frac{V_1}{V_2} = 19$

Initial pressure, $P_1 = 95\ \text{kPa}$

Initial temperature, $T_1 = 67°\text{C} = 340\ \text{K}$

Swept volume, $V_s = 3.2\ \text{L} = 0.0032\ \text{m}^3$

Speed of the engine, $N = 1750\ \text{rpm}$

Heating value of diesel fuel, $HV = 42{,}500\ \text{kJ/kg}$

Air fuel ratio, $\frac{m_a}{m_f} = 28$

Combustion efficiency, $\eta_{comb} = 98\%$

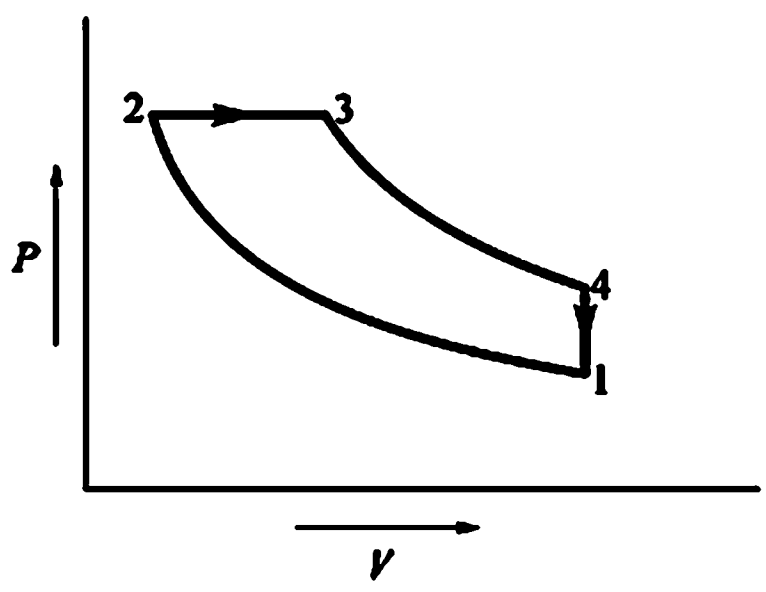
Number of cylinders, $n = 6$

Step 2 of 14

Taking constant specific heats at temperature 850K from the table of ideal gas specific heats of various common gases, we get

Gas constant, $R = 0.287\ \text{kJ/kg}\cdot\text{K}$

Specific heat at constant pressure, $c_p = 1.11\ \text{kJ/kg}\cdot\text{K}$



Specific heat at constant volume, $c_v = 0.823\ \text{kJ/kg}\cdot\text{K}$

The ratio of specific heats,

$$k = \frac{c_p}{c_v} = \frac{1.11}{0.823} = 1.349$$

Step 3 of 14

The *P-V* diagram of the process:

An ideal Diesel cycle consists of four internally reversible processes:

1-2 – An Isentropic compression

2-3 – A Constant-pressure heat addition

3-4 – An Isentropic expansion

4-1 – A Constant-volume heat rejection

Step 4 of 14

As the process 1-2 is isentropic compression, we can write

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{k-1}$$

$$\frac{T_2}{T_1} = r^{k-1}$$

$$T_2 = T_1 r^{k-1} = (340\ \text{K})(19)^{1.349-1} = 950\ \text{K}$$

Step 5 of 14

Let $V_2 = V_c$ be the volume at the end of the compression.

Thus, total volume of the cylinder at the beginning of the compression is

$V_1 = V_c + V_s$

We have,

$$r = \frac{V_1}{V_2} = \frac{V_c + V_s}{V_c}$$

$$19 = \frac{V_c + 0.0032}{V_c}$$

$$19V_c = V_c + 0.0032$$

$$V_c = 0.00018\ \text{m}^3$$

Thus,

$$V_1 = V_c + V_s = (0.00018\ \text{m}^3) + (0.0032\ \text{m}^3) = 0.00338\ \text{m}^3$$

Step 6 of 14

The total mass in the cylinder is

$$\frac{P_1 V_1}{}$$

Step 6 of 14

The total mass in the cylinder is

$$m = \frac{P_1 V_1}{R T_1}$$

$$= \frac{(95\ \text{kPa})(0.00338\ \text{m}^3)}{(0.287)(340\ \text{K})}$$

$$= 0.00329\ \text{kg}$$

The total mass is the sum of the air mass and fuel mass in the cylinder.

$$m = m_a + m_f$$

Air-fuel ratio is given by

$$\frac{m_a}{m_f} = 28$$

$$\frac{m - m_f}{m_f} = 28$$

$$0.00329 - m_f = 28 m_f$$

$$m_f = \frac{0.00329}{29}$$

$$= 0.00011\ \text{kg}$$

Step 7 of 14

(a)

The heat supplied is expressed in terms of combustion of fuel and heat addition takes place at constant pressure process

$$Q_{in} = mc_p(T_3 - T_2)$$

$$m_f \times HV \times \eta_{cc} = mc_p(T_3 - T_2)$$

$$(0.00011\ \text{kg})(42{,}500\ \text{kJ/kg})(0.98) = (0.00329\ \text{kg})(1.11\ \text{kJ/kg·K})(T_3 - 949.3\ \text{K})$$

$$T_3 - 949.3 = 1294.7$$

$$T_3 = 2244\ \text{K}$$

Hence, the maximum temperature is $\boxed{T_3 = 2244\ \text{K}}$

Step 8 of 14

The cutoff ratio is expressed as

From process 2-3

$$r_c = \frac{V_3}{V_2} = \frac{T_3}{T_2}$$

$$= \frac{2244}{950}$$

$$= 2.36$$

Hence, the cutoff ratio is $\boxed{r_c = 2.36}$

Step 9 of 14

(b)

Process 4-1 is isentropic expansion

$$\frac{T_4}{T_3} = \left(\frac{v_3}{v_4}\right)^{k-1}$$

Since $\frac{v_3}{v_4} = \frac{r_c}{r}$,

$$\frac{T_4}{T_3} = \left(\frac{r_c}{r}\right)^{k-1}$$

$$\frac{T_4}{2244} = \left(\frac{2.36}{19}\right)^{1.349-1}$$

$$T_4 = 1084\ \text{K}$$

Step 10 of 14

The heat rejection during the constant volume process is

$$Q_{out} = mc_v(T_4 - T_1)$$

$$= (0.00329\ \text{kg})(0.823)(1220.5 - 340)$$

$$= 2.01\ \text{kJ}$$

Heat input during the isobaric process,

$$Q_{in} = mc_p(T_3 - T_2)$$

$$= (0.00329\ \text{kg})(1.11)(2244 - 950)$$

$$= 4.73\ \text{kJ}$$

Step 11 of 14

The net work is expressed as

$$W_{net} = Q_{in} - Q_{out}$$

$$= 4.73 - 2.01$$

$$= 2.72\ \text{kJ}$$

Hence, the net work output is $\boxed{W_{net} = 2.72\ \text{kJ}}$

The thermal efficiency is expressed as

$$\eta_{th} = \frac{W_{net}}{Q_{in}}$$

$$= \frac{2.72}{4.73}$$

$$= 0.5755 \text{ or } 57.55\%$$

$\boxed{\eta_{th} = 57.55\%}$

Step 12 of 14

(c)

Step 12 of 14

(c)

Mean effective pressure

$$MEP = \frac{W_{net}}{V_1 - V_2}$$

$$= \frac{W_{net}}{V_1\left(1 - \frac{1}{r}\right)}$$

$$= \frac{2.72}{(0.00338)\left(1 - \frac{1}{19}\right)}$$

$$= 849 \text{ kPa}$$

Hence, the mean effective pressure is $\boxed{MEP = 849 \text{ kPa}}$

Step 13 of 14

(d)

The net power output

$$P = \frac{N}{2} \times W$$

$$= \frac{1750}{2 \times 60}(2.72)$$

$$= 39.7 \text{ kW}$$

Hence, the net power output is $\boxed{P = 45.2 \text{ kW}}$

Step 14 of 14

(e) The specific fuel consumption is given by

$$SFC = \frac{m_f}{W_{net}}$$

$$= \frac{0.00011}{2.72} \times 10^3 \times 3600$$

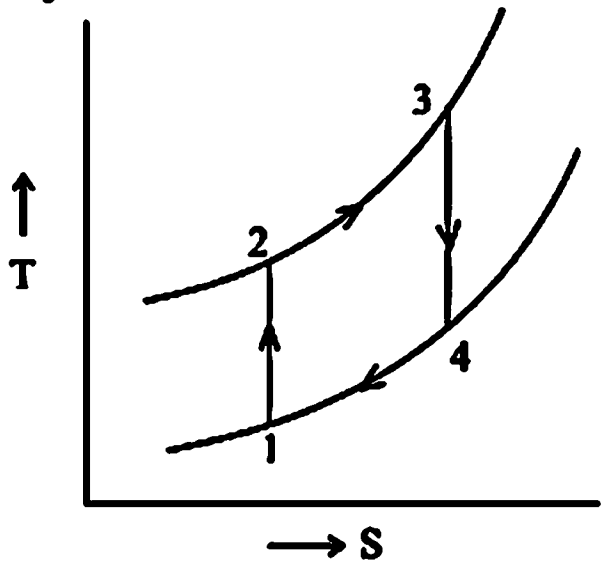
$$= 150 \text{ g/kWh}$$

Hence, the specific fuel consumption is $\boxed{SFC = 150 \text{ g/kWh}}$

Question: 9.064P

What four processes make up the simple ideal Brayton cycle?

Step 1 of 1



An ideal Brayton cycle consists of four processes:

1-2 isentropic compression

2-3 Constant pressure heat addition

3-4 isentropic expansion

4-1 Constant pressure heat rejection

Question: 9.065P

For fixed maximum and minimum temperatures, what is the effect of the pressure ratio on (*a*) the thermal efficiency and (*b*) the network output of a simple ideal Brayton cycle?

Step 1 of 1

The efficiency of a Brayton cycle is expressed as

$$\eta = 1 - \frac{1}{r_p^{\frac{k-1}{k}}}$$

(a) As the pressure ratio increases the thermal efficiency also increases.

(b) The work output first increases then decreases because at very high pressure ratios the increased turbine inlet temperature will destroy the blades for turbine will leads to loss in work output.

Question: 9.066P

What is the back work ratio? What arc typical back work ratio values for gas-turbine engines?

Step 1 of 1

The fraction of the turbine work used to drive the compressor is called the back work ratio.

$$r_{bw} = \frac{\dot{W}_{comp,in}}{\dot{W}_{turb,out}}$$

In gas turbine power plants the back work ratio is high compared to the steam power plants. In gas turbine engines the back work ratio lies between 0.4 to 0.6

Question: 9.067P

Why are the back work ratios relatively high in gas-turbine engines?

Step 1 of 1

The fraction of the turbine work used to drive the compressor is called the back work ratio. The back work ratio is usually very high in gas turbine power plants; usually more than one half of the turbine work output is used to drive the compressor.

In steam power plants the back work ratio is only a few percent. Liquid is compressed in steam power plants where as in gas turbine, gas is compressed and the steady-flow work is proportional to the specific volume of the working fluid.

Question: 9.068P

How do the inefficiencies of the turbine and the compressor affect (*a*) the back work ratio and (*b*) the thermal efficiency of a gas-turbine engine?

Step 1 of 1

Usually more than one half of the turbine work output is used to drive the compressor. The back work of the gas turbine still increases when the isentropic efficiencies of the compressor and the turbine are low and the efficiency of the gas turbine decreases. So the inefficiencies of the turbine and the compressor

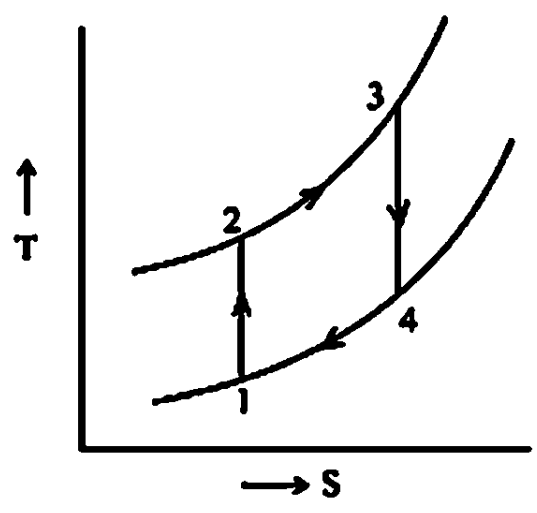
(a) The back work ratio of the gas turbine engine increases

(b) The thermal efficiency decreases.

Question: 9.069P

A simple ideal Brayton cycle with air as the working fluid has a pressure ratio of 10. The air enters the compressor at 520 R and the turbine at 2000 R. Accounting for the variation of specific heats with temperature, determine (*a*) the air temperature at the compressor exit, (*b*) the back work ratio, and (*c*) the thermal efficiency.

Step 1 of 12



Given

Pressure ratio $r_p = 10$

Compressor inlet temperature $T_1 = 520\text{R}$

Turbine inlet temperature to $T_3 = 2000\text{R}$

Step 2 of 12

Step 3 of 12

Since we are considering variable specific heats the specific heat at constant pressure and specific heat at constant volume will be different at different temperatures.

At $T_1 = 520\text{R}$ from ideal gas properties of air tables

$h_1 = 124.27\ \text{Btu/lbm}$

$P_{r1} = 1.2147$

At $T_3 = 2000\text{R}$ from ideal gas properties of air tables

$h_3 = 504.71\ \text{Btu/lbm}$

$P_{r3} = 174.0$

Step 4 of 12

(a)

Process 1-2 is isentropic compression

$$\frac{P_2}{P_1} = \frac{P_{r2}}{P_{r1}}$$

$$P_{r2} = P_{r1}\frac{P_2}{P_1}$$

$$P_{r2} = 1.2147 \times 10$$

$$P_{r2} = 12.147$$

At $P_{r2} = 12.147$ from ideal gas properties of air

$$T_2 = 980 + (1000 - 980)\left(\frac{12.147 - 11.43}{12.30 - 11.43}\right)$$

$$\boxed{T_2 = 996.48\text{R}}$$

$$h_2 = 236.02 + (240.98 - 236.02)\left(\frac{12.147 - 11.43}{12.30 - 11.43}\right)$$

$$h_2 = 240.107\ \text{Btu/lbm}$$

Step 5 of 12

(b)

Process 3-4 is isentropic expansion

We know that

$$\frac{P_4}{P_3} = \frac{P_{r4}}{P_{r3}}$$

$$\frac{P_1}{P_2} = \frac{P_{r4}}{P_{r3}}$$

$$P_{r4} = P_{r3} \times \frac{P_1}{P_2}$$

$$P_{r4} = 174 \times \frac{1}{10}$$

$$P_{r4} = 17.4$$

Step 6 of 12

At $P_{r4} = 17.4$ from ideal gas properties of air

$$T_4 = 1080 + (1120 - 1080)\left(\frac{17.4 - 16.28}{18.60 - 16.28}\right)$$

$$T_4 = 1099.31\text{R}$$

$$h_4 = 260.97 + (271.03 - 260.97)\left(\frac{17.4 - 16.28}{18.60 - 16.28}\right)$$

$$h_4 = 265.826\ \text{Btu/lbm}$$

Step 7 of 12

The work required by compressor is expressed as

$$w_c = h_2 - h_1$$

$$w_c = 240.107 - 124.27$$

$$w_c = 115.837\ \text{Btu/lbm}$$

Step 8 of 12

The work done by turbine is expressed as

$$w_t = h_3 - h_4$$

$$w_t = 504.71 - 265.826$$

$$w_t = 238.884\ \text{Btu/lbm}$$

Step 9 of 12

The back work ratio

$$r_{bw} = \frac{w_c}{w_t}$$

$$= \frac{115.837}{238.884}$$

$$\boxed{r_{bw} = 0.484}$$

Step 10 of 12

(c) The thermal efficiency

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

Heat supplied

$$q_{in} = h_3 - h_2$$

$$= 504.71 - 240.107$$

$$q_{in} = 264.603\ \text{Btu/lbm}$$

Step 11 of 12

Net work is expressed as

$$w_{net} = w_t - w_c$$

$$= 238.884 - 115.837$$

$$w_{net} = 123.047\ \text{Btu/lbm}$$

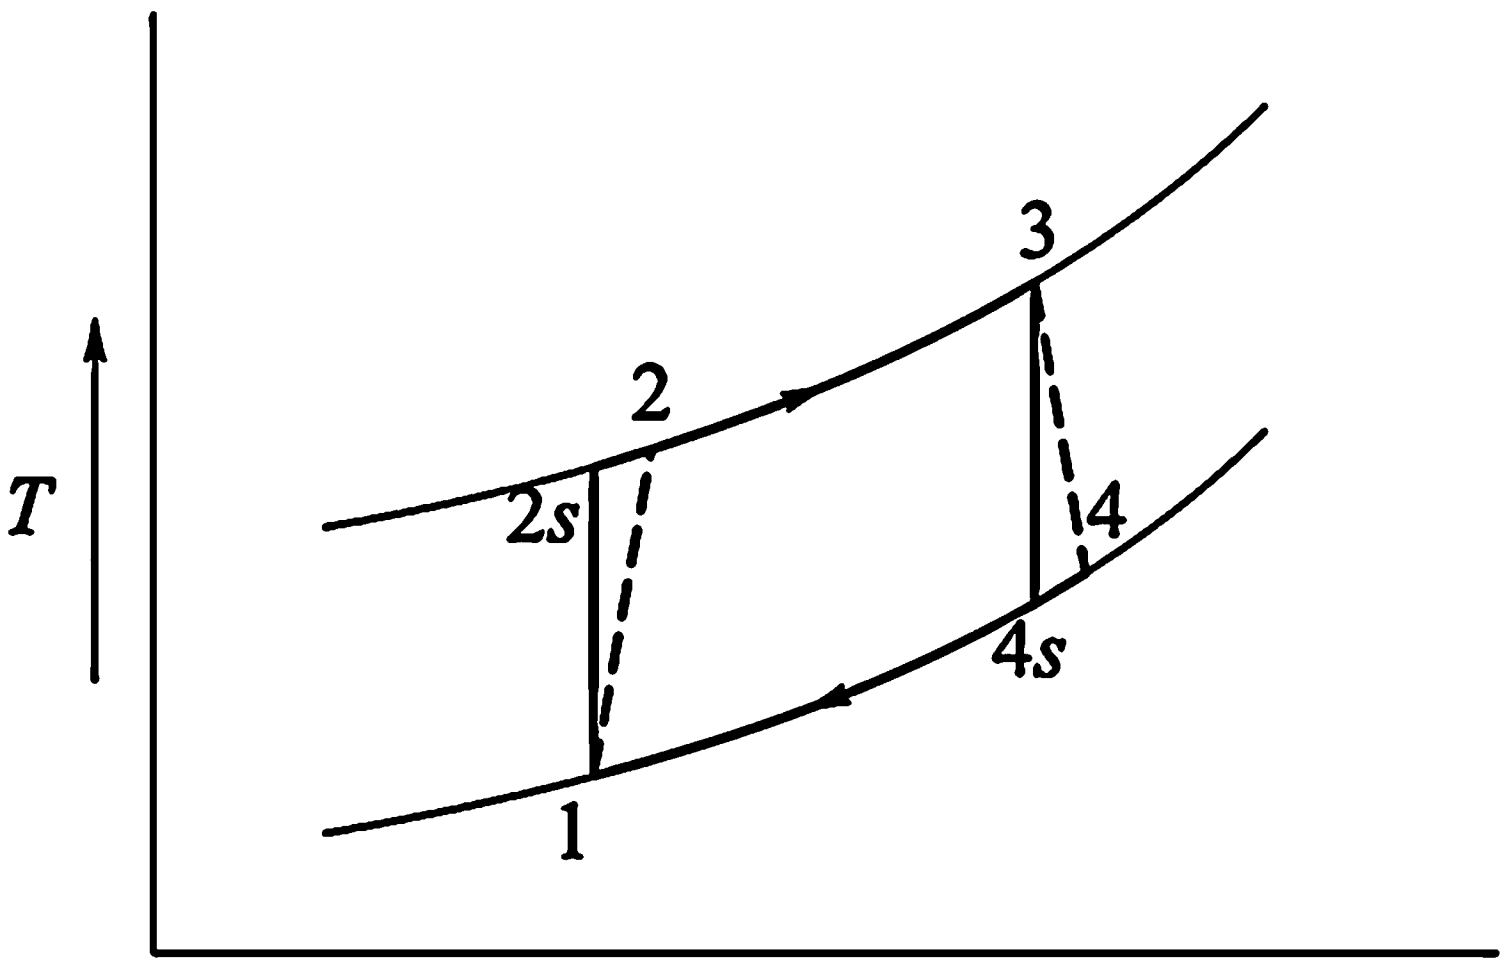
Step 12 of 12

Therefore the thermal efficiency

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$\eta_{th} = \frac{123.047}{264.603}$$

$$= 0.465$$



$$\boxed{\eta_{th} = 46.5\%}$$

Question:

A simple Brayton cycle using air as the working fluid has a pressure ratio of 10. The minimum and maximum temperatures in the cycle are 295 and 1240 K. Assuming an isentropic efficiency of 83 percent for the compressor and 87 percent for the turbine, determine (*a*) the air temperature at the turbine exit, (*b*) the net work output, and (*c*) the thermal efficiency.

Step 1 of 8

The *T-s* diagram of the process:

Step 2 of 8

Find the pressure using isentropic compression from process 1-2*s*.

$$\frac{P_2}{P_1} = \frac{P_{r2s}}{P_{r1}}$$

$$P_{r2s} = \left(\frac{P_2}{P_1}\right) P_{r1}$$

$$= r_p P_{r1}$$

Here, pressure ration is r_p and pressure at 295 K is P_{r1}

Form ideal gas properties of air table at $295\ \text{K}$, saturation pressure is $1.3068\ \text{kPa}$.

Substitute, 10 for r_p and $1.3068\ \text{kPa}$ for P_{r1} .

$$P_{r2s} = r_p P_{r1}$$

$$= 10 \times (1.3068)$$

$$= 13.068\ \text{kPa}$$

Step 3 of 8

Form ideal gas properties of air table at pressure is $13.068\ \text{kPa}$ interpolate for enthalpy.

$$h_{2s} = 565.17 + (575.59 - 565.17)\left(\frac{13.068 - 12.66}{13.5 - 12.66}\right)$$

$$= 570.23\ \text{kJ/kg}$$

Find the enthalpy at stage 2 using isentropic efficiency of the compressor is given by

$$\eta_c = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.83 = \frac{570.23 - 295.17}{h_2 - 295.17}$$

$$h_2 = 626.57\ \text{kJ/kg}$$

Step 4 of 8

Form ideal gas properties of air table at $1240\ \text{K}$. pressure is $272.3\ \text{kPa}$.

Process 3-4*s* is an isentropic expansion

$$\frac{P_4}{P_3} = \frac{P_{r4s}}{P_{r3}}$$

$$\frac{P_1}{P_2} = \frac{P_{r4s}}{P_{r3}}$$

$$P_{r4s} = \left(\frac{P_1}{P_2}\right) P_{r3}$$

$$P_{r4s} = \frac{1}{r_p} P_{r3}$$

Substitute, 10 for r_p and $272.3\ \text{kPa}$ for P_{r2} .

$$P_{r4s} = \frac{1}{r_p} P_{r3}$$

$$= \left(\frac{1}{10}\right)(272.3)$$

$$= 27.23$$

Interpolate for enthalpy at $27.23\ \text{kPa}$ from ideal gas properties of air.

$$h_{4s} = 691.82 + (702.52 - 691.82)\left(\frac{27.23 - 25.85}{27.29 - 25.85}\right)$$

$$= 702.07\ \text{kJ/kg}$$

Find the actual enthalpy at stage 4 isentropic efficiency of the turbine is given by

$$\eta_t = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$= 702.07 \text{ kJ/kg}$

Find the actual enthalpy at stage 4 isentropic efficiency of the turbine is given by

$$\eta_t = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$0.87 = \frac{1324.93 - h_4}{1324.93 - 702.07}$$

$$h_4 = 783.05 \text{ kJ/kg}$$

Step 5 of 8

(a)

Find the temperature at turbine exit by interpolating for enthalpy at stage 4.

$$T_4 = 760 + (780 - 760)\left(\frac{783.05 - 778.18}{800.03 - 778.18}\right)$$

$$= 764.45 \text{ K}$$

Therefore, the temperature at the exit of the turbine is $\boxed{T_4 = 764.45 \text{ K}}$

Step 6 of 8

(b)

Find work input to compressor is

$$w_c = h_2 - h_1$$

Form ideal gas properties of air table at 295 K, enthalpy is 295.17 kJ/kg.

Substitute, 626.57 kJ/kg for h_2 and 295.17 kJ/kg for h_1.

$$w_c = h_2 - h_1$$
$$= 626.57 - 295.17$$
$$= 331.4 \text{ kJ/kg}$$

Step 7 of 8

Find work input to compressor is

$$w_t = h_3 - h_4$$

Form ideal gas properties of air table at 1240 K, enthalpy is 1324.93 kJ/kg.

Substitute, 1324.93 kJ/kg for h_3 and 783.05 kJ/kg for h_1.

$$w_t = h_3 - h_4$$
$$= 1324.93 - 783.05$$
$$= 541.88 \text{ kJ/kg}$$

Find Net-work can be expressed as the difference of the turbine output and compressor input.

$$w_{net} = w_t - w_c$$
$$= 541.88 - 331.4$$
$$= 210.48$$

Hence, the net-work output of the cycle is $\boxed{w_{net} = 210.48 \text{ kJ/kg}}$

Step 8 of 8

(c)

The thermal efficiency is given by

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$
$$= \frac{w_{net}}{h_3 - h_2}$$

Substitute, 210.48 kJ/kg for w_{net}, 1324.93 kJ/kg for h_3 and 626.57 kJ/kg for h_2

$$\eta_{th} = \frac{w_{net}}{h_3 - h_2}$$
$$= \frac{210.48}{1324.93 - 626.57}$$
$$= 0.3014$$
$$= 30.14\%$$

Therefore, the thermal efficiency is $\boxed{\eta_{th} = 30.14\%}$

Question: 9.071P

Reconsider Prob. 9–70. Using EES (or other) software, allow the mass flow rate, pressure ratio, turbine inlet temperature, and the isentropic efficiencies of the turbine and compressor to vary. Assume the compressor inlet pressure is kPa. Develop a general solution for the problem by taking advantage of the diagram window method for supplying data to EES software.

We don't have the solution to this problem yet.

Get help from a Chegg subject expert.

Ask an expert

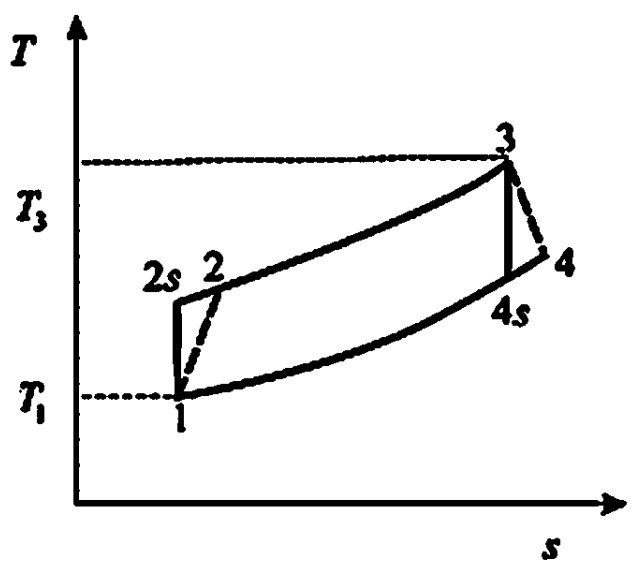
Question: 9.072P

Repeat Prob. 9–70 using constant specific heats at room temperature.

Step 1 of 8

Pressure ratio, $r = \frac{P_2}{P_1} = 10$

Minimum temperature of the cycle, $T_1 = 295\text{K}$



Maximum temperature of the cycle, $T_3 = 1240\text{K}$

Isentropic efficiency of the compressor, $\eta_c = 0.83$

Isentropic turbine efficiency of the compressor, $\eta_T = 0.87$

Step 2 of 8

T-s diagram of cycle:

Step 3 of 8

a)

From the isentropic relation of the compressor is

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{2s}}{295} = (10)^{\frac{1.4-1}{1.4}}$$

$$T_{2s} = 569.55\text{K}$$

Similarly, for turbine

$$\frac{T_{4s}}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{4s}}{1240} = \left(\frac{1}{10}\right)^{\frac{1.4-1}{1.4}}$$

$$T_{4s} = 642.254\text{K}$$

Step 4 of 8

From the relation of isentropic efficiency of the compressor is

$$\eta_c = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)}$$

$$0.83 = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_c}$$

$$= 295 + \frac{569.55 - 295}{0.83}$$

$$= 625.783\text{K}$$

Step 5 of 8

Similarly for turbine, isentropic efficiency of the turbine is given as

$$\eta_T = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})}$$

$$0.87 = \frac{T_3 - T_4}{T_3 - T_{4s}}$$

$$T_4 = T_3 - \eta(T_3 - T_{4s})$$

$$= 1240 - 0.87(1240 - 642.254)$$

$$= 719.96\text{K}$$

Therefore, turbine exit temperature is $\boxed{T_4 = 719.96\text{K}}$

Step 6 of 8

b)

Heat input to the compressor is

$$q_{23} = c_p(T_3 - T_2)$$

$$= 1.005(1240 - 625.783)$$

$$= 617.288\ \text{kJ/kg}$$

Power output from the turbine is

$$q_{41} = c_p(T_4 - T_1)$$

$$= 1.005(719.96 - 295)$$

$$= 427.08\text{kJ/kg}$$

Step 7 of 8

Net work done of the cycle is

$$W_{net} = q_{23} - q_{41}$$

$$= 617.288 - 427.08$$

$$= 190.208\text{kJ/kg}$$

Therefore, net work done of the turbine is $\boxed{W_{net} = 190.208\text{kJ/kg}}$

Step 8 of 8

c)

Thermal efficiency of the cycle is

$$\eta = \frac{W_{net}}{q_{23}}$$

$$= \frac{190.208}{617.288}$$

$$= 0.308$$

$$= 30.81\%$$

Therefore, turbine efficiency is $\boxed{\eta = 30.81\%}$

Question: 9.073P

A simple ideal Brayton cycle uses helium as the working fluid; operates with 12 psia and 60°F at the compressor inlet; has a pressure ratio of 14; and a maximum cycle temperature of 1300°F. How much power will this cycle produce when the rate at which the helium is circulated about the cycle is 100 lbm/min? Use constant specific heats at room temperature.

Step 1 of 7

Given,

Temperature of gas at compressor inlet, $T_1 = 60^0\text{F}$

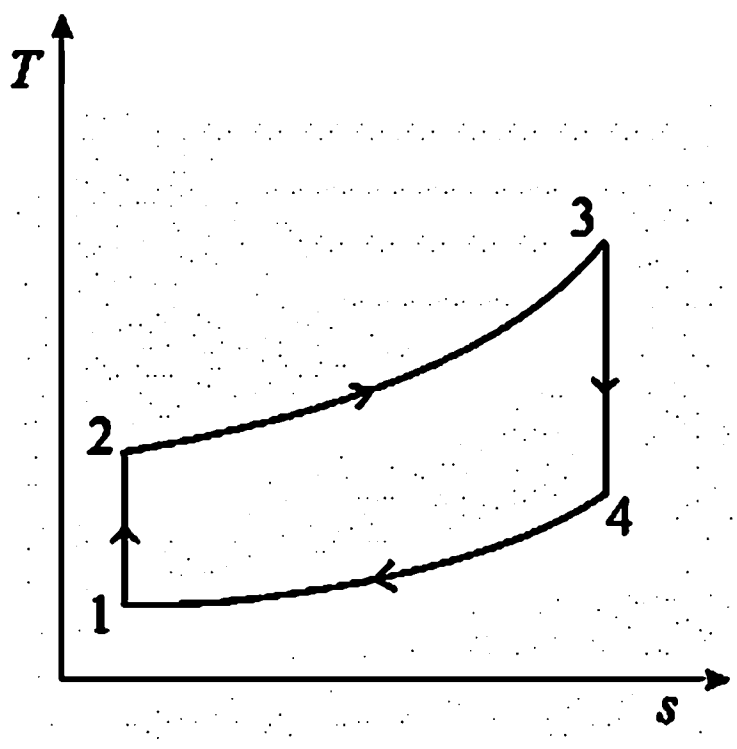
Pressure of gas at compressor inlet, $P_1 = 12$ psia

Pressure ratio, $r_p = 14$

Maximum temperature, $T_3 = 1300^0\text{F}$

$T_3 = 1760$ R

Mass flow rate of gas, $\dot{m} = 100$ lbm/min



Properties of helium, $R = 0.5$ Btu/lbmF

$c_p = 1.25$ Btu/lbmF

$c_v = 0.75$ Btu/lbmF

$k = 1.667$

Step 2 of 7

Step 3 of 7

Process 1-2 is of Isentropic Compression and hence it follows $\frac{P_1^{(k-1)/k}}{T_1} = \frac{P_2^{(k-1)/k}}{T_2}$

$$T_2 = T_1 \frac{P_2^{(k-1)/k}}{P_1^{(k-1)/k}}$$

$$T_2 = T_1 \left(\frac{P_2}{P_1}\right)^{(k-1)/k}$$

$$T_2 = T_1 \times (r)^{(k-1)/k}$$

$$T_2 = (60+460) \times (14)^{(1.667-1)/1.667}$$

$$T_2 = 1494.8 \text{ R}$$

Step 4 of 7

Process 3-4 is of Isentropic expansion and hence it follows $\frac{P_3^{(k-1)/k}}{T_3} = \frac{P_4^{(k-1)/k}}{T_4}$

$$T_4 = T_3 \frac{P_4^{(k-1)/k}}{P_3^{(k-1)/k}}$$

$$T_4 = T_3 \times \left(\frac{P_1}{P_2}\right)^{(k-1)/k}$$

$$T_4 = T_3 \times \left(\frac{1}{r}\right)^{(k-1)/k}$$

$$T_4 = (1760) \times \left(\frac{1}{14}\right)^{(1.667-1)/1.667}$$

$$T_4 = 612.24 \text{ R}$$

Step 5 of 7

Process 2-3 is Constant pressure heat addition hence heat supplied is

$$Q_{in} = mc_p (T_3 - T_2)$$

$$Q_{in} = \frac{100}{60} \times 1.25 \times (1760 - 1494.8)$$

$$Q_{in} = 552.5 \text{ Btu/s}$$

Hence heat input is $\boxed{Q_{in} = 552.5 \text{ Btu/s}}$

Step 6 of 7

Process 4-1 is a Constant pressure heat rejection hence heat rejected is,

$$Q_{out} = mc_p (T_4 - T_1)$$

$$Q_{out} = \frac{100}{60} \times 1.25 \times (612.24 - 520)$$

$$Q_{out} = 192.17 \text{ Btu/s}$$

Hence heat rejected is $\boxed{Q_{out} = 192.17 \text{ Btu/s}}$

Step 7 of 7

Net work output obtained is given by,

$$W_{net} = Q_{in} - Q_{out}$$

$$W_{net} = 552.5 - 192.17$$

$$W_{net} = 360.33 \text{ Btu/s}$$

Net work output is $\boxed{W_{net} = 360.33 \text{ Btu/s}}$

Question: 9.074P

Repeat Prob. 9-73E when the isentropic efficiency of the compressor is 95 percent.

Step 1 of 8

Given,

Temperature of gas at compressor inlet, $T_1 = 60^0\text{F}$

Pressure of gas at compressor inlet, $P_1 = 12$ psia

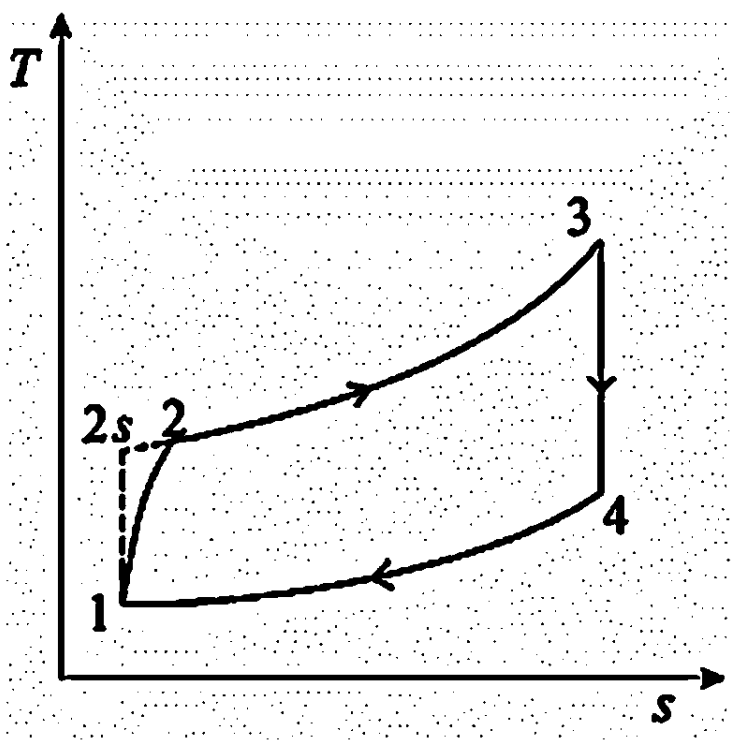
Pressure ratio, $r_p = 14$

Maximum temperature, $T_3 = 1300^0\text{F}$

$T_3 = 1760$ R

Mass flow rate of gas, $m = 100$ lbm/min

Isentropic efficiency of $\eta_{comp} = 0.95$



Properties of helium, $R = 0.5$ Btu/lbmF

$c_p = 1.25$ Btu/lbmF

$c_v = 0.75$ Btu/lbmF

$k = 1.667$

Step 2 of 8

Step 3 of 8

Process 1-2s is of Isentropic Compression and hence it follows $\frac{P_1^{(k-1)/k}}{T_1} = \frac{P_2^{(k-1)/k}}{T_{2s}}$

$$T_{2s} = T_1 \frac{P_2^{(k-1)/k}}{P_1^{(k-1)/k}}$$

$$T_{2s} = T_1 \left(\frac{P_2}{P_1}\right)^{(k-1)/k}$$

$$T_{2s} = T_1 \times (r)^{(k-1)/k}$$

$$T_{2s} = (60+460) \times (14)^{(1.667-1)/1.667}$$

$$T_{2s} = 1494.8 \text{ R}$$

Step 4 of 8

Compressor isentropic efficiency is

$$\eta_{comp} = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$0.95 = \frac{1494.8 - 520}{T_2 - 520}$$

$$T_2 - 520 = \frac{1494.8 - 520}{0.95}$$

$$T_2 = 520 + \frac{1494.8 - 520}{0.95}$$

$$T_2 = 1546.1 \text{ R}$$

Step 5 of 8

Process 3-4 is of isentropic expansion and hence it follows

$$\frac{P_3^{(k-1)/k}}{T_3} = \frac{P_4^{(k-1)/k}}{T_4}$$

$$T_4 = T_3 \frac{P_4^{(k-1)/k}}{P_3^{(k-1)/k}}$$

$$T_4 = T_3 \times \left(\frac{P_1}{P_2}\right)^{(k-1)/k}$$

$$T_4 = T_3 \times \left(\frac{1}{r}\right)^{(k-1)/k}$$

$$T_4 = (1760) \times \left(\frac{1}{14}\right)^{(1.667-1)/1.667}$$

$$T_4 = 612.24 \text{ R}$$

Step 6 of 8

Process 2-3 is Constant pressure heat addition hence heat supplied is

$$Q_{in} = mc_p (T_3 - T_2)$$

$$Q_{in} = \frac{100}{60} \times 1.25 \times (1760 - 1546.1)$$

$$Q_{in} = 445.625 \text{ Btu/s}$$

Hence heat input is $\boxed{Q_{in} = 445.625 \text{ Btu/s}}$

Step 7 of 8

Process 4-1 is a Constant pressure heat rejection hence heat rejected is,

$$Q_{out} = mc_p (T_4 - T_1)$$

$$Q_{out} = \frac{100}{60} \times 1.25 \times (612.24 - 520)$$

$$Q_{out} = 192.17 \text{ Btu/s}$$

Hence heat rejected is $\boxed{Q_{out} = 192.17 \text{ Btu/s}}$

Step 8 of 8

Net work output obtained is given by,

$$W_{net} = Q_{in} - Q_{out}$$

$$W_{net} = 445.625 - 192.17$$

$$W_{net} = 253.455 \text{ Btu/s}$$

Net work output is $\boxed{W_{net} = 253.455 \text{ Btu/s}}$

Question: 9.075P pg 1

Consider a simple Brayton cycle using air as the working fluid; has a pressure ratio of 12; has a maximum cycle temperature of 600°C; and operates the compressor inlet at 90 kPa and 15°C. Which will have the greatest impact on the back-work ratio: a compressor isentropic efficiency of 90 percent or a turbine isentropic efficiency of 90 percent? Use constant specific heats at room temperature.

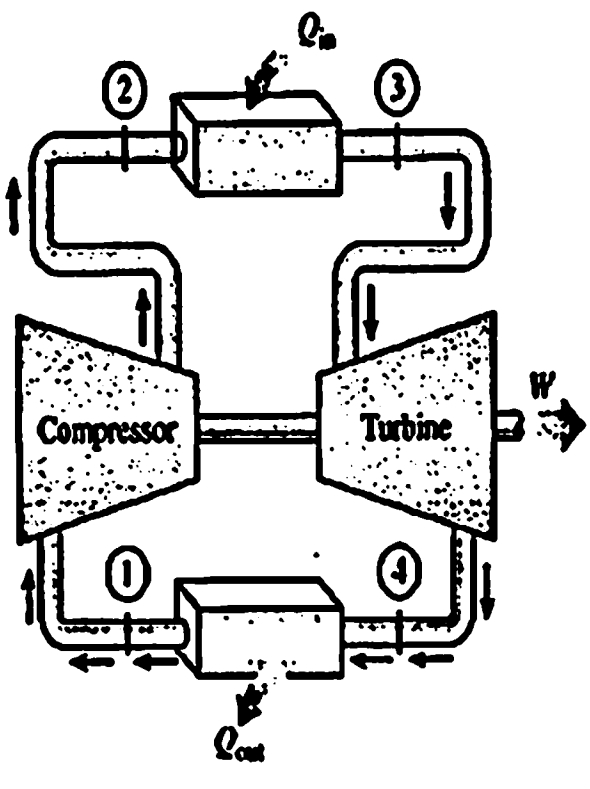


FIGURE P9–75

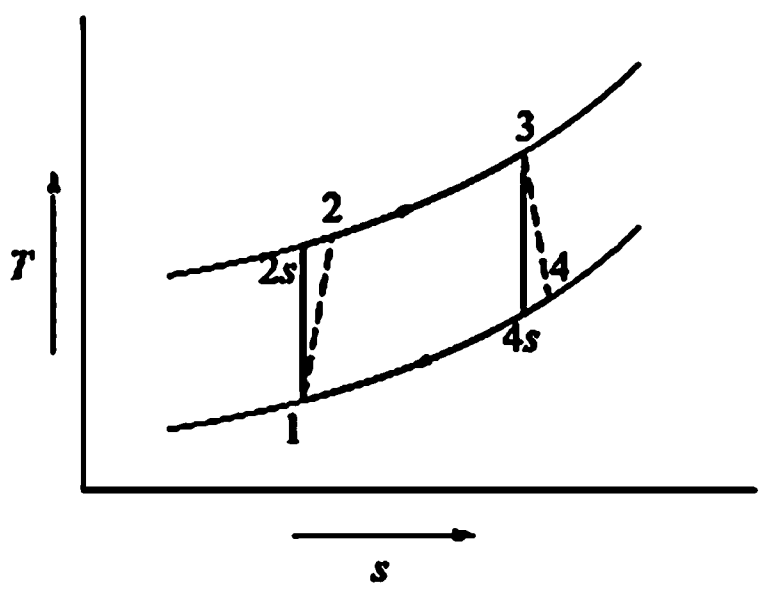
Step 1 of 11

Given data:

Pressure ratio, $r_p = \frac{P_2}{P_1} = \frac{P_3}{P_4} = 12$

The maximum temperature, $T_3 = 600°C = 873\ K$

Inlet temperature to the compressor, $T_1 = 15°C = 288\ K$



Inlet pressure to the compressor, $P_1 = 90\ kPa$

Isentropic efficiency of the compressor, $\eta_c = 90\%$

Isentropic efficiency of the turbine, $\eta_t = 90\%$

Step 2 of 11

The *T*-*s* diagram of the process:

Step 3 of 11

Since we are considering variable specific heats the specific heats at constant pressure and constant volume will be different at different temperatures

At $T_1 = 288\ K$, from ideal gas properties of air table and interpolation, we get

$$h_1 = (285.14\ kJ/kg) + (290.16\ kJ/kg - 285.14\ kJ/kg)\left(\frac{288\ K - 285\ K}{290\ K - 285\ K}\right)$$

$$= 288.15\ kJ/kg$$

$$P_{r1} = 1.1584 + (1.2311 - 1.1584)\left(\frac{288\ K - 285\ K}{290\ K - 285\ K}\right)$$

$$= 1.2020$$

At $T_3 = 873\ K$, from ideal gas properties of air table and interpolation, we get

$$h_3 = (888.27\ kJ/kg) + (910.56\ kJ/kg - 888.27\ kJ/kg)\left(\frac{873\ K - 860\ K}{880\ K - 860\ K}\right)$$

$$= 902.76\ kJ/kg$$

$$P_{r3} = 63.09 + (68.98 - 63.09)\left(\frac{873\ K - 860\ K}{880\ K - 860\ K}\right)$$

$$= 66.92$$

Step 4 of 11

Process 1-2*s* is isentropic compression

$$\frac{P_2}{P_1} = \frac{P_{r2s}}{P_{r1}}$$

$$P_{r2s} = \left(\frac{P_2}{P_1}\right) P_{r1}$$

$$= 12 \times (1.2020)$$

$$= 14.424$$

At $P_{r2s} = 14.424$ from ideal gas properties of air and interpolation, we get

$$h_{2s} = (586.04\ kJ/kg) + (596.52\ kJ/kg - 586.04\ kJ/kg)\left(\frac{14.424 - 14.38}{15.31 - 14.38}\right)$$

$$= 586.54\ kJ/kg$$

Step 5 of 11

Process 3-4*s* is an isentropic expansion

$$\frac{P_4}{P_3} = \frac{P_{r4s}}{P_{r3}}$$

$$P_{r4s} = \left(\frac{P_4}{P_3}\right) P_{r3}$$

$$= \left(\frac{1}{12}\right)(66.92)$$

$$= 5.577$$

$$= \left(\frac{1}{12}\right)(66.92)$$
$$= 5.577$$

At $P_{r4,s} = 5.577$ from ideal gas properties of air and interpolation, we get

$$h_{4,s} = (441.61\ \text{kJ/kg}) + (451.80\ \text{kJ/kg} - 441.61\ \text{kJ/kg})\left(\frac{5.577 - 5.332}{5.775 - 5.332}\right)$$
$$= 447.24\ \text{kJ/kg}$$

Step 6 of 11

To figure out the impact of the isentropic efficiencies on the back work ratios, we shall consider three cases to evaluate back work ratio.

Case 1:
When both the turbine and compressor are ideal having an isentropic efficiency of 100%
Then, $h_2 = h_{2,s} = 586.54\ \text{kJ/kg}$ and $h_4 = h_{4,s} = 447.24\ \text{kJ/kg}$

Input to the compressor,
$$w_{comp,in} = h_2 - h_1$$
$$= 586.54\ \text{kJ/kg} - 288.15\ \text{kJ/kg}$$
$$= 298.39\ \text{kJ/kg}$$

Output from the turbine,
$$w_{turbine,out} = h_3 - h_4$$
$$= 902.76\ \text{kJ/kg} - 447.24\ \text{kJ/kg}$$
$$= 455.52\ \text{kJ/kg}$$

Step 7 of 11

The back work ratio can be calculated as

$$r_{bw} = \frac{w_{comp,in}}{w_{turbine,out}}$$
$$= \frac{298.39\ \text{kJ/kg}}{455.52\ \text{kJ/kg}}$$
$$= 0.655$$

Hence, the back work ratio in this case is $r_{bw} = 0.655$

Step 8 of 11

Case 2:
When the compressor's isentropic efficiency is 90% and turbine is ideal
Then, $h_4 = h_{4,s} = 447.24\ \text{kJ/kg}$

Isentropic efficiency of the compressor is given by

$$\eta_c = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$h_2 - h_1 = \frac{h_{2s} - h_1}{\eta_c}$$
$$= \frac{586.54\ \text{kJ/kg} - 288.15\ \text{kJ/kg}}{0.90}$$
$$= 331.54\ \text{kJ/kg}$$

The input to the compressor,
$$w_{comp,in} = h_2 - h_1$$
$$= 331.54\ \text{kJ/kg}$$

Step 9 of 11

Output from the turbine,
$$w_{turbine,out} = h_3 - h_4$$
$$= 902.76\ \text{kJ/kg} - 447.24\ \text{kJ/kg}$$
$$= 455.52\ \text{kJ/kg}$$

The back work ratio can be calculated as

$$r_{bw} = \frac{w_{comp,in}}{w_{turbine,out}}$$
$$= \frac{331.54\ \text{kJ/kg}}{455.52\ \text{kJ/kg}}$$
$$= 0.728$$

Hence, the back work ratio in this case is $r_{bw} = 0.728$

Therefore, if the isentropic compressor efficiency is 90%, the back work ratio increased by 0.073.

Step 10 of 11

Case 2:
When the turbine's isentropic efficiency is 90% and compressor is ideal
Then, $h_2 = h_{2,s} = 586.54\ \text{kJ/kg}$

Isentropic efficiency of the turbine is given by

$$\eta_t = \frac{h_3 - h_4}{h_3 - h_{4,s}}$$

$$h_3 - h_4 = \eta_t (h_3 - h_{4,s})$$
$$= 0.90(902.76\ \text{kJ/kg} - 447.24\ \text{kJ/kg})$$
$$= 408.97\ \text{kJ/kg}$$

Work output from the turbine,
$$w_{turbine,out} = h_3 - h_4$$
$$= 408.97\ \text{kJ/kg}$$

Work output from the turbine, 9.075P pg 3

$$w_{turbine,out} = h_3 - h_4$$
$$= 408.97 \text{ kJ/kg}$$

Step 11 of 11

Work input to the compressor,

$$w_{comp,in} = h_2 - h_1$$
$$= 586.54 \text{ kJ/kg} - 288.15 \text{ kJ/kg}$$
$$= 298.39 \text{ kJ/kg}$$

The back work ratio can be calculated as

$$r_{bw} = \frac{w_{comp,in}}{w_{turbine,out}}$$
$$= \frac{298.39 \text{ kJ/kg}}{409.97 \text{ kJ/kg}}$$
$$= 0.728$$

Hence, the back work ratio in this case is $r_{bw} = 0.728$

Therefore, if the isentropic turbine efficiency is 90%, the back work ratio increased by 0.073.

Thus, the impact is same for both the cases of turbine having an isentropic efficiency of 90% and compressor having an isentropic efficiency of 90%.

Question:

Air is used as the working fluid in a simple ideal Brayton cycle that has a pressure ratio of 12, a compressor inlet temperature of 300 K, and a turbine inlet temperature of 1000 K. Determine the required mass flow rate of air for a net power output of 70 MW, assuming both the compressor and the turbine have an isentropic efficiency of (*a*) 100 percent and (*b*) 85 percent. Assume constant specific heats at room temperature.

Step 1 of 14

Given

Pressure ratio $r_p = \frac{P_2}{P_1} = 12$

Maximum temperature $T_3 = 1000\text{K}$

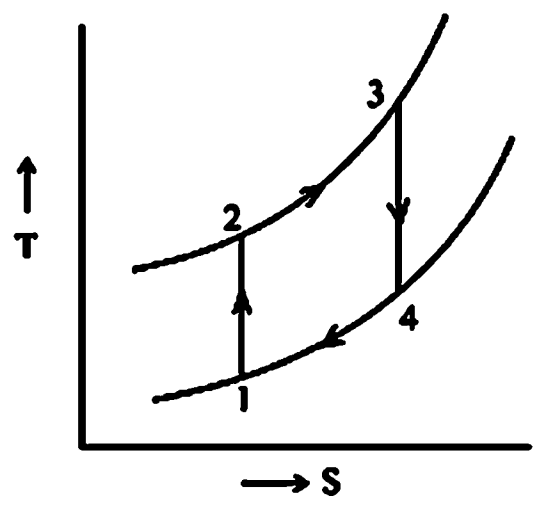
Minimum temperature $T_1 = 300\text{K}$

Power output $P = 70\,\text{MW}$

Step 2 of 14

Considering constant specific heats at room temperature

Gas constant $R = 0.287\,\text{kJ/kg.K}$



$c_p = 1.005\,\text{kJ/kg.K}$

$c_v = 0.718\,\text{kJ/kg.K}$

$k = 1.4$

Step 3 of 14

(a) When isentropic efficiency of compressor and turbine each are having 100%

Step 4 of 14

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_2}{300} = (12)^{\frac{1.4-1}{1.4}}$$

$$T_2 = 610.18\text{K}$$

Step 5 of 14

Similarly process 3-4 is isentropic expansion

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{T_3} = \left(\frac{P_1}{P_2}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{1000} = \left(\frac{1}{12}\right)^{\frac{1.4-1}{1.4}}$$

$$T_4 = 491.657\text{K}$$

Step 6 of 14

The net work produced per unit mass is given by

$$w_{net} = w_t - w_c$$

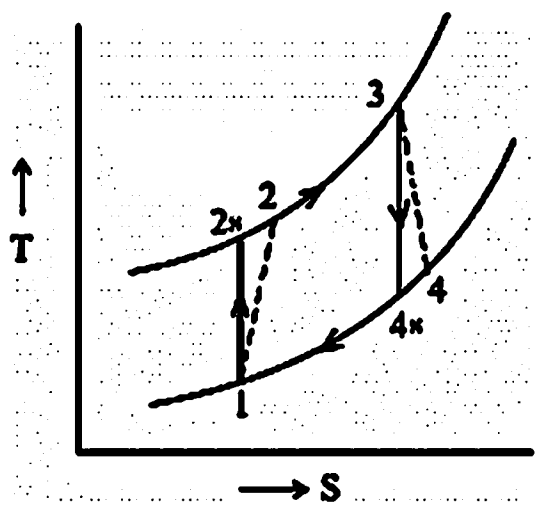
$$w_{net} = c_p(T_3 - T_4) - c_p(T_2 - T_1)$$

$$= (1.005)\{(1000 - 491.657) - (610.18 - 300)\}$$

$$w_{net} = 199.153\,\text{kJ/kg}$$

Step 7 of 14

Power output is expressed as



$$P = \dot{m} w_{net}$$

$$70\times10^3 = \dot{m}(199.153)$$

$$\boxed{\dot{m} = 351.48\,\text{kg/s}}$$

Step 8 of 14

(b) When isentropic efficiencies of turbine and compressor each are having $\eta_c = \eta_t = 85\%$

Step 9 of 14

Process 1-2s is isentropic compression

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Step 9 of 14

Process 1-2s is isentropic compression

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{2s}}{300} = (12)^{\frac{1.4-1}{1.4}}$$

$$T_{2s} = 610.18\text{K}$$

Step 10 of 14

Since the isentropic efficiency of the compressor is given by

$$\eta_c = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$0.85 = \frac{610.18 - 300}{T_2 - 300}$$

$$T_2 = 664.9176\text{K}$$

Step 11 of 14

Similarly process 3-4s is isentropic expansion

$$\frac{T_{4s}}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{4s}}{T_3} = \left(\frac{P_1}{P_2}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{4s}}{1000} = \left(\frac{1}{12}\right)^{\frac{1.4-1}{1.4}}$$

$$T_{4s} = 491.657\text{K}$$

Step 12 of 14

Since the isentropic efficiency of the turbine is given by

$$\eta_T = \frac{T_3 - T_4}{T_3 - T_{4s}}$$

$$0.85 = \frac{1000 - T_4}{1000 - 491.657}$$

$$T_4 = 567.9\text{K}$$

Step 13 of 14

The net work produced per unit mass is given by

$$w_{net} = w_t - w_c$$

$$w_{net} = c_p(T_3 - T_4) - c_p(T_2 - T_1)$$

$$= (1.005)\{(1000 - 567.9) - (664.9176 - 300)\}$$

$$= 1.005\{432.1 - 364.9176\}$$

$$w_{net} = 67.518\ \text{kJ/kg}$$

Step 14 of 14

Power output is expressed as

$$P = \dot{m} w_{net}$$

$$70 \times 10^3 = \dot{m}(67.518)$$

$$\boxed{\dot{m} = 1036.76\ \text{kg/s}}$$

Question: 9.077P

Air enters the compressor of a gas-turbine engine at 300 K and 100 kPa, where it is compressed to 700 kPa and 580 K. Heat is transferred to air in the amount of 950 kJ/kg before it enters the turbine. For a turbine efficiency of 86 percent. determine (*a*) the fraction of the turbine work output used t I drive the compressor and (*b*) the thermal efficiency. Assume variable specific heats for air.

Step 1 of 11

Given

Initial pressure $P_1 = 100\ \text{kPa}$

Initial temperature $T_1 = 300\text{K}$

Compressor exit pressure $P_2 = 700\ \text{kPa}$

Compressor exit temperature $T_2 = 580\text{K}$

Heat input $q_{in} = 950\ \text{kJ/kg}$

Turbine efficiency $\eta_t = 86\%$

Step 2 of 11

Since we are considering variable specific heats the specific heat at constant pressure and at constant volume will be different at different temperatures.

At $T_1 = 300\text{K}$ from ideal gas properties of air

$h_1 = 300.19\ \text{kJ/kg}$

$P_{r1} = 1.386$

At $T_2 = 580\text{K}$ from ideal gas properties of air

$h_2 = 586.04\ \text{kJ/kg}$

$P_{r3} = 14.38$

Step 3 of 11

Pressure ratio

$$r_p = \frac{P_2}{P_1}$$

$$r_p = \frac{700}{100}$$

$$r_p = 7$$

Step 4 of 11

The heat input is expressed as

$$q_{in} = h_3 - h_2$$

$$950 = h_3 - 586.04$$

$$h_3 = 1536.04\ \text{kJ/kg}$$

Step 5 of 11

At $h_3 = 1536.04\ \text{kJ/kg}$ from ideal gas properties of air

$$P_{r3} = 450.5 + (478.0 - 450.5)\left(\frac{1536.04 - 1515.42}{1539.44 - 1515.42}\right)$$

$$P_{r3} = 474.107$$

Step 6 of 11

Process 3-4s is isentropic expansion

$$\frac{P_4}{P_3} = \frac{P_{r4s}}{P_{r3}}$$

$$P_{r4s} = P_{r3} \times \frac{P_4}{P_3}$$

$$P_{r4} = 474.107 \times \frac{1}{7}$$

$$P_{r4s} = 67.729$$

Step 7 of 11

At $P_{r4s} = 67.729$ from ideal gas properties of air

$$h_{4s} = 888.27 + (910.56 - 888.27)\left(\frac{67.729 - 63.09}{68.98 - 63.09}\right)$$

$$h_{4s} = 905.825\ \text{kJ/kg}$$

Step 8 of 11

Since the isentropic efficiency of the turbine is given by

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$0.86 = \frac{1536.04 - h_4}{1536.04 - 905.825}$$

$$h_4 = 994.055\text{kJ/kg}$$

Step 9 of 11

The work required to compressor is expressed as

$$w_c = h_2 - h_1$$

$$w_c = 586.04 - 300.19$$

$$w_c = 285.85\ \text{kJ/kg}$$

The work done by turbine is expressed as

$$w_t = h_3 - h_4$$

$$w_t = 1536.04 - 994.055$$

$$w_t = 541.985\text{kJ/kg}$$

Step 10 of 11

(a) The fraction of turbine work output used to drive the compressor

$$r_{bw} = \frac{w_c}{w_t}$$

$$= \frac{285.85}{541.985}$$

$$r_{bw} = 0.527$$

Fraction of 0.527 of work is delivered by turbine to run the compressor

Step 11 of 11

(b) The thermal efficiency

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$\eta_{th} = \frac{w_t - w_c}{q_{in}}$$

$$\eta_{th} = \frac{541.985 - 285.85}{950}$$

$$= 0.2696$$

$$\boxed{\eta_{th} = 26.96\%}$$

Question: 9.078P pg 1

Repeat Prob. 9–77 using constant specific heats at room temperature.

Step 1 of 7

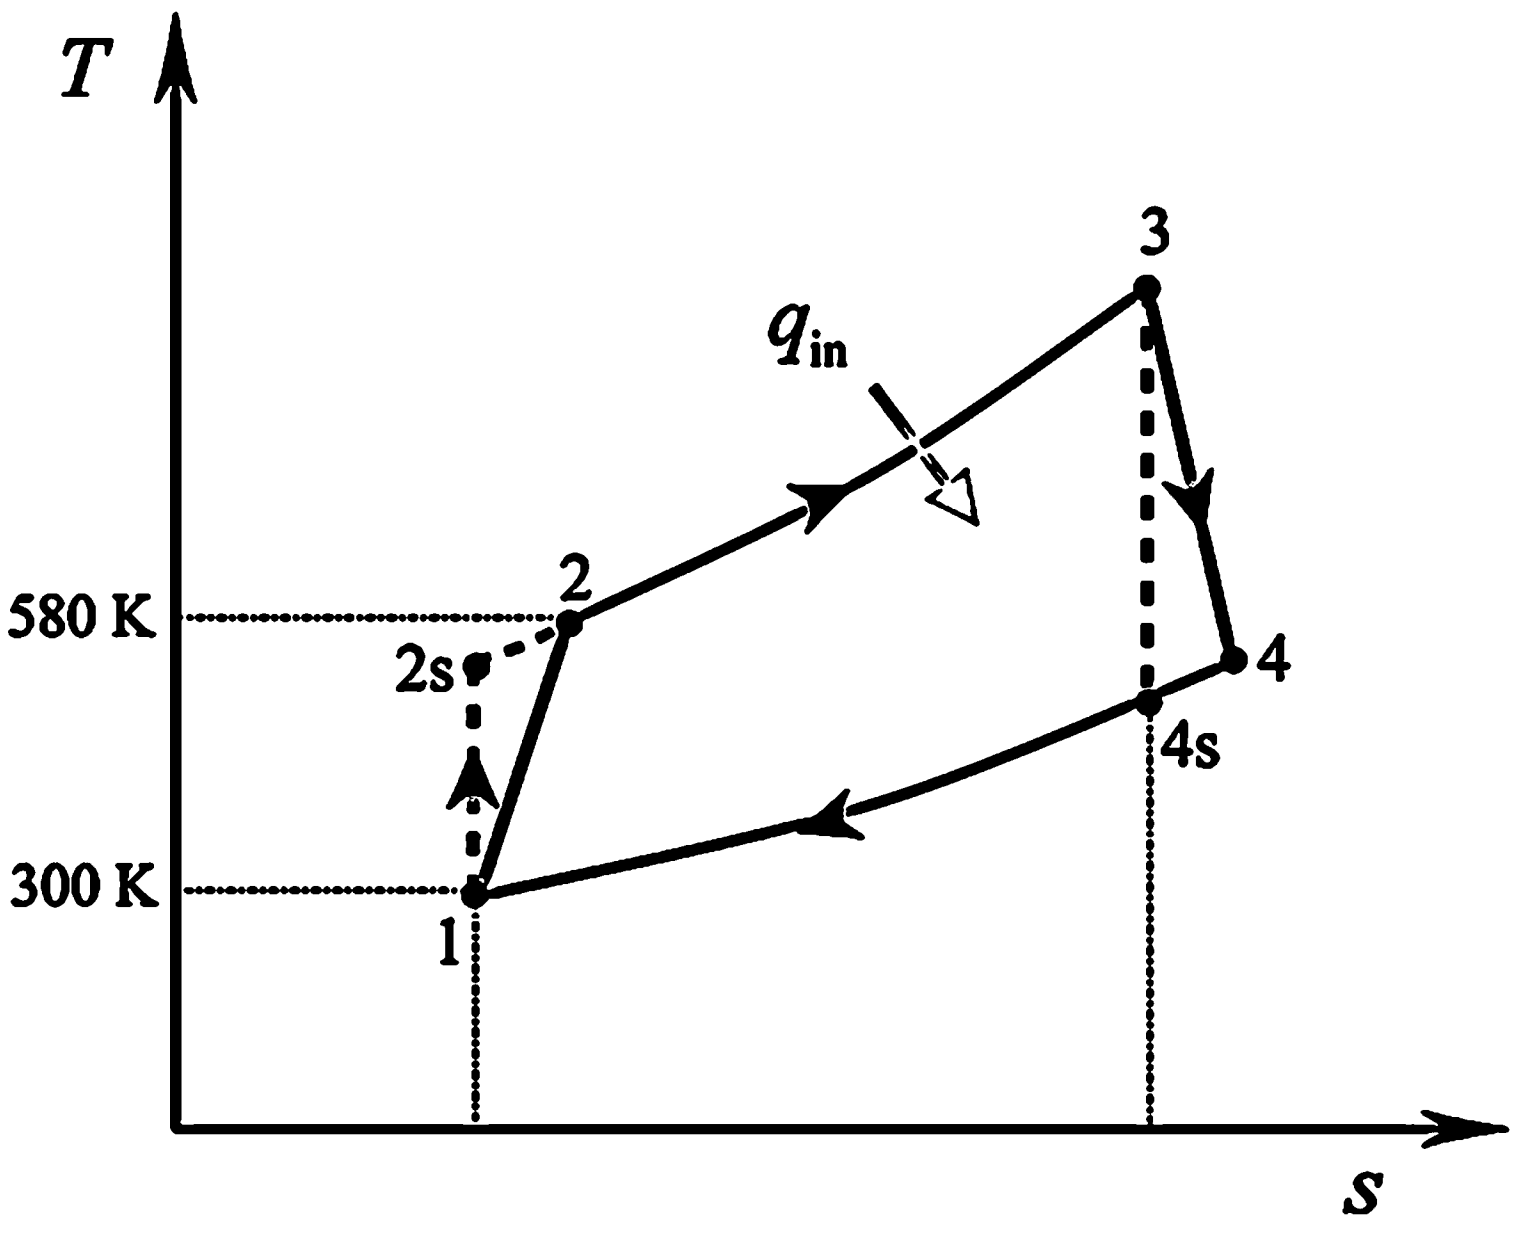
Solving the Prob. 9-78 using constant specific heats at room temperature yields the same result obtained for the Prob. 9-78.

Instead of that, solve the Prob. 9-100 using constant specific heats at room temperature as follows:

Obtain the properties of air from the **Table A-2a**.

At room temperature,

Gas constant, $R = 0.287\,\text{kJ/kg}\cdot\text{K}$



Specific heats at constant pressure, $c_p = 1.005\,\text{kJ/kg}\cdot\text{K}$

Specific heats at constant volume, $c_v = 0.718\,\text{kJ/kg}\cdot\text{K}$

Ratio of specific heats (or) Specific heat ratio, $k = 1.4$

Step 2 of 7

Draw the cyclical process on $T-s$ coordinates as follow:

Step 3 of 7

Write an expression for the heat input to the system during the constant pressure heat addition process $2-3$.

$$q_{in,2\text{-}3} = c_p(T_3 - T_2)$$

Here, the heat input to the system during the process $2-3$ is $q_{in,2\text{-}3}$, the temperature of air at the beginning of heat addition process is T_2, the temperature of air at the end of heat addition process is T_3 and the specific heat at constant pressure is c_p.

Substitute $950\,\text{kJ/kg}$ for $q_{in,2\text{-}3}$, $580\,\text{K}$ for T_2 and $1.005\ \text{kJ/kg}\cdot\text{K}$ for c_p.

$$950 = 1.005(T_3 - 580)$$
$$T_3 = 1525.27\,\text{K}$$

Step 4 of 7

Consider the process $3-4s$ (Isentropic Expansion process):

Calculate the temperature at the end of expansion in an isentropic expansion process (T_{4s}) by using the following equation,

$$\frac{T_{4s}}{T_3} = \left(\frac{P_4}{P_3}\right)^{\left(\frac{k-1}{k}\right)}$$

$$\frac{T_{4s}}{T_3} = \left(\frac{P_1}{P_2}\right)^{\left(\frac{k-1}{k}\right)} \qquad \left(\because P_1 = P_{4s} = P_4 \text{ and } P_{2s} = P_2 = P_3\right)$$

$$T_{4s} = T_3\left(\frac{P_1}{P_2}\right)^{\left(\frac{k-1}{k}\right)}$$

Here, the temperature of air before expansion is T_3, the pressure of air before expansion is P_3, the temperature at the end of expansion in an isentropic expansion process is T_{4s} and the pressure of air at the end of expansion is P_4.

Substitute $1525.27\,\text{K}$ for T_3, 1.4 for k, $100\,\text{kPa}$ for P_1, and $700\,\text{kPa}$ for P_2.

$$T_{4s} = 1525.27 \times \left(\frac{100}{700}\right)^{\left(\frac{1.4-1}{1.4}\right)}$$
$$= 874.76\,\text{K}$$

Step 5 of 7

Calculate the work done in compressing the air by using the following equation,

$$w_{C,in} = h_2 - h_1$$
$$= c_p(T_2 - T_1)$$

Here, the temperature of air before compression is T_1, and the temperature of air after compression is T_2.

Substitute $300\,\text{K}$ for T_1, $580\,\text{K}$ for T_2 and $1.005\ \text{kJ/kg}\cdot\text{K}$ for c_p.

$$= c_p(T_2 - T_1)$$

Here, the temperature of air before compression is T_1, and the temperature of air after compression is T_2.

Substitute $300\ \text{K}$ for T_1, $580\ \text{K}$ for T_2 and $1.005\ \text{kJ/kg·K}$ for c_p.

$$\begin{aligned} w_{C,in} &= c_p(T_2 - T_1) \\ &= 1.005(580 - 300) \\ &= 281.4\ \text{kJ/kg} \end{aligned}$$

Calculate the actual work developed by the turbine during the expansion process.

$$\begin{aligned} (w_{T,out})_{Actual} &= \eta_T (w_{T,out})_{Ideal} \\ &= \eta_T (h_3 - h_{4s}) \\ &= \eta_T c_p (T_3 - T_{4s}) \end{aligned}$$

Here, the efficiency of the turbine is η_T.

Substitute $1525.27\ \text{K}$ for T_3, $874.76\ \text{K}$ for T_{4s}, $1.005\ \text{kJ/kg·K}$ for c_p and 0.86 for η_T.

$$\begin{aligned} (w_{T,out})_{Actual} &= \eta_T c_p (T_3 - T_{4s}) \\ &= 0.86 \times 1.005(1525.27 - 874.76) \\ &= 562.23\ \text{kJ/kg} \end{aligned}$$

Step 6 of 7

(a)

Calculate the fraction of turbine work, used to drive the compressor by using the following equation,

$$r_{bw} = \frac{w_{C,in}}{(w_{T,out})_{Actual}}$$

Substitute $281.4\ \text{kJ/kg}$ for $w_{C,in}$ and $562.23\ \text{kJ/kg}$ for $(w_{T,out})_{Actual}$.

$$\begin{aligned} r_{bw} &= \frac{281.4\ \text{kJ/kg}}{562.23\ \text{kJ/kg}} \\ &= 0.5005 \\ &= 50.05\% \end{aligned}$$

Therefore, a fraction of $\boxed{50.05\%}$ of the turbine work is used to drive the compressor.

Step 7 of 7

(b)

Calculate the net work done by the system.

$$w_{act,out} = (w_{T,out})_{Actual} - w_{C,in}$$

Substitute $281.4\ \text{kJ/kg}$ for $w_{C,in}$ and $562.23\ \text{kJ/kg}$ for $(w_{T,out})_{Actual}$.

$$\begin{aligned} w_{act,out} &= 562.23\ \text{kJ/kg} - 281.4\ \text{kJ/kg} \\ &= 280.83\ \text{kJ/kg} \end{aligned}$$

Calculate the thermal efficiency of the cycle by using the following equation,

$$\eta_{th} = \frac{w_{act,out}}{q_{in,2\text{-}3}}$$

Substitute 950kJ/kg for $q_{in,2\text{-}3}$, and $280.83\ \text{kJ/kg}$ for $w_{act,out}$.

$$\begin{aligned} \eta_{th} &= \frac{280.83\ \text{kJ/kg}}{950\ \text{kJ/kg}} \\ &= 0.2956 \\ &= 29.56\% \end{aligned}$$

Therefore, the thermal efficiency of the cycle is $\boxed{29.56\%}$.

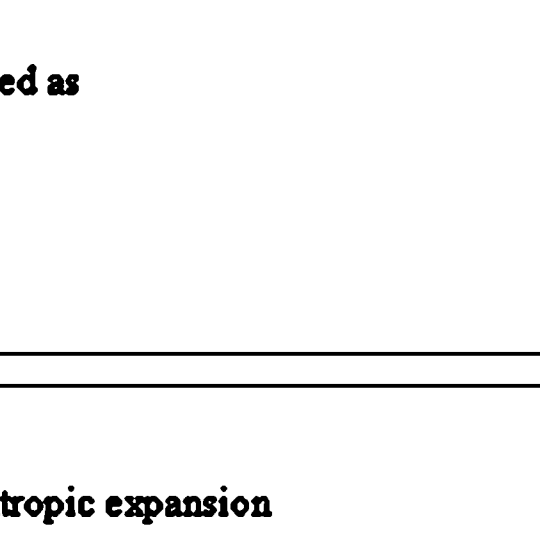
Question: 9.079P

An aircraft engine operates on a simple ideal Brayton cycle with a pressure ratio of 10. Heat is added to the eyclj at a rate of 500 kW; air passes through the engine at a rate of 1 kg/s; and the air at the beginning of the compression is ati 70 kPa and 0°C Determine the power produced by this engine and its thermal efficiency. Use constant specific heats at room temperature.

Step 1 of 8

Given

Pressure ratio $r_p = 10$



Initial pressure $P_1 = 70\ \text{kPa}$

Inlet temperature $T_1 = 0°\text{C} + 273 = 273\text{K}$

Heat supplied $\dot{Q}_{in} = 500\ \text{kW}$

Mass flow rate $\dot{m} = 1\ \text{kg/s}$

Step 2 of 8

Step 3 of 8

Considering constant specific heats at room temperature the properties of air will be

Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 4 of 8

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_2}{273} = (10)^{\frac{1.4-1}{1.4}}$$

$$T_2 = 527.08\text{K}$$

Step 5 of 8

The heat supplied is expressed as

$$\dot{Q}_{in} = \dot{m}c_p(T_3 - T_2)$$

$$500 = 1 \times 1.005(T_3 - 527)$$

$$T_3 = 1024.5\text{K}$$

Step 6 of 8

Similarly process 3-4 is isentropic expansion

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{1024.5} = \left(\frac{1}{10}\right)^{\frac{1.4-1}{1.4}}$$

$$T_4 = 530.637\text{K}$$

Step 7 of 8

The Power produced by this engine

$$\dot{W}_{net} = \dot{m}(w_T - w_c)$$

$$\dot{W}_{net} = \dot{m}\{c_p(T_3 - T_4) - c_p(T_2 - T_1)\}$$

$$= (1)(1.005)\{(1024.5 - 530.637) - (527.08 - 273)\}$$

$$= 1.005\{493.863 - 254.08\}$$

$$\boxed{\dot{W}_{net} = 240.98\ \text{kW}}$$

Step 8 of 8

The thermal efficiency is defined as

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}}$$

$$= \frac{240.98}{500}$$

$$= 0.48196$$

$$\boxed{\eta_{th} = 48.19\%}$$

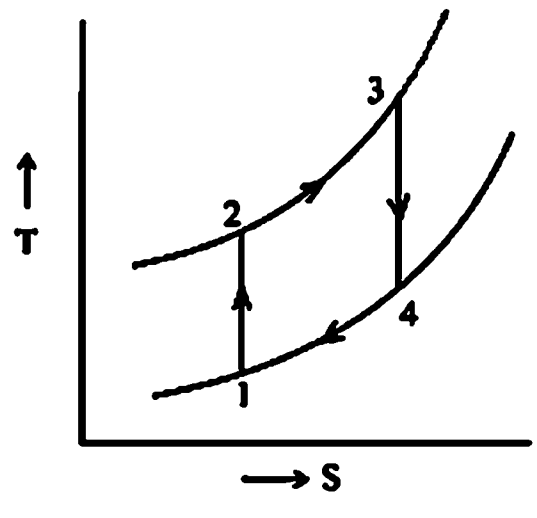
Question: 9.080P

Repeat Prob. 9–79 for a pressure ratio of 15.

Step 1 of 8

Given

Pressure ratio $r_p = 15$



Initial pressure $P_1 = 70\ \text{kPa}$

Inlet temperature $T_1 = 0°\text{C} + 273 = 273\text{K}$

Heat supplied $\dot{Q}_{in} = 500\ \text{kW}$

Mass flow rate $\dot{m} = 1\ \text{kg/s}$

Step 2 of 8

Step 3 of 8

Considering constant specific heats at room temperature the properties of air will be

Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 4 of 8

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_2}{273} = (15)^{\frac{1.4-1}{1.4}}$$

$$T_2 = 591.818\text{K}$$

Step 5 of 8

The heat supplied is expressed as

$$\dot{Q}_{in} = \dot{m}c_p(T_3 - T_2)$$

$$500 = 1 \times 1.005(T_3 - 591.818)$$

$$T_3 = 1089.33\text{K}$$

Step 6 of 8

Similarly process 3-4 is isentropic expansion

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{1089.33} = \left(\frac{1}{15}\right)^{\frac{1.4-1}{1.4}}$$

$$T_4 = 502.496\text{K}$$

Step 7 of 8

The Power produced by this engine

$$\dot{W}_{net} = \dot{m}(w_T - w_c)$$

$$\dot{W}_{net} = \dot{m}\{c_p(T_3 - T_4) - c_p(T_2 - T_1)\}$$

$$= (1)(1.005)\{(1089.33 - 502.496) - (591.818 - 273)\}$$

$$= 1.005(586.834 - 318.818)$$

$$\boxed{\dot{W}_{net} = 269.356\ \text{kW}}$$

Step 8 of 8

The thermal efficiency is defined as

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}}$$

$$= \frac{269.356}{500}$$

$$= 0.5387$$

$$\boxed{\eta_{th} = 53.87\%}$$

Question: 9.081P pg 1

A gas-turbine power plant operates on the simple Brayton cycle between the pressure limits of 100 and 2000 kPa. The working fluid is air, which enters the compressor at 40°C at a] rate of 700 m3/Vmin and leaves the turbine at 650°C. Using variable specific heats for air and assuming a compressor isentropic efficiency of 85 percent and a turbine isentropic efficiency of 88 percent, determine *(a)* the net power /output *(b)* the back work ratio, and (c) the thermal efficiency.

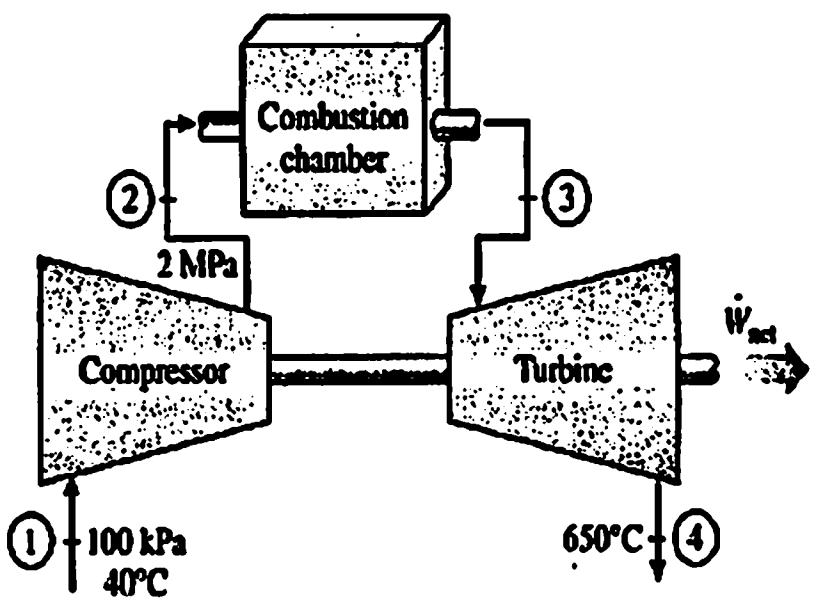


FIGURE P9–81

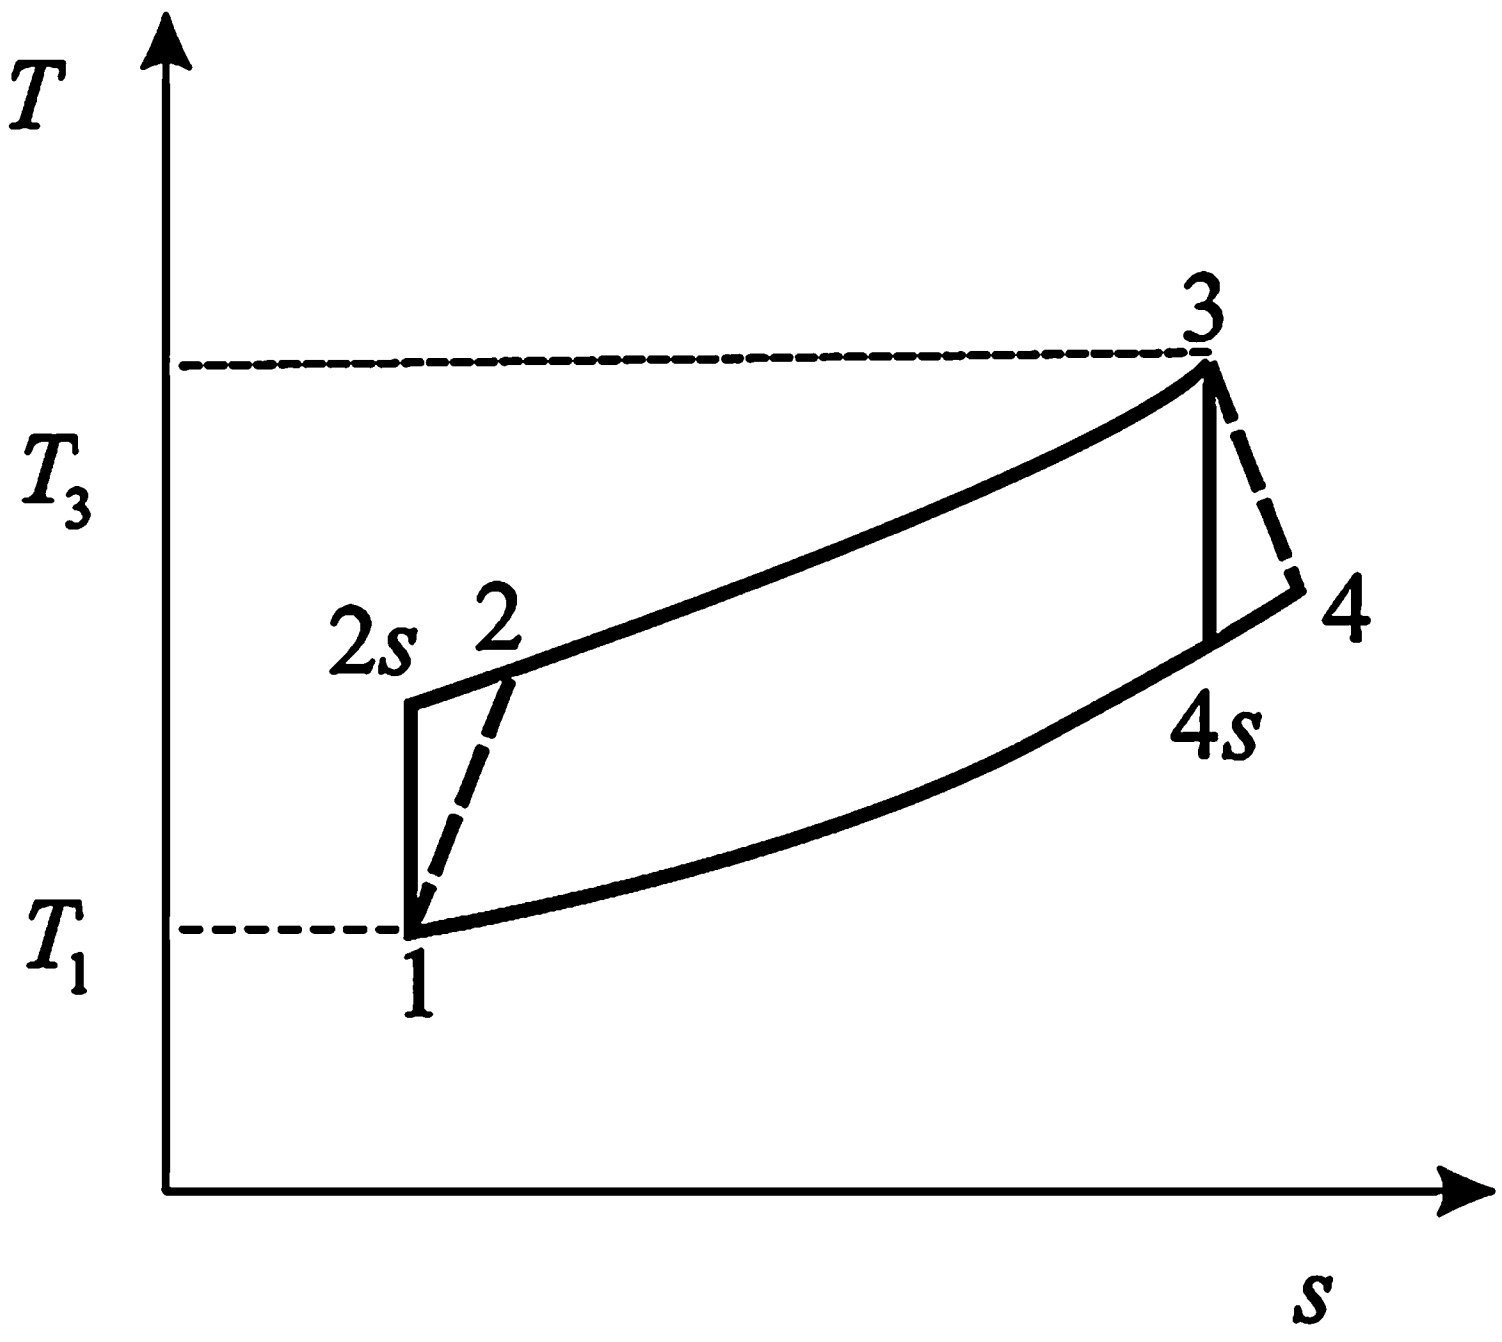
Step 1 of 11

Pressure inlet to the compressor, $P_1 = 100\,\text{kPa}$

Pressure outlet to the compressor, $P_2 = 2000\,\text{kPa}$

Inlet temperature of working fluid enters into compressor, $T_1 = 40°C = 313\,\text{K}$

Mass flow rate of the working fluid, $V_1 = 700\,\text{m}^3/\text{min}$



Exit temperature of the working fluid from the turbine, $T_4 = 650°C$

Isentropic efficiency of the compressor, $\eta_c = 0.85$

Isentropic efficiency of the turbine, $\eta_T = 0.88$

Step 2 of 11

Ts diagram:

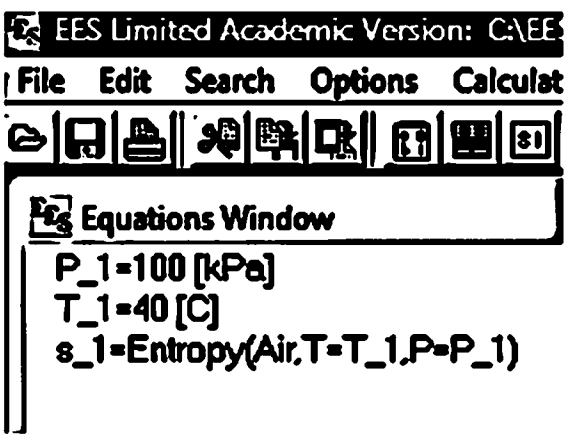
Step 3 of 11

Properties of the gas at various states can be finding by using EES software only. Because in this problems we have more number of unknowns,

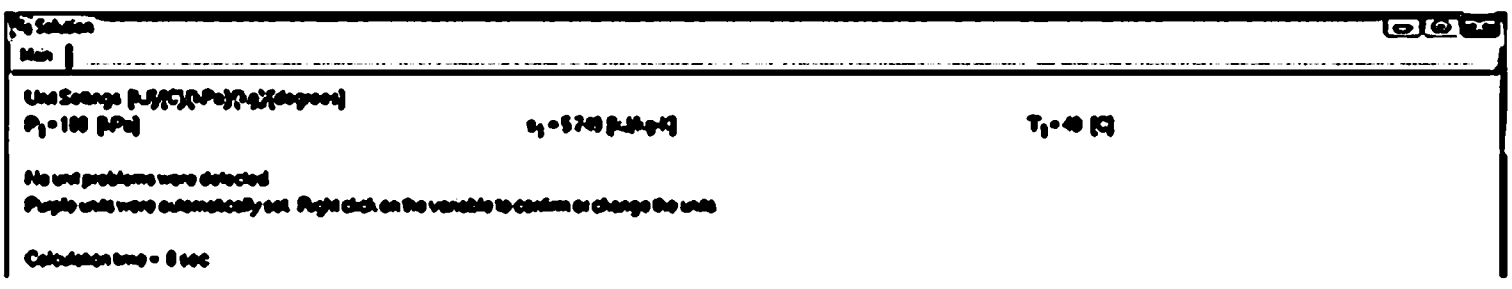
From the properties of the ideal gas air

At $T_1 = 313\,\text{K}$

By using the method of interpolation



$$h_1 = 310.24 + \frac{(313-310)(315.27-310.24)}{(315-310)}$$



$$= 313.258\,\text{kJ/kg}$$

By using EES software

At pressure $P_1 = 100\,\text{kPa}$ and $T_1 = 313\,\text{K}$

Step 4 of 11

Unit Settings: [kJ/(C)/(kPa)/[kg]/[degree]
$P_1 = 100$ [kPa] $s_1 = 5.749$ [kJ/kg-K] $T_1 = 40$ [C]

No unit problems were detected.
Duplicate units were automatically set. Right click on the variable to confirm or change the units.

Calculation time = 0 sec

Entropy $s_1 = 5.749\,\text{kJ/kg}\cdot\text{K}$

Step 5 of 11

From the table of "Ideal gas properties of the air"

At $T_4 = 650°\text{C}$

$$h_4 = 955.38 + \frac{(923-920)(977.92-955.38)}{(940-920)}$$
$$= 958.761\,\text{kJ/kg}$$

Step 6 of 11

Enthalpy at state 2s is

Equations Window

```
P_2=2000 [kPa]
s_2=5.749 [kJ/kgK]
h_2s=Enthalpy(Air,P=P_2,s=s_2)
```

Solution
Main

Unit Settings: [kJ/(C)/(kPa)/[kg]/[degree]
$h_{2s} = 737$ $P_2 = 2000$ [kPa] $s_2 = 5.749$ [kJ/kgK]

2 potential unit problems were detected. Check Units

Calculation time = 0 sec

Then, from the relation of isentropic efficiency is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$
$$0.85 = \frac{737 - 313.258}{h_2 - 313.258}$$
$$h_2 = 811.778\,\text{kJ/kg}$$

Similarly, for turbine is given as

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$
$$0.88 = \frac{h_3 - 958.761}{h_3 - 313.258}$$

Step 7 of 11

The enthalpy at state 3 can be finding by using the EES software.

Equations Window

```
h_3=Enthalpy(Air,T=T_3)
s_3=Entropy(Air,T=T_3,P=P_2)
h_4s=Enthalpy(Air,P=P_1,s=s_3)
0.88=h_3-959.2/h_3-h_4s
P_1=100 [kPa]
P_2=2000 [kPa]
```

Solution
Main

Unit Settings: [kJ/(C)/(kPa)/[kg]/[degree]
$h_3 = 1873$ $T_3 = 1421$ [C] $s_3 = 6.736$ [kJ/kgK]

2 potential unit problems were detected. Check Units

Calculation time = 0 sec

From the above solution window, we get

Enthalpy at state 3 is $h_3 = 1873\,\text{kJ/kg}$

Temperature at state 3 is $T_3 = 1421°\text{C}$

Entropy at state 3 is $s_3 = 6.736\,\text{kJ/kg}\cdot\text{K}$

Step 8 of 11

Mass flow rate of air in compressor is given as

$$P_1V_1 = mRT_1$$
$$m = \frac{\left(100 \times \frac{700}{60}\,\text{m}^3/\text{s}\right)}{0.287 \times (40+273)}$$
$$= 12.99\,\text{kg/s}$$

Work input to the compressor is

$$W_{in,c} = m(h_2 - h_1)$$
$$= 12.99(811.778 - 313.258)$$
$$= 6475.774\,\text{kW}$$

Step 9 of 11

Power produced by turbine is

$$W_T = m(h_3 - h_4)$$
$$= 12.99(1873 - 958.761)$$
$$= 11875.96\,\text{kW}$$

Net power produced by cycle is

$$W_{net} = W_T - W_{in,c}$$
$$= 11875.96 - 6475.774$$
$$= 5400.1906\,\text{kW}$$

Net power produced by cycle is

$$\begin{aligned} W_{net} &= W_T - W_{in,c} \\ &= 11875.96 - 6475.774 \\ &= 5400.1906\,\text{kW} \end{aligned}$$

Therefore, net power produced by the cycle is $\boxed{W_{net} = 5400.1906\,\text{kW}}$

Step 10 of 11

b)

The back work ratio is

$$\begin{aligned} W_{back} &= \frac{W_{in,c}}{W_T} \\ &= \frac{6475.774}{11875.96} \\ &= 0.5452 \end{aligned}$$

Therefore, back work ratio is $\boxed{W_{back} = 0.5452}$

Step 11 of 11

c)

Heat input to the combustion chamber is

$$\begin{aligned} q_{in} &= m(h_3 - h_2) \\ &= 12.99(1873 - 811.778) \\ &= 13785.273\,\text{kW} \end{aligned}$$

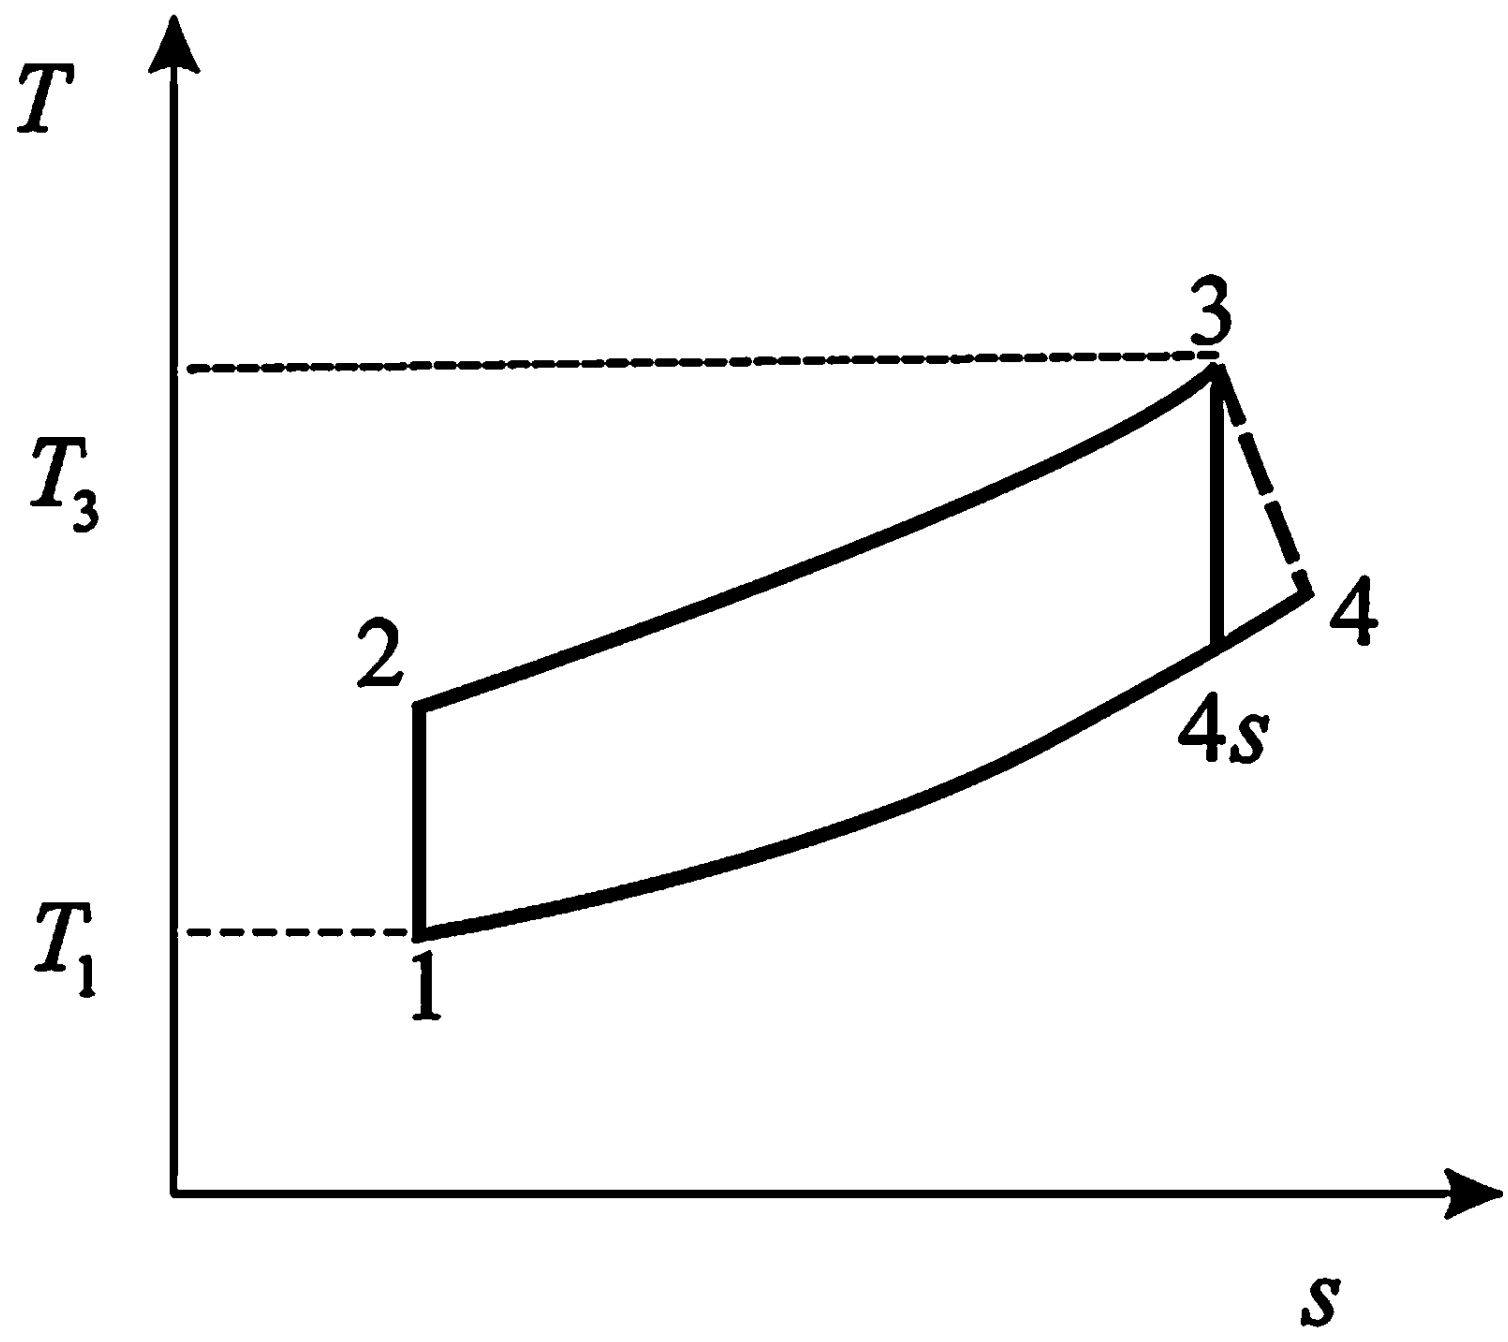
Thermal efficiency is

$$\begin{aligned} \eta_{Th} &= \frac{W_{net}}{q_{in}} \\ &= \frac{5400.1906}{13785.273} \\ &= 0.3917 \\ &= 39.17\% \end{aligned}$$

Therefore, thermal efficiency of the cycle is $\boxed{\eta_{Th} = 39.17\%}$

Question: 9.082P

A gas-turbine power plant operates on the simple Brayton cycle between the pressure limits of 100 and 800 kPa. Air enters the compressor at 30°C and leaves at 3300C at a mass flow rate of 200 kg/s. The maximum cycle temperature is 1400 K. During operation of the cycle, the net power output is measured experimentally to be 60 MW. Assume constant properties for air at 300 K with *cv* -0.718 kJ/kg-K*k cp* =1.005 kJ/kg-K. *R*= 0.287 kJ/kg.K *k* = 1.4.



(a) Sketch the *T-s* diagram for the cycle.

(b) Determine the isentropic efficiency of the turbine for these operating conditions.

(c) Determine the cycle thermal efficiency.

Step 1 of 6

T-s diagram for gas turbine cycle shown in below:

Process 1-2 is isentropic compression in the compressor

Process 2-3 is constant pressure heat addition,

Process 3-4s is isentropic expansion

Process 3-4 is actual expansion in the turbine

Process 4s-1 is constant pressure heat rejection.

Step 2 of 6

From the relation of isentropic process,

$$\left(\frac{P_3}{P_4}\right)^{\frac{k-1}{k}}=\frac{T_3}{T_4}$$

Here, P_3 and P_4 are the pressure at state point 3 and 4 respectively and T_3 and T_4 are the temperature at state points 3 and 4 respectively.

Substitute $800\,\text{kPa}$ for P_3, $100\,\text{kPa}$ for P_4 and $1400\,\text{K}$ for T_3

$$\left(\frac{P_3}{P_4}\right)^{\frac{k-1}{k}}=\frac{T_3}{T_4}$$

$$\left(\frac{800}{100}\right)^{\frac{1.4-1}{1.4}}=\frac{1400}{T_4}$$

$$T_4=772.862\,\text{K}$$

Step 3 of 6

Calculate the actual work done turbine

$$W_{turb}=mc_p(T_3-T_4)$$
$$=(200)(1.005)(1400-772.862)$$
$$=126054.738\,\text{kW}$$

Step 4 of 6

Calculate the compressor work

$$W_{comp}=mc_p(T_2-T_1)$$

Here, c_p is the specific heat and m is the mass flow rate

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p and $200\,\text{kg/s}$ for m $330°\text{C}$ for T_2 and $30°\text{C}$ for T_1

$$W_{comp}=mc_p(T_2-T_1)$$
$$=200(1.005)(330-30)$$
$$=60300\,\text{kW}$$

Step 5 of 6

Calculate the turbine work done by using the relation of net work done by cycle

$$W_{net}=-W_{comp}+W_{turb}$$
$$W_{turb}=W_{comp}+W_{net}$$

Substitute $60\times10^3\,\text{kW}$ for W_{net}, $60300\,\text{kW}$ for W_{comp}

$$W_{turb}=W_{comp}+W_{net}$$
$$=60300+\left(60\times10^3\right)$$
$$=120300\,\text{kW}$$

Step 6 of 6

b)

Calculate the isotropic efficiency of the turbine is

$$\eta_{turb}=\frac{W_{turb}}{W_{turb,s}}$$
$$=\frac{120300}{126054.738}$$
$$=0.9543$$
$$=95.43\%$$

Hence, isentropic efficiency of the turbine is $\boxed{95.43\%}$

c)

Calculate the Thermal efficiency of the cycle

$$\eta_{Thur}=\frac{P}{q_{in}}$$
$$=\frac{P}{c_p(T_3-T_2)}$$
$$=\frac{60\times10^3}{200\times1.005(1400-603)}$$
$$=0.374$$

$$=37.4\%$$

Therefore, thermal efficiency of the cycle is $\boxed{37.4\%}$

Question: 9.083P pg 1

A gas-turbine power plant operates on a modified Brayton cycle shown in the figure with an overall pressure ratio of 8- Air enters the compressor at 0°C and 100 kPa. The maximum cycle temperature is 1500 K. The compressor and the turbines are isentropic. The high pressure turbine develops just enough power to run the compressor. Assume constant properties for air at 300 K with cv = 0.718 kJ/kg-K, Cp = 1.005 kJ/kg.K, *R* =0.287 kJ/kg.K, *k* =1.4.

(a)Sketch the *T-s* diagram for the cycle. Label the data states.

(b) Determine the temperature and pressure at state 4, the exit of the high pressure turbine.

(c) If the net power output is 200 MW, determine mass flow rate of the air into the compressor, in kg/s.

Answers: *(b)*1279 K, 457 kPa, (c) 442 kg/s

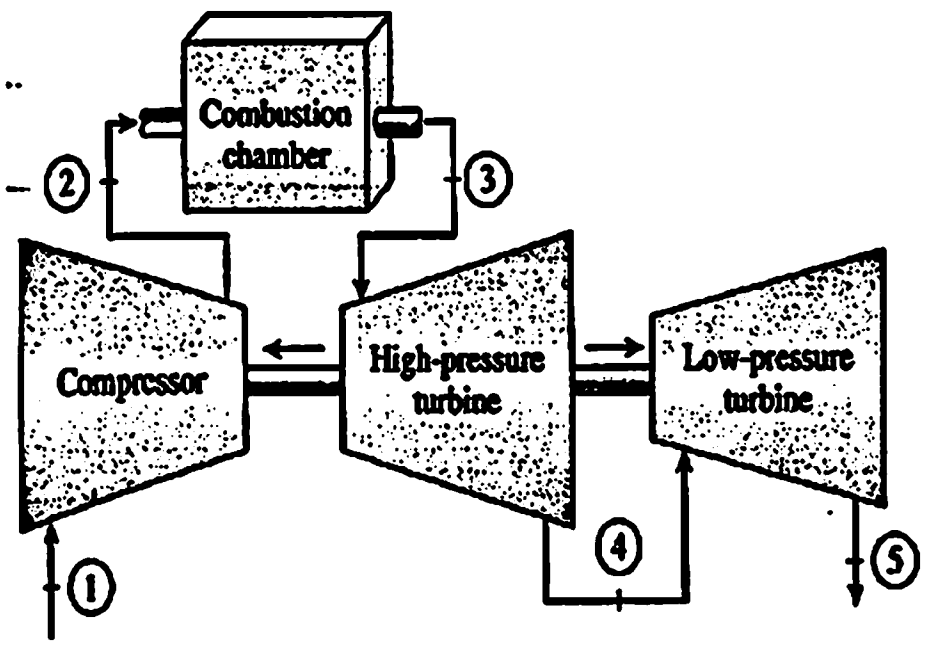


FIGURE P9–83

Step 1 of 7

Overall pressure ratio $r = 8$

Inlet temperature of the air enters into the compressor, $T_1 = 0°C$

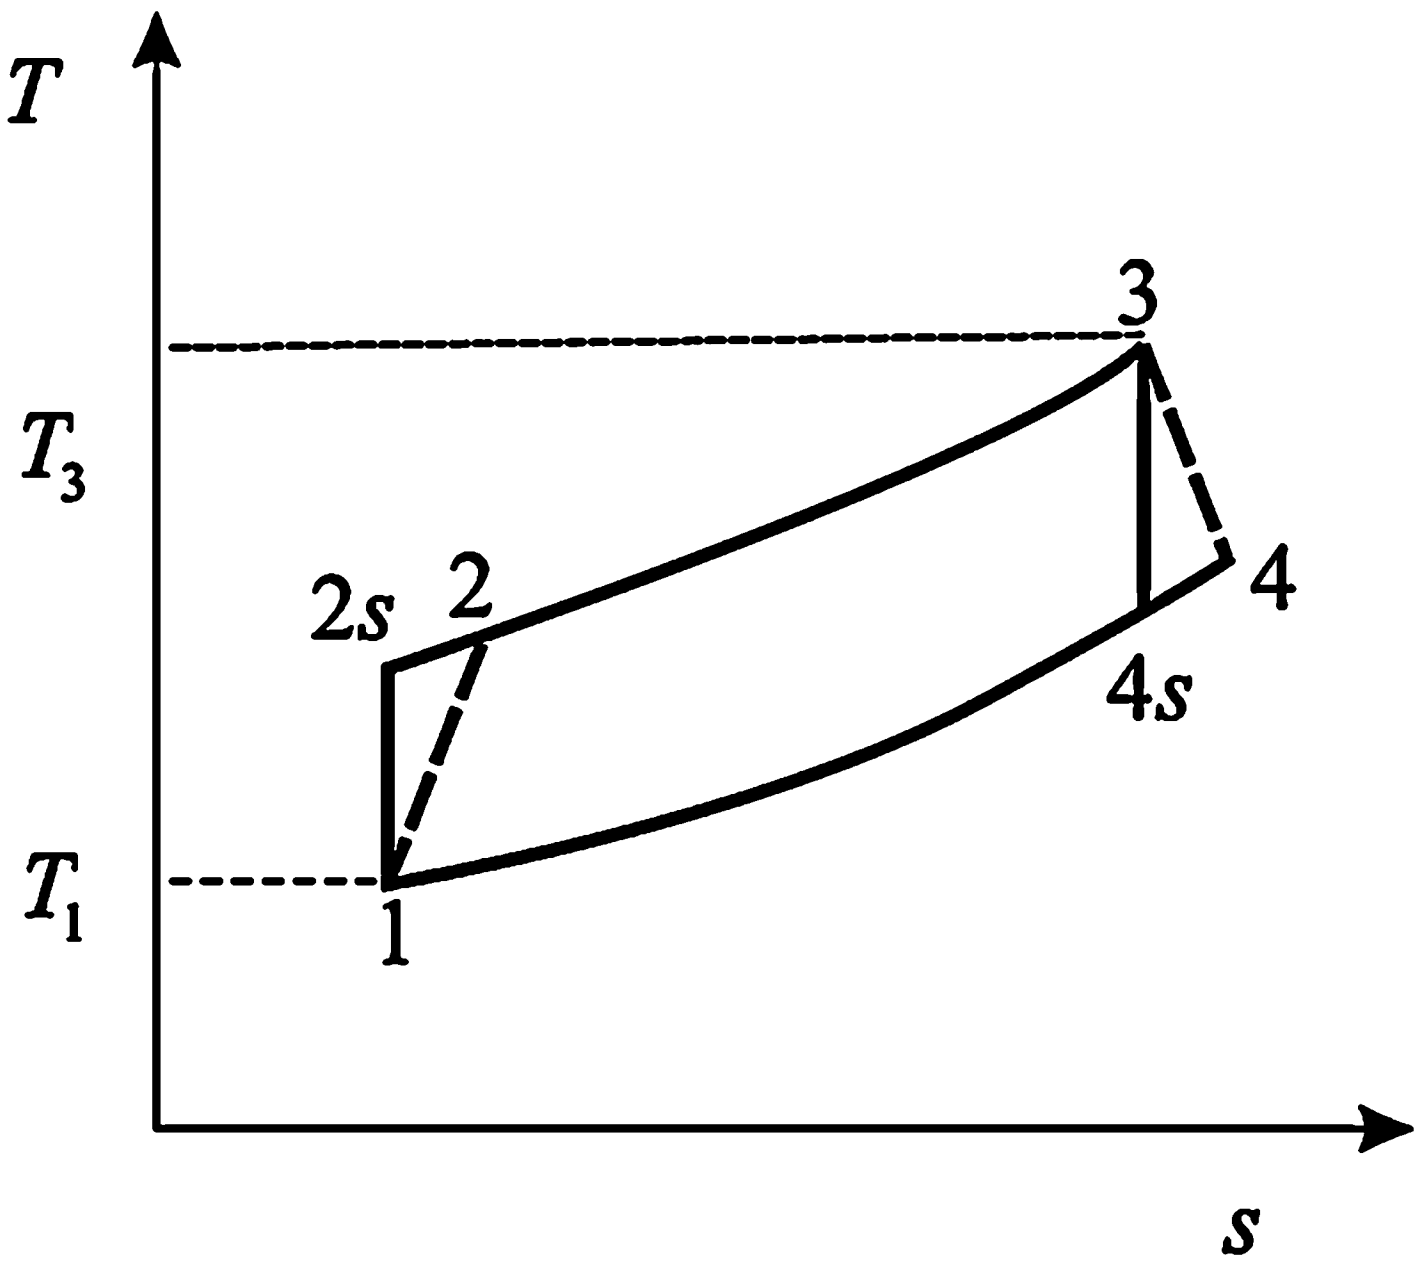
Inlet Pressure of the air enters into the compressor, $P_1 = 100\,kPa$

Maximum cycle temperature, $T_3 = 1500\,K$

Properties of the air at 300 K temperature are:

Specific heat of air at constant volume, $c_v = 0.718\,kJ/kg \cdot K$

Specific heat of air at constant pressure, $c_p = 1.005\,kJ/kg \cdot K$



Gas constant, $R = 0.287\,kJ/kg \cdot K$

Specific heat ratio, $k = 1.4$

Step 2 of 7

(a)

The *T-s* diagram is shown below:

Step 3 of 7

(b)

For the process 1-2: isentropic compression

From the relation of isentropic process, we have

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{1}}$$

$$\frac{T_2}{273} = (8)^{\frac{1.4-1}{1}}$$

$$T_2 = 494.819\,K$$

Step 4 of 7

Since turbine and compressor both are mounted on the same shaft, therefore compressor power input to the compressor is equal to turbine output power.

By applying the energy balance equation, we have

$$mc_p(T_2 - T_1) = mc_p(T_3 - T_4)$$

$$T_2 - T_1 = T_3 - T_4$$

$$494.819 - 273 = 1500 - T_4$$

$$T_4 = 1278.181\,K$$

$$mc_p(T_2-T_1)=mc_p(T_3-T_4)$$
$$T_2-T_1=T_3-T_4$$
$$494.819-273=1500-T_4$$
$$T_4=1278.181\,\text{K}$$

Therefore, exit temperature of the high pressure turbine is $\boxed{T_4=1278.181\,\text{K}}$

Step 5 of 7

For the process 3-4: isentropic expansion

From the relation of isentropic process, we have

$$\frac{T_4}{T_3}=\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{1}}$$
$$\frac{1278.181}{1500}=\left(\frac{P_4}{r\times P_1}\right)^{\frac{1.4-1}{1}} \qquad \left(\because r=\frac{P_2}{P_1}=\frac{P_3}{P_4}\right)$$
$$\frac{1278.181}{1500}=\left(\frac{P_4}{8\times 100}\right)^{\frac{1.4-1}{1}}$$
$$P_4=457.179\,\text{kPa}$$

Therefore, exit pressure of the high pressure turbine is $\boxed{P_4=457.179\,\text{kPa}}$.

Step 6 of 7

(c)

For the process 4-5: isentropic expansion

From the relation of isentropic process, we have

$$\frac{T_5}{T_4}=\left(\frac{P_5}{P_4}\right)^{\frac{k-1}{1}}$$
$$\frac{T_5}{1278.181}=\left(\frac{100}{457.179}\right)^{\frac{1.4-1}{1.4}}$$
$$T_5=827.575\,\text{K}$$

Step 7 of 7

Mass flow rate of the air into the compressor is

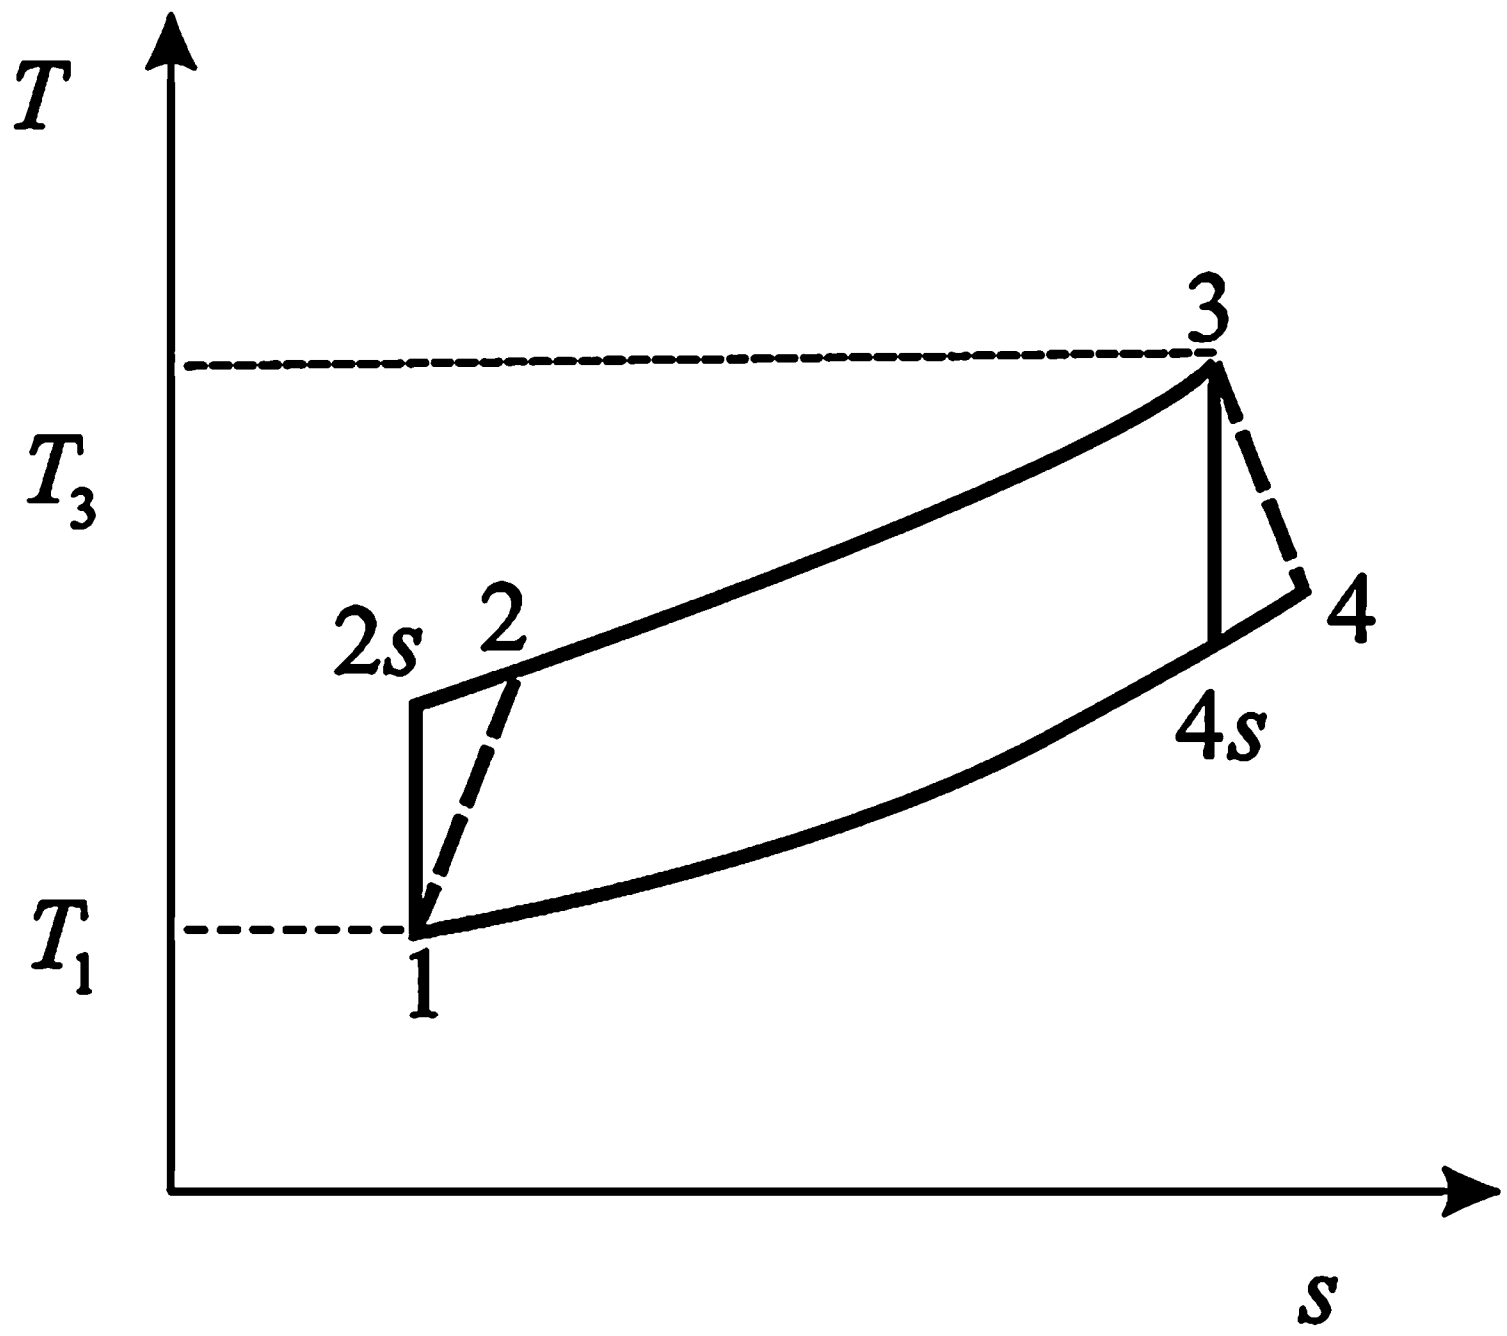
$$P=mc_p(T_4-T_5)$$
$$200\times 10^3=m\times 1.005(1278.181-827.575)$$
$$m=441.638\,\text{kg/s}$$

Therefore, mass flow rate of the air into the compressor is $\boxed{m=441.638\,\text{kg/s}}$.

Question: 9.084P pg 1

A gas-turbine power plant operating on the simple Brayton has a pressure ratio of 7. Air enters the compressor at 00C and 100 kPa. The maximum cycle temperature is 1500 K. The compressor has an isentropic efficiency of 80 percent, and the turbine has an isentropic efficiency of 90 percent. Assume constant properties for air at 300 K with *cv*= 0.718 kJ/kg.K, *cp* =1.005 kJ/kg.K, *R*= 0.287 kJ/kg-K, *k*=1.4.

(a) Sketch the *T-s* diagram for the cycle.



(b) If the net power output is 150 MW, determine the volume flow rate of the air into the compressor, in m3/Vs.

(c) For a fixed compressor inlet velocity and flow area, explain the effect of increasing compressor inlet temperature (i.e., summertime operation versus wintertime operation) on the inlet mass flow rate and the net power output with all other parameters of the problem being the same.

Step 1 of 7

a)

Draw the *T-s* diagram of the simple Brayton cycle:

Process 1-2s is isentropic compression

Process 1-2 is actual compression in the compressor

Process 2-3 is constant pressure heat addition,

Process 3-4s is isentropic expansion

Process 3-4 is actual expansion in the turbine

Process 4s-1 is constant pressure heat rejection.

Step 2 of 7

b)

Use the relation for process 1-2

$$\frac{T_{2s}}{T_1}=\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{1}}$$

Here, T_{2s} is the temperature at state point 2s, T_1 is the temperature at state point 1 and P_2 and P_1 are the pressure at state point 2 and 1 respectively.

Substitute 7 for $\frac{P_2}{P_1}$, 1.4 for k, $273\,\text{K}$ for T_1

$$\frac{T_{2s}}{T_1}=\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{1}}$$
$$\frac{T_{2s}}{273}=(7)^{\frac{1.4-1}{1.4}}$$
$$T_{2s}=476.278\,\text{K}$$

Step 3 of 7

Calculate the temperature at state point 2 by using the relation of isentropic efficiency of the compressor

$$\eta_C=\frac{T_{2s}-T_1}{T_2-T_1}$$

Here, η_C is the isentropic efficiency of the compressor,

Substitute $476.278\,\text{K}$ for T_{2s} and 0.80 for η_c

$$\eta_C=\frac{T_{2s}-T_1}{T_2-T_1}$$
$$0.80=\frac{476.278-273}{T_2-273}$$
$$T_{2s}=527.097\,\text{K}$$

Step 4 of 7

Calculate the temperature at state point 4s by using the relation of isentropic process

$$\frac{T_{4s}}{T_3}=\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

Substitute $1500\,\text{K}$ for T_3, $\frac{1}{7}$ for $\frac{P_4}{P_3}$

$$\frac{T_{4s}}{T_3}=\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$\frac{T_4}{T_3}\left(\frac{P_4}{P_3}\right)$

Substitute $1500\,\text{K}$ for T_3, $\frac{1}{7}$ for $\frac{P_4}{P_3}$

$$\frac{T_{4s}}{T_3}=\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{4s}}{1500}=\left(\frac{1}{7}\right)^{\left(\frac{1.4-1}{1.4}\right)}$$

$$T_{4s}=859.791\,\text{K}$$

Step 5 of 7

Calculate the temperature at state point 2 by using the relation of isentropic efficiency of the turbine

$$\eta_T=\frac{T_3-T_4}{T_3-T_{4s}}$$

Here, η_T is the isentropic efficiency of the turbine,

Substitute $859.791\,\text{K}$ for T_{4s} and 0.90 for η_T

$$\eta_T=\frac{T_3-T_4}{T_3-T_{4s}}$$

$$0.90=\frac{1500-T_4}{1500-859.791}$$

$$T_4=923.811\,\text{K}$$

Calculate the mass flow rate through a turbine by using the net work done in cycle

$$W_{net}=mc_p\left((T_3-T_4)-(T_2-T_1)\right)$$

Here, c_p is the specific heat of the air and W_{net} is the net work done

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p, $923.811\,\text{K}$ for T_3

$$W_{net}=mc_p\left((T_3-T_4)-(T_2-T_1)\right)$$

$$150000=m\times1.005\left((1500-923.811)-(527.097-273)\right)$$

$$m=463.388\,\text{kg/s}$$

Step 6 of 7

Calculate the specific volume by using the ideal gas relation

$$P_1v_1=RT_1$$

$$v_1=\frac{RT_1}{P_1}$$

Here, R is the gas constant

Substitute $0.287\,\text{kJ/kg}\cdot\text{K}$ for R

$$v_1=\frac{RT_1}{P_1}$$

$$=\frac{0.287\times273}{100}$$

$$=0.7835\,\text{m}^3/\text{kg}$$

Calculate the volume flow rate

$$V=mv_1$$

$$=0.78363.35\times463.388$$

$$=363.0644\,\text{m}^3/\text{s}$$

Hence, Volume flow rate is $\boxed{363.0644\,\text{m}^3/\text{s}}$

Step 7 of 7

c)

Effect of increasing compressor inlet temperature

From the ideal gas equation

$$PV=mRT$$

$$P=\rho RT$$

$$T\propto\frac{1}{\rho}$$

From the above we say that temperature is inversely proportional to the density of the gas.

Mass flow rate through a compressor is given as

$$m=\rho AV$$

Given inlet velocity and flow area remains constant.

Hence,

$$m\propto\rho$$

$$m\propto\rho\propto\frac{1}{T}$$

And power input to the compressor is

$$\text{Power}(\text{P})=mc_p\Delta T$$

$$P\propto m\propto\rho\propto\frac{1}{T}$$

From the above two relation we concluded that the effect of increasing the temperature mass flow rate of the air decreases, thereby decreases the power input to the compressor.

Question: 9.085P

How does regeneration affect the efficiency of a Brayton cycle, and how does it accomplish it?

Step 1 of 1

The thermal efficiency of the Brayton cycle increases as a result of regeneration since the portion of energy of the exhaust gases that is normally rejected to the surroundings is now used to preheat the air entering the combustion chamber. This, in turn, decreases the heat input (thus fuel) requirements for the same net work output.

Question: 9.086P

Somebody claims that at very high pressure ratios, the use of regeneration actually decreases the thermal efficiency of a gas-turbine engine. Is there any truth in this claim? Explain.

Step 1 of 1

The Brayton cycle with regeneration increases the thermal efficiency of the cycle. However the use of regenerator is recommended only when the turbine exhaust temperature is higher than the compressor exit temperature. Otherwise heat will flow in the reverse direction (heat addition to the exhaust gases) decreasing the efficiency.
At very high pressure ratios the gas temperature at the turbine exit may be lower than the temperature at the compressor exit which allows heat to flow in the reverse direction (heat addition to the exhaust gases), decreasing the efficiency.

Question: 9.087P

Define the effectiveness of a regenerator used in gas-turbine cycles.

Step 1 of 1

The extent to which a regenerator approaches an ideal regenerator is called the effectiveness and is defined as the ratio of the actual enthalpy increase of the air flowing through the compressor side of the regenerator to the maximum theoretical enthalpy increase. That is

$$\varepsilon = \frac{q_{regen,act}}{q_{regen,max}}$$

Question: 9.088P

In an ideal regenerator, is the air leaving the compressor heated to the temperature at *(a)* turbine inlet, *(b)* turbine exit, (c) slightly above turbine exit?

Step 1 of 1

Regeneration means the portion of energy of the exhaust gases that is normally rejected to the surroundings is now used to preheat the air entering the combustion chamber. In an ideal regenerator the air leaving the compressor heated to the temperature at turbine exit temperature.

So the correct option is (b) Turbine exit

Question: 9.089P

In 1903, Aegidius Elling of Norway designed and built an 11-hp gas turbine that used steam injection between the combustion chamber and the turbine to cool the combustion gases to a safe temperature for the materials available at the time. Currently there are several gas-turbine power plants that use steam injection to augment power and improve thermal efficiency. For example, the thermal efficiency of the General Electric LM5000 gas turbine is reported to increase from 35.8 percent in simple-cycle operation to 43 percent when steam injection is used. Explain why steam injection increases the power output and the efficiency of gas turbines. Also, explain how you would obtain the steam.

Step 1 of 1

Steam injection increases the mass flow rate of steam in the turbine and this leads to increase the power output from the turbine.

We know thermal efficiency

$$\eta = \frac{W}{Q_{in}}$$

Since work output increases and heat addition remains constant so thermal efficiency increases. The process of steam injection is like regeneration process. The steam can be obtained from the exhaust gases which are coming from exit of turbine.

Question: 9.090P

A gas turbine for an automobile is designed with a regenerator. Air enters the compressor of this engine at 100 kPa and 20°C. The compressor pressure ratio is 8; the maximum cycle temperature is 800°C. and the cold air stream leaves the regenerator 10°C cooler than the hot air stream at the inlet of the regenerator. Assuming both the compressor and the turbine to be isentropic, determine the rates of heat addition and rejection for this cycle when it produces 150 kW. Use constant specific heats at room temperature.

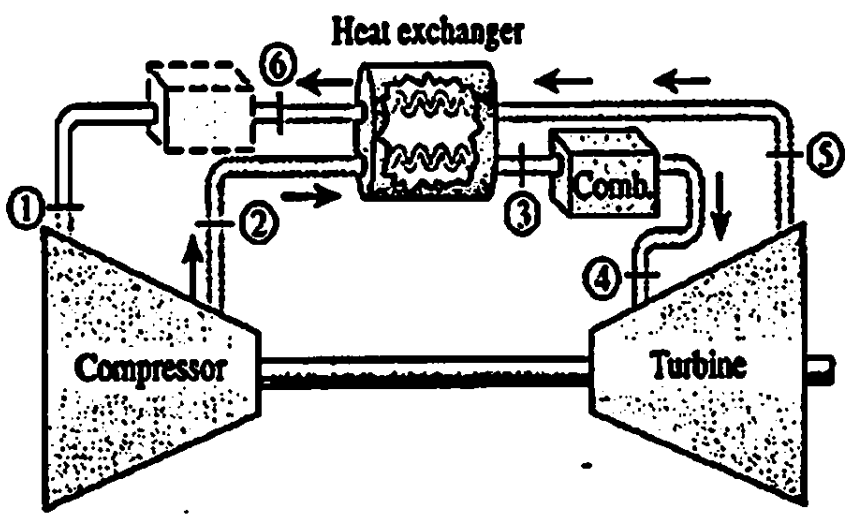


FIGURE P9-90

Step 1 of 10

Given

Compressor pressure ratio $r_p = 8$

Compressor inlet pressure $P_1 = 100\ \text{kPa}$

Compressor inlet temperature $T_1 = 20°C + 273 = 293K$

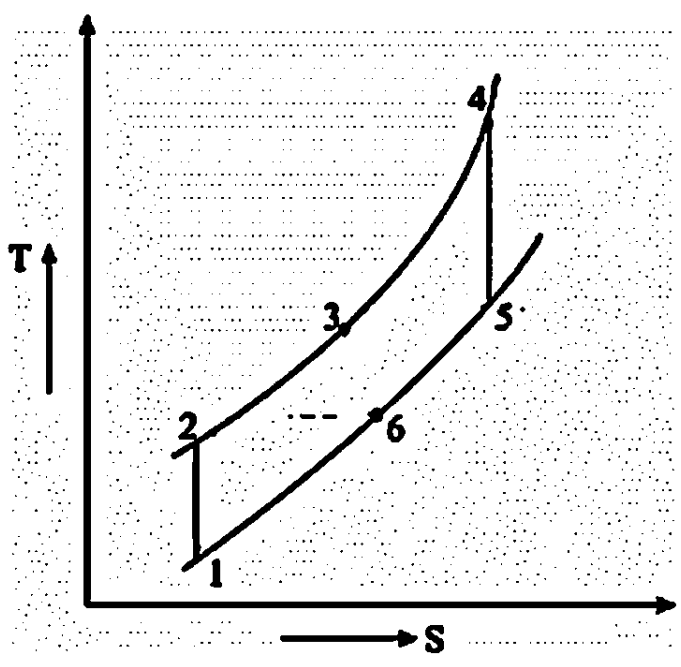
Maximum cycle temperature $T_4 = 800°C + 273 = 1073K$

Power produced $\dot{W}_{net} = 150\ \text{kW}$

The regeneration temperature $T_3 = T_5 - 10$

Step 2 of 10

Considering constant specific heats at room temperature



Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 10

Step 4 of 10

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_2}{293} = (8)^{\frac{1.4-1}{1.4}}$$

$$T_2 = 530.75K$$

Step 5 of 10

Similarly process 4-5 is isentropic expansion

$$\frac{T_5}{T_4} = \left(\frac{P_5}{P_4}\right)^{\frac{k-1}{k}}$$

$$\frac{T_5}{T_4} = \left(\frac{P_1}{P_2}\right)^{\frac{k-1}{k}}$$

$$\frac{T_5}{1073} = \left(\frac{1}{8}\right)^{\frac{1.4-1}{1.4}}$$

$$T_5 = 592.344K$$

Step 6 of 10

Temperature at state 3

$$T_3 = T_5 - 10$$

$$T_3 = 592.344 - 10$$

$$T_3 = 582.344K$$

The temperature of the gas after regeneration is determined by using energy balance to the regenerator

$$T_5 - T_6 = T_3 - T_2$$

$$T_6 = T_5 - (T_3 - T_2)$$

$$T_6 = 592.344 - (582.344 - 530.75)$$

$$T_6 = 540.75K$$

Step 7 of 10

Net work output of the cycle is expressed as

$$w_{net} = w_t - w_c$$

$$w_{net} = c_p(T_4 - T_5) - c_p(T_2 - T_1)$$

$$= (1.005)\{(1073 - 592.344) - (530.75 - 293)\}$$

$$w_{net} = 244.12\ \text{kJ/kg}$$

Step 8 of 10

Power produced

$$\dot{W}_{net} = \dot{m} w_{net}$$

$$150 = \dot{m} \times 244.12$$

$$\dot{m} = 0.6145\text{kg/sec}$$

Step 9 of 10

The rate of heat addition

$$\dot{Q}_{in} = \dot{m} c_p (T_4 - T_3)$$

$$= (0.6145)(1.005)(1073 - 582.344)$$

$$\boxed{\dot{Q}_{in} = 303.015\ \text{kW}}$$

Step 10 of 10

The rate of heat rejection

$$\dot{Q}_{out} = \dot{m} c_p (T_6 - T_1)$$

$$= (0.6145)(1.005)(540.75 - 293)$$

$$\boxed{\dot{Q}_{out} = 153\ \text{kW}}$$

Question: 9.091P

Rework Prob. 9–90 when the compressor isentropic efficiency is 87 percent and the turbine isentropic efficiency is 93 percent.

Step 1 of 13

Given

Compressor pressure ratio $r_p = 8$

Compressor inlet pressure $P_1 = 100\ \text{kPa}$

Compressor inlet temperature $T_1 = 20°\text{C} + 273 = 293\text{K}$

Maximum cycle temperature $T_4 = 800°\text{C} + 273 = 1073\text{K}$

The isentropic efficiency of the turbine $\eta_t = 93\%$

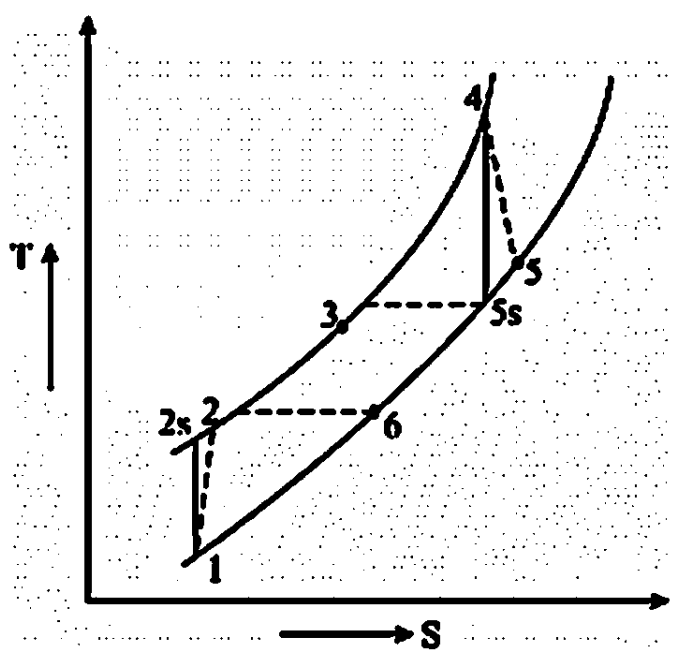
The isentropic efficiency of the compressor $\eta_c = 87\%$

Power produced $\dot{W}_{net} = 150\ \text{kW}$

The regeneration temperature $T_3 = T_5 - 10$

Step 2 of 13

Considering constant specific heats at room temperature



Gas constant $R = 0.287\ \text{kJ/kg.K}$

$c_p = 1.005\ \text{kJ/kg.K}$

$c_v = 0.718\ \text{kJ/kg.K}$

$k = 1.4$

Step 3 of 13

Step 4 of 13

Process 1-2s is isentropic compression

$$\frac{T_{2s}}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{2s}}{293} = (8)^{\frac{1.4-1}{1.4}}$$

$$T_2 = 530.75\text{K}$$

Step 5 of 13

Since the isentropic efficiency of the compression is given

$$\eta_c = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$0.87 = \frac{530.75 - 293}{T_2 - 293}$$

$$T_2 = 566.275\text{K}$$

Step 6 of 13

Similarly process 4-5s is isentropic expansion

$$\frac{T_{5s}}{T_4} = \left(\frac{P_5}{P_4}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{5s}}{T_4} = \left(\frac{P_1}{P_2}\right)^{\frac{k-1}{k}}$$

$$\frac{T_{5s}}{1073} = \left(\frac{1}{8}\right)^{\frac{1.4-1}{1.4}}$$

$$T_{5s} = 592.344\text{K}$$

Step 7 of 13

Turbine isentropic efficiency is given by

$$\eta_T = \frac{T_4 - T_5}{T_4 - T_{5s}}$$

$$0.93 = \frac{1073 - T_5}{1073 - 592.344}$$

$$T_5 = 625.98\text{K}$$

Step 8 of 13

Temperature at state 3

$$T_3 = T_5 - 10$$

$$T_3 = 625.98 - 10$$

$$T_3 = 615.98\text{K}$$

Step 9 of 13

The temperature of the gas after regeneration is determined by using energy balance to the regenerator

$$T_5 - T_6 = T_3 - T_2$$

$$T_6 = T_5 - (T_3 - T_2)$$

$$T_6 = 625.98 - (615.98 - 566.275)$$

$$T_6 = 576.275\text{K}$$

Step 10 of 13

Net work output of the cycle is expressed as

$$w_{net} = w_t - w_c$$

$$w_{net} = c_p(T_4 - T_5) - c_p(T_2 - T_1)$$

$$= (1.005)\{(1073 - 625.98) - (566.275 - 293)\}$$

$$w_{net} = 174.613\ \text{kJ/kg}$$

Step 11 of 13

Power produced

$$\dot{W}_{net} = \dot{m} \times w_{net}$$

$$150 = \dot{m} \times 174.613$$

$$\dot{m} = 0.859\ \text{kg/s}$$

Step 12 of 13

The rate of heat addition

$$\dot{Q}_{in} = \dot{m} c_p (T_4 - T_3)$$

$$= (0.859)(1.005)(1073 - 615.98)$$

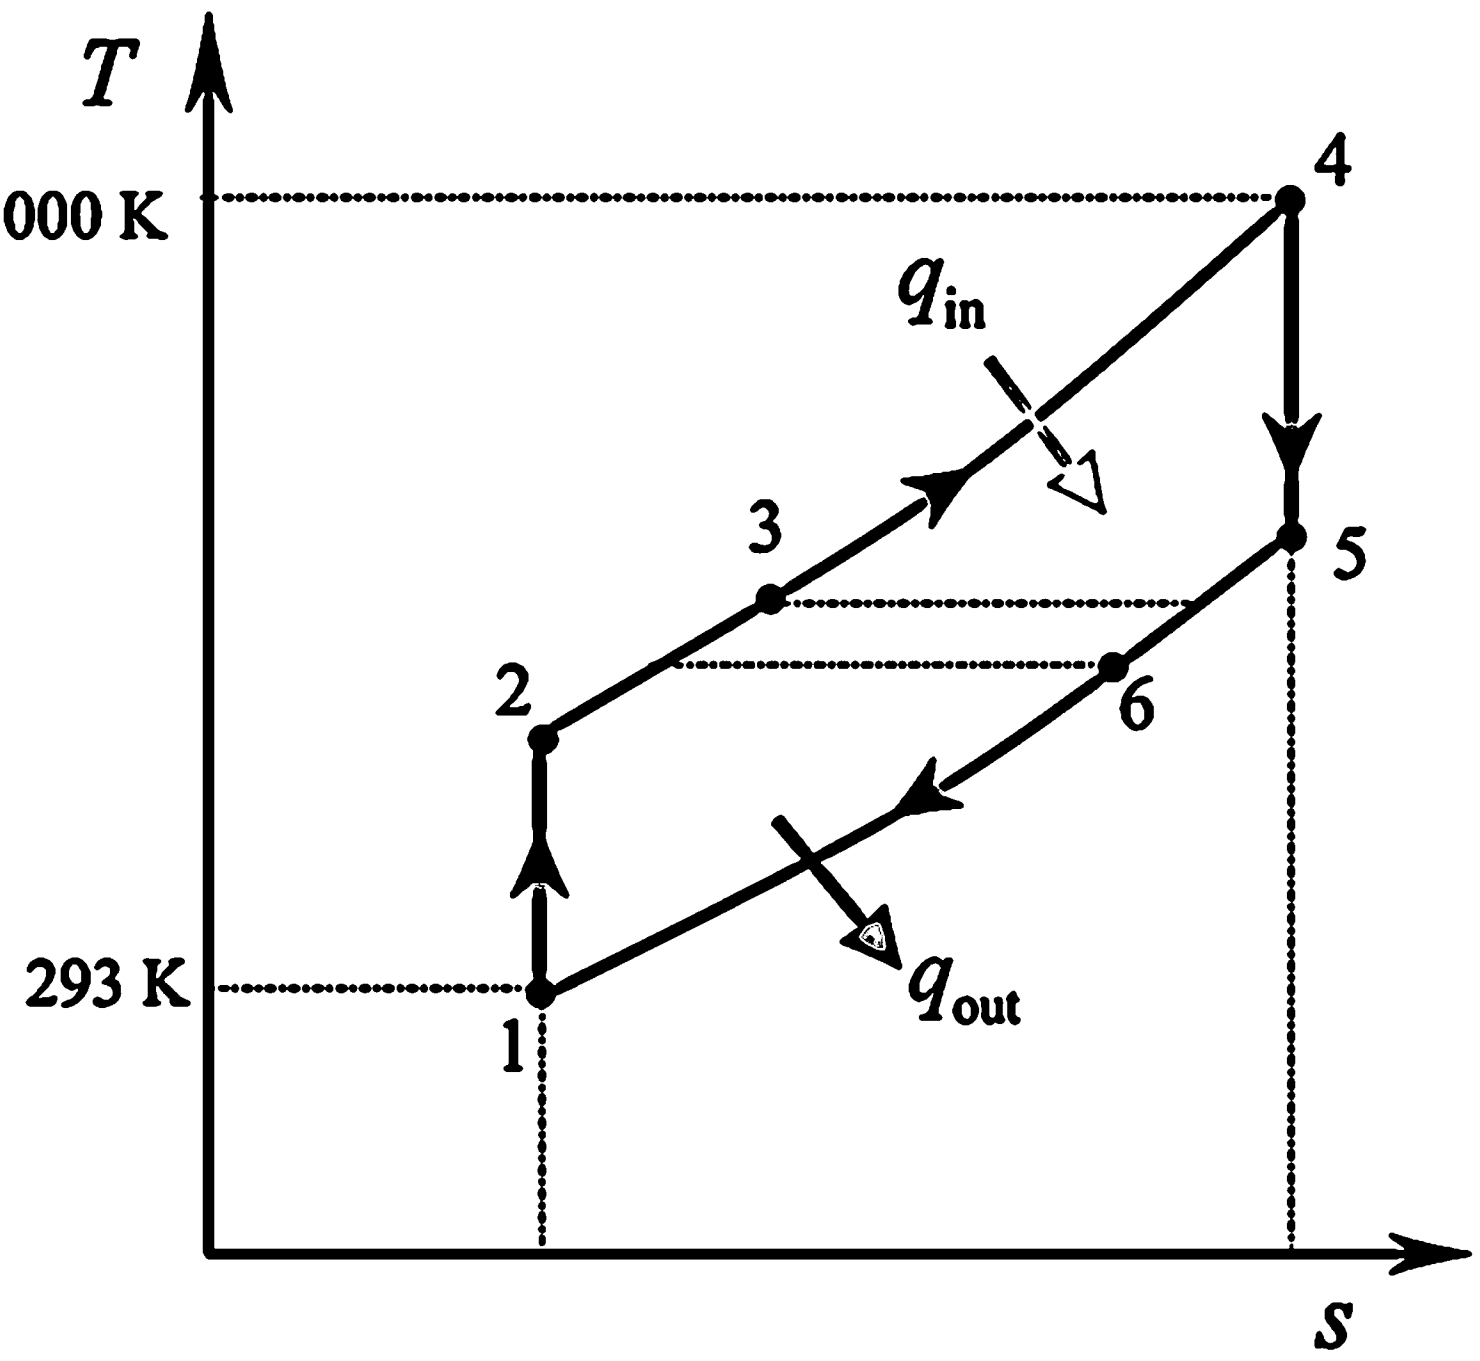
$$\boxed{\dot{Q}_{in} = 394.543\ \text{kW}}$$

Step 13 of 13

The rate of heat rejection

$$\dot{Q}_{out} = \dot{m} c_p (T_6 - T_1)$$

$$= (0.859)(1.005)(576.275 - 293)$$



$$\boxed{\dot{Q}_{out} = 244.549\ \text{kW}}$$

Question: 9.092P pg 1

A gas turbine engine operates on the ideal Brayton cycle with regeneration, as shown in Fig. P9-90. Now the regenerator is rearranged so that the air streams of states 2 and 5 enter at one end of the regenerator and streams 3 and 6 exit at the other end (i.e., parallel flow arrangement of a heat exchanger). Consider such a system when air enters the compressor at 100 kPa and 20°C; the compressor pressure ratio is 7; the maximum cycle temperature is 727°C; and the difference between the hot and cold air stream temperatures is 6°C at the end of the regenerator where the cold stream leaves the regenerator. Is the cycle arrangement shown in the figure more or less efficient than this arrangement? Assume both the compressor and the turbine are isentropic, and use constant specific heats at room temperature.

Step 1 of 11

Draw the property curve between T and s for an Ideal Brayton cycle with regeneration as follows:

Step 2 of 11

Obtain the properties of air from the **Table A-2a**.

At room temperature,

Gas constant, $R = 0.287\,\text{kJ/kg}\cdot\text{K}$

Specific heats at constant pressure, $c_p = 1.005\,\text{kJ/kg}\cdot\text{K}$

Specific heats at constant volume, $c_v = 0.718\,\text{kJ/kg}\cdot\text{K}$

Ratio of specific heats (or) Specific heat ratio, $k = 1.4$

Step 3 of 11

Consider the process $1-2$ **(Isentropic Compression process)**:

Calculate the temperature at the end of compression in an isentropic compression process by using the following equation,

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\left(\frac{k-1}{k}\right)}$$

$$T_2 = T_1\left(r_p\right)^{\left(\frac{k-1}{k}\right)}$$

Here, the temperature of air before compression is T_1, the pressure of air before compression is P_1, the temperature of air at the end of compression is T_2, the pressure of air after compression is P_2, the compressor pressure ratio is r_p and the specific heat ratio is k.

Substitute $293\,\text{K}$ for T_1, 7 for r_p, and 1.4 for k.

$$\begin{aligned} T_2 &= T_1\left(r_p\right)^{\left(\frac{k-1}{k}\right)} \\ &= 293(7)^{\left(\frac{1.4-1}{1.4}\right)} \\ &= 510.88\,\text{K} \end{aligned}$$

Step 4 of 11

Consider the process $4-5$ **(Isentropic Expansion process)**:

Calculate the temperature at the end of expansion in an isentropic expansion process by using the following equation,

$$\frac{T_5}{T_4} = \left(\frac{P_5}{P_4}\right)^{\left(\frac{k-1}{k}\right)}$$

Substitute P_1 for P_5 and P_2 for P_4.

$$\frac{T_5}{T_4} = \left(\frac{P_1}{P_2}\right)^{\left(\frac{k-1}{k}\right)}$$

$$T_5 = T_4\left(\frac{1}{r_p}\right)^{\left(\frac{k-1}{k}\right)}$$

Here, the temperature of air at the end of expansion is T_5, the pressure of air at the end of expansion is P_5, the temperature of air before expansion is T_4, and the pressure of air before expansion is P_4.

Substitute $1000\,\text{K}$ for T_4, 7 for r_p, and 1.4 for k.

$$T_5 = 1000\left(\frac{1}{\quad}\right)^{\left(\frac{1.4-1}{1.4}\right)}$$

the temperature of air before expansion is T_4, and the pressure of air before expansion is P_4.

Substitute $1000\ \text{K}$ for T_4, 7 for r_p, and 1.4 for k.

$$T_5 = 1000\left(\frac{1}{7}\right)^{\left(\frac{1.4-1}{1.4}\right)}$$
$$= 573.51\ \text{K}$$

Step 5 of 11

Write the relation between the hot and the cold air stream temperatures at the outlet of the regenerator as follows:

$$T_5 - T_3 = 6$$

Here, the temperature of hot air entering the heat addition process is T_3.

Substitute $573.51\ \text{K}$ for T_5.

$$573.51 - T_3 = 6$$
$$T_3 = 567.51\ \text{K}$$

Step 6 of 11

Apply the energy balance equation for the regenerator.

$$\begin{pmatrix}\text{Heat gained by the cold air}\\ \text{during the process 2-3}\end{pmatrix} = \begin{pmatrix}\text{Heat lost by the hot air}\\ \text{during the process 5-6}\end{pmatrix}$$
$$mc_p(T_3 - T_2) = mc_p(T_5 - T_6)$$
$$(T_3 - T_2) = (T_5 - T_6)$$

Here, the temperature of cold air at the outlet of the regenerator is T_6.

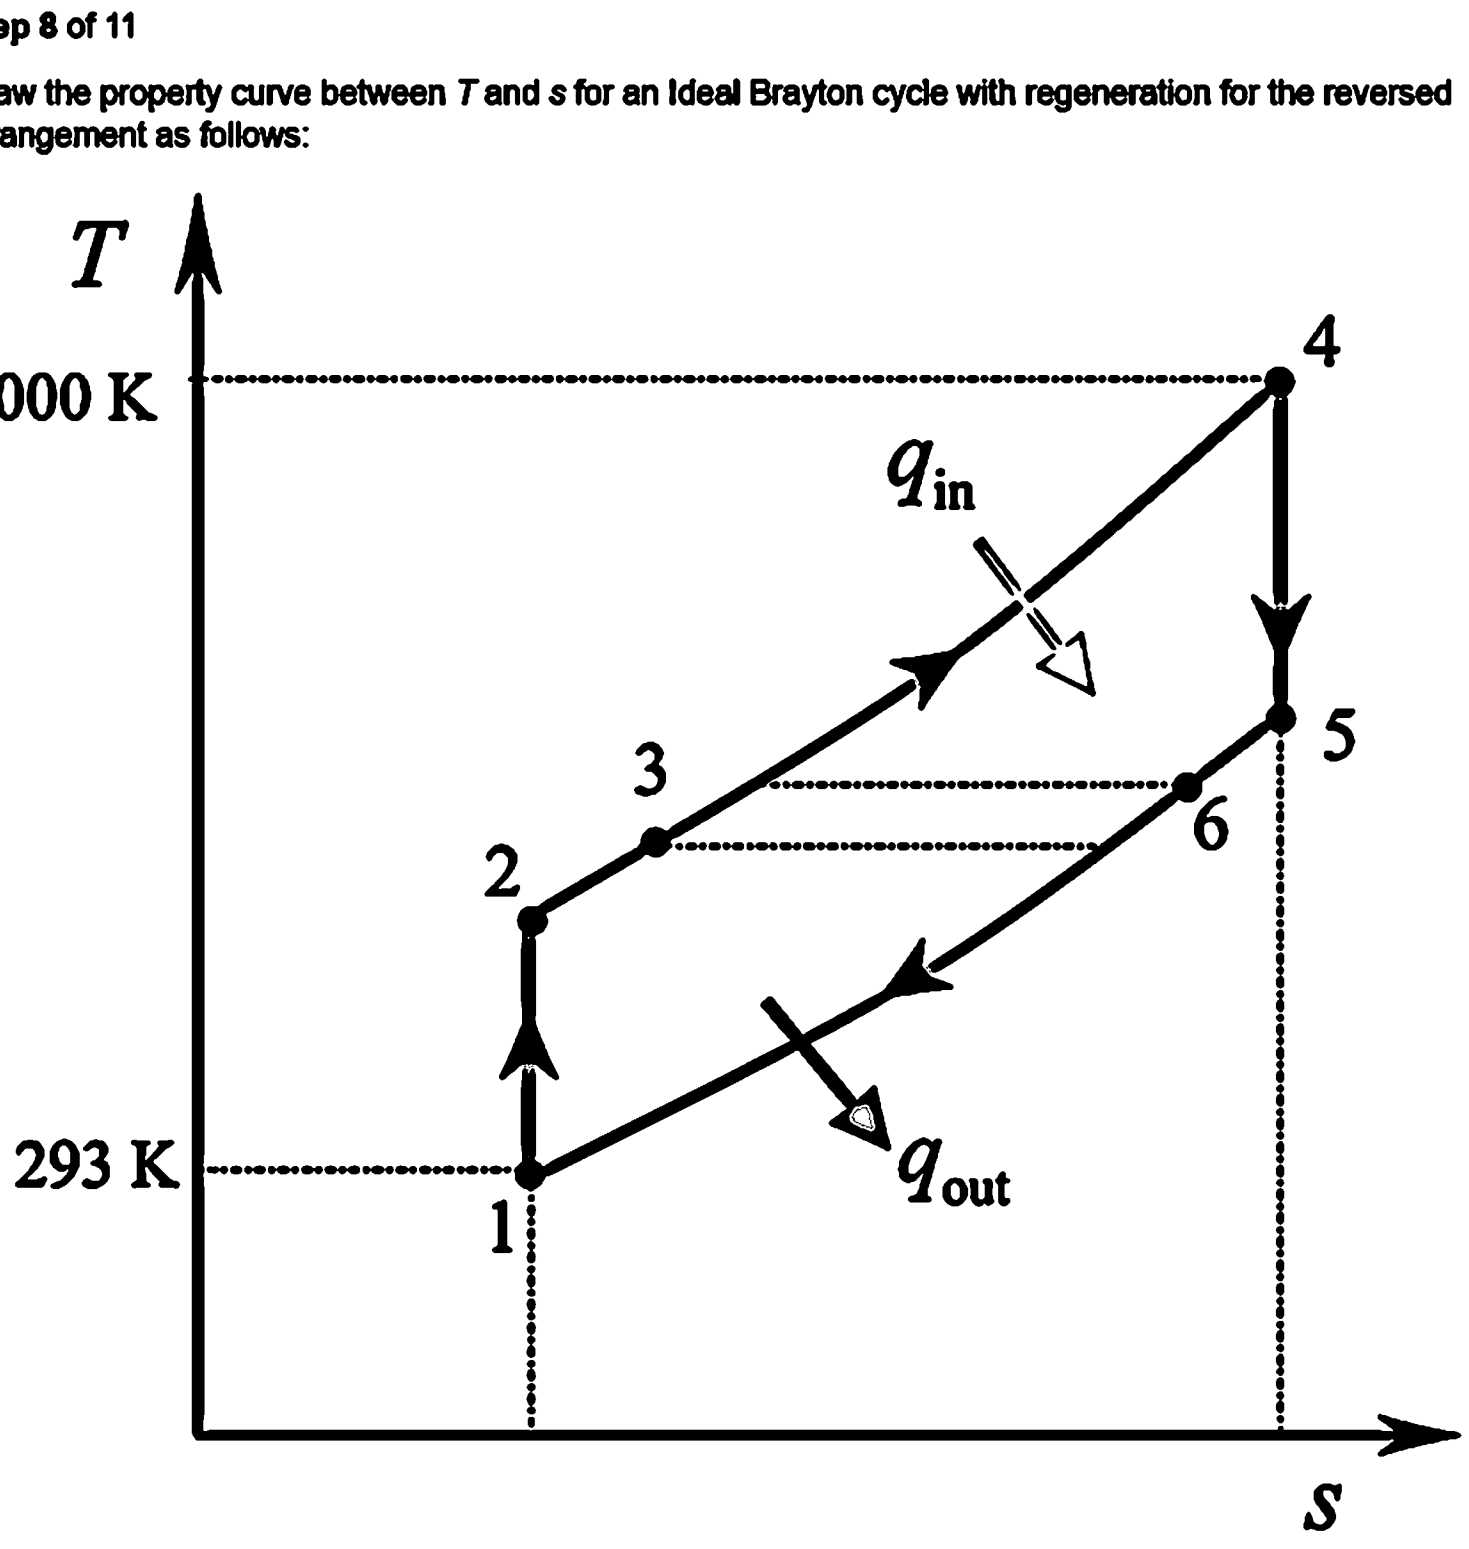
Substitute $510.88\ \text{K}$ for T_2, $567.51\ \text{K}$ for T_3 and $573.51\ \text{K}$ for T_5.

$$(567.51 - 510.88) = (573.51 - T_6)$$
$$T_6 = 516.88\ \text{K}$$

Step 7 of 11

Calculate the thermal efficiency of the cycle by using the following equation,

$$\eta_{th} = \frac{q_{in} - q_{out}}{q_{in}}$$
$$= 1 - \frac{q_{out}}{q_{in}}$$
$$= 1 - \frac{c_p(T_6 - T_1)}{c_p(T_4 - T_3)}$$
$$= 1 - \frac{(T_6 - T_1)}{(T_4 - T_3)}$$



Substitute $516.88\ \text{K}$ for T_6, $567.51\ \text{K}$ for T_3, $293\ \text{K}$ for T_1, and $1000\ \text{K}$ for T_4.

$$\eta_{th} = 1 - \frac{(516.88 - 293)}{(1000 - 567.51)}$$
$$= 1 - \frac{223.88}{432.49}$$
$$= 0.4823$$
$$= 48.23\%$$

Therefore, the thermal efficiency of the cycle is 48.23%.

Step 8 of 11

Draw the property curve between *T* and *s* for an Ideal Brayton cycle with regeneration for the reversed arrangement as follows:

Step 9 of 11

Write the relation between the hot and the cold air stream temperatures at the outlet of the regenerator as follows:

$$T_6 - T_3 = 6$$
$$T_6 = T_3 + 6 \quad \text{..... (1)}$$

Here, the temperature of hot air entering the heat addition process is T_3 and the temperature of cold air at

follows:

$$T_6 - T_3 = 6$$
$$T_6 = T_3 + 6 \quad \text{..... (1)}$$

Here, the temperature of hot air entering the heat addition process is T_3 and the temperature of cold air at the outlet of the regenerator is T_6.

Apply the energy balance equation for the regenerator.

$$\begin{pmatrix}\text{Heat gained by the cold air}\\ \text{during the process 2-3}\end{pmatrix} = \begin{pmatrix}\text{Heat lost by the hot air}\\ \text{during the process 5-6}\end{pmatrix}$$
$$mc_p(T_3 - T_2) = mc_p(T_5 - T_6)$$
$$(T_3 - T_2) = (T_5 - T_6)$$

Here, the temperature of cold air at the outlet of the regenerator is T_6.

Substitute $510.88\ \text{K}$ for T_2, and $573.51\ \text{K}$ for T_5.

$$(T_3 - 510.88) = (573.51 - T_6)$$
$$T_3 + T_6 = 1084.39\ \text{K} \quad \text{..... (2)}$$

Step 10 of 11

Substitute equation (1) in (2).

$$T_3 + (T_3 + 6) = 1084.39\ \text{K}$$
$$2T_3 = 1078.39$$
$$T_3 = 539.195\ \text{K}$$

Substitute $539.195\ \text{K}$ for T_3 in equation (1).

$$T_6 = T_3 + 6$$
$$= 539.195 + 6$$
$$= 545.195\ \text{K}$$

Step 11 of 11

Calculate the thermal efficiency of the cycle for the reversed arrangement by using the following equation,

$$\eta_{th} = \frac{q_{in} - q_{out}}{q_{in}}$$
$$= 1 - \frac{q_{out}}{q_{in}}$$
$$= 1 - \frac{c_p(T_6 - T_1)}{c_p(T_4 - T_3)}$$
$$= 1 - \frac{(T_6 - T_1)}{(T_4 - T_3)}$$

Substitute $545.195\ \text{K}$ for T_6, $539.195\ \text{K}$ for T_3, $293\ \text{K}$ for T_1, and $1000\ \text{K}$ for T_4.

$$\eta_{th} = 1 - \frac{(545.195 - 293)}{(1000 - 539.195)}$$
$$= 1 - \frac{252.195}{460.805}$$
$$= 0.4527$$
$$= 45.27\%$$

Therefore, the thermal efficiency of the cycle for the reversed arrangement is 45.27%.

Therefore, from the obtained values of the thermal efficiencies for both the arrangements, it is clear that, the cycle arrangement shown in the figure P9-111 is more efficient than the reversed arrangement.

Question: 9.093P pg 1

The 7FA gas turbine manufactured by General W Electric is reported to have an efficiency of 35.9 percent in the simple-cycle mode and to produce 159 MW of net power. The pressure ratio is 14.7 and the turbine inlet temperature is 1288°C The mass flow rate through the turbine is 1,536,000 kg/h. Taking the ambient conditions to be 30°C and 100 kPa, determine the isentropic efficiency of the turbine and the compressor. Also, determine the thermal efficiency of this gas turbine if a regenerator with an effectiveness of 65 percent is added.

Step 1 of 12

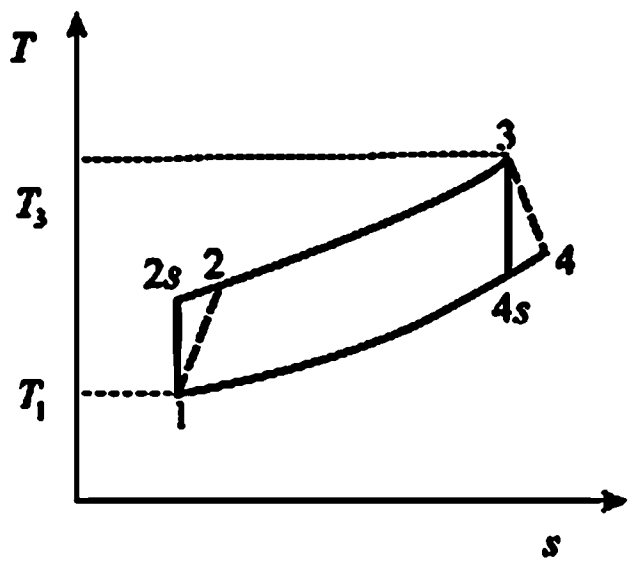
Efficiency of the gas turbine, $\eta_{th} = 35.9\% = 0.359$

Net power $P_{net} = 159\,\text{MW}$

Pressure ratio, $r = 14.7$

Turbine inlet temperature, $T_3 = 1288\,^{\circ}\text{C}$

Mass flow rate through the turbine, $m = 1536000\,\text{kg/h}$



Ambient temperature $T_1 = 30^{\circ}\text{C}=303\text{K}$

Inlet pressure $P_1 = 100\,\text{kPa}$

Effectiveness of the regenerator, $\varepsilon = 0.65$

Step 2 of 12

Ts diagram:

Step 3 of 12

From the properties of the ideal gas air,

At $T_1 = 303\text{K}$

By using the method of interpolation

$$h_1 = 300.19 + \frac{(303-300)(305.22-300.19)}{(305-300)}$$

$$= 303.21\,\text{kJ/kg}$$

Pressure ratio is

$$\text{Pr}_1 = 1.3860 + \frac{(303-300)(1.4686-1.3860)}{(305-300)}$$

$$= 1.4356$$

Step 4 of 12

From the relation of isentropic process, we have

$$\frac{P_2}{P_1} = \left(\frac{\text{Pr}_2}{\text{P}_{r1}}\right)$$

$$14.7 \times 1.4356 = \text{P}_{r2}$$

$$\text{P}_{r2} = 21.10$$

From the properties of the ideal gas air,

At $\text{P}_{r2} = 21.10$

By using the method of interpolation

$$h_{2s} = 649.22 + \frac{(21.10-20.64)(659.84-649.22)}{(21.86-20.64)}$$

$$= 653.25\,\text{kJ/kg}$$

Step 5 of 12

From the properties of the ideal gas air,

At $T_3 = 1561\text{K}$

By using the method of interpolation

$$h_3 = 1708.82 + \frac{(1561-1560)(1733.17-1708.82)}{(1580-1560)}$$

$$= 1710\,\text{kJ/kg}$$

Pressure ratio is

$$\text{P}_{r3} = 710.5 + \frac{(1561-1560)(750-710.5)}{(1580-1560)}$$

$$= 712.5$$

Step 6 of 12

From the relation of isentropic process, we have

$$\frac{P_4}{P_3} = \left(\frac{\text{Pr}_4}{\text{P}_{r3}}\right)$$

$$\frac{1}{14.7} \times 712.5 = \text{P}_{r4}$$

$$\text{P}_{r2} = 48.47$$

From the properties of the ideal gas air,

At $\text{P}_{r4} = 48.47$

By using the method of interpolation

$$h_{4s} = 821.95 + \frac{(48.47-47.75)(843.98-821.95)}{(52.59-47.75)}$$

$$= 825.23\,\text{kJ/kg}$$

Step 7 of 12

Net work done per unit mass is

$$W_{net} = \frac{P_{net}}{m}$$

$$= \frac{159000\,\text{kW}}{} \left(\frac{3600\,\text{sec}}{}\right)$$

Net work done per unit mass is

$$W_{net} = \frac{P_{net}}{m}$$
$$= \frac{159000\,\text{kW}}{1536000\,\text{kg/h}}\left(\frac{3600\,\text{sec}}{1\text{h}}\right)$$
$$= 372.66\,\text{kJ/kg}$$

Heat input is

$$q_{in} = \frac{w_{net}}{\eta_{th}}$$
$$= \frac{372.66}{0.359}$$
$$= 1038\,\text{kJ/kg}$$

Step 8 of 12

Enthalpy at state 2 is

$$q_{in} = h_3 - h_2$$
$$h_2 = 1710 - 1038$$
$$= 672\,\text{kJ/kg}$$

Heat output of the turbine is

$$W_{net} = q_{in} - q_{out}$$
$$q_{out} = q_{in} - W_{net}$$
$$= 1038 - 372.66$$
$$= 665.34\,\text{kJ/kg}$$

And

$$q_{out} = h_4 - h_1$$
$$665.34 = h_4 - 303.21$$
$$h_4 = 968.55\,\text{kJ/kg}$$

Step 9 of 12

Then, isentropic efficiency of the turbine is

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$
$$= \frac{1710 - 968.55}{1710 - 825.33}$$
$$= 0.838$$
$$= 83.8\%$$

Therefore, isentropic turbine efficiency is $\boxed{\eta_T = 83.8\%}$

Step 10 of 12

Then, isentropic efficiency of the compressor is

$$\eta_c = \frac{h_1 - h_{2s}}{h_1 - h_2}$$
$$= \frac{303.21 - 653.25}{303.21 - 672}$$
$$= 0.9491$$
$$= 94.91\%$$

Therefore, isentropic compressor efficiency is $\boxed{\eta_C = 94.91\%}$

Step 11 of 12

By using the regenerator, the new heat input becomes

$$q_{gen} = \varepsilon(h_4 - h_2)$$
$$= 0.65(968.55 - 672)$$
$$= 192.80\,\text{kJ/kg}$$

The new heat input becomes

$$q_{in,reg} = q_{in} - q_{gen}$$
$$= 1038 - 192.8$$
$$= 845.20\,\text{kJ/kg}$$

Step 12 of 12

Then, thermal efficiency of the cycle is

$$\eta_{T,gen} = \frac{W_{net}}{q_{in}}$$
$$= \frac{372.66}{845.20}$$
$$= 0.4409$$
$$= 44.09\%$$

Therefore, new thermal efficiency due to regenerator is $\boxed{\eta_{T,gen} = 44.09\%}$

Question: 9.094P

Reconsider Prob. 9–93. Using EES (or other) software, develop a solution that allows different isentropic efficiencies for the compressor and turbine and study the effect of the isentropic efficiencies on net work done and the heat supplied to the cycle. Plot the *T*-*s* diagram for the cycle.

We don't have the solution to this problem yet.

Question:

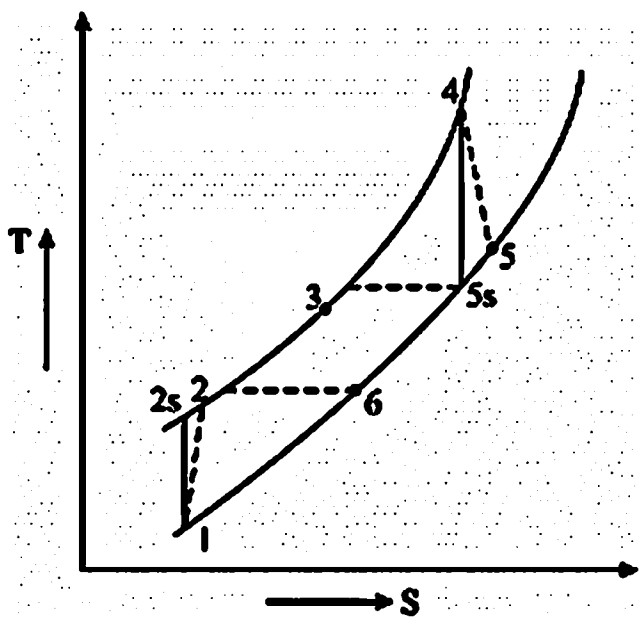
A Brayton cycle with regeneration using air as the working fluid has a pressure ratio of 7. The minimum and maximum temperatures in the cycle are 310 and 1150 K. Assuming an isentropic efficiency of 75 percent for the compressor and 82 percent for the turbine and an effectiveness of 65 percent for the regenerator, determine *(a)* the air temperature at the turbine exit, *(b)* the net work output, and (c) the thermal efficiency.
Answers: *(a)*783 K, *(b)*108.1 kJ/kg, (c) 22.5 Dercent

Step 1 of 13

Given

Pressure ratio $r_p = 7$

Minimum temperature $T_1 = 310\text{K}$



Maximum temperature $T_4 = 1150\text{K}$

Isentropic efficiency of the turbine $\eta_t = 82\%$

Isentropic efficiency of the compressor $\eta_c = 75\%$

The regenerator effectiveness $\varepsilon = 65\%$

Step 2 of 13

Step 3 of 13

At $T_1 = 310\text{K}$ from ideal gas properties of air

$h_1 = 310.24\text{kJ/kg}$

$P_{r_1} = 1.5546$

Process 1-2s is isentropic compression

$$\frac{P_{r_{2s}}}{P_{r_1}} = \left(\frac{P_2}{P_1}\right)$$

$$P_{r_{2s}} = P_{r_1}\left(\frac{P_2}{P_1}\right)$$

$$P_{r_{2s}} = 1.5546 \times 7$$

$$P_{r_{2s}} = 10.8822$$

At $P_{r_{2s}} = 10.8822$ from ideal gas properties of air

$$h_{2s} = 533.98 + (544.35 - 533.98)\left(\frac{10.8822 - 10.37}{11.10 - 10.37}\right)$$

$$h_{2s} = 541.256\text{kJ/kg}$$

Step 4 of 13

Isentropic efficiency of the compression is given by

$$\eta_c = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.75 = \frac{541.256 - 310.24}{h_2 - 310.24}$$

$$h_2 = 618.261\text{kJ/kg}$$

Step 5 of 13

At $T_4 = 1150\text{K}$ from ideal gas properties of air

$$h_4 = 1207.57 + (1230.92 - 1207.57)\left(\frac{1150 - 1140}{1160 - 1140}\right)$$

$$h_4 = 1219.245\text{kJ/kg}$$

$$P_{r_4} = 193.1 + (207.2 - 193.1)\left(\frac{1150 - 1140}{1160 - 1140}\right)$$

$$P_{r_4} = 200.15$$

Step 6 of 13

Process 4-5s is isentropic expansion

$$\frac{P_{r_4}}{P_{r_{5s}}} = \frac{P_4}{P_5}$$

$$\frac{P_{r_4}}{P_{r_{5s}}} = \frac{P_2}{P_1}$$

$$\frac{200.15}{P_{r_{5s}}} = 7$$

$$P_{r_{5s}} = 28.592$$

Step 7 of 13

At $P_{r_{5s}} = 28.592$ from ideal gas properties of air

$$h_{5s} = 702.52 + (713.27 - 702.52)\left(\frac{28.592 - 27.29}{28.80 - 27.29}\right)$$

$$h_{5s} = 711.789\text{kJ/kg}$$

Step 8 of 13

Since the isentropic efficiency of the turbine is given by

$$\eta_t = \frac{h_4 - h_5}{h_4 - h_{5s}}$$

Step 8 of 13

Since the isentropic efficiency of the turbine is given by

$$\eta_t = \frac{h_4 - h_5}{h_4 - h_{5s}}$$

$$0.82 = \frac{1219.245 - h_5}{1219.245 - 711.789}$$

$$h_5 = 803.131 \text{kJ/kg}$$

Step 9 of 13

(a)The exit temperature of air from turbine

At $h_5 = 803.131$kJ/kg from ideal gas properties of air

$$T_5 = 780 + (800 - 780)\left(\frac{803.13 - 800.03}{821.95 - 800.03}\right)$$

$$\boxed{T_5 = 782.82\text{K}}$$

Step 10 of 13

(b) The net work output

We know the regenerator effectiveness

$$\varepsilon = \frac{q_{reg,act}}{q_{reg,max}}$$

$$\varepsilon = \frac{h_3 - h_2}{h_5 - h_2}$$

$$0.65 = \frac{h_3 - 618.26}{803.13 - 618.26}$$

$$h_3 = 738.425 \text{kJ/kg}$$

Step 11 of 13

The net work out of the cycle is expressed as

$$w_{net} = w_t - w_c$$

$$w_{net} = (h_4 - h_5) - (h_2 - h_1)$$

$$= \{(1219.245 - 803.131) - (618.26 - 310.24)\}$$

$$\boxed{w_{net} = 108.094 \text{ kJ/kg}}$$

Step 12 of 13

(c) The heat supplied is expressed as

$$q_{in} = (h_4 - h_3)$$

$$= (1219.245 - 738.425)$$

$$q_{in} = 480.82 \text{ kJ/kg}$$

Step 13 of 13

The thermal efficiency is defined as

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

$$= \frac{108.094}{480.82}$$

$$= 0.2248$$

$$\boxed{\eta_{th} = 22.48\%}$$

Question: 9.096P pg 1

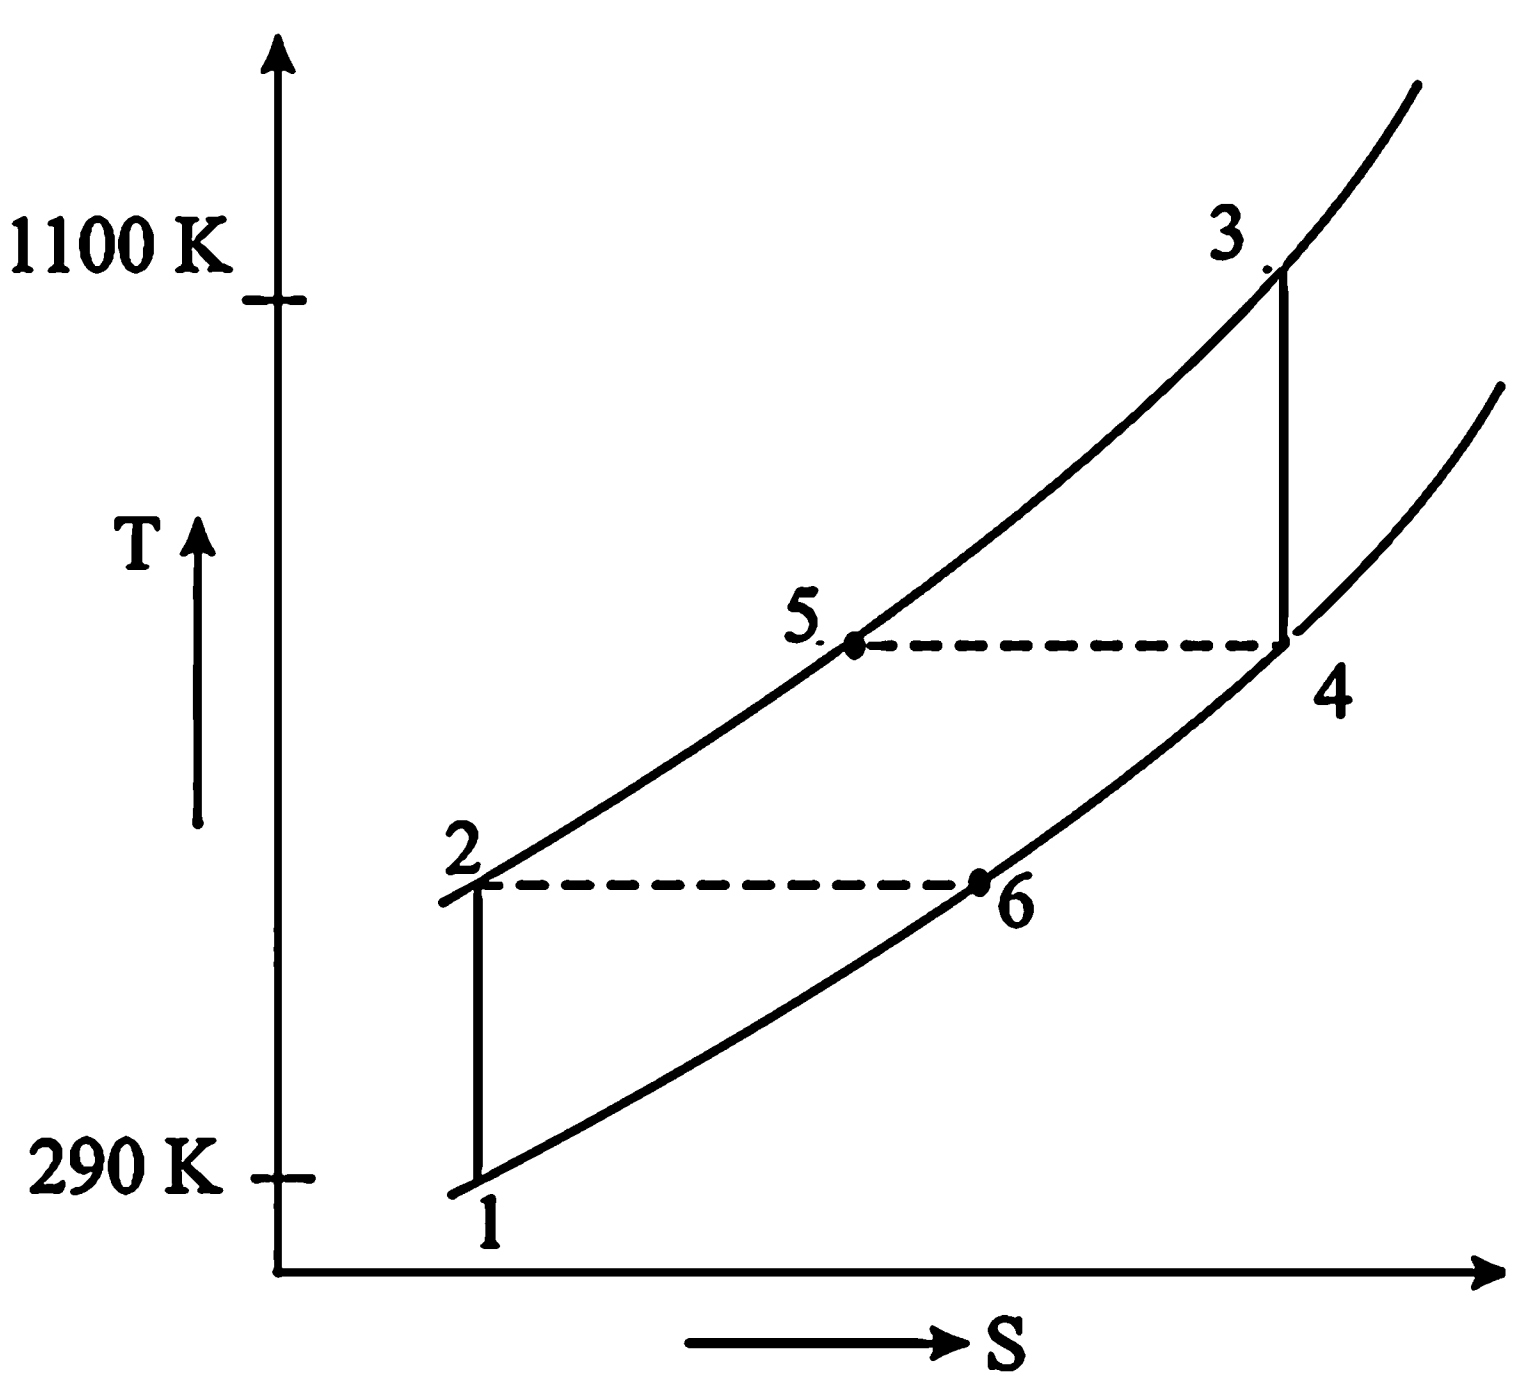
A stationary gas-turbine power plant operates on an ideal regenerative Brayton cycle (ϵ = 100 percent) with air as the working fluid. Air enters the compressor at 95 kPa and 290 K and the turbine at 760 kPa and 1100 K. Heat is transferred to air from an external source at a rate of 75,000 kJ/s. Determine the power delivered by this plant (a) assuming constant specific heats for air at room temperature and *(b)* accounting for the variation of specific heats with temperature.

Step 1 of 9

(a)

Obtain the values of constant specific heats at room temperature.

Gas constant $R = 0.287\ \text{kJ/kg.K}$



Specific heat at constant pressure, $c_p = 1.005\ \text{kJ/kg.K}$

Specific heat at constant volume, $c_v = 0.718\ \text{kJ/kg.K}$

Ratio of specific heats, $k = 1.4$

Step 2 of 9

Draw the T-s diagram for the Brayton cycle.

Step 3 of 9

For the Process 1-2(isentropic compression.):

Calculate the temperature at state 2 using the relation:

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Here, compressor inlet pressure is P_1, temperature is T_1, and exit pressure is P_2.

Substitute $760\,\text{kPa}$ for P_2, $95\,\text{kPa}$ for P_1, 290 K for T_1.

$$\frac{T_2}{290} = \left(\frac{760}{95}\right)^{\frac{1.4-1}{1.4}}$$

$$T_2 = 525.319\text{K}$$

Step 4 of 9

Similarly for process 3-4 (isentropic expansion):

Calculate the temperature at state 4, using the relation:

$$\frac{T_4}{T_3} = \left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

Here, turbine exit pressure is P_4, temperature is T_4, turbine inlet temperature is T_3 and pressure P_3.

Substitute $760\,\text{kPa}$ for P_3, $95\,\text{kPa}$ for P_4, and 1100 K for T_3.

$$\frac{T_4}{1100} = \left(\frac{95}{760}\right)^{\frac{1.4-1}{1.4}}$$

$$T_4 = 607.249\text{K}$$

Step 5 of 9

For 100% regenerator effectiveness,

Take $T_5 = T_4$ also $h_5 = h_4$.

$T_6 = T_2$ also $h_6 = h_2$.

Calculate the power delivered by the gas turbine.

$$\eta = \frac{\dot{W}}{\dot{Q}_{in}} = 1 - \frac{q_{out}}{q_{in}}$$

$$\frac{\dot{W}}{\dot{Q}} = 1 - \frac{c_p(T_2 - T_1)}{c_p(T_3 - T_4)}$$

$$\frac{\dot{W}}{\dot{Q}} = 1 - \frac{c_p(T_2 - T_1)}{c_p(T_3 - T_4)}$$

Substitute $1.005\ \text{kJ/kg.K}$ for c_p, 525.319 K for T_2, 290K for T_1, 1100K for T_3, and 607.249K for T_4.

$$\frac{\dot{W}}{75,000} = 1 - \frac{(525.319 - 290)}{(1100 - 607.249)}$$

$$\frac{\dot{W}}{75,000} = 0.52243$$

$$\dot{W} = 39182.25\text{kW}$$

Therefore the power delivered by the plant is $\boxed{39.18\ \text{MW}}$.

(b)

Obtain the properties of air from, "TABLE-17 Ideal-gas properties of air", in the text book

by using variable specific heats

At temperature, $T_1 = 290\text{K}$.

Specific enthalpy, $h_1 = 290.16\text{kJ/kg}$

Relative pressure, $P_{r1} = 1.2311$

For Process 1-2 (isentropic compression):

Calculate the relative pressure at state 2 using the relation:

$$\frac{P_{r2}}{P_{r1}} = \frac{P_2}{P_1}$$

$$\frac{P_{r2}}{1.2311} = \frac{760}{95}$$

$$P_{r2} = 9.8488$$

Step 6 of 9

Obtain the value of specific enthalpy from "TABLE-17 Ideal-gas properties of air", in the text book.

At $P_{r2} = 9.8488$

By the method of interpolation, calculate the specific enthalpy as shown:

$$h_2 = 523.63 + (533.98 - 523.63)\left(\frac{9.8488 - 9.684}{10.37 - 9.684}\right)$$

$$h_2 = 526.1164\,\text{kJ/kg}$$

Step 7 of 9

Obtain the value of specific enthalpy from "TABLE-17 Ideal-gas properties of air", in the text book.

At $T_3 = 1100\text{K}$

The specific enthalpy, $h_3 = 1161.07\text{kJ/kg}$

Relative pressure, $P_{r3} = 167.1$

For Process 4-5 (isentropic expansion process):

Calculate the relative pressure at state 5.

$$\frac{P_{r3}}{P_{r4}} = \frac{P_3}{P_4}$$

$$\frac{167.1}{P_{r4}} = \frac{760}{95}$$

$$P_{r4} = 20.89$$

Step 8 of 9

Obtain the value of specific enthalpy from "TABLE-17 Ideal-gas properties of air", in the text book.

At $P_{r4} = 20.89$ from ideal gas properties of air

$$h_4 = 649.22 + (659.84 - 649.22)\left(\frac{20.89 - 20.64}{21.86 - 20.64}\right)$$

$$h_4 = 651.374\,\text{kJ/kg}$$

Step 9 of 9

Calculate the power delivered by the gas turbine.

$$\eta = \frac{\dot{W}}{\dot{Q}_{in}} = 1 - \frac{q_{out}}{q_{in}}$$

$$\frac{\dot{W}}{\dot{Q}} = 1 - \frac{(h_6 - h_1)}{(h_3 - h_5)}$$

Substitute $75000\,\text{kW}$ for $\dot{Q}$, $651.374\,\text{kJ/kg}$ for h_5, $526.1164\,\text{kJ/kg}$ for h_6, 1161.07kJ/kg for h_3, $290.16\,\text{kJ/kg}$ for h_1.

$$\frac{\dot{W}}{75,000} = 1 - \frac{(526.1164 - 290.16)}{(1161.07 - 651.374)}$$

$$\frac{\dot{W}}{75,000} = 0.53706$$

$$\dot{W} = 40283\,\text{kW}$$

Therefore, the power delivered by the plant is $\boxed{\dot{W} = 40.283\,\text{MW}}$

$$\frac{\dot{W}}{75{,}000} = 0.53706$$

9.096P pg 3

$$\dot{W} = 40283\,\text{kW}$$

Therefore, the power delivered by the plant is $\boxed{\dot{W} = 40.283\,\text{MW}}$

Question: 9.097P

Air enters the compressor of a regenerative gas-turbine engine at 310 K and 100 kPa, where it is compressed to 900 kPa and 650 K. The regenerator has an effectiveness of 80 percent, and the air enters the turbine at 1400 K. For a turbine efficiency of 90 percent, determine *(a)* the amount of heat transfer in the regenerator and *(b)* the thermal efficiency. Assume variable specific heats for air. Answers: *(a)*193 kJ/kg, *(b)*40.0 percent

Step 1 of 6

(a)

Consider constant specific heats at room temperature (From table A-2)

Gas constant

$$R = 0.287\ \text{kJ/kg}\cdot\text{K}$$

Specific heats,

$$c_v = 0.718\ \text{kJ/kg}\cdot\text{K}$$

$$c_p = 1.005\ \text{kJ/kg}\cdot\text{K}$$

Specific heat ratio

$$k = 1.4$$

Calculate the compression ratio

$$r_p = \frac{P_2}{P_1}$$

Here, Pressures at state 1 and 2 are P_1, P_2 respectively

Substitute 900 kPa for P_2, 100 kPa for P_1

$$\begin{aligned} r_p &= \frac{P_2}{P_1} \\ &= \frac{900}{100} \\ &= 9 \end{aligned}$$

Step 2 of 6

Obtain the enthalpies from properties of air table (TABLE A17) at each stage as below:

For temperature $T_1 = 310\ \text{K}$, enthalpy $h_1 = 310.24\ \text{kJ/kg}$

For temperature $T_2 = 650\ \text{K}$, enthalpy $h_2 = 659.84\ \text{kJ/kg}$

For temperature $T_3 = 1400\ \text{K}$, enthalpy $h_3 = 1515.42\ \text{kJ/kg}$ and corresponding pressure ratio is $P_{r3} = 450.5$

Find the pressure ratio between point 4 and point 3

$$P_{r4} = \frac{P_4}{P_3} P_{r3}$$

Here, Pressure at state 3 and 4 is P_3, P_4 respectively.

Substitute 100 kPa for P_4, 900 kPa for P_3, 238 for P_{r3} in the above equation

$$\begin{aligned} P_{r4} &= \frac{100}{900} \times 450.5 \\ &= 50.05 \end{aligned}$$

Obtain isentropic enthalpy at state 4s from the table at $P_{r4} = 50.05$

$$h_{4s} = 835.12\ \text{kJ/kg}$$

Step 3 of 6

Find enthalpy at state 4 using below relation

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

Here, η_T is efficiency of turbine.

Substitute $1515.42\ \text{kJ/kg}$ for h_3, 835.12 for h_{4s}, 0.90 for η_T.

$$\begin{aligned} h_4 &= 1515.42 - (0.90)(1515.42 - 835.12) \\ &= 903.15\ \text{kJ/kg} \end{aligned}$$

Step 4 of 6

Calculate the amount of heat transfer in the regenerator having effectiveness $\varepsilon = 0.8$ as follows,

$$q_R = \varepsilon (h_4 - h_2)$$

Substitute $903.15\ \text{kJ/kg}$ for h_4, $659.84\ \text{kJ/kg}$ for h_2, and 0.80 for ε

$$\begin{aligned} q_R &= 0.80(903.15 - 659.84) \\ &= 194.68\ \text{kJ/kg} \end{aligned}$$

Therefore, the amount of heat transfer in the regenerator is $\boxed{194.648\ \text{kJ/kg}}$

Step 5 of 6

(b)

Find the net work developed

$$\begin{aligned} w_{net} &= w_{T,out} - w_{C,in} \\ &= (h_3 - h_4) - (h_2 - h_1) \end{aligned}$$

Substitute $903.15\ \text{kJ/kg}$ for h_4, $659.84\ \text{kJ/kg}$ for h_2, $1515.42\ \text{kJ/kg}$ for h_3, and $310.24\ \text{kJ/kg}$ for h_1

$$\begin{aligned} w_{net} &= (1515.42 - 903.15) - (659.84 - 310.24) \\ &= 262.67\ \text{kJ/kg} \end{aligned}$$

Step 6 of 6

Find the heat input to the system

$$q_{in} = (h_3 - h_2) - q_R$$

Substitute $194.68\ \text{kJ/kg}$ for q_R, $659.84\ \text{kJ/kg}$ for h_2, and $1515.42\ \text{kJ/kg}$ for h_3.

$$\begin{aligned} q_{in} &= (1515.42 - 659.84) - 194.68 \\ &= 660.9\ \text{kJ/kg} \end{aligned}$$

Find the thermal efficiency of the system

$$\eta_{th} = \frac{w_{net}}{q_{in}}$$

Substitute $262.67\ \text{kJ/kg}$ for w_{net}, and $660.9\ \text{kJ/kg}$ for q_{in}.

$$\begin{aligned} \eta_{th} &= \frac{267.62}{660.9} \\ &= 40\ \% \end{aligned}$$

Therefore, the thermal efficiency is $\boxed{40\%}$.

Question: 9.098P

Repeat Prob. 9–97 using constant specific heats at room temperature.

Step 1 of 6

a)

Step 2 of 6

Calculate the actual temperature at stage 4 (T_{4s}) from isentropic process 3-4 as follows.

$$T_{4s} = T_3\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}}$$

Step 3 of 6

Substitute 100 kPa for P_4, 900 kPa for P_3, and 1.4 for k.

$$T_{4s} = 1400\left(\frac{100}{900}\right)^{\frac{0.4}{1.4}}$$
$$= 747.28\ \text{K}$$

Step 4 of 6

Find enthalpy at state 4 as follows,

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$
$$\eta_T = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})}$$
$$T_4 = T_3 - \eta_T(T_3 - T_{4s})$$

Here, η_T is turbine efficiency.

Substitute 1400 K for T_3, 0.90 for η_T, and 747.28 K for T_{4s}.

$$T_4 = 1400 - 0.90(1400 - 747.28)$$
$$= 812.552\ \text{K}$$

Find the amount of heat transfer in the regenerator having effectiveness $\varepsilon = 0.80$ as follows,

$$q_R = \varepsilon c_p(T_4 - T_2)$$

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p, 650 K for T_2, 0.90 for η_T, and 812.552 K for T_4.

$$q_R = 0.90(1.005)(812.552 - 650)$$
$$= 147.02\ \text{kJ/kg}$$

Therefore, the amount of heat transfer in the regenerator is $\boxed{147.02\ \text{kJ/kg}}$.

Step 5 of 6

(b)

Calculate the net-work developed as follows,

$$w_{net} = w_{T,out} - w_{C,in}$$
$$= c_p(T_3 - T_4) - c_p(T_2 - T_1)$$
$$w_{net} = c_p\left[(T_3 - T_4) - (T_2 - T_1)\right]$$

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p, 310 K for T_1, 1400 K for T_3, 650 K for T_2, and 812.552 K for T_4.

$$w_{net} = 1.005\left[(1400 - 812.552) - (650 - 310)\right]$$
$$= 248.68\,\text{kJ/kg}$$

Step 6 of 6

Find the heat input to the system

$$q_{in} = (h_3 - h_2) - q_R$$
$$= c_p(T_3 - T_2) - q_R$$

Substitute $1.005\,\text{kJ/kg}\cdot\text{K}$ for c_p, 1400 K for T_3, 650 K for T_2, and $147.02\ \text{kJ/kg}$ for q_R.

$$q_{in} = (1.005\ \text{kJ/kg K})(1400 - 650)\,\text{K} - 147.02\,\text{kJ/kg}$$
$$= 606.73\,\text{kJ/kg}$$

Find the thermal efficiency as follows,

$$\eta_T = \frac{w_{net}}{q_{in}}$$

Substitute $248.68\,\text{kJ/kg}$ for w_{net}, and $606.73\,\text{kJ/kg}$ for q_{in}

$$\eta_T = \frac{248.68\ \text{kJ/kg}}{606.73\ \text{kJ/kg}}$$
$$\approx 41\,\%$$

Therefore, the thermal efficiency is $\boxed{41\,\%}$.

Question: 9.099P

Repeat Prob. 9–97 for a regenerator effectiveness of 70 percent.

Step 1 of 5

a)

Consider constant specific heats at room temperature (From table A-2)

Gas constant

$$R = 0.287\ \text{kJ/kg}\cdot\text{K}$$

Specific heats,

$$c_v = 0.718\ \text{kJ/kg}\cdot\text{K}$$

$$c_p = 1.005\ \text{kJ/kg}\cdot\text{K}$$

Specific heat ratio

$$k = 1.4$$

Calculate the compression ratio

$$r_p = \frac{P_2}{P_1}$$

Here, Pressures at state 1 and 2 are P_1, P_2 respectively

Substitute 900 kPa for P_2, and 100 kPa for P_1

$$\begin{aligned} r_p &= \frac{P_2}{P_1} \\ &= \frac{900}{100} \\ &= 9 \end{aligned}$$

Step 2 of 5

Obtain the enthalpies from properties of air table (TABLE A17) at each stage as below:

For temperature $T_1 = 310\ \text{K}$, enthalpy $h_1 = 310.24\ \text{kJ/kg}$

For temperature $T_2 = 650\ \text{K}$, enthalpy $h_2 = 659.84\ \text{kJ/kg}$

For temperature $T_3 = 1400\ \text{K}$, enthalpy $h_3 = 1515.42\ \text{kJ/kg}$ and corresponding pressure ratio is $P_{r3} = 450.5$

Find the pressure ratio between point 4 and point 3

$$P_{r4} = \frac{P_4}{P_3} P_{r3}$$

Here, Pressure at state 3 and 4 is P_3, P_4 respectively.

Substitute 100 kPa for P_4, 900 kPa for P_3 , 238 for P_{r3} in the above equation

$$\begin{aligned} P_{r4} &= \frac{100}{900} \times 450.5 \\ &= 50.05 \end{aligned}$$

Obtain isentropic enthalpy at state 4s from the table at $P_{r4} = 50.05$

$$h_{4s} = 835.12\ \text{kJ/kg}$$

Step 3 of 5

Find enthalpy at state 4 using below relation

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

Here, η_T is efficiency of turbine.

Substitute $1515.42\ \text{kJ/kg}$ for h_3 , 835.12 for h_{4s} , 0.90 for η_T .

$$\begin{aligned} h_4 &= 1515.42 - (0.90)(1515.42 - 835.12) \\ &= 903.15\ \text{kJ/kg} \end{aligned}$$

Step 4 of 5

Calculate the amount of heat transfer in the regenerator having effectiveness $\varepsilon = 0.70$ as follows

$$q_R = \varepsilon (h_4 - h_2)$$

Substitute $903.15\ \text{kJ/kg}$ for h_4 , $659.84\ \text{kJ/kg}$ for h_2 , and 0.70 for ε in equation

$$\begin{aligned} q_R &= 0.70(903.15 - 659.84) \\ &= 170.317\ \text{kJ/kg} \end{aligned}$$

Therefore, the amount of heat transfer in the regenerator is $\boxed{170.317\ \text{kJ/kg}}$.

Step 5 of 5

(b)

Find the net work developed

$$\begin{aligned} w_{net} &= w_{T,out} - w_{C,in} \\ &= (h_3 - h_4) - (h_2 - h_1) \end{aligned}$$

Substitute $903.15\ \text{kJ/kg}$ for h_4 , $659.84\ \text{kJ/kg}$ for h_2 , $1515.42\ \text{kJ/kg}$ for h_3 , and $310.24\ \text{kJ/kg}$ for h_1

$$\begin{aligned} w_{net} &= (1515.42 - 903.15) - (659.84 - 310.24) \\ &= 262.67\ \text{kJ/kg} \end{aligned}$$

Find the heat input to the system

$$q_{in} = (h_3 - h_2) - q_R$$

Substitute $170.317\ \text{kJ/kg}$ for q_R , $659.84\ \text{kJ/kg}$ for h_2 , and $1515.42\ \text{kJ/kg}$ for h_3 .

$$\begin{aligned} q_{in} &= (1515.42 - 659.84) - 170.317 \\ &= 685.263\ \text{kJ/kg} \end{aligned}$$

Find the thermal efficiency

$$\eta_T = \frac{w_{net}}{q_{in}}$$

Substitute $262.67\ \text{kJ/kg}$ for w_{net} , and $685.263\ \text{kJ/kg}$ for q_{in} .

$$\begin{aligned} \eta_T &= \frac{262.67}{685.263} \\ &= 38\ \% \end{aligned}$$

Therefore, the thermal efficiency is $\boxed{38\%}$.

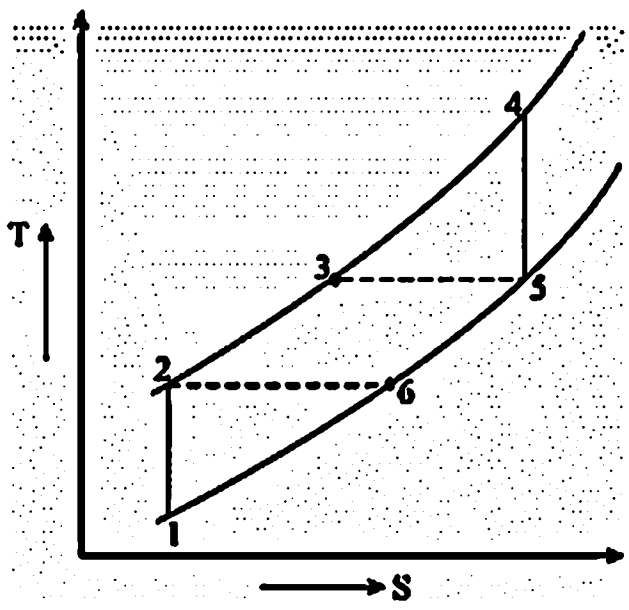
Question: 9.100P

Develop an expression for the thermal efficiency 0 f an ideal Brayton cycle with an ideal regenerator of effectiveness 100 percent. Use constant specific heats at room temperature

Step 1 of 4

The efficiency of the cycle is defined as

$$\eta_{bry} = 1 - \frac{q_{out}}{q_{in}}$$



The rate of heat addition

$$q_{in} = c_p (T_4 - T_3)$$

The rate of heat rejection

$$q_{out} = c_p (T_6 - T_1)$$

Step 2 of 4

Step 3 of 4

For an ideal regenerator of 100% effectiveness

$T_5 = T_3$ And $T_2 = T_6$

Process 1-2 is isentropic compression

$$\frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

Assuming pressure ratio $r_p = \frac{P_2}{P_1}$ then

$$\frac{T_2}{T_1} = (r_p)^{\frac{k-1}{k}}$$

Similarly process 4-5 is isentropic expansion

$$\frac{T_4}{T_5} = \left(\frac{P_4}{P_5}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{T_5} = \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}$$

$$\frac{T_4}{T_5} = (r_p)^{\frac{k-1}{k}}$$

Step 4 of 4

We know thermal efficiency of the cycle is

$$\eta = 1 - \frac{q_{out}}{q_{in}}$$

$$\eta = 1 - \frac{T_6 - T_1}{T_4 - T_3}$$

$$= 1 - \frac{T_2 - T_1}{T_4 - T_5}$$

$$= 1 - \frac{T_1}{T_4}\left(\frac{\frac{T_2}{T_1} - 1}{1 - \frac{T_5}{T_4}}\right)$$

$$= 1 - \frac{T_1}{T_4}\left[\frac{(r_p)^{\frac{k-1}{k}} - 1}{1 - \frac{1}{(r_p)^{\frac{k-1}{k}}}}\right]$$

$$\eta = 1 - \frac{T_1}{T_4}(r_p)^{\frac{k-1}{k}}$$

Therefore efficiency of an ideal Brayton cycle with an ideal regenerator of effectiveness 100% is

$$\boxed{\eta = 1 - \frac{T_1}{T_4}(r_p)^{\frac{k-1}{k}}}$$

Question: 9.101P

Why is the Carnot cycle not a realistic model for steam power plants?

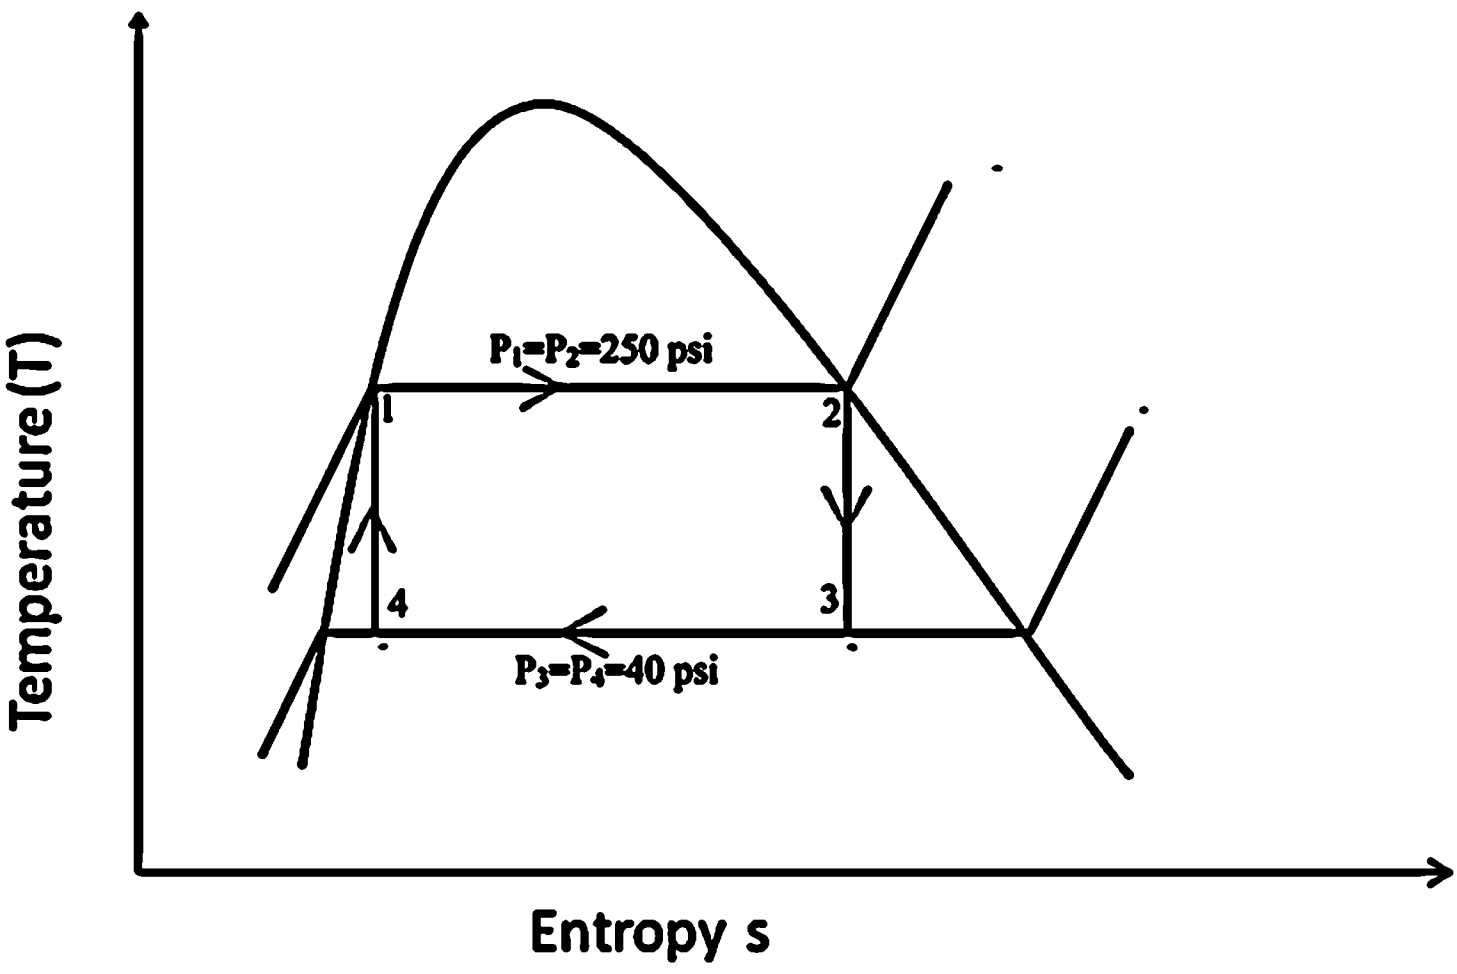
Step 1 of 1

Carnot cycle is not a realistic model for steam power plant due to the following reasons.

(1) Limiting the heat transfer processes to two-phase systems for maintaining isothermal conditions severely limits the maximum temperature that can be used in the cycle.

(2) Turbine handles steam with high moisture content that causes erosion.

(3) It is not easy to control the condensation process so precisely as to end up with the desired quality at state.



(4) Designing a compressor that can handle two phases is not practiacal.

Question: 9.102P pg 1

Water enters the boiler of a steady-flow Carnot engine as a saturated liquid at 250 psia and leaves with a quality of 0.95. Steam leaves the turbine at a pressure of 40 psia. Show the cycle on a *T-s* diagram relative to the saturation lines, and determine (a) the thermal efficiency *(b)* the quality at the end of the isothermal heat-rejection process, and *(c)* the net work output.

Step 1 of 9

Draw the T-s diagram of the Carnot cycle.

Step 2 of 9

(a)

Obtain the properties at state1 from the saturated water pressure table,

At $P_1 = 250$ psia Saturated liquid, at this pressure,

$$T_1 = T_{sat} = 400.97°F$$
$$h_1 = (h_f) = 376.09 \text{ Btu/lbm}$$
$$s_1 = (s_f) = 0.56784 \text{ Btu/lbm°F}$$

Here, T_1 is the saturation temperature at state 1 h_1 is the enthalpy at state 1 and s_1 is the entropy at state 1.

Step 3 of 9

At state 2:

Obtain the properties at state 2 from the saturated water pressure table,

$P_1 = 250$ psi and is 95% saturated vapor

$$T_2 = T_1 = 400.97°F$$

Calculate the enthalpy at state 2 by using the equation,

$$h_2 = (h_f) + x(h_{fg})$$

Here, h_2 is the enthalpy at state 2, h_f is the enthalpy of saturated liquid at state 2 and h_{fg} is the enthalpy of wet steam at state 2.

Substitute 376.09 Btu/lbm for h_f . 0.95 for x and 825.47 Btu/lbm for h_{fg} .

$$h_2 = 376.09 + (0.95 \times 825.47)$$
$$= 1160.286 \text{ Btu/lbm}$$

Calculate the entropy at state 2 by using equation,

$$s_2 = (s_f) + x(s_{fg})$$

Here, s_2 is the entropy at state 2 , s_f is the entropy of saturated liquid at state 2 and s_{fg} is the entropy of wet steam at state 2.

Substitute $0.56784 \text{ Btu/lbm°F}$ for s_f . 0.95 for x and $0.95912 \text{ Btu/lbm°F}$ for s_{fg} .

$$s_2 = 0.56784 + (0.95 \times 0.95912)$$
$$= 1.479 \text{ Btu/lbm°F}$$

Step 4 of 9

State 3:

Obtain the properties of steam at state 3 from the saturated water table.

Since process 2-3 isentropic process.

So $s_3 = s_2 = 1.479 \text{ Btu/lbm°F}$

From the saturated water pressure table,

At $P_3 = 40$ psi

At this pressure and entropy,

$$T_3 = (T_{sat}) = 267.22°F$$
$$(s_g) = 1.6766 \text{ Btu/lbm°F}$$
$$(s_f) = 0.39213 \text{ Btu/lbm°F}$$

$$h_f = 236.14 \text{ Btu/lbm}$$
$$h_g = 1169.8 \text{ Btu/lbm}$$
$$h_{fg} = 933.66 \text{ Btu/lbm}$$

Step 5 of 9

Calculate the entropy at state 3 by using the equation,

Step 5 of 9

Calculate the entropy at state 3 by using the equation,

$$s_3 = s_2 = (s_f) + x_3(s_g - s_f)$$

Here, s_2 is the entropy at state 2 , s_f is the entropy of saturated liquid a state 3, s_g is the entropy of saturated vapour state 3 and x_3 is the quality of steam at state 3.

Substitute $1.479\,\text{Btu/lbm°F}$ for s_2 , $0.39213\,\text{Btu/lbm°F}$ for s_f and $1.6766\ \text{Btu/lbm°F}$ for s_g .

$$1.479 = 0.39213 + x_3(1.6766 - 0.39213)$$
$$x_3 = 0.846$$

Calculate the enthalpy at state 3 by using the equation,

$$h_3 = (h_f) + x_3(h_g - h_f)$$

Here, h_3 is the enthalpy at state 3 , h_f is the enthalpy of saturated liquid at state 3 and h_g is the enthalpy of saturated vapour at state 3.

Substitute $236.14\,\text{Btu/lbm}$ for h_f , 0.846 for x_3 and $1169.8\,\text{Btu/lbm}$ for h_g .

$$h_3 = 236.14 + 0.846 \times (1169.8 - 236.14)$$
$$h_3 = 1026.01\ \text{Btu/lbm}$$

Step 6 of 9

State 4:

Obtain the properties of steam at state 4 from the saturated water table.

Since Process 4-1 isentropic process

$$s_4 = s_1 = 0.56784\,\text{Btu/lbm°F}$$

$$P_3 = 40\ \text{psi}$$

Calculate the entropy at state 4 by using the equation,

$$s_4 = s_1 = (s_f) + x_4(s_g - s_f)$$

Here, s_1 is the entropy at state 1, s_f is the entropy of saturated liquid a state 4 and s_{fg} is the entropy of wet steam state 4 and x_4 is the quality of steam at the end of the heat rejection.

Substitute $0.56784\,\text{Btu/lbm°F}$ for s_4 , $0.39213\,\text{Btu/lbm°F}$ for s_f and $1.6766\ \text{Btu/lbm°F}$ for s_g .

$$0.56784 = 0.39213 + x_4(1.6766 - 0.39213)$$
$$x_4 = 0.137$$

Therefore, the quality of steam at the end of the heat rejection is $\boxed{x_4 = 0.137}$.

Step 7 of 9

Calculate the entropy at state 4 by using the equation,

$$h_4 = (h_f) + x_4(h_g - h_f)$$

Here, h_4 is the enthalpy at state 4 , h_f is the enthalpy of saturated liquid at state 4 and h_g is the enthalpy of saturated vapour state 4.

Substitute $236.14\,\text{Btu/lbm}$ for h_f , 0.137 for x_4 and $1169.8\,\text{Btu/lbm}$ for h_g .

$$h_4 = 236.14 + [0.137 \times (1169.8 - 236.14)]$$
$$h_4 = 364.051\ \text{Btu/lbm}$$

Step 8 of 9

(b)

Calculate the thermal efficiency of the Carnot cycle by using the equation,

$$\eta_{Carnot} = 1 - \frac{q_{rej}}{q_{in}}$$
$$= 1 - \frac{h_3 - h_4}{h_2 - h_1}$$

Here, η_{carnot} is the thermal efficiency of Carnot cycle.

Substitute $376.09\,\text{Btu/lbm}$ for h_1 , $1160.286\,\text{Btu/lbm}$ for h_2 , $1026.01\,\text{Btu/lbm}$ for h_3 and $364.0514\,\text{Btu/lbm}$ for h_4 .

$$\eta_{Carnot} = 1 - \left(\frac{1026.01 - 364.0514}{1160.286 - 376.09}\right)$$
$$= 0.155$$

Therefore, the efficiency of the Carnot cycle is $\boxed{\eta_C = 15.5\%}$.

Step 9 of 9

(c)

Calculate the net work output of the cycle by using the equation,

$$W_{net} = (h_2 - h_3) - (h_1 - h_4)$$

Here, W_{net} is the net work output of the cycle.

Substitute $376.09\,\text{Btu/lbm}$ for h_1 , $1160.286\,\text{Btu/lbm}$ for h_2 , $1026.01\,\text{Btu/lbm}$ for h_3 and $364.0514\,\text{Btu/lbm}$ for h_4 .

$$W_{net} = ((1160.286 - 1026.57) - (376.09 - 364.0514))$$
$$= 133.716 - 12.0386$$
$$= 121.6774$$

364.0514 Btu/lbm for h_4.

9.102P pg 3

$$W_{net} = ((1160.286 - 1026.57) - (376.09 - 364.0514))$$

$$= 133.716 - 12.0386$$

$$= 121.6774$$

$$\simeq 122 \text{ Btu/lbm}$$

Therefore, the net work output of the cycle is $W_{net} = 122$ Btu/lbm .

Question: 9.103P

A steady-flow Carnot cycle uses water as the working fluid. Water changes from saturated liquid to saturated vapor as heat is transferred to it from a source at 250°G Heat rejection takes place at a pressure of 20 kPa. Show the cycle on a *Ts* diagram relative to the saturation lines, and determine *(a)* the thermal efficiency, *(b)* the amount of heat rejected, and

(c) the net work output.

Step 1 of 5

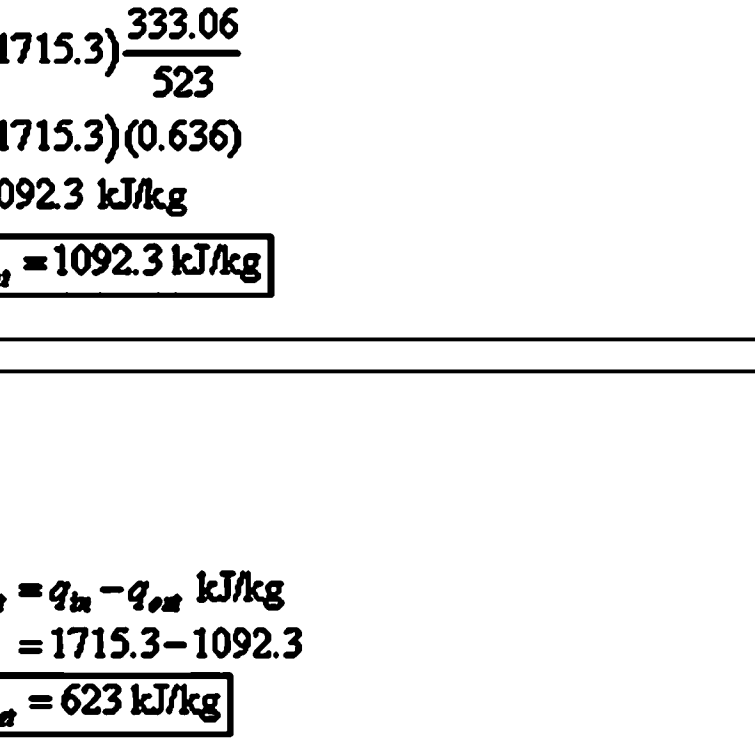
Given

Temperature of the source $T_H = 250°C$

$= 250 + 273K$

$= 523K$

Temperature at which heat is rejected $= T_L$



$T_L = T_{sat20kpa}$

$= 60.06°C$ (From Saturated water – Pressure table)

$= 273 + 60.06K$

$T_L = 333.06K$

Step 2 of 5

Step 3 of 5

(a)The Carnot cycle efficiency is defined as

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$= 1 - \frac{333.06}{523}$$

$$= 1 - 0.636$$

$$= 0.363$$

$$\boxed{\eta_{th} = 36.3\%}$$

Step 4 of 5

b)

The heat supplied during this cycle is simply the enthalpy of vaporization

$q_{in} = h_{fg} = 1715.3$ kJ/kg (From Saturated water – Pressure table)

Heat rejected $q_{out} = q_{in}\frac{T_L}{T_H}$

$$= (1715.3)\frac{333.06}{523}$$

$$= (1715.3)(0.636)$$

$$= 1092.3 \text{ kJ/kg}$$

$$\boxed{q_{out} = 1092.3 \text{ kJ/kg}}$$

Step 5 of 5

(c)

The work is expressed as

$$w_{net} = q_{in} - q_{out} \text{ kJ/kg}$$

$$= 1715.3 - 1092.3$$

$$\boxed{w_{net} = 623 \text{ kJ/kg}}$$

Question: 9.104P

Repeat Prob. 9–103 for a heal rejection pressure of 10 kPa.

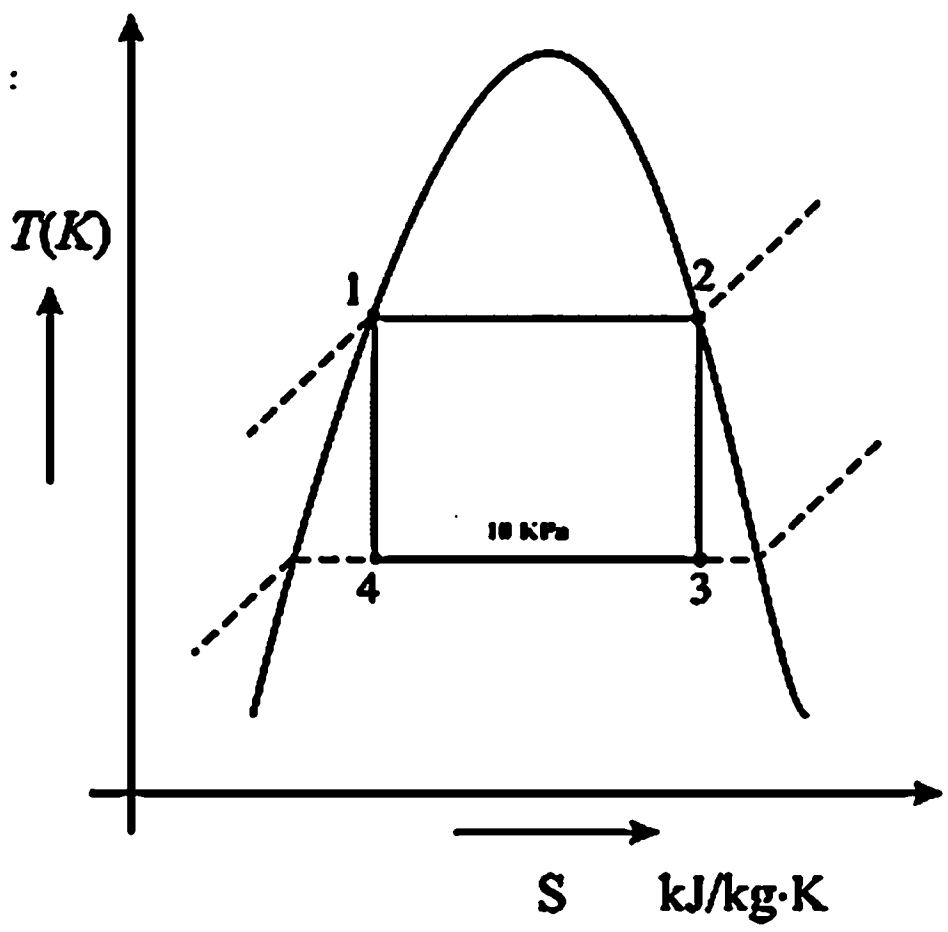
Step 1 of 5

Given

Temperature of the source $T_H = 250°C$

$= 250 + 273K$

$= 523K$



Temperature at which heat is rejected $= T_L$

$T_L = T_{sat@10kpa} = 45.81°C$ (From Saturated water – Pressure table)

$= 45.81 + 273K$

$= 318.81K$

Step 2 of 5

Step 3 of 5

(a)

The Carnot cycle efficiency is defined as

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$= 1 - \frac{318.81}{523}$$

$$= 1 - 0.609$$

$$\boxed{\eta_{th} = 39\%}$$

Step 4 of 5

(b)

The heat supplied during this cycle is simply the enthalpy of vaporization

$q_{in} = h_{fg} = 1715.3$ kJ/kg (From Saturated water – Pressure table)

Heat rejected $q_{out} = q_{in} \frac{T_L}{T_H}$

$$= (1715.3)\frac{318.81}{523}$$

$$= (1715.3)(0.609)$$

$$\boxed{q_{out} = 1045.6 \text{ kJ/kg}}$$

Step 5 of 5

(c)

The work is expressed as

$$w_{net} = q_{in} - q_{out} \text{ kJ/kg}$$

$$= 1715.3 - 1045.6$$

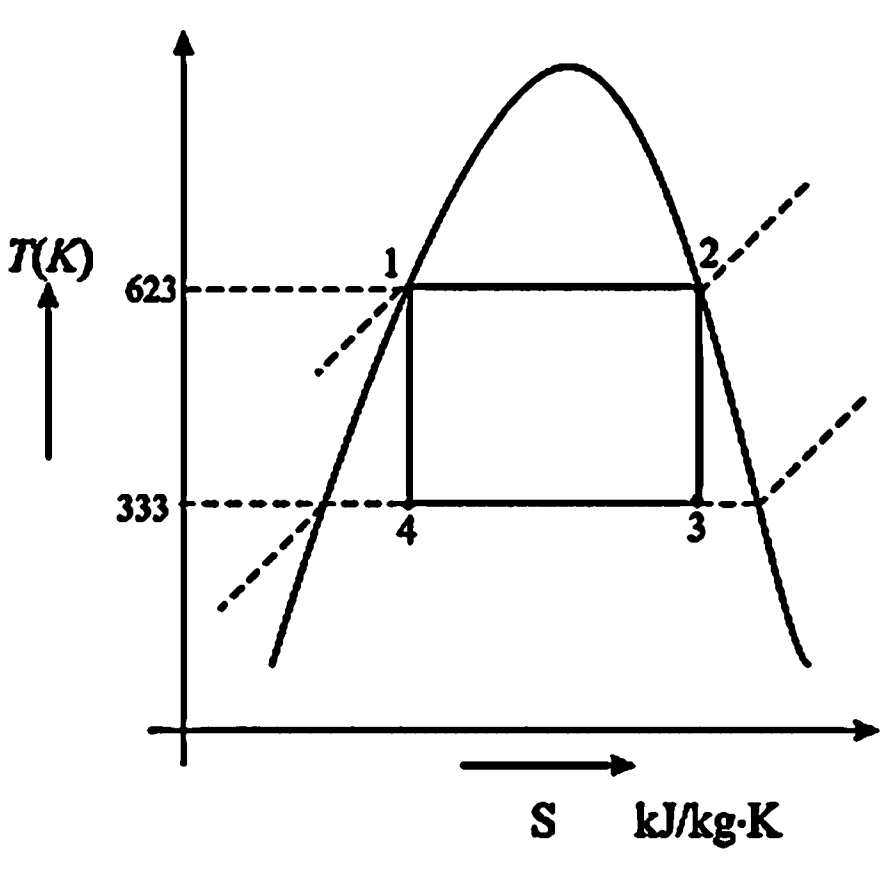
$$\boxed{w_{net} = 670 \text{ kJ/kg}}$$

Question: 9.105P

Consider a steady-flow Carnot cycle with water as the working fluid. The maximum and minimum temperatures in the cycle are 350 and 60°C. The quality of water is 0.891 at the beginning of the heat-rejection process and 0.1 at the end. Show the cycle on a *T-s* diagram relative to the saturation lines, and determine *(a)* the thermal efficiency, *(b)* the pressure at the turbine inlet, and (c) the net work output. Answers:(a) 0.465, *[b)*1.40 MPa, (c) 1623 kJ/kg

Step 1 of 6

Given



Maximum temperature of Carnot cycle $T_H = 350°C = 350+273 = 623K$

Minimum temperature of Carnot cycle $T_L = 60°C = 333K$

Dryness fraction at point turbine outlet (At point 3) = $x_3 = 0.891$

Dryness fraction at condenser outlet (At point 4) = $x_4 = 0.1$

Step 2 of 6

Step 3 of 6

(a)

The Carnot cycle efficiency is defined as

$$\eta_{th} = 1 - \frac{T_L}{T_H}$$

$$= 1 - \frac{333}{623} = 0.465$$

$$\boxed{\eta_{th} = 46.5\%}$$

Step 4 of 6

(b)

At $T_3 = 60°C \rightarrow s_f = 0.8313$ kJ/kg.K , $s_{fg} = 7.0769$ kJ/kg.K (From Saturated water – Temperature table)

We know that $s_2 = s_3 = s_f + x_3 s_{fg}$

$$s_3 = 0.8313 + (0.891)7.0769$$

$$s_2 = s_3 = 7.1368 \text{ kJ/kg.K}$$

Step 5 of 6

At $T_2 = 350°C$, $s_2 = 7.1368$ kJ/kg.K $\rightarrow P_2 = 1.40$ MPa (From Superheated water table)

$$\boxed{P_2 = 1.40 \text{ MPa}}$$

Step 6 of 6

(c) The net work output

At $T_3 = 60°C \rightarrow s_f = 0.8313$ kJ/kg.K , $s_{fg} = 7.0769$ kJ/kg.K (From Saturated water – Temperature table)

We know that $s_4 = s_f + x_4 s_{fg}$

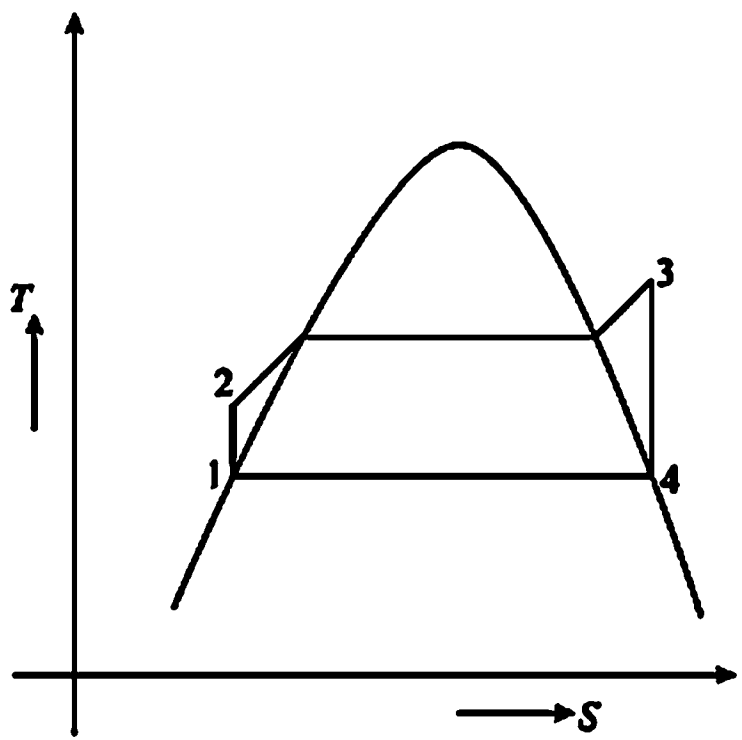
$$s_4 = 0.8313 + (0.1)7.0769$$

$$s_4 = 1.538 \text{ kJ/kg.K}$$

The work is expressed as

$$w_{net} = (T_H - T_L)(s_3 - s_4) \text{ kJ/kg}$$

$$= (623-333)(7.14-1.538)$$



$$\boxed{w_{net} = 1624 \text{ kJ/kg}}$$

Question: 9.106P

What four processes make up the simple ideal Rankine cycle?

Step 1 of 2

T-S Diagram of Rankine cycle

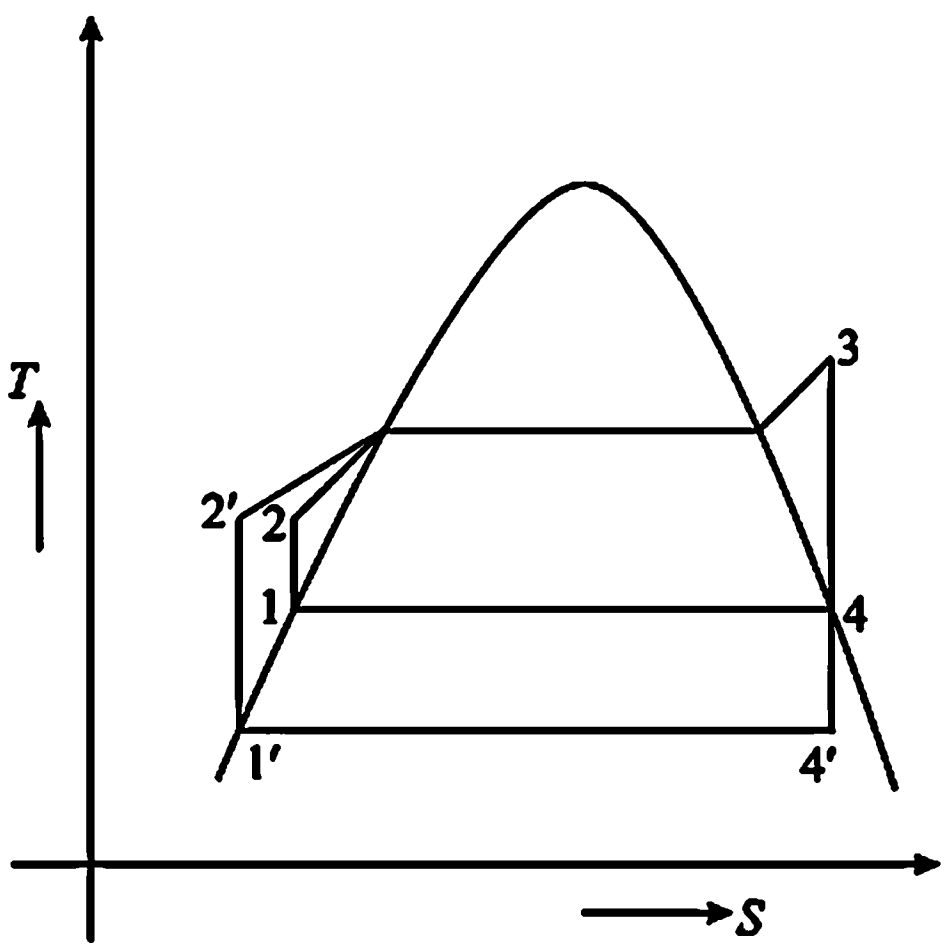
Step 2 of 2

The ideal Rankine cycle does not involve any internal irreversibility's and consists of the following four processes:

1-2 Isentropic compression in a pump
2-3 Constant pressure heat addition in a boiler
3-4 Isentropic expansion in a turbine
4-1 Constant pressure heat rejection in a condenser

Question: 9.107P

Consider a simple ideal Rankine cycle with fixed turbine inlet conditions. What is the effect of lowering the ! condenser pressure on



Pump work input:	(a) increases, (b) decreases, (c)remains the same
Turbine work ouput:	(a) increases (b) decreases, (c) remains the same
Heat supplied:	(a) increases (b) decreases, (c) remains the same
Heat rejected:	(a) increases, (b) decreases, (c) remains the same
Cycle efficiency:	(a) increases, (b) decreases, (c) remains the same
Moisture content at turbine exit:	(a) increases, (b) decreases, (c) remains the same

Step 1 of 8

Given: Turbine inlet conditions are fixed

Step 2 of 8

T-S Diagram of Rankine Cycle

Step 3 of 8

Pump work input: (a) increases

As the pressure difference has increased in process $1'-2'$ compared to process $1-2$ hence pump work increases

Step 4 of 8

Turbine work output: (a) increases

As the enthalpy difference has increased in process $3-4'$ compared to process $3-4$ hence turbine output work increases

Step 5 of 8

Heat supplied: (a) increases

As the area under $2'-3$ has increased compared to process $2-3$ hence heat supplied increases

Step 6 of 8

Heat rejected: (b) decreases

As the area under $4'-1'$ has increased compared to process $4-1$ hence heat rejected decreases

Step 7 of 8

Cycle efficiency: (a) increases

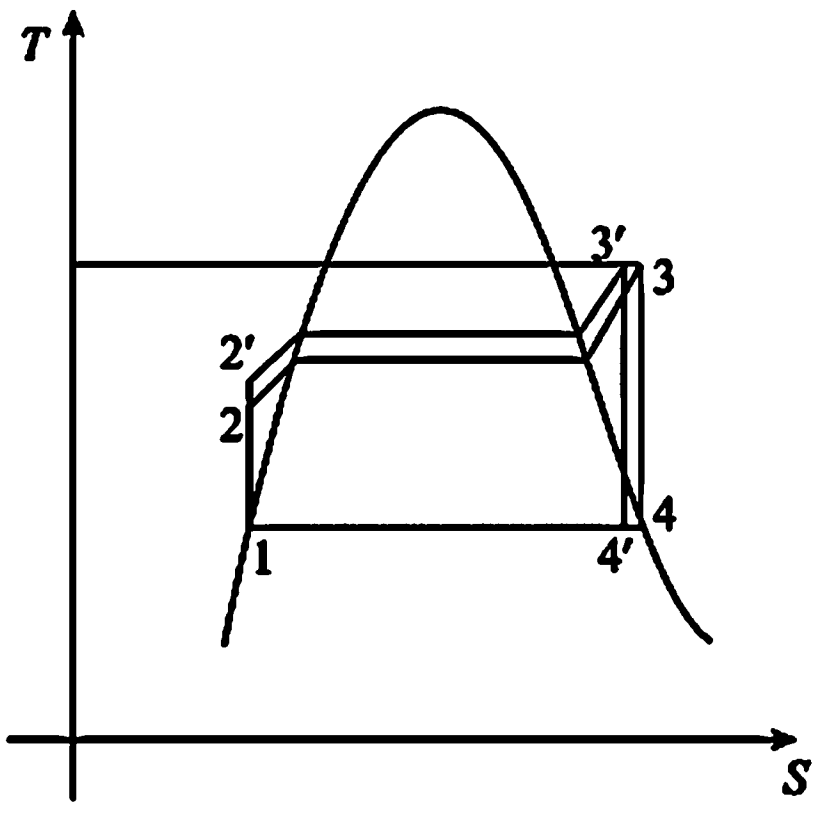
As the compressor pressure is reduced net work increases hence efficiency increases

Step 8 of 8

Moisture content at turbine exit: (a) increases

As point 4 changes its position into $4'$ hence moisture content will increases

Question: 9.108P



Consider a simple ideal Rankine cycle with fixed turbine intel temperature and condenser pressure. What is the effect of increasing the boiler pressure on

Pump work input:	(*a*) increases, (*b*) decreases, (c)remains the same
Turbine work ouput:	(*a*) increases (b) decreases, (c) remains the same
Heat supplied:	(*a*) increases (b) decreases, (c) remains the same
Heat rejected:	(*a*) increases, (b) decreases, (c) remains the same
Cycle efficiency:	(*a*) increases, (b) decreases, (c) remains the same
Moisture content at turbine exit:	(*a*) increases, (b) decreases, (c) remains the same

Step 1 of 8

Given: Turbine inlet temperature is constant
Condenser pressure is constant

Step 2 of 8

Step 3 of 8

Pump work input: (a) increases
If boiler pressure increases pump work increases as $1-2$ has increased to $1-2'$

Step 4 of 8

Turbine work output: (a) increases
If the boiler pressure increases enthalpy difference increases from $3-4$ to $3'-4$ and hence turbine work output increases

Step 5 of 8

Heat supplied: (a) increases
If the boiler pressure increases area under $2-3$ has increased to area under $2'-3'$ and hence heat supplied increases

Step 6 of 8

Heat rejected: (b) decreases
If the boiler pressure increases the turbine outlet point goes less than saturated vapor region for given conditions and hence heat rejected decreases

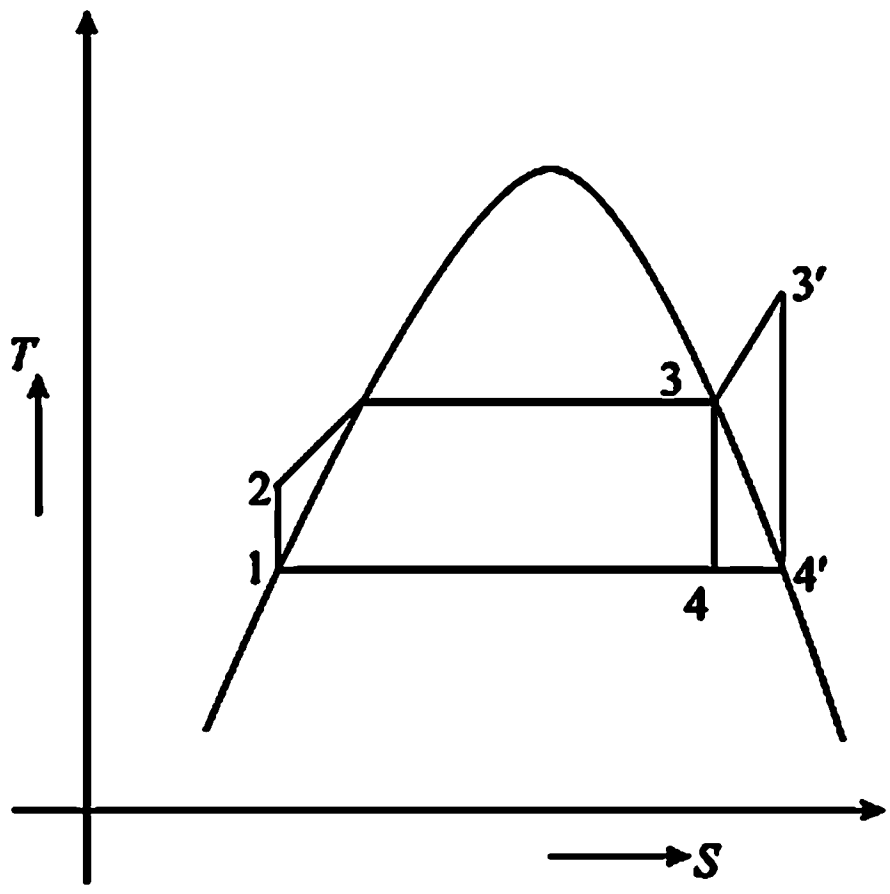
Step 7 of 8

Cycle efficiency: (a) increases
If the boiler pressure increases heat supplied increases and hence cycle efficiency increases

Step 8 of 8

Moisture content at turbine exit: (a) increases
If the boiler pressure increases the turbine outlet point goes less than saturated vapor region for given conditions and hence moisture content decreases

Question: 9.109P



Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. What is the effect of super- heating the steam to a higher temperature on

Pump work input:	(a) increases, (b) decreases, (c)remains the same
Turbine work ouput:	(a) increases (b) decreases, (c) remains the same
Heat supplied:	(a) increases (b) decreases, (c) remains the same
Heat rejected:	(a) increases, (b) decreases, (c) remains the same
Cycle efficiency:	(a) increases, (b) decreases, (c) remains the same
Moisture content at turbine exit:	(a) increases, (b) decreases, (c) remains the same

Step 1 of 8

Given: Boiler pressure is constant
Condenser pressure is constant

Step 2 of 8

Step 3 of 8

Pump work input: (c) remains the same
As there is no change in the curve $1-2$ pump work remains same

Step 4 of 8

Turbine work output: (a) increases
As the enthalpy has been from $3-4$ to $3'-4'$ turbine work output increases

Step 5 of 8

Heat supplied: (a) increases
As the area under curve $2-3'$ has increased in boiler compared to $2-3$ hence heat supplied increases

Step 6 of 8

Heat rejected: (a) increases
As the area under curve $1-4'$ has increased in boiler compared to $1-4$ hence heat supplied increases

Step 7 of 8

Cycle efficiency: (a) increases
As the heat supplied is increased cycle efficiency increases

Step 8 of 8

Moisture content at turbine exit: (b) decreases
As the point 4 has tend towards saturated and supersaturated region (point $4'$) moisture content decreases

Question: 9.110P

How do actual vapor power cycles differ from idealized ones?

Step 1 of 4

The actual vapor power cycles differ from the idealized ones as a result of irreversibilities in various components . Fluid friction and heat loss are the common sources of irreversibilities.

Step 2 of 4

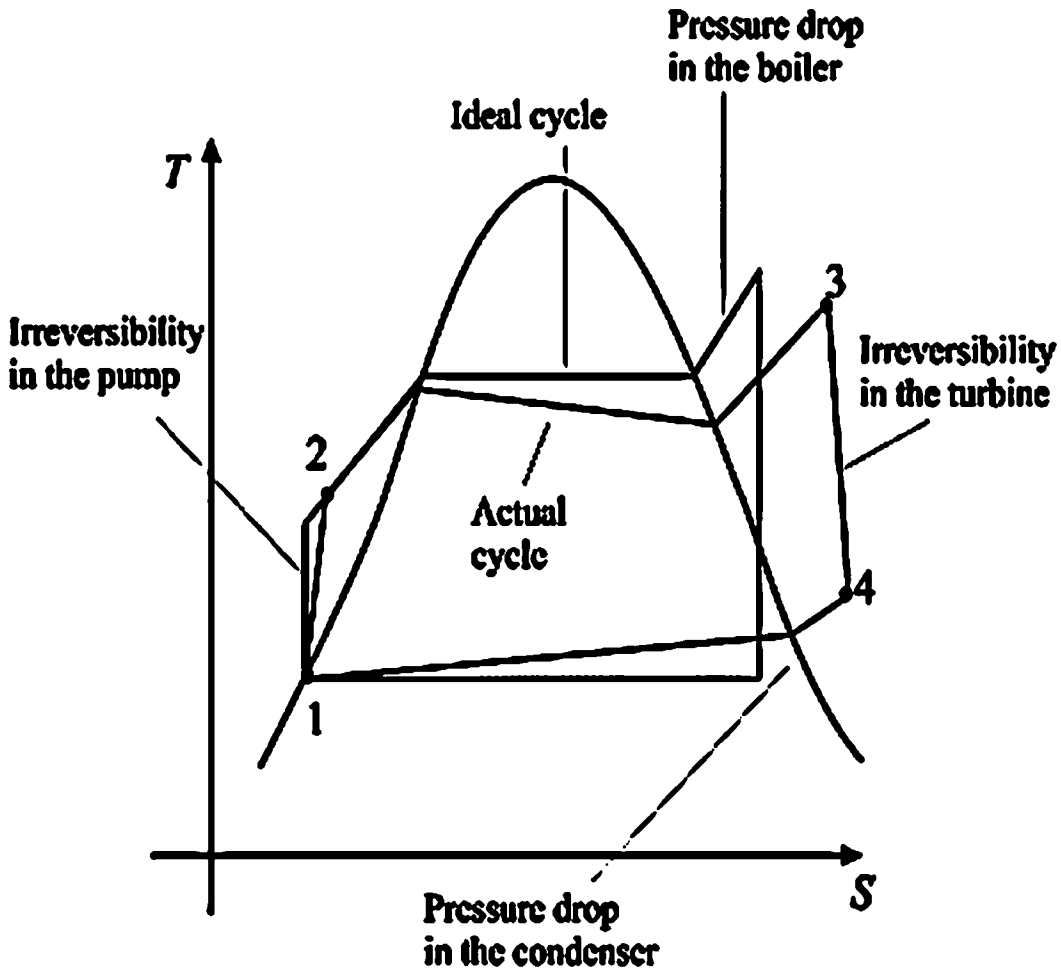
Fluid friction:

It causes pressure drops in the boiler, the condenser, and the piping between various components. As a result, steam leaves the boiler at a somewhat lower pressure. Also, the pressure at the turbine inlet is somewhat lower than that at the boiler exit due to pressure drop in the connecting pipes.

Step 3 of 4

Heat loss:

There will be heat loss from the steam to the surroundings as the steam flows through various components. To maintain the same level of net work output, more heat needs to be transferred to the steam in the boiler to compensate for these undesired heat losses. As a result cycle efficiency decreases.



Step 4 of 4

Other irreversibilities are bearings at moving parts, steam leakage and air entering into the condenser.

Question: 9.111P

Compare the pressures at the inlet and the exit of the boiler for *(a)* actual and *ib)* ideal cycles,

Step 1 of 3

Step 2 of 3

(a) In actual cases the boiler exit pressure will be lower than the inlet pressure. Due to fluid friction there will be pressure drop in the boiler. As a result steam leaves the boiler at a somewhat lower pressure.

Step 3 of 3

(b) In ideal case inlet and outlet pressure will be same.

Question:

9.112P

The entropy of steam increases in actual steam turbines as a result of irreversibilities. In an effort to control entropy increase, it is proposed to cool the steam in the turbine by running cooling water around the turbine casing. It is argued that this will reduce the entropy and the enthalpy of the steam at the turbine exit and thus increase the work output. How would you evaluate this proposal?

Step 1 of 1

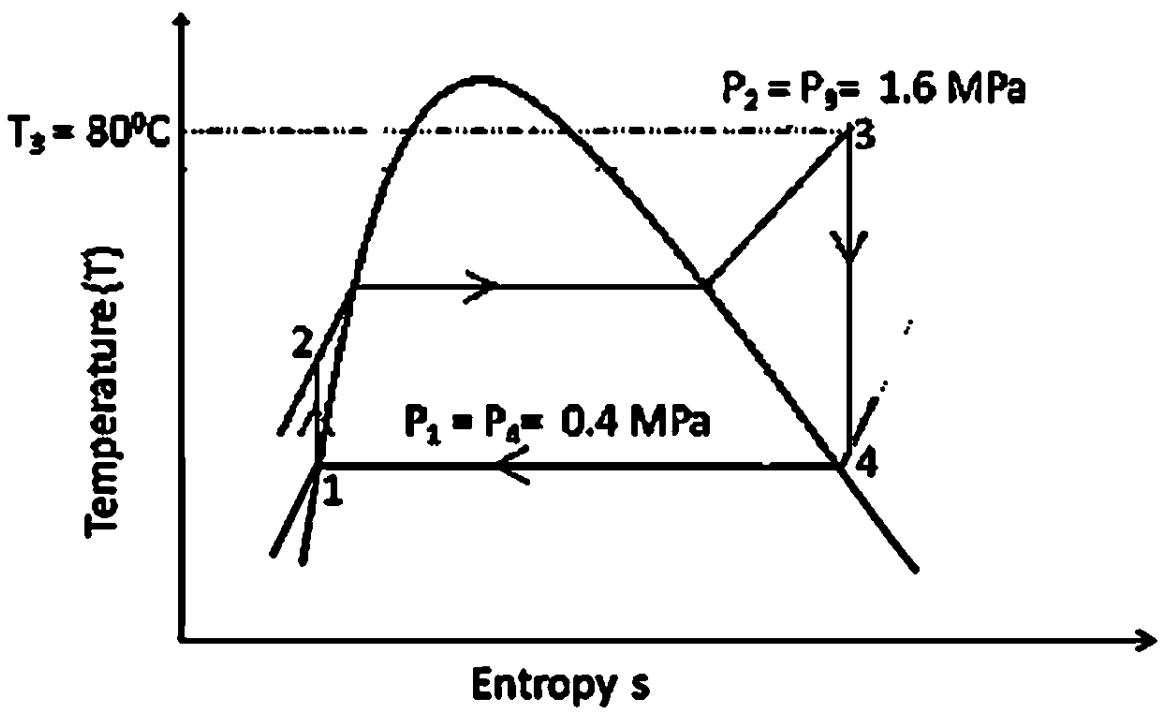
I will not agree the proposal, as turbine work output depends on enthalpy at boiler exit point. If the boiler is cooled by cool water there will be heat lost from boiler and thus enthalpy decreases. As a result turbine work output decreases.

Question: 9.113P

Is it possible to maintain a pressure of 10 kPa in a condenser that is being cooled by river water entering at 20°C?

Step 1 of 1

Yes, because the saturation temperature of steam at 10 KPa is 45.81°C, Cooling water temperature is 20°c which is less than that of saturation temperature of steam .And hence cooling water with given temperature can be used.



Question:

9.114P

An engineer has proposed that a simple ideal Rankine cycle that uses refrigerant-134a be used to produce work with heat from a low-temperature thermal energy reservoir. The boiler operates at 1.6 MPa. the condenser at 0.4 MPa, and the turbine inlet at 80°C. Determine the R-134a mass flow rate needed for this cycle to produce 750 kW of power and the thermal efficiency of the cycle.

Step 1 of 7

The rankine cycle representing the operating conditions is,

Step 2 of 7

At state1 from the diagram:

From the Saturated R-134a Pressure table
At a pressure of 0.4 MPa ($P_1 = 0.4$ MPa) the properties of enthalpy and specific volume are,

$$h_1 = (h_f) = 63.94 \text{ kJ/kg}$$

$$v_1 = (v_f) = 0.0007907 \text{ m}^3/\text{kg}$$

Step 3 of 7

At state2 from the diagram:

From the Saturated R-134a Pressure table
At a pressure of 1.6 MPa ($P_2 = 1.6$ MPa),

$$P_2 = 1.6 \text{ MPa} = 1600 \text{ kPa}$$

From process 1-2,
The work done in the compression process is,

$$w_{pump} = v_1 \times (P_2 - P_1)$$

$$w_{pump} = 0.0007907 \left(\frac{\text{m}^3}{\text{kg}}\right) \times (1600 \text{ kPa} - 400 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \left(\text{kPa m}^3\right)}\right)$$

$$w_{pump} = 0.949 \text{ kJ/kg}$$

Enthalpy at state 2 is,

$$h_2 = h_1 + w_{pump} = 63.94 + 0.949 = 64.889 \text{ kJ/kg}$$

Step 4 of 7

At state3 from the diagram:

From the Superheated refrigerant-134a tables,
At pressure of 1.6 MPa ($P_3 = P_2 = 1.6$ MPa) and temperature of 80°C ($T_3 = 80^0$C) the properties of enthalpy and specific volume are,

$$h_3 = 305.07 \text{ kJ/kg}$$

$$s_3 = 0.9875 \text{ kJ/kg} \cdot \text{K}$$

Step 5 of 7

At state4 from the diagram:

Consider isentropic expansion of turbine at pressure ,

$$P_4 = 0.4 \text{ MPa}$$

From the Superheated refrigerant -134a,
The enthalpies along the vertical line are equal so,

$$s_4 = s_3 = 0.9875 \text{ kJ/kg} \cdot \text{K}$$

By using the interpolation method in between 20°c and 30°c at 0.4 MPa the enthalpy at state 4 is,

$$h_4 = 265.86 + \frac{(275.07 - 265.86)(0.9875 - 0.9628)}{(0.9937 - 0.9628)}$$

$$h_4 = 273.22 \text{ kJ/kg}$$

Step 6 of 7

(a)
Consider the net power output as 750 kJ/s.
The work obtained in the expansion process is,

$$W_{net} = \dot{m} (h_3 - h_4)$$

$$750 = \dot{m} (305.07 - 273.22)$$

$$\dot{m} = 23.54 \text{ kg/s}$$

mass flow rate of R-134a is $\boxed{23.54 \frac{\text{kg}}{\text{s}}}$.

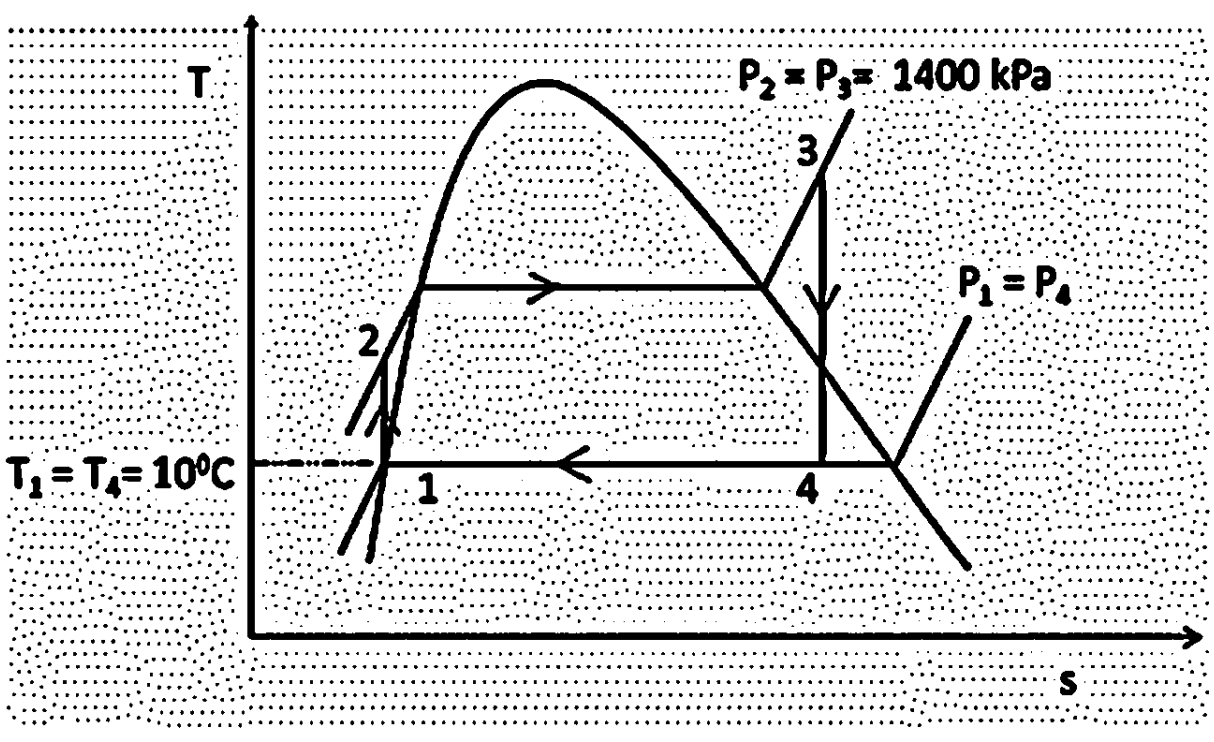
Step 7 of 7

(b)
Thermal efficiency of the Rankin cycle is the net power produced per unit input of heat supplied. So,

$$\eta_{Rankin} = \frac{W_{net}}{Q_{in}} = \frac{(h_3 - h_4) - (h_2 - h_1)}{(h_3 - h_2)} = \frac{(305.07 - 273.22) - (64.889 - 63.94)}{(305.07 - 64.889)} = 0.128$$

Therefore the efficiency of the cycle is, $\boxed{12.8\ \%}$.

Question: 9.115P



Refrigerant-134a is used as the working fluid in a simple ideal Rankine cycle which operates the boiler at 1400 kPa and the condenser at 10°C. The mixture at the exit of the turbine has a quality of 98 percent. Determine the turbine inlet temperature, the cycle thermal efficiency, and the back-work ratio of this cycle.

Step 1 of 11

Given:
Process: Rankine cycle.
Working fluid: 134a.
The boiler operates pressure $P_2=P_3=1400$ kPa.
The condenser operating Temperature $T_1 = T_4 = 10^\circ C$.
The mixture at the exit of the turbine has a quality of 0.98.

Step 2 of 11

The Ideal Rankin cycle operating between the given conditions is shown below.

Step 3 of 11

State 1:
From the saturated refrigerant-134a
At $T_1 = 10^\circ C$
$P_1 = P_{sat} = 414.89$ kPa
$h_1 = h_f = 65.43$ kJ/kg
$h_g = 256.16$ kJ/kg
$s_1 = s_f = 0.25286$ kJ/kg K
$s_g = 0.92641$ kJ/kg K
$v_1 = v_f = 0.0007930\ m^3/kg$

Step 4 of 11

State 2:
$P_2 = 1.4$ MPa
$= 1400$ kPa
The work done in the compression process is given by,

$$w_{pump} = v_1 \times (P_2 - P_1)$$

$$w_{pump} = 0.0007930\left(\frac{m^3}{kg}\right) \times (1400\ kPa - 414.89\ kPa)\left(\frac{1\ kJ}{1\ (kPa\ m^3)}\right)$$

$$w_{pump} = 0.781\ kJ/kg$$

Step 5 of 11

Enthalpy at state 2 is

$$h_2 = h_1 + w_{pump}$$
$$= 65.43 + 0.781$$
$$= 66.211\ kJ/kg$$

Step 6 of 11

State 4:
From the saturated refrigerant-134a Temperature table
At $T_4 = 10^\circ C$ And the quality is given as $x_4 = 0.98$

$$h_4 = (h_f) + x_4(h_{fg})$$
$$h_4 = 65.43 + 0.98 \times (190.73)$$
$$= 252.35 kJ/kg$$
$$s_4 = (s_f) + x_4(s_{fg})$$
$$s_4 = 0.25286 + 0.98 \times (0.67356)$$
$$= 0.91295\ kJ/kg^\circ K$$

Step 7 of 11

State 3:
Assume the expansion in turbine is isentropic in nature,
Then $s_3 = s_4 = 0.91295\ kJ/kg^\circ K$
From the saturated refrigerant-134a Temperature table
At $P_4 = P_1 = 1400$ kPa

$$\boxed{T_4 = 52.40^0 C}$$

And $h_3 = h_g = 276.12 kJ/kg$

Step 8 of 11

Heat input is

$$q_{in} = h_3 - h_2$$
$$= 276.12 - 66.21$$
$$= 209.91 kJ/kg$$

Step 9 of 11

Heat rejected

$$q_{out} = h_4 - h_1$$
$$= 252.35 - 65.43$$
$$= 186.92 kJ/kg$$

Step 10 of 11

Thermal efficiency of the Rankin cycle is given by,

$$\eta_{Rankin} = \frac{W_{net}}{Q_{in}}$$
$$= 1 - \frac{q_{out}}{q_{in}}$$
$$= 1 - \frac{186.92}{209.91}$$
$$= 0.11$$

$$\boxed{\eta_{Rankin} = 11\ \%}$$

Step 11 of 11

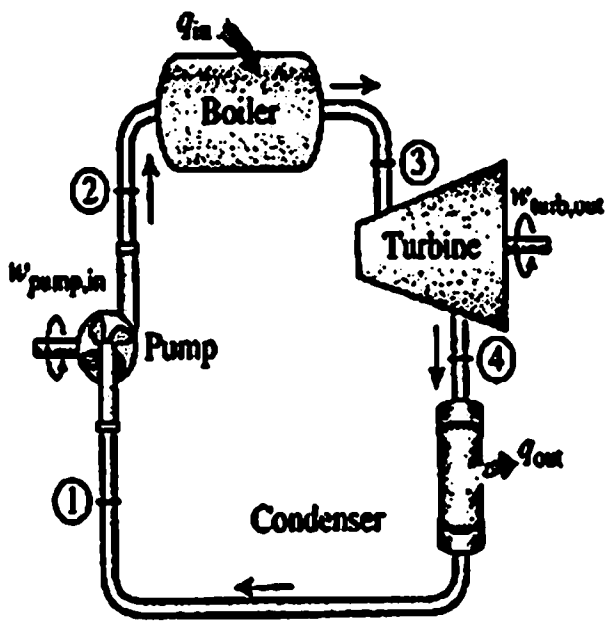
Back work ratio

$$r_{bw} = \frac{W_{in}}{W_{Tout}}$$
$$= \frac{W_{Pin}}{h_3 - h_4}$$
$$= \frac{0.781}{(276.12 - 252.35)}$$
$$= 0.03285$$

$$\boxed{r_{bw} = 0.03285}$$

Question: 9.116P pg 1

A simple ideal Rankine cycle which uses water as the working fluid operates its condenser at 40°C and its boiler at 300°C. Calculate the work produced by the turbine, the heat supplied in the boiler, and the thermal efficiency of this cycle when the steam enters the turbine without any superheating,



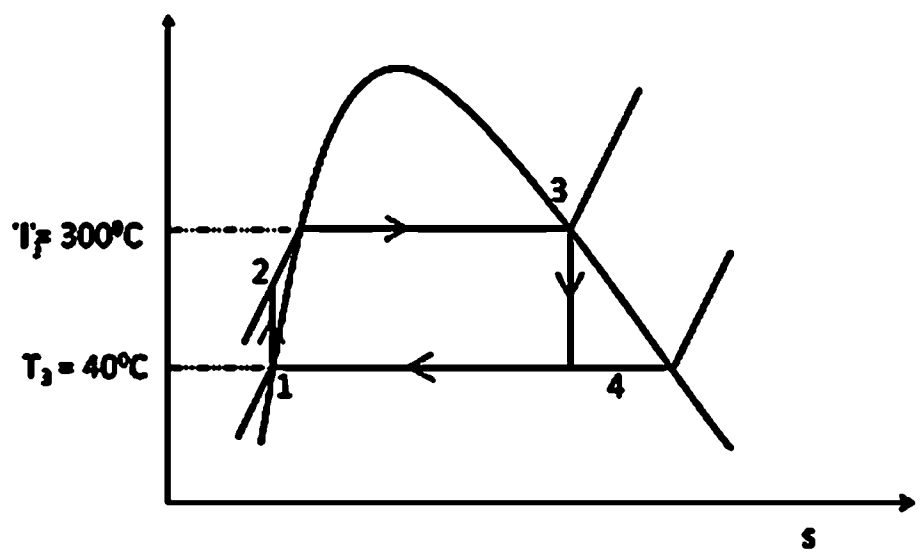


FIGURE P9–116

Step 1 of 10

Draw the different processes of Rankine cycle on T-s diagram as shown below:

Step 2 of 10

At state1 of the cycle:

From the saturated water Temperature table at temperature of 40°C(T_1 = 40°C) the properties of pressure, enthalpy, entropy, and specific volume are,

$$P_1 = P_{sat} = 7.3851 \text{ kPa}$$

$$h_1 = h_f = 167.53 \text{ kJ/kg}$$

$$s_1 = s_f = 0.5724 \text{ kJ/kg} \cdot \text{K}$$

$$v_1 = v_f = 0.001008 \text{ m}^3/\text{kg}$$

Step 3 of 10

At state2 of the cycle:

The pump work done in the compression process is,

$$w_{pump} = v_1 \times (P_2 - P_1)$$

Here, P_2 is the pressure at state 2.

At temperature of $T_3 = 300°\text{C}$ from saturated water table temperature table the pressure P_2 is 8587.9 kPa.

Substitute the corresponding values in the pump work equation.

$$w_{pump} = v_1 \times (P_2 - P_1)$$

$$= 0.001008 \text{ m}^3/\text{kg} \times (8587.9 \text{ kPa} - 7.3851 \text{ kPa})(\text{kJ/ kPa m}^3)$$

$$= 8.649 \text{ kJ/kg}$$

Enthalpy corresponding to state 2 is,

$$h_2 = h_1 + w_{pump}$$

$$= 167.53 + 8.649$$

$$= 176.189 \text{ kJ/kg}$$

Step 4 of 10

At state3 of the cycle:

At temperature of $T_3 = 300°\text{C}$, from saturated water table temperature table the enthalpy and entropy are,

$$h_3 = h_g = 2749.6 \text{ kJ/kg}$$

$$s_3 = s_g = 5.7059 \text{ kJ/kg} \cdot \text{K}$$

Step 5 of 10

At state 4 of the cycle:

Process 3-4 is isentropic expansion of the turbine.

The entropy remains constant during the process 3-4

$$s_4 = s_3 = s_g = 5.7059 \text{ kJ/kg} \cdot \text{K}$$

From the saturated water Temperature table

Find the dryness fraction of the of the liquid-vapor mixture at state 4 by using the equation

$$s_4 = s_f + x_4 s_{fg}$$

Here s_f is the entropy of the saturated liquid, x_4 is the dryness fraction corresponding to point 4 and s_{fg} is the entropy of evaporation.

Substitute corresponding values.

$$s_4 = s_f + x_4 s_{fg}$$

$$5.7059 = 0.5724 + x_4 (7.6832)$$

$$x_4 = 0.6681$$

So, the dryness fraction of liquid-vapor at state 4 is 0.6681.

Step 6 of 10

Calculate the enthalpy at state 4 by using the equation,

$$h_4 = h_f + x_4 h_{fg}$$

Here h_f is the enthalpy of the saturated liquid, x_4 is the dryness fraction corresponding to

Step 6 of 10

Calculate the enthalpy at state 4 by using the equation,

$$h_4 = h_f + x_4 h_{fg}$$

Here h_f is the enthalpy of the saturated liquid, x_4 is the dryness fraction corresponding to point 4 and h_{fg} is the enthalpy of evaporation.

Substitute the corresponding values in the above equation.

$$\begin{aligned} h_4 &= h_f + x_4 h_{fg} \\ &= 167.53 + 0.6681(2406.0) \\ &= 1774.978 \text{kJ/kg} \end{aligned}$$

Step 7 of 10

The work obtained in the turbine is,

$$W_T = (h_3 - h_4)$$

Substitute the corresponding values in the equation above.

$$\begin{aligned} W_T &= (h_3 - h_4) \\ &= 2749.6 - 1774.978 \\ &= 974.622 \text{kJ/kg} \end{aligned}$$

Therefore the work obtained in the turbine is

$\boxed{974.622 \text{ kJ/kg}}$

Step 8 of 10

The amount of the heat supplied to the boiler is,

$$Q_{in} = (h_3 - h_2)$$

Substitute the corresponding values.

$$\begin{aligned} Q_{in} &= (h_3 - h_2) \\ &= (2749.6 - 176.189) \\ &= 2573.411 \text{kJ/kg} \end{aligned}$$

Therefore the heat supplied to the boiler is $\boxed{2573.411 \text{kJ/kg}}$

Step 9 of 10

The amount of Heat rejected in condenser is,

$$Q_{out} = h_4 - h_1$$

Substitute the corresponding values

$$\begin{aligned} Q_{out} &= h_4 - h_1 \\ &= 1774.978 - 167.53 \\ &= 1607.448 \text{kJ/kg} \end{aligned}$$

Step 10 of 10

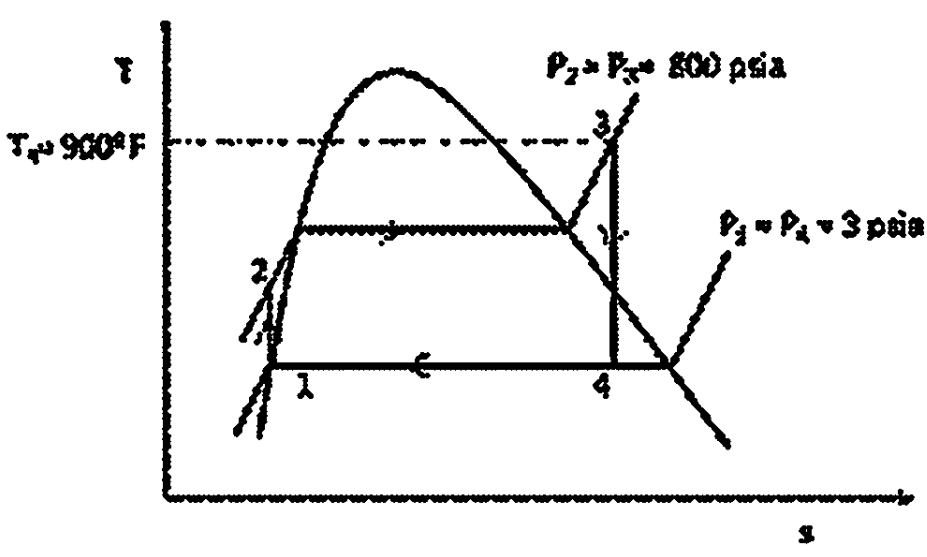
Find the thermal Efficiency of the Rankine cycle by using the equation,

$$\begin{aligned} \eta_{Rankine} &= 1 - \frac{Q_{out}}{Q_{in}} \\ &= 1 - \frac{1607.448}{2573.411} \\ &= 0.375 \\ &= 0.375 \times 100 \\ &= 37.5\% \end{aligned}$$

Therefore the thermal efficiency of the Rankine cycle is $\boxed{37.5\ \%}$

Question:

9.117P



The turbine of a steam power plant operating on a simple ideal Rankine cycle produces 1750 kW of power when the boiler is operated at 800 psia, the condenser at 3 psia, and the temperature at the turbine entrance is 900°F. Determine the rate of heat supply in the boiler, the rate of heat rejection in the condenser, and the thermal efficiency of the cycle.

Step 1 of 11

Given,
Process: Rankine cycle.
The boiler operates Pressure $P_2 = P_3 = 800\text{psia}$.
The condenser Pressure $P_1 = P_4 = 3\text{psia}$.
Turbine inlet temperature $T_3 = 900^0\text{F}$.
Power produced by the cycle = 1750 kW.

Step 2 of 11

The Ideal Rankin cycle operating between the given conditions is shown below.

Step 3 of 11

State1:
From the saturated water pressure table
$P_1 = 3$ psia At this pressure,
$h_1 = h_f = 109.40$ Btu/lb
$v_1 = v_f = 0.01630\ \text{ft}^3/\text{lb}$

Step 4 of 11

State2:
Pressure at state 2 is $P_2 = 800$ psia
The work done in the compression process is given by,

$$w_{pump} = v_1 \times (P_2 - P_1)$$
$$w_{pump} = 0.01630\ (\text{ft}^3/\text{lb}) \times (800 - 3)\text{psia}$$
$$w_{pump} = 13\ (\text{psia ft}^3/\text{lb})(1\text{Btu}/5.40395\ \text{psia}\cdot\text{ft}^3)$$
$$= 2.4\ \text{Btu/lbm}$$

Step 5 of 11

Enthalpy at state 2 is

$$h_2 = h_1 + w_{pump}$$
$$= (109.40 + 2.4)$$
$$= 111.8\text{Btu/lbm}$$

Step 6 of 11

State3:
From the superheated water
$P_3 = P_2 = 800$ psia And $T_3 = 900^0$F at this pressure and temperature,
$h_3 = 1456$ Btu/lbm
$s_3 = 1.6413\text{Btu/lbm}\cdot\text{R}$

Step 7 of 11

State4:
Assume the expansion in turbine is isentropic in nature,
then $s_3 = s_4$
$s_4 = s_3 = 1.6413\text{Btu/lbm}\cdot\text{R}$
From the saturated water pressure table
At $P_4 = P_1 = 3$ psia and $s_4 = s_3 = 1.6413\text{Btu/lbm}\cdot\text{R}$

$$s_4 = s_f + x_4 s_{fg}$$
$$1.6413 = 0.20090 + x_4 (1.6849)$$
$$x_4 = 0.8549$$

Step 8 of 11

Enthalpy at state 4 is

$$h_4 = h_f + x_4 h_{fg}$$
$$= 109.40 + 0.8549(1012.8)$$
$$= 975.24\text{Btu/lbm}$$

Step 9 of 11

power output from the turbine = 1750 kW

$$W_{net} = \dot{m}\ (h_3 - h_4)$$
$$(1750\ \text{kW})\left(\frac{3412.14(\text{Btu/h})}{1\ \text{kW}}\right) = \dot{m}\ (1456.0 - 975.24)\ \text{Btu/lbm}$$
$$\dot{m} = 12418.1\ (\text{lbm/h})(1\text{h}/3600\ \text{s})$$
$$= 3.45\ \text{lbm/s}$$
$$\boxed{\dot{m} = 3.45\ \text{lbm/s}}$$

Step 10 of 11

Rate flow of heat supply is given by,

$$Q_{in} = \dot{m}\ (h_3 - h_2)$$
$$Q_{in} = 3.45 \times (1456.0 - 111.81)$$
$$= 4637.45\ (\text{Btu/s})(3600/1\text{h})(1\text{kW}/3412.14\text{Btu/h})$$
$$= 4892.776\text{kW}$$
$$\boxed{Q_{in} = 4892.766\ \text{kW}}$$

Step 11 of 11

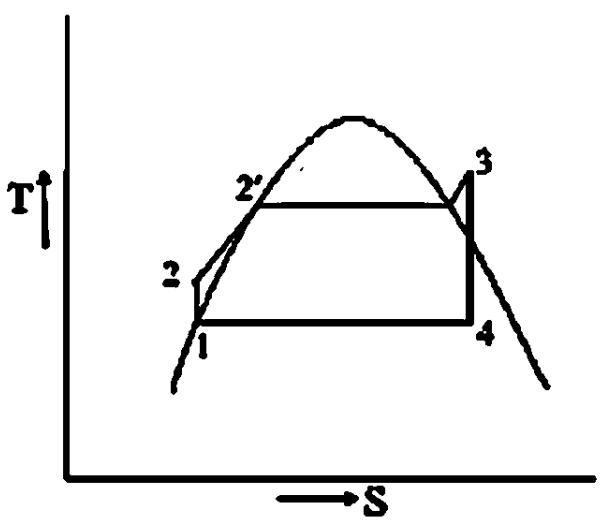
Thermal efficiency of the Rankin cycle is given by,

$$\eta_{Rankin} = \frac{W_{net}}{Q_{in}}$$
$$= \frac{(h_3 - h_4) - (h_2 - h_1)}{(h_3 - h_2)}$$
$$= \frac{(1456.0 - 975.24) - (111.81 - 109.40)}{(1456.0 - 111.81)}$$
$$= 0.355$$
$$= 35.5\%$$
$$\boxed{\eta_{Rankin} = 35.5\%}$$

Question: 9.118P

A simple ideal Rankine cycle with water as the working fluid operates between the pressure limits of 2500 psia in the boiler and 5 psia in the condenser. What is the minimum temperature required at the turbine inlet such that the quality of the steam leaving the turbine is not below 80 percent. When operated at this temperature, what is the thermal efficiency of this cycle?

Step 1 of 11



Given

High pressure in the boiler $P_3 = P_2 = 2500\,\text{psia}$

Low pressure in the condenser $P_4 = P_1 = 5\,\text{psia}$

Quality at the exit of the turbine $x_4 = 80\%$

Step 2 of 11

Step 3 of 11

At $P_4 = 5\,\text{psia}$ from saturated water tables

$h_f = 130.18\,\text{Btu/lbm}$

$h_{fg} = 1000.5\,\text{Btu/lbm}$

$s_f = 0.23488\,\text{Btu/lbm.R}$

$s_{fg} = 1.60894\,\text{Btu/lbm.R}$

Step 4 of 11

Enthalpy at state-4

$h_4 = h_f + x_4 h_{fg}$

$h_4 = 130.18 + 0.80 \times 1000.5$

$h_4 = 930.58\,\text{Btu/lbm}$

Step 5 of 11

Similarly entropy at state-4

$s_4 = s_f + x_4 s_{fg}$

$s_4 = 0.23488 + 0.80 \times 1.60894$

$s_4 = 1.522\,\text{Btu/lbm.R}$

Step 6 of 11

The expansion process through the turbine is isentropic

At $P_3 = 2500\,\text{psia}$ and $s_3 = s_4 = 1.522\,\text{Btu/lbm.R}$ from superheated water tables

$$h_3 = 1423.3 + (1458.2 - 1423.3)\left(\frac{1.522 - 1.5028}{1.5271 - 1.5028}\right)$$

$h_3 = 1450.875\,\text{Btu/lbm}$

$$T_3 = 950 + (1000 - 950)\left(\frac{1.522 - 1.5028}{1.5271 - 1.5028}\right)$$

$T_3 = 989.506\,^0\text{R}$

Therefore minimum temperature required at turbine inlet is

$\boxed{T_3 = 989.506\,^0\text{R}}$

Step 7 of 11

Enthalpy at state-1

$h_1 = h_{f@5\text{Psia}} = 130.18\,\text{Btu/lbm}$

Specific volume at state-1

$v_1 = v_{f@5\text{Psia}} = 0.01641\,\text{m}^3/\text{kg}$

Pump work

$w_{pump} = -v_{f@5\text{psia}}(P_2 - P_1)$

$$w_{pump} = -0.010641\frac{\text{ft}^3}{\text{lbm}} \times (2500 - 5)\frac{\text{lbf}}{\text{in}^2} \times 144\frac{\text{in}^2}{\text{ft}^2} \times \frac{1}{778}\frac{\text{Btu}}{\text{lbf-ft}}$$

$w_{pump} = -7.578\,\text{Btu/lbm}$

Step 8 of 11

By applying first law to the process 1-2

$h_1 = h_2 + w_{pump}$

$h_2 = h_1 - w_{pump}$

$h_2 = 130.18 + 7.578$

$h_2 = 137.758\,\text{Btu/lbm}$

Step 9 of 11

Heat addition in the boiler

$q_{in} = (h_3 - h_2)$

$q_{in} = 1450.875 - 137.758$

$q_{in} = 1313.117\,\text{Btu/lbm}$

Step 10 of 11

Heat rejection in the condenser

$q_{out} = (h_4 - h_1)$

$q_{out} = 930.58 - 130.18$

$q_{out} = 800.4\,\text{Btu/lbm}$

Step 11 of 11

Thermal efficiency of the cycle is

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}}$$

$$= 1 - \frac{800.4}{1313.117}$$

$\boxed{\eta_{th} = 39.045\%}$

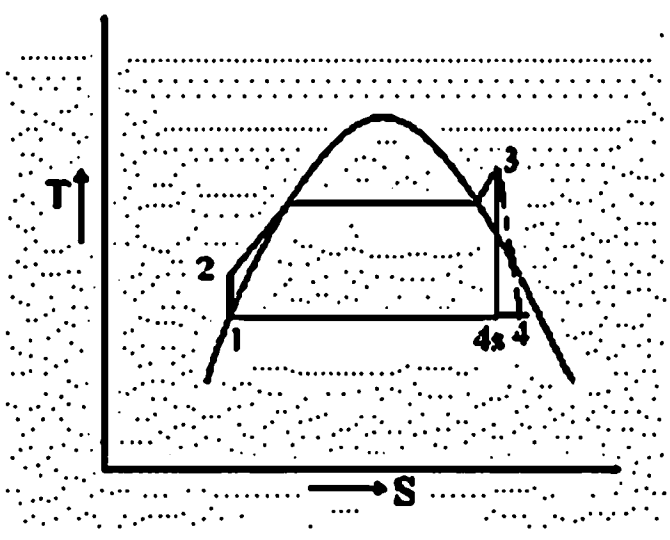
Question: 9.119P pg 1

A steam Rankine cycle operates between the pressure limits of 2500 psia in the boiler and 1 psia in the condenser. The turbine inlet temperature is 800°F. The turbine isentropic efficiency is 90 percent, the pump losses are negligible, and the cycle is sized to produce 1000 kW of power. Calculate the mass flow rate through the boiler, the power produced by the turbine, the rate of heat supply in the boiler, and the thermal efficiency.

Step 1 of 16

Given

Boiler pressure $P_3 = P_2 = 2500\,\text{psia}$



Condenser pressure $P_4 = P_1 = 1\,\text{psia}$

Turbine inlet temperature $T_3 = 800^0\text{F}$

Turbine isentropic efficiency $\eta_T = 90\%$

Power developed $\dot{W}_{net} = 1000\,\text{kW}$

Step 2 of 16

Step 3 of 16

At $P_1 = 1\,\text{psia}$ from saturated water tables

$h_1 = h_f = 69.72\ \text{Btu/lbm}$

$h_{fg} = 1035.7\,\text{Btu/lbm}$

$s_f = 0.13262\,\text{Btu/lbm.R}$

$s_{fg} = 1.84495\,\text{Btu/lbm.R}$

$v_1 = v_{f\,@\,1\,psia} = 0.01614\ \text{ft}^3\text{/lbm}$

Step 4 of 16

Pump work

$$w_{pump} = -v_1(P_2 - P_1)$$

$$w_{pump} = -0.01614\ \text{ft}^3\text{/lbm} \times (2500-1)\frac{\text{lbf}}{\text{in}^2} \times 144 \times \frac{\text{in}^2}{\text{ft}^2} \times \frac{1}{778}\frac{\text{Btu}}{\text{lbf-ft}}$$

$$w_{pump} = -7.46\,\text{Btu/lbm}$$

Step 5 of 16

Applying energy equation to the process 1-2

$$h_1 = h_2 + w_{pump}$$

$$h_2 = h_1 - w_{pump}$$

$$h_2 = 69.72 + 7.46$$

$$h_2 = 77.18\ \text{Btu/lbm}$$

Step 6 of 16

At $P_3 = 2500$ psia and $T_3 = 800^0$ F from superheated water tables

$h_3 = 1302\ \text{Btu/lbm}$

$s_3 = 1.4116\ \text{Btu/lbm.R}$

Step 7 of 16

Process 3-4s is isentropic process entropy remains constant

$$s_4 = s_3$$

$$s_3 = s_{f@1psia} + x_4 s_{fg@psia}$$

$$x_{4s} = \frac{(s_4 - s_f)}{s_{fg}}$$

$$x_{4s} = \frac{(1.4116 - 0.13262)}{1.84495}$$

$$x_{4s} = 0.6932$$

Step 8 of 16

Enthalpy at state-4s,

$$h_{4s} = h_f + x_{4s} h_{fg}$$

$$h_{4s} = 69.72 + (0.6932 \times 1035.7)$$

$$h_{4s} = 787.7\ \text{Btu/lbm}$$

Step 9 of 16

Isentropic efficiency of the turbine is defined as,

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

$$h_4 = 1302 - (0.9 \times (1302 - 787.7))$$

$$h_4 = 839.13\ \text{Btu/lbm}$$

Step 10 of 16

Heat addition in the boiler is given by

$$q_{in} = h_3 - h_2$$

$$q_{in} = 1302 - 77.18$$

$$q_{in} = 1224.82\ \text{Btu/lbm}$$

$q_{in} = h_3 - h_2$

$q_{in} = 1302 - 77.18$

$q_{in} = 1224.82 \text{ Btu/lbm}$

Step 11 of 16

Heat rejected is given by

$q_{out} = h_4 - h_1$

$q_{out} = 839.13 - 69.72$

$q_{out} = 769.41 \text{ Btu/lbm}$

Step 12 of 16

Network output is defined as

$w_{net} = q_{in} - q_{out}$

$w_{net} = 1224.82 - 769.41$

$w_{net} = 455.41 \text{ Btu/lbm}$

Step 13 of 16

The mass flow rate of steam can be obtained from the relation,

$W_{net} = \dot{m} w_{net}$

$$\dot{m} = \frac{W_{net}}{w_{net}}$$

$$\dot{m} = \frac{1000 \text{ kJ/s}}{455.41 \text{ Btu/lbm}} \left(\frac{0.9478 \text{Btu}}{1 \text{kJ}} \right)$$

$\boxed{\dot{m} = 2.081 \text{ lbm/s}}$

Step 14 of 16

The power output from the turbine

$W_T = \dot{m}(h_3 - h_4)$

$$W_T = 2.081 \frac{\text{lbm}}{\text{s}} \times (1302 - 839.13) \frac{\text{Btu}}{\text{lbm}} \times \frac{1 \text{kJ}}{0.9478 \text{Btu}}$$

$\boxed{W_T = 1016.28 \text{ kW}}$

Step 15 of 16

The rate of heat addition in the boiler is given by

$Q_{in} = \dot{m} q_{in}$

$Q_{in} = 2.081 \times (1224.82)$

$\boxed{Q_{in} = 2548.85 \text{Btu/s}}$

$$Q_{in} = 2548.85 \frac{\text{Btu}}{\text{s}} \times \frac{1}{0.9478} \times \frac{\text{kJ}}{\text{Btu}}$$

$\boxed{Q_{in} = 2689.227 \text{kW}}$

Step 16 of 16

Thermal efficiency of the cycle,

$$\eta_{th} = \frac{W_{net}}{Q_{in}}$$

$$\eta_{th} = \frac{1000}{2689.227}$$

$$= 0.3718$$

$\boxed{\eta_{th} = 37.18\%}$

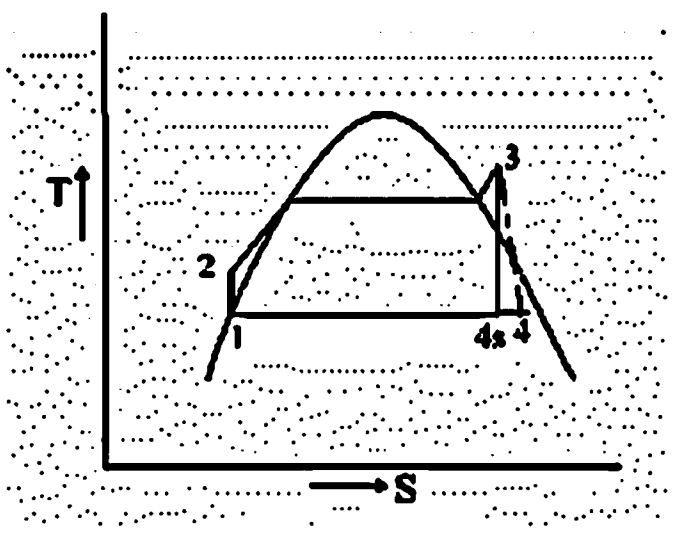
Question:

Reconsider Prob. 10—119E. How much error is caused in the thermal efficiency if the power required by the pump were completely neglected?

Step 1 of 21

Given

Boiler pressure $P_3 = P_2 = 2500\,\text{psia}$



Condenser pressure $P_4 = P_1 = 1\,\text{psia}$

Turbine inlet temperature $T_3 = 800^0\text{F}$

Turbine isentropic efficiency $\eta_T = 90\%$

Power developed $\dot{W}_{net} = 1000\,\text{kW}$

Step 2 of 21

Step 3 of 21

At $P_1 = 1\,\text{psia}$ from saturated water tables

$h_1 = h_f = 69.72\ \text{Btu/lbm}$

$h_{fg} = 1035.7\,\text{Btu/lbm}$

$s_f = 0.13262\,\text{Btu/lbm.R}$

$s_{fg} = 1.84495\,\text{Btu/lbm.R}$

$v_1 = v_{f\,@\,1\text{psia}} = 0.01614\ \text{ft}^3\text{/lbm}$

Step 4 of 21

Pump work

$$w_{pump} = -v_1(P_2 - P_1)$$

$$w_{pump} = -0.01614\ \text{ft}^3\text{/lbm} \times (2500-1)\frac{\text{lbf}}{\text{in}^2} \times 144 \times \frac{\text{in}^2}{\text{ft}^2} \times \frac{1}{778}\frac{\text{Btu}}{\text{lbf-ft}}$$

$$w_{pump} = -7.46\,\text{Btu/lbm}$$

Step 5 of 21

Applying energy equation to the process 1-2

$$h_1 = h_2 + w_{pump}$$

$$h_2 = h_1 - w_{pump}$$

$$h_2 = 69.72 + 7.46$$

$$h_2 = 77.18\ \text{Btu/lbm}$$

Step 6 of 21

At $P_3 = 2500$ psia and $T_3 = 800^0$F from superheated water tables

$h_3 = 1302\ \text{Btu/lbm}$

$s_3 = 1.4116\ \text{Btu/lbm.R}$

Step 7 of 21

Process 3-4s is isentropic process entropy remains constant

$$s_4 = s_3$$

$$s_3 = s_{f@1\text{psia}} + x_4 s_{fg@\text{psia}}$$

$$x_{4s} = \frac{(s_4 - s_f)}{s_{fg}}$$

$$x_{4s} = \frac{(1.4116 - 0.13262)}{1.84495}$$

$$x_{4s} = 0.6932$$

Step 8 of 21

Enthalpy at state-4s,

$$h_{4s} = h_f + x_{4s} h_{fg}$$

$$h_{4s} = 69.72 + (0.6932 \times 1035.7)$$

$$h_{4s} = 787.7\ \text{Btu/lbm}$$

Step 9 of 21

Isentropic efficiency of the turbine is defined as,

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

$$h_4 = 1302 - (0.9 \times (1302 - 787.7))$$

$$h_4 = 839.13\ \text{Btu/lbm}$$

Step 10 of 21

Heat addition in the boiler is given by

$$q_{in} = h_3 - h_2$$

$$q_{in} = 1302 - 77.18$$

$$q_{in} = 1224.82\ \text{Btu/lbm}$$

Step 11 of 21

Heat rejected is given by

$$q_{out} = h_4 - h_1$$

Step 11 of 21

Heat rejected is given by

$$q_{out} = h_4 - h_1$$
$$q_{out} = 839.13 - 69.72$$
$$q_{out} = 769.41 \text{ Btu/lbm}$$

Step 12 of 21

Work output from the turbine

$$w_T = (h_3 - h_4)$$
$$= 1302 - 839.13$$
$$w_T = 462.87 \text{ Btu/lbm}$$

Step 13 of 21

The mass flow rate of steam can be obtained from the relation,

$$W_{net} = \dot{m} w_{net}$$
$$\dot{m} = \frac{W_{net}}{w_T}$$
$$\dot{m} = \frac{1000 \text{ kJ/s}}{462.87 \text{ Btu/lbm}} \left(\frac{0.9478 \text{Btu}}{1 \text{kJ}} \right)$$
$$\dot{m} = 2.047 \text{ lbm/s}$$

Step 14 of 21

The power output from the turbine

$$W_T = \dot{m}(h_3 - h_4)$$
$$W_T = 2.047 \frac{\text{lbm}}{s} \times (1302 - 839.13) \frac{\text{Btu}}{\text{lbm}} \times \frac{1 \text{kJ}}{0.9478 \text{Btu}}$$
$$W_T = 999.678 \text{ kW}$$

Step 15 of 21

The rate of heat addition in the boiler is given by

$$Q_{in} = \dot{m} q_{in}$$
$$Q_{in} = 2.047 \times (1224.82)$$
$$Q_{in} = 2507.206 \text{Btu/s}$$
$$Q_{in} = 2507.206 \frac{\text{Btu}}{s} \times \frac{1}{0.9478} \times \frac{\text{kJ}}{\text{Btu}}$$
$$Q_{in} = 2645.29 \text{kW}$$

Step 16 of 21

Thermal efficiency of the cycle,

$$\eta_{th} = \frac{W_{net}}{Q_{in}}$$
$$\eta_{th} = \frac{1000}{2645.29}$$
$$= 0.378$$
$$\eta_{th} = 37.8\%$$

Step 17 of 21

When pump work is considered

Network output is defined as

$$w_{net} = q_{in} - q_{out}$$
$$w_{net} = 1224.82 - 769.41$$
$$w_{net} = 455.41 \text{ Btu/lbm}$$

Step 18 of 21

The mass flow rate of steam can be obtained from the relation,

$$W_{net} = \dot{m} w_{net}$$
$$\dot{m} = \frac{W_{net}}{w_{net}}$$
$$\dot{m} = \frac{1000 \text{ kJ/s}}{455.41 \text{ Btu/lbm}} \left(\frac{0.9478 \text{Btu}}{1 \text{kJ}} \right)$$
$$\dot{m} = 2.081 \text{ lbm/s}$$

Step 19 of 21

The rate of heat addition in the boiler is given by

$$Q_{in} = \dot{m} q_{in}$$
$$Q_{in} = 2.081 \times (1224.82)$$
$$Q_{in} = 2548.85 \text{Btu/s}$$
$$Q_{in} = 2548.85 \frac{\text{Btu}}{s} \times \frac{1}{0.9478} \times \frac{\text{kJ}}{\text{Btu}}$$
$$Q_{in} = 2689.227 \text{kW}$$

Step 20 of 21

Thermal efficiency of the cycle,

$$\eta_{th} = \frac{W_{net}}{Q_{in}}$$
$$\eta_{th} = \frac{1000}{2689.227}$$
$$= 0.3718$$
$$\eta_{th} = 37.18\%$$

Step 21 of 21
