We get: $\lambda = 1.2792, A = 1.231$

Putting this into the expression:

$$\frac{T(t)-T_\alpha}{T_i-T_\alpha} = Ae^{-\lambda^2\tau}$$

$$\frac{T(t)-0}{30-0} = 1.231e^{-1.2792^2\times1.485}$$

$$T(t) = 3.25^\circ\text{C}$$

So the centre temperature of margarine after 6 hr is $\boxed{T(t) = 3.25^\circ\text{C}}$.

Step 7 of 12

For white cake:

Biot number is

$$Bi = \frac{hL_c}{k}$$

$$= \frac{25\times(0.04)}{0.082}$$

$$= 12.2$$

Since Biot number greater than 0.1, therefore lumped system analysis not applicable.

Step 8 of 12

So, for white cake, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.10\times10^{-6}\times(6\times3600SEC)}{(0.04)^2}$$

$$= 1.35$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 9 of 12

From the one dimension term approximation solution of transient heat conduction for plane wall

Step 9 of 12

From the one dimension term approximation solution of transient heat conduction for plane wall

We get: $\lambda = 1.4311, A = 1.2631$

Putting this into the expression:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 0}{30 - 0} = 1.2631e^{-1.4311^2 \times 1.35}$$

$$T(t) = 2.38^\circ \text{C}$$

So the centre temperature of white cake after 6 hr is $\boxed{T(t) = 2.38^\circ \text{C}}$.

Step 10 of 12

For chocolate cake:

$$Bi = \frac{hL_c}{k}$$

$$= \frac{25 \times (0.04)}{0.106}$$

$$= 9.43$$

Since Biot number greater than 0.1, therefore lumped system analysis not applicable.

Step 11 of 12

So, for chocolate cake, Fourier number is obtained to be:

$$\tau = \frac{\alpha t}{L_c^2}$$

$$= \frac{0.12 \times 10^{-6} \times (6 \times 3600 SEC)}{(0.04)^2}$$

$$= 2.7$$

Since Fourier number greater than the 0.2. .So one term approximation is applicable.

Step 12 of 12

From the one dimension term approximation solution of transient heat conduction for plane wall

$\lambda = 1.416, A = 1.261$

Putting this into the expression:

$$\frac{T(t) - T_\alpha}{T_i - T_\alpha} = Ae^{-\lambda^2 \tau}$$

$$\frac{T(t) - 0}{30 - 0} = 1.261e^{-1.416^2 \times 2.7}$$

$$T(t) = 0.2^\circ \text{C}$$

So the centre temperature of chocolate cake after 6 hr is $\boxed{T(t) = 0.2^\circ \text{C}}$.

Question: 18.108P

Long aluminum wires of diameter 3 mm (ρ = 2702 kg/m3 , cp = 0.896 kJ/kg·K, k = 236 W/m·K, and α = 9.75 × 10–5 m2 /s) are extruded at a temperature of 350°C and exposed to atmospheric air at 30°C with a heat transfer coefficient of 35 W/m2 ·K. (*a*) Determine how long it will take for the wire temperature to drop to 50°C. (*b*) If the wire is extruded at a velocity of 10 m/min, determine how far the

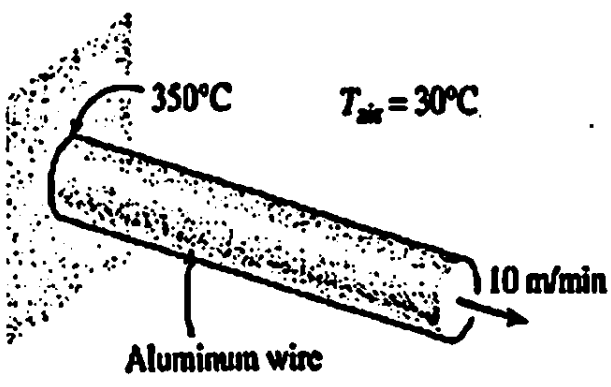

FIGURE P18–108

wire travels after extrusion by the time its temperature drops to50°C. What change in the cooling process would you propose to shorten this distance? (*c*) Assuming the aluminum wire leaves the extrusion room at 50°C, determine the rate of heat transfer from the wire to the extrusion room.

Step 1 of 7

Given:

Diameter of aluminum D= 3mm

Thermal conductivity $k = 236\ W/m\cdot^\circ C$

Density $\rho = 2702\ kg/m^3$

specific heat $C_p = 0.896\ kJ/kg\cdot^\circ C$

thermal diffusivity $\alpha = 9.75\ 10^{-5} m^2/s$

Extruded temperature $T_i = 350^\circ C$

Atmospheric temperature $T_\infty = 30^\circ C$

Step 2 of 7

Long aluminum wires are extruded and exposed to atmospheric air. Heat conduction in the wires is one-dimensional in the radial direction. The thermal properties of the aluminum are constant.

Step 3 of 7

(a) The characteristic length of the wire and the Biot number are

$$L_c = \frac{V}{A_s}$$

$$= \frac{\pi r_o^2 L}{2\pi r_o L}$$

$$= \frac{r_o}{2}$$

$$= \frac{0.0015\ m}{2}$$

$$= 0.00075\ m$$

$$Bi = \frac{hL_c}{k}$$

$$= \frac{(35\ W/m^2.^\circ C)(0.00075\ m)}{236\ W/m.^\circ C}$$

$$= 0.00011 < 0.1$$

Since Bi < 0.1, the lumped system analysis is applicable.

Step 4 of 7

Then,

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

$$b = \frac{hA_s}{\rho C_p V}$$

$$= \frac{h}{\rho C_p L_c}$$

$$= \frac{35\ W/m^2.^\circ C}{(2702\ kg/m^3)(896\ J/kg.^\circ C)(0.00075\ m)}$$

$$= 0.0193\ s^{-1}$$

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

$$\frac{50 - 30}{350 - 30} = e^{-(0.0193\ s^{-1})t}$$

$t = 144\ s$

Time required to drop temperature is $\boxed{t = 144\ s}$

Step 5 of 7

(b) The wire travels a distance of

$$\text{velocity} = \frac{\text{length}}{\text{time}}$$

$$\text{Length} = (10/60\ m/s)(144\ s)$$

$$= 24\ m$$

length of the wire travel is $\boxed{L = 24\ m}$

This distance can be reduced by cooling the wire in a water or oil bath.

Step 6 of 7

(C) The mass flow rate of the extruded wire through the air is

$$\dot{m} = \rho \dot{V}$$

$$= \rho(\pi r_0^2 / 4)V$$

$$= (2702\ kg/m^3)\pi(0.0015\ m)^2(10\ m/min)$$

$$= 0.191\ kg/min$$

Then the rate of heat transfer from the wire to the air becomes

$$\dot{Q} = \dot{m} C_p [T(t) - T_\infty]$$

$$= (0.191\ kg/min)(0.896\ kJ/kg.^\circ C)(350 - 50)^\circ C$$

$$= 51.3\ kJ/min$$

Step 7 of 7

$$= 856\ W$$

The rate of heat transfer from the wire is $\boxed{856\ W}$

Question: 18.109P

Repeat Prob. 18-108 for a copper wire (ρ = 8950 kg/m3 , cp = 0.383 kJ/kg·K, k = 386 W/m·K, and α = 1.13 × 10–4 m2 /s).

Step 1 of 7

Given:

Diameter of aluminum D= 3mm

Thermal conductivity $k = 386\ W/m\cdot{}^{\circ}C$

Density $\rho = 8950\ kg/m^3$

Specific heat $C_p = 0.383\ kJ/kg\cdot{}^{\circ}C$

Thermal diffusivity $\alpha = 1.13\times 10^{-4} m^2/s$

Extruded temperature $T_i = 350^{\circ}C$

Atmospheric temperature $T_\infty = 30^{\circ}C$

Step 2 of 7

Long copper wires are extruded and exposed to atmospheric air.

Heat conduction in the wires is one-dimensional in the radial direction.The thermal properties of the copper are constant.

Step 3 of 7

Biot number is

$$L_c = \frac{V}{A_s}$$

$$= \frac{\pi r_o^2 L}{2\pi r_o L}$$

$$= \frac{r_o}{2}$$

$$= \frac{0.0015\ m}{2}$$

$$= 0.00075\ m$$

$$Bi = \frac{hL_c}{k}$$

$$= \frac{(35\ W/m^2.{}^{\circ}C)(0.00075\ m)}{386\ W/m.{}^{\circ}C}$$

$$= 0.000068 < 0.1$$

Since Bi < 0.1 the lumped system analysis is applicable.

Step 4 of 7

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

$$b = \frac{hA_s}{\rho C_p V}$$

$$= \frac{h}{\rho C_p L_c}$$

$$= \frac{35\ W/m^2.{}^{\circ}C}{(8950\ kg/m^3)(383\ J/kg.{}^{\circ}C)(0.00075\ m)}$$

$$= 0.0136\ s^{-1}$$

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

$$\frac{50-30}{350-30} = e^{-(0.0136\ s^{-1})t}$$

$$t = 204\ s$$

Time required to drop temperature is $\boxed{t=204\ s}$

Step 5 of 7

(*b*) The wire travels a distance of

$$\text{velocity} = \frac{\text{length}}{\text{time}}$$

$$\text{length} = \left(\frac{10\ m/min}{60\ s/min}\right)(204\ s)$$

$$= 34\ m$$

Length of the wire travel is $\boxed{L=34\ m}$

This distance can be reduced by cooling the wire in a water or oil bath.

Step 6 of 7

(*c*) The mass flow rate of the extruded wire through the air is

$$\dot{m} = \rho \dot{V}$$

$$= \rho(\pi r_0^2 / 4)V$$

$$= (8950\ kg/m^3)\pi(0.0015\ m)^2(10\ m/min)$$

$$= 0.633\ kg/min$$

Then the rate of heat transfer from the wire to the air becomes

$$\dot{Q} = \dot{m}C_p[T(t)-T_\infty]$$

$$\dot{Q} = (0.633\ kg/min)(0.383\ kJ/kg.{}^{\circ}C)(350-50)^{\circ}C$$

Step 7 of 7

$$\dot{Q} = 72.7\ kJ/min$$

$$\dot{Q} = 1212\ W$$

Rate of heat transfer from the wire is $\boxed{Q=1212\ W}$

Question: 18.110P

A 40-cm-thick brick wall (k = 0.72 W/m·K, and α = 1.6 × 10–6 m2 /s) is heated to an average temperature of 18°C by the heating system and the solar radiation incident on it during the day. During the night, the outer surface of the wall is exposed to cold air at –3°C with an average heat transfer coefficient of 20 W/m2 ·K, determine the wall temperatures at distances 15, 30, and 40 cm from the outer surface for a period of 2 h.

Step 1 of 3

Given:

Dimensions of brick wall $= 10\text{m}(\text{long}) \times 3\text{m}(\text{high}) \times 0.3\text{m}(\text{thick})$

Temperature of inner part of house $T_i = 5^\circ\text{C}$

Outer surface temperature $T_s = 15^\circ\text{C}$

Thermal conductivity of brick $k = 0.72\ \text{W/m} \cdot {}^\circ\text{C}$

Thermal diffusivity $\alpha = 0.45\ 10^{-4}\ \text{m}^2/\text{s}$.

Step 2 of 3

A brick house made of brick that was initially cold is exposed to warm atmospheric air at the outer surfaces.

The exact analytical solution to this problem is

$$\frac{T(x,t)-T_i}{T_s-T_i} = erfc\left(\frac{x}{\sqrt{\alpha t}}\right)$$

Step 3 of 3

Substituting,

$$\frac{5.1-5}{15-5} = erfc\left(\frac{0.3\,\text{m}}{2\sqrt{(0.45\times10^{-6}\,\text{m}^2/\text{s})t}}\right)$$

$0.01 = \text{erfc}(1.8215)$

The time is determined to be

$$\left(\frac{0.3\,\text{m}}{2\sqrt{(0.45\times10^{-6}\,\text{m}^2/\text{s})t}}\right) = 1.8215$$

$t = 15{,}070\ \text{s}$

$= 251\ \text{min}$

Time taken to increase the temperature is $\boxed{251\ \text{min}}$

Question: 18.111P

Large steel plates 1.0-cm in thickness are quenched from 600°C to 100°C by submerging them in an oil reservoir held at 30°C. The average heat transfer coefficient for both faces of steel plates is 400 W/m2 ·K. Average steel properties are k = 45 W/m·K. ρ = 7800 kg/m3 , and cp = 470 J/kg·K. Calculate the quench time for steel plates.

Step 1 of 3

Given:

Thickness of steel plate $t = 1.0$ cm

Temperature of oil reservoir $= 30\ ^\circ C$

Heat transfer coefficient $h = 400\ W/m^2 \cdot K$

Thermal conductivity of steel $k = 45\ W/m \cdot K$

Density of steel $\rho = 7800\ kg/m^3$

Specific heat of steel $c_p = 470\ J/kg \cdot K$

Step 2 of 3

The thermal properties of the rod are constant. If the heat transfer coefficient is constant and uniform over the entire surface. Then the characteristic length and the Biot number for the copper rod are

$$L_c = \frac{V}{A_s}$$

$$= \frac{L}{2}$$

$$= \frac{0.01m}{2}$$

$$= 0.005m$$

$$Bi = \frac{hL_c}{k}$$

$$= \frac{(400 W/m^2.^\circ C)(0.005m)}{(45\ W/m.^\circ C)}$$

$$= 0.0044 < 0.1$$

Step 3 of 3

The lumped system analysis is applicable since Bi < 0.1. Then the temperature of the rod becomes

$$b = \frac{hA}{\rho C_p V}$$

$$= \frac{h}{\rho C_p L_c}$$

$$= \frac{400\ W/m^2.^\circ C}{(7800\ kg/m^3)(470\ J/kg.^\circ C)(0.005m)}$$

$$= 0.02182\ s^{-1}$$

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

$$\frac{100 - 30}{600 - 30} = e^{-(0.02182 s^{-1})t}$$

$t = 96s$

$t = 1.6min$

$\boxed{time = 1.6min}$

Question: 18.112P

Aluminium wires, 4 mm in diameter, are produced by extrusion. The wires leave the extruder at an average temperature of 350°C and at a linear rate of 10 m/min. Before leaving the extrusion room, the wires are cooled to an average temperature of 50°C by transferring heat to the surrounding air at 25°C with a heat transfer coefficient of 50 W/m·K. Calculate the necessary length of the wire cooling section in the extrusion room.

Step 1 of 4

Characteristic length and Biot number for long cylinder can be calculated as follows

$$L_c = \frac{V}{A_s}$$

$$= \frac{(\pi D^2/4)L}{\pi DL}$$

$$L_c = \frac{D}{4}$$

Substitute 0.004 m for D,

$$L_c = \frac{D}{4}$$

$$= \frac{0.004\text{m}}{4}$$

$$= 0.001\text{m}$$

Step 2 of 4

From the equation of Biot number is given as

$$Bi = \frac{hL_c}{k}$$

Substitute 50 $\text{W/m}^2\cdot\text{K}$ for h and 237 $\text{W/m}\cdot^\circ\text{C}$ for k

$$Bi = \frac{hL_c}{k}$$

$$= \frac{(50)(0.001)}{(237)}$$

$$= 0.000210$$

Since Biot number is less than 0.1, therefore lumped system analysis is applicable.

Step 3 of 4

From the equation of lumped system analysis, we have

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

Where,

$$b = \frac{hA}{\rho c_p V}$$

$$= \frac{h}{\rho c_p L_c}$$

Substitute 50 $\text{W/m}^2\cdot\text{K}$ for h, 2702 kg/m^3 for ρ and 903 $\text{kJ/kg}\cdot\text{K}$ for c_p

$$b = \frac{h}{\rho c_p L_c}$$

$$= \frac{50}{(2702)(903)(0.001)}$$

$$= 0.0204\ \text{s}^{-1}$$

Step 4 of 4

Then, substituting the known values, we get

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

Substitute 50°C for $T(t)$, 350°C for T_i and 25°C for T_∞

$$\frac{T(t)-T_\infty}{T_i-T_\infty} = e^{-bt}$$

$$\frac{50-25}{350-25} = e^{-(0.0204)t}$$

$$t = 126\text{s}$$

Length if wire necessary for cooling section will be calculated as

$$L = \frac{t}{V}$$

$$= \frac{126\text{sec} \times \frac{1\text{min}}{60\text{sec}}}{10\text{m/min}}$$

$$\boxed{L = 0.21\text{m}}$$

Therefore, length of the steel wire is 0.21m.

Question: 18.113P

Two metal rods are being heated in an oven with uniform ambient temperature of 1000°C and convection heat transfer coefficient of 25 W/m2 ·K. Rod A is made of aluminum (ρ = 2702 kg/m3 cp = 903 J/kg·K, and k = 237 W/m·K) and rod B is made of stainless steel (ρ = 8238 kg/m3 , cp 468 J/kg·K, and k = 13.4 W/m·K). Both rods have diameter of 25 mm and length of 1 m. If the initial temperature of both rods is 15°C, determine the average temperatures of both rods after 5 minutes elapsed time.

Step 1 of 4

The characteristic length of the cylinder ,

$$L_c = \frac{D}{4}$$

Substitute 0.025 m for D,

$$L_c = \frac{D}{4}$$
$$= \frac{0.025}{4}$$
$$= 0.00625 \text{ m}$$

The temperature of the rod after 't' mins of elapsed time is given by

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

Where,

$$b = \frac{h}{\rho c_p L_c}$$

Step 2 of 4

For rod A:

$$b = \frac{h}{\rho_A c_{p,A} L_c}$$

Substitute 25 W/m^2 ·K for h, 2702 kg/m^3 for ρ and 903 J/kg·K for c_p

$$b = \frac{h}{\rho_A c_{p,A} L_c}$$
$$= \frac{25}{(2702)(903)(0.00625)}$$
$$= 1.639 \times 10^{-3}$$

The temperature of the rod A after 5mins of elapsed time is given by

$$\frac{T(t)_A - T_\infty}{T_i - T_\infty} = e^{-bt}$$

Substitute 15°C for T_i and 1000°C for T_∞

$$\frac{T(t)_A - T_\infty}{T_i - T_\infty} = e^{-bt}$$
$$\frac{T(t)_A - 1000}{15 - 1000} = e^{-1.639 \times 10^{-3}(5 \times 60)}$$
$$T(t)_A - 1000 = -602.412$$
$$T(t)_A = 397.59°C$$

Therefore, the temperature of the rod A after 5mins of elapsed time is $T(t)_A = 397.59°C$

Step 3 of 4

For rod B:

$$b = \frac{h}{\rho_B c_{p,B} L_c}$$

Substitute 25 W/m^2 ·K for h, 8238 kg/m^3 for ρ and 468 J/kg·K for c_p

$$b = \frac{h}{\rho_B c_{p,B} L_c}$$
$$= \frac{25}{(8238)(468)(0.00625)}$$
$$= 1.0375 \times 10^{-3}$$

The temperature of the rod B after 5mins of elapsed time is given by

$$\frac{T(t)_B - T_\infty}{T_i - T_\infty} = e^{-bt}$$
$$\frac{T(t)_B - 1000}{15 - 1000} = e^{-1.0375 \times 10^{-3}(5 \times 60)}$$
$$T(t)_B - 1000 = -721.54$$
$$T(t)_B = 278.46°C$$

Therefore, the temperature of the rod B after 5mins of elapsed time is $T(t)_B = 278.46°C$

Step 4 of 4

The average temperature of both the rods after 5mins of elapsed time is given by

$$T_{avg} = \frac{T(t)_A + T(t)_B}{2}$$
$$= \frac{397.59 + 278.46}{2}$$
$$\boxed{T_{avg} = 338.025°C}$$

Therefore, the average temperature of both the rods after 5mins of elapsed time is 338.025°C

Question: 18.114P

In an event of a volcano eruption, lava at 1200°C is found flowing on the ground. The ground was initially at 15°C and the lava flow has a convection heat transfer coefficient of 3500 W/m2 ·K. Determine the ground surface (*a*) temperature and (*b*) heat flux after 2 s of lava flow. Assume the ground has properties of dry soil.

Step 1 of 4

(a).

Obtain the values for properties of ground from Appendix table A-8 as shown.

$$k = 1.0 \text{ W/m} \cdot \text{K}$$

$$\rho = 1500 \text{ kg/m}^3$$

$$C_p = 1900 \text{ J/kg} \cdot \text{K}$$

Calculate the thermal diffusivity of ground by using the relation,

$$\alpha = \frac{k}{\rho C_p}$$

Here, thermal conductivity of the ground is k , density of the ground material is ρ , and specific heat of the material is C_p .

Substitute $1.0 \text{ W/m} \cdot \text{K}$ for k , 1500 kg/m^3 for ρ , and $1900 \text{ J/kg} \cdot \text{K}$ for ρ .

$$\alpha = \frac{1}{1500 \times 1900}$$
$$= 3.509 \times 10^{-7} \text{ m}^2/\text{s}$$

Step 2 of 4

Calculate the surface temperature of the ground using the relation,

$$\frac{T_s - T_i}{T_\infty - T_i} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{h^2 \alpha t}{k^2}\right)\text{erfc}\left(\frac{h\sqrt{\alpha t}}{k}\right) \quad \text{..... (1)}$$

Here, initial temperature is T_i , surface temperature is T_s , surrounding temperature is T_∞ , depth from the ground surface is x , convection heat transfer of lava flow is h , and time required for heat flux transfer is t .

Calculate the value of $\frac{h^2 \alpha t}{k^2}$ as shown.

Substitute $3500 \text{ W/m}^2 \cdot \text{K}$ for h , $3.509 \times 10^{-7} \text{ m}^2/\text{s}$ for α , 2 s for t , $1.0 \text{ W/m} \cdot \text{K}$ for k

$$\frac{h^2 \alpha t}{k^2} = \frac{3500^2 \times 3.509 \times 10^{-7} \times 2}{1^2}$$
$$= 8.597$$

Calculate the value of $\frac{h\sqrt{\alpha t}}{k}$ as shown.

Substitute $3500 \text{ W/m}^2 \cdot \text{K}$ for h , $3.509 \times 10^{-7} \text{ m}^2/\text{s}$ for α , 2 s for t , $1.0 \text{ W/m} \cdot \text{K}$ for k

$$\frac{h\sqrt{\alpha t}}{k} = \frac{3500 \times \sqrt{3.509 \times 10^{-7} \times 2}}{1}$$
$$= 2.932$$

Step 3 of 4

Calculate the surface temperature of the ground 2 s after the eruption of lava as shown.

Substitute 1200 °C for T_∞ , 15 °C for T_i , 0 for x , $3.509 \times 10^{-7} \text{ m}^2/\text{s}$ for α , 2 s for t , 8.597 for $\frac{h^2 \alpha t}{k^2}$, and 2.932 for $\frac{h\sqrt{\alpha t}}{k}$ in equation (1).

$$\frac{T_s - 15}{1200 - 15} = \text{erfc}\left(\frac{(0)}{2\sqrt{3.509 \times 10^{-7} \times 2}}\right) - \exp(8.597)\text{erfc}(2.932)$$

$$T_s - 15 = (1200 - 15)\left[1 - (5415.39)\left(3.37 \times 10^{-5}\right)\right]$$

$$T_s = 15 + 1185(1 - 0.182)$$
$$= 983.74 \text{ °C}$$

Therefore, the surface temperature of the ground 2 s after the eruption of lava is $\boxed{983.74 \text{ °C}}$.

Step 4 of 4

(b).

Calculate the heat flux of the lava flow 2 s after eruption using the relation,

$$\dot{q}_s = h(T_\infty - T_s)$$

Substitute 1200 °C for T_∞ , 983.74 °C for T_s , and $3500 \text{ W/m}^2 \cdot \text{K}$ for h .

$$\dot{q}_s = 3500(1200 - 983.74)$$
$$= 759610 \text{ W/m}^2$$
$$= 759.61 \text{ kW/m}^2$$

Therefore, the heat flux of the lava flow 2 s after eruption is $\boxed{759.61 \text{ kW/m}^2}$.

Question: 18.115P

A large heated steel block (ρ = 7832 kg/m3 cp = 434 J/kg·K. k = 63.9 W/m·K. and α = 18.8 × 10–6 m2 /s) is allowed to cool in a room at 25°C. The steel block has an initial temperature of 450°C and the convection heal transfer coefficient is 25 W/m2 ·K. Assuming that the steel block can be treated as a quarter-infinite medium, determine the e temperature at the edge of the steel block after 10 minutes of cooling.

Step 1 of 4

Multidimensional solutions expressed as products of one-dimensional solutions for bodies that are initially at a uniform temperature T_i and expose to convection from all surfaces to a medium at T_∞ table for Quater-infinite medium the one term approximation is expressed as

$$\theta(x,y,t)=\theta_{\text{semi-inf}}(x,t)\theta_{\text{semi-inf}}(y,t) \quad \text{..... (1)}$$

Convection on the surface at the edge of the steel block along the x-axis is given by,

$$1-\frac{T(x,t)-T_i}{T_\infty-T_i}=1-\operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)-\exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right)$$

$$\frac{T_\infty-T_i-T(x,t)+T_i}{T_\infty-T_i}=1-\left[\begin{array}{l}\operatorname{erfc}\left(\dfrac{0}{2\sqrt{(18.8\times10^{-6}\times600)}}\right)\\ -\exp\left(\dfrac{25\times0}{63.9}+\dfrac{(25^2\times18.8\times10^{-6}\times600)}{63.9^2}\right)\operatorname{erfc}\left(\dfrac{0}{2\sqrt{(18.8\times10^{-6}\times600)}}+\dfrac{\left(25\sqrt{18.8\times10^{-6}\times600}\right)}{63.9}\right)\end{array}\right]$$

$$\frac{T(x,t)-T_\infty}{T_i-T_\infty}=1-\left[\operatorname{erfc}(0)-\exp(0+1.727\times10^{-3})\operatorname{erfc}(0+0.0415)\right]$$

$$=1-[1-1.00173\times0.9549]$$

$$=0.9565$$

Step 2 of 4

Specified surface temperature at the edge of the steel block along the y-axis is given by,

$$1-\frac{T(y,t)-T_i}{T_\infty-T_i}=1-\operatorname{erfc}\left(\frac{y}{2\sqrt{\alpha t}}\right)-\exp\left(\frac{hy}{k}+\frac{h^2\alpha t}{k^2}\right)\operatorname{erfc}\left(\frac{y}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right)$$

Substitute 25 $\text{W/m}^2\cdot\text{K}$ for h, $18.8\times10^{-6}\ \text{m}^2/\text{s}$ for α and 600 sec for t,

$$1-\frac{T(y,t)-T_i}{T_\infty-T_i}=1-\operatorname{erfc}\left(\frac{y}{2\sqrt{\alpha t}}\right)-\exp\left(\frac{hy}{k}+\frac{h^2\alpha t}{k^2}\right)\operatorname{erfc}\left(\frac{y}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right)$$

$$\frac{T_\infty-T_i-T(y,t)+T_i}{T_\infty-T_i}=1-\left[\begin{array}{l}\operatorname{erfc}\left(\dfrac{0}{2\sqrt{(18.8\times10^{-6}\times600)}}\right)\\ -\exp\left(\dfrac{25\times0}{63.9}+\dfrac{(25^2\times18.8\times10^{-6}\times600)}{63.9^2}\right)\operatorname{erfc}\left(\dfrac{0}{2\sqrt{(18.8\times10^{-6}\times600)}}+\dfrac{\left(25\sqrt{18.8\times10^{-6}\times600}\right)}{63.9}\right)\end{array}\right]$$

$$\frac{T(x,t)-T_\infty}{T_i-T_\infty}=1-\left[\operatorname{erfc}(0)-\exp(0+1.727\times10^{-3})\operatorname{erfc}(0+0.0415)\right]$$

$$=1-[1-1.00173\times0.9549]$$

$$=0.9565$$

Step 3 of 4

The one dimensional solution for the semi infinite solid along the x-axis is given by,

$$\theta_{\text{semi-infinite}}(x,t)=\left(\frac{T(x,t)-T_\infty}{T_i-T_\infty}\right)$$

$$=0.9565$$

The one dimensional solution for the semi infinite solid along the y-axis is given by,

$$\theta_{\text{semi-infinite}}(y,t)=\left(\frac{T(y,t)-T_\infty}{T_i-T_\infty}\right)$$

$$=0.9565$$

Step 4 of 4

Thus the transient temperature distribution for the steel block is given by

$$\left(\frac{T(x,y,t)-T_\infty}{T_i-T_\infty}\right)_{\text{steelblock}}=\theta_{\text{semi-infinite}}(x,t)\theta_{\text{semi-infinite}}(y,t)$$

$$=0.9565\times0.9565$$

$$\frac{T(x,y,t)-T_\infty}{T_i-T_\infty}=0.9149$$

$$T(x,y,t)=0.9149(T_i-T_\infty)+T_\infty$$

$$=0.9149(450-25)+25$$

$$\boxed{T=413.87^\circ\text{C}}$$

The temperature at the edge of the steel block after 10 minutes of cooling is 413.87°C

CHAPTER 19
SOLUTIONS

Question: 19.001P

Define incompressible flow and incompressible fluid. Must the flow of a compressible fluid necessarily be treated as compressible?

Step 1 of 1

Incompressible flow is type of flow in which density of the fluid remains constant. Incompressible fluids are those fluids whose density is independent of pressure.

It is not necessary that flow of compressible fluid is compressible as during the flow of compressible fluid density may remain constant.

Question: 19.002P

What is forced convection? How does it differ from natural convection? Is convection caused by winds forced or natural convection?

Step 1 of 1

Forced or natural convection can be distinguished only based on how the motion of fluid is initiated.

When the fluid motion is initiated by an external means such as a pump or a fan to cause the fluid to flow over a surface or in a tube, it is called forced convection.

If any fluid motion is caused by natural means such as the buoyancy effect that manifests itself as the rise of the warmer fluid and the fall of the cooler fluid then it is called as natural convection.

Convection by winds will be natural convection for the earth, whereas these will be forced convection for bodies subjected to the winds as it makes no difference for the body whether the air motion is caused by a fan or by the winds.

Question: 19.003P

What is external forced convection? How does it differ from internal forced convection? Can a heat transfer system involve both internal and external convection at the same time? Give an example.

Step 1 of 1

When the fluid is forced to flow over a surface it is external forced convection. When the fluid is forced to flow in a tube it is Internal forced convection. It is possible to have both Internal and external convection simultaneously as is case of pipe transporting a fluid in a windy area.

Question: 19.004P

In which mode of heat transfer is the convection heat transfer coefficient usually higher, natural convection or forced convection? Why?

Step 1 of 1

As coefficient of heat transfer depends on the fluid velocity.

Coefficient of convective heat transfer will be higher in case of forced convection as it involves high velocity of fluid.

Question: 19.005P

Consider a hot baked potato. Will the potato cool faster or slower when we blow the warm air coming from our lungs on it instead of letting it cool naturally in the cooler air in the room? Explain.

Step 1 of 1

As motion of fluid causes heat transfer to raise so despite smaller temperature difference potato will cool faster by blowing warm air to it.

Question: 19.006P

What is the physical significance of the Nusselt number? How is it defined?

Step 1 of 2

Nusselt number represents the ratio of heat flux by fluid when heat is transferred through fluid layer by convection when fluid involves some motion to heat flux by fluid when heat is transferred through fluid layer by conduction when fluid is motionless. Nusselt number is defines as

$$Nu = \frac{hL}{k}$$

Where L is the characteristic length of the surface

k is the thermal conductivity of the fluid

h is coefficient of heat transfer by convection

Step 2 of 2

A Nusselt number close to unity, namely convection and conduction of similar magnitude, is characteristic of "slug flow" or laminar flow. A larger Nusselt number corresponds to more active convection, with turbulent flow typically in the 100-1000 range

magnitude, is characteristic of "slug flow" or laminar flow. A larger Nusselt number corresponds to more active convection, with turbulent flow typically in the 100-1000 range

Question: 19.007P

When is heat transfer through a fluid conduction and when is it convection? For what case is the rate of heat transfer higher? How does the convection heat transfer coefficient differ from the thermal conductivity of a fluid?

Step 1 of 1

In the absence heat transfer through a fluid is conduction and in the presence of bulk fluid motion it is convection.

Heat transfer rate will be higher in convection due to presence of fluid motion. Coefficient of heat transfer by convection depends on fluid properties as well as fluid motion whereas thermal conductivity does not depend on the flow it is a material property. And also it is depends on the temperature of the metal or material.

Question: 19.008P

During air cooling of potatoes, the heat transfer coefficient for combined convection, radiation, and evaporation is determined experimentally to be as shown:

Air Velocity, m/s	Heat Transfer Coefficient, W/m2·K
0.66	14.0
1.00	19.1
1.36	20.2
1.73	24.4

Consider an 8-cm-diameter potato initially at 20°C with a thermal conductivity of 0.49 W/m•K. Potatoes are cooled by refrigerated air at 5°C at a velocity of 1 m/s. Determine the initial rate of heat transfer from a potato, and the initial value of the temperature gradient in the potato at the surface.

Step 1 of 5

Given: -

Diameter of potato = 8 cm

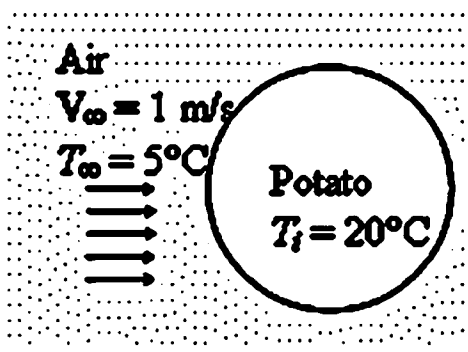
Initial temperature = 20

Thermal conductivity = 0.49 W/m.°C

Final temperature of potato = 5°C

Velocity = 1 m/s

Step 2 of 5



Heat transfer area

$$A_s = \pi D^2$$

$$= \pi(0.08\ \text{m})^2$$

$$= 0.020096\ \text{m}^2$$

Step 3 of 5

Step 4 of 5

Heat transfer rate can be calculated as

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$\dot{Q} = (19.1\ \text{W/m}^2.\text{°C})(0.020096\ \text{m}^2)(20-5)\text{°C}$$

$$\dot{Q} = 5.8\ \text{W}$$

Step 5 of 5

Initial value of temperature gradient can be calculated as follows

$$\dot{q}_{conv} = \dot{q}_{cond}$$

$$= -k\left(\frac{\partial T}{\partial r}\right)_{r=R} = h(T_s - T_\infty)$$

$$\left.\frac{\partial T}{\partial r}\right|_{r=R} = -\frac{h(T_s - T_\infty)}{k}$$

$$= -\frac{(19.1\ \text{W/m}^2.\text{°C})(20-5)\text{°C}}{(0.49\ \text{W/m.°C})}$$

$$= -585\ \text{°C/m}$$

Question: 19.009P

An average man has a body surface area of 1.8 m2 and a skin temperature of 33°C. The convection heat transfer coefficient for a clothed person walking in still air is expressed as h =8.6V0.53 for 0.5 < V < 2 m/s, where V is the walking velocity in m/s. Assuming the average surface temperature of the clothed person to be 30°C, determine the rate of heat loss from an average man walking in still air at 7°C by convection at a walking velocity of (*a*) 0.5 m/s. (*b*) 1.0 m/s, (*c*) 1.5 m/s, and (*d*) 2.0 m/s.

Step 1 of 9

Given data:

Surface area of body, $A_s = 1.8\,\text{m}^2$

Skin temperature, $T_{skin} = 33°\text{C}$

Average surface temperature of clothed person, $T_s = 30°\text{C}$

The temperature of still air, $T_\infty = 7°\text{C}$

Coefficient of heat transfer for convection, $h = 8.6V^{0.53}$

Step 2 of 9

(*a*)

The walking velocity of average man, $V = 0.5\,\text{m/s}$

Coefficient of heat transfer for convection,

$$h = 8.6V^{0.53}$$
$$= 8.6\times(0.5)^{0.53}$$
$$= 5.956\ \text{W/m}^2\cdot°\text{C}$$

Coefficient of heat transfer for convection is $\boxed{h = 5.956\ \text{W/m}^2\cdot°\text{C}}$

Step 3 of 9

By using the formula for rate of heat loss, we get

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$= 5.956\times1.8\times(30-7)$$
$$= 246.578\,\text{W}$$

Rate of heat loss from average man is $\boxed{\dot{Q} = 246.578\,\text{W}}$

Step 4 of 9

(*b*)

The walking velocity of average man, $V = 1.0\,\text{m/s}$

Coefficient of heat transfer for convection,

$$h = 8.6V^{0.53}$$
$$= 8.6\times(1.0)^{0.53}$$
$$= 8.6\ \text{W/m}^2\cdot°\text{C}$$

Coefficient of heat transfer for convection is $\boxed{h = 8.6\ \text{W/m}^2\cdot°\text{C}}$

Step 5 of 9

By using the formula for rate of heat loss, we get

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$= 8.6\times1.8\times(30-7)$$
$$= 356.04\,\text{W}$$

Rate of heat loss from average man is $\boxed{\dot{Q} = 356.04\,\text{W}}$

Step 6 of 9

(*c*)

The walking velocity of average man, $V = 1.5\,\text{m/s}$

Coefficient of heat transfer for convection,

$$h = 8.6V^{0.53}$$
$$= 8.6\times(1.5)^{0.53}$$
$$= 10.661\ \text{W/m}^2\cdot°\text{C}$$

Coefficient of heat transfer for convection is $\boxed{h = 10.661\ \text{W/m}^2\cdot°\text{C}}$

Step 7 of 9

By using the formula for rate of heat loss, we get

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$= 10.661\times1.8\times(30-7)$$
$$= 441.365\,\text{W}$$

Rate of heat loss from average man is $\boxed{\dot{Q} = 441.365\,\text{W}}$

Step 8 of 9

(*d*)

The walking velocity of average man, $V = 2.0\,\text{m/s}$

Coefficient of heat transfer for convection,

$$h = 8.6V^{0.53}$$
$$= 8.6\times(2.0)^{0.53}$$
$$= 12.417\ \text{W/m}^2\cdot°\text{C}$$

Coefficient of heat transfer for convection is $\boxed{h = 12.417\ \text{W/m}^2\cdot°\text{C}}$

Step 9 of 9

By using the formula for rate of heat loss, we get

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$= 12.417\times1.8\times(30-7)$$
$$= 514.063\,\text{W}$$

Rate of heat loss from average man is $\boxed{\dot{Q} = 514.063\,\text{W}}$

Question: 19.010P

The upper surface of a 50-cm-thick solid plate (k= 237 W/m·K) is being cooled by water with temperature of 20°C. The upper and lower surfaces of the solid plate maintained at constant temperatures of 60°C and 120°C, respectively. Determine the water convection heat transfer coefficient and the water temperature gradient at the upper plate surface.

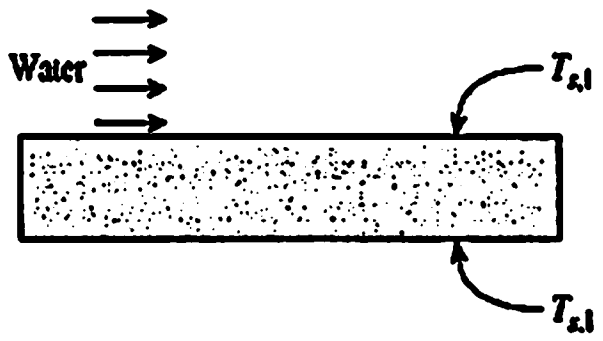


FIGURE P19-10

Step 1 of 3

Calculate the amount of heat transfer through a solid plate by using the Fourier conduction equation

$$\dot{q} = k\frac{dT}{dy}$$
$$= k\frac{(T_L - T_s)}{dy}$$

Here,

Thermal conductivity of the solid plate is k

Temperature gradient is $\frac{dT}{dy}$

Thickness of the solid plate is dy

Lower temperature of the solid plate is T_L

Upper or surface temperature of the solid plate is T_s

Amount of heat flux is $\dot{q}$

Substitute $237\,\text{W/m}\cdot\text{K}$ **for** k. $120°\text{C}$ **for** T_L, $60°\text{C}$ **for** T_s 0.5m **for** dy

$$\dot{q} = k\frac{dT}{dy}$$
$$= k\frac{(T_L - T_s)}{dy}$$
$$= 237\frac{(120-60)}{0.5}$$
$$= 28440\,\text{W/m}^2$$

Step 2 of 3

Calculate the mean film temperature of the water is

$$T_f = \frac{20+60}{2}$$
$$= 40°\text{C}$$

From the properties saturated water table

At $T_f = 40°\text{C}$

Thermal conductivity of water is $k_w = 0.631\,\text{W/m}\cdot\text{K}$

Calculate the heat transfer coefficient by using the energy balance equation

$$\dot{q} = h(T_s - T_\infty)$$

Here,

Ambient temperature of the water is T_∞

Heat transfer coefficient is h

Substitute $28440\,\text{W/m}^2$ **for** $\dot{q}$, $60°\text{C}$ **for** T_s, $20°\text{C}$ **for** T_∞ **in above equation**

$$\dot{q} = h(T_s - T_\infty)$$
$$28440 = h(60-20)$$
$$h = 711\,\text{W/m}^2\cdot\text{K}$$

Hence, heat transfer coiffing of water is $\boxed{711\,\text{W/m}^2\cdot\text{K}}$

Step 3 of 3

Calculate the temperature gradient between the water and surface of the solid plate is

$$\dot{q} = -k_w\frac{dT}{dy}$$

Substitute $28440\,\text{W/m}^2$ **for** $\dot{q}$, $0.631\,\text{W/m}\cdot\text{K}$ **for** k_w, 0.5m **for** dy

$$\dot{q} = -k_w\frac{dT}{dy}$$
$$28440 = -0.631\frac{dT}{dy}$$
$$\frac{dT}{dy} = -45071.31°\text{C/m}$$

Hence, temperature gradient is $\boxed{-45071.31°\text{C/m}}$

Question: 19.011P

Consider airflow over a plate surface maintained at a temperature of 220°C. The temperature profile of the airflow is given as

$$T(y) = T_\infty - (T_\infty - T_s)\exp\left(-\frac{V}{\alpha_{fluid}}y\right)$$

The airflow at 1 atm has a free stream velocity and temperature of 0.08 m/s and 20°C, respectively. Determine the heat flux on the plate surface and the convection heat transfer coefficient of the airflow.

Step 1 of 4

Calculate the mean film temperature of air.

$$T_f = \frac{T_s + T_\infty}{2}$$

Here, T_s is the surface temperature of the plate and T_∞ is the temperature of free stream.

Substitute $220°C$ for T_s and $20°C$ for T_∞.

$$T_f = \frac{220+20}{2}$$
$$= 120°C$$

Obtain the properties of air from Table A-15 (Properties of air at 1 atm pressure) in the text book, at $T_f = 120°C$. find the value of thermal diffusivity (α_{fluid}) and thermal conductivity (k) of air.

Thermal diffusivity is $\alpha_{fluid} = 3.565\times10^{-5}\ m^2/s$.

Thermal conductivity is $k = 0.03235\ W/m\cdot K$.

Step 2 of 4

Calculate the temperature gradient for the given profile.

$$T(y) = T_\infty - (T_\infty - T_s)\exp\left(\frac{-V}{\alpha_{fluid}}y\right)$$

Here, T_∞ is the ambient temperature, V is the free stream velocity of air, and y is the temperature displacement thickness.

Differentiate the expression with respect to y.

$$T(y) = T_\infty - (T_\infty - T_s)\exp\left(\frac{-V}{\alpha_{fluid}}y\right)$$
$$\frac{dT}{dy} = T_\infty - (T_\infty - T_s)\frac{-V}{\alpha_{fluid}}\exp\left(\frac{-V}{\alpha_{fluid}}y\right)$$

Substitute 0 for y to calculate the temperature gradient at the surface of the plate.

$$\frac{dT}{dy} = T_\infty - (T_\infty - T_s)\frac{-V}{\alpha_{fluid}}\exp\left(\frac{-V}{\alpha_{fluid}}0\right) \quad \text{..... (1)}$$
$$= T_\infty - (T_\infty - T_s)\frac{-V}{\alpha_{fluid}}$$

Step 3 of 4

Substitute $20°C$ for T_∞, $220°C$ for T_s, $0.08\ m/s$ for V and $3.565\times10^{-5}\ m^2/s$ for α in equation (1).

$$\frac{dT}{dy} = T_\infty - (T_\infty - T_s)\frac{-V}{\alpha_{fluid}}$$
$$= 20 - (20-220)\frac{-0.08}{3.565\times10^{-5}}$$
$$= -448787.8541°C/m$$

Calculate the heat flux on the plate surface.

$$\dot{q} = -k\frac{dT}{dy}$$

Substitute $0.03235\ W/m\cdot K$ for k, $448787.8541°C/m$ for $\frac{dT}{dy}$.

$$\dot{q} = -(0.03235)(-448787.8541)$$
$$= 1.45\times10^4\ W/m^2$$

Therefore, the heat flux on the plate surface is $\boxed{1.45\times10^4\ W/m^2}$.

Step 4 of 4

Calculate the heat transfer coefficient.

$$\dot{q} = h(T_s - T_\infty)$$

Here, h is the heat transfer coefficient.

Substitute $1.45\times10^4\ W/m^2$ for $\dot{q}$, $20°C$ for T_∞, and $220°C$ for T_s.

$$1.45\times10^4 = h(220-20)$$
$$h = 72.6\ W/m^2\cdot K$$

Therefore, the heat transfer coefficient is $\boxed{72.6\ W/m^2\cdot K}$.

Question: 19.012P

The convection heat transfer coefficient for a clothed person standing in moving air is expressed as h =14.8V0.69 for 0.15 < V < 1.5 m/s, where V is the air velocity. For a person with a body surface area of 1.7 m2 and an average surface temperature of 29°C, determine the rate of heat loss from the person in windy air at 10°C by convection for air velocities of (*a*) 0.5 m/s, (*b*) 1.0 m/s, and (*c*) 1.5 m/s.

Step 1 of 4

Given: -

Body surface area = 1.7m

Average surface temperature = 29°C

Step 2 of 4

Coefficient of heat transfer for convection and heat loss rate for different velocities are

$(a)\ h = 14.8V^{0.53}$

$h = 14.8(0.5\ \text{m/s})^{0.69}$

$h = 9.174\ \text{W/m}^2.^\circ\text{C}$

$\dot{Q} = hA_s(T_s - T_\infty)$

$\dot{Q} = (9.174\ \text{W/m}^2.^\circ\text{C})(1.7\ \text{m}^2)(29-10)^\circ\text{C}$

$\dot{Q} = 296.3\ \text{W}$

Heat loss from the person is $\boxed{\dot{Q} = 296.3\ \text{W}}$

Step 3 of 4

$(b)\ h = 14.8V^{0.53}$

$h = 14.8(1.0\ \text{m/s})^{0.69}$

$h = 14.8\ \text{W/m}^2.^\circ\text{C}$

$\dot{Q} = hA_s(T_s - T_\infty)$

$\dot{Q} = (14.8\ \text{W/m}^2.^\circ\text{C})(1.7\ \text{m}^2)(29-10)^\circ\text{C}$

$\dot{Q} = 478.0\ \text{W}$

Heat loss from the person is $\boxed{\dot{Q} = 478.0\ \text{W}}$

Step 4 of 4

$(c)\ h = 14.8V^{0.53}$

$h = 14.8(1.5\ \text{m/s})^{0.69}$

$h = 19.58\ \text{W/m}^2.^\circ\text{C}$

$\dot{Q} = hA_s(T_s - T_\infty)$

$\dot{Q} = (19.58\ \text{W/m}^2.^\circ\text{C})(1.7\ \text{m}^2)(29-10)^\circ\text{C}$

$\dot{Q} = 632.4\ \text{W}$

Heat loss from the person is $\boxed{\dot{Q} = 632.4\ \text{W}}$

Question: 19.013P

During air cooling of oranges, grapefruit, and tangelos, the heat transfer coefficient for combined convection, radiation, and evaporation for air velocities of $0.11 < V < 0.33$ m/s is determined experimentally and is expressed as $h = 5.05\,k_{air}\,Re^{1/3}/D$, where the diameter D is the characteristic length. Oranges arc cooled by refrigerated air at 3°C and 1 atm at a velocity of 0.3 m/s. Determine (*a*) the initial rate of heat transfer from a 7-cm-diameter orange initially at 15°C with a thermal conductivity of 0.70 W/m·K, (*b*) the value of the initial temperature gradient inside the orange at the surface, and (*c*) the value of the Nusselt number.

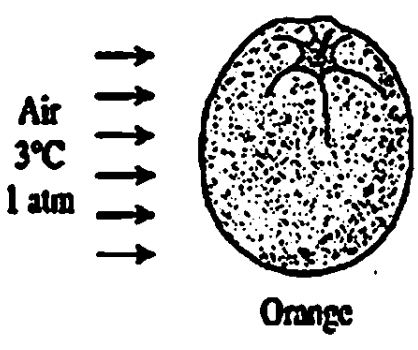

FIGURE P19-13

Step 1 of 6

Calculate the mean film temperature of the air is

$$T_f = \frac{T_\infty + T}{2}$$

Here,

Ambient air temperature is T_∞

Temperature of the orange is T

Substitute $15°C$ for T, $3°C$ for T_∞

$$T_f = \frac{15+3}{2}$$
$$= 9°C$$

From the properties of air

At $T_f = 9°C$

Use interpolation between temperature ranges of $5°C$ to $10°C$

Thermal conductivity of air is

$$k_{air} = 0.02401 + \frac{(9-5)(0.02439-0.02401)}{(10-5)}$$
$$= 0.024314\,W/m\cdot K$$

Kinematic viscosity is

$$\nu = 1.382\times10^{-5} + \frac{(9-5)(1.426-1.382)10^{-5}}{(10-5)}$$
$$= 1.41\times10^{-5}\,m^2/s$$

Step 2 of 6

Calculate the area of the orange is

$$A = \pi D^2$$

Here,

Area of the orange is A

Diameter of the orange is D

Substitute $0.07\,m$ for D in above expression

$$A = \pi D^2$$
$$= \pi(0.07)^2$$
$$= 0.01539\,m^2$$

Step 3 of 6

Calculate the Reynolds number

$$Re = \frac{VD}{\nu}$$

Here,

Reynolds number is Re

Velocity of the air is V

Substitute $0.3\,m/s$ for V, $1.41\times10^{-5}\,m^2/s$ for ν $0.07\,m$ for D,

$$Re = \frac{VD}{\nu}$$
$$= \frac{0.3\times0.07}{1.41\times10^{-5}}$$
$$= 1489.361$$

Calculate the heat transfer coefficient is

$$h = \frac{5.05\times k_{air}\times Re^{1/3}}{D}$$

Here,

Heat transfer coefficient is h

Substitute $0.024314\,W/m\cdot K$ for k_{air}. $0.07\,m$ for D, 1489.361 for Re

$$h = \frac{5.05\times k_{air}\times Re^{1/3}}{D}$$
$$= \frac{5.05\times0.024314\times(1489.361)^{1/3}}{0.07}$$
$$= 19.54\,W/m^2\cdot K$$

Step 4 of 6

a)

Calculate the initial rate of heat transfer is

$$Q = Ah(T_s - T_\infty)$$

Substitute $0.01539\,m^2$ for A. $19.54\,W/m^2\cdot K$ for h. $15°C$ for T, $3°C$ for T_∞

$$Q = Ah(T_s - T_\infty)$$
$$= 0.01539\times19.54(15-3)$$
$$= 3.61W$$

Hence, the initial rate of heat transfer is $\boxed{3.61\,W}$

Step 5 of 6

b)

Calculate the temperature gradient at surface of orange by using the energy balance equation

$$Q = -kA\frac{dT}{dy} = hA(T_s - T_\infty)$$

$$-k\frac{dT}{dy} = h(T_s - T_\infty)$$

Here,

Thermal conductivity of orange is k

Substitute $0.70\,W/m\cdot K$ for k, $19.54\,W/m^2\cdot K$ for h. $15°C$ for T, $3°C$ for T_∞

$$Q = -kA\frac{dT}{dy} = hA(T_s - T_\infty)$$

$$-k\frac{dT}{dy} = h(T_s - T_\infty)$$

Question: 19.014P

What does the friction coefficient represent in flow over a flat plate? How is it related to the drag force acting on the plate?

Step 1 of 1

Resistance to fluid flow over a flat plate is represented by friction coefficient. Friction coefficient is proportional to the drag force acting on the plate. The drag coefficient is equivalent to the mean friction coefficient for a flat surface.

Question: 19.015P

In an experiment, the local heat transfer over a flat plate was correlated in the form of local Nusselt number as expressed by the following correlation

$$Nu_x = 0.035 Re_x^{0.8} Pr^{1/3}$$

Determine the ratio of the average convection heat transfer coefficient *(h)* over the entire plate length to the local convection heat transfer coefficient *(hx)* at $x = L$.

Step 1 of 5

Given data:

Nusselt number is expressed by the following correlation,

$$Nu_x = 0.035 Re_x^{0.8} Pr^{1/3}$$

Step 2 of 5

As given the local heat transfer over flat plate (in form of Nusselt number)

$$Nu_x = 0.035 Re_x^{0.8} Pr^{1/3}$$

As we also know that heat transfer coefficient can be expressed by using the relation

$$Nu = \frac{hx}{k}$$

$$h = \frac{Nu \cdot k}{x}$$

Then the local heat transfer coefficient,

$$h_x = Nu_x \frac{k}{x}$$

$$= 0.035 Re_x^{0.8} Pr^{1/3} . \frac{k}{x}$$

Step 3 of 5

Let

Velocity of the fluid be V

Kinematic viscosity of the fluid be ν

Reynolds number we can write it as,

$$Re_x = \frac{Vx}{\nu}$$

Local heat transfer coefficient,

$$h_x = 0.035 \left(\frac{V \times x}{\nu}\right)^{0.8} Pr^{1/3} k \cdot x^{-1}$$

$$= 0.035 \left(\frac{V}{\nu}\right)^{0.8} Pr^{1/3} . k x^{0.8-1}$$

$$= Ax^{-0.2}$$

Where A is a constant and $A = 0.035 \left(\frac{V}{\nu}\right)^{0.8} Pr^{1/3} . k$

Therefore at $x = L$ the local convection heat transfer coefficient can be re written as,

$$h_{x=L} = AL^{-0.2}$$

Step 4 of 5

The average convection heat transfer coefficient over entire plate length is,

$$h = \frac{1}{L} \int_0^L h_x dx$$

$$= \frac{1}{L} \int_0^L AL^{-0.2} dx$$

$$= \frac{A}{L} \int_0^L L^{-0.2}$$

$$= \frac{A}{L} \frac{L^{-0.2+1}}{(-0.2+1)}$$

$$= \frac{A}{0.8L} L^{0.8}$$

$$= 1.25 AL^{-0.2}$$

Step 5 of 5

The ratio of the average heat transfer coefficient over the entire plate length to the local convection heat transfer coefficient is,

$$R = \frac{h}{h_L}$$

$$= \frac{1.25 AL^{-0.2}}{AL^{-0.2}}$$

$$= 1.25$$

Therefore, the ratio of the average heat transfer coefficient over the entire plate length to the local convection heat transfer coefficient is $\boxed{R = 1.25}$

Question: 19.016P

A 5-m long strip of sheet metal is being transported on a conveyor at a velocity of 5 m/s, while the coating on the upper surface is being cured by infrared lamps. The coating on the upper surface of the metal strip has an absorptivity of 0.6 and an emissivity of 0.7, while the surrounding ambient air temperature is 25°C. Radiation heat transfer occurs only on the upper surface, while convection heat transfer occurs on both upper and lower surfaces of the sheet metal. If the infrared lamps supply a constant heat flux of 5000 W/m2, determine the surface temperature of the sheet metal. Evaluate the properties of air at 80°C.

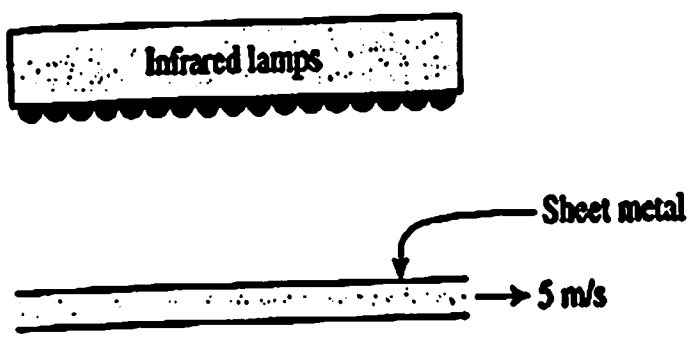

FIGURE P19-16

Step 1 of 4

Given data:

Length of sheet metal strip $L = 5\text{m}$

Velocity of conveyor $V = 5\text{m/s}$

Absorptivity of metal strip $\alpha = 0.6$

Emissivity of metal strip $\varepsilon = 0.7$

Surrounding ambient temperature,

$T_\infty = 25°\text{C}$

$= 25+273\,\text{K}$

$= 298\,\text{K}$

Heat flux supplied by infrared lamps, $q_s = 5000\,\text{W/m}^2$

Step 2 of 4

From properties of air table at temperature at $T = 80°\text{C}$, we have

Thermal conductivity $k = 0.02953\,\text{W/m}\cdot\text{K}$

Kinematic viscosity $\nu = 2.097\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number $\text{Pr} = 0.7154$

Now calculating Reynolds number

$$\text{Re}_L = \frac{VL}{\nu}$$

$$= \frac{5\times5}{2.097\times10^{-5}}$$

$$= 1.192\times10^{6}$$

Since Reynolds number is in between $5\times10^5 < \text{Re}_L < 10^7$ therefore the flow is combined laminar and turbulent flow

Step 3 of 4

Nusselt number for this combined flow can be expressed as,

[Combined flow, $0.6 \le \text{Pr} \le 60,\ 5\times10^5 \le \text{Re}_L \le 10^7$]

$$\text{Nu} = \frac{hL}{k}$$

$$= \left(0.037\text{Re}_L^{0.8} - 871\right)\text{Pr}^{1/3}$$

$$= \left(0.037\left(1.192\times10^6\right)^{0.8} - 871\right)(0.7154)^{1/3}$$

$$= 1815.721\times0.8943$$

$$= 1623.79$$

And Heat transfer coefficient,

$$h = \frac{k\cdot\text{Nu}}{L}$$

$$= \frac{1623.79\times0.02953}{5}$$

$$= 9.5901\,\text{W/m}^2\cdot\text{K}$$

Step 4 of 4

Now from the steady state condition and the energy balance equation,

$$Q_{in} - Q_{out} = 0$$

$$Q_{absorbed} - Q_{radiation} - Q_{convection} = 0$$

As radiation is only from upper surface and convection from both sides,

$$Q_{absorbed} = Q_{radiation} + 2Q_{convection}$$

$$\alpha\cdot q_s\cdot A_s = A_s\varepsilon\sigma\left(T_s^4 - T_\infty^4\right) + 2\cdot h\cdot A_s\left(T_s - T_\infty\right)$$

$$\alpha\cdot q_s = \varepsilon\sigma\left(T_s^4 - T_\infty^4\right) + 2\cdot h\left(T_s - T_\infty\right)$$

$$0.6\times5000 = 0.7\times5.67\times10^{-8}\left((T_s+273)^4 - (298)^4\right) + 2\times9.593\times(T_s - 25)$$

$$3000 = 3.969\times10^{-8}\left((T_s+273)^4 - (298)^4\right) + 19.186(T_s - 25)$$

Solving the above equation, we get $T_s = 138.412°\text{C}$

Therefore the surface temperature of the sheet metal is $\boxed{T_s = 138.412°\text{C}}$

Question:

The local atmospheric pressure in Denver, Colorado (elevation 1610 m), is 83.4 kPa. Air at this pressure and at 30°C flows with a velocity of 6 m/s over a 2.5-m × 8-m flat plate whose temperature is 120°C. Determine the rate of heat transfer from the plate if the air flows parallel to the (*a*) 8-m-long side and (*b*) the 2.5-m side.

Step 1 of 10

Given: -
Pressure of air = 83.4 kPa
Temperature of air = 30°C
Air flows at velocity = 6m/s
Size of flat plate = 2.5m × 8m
Temperature of flat plate = 120

Step 2 of 10

Pressure in atm units is

$$P = (83.4 \text{ kPa})\frac{1 \text{ atm}}{101.325 \text{ kPa}} = 0.823 \text{ atm}$$

Properties of air at 0.823 atm and average film temperature (120 + 30)/2 =75°C is taken from properties of air table

$k = 0.02917$ W/m.°C

$$\upsilon = \frac{\upsilon_{@1atm}}{P_{atm}}$$

$$\frac{(2.046\times10^{-5} \text{ m}^2/\text{s})}{0.823}$$

$$=2.486\times10^{-5} \text{ m}^2/\text{s}$$

$\text{Pr} = 0.7166$

Step 3 of 10

(a) Reynolds number when air flows parallel to 8 m side

$$\text{Re}_L = \frac{VL}{\upsilon}$$

$$= \frac{(6 \text{ m/s})(8 \text{ m})}{2.486\times10^{-5} \text{ m}^2/\text{s}}$$

$$=1.931\times10^6$$

Step 4 of 10

This is greater than value of critical Reynolds number. Therefore combined laminar and turbulent flow will be there. So heat transfer rate using nusselt number is calculated as follows

$$Nu = \frac{hL}{k}$$

$$= (0.037\text{Re}_L^{0.8} - 871)\text{Pr}^{1/3}$$

$$= [0.037(1.931\times10^6)^{0.8} - 871](0.7166)^{1/3}$$

$$= 2757$$

$$h = \frac{k}{L}Nu$$

$$= \frac{0.02917 \text{ W/m.°C}}{8 \text{ m}}(2757)$$

$$= 10.05 \text{ W/m}^2\text{.°C}$$

$$A_s = wL$$

$$= (2.5 \text{ m})(8 \text{ m})$$

$$=20 \text{ m}^2$$

Step 5 of 10

$$\dot{Q} = hA_s(T_\infty - T_s)$$

$$= (10.05 \text{ W/m}^2\text{.°C})(20 \text{ m}^2)(120\text{-}30)\text{°C}$$

$$= 18{,}096 \text{ W}$$

Rate of heat transfer is $\boxed{18.10 \text{ kW}}$

Step 6 of 10

(b) Reynolds number when air flows parallel to 2.5 m side

$$\text{Re}_L = \frac{V_\infty L}{\upsilon}$$

$$= \frac{(6 \text{ m/s})(2.5 \text{ m})}{2.486\times10^{-5} \text{ m}^2/\text{s}}$$

$$= 6.034\times10^5$$

Step 7 of 10

This is greater than value of critical Reynolds number. Therefore combined laminar and turbulent flow will be there. So heat transfer rate using nusselt number is calculated as follows

$$Nu = \frac{hL}{k}$$

$$= (0.037\text{Re}_L^{0.8} - 871)\text{Pr}^{1/3}$$

$$= [0.037(6.034\times10^5)^{0.8} - 871](0.7166)^{1/3}$$

$$= 615.1$$

$$h = \frac{k}{L}Nu$$

$$= \frac{0.029717 \text{ W/m.°C}}{2.5 \text{ m}}(615.1)$$

$$= 7.177 \text{ W/m}^2\text{.°C}$$

$$A_s = wL$$

$$= (8 \text{ m})(2.5 \text{ m})$$

$$=20 \text{ m}^2$$

Step 8 of 10

$$\dot{Q} = hA_s(T_\infty - T_s)$$

$$= (7.177 \text{ W/m}^2\text{.°C})(20 \text{ m}^2)(120\text{-}30)\text{°C}$$

$$= 12{,}919 \text{ W}$$

Step 9 of 10

$= (7.177\ W/m^2.°C)(20\ m^2)(12-30)°C$ 109017P pg 2

$= 12{,}919\ W$

Step 9 of 10

Rate of heat transfer is $\boxed{12.92\ kW}$

Step 10 of 10

Question: 19.018P pg 1

During a cold winter day, wind at 42 km/h is blowing parallel to a 6-m-high and 10-m-long wall of a house. If the air outside is at 5°C and the surface temperature of the wall is 12°C, determine the rate of heat loss from that wall by convection. What would your answer be if the wind velocity was doubled?

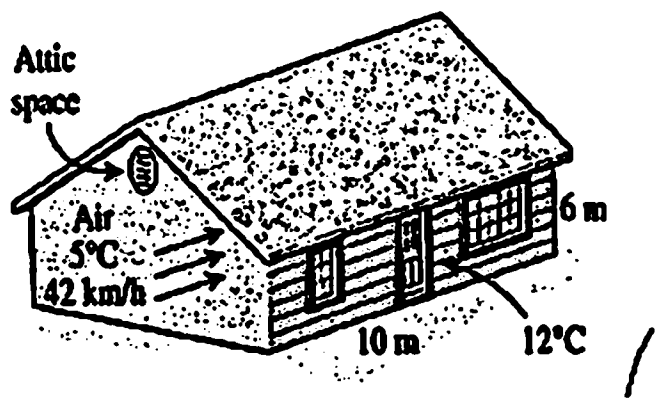

FIGURE P19-18

Step 1 of 9

Given data:

Height of wall, $H = 6\,\text{m}$

Length of wall, $L = 10\,\text{m}$

Velocity of wind flow,

$V = 42\,\text{km/h}$

$= 42 \times 1000/3600\ \text{m/s}$

$= 11.67\,\text{m/s}$

Temperature of air flow, $T_\infty = 5°\text{C}$

Surface temperature of the wall, $T_s = 12°\text{C}$

Step 2 of 9

By using the formula for film temperature, we get

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{12+5}{2}$$

$$= 8.5°\text{C}$$

From table properties of air, by using interpolation method the values between $5°\text{C} - 10°\text{C}$

Thermal conductivity,

$$k = 0.02401 + \frac{0.02439 - 0.02401}{(10-5)}(8.5-5)$$

$$k = 0.024276\,\text{W/m}\cdot\text{K}$$

Kinematic viscosity,

$$\nu = 1.382\times10^{-5} + \frac{(1.426-1.382)10^{-5}}{(10-5)(8.5-5)}$$

$$\nu = 1.4128\times10^{-5}\,\text{m}^2/\text{s}$$

Step 3 of 9

From table properties of air, by using interpolation method the values between $5°\text{C} - 10°\text{C}$

Prandtl number,

$$\text{Pr} = 0.7350 + \frac{0.7336 - 0.7350}{(10-5)}(8.5-5)$$

$$\text{Pr} = 0.73402$$

The Reynolds number of the flow,

$$\text{Re}_L = \frac{VL}{\nu}$$

$$= \frac{11.67\times10}{1.4128\times10^{-5}}$$

$$= 8.26\times10^6$$

Since Reynolds number is in between $5\times10^5 < \text{Re}_L < 10^7$ therefore the flow is combined laminar and turbulent flow

Step 4 of 9

Nusselt number for this combined flow can be expressed as,

[Combined flow, $0.6 \le \text{Pr} \le 60,\ 5\times10^5 \le \text{Re}_L \le 10^7$]

$$\text{Nu} = \frac{hL}{k}$$

$$= \left(0.037\text{Re}_L^{0.8} - 871\right)\text{Pr}^{1/3}$$

$$= \left[0.037\left(8.26\times10^6\right)^{0.8} - 871\right](0.73402)^{1/3}$$

$$= 10617.37$$

Step 5 of 9

Then heat transfer coefficient,

$$\frac{hL}{k} = 10617.37$$

$$h = \frac{10617.37\times k}{L}$$

$$= \frac{10617.37\times0.024276}{10}$$

$$= 25.77\ \text{W/m}^2\cdot\text{K}$$

Step 6 of 9

Heat transfer surface area,

$$A_s = h\times L$$

$$= 10\times6$$

$$= 60\,\text{m}^2$$

Rate of heat loss by convection is,

$$Q = hA_s(T_s - T_\infty)$$

$$= 25.77\times60\times(12-5)$$

$$= 10823.4\,\text{W}$$

$$= 10.8\,\text{kW}$$

$$Q = hA_s(T_s - T_\infty)$$
$$= 25.77 \times 60 \times (12-5)$$
$$= 10823.4\,\text{W}$$
$$= 10.8\,\text{kW}$$

Therefore, rate of heat loss by convection is, $\boxed{Q = 10.8\,\text{kW}}$

Step 7 of 9

If the wind velocity is doubled

$$V = 2V$$
$$= 84\,\text{km/h}$$
$$= 84 \times \frac{1000}{3600}$$
$$= 23.33\,\text{m/s}$$

Reynolds number,

$$\text{Re}_L = \frac{VL}{\nu}$$
$$= \frac{23.33 \times 10}{1.4128 \times 10^{-5}}$$
$$= 1.65 \times 10^7$$

Step 8 of 9

Assuming Nusselt number is,

$$Nu = \frac{hL}{k}$$
$$= \left(0.037\,\text{Re}_L^{0.8} - 871\right)\text{Pr}^{1/3}$$
$$= \left[0.037\left(1.65 \times 10^7\right)^{0.8} - 871\right](0.73402)^{1/3}$$
$$= 19048.96$$

Heat transfer coefficient,

$$h_{2V} = \frac{\text{Nu} \cdot k}{L}$$
$$= \frac{19048.96 \times 0.024276}{10}$$
$$= 46.243\,\text{W/m}^2 \cdot \text{K}$$

Step 9 of 9

Then the rate of heat loss from the wall by convection is,

$$Q_{2V} = h_{2V} A_s (T_s - T_\infty)$$
$$= 46.243 \times 60 \times (12-5)$$
$$= 19422.06\,\text{W}$$
$$= 19 \cdot 422\,\text{kW}$$

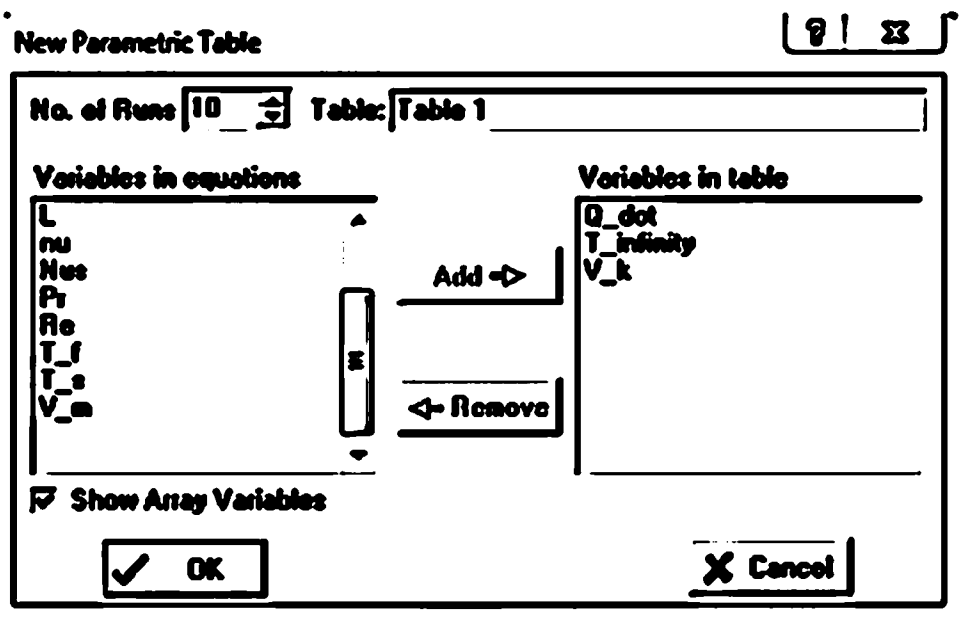
Therefore, rate of heat loss by convection when velocity doubled is, $\boxed{Q_{2V} = 19 \cdot 422\,\text{kW}}$

Question: 19.019P pg 1

Reconsider Prob. 19-18. Using EES (or other) software, investigate the effects of wind velocity and outside air temperature on the rate of heat loss from the wall by convection. Let the wind velocity vary from 10 km/h to 80 km/h and the outside air temperature from 0°C to 10°C. Plot the rate of heat loss as a function of the wind velocity and of the outside temperature, and discuss the results.

Step 1 of 8

The given problem can be solved using EES software by following the below steps.

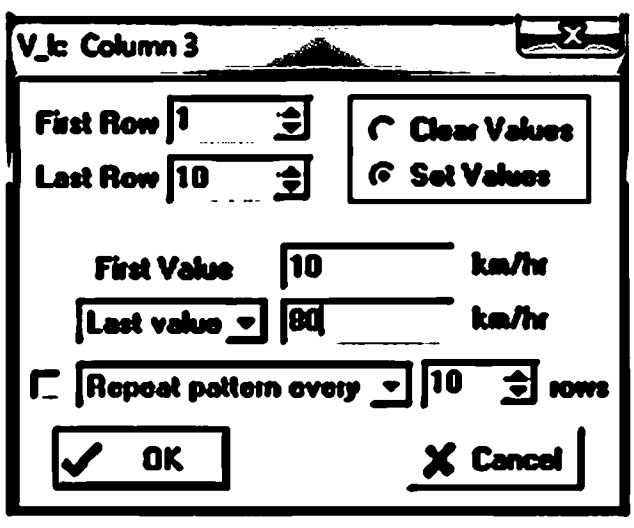


1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
H_1=6[m]                                        "Height of the wall"
L=10[m]                                         "Length of the wall"
"V_k is varied from 10[km/hr] to 80[km/hr]"     "Velocity of air"
V_m=V_k*convert(km/hr,m/s)
"T_infinity is varied from 0[C] to 10[C]"       "Temperature of air"
T_s=12[C]                                       "Temperature of wall"

T_f=(T_s+T_infinity)/2
k=Conductivity(Air,T=T_f)                       "Properties of air at T_f temperature"
nu=Viscosity(Air,T=T_f)/Density(Air,T=T_f,P=1[atm]*convert(atm,kPa))
Pr=Prandtl(Air,T=T_f)
Re=V_m*L/nu                                     "Reynolds number"
Nus=(0.037*Re^0.8-871)*Pr^(1/3)
Nus=h*L/k
A_s=H_1*L
Q_dot=h*A_s*(T_s-T_infinity)*convert(W,kW)
```

Step 2 of 8



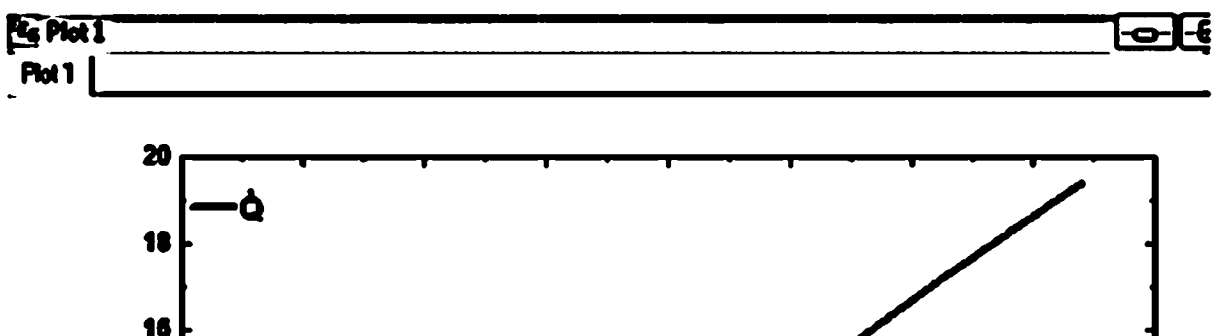
Now to solve the equation for a range of wind velocities and outside air temperatures, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 10.
Select variables in equations as "Q_dot", "T_infinity", and "V_k" and press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 8

First the wind velocity is varied at constant outside air temperature of $T_\infty = 5°C$

To enter the values in the "V_k" column, click on the drop tab in "V_k" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 8



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

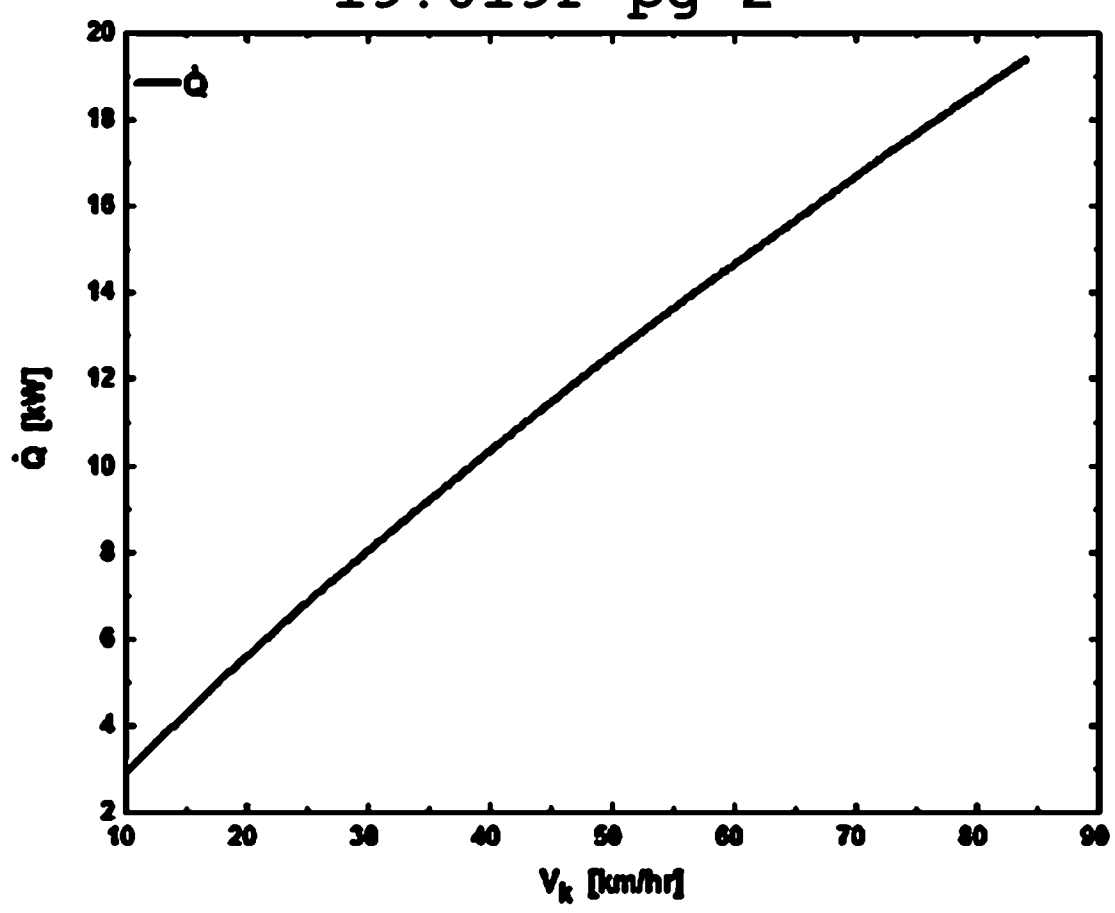


Table 1

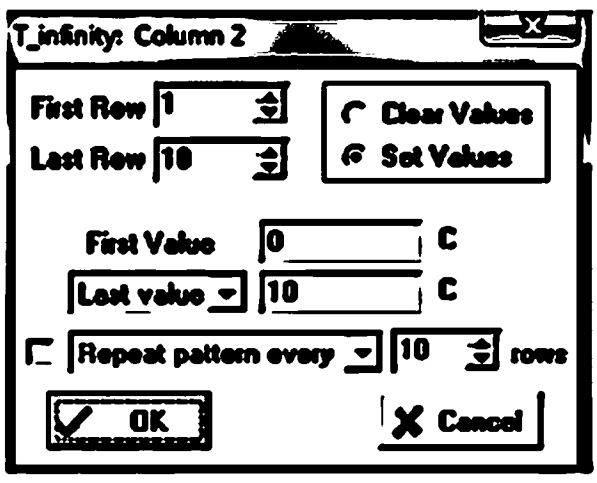
$\blacktriangleright_{1..10}$	1 $\dot{Q}$ [kW]	2 T_∞ [C]	3 V_k [km/hr]
Run 1	2.885	5	10
Run 2	5.039	5	17.78
Run 3	7.006	5	25.56
Run 4	8.855	5	33.33
Run 5	10.62	5	41.11
Run 6	12.32	5	48.89
Run 7	13.96	5	56.67
Run 8	15.56	5	64.44
Run 9	17.12	5	72.22
Run 10	19.42	5	84

Step 5 of 8

Inorder to plot the rate of heat loss as a function of wind velocity, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the rate of heat loss as a function of wind velocity:



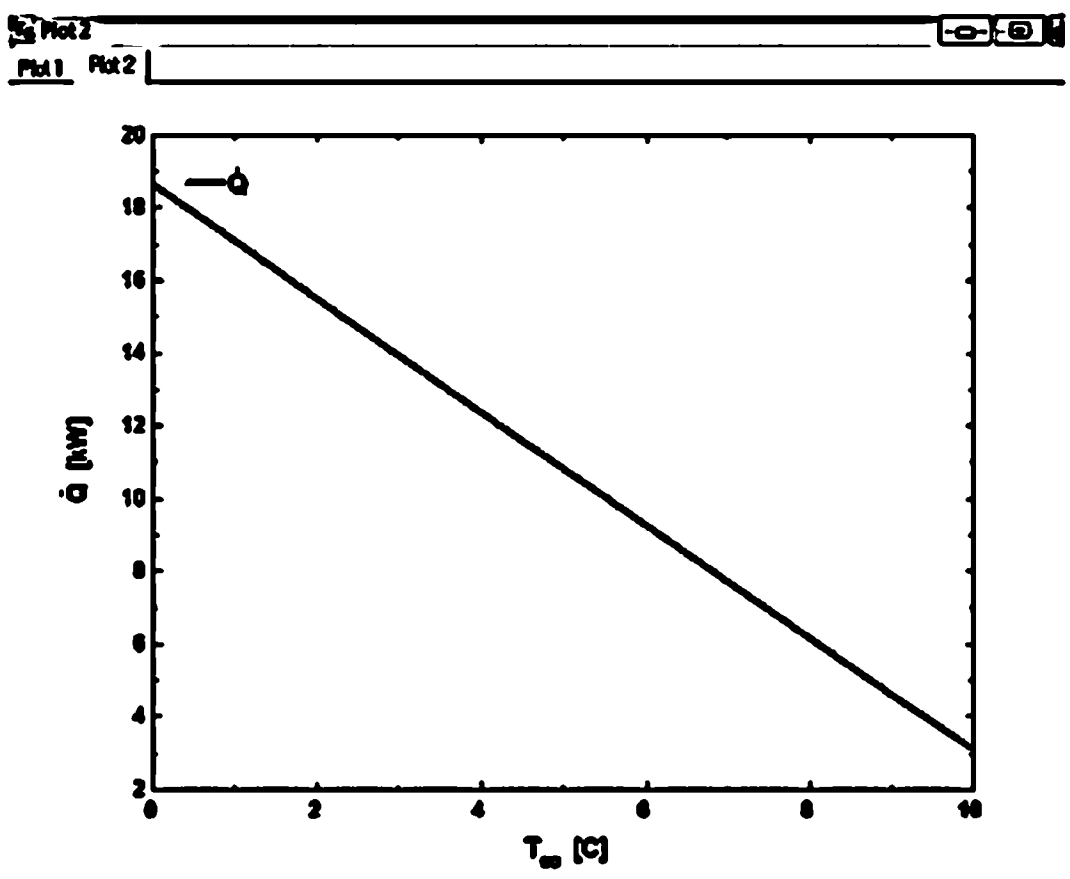
From the above plot we can interpret that as the wind velocity increases, the rate of heat loss also increases.

Step 6 of 8

Now the outside temperature of the air is varied at constant wind velocity of V_k = 42 km/hr

To enter the values in the "T_infinity" column, click on the drop tab in "T_infinity" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 7 of 8



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1_10	1 Q̇ [kW]	2 T∞ [C]	3 V_k [km/hr]
Run 1	18.65	0	42
Run 2	16.9	1.111	42
Run 3	15.16	2.222	42
Run 4	13.42	3.333	42
Run 5	11.68	4.444	42
Run 6	9.95	5.556	42
Run 7	8.224	6.667	42
Run 8	6.502	7.778	42
Run 9	4.785	8.889	42
Run 10	3.072	10	42

Step 8 of 8

Inorder to plot the rate of heat loss as a function of outside air temperature, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the rate of heat loss as a function of outside air temperature:

From the above plot we can interpret that as the temperature of the outside air increases, the rate of heat loss decreases.

Question: 19.020P

Water at 43.3°C flows over a large plate at a velocity of 30.0 cm/s. The plate is 1.0 m long (in the flow direction), and its surface is maintained at a uniform temperature of 10.0°C. Calculate the steady rate of heat transfer per unit width of the plate.

Step 1 of 5

Given: - Temperature of water $T_\infty = 43.3°C$

Velocity of air $V = 30.0$ cm/s

Length of plate $L = 1.0$ m

Temperature of surface $T_w = 10°C$

Step 2 of 5

Properties of water at 1 atm and average film temperature $\frac{(10+43.3)}{2} = 26.65^0C$ is taken from properties of saturated water table

Density, $\rho = 996.6 kg/m^3$

Thermal conductivity $k = 0.610$ W/m°C

Dynamic viscosity, $\mu = 0.854 \times 10^{-3}$ kg/ms

Prandtl number $Pr = 5.85$

Step 3 of 5

Reynolds number when air flows parallel to 1 m side

$$Re_L = \frac{VL\rho}{\mu}$$

$$= \frac{[0.3 m/s](1 m)(996.6 kg/m^3)}{0.854 \times 10^{-3} kg/m \cdot s}$$

$$Re_L = 3.501 \times 10^5$$

Since $Re_L < 5 \times 10^5$, the flow is laminar.

Step 4 of 5

For flow over a flat plate,
Nusselt number will be calculated as

$$Nu = \frac{hL}{k}$$

$$= 0.664 Re_L^{1/2} Pr^{1/3} = 0.664(3.501 \times 10^5)^{1/2}(5.85)^{1/3}$$

$$Nu = 707.9$$

$$h = \frac{k}{L} Nu$$

$$= \frac{0.610 \text{ W/m °C}}{1 m}(707.9)$$

$$h = 431.8 \text{ W/m}^2 \text{ °C}$$

Step 5 of 5

Steady rate of heat transfer per unit width will be

$$\dot{Q} = hA_s(T_\infty - T_s)$$

$$= (431.8 \text{ W/m}^2 \text{ °C})(1 m^2)(43.3\text{-}10)°C$$

$$\boxed{\dot{Q} = 14379.93 \text{ W}}$$

Question: 19.021P

Warm air is blown over the inner surface of an automobile windshield to defrost ice accumulated on the outer surface of the windshield. Consider an automobile windshield (kW= 0.8 Btu/h·ft·R) with an overall height of 20 in. and thickness of 0.2 in. The outside air (1 atm) ambient temperature is 8°F and the average airflow velocity over the outer windshield surface is 50 mph, while the ambient temperature inside the automobile is 77°F. Determine the value of the convection heat transfer coefficient, for the warm air blowing over the inner surface of the windshield, necessary to cause the accumulated ice to begin melting. Assume the windshield surface can be treated as a flat plate surface.

We don't have the solution to this problem yet.

Question: 19.022P

Hot carbon dioxide exhaust gas at 1 atm is being cooled by flat plates. The gas at 220°C flows in parallel over the upper and lower surfaces of a 1.5 m-long flat plate at a velocity of 3 m/s. If the flat plate surface temperature is maintained at 80°C, determine (*a*) the local convection heat transfer coefficient at 1 m from the leading edge, (*b*) the average convection heat transfer coefficient over the entire plate, and (*c*) the total heat flux transfer to the plate.

Step 1 of 7

Given data:

Length of flat plate, $L = 1.5\text{m}$

Velocity of flow, $V = 3\text{m/s}$

Temperatures of hot carbon dioxide exhaust gas, $T_\infty = 220°\text{C}$

Temperature of flat surface, $T_s = 80°\text{C}$

Step 2 of 7

By using the formula for film temperature, we get

$$T_f = \left(\frac{T_s + T_\infty}{2}\right)$$

$$= \frac{(220+80)}{2}$$

$$= 150°\text{C}$$

From the table properties of carbon dioxide, at film temperature $T_f = 150°\text{C}$

Thermal conductivity, $k = 0.02652\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.627\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7445$

Step 3 of 7

(a)

First of all we will calculate the Reynolds number at $x = 1\text{m}$

$$\text{Re}_x = \frac{Vx}{\nu}$$

$$= \frac{3\times1}{\left(1.627\times10^{-5}\right)}$$

$$\text{Re}_x = 184388.45$$

Since $\text{Re}_x < 5\times10^5$ therefore the flow is laminar

Nusselt number for laminar flow can be expressed as,

$$\text{Nu}_x = 0.332\text{Re}_x^{0.5}\text{Pr}^{1/3}$$

$$= 0.332(184388.45)^{0.5}(0.7445)^{1/3}$$

$$= 129.209$$

Step 4 of 7

Now, local heat transfer coefficient,

$$\text{Nu}_x = \frac{h_x \cdot x}{k}$$

$$h_x = \frac{\text{Nu}_x \cdot k}{x}$$

$$= \frac{129.209\times0.02652}{1}$$

$$= 3.427\ \text{W/m}^2\cdot\text{K}$$

Therefore, the local convection coefficient is $\boxed{h_x = 3.427\ \text{W/m}^2\cdot\text{K}}$

Step 5 of 7

(b)

Reynolds number for entire length of the plate is

$$\text{Re}_L = \frac{VL}{\nu}$$

$$= \frac{3\times1.5}{1.627\times10^{-5}}$$

$$= 2.76582\times10^5$$

Since $\text{Re}_L < 5\times10^5$ therefore the flow is laminar

So, the average Nusselt number relation for heat transfer coefficient.

$$\text{Nu}_L = 0.664\text{Re}_L^{0.5}\text{Pr}^{1/3}$$

$$= 0.664\left(2.76582\times10^5\right)^{0.5}(0.7445)^{1/3}$$

$$= 316.496$$

Step 6 of 7

Therefore average heat transfer coefficient,

$$\text{Nu}_L = \frac{hL}{k}$$

$$h = \frac{\text{Nu}_L \cdot k}{L}$$

$$= \frac{316.496\times0.02652}{1.5}$$

$$= 5.595\ \text{W/m}^2\cdot\text{K}$$

Therefore, average heat transfer coefficient is $\boxed{h = 5.595\ \text{W/m}^2\cdot\text{K}}$

Step 7 of 7

(c)

Now, the total heat flux to the flat plate surface for both upper and lower portion can be expressed as,

$$\dot{q}_s = 2\times h\left(T_\infty - T_s\right)$$

$$= 2\times5.595(220-80)$$

$$= 1566.6\ \text{W/m}^2$$

The total heat flux to the flat plate surface for both upper and lower portion is,

$\boxed{\dot{q}_s = 1566.6\ \text{W/m}^2}$

Question: 19.023P

Hot engine oil tit 150°C is flowing in parallel over a flat plate at a velocity of 2 m/s. Surface temperature of the 0.5-m long flat plate is constant at 50°C. Determine (*a*) the local convection heat transfer coefficient at 0.2 m from the leading edge and the average convection heat transfer coefficient, and (*b*) repeat part (*a*) using the Churchill and Ozoe (1973) relation.

Step 1 of 8

Given data:

Temperature of hot engine oil, $T_s = 150°C$

Velocity of oil flow, $V = 2 m/s$

Length of flat plate, $L = 0.5m$

Temperature of flat plate, $T_\infty = 50°C$

Step 2 of 8

By using the formula for film temperature, we get

$$T_f = (T_s + T_\infty)/2$$
$$= (50+150)/2$$
$$= 100°C$$

From table properties of engine oil at film temperature, $T_f = 100°C$

Kinematic viscosity $\nu = 2.046\times10^{-5} m^2/s$

Thermal conductivity $k = 0.1367 W/m\cdot K$

Prandtl number $Pr = 279.1$

Step 3 of 8

(a)

Now, we will calculate Reynolds number, Re at $x = 0.2m$

$$Re_x = \frac{Vx}{\nu}$$
$$= \frac{2\times0.2}{2.046\times10^{-5}}$$
$$Re_x = 19550.34$$

Since $Re_x < 5\times10^5$ therefore the flow is laminar

Nusselt number relation for local convection heat transfer coefficient is:

$$Nu_x = 0.332 Re_x^{0.5} Pr^{1/3}$$
$$= 0.332(19550.34)^{0.5}(279.1)^{1/3}$$
$$Nu_x = 303.4$$

Step 4 of 8

Local heat transfer coefficient is,

$$Nu_x = \frac{h_x \cdot x}{k}$$
$$h_x = \frac{Nu_x \cdot k}{x}$$
$$= \frac{303.4\times0.1307}{0.2}$$
$$= 207.35 W/m^2\cdot K$$

Therefore local heat transfer coefficient, $\boxed{h_x = 207.35 W/m^2\cdot K}$

Step 5 of 8

Now for Average heat transfer coefficient:

$$Re_L = \frac{VL}{\nu}$$
$$= \frac{2\times0.5}{2.046\times10^{-5}}$$
$$Re_L = 48875.9$$

Since $Re_L < 5\times10^5$ therefore the flow is laminar

Nusselt number relation for average convection heat transfer coefficient is:

$$Nu_L = \frac{hL}{k}$$
$$= 0.664 Re_L^{0.5} Pr^{1/3}$$
$$= 0.664\times(48875.9)^{0.5}(279.1)^{1/3}$$
$$Nu_L = 959.33$$

Step 6 of 8

Average convection heat transfer coefficient is,

$$h = \frac{Nu_L \cdot k}{L}$$
$$= \frac{959.33\times0.1367}{0.5}$$
$$= 262.28 W/m^2\cdot K$$

Therefore Average convection heat transfer coefficient, $\boxed{h = 262.28 W/m^2\cdot K}$

Step 7 of 8

(b)

Now by using Churchill and Ozoe relation

Taking Nusselt number relation for local convection heat transfer coefficient:

At $x = 0.2m$ from loading edge

$$Nu_x = \frac{0.3387 Pr^{1/3} Re_x^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}$$

$$\frac{h_x \cdot x}{k} = \frac{0.3387 Pr^{1/3} Re_x^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}$$

$$h_x = \frac{0.3387 Pr^{1/3} Re_x^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}} \times \frac{k}{x}$$

$$= \frac{0.3387(279.1)^{1/3}(19550.34)^{0.5}}{\left[1+(0.0468/279.1)^{2/3}\right]^{0.25}} \times \frac{0.1367}{0.2}$$

$$= \frac{309.489}{1.00075} \times \frac{0.1367}{0.2}$$

$$= 211.377 W/m^2\cdot K$$

Therefore local heat transfer coefficient is $\boxed{h_x = 211.377 W/m^2\cdot K}$

Step 8 of 8

The average convection heat transfer coefficient for the entire plate will be

$$h = \frac{1}{L}\int_0^L h_x dm$$

$$= \frac{1}{L}\int_0^L \frac{0.3387 Pr^{1/3} Re_x^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}} \cdot \frac{k}{x}$$

$$= \frac{0.3387 Pr^{1/3}\left(\frac{V}{\nu}\right)^{1/2}\cdot k}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}\cdot L}\int_0^L \frac{x^{1/2}}{x} \qquad \left[\text{since } Re_x = \frac{Vx}{\nu}\right]$$

$$= \frac{0.3387 Pr^{1/3}\left(\frac{V}{\nu}\right)^{1/2}\cdot k}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}\cdot L}\left[\frac{x^{-1/2+1}}{-1/2+1}\right]_0^L$$

$$= \frac{0.3387 Pr^{1/3}\left(\frac{V}{\nu}\right)^{1/2}\cdot k}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}\cdot L} 2L^{1/2}$$

$$= \frac{0.3387(279.1)^{1/3}\times\left(\frac{2}{2.046\times10^{-5}}\right)^{1/2}\times0.1367\times2\times(0.5)^{1/2}}{\left[1+(0.0468/279.1)^{2/3}\right]^{1/4}\times0.5}$$

$$= \frac{2.2134\times312.652\times0.1933}{0.5}$$

$$= 267.536 W/m^2\cdot K$$

Therefore, by using the Churchill and Ozoe relation the average convection heat transfer coefficient is $\boxed{h = 267.536 W/m^2\cdot K}$

Question: 19.024P

Mercury at 25°C flows over a 3-m-long and 2-m-wide flat plate maintained at 75°C with a velocity of 0.8 m/s. Determine the rate of heat transfer from the entire plate.

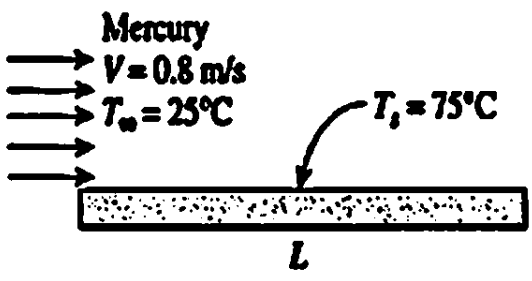

FIGURE P19-24

Step 1 of 6

Find the average film temperature by using the expression.

$$T_f = \frac{T_s + T_\infty}{2}$$

Here, T_s is temperature of the plate and T_∞ is the mercury temperature.

Substitute $75°C$ for T_s and $25°C$ for T_∞

$$T_f = \frac{75+25}{2}$$
$$= 50°C$$

Obtain the properties of mercury at $T_f = 50°C$ from properties of liquid metals.

Thermal conductivity, $k = 8.83632\ W/m°C$.

Prandtl number $Pr = 0.0223$

Kinematic viscosity, $\nu = 1.056\times10^{-7}\ m^2/s$

Step 2 of 6

Write the expression for the local Nusselt number for liquid metals.

$$Nu_x = \frac{h_x L}{k} = 0.565(Re_x\ Pr)^{1/2}$$

$$h_x = \frac{k}{L}0.565(Re_x\ Pr)^{1/2}$$

Here, h_x is the local heat transfer coefficient, L is the length of the plate.

Calculate the average heat transfer coefficient for the entire surface of the plate by using the equation.

$$h = \frac{1}{L}\int_0^L h_x dx$$

$$h = \frac{1}{L}\frac{k}{L}0.565(Pr)^{1/2}\left(\frac{V}{\nu}\right)^{1/2} 2L^{3/2}$$

$$\frac{hL}{k} = 1.13(Pr)^{1/2}\left(\frac{VL}{\nu}\right)^{1/2}$$

$$Nu = 1.13(Re_L\ Pr)^{1/2}$$

Step 3 of 6

Find the Reynolds number by using the equation.

$$Re_L = \frac{VL}{\nu}$$

Here, L is length of the plate, V is velocity of mercury.

Substitute 3 m for L and 0.8 m/s for V.

$$Re_L = \frac{0.8\times3}{1.056\times10^{-7}}$$
$$= 2.272\times10^7$$

The flow is turbulent, since Reynold's number $Re_L > 10^7$.

Step 4 of 6

Find the Nusselt number by using the above expression.

$$Nu = 1.13(Re_L\ Pr)^{1/2}$$
$$= 1.13[(2.272\times10^7)(0.0223)]^{1/2}$$
$$= 804.33$$

Step 5 of 6

Find the heat transfer coefficient by using the equation.

$$Nu = \frac{hL}{k}$$

$$804.33 = \frac{h\times3}{8.83632}$$

$$h = 2369.11\ W/m^2\cdot K$$

Find the surface area of the plate by using the equation.

$$A_s = wL$$

Here, w is width of the plate.

Substitute 2 m for w .

$$A_s = 2\times3$$
$$= 6\ m^2$$

Step 6 of 6

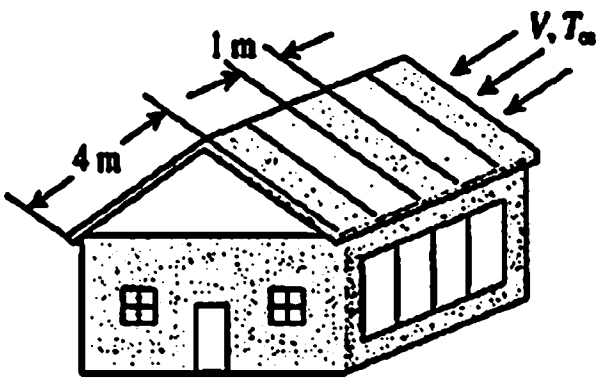
Determine the rate of heat transfer by using the equation.

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$= 2369.11\times6\times(75-25)$$
$$= 710733\ W$$
$$= 710.7\ kW$$

Therefore, rate of heat transfer from the entire plate is $\boxed{710.7\ kW}$.

Question:

Parallel plates form a solar collector that covers a roof, as shown in the figure. The plates are maintained at 15°C, while ambient air at 10°C flows over the roof with V= 4 m/s. Determine the rate of convective heat loss from (*a*) the first plate and (*b*) the third plate.



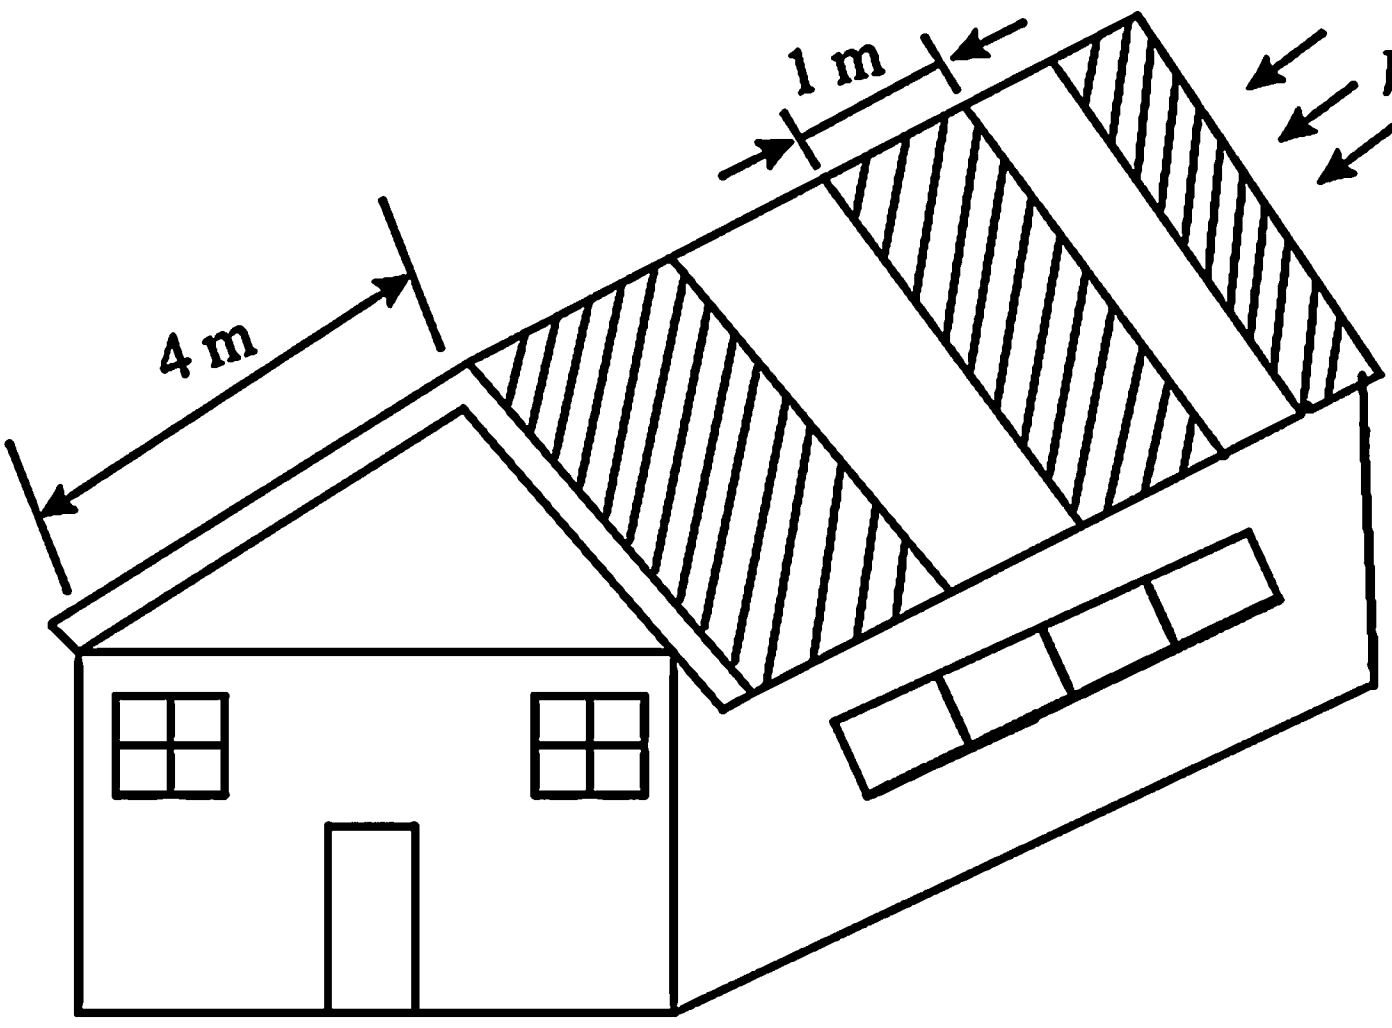


FIGURE P19-25

Step 1 of 9

Parallel plates form a solar collector that covers a roof is as follows.

Step 2 of 9

Consider Steady state operations exist and Radiation is ignored.

Consider the Temperature of the plates, $T_s = 15°C$.

Consider the Ambient air temperature, $T_\infty = 10°C$

Take the properties of air at film temperature, $\left(T_f\right)$.

The film temperature is given by equation as follows,

$$T_f = \frac{(T_s + T_\infty)}{2}$$

Substitute the corresponding values in the above equation.

$$T_f = \frac{(T_s + T_\infty)}{2}$$
$$= \frac{(15+10)}{2}$$
$$= 12.5°C$$

Find the properties of air at 1 atm pressure and film temperature.

The Kinematic viscosity at film temperature is mean value of the kinematic viscosities of temperature between $10°C$ and $15°C$. The kinematic viscosity is as follows.

$$\nu = \frac{(1.470+1.426)\times 10^{-5}}{2}$$
$$= 1.448\times 10^{-5}\ m^2/s$$

Step 3 of 9

The Thermal conductivity at film temperature is mean value of the Thermal conductivities of temperature between $10°C$ and $15°C$. The Thermal conductivity is as follows.

$$k = \frac{0.02439 + 0.02476}{2}$$
$$= 0.024575\ W/m\cdot K$$

The Prandtl number at film temperature is mean value of the Prandtl numbers of temperature between $10°C$ and $15°C$. The Prandtl number is as follows.

$$Pr = \frac{0.7323+0.7336}{2}$$
$$= 0.73295$$

Step 4 of 9

Calculate the critical length first for the $\mathrm{Re}_{critical} = 5\times 10^5$.

The Reynolds number is given by the equation as follows.

$$\mathrm{Re} = \frac{Vx}{\nu}$$

Here, V is the velocity of the flow, x is the distance from the leading edge to point of interest, and ν is the kinematic viscosity of the flow.

The critical Reynolds number is given by the equation as follows.

$$\mathrm{Re}_{critical} = \frac{Vx_{cr}}{\nu}$$
$$x_{cr} = \frac{\mathrm{Re}_{critical}\times \nu}{V}$$
$$= \frac{5\times 10^5 \times 1.448\times 10^{-5}}{4}$$

$$x_{cr} = \frac{\mathrm{Re}_{critical} \times \nu}{V}$$

$$= \frac{5\times10^{5} \times 1.448\times10^{-5}}{4}$$

$$x_{cr} = 1.81$$

(a)

Calculating the Reynolds number for the first plate.

$$\mathrm{Re}_1 = \frac{VL_1}{\nu}$$

Substitute $1\ \mathrm{m}$ for L_1 and other corresponding values in the above equation.

$$\mathrm{Re}_1 = \frac{VL_1}{\nu}$$

$$= \frac{4\times1}{1.448\times10^{-5}}$$

$$= 2.76\times10^{5}$$

Nusselt number is given by the expression as follows.

$$\mathrm{Nu} = 0.664\,\mathrm{Re}^{0.5}\,\mathrm{Pr}^{1/3}$$

Here, Nu is the Nusselt number.

Calculating the Nusselt number for the first plate.

$$\mathrm{Nu}_1 = 0.664\,\mathrm{Re}_1^{0.5}\,\mathrm{Pr}^{1/3}$$

$$= 0.664\left(2.76\times10^{5}\right)^{0.5}(0.73295)^{1/3}$$

$$= 314.519$$

Step 5 of 9

The Nusselt number is also given by the expression as follows.

$$\mathrm{Nu} = \frac{hL}{k}$$

Here, h is the coefficient of heat transfer and L is the length of the plate.

The Nusselt number for the first plate is,

$$\mathrm{Nu}_1 = \frac{h_1 L}{k}$$

Substitute the corresponding values in the above equation.

$$\mathrm{Nu}_1 = \frac{h_1 L}{k}$$

$$314.519 = \frac{h_1 \times 1}{0.024575}$$

$$h_1 = 7.73\ \mathrm{W/m^2{\cdot}^{\circ}C}$$

Surface Area of the plate is, $A = lb$

Here, l is the length of the plate and b is the width of the plate.

Substitute $1\mathrm{m}^2$ for l and $4\ \mathrm{m}^2$ for b in the above equation of area.

$$A_{s_1} = lb$$

$$= 1\times4$$

$$= 4\mathrm{m}^2$$

The convection heat transfer is as follows.

$$Q = h_1 A_{s_1}\left(T_s - T_\infty\right)$$

Substitute the corresponding values of plate 1 in the above equation.

$$Q = h_1 A_{s_1}\left(T_s - T_\infty\right)$$

$$= 7.73\times4(15-10)$$

$$= 154.6\ \mathrm{W}$$

Therefore the convection heat transfer from the first plate is $\boxed{154.65\ \mathrm{W}}$

Step 6 of 9

(b)

Calculating the Reynolds number for the second plate.

$$\mathrm{Re}_2 = \frac{VL_2}{\nu}$$

Substitute $2\ \mathrm{m}$ for L_2 and other corresponding values in the above equation.

$$\mathrm{Re}_2 = \frac{VL_2}{\nu}$$

$$= \frac{4\times2}{1.448\times10^{-5}}$$

$$= 5.52\times10^{5}$$

Because the Reynolds number is greater than 5×10^{5} the Nusselt number is,

$$\mathrm{Nu} = \left(0.037\,\mathrm{Re}^{0.8} - 871\right)\mathrm{Pr}^{1/3}$$

Substitute the corresponding values of plate 2 in the above equation.

$$\mathrm{Nu}_2 = \left(0.037\,\mathrm{Re}^{0.8} - 871\right)\mathrm{Pr}^{1/3}$$

$$= \left(0.037\left(5.52\times10^{5}\right)^{0.8} - 871\right)(0.73295)^{1/3}$$

$$= 523.2$$

Step 7 of 9

The Nusselt number for the second plate is,

$=323.2$

Step 7 of 9

The Nusselt number for the second plate is,

$$\mathrm{Nu}_2 = \frac{h_2 \cdot L_2}{k}$$

Substitute the corresponding values in the above equation.

$$h_2 = \frac{\mathrm{Nu}_2 \cdot k}{L_2}$$
$$= \frac{444.79 \times 0.024575}{2}$$
$$= 5.465\ \mathrm{W/m^2{}^\circ C}$$

Calculating the Reynolds number for third plate.

$$\mathrm{Re}_3 = \frac{VL_3}{\nu}$$

Substitute $3\ \mathrm{m}$ for L_3 and other corresponding values in the above equation.

$$\mathrm{Re}_3 = \frac{VL_3}{\nu}$$
$$= \frac{4 \times 3}{\left(1.448 \times 10^{-5}\right)}$$
$$= 8.287 \times 10^5$$

Because the Reynolds number is greater than 5×10^5 the Nusselt number is,

$$\mathrm{Nu} = \left(0.037\,\mathrm{Re}^{0.8} - 871\right)\mathrm{Pr}^{1/3}$$

Substitute the corresponding values of plate 3 in the above equation.

$$\mathrm{Nu}_2 = \left(0.037\,\mathrm{Re}^{0.8} - 871\right)\mathrm{Pr}^{1/3}$$
$$= \left(0.037\left(8.287 \times 10^5\right)^{0.8} - 871\right)(0.73295)^{1/3}$$
$$= 1025.8$$

Step 8 of 9

The Nusselt number for the third plate is,

$$\mathrm{Nu}_3 = \frac{h_3 \cdot L_3}{k}$$

Substitute the corresponding values in the above equation.

$$\mathrm{Nu}_3 = \frac{h_3 \cdot L_3}{k}$$
$$1025.8 = \frac{h_3 \times 3}{0.024575}$$
$$h_3 = 8.4\ \mathrm{W/m^2{}^\circ C}$$

Surface Area of the plate is, $A = lb$

Here, l is the length of the plate and b is the width of the plate.

Substitute $1\mathrm{m}^2$ for l and $4\ \mathrm{m}^2$ for b in the above equation of area.

$$A_{s_3} = lb$$
$$= 1 \times 4$$
$$= 4\mathrm{m}^2$$

Step 9 of 9

The convection heat transfer for plate 3 is as follows.

$$Q = h_3 A_{s_3}\left(T_s - T_\infty\right)$$

Substitute the corresponding values of plate 3 in the above equation.

$$Q = h_3 A_{s_3}\left(T_s - T_\infty\right)$$
$$= 8.4 \times 4 \times (15 - 10)$$
$$= 168\ \mathrm{W}$$

Therefore heat loss from the third plate is, $\boxed{168\ \mathrm{W}}$.

Question: 19.026P

Consider a hot automotive engine, which can be approximated as a 0.5-m-high, 0.40-m-wide, and 0.8-m-long rectangular block. The bottom surface of the block is at a temperature of 100°C and has an emissivity of 0.95. The ambient air is at 20°C, and the road surface is at 25°C. Determine the rate of heat transfer from the bottom surface of the engine block by convection and radiation as the car travels at a velocity of 80 km/h. Assume the flow to be turbulent over the entire surface because of the constant agitation of the engine block.

Step 1 of 8

Given: - Size of engine = 0.8m × 0.40m × 0.5m

Temperature of bottom surface of block T_s = 100°C

Emissivity of surface $\varepsilon = 0.95$

Road surface temperature $T_{sur} = 25°C$

Ambient air temperature $T_\infty = 20°C$

Step 2 of 8

Properties of air at 1 atm and average film temperature $\frac{(100+20)}{2} = 60°C$ is taken from properties of air table

Thermal conductivity, $k = 0.02808$ W/m°C

Kinematic viscosity, $\upsilon = 1.896\times10^{-5}$ m^2/s

Prandtl number, Pr = 0.7202

Step 3 of 8

Reynolds number is calculated as follows

$$\mathrm{Re}_L = \frac{VL}{\upsilon}$$

$$= \frac{\left[(80\times\frac{1000}{3600})\ \text{m/s}\right](0.8\ \text{m})}{1.896\times10^{-5}\ \text{m}^2/\text{s}}$$

$$\mathrm{Re}_L = 9.376\times10^5$$

Since $5\times10^5 < \mathrm{Re}_L < 10^7$, the flow is laminar turbulent.

But turbulent flow will be assumed here due to agitation of engine block.

Step 4 of 8

So Nusselt number is calculated as follows

$$Nu = \frac{hL}{k}$$

$$= 0.037\,\mathrm{Re}_L^{0.8}\,\mathrm{Pr}^{1/3}$$

$$= 0.037(9.376\times10^5)^{0.8}(0.7202)^{1/3}$$

$$Nu = 1988$$

Step 5 of 8

Coefficient of heat transfer :

$$h = \frac{k}{L}Nu$$

$$= \frac{0.02808\ \text{W/m°C}}{0.8\ \text{m}}(1988)$$

$$h = 69.78\ \text{W/m}^2\text{°C}$$

Step 6 of 8

Heat transfer surface area,

$$A_s = wL$$

$$= (0.8\ \text{m})(0.4\ \text{m})$$

$$A_s = 0.32\ \text{m}^2$$

Rate of heat transfer:

$$\dot{Q}_{conv} = hA_s(T_s - T_\infty)$$

$$= (69.78\ \text{W/m}^2\text{°C})(0.32\ \text{m}^2)(100\text{-}20)\text{°C}$$

$$\dot{Q}_{conv} = 1786.37\ \text{W}$$

Step 7 of 8

The radiation heat transfer from the same surface is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s^4 - T_{sur}^4)$$

$$= (0.95)(0.32\ \text{m}^2)(5.67\times10^{-8}\ \text{W/m}^2\text{K}^4)\left[(100+273\ \text{K})^4 - (25+273\ \text{K})^4\right]$$

$$\dot{Q}_{rad} = 197.7\ \text{W}$$

Step 8 of 8

Then the total rate of heat transfer from that surface becomes

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$

$$= (1786.37+197.7)\ \text{W}$$

$$\boxed{\dot{Q}_{total} = 1984\ \text{W}}$$

Question: 19.027P

The top surface of the passenger car of a train moving at a velocity of 95 km/h is 2.8 m wide and 8 m long. The top surface is absorbing solar radiation at a rate of 380 W/m2, and the temperature of the ambient air is 30°C. Assuming the roof of the car to be perfectly insulated and the radiation heat exchange with the surroundings to be small relative to convection, determine the equilibrium temperature of the top surface of the car.

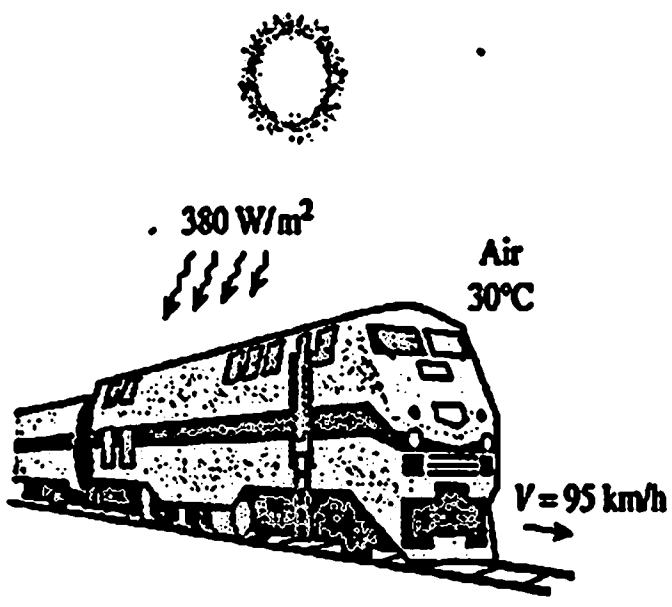

FIGURE P19-27

Step 1 of 4

Given data:

Velocity of the passenger car,

$V = 95\,\text{km/h}$

$$= \frac{95\times1000}{3600}$$

$$= 26.39\ \text{m/s}$$

Length of the surface, $L = 8\,\text{m}$

Width of the surface, $w = 2.8\,\text{m}$

Rate of solar radiation absorbed on the top surface, $\dot{q}_r = 380\,\text{W/m}^2$

Ambient air temperature, $T_\infty = 30°\text{C}$

Step 2 of 4

From the table of air properties, at ambient temperature $T_\infty = 30°\text{C}$

Thermal conductivity $k = 0.02588\,\text{w/m}°\text{C}$

Kinematic viscosity $\nu = 1.608\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number $\text{Pr} = 0.7282$

The convection heat transfer rate from the top surface of the car to the air must be equal to the solar radiation absorbed by the same surface in order to reach steady state conditions

$$\dot{q}_r = \dot{q}_s = h\left(T_s - T_\infty\right) \quad \ldots\ldots (1)$$

Calculating Reynolds number to get flow regime

$$\text{Re} = \frac{VL}{\nu}$$

$$= \frac{26.39\times8}{1.608\times10^{-5}}$$

$$= 1.312\times10^{7}$$

Reynolds number is greater than 5×10^5 then the flow is combined laminar and turbulent flow

Step 3 of 4

Then the Nusselt number relationship for average heat transfer coefficient can be calculated as,

$$\text{Nu} = \left(0.037\text{Re}_L^{0.8} - 871\right)\text{Pr}^{1/3}$$

$$= \left(0.037\left(1.312\times10^7\right)^{0.8} - 871\right)\times(0.7282)^{1/3}$$

$$= 17433.117\times0.8996$$

$$= 15682.83$$

Step 4 of 4

Then the heat transfer coefficient is,

$$\text{Nu} = \frac{hL}{k}$$

$$15682.83 = \frac{h\times8}{0.02588}$$

$$h = 50.733\,\text{W/m}^2\cdot\text{K}$$

Substituting the values T_s, T_∞ and h in equation (1), we get

$$\dot{q}_s = h\left(T_s - T_\infty\right)$$

$$380 = 50.733\left(T_s - 30\right)$$

$$T_s = 37.49°\text{C}$$

Therefore, equilibrium temperature of the top surface of the car $\boxed{T_s = 37.49°\text{C}}$

Question: 19.028P pg 1

Reconsider Prob. 19-27. Using EES (or other) software, investigate the effects of the train velocity and the rate of absorption of solar radiation on the equilibrium temperature of the top surface of the car. Let the train velocity vary from 10 km/h to 120 km/h and the rate of solar absorption from 100 W/m2 to 500 W/m2. Plot the equilibrium temperature as functions of train velocity and solar radiation absorption rate, and discuss the results.

Step 1 of 10

Case 1: Varying air velocity

This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below,

Equations Window

```
" Given data"
"V=95 [km/h]"convert(km/h,m/s)"
L=8 [m]
w=2.8 [m]
q_dot_r=380 [W/m^2]
T_infinity=30 [C]
P_1=1 [atm]"convert(atm,kPa)

rho_1=Density(Air,T=T_infinity,P=P_1)
k_1=Conductivity(Air,T=T_infinity)
mu_1=Viscosity(Air,T=T_infinity)
Pr_1=Prandtl(Air,T=T_infinity)

"Reynolds number "
Re=(rho_1*V*L)/mu_1

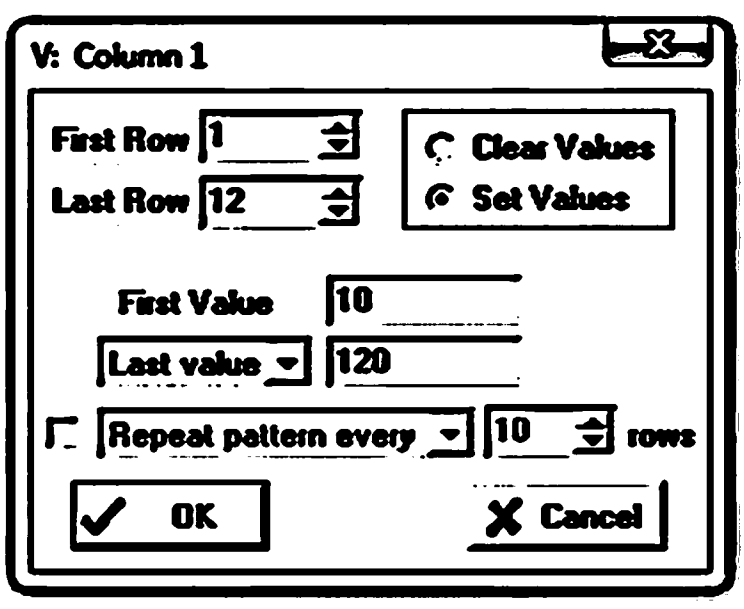
```



Step 2 of 10

Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

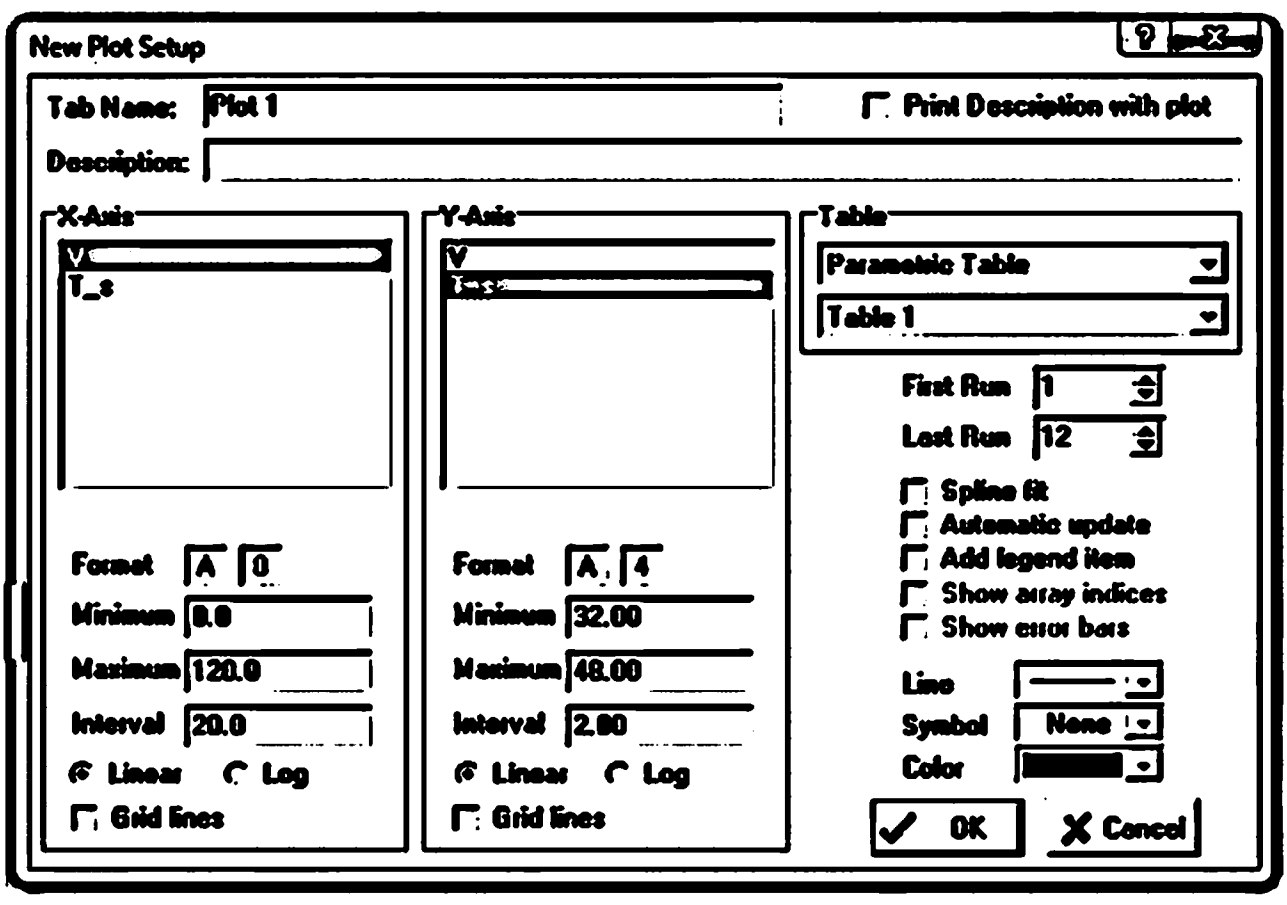
Step 3 of 10

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Parametric Table

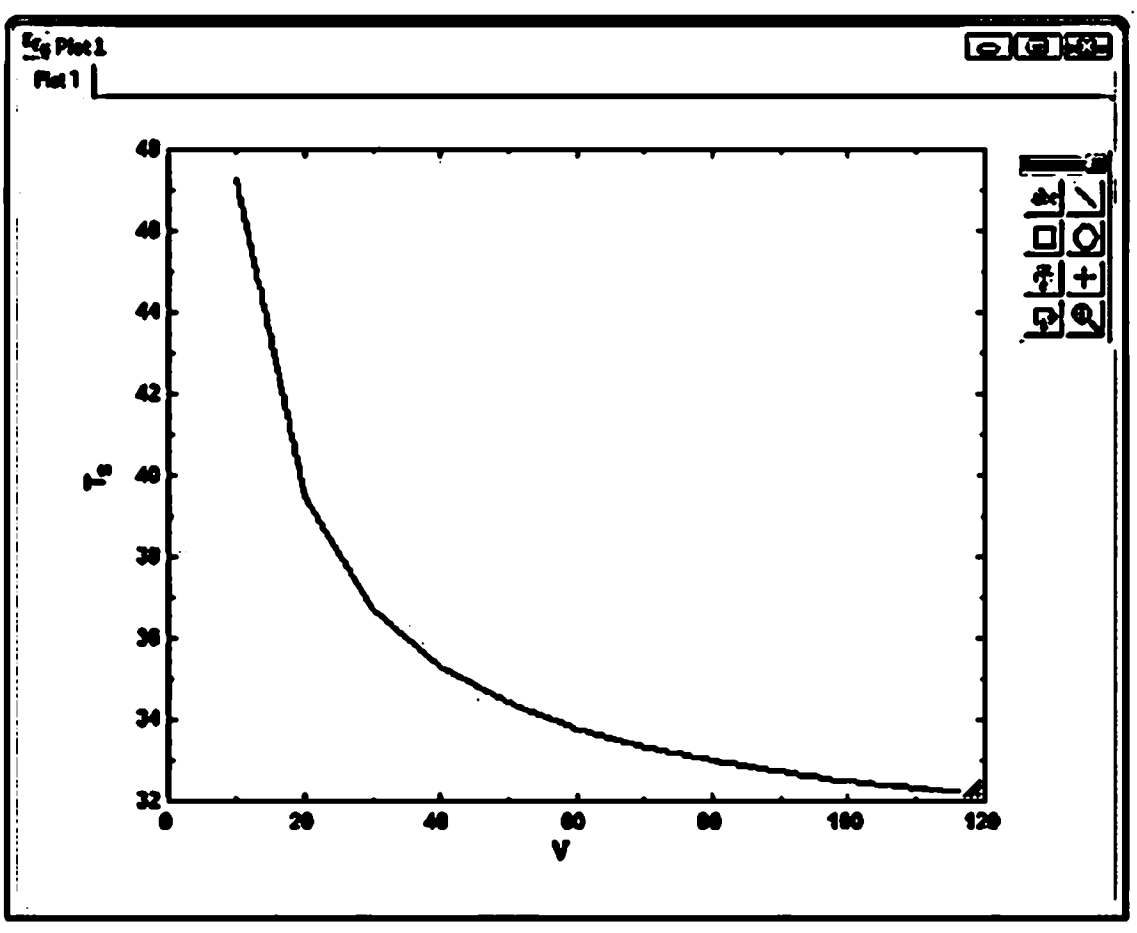
Table 1



1..12	V	T_s
Run 1	10	47.29
Run 2	20	39.46
Run 3	30	36.73
Run 4	40	35.29
Run 5	50	34.4
Run 6	60	33.79
Run 7	70	33.34
Run 8	80	33
Run 9	90	32.72
Run 10	100	32.5
Run 11	110	32.31
Run 12	120	32.15

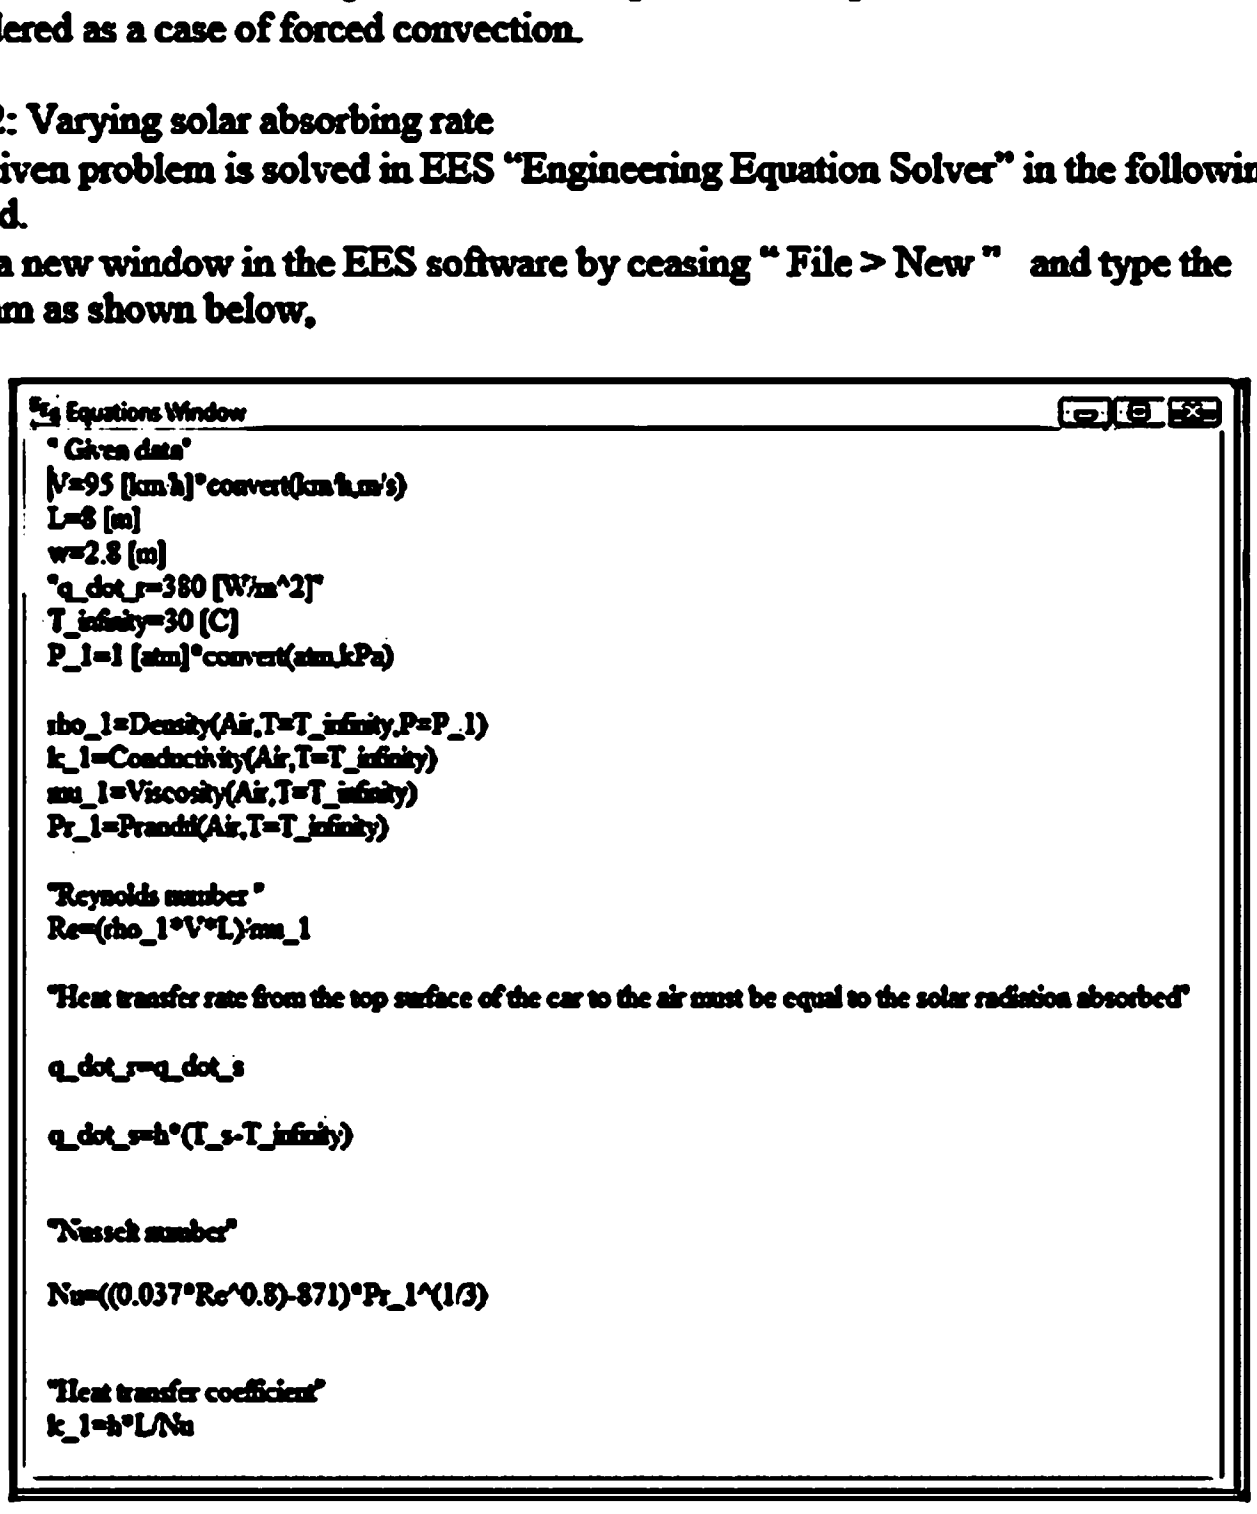
Step 4 of 10

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,



Step 4 of 10

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

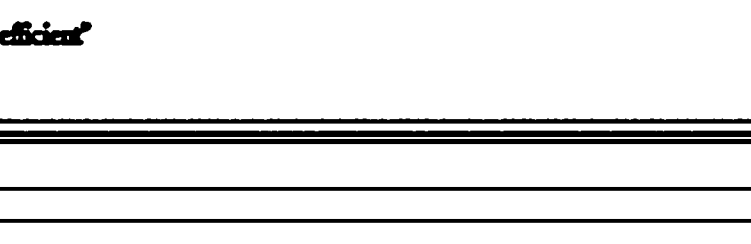


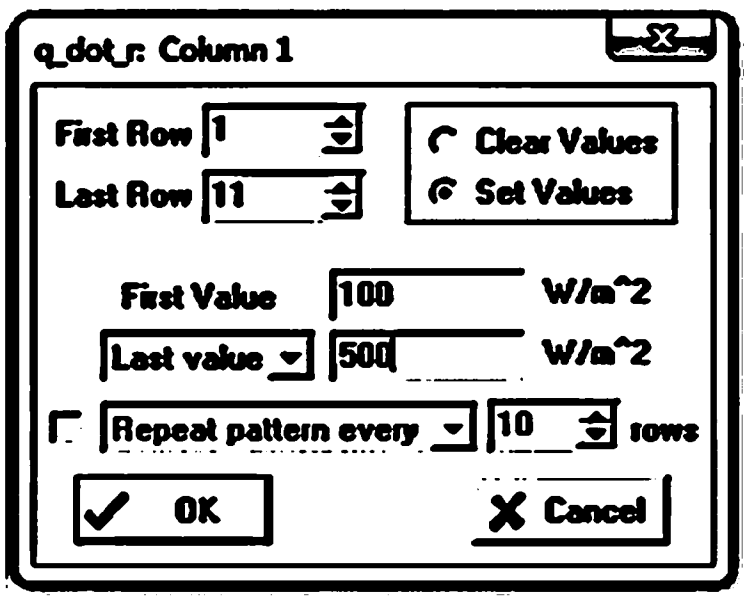
Step 5 of 10

By clicking on OK the graph will be generated as shown,

With the increase in velocity of the car the top surface temperature decreases.This can be considered as a case of forced convection.

Case 2: Varying solar absorbing rate
This given problem is solved in EES "Engineering Equation Solver" in the following method.
Open a new window in the EES software by ceasing " File > New " and type the program as shown below,





Step 6 of 10

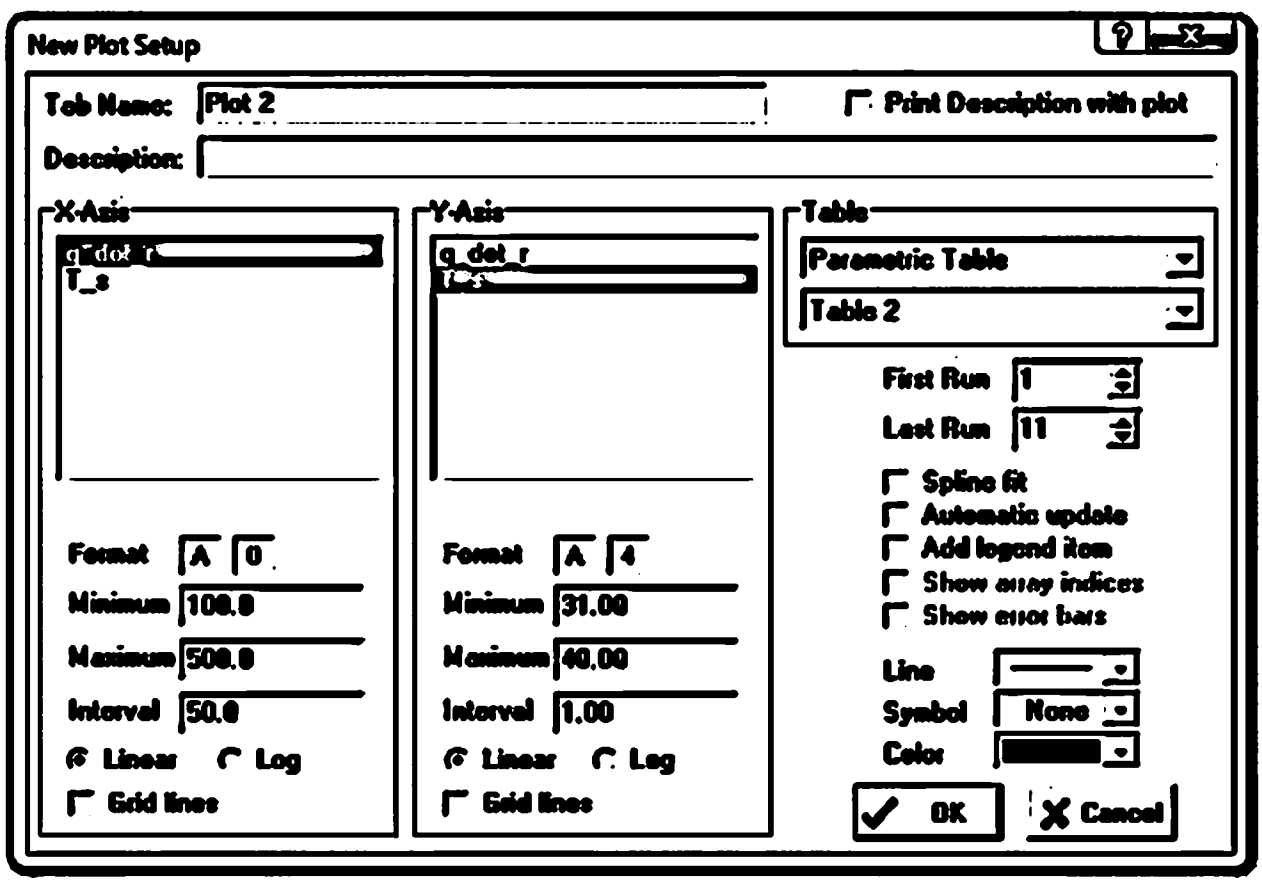
Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

Step 7 of 10

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Step 8 of 10

Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,



Parametric Table

Table 1 | Table 2

1..11	$\dot{q}_r$ [W/m2]	T_s
Run 1	100	31.97
Run 2	140	32.76
Run 3	180	33.55
Run 4	220	34.34
Run 5	260	35.12

Step 9 of 10

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 10 of 10

By clicking on OK the graph will be generated as shown,

From the graph we can see that with the increase in the solar absorption rate the top surface temperature of the car increases linearly.

Question: 19.029P

A 15-cm × 15-cm circuit board dissipating 20 W of power uniformly is cooled by air, which approaches the circuit board at 20°C with a velocity of 6 m/s. Disregarding any heat transfer from the back surface of the board, determine the surface temperature of the electronic components (*a*) at the leading edge and (*b*) at the end of the board. Assume the flow to be turbulent since the electronic components are expected to act as turbulators.

Step 1 of 6

Obtain the Properties of air at 1 atm. and an assumed film temperature of $35°C$ from the table A-22 "ideal gas properties of air at 1 atm. Pressure".

Thermal conductivity, $k = 0.0265\ \text{W/m°C}$

Kinematic viscosity, $\nu = 1.655\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7268$

Step 2 of 6

(a)

Write the relation for Nusselt number.

$$\text{Nu}_x = \frac{h_x x}{k}$$

$$h_x = \frac{k_x}{x}\text{Nu}_x$$

Here, Nu_x is the local Nusselt number and x is the distance from the leading edge.

Substitute 0 for x as the heat transfer at the leading edge of the board is determined.

$$\begin{aligned} h_x &= \frac{k_x}{x}\text{Nu}_x \\ &= \frac{k_x}{0}\times\text{Nu}_x \\ &= \infty \end{aligned}$$

Step 3 of 6

Calculate the surface temperature at the end of the board.

$$\dot{Q} = h_x A_s (T_s - T_\infty)$$

$$T_s = \frac{\dot{Q}}{h_x A_s} + T_\infty$$

Here, $\dot{Q}$ is the rate of heat dissipation, T_s is the surface temperature and T_∞ is the air temperature.

Substitute ∞ for h_x and $20°C$ for T_∞.

$$\begin{aligned} T_s &= \frac{\dot{Q}}{h_x A_s} + T_\infty \\ &= \frac{20}{\infty\times A_s} + 20 \\ &= 0 + 20 \\ &= 20°C \end{aligned}$$

As the Coefficient of heat transfer by convection at leading edge tends to infinity, the temperature of surface at the leading edge would be approaching temperature of air that is $\boxed{20°C}$.

Step 4 of 6

(b)

Determine the Reynolds number.

$$\text{Re}_x = \frac{Vx}{\upsilon}$$

Here, V is the velocity of air and x is the distance from the leading edge.

Substitute $6\ \text{m/s}$ for V, $1.655\times10^{-5}\ \text{m}^2/\text{s}$ for ν, and 0.15 m for x.

$$\begin{aligned} \text{Re} &= \frac{(6\ \text{m/s})(0.15\ \text{m})}{1.655\times10^{-5}\ \text{m}^2/\text{s}} \\ &= 5.438\times10^4 \end{aligned}$$

Since $\text{Re} < 5\times10^5$, the flow is laminar. But turbulent flow is assumed as electronic component are expected to act as turbulators.

Step 5 of 6

Calculate the Nusselt number assuming a uniform heat flux using the relation,

$$\text{Nu}_x = 0.0308\,\text{Re}_x^{0.8}\,\text{Pr}^{1/3}$$

Substitute 5.438×10^4 for Re and 0.7268 for Pr.

$$\begin{aligned} \text{Nu}_x &= 0.0308(5.438\times10^4)^{0.8}(0.7268)^{1/3} \\ &= 170.10 \end{aligned}$$

Step 6 of 6

Calculate the heat transfer coefficient using the relation,

$$\text{Nu}_x = \frac{h_x x}{k}$$

$$h_x = \frac{k_x}{x}\text{Nu}_x$$

Substitute 170.10 for Nu_x, $0.0265\ \text{W/m°C}$ for k and 0.15 m for x as the heat transfer is to be determined at the end of the borad.

$$h_x = \frac{0.0265\ \text{W/m°C}}{0.15\ \text{m}}(170.10)$$

$$h_x = 30.051\ \text{W/m}^2\cdot°\text{C}$$

Calculate the surface area of the board.

$$\begin{aligned} A_s &= 0.15\times0.15 \\ &= 0.0225\ \text{m}^2 \end{aligned}$$

Here, A_s is the surface area.

Calculate the surface temperature at the end of the board.

$$\dot{Q} = h_x A_s (T_s - T_\infty)$$

Here, T_s is the surface temperature and T_∞ is the air temperature.

Substitute $20°C$ for T_∞, $0.0225\ \text{m}^2$ for A_s, and $30.051\ \text{W/m}^2\cdot°\text{C}$ for h_x

$$20 = 30.051\times0.0225(T_s - 20)$$

$$20 = 0.676(T_s - 20)$$

$$T_s = 49.58°C$$

Therefore, the surface temperature at the end of the board is $\boxed{49.58°C}$.

Question: 19.030P

Consider a refrigeration truck traveling at 70 mph at a location where the air temperature is 80°F. The refrigerated compartment of the truck can be considered to be a 9-ft-wide, 7-ft-high, and 20-ft-long rectangular box. The refrigeration system of the truck can provide 3 tons of refrigeration (i.e., it can remove heat at a rate of 600 Btu/min). The outer surface of the truck is coated with a low-emissivity material, and thus radiation heat transfer is very small. Determine the average temperature of the outer surface of the refrigeration compartment of the truck if the refrigeration system is observed to be operating at half the capacity. Assume the air flow over the entire outer surface to be turbulent and the heat transfer coefficient at the front and rear surfaces to be equal to that on side surfaces.

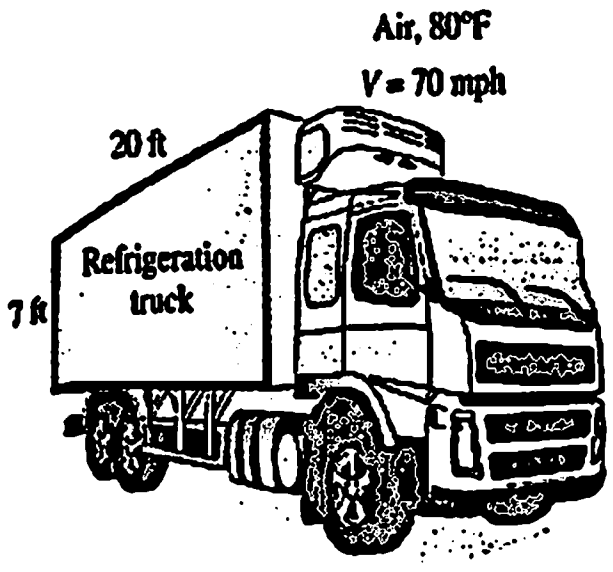

FIGURE P19-30E

Step 1 of 5

Given data:

Temperature of air $T_\infty = 80°F$

Truck velocity,

$V = 70\,\text{mph}$

$$= \frac{70 \times 5280}{3600}$$

$$= 102.67\,\text{ft/s}$$

Width of compartment, $w = 9\text{ft}$

Height of compartment, $H = 7\text{ft}$

Length of compartment, $L = 20\text{ft}$

Capacity of Refrigeration system, $Q_r = 3\text{tons}$

We know one ton of refrigeration is

$1\text{ton} = 200\,\text{Btu/min}$

Then

$Q_r = 3 \times 200$

$= 600\,\text{Btu/min}$

$= 36000\,\text{Btu/hour}$

Step 2 of 5

Loading solution. Please wait ...

Step 3 of 5

Then from equation (1), we get Nusselt number

$$\text{Nu} = 0.037\,\text{Re}_L^{0.8}\,\text{Pr}^{1/3}$$

$$= 0.037\left(1.21 \times 10^7\right)^{0.8}(0.7290)^{1/3}$$

$$\text{Nu} = 15440.89$$

Then the heat transfer coefficient will be

$$\text{Nu} = \frac{hL}{k}$$

$$15440.89 = \frac{h \times 20}{0.01481}$$

$$h = 11.434\,\text{Btu/h} \cdot \text{ft}^2 \cdot \text{R}$$

Step 4 of 5

Since it is given that the system is observed to be operated at half of its capacity

Therefore

$$\dot{Q} = \frac{Q_r}{2}$$

$$= \frac{36000}{2}$$

$$= 18000\,\text{Btu/h}$$

Heat transfer surface area is,

$$A_s = 2\left[(20 \times 9) + (20 \times 7) + (9 \times 7)\right]$$

$$= 766\,\text{ft}^2$$

Step 5 of 5

We know the newton's law of cooling,

$$\dot{Q} = hA_s\left(T_\infty - T_s\right)$$

$$18000 = 11.434 \times 766\left(80 - T_s\right)$$

$$2.055 = \left(80 - T_s\right)$$

$$T_s = 77.945°F$$

Therefore, the average temperature of the outer surface of the refrigeration compartment of the truck is $\boxed{T_s = 77.945°F}$

Question: 19.031P

Liquid mercury at 250°C is flowing in parallel over a flat plate at a velocity of 0.3 m/s. Surface temperature of the 0.1-m-long flat plate is constant at 50°C. Determine (*a*) the local convection heat transfer coefficient at 5 cm from the leading edge and (*b*) the average convection heat transfer coefficient over the entire plate.

Step 1 of 6

Given data:

Temperature of liquid mercury, $T_\infty = 250°C$

Velocity of flow, $V = 0.3\ m/s$

Length of the plate, $L = 0.1\ m$

Temperature of the flat plate, $T_s = 50°C$

Distance from the leading edge, $x = 5\ cm$

Step 2 of 6

The film temperature of the liquid mercury is determined as,

$$T_f = \frac{(T_s + T_\infty)}{2}$$
$$= \frac{(50+250)}{2}$$
$$= 150°C$$

From the table, properties of liquid mercury at 1 atm pressure and at $T = 150°C$

Thermal conductivity, $k = 10.07780\ W/m \cdot K$

Kinematic viscosity, $\nu = 8.514\times10^{-8}\ m^2/s$

Prandtl number, $Pr = 0.0152$

Step 3 of 6

(a)

The Reynolds number for the flow is determined from the equation given by

$$Re_x = \frac{Vx}{\nu}$$
$$= \frac{0.3\times\left(5\times10^{-2}\right)}{8.514\times10^{-8}}$$
$$= 176180.41$$

Since the obtained Reynolds number is less than 5×10^5 i.e. $Re < 5\times10^5$, the flow is said to be laminar.

Step 4 of 6

The average Nusselt number for parallel flow over flat plate is determined from the Churchill & Ozoe relation given by

$$Nu_x = \frac{0.3387Pr^{1/3}Re_x^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}$$
$$= \frac{0.3387\times(0.0152)^{1/3}\times(176180.41)^{1/2}}{\left[1+\left(\frac{0.0468}{0.0152}\right)^{2/3}\right]^{1/4}}$$
$$= 26.51$$

The local convective heat transfer coefficient at 5 cm from the leading edge is determined from the equation given by,

$$Nu_x = \frac{h_x x}{k}$$
$$h_x = \frac{Nu_x \times k}{x}$$
$$= \frac{26.51\times10.07780}{\left(5\times10^{-2}\right)}$$
$$= 5342.24\ W/m^2 \cdot K$$

The local convective heat transfer coefficient at 5 cm from the leading edge is

$$\boxed{h_x = 5342.24\ W/m^2 \cdot K}$$

Step 5 of 6

(b)

The Average convection heat transfer coefficient over entire plate can be calculated by integrating h_x over the entire length,

$$h = \frac{1}{L}\int_0^L h_x dx \qquad \ldots\ldots (1)$$

Local heat transfer coefficient,

$$h_x = \frac{0.3387Pr^{1/3}Re_x^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}\times\frac{k}{x}$$
$$= \frac{0.3387Pr^{1/3}\left(\frac{V}{\nu}\right)^{1/2}\times x^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}\times\frac{k}{x}$$

As other values will remain constant during integrating

Therefore $h_x = Ax^{-1/2}$

Where

$$A = \frac{0.3387Pr^{1/3}\left(\frac{V}{\nu}\right)^{1/2}\times k}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}$$

Step 6 of 6

Substituting the value of h_x in equation (1), we get

$$h = \frac{1}{L}\int_0^L Ax^{-1/2}dx$$
$$= \frac{A}{L}\int_0^L x^{-1/2}dx$$
$$= \frac{A}{L}\left[2x^{1/2}\right]_0^L$$
$$= \frac{2A}{L^{1/2}}$$

The average convective heat transfer coefficient over the entire plate is determined as,

$$h = \frac{2}{L^{1/2}}\times\frac{0.3387Pr^{1/3}\left(\frac{V}{\nu}\right)^{1/2}\times k}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}$$
$$= \frac{2}{(0.1)^{1/2}}\times\frac{0.3387\times(0.0152)^{1/3}\times\left(\frac{0.3}{8.514\times10^{-8}}\right)^{1/2}\times10.07780}{\left[1+\left(\frac{0.0468}{0.0152}\right)^{2/3}\right]^{1/4}}$$
$$= 7555\ W/m^2 \cdot K$$

Therefore, the average convective heat transfer coefficient over the entire plate is

$$\boxed{h = 7555\ W/m^2 \cdot K}$$

Question: 19.032P

Liquid mercury at 250°C is flowing with a velocity of 3 m/s in parallel over a 0.1 -m long flat plate where there is an unheated starting length of 5cm. The heated section of the flat Plate is maintained at a constant temperature of 50°C. Determine (*a*) the local convection heat transfer coefficient at the trailing edge, (*b*) the average convection heat transfer coefficient for the heated section, and (*c*) the rate of heat transfer per unit width for the heated section.

Step 1 of 7

Given data:

Temperature of liquid Mercury, $T_\infty = 250°C$

Velocity of flow, $V = 0.3\ m/s$

Length of the flat plate, $L = 0.1\ m$

Temperature of the flat plate, $T_s = 50°C$

Length of unheated portion, $\xi = 5\ cm$

Step 2 of 7

The film temperature of the liquid mercury is determined as,

$$T_f = \frac{(T_s + T_\infty)}{2}$$

$$= \frac{(50+250)}{2}$$

$$= 150°C$$

From the table, properties of liquid mercury at 1 atm pressure and at $T = 150°C$

Thermal conductivity, $k = 10.07780\ W/m \cdot K$

Kinematic viscosity, $\nu = 8.514 \times 10^{-6}\ m^2/s$

Prandtl number, $Pr = 0.0152$

Step 3 of 7

(a)

The Reynolds number for the flow at the trailing edge, $x = L$ is determined from the equation given by,

$$Re_{x=L} = \frac{Vx}{\nu}$$

$$= \frac{0.3 \times 0.1}{8.514 \times 10^{-6}}$$

$$= 352360.82$$

Since the obtained Reynolds number is less than 5×10^5 i.e. $Re < 5 \times 10^5$, the flow is said to be laminar.

The average Nusselt number for parallel flow over flat plate is determined from the Churchill & Ozoe relation given by

$$Nu_x = \frac{Nu_{x(\xi=0)}}{\left[1-(\xi/x)^{3/4}\right]^{1/3}} \qquad \ldots\ldots (1)$$

Step 4 of 7

$$Nu_{x(\xi=0)} = \frac{0.3387 Pr^{1/3} Re_{x=L}^{1/2}}{\left[1+(0.0468/Pr)^{2/3}\right]^{1/4}}$$

$$= \frac{0.3387 \times (0.0152)^{1/3} \times (352360.82)^{1/2}}{\left[1+\left(\frac{0.0468}{0.0152}\right)^{2/3}\right]^{1/4}}$$

$$= 37.48$$

Substituting the above value $Nu_{x(\xi=0)}$ in equation (1), we get

$$Nu_x = \frac{37.48}{\left[1-\left(\frac{5\times10^{-2}}{0.1}\right)^{3/4}\right]^{1/3}}$$

$$= 50.65$$

Step 5 of 7

The local convective heat transfer coefficient at the trailing edge is determined from the equation given by

$$Nu_x = \frac{h_x L}{k}$$

$$h_x = \frac{Nu_x \times k}{L}$$

$$= \frac{50.65 \times 10.07780}{0.1}$$

$$= 5104.05\ W/m^2 \cdot K$$

Therefore, the local convective heat transfer coefficient at the trailing edge is

$$\boxed{h_x = 5104.05\ W/m^2 \cdot K}$$

Step 6 of 7

(b)

The average convection heat transfer coefficient for the heated section is determined from the equation given by

$$h = \frac{2\left[1-(\xi/x)^{3/4}\right]}{1-\xi/L} \times h_{x=L}$$

$$= \frac{2 \times \left(1-\left(\frac{5\times10^{-2}}{0.1}\right)^{3/4}\right)}{1-\frac{5\times10^{-2}}{0.1}} \times 5104.05$$

$$= 8276.65\ W/m^2 \cdot K$$

Therefore, the average convection heat transfer coefficient for the heated section is

$$\boxed{h = 8276.65\ W/m^2 \cdot K}$$

Step 7 of 7

(c)

The rate of heat transfer per unit width for the heated section is determined from the equation given by,

$$\dot{Q} = hA_s(T_\infty - T_s)$$

$$= h \times \left((L-\xi) \times w\right) \times (T_\infty - T_s)$$

$$= 8276.65 \times \left(\left(0.1-5\times10^{-2}\right) \times 1\right) \times (250-50)$$

$$= 82766.5\ W/m$$

Therefore, the rate of heat transfer per unit width for the heated section is

$$\boxed{\dot{Q} = 82766.5\ W/m}$$

Question: 19.033P

Air at 60°F flows over a 10-ft-long flat plate at 7 ft/s Determine the local heat transfer coefficient at intervals of 1ft and plot the results against the distance from the leading edge.

Step 1 of 6

Given data:

Temperature of air, $T = 60°C$

Velocity of air, $V = 7\,ft/s$

Length of flat plate, $L = 10\,ft$

Step 2 of 6

Properties of air at 1 atm and average film temperature 60°F is taken from properties of air table

$k = 0.01433\ Btu/h \cdot ft \cdot °F$

$\upsilon = 0.1588 \times 10^{-3}\ ft^2/s$

$Pr = 0.7321$

Reynolds number for 1 ft is calculated as

$$Re_L = \frac{VL}{\upsilon}$$
$$= \frac{(7\ ft/s)(1\ ft)}{0.1588 \times 10^{-3}\ ft^2/s}$$
$$= 4.408 \times 10^4$$

This is less than critical value of Reynolds number. So, the flow is laminar.

Step 3 of 6

The local Nusselt number is given by

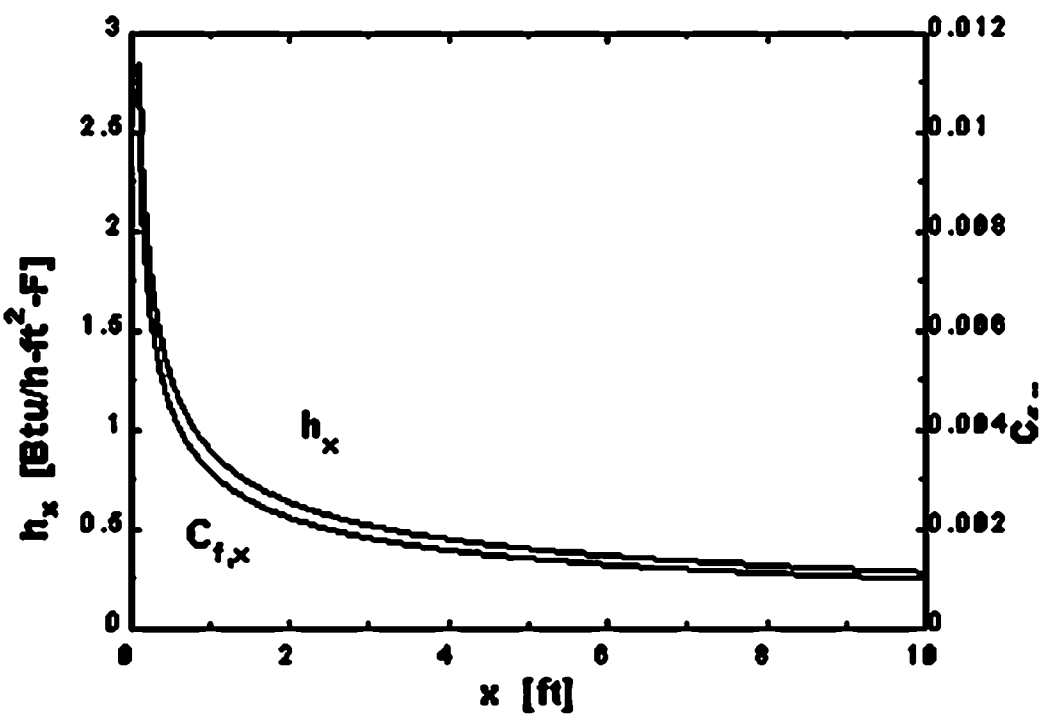
$$Nu_x = \frac{hx}{k}$$
$$= 0.332 Re_x^{0.5} Pr^{1/3}$$
$$= 0.332\left(4.408 \times 10^4\right)^{0.5} (0.7321)^{1/3}$$
$$= 62.82$$

Step 4 of 6

The local heat transfer and friction coefficients are given by

$$h_x = \frac{k}{x} Nu$$
$$= \frac{0.01433\ Btu/h \cdot ft \cdot °F}{1\,ft}(62.82)$$
$$= 0.9002\ Btu/h \cdot ft^2 \cdot °F$$

$$C_{f,x} = \frac{0.664}{Re^{0.5}}$$
$$= \frac{0.664}{\left(4.407 \times 10^4\right)^{0.5}}$$
$$= 0.00316$$



Step 5 of 6

We repeat calculations for all 1-ft intervals. The results are

x	h_x	$C_{f,x}$
1	0.9005	0.003162
2	0.6367	0.002236
3	0.5199	0.001826
4	0.4502	0.001581
5	0.4027	0.001414
6	0.3676	0.001291
7	0.3404	0.001195
8	0.3184	0.001118
9	0.3002	0.001054
10	0.2848	0.001

Step 6 of 6

Graph:

Question:

Reconsider Prob. 19-33E. Using EES (or other) software, evaluate the local heat transfer coefficieot along the plate at intervals of 0.1 ft, and plot them against the distance from the fading edge.

Step 1 of 2

4749-19-34P

AID: 530 | 28/05/2012

Given data:

Temperature of the air, $T_{air} = 60°F$

Length of the flat plate, $L = 10 ft$

Velocity of the air, $V_{air} = 7 ft/s$

Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

Question: 19.035P

An array of power transistors, dissipating 5 W of power each, are to be cooled by mounting them on a 25-cm × 25-cm square aluminum plate and blowing air at 35°C over the plate with a fan at a velocity of 4 m/s. The average temperature of the plate is not to exceed 65°C. Assuming the heat transfer from the back side of me Plate to be negligible and disregarding radiation, determine the number of transistors that can be placed on this plate.

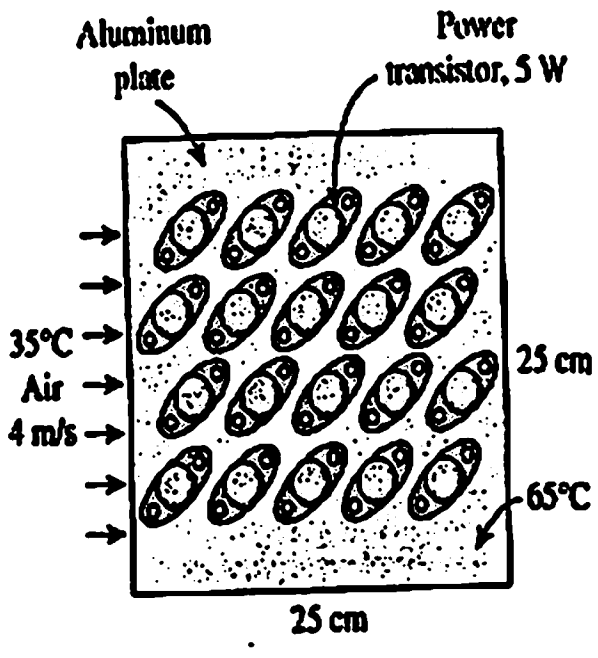

FIGURE P1 9-35

Step 1 of 3

Calculate the film temperature of the air

$$T_f = \frac{(T_s + T_\infty)}{2}$$

Substitute $35°C$ for T_∞ , and $65°C$ for T_s

$$T_f = \frac{(T_s + T_\infty)}{2}$$
$$= \frac{(65+35)}{2}$$
$$= 50°C$$

From the table, properties of air at $1\ \text{atm}$ pressure and at $T = 50°C$

Thermal conductivity, $k = 0.02735\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

Step 2 of 3

Determine the Reynolds number

$$\text{Re} = \frac{VL}{\nu}$$

Substitute $4\ \text{m/s}$ for V , 0.25 m for L, and $1.798\times10^{-5}\ \text{m}^2/\text{s}$ for ν

$$\text{Re} = \frac{VL}{\nu}$$
$$= \frac{4\times\left(25\times10^{-2}\right)}{1.798\times10^{-5}}$$
$$= 55617.35$$

Since the obtained Reynolds number is less than 5×10^5 i.e. $\text{Re} < 5\times10^5$, the flow is said to be laminar. So determine the average Nusselt number for laminar flow substituting 55617.35 for Re and 0.7228 for Pr

$$\text{Nu} = 0.664\text{Re}^{0.5}\text{Pr}^{1/3}$$
$$= 0.664\times(55617.35)^{0.5}\times(0.7228)^{1/3}$$
$$= 140.53$$

Step 3 of 3

Calculate the heat transfer coefficient using the Nusselt number. Substitute 0.25 m for L and $0.02735\ \text{W/m}\cdot\text{K}$ for k

$$h = \frac{\text{Nu}\times k}{L}$$
$$= \frac{140.53\times0.02735}{0.25}$$
$$= 15.37\ \text{W/m}^2\cdot\text{K}$$

Determine the number of transistors that can be placed on the plate by using the heat transfer rates.

$$N = \frac{\dot{Q}}{P}$$
$$= \frac{hA(T_s - T_\infty)}{P}$$

Substitute $5\ \text{W}$ for P , $\left(0.25\times0.25\ \text{m}^2\right)$ for A , $35°C$ for T_∞ , $15.37\ \text{W/m}^2\cdot\text{K}$ for h , and $65°C$ for T_s in the above equation

$$N = \frac{hA(T_s - T_\infty)}{P}$$
$$= \frac{15.37(0.25\times0.25)(65-35)}{5}$$
$$= 5.76$$

The number of transistors that can be placed on the on the plate is $\boxed{N = 5}$

Question: 19.036P

Repeat Prob. 19-35 for a location at an elevation of 1610 m where the atmospheric pressure is 83.4 kPa.

Step 1 of 6

Given data:

Power dissipation by each transistor, $\dot{Q} = 5\,\text{W}$

Temperature of air, $T_\infty = 35°\text{C}$

Velocity of air, $V = 4\,\text{m/s}$

Size of square plate,

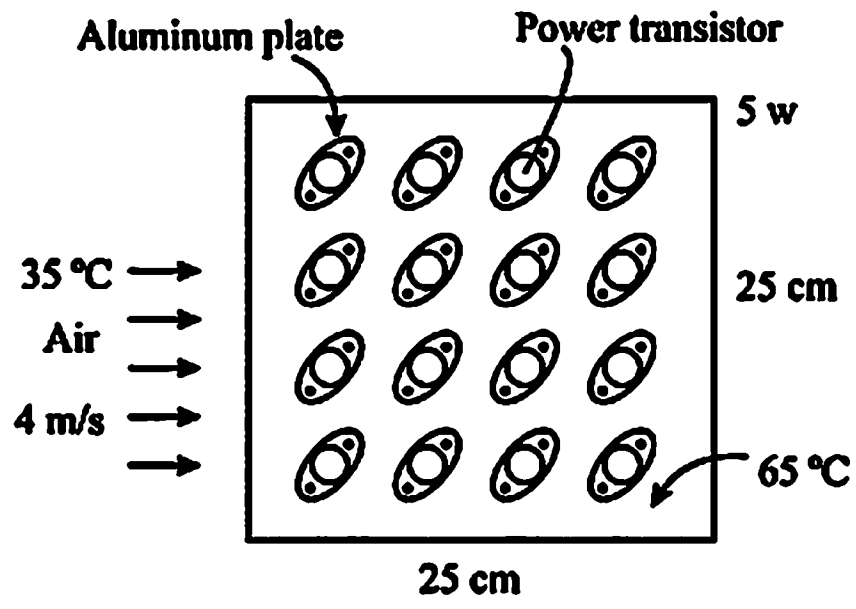
$L = 25\ \text{cm}$

$= 0.25\text{m}$

Plate average temperature, $T_s = 65°\text{C}$

Location elevation, $z = 1610\,\text{m}$

Atmospheric pressure,



$p_{atm} = 83.4\,\text{kPa}$

$= (83.4)/101.325$

$= 0.823\ \text{atm}$

Step 2 of 6

An array of power transistors are placed on square aluminum plate is as shown below:

Step 3 of 6

Assuming no heat transfer from back side of the plate and there is no radiation heat transfer

By using the formula for film temperature, we get

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{65+35}{2}$$

$$= 50°\text{C}$$

At 1atm pressure and film temperature $T_f = 50°\text{C}$ from properties of air table

Thermal conductivity, $k = 0.02735\,\text{W/m}\cdot°\text{C}$

Kinematic viscosity, $\nu_{1\,atm} = 1.798\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

There is no change in properties of Prandtl number and thermal conductivity when pressure changes but kinematic viscosity of air at 0.823 atm is

$\nu = 1.798\times10^{-5}/0.823$

$= 2.184\times10^{-5}\,\text{m}^2/\text{s}$

Step 4 of 6

Loading solution. Please wait ...

Step 5 of 6

Nusselt number can be written as

$$\text{Nu} = \frac{hL}{k}$$

$$102.697 = \frac{h\times0.25}{0.02735}$$

$h = 11.235\,\text{W/m}^2\cdot\text{K}$

Heat transfer surface Area of the square plate

$A_s = L^2$

$= (0.25)^2$

$= 0.0625\,\text{m}^2$

Step 6 of 6

By Newton's law of cooling, the total heat transfer from the plate will be,

$\dot{Q}_t = hA_s(T_s - T_\infty)$

$= 11.235\times0.0625\times(65-35)$

$= 21.0656\,\text{W}$

Therefore Number of transistors that can be placed over plate can be

$$N = \frac{\text{Total heat transfer, } \dot{Q}_{total}}{\text{heat transfer by one transistor, } \dot{Q}}$$

$$= \frac{21.0656}{5}$$

$= 4.213$

$= 5$

Therefore the number of transistors that can be placed on this plate is $\boxed{N = 5}$

Question: 19.037P

Air at 25°C and 1 atm is flowing over a long flat plate with a velocity of 8 m/s. Determine the distance from the leading edge of the plate where the flow becomes turbulent, and the thickness of the boundary layer at that location.

Step 1 of 2

Obtain properties of air at temperature $25°C$ from table A-15, "Properties of air at 1 atm pressure" in the text book.

Density, $\rho = 1.184\ kg/m^3$ and

Kinematic viscosity, $\nu = 1.562\times10^{-5}\ m^2/s$

Find the distance from the leading edge of the plate where the flow becomes turbulent by using the following equation:

$$Re_{cr} = \frac{V_\infty x}{\nu}$$

Here, V_∞ is fluid velocity, Re_{cr} is Reynolds number where the flow is turbulent, and x is distance from the leading edge of the plate where the flow becomes turbulent.

Substitute 5×10^5 for Re_{cr}, $1.562\times10^{-5}\ m^2/s$ for ν, and 8 m/s for V_∞

$$5\times10^5 = \frac{8\times x}{1.562\times10^{-5}}$$
$$x = 0.976\,m$$

Therefore, the distance from the leading edge of the plate is $\boxed{0.976\,m}$

Step 2 of 2

Find the thickness of boundary layer by using the following equation:

$$\delta_x = \frac{5x}{Re_x^{1/2}}$$

Substitute 0.976 m for x and 5×10^5 for Re_x

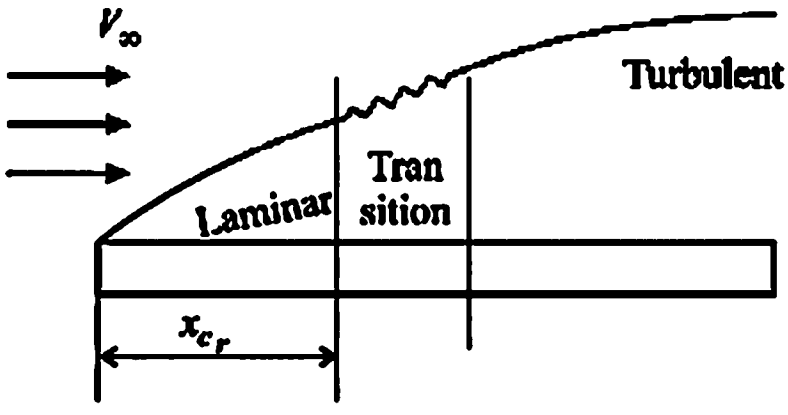
$$\delta_{cr} = \frac{5\times0.976}{(5\times10^5)^{1/2}}$$
$$= 0.0069\,m$$
$$= 0.69\,cm$$

Therefore, thickness of the boundary layer where the flow becomes turbulent is $\boxed{0.69\ cm}$

Question: 19.038P

Repeat Prob. 19-37 for water.

Step 1 of 4



Given: - Temperature of water = 25°C

Velocity of water $V_\infty = 8$ m/s

Step 2 of 4

Properties of water at 1 atm and temperature 25°C is taken from properties of saturated water table

$\rho = 997\ \text{kg/m}^3$ and $\mu = 0.891\times10^{-3}\ \text{kg/ms}$

Step 3 of 4

Taking value of Reynolds number as 5×10^5 distance from the leading edge of the plate where the flow becomes turbulent is calculated as follows

$$\text{Re}_{cr} = \frac{\rho V_\infty x_{cr}}{\mu}$$

$$x_{cr} = \frac{\mu \text{Re}_{cr}}{\rho V_\infty}$$

$$= \frac{(0.891\times10^{-3}\ \text{kg/m}\cdot\text{s})(5\times10^5)}{(997\ \text{kg/m}^3)(8\ \text{m/s})}$$

$$= 0.056\ \text{m}$$

$$\boxed{x_{cr} = 5.6\ \text{cm}}$$

Step 4 of 4

Thickness of boundary layer is

$$\delta_{cr} = \frac{5x}{\text{Re}_x^{1/2}}$$

$$\delta_{cr} = \frac{5x_{cr}}{\text{Re}_{cr}^{1/2}}$$

$$= \frac{5(0.056\ \text{m})}{(5\times10^5)^{1/2}}$$

$$= 0.00040\ \text{m}$$

$$\boxed{\delta_{cr} = 0.4\ \text{mm}}$$

Question: 19.039P

Solar radiation is incident on the glass cover of a solar collector at a rate of 700 W/m2. The glass transmits 88 percent of the incident radiation and has an emissivity of 0.90. The entire hot water needs of a family in summer can be met by two collectors 1.2 m high and 1 m wide. The two collectors are attached to each other on one side so that they appear like a single collector 1.2 m × 2 m in size. The temperature of the glass cover is measured to be 35°C on a day when the surrounding air temperature is 25°C and the wind is blowing al 30 km/h. The effective sky temperature for radiation exchange between the glass cover and the open sky is -40°C. Water enters the tubes attached to the absorber plate at a rate of 1 kg/min. Assuming the back surface of the absorber plate to be heavily insulated and the only heat loss to occur through the glass cover, determine (*a*) the total rate of heat loss from the collector, (*b*) the collector efficiency, which is the ratio of the amount of heat transferred to the water to the solar energy incident on the collector, and (*c*) the temperature rise of water as it flows through the collector.

Tsky=-40°C

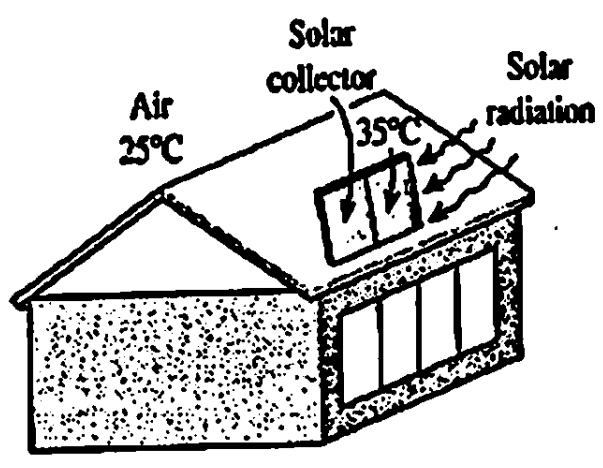


FIGURE P19-39

Step 1 of 10

Given: - Rate of incident solar radiation $= 700\ W/m^2$
Emissivity of glass $= 0.90$
Radiation transmitted by glass $= 88\%$
Dimension of collector $= 1.2\ m \times 2\ m$
Temperature of glass $= 35°C$
Surrounding temperature $= 25°C$
Velocity of wind $= 30\ km/h$

Step 2 of 10

Properties of air at 1 atm and average film temperature $\frac{(35+25)}{2} = 30°C$ is taken from properties of air table

$k = 0.02588\ W/m°C$
$\upsilon = 1.608 \times 10^{-5}\ m^2/s$
$Pr = 0.7282$

Step 3 of 10

(*a*) Reynolds number is calculated assuming that wind flows across 2 m surface

$$Re_L = \frac{VL}{\upsilon}$$
$$= \frac{(30 \times 1000/3600)m/s(2\ m)}{1.608 \times 10^{-5}\ m^2/s}$$
$$Re_L = 1.036 \times 10^6$$

Since $5 \times 0^5 \le Re_L \le 10^7$
Combined laminar and turbulent flow will be there.

Step 4 of 10

Nusslt number is calculated as follows:

$$Nu = \frac{hL}{k}$$
$$= (0.037 Re^{0.8} - 871) Pr^{1/3}$$
$$= [0.037(1.036 \times 10^6)^{0.8} - 871](0.7282)^{1/3}$$
$$Nu = 1376.98$$
$$h = \frac{k}{L} Nu$$
$$= \frac{0.02588\ W/m°C}{2\ m}(1376.98)$$
$$h = 17.82\ W/m^2\ °C$$

Step 5 of 10

Rate of heat loss by convection from collector is

$$\dot{Q}_{conv} = hA_s(T_\infty - T_s)$$
$$= (17.82\ W/m^2\ °C)(2 \times 1.2\ m^2)(35\text{-}25)°C$$
$$\dot{Q}_{conv} = 427.68\ W$$

Step 6 of 10

Heat loss rate by radiation from collector is

$$\dot{Q}_{rad} = \varepsilon A_s \sigma (T_s^4 - T_{sur}^4)$$
$$= (0.90)(2 \times 1.2\ m^2)(5.67 \times 10^{-8}\ W/m^{2\circ}C)\left[(35+273\ K)^4 - (-40+273\ K)^4\right]$$
$$\dot{Q}_{rad} = 741.2\ W$$

Step 7 of 10

And $\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$
$= 427.68 + 741.2$
$\boxed{\dot{Q}_{total} = 1169.88 W}$

Step 8 of 10

(*b*) Net heat transfer rate is

$$\dot{Q}_{net} = \dot{Q}_{in} - \dot{Q}_{out}$$
$$= \alpha A I - \dot{Q}_{out}$$
$$= (0.88)(2 \times 1.2\ m^2)(700\ W/m^2) - 1169.88\ W$$
$$\dot{Q}_{net} = 1478.4 - 1169.88$$
$$\dot{Q}_{net} = 308.52\ W$$

Step 9 of 10

$$\eta_{collector} = \frac{\dot{Q}_{net}}{\dot{Q}_{in}}$$
$$= \frac{308.52\ W}{1478.4\ W}$$
$$\boxed{\eta_{collector} = 20.9\%}$$

Step 10 of 10

(*c*) Temperature change in water flowing through collector

$$\dot{Q}_{net} = \dot{m} C_p \Delta T$$
$$\Delta T = \frac{\dot{Q}_{net}}{\dot{m} C_p}$$
$$= \frac{308.52\ W}{(1/60\ kg/s)(4180\ J/kg°C)}$$
$$\boxed{\Delta T = 4.43°C}$$

Question: 19.040P

A 15-mm × 15-mm silicon chip is mounted such that the edges are flush in a substrate. The chip dissipates 1.4 W of power uniformly, while air at 20°C (1 atm) with a velocity of 25 m/s is used to cool the upper surface of the chip. If the substrate provides an unheated starting length of 15 mm, determine the surface temperature at the trailing edge of the chip. Evaluate the air properties at 50°C.

Step 1 of 4

Consider the properties of air from the table, "properties of air at $1\ \text{atm}$ pressure" recorded at temperature, $T = 50°\text{C}$

Thermal conductivity, $k = 0.02735\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

Determine the characteristic length, *L*.

$$L = x + \xi$$

Here, *x* is the length of the chip and ξ is the unheated stating length.

Substitute $15\ \text{mm}$ for *x* and $15\ \text{mm}$ for ξ.

$$L = 15 + 15$$
$$L = 30\ \text{mm}$$

Determine the Reynolds number for the flow at the trailing edge $(x = L + \xi)$.

$$\text{Re} = \frac{VL}{\nu}$$

Here, Re_x is the Reynolds number and L is the characteristic length.

Substitute $25\ \text{m/s}$ for *V*, $30\ \text{mm}$ for L, and $1.798\times10^{-5}\ \text{m}^2/\text{s}$ for ν.

$$\text{Re} = \frac{25\times\left(\left(15\times10^{-3}\right)+\left(15\times10^{-3}\right)\right)}{1.798\times10^{-5}}$$
$$= 41713.014$$

Since the obtained Reynolds number is less than 5×10^5 i.e. $\text{Re} < 5\times10^5$, the flow is laminar.

Step 2 of 4

Calculate the local Nusselt number, $\text{Nu}_{x(\xi=0)}$ for laminar flow with uniform heat flux.

$$\text{Nu}_{x(\xi=0)} = 0.453\text{Re}^{0.5}\text{Pr}^{1/3}$$

Substitute 41713.014 for Re and 0.7228 for Pr.

$$\text{Nu}_{x(\xi=0)} = 0.453(41713.014)^{0.5}(0.7228)^{1/3}$$
$$\text{Nu}_{x(\xi=0)} = 83.03$$

Calculate the Nusselt number for the silicon chip whose edges are flush in substrate.

$$\text{Nu}_x = \frac{\text{Nu}_{x(\xi=0)}}{\left[1-(\xi/x)^{3/4}\right]^{1/3}}$$

Substitute 83.03 for $\text{Nu}_{x(\xi=0)}$, $15\ \text{mm}$ for *x*, and $15\ \text{mm}$ for ξ.

$$\text{Nu}_x = \frac{83.03}{\left[1-\left(\frac{15\times10^{-3}}{0.03}\right)^{3/4}\right]^{1/3}}$$
$$= 112.19$$

Step 3 of 4

Calculate the local heat transfer coefficient.

$$\text{Nu}_x = \frac{h_x x}{k}$$

Rewrite the equation.

$$h_x = \frac{\text{Nu}_x \times k}{x}$$

Substitute 112.19 for Nu_x, $15\ \text{mm}$ for *x*, and $0.02735\ \text{W/m}\cdot\text{K}$ for *k*.

$$h_x = \frac{112.19\times0.02735}{0.03}$$
$$= 102.28\ \text{W/m}^2\cdot\text{K}$$

Step 4 of 4

Consider Newton's law of cooling and calculate the surface temperature.

$$\dot{Q} = h_x A_s (T_s - T_\infty)$$
$$= h_x \times x^2 \times (T_s - T_\infty)$$

Rewrite and solve for T_s.

$$T_s = T_\infty + \frac{\dot{Q}}{h_x x^2}$$

Here, $\dot{Q}$ is the rate of heat transfer and T_∞ is ambient temperature.

Substitute $20°\text{C}$ for T_∞, $1.4\ \text{W}$ for $\dot{Q}$, $102.28\ \text{W/m}^2\cdot\text{K}$ for h_x, and $15\ \text{mm}$ for *x*.

$$T_s = 20 + \frac{1.4}{102.28\times\left(15\times10^{-3}\right)^2}$$
$$= 80.8°\text{C}$$

Thus, the surface temperature at the trailing edge of the chip is $\boxed{T_s = 80.8°\text{C}}$

Question: 19.041P

Air at 1 atm and 20°C is flowing over the top surface of a 0.5-m long thin flat plate. The air stream velocity is 50 m/s and the plate is maintained at a constant surface temperature of 180°C. Determine (*a*) the average convection heat transfer coefficient, and (*b*) repeat part (*a*) using the modified Reynolds analogy.

FIGURE P19-41

Step 1 of 5

Given data:

Pressure of the air, $p = 1$ atm

Temperature of the air, $T_\infty = 20°C$

Length of the plate, $L = 0.5$ m

Velocity of air stream, $V = 50$ m/s

Surface temperature of the plate, $T_s = 180°C$

Step 2 of 5

The film temperature of air,

$$T_f = \frac{(T_s + T_\infty)}{2}$$

$$= \frac{(180 + 20)}{2}$$

$$= 100°C$$

From the table, properties of air at 1 atm pressure

At $T = 100°C$

Thermal conductivity, $k = 0.03095$ W/m·K

Kinematic viscosity, $\nu = 2.306 \times 10^{-5}$ m^2/s

Prandtl number, $Pr = 0.7111$

Step 3 of 5

(a)

The Reynolds number for the flow of the given system,

$$Re_L = \frac{VL}{\nu}$$

$$= \frac{50 \times 0.5}{2.306 \times 10^{-5}}$$

$$= 1084128.36$$

Since the obtained Reynolds number is greater than 5×10^5 ($Re > 5 \times 10^5$), the flow is said to be combined laminar and turbulent.

The average friction coefficient over the entire plate for the combined laminar and turbulent flow,

$$C_f = \frac{0.074}{Re_L^{1/5}} - \frac{1742}{Re_L}$$

$$= \frac{0.074}{(1084128.36)^{1/5}} - \frac{1742}{1084128.36}$$

$$= 2.987 \times 10^{-3}$$

Therefore, the average friction coefficient, $\boxed{C_f = 2.987 \times 10^{-3}}$

Step 4 of 5

(b)

The Nusselt number for the combined flow,

$$Nu_L = \left(0.037 Re_L^{0.8} - 871\right) Pr^{1/3}$$

$$= \left(0.037 \times (1084128.36)^{0.8} - 871\right) \times (0.7111)^{1/3}$$

$$= 1445.4$$

The average convection heat transfer,

$$Nu_L = \frac{hL}{k}$$

$$h = \frac{Nu_L \times k}{L}$$

$$= \frac{1445.4 \times 0.03095}{0.5}$$

$$= 89.47 \text{ W/m}^2 \cdot \text{K}$$

Therefore, the average convection heat transfer coefficient, $\boxed{h = 89.47 \text{ W/m}^2 \cdot \text{K}}$

Step 5 of 5

(c)

The Nusselt number using the modified Reynolds analogy,

$$Nu_L = C_f \frac{Re}{2} Pr^{1/3}$$

$$= 2.987 \times 10^{-3} \times \frac{1084128.36}{2} \times (0.7111)^{1/3}$$

$$= 1445.2$$

The average convection heat transfer coefficient,

$$Nu_L = \frac{hL}{k}$$

$$h = \frac{Nu_L \times k}{L}$$

$$= \frac{1445.2 \times 0.03095}{0.5}$$

$$= 89.46 \text{ W/m}^2 \cdot \text{K}$$

Therefore, the average convection heat transfer coefficient by modified Reynolds analogy, $\boxed{h = 89.46 \text{ W/m}^2 \cdot \text{K}}$

Question: 19.042P

Consider laminar flow of air across a hot circular cylinder. At what point on the cylinder will the heat transfer be highest? What would your answer be if the flow were turbulent?

Step 1 of 1

For laminar flow, the heat transfer coefficient will be the highest at the stagnation point which corresponds to $\theta = 0^\circ$. This answer changes to $\theta = 90^\circ$ to $\theta = 120^\circ$ for turbulent flow.

Question: 19.043P

A heated long cylindrical rod is placed in a cross flow of air at 20°C (1 atm) with velocity of 10 m/s. The rod has a diameter of 5 mm and its surface has an emissivity of 0.95. If the surrounding temperature is 20°C and the heat flux dissipated from the rod is 16000 W/m2, determine the surface temperature of the rod. Evaluate the air properties al 70°C.

Step 1 of 4

Given data:

Temperature of air, $T_\infty = 20°C$

Velocity of air, $V = 10$ m/s

Diameter of the rod, $D = 5$ mm

Surface emissivity of the rod, $\varepsilon = 0.95$

Temperature of the surroundings, $T_{sur} = 20°C$

Heat flux dissipated from the rod, $\dot{q}_s = 16000$ W/m^2

Step 2 of 4

From the table, properties of air at 1 atm pressure

At $T = 70°C$

Thermal conductivity, $k = 0.02881$ W/m·K

Kinematic viscosity, $\nu = 1.995\times10^{-5}$ m^2/s

Prandtl number, Pr = 0.7177

The Reynolds number for the flow,

$$\mathrm{Re} = \frac{VD}{\nu}$$

$$= \frac{10\times\left(5\times10^{-3}\right)}{1.995\times10^{-5}}$$

$$= 2506.26$$

Since the obtained Reynolds number is less than 2×10^5 ($\mathrm{Re} < 2\times10^5$), the flow is said to be laminar.

Step 3 of 4

The average Nusselt number for cross flow over cylinder,

Churchill & Bernstein relation,

$$\mathrm{Nu}_{cyl} = 0.3 + \frac{0.62\mathrm{R}_e^{1/2}\mathrm{P}_r^{1/3}}{\left[1+\left(\frac{0.4}{\mathrm{Pr}}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(2506.26)^{0.5}(0.7177)^{1/3}}{\left[1+\left(\frac{0.4}{0.7177}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{2506.26}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 25.735$$

The convective heat transfer coefficient of air,

$$\mathrm{Nu}_{cyl} = \frac{hD}{k}$$

$$h = \frac{\mathrm{Nu}_{cyl}\times k}{D}$$

$$= \frac{25.735\times0.02881}{\left(5\times10^{-3}\right)}$$

$$= 148.28\ \mathrm{W/m^2\cdot K}$$

Step 4 of 4

The surface temperature of the rod,

$$\dot{q}_s = \dot{q}_{conv} + \dot{q}_{rad}$$

$$16000 = \left[h\left(T_s - T_\infty\right)\right] + \left[\varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]$$

$$16000 = \left[148.28\left(T_s - 20\right)\right] + \left[0.95\times5.67\times10^{-8}\left(\left(T_s + 273\right)^4 - 293^4\right)\right]$$

$$T_s = 121.8°C$$

Therefore the surface temperature of the rod, $\boxed{T_s = 121.8°C}$

Question: 19.044P

A stainless steel ball (ρ = 8055 kg/m3, *cp* = 480 J/kg·K) of diameter *D* =15 cm is removed from the oven at a uniform temperature of 350°C. The ball is then subjected to the flow of air at 1 atm pressure and 30°C with a velocity of 6 m/s. The surface temperature of the ball eventually drops to 250°C. Determine the average convection heat transfer coefficient during this cooling process and estimate how long this process has taken.

Step 1 of 6

Take the properties of air at 1 atm and average film temperature $\frac{(350+250)}{2}=300°C$ from the table A-21, "Ideal gas properties of air" in the textbook.

Thermal conductivity, $k=0.04418\ \text{W/m}\cdot°\text{C}$

Kinematic viscosity, $\upsilon=4.765\times10^{-5}\ \text{m}^2/\text{s}$

Density, $\rho=0.6158\text{kg/m}^3$

Specific heat, $C_p=1044\text{J/kg}\cdot\text{K}$

Dynamic viscosity, $\mu_{@30°C}=1.872\times10^{-5}\ \text{kg/m}\cdot\text{s}$

Dynamic viscosity, $\mu_{s,@300\,°C}=2.934\times10^{-5}\ \text{kg/m}\cdot\text{s}$

Prandtl number, $\text{Pr}=0.6935$

Step 2 of 6

Find the Reynolds number by using the equation as follows:

$$\text{Re}=\frac{VD}{\upsilon}$$

Here, *V* is velocity of air flow, and *D* is diameter of the steel ball.

Substitute 6 m/s for *V* and 0.15 m for *D*.

$$\text{Re}=\frac{6\times0.15}{4.765\times10^{-5}}$$
$$=1.888\times10^{4}$$

Find the Nusselt number by using the equation as follows:

$$\text{Nu}=2+\left[0.4\,\text{Re}^{0.5}+0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

Substitute 1.888×10^{4} for Re, 0.6935 for Pr, 1.872×10^{-5} for μ_∞, and 2.934×10^{-5} for μ_s.

$$\text{Nu}=2+\left[0.4(1.888\times10^{4})^{0.5}+0.06(1.888\times10^{4})^{2/3}\right](0.6935)^{0.4}\left(\frac{1.872\times10^{-5}}{2.934\times10^{-5}}\right)^{1/4}$$
$$=2+[54.96+42.514]0.772$$
$$=77.249$$

Step 3 of 6

Find the heat transfer coefficient by using Nusselt's number value as follows:

$$\text{Nu}=\frac{hD}{k}$$

$$h=\frac{k}{D}\text{Nu}$$
$$=\frac{0.04418}{0.15}\times77.249$$
$$=22.752\ \text{W/m}^2\cdot\text{K}$$

Therefore, heat transfer coefficient during the cooling process is $\boxed{22.752\ \text{W/m}^2\cdot\text{K}}$

Find the average convection heat transfer rate by using the equation as follows:

$$\dot{Q}_{conv}=hA_s(T_s-T_\infty)$$

Here, A_s is the surface area of the steel ball.

Calculate the surface area of the shell as follows:

$$A_s=\pi D^2$$

Substitute 0.15 m for *D*.

$$A_s=\pi(0.15)^2$$
$$=0.07069\ \text{m}^2$$

Substitute $0.07069\ \text{m}^2$ for A_s, 350°C for T_s and 30°C for T_∞.

$$\dot{Q}_{conv}=hA_s(T_s-T_\infty)$$
$$=22.752\times(0.07069)(350\text{-}30)$$
$$=514.668\ \text{W}$$

Step 4 of 6

Find the total heat transfer rate as follows:

$$Q_{total}=mC_{p,ball}(T_1-T_2)$$

Here, m is mass of the ball, T_1 is initial temperature and T_2 is final temperature, and $C_{p,ball}$ is specific heat of steel ball.

Find the mass of steel ball by using the equation.

$$m=\rho V$$
$$=\rho\times\frac{\pi D^3}{6}$$

Substitute 0.15 m for *D*.

$$m=(8055)\frac{\pi(0.15)^3}{6}$$
$$=14.234\,\text{kg}$$

Step 5 of 6

Now find the total heat transfer by substituting 350°C for T_1, 250°C for T_2 and 480 J/kg for $C_{p,ball}$ in the equation,

$$Q_{total}=14.234\times480\times(350-250)$$
$$=683232\,\text{J}$$

Calculate the time of cooling process as follows:

$$\Delta t=\frac{Q_{total}}{\dot{Q}_{conv}}$$
$$=\frac{683232}{514.668}$$
$$=1327.519\,\text{s}$$
$$=22.125\,\text{min}$$

Therefore, the total time taken during the cooling process is $\boxed{22.125\,\text{min}}$.

Step 6 of 6

Question: 19.045P

Reconsider Prob. 19-44. Using EES (or other) software, investigate the effect of air velocity on the average convection heat transfer coefficient and the cooling time. Let the air velocity vary from 1 m/s to 10 m/s. Plot the heat transfer coefficient and the cooling time as a function of air velocity, and discuss the results.

Step 1 of 4

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click table on menu bar, select the new parameter table.

And run the table for now values.

Then click ok.

Now again select the plot command on menu bar .then select the required variables from the list, then click okay.

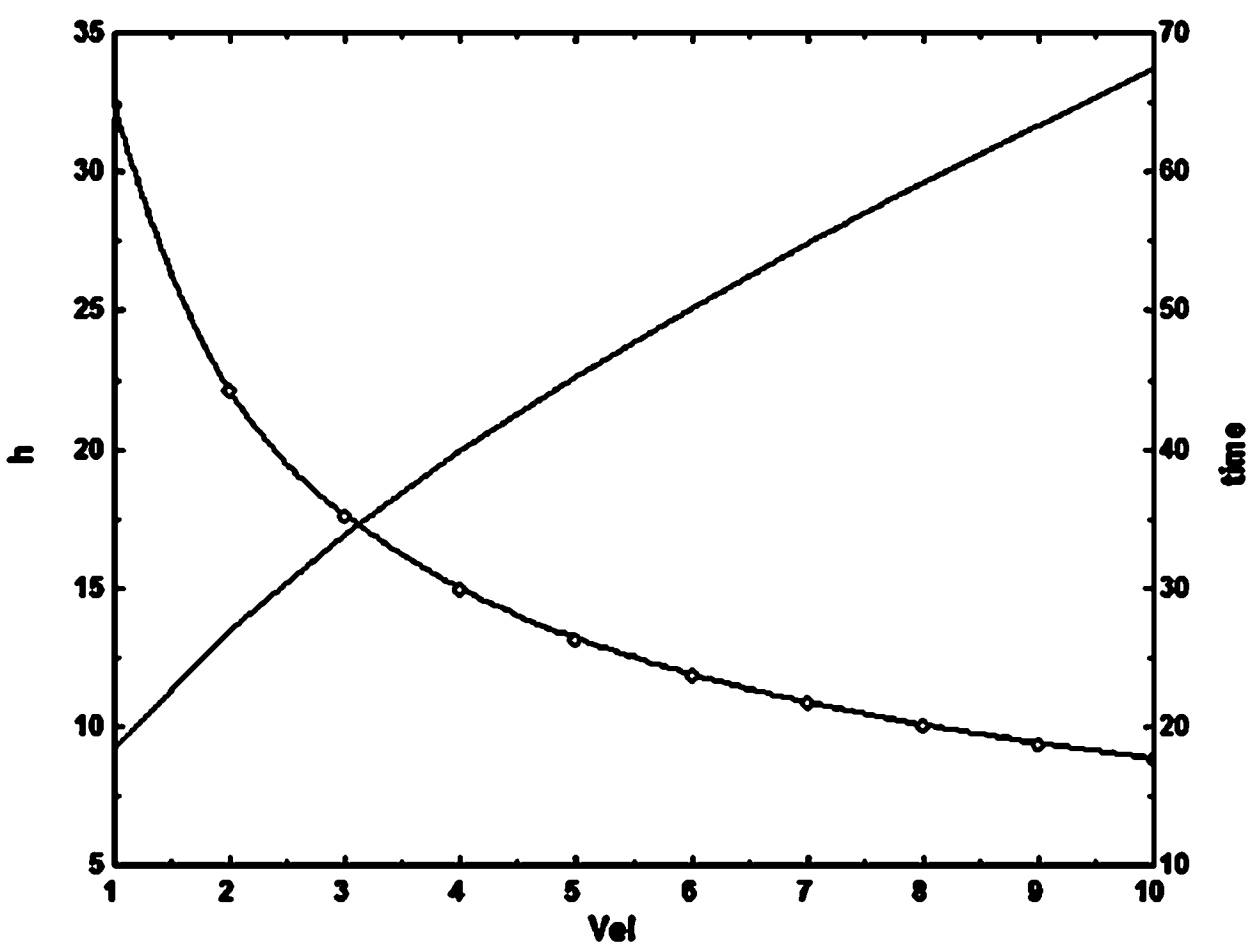
Step 2 of 4

Equation window:

```
"Known"
D=0.15 "[m]"
T_1=350 "[C]"
T_2=250 "[C]"
T_infinity=30 "[C]"
P=101.3 "[kPa]"
"Vel=6 [m/s], parameter to be varied"
rho_ball=8055 "[kg/m^3]"
C_p_ball=480 "[J/kg-C]"

"PROPERTIES"
Fluid$='air'
k=Conductivity(Fluid$, T=T_infinity)
Pr=Prandtl(Fluid$, T=T_infinity)
rho=Density(Fluid$, T=T_infinity, P=P)
mu_infinity=Viscosity(Fluid$, T=T_infinity)
nu=mu_infinity/rho
mu_s=Viscosity(Fluid$, T=T_s_ave)
T_s_ave=1/2*(T_1+T_2)

"ANALYSIS"
Re=(Vel*D)/nu
Nusselt=2+(0.4*Re^0.5+0.06*Re^(2/3))*Pr^0.4*(mu_infinity/mu_s)^0.25
h=k/D*Nusselt
A=pi*D^2
Q_dot_ave=h*A*(T_s_ave-T_infinity)
Q_total=m_ball*C_p_ball*(T_1-T_2)
m_ball=rho_ball*V_ball
V_ball=(pi*D^3)/6
time=Q_total/Q_dot_ave*Convert(s, min)
```



Step 3 of 4

Table of heat transfer coefficient and time as a function of velocity:

1..10	1 Vel	2 time	3 h
Run 1	1	64.87	9.198
Run 2	2	44.23	13.49
Run 3	3	35.23	16.93
Run 4	4	29.94	19.93
Run 5	5	26.37	22.62
Run 6	6	23.77	25.11
Run 7	7	21.76	27.42
Run 8	8	20.15	29.61
Run 9	9	18.83	31.69
Run 10	10	17.72	33.68

Step 4 of 4

Graph between heat transfer coefficient and time as a function of velocity:

Question: 19.046P

A person extends his uncovered arms into the windy air outside at 54°F and 30 mph in order to feel nature closely. Initially, the skin temperature of the arm is 84°F. Treating the arm as a 2-ft-long and 3-in-diameter cylinder, determine the rate of heat loss from the arm.

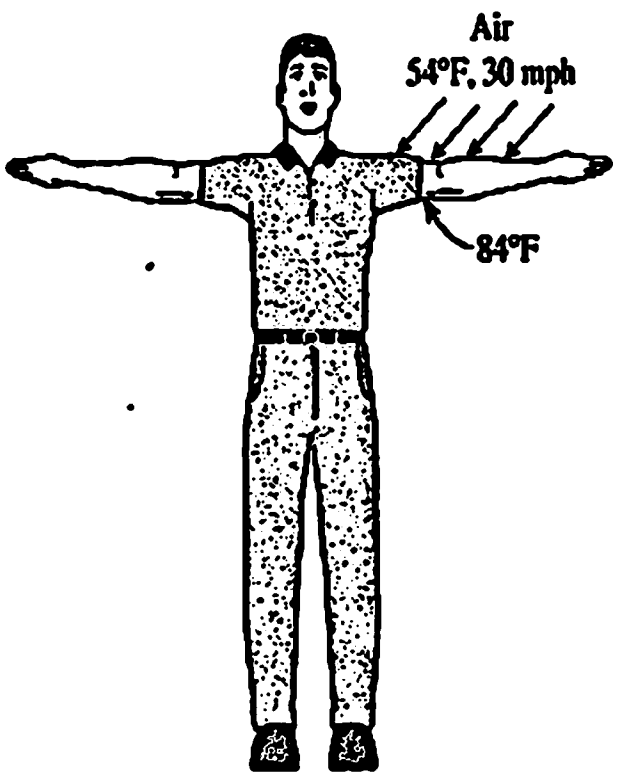


FIGURE P19-46E

Step 1 of 4

Given data:

Temperature of air, $T_\infty = 54°F$

Velocity of air,

$$V = 30\,\text{mph} = \frac{30\times 5280}{3600} = 44\ \text{ft/s}$$

Skin temperature of the arm, $T_s = 84°F$

Diameter of arm, $D = 3\text{in} = 0.25\text{ft}$

Length of the arm, $L = 2\text{ft}$

Step 2 of 4

The film temperature,

$$T_f = \frac{(T_s + T_\infty)}{2} = \frac{(84+54)}{2} = 69°F$$

From the table, properties of air at 1 atm pressure

At $T_f = 69°F$

By linear interpolation

Thermal conductivity,

$$k = 0.01433 + \frac{0.01457 - 0.01433}{(70-60)}(69-60) = 0.014546\ \text{Btu/h}\cdot\text{ft}\cdot\text{R}$$

Kinematic viscosity,

$$\nu = 1.588\times 10^{-4} + \frac{(1.643-1.588)\times 10^{-4}}{(70-60)}(69-60) = 0.73075\ \text{ft}^2/\text{s}$$

Prandtl number,

$$\text{Pr} = 0.7321 + \frac{0.7306 - 0.7321}{(70-60)}(69-60) = 0.73075$$

Step 3 of 4

The Reynolds number for the flow,

$$\text{Re} = \frac{VD}{\nu} = \frac{44\times 0.25}{1.6375\times 10^{-4}} = 67175.57$$

Since the obtained Reynolds number is less than 2×10^5 i.e. $\text{Re} < 2\times 10^5$, the flow is said to be laminar.

The Nusselt number,

$$\text{Nu}_{cyl} = 0.3 + \frac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1+\left(\frac{0.4}{\text{Pr}}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(67175.57)^{0.5}(0.73075)^{1/3}}{\left[1+\left(\frac{0.4}{0.73075}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{67175.57}{282000}\right)^{5/8}\right]^{4/5} = 167.73$$

Step 4 of 4

The convective heat transfer coefficient,

$$\text{Nu}_{cyl} = \frac{hD}{k}$$

$$h = \frac{\text{Nu}_{cyl}\times k}{D} = \frac{167.73\times 0.014546}{0.25} = 9.76\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}$$

The rate of heat loss from the arm,

$$\dot{Q} = hA_s(T_s - T_\infty) = h\times(\pi DL)\times(T_s - T_\infty)$$

$$= 9.76\times(\pi\times 0.25\times 2)\times(84-54) = 459.93\ \text{Btu/h}$$

Therefore the rate of heat loss from the arm, $\boxed{\dot{Q} = 459.93\ \text{Btu/h}}$

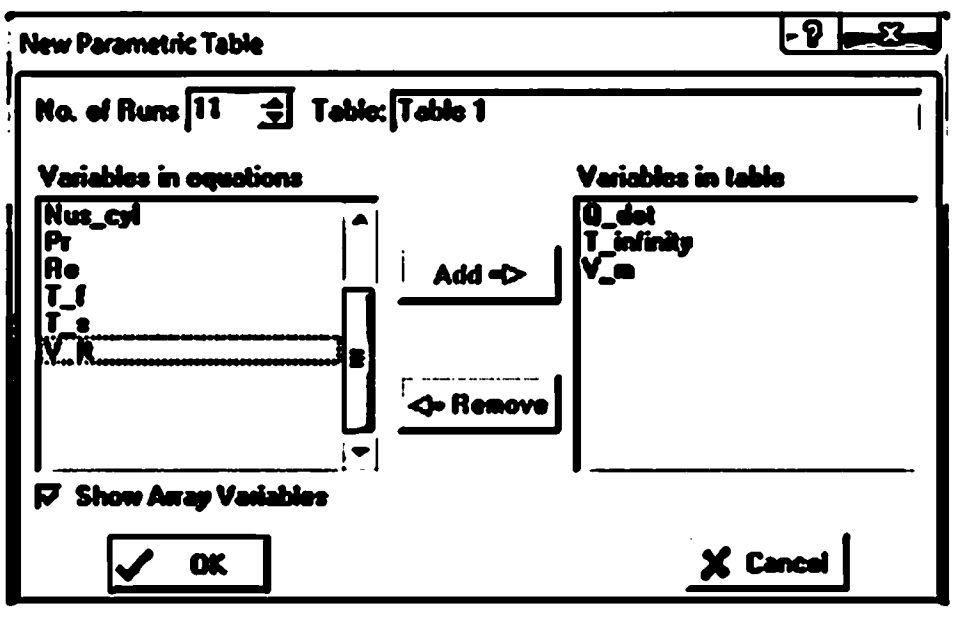
Question: 19.047P pg 1

Reconsider Prob. 19-46E. Using EES (or other) software, investigate the effects of air temperature and wind velocity on the rate of heat loss from the arm. Let the air temperature vary from 20°F to 80°F and the wind velocity from 10 mph to 40 mph. Plot the rate of heat loss as a function of air temperature and of wind velocity, and discuss the results.

Step 1 of 8

The given problem can be solved using EES software by following the below steps.

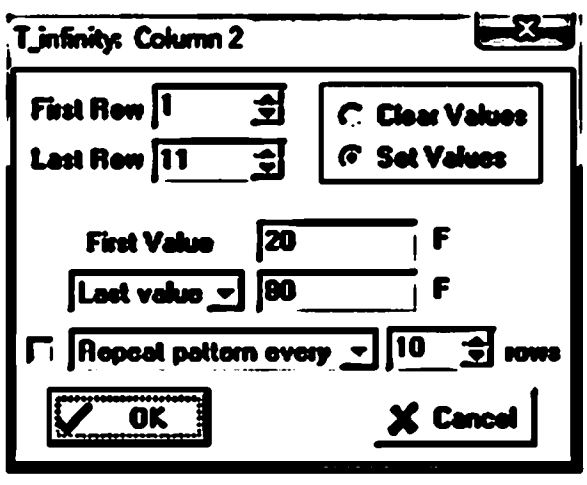
1. **Open EES software**
2. **Create a new file by clicking on the 'New' of the 'File menu'**
3. **Now type the following code in dailog box**



```
"T_infinity is varied from 20[F] to 80[F]"          "Temperature of air"
"V_m=10[mph] to 40[mph]"                            "Velocity of air"
V_ft=V_m*convert(mile/hr,ft/sec)
T_s=84[F]                                           "Temperature of skin"
D=3[in]*convert(in,ft)                              "Diameter of arm"
L=2[ft]                                             "Length of arm"

T_f=(T_s+T_infinity)/2                              "Film temperature"
k=Conductivity(Air,T=T_f)                           "Properties of air at T_f temperature"
nu=Viscosity(Air,T=T_f)/Density(Air,T=T_f,P=1[atm]*convert(atm,psi))*convert(ft^2/hr,ft^2/s)
Pr=Prandtl(Air,T=T_f)
Re=V_ft*D/nu                                        "Reynolds number"
Nus_cyl=0.3+0.62*Re^0.5*Pr^(1/3)/(1+(0.4/Pr)^(2/3))^(1/4)*(1+(re/282000)^(5/8))^(4/5)
Nus_cyl=h*D/k
A_s=pi*D*L
Q_dot=h*A_s*(T_s-T_infinity)
```

Step 2 of 8



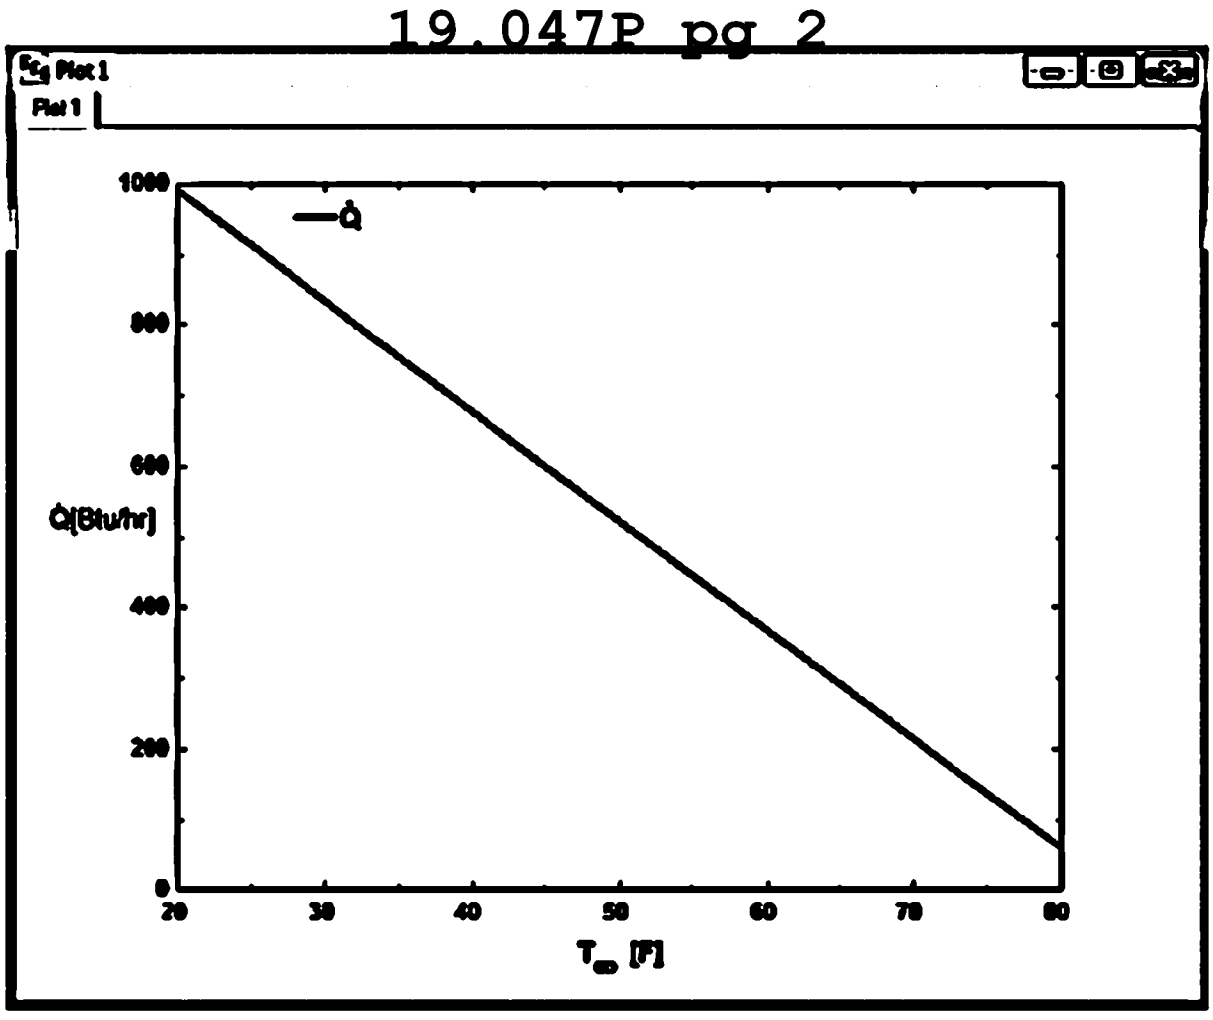
The units are in English system. So, click on "unit system" in "options menu" and change to English system.

Now to solve the equation for a range of air temperatures and range of wind velocities, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "Q_dot", "T_infinity", and "V_m" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 8

First the temperature of air is varied at constant overall constant velocity of air, V = 30 mph
To enter the values in the "T_infinity" column, click on the drop tab in "T_infinity" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 8



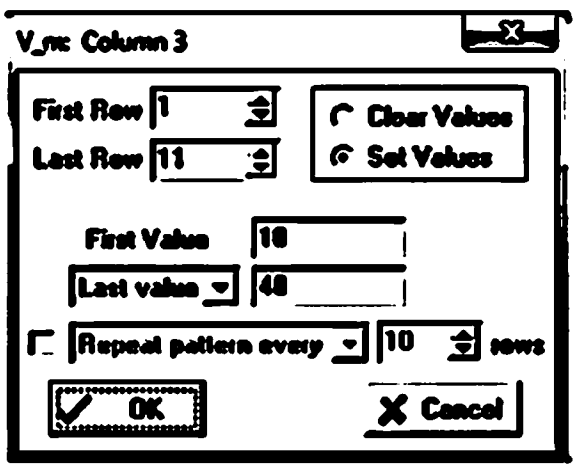
Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	1 $\dot{Q}$	2 T_∞ [F]	3 V_m
Run 1	990.4	20	30
Run 2	896	26	30
Run 3	801.8	32	30
Run 4	708.1	38	30
Run 5	614.6	44	30
Run 6	521.5	50	30
Run 7	428.8	56	30
Run 8	336.3	62	30
Run 9	244.2	68	30
Run 10	152.4	74	30
Run 11	60.85	80	30

Step 5 of 8

Inorder to plot the rate of heat loss as function of temperature of air, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the plot showing the rate of heat loss as function of temperature of air is shown:



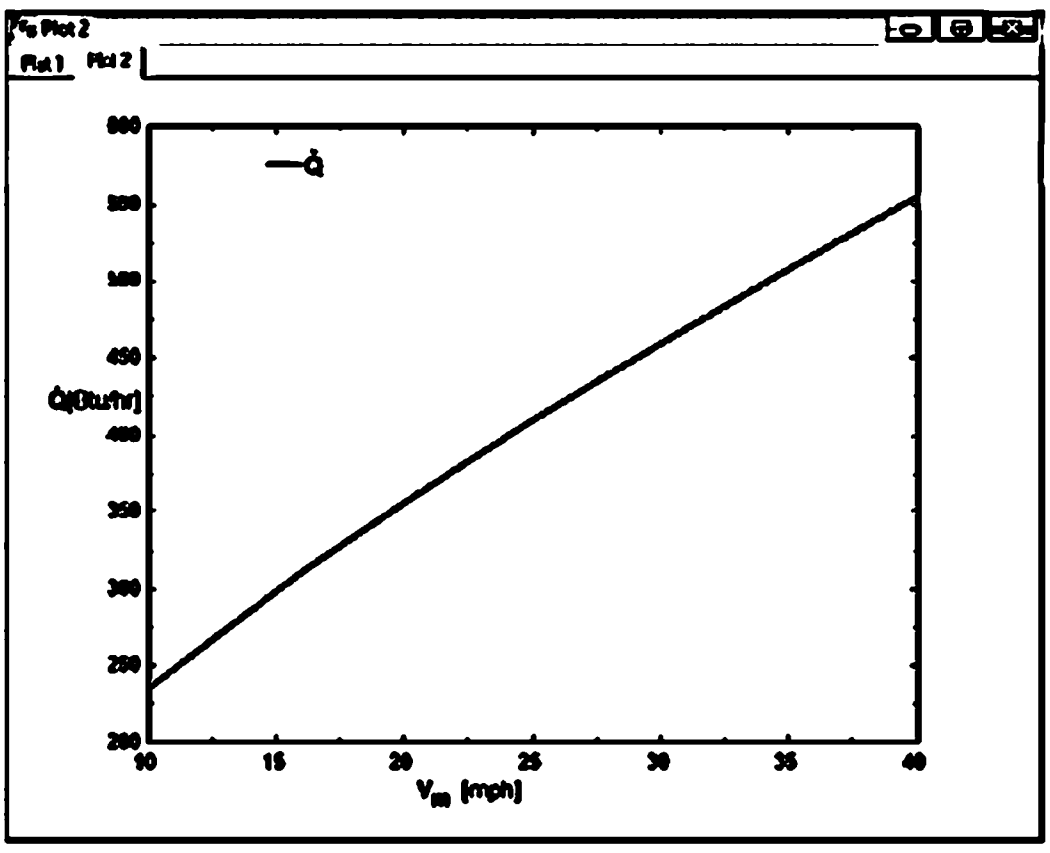
From the above plot we can interpret that as the temperature of air increases, the rate of heat loss decreases.

Step 6 of 8

Now the velocity of air is varied at constant temperature of air, $T_\infty = 54°F$

To enter the values in the "V_m" column, click on the drop tab in "V_m" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 7 of 8



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	1 Q̇	2 T_∞ [F]	3 V_m
Rm 1	234.8	54	10
Rm 2	274	54	13
Rm 3	310.4	54	16
Rm 4	344.8	54	19
Rm 5	377.6	54	22
Rm 6	409.2	54	25
Rm 7	439.8	54	28
Rm 8	469.5	54	31
Rm 9	498.5	54	34
Rm 10	526.9	54	37
Rm 11	554.7	54	40

Step 8 of 8

Inorder to the rate of heat loss as function of velocity of air, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the plot showing the rate of heat loss as function of velocity of air is shown:

From the above plot we can interpret that as the velocity of air increases, the rate of heat loss also increases.

Question: 19.048P

An average person generates heat at a rate of 84 W while resting. Assuming one-quarter of this heat is lost from the head and disregarding radiation, determine the average surface temperature of the head when it is not covered and is subjected to winds at 10°C and 25 km/h. The head can be approximated as a 30-cm-diameter sphere.

Step 1 of 5

From the properties of air table,

At pressure $1\,\text{atm}$ and average film temperature $10°\text{C}$.

The thermal conductivity is $k = 0.02439\ \text{W/m.°C}$

The kinematic viscosity is $\upsilon = 1.426\times10^{-5}\ \text{m}^2/\text{s}$

The dynamic viscosity is $\mu_\infty = 1.778\times10^{-5}\ \text{kg/m.s}$

At $15°\text{C}$

The dynamic viscosity is $\mu_{s,@15°\text{C}} = 1.802\times10^{-5}\ \text{kg/m.s}$

The Prandtl number is $\text{Pr} = 0.7336$

Step 2 of 5

Calculate the Reynolds number,

$$\text{Re} = \frac{VD}{\upsilon}$$

Here,

The velocity of the wind is V

The diameter of the sphere is D

Substitute $6.94\,\text{m/s}$ for V, $0.3\,\text{m}$ for D and $1.426\times10^{-5}\ \text{m}^2/\text{s}$ for υ

$$\begin{aligned}\text{Re} &= \frac{VD}{\upsilon}\\ &= \frac{(6.94\,\text{m/s})(0.3\,\text{m})}{1.426\times10^{-5}\ \text{m}^2/\text{s}}\\ &= 1.461\times10^5\end{aligned}$$

Step 3 of 5

Calculate the Nusselt number,

$$Nu = 2+\left[0.4\,\text{Re}^{0.5}+0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

Substitute 1.461 for Re, 0.7336 for Pr, $1.778\times10^{-5}\ \text{kg/m}\cdot\text{s}$ for μ_∞ and

$1.802\times10^{-5}\ \text{kg/m.s}$ for $\mu_{s,@15°\text{C}}$

$$\begin{aligned}Nu &= 2+\left[0.4\,\text{Re}^{0.5}+0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}\\ &= 2+\left[0.4(1.461\times10^5)^{0.5}+0.06(1.461\times10^4)^{2/3}\right](0.7336)^{0.4}\left(\frac{1.778\times10^{-5}}{1.802\times10^{-5}}\right)^{1/4}\\ &= 283.2\end{aligned}$$

Calculate the Coefficient for heat transfer,

$$h = \left(\frac{k}{D}\right)Nu$$

Substitute $0.02439\ \text{W/m}\cdot°\text{C}$ for k, $0.3\,\text{m}$ for D and 283.2 for Nu

$$\begin{aligned}h &= \left(\frac{k}{D}\right)Nu\\ &= \left(\frac{0.02439\ \text{W/m.°C}}{0.3\,\text{m}}\right)283.2\\ &= 23.02\ \text{W/m}^2\cdot°\text{C}\end{aligned}$$

Step 4 of 5

Calculate the Surface temperature of the head,

$$T_s = T_\infty + \frac{\dot{Q}}{hA_s} \quad \text{..... (1)}$$

Here,

The heat generated by the average person is $\dot{Q}$

The surface area of the head is A_s

Find the surface area of the head,

$$A_s = \pi D^2$$

Substitute $0.3\,\text{m}$ for D,

$$\begin{aligned}A_s &= \pi D^2\\ &= \pi(0.3\,\text{m})^2\\ &= 0.2827\ \text{m}^2\end{aligned}$$

Step 5 of 5

Substitute $23.02\ \text{W/m}^2\cdot°\text{C}$ for h, $0.2827\ \text{m}^2$ for A_s and $84\,\text{W}$ for $\dot{Q}$ in equation (1)

$$\begin{aligned}T_s &= T_\infty + \frac{\dot{Q}}{hA_s}\\ &= 10\ °\text{C}+\left(\frac{(84/4)}{(23.02\ \text{W/m}^2.°\text{C})(0.2827\ \text{m}^2)}\right)\\ &= 13.2\ °\text{C}\end{aligned}$$

Therefore, the average surface temperature of the person is $\boxed{13.2\ °\text{C}}$

Question: 19.049P

A long 12-cm-diameter steam pipe whose external surface temperature is 90°C passes through some open area that is not protected against the winds. Determine the rate of heat loss from the pipe per unit of its length when the air is at 1 atm pressure and 7°C and the wind is blowing across the pipe at a velocity of 65 km/h.

Step 1 of 4

Given data:

Diameter of the pipe, $D = 12\,\text{cm}$

Surface temperature of the pipe, $T_s = 90°\text{C}$

Temperature of the air, $T_\infty = 7°\text{C}$

Pressure of the air, $p = 1\,\text{atm}$

Wind flow velocity,

$$V = 65\,\text{km/h} = \frac{65\times 1000}{3600}$$

$$V = 18.06\,\text{m/s}$$

Step 2 of 4

The film temperature,

$$T_f = \frac{(T_s + T_\infty)}{2} = \frac{(90+7)}{2} = 48.5°\text{C}$$

From the table, properties of air at 1 atm pressure

At $T_f = 48.5°\text{C}$

By linear interpolation

Thermal conductivity,

$$k = 0.02699 + \frac{0.02735 - 0.02699}{50-45}(48.5-45) = 0.027242\,\text{W/m}\cdot\text{K}$$

Kinematic viscosity,

$$\nu = 1.750\times 10^{-5} + \frac{(1.798-1.750)10^{-5}}{(50-45)}(48.5-45) = 1.7836\times 10^{-5}\,\text{m}^2/\text{s}$$

Prandtl number,

$$\text{Pr} = 0.7241 + \frac{0.7228-0.7241}{(50-45)}(48.5-45) = 0.72319$$

Step 3 of 4

The Reynolds number for the flow,

$$\text{Re} = \frac{VD}{\nu} = \frac{18.06\times\left(12\times 10^{-2}\right)}{1.7836\times 10^{-5}} = 121507.06$$

Since the obtained Reynolds number is less than 2×10^5 i.e. $\text{Re} < 2\times 10^5$, the flow is said to be laminar.

The Nusselt number,

$$\text{Nu}_{cyl} = 0.3 + \frac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1+\left(\frac{0.4}{\text{Pr}}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(121507.06)^{0.5}(0.72319)^{1/3}}{\left[1+\left(\frac{0.4}{0.72319}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{121507.06}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 247.56$$

Step 4 of 4

The convective heat transfer coefficient,

$$\text{Nu}_{cyl} = \frac{hD}{k}$$

$$h = \frac{\text{Nu}_{cyl}\times k}{D} = \frac{247.56\times 0.027242}{\left(12\times 10^{-2}\right)} = 56.2\,\text{W/m}^2\cdot\text{K}$$

The rate of heat loss from the pipe per unit length,

$$\dot{Q} = hA_s(T_s - T_\infty) = h\times(\pi DL)\times(T_s - T_\infty)$$

$$= 56.2\times\left(\pi\times 12\times 10^{-2}\times 1\right)\times(90-7) = 1758.5\,\text{W/m}$$

Therefore the rate of heat loss from the pipe per unit length, $\boxed{\dot{Q} = 1758.5\,\text{W/m}}$

Question: 19.050P

In a geothermal power plant, the used geothermal water at 80°C enters a 15-cm-diameter and 400-m-long uninsulated pipe at a rate of 8.5 kg/s and leaves at 70°C before being reinjected back to the ground. Windy air at 15°C flows normal to the pipe. Disregarding radiation, determine the average wind velocity in km/h.

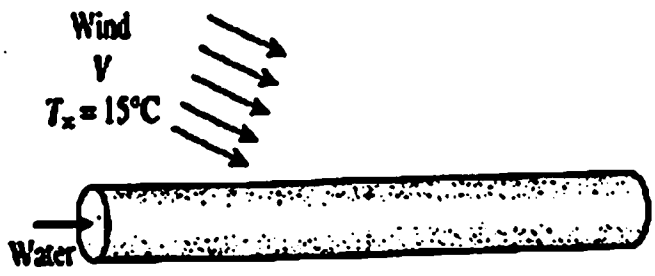


FIGURE P19-50

Step 1 of 4

Calculate the film temperature.

$$T_f = \frac{\frac{(70+80)}{2}+15}{2}$$
$$= 45°C$$

Obtain the properties of air at 1 atm and average film temperature $45°C$ from properties of air table.

Thermal conductivity is, $k = 0.02699\ W/m°C$

Kinematic viscosity is, $\upsilon = 1.75\times10^{-5}\ m^2/s$

Prandtl number is, $Pr = 0.7241$

Obtain the Specific heat of water at average temperature of water $75°C$ is $C_p = 4193\ J/kg°C$

Step 2 of 4

Energy change from inlet to outlet gives rate of heat transfer from pipe

$$\dot{Q} = \dot{m}C_p(\Delta T)$$
$$= (8.5)(4193\times(80\text{-}70))$$
$$\dot{Q} = 356{,}405\ W$$

Calculate the coefficient of heat transfer by using the following relation:

$$h = \frac{\dot{Q}}{A_s(T_s - T_\infty)}$$
$$= \frac{356{,}150W}{\pi(0.15\ m)(400m)(75-15)°C}$$
$$h = 31.51 W/m^2\,°C$$

Step 3 of 4

Calculate the Nusselt number by using the following relation:

$$Nu = \frac{hD}{k}$$
$$= \frac{(31.51W/m^2\,°C)(0.15m)}{0.02699W/m°C}$$
$$Nu = 175.13$$

Calculate the Reynolds number from Nusselt number equation.

$$Nu = 0.3 + \frac{0.62\,Re^{0.5}\,Pr^{1/3}}{\left[1+\left(\frac{0.4}{Pr}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$175.13 = 0.3 + \frac{0.62(Re)^{0.5}\times(0.7241)^{1/3}}{\left[1+\left(\frac{0.4}{0.7241}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$175.13 = 0.3 + 0.4895(Re)^{0.5}\left(\frac{2549.21+Re^{5/8}}{2549.21}\right)^{4/5}$$

$$Re = 71{,}900$$

Step 4 of 4

Calculate the velocity of wind.

$$Re = \frac{VD}{\upsilon}$$
$$71{,}900 = \frac{V(0.15m)}{1.726\times10^{-5}\ m^2/s}$$
$$V = 8.273\ m/s\times\frac{18}{5}$$
$$V = 29.783\ kmph$$

Therefore the wind velocity is, $\boxed{V = 29.783\ kmph}$.

Question: 19.051P

A 5-mm-diameter electrical transmission line carries an electric current of 50 A and has a resistance of 0.002 ohm per meter length. Determine the surface temperature of the wire during a windy day when the air temperature is 10°C and the wind is blowing across the transmission line at 50 km/h.

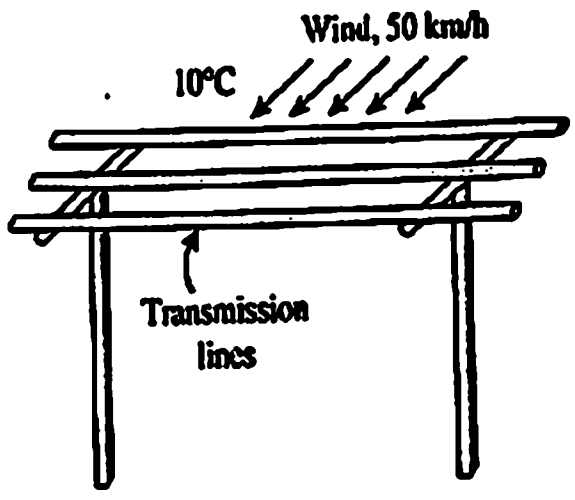

FIGURE P19-51

Step 1 of 5

Given data:

Diameter of transmission line, $D = 5\,\text{mm}$

Electrical current, $I = 50\,\text{A}$

Resistance of the transmission line per meter length, $R = 0.002\ \Omega/\text{m}$

Temperature of the air, $T_\infty = 10°\text{C}$

Air flow velocity,

$$V = 50\ \text{km/h} = \frac{50\times1000}{3600} = 13.89\ \text{m/s}$$

Step 2 of 5

The film temperature of air is assumed as $T_f = 10°\text{C}$

From the table, properties of air at 1 atm

At $T_f = 10°\text{C}$

Thermal conductivity, $k = 0.02439\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.426\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7336$

The Reynolds number for the flow,

$$\text{Re} = \frac{VD}{\nu} = \frac{13.89\times\left(5\times10^{-3}\right)}{1.426\times10^{-5}} = 4870.26$$

Since the obtained Reynolds number is less than 2×10^5 ($\text{Re} < 2\times10^5$), the flow is said to be laminar.

Step 3 of 5

The Nusselt number,

$$\text{Nu}_{cyl} = 0.3+\frac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1+\left(\frac{0.4}{\text{Pr}}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3+\frac{0.62(4870.26)^{0.5}(0.7336)^{1/3}}{\left[1+\left(\frac{0.4}{0.7336}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{4870.26}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 36.8$$

Step 4 of 5

The convective heat transfer coefficient,

$$\text{Nu}_{cyl} = \frac{hD}{k}$$

$$h = \frac{\text{Nu}_{cyl}\times k}{D} = \frac{36.8\times0.02439}{\left(5\times10^{-3}\right)} = 179.5\ \text{W/m}^2\cdot\text{K}$$

The rate of heat generation in the transmission line per unit length,

$$\dot{Q} = I^2R = 50^2\times0.002 = 5\ \text{W/m}$$

Step 5 of 5

The surface temperature of the wire,

$$\dot{Q} = hA_s\left(T_s - T_\infty\right)$$

$$T_s = T_\infty + \frac{\dot{Q}}{hA_s} = T_\infty + \frac{\dot{Q}}{h\times(\pi DL)} = 10+\frac{5}{179.5\times\left(\pi\times5\times10^{-3}\times1\right)} = 11.8°\text{C}$$

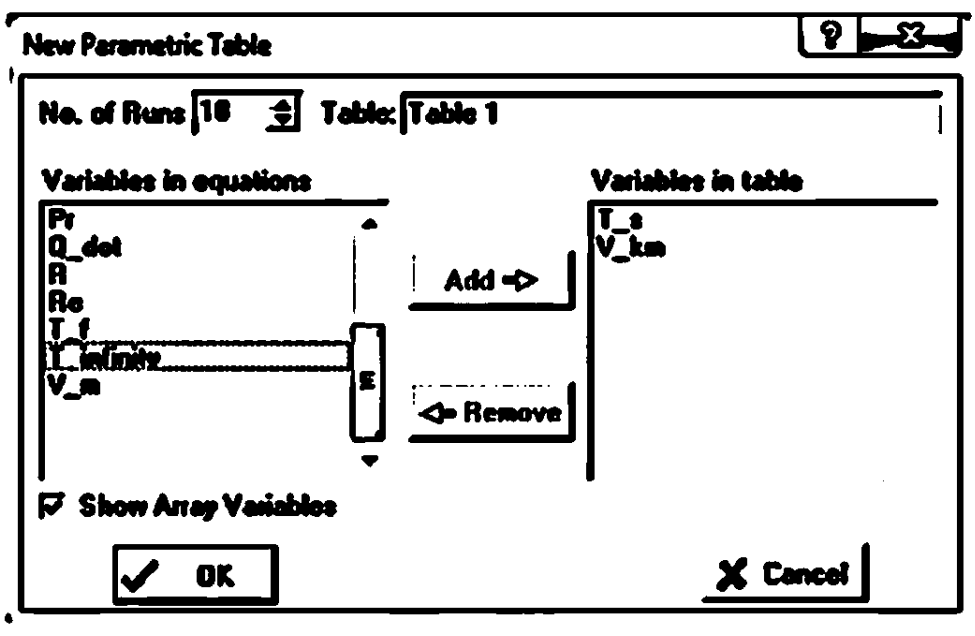
Therefore the surface temperature of the wire, $\boxed{T_s = 11.8°\text{C}}$

Question: 19.052P

Reconsider Prob. 19-51. Using EES (or other) software, investigate the effect of the wind velocity on the surface temperature of the wire. Let the wind velocity vary from 10 km/h to 80 km/h. Plot the surface temperature as a function of wind velocity, and discuss the results.

Step 1 of 5

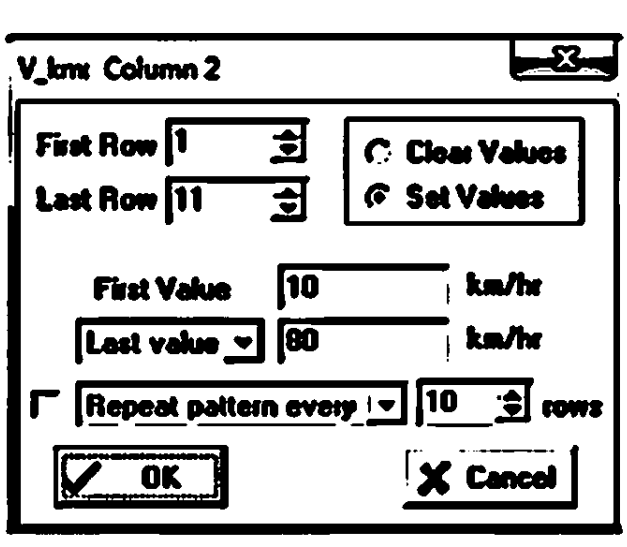
The given problem can be solved using EES software by following the below steps.



1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
D=5[mm]*convert(mm,m)                          "Diameter of wire"
I=50[Amp]                                      "Electric Current"
R=0.002[ohm]                                   "Resistance of wire"
T_infinity=10[C]                               "Temperature of air"
"V_km is varied from 10[km/hr] to 80[km/hr]"   "Velocity of air"
L=1[m]

T_f=(T_s+T_infinity)/2
V_m=V_km*convert(km/hr,m/s)
k=Conductivity(Air,T=T_f)                      "Properties of air at T_f temperature"
nu=Viscosity(Air,T=T_f)/Density(Air,T=T_f,P=1[atm]*convert(atm,kPa))
Pr=Prandtl(Air,T=T_f)
Re=V_m*D/nu                                    "Reynolds number"
Nus_cyl=0.3+0.62*Re^0.5*Pr^(1/3)/(1+(0.4/Pr)^(2/3))^(1/4)*(1+(re/282000)^(5/8))^(4/5)
Nus_cyl=h*D/k
Q_dot=I^2*R
A_s=pi*D*L
Q_dot=h*A_s*(T_s-T_infinity)
```



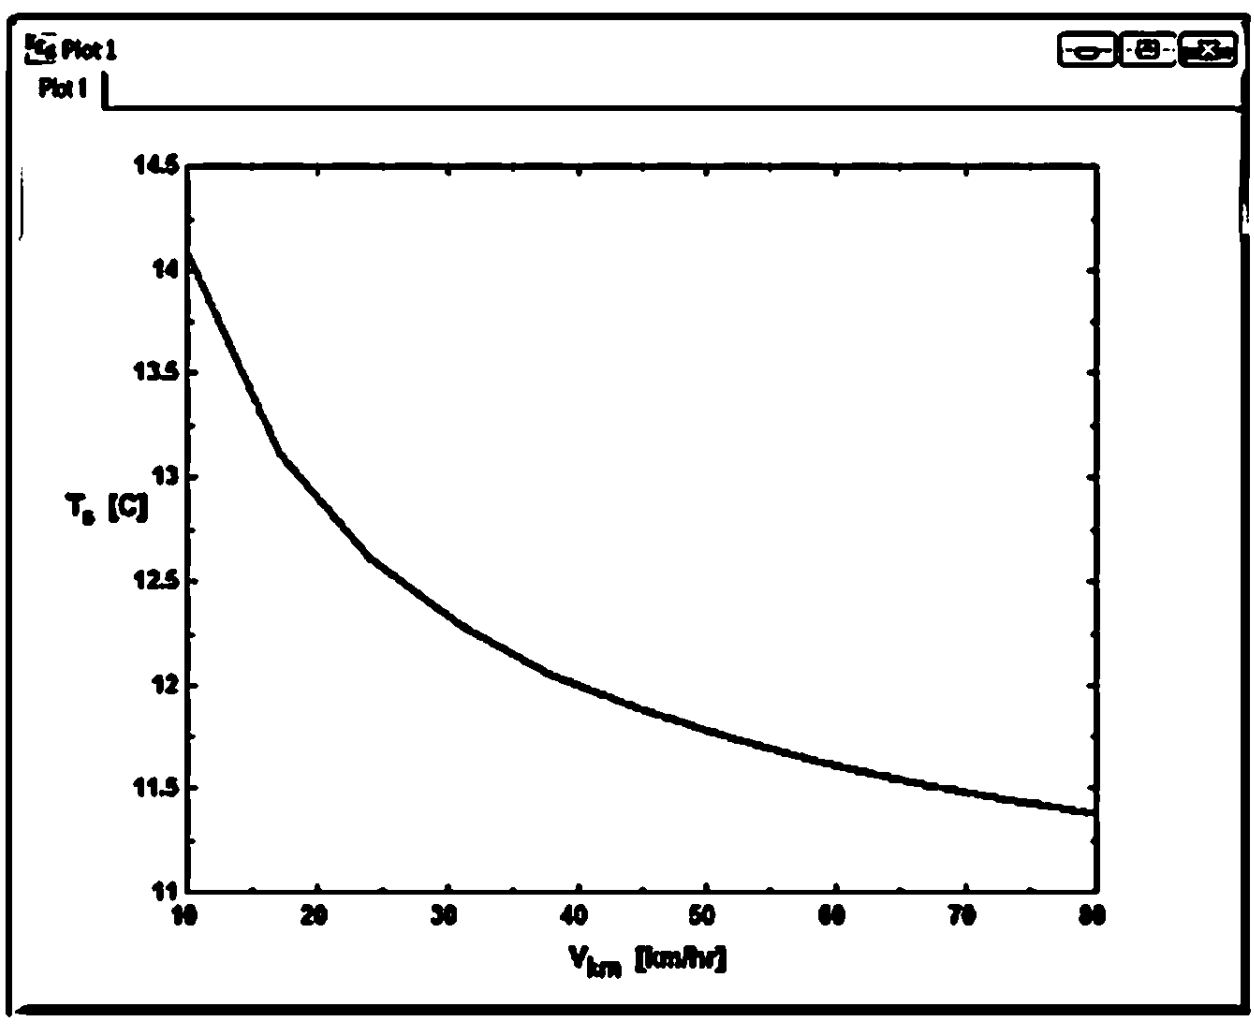
Step 2 of 5

Now to solve the equation for a range of velocity of air, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "T_s" and "V_km" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 5

The velocity of the air is varied from 10 km/hr to 80 km/hr
To enter the values in the "V_km" column, click on the drop tab in "V_km" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 5



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	T_s [C]	V_{km} [km/hr]
Run 1	14.08	10
Run 2	13.12	17
Run 3	12.61	24
Run 4	12.28	31
Run 5	12.05	38
Run 6	11.88	45
Run 7	11.74	52
Run 8	11.63	59
Run 9	11.53	66
Run 10	11.45	73
Run 11	11.38	80

Step 5 of 5

To plot surface temperature of transmission line as function of velocity of air, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the plot surface temperature of transmission line as function of velocity of air is shown:

From the above plot we can interpret that as velocity of air increases the temperature of transmission line decreases.

Question: 19.053P

A heating system is to be designed to keep the wings of an aircraft cruising al a velocity of 900 km/h above freezing temperatures during flight at 12,200-m altitude where the standard atmospheric conditions are -55.4T and 18.8 kPa. Approximating the wing as a cylinder of elliptical cross section whose minor axis is 50 cm and disregarding radiation, determine the average convection heat transfer coefficient on the wing surface and the average rate of heat transfer per unit surface area.

Step 1 of 4

Take the freezing temperature is $T_s = 0°C$

Now calculate the average film temperature by using the expression,

$$T_{avg} = \frac{T_s + T_\infty}{2}$$

Here, T_∞ is atmospheric temperature

Substitute $-55.4°C$ for T_∞

$$T_{avg} = \frac{0-55.4}{2}$$
$$= -27.7°C$$

Obtain the properties of air at 1 atm and film temperature $T_{avg} = -27.7°C$ from "properties of air table"

Thermal conductivity

$$k = 0.02134 + (0.02211 - 0.02134)\left(\frac{-27.7-(-30)}{-20-(-30)}\right)$$
$$= 0.02152\ W/m°C$$

Kinematic viscosity

$$v = 1.087\times10^{-5} + (1.169\times10^{-5} - 1.087\times10^{-5})\left(\frac{-27.7-(-30)}{-20-(-30)}\right)$$
$$= 1.1058\times10^{-5}\ m^2/s$$

Prandtl number

$$Pr = 0.7425 + (0.7408 - 0.7425)\left(\frac{-27.7-(-30)}{-20-(-30)}\right)$$
$$= 0.7422$$

Step 2 of 4

Kinematic viscosity will be affected by change in atmospheric pressure. Convert atmospheric pressure in atm unit

$$P = (18.8\ kPa)\frac{1\ atm}{101.325\ kPa}$$
$$= 0.1855\ atm$$

Kinematic viscosity depends on pressure. Find the viscosity at this pressure by using the expression,

$$v = \frac{v_{@1atm}}{0.1855}$$
$$= \frac{(1.1058\times10^{-5})}{0.1855}$$
$$= 5.961\times10^{-5}\ m^2/s$$

Step 3 of 4

Find the Reynolds number by using the equation,

$$Re = \frac{VD}{v}$$

Here, V is velocity of air, D is diameter of the cylinder

Substitute $\left(900\ km/h = 900\times\frac{1000}{3600}\ m/s\right)$ for V and 0.5 m for D

$$Re = \frac{\left[900\times\frac{1000}{3600}\right](0.5)}{5.961\times10^{-5}}$$
$$= 2.096\times10^{6}$$

Assume the Nusselt number relation by using the below equation and find the Nusselt number,

$$Nu = 0.248\,Re^{0.612}\,Pr^{1/3}$$
$$= 0.248\times(2.096\times10^{6})^{0.612}\times0.7422^{1/3}$$
$$= 1659.54$$

Step 4 of 4

Now find the heat transfer coefficient for wing surface

$$Nu = \frac{hD}{k}$$

$$h = \frac{k}{D}Nu$$

$$h = \frac{0.02152}{0.5}\times1659.54$$
$$= 71.42\ W/m^2\cdot K$$

Now find the heat transfer rate per unit surface area by using the equation,

$$\dot{q} = h(T_s - T_\infty)$$
$$= 71.42\times(0-(-55.4))$$
$$= 3956.668\ W/m^2$$

Therefore, heat transfer per unit area is $\boxed{3956.668\ W/m^2}$

Question: 19.054P

A long aluminum wire of diameter 3 mm is extruded at a temperature of 280°C. The wire is subjected to cross air flow at 20°C at a velocity of 6 m/s. Determine the rate of heat transfer from the wire to the air per meter length when it is first exposed to the air.

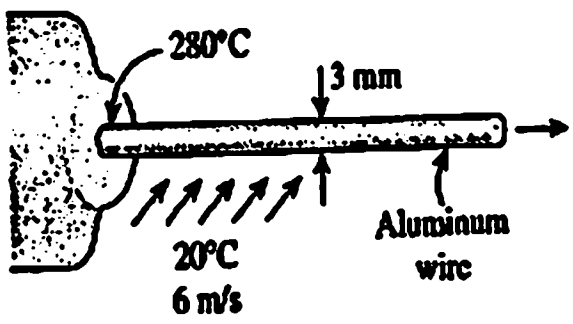


FIGURE P19-54

Step 1 of 4

Given data:

Diameter of aluminum wire, $D = 3\text{mm}$

Temperature of aluminum wire, $T_s = 280°\text{C}$

Temperature of air, $T_\infty = 20°\text{C}$

Velocity of air flow, $V = 6\ \text{m/s}$

Step 2 of 4

The film temperature,

$$T_f = \frac{(T_s + T_\infty)}{2}$$

$$= \frac{(280+20)}{2}$$

$$= 150°\text{C}$$

From the table, properties of air at 1 atm pressure

At $T_f = 150°\text{C}$

Thermal conductivity,

$$k = \frac{0.03374+0.03511}{2}$$

$$= 0.034425\ \text{W/m}\cdot\text{K}$$

Kinematic viscosity,

$$\nu = \frac{(2.745+2.975)\times10^{-5}}{2}$$

$$= 2.86\times10^{-5}\ \text{m}^2/\text{s}$$

Prandtl number,

$$\text{Pr} = \frac{0.7041+0.7014}{2}$$

$$= 0.70275$$

Step 3 of 4

The Reynolds number for the flow,

$$\text{Re} = \frac{VD}{\nu}$$

$$= \frac{6\times\left(3\times10^{-3}\right)}{2.86\times10^{-5}}$$

$$= 629.37$$

Since the obtained Reynolds number is less than 2×10^5 ($\text{Re} < 2\times10^5$), the flow is said to be laminar.

The Nusselt number is determined from the relation given by

$$\text{Nu}_{cyl} = 0.3 + \frac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1+\left(\frac{0.4}{\text{Pr}}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(629.37)^{0.5}(0.70275)^{1/3}}{\left[1+\left(\frac{0.4}{0.70275}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{629.37}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 12.65$$

Step 4 of 4

The convective heat transfer coefficient,

$$\text{Nu}_{cyl} = \frac{hD}{k}$$

Rewrite and solve for h:

$$h = \frac{\text{Nu}_{cyl}\times k}{D}$$

$$= \frac{12.65\times0.034425}{\left(3\times10^{-3}\right)}$$

$$= 145.16\ \text{W/m}^2\cdot\text{K}$$

The rate of heat transfer from the wire to the air per meter length is determined from the equation given by

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$= h\times(\pi DL)\times(T_s - T_\infty)$$

$$= 145.16\times\left(\pi\times3\times10^{-3}\times1\right)\times(280-20)$$

$$= 355.7\ \text{W/m}$$

Therefore the rate of heat transfer from the wire to the air per meter length,

$$\boxed{\dot{Q} = 355.7\ \text{W/m}}$$

Question: 19.055P

An incandescent lightbulb is an inexpensive but 1 highly inefficient device that converts electrical energy into light. It converts about 10 percent of the electrical energy it consumes into light while converting the remaining 90 percent into heat. (A fluorescent lightbulb will give the same amount of light while consuming only one-fourth of the electrical energy, and it will last 10 times longer than an incandescent lightbulb.) The glass bulb of the lamp heats up very quickly as a result of absorbing all that heat and dissipating it to the surroundings by convection and radiation.

Consider a 10-cm-diameter 100-W lightbulb cooled by a fan that blows air at 30°C to the bulb at a velocity of 2 m/s. The surrounding surfaces are also at 30°C, and the emissivity of the glass is 0.9. Assuming 10 percent of the energy passes through the glass bulb as light with negligible absorption and the rest of the energy is absorbed and dissipated by the bulb itself, determine the equilibrium temperature of the glass bulb,

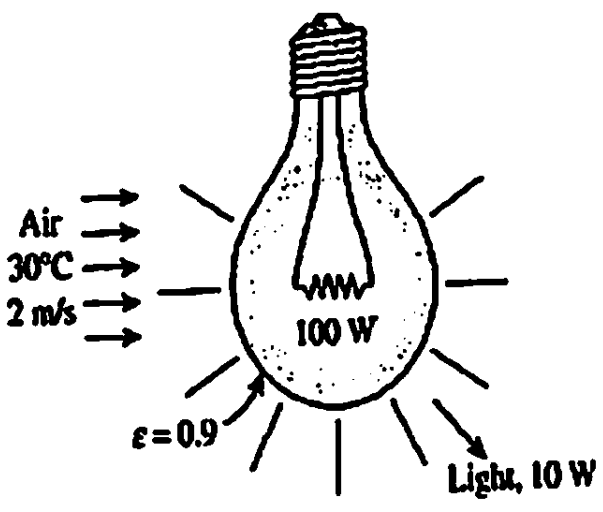

FIGURE P19-55

Step 1 of 5

Obtain the Properties of air at 1 atm. and 30C from the table A-22 "ideal gas properties of air at 1 atm. Pressure".

Thermal conductivity, $k = 0.02588\ \text{W/m.°C}$

Kinematic viscosity, $\upsilon = 1.608\times10^{-5}\ \text{m}^2/\text{s}$

Dynamic viscosity at ambient air temperature, $\mu_\infty = 1.872\times10^{-5}\ \text{kg/m.s}$

Prandtil number, $\text{Pr} = 0.7282$

Step 2 of 5

Calculate the Reynolds number.

$$\text{Re} = \frac{VD}{\upsilon}$$

Here, D is the diameter of the bulb.

Substitute $2\ \text{m/s}$ for V, $1.608\times10^{-5}\ \text{m}^2/\text{s}$ for v and 0.1 m for D.

$$\text{Re} = \frac{(2\ \text{m/s})(0.1\ \text{m})}{1.608\times10^{-5}\ \text{m}^2/\text{s}}$$
$$= 1.244\times10^4$$

Step 3 of 5

Calculate the Nusselt number using the relation,

$$Nu = 2 + \left[0.4\,\text{Re}^{0.5} + 0.06\,\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

Here, μ_s is the dynamic viscosity of air at the surface temperature of the bulb.

As the surface temperature of the bulb is not known, assume a surface temperature of $100°\text{C}$ to proceed with the calculations.

Obtain the Properties of air at 1 atm. and 30C from the table A-22 "ideal gas properties of air at 1 atm. Pressure".

Dynamic viscosity at surface temperature, $\mu_{s,\text{at }100°\text{C}} = 2.181\times10^{-5}\ \text{kg/m}\cdot\text{s}$

Substitute 1.244×10^4 for Re, 0.7282 for Pr, $1.872\times10^{-5}\ \text{kg/m}\cdot\text{s}$ for μ_∞ and $2.181\times10^{-5}\ \text{kg/m}\cdot\text{s}$ for $\mu_{s,\text{at }100°\text{C}}$.

$$Nu = 2 + \left[0.4(1.244\times10^4)^{0.5} + 0.06(1.244\times10^4)^{2/3}\right](0.7282)^{0.4}\left(\frac{1.872\times10^{-5}}{2.181\times10^{-5}}\right)^{1/4}$$

$$Nu = 67.14$$

Step 4 of 5

Calculate the heat transfer coefficient using the relation,

$$Nu = \frac{hD}{k}$$
$$h = \frac{k}{D}Nu$$

Substitute $0.02588\ \text{W/m.°C}$ for k, 0.1 m for D and 67.14 for Nu.

$$h = \frac{0.02588\ \text{W/m.°C}}{0.1\ \text{m}}(67.14)$$
$$= 17.37\ \text{W/m}^2\cdot\text{°C}$$

Calculate the amount of heat generated from the bulb.

$$\dot{Q}_{lost} = 0.9\times100\ \text{W}$$
$$= 90\ \text{W}$$

Calculate the surface area of the bulb.

$$A_s = \pi D^2$$

Substitute 0.1 m for D.

$$A_s = \pi D^2$$
$$= \pi(0.1\ \text{m})^2$$
$$= 0.0314\ \text{m}^2$$

Step 5 of 5

Calculate the surface temperature by applying heat balance to the bulb.

$$\dot{Q}_{lost} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$\dot{Q}_{lost} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^4 - T_{surr}^4)$$

Here, T_s is surface temperature of bulb, T_∞ is ambient temperature, ε is the emissivity and σ is the Stefan-Boltzmann constant.

Substitute 90 W for $\dot{Q}_{lost}$, $17.37\ \text{W/m}^2\cdot\text{°C}$ for h, 0.9 for ε and $5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4$ for σ, and $30°\text{C}$ for T_s.

$$90 = (17.37\times0.0314)\left[T_s - (30+273)\right] + \left(0.9\times0.0314\times5.67\times10^{-8}\right)\left[T_s^4 - (30+273)^4\right]$$
$$90 = (0.54542)\left[T_s - 303\right] + \left(1.6023\times10^{-9}\right)\left[T_s^4 - (303)^4\right]$$
$$T_s = 409.9\ \text{K}$$
$$T_s = 409.9 - 273$$
$$T_s = 136.9°\text{C}$$

Therefore, the equilibrium temperature of the glass bulb is $\boxed{T_s = 136.9°\text{C}}$.

Question: 19.056P

A 12-ft-long, 1.5-kW electrical resistance wire is made of 0.1-in-diameter stainless steel (k = 8.7 Btu/h-ft-°F). The resistance wire operates in an environment at 85°F. Determine the surface temperature of the wire if it is cooled by a fan blowing air at a velocity of 20 ft/s.

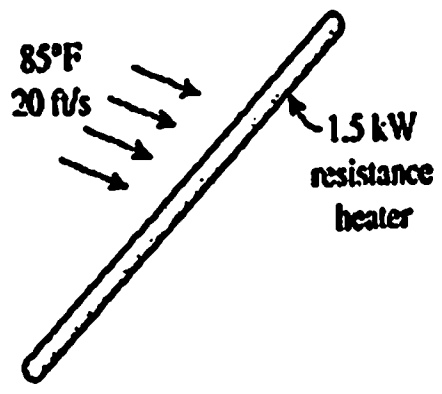

FIGURE P19-56

Step 1 of 2

Given

Length of wire (L) = 12 ft

Diameter of wire (D) = 0.1 in

$= 8.33\times10^{-3}$ ft

Electric resistance of wire = 1.5 kW

Thermal conductivity of stainless steel (k) = 8.7 Btu/h.ft.°F

Temperature of air = 85°F

Velocity of air (V) = 20 ft/s

Step 2 of 2

Properties of air from ideal gas properties of air table at 1 atm and 200°F are

$k = 0.01761$ Btu/h.ft.°F

$\upsilon = 0.2406\times10^{-3}$ ft^2/s

Pr = 0.7124

Reynolds number, $\mathrm{Re} = \dfrac{VD}{\upsilon}$

$$\mathrm{Re} = \frac{(20\text{ ft/s})(0.1/12\text{ ft})}{0.2406\times10^{-3}\text{ ft}^2/\text{s}}$$

$$\mathrm{Re} = 692.8$$

Nusselt number, $Nu = \dfrac{hD}{k}$

$$Nu = 0.3+\frac{0.62\mathrm{Re}^{0.5}\mathrm{Pr}^{1/3}}{\left[1+(0.4/\mathrm{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$Nu = 0.3+\frac{0.62(692.8)^{0.5}(0.7124)^{1/3}}{\left[1+(0.4/0.7124)^{2/3}\right]^{1/4}}\left[1+\left(\frac{692.8}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$Nu = 13.34$$

Coefficient of heat transfer, $h = \dfrac{k}{D}Nu$

$$h = 28.19\text{ Btu/h.ft}^2\text{.°F}$$

$$h = \frac{0.01761\text{ Btu/h.ft.°F}}{(0.1/12\text{ ft})}(13.34)$$

Outer surface temperature of wire is calculated using $T_s = T_\infty + \dfrac{\dot{Q}}{hA}$

Where $A_s = \pi DL$

$$= \pi\times8.33\times10^{-3}\times12$$

$$= 0.3142\text{ ft}^2$$

$$T_s = T_\infty + \frac{\dot{Q}}{hA}$$

$$T_s = 85°\text{F} + \frac{(1500\times3.41214)\text{ Btu/h}}{(28.19\text{ Btu/h.ft}^2\text{.°F})(0.3142\text{ ft}^2)}$$

$$T_s = 662.9°\text{F}$$

Hence surface temperature of the wire is, $\boxed{T_s = 662.9°\text{F}}$

Question: 19.057P

The components of an electronic system arc located in a 1.5-m-long horizontal duct whose cross section is 20 cm × 20 cm. The components in the duct are not allowed to come into direct contact with cooling air, and thus are cooled by air at 30°C flowing over the duct with a velocity of 200 m/min. If the surface temperature of the duct is not to exceed 65°C, determine the total power rating of the electronic devices that can be mounted into the duct.

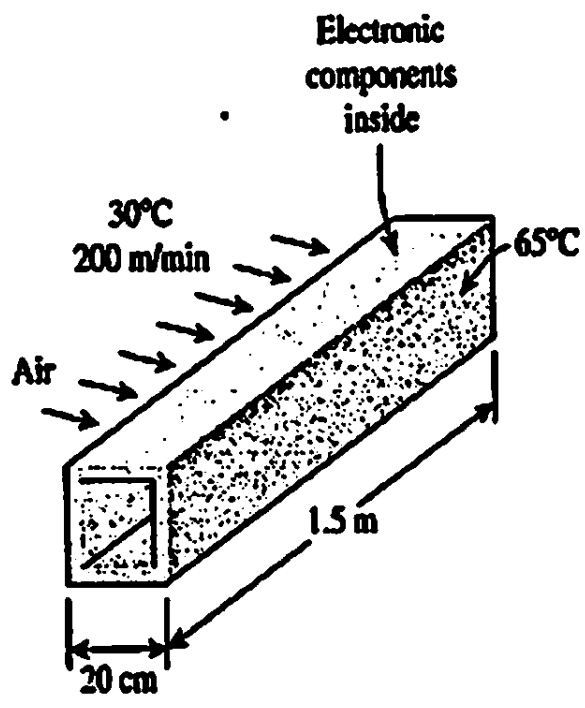

FIGURE P19-57

Step 1 of 9

Calculate the average film mean temperature by using the equation:

$$T_{avg} = \frac{T_\infty + T_s}{2}$$

Here, T_{avg} is the average film mean temperature, T_∞ is the temperature of air and T_s is the surface temperature of the duct.

Substitute $30°C$ for T_∞ and $65°C$ for T_s .

$$T_{avg} = \frac{30+65}{2}$$
$$= 47.5°C$$

Step 2 of 9

Obtain the properties of air at a temperature of $47.5°C$, from the "Properties of air at 1 atm pressure" table.

$$k = 0.02717 \text{ W/m.°C}$$

$$\upsilon = 1.774 \times 10^{-5} \text{ m}^2/\text{s}$$

$$\text{Pr} = 0.7235$$

Here, k is the thermal conductivity, υ is the kinematic viscosity and Pr is the Prandtl number.

Step 3 of 9

Calculate the Reynolds number for the given flow by using the equation:

$$\text{Re} = \frac{VD}{\upsilon}$$

Here, Re is the Reynolds number for the given flow, V is the velocity of flow and D is the length of the side of the duct.

Substitute 60 m/min for V , 0.2 m for D and $1.774 \times 10^{-5} \text{ m}^2/\text{s}$.

$$\text{Re} = \frac{200 \times 0.2}{60 \times 1.774 \times 10^{-5}}$$
$$= 3.578 \times 10^4$$

Step 4 of 9

Here, the Reynold's number is in between 5000 and 10000.So, obtain the equation for the Nusselt number for the flow of air over a square cross sectioned duct from the "Emperical correlations for the average Nusselt number for the forced convection over circular and noncircular cylinders in cross flow" table.

$$Nu = 0.102 \text{Re}^{0.675} \text{Pr}^{1/3}$$

Here, Nu is the Nusselt number for the flow of air.

Step 5 of 9

Calculate the Nusselt number for the flow by using the equation:

$$Nu = 0.102 \text{Re}^{0.675} \text{Pr}^{1/3}$$

Substitute $\left(3.758 \times 10^4\right)$ for Re and 0.7235 for Pr .

$$Nu = 0.102 \times (3.758 \times 10^4)^{0.675} \times (0.7235)^{1/3}$$
$$= 112.2$$

Step 6 of 9

Calculate the heat transfer coefficient by using the equation:

$$h = \frac{k}{D} Nu$$

Here, h is the heat transfer coefficient.

Substitute $0.0217 \text{ W/m} \cdot °C$ for k , 0.2 m for D and 112.2 for Nu .

$$h = \frac{0.02717 \times 112.2}{0.2}$$
$$= 15.24 \text{ W/m}^2 \cdot \text{C}$$

Step 7 of 9

Calculate the surface area of the duct by using the equation:

$$A_s = 4DL$$

Here, A_s is the surface area of the duct and L is the length of the duct.

Substitute 0.2 m for D and 1.5 m for L .

$$A_s = (4 \times 0.2 \times 1.5)$$
$$= 1.2 \text{ m}^2$$

Step 8 of 9

Calculate the rate of heat transfer by using the equation:

$$\dot{Q} = hA_s(T_s - T_\infty)$$

Here, $\dot{Q}$ is the rate of heat transfer.

Substitute $15.24 \text{ W/m}^2 \cdot °C$ for h , 1.2 m^2 for A_s , $65°C$ for T_s and $30°C$ for T_∞ .

$$\dot{Q} = 15.24 \times 1.2 \times (65 - 30)$$
$$= 640.08 \text{ W}$$
$$\simeq 640 \text{ W}$$

Therefore, the total power rating of the electronic device is $\boxed{\dot{Q} = 640 \text{ W}}$.

Step 9 of 9

Question: 19.058P

Repeat Prob. 19-57 for a location at 3000-m altitude where the atmospheric pressure is 70.12 kPa.

Step 1 of 5

Length of duct $L = 1.5\,\text{m}$

Cross section of duct $A_c = 20\,\text{cm} \times 20\,\text{cm}$

Temperature of air $T = 30°\text{C}$

Velocity of air flowing over the duct $V = 200\,\text{m/min}$

Surface temperature of duct $T_s = 65°\text{C}$

Atmospheric pressure at location 3000 m altitude is $p_{3000\text{m}} = 70.12\,\text{kPa}$

Step 2 of 5

Average film temperature

$$T_{avg} = \frac{T_s + T}{2}$$
$$= \frac{65+30}{2}$$
$$= 47.5°\text{C}$$

Properties of air from ideal gas properties of air table at 1atm and $T_{avg} = 47.5°\text{C}$

$$k = 0.02699 + (0.02735 - 0.02699)\left(\frac{47.5-45}{50-45}\right)$$
$$= 0.02717\ \text{W/m.°C}$$
$$\nu = 1.750\times10^{-5} + (1.798\times10^{-5} - 1.750\times10^{-5})\left(\frac{47.5-45}{50-45}\right)$$
$$= 1.774\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Pr} = 0.7241 + (0.7228 - 0.7241)\left(\frac{47.5-45}{50-45}\right)$$
$$= 0.72345$$

There is a change in kinematic viscosity of air if atmospheric pressure changes.

Therefore, kinematic viscosity of air at $p_{3000\text{m}} = 70.12\,\text{kPa}$

$$\nu_{@70.12\,\text{kPa}} = \left(\frac{101.325}{70.12}\right)\times1.774\times10^{-5}$$
$$= 2.5634\times10^{-5}\ \text{m}^2/\text{s}$$

Step 3 of 5

Reynolds number,

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{\frac{200}{60}\times0.2}{2.5634\times10^{-5}}$$
$$= 2.6007\times10^{4}$$

Nusselt number can be calculated by using the equation,

$$\text{Nu} = \frac{hD}{k}$$
$$= 0.102\,\text{Re}^{0.675}\,\text{Pr}^{1/3}$$
$$= 0.102\left(2.6007\times10^{4}\right)^{0.675}(0.72345)^{1/3}$$
$$= 87.482$$

Step 4 of 5

Heat transfer coefficient can be calculated as,

$$\text{Nu} = \frac{hD}{k}$$
$$h = \frac{k}{D}\text{Nu}$$
$$= \frac{0.02717}{0.2}\times87.482$$
$$= 11.884\,\text{W/m}^2\cdot°\text{C}$$

Step 5 of 5

Rate of heat transfer

$$\dot{Q} = hA_s(T_s - T_\infty)$$

Where surface area is

$$A_s = 4sL$$
$$= 4\times0.2\times1.5$$
$$= 1.2\,\text{m}^2$$

Hence,

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$= 11.884\times1.2\times(65-30)$$
$$= 499.128\,\text{W}$$

The total power rating of the electronic device is $\boxed{\dot{Q} = 499.128\,\text{W}}$

Question: 19.059P pg 1

A 0.4-W cylindrical electronic component with diameter 0.3 cm and length 1.8 cm and mounted on a circuit board is cooled by air flowing across it at a velocity of 240 m/min. If the air temperature is 35°C, determine the surface temperature of the component.

Step 1 of 4

Given
Diameter of electronic component (D) = 0.3 cm
Length of electronic component (L) = 1.8 cm
Velocity of air (V) = 240 m/min
Temperature of air = 35°C

Step 2 of 4

Properties of air from ideal gas properties of air table at 1 atm and 50°C are

$k = 0.02735$ W/m.°C

$\upsilon = 1.798\times10^{-5}$ m^2/s

Pr = 0.7228

Reynolds number, $\mathrm{Re} = \dfrac{VD}{\upsilon}$

$$\mathrm{Re} = \frac{(240/60\ \text{m/s})(0.003\ \text{m})}{1.798\times10^{-5}\ \text{m}^2/\text{s}}$$

$$\mathrm{Re} = 667.4$$

Nusselt number, $Nu = \dfrac{hD}{k}$

$$Nu = 0.3+\frac{0.62\mathrm{Re}^{0.5}\mathrm{Pr}^{1/3}}{\left[1+(0.4/\mathrm{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$Nu = 0.3+\frac{0.62(667.4)^{0.5}(0.7228)^{1/3}}{\left[1+(0.4/0.7228)^{2/3}\right]^{1/4}}\left[1+\left(\frac{667.4}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$Nu = 13.17$$

Step 3 of 4

Convective heat transfer coefficient is $h = \dfrac{k}{D}Nu$

$$h = \frac{0.02735}{0.003}(13.17)$$

$$h = 120.0\ \text{W/m}^2.°\text{C}$$

Temperature of surface is calculated using, $T_s = T_\infty + \dfrac{\dot{Q}}{hA}$

Where, $A_s = \pi DL$

$$A_s = \pi\times0.003\times0.018$$

$$A_s = 0.0001696\ \text{m}^2$$

Hence, $T_s = 35+\dfrac{0.4}{120.0\times0.0001696}$

$$T_s = 54.6°\text{C}$$

Surface temperature of the component is $\boxed{T_s = 54.6°\text{C}}$

Step 4 of 4

Question: 19.060P

Consider a 50-cm-diameter and 95-cm-long hot water tank. The tank is placed on the roof of a house. The water inside the tank is heated to 80°C by a flat-plate solar collector during the day. The tank is then exposed to windy air at 18°C with an average velocity of 40 km/h during the night. Estimate the temperature of the tank after a 45-min period. Assume the tank surface to be at the same temperature as the water inside, and the heat transfer coefficient on the top and bottom surfaces to be the same as that on the side surface.

Step 1 of 5

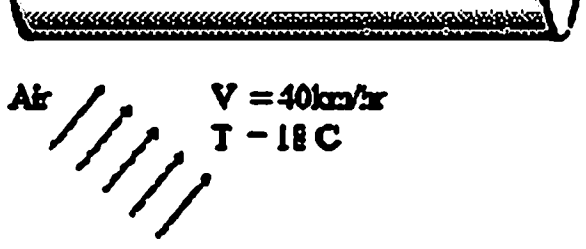
Given
Diameter of water tank (D) = 50 cm
Length of tank (L) = 90 cm
Temperature of water = 80°C
Temperature of air = 18°C
Velocity of air (V) = 40 km/h

Step 2 of 5

Properties of water at 80°C from properties of water table

$\rho = 971.8\ \text{kg/m}^3$

$C_p = 4.197\ \text{kJ/kg.°C}$



Properties of air from properties of air table at 1 atm and 50°C,

$k = 0.02735\ \text{W/m.°C}$

$\upsilon = 1.798\times10^{-5}\ \text{m}^2/\text{s}$

$\text{Pr} = 0.7228$

Step 3 of 5

Step 4 of 5

Reynolds number, $\text{Re} = \dfrac{VD}{\upsilon}$

$$\text{Re} = \frac{\left(\frac{40\times1000}{3600}\ \text{m/s}\right)(0.50\ \text{m})}{1.798\times10^{-5}\ \text{m}^2/\text{s}}$$

$$\text{Re} = 309{,}015$$

Nusselt number, $\text{Nu} = 0.3+\dfrac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\dfrac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$

$$\text{Nu} = 0.3+\frac{0.62(309{,}015)^{0.5}(0.7228)^{1/3}}{\left[1+(0.4/0.7228)^{2/3}\right]^{1/4}}\left[1+\left(\frac{309{,}015}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$\text{Nu} = 484.9$$

Coefficient of heat transfer, $h = \dfrac{k}{D}\text{Nu}$

$$h = \frac{0.02735\ \text{W/m.°C}}{0.50\ \text{m}}(484.9)$$

$$h = 26.53\ \text{W/m}^2\text{.°C}$$

Step 5 of 5

Mass of water in the tank is $m = \rho V$

$$m = \rho\pi\frac{D^2}{4}L$$

$$m = (971.8\ \text{kg/m}^3)\pi\frac{(0.50\ \text{m})^2}{4}(0.95\ \text{m})$$

$$m = 181.27\ \text{kg}$$

Heat rejected by water is $Q = mC_p(T_2 - T_1)$

$$Q = (181.27\,\text{kg})(4.197\ \text{kJ/kg°C})(80 - T_2)\text{°C}$$

$$Q = 760.798\times(80 - T_2)\ \text{kJ}$$

Average heat transfer rate is $\dot{Q} = \dfrac{Q}{\Delta t}$

$$\dot{Q} = \frac{760.798\times(80-T_2)}{45\times60}\ \text{kJ/s}$$

$$\dot{Q} = 0.28178\times(80-T_2)\ \text{kW}$$

Surface area, $A_s = \pi DL + 2\pi\dfrac{D^2}{4}$

$$A_s = \pi(0.5)(0.95) + 2\pi(0.5)^2/4$$

$$A_s = 1.885\ \text{m}^2$$

Heat transfer rate, $\dot{Q} = hA_s(T_s - T_\infty)$

$$\dot{Q} = (26.53\ \text{W/m}^2\text{.°C})(1.885\ \text{m}^2)\left(\frac{80+T_2}{2} - 18\right)\text{°C}$$

$$\dot{Q} = 0.05\times\left(\frac{80+T_2}{2} - 18\right)\ \text{kW}$$

By equating both the values of $\dot{Q}$, we get

$$0.28178\times(80 - T_2) = 0.05\times\left(\frac{80+T_2}{2} - 18\right)$$

$$22.5424 - (0.28178\times T_2) = 2 + (0.025\times T_2) - 0.9$$

$$21.4424 = 0.30678\times T_2$$

$$T_2 = 69.89\ ^0\text{C}$$

Final temperature of tank, $\boxed{T_2 = 69.89\ ^0\text{C}}$

Question: 19.061P pg 1

Reconsider Prob. 19-60. Using EES (or other) software, plot the temperature of the tank as a function of the cooling time as the time varies from 30 min to 5 h, and discuss the results.

Step 1 of 7

To solve this question using EES software open EES software

```

Step 3 of 7

Then from Tables -> New parametric table
A dailog box will open
Select no of runs = 19
Select variables in equations as time and T_{w2} press ADD and then press ok
A table will appear put values of time as 30,45,60....300 in run 1to 19
Then from Calculate -> Solve table
Solution will appear

time [min]	T_{w2} [C]
30	73.06
45	69.86
60	66.83
75	63.96
90	61.23
105	58.63
120	56.16
135	53.8
150	51.54
165	49.39
180	47.33
195	45.36
210	43.47
225	41.65
240	39.91
255	38.24
270	36.63
285	35.09
300	33.6

Step 4 of 7

Then from Plot -> New plot window -> X-Y Plot
Select X-axis time and Y-axis T_{w2}
Press OK
Graph will be plotted.

Step 5 of 7

Now change the code in the dialog box as

```
"GIVEN"
```

Step 5 of 7

Now change the code in the dialog box as

```
"GIVEN"
Vel=70 "[km/h], parameter to be varied"
w=2.8 "[m]"
L=8 "[m]"
"q_dot_rad=200 [W/m^2], parameter to be varied"
T_infinity=30 "[C]"

Question: 19.062P

A 2.2-m-diameter spherical tank of negligible thickness contains iced water at 0°C. Air at 25°C flows over the tank with a velocity of 6 m/s. Determine the rate of heat transfer to the tank and the rate at which ice melts. The heat of fusion of water at 0°C is 333.7 U/kg.

Step 1 of 5

Given data:

Diameter of spherical tank, $D = 2.2$ m

Temperature of the air, $T_\infty = 25°C$

Air flow velocity, $V = 6$ m/s

Temperature of the surface of the tank, $T_s = 0°C$

Heat of fusion of water, $h_{fg} = 337.7$ kJ/kg

Step 2 of 5

Loading solution. Please wait ...

Step 3 of 5

The Nusselt number,

$$Nu_{sph} = 2+\left[0.4R_e^{1/2}+0.06R_e^{2/3}\right]P_r^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2+\left[0.4(845256.9)^{0.5}+0.06(845256.9)^{2/3}\right](0.7296)^{0.4}\left(\frac{1.849\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4}$$

$$= 810.5$$

Step 4 of 5

The convective heat transfer,

$$Nu_{sph} = \frac{hD}{k}$$

$$h = \frac{Nu_{sph}\times k}{D}$$

$$= \frac{810.5\times0.02551}{2.2}$$

$$= 9.4\ W/m^2\cdot K$$

The rate of heat transfer to the tank,

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$= 9.4\times\left(\pi\times2.2^2\right)\times(25-0)$$

$$= 3572.54\ W$$

Therefore the rate of heat transfer to the tank, $\boxed{\dot{Q} = 3572.54\ W}$

Step 5 of 5

The rate at which ice melts,

$$\dot{m} = \frac{\dot{Q}}{h_{fg}}$$

$$= \frac{3572.54}{333.7\times10^3}$$

$$= 0.0107\ kg/s$$

Therefore the rate at which ice melts, $\boxed{\dot{m} = 0.0107\ kg/s}$

Question: 19.063P

During a plant visit, it was noticed that a 12-m-long section of a 12-cm-diameter steam pipe is completely exposed to the ambient air. The temperature measurements indicate that the average temperature of the outer surface of the steam pipe is 75°C when the ambient temperature is 5°C. There are also light winds in the area at 25 km/h. The emissivity of the outer surface of the pipe is 0.8, and the average temperature of the surfaces surrounding the pipe, including the sky, is estimated to be 0°C. Determine the amount of heat lost from the steam during a 10-h-long work day.

Steam is supplied by a gas-fired steam generator that has an efficiency of 80 percent, and the plant pays $1.05/therm of natural gas. If the pipe is insulated and 90 percent of the heat loss is saved, determine the amount of money this facility will save a year as a result of insulating the steam pipes. Assume the plant operates every day of the year for 10 h. State your assumptions.

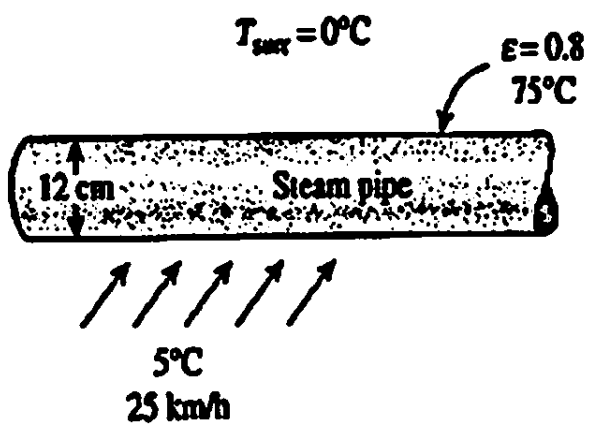

FIGURE P19-63

Step 1 of 8

Given data:

Diameter of the steam pipe, $D=12$ cm

Length of the steam pipe, $L=12$ m

Outer surface temperature of the pipe, $T_s=75°C$

Ambient air temperature, $T_\infty=5°C$

Velocity of air, $V=25$ km/h $=6.94$ m/s

Emissivity of the pipe, $\varepsilon=0.8$

Temperature of the surroundings, $T_{surr}=0°C$

Efficiency of the steam generator, $\eta_g=0.8$

Step 2 of 8

The film temperature of the air is determined as

$$T_f=\frac{(T_s+T_\infty)}{2}$$
$$=\frac{(75+5)}{2}$$
$$=40°C$$

From the table, properties of air at 1 atm pressure and $T=40°C$ we get

Thermal conductivity, $k=0.02662$ W/m·K

Kinematic viscosity, $\nu=1.702\times10^{-5}$ m^2/s

Prandtl number, $\Pr=0.7255$

The Reynolds number for the flow is determined from the equation given by

$$\mathrm{Re}=\frac{VD}{\nu}$$
$$=\frac{6.94\times\left(12\times10^{-2}\right)}{1.702\times10^{-5}}$$
$$=48930.67$$

Since the obtained Reynolds number is less than 2×10^5, the flow is said to be laminar.

Step 3 of 8

The average Nusselt number for cross flow over cylinder is determined from the Churchill & Bernstein relation given by

$$\mathrm{Nu}_{cyl}=0.3+\frac{0.62\mathrm{R}_e^{1/2}\mathrm{P}_r^{1/3}}{\left[1+\left(\frac{0.4}{\mathrm{Pr}}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$=0.3+\frac{0.62(48930.67)^{0.5}(0.7255)^{1/3}}{\left[1+\left(\frac{0.4}{0.7255}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{48930.67}{282000}\right)^{5/8}\right]^{4/5}$$

$$=136.82$$

Step 4 of 8

The convective heat transfer coefficient of air is determined from the equation given by

$$\mathrm{Nu}_{cyl}=\frac{hD}{k}$$

Rewrite and solve for h:

$$h=\frac{\mathrm{Nu}_{cyl}\times k}{D}$$
$$=\frac{136.82\times0.02662}{\left(12\times10^{-2}\right)}$$
$$=30.35\ \mathrm{W/m^2\cdot K}$$

Step 5 of 8

The rate of heat loss from the pipe is determined from the equation given by

$$\dot{Q}=\dot{Q}_{conv}+\dot{Q}_{rad}$$
$$=hA_s(T_s-T_\infty)+\varepsilon A_s\sigma\left(T_s^4-T_{surr}^4\right)$$
$$=\left[h\times(\pi DL)\times(T_s-T_\infty)\right]+\left[\varepsilon\times(\pi DL)\times\sigma\times\left(T_s^4-T_{surr}^4\right)\right]$$
$$=\left[30.35\times\left(\pi\times12\times10^{-2}\times12\right)\times(75-5)\right]$$
$$+\left[0.8\times\left(\pi\times12\times10^{-2}\times12\right)\times5.67\times10^{-8}\times\left((75+273)^4-(0+273)^4\right)\right]$$
$$=11480.748\ \mathrm{W}$$

Step 6 of 8

The amount of heat lost from the steam is determined as

$$Q=\dot{Q}\times10\ \mathrm{hr}$$
$$=11480.748\times10\times3600$$
$$=413306928\ \mathrm{J}$$
$$=4.13\times10^5\ \mathrm{kJ}$$

The amount of heat lost from the steam during a 10-h-long work day is $\boxed{Q=4.13\times10^5\ \mathrm{kJ}}$

Step 7 of 8

The amount of heat lost per year is determined as

$$Q_y=4.13\times10^5\times365$$
$$=1.51\times10^8\ \mathrm{kJ/year}$$

The amount of heat lost per year considering the generator efficiency is determined as

$$Q_g=\frac{Q_y}{\eta_g}$$
$$=\frac{1.51\times10^8}{0.8}$$
$$=1.89\times10^8\ \mathrm{kJ/year}$$
$$=\frac{1.8857\times10^8}{105500}$$
$$=1787.31\ \mathrm{therms/year}$$

Step 8 of 8

Given that if the pipe is insulated 90% of heat lost is saved

The amount of heat lost saved is determined as

$$Q_{saved}=0.9\times Q_g$$
$$=0.9\times1787.31$$
$$=1608.58\ \mathrm{therms/year}$$

The amount of money saved by insulating the steam pipe is determined as

$$\$_{saved}=Q_{saved}\times1.05$$
$$=1608.58\times1.05$$
$$=1689\$$$

The amount of money saved per year by insulating the steam pipe is $\boxed{\$_{saved}=1689\$}$

Question: 19.064P

Reconsider Prob. 19-63. There seems to be some uncertainty about the average temperature of the surfaces surrounding the pipe used in radiation calculations, and you are asked to determine if it makes any significant difference in overall heat transfer. Repeat the calculations for average surrounding and surface temperatures of -20°C and 25°C, respectively, and determine the change in the values obtained.

Step 1 of 7

Given:

Diameter of steam pipe, $D = 12\,\text{cm} = 0.12\,\text{m}$

Length of steam pipe, $L = 12\,\text{m}$

Outer surface temperature of pipe, $T_s = 75°\text{C}$

Ambient air temperature, $T_\infty = 5°\text{C}$

Velocity of air,

$$V = 25\,\text{km/h}$$

$$= 25 \times \frac{1000}{3600}$$

$$= 6.944\,\text{m/s}$$

Emissivity of the surface of the pipe, $\varepsilon = 0.8$

Surrounding temperature, $T_{sur} = 0°\text{C}$

Step 2 of 7

Film temperature of air is

$$T_f = (T_s + T_\infty)/2$$

$$= (75+5)/2$$

$$= 40°\text{C}$$

Let us take the air properties at film temperature, T_f

From the table, properties of air at 1 atm pressure and $T = 40°\text{C}$

Thermal conductivity, $k = 0.02662\,\text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.702 \times 10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7255$

Calculating Reynolds number to know the flow conditions,

$$\text{Re} = \frac{VD}{\nu}$$

$$= \frac{6.944 \times 0.12}{1.702 \times 10^{-5}}$$

$$= 48958.87$$

This is less than $\text{Re} < \text{Re}_{\text{critical}} = 5 \times 10^5$, therefore the flow is laminar flow.

Step 3 of 7

The average Nusselt number for cross flow over cylinder is determined from the Churchill & Bernstein relation given by

$$Nu = 0.3 + \frac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(48958.87)^{0.5}(0.7255)^{1/3}}{\left[1+\left(\frac{0.4}{0.7255}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{48958.87}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{123.268}{1.1371} \times (1.2598)$$

$$= 136.87$$

Step 4 of 7

The convective heat transfer coefficient of air is determined from the equation given by

$$\text{Nu} = \frac{hD}{k}$$

Rewrite and solve for h:

$$h = \frac{\text{Nu} \times k}{D}$$

$$= \frac{136.87 \times 0.02662}{\left(12 \times 10^{-2}\right)}$$

$$= 30.368\ \text{W/m}^2\cdot\text{K}$$

Step 5 of 7

Therefore rate of heat loss by convection and radiation will be

$$\dot{Q}_t = R_{conv} + Q_{rad}$$

$$= hA_s\left(T_s - T_\infty\right) + \varepsilon A_s \sigma\left(T_s^4 - T_\infty^4\right)$$

$$= h\pi DL\left(T_s - T_\infty\right) + \varepsilon\pi DL\sigma\left(T_s^4 - T_\infty^4\right) \quad \ldots\ldots (1)$$

$$= 30.368 \times \pi \times 0.12 \times 12(75-5) + 0.8 \times \pi \times 0.12 \times 12 \times 5.67 \times 10^{-8} \times \left((75+273)^4 - (273+5)^4\right)$$

$$= 9516.71 + 1783.91$$

$$= 11300.62\,\text{W}$$

Step 6 of 7

Now as given the new average surrounding temperature $T_\infty = -20°\text{C}$ used in radiation calculations

From equation (1) calculating $\dot{Q}_t$ by putting this new value of surrounding temperature in radiation calculation

$$\dot{Q}_{t1} = h\pi DL\left(T_s - T_\infty\right) + \varepsilon\pi DL\sigma\left(T_s^4 - T_\infty^4\right)$$

$$= 30.368 \times \pi \times 0.12 \times 12(75-5) + 0.8 \times \pi \times 0.12 \times 12 \times 5.67 \times 10^{-8} \times \left((75+273)^4 - (-20+273)^4\right)$$

$$= 9616.71 + 2168.804$$

$$= 11785.514\,\text{W}$$

Therefore the change in amount of heat transfer when the new average surrounding temperature $T_\infty = -20°\text{C}$ used in radiation calculation is

$$\dot{Q}_{t1} - \dot{Q}_t = 11785.514 - 11300.62$$

$$= 484.894\,\text{W}$$

Therefore, the change in amount of heat transfer when the new average surrounding temperature $T_\infty = -20°\text{C}$ used is $\boxed{\dot{Q}_{t1} - \dot{Q}_t = 484.894\,\text{W}}$

Step 7 of 7

Now as given the new average surface temperature $T_s = 25°\text{C}$ used in radiation calculations

From equation (1) calculating $\dot{Q}_t$ by putting this new value of surface temperature in radiation calculation

$$\dot{Q}_{t2} = h\pi DL\left(T_s - T_\infty\right) + \varepsilon\pi DL\sigma\left(T_s^4 - T_\infty^4\right)$$

$$= 30.368 \times \pi \times 0.12 \times 12(75-5) + 0.8 \times \pi \times 0.12 \times 12 \times 5.67 \times 10^{-8} \times \left((25+273)^4 - (5+273)^4\right)$$

$$= 9616.711 + 392.623$$

$$= 10009.334\,\text{W}$$

Here we can see that the heat transfer is decreases when the surface temperature $T_s = 25°\text{C}$ used in radiation calculation

The change in heat transfer is given by

$$\dot{Q}_t - \dot{Q}_{t2} = 11300.62 - 10009.334$$

$$= 1291.286\,\text{W}$$

Therefore, the change in heat transfer is $\boxed{\dot{Q}_t - \dot{Q}_{t2} = 1291.286\,\text{W}}$

Question: 19.065P

A 10-cm-diameters, 30-cm-high cylindrical bottle contains cold water at 3°C. The bottle is placed in windy air at 27°C. The water temperature is measured to be 11°C after 45 min of cooling. Disregarding radiation effects and heat transfer from the top and bottom surfaces, estimate the average wind velocity.

Step 1 of 6

Given
Diameter of bottle = 10 cm
Height of bottle = 30 cm
Temperature of cold water = 3°C
Temperature of air = 27°C
Temperature of water after 45 min = 11°C

Step 2 of 6

Average film temperature of water, $T = \frac{3+11}{2}$

$$T = 7^0\text{C}$$

Properties of water from properties of water table at 7°C are

$\rho = 999.8\ \text{kg/m}^3$

$C_p = 4200\ \text{J/kg.°C}$

Average film temperature of air, $T = \frac{7+27}{2}$

$$T = 17^0\text{C}$$

Properties of air from properties of air table at 1 atm and 17°C are

$k = 0.02491\ \text{W/m.°C}$

$\upsilon = 1.489\times10^{-5}\ \text{m}^2/\text{s}$

$\text{Pr} = 0.7317$

Step 3 of 6

Mass of water in the bottle, $m = \rho V$

$$m = \rho\pi\frac{D^2}{4}L$$

$$m = (999.8\ \text{kg/m}^3)\pi\frac{(0.10\ \text{m})^2}{4}(0.30\ \text{m})$$

$$m = 2.356\ \text{kg}$$

Heat added to water, $Q = mC_p(T_2 - T_1)$

$Q = (2.356\ \text{kg})(4200\ \text{J/kg.°C})(11\text{-}3)\text{°C}$

$Q = 79{,}162\ \text{J}$

Heat transfer rate, $\dot{Q} = \frac{Q}{\Delta t}$

$$\dot{Q} = \frac{79{,}162\ \text{J}}{45\times60\ \text{s}}$$

$$\dot{Q} = 29.32\ \text{W}$$

Step 4 of 6

Surface area of the cylinder, $A_s = \pi DL$

$$A_s = \pi(0.10\ \text{m})(0.30\ \text{m})$$

$$A_s = 0.09425\ \text{m}^2$$

Heat transfer rate of conduction, $\dot{Q}_{conv} = hA_s(T_s - T_\infty)$

Equating the heat transfer rates,

$29.32\ \text{W} = h\times(0.09425\ \text{m}^2)(27\text{-}7)\text{°C}$

$h = 15.55\ \text{W/m}^2\text{.°C}$

Step 5 of 6

Nusselt number, $Nu = \frac{hD}{k}$

$$Nu = \frac{(15.55\ \text{W/m}^2\text{.°C})(0.10\ \text{m})}{0.02491\ \text{W/m.°C}}$$

$$Nu = 62.42$$

Reynolds number is calculate using the relation,

$$Nu = 0.3 + \frac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1+(0.4/\text{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$62.42 = 0.3 + \frac{0.62\text{Re}^{0.5}(0.7317)^{1/3}}{\left[1+(0.4/0.7317)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\text{Re}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$\text{Re} = 12{,}856$

Step 6 of 6

Velocity of air is calculated using the relation,

$$\text{Re} = \frac{VD}{\upsilon}$$

$$12{,}856 = \frac{V(0.10\ \text{m})}{1.489\times10^{-5}\ \text{m}^2/\text{s}}$$

$V = 1.91\ \text{m/s}$

Average wind velocity is $\boxed{V = 1.91\ \text{m/s}}$

Question: 19.066P

A 0.2 m ×0.2 m street sign surface has an absorptivity of 0.6 and an emissivity of 0.7, while the street sign is subjected to a cross flow wind at 20°C with a velocity of 1 m/s. Solar radiation is incident on the street sign at a rate of 1100 W/m2, and the surrounding temperature is 20°C. Determine the surface temperature of the street sign. Evaluate the air properties at 30°C.

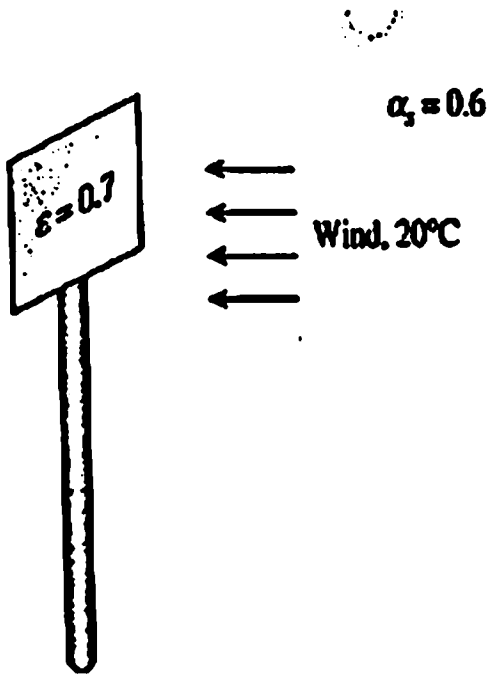

FIGURE P19-66

Step 1 of 5

Given data:

Size of street sign surface, $L \times w = 0.2\text{m} \times 0.2\text{m}$

Absorptivity of the surface, $\alpha = 0.6$

Emissivity of the surface, $\varepsilon = 0.7$

Wind flow velocity, $V = 1\ \text{m/s}$

Temperature of the air, $T_\infty = 20°\text{C}$

Incident solar radiation, $\dot{q}_s = 1100\ \text{W/m}^2$

Temperature of the surroundings, $T_{sur} = 20°\text{C}$

Step 2 of 5

From the table, properties of air at 1 atm pressure and $T = 30°\text{C}$

Thermal conductivity, $k = 0.02588\ \text{W/m} \cdot \text{K}$

Kinematic viscosity, $\nu = 1.608 \times 10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7282$

The Reynolds number for the flow is determined from the equation given by

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{1 \times 0.2}{1.608 \times 10^{-5}}$$
$$= 12437.81$$

Step 3 of 5

From the table, empirical correlations for the average Nusselt number for forced convection over circular and noncircular cylinders in cross flow

For vertical plate Reynolds number ranging $4000 - 15000$

$$\text{Nu} = 0.228\text{Re}^{0.731}\text{Pr}^{1/3}$$

The Nusselt number from the given equation is determined as

$$\text{Nu} = 0.228 \times (12437.81)^{0.731} \times (0.7282)^{1/3}$$
$$= 201.96$$

Step 4 of 5

The convective heat transfer coefficient of air is determined from the equation given by

$$\text{Nu} = \frac{hD}{k}$$

Rewrite and solve for h:

$$h = \frac{\text{Nu} \times k}{D}$$
$$= \frac{201.96 \times 0.02588}{0.2}$$
$$= 26.13\ \text{W/m}^2 \cdot \text{K}$$

Step 5 of 5

The surface temperature of the street sign is determined by applying the energy balance given by

$$\alpha \times \dot{q}_s = \dot{q}_{conv} + \dot{q}_{rad}$$
$$\alpha \times \dot{q}_s = \left[h(T_s - T_\infty)\right] + \left[\varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]$$
$$0.6 \times 1100 = \left[26.13 \times (T_s - 20)\right] + \left[0.7 \times 5.67 \times 10^{-8}\left((T_s + 273)^4 - (20 + 273)^4\right)\right]$$
$$T_s = 41.6°\text{C}$$

Hence, the surface temperature of the street sign is $\boxed{T_s = 41.6°\text{C}}$

Question: 19.067P

What is the physical significance of the number of transfer units NTU = *hAs/mcp*? What do small and large NTU values tell about a heat transfer system?

Step 1 of 1

NTU (i.e. number of transfer units) is one of the parameters for the measure of effectiveness of the heat transfer system.
Larger NTU value indicates that the limit has reached for heat transfer whereas smaller value of NTU indicates more opportunities for heat transfer.

Question: 19.068P

Consider the flow of mercury (a liquid metal) in a tube. How will the hydrodynamic and thermal entry lengths compare if the flow is laminar? How would they compare if the How were turbulent?

Step 1 of 1

Considering the flow of mercury in a tube:

In laminar flow of mercury, thermal entry length is smaller than the hydrodynamic entry length.
For turbulent flow of mercury, thermal entry length is equal to the hydrodynamic entry length.

Question: 19.069P

What do the average velocity Vavg and the mean temperature *Tm* represent in flow through circular tubes of constant diameter?

Step 1 of 1

Average velocity represents the velocity which satisfies the conservation of mass in incompressible flow of fluid in circular tube of constant diameter.

Average temperature or mean temperature represents the temperature which satisfies the conservation of energy in incompressible flow of fluid in a circular tube of constant diameter.

Question: 19.070P

What does the logarithmic mean temperature difference represent for flow in a tube whose surface temperature is constant? Why do we use the logarithmic mean temperature instead of the arithmetic mean temperature?

Step 1 of 1

Logarithmic Mean Temperature Difference represents average temperature difference between the fluid and the surface. It reflects the exponential decay of local temperature difference.

$$\Delta T_{ln} = \frac{\Delta T_e - \Delta T_i}{\ln\left(\frac{\Delta T_e}{\Delta T_i}\right)}$$

here $\Delta T_e = T_s - T_e$

$\Delta T_i = T_s - T_i$

T_s = Surface temperature

T_i = Inlet temperature

T_e = Exit temperature

If we use arithmetic mean temperature difference instead of LMTD then if there is a larger difference between ΔT_e and ΔT_i, error increases to the undesirable level.

Question: 19.071P

How is the thermal entry length defined for flow in a tube? In what region is the flow in a tube fully developed?

Step 1 of 2

When a fluid enters a circular tube with different surface temperature, convection heat transfer takes place between the surface and fluid particles and thermal boundary layer develops.

Step 2 of 2

The thermal boundary layer develops from the surface and reaches the tube center; this region is called the thermal entrance region.

The length of tube in thermal entrance region is called the thermal entry length, L_t .

Fully developed region occurs after the thermal entry length and the dimensionless temperature profile, $\frac{(T_s - T)}{(T_s - T_m)}$ remains constant.

Question: 19.072P

Consider laminar forced convection in a circular tube. Will the heat flux be higher near the inlet of the tube or near the exit? Why?

Step 1 of 2

For a laminar flow the thickness of the thermal boundary layer near the entry of the circular tube is zero and gradually increases up to the fully developed region.

Step 2 of 2

The heat transfer coefficient depends on boundary layer thickness hence heat transfer coefficient is more at the tube inlet where thickness of boundary layer is small.

The heat flux is directly proportional to the heat transfer coefficient, so the heat flux is higher near the tube inlet.

Question: 19.073P

Consider turbulent forced convection in a circular tube. Will the heat flux be higher near the inlet of the tube or near the exit? Why?

Step 1 of 1

The heat flux will be always higher at the inlet of the tube. This is mainly due to decrease in the heat transfer coefficient with increase in the thickness of the boundary layer.

The heat transfer coefficient will be highest at the tube inlet where the thickness of the thermal boundary layer is zero. The heat transfer coefficient decreases gradually to the fully developed value.

Question: 19.074P

Consider fluid flow in a tube whose surface temperature remains constant. What is the appropriate temperature difference for use in Newton's law of cooling with an average heat transfer coefficient?

Step 1 of 1

The appropriate temperature difference for use in Newton's law of cooling with an average heat transfer coefficient is arithmetic mean temperature difference (ΔT_{am}).

$$\Delta T_{am} = T_s - T_b$$

Where, T_s is surface temperature of the tube

T_b is the bulk mean temperature

$$T_b = \frac{T_i + T_e}{2}$$

T_i is mean fluid temperature at the inlet of the tube

T_e is mean fluid temperature at the exit of the tube

Therefore the arithmetic mean temperature difference is

$$\Delta T_{am} = T_s - \left(\frac{T_i + T_e}{2}\right)$$

Question: 19.075P

Air enters an 18-cm-diameter 12-m-long underwater duct at 50°C and 1 atm at a mean velocity of 7 m/s, and is cooled by the water outside. If the average heat transfer coefficient is 65 W/m2-K and the tube temperature is nearly equal to the water temperature of 10°C, determine the exit temperature of air and the rate of heat transfer.

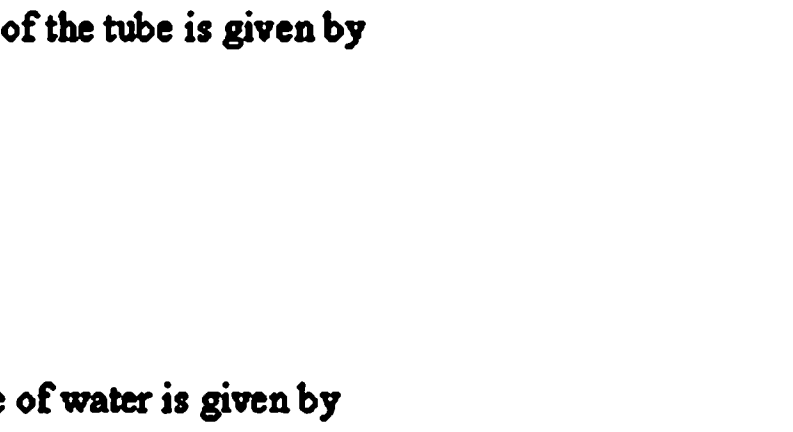
Step 1 of 7

Given:

Diameter of duct, $D = 18 \text{ cm} = 0.18 \text{ m}$

Length of duct, $L = 12 \text{ m}$

Temperature of air, $T_i = 50°C$



Mean velocity of air, $V_{avg} = 7 \text{ m/s}$

Tube temperature, $T_s = 10°C$

Average heat transfer co-efficient is $h = 65 \text{ W/m}^2 \cdot \text{K}$

Step 2 of 7

Schematic diagram for pipe flow:

Step 3 of 7

As we know, the rate of heat transfer can be expressed by

$\dot{Q} = hA_s \Delta T_{ln}$

where, A_s – Surface area of heat transfer.

h – Heat transfer coefficient (average)

ΔT_{ln} – Log mean temperature difference

Step 4 of 7

Mean film temperature of the air is

$$T_f = \frac{50+10}{2}$$

$$= 30°C$$

From the properties of the air at $T_f = 30°C$

Density, $\rho = 1.164 \text{ kg/m}^3$

Specific heat, $c_p = 1007 \text{ J/kg} \cdot \text{k}$

Step 5 of 7

Cross sectional area of the tube is given by

$$A_c = \frac{\pi}{4} D^2$$

$$= \frac{\pi}{4}(0.18)^2$$

$$= 0.0254 \text{ m}^2$$

Then, mass flow rate of water is given by

$$\dot{m} = \rho A_c V_{avg}$$

$$= (1.164)(0.0254)(7)$$

$$= 0.207 \text{ kg/s}$$

Therefore surface area of heat transfer,

$$A_s = \pi D L$$

$$= \pi \times (0.18) \times 12$$

$$= 6.786 \text{ m}^2$$

Step 6 of 7

We know exit temperature can be expressed by the relationship i.e. for mean fluid temperature at the tube exit.

$$T_e = T_s - (T_s - T_i) exp(-hA_s / \dot{m} c_p)$$

$$= 10 - (10 - 50) \exp\left(\frac{-65 \times 6.786}{0.207 \times 1007}\right)$$

$$= 14.82°C$$

Therefore, the exit temperature is $\boxed{T_e = 14.82°C}$

Step 7 of 7

Logarithmic mean temperature deference, T_{ln}

$$\Delta T_{ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)}$$

$$= \frac{14.82 - 50}{\ln\left(\frac{10 - 14.82}{10 - 50}\right)}$$

$$= 16.625°C$$

Rate of heat transfer,

$$\dot{Q} = hA_s \Delta T_{ln}$$

$$= 65 \times 6.786 \times 16.625$$

$$= 7333.07 \text{ W}$$

Therefore, rate of heat transfer is $\boxed{\dot{Q} = 7333.07 \text{ W}}$

Question:

Cooling water available at 10°C is used to condense steam at 30°C in the condenser of a power plant at arate of 0.15 kg/s by circulating the cooling water through a bank of 15-m-long 1.2-cm-internal-diameter thin copper tubes. Water enters the tubes at a mean velocity of 4 m/s and leaves at al temperature of 24°C. The tubes are nearly isothermal at 30° C Determine the average heat transfer coefficient between the water, the tubes, and the number of tubes needed to achieve the indicated heat transfer rate in the condenser.

Step 1 of 11

Calculate the bulk mean temperature of water to evaluate the properties of water.

$$T_b = \frac{T_i + T_e}{2}$$

Here, T_b is the bulk mean temperature of water, T_i is the inlet temperature and T_e is the exit temperature.

Substitute $24°C$ for T_e and $10°C$ for T_i.

$$\begin{aligned} T_b &= \frac{T_i + T_e}{2} \\ &= \frac{10+24}{2} \\ &= 17°C \end{aligned}$$

Step 2 of 11

Obtain the properties of water at the bulk mean temperature $17°C$ from the "Properties of saturated water" table.

Density of the water, $\rho = 998.7\,kg/m^3$

Viscosity of the water, $\nu = 1.1233\times10^{-6}\,m^2/s$

Prandtl number of the water, $Pr = 7.99$

Thermal conductivity of the water, $k = 0.590\ W/m\cdot K$

Specific heat of the water, $C_p = 4.183\ kJ/kg\cdot K$

Step 3 of 11

Calculate the cross sectional area of the copper tube by using the equation:

$$A = \frac{\pi}{4}d^2$$

Here, A is the cross sectional area of the copper tube and d is the internal diameter of the copper tube.

Substitute $0.012\,m$ for d.

$$\begin{aligned} A &= \frac{\pi}{4}\times0.012^2 \\ &= 1.1309\times10^{-4}\,m^2 \end{aligned}$$

Step 4 of 11

Calculate the mass flow rate of water passing through the tubes by using the equation:

$$\dot{m} = \rho A V$$

Here, $\dot{m}$ is the mass flow rate of water passing through the tubes and V is the flow velocity.

Substitute $998.7\,kg/m^3$ for ρ, $\left(1.1309\times10^{-4}\right)m^2$ for A and $4\,m/s$ for V

$$\begin{aligned} \dot{m} &= 998.7\times1.1309\times10^{-4}\times4 \\ &= 0.4518\,kg/s \end{aligned}$$

Step 5 of 11

Calculate the heat transfer through one tube.

$$\dot{Q} = \dot{m}c_p\left(T_e - T_i\right)$$

Here, $\dot{Q}$ is the heat transfer through one tube, T_e is the exit temperature and T_i is the inlet temperature.

Substitute $0.4518\,kg/s$ for $\dot{m}$, $4.183\,kJ/kg\cdot K$ for c_p, $24°C$ for T_e and $10°C$ for T_i.

$$\begin{aligned} \dot{Q} &= 0.4518\times4.183\times(24-10) \\ &= 26.46\,kW \end{aligned}$$

Step 6 of 11

Calculate the log-mean temperature difference by using the equation:

$$\Delta T_{ln} = \frac{\Delta T_e - \Delta T_i}{\ln\left(\Delta T_e / \Delta T_i\right)}$$

Substitute $\left(T_s - T_e\right)$ for ΔT_e and $\left(T_s - T_i\right)$ for ΔT_i.

$$\Delta T_{ln} = \frac{\left(T_s - T_e\right)-\left(T_s - T_i\right)}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)}$$

Substitute $30°C$ for T_s, $24°C$ for T_e and $10°C$ for T_i.

$$\begin{aligned} \Delta T_{ln} &= \frac{(30-24)-(30-10)}{\ln\left(\frac{30-24}{30-10}\right)} \\ &= \frac{6-20}{\ln\left(\frac{6}{20}\right)} \\ &= 11.63°C \end{aligned}$$

Step 7 of 11

$= 11.63°C$

Step 7 of 11

Calculate the surface area of each copper tube by using the equation:

$$A_s = \pi dL$$

Here, A_s is the surface area of each copper tube and L is the length of each copper tube.

Substitute $0.012\,\text{m}$ for d and $5\,\text{m}$ for L.

$$\begin{aligned} A_s &= \pi \times 0.012 \times 5 \\ &= 0.1885\,\text{m}^2 \end{aligned}$$

Step 8 of 11

Calculate the average heat transfer coefficient by using the equation:

$$\dot{Q} = hA_s\Delta T_{lm}$$

$$\Rightarrow h = \frac{\dot{Q}}{A_s\Delta T_{lm}}$$

Here, $\dot{Q}$ is the heat transfer through one tube and h is the average heat transfer coefficient.

Substitute $26.46\,\text{kW}$ for $\dot{Q}$, $0.1885\,\text{m}^2$ for A_s and $11.63°C$ for ΔT_{lm}.

$$\begin{aligned} h &= \frac{26.46}{0.1885 \times 11.63} \\ &= 12.1\,\text{W/m}^2 \cdot °C \end{aligned}$$

Step 9 of 11

Obtain the enthalpy of vaporization of water at $30°C$ from the "Properties of saturated water" table.

$$h_{fg} = 2431\,\text{kJ/kg}$$

Here, h_{fg} is the enthalpy of vaporization of water at $30°C$.

Step 10 of 11

Calculate the total heat transfer rate by using the equation:

$$\dot{Q}_{total} = \dot{m}_{cond} h_{fg}$$

Here, $\dot{Q}_{total}$ is the total heat transfer rate and $\dot{m}_{cond}$ is the mass flow rate of the condensate.

Substitute $0.15\,\text{kg/s}$ for $\dot{m}_{cond}$ and $2431\,\text{kJ/kg}$ for h_{fg}.

$$\begin{aligned} \dot{Q}_{total} &= 0.15 \times 2431 \\ &= 364.65\,\text{kW} \end{aligned}$$

Step 11 of 11

Calculate the number of tubes needed to achieve the indicated heat transfer rate in the condenser by using the equation:

$$n = \frac{\dot{Q}_{total}}{\dot{Q}}$$

Here, n is the number of tubes needed to achieve the indicated heat transfer rate in the condenser.

Substitute $364.65\,\text{kW}$ for $\dot{Q}_{total}$ and $26.46\,\text{kW}$ for $\dot{Q}$.

$$\begin{aligned} n &= \frac{364.65}{26.46} \\ &= 13.78 \\ &\simeq 14 \end{aligned}$$

Therefore, the number of tubes needed to achieve the indicated heat transfer rate in the condenser is $\boxed{14}$.

Question: 19.077P

Repeat Prob. 19-76 for steam condensing at a rate of 0.60 kg/s.

Step 1 of 4

Calculate the Mass flow rate of water

$$\dot{m}_w = \rho A V_{mean}$$
$$= \rho \frac{\pi}{4} D^2 V_{mean}$$

Here,

Density of the water is ρ

Diameter of the tube is D

Mean velocity of flow, V_{mean}

Substitute $4\ \text{m/s}$ for V_{mean}, $0.012\ \text{m}$ for D, $998.7\ \text{kg/m}^3$ for ρ

$$\dot{m}_w = \rho A V_{mean}$$
$$= \rho \frac{\pi}{4} D^2 V_{mean}$$
$$= 998.7 \times \frac{\pi}{4} \times 0.012^2 \times 4$$
$$= 0.4518\ \text{kg/sec}$$

Step 2 of 4

Calculate the rate of heat transfer from one tube is

$$\dot{Q} = \dot{m}_w c_p (T_e - T_i)$$

Substitute $4.183\ \text{kJ/kg} \cdot \text{K}$ for c_p, $0.4518\ \text{kg/sec}$ for $\dot{m}_w$

$$\dot{Q} = \dot{m}_w c_p (T_e - T_i)$$
$$= 0.4518 \times 4.183 \times (24 - 10)$$
$$= 26.458\ \text{kW}$$

Step 3 of 4

Calculate the Surface area of the tube

$$A_s = \pi D L$$

Here,

Length of the tube is L

Substitute $5\ \text{m}$ for L, $0.012\ \text{m}$ for D

$$A_s = \pi D L$$
$$= \pi \times 0.012 \times 5$$
$$= 0.1884\ \text{m}^2$$

Now, log-mean temperature difference is to be determined

$$\Delta T_{lm} = \frac{\Delta T_e - \Delta T_i}{\ln(\Delta T_e / \Delta T_i)}$$

Where $\Delta T_e = T_s - T_e$

$$= 30 - 24$$
$$= 6°\text{C}$$

$$\Delta T_i = T_s - T_i$$
$$= 30 - 10$$
$$= 20°\text{C}$$

Substitute $6°\text{C}$ for ΔT_e, $20°\text{C}$ for ΔT_i

$$\Delta T_{lm} = \frac{6 - 20}{\ln\left(\frac{6}{20}\right)}$$

$$\Delta T_{lm} = 11.62°\text{C}$$

Step 4 of 4

Calculate the total heat transfer required or indicated heat transfer rate are:

$$Q_1 = h A_s \Delta T_{lm}$$

Substitute $13152.08\ \text{W/m}^2 \cdot \text{K}$ for h, $284.6°\text{C}$ for ΔT_{lm}

$$= 13152.08 \times 3.14 \times 0.012 \times 5 \times 284.62$$
$$= 141.05\ \text{kW}$$

Calculate the Number of tube required be n

$$n = \frac{\dot{Q}_1}{\dot{Q}}$$

Substitute $141.05\ \text{kW}$ for Q_1, $8.788\ \text{kW}$ for Q

$$n = \frac{\dot{Q}_1}{\dot{Q}}$$
$$= \frac{141.05}{8.788}$$
$$= 16.05$$

Hence, the number of tubes is required for heat transfer is **17**

Question: 19.078P

Combustion gases passing through a 5-cm-internal-diameter circular tube are used to vaporize waste water at atmospheric pressure. Hot gases enter the tube at 115 kPa 1 and 250°C at a mean velocity of 5 m/s, and leave at 150°C. If the average heat transfer coefficient is 120 W/m2·K and the j inner surface temperature of the tube is 110°C, determine (*a*) the tube length and (*b*) the rate of evaporation of water.

Step 1 of 8

Given data:

Diameter of tube, $D = 5\text{ cm} = 0.05\text{ m}$

Hot gases inlet temperature, $T_i = 250°C$

Mean velocity, $V_{avg} = 5\text{ m/s}$

Exit temperature, $T_e = 150°C$

Average heat transfer coefficient, $h = 120\text{ W/m}^2\cdot\text{K}$

Inner surface temperature of tube, $T_s = 110°C$

Hot gases entry pressure, $P = 115\text{ kPa}$

Step 2 of 8

Mean film temperature of gas is given by

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{(250+150)}{2}$$
$$= 200°C$$

From the table of 'properties of air at 1 atm pressure' at $T_{avg} = 200°C$ we get

Specific heat, $c_p = 1023\text{ J/kg}\cdot\text{K}$

Constant, $R = 0.287\text{ kJ/kg}\cdot\text{K}$

Step 3 of 8

Density of the air,

$$\rho = \frac{P}{RT}$$
$$= \frac{115}{0.287\times(250+273)}$$
$$= 0.766\text{kg/m}^3$$

Step 4 of 8

Mass flow rate,

$$\dot{m} = \rho A_C \cdot V_{avg}$$
$$= 0.766\times\frac{\pi D^2}{4}\times 5$$
$$= \frac{0.766\times\pi\times(0.05)^2\times 5}{4}$$
$$= 7.52\times10^{-3}\text{ kg/s}$$

Therefore rate of heat transfer,

$$\dot{Q} = \dot{m}c_p(T_i - T_e)$$
$$= 7.52\times10^{-3}\times1023\times(250-150)$$
$$= 769.32\text{W}$$

Step 5 of 8

Therefore logarithmic mean temperature,

$$\Delta T_{ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)}$$
$$= \frac{150-250}{\ln\left[\frac{110-150}{110-250}\right]}$$
$$= 79.82°C$$

Step 6 of 8

The amount of heat transfer is determined by the relation

$$Q = hA_s\Delta T_{ln}$$

Re-arranging the above relation for area we get

$$A_s = \frac{Q}{h\Delta T_{ln}}$$
$$= \frac{769.32}{120\times79.82}$$
$$= 0.0803\text{m}^2$$

Step 7 of 8

a)

We know surface area A_s can also be expressed by

$$A_s = \pi DL$$

Therefore

$$L = \frac{A_s}{\pi D}$$
$$= \frac{0.0803}{\pi\times(0.05)}$$
$$= 0.511\text{m}$$

Therefore length of the tube is $\boxed{L = 51.13\text{ cm}}$

Step 8 of 8

b)

Rate of evaporation, $\dot{m}_w$ can be determined from i.e for water

$$\dot{Q} = \dot{m}_w$$

As heat transfer rate, $\dot{Q}$ to water can also be expressed as:

$\dot{Q}$ = Rate of evaporation of water × Enthalpy of vaporization

$$\dot{Q} = \dot{m}_w \times h_{fg}$$

Take value of h_{fg} from saturated water properties table.

At $T = 100°C$

$h_{fg} = 2257\text{ kJ/kg}$

Rate of evaporation of water is given by

$$\dot{m}_w = \frac{\dot{Q}}{h_{fg}}$$
$$= \frac{769.32}{2257\times1000}$$

Therefore, rate of evaporation of water is $\boxed{\dot{m}_w = 3.409\times10^{-4}\text{ kg/s}}$

Question: 19.079P

Repeat Prob. 19-78 for a heat transfer coefficient of 40 W/m2·K.

Step 1 of 8

Given data:

Diameter of tube, $D = 5\text{ cm} = 0.05\text{ m}$

Hot gases inlet temperature, $T_i = 250°\text{C}$

Mean velocity, $V_{avg} = 5\text{ m/s}$

Exit temperature, $T_e = 150°\text{C}$

Average heat transfer coefficient, $h = 40\text{ W/m}^2\text{-K}$

Inner surface temperature of tube, $T_s = 110°\text{C}$

Hot gases entry pressure, $P = 115\text{ kPa}$

Step 2 of 8

Calculate the mean film temperature of gas,

$$T_{avg} = \frac{T_i + T_e}{2}$$

Where,

T_i is hot gases inlet temperature,

T_e is the exit temperature.

Substitute $T_i = 250°\text{C}$ and $T_e = 150°\text{C}$ in the above equation,

$$T_{avg} = \frac{(250+150)}{2}$$

$$= 200°\text{C}$$

From the table of 'properties of air at 1 atm pressure'

At $T_{avg} = 200°\text{C}$

Specific heat, $c_p = 1023\text{ J/kg·K}$

Constant, $R = 0.287\text{ kJ/kg·K}$

Step 3 of 8

Calculate the density of the air,

$$\rho = \frac{P}{RT_i}$$

Where,

P is the hot gases entry pressure,

Substitute $P = 115\text{ kPa}$, $R = 0.287\text{ kJ/kg·K}$ and $T_i = 250°\text{C}$ in the above equation,

$$\rho = \frac{115}{0.287\times(250+273)}$$

$$= 0.766\text{kg/m}^3$$

Step 4 of 8

Calculate the mass flow rate,

$$\dot{m} = \rho A_C \cdot V_{avg}$$

Where,

A_C is the area of the cross-section of the tube,

V_{avg} is the mean velocity.

$$\dot{m} = 0.766\times\frac{\pi D^2}{4}\times 5$$

$$= \frac{0.766\times\pi\times(0.05)^2\times 5}{4}$$

$$= 7.52\times10^{-3}\text{ kg/s}$$

Calculate the rate of heat transfer,

$$\dot{Q} = \dot{m}c_p(T_i - T_e)$$

$$= 7.52\times10^{-3}\times1023\times(250-150)$$

$$= 769.32\text{W}$$

Step 5 of 8

Calculate the logarithmic mean temperature,

$$\Delta T_{ln} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)}$$

T_s is the inner surface temperature of tube,

Substitute $T_s = 110°\text{C}$ and the respective values in the above equation,

$$\Delta T_{ln} = \frac{150-250}{\ln\left[\frac{110-150}{110-250}\right]}$$

$$= 79.82°\text{C}$$

Step 6 of 8

Calculate the amount of heat transfer,

$$Q = hA_s\Delta T_{ln}$$

Re-arranging the above relation for area we get

$$A_s = \frac{Q}{h\Delta T_{ln}}$$

h is the average heat transfer coefficient,

Substitute $h = 40\text{ W/m}^2\text{-K}$ and the respective values in the above equation,

$$A_s = \frac{769.32}{40\times79.82}$$

$$= 0.2409\text{ m}^2$$

Step 7 of 8

(a)

calculate the surface area A_s,

$$A_s = \pi DL$$

$$L = \frac{A_s}{\pi D}$$

$$= \frac{0.2409}{\pi\times(0.05)}$$

$$= 1.534\text{m}$$

Therefore length of the tube is $\boxed{153.4\text{ cm}}$

Step 8 of 8

b)

Rate of evaporation, $\dot{m}_w$ can be determined from i.e for water

$$\dot{Q} = \dot{m}_w$$

As heat transfer rate, $\dot{Q}$ to water can also be expressed as:

$\dot{Q}$ = Rate of evaporation of water × Enthalpy of vaporization

$$\dot{Q} = \dot{m}_w \times h_{fg}$$

Take value of h_{fg} from saturated water properties table.

At $T = 100°\text{C}$

$h_{fg} = 2257\text{ kJ/kg}$

Rate of evaporation of water is given by

$$\dot{m}_w = \frac{\dot{Q}}{h_{fg}}$$

$$= \frac{769.32}{2257\times1000}$$

Therefore, rate of evaporation of water is $\boxed{\dot{m}_w = 3.409\times10^{-4}\text{ kg/s}}$

Question: 19.080P

Determine the convection heat transfer coefficient for the flow of (*a*) air and (*b*) water at a velocity of 5 m/s in an 8-cm-diameter and 10-m-long tube when the tube is subjected to uniform heat flux from all surfaces. Use fluid properties at 25°C.

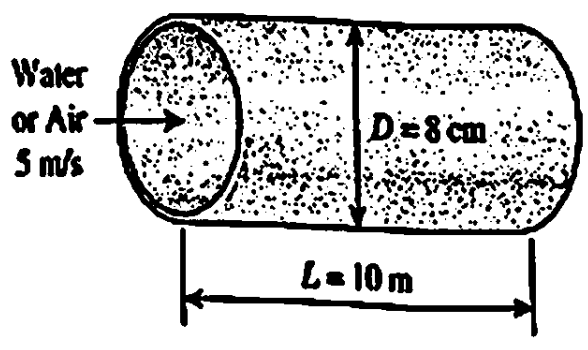


FIGURE P19-80

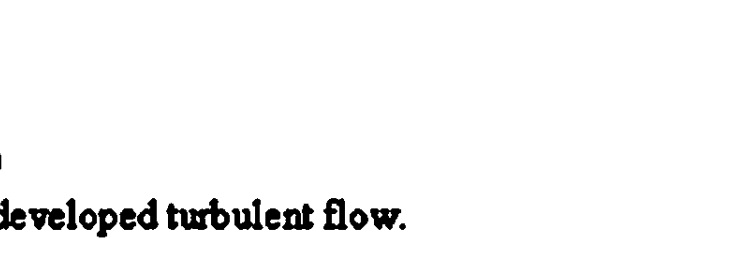
Step 1 of 8

Given data:

Diameter of pipe, $D = 8\,\text{cm} = 0.08\,\text{m}$



Length of pipe, $L = 10\,\text{m}$

Mean velocity of fluid flow, $V = 5\,\text{m/s}$

Fluid temperature, $T_f = 25°\text{C}$

Step 2 of 8

Schematic Diagram of pipe flow:

Step 3 of 8

(a)

For Air,

From the table properties of air at 1 atm pressure at $T = 25°\text{C}$

Thermal conductivity, $k = 0.02551\ \text{w/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.562\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7296$

Reynolds number is

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{5\times0.08}{1.562\times10^{-5}}$$
$$= 25608.19$$

As $\text{Re} > 10{,}000$. Therefore it is a turbulent flow.

Step 4 of 8

Now, entry length L_h, Turbulent

$$L_h = 10\text{D}$$
$$= 10\times0.08$$
$$= 0.8\ \text{m}$$

As $L_h < L$ (given)

Therefore it's a fully developed turbulent flow.

Step 5 of 8

Then, Nusselt number is given by

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$
$$= 0.023(25608.19)^{0.8}\,\text{Pr}^{0.4}$$
$$= 68.18$$

Also, N_u can be expressed as:

$$Nu = \frac{hD}{k}$$

Therefore heat transfer coefficient,

$$h = \frac{k}{D}\times Nu$$
$$= \frac{0.02551}{0.08}\times68.18$$
$$= 21.74$$

Therefore, heat transfer coefficient is $\boxed{h_{air} = 21.74\ \text{W/m}^2\cdot\text{K}}$

Step 6 of 8

(b)

For water,

From the properties of saturated water at $T = 25°\text{C}$

Thermal conductivity, $k = 0.607\ \text{W/m}\cdot\text{K}$

Density, $\rho = 997\ \text{kg/m}^3$

Dynamic viscosity, $\mu = 0.891\times10^{-3}\ \text{kg/m}\cdot\text{s}$

Prandtl number, $\text{Pr} = 6.14$

Step 7 of 8

Kinematic viscosity is given by

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{0.891\times10^{-3}}{997}$$
$$= 8.937\times10^{-7}\,\text{m}^2/\text{s}$$

Reynolds number is given by

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{5\times0.08}{8.937\times10^{-7}}$$
$$= 447577.49$$

Step 8 of 8

Definitely the flow is fully developed turbulent flow,

$$Nu = 0.23\text{Re}^{0.8}\text{Pr}^{0.4}.$$
$$= 0.023(447577.49)^{0.8}(6.14)^{0.4}$$
$$= 1576.485$$

Heat transfer coefficient for water,

$$h_{water} = \frac{k\cdot Nu}{D}$$
$$= \frac{0.607\times1576.485}{0.08}$$
$$= 11961.58\ \text{W/m}^2\cdot\text{K}$$

Therefore, heat transfer coefficient for water $\boxed{h_{water} = 11961.58\ \text{W/m}^2\cdot\text{K}}$

Question: 19.081P pg 1

An 8-m long, uninsulated square duct of cross section 0.2 m × 0.2 m and relative roughness 10-3 passes through the attic space of a house. Hot air enters the duct at 1 atm and 80°C at a volume flow rate of 0.15 m3/s. The duel surface is nearly isothermal at 60°C. Determine the rate of heat loss from the duct to the attic space and the pressure difference between the inlet and outlet sections of the duct.

Step 1 of 9

Given data:

The length of the square duct, $L = 8\ \text{m}$

Cross section of square duct, $a \times a = 0.2\text{m} \times 0.2\text{m}$

Relative roughness of the duct, $\frac{\varepsilon}{D} = 10^{-3}$

Temperature of air enters the duct, $T_i = 80°\text{C}$

Volume flow rate of air at inlet, $\dot{V} = \dot{V}_i = 0.15\text{m}^3/s$

Surface temperature of the duct, $T_s = 60°\text{C}$

Step 2 of 9

Properties of air at 80°C and 1atm are

$\rho = 0.9994\ \text{kg/m}^3$

$C_p = 1008\ \text{J/kg}\cdot\text{K}$

$k = 0.02953\ \text{W/m}\cdot\text{K}$

$\text{Pr} = 0.7154$

$\nu = 2.097\times10^{-5}\ \text{m}^2/s$

Step 3 of 9

Characteristic length of square duct D_h is given by

$$D_h = \frac{4A_c}{p}$$

Where A_c is the Cross-sectional area of square duct and p is the wetted perimeter

Now

$$D_h = \frac{4a^2}{4a}$$
$$= a$$
$$= 0.2\ \text{m}$$

Average velocity of air

$$V_{avg} = \frac{\dot{V}}{A_c}$$
$$= \frac{0.15}{(0.2)^2}$$
$$= 3.75\ \text{m/s}$$

Step 4 of 9

Reynolds number

$$\text{Re} = \frac{V_{avg}D_h}{\nu}$$
$$= \frac{3.75\times0.2}{2.097\times10^{-5}}$$
$$= 35765.379$$

Here Reynolds number is greater than 10,000. Hence the flow is turbulent and entry lengths in this case is roughly 10 times the hydraulic diameter

$$L_h \approx L_t \approx 10D$$
$$= 10\times0.2$$
$$= 2\text{m}$$

As this length is quite small when compared to the total length of tube, we can assume fully developed flow for the entire tube length.

Step 5 of 9

Nusselt number,

$$\text{Nu} = \frac{hD_h}{k} = 0.023\text{Re}^{0.8}\text{Pr}^{0.3}$$

$$\frac{hD_h}{k} = 0.023(35765.379)^{0.8}(0.7154)^{0.3}$$

$$\frac{hD_h}{k} = 91.38$$

Then, heat transfer coefficient

$$h = \frac{k}{D_h}\times91.38$$
$$= \frac{0.02953\times(91.38)}{0.2}$$
$$= 13.49\ \text{W/m}^2\cdot\text{K}$$

Step 6 of 9

Surface area of square duct

$$A_s = 4aL$$
$$= 4\times(0.2)\times(8)$$
$$= 6.4\ \text{m}^2$$

Mass flow rate,

$$\dot{m} = \rho\dot{V}$$
$$= (0.9994)\times(0.15)$$
$$= 0.150\ \text{kg/s}$$

Step 7 of 9

Exit temperature of air,

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{hA_s}{\dot{m}C_p}\right)$$

Step 7 of 9

Exit temperature of air,

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{hA_s}{\dot{m}C_p}\right)$$

$$= 60 - (60-80)\exp\left(-\frac{13.5\times 6.4}{0.15\times 1008}\right)$$

$$T_e = 71.3^0\text{C}$$

Logarithmic mean temperature difference,

$$\Delta T_{lm} = \frac{T_i - T_e}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)}$$

$$= \frac{80-71.3}{\ln\left(\frac{60-71.3}{60-80}\right)}$$

$$= -15.2^\circ\text{C}$$

Step 8 of 9

Heat transfer,

$$Q = hA_s\Delta T_{lm}$$

$$= (13.5)(6.4)(-15.2)$$

$$= -1313.28\ \text{W}$$

Therefore air will lose heat at the rate of $\boxed{1313.28\ \text{W}}$ as it flows through the duct in the attic.

Step 9 of 9

The friction factor can be determined by using the equation

$$\frac{1}{\sqrt{f}} = -1.8\log\left(\frac{6.9}{\text{Re}} + \left(\frac{\varepsilon/D}{3.7}\right)^{1.11}\right)$$

$$= -1.8\log\left(\frac{6.9}{35765.379} + \left(\frac{10^{-3}}{3.7}\right)^{1.11}\right)$$

$$f = 0.024$$

Pressure difference between inlet and outlet sections of the duct can be calculated as

$$\Delta P_f = \frac{fL\rho V_{avg}^2}{D_h\times 2}$$

$$= \frac{0.024\times 8\times 0.9994\times (3.75)^2}{0.2\times 2}$$

$$= 6.74595\ \text{N/m}^2$$

Pressure difference, $\boxed{\Delta P_f = 6.74595\ \text{N/m}^2}$

Question: 19.082P

A 12-m long and 12-mm inner-diameter pipe made of commercial steel is used to heat a liquid in an industrial process. The liquid enters the pipe with *Ti*= 25°C, *V* = 0.8 m/s. A uniform heat flux is maintained by anelectric resistance heater wrapped around the outer surface of the pipe, so that the fluid exits at75°C. Assuming fully developed flow and taking the average fluid properties to be ρ =1000 kg/m3, $c\rho$ =4000 J/kg·K, μ= 2 x 10-3 kg/m·s. *k* =0.48 W/m·K, and Pr = 10, determine:

(a) The required surface heat flux *qs* produced by the heater

(b) The surface temperature at the exit, *Ts*

Step 1 of 6

Given data:

Length of pipe, $L = 12$ m

Diameter of pipe, $D = 12$ mm

Liquid entry temperature, $T_i = 25°C$

Velocity, $V = 0.8 m/s$

Exit temperature of fluid, $T_e = 75°C$

Density, $\rho = 1000 kg/m^3$

Specific heat, $C_p = 4000$ J/kg·K

Dynamic viscosity, $\mu = 2 \times 10^{-3}$ kg/m·s

Thermal conductivity, $k = 0.48$ W/m·K

Prandtl number, $Pr = 10$

Step 2 of 6

(a) The required surface heat flux, $\dot{q}_s$

Mass flow rate of the liquid

$$\dot{m} = \rho A V$$

$$= 1000 \times \pi \frac{(0.012)^2}{4} \times 0.8$$

$$= 0.09048 kg/s$$

Rate of heat transfer

$$\dot{Q} = \dot{m} C_p (T_e - T_i)$$

$$= 0.09048 \times 4000 \times (75 - 25)$$

$$= 18095.6 W$$

Step 3 of 6

Therefore surface heat flux produced by the heater

$$\dot{q}_s = \frac{\dot{Q}}{A_s}$$

$$= \frac{18095.6}{\pi D L}$$

$$= \frac{18095.6}{\pi \times 0.012 \times 12}$$

$$= 40000 W/m^2$$

The required surface heat flux is given by $\boxed{\dot{q}_s = 40,000 W/m^2}$

Step 4 of 6

(b) Surface temperature at exit, T_s

Let us calculate the Reynolds number to see the flow regime

$$R_e = \frac{\rho V D}{\mu}$$

$$= \frac{1000 \times 0.8 \times 0.012}{2 \times 10^{-3}}$$

$$= 4800$$

Since R_e calculated is more than 2300 but less than 10,000, the flow is a transitional flow as given, assuming it as fully developed turbulent flow, the Nusselt number can be

$$Nu = 0.023 Re^{0.8} Pr^{0.4}$$

$$= 0.023 (4800)^{0.8} (10)^{0.4}$$

$$= 50.90$$

Step 5 of 6

Heat transfer coefficient using the Nusselt number as

$$Nu = \frac{hD}{k}$$

$$h = \frac{k}{D} \times Nu$$

$$= \frac{0.48}{0.012} \times (50.90)$$

$$= 2036 W/m^2 \cdot K$$

Step 6 of 6

The surface heat flux can be given by the relation,

$$\dot{q}_s = h(T_s - T_e)$$

$$T_s = \frac{\dot{q}_s}{h} + T_e$$

$$= \frac{40,000}{2036} + 75$$

$$= 94.65°C$$

Hence the surface temperature at the exit is $\boxed{T_s = 94.65°C}$

Question: 19.083P

Determine the hydrodynamic and thermal entry lengths for water, engine oil, and liquid mercury flowing through a 2.5-cm-diameter smooth tube with mass flow rate of 0.01 kg/s and temperature of 100°C.

Step 1 of 7

Given data:

Diameter of smooth tube, $D = 2.5\ \text{cm}$

Mass flow rate of the fluid, $\dot{m} = 0.01\ \text{kg/s}$

Temperature of fluid, $T_f = 100°\text{C}$

Step 2 of 7

If the flowing fluid is water:

Taking properties of water at $T = 100°\text{C}$

Dynamic viscosity $\mu = 0.282\times10^{-3}\ \text{kg/m}\cdot\text{s}$

Prandtl number $\text{Pr} = 1.75$

Now calculating Reynolds number, Re to know about flow region

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times0.01}{\pi\times0.025\times0.282\times10^{-3}}$$

$$= 1806.013$$

Since it is less than 2300, therefore it is a laminar flow.

Step 3 of 7

Hydrodynamic length for laminar flow

$$L_h \approx 0.05\text{Re}\times\text{D}$$

$$\approx 0.05\times1806.013\times0.025$$

$$\approx 2.26\,\text{m}$$

Hence the Hydrodynamic length for water is $\boxed{L_h \approx 2.26\,\text{m}}$

Thermal entry length for laminar flow

$$L_t \approx 0.05\text{Re}\times\text{Pr}\times\text{D}$$

$$\approx 0.05\times1806.013\times1.75\times0.025$$

$$\approx 3.95\,\text{m}$$

Hence the thermal entry length for water is $\boxed{L_t \approx 3.95\,\text{m}}$

Step 4 of 7

If the flowing fluid is Engine oil:

Taking properties of Engine oil at 100°C

Dynamic viscosity $\mu = 0.01718\ \text{kg/m}\cdot\text{s}$

Prandtl number $\text{Pr} = 279.1$

Now calculating Reynolds number, Re to know about flow region

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times0.01}{\pi\times0.025\times0.01718}$$

$$= 29.645$$

Since it is less than 2300, therefore it is a laminar flow

Step 5 of 7

Hydrodynamic length for laminar flow

$$L_h \approx 0.05\text{Re}\times\text{D}$$

$$\approx 0.05\times29.645\times0.025$$

$$\approx 0.0371\,\text{m}$$

Hence the Hydrodynamic length for engine oil is $\boxed{L_h \approx 0.0371\,\text{m}}$

Thermal entry length for laminar flow

$$L_t \approx 0.05\text{Re}\times\text{Pr}\times\text{D}$$

$$\approx 0.05\times29.645\times279.1\times0.025$$

$$\approx 10.34\,\text{m}$$

Hence the thermal entry length for engine oil is $\boxed{L_t \approx 10.34\,\text{m}}$

Step 6 of 7

If the flowing fluid is Mercury:

Taking properties of liquid mercury at 100°C

Dynamic viscosity $\mu = 1.245\times10^{-3}\ \text{kg/m}\cdot\text{s}$

Prandtl number $\text{Pr} = 0.018$

Now calculating Reynolds number, Re to know about flow region

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times0.01}{\pi\times0.025\times1.245\times10^{-3}}$$

$$= 409.07$$

Since is less than 2300, therefore flow is laminar

Step 7 of 7

Hydrodynamic length for laminar flow

$$L_h \approx 0.05\text{Re}\times\text{D}$$

$$\approx 0.05\times409.07\times0.025$$

$$\approx 0.5113\,\text{m}$$

Hence the Hydrodynamic length for mercury is $\boxed{L_h \approx 0.5113\,\text{m}}$

Thermal entry length for laminar flow

$$L_t \approx 0.05\text{Re}\times\text{Pr}\times D$$

$$\approx 0.05\times409.07\times0.0180\times0.025$$

$$\approx 9.204\times10^{-3}\,\text{m}$$

Hence the thermal entry length for mercury is $\boxed{L_t \approx 9.204\times10^{-3}\,\text{m}}$

Question: 19.084P

Water is to be heated from 10°C to 80°C as it flows through a 2-cm-internal-diameter, 13-m-long tube. The tube is equipped with an electric resistance heater, which provides uniform heating throughout the surface of the tube. The outer surface of the heater is well insulated, so that in steady operation all the heat generated in the heater is transferred to the water in the tube. If the system is to provide hot water at a rate of 5 L/min, determine the power rating of the resistance heater. Also, estimate the inner surface temperature of the pipe at the exit.

Step 1 of 8

Convert water flow rate in the tube from L/min to m^3/s by using conversion factor,

$$\dot{V} = 5\,L/min$$

$$= \frac{5\,L \times 10^{-3}\,\frac{m^3}{L}}{1\,min \times 60\,\frac{s}{min}}$$

$$= 8.33 \times 10^{-5}\,m^3/s$$

Step 2 of 8

Calculate the average temperature of water by using the equation,

$$T_{avg} = \frac{T_i + T_e}{2}$$

Here, T_i is water inlet temperature and T_e is Water outlet or exit temperature

Substitute 10°C for T_i and 80°C for T_e

$$T_{avg} = \frac{10+80}{2}$$

$$= 45°C$$

Take properties of water at average temperature $T_{avg} = 45°C$ from properties of water table.

Density $\rho = 990.1\,kg/m^3$

Specific heat $c_p = 4180\,J/kg\cdot K$

Thermal conductivity $k = 0.637\,W/m\cdot °C$

Step 3 of 8

Calculate mass flow rate of the water

$$\dot{m} = \rho\dot{V}$$

$$= 990.1 \times 8.33 \times 10^{-5}$$

$$= 0.0825\,kg/s$$

Power rating of the resistance heater is equal to the heat transfer rate to the water

$$\dot{Q} = \dot{m}c_p(T_e - T_i)$$

$$= 0.0825 \times 4180(80-10)$$

$$= 24132.28\,W$$

Therefore, the power rating of the resistance heater $\dot{Q}$ is $\boxed{24132.28\,W}$

Step 4 of 8

Calculate average velocity of the water in the tube

$$V_{avg} = \frac{\dot{V}}{A_c}$$

Here, A_c is cross sectional area of the tube of diameter D

Substitute $\frac{\pi D^2}{4}$ for A_c

$$V_{avg} = \frac{\dot{V}}{\frac{\pi D^2}{4}}$$

$$= \frac{4\dot{V}}{\pi D^2}$$

Substitute 0.02 m for D

$$V_{avg} = \frac{4 \times 8.33 \times 10^{-5}}{\pi \times (0.02)^2}$$

$$= 0.265\,m/s$$

Step 5 of 8

Take properties from saturated water property table at 45°C

Dynamic Viscosity $\mu = 0.596 \times 10^{-3}\,kg/m\cdot s$

Prandtl number $Pr = 3.91$

Kinematic viscosity of water is

$$\nu = \frac{\mu}{\rho}$$

$$= \frac{0.596 \times 10^{-3}}{990.1}$$

$$= 6.02 \times 10^{-7}\,m^2/s$$

+

Step 6 of 8

Calculate the Reynolds number of flow region

$$Re = \frac{V_{avg}D}{\nu}$$

$$= \frac{0.265 \times 0.02}{6.02 \times 10^{-7}}$$

$$= 8804.58$$

Hydraulic and thermal entry lengths are equal in this flow region so that

$$L_h = L_t$$

$$= 10D$$

$$= 10 \times 0.02$$

$$= 0.2\,m$$

Step 7 of 8

The entry length is very less than the given length $L = 13\,m$ so that the flow is a fully developed turbulent flow

Calculate the Nusselt number by using the equation,

$$Nu = 0.023\,Re^{0.8}Pr^{0.4}$$

$$= 0.023 \times (8804.58)^{0.8} \times (3.91)^{0.4}$$

$$= 56.8$$

Find the heat transfer coefficient by using the equation,

$$h = \frac{k}{D}Nu$$

$$= \frac{0.637}{0.02} \times 56.80$$

$$= 1809.15\,W/m^2\cdot °C$$

Step 8 of 8

Calculate heat transferred surface area of the tube is

$$A_s = \pi DL$$

$$= \pi \times 0.02 \times 13$$

$$= 0.8168\,m^2$$

Calculate inner surface temperature, T_s by using heat transfer equation,

$$\dot{Q} = hA_s(T_s - T_e)$$

$$24132.28 = 1809.15 \times 0.8168 \times (T_s - 80)$$

$$T_s = \frac{24132.28}{1809.15 \times 0.8168} + 80$$

$$= 96.33°C$$

Hence the inner surface temperature, T_s at the exit is $\boxed{96.33°C}$

Question: 19.085P

Hot air at atmospheric pressure and 75°C enters a 10-m-long uninsulated square duct of cross section 0.15 m × 0.15 m that passes through the attic of a house at a rate of 0.2 m3/s. The duct is observed to be nearly isothermal at 70°C. Determine the exit temperature of the air and the rate of heat loss from the duct to the air space in the attic.

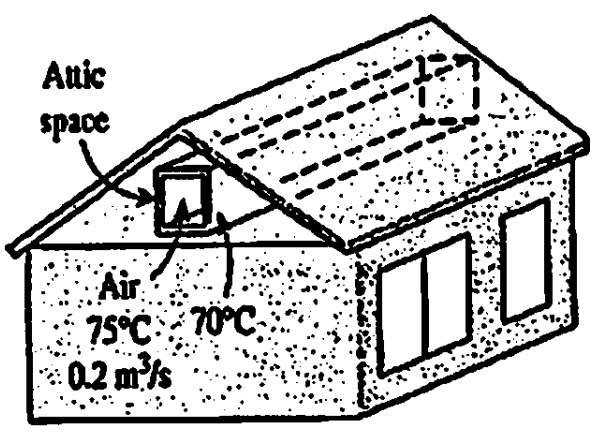


FIGURE PI 9-85

Step 1 of 9

Given data:

Length of square duct $L = 10\text{m}$

Dimensions of duct $H \times W = 0.15 \times 0.15\text{m}$

Inlet temperature of Air $T_i = 75°\text{C}$

Duct temperature $T_s = 70°\text{C}$

Volume flow rate $\dot{V} = 0.2\text{m}^3/s$

Step 2 of 9

The expression for determining the exit temperature of hot air is given by

$$T_e = T_s - (T_s - T_i)\exp\left(-hA/\dot{m}C_p\right)$$

Taking properties of hot air at 75°C the properties of air are

Thermal conductivity of air, $k = 0.02917\,\text{W/m}\cdot°\text{C}$

Density of air, $\rho = 1.0137\,\text{kg/m}^3$

Kinematic viscosity of air, $\nu = 2.046\times10^{-5}\,\text{m}^2/s$

Specific heat of air, $c_p = 1007.5\,\text{J/kg}\cdot\text{K}$

Prandtl number $\text{Pr} = 0.71655$

Step 3 of 9

The hydraulic diameter for the square pipe is

$$D_h = \frac{4A_c}{p}$$
$$= \frac{4\times0.15\times0.15}{4\times0.15}$$
$$= 0.15\text{m}$$

Average velocity of the flow is

$$V_{avg} = \frac{\dot{V}}{A_c}$$
$$= \frac{0.20}{(0.15)^2}$$
$$= 8.889\,\text{m/s}$$

Step 4 of 9

Reynolds number for the flow is given by

$$\text{Re} = \frac{V_{avg}\cdot D_h}{\nu}$$
$$= \frac{8.889\times0.15}{2.046\times10^{-5}}$$
$$= 65167.8$$

Since the Reynolds number is greater than 10,000 , the flow is turbulent

The hydraulic entry length is

$$L_h \approx 10D_h$$
$$= 10\times0.15$$
$$= 1.5\text{m}$$

Step 5 of 9

Hydraulic entry length is much shorter than the given duct length so the flow is a fully developed turbulent flow. Now the Nusselt number is given by

$$N_u = 0.023\text{Re}^{0.8}\text{Pr}^{0.3}$$
$$= 0.023\times(65167.8)^{0.8}\times(0.71655)^{0.3}$$
$$= 147.75$$

Heat transfer coefficient is given by the expression

$$h = \frac{k\cdot N_u}{D_h}$$
$$= \frac{0.02917\times147.75}{0.15}$$
$$= 28.73\,\text{W/m}^2\cdot°\text{C}$$

Step 6 of 9

Surface area of the duct is

$$A_s = 4aL$$
$$= 4\times0.15\times10$$
$$= 6\text{m}^2$$

Mass flow rate of the air is

$$\dot{m} = \rho\dot{V}$$
$$= 1.0137\times0.20$$
$$= 0.20274\,\text{kg/s}$$

Step 7 of 9

Exit temperature of hot air, which can be determined by the relation as

$$T_e = T_s - (T_s - T_i)\exp\left(-hA/\dot{m}C_p\right)$$
$$= 70-(70-75)\exp\left(\frac{-28.73\times6}{0.20274\times1007.5}\right)$$
$$= 72.15°\text{C}$$

Hence Exit temperature of hot air is given by $\boxed{T_e = 72.15°\text{C}}$

Step 8 of 9

Logarithmic mean temperature ΔT_{lm} for the given system is given by

$$\Delta T_{lm} = \frac{T_e - T_i}{\ln\left[\frac{T_s - T_e}{T_s - T_i}\right]}$$
$$= \frac{72.15-75}{\ln\left[\frac{70-72.15}{70-75}\right]}$$
$$= \frac{-2.85}{-0.843}$$
$$= 3.3768°\text{C}$$

Step 9 of 9

Rate of heat loss from the duct to the air space in the attic is given by

$$\dot{Q} = hA_s\Delta T_{lm}$$
$$= 28.73\times6\times3.3768$$
$$= 581.954\,\text{W}$$
$$= 582\,\text{W}$$

Hence the rate of heat loss from the duct is $\boxed{\dot{Q} = 582\,\text{W}}$

Question: 19.086P

Reconsider Prob. 19-85. Using EES (or other) software, investigate the effect of the volume flow rate of air on the exit temperature of air and the rate of heat loss. Let the flow rate vary from 0.05 m3/s to 0.15 m3/s. Plot the exit temperature and the rate of heat loss as a function of flow rate, and discuss the results.

Step 1 of 4

The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Crease a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
"Given"
L=10[m]                 "Length of the duct"
a=0.15[m]               "Side of the cross-section"
T_i=75[C]               "Inlet temperature"
T_s=70[C]               "Surface temperature"
"V_dot=0.2[m^3/s]"      "Volumetric flow rate"
P_1=101.3[kPa]          "assume atmospheric pressure"

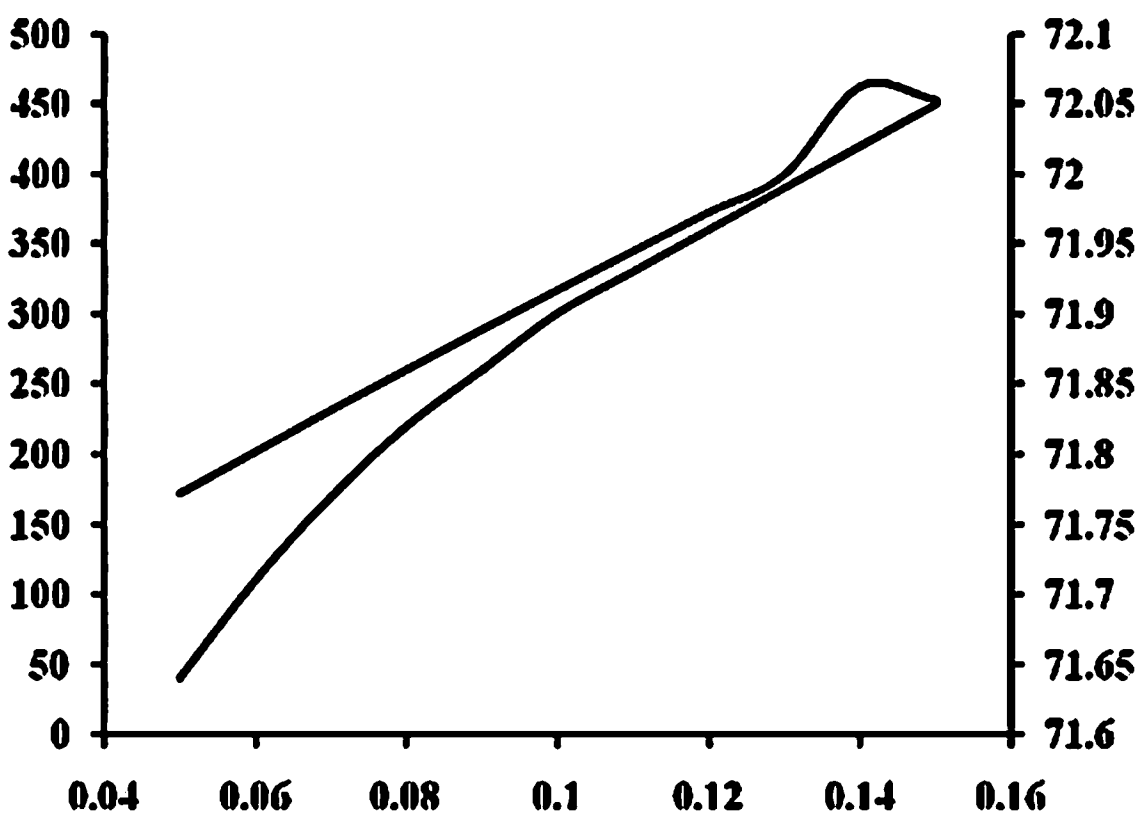
"Properties"
k=Conductivity(Air,T=T_i)              "thermal conductivity"
rho=Density(Air,T=T_i,P=P_1)           "Density"
mu=Viscosity(Air,T=T_i)                "kinematic viscosity"
cp=SpecHeat(Air,T=T_i)*1000            "Specific Heat in J/kg-K"
Pr=Prandtl(Air,T=T_i)                  "Prandtl number"
```

Step 2 of 4

```
"Analysis"
D_h=4*A_c/p                            "hydraulic diameter"
A_c=a^2                                "cross-sectional area"
p=4*a                                  "perimeter"
V_avg=V_dot/A_c                        "Average velocity"
Re= V_avg*D_h* rho/ mu                 "Reynolds number"
L_h=10*D_h                             "Charecteristic length"
N_u=0.023*(Re^0.8)*(Pr^0.3)            "Nusselt number"
h=k*N_u/D_h                            "Heat transfer coefficient"
A_s=4*a*L                              "Surface area"
m_dot=rho*V_dot                        "Mass flow rate"
T_e=T_s-((T_s-T_i)*(exp(-h*A_s/(m_dot*cp))))
                                       "Exit temperature"
Delta_lm=(T_e-T_i)/(ln((T_s-T_e)/(T_s-T_i)))
                                       "log mean temperature difference"
Q_dot=h*A_s*Delta_lm                   "Heat loss"
```

Step 3 of 4

Now to solve the equation for a range of volume flow rate values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 11



Select variables in equations as $\dot{V}$, T_e and $\dot{Q}$ press 'Add' and then press 'ok'

A table will appear and enter the values of volume flow rate '$\dot{V}$' as 0.05,0.06....0.15 in runs 1 to 11. Then click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below

1..11	1 $\dot{V}$ [m3/s]	2 $\dot{Q}$ [W]	3 T_e [C]
Run 1	0.05	171.5	71.64
Run 2	0.06	201.7	71.71
Run 3	0.07	231.3	71.77
Run 4	0.08	260.3	71.82
Run 5	0.09	288.9	71.86
Run 6	0.1	317	71.9
Run 7	0.11	344.8	71.93
Run 8	0.12	372.2	71.96
Run 9	0.13	399.3	71.99
Run 10	0.14	426.2	72.02
Run 11	0.15	452.7	72.05

Step 4 of 4

Inorder to find the variation of exit temperature and heat loss with volumetric flow rate, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Select X-axis as $\dot{V}$ and Y-axis as $\dot{Q}$ and T_e. Press OK
The Graph will be plotted as shown below.

This graph represents that by increasing the volumetric flow rate, the temperature and heat loss increases.

Question: 19.087P

Consider a fluid with a Prandtl number of 7 flowing through a smooth circular tube. Using the Colburn, Petukhov, and Gnielinski equations, determine the Nusselt numbers for Reynolds numbers at 3500, 104, and 5 × 105.Compare and discuss the results.

Step 1 of 8

Given data:
A fluid flowing through a smooth circular tube
Fluid Prandtl number $\mathrm{Pr} = 7$
The Reynolds numbers are
$\mathrm{Re}_1 = 3500$
$\mathrm{Re}_2 = 10^4$
$\mathrm{Re}_3 = 5\times10^5$

Step 2 of 8

The Colburn equation is given as

$$Nu = 0.023\mathrm{Re}^{0.8}\mathrm{Pr}^{1/3} \quad \ldots\ldots (1)$$

The Petukhov equation is given as

$$Nu = \frac{(f/8)\mathrm{Re}\cdot\mathrm{Pr}}{1.07+12.7(f/8)^{0.5}\left(\mathrm{Pr}^{2/3}-1\right)} \quad \ldots\ldots (2)$$

Where $f = (0.790\ln\mathrm{Re}-1.64)^{-2}$ ..... (3)

The Gnielinski equation is given as

$$Nu = \frac{(f/8)(\mathrm{Re}-1000)\mathrm{Pr}}{1+12.7(f/8)^{0.5}\left(\mathrm{Pr}^{2/3}-1\right)} \quad \ldots\ldots (4)$$

Step 3 of 8

For $\mathrm{Re}_1 = 3500$ the equation (1) becomes,

$$Nu = 0.023(3500)^{0.8}(7)^{1/3}$$
$$= 30.108$$

Hence the Nusselt number as per Colburn equation is $\boxed{Nu = 30.108}$

For $\mathrm{Re}_1 = 3500$ the equation (3) becomes,

$$f = (0.79\ln 3500 - 1.64)^{-2}$$
$$= 0.04328$$

Step 4 of 8

Thus the Nusselt number according to equation (2) is given by

$$Nu = \frac{(0.04328/8)\times3500\times7}{1.07+12.7(0.04328/8)^{0.5}\left(7^{2/3}-1\right)}$$
$$= \frac{132.545}{3.554}$$
$$= 37.29$$

Hence the Nusselt number as per Petukhov equation is $\boxed{Nu = 37.29}$

For $\mathrm{Re}_1 = 3500$ the equation (4) becomes,

$$Nu = \frac{(0.04328/8)(3500-1000)\times7}{1+12.7(0.04328/8)^{0.5}\left(7^{2/3}-1\right)}$$
$$= \frac{94.675}{3.484}$$
$$= 27.174$$

Hence the Nusselt number as per Gnielinski equation is $\boxed{Nu = 27.174}$

Step 5 of 8

For $\mathrm{Re}_2 = 10^4$ the equation (1) becomes,

$$Nu = 0.023\left(10^4\right)^{0.8}(7)^{1/3}$$
$$= 69.73$$

Hence the Nusselt number as per Colburn equation is $\boxed{Nu = 69.37}$

For $\mathrm{Re}_2 = 10^4$ the equation (3) becomes,

$$f = \left[0.79\ln\left(10^4\right)-1.64\right]^{-2}$$
$$= 0.03148$$

Step 6 of 8

Thus the Nusselt number according to equation (2) is given by

$$Nu = \frac{(0.03148/8)\times10^4\times7}{1.07+12.7(0.03148/8)^{0.5}\left(7^{2/3}-1\right)}$$
$$= \frac{275.45}{3.1886}$$
$$= 86.48$$

Hence the Nusselt number as per Petukhov equation is $\boxed{Nu = 86.48}$

For $\mathrm{Re}_2 = 10^4$ the equation (4) becomes,

$$Nu = \frac{(0.03148/8)\left(10^4-1000\right)\times7}{1+12.7(0.03148/8)^{0.5}\left(7^{2/3}-1\right)}$$
$$= \frac{247.905}{3.1186}$$
$$= 79.49$$

Hence the Nusselt number as per Gnielinski equation is $\boxed{Nu = 79.49}$

Step 7 of 8

For $\mathrm{Re}_3 = 5\times10^5$ the equation (1) becomes,

$$Nu = 0.023\left(5\times10^5\right)^{0.8}(7)^{1/3}$$
$$= 1594$$

Hence the Nusselt number as per Colburn equation is $\boxed{Nu = 1594}$

For $\mathrm{Re}_3 = 5\times10^5$ the equation (3) becomes,

$$f = \left[0.79\ln\left(5\times10^5\right)-1.64\right]^{-2}$$
$$= 0.01313$$

Step 8 of 8

Thus the Nusselt number according to equation (2) is given by

$$Nu = \frac{(0.01313/8)\times\left(5\times10^5\right)\times7}{1.07+12.7(0.01313/8)^{0.5}\left(7^{2/3}-1\right)}$$
$$= \frac{5744.375}{2.438}$$
$$= 2356$$

Hence the Nusselt number as per Petukhov equation is $\boxed{Nu = 2356}$

For $\mathrm{Re}_3 = 5\times10^5$ the equation (4) becomes,

$$Nu = \frac{(0.01313/8)\left(5\times10^5-1000\right)\times7}{1+12.7(0.01313/8)^{0.5}\left(7^{2/3}-1\right)}$$
$$= \frac{5732.88}{2.368}$$
$$= 2421$$

Hence the Nusselt number as per Gnielinski equation is $\boxed{Nu = 2421}$

Question: 19.088P

A concentric annulus tube has inner and outer diameters of 25 mm and 100 mm, respectively. Liquid water flows at a mass flow rate of 0.05 kg/s through the annulus with the inlet and outlet mean temperatures of 20°C and 80°C, respectively. The inner tube wall is maintained with a constant surface temperature of 120°C, while the outer tube surface is insulated. Determine the length of the concentric annulus tube.

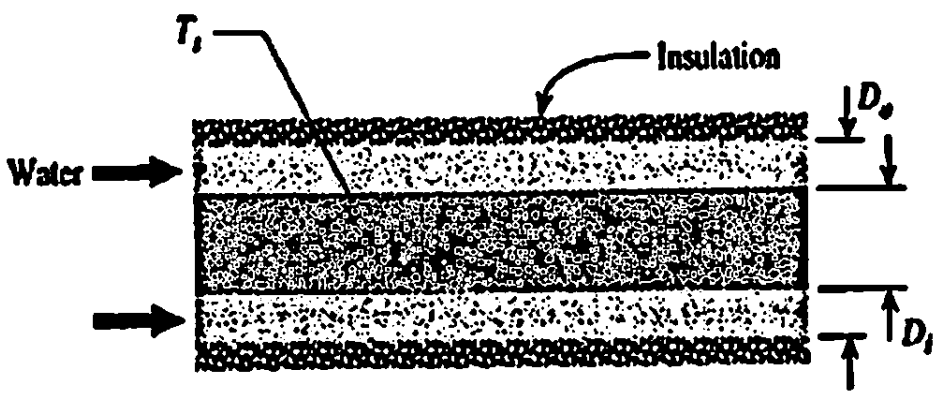


FIGURE P19-88

Step 1 of 5

Calculate the average temperature of water

$$T_{avg} = \frac{T_e + T_i}{2}$$

Here, T_e is the outer temperature and T_i is the initially temperature.

Substitute $20°C$ for T_e and $80°C$ for T_i.

$$\begin{aligned} T_{avg} &= \frac{T_e + T_i}{2} \\ &= \frac{20+80}{2} \\ &= 50°C \end{aligned}$$

Step 2 of 5

From the properties of water, the average temperature is $50°C$.

Thermal conductional, $k = 0.644\ W/m \cdot °C$

Dynamic viscosity, $\mu = 0.547 \times 10^{-3}\ kg/m \cdot s$

Calculate the Reynolds number.

$$R_e = \frac{4\dot{m}}{\pi(D_o - D_i)\mu}$$

Here, $\dot{m}$ is the mass flow rate, μ is the dynamic viscosity, D_o is the outer diameter of the pipe and D_i is the inner diameter of the pipe

Substitute $0.05\ m/s$ for $\dot{m}$, $0.1\ m$ for D_o and $0.025\ m$ for D_i

$$\begin{aligned} R_e &= \frac{4\dot{m}}{\pi(D_o - D_i)\mu} \\ &= \frac{4 \times 0.05}{\pi(0.1 - 0.025)\left(0.547 \times 10^{-3}\right)} \\ &= 931 \end{aligned}$$

Step 3 of 5

Reynolds number is less than $2,300$, so flow is laminar and assuming it is a fully developed flow.

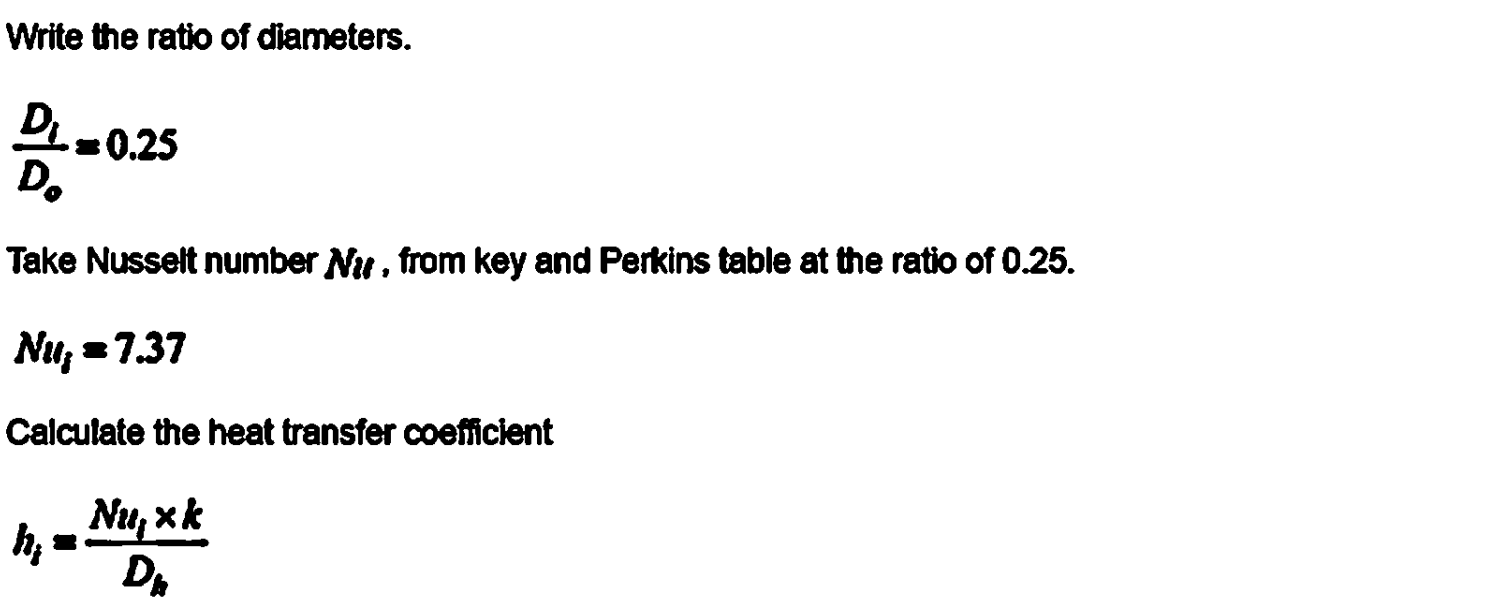
Write the ratio of diameters.

$$\frac{D_i}{D_o} = 0.25$$

Take Nusselt number Nu_i, from key and Perkins table at the ratio of 0.25.

$$Nu_i = 7.37$$

Calculate the heat transfer coefficient



$$h_i = \frac{Nu_i \times k}{D_h}$$

Substitute 7.37 for Nu_i, $0.644\ W/m \cdot K$ for k

$$\begin{aligned} h_i &= \frac{Nu_i \times k}{D_h} \\ &= \frac{7.37 \times 0.644}{0.1 - 0.025} \\ &= \frac{7.37 \times 0.644}{0.075} \\ &= 63.28\ W/m^2 \cdot K \end{aligned}$$

Step 4 of 5

The given figure is shown as follows:

Step 5 of 5

Calculate the Logarithmic mean temperature of the annulus tube.

$$\begin{aligned} \Delta T_{lm} &= \frac{T_i - T_e}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)} \\ &= \frac{20-80}{\ln\left(\frac{120-80}{120-20}\right)} \\ &= \frac{-60}{\ln(0.4)} \\ &= 65.48°C \end{aligned}$$

Calculate the heat transfer in the system

$$\dot{Q} = h A_S \Delta T_m$$

Here, A_s is the surface area of the tube.

Substitute $65.48°C$ for ΔT_m

$$\begin{aligned} \dot{Q} &= h A_S \Delta T_m \\ &= 63.28 \times (\pi D_i L) \times 65.48 \\ &= 63.28 \times \pi \times 0.025L \times 65.48 \\ &= 325.44L \end{aligned}$$

The heat transfer is equal to the heat gained by water. Hence, obtain as follows: $\dot{Q} = \dot{m} C_p (T_e - T_i)$

$$\begin{aligned} 325.44L &= 0.05 \times 4181 \times (80-20) \\ L &= \frac{0.05 \times 4181 \times 60}{325.44} \\ &= 38.54\ m \end{aligned}$$

Hence, the length of the concrete annulus tube is $\boxed{38.54\ m}$.

Question: 19.089P pg 1

The hot water needs of a household are to be met by heating water at 55°F to 180°F by a parabolic solar collector at a rate of 5 lbm/s. Water flows through a 1.25-in-diame-ter thin aluminum tube whose outer surface is blackanodized in order to maximize its solar absorption ability. The center-line of the tube coincides with the focal line of the collector, and a glass sleeve is placed outside the tube to minimize the heat losses. If solar energy is transferred to water at a net rate of 350 Btu/h per ft length of the tube, determine the required length of the parabolic collector to meet the hot water requirements of this house. Also, determine the surface temperature of the tube at the exit.

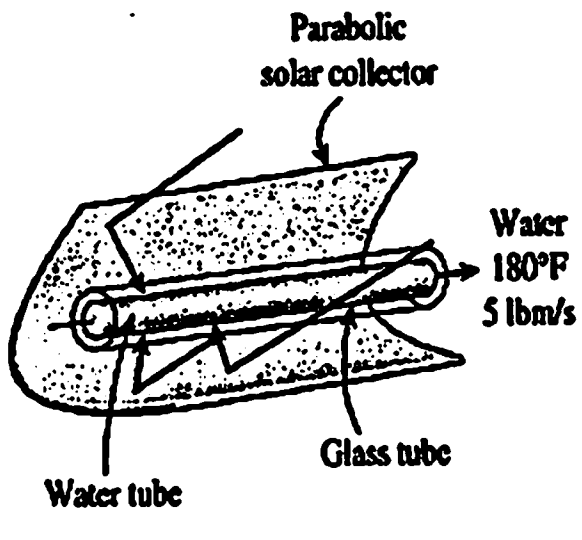


FIGURE P19-89E

Step 1 of 8

Given data:

Inlet water temperature $T_i = 55°F$

Outlet water temperature $T_e = 180°F$

Mass flow rate $\dot{m} = 5 lbm/s$

Diameter of aluminum tube $D = 1.25 in$

Solar energy transferred $\dot{Q} = 350 Btu/h \cdot ft$

Step 2 of 8

Average temperature of the water,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= (180 + 55)/2$$
$$= 117.5°F$$

Properties of water at an average temperature,

Density $\rho = 61.75 lbm/ft^3$

Thermal conductivity $k = 0.370 Btu/ft \cdot °F$

Specific heat $C_p = 0.999 Btu/lbm \cdot °F$

Prandtl number $Pr = 3.75$

Step 3 of 8

Kinematic viscosity is

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{3.84 \times 10^{-4}}{61.75}$$
$$= 6.219 \times 10^{-6} m^2/s$$

Now, the total rate of heat transfer can be expressed as

$$\dot{Q}_t = \dot{m} C_p (T_e - T_i)$$
$$= 5 \times 0.999 (180 - 55)$$
$$= 624.375 Btu/s$$
$$= 2.25 \times 10^6 Btu/h$$

Step 4 of 8

In steady condition, the heat transferred to water is equal to the net rate per feet length so that

$$\dot{Q} = 350 Btu/h \cdot ft$$

The expression for length is

$$L = \frac{\dot{Q}_t}{\dot{Q}}$$
$$= \frac{2.25 \times 10^6}{350}$$
$$= 6422.14 ft$$

Required length of the parabolic collector is $\boxed{L = 6422.14 ft}$

Step 5 of 8

Surface temperature of the tube at the exit:

Average velocity of the water is

$$V_{avg} = \frac{\dot{m}}{\rho A_c}$$
$$= \frac{\dot{m} \times 4}{\rho \times \pi D^2}$$
$$= \frac{5 \times 4}{61.75 \times \pi \times (0.1042)^2}$$
$$= 9.495 ft/s$$

Step 6 of 8

The hydraulic diameter is

$$D_h = D$$
$$= 0.1042$$

Reynolds number of the flow in the tube

$$Re = \frac{V_{avg} \cdot D_h}{\nu}$$
$$= \frac{9.495 \times 0.1042}{6.219 \times 10^{-6}}$$

Reynolds number of the flow in the tube

$$\mathrm{Re} = \frac{V_{avg} \cdot D_h}{\nu}$$
$$= \frac{9.495 \times 0.1042}{6.219 \times 10^{-6}}$$
$$= 159089.4$$

Since it is much larger than 10,000 , it's a fully turbulent flow so entry length can be

$$L_h \approx L_t$$
$$\approx 10\mathrm{D}$$
$$\approx 10 \times 0.1042$$
$$\approx 1.042\,\mathrm{ft}$$

Step 7 of 8

The above entry length is much shorter than the calculated length, therefore fully developed turbulent flow

Nusselt number is

$$Nu = 0.023\mathrm{Re}^{0.8}\mathrm{Pr}^{0.4}$$
$$= 0.023 \times 159089.4^{0.8} \times 3.75^{0.4}$$
$$= 565.78$$

Therefore heat transfer coefficient can be

$$h = \frac{k \cdot Nu}{D_h}$$
$$= \frac{0.370 \times 565.8}{0.1042}$$
$$= 2009\,\mathrm{Btu/h \cdot ft^2 \cdot {}^\circ F}$$

Step 8 of 8

Total Heat flux on the tube is

$$\dot{q}_s = \frac{\dot{Q}_t}{A_s}$$
$$= \frac{2.25 \times 10^6}{\pi(0.1042) \times 6422}$$
$$= 1070.3\,\mathrm{Btu/h \cdot ft^2}$$

The heat flux on the tube can be written as follows

$$\dot{q}_s = h(T_s - T_e)$$

$$T_s = \frac{\dot{q}_s}{h} + T_e$$
$$= \frac{1070.3}{2009} + 180$$
$$= 180.53^\circ\mathrm{C}$$

Hence the surface temperature of the at the exit is given by $\boxed{T_s = 180.53^\circ\mathrm{C}}$

Question: 19.090P

Determine the average velocity, hydrodynamic and thermal entry lengths for water, engine oil, and liquid mercury flowing through a standard 2-in Schedule 40 pipe with mass flow rate of 0.1 lbm/s and temperature of 100°F.

Step 1 of 8

Given data:

Mass flow rate, $\dot{m} = 0.1\,\text{lbm/s}$

Inlet temperature, $T_i = 100°\text{F}$

Pipe considered is 'Standard 2-in schedule 40 pipe'

Step 2 of 8

The diameter for nominal size of given pipe is $D = 2.067$ in

Area of pipe cross section,

$$A_c = \frac{\pi D^2}{4}$$

$$= \frac{\pi(2.067/12)^2}{4}$$

$$= 0.0233\,\text{ft}^2$$

From the properties table of water at 100°F,

Density, $\rho = 62\,\text{lbm/ft}^3$

Dynamic viscosity, $\mu = 4.578\times10^{-4}\,\text{lbm/ft-s}$

Prandtl number, $\text{Pr} = 4.54$

Step 3 of 8

Average velocity of flow,

$$V_{avg} = \frac{\dot{m}}{\rho A_c}$$

$$= \frac{0.1}{62\times0.0233}$$

$$= 0.0692\,\text{ft/s}$$

Therefore the average velocity of flow is $\boxed{V_{avg} = 0.0692\,\text{ft/s}}$

Reynolds number,

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times0.1}{\pi\times0.17225\times4.578\times10^{-4}}$$

$$= 1614.64$$

Step 4 of 8

As the Reynolds number is less than 2300, the flow is laminar flow. Hence

$$L_h = 0.05\times\text{Re}\times D$$

$$= 0.05\times1614.64\times0.17225$$

$$= 13.9\,\text{ft}$$

Hence the hydrodynamic entry length is $\boxed{L_h = 13.9\,\text{ft}}$

Now the thermal entry length,

$$L_t = \text{Pr}\times L_h$$

$$= 4.54\times13.90$$

$$= 63.13\,\text{ft}$$

Hence the thermal entry length is $\boxed{L_t = 63.13\,\text{ft}}$

Step 5 of 8

From the properties table of Engine oil at 100°F,

Density, $\rho = 54.77\,\text{lbm/ft}^3$

Dynamic viscosity, $\mu = 163\times10^{-3}\,\text{lbm/ft-s}$

Prandtl number, $\text{Pr} = 3275$

Average velocity of flow,

$$V_{avg} = \frac{\dot{m}}{\rho A_c}$$

$$= \frac{0.1}{54.77\times0.0233}$$

$$= 0.07836\,\text{ft/s}$$

Therefore the average velocity of flow is $\boxed{V_{avg} = 0.07836\,\text{ft/s}}$

Step 6 of 8

Reynolds number is determined by

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times0.1}{\pi\times0.17225\times163\times10^{-3}}$$

$$= 4.535$$

As the Reynolds number is less than 2300, the flow is laminar flow. Hence

$$L_h = 0.05\times\text{Re}\times\text{D}$$

$$= 0.05\times4.535\times0.17225$$

$$= 0.0391\,\text{ft}$$

Hence the hydrodynamic entry length is $\boxed{L_h = 0.0391\,\text{ft}}$

Now the thermal entry length,

$$L_t = L_h\times\text{Pr}$$

$$= 0.0391\times3275$$

$$= 127.91\,\text{ft}$$

Hence the thermal entry length is $\boxed{L_t = 127.91\,\text{ft}}$

Step 7 of 8

From the properties table of liquid mercury at 100°F,

Density, $\rho = 842.9\,\text{lbm/ft}^3$

Dynamic viscosity, $\mu = 9.919\times10^{-4}\,\text{lbm/ft.s}$

Prandtl number, $\text{Pr} = 0.02363$

Average velocity of flow,

$$V_{avg} = \frac{\dot{m}}{\rho A_C}$$

$$= \frac{0.1}{842.9\times0.0233}$$

$$= 5.09\times10^{-3}\,\text{ft/s}$$

Therefore the average velocity of flow is $\boxed{V_{avg} = 5.09\times10^{-3}\,\text{ft/s}}$

Step 8 of 8

Reynolds number,

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times0.1}{\pi\times0.17225\times9.919\times10^{-4}}$$

$$= 745.22$$

As the Reynolds number is less than 2300, the flow is laminar flow. Hence

$$L_h = 0.05\times\text{Re}\times D$$

$$= 0.05\times745.22\times0.17225$$

$$= 6.418\,\text{ft}$$

Hence the hydrodynamic entry length is $\boxed{L_h = 6.418\,\text{ft}}$

Now the thermal entry length,

$$L_t = \text{Pr}\times L_h$$

$$= 6.418\times0.02363$$

$$= 0.152\,\text{ft}$$

Hence the thermal entry length is $\boxed{L_t = 0.152\,\text{ft}}$

Question: 19.091P

In a manufacturing plant that produces cosmetic products, glycerin is being heated by flowing through a 25-mm-diamcter and 10-m long tube. With a mass flow rate of 0.5 kg/s, the flow of glycerin enters the tube at 25°C. The tube surface is maintained at a constant surface temperature of 140°C. Determine the outlet mean temperature and the total rate of heat transfer for the tube. Evaluate the properties for glycerin at 30°C.

Step 1 of 6

Given data:

Diameter of the tube, $D = 0.025$ m

Length of the tube, $L = 10$ m

Mass flow rate, $\dot{m} = 0.5$ kg/s

Glycerin inlet temperature, $T_i = 25°C$

Tube surface temperature, $T_s = 140°C$

Step 2 of 6

The expression for the outlet temperature T_o is

$$T_o = T_s - (T_s - T_i)\exp\left[-\frac{hA_s}{\dot{m}c_p}\right]$$

where h - Heat transfer coefficient

A_s - Heat transfer surface area

$\dot{m}$ - Mass flow rate

c_p - Specific heat at constant pressure

Step 3 of 6

Properties of glycerin at 30°C:

Density, $\rho = 1258$ kg/m^3

Specific heat at constant pressure, $c_p = 2447$ J/kg·K

Thermal conductivity, $k = 0.2860$ W/m·K

Dynamic viscosity, $\mu = 0.6582$ kg/m·s

Prandtl number, $\Pr = 5631$

Now Reynolds number can be calculated using the equation,

$$\begin{aligned}\mathrm{Re} &= \frac{\rho VD}{\mu}\\ &= \frac{\rho \dot{v} D}{A\mu}\\ &= \frac{4\dot{m}}{\pi D\mu}\\ &= \frac{4\times 0.5}{\pi\times 0.025\times 0.6582}\\ &= 38.69\end{aligned}$$

Since the value is less than 2300, the flow is laminar.

Step 4 of 6

Now, the hydrodynamic entry length is given by,

$$\begin{aligned}L_h &= 0.05\mathrm{Re}.D\\ &= 0.05\times 38.69\times 0.025\\ &= 0.04836 \text{ m}\end{aligned}$$

Thermal entry length is given by,

$$\begin{aligned}L_t &= L_h \times \Pr\\ &= 0.04836\times 5631\\ &= 272.32 \text{ m}\end{aligned}$$

As the thermal entry length is greater than the given tube length, the flow is not thermally developed but developing. Therefore, the average Nusselt number for the thermal entrance region can be determined using the following equation.

$$\begin{aligned}\mathrm{Nu} &= 3.66 + \frac{0.065(D/L)\mathrm{Re}\cdot\Pr}{1+0.04\left[(D/L)\cdot\mathrm{Re}\cdot\Pr\right]^{2/3}}\\ &= 3.66 + \frac{0.065(0.025/10)(38.69)(5631)}{1+0.04\left[(0.025/10)(38.69)(5631)\right]^{2/3}}\\ &= 3.66 + \frac{35.4}{1+2.6677}\\ &= 13.312\end{aligned}$$

Step 5 of 6

The convective heat transfer coefficient,

$$\begin{aligned}h &= \frac{k\cdot\mathrm{Nu}}{D}\\ &= \frac{0.2860\times 13.312}{0.025}\\ &= 152.29 \text{ W/m}^2\cdot\text{K}\end{aligned}$$

Heat transfer surface area,

$$\begin{aligned}A_s &= \pi DL\\ &= \pi\times 0.025\times 10\\ &= 0.7854 \text{ m}^2\end{aligned}$$

The mean temperature at outlet,

$$\begin{aligned}T_o &= 140 - (140-25)\times\exp\left[-\frac{152.29\times 0.7854}{0.5\times 2447}\right]\\ &= 140 - (115\times 0.907)\\ &= 35.7°C\end{aligned}$$

Hence the mean temperature at outlet of the tube, $\boxed{T_o = 35.7°C}$

Step 6 of 6

The total rate of heat transfer for the tube,

$$\begin{aligned}\dot{Q} &= \dot{m}c_p(T_o - T_i)\\ &= 0.5\times 2447\times(35.71-25)\\ &= 0.5\times 2447\times 10.7\\ &= 13091.45 \text{ W}\\ &= 13.1 \text{ kW}\end{aligned}$$

Therefore, the total rate of heat transfer for the tube, $\boxed{\dot{Q} = 13.1 \text{ kW}}$

Question: 19.092P

Liquid glycerin is flowing through a 25-mm-diametcr and 10-m-long tube. The liquid glycerin enters the tube at 20°C with a mass flow rate of 0.5 kg/s. If the outlet mean temperature is 40°C and the tube surface temperature is constant, determine the surface temperature of the tube.

Step 1 of 6

Calculate the bulk mean temperature.

$$T_b = \frac{T_i + T_e}{2}$$

Here, T_i is the inlet temperature, and T_e is the outlet mean temperature.

Substitute $20°C$ for T_i and $40°C$ for T_e.

$$T_b = \frac{20+40}{2}$$
$$= 30°C$$

Obtain the properties of glycerin at $30°C$ from the table A-13, "Properties of liquids" in the textbook.

$$\rho = 1258\,kg/m^3$$
$$c_p = 2447\,J/kg \cdot K$$
$$k = 0.286\ W/m \cdot K$$
$$\mu = 0.6582\ kg/m \cdot s$$
$$Pr = 5631$$

Step 2 of 6

Calculate the Reynolds number.

$$Re = \frac{4\dot{m}}{\pi D \mu}$$

Here, $\dot{m}$ is the mass flow rate, and D is the diameter of the tube.

Substitute $0.5\ kg/s$ for $\dot{m}$, 25 mm for *D*, and $0.6582\ kg/m \cdot s$ for μ.

$$Re = \frac{4 \times 0.5}{\pi \times 25 \times 10^{-3} \times 0.6582}$$
$$= 38.68$$

As the Reynolds number is less than 2300, the flow is a laminar flow.

Step 3 of 6

Calculate the hydrodynamic entry length.

$$L_h = 0.05 \times Re \times D$$

Substitute 38.68 for Re and 0.025 m for *D*.

$$L_h = 0.05 \times 38.68 \times 0.025$$
$$= 0.04835\ m$$

The hydrodynamic entry length is shorter then given length, L. So the flow is hydrodynamically developed.

Now thermal entry length,

$$L_t = L_h \times Pr$$

Substitute 0.04835 m for L_h and 5631 for Pr.

$$L_t = 0.04835 \times 5631$$
$$= 272.25\,m$$

Step 4 of 6

As the thermal entry length is greater than the given length, the flow is not thermally developed but developing.

Calculate the average Nusselt's number.

$$Nu = 3.66 + \frac{0.065(D/L)Re \cdot Pr}{1 + 0.04\left[(D/L) \cdot Re \cdot Pr\right]^{2/3}}$$

Substitute 0.025 m for *D*, 10 m or *L*, 38.68 for Re, and 5631 for Pr.

$$Nu = 3.66 + \frac{0.065(0.025/10)(38.69)(5631)}{1 + 0.04\left[(0.025/10)(38.69)(5631)\right]^{2/3}}$$
$$= 13.312$$

Calculate the heat transfer coefficient.

$$h = \frac{k \times Nu}{D}$$

Substitute 13.312 for Nu, $0.286\ W/m \cdot K$ for *k*, and 0.025 m for *D*.

$$h = \frac{0.2860 \times 13.312}{0.025}$$
$$= 152.29\,W/m^2\,K$$

Step 5 of 6

Calculate the heat transfer surface area.

$$A_s = \pi DL$$

Substitute 0.025 m for *D* and 10 m or *L*.

$$A_s = \pi \times 0.025 \times 10$$
$$= 0.7854\ m^2$$

Step 6 of 6

Calculate the exit temperature relation as follows:

$$T_e = T_s - (T_s - T_e)\exp\left[-\frac{hA_s}{\dot{m}c_p}\right]$$

Substitute $40°C$ for T_e, $152.29\ W/m^2 \cdot K$ for *h*, $0.7854\ m^2$ for A_s, $0.5\ kg/s$ for $\dot{m}$, and $2447\,J/kg \cdot K$ for c_p.

$$40 = T_s - (T_s - 25)\exp\left[-\frac{152.29 \times 0.7854}{0.5 \times 2447}\right]$$
$$T_s = 40 + 0.907(T_s - 25)$$
$$T_s = 40 + 0.907T_s - 22.675$$
$$= 186.3°C$$

Hence, the surface temperature of the tube is $\boxed{T_s = 234.75°C}$

Question: 19.093P

A 15-cm ×20-cm printed circuit board whose components are not allowed to come into direct contact with air for reliability reasons is to be cooled by passing cool air through a 20- cm-long channel of rectangular cross section 0.2 cm × 14 cm drilled into the board. The heat generated by the electronic components is conducted across the thin layer of the board to the channel, where it is removed by air that enters the channel at 15°C. The heat flux at the top surface of the channel can be considered to be uniform, and heat transfer through other surfaces is negligible. If the velocity of the air at the inlet of the channel is not to exceed 4 m/s and the surface temperature of the channel is to remain under 50°C, determine the maximum total power of the electronic components that can safely be mounted on this circuit board.

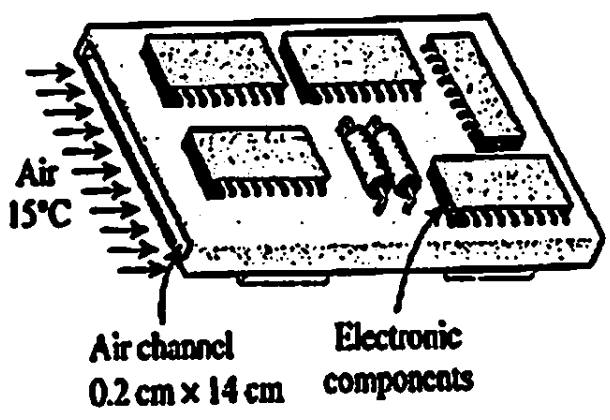

FIGURE P19-93

Step 1 of 6

Calculate the Hydraulic diameter of the channel cross section,

$$D_h = \frac{4A_c}{p}$$

Here, A_c is channel cross section and p is perimeter of the cross section

Substitute $0.002\,\text{m} \times 0.14\,\text{m}$ for A_c and $0.002\,\text{m} + 0.14\,\text{m}$ for p

$$D_h = \frac{4\times(0.002\times0.14)}{2(0.002+0.14)}$$

$$= 3.94\times10^{-3}\,\text{m}$$

Assume average temperature of air is at $30\,^\circ\text{C}$ and take properties of air at average temperature,

Density, $\rho = 1.164\ \text{kg/m}^3$

Thermal conductivity, $k = 0.02588\ \text{W/m}\cdot\text{K}$

Specific heat, $c_p = 1007\ \text{J/kg}\cdot\text{K}$

Kinematic viscosity, $v = 1.608\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7282$

Step 2 of 6

The Reynolds number for flow is

$$\text{Re} = \frac{V_{avg} D_h}{v}$$

$$= \frac{4\times3.94\times10^{-3}}{1.608\times10^{-5}}$$

$$= 980$$

Since the Reynolds number, is less than 2300, the flow is laminar flow.

Calculate the hydrodynamic entry length by using the equation,

$$L_h = 0.05\times\text{Re}\times D_h$$

$$= 0.05\times980\times3.94\times10^{-3}$$

$$= 0.193\ \text{m}$$

This is less than the length of PCB; $L = 20\,\text{cm} = 0.2\,\text{m}$ hence the flow is fully developed laminar flow.

Step 3 of 6

Calculate the ratio of the channel cross section,

$$\frac{a}{b} = \frac{0.14}{0.002}$$

$$= 70$$

From the table of Nusselt number for different cross-sections, for $a/b = 70$ the Nusselt number is,

$$Nu = 8.24$$

Find the heat transfer coefficient,

$$h = \frac{k\times Nu}{D_h}$$

$$= \frac{0.02588\times8.24}{3.94\times10^{-3}}$$

$$= 54.12\ \text{W/m}^2\,^\circ\text{C}$$

Calculate the mass flow rate by using the equation,

$$\dot{m} = \rho V A_c$$

Here, Velocity of inlet air, V

Substitute $4\,\text{m/s}$ for V

$$\dot{m} = 1.164\times4\times(0.002\times0.14)$$

$$= 1.304\times10^{-3}\ \text{kg/s}$$

Step 4 of 6

Calculate the rate of heat transfer due to convection by using the equation,

$$\dot{Q} = hA_s(T_s - T_e)$$

Here, surface temperature of channel is T_s

Substitute $50\,^\circ\text{C}$ for T_s

$$\dot{Q} = (54.12)(0.14\times0.2)(50 - T_e)$$

$$= 1.515(50 - T_e)$$

Calculate the rate of heat transfer by using another equation,

$$\dot{Q} = \dot{m}c_p(T_e - T_i)$$

Here, Inlet temperature of air, T_i

Substitute $15\,^\circ\text{C}$ for T_i

$$\dot{Q} = 1.304\times10^{-3}\times1007\times(T_e - 15)$$

$$= 1.313(T_e - 15)$$

Step 5 of 6

By equating the heat transfer rates,

$$1.515(50 - T_e) = 1.313(T_e - 15)$$

$$75.75 - 1.515T_e = 1.313T_e - 19.695$$

$$2.828T_e = 95.445$$

$$T_e = 33.75\,^\circ\text{C}$$

Step 6 of 6

Calculate heat transfer rate by using the equation,

$$\dot{Q} = \dot{m}c_p(T_e - T_i)$$

$$= 1.304\times10^{-3}\times1007(33.75 - 15)$$

$$= 24.62\ \text{W}$$

Therefore, the total power, $\dot{Q}$ can be mounted on PCB is $\boxed{24.62\ \text{W}}$

Question: 19.094P

Repeat Prob. 19-93 by replacing air with helium, which has six times the thermal conductivity of air.

Step 1 of 6

Given data:

Length of PCB, $L = 20\text{cm} = 0.2\text{m}$

Width of PCB, $W = 15\text{cm} = 0.15\text{m}$

Channel cross section dimension is $= 0.002\text{m} \times 0.14\text{m}$

Inlet temperature of helium, $T_i = 15^\circ\text{C}$

Velocity of inlet helium, $V = 4\text{m/s}$

Surface temperature of channel, $T_s = 50^\circ\text{C}$

Step 2 of 6

Hydraulic diameter

$$D_h = \frac{4A_c}{p}$$

$$= \frac{4\times(0.002\times0.14)}{2(0.002+0.14)}$$

$$= 3.94\times10^{-3}\text{m}$$

From properties table of air at average temperature of 30°C,

Thermal conductivity of air, $k = 0.02588\ \text{W/m-K}$

Specific heat, $c_p = 1007\ \text{J/kg-K}$

Kinematic viscosity, $\nu = 1.608\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7282$

As Thermal conductivity of Helium is 6 times that of the air, $k = 0.15528\ \text{W/mK}$

Step 3 of 6

The Reynolds number for flow is

$$\text{Re} = \frac{V_{avg} D_h}{\nu}$$

$$= \frac{4\times3.94\times10^{-3}}{1.608\times10^{-5}}$$

$$= 980$$

Since the Reynolds number, is less than 2300, the flow is laminar flow.

Hydrodynamic entry length,

$$L_h = 0.05\times\text{Re}\times D_h$$

$$= 0.05\times980\times3.94\times10^{-3}$$

$$= 0.193\,\text{m}$$

This is less than the length of PCB hence the flow is fully developed laminar flow.

Step 4 of 6

From the table of Nusselt number for different cross-sections, for $a/v = 70$ the Nusselt number is,

$$Nu = 8.24$$

Now heat transfer coefficient,

$$h = \frac{k\cdot Nu}{D_h}$$

$$= \frac{0.15528\times8.24}{3.94\times10^{-3}}$$

$$= 324.72\ \text{W/m}^2\text{°C}$$

The mass flow rate,

$$\dot{m} = \rho V A_c$$

$$= 1.164\times4\times2.8\times10^{-4}$$

$$= 1.304\times10^{-3}\ \text{kg/s}$$

Step 5 of 6

The rate of heat transfer due to convection is,

$$\dot{Q} = hA_s(T_s - T_e)$$

$$= (324.72)(0.14\times0.2)(50 - T_e)$$

$$= 9.09(50 - T_e)$$

The rate of heat transfer is also given by,

$$\dot{Q} = \dot{m}c_p(T_e - T_i)$$

$$= 1.304\times10^{-3}\times1007\times(T_e - 15)$$

$$= 1.313(T_e - 15)$$

Step 6 of 6

By equating the heat transfer rates,

$$9.09(50 - T_e) = 1.313(T_e - 15)$$

$$454.5 - 9.09T_e = 1.313T_e - 19.695$$

$$10.403T_e = 474.195$$

$$T_e = 45.58^0$$

Now heat transfer rate is

$$\dot{Q} = \dot{m}c_p(T_e - T_i)$$

$$= 1.304\times10^{-3}\times1007(45.58 - 15)$$

$$= 40.155\ \text{W}$$

Therefore the total power that can be mounted on PCB is $\boxed{\dot{Q} = 40.155\ \text{W}}$

Question:

Reconsider Prob. 19-93. Using EES (or other) software, investigate the effects of air velocity at the inlet of the channel and the maximum surface temperature on the maximum total power dissipation of electronic components. Let the air velocity vary from 1 m/s to 20 m/s and the surface temperature from 30°C to 90°C. Plot the power dissipation as functions of air velocity and surface temperature, and discuss the results.

Step 1 of 10

Given data:

Length of the *PCB*, $L = 20\ \text{cm} = 0.2\ \text{m}$

Width of *PCB*, $w = 15\ \text{cm} = 0.15\ \text{m}$

Cross-section of the channel, $0.002\ \text{m} \times 0.14\ \text{m}$

Inlet temperature of air, $T_i = 15°\text{C}$

Velocity of inlet air, $V = 4\ \text{m/s}$

Surface temperature of the channel, $T_s = 50°\text{C}$

Step 2 of 10

Case 1: Varying air velocity

This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below,

Equations Window

```

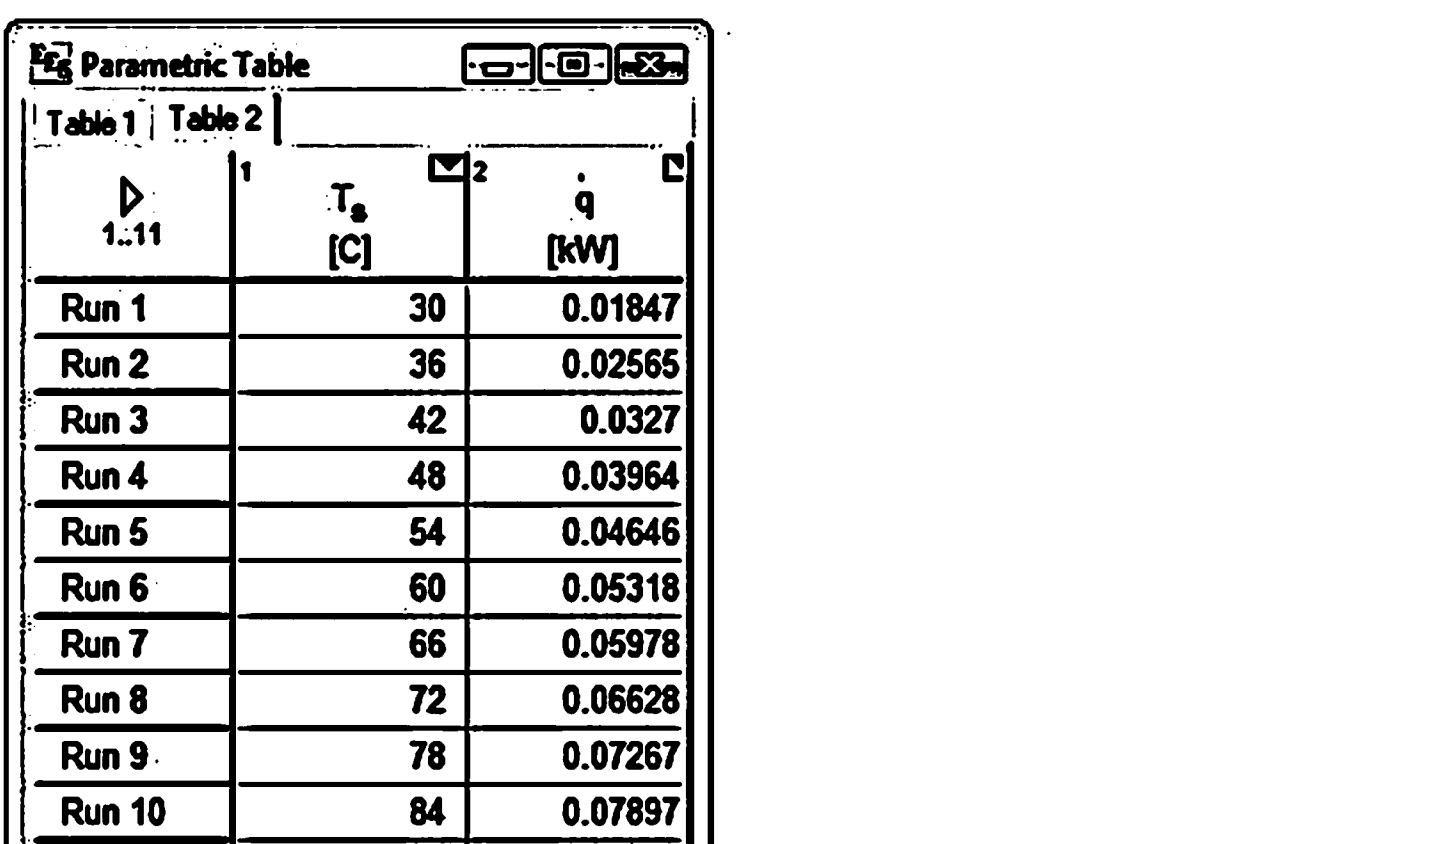
Step 7 of 10

Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

Step 8 of 10

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,



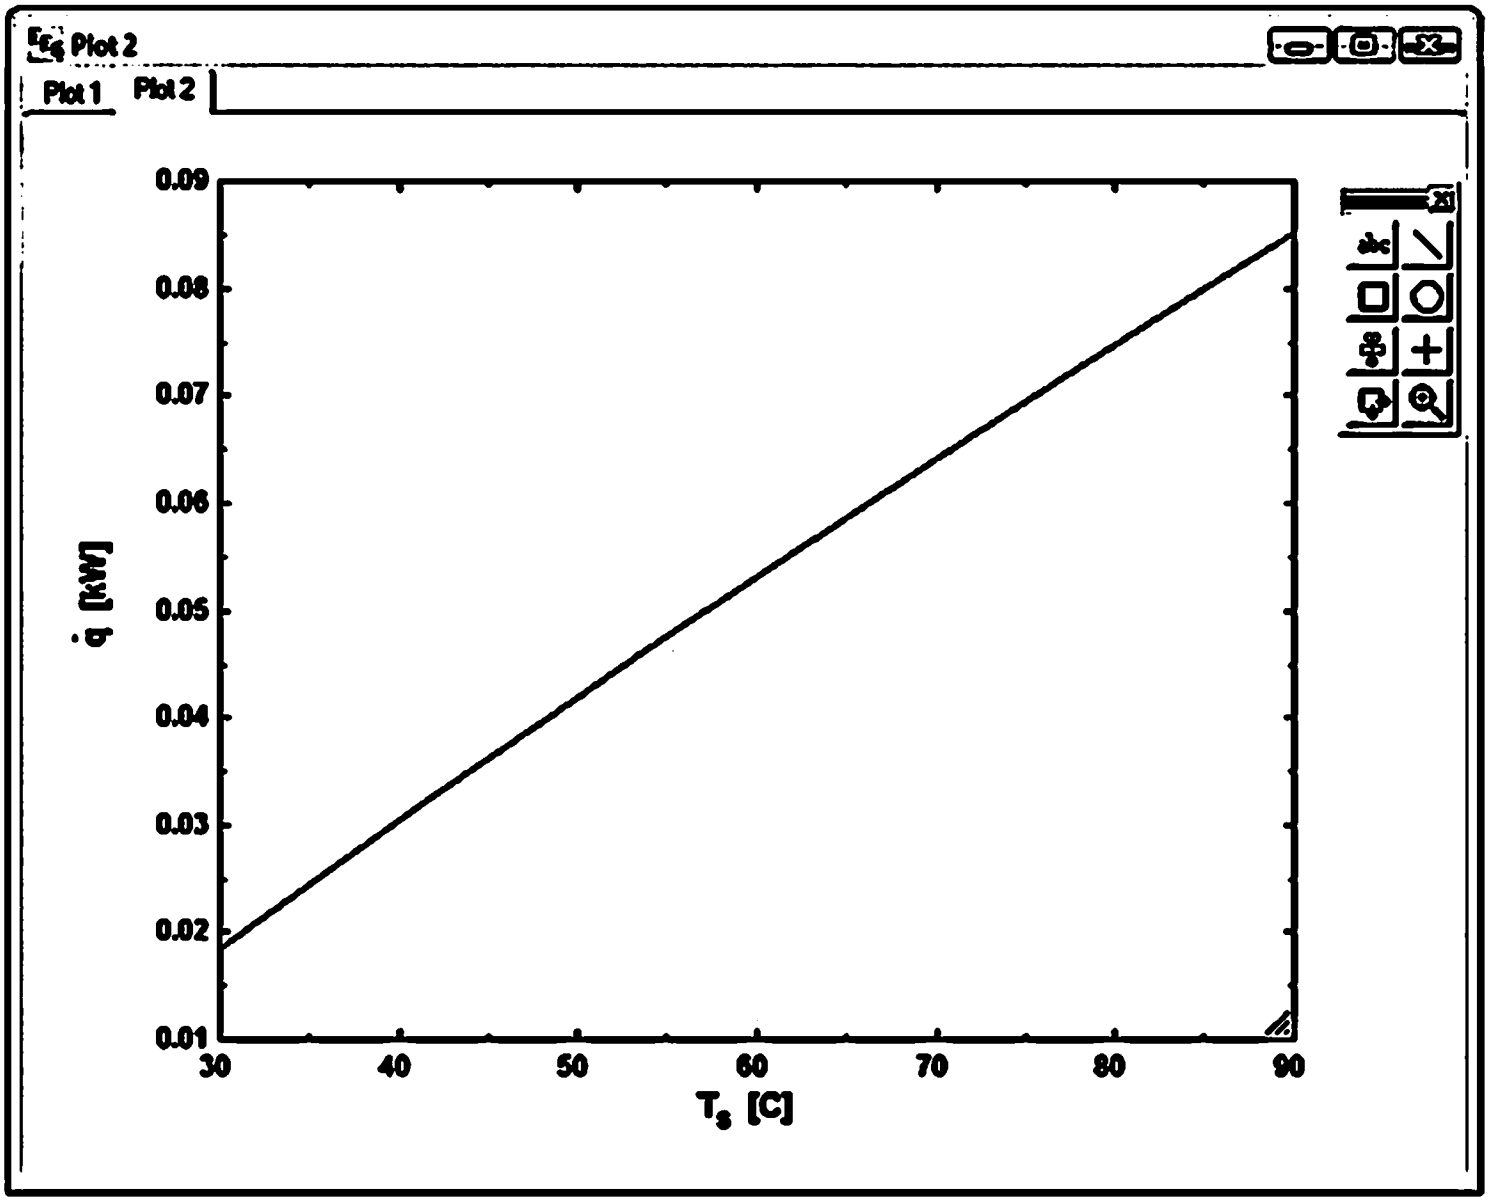
Parametric Table

Table 1 | Table 2

1..11	T_s [C]	$\dot{q}$ [kW]
Run 1	30	0.01847
Run 2	36	0.02565
Run 3	42	0.0327
Run 4	48	0.03964
Run 5	54	0.04646
Run 6	60	0.05318
Run 7	66	0.05978
Run 8	72	0.06628
Run 9	78	0.07267
Run 10	84	0.07897
Run 11	90	0.08516

Step 9 of 10

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,



Step 10 of 10

By clicking on OK the graph will be generated as shown,

Step 10 of 10

By clicking on OK the graph will be generated as shown,

With the increase in surface temperature the maximum power dissipation increases with a decreasing slope which is much slower rate comparatively to increase in air velocity.

Question: 19.096P

Hot air at 60°C leaving the furnace of a house enters a 12-m-long section of a sheet metal duct of rectangular cross section 20 cm ×20 cm at an average velocity of 4 m/s. The thermal resistance of the duct is negligible, and the outer surface of the duct, whose emissivity is 0.3, is exposed to the cold air at 10°C in the basement, with a convection heat transfer coefficient of 10 W/m2·K. Taking the walls of the basement to be at 10°C also, determine (*a*) the temperature at which the hot air will leave the basement and (*b*) the rate of heat loss from the hot air in the duct to the basement.

Step 1 of 5

Calculate the characteristic length,

$$L_h = \frac{4A_c}{p}$$

Here,

The cross-section area of the duct is A_c

The perimeter of the duct

$$\begin{aligned} L_h &= \frac{4A_c}{p} \\ &= \frac{4(0.2\times 0.2)}{4\times 0.2} \\ &= 0.2\,\text{m} \end{aligned}$$

Step 2 of 5

Calculate the Reynolds's number,

$$\text{Re} = \frac{\rho V_{avg} D}{\mu}$$

Here,

The density of air is ρ

The average velocity of the air is V_{avg}

$$\begin{aligned} \text{Re} &= \frac{\rho V_{avg} D}{\mu} \\ &= \frac{4\times 0.2}{1.896\times 10^{-5}} \\ &= 42194.09 \end{aligned}$$

Since $\text{Re} > 10000$, the flow is turbulent flow.

Entry lengths, $L_h \approx L_t \approx 10D$

$$\begin{aligned} L_h &= 10D \\ &= 10\times 0.2 \\ &= 2\,\text{m} \end{aligned}$$

Step 3 of 5

Since, the entry length is shorter than the total length of the duct.

Therefore, the flow is fully turbulent.

Calculate the nusselt number,

$$\begin{aligned} Nu &= 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3} \\ &= 0.023\times 42194.03^{0.8}\times 0.7202^{0.3} \\ &= 104.5116 \end{aligned}$$

Calculate the heat transfer coefficient by using Nusselt number,

$$Nu = \frac{hD_h}{k}$$

$$\begin{aligned} h &= \frac{Nu\times k}{D_h} \\ &= \frac{104.5116\times 0.02808}{0.2} \\ &= 14.67\,\text{W/m}^2\cdot\text{K} \end{aligned}$$

Step 4 of 5

Calculate the surface area of the tube,

$$A_s = 4aL$$

Here,

The length of the sheet metal is *L*

$$\begin{aligned} A_s &= 4aL \\ &= 4\times 0.2\times 12 \\ &= 9.6\ \text{m}^2 \end{aligned}$$

Calculate the mass flow rate of the air,

$$\begin{aligned} \dot{m} &= \rho A_c V \\ &= 1.059\times(0.2\times 0.2)4 \\ &= 0.16944\ \text{kg/sec} \end{aligned}$$

Step 5 of 5

a) Find the exit temperature of the air by using the equation,

$$\begin{aligned} T_e &= T_s - (T_s - T_i)\exp\left(-\frac{hA_s}{\dot{m}c_p}\right) \\ &= 10 - (10-60)\exp\left(-\frac{14.67\times 9.6}{0.16944\times 1007}\right) \\ &= 31.9°\text{C} \end{aligned}$$

Therefore, the exit temperature of the air is $\boxed{31.9°\text{C}}$

b) Calculate the logarithmic mean temperature difference,

$$\begin{aligned} \Delta T_{lm} &= \frac{60-31.90}{\ln\left(\frac{10-31.90}{10-60}\right)} \\ &= -34.03°\text{C} \end{aligned}$$

Calculate the heat loss from the air,

$$\dot{Q} = hA_s\Delta T_{lm}$$

Here,

The Convection heat coefficient is *h*

The Surface area of the tube is A_s

The logarithmic mean temperature difference is ΔT_{lm}

Now substitute the known values in the above expression,

$$\begin{aligned} \dot{Q} &= hA_s\Delta T_{lm} \\ &= 14.67\times 9.6\times(-34.038) \\ &= -4793.70\,\text{W} \end{aligned}$$

Therefore, the heat loss from the duct, $\boxed{-4793.70\,\text{W}}$

Question: 19.097P pg 1

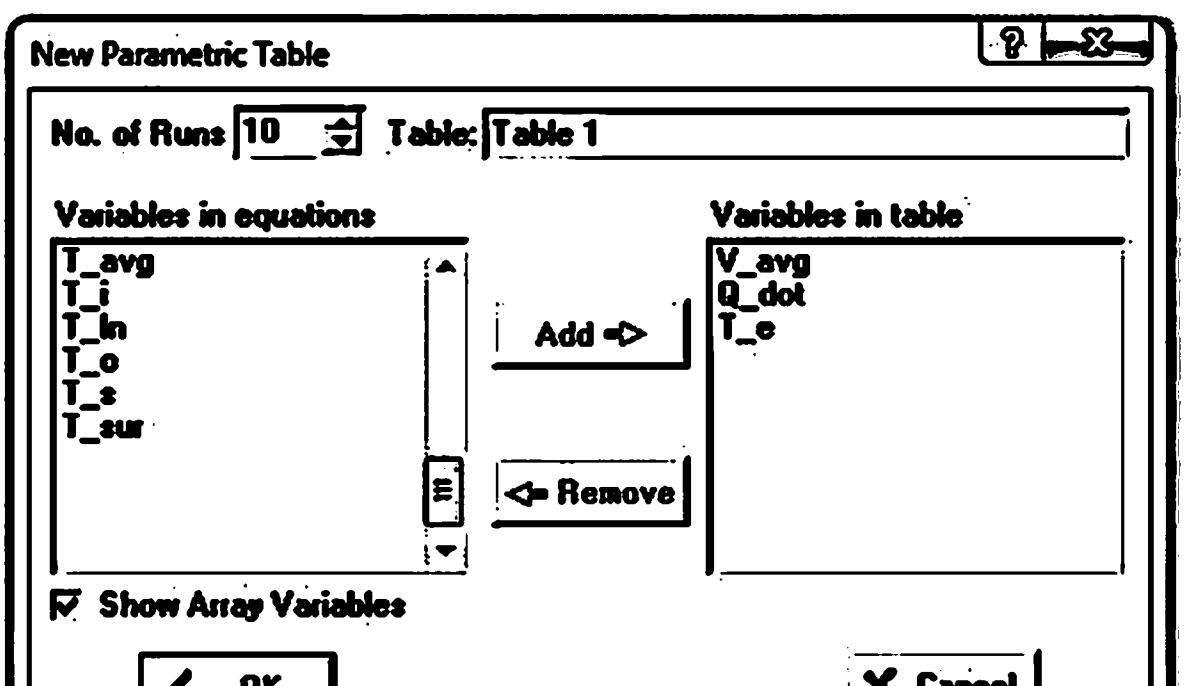
Reconsider Prob. 19-96. Using EES (or other) software, investigate the effect of air velocity and the surface emissivity on the exit temperature of air and the rate of heat loss. Let the air velocity vary from 1 m/s to 10 m/s and the emissivity from 0.1 to 1.0. Plot the exit temperature and the rate of heat loss function the air velocity and emissivity, and discuss the results.

Step 1 of 9

Case 1: Varying air velocity

This given problem is solved in EES "Engineering Equation Solver" in the following method.

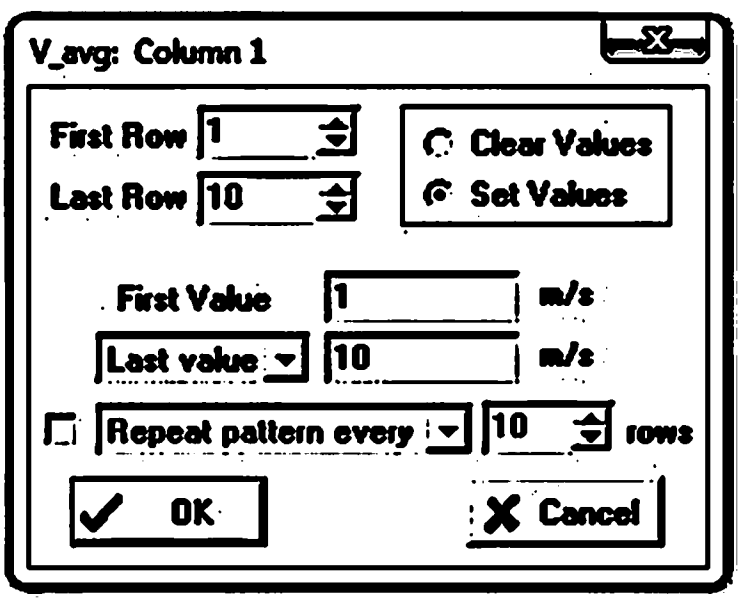
Open a new window in the EES software by ceasing " File > New " and type the program as shown below,



Equations Window

```
"Given data"
L=12 [m]
s=0.20 [m]
"V_avg=4 [m/s]"                    "Variable in case 1"
epsilon=0.3                        "Variable in case 2"
T_i=60 [C]
T_o=10 [C]
h_o=10 [W/m^2-C]
T_sur=10 [C]

"Properties of the air at inlet temprature "
Fluid$='air'
Cp=CP(Fluid$, T=T_avg)*Convert(kJ/kg-C, J/kg-C)
k=Conductivity(Fluid$, T=T_avg)
Pr=Prandtl(Fluid$, T=T_avg)
rho=Density(Fluid$, T=T_avg, P=101.3)
mu=Viscosity(Fluid$, T=T_avg)
```



Step 2 of 9

Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

Step 3 of 9

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Parametric Table

Table 1

1..10	1 V_{avg} [m/s]	2 $\dot{Q}$	3 T_e
Run 1	1	1150	33.84
Run 2	2	1809	39.41

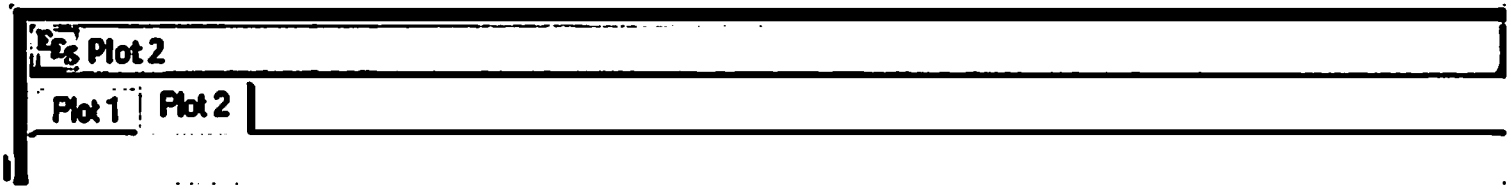
19.097P pg 3



Step 8 of 9

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 9 of 9

By clicking on OK the graph will be generated as shown,

With the increase in the values of epsilon the exit temperature decreases with heat lost to air increase.

Question: 19.098P

Liquid water flows at a mass flow rate of 0.7 kg/s through the concentric annulus tube with the inlet and outlet mean temperature of 20°C and 80°C, respectively. The concentric annulus tube has inner and outer diameters of 10 mm and 100 mm, respectively. the inner tube wall is maintained with a constant surface temperature of 120°C, while the outer tube surface is insulated. Determine the length of the concentric annulus tube.

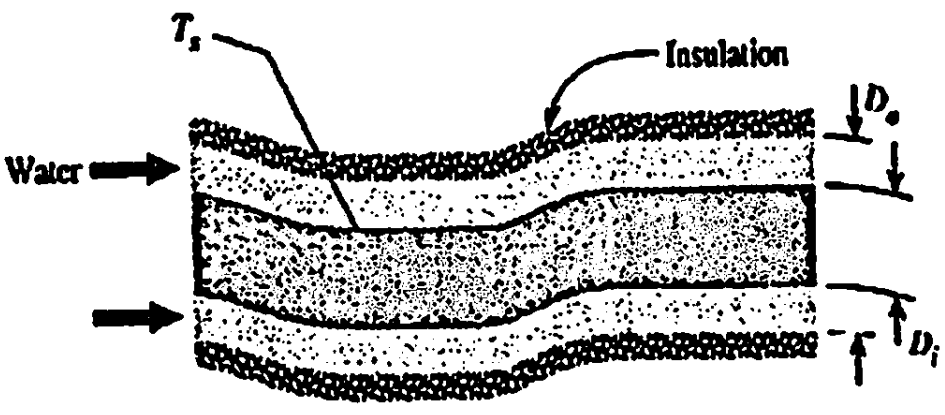


FIGURE P19–98

Step 1 of 5

Calculate the average temperature of water.

$$T_{avg} = \frac{T_e + T_i}{2}$$

Here, T_i is the inlet mean temperature and T_e is the outlet mean temperature of water.

Substitute $20°C$ for T_i and $80°C$ for T_e .

$$T_{avg} = \frac{20+80}{2}$$
$$= 50°C$$

Step 2 of 5

Obtain the following properties from Table A-9 "Properties of Saturated water" at average temperature of $50°C$.

Thermal conductivity, $k = 0.644\ \mathrm{W/m°C}$

Dynamic viscosity, $\mu = 0.547\times10^{-3}\ \mathrm{kg/m\cdot s}$

Specific heat, $c_p = 4181\ \mathrm{J/kg\cdot K}$

Obtain a relation for average velocity of flow.

$$V_{avg} = \frac{\dot{m}}{\rho A_c}$$
$$= \frac{\dot{m}}{\rho\frac{\pi\left(D_0^2 - D_i^2\right)}{4}}$$
$$= \frac{4\dot{m}}{\rho\pi\left(D_0^2 - D_i^2\right)}$$

Here, D_0 is the outer diameter of the annular tube, D_i is the inner diameter of the annular tube, and $\dot{m}$ is the mass flow rate.

Step 3 of 5

Calculate the Reynolds number using the following relation.

$$\mathrm{Re} = \frac{\rho V_{avg}(D_o - D_i)}{\mu}$$
$$= \frac{\rho 4\dot{m}(D_o - D_i)}{\mu\rho\pi\left(D_0^2 - D_i^2\right)}$$
$$= \frac{4\dot{m}}{\mu\pi(D_o + D_i)}$$

Substitute $0.01\mathrm{m}$ for D_i , $0.1\mathrm{m}$ for D_o , $0.547\times10^{-3}\ \mathrm{kg/m\cdot s}$ for μ , and $0.7\mathrm{kg/s}$ for $\dot{m}$.

$$\mathrm{Re} = \frac{4\times0.7}{\pi\times0.547\times10^{-3}(0.1+0.01)}$$
$$= 14812.49$$

As the Reynolds number is more than 10000, the flow through the annulus is turbulent.

Step 4 of 5

Use Dittus-Boelter relation for Nusselt number:

$$Nu = 0.023\,\mathrm{Re}^{0.8}\,\mathrm{Pr}^{0.4}$$
$$= 0.023\times(14812.49)^{0.8}\times3.55^{0.4}$$
$$= 82.85$$

Calculate the convection heat transfer coefficient,

$$h_i = \frac{Nu\times k}{(D_o - D_i)}$$

Substitute 82.85 for Nu , $0.644\ \mathrm{W/m°C}$ for k , $0.01\mathrm{m}$ for D_i , and $0.1\mathrm{m}$ for D_o .

$$h_i = \frac{82.85\times0.644}{(0.1-0.01)}$$
$$= 592.83\ \mathrm{W/m^2°C}$$

Step 5 of 5

Calculate the length of the concentric annulus tube using the following relation:

$$L = -\frac{\dot{m}c_p}{\pi D_i h_i}\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)$$

Here, T_s is the surface temperature of inner tube, c_p is the specific heat of water.

Substitute $0.7\mathrm{kg/s}$ for $\dot{m}$, $4181\ \mathrm{J/kg\cdot K}$ for c_p , $0.01\mathrm{m}$ for D_i , $592.83\ \mathrm{W/m^2°C}$ for h_i , $120°C$ for T_s , $20°C$ for T_i , and $80°C$ for T_e .

$$L = -\frac{0.7\times4181}{\pi(0.01)(592.83)}\ln\left(\frac{120-80}{120-20}\right)$$
$$= -(-144\ \mathrm{m})$$
$$= 144\mathrm{m}$$

Therefore, the length of the concentric annulus tube is $\boxed{144\ \mathrm{m}}$.

Question: 19.099P

Consider a 10-m-long smooth rectangular tube, with a=50 mm and b = 25 mm, that is maintained at a constant surface temperature. Liquid water enters the tube at 20° with a mass flow rate of 0.01 kg/s. Determine the tube surface temperature necessary to heat the water to the desired outlet temperature of 80°C.

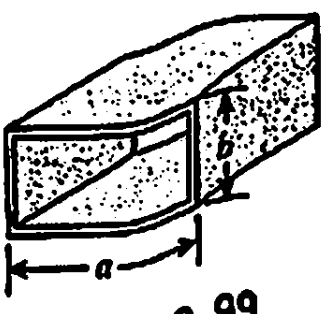

FIGURE P19–99

Step 1 of 6

Given:

Length of rectangular tube, $L = 10\,\text{m}$

Width, $a = 0.05\text{m}$

Height, $b = 0.025\text{m}$

Inlet flow temperature, $T_i = 20°\text{C}$

Mass flow rate, $\dot{m} = 0.01\,\text{kg/s}$

Outlet flow temperature, $T_e = 80°\text{C}$

Step 2 of 6

Average temperature,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{20+80}{2}$$
$$= 50°\text{C}$$

Hydraulic diameter of rectangular tube,

$$D_h = \frac{4A_c}{p}$$
$$= \frac{4(a\times b)}{2(a+b)}$$
$$= \frac{4(0.05\times 0.025)}{2(0.05+0.025)}$$
$$= 0.0333\text{m}$$

Step 3 of 6

Average velocity,

$$V_{avg} = \frac{\dot{m}}{\rho A_c}$$
$$= \frac{0.01}{988.1\times(0.05\times 0.025)}$$
$$= 8.096\times 10^{-3}\,\text{m/s}$$

Properties of water at 1atm & average temperature,

Density, $\rho = 988.1\,\text{kg/m}^3$

Specific heat, $c_p = 4181\,\text{J/kg-K}$

Thermal conductivity, $k = 0.644\,\text{W/m-K}$

Kinematic viscosity, $\mu = 0.547\times 10^{-3}\,\text{kg/m-s}$

Prandtl number, $\text{Pr} = 3.55$

Step 4 of 6

Reynolds number,

$$\text{Re} = \frac{\rho V_{avg} D_h}{\mu}$$
$$= \frac{988.1\times 8.096\times 10^{-3}\times 0.0333}{0.547\times 10^{-3}}$$
$$= 487.02$$

As the obtained Reynolds number is less than the 2300, the flow is laminar.

Hydrodynamic entry length,

$$L_h = 0.05\times\text{Re}\times D_h$$
$$= 0.05\times 487.02\times 0.0333$$
$$= 0.811\,\text{m}$$

Thermal entry length,

$$L_t = \text{Pr}\times L_h$$
$$= 3.55\times 0.811$$
$$= 2.879\text{m}$$

Step 5 of 6

As both the entry lengths are shorter than the total tube length, the flow is a fully developed laminar flow. Now a/b value is

$$a/b = \frac{0.05}{0.025}$$
$$= 2$$

From the table of 'Nusselt numbers for different cross sections', the Nusselt number for $a/b = 2$ is

$$Nu = 3.39$$

Heat transfer coefficient,

$$h = \frac{k\times Nu}{D_h}$$
$$= \frac{0.644\times 3.39}{0.0333}$$
$$= 65.56\,\text{W/m}^2\text{K}$$

Step 6 of 6

The surface area,

$$A_s = 2(a+b)L$$
$$= 2(0.05+0.025)10$$
$$= 1.5\,\text{m}^2$$

The tube exit temperature,

$$T_e = T_s - (T_s - T_i)\exp\left[-\frac{hA_s}{\dot{m}C_p}\right]$$
$$80 = T_s - (T_s - 20)\exp\left[-\frac{65.56\times 1.5}{0.01\times 4181}\right]$$
$$80 = T_s - (T_s - 20)\exp[-2.352]$$

By solving this, we get $T_s = 86.31°\text{C}$

Hence the surface temperature is $\boxed{T_s = 86.31°\text{C}}$

Question: 19.100P

The components of an electronic system dissipating 220 W are located in a l-m-long horizontal duct whose cross section is 16 cm ×16 cm. The components in the duct are cooled by forced air, which enters at 27°C at a rate of 0.65 m3/min. Assuming 85 percent of the heat generated inside is transferred to air flowing through the duet and the remaining 15 percent is lost through the outer surfaces of the duct, determine (*a*) the exit temperature of air and (*b*) the highest component surface temperature in the duct.

Step 1 of 4

Given data:

Width of horizontal duct, $W = 0.16\,\text{m}$

Height of horizontal duct, $H = 0.16\,\text{m}$

Length of duct, $L = 1\text{m}$

Air inlet temperature, $T_i = 27^\circ\text{C}$

Volume flow rate, $\dot{V} = 0.65\,\text{m}^3/\text{min} = 0.01083\,\text{m}^3/\text{s}$

Heat dissipation, $\dot{Q} = 220\ \text{W}$

Step 2 of 4

Assuming average temperature as 35°C, the properties of air are

Density, $\rho = 1.145\,\text{kg}/\text{m}^3$

Specific heat, $c_p = 1007\,\text{J}/\text{kg}\cdot\text{k}$

Thermal conductivity, $k = 1.655\times10^{-5}\,\text{m}^2/\text{s}$

Kinematic viscosity, $\nu = 1.655\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7268$

As 85% of heat is transferred to air, the heat transfer to air can be written as

$$\dot{Q}_{air} = \dot{m}c_p(T_e - T_i)$$

$$0.85\dot{Q} = \rho\dot{V}c_p(T_e - T_i)$$

$$0.85\times220 = 1.145\times0.01083\times1007\times(T_e - 27)$$

$$187 = 12.487(T_e - 27)$$

$$T_e - 27 = 14.9754$$

$$T_e = 41.98^\circ\text{C}$$

Therefore the exit temperature of air is $\boxed{T_e = 41.98^\circ\text{C}}$

Step 3 of 4

The average velocity of the flow,

$$V_{avg} = \frac{\dot{V}}{A_c}$$

$$= \frac{0.01083}{0.16\times0.16}$$

$$= 0.423\,\text{m}/\text{s}$$

Reynolds number is determined by

$$\text{Re} = \frac{V_{avg}}{\nu}\times D_h$$

$$= \frac{0.423}{1.655\times10^{-5}}\times\left(\frac{4\times0.16\times0.16}{4\times0.16}\right)$$

$$= 4089.88$$

As the value of Reynolds number lies in between 2300 to 10000, there is turbulence in the flow. So by considering the flow as fully developed turbulent flow,

Step 4 of 4

Therefore Nusselt number is determined by using the following equation

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$

$$= 0.023(4089.88)^{0.8}(0.7268)^{0.4}$$

$$= 15.69$$

Now heat transfer coefficient is determined by

$$h = \frac{Nu\times k}{D_h}$$

$$= \frac{15.69\times0.02625}{0.16}$$

$$= 2.574\ \text{W}/\text{m}^2\,^\circ\text{C}$$

Therefore heat transfer rate,

$$\dot{Q} = hA_s(T_s - T_e)$$

$$187 = 2.574\times(4\times0.16)(T_s - 41.98)$$

$$T_s - 41.98 = 113.515$$

$$T_s = 155.5^0\text{C}$$

Hence the highest component surface temperature is $\boxed{T_s = 155.5^\circ\text{C}}$

Question: 19.101P

Repeat Prob. 19-100 for a circular horizontal duct of 15-cm diameter.

Step 1 of 4

Given data:

Diameter of duct, $D = 0.15\text{m}$

Length of duct, $L = 1\text{m}$

Air inlet temperature, $T_i = 27^\circ\text{C}$

Volume flow rate, $\dot{V} = 0.65\ \text{m}^3/\text{min} = 0.01083\ \text{m}^3/\text{s}$

Heat dissipation, $\dot{Q} = 220\ \text{W}$

Step 2 of 4

Assuming average temperature as 35°C,

The properties of air are

Density, $\rho = 1.145\ \text{kg}/\text{m}^3$

Specific heat, $c_p = 1007\text{J/kg}-\text{k}$

Thermal conductivity, $k = 1.655\times10^{-5}\ \text{m}^2/\text{s}$

Kinematic viscosity, $\nu = 1.655\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7268$

As 85% of heat is transferred to air, the heat transfer to air can be written as

$$\dot{Q}_{air} = \dot{m}c_p(T_e - T_i)$$

$$0.85\dot{Q} = \rho\dot{V}c_p(T_e - T_i)$$

$$0.85\times220 = 1.145\times0.01083\times1007\times(T_e - 27)$$

$$187 = 12.487(T_e - 27)$$

$$T_e - 27 = 14.9754$$

$$T_e = 41.98^\circ\text{C}$$

Therefore the exit temperature of air is $\boxed{T_e = 41.98^\circ\text{C}}$

Step 3 of 4

The average velocity of the flow,

$$V_{avg} = \frac{\dot{V}}{A_c}$$

$$= \frac{0.01083\times4}{\pi\times(0.15)^2}$$

$$= 0.6129\ \text{m/s}$$

Thus the Reynolds number is determined by

$$\text{Re} = \frac{V_{avg}\times D_h}{\nu}$$

$$= \frac{0.6129\times0.15}{1.655\times10^{-5}}$$

$$= 5554.98$$

As the value of Reynolds number lies in between 2300 to 10000, there is turbulence in the flow. So by considering the flow as fully developed turbulent flow,

Step 4 of 4

Therefore Nusselt number,

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$

$$= 0.023(5554.98)^{0.8}(0.7268)^{0.4}$$

$$= 20.05$$

Now heat transfer coefficient,

$$h = \frac{Nu\times k}{D_h}$$

$$= \frac{20.05\times0.02625}{0.15}$$

$$= 3.51\ \text{W}/\text{m}^2\,^\circ\text{C}$$

Therefore heat transfer rate,

$$\dot{Q} = hA_s(T_s - T_e)$$

$$187 = 3.51\times\pi\times0.15\times1(T_s - 41.98)$$

$$T_s - 41.98 = 113.065$$

$$T_s = 155.04^\circ\text{C}$$

Hence the highest component surface temperature is $\boxed{T_s = 155.04^\circ\text{C}}$

Question: 19.102P pg 1

A computer cooled by a fan contains eight printed circuit boards (PCBs), each dissipating 12 W of power. The height of the PCBs is 12 cm and the length is 15 cm. The clearance between the tips of the components on the PCB and the back surface of the adjacent PCB is 0.3 cm. The cooling air is supplied by a 10-W fan mounted at the inlet. If the temperature rise of air as it flows through the case of the computer is not to exceed 10°C, determine (*a*) the flow rate of the air that the fan needs to deliver, (*b*) the fraction of the temperature rise of air that is due to the heat generated by the fan and its motor, and (*c*) the highest allowable inlet air temperature if the surface temperature of the components is not to exceed 70°C anywhere in the system. Use air properties at 25°C.

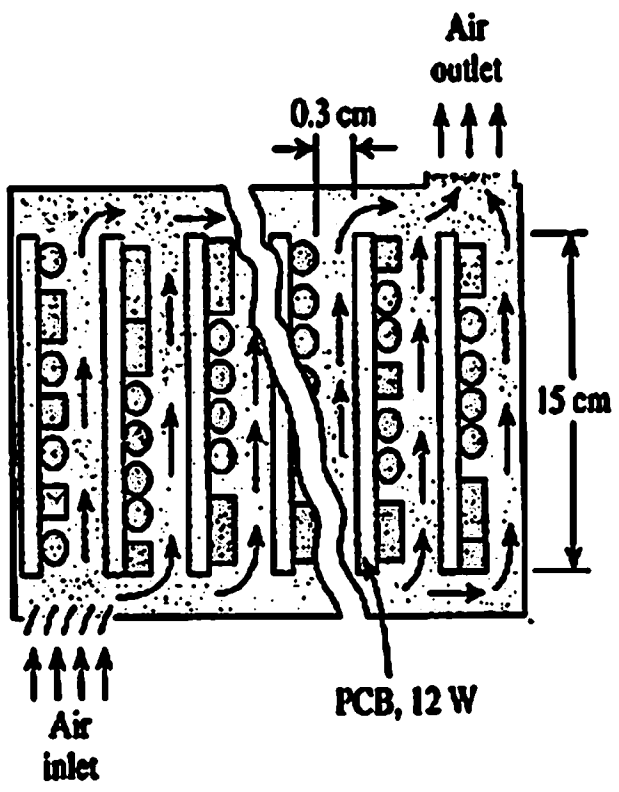

FIGURE P19–102

Step 1 of 5

Given:

Number of circuit boards, $N = 8$

Heat dissipated by each circuit board, $Q = 12\,\text{W}$

Height of *PCB*, $H = 0.12\,\text{m}$

Length of *PCB*, $L = 0.15\,\text{m}$

Clearance between the circuit boards, $w = 0.003\,\text{m}$

Fan power, $p = 10\,\text{W}$

Temperature rise allowed $(T_e - T_i) = 10°\text{C}$

Surface temperature of components, $T_s = 70°\text{C}$

Step 2 of 5

(*a*)

The properties of air at $25°\text{C}$

Therefore density, $\rho = 1.184\ \text{kg/m}^3$

Specific heat, $c_p = 1007\ \text{J/kg-k}$

Thermal conductivity, $k = 0.02551\ \text{W/m-k}$

Kinematic viscosity, $v = 1.562 \times 10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7296$

The heat transfer rate,

$$\dot{Q}_t = \dot{m} c_p (T_e - T_i)$$

$$\dot{m} = \frac{\dot{Q}_t}{c_p (T_e - T_i)}$$

$$= \frac{(N \times Q) + p}{c_p (T_e - T_i)}$$

$$= \frac{(8 \times 12) + 10}{1007 \times 10}$$

$$= 0.01053\ \text{kg/s}$$

Therefore the mass flow rate is $\boxed{\dot{m} = 0.01053\,\text{kg/s}}$

Step 3 of 5

(*b*)

The power used by the fan is

$$p = \dot{m} C_p (T_e - T_i)$$

$$T_e - T_i = \frac{p}{\dot{m} C_p}$$

$$= \frac{10}{0.01053 \times 1007}$$

$$= 0.943°\text{C}$$

The fraction of heat generated by the fan,

$$f = \frac{(T_e - T_i)_p}{T_e + T_i}$$

$$= \frac{0.943}{10}$$

$$= 0.0943$$

Therefore fraction of heat generated by the fan, $\boxed{f = 0.0943}$

Step 4 of 5

Average velocity,

Step 4 of 5

Average velocity,

$$V_{avg} = \frac{\dot{m}}{N\rho A_c}$$
$$= \frac{\dot{m}}{N \times \rho \times (w \times H)}$$
$$= \frac{0.01053}{8 \times 1.184(0.003 \times 0.12)}$$
$$= 3.08\,\text{m/s}$$

Hydraulic diameter,

$$D_h = \frac{4A_c}{p}$$
$$= \frac{4(w \times H)}{2(w + H)}$$
$$= \frac{2(0.003 \times 0.12)}{(0.003 + 0.12)}$$
$$= 5.854 \times 10^{-3}\,\text{m}$$

Reynolds number,

$$\text{Re} = \frac{V_{avg} \times D_h}{\nu}$$
$$= \frac{3.08 \times 5.854 \times 10^{-3}}{1.562 \times 10^{-5}}$$
$$= 1154.24$$

As the Reynolds number is less than 2300, the flow is laminar.

Now the entry length,

$$L_h = 0.05 \times R_e \times D_h$$
$$= 0.3378\,\text{m}$$

This length is less than the total length, therefore the flow is fully developed laminar flow. Now the *a*/*b* ratio is

$$a/b = \frac{0.12}{0.003}$$
$$= 40$$

From the table of 'Nusselt Numbers for various cross-sections', for *a*/*b* ratio 40,

$$Nu = 8.24$$

Step 5 of 5

The heat transfer coefficient

$$h = \frac{k \times Nu}{D_h}$$
$$= \frac{0.02551 \times 8.24}{5.854 \times 10^{-3}}$$
$$= 35.91\,\text{W/m}^2\text{°C}$$

Since we know highest temperature will be at exit point, the heat transfer

$$Q_t = hA_s(T_s - T_e)$$
$$106 = 35.91 \times \left[8 \times 2(0.12 \times 0.15 + 0.003 \times 0.15)\right](70 - T_e)$$
$$106 = 35.91 \times 0.2952(70 - T_e)$$
$$T_e = 60°\text{C}$$

Therefore the exit temperature is $\boxed{T_e = 60°\text{C}}$

Inlet temperature,

$$T_i = T_e - 10$$
$$= 60 - 10$$
$$= 50°\text{C}$$

Therefore the inlet temperature is $\boxed{T_i = 50°\text{C}}$

Question: 19.103P

Consider a 25-mm diameter and 15-m long smooth tube that is used for heating fluids. The wall is heated electrically to provide a constant surface heat flux along the entire tube. Fluids enter the tube at 50°C and exit at 150°C. If the mass flow rate is maintained at 0.01 kg/s, determine the convection heat transfer coefficients at the tube outlet for water, engine oil, and liquid mercury.

Step 1 of 8

Given data:

Diameter of tube, $D = 0.025\text{m}$

Length of tube, $L = 15\text{m}$

Inlet temperature of fluid, $T_i = 50°\text{C}$

Outlet temperature of liquid $T_e = 150°\text{C}$

Mass flow rate, $\dot{m} = 0.01\text{kg/s}$

Step 2 of 8

Average temperature,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{50+150}{2}$$
$$= 100°\text{C}$$

The properties of water at average temperature,

Density, $\rho = 957.9\ \text{kg/m}^3$

Thermal conductivity, $k = 0.679\ \text{W/m}\cdot\text{K}$

Specific heat, $c_p = 4217\text{J/kg}\cdot\text{K}$

Prandtl Number, $\text{Pr} = 1.75$

Kinematic viscosity, $\mu = 0.282\times10^{-3}\ \text{kg/m}\cdot s$

Step 3 of 8

Reynolds number,

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$
$$= \frac{4\times0.01}{\pi\times0.025\times0.282\times10^{-3}}$$
$$= 1806$$

As the Reynolds number is less than 2300. The flow is laminar.

The hydrodynamic entry length,

$$L_h = 0.05\times\text{Re}\times D$$
$$= 0.05\times1806\times0.025$$
$$= 2.257\text{m}$$

The thermal entry length,

$$L_t = \text{Pr}\times L_h$$
$$= 1.75\times2.257$$
$$= 3.951\text{m}$$

As the entry lengths are shorter, the flow is a fully developed laminar flow

Step 4 of 8

By taking Nusselt number value from the table 'Nusselt numbers for fully developed laminar flows', for circular tube cross section, $Nu = 4.36$

Heat transfer coefficient

$$h = \frac{k\cdot Nu}{D}$$
$$= \frac{0.679\times4.36}{0.025}$$
$$= 118.42\text{W/m}^2°\text{C}$$

Therefore, the heat transfer coefficient $\boxed{h = 118.42\text{W/m}^2°\text{C}}$

Step 5 of 8

The properties of engine oil at average temperature,

Thermal conductivity, $k = 0.1367\ \text{W/m}\cdot\text{K}$

Prandtl Number, $\text{Pr} = 279.1$

Kinematic viscosity, $\mu = 0.01718\ \text{kg/m}\cdot s$

Reynolds number,

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$
$$= \frac{4\times0.01}{\pi\times0.025\times0.01718}$$
$$= 29.64$$

As the Reynolds number is less than 2300. The flow is laminar.

The hydrodynamic entry length,

$$L_h = 0.05\times\text{Re}\times D$$
$$= 0.05\times29.64\times0.025$$
$$= 0.037\text{m}$$

The thermal entry length,

$$L_t = \text{Pr}\times L_h$$
$$= 279.1\times0.037$$
$$= 10.34\text{ m}$$

As the entry lengths are shorter, the flow is a fully developed laminar flow

Step 6 of 8

By taking Nusselt number value from the table 'Nusselt numbers for fully developed laminar flows', for circular tube cross section, $Nu = 4.36$

Heat transfer coefficient

$$h = \frac{k\cdot Nu}{D}$$
$$= \frac{0.1367\times4.36}{0.025}$$
$$= 23.84\text{W/m}^2°\text{C}$$

Therefore, the heat transfer coefficient $\boxed{h = 23.84\text{W/m}^2°\text{C}}$

Step 7 of 8

The properties of engine oil at average temperature,

Thermal conductivity, $k = 9.46706\ \text{W/m}°\text{C}$

Prandtl Number, $\text{Pr} = 0.018$

Kinematic viscosity, $\mu = 1.245\times10^{-3}\ \text{kg/m}\cdot s$

Reynolds number is determined by

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$
$$= \frac{4\times0.01}{\pi\times0.025\times1.245\times10^{-3}}$$
$$= 409$$

As the Reynolds number is less than 2300. The flow is laminar.

The hydrodynamic entry length,

$$L_h = 0.05\times\text{Re}\times D$$
$$= 0.05\times409\times0.025$$
$$= 0.511\text{m}$$

As the entry length is shorter, the flow is a fully developed laminar flow

Step 8 of 8

By taking Nusselt number value from the table 'Nusselt numbers for fully developed laminar flows', for circular tube cross section, $Nu = 4.36$

Heat transfer coefficient

$$h = \frac{k\cdot Nu}{D}$$
$$= \frac{9.46706\times4.36}{0.025}$$
$$= 1651.05\text{W/m}^2°\text{C}$$

Therefore, the heat transfer coefficient $\boxed{h = 1651.05\text{W/m}^2°\text{C}}$

Hence liquid mercury has largest heat transfer coefficient out of all three given fluids.

Question:

Consider a 25-mm diameter and 15-m long smooth tube that is maintained at a constant surface temperature. Fluids enter the tube at 50°C with a mass flow rate of 0.01 kg/s. Determine the tube surface temperatures necessary to heat water, engine oil, and liquid mercury to the desired outlet temperature of 150°C.

Step 1 of 13

Given data:

Diameter of smooth tube, $D = 0.025\text{m}$

Length of tube, $L = 15\text{m}$

Inlet temperature of fluid, $T_i = 50°\text{C}$

Mass flow rate, $\dot{m} = 0.01\ \text{kg/s}$

Desired outlet temperature, $T_e = 150°\text{C}$

Step 2 of 13

Average temperature of water,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{50+150}{2}$$
$$= 100°\text{C}$$

The properties of water at average temperature,

Thermal conductivity, $k = 0.679\ \text{W/m}\cdot\text{K}$

Specific heat, $c_p = 4217\ \text{J/kg}\cdot\text{K}$

Prandtl number, $\text{Pr} = 1.75$

Kinematic viscosity, $\mu = 0.282\times10^{-3}\ \text{kg/m}\cdot s$

Step 3 of 13

Reynolds number,

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$
$$= \frac{4\times0.01}{\pi\times0.025\times\left(0.282\times10^{-3}\right)}$$
$$= 1806$$

As the Reynolds number is less than 2300, the flow is laminar.

Now hydrodynamic entry length,

$$L_h = 0.05\times\text{Re}\times D$$
$$= 0.05\times1806\times0.025$$
$$= 2.257\text{m}$$

Thermal entry length,

$$L_t = \text{Pr}\times L_h$$
$$= 2.257\times1.75$$
$$= 3.951\text{m}$$

As both the values are less than the tube length, the flow is fully developed laminar flow.

Step 4 of 13

Taking Nusselt number value from the table of 'Nusselt numbers and friction factors for fully developed laminar flows', for Circular tube cross section at constant surface temperature, we get $Nu = 3.66$

Heat transfer coefficient,

$$h = \frac{k\cdot Nu}{D}$$
$$= \frac{0.679\times3.66}{0.025}$$
$$= 99.41\ \text{W/m}^2°\text{C}$$

Also the surface area of tube is

$$A_s = \pi DL$$
$$= \pi\times0.025\times15$$
$$= 1.178\ \text{m}^2$$

Step 5 of 13

The exit temperature of the fluid can be determined using

$$T_e = T_s - (T_s - T_i)\exp\left[-\frac{hA_s}{\dot{m}C_p}\right]$$
$$150 = T_s - (T_s - 50)\exp\left[-\frac{99.41\times1.178}{0.01\times4217}\right]$$
$$150 = T_s - (T_s - 50)\exp[-2.7769]$$
$$150 = T_s - 0.062T_s + 3.1$$
$$146.9 = 0.938T_s$$
$$T_s = 156.6°\text{C}$$

Hence the tube surface temperature is $\boxed{T_s = 156.63°\text{C}}$

Step 6 of 13

Average temperature of Engine oil,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{50+150}{2}$$
$$= 100°\text{C}$$

The properties of Engine oil at average temperature,

Thermal conductivity, $k = 0.1367\ \text{W/m}\cdot\text{K}$

Specific heat, $c_p = 2220\ \text{J/kg}\cdot\text{K}$

Prandtl number, $\text{Pr} = 279.1$

Kinematic viscosity, $\mu = 0.01718\ \text{kg/m}\cdot s$

Step 7 of 13

Reynolds number,

Kinematic viscosity, $\mu = 0.01718$ kg/m·s

Step 7 of 13

Reynolds number,

$$\mathrm{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times 0.01}{\pi\times 0.025\times 0.01718}$$

$$= 29.64$$

As the Reynolds number is less than 2300, the flow is laminar.

Now hydrodynamic entry length,

$$L_h = 0.05\times R_e \times D$$

$$= 0.05\times 29.64\times 0.025$$

$$= 0.037\,\mathrm{m}$$

Thermal entry length,

$$L_t = P_r \times L_h$$

$$= 279.1\times 0.037$$

$$= 10.34\,\mathrm{m}$$

As both the values are less than the tube length, the flow is fully developed laminar flow.

Step 8 of 13

Taking Nusselt number value from the table of 'Nusselt numbers and friction factors for fully developed laminar flows', for Circular tube cross section at constant surface temperature, we get $Nu = 3.66$

Heat transfer coefficient,

$$h = \frac{k\cdot Nu}{D}$$

$$= \frac{3.66\times 0.1367}{0.025}$$

$$= 20\ \mathrm{W/m^2{}^\circ C}$$

Also the surface area of tube is

$$A_s = \pi DL$$

$$= \pi\times 0.025\times 15$$

$$= 1.178\,\mathrm{m^2}$$

Step 9 of 13

The exit temperature of the fluid can be determined using

$$T_e = T_s - (T_s - T_i)\exp\left[-\frac{hA_s}{\dot{m}C_p}\right]$$

$$150 = T_s - (T_s - 50)\exp\left(\frac{-20\times 1.178}{0.01\times 2220}\right)$$

$$150 = T_s - (T_s - 50)\exp(-1.06126)$$

$$150 = T_s - 0.346T_s + 17.3$$

$$132.7 = 0.654T_s$$

$$T_s = 202.9^\circ\mathrm{C}$$

Hence the tube surface temperature is $\boxed{T_s = 202.9^\circ\mathrm{C}}$

Step 10 of 13

Average temperature of liquid mercury,

$$T_{avg} = \frac{T_i + T_e}{2}$$

$$= \frac{50+150}{2}$$

$$= 100^\circ\mathrm{C}$$

The properties of liquid mercury at average temperature,

Thermal conductivity, $k = 9.46706\ \mathrm{W/m\cdot K}$

Specific heat, $c_p = 137.1\ \mathrm{J/kg\cdot K}$

Prandtl number, $\mathrm{Pr} = 0.0180$

Kinematic viscosity, $\mu = 1.245\times 10^{-3}\ \mathrm{kg/m\cdot s}$

Step 11 of 13

Reynolds number,

$$\mathrm{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times 0.01}{\pi\times 0.025\times 1.245\times 10^{-3}}$$

$$= 409$$

As the Reynolds number is less than 2300, the flow is laminar.

Now hydrodynamic entry length,

$$L_h = 0.05\times \mathrm{Re}\times D$$

$$= 0.05\times 409\times 0.025$$

$$= 0.511\,\mathrm{m}$$

As the value is less than the tube length, the flow is fully developed laminar flow.

Step 12 of 13

Taking Nusselt number value from the table of 'Nusselt numbers and friction factors for fully developed laminar flows', for Circular tube cross section at constant surface temperature, we get $Nu = 3.66$

Heat transfer coefficient,

$$h = \frac{k\cdot Nu}{D}$$

$$= \frac{3.66\times 9.46706}{0.025}$$

$$= 1385.98\ \mathrm{W/m^2{}^\circ C}$$

Also the surface area of tube is

$$A_s = \pi DL$$

$$= \pi\times 0.025\times 15$$

$= 1385.98\ \mathrm{W/m^2{}^\circ C}$

Also the surface area of tube is

$$A_s = \pi DL$$
$$= \pi \times 0.025 \times 15$$
$$= 1.178\ \mathrm{m^2}$$

Step 13 of 13

The exit temperature of the fluid can be determined using

$$T_e = T_s - (T_s - T_i)\exp\left[-\frac{hA_s}{\dot{m}C_p}\right]$$

$$150 = T_s - (T_s - 50)\exp\left(-\frac{1385.98 \times 1.178}{0.01 \times 137.1}\right)$$

$$150 = T_s - (T_s - 50)\exp[-1190.87]$$

$$150 = T_s - 0$$

$$T_s = 150^\circ C$$

Therefore the tube surface temperature is $\boxed{T_s = 150^\circ C}$

Question: 19.105P

Air at 20°C (1 atm) enters into a 5-mm diameter and 10-cm long circular tube at an average velocity of 5 m/s. The tube wall is maintained at a constant surface temperature of 160°C. Determine the convection heat transfer coefficient and the outlet mean temperature. Evaluate the air properties at 50°C

Step 1 of 7

Given data:

Diameter of circular tube, $D = 0.005\text{m}$

Length of tube, $L = 0.1\text{m}$

Average velocity, $V_{avg} = 5\text{m/s}$

Tube wall surface temperature, $T_s = 160°\text{C}$

Air inlet temperature, $T_i = 20°\text{C}$

Step 2 of 7

The properties of air at 50°C,

Specific heat, $c_p = 1007\ \text{J/kg}\cdot\text{K}$

Thermal conductivity, $k = 0.02735\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

Reynolds number is determined by

$$\text{Re} = \frac{V_{avg}D}{\nu}$$
$$= \frac{5\times0.005}{1.798\times10^{-5}}$$
$$= 1390.4$$

As the Reynolds number is less than 2300, the flow is laminar.

Step 3 of 7

The hydrodynamic entry length,

$$L_h = 0.05\times\text{Re}\times D$$
$$= 0.05\times1390.4\times0.005$$
$$= 0.348\text{m}$$

The thermal entry length,

$$L_t = L_h\cdot\text{Pr}$$
$$= 0.348\times0.7228$$
$$= 0.25\ \text{m}$$

The hydrodynamic and thermal entry lengths are more than the total length. So the flow is not a fully developed laminar flow but a hydro-dynamically & thermally developing flow.

Step 4 of 7

From Sieder and Tate equation,

$$Nu = 1.86\left(\frac{\text{RePr}\,D}{L}\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.14}$$

Where

μ_b – Dynamic viscosity taken at average temperature, 50°C

μ_s – Dynamic viscosity taken at tube surface temperature,

From properties tables, we get the values as

$\mu_b = 1.963\times10^{-5}\ \text{kg/m-s}$

$\mu_s = 2.420\times10^{-5}\ \text{kg/m-s}$

Hence the Nusselt number is

$$Nu = 1.86\left(\frac{1390.4\times0.7228\times0.005}{0.1}\right)^{1/3}\left(\frac{1.963\times10^{-5}}{2.420\times10^{-5}}\right)^{0.14}$$
$$= 1.86\left(\frac{5.0249}{0.1}\right)^{1/3}(0.811157)^{0.14}$$
$$= 6.665$$

Step 5 of 7

Therefore heat transfer coefficient,

$$h = \frac{Nu\cdot k}{D}$$
$$= \frac{6.665\times0.02735}{0.005}$$
$$= 36.46\ \text{W/m}^2°\text{C}$$

Hence the heat transfer coefficient is $\boxed{h = 36.46\ \text{W/m}^2°\text{C}}$

Step 6 of 7

Now heat transfer surface area,

$$A_s = \pi DL$$
$$= \pi\times0.005\times0.1$$
$$= 1.571\times10^{-3}\ \text{m}^2$$

Mass flow rate,

$$\dot{m} = \rho A_c V_{avg}$$
$$= 1.092\times\frac{\pi(0.005)^2}{4}\times5$$
$$= 1.072\times10^{-4}\ \text{kg/s}$$

Step 7 of 7

From the relation for exit temperature,

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{hA_s}{\dot{m}C_p}\right)$$
$$= 160 - (160-20)\exp\left(\frac{-36.46\times1.571\times10^{-3}}{1.072\times10^{-4}\times1007}\right)$$
$$= 160 - 140\exp\left(\frac{-0.057388}{0.10795}\right)$$
$$= 77.728°\text{C}$$

Therefore the outlet mean temperature is $\boxed{T_e = 77.728°\text{C}}$

Question: 19.106P

Air (1 atm) enters into a 5-cm diameter circular tube at 20°C with an average velocity of 5 m/s. The tube wall is maintained at a constant surface temperature of 160°C, and the outlet mean temperature is 80°C. Estimate the length of the tube.

Step 1 of 6

Given data:

Diameter of tube, $D = 0.05\text{m}$

Inlet air temperature, $T_i = 20°\text{C}$

Average velocity of air, $V_{avg} = 5\ \text{m/s}$

Tube wall constant temperature, $T_s = 160°\text{C}$

Outlet air temperature, $T_e = 80°\text{C}$

Step 2 of 6

Average temperature,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{80+20}{2}$$
$$= 50°\text{C}$$

The properties of air at average temperature,

Specific heat, $c_p = 1007\ \text{J/kg-K}$

Thermal conductivity, $k = 0.02735\ \text{W/m°C}$

Dynamic viscosity, $\nu = 1.798\times10^{-5}\ \text{m}^2/\text{s}$

Kinematic viscosity, $\mu = 1.963\times10^{-5}\ \text{kg/m}\cdot\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

Density, $\rho = 1.092\ \text{kg/m}^3$

Step 3 of 6

Reynolds number,

$$\text{Re} = \frac{V_{avg}\times D}{\nu}$$
$$= \frac{5\times0.05}{1.798\times10^{-5}}$$
$$= 13904.34$$

As the Reynolds number is more than 10000, the flow is turbulent.

Now entry lengths,

$$L_h \approx L_t$$
$$= 10D$$
$$= 10\times0.05$$
$$= 0.5\text{m}$$

Step 4 of 6

By assuming that the entry length is shorter than the total flow length, we get the Nusselt number as

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$
$$= 0.023(13904.34)^{0.8}(0.7228)^{0.4}$$
$$= 41.67$$

Now heat transfer coefficient,

$$h = \frac{k\times Nu}{D}$$
$$= \frac{0.02735\times41.67}{0.05}$$
$$= 22.795\ \text{W/m}^2\text{°C}$$

Step 5 of 6

The surface area of the flow,

$$A_s = \pi DL$$
$$= \pi\times0.05\times L$$
$$= 0.15708\times L$$

Mass flow rate,

$$\dot{m} = \rho A_c V_{avg}$$
$$= \rho\left(\frac{\pi D^2}{4}\right)V_{avg}$$
$$= 1.092\times\frac{\pi(0.05)^2}{4}\times5$$
$$= 0.01072\ \text{kg/s}$$

Step 6 of 6

From the relation from energy balance on a control volume,

$$\ln\frac{T_s - T_e}{T_s - T_i} = -\frac{hA_s}{\dot{m}C_p}$$
$$\ln\frac{160-80}{160-20} = -\frac{22.795\times0.15708\times L}{0.01072\times1007}$$
$$-0.5596 = -0.33169\times L$$
$$L = \frac{0.5596}{0.33169}$$
$$L = 1.687\ \text{m}$$

As the entry length (0.5m) is less than the total tube length (1.687m), our assumption is valid. Hence the length of the tube is $\boxed{L = 1.687\text{m}}$

Question: 19.107P

A 20 mm × 20 mm silicon chip is mounted such that the edges are flush in a substrate. The substrate provides an unheated starting length of 20 mm that acts as turbulator. Airflow at 25°C (1 atm) with a velocity of 25 m/s is used to cool the upper surface of the chip. If the maximum surface temperature of the chip cannot exceed 75°C. determine the maximum allowable power dissipation on the chip surface.

Step 1 of 4

Given data:

Dimensions of the silicon chip, $L \times w = 20 \text{ mm} \times 20 \text{ mm}$

Unheated starting length, $\xi = 20 \text{ mm}$

Air flow temperature, $T_\infty = 25°C$

Velocity of flow, $V = 25 \text{ m/s}$

Surface temperature of chip, $T_s = 75°C$

Step 2 of 4

Film temperature of air is determined as

$$T_f = \frac{(T_s + T_\infty)}{2}$$
$$= \frac{(75+25)}{2}$$
$$= 50°C$$

From the table, properties of air at 1 atm pressure

At $T = 50°C$

Thermal conductivity, $k = 0.02735 \text{ W/m} \cdot \text{K}$

Kinematic viscosity, $\nu = 1.798 \times 10^{-5} \text{ m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

Here in this case, as uniform heat flux is there on chip surface, the maximum surface temperature occurs at trailing edge where heat transfer coefficient is minimum.

The Reynolds number for the flow at the trailing edge $(x = L + \xi)$ is determined from the equation given by

$$\text{Re}_x = \frac{Vx}{\nu}$$
$$= \frac{25 \times \left(\left(20 \times 10^{-3}\right) + \left(20 \times 10^{-3}\right)\right)}{1.798 \times 10^{-5}}$$
$$= 55617.35$$

Since the obtained Reynolds number is less than 5×10^5 i.e. $\text{Re} < 5 \times 10^5$, the flow is said to be laminar.

Step 3 of 4

The average Nusselt number for parallel flow over flat plate is determined from the Churchill & Ozoe relation given by

$$\text{Nu}_x = \frac{\text{Nu}_{x(\xi=0)}}{\left[1 - (\xi / x)^{3/4}\right]^{1/3}}$$
$$= \frac{0.453 \text{Re}^{0.5} \text{Pr}^{1/3}}{\left[1 - (\xi / x)^{3/4}\right]^{1/3}}$$
$$= \frac{0.453 \times (55617.35)^{0.5} \times (0.7228)^{1/3}}{\left[1 - \left(\frac{20 \times 10^{-3}}{0.04}\right)^{3/4}\right]^{1/3}}$$
$$= 129.54$$

The local convective heat transfer coefficient at the trailing edge is determined from the equation given by

$$\text{Nu}_x = \frac{h_x x}{k}$$

Rewrite and solve for h_x is

$$h_x = \frac{\text{Nu}_x \times k}{x}$$
$$= \frac{129.54 \times 0.02735}{0.04}$$
$$= 88.57 \text{ W/m}^2 \cdot \text{K}$$

Step 4 of 4

The maximum allowable power dissipation on the surface of the chip is determined from the equation given by

$$\dot{Q} = h_x A_s (T_s - T_\infty)$$
$$= h_x \times L^2 \times (T_s - T_\infty)$$
$$= 88.57 \times \left(20 \times 10^{-3}\right)^2 \times (75 - 25)$$
$$= 1.77 \text{ W}$$

Therefore, the maximum allowable power dissipation on the surface of the chip is $\boxed{\dot{Q} = 1.77 \text{ W}}$

Question: 19.108P

In the effort to increase the removal of heat from a hot surface at 120°C, a cylindrical pin fin (kf =237 W/m · K) with diameter of 5 mm is attached to the hot surface. Air at 20°C (1 atm) is flowing across the pin fin with a velocity of 10 m/s. Determine the maximum possible rate of heat transfer from the pin fin. Evaluate the air properties at 70°C.

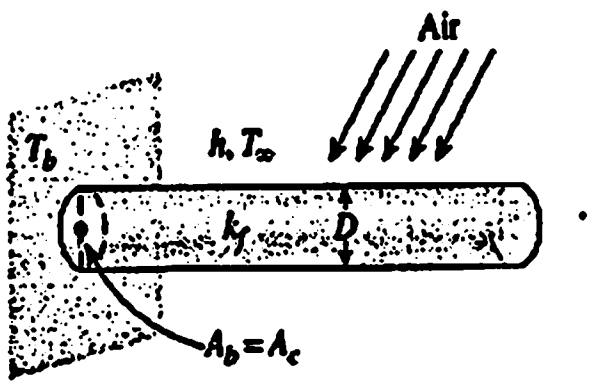

FIGURE P19–108

Step 1 of 5

Given data:

Temperature of hot surface $T_b = 120°C$

Thermal conductivity of fin $k_f = 237\ W/m \cdot K$

Diameter of fin $D = 5mm = 0.005m$

Outside air temperature $T_\infty = 20°C$

Velocity of air flow $V = 10\ m/s$

Step 2 of 5

Film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{120 + 20}{2}$$

$$T_f = 70°C$$

By taking properties of air at $T_f = 70°C$

From the properties of air table,

Thermal conductivity $k = 0.02881\ W/m \cdot K$

Density $\rho = 1.028\ kg/m^3$

Specific heat $c_p = 1007\ J/kg \cdot K$

Dynamic viscosity $\mu = 2.052 \times 10^{-5}\ N \cdot s/m^2$

Kinematic viscosity $\nu = 1.995 \times 10^{-5}\ m^2/s$

Prandtl number $Pr = 0.7177$

Step 3 of 5

Calculating the Reynolds number

$$Re_D = \frac{VD}{\nu}$$

$$= \frac{10 \times 0.005}{1.995 \times 10^{-5}}$$

$$Re_D = 2506.265$$

Now as we know Churchill and Bernstein relation for the Nusselt number calculation

$$Nu_{cyl} = \frac{hD}{k} = 0.3 + \frac{0.62 Re^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re}{282000}\right)^{5/8}\right]^{4/5}$$

$$\frac{h \times 0.005}{0.02881} = 0.3 + \frac{0.62(2506.3)^{1/2}(0.7177)^{1/3}}{\left[1 + (0.4/0.7177)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{2506.3}{282000}\right)^{5/8}\right]^{4/5}$$

$$h \times 0.1735 = 0.3 + \frac{27.79}{1.138} \times 1.0415$$

$$h = 148.319\ W/m^2 \cdot K$$

Step 4 of 5

As per the requirement of the statement we need to calculate the maximum rate of heat transfer from pin fin and we know maximum heat transfer occurs when the fin is infinitely long.

$$Q_{infinite} = \sqrt{hpk_f} A_c (T_b - T_\infty) \qquad \ldots\ldots (1)$$

Where perimeter of the surface

$$p = \pi D$$

$$= \pi \times 0.005$$

$$p = 0.0157m$$

Cross sectional area of the pin fin is

$$A_c = \pi D^2/4$$

$$= \frac{\pi}{4} \times 0.005^2$$

$$A_c = 1.96 \times 10^{-5}\ m^2$$

Step 5 of 5

Now substituting the values in the equation (1)

$$Q_{infinite} = \sqrt{hpk_f} A_c (T_b - T_\infty)$$

$$= \sqrt{148.28 \times 0.0157 \times 237 \times 1.96 \times 10^{-5}} (120 - 20)$$

$$Q_{infinite} = 10.399\ W$$

Therefore, the maximum possible rate of heat transfer from the pin fin is

$$\boxed{Q_{infinite} = 10.399\ W}$$

Question: 19.109P

The passenger compartment of a minivan traveling at 70 mph can be modeled as a 3.2-ft-high, 6-ft-wide, and 12-ft-long rectangular box whose walls have an insulating value of *R*-3 (i.e., a wall thickness-to-thermal conductivity ratio of 3 h·ft2·°F/Btu). The interior of a minivan is maintained at an average temperature of 70°F during a trip at night while the outside air temperature is 90°F.

The average heat transfer coefficient on the interior surfaces of the van is 1.2 Btu/h·ft2·°F. The air flow over the exterior surfaces can be assumed to be turbulent because of the intense vibrations involved, and the heat transfer coefficient on the front and back surfaces can be taken to be equal to that on the top surface. Disregarding any heat gain or loss by radiation, determine the rate of heat transfer from the ambient air to the van.

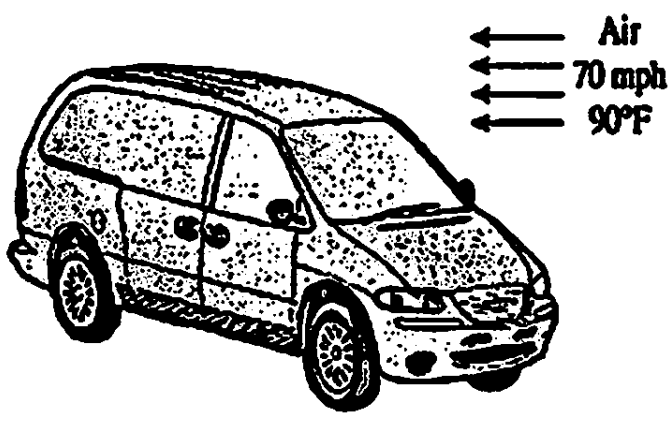

FIGURE P19–109E

Step 1 of 6

Average film temperature,

$$T_{avg} = \frac{70+90}{2}$$
$$= 80°F$$

From properties of air table at 1 atm and 80°F,
Thermal conductivity, $k = 0.01481$ Btu/h·ft·°F
Kinematic viscosity, $\upsilon = 0.1697\times10^{-3}$ ft^2/s
Prandtl number, Pr = 0.7290

Step 2 of 6

Reynolds number,

$$\mathrm{Re}_L = \frac{VL}{\upsilon}$$

Where
V is the velocity of the van,
L is the length of the van and
ν is the kinematic viscosity.
Substitute 70 mph for V, 12 ft for L and 0.1697×10^{-3} ft^2/s for ν in the above equation,

$$\mathrm{Re}_L = \frac{\left(70\,\mathrm{mph}\times\frac{5288\,\mathrm{ft/s}}{3600\,\mathrm{mph}}\right)(12\,\mathrm{ft})}{0.1697\times10^{-3}\ \mathrm{ft^2/s}}$$
$$= 7.27\times10^{6}$$

This value is greater than the value of critical Reynolds number. Therefore turbulent flow will exist.

Step 3 of 6

Calculate the Nusselt number for the given system,

$$\mathrm{Nu} = \frac{h_0 L}{k}$$
$$= 0.037\,\mathrm{Re}_L^{0.8}\,\mathrm{Pr}^{1/3}$$
$$= 0.037\left(7.27\times10^{6}\right)^{0.8}(0.7290)^{1/3}$$
$$= 10284.20$$

Calculate the hence heat transfer coefficient,

$$h_0 = \frac{k}{L}\mathrm{Nu}$$

Where,
k is the thermal coefficient.

Substitute $(0.01481\,\mathrm{Btu/ft\cdot°F})$ for k and the respective values in the above equation,

$$h_0 = \frac{0.01481}{12}\times10284.20$$
$$= 12.69\ \mathrm{Btu/h\cdot ft^2\cdot °F}$$

Step 4 of 6

Calculate the surface area of the van,

$$A_s = 2\left[(3.2\times6)+(6\times12)+(12\times3.2)\right]$$
$$= 259.20\,\mathrm{ft^2}$$

Calculate the thermal resistances for system,

$$R_i = \frac{1}{h_i A_s}$$

Where,
h_i is the average heat transfer co-efficient on the interior surfaces of the van.

Substitute $(1.2\,\mathrm{Btu/h\cdot ft^2\cdot °F})$ for h_i and the respective values in the above equation,

$$R_i = \frac{1}{1.2\times259.20}$$
$$= 0.00321\ \mathrm{h\cdot °F/Btu}$$

Step 5 of 6

Calculate the insulation thermal resistances for system,

$$R_{ins} = \frac{(R-3)_{value}}{A_s}$$
$$= \frac{3}{259.20}$$
$$= 0.01157\ \mathrm{h\cdot °F/Btu}$$
$$R_0 = \frac{1}{h_0 A_s}$$
$$= \frac{1}{(12.69)(259.20)}$$
$$= 0.00030\ \mathrm{h\cdot °F/Btu}$$

Step 6 of 6

Calculate the total resistance,

$$R_{total} = R_i + R_{ins} + R_0$$
$$= 0.00321+0.01157+0.00030$$
$$= 0.0150\ \mathrm{h\cdot °F/Btu}$$

Calculate the heat transfer rate,

$$\dot{Q} = \frac{T_{air} - T_{van}}{R_{total}}$$

Where,
T_{air} is the temperature of the air and
T_{van} is the temperature of the van.

Substitute 90°F for T_{air}, 70°F for T_{van} and the respective values in the above equation,

$$\dot{Q} = \frac{90-70}{0.0150}$$
$$= 1333.34\ \mathrm{Btu/h}$$

Therefore, heat transferred from ambient air to van is **1333.34 Btu/h**

Question: 19.110P

Consider a house that is maintained at a constant temperature of 22°C. One of the walls of the house has three single-pane glass windows that are 1.5 m high and 1.8 m long. The glass (k =0.78 W/m.K) is 0.5 cm thick, and the heat transfer coefficient on the inner surface of the glass is 8 W/m2·K. Now winds at 35 km/h start to blow parallel to the surface of this wall. If the air temperature outside is −2°C, determine the rate of heat loss through the windows of this wall. Assume radiation heat transfer to be negligible.

Step 1 of 6

Given

Spectral transmissivity of a glass cover can be expressed as

$\tau_1 = 0$ for $\lambda < 0.3\mu m$

$\tau_2 = 0.9$ for $0.3 \le \lambda \le 3\mu m$

$\tau_3 = 0$ for $\lambda > 3\mu m$

Rate of solar radiation, $I = 950\ W/m^2$

Temperature of absorber plate, $T_a = 340K$

Step 2 of 6

(a) The solar flux incident on the absorber plate at temperature is $T = 5800K$ is calculated as follows

$\lambda_1 T = 0.3 \times 5800$

$= 1740\ \mu mK$

$\lambda_2 T = 3 \times 5800$

$= 17400\ \mu mK$

From table, Black body radiation functions

The blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$ are determined as

$f_{\lambda_1} = 0.033454$

$f_{\lambda_2} = 0.978746$

Step 3 of 6

The absorptivity of the surface becomes

$$\tau(T) = \tau_1 f_{\lambda_1} + \tau_2 \left(f_{\lambda_2} - f_{\lambda_1}\right) + \tau_3 \left(1 - f_{\lambda_2}\right)$$

$$= 0.0 \times 0.033454 + 0.9(0.978746 - 0.033454) + 0.0(1 - 0.978746)$$

$$= 0 + 0.851 + 0$$

$$= 0.851$$

The rate of absorption of solar radiation is given by

$$E_{absorbed} = \alpha I$$

$$= 0.851 \times 950$$

$$= 808.45\ W/m^2$$

Rate of absorption of solar radiation, $\boxed{E_{absorbed} = 808.45\ W/m^2}$

Step 4 of 6

(b) The transmissivity of the glass cover for radiation emitted by the absorber plate temperature at $T_a = 340K$ is determined as follows

$\lambda_1 T_a = 0.3 \times 300$

$= 90\ \mu mK$

$\lambda_2 T_a = 3 \times 300$

$= 900\ \mu mK$

From table, Black body radiation functions

The blackbody radiation functions corresponding to $\lambda_1 T_a$ and $\lambda_2 T_a$ are determined as

$f_{\lambda_1} = 0.0$

$f_{\lambda_2} = 0.000169$

Step 5 of 6

Then, the absorptivity of the surface becomes

$$\tau(T) = \tau_1 f_{\lambda_1} + \tau_2 \left(f_{\lambda_2} - f_{\lambda_1}\right) + \tau_3 \left(1 - f_{\lambda_2}\right)$$

$$= 0.0 \times 0.0 + 0.9(0.000169 - 0.0) + 0.0(1 - 0.000169)$$

$$= 0 + 0.0001521 + 0$$

$$= 0.00015$$

The absorptivity of the surface, $\boxed{\tau(T) = 0.00015}$

Step 6 of 6

(c) The rate of heat transfer to the cooling water if the glass temperature is $T_a = 340K$ is determined as follows

Rate of heat transfer is given by

$$\dot{Q}_{water} = (\tau_{solar} - \tau_{room})I$$

$$= (0.851 - 0.00015)950$$

$$= 0.85085 \times 950$$

$$= 808.31\ W/m^2$$

Rate of heat transfer to the cooling water, $\boxed{\dot{Q}_{water} = 808.31\ W/m^2}$

Question: 19.111P

Consider a person who is trying to keep cool on a hot summer day by turning a fan on and exposing his body to air flow. The air temperature is 32°C, and the fan is blowing air at a velocity of 5 m/s. The surrounding surfaces are at 40°C. and the emissivity of the person can be taken to be 0.9. If the person is doing light work and generating sensible heat at a rate of 90 W, determine the average temperature of the outer surface (skin or clothing) of the person. The average human body can be treated as a 30-cm-diameter cylinder with an exposed surface area of 1.7 m2.

Step 1 of 2

Given

Temperature of wall, $T_w = 500\ K$

Temperature reading of thermo couple, $T_{th} = 850\ K$

Emissivity of the thermocouple junction, $\varepsilon = 0.6$

Coefficient of convection heat transfer, $h = 60\ W/m^2$

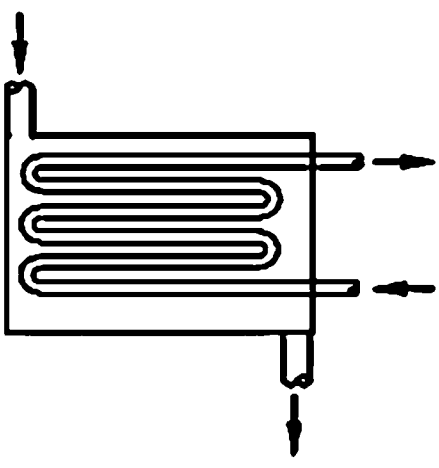
Step 2 of 2

Temperature of the air is calculated as

$$T_f = T_{th} + \frac{\varepsilon\sigma\left(T_{th}^4 - T_w^4\right)}{h}$$

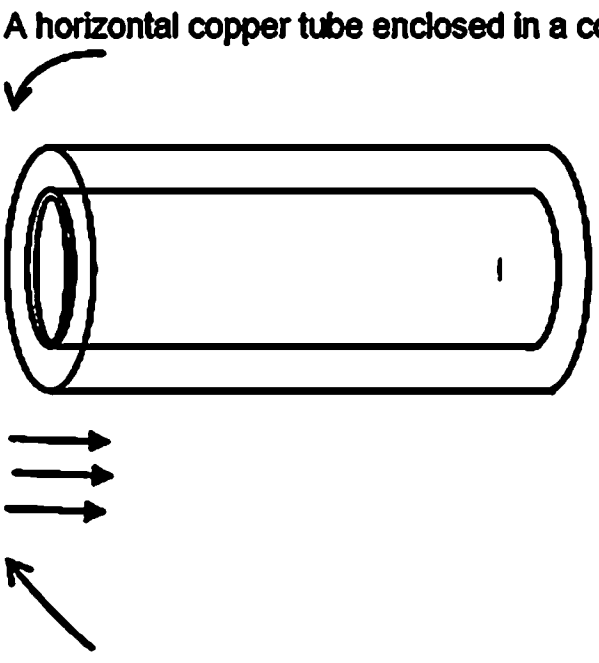
$$= 850 + \frac{0.6\left(5.67\times10^{-8}\right)\left(850^4 - 500^4\right)}{60}$$

$$= 850 + 260.54$$



$$= 1110.54\,K$$

Temperature of the air, $\boxed{T_f = 1110.54\,K}$



Question: 19.112P pg 1

A 0.5-cm-thick, 12-cm-high, and 18-cm-long circuit board houses 80 closely spaced logic chips on one side, each dissipating 0.06 W. The board is impregnated with copper fillings and has an effective thermal conductivity of 16 W/m-K. All the heat generated in the chips is conducted across the circuit board and is dissipated from the back side of the board to the ambient air at 30°C, which is forced to flow over the surface by a fan at a free-stream velocity of 300 m/min. Determine the temperatures on the two sides of the circuit board.

Step 1 of 8

A horizontal copper tube enclosed in a concentric thin glass tube is as shown in figure,

Step 2 of 8

Calculate the average temperature

$$T_f = \frac{(T_1 + T_2)}{2}$$

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Substitute $60°C$ for T_1, $40°C$ for T_2

$$\begin{aligned} T_{avg} &= \frac{T_1 + T_2}{2} \\ &= \frac{60+40}{2} \\ &= 50°C \end{aligned}$$

From table properties of air at 1atm and the average temperature $T_{avg} = 50°C$ the properties of air are

$$\text{Thermal conductivity}, k = 0.02735\ \text{W/m}\cdot\text{K}$$
$$\text{kinematic viscosity}, \nu = 1.798\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Prandtle number}, \text{Pr} = 0.7228$$

Step 3 of 8

Use the conversion factor to convert the temperature from $1°C$ to $1K$ is

$$1K = 1°C + 273$$

Find the Coefficient of volume expansion

$$\begin{aligned} \beta &= \frac{1}{T_{avg}} \\ &= \frac{1}{(50+273)} \\ &= 3.0959\times10^{-3}\ K^{-1} \end{aligned}$$

Calculate the characteristic length in this case is the distance between the two cylinders,

$$L_c = \frac{(D_2 - D_1)}{2}$$

Here,

Outer diameter of the solar collector, D_1

Diameter of the glass tube, D_2

Substitute $5\,\text{cm}$ for D_1, $12\,\text{cm}$ for D_2

$$\begin{aligned} L_c &= \frac{(D_2 - D_1)}{2} \\ &= \frac{(0.12-0.05)}{2} \\ &= 0.035\,\text{m} \end{aligned}$$

Step 4 of 8

Calculate the Rayleigh number

$$\text{Ra} = \frac{g\beta(T_1 - T_2)L_c^3}{\nu^2}\text{Pr}$$

Here,

Acceleration due to gravity is g

Substitute $3.0959\,\text{K}^{-1}$ for β, $60°C$ for T_1, $40°C$ for T_2, $0.035\,\text{m}$ for L, $9.81\,\text{m/s}^2$ for g, $1.798\times10^{-5}\ \text{m}^2/\text{s}$ for ν

$$\frac{g\beta(T_1 - T_2)L_c^3}{\nu^2}$$

Acceleration due to gravity is g

Substitute $3.0959\,K^{-1}$ for β, $60°C$ for T_1, $40°C$ for T_2, $0.035\,m$ for L, $9.81\,m/s^2$ for g, $1.798\times10^{-5}\ m^2/s$ for ν

$$Ra = \frac{g\beta(T_1-T_2)L_c^3}{\nu^2}Pr$$

$$= \frac{9.81(m/s^2)\times3.0959\times10^{-3}(K^{-1})\times(60-40)(K)\times(0.035)^3(m^3)}{(1.798\times10^{-5}\,m^2/s)^2}\times0.7228$$

$$= 58229$$

Calculate the effective thermal conductivity

$$F_{cyc} = \frac{\left[\ln\left(\frac{D_2}{D_1}\right)\right]^4}{L_c^3\left(D_1^{-3/5}+D_2^{-3/5}\right)^5}$$

$$= \frac{\left[\ln\left(\frac{0.12}{0.05}\right)\right]^4}{(0.035)^3\left[(0.05\,m)^{-3/5}+(0.12\,m)^{-3/5}\right]^5}$$

$$= \frac{0.5874}{3.5008}$$

$$= 0.1678$$

Step 5 of 8

Calculate the Further calculation,

$$k_{eff} = 0.386k\left(\frac{Pr}{0.861+Pr}\right)^{1/4}\left(F_{cyc}Ra_L\right)^{1/4}$$

Substitute 0.7228 for Pr, 0.1678 for F_{cyl}

$$k_{eff} = 0.386k\left(\frac{Pr}{0.861+Pr}\right)^{1/4}\left(F_{cyc}Ra_L\right)^{1/4}$$

$$= 0.386\times0.02735(W/m\cdot K)\times\left(\frac{0.7228}{0.861+0.7228}\right)^{1/4}\times(0.1678\times58229)^{1/4}$$

$$= 0.01055\times0.8219\times9.942$$

$$= 0.086207\ W/m\cdot K$$

Step 6 of 8

Calculate the rate of heat transfer between the cylinders by convection

$$\dot{Q}_{conv} = \frac{2\pi k_{eff}}{\ln\left(\frac{D_2}{D_1}\right)}(T_1-T_2)$$

$$= \frac{2\pi\times0.08620}{\ln\left(\frac{12}{5}\right)}(60-40)$$

$$= 12.374\,W$$

Step 7 of 8

Calculate the rate of heat transfer by radiation is

$$\dot{Q}_{rad} = \frac{\sigma A_1\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)}$$

Here,

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Emissivity of the absorber plate, ε_1

Emissivity of the glass surface, ε_2

Substitute, $333\,K$ for T_1, $313\,K$ for T_2, 0.85 for ε_1, $5.67\times10^{-8}\,W/m^2K^4$ for σ, 0.9 for ε_2

$$\dot{Q}_{rad} = \frac{\sigma A_1\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)}$$

$$= \frac{5.67\times10^{-8}(W/m^2\text{-}K^4)\times\pi\times0.05(m)\times1(m)\times(333^4-313^4)}{\frac{1}{0.85}+\frac{1-0.9}{0.9}\left(\frac{5}{12}\right)}$$

$$= \frac{24.033}{1.2227}$$

$$= 19.655\,W$$

Step 8 of 8

Calculate the total rate of heat loss from the glass cover becomes

$$\dot{Q}_{total} = \dot{Q}_{conv}+\dot{Q}_{rad}$$

$$= 12.374(W)+19.655(W)$$

$$= 32.029\,W$$

Therefore, the rate of heat loss from the collector by natural convection and radiation per meter length of the tube is $\boxed{32.029\,W}$

Question: 19.113P

A 3-m-internal-diameter spherical tank made of 1-cm-thick stainless steel (k= 15 W/m·K) is used to store iced water at 0°C. The tank is located outdoors at 30°C and is subjected to winds at 25 km/h. Assuming the entire steel tank to be at 0°C and thus its thermal resistance to be negligible, determine (*a*) the rate of heat transfer to the iced water in the tank and (*b*) the amount of ice at 0°C that melts during a 24-h period. The heat of fusion of water atl atmospheric pressure is *hif* = 333.7 kJ/kg. Disregard any heat transfer by radiation.

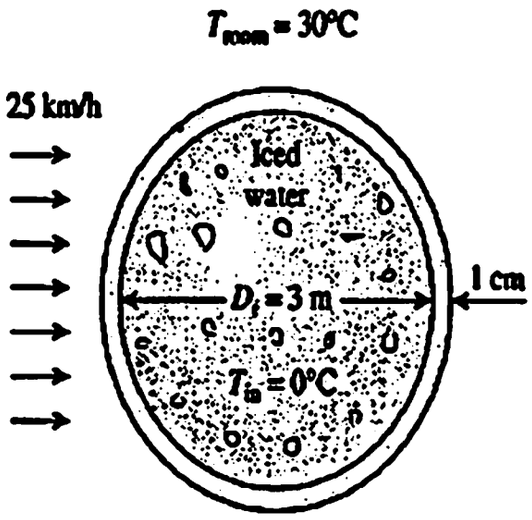


FIGURE P19–113

Step 1 of 2

Given

Height of the cube, $h = 8$ in

Length of the cube, $L = 12$ in

Width of the cube is, $w = 12$ in

Surface temperature of the box, $T_s = 130\ °F$

Emissivity of the outer surface of the box, $\varepsilon = 0.95$

Power dissipation from the box, $\dot{Q} = 90$ W

Step 2 of 2

Surface area of the electronic box,

$$A_s = 4\times(8\times12)+(12\times12)$$
$$= 528\text{in}^2$$
$$= 3.67\text{ft}^2$$

Radiation heat transfer is given by

$$\dot{Q}_{rad} = \varepsilon A_s \sigma\left(T_s^4 - T_{surr}^4\right)$$

$$\Rightarrow 90\times3.41 = 0.95\times3.67\times0.1714\times10^{-8}\left(590^4 - T_{surr}^4\right)$$

$$\Rightarrow 590^4 - T_{surr}^4 = 5.136\times10^{10}$$

$$\Rightarrow T_{surr}^4 = 6.98\times10^{10}$$

$$\Rightarrow T_{surr} = 514\text{R}$$
$$= 54°\text{F}$$

Highest surrounding temperature, $\boxed{T_{surr} = 54°\text{F}}$

Question: 19.114P

Repeat Prob. 19-113, assuming the inner surface of the tank to be at 0°C but by taking the thermal resistance of the tank and heat transfer by radiation into consideration. Assume the average surrounding surface temperature for radiation exchange to be 25°C and the outer surface of the tank to have an emissivity of 0.75.

Step 1 of 4

Assume outer surface of the inner tank to be surface 1 and inner surface of outer tank to be surface 2.

Find the inner diameter of the spherical tank,

$$D_1 = D_i + 2t$$

Here, D_i is inner diameter of the sphere and t is thickness of the wall.

Substitute 2 m for D_i and 0.005 m for t

$$\begin{aligned} D_1 &= 2 + 2\times 0.005 \\ &= 2.01\,\text{m} \end{aligned}$$

Find the inner diameter of the outer tank,

$$D_2 = D_1 + 2l_{air}$$

Here, l_{air} is thickness of air space between two walls.

Substitute 2.01 m for D_1 and 0.015 m for l_{air}

$$\begin{aligned} D_2 &= 2.01 + 2\times 0.015 \\ &= 2.04\,\text{m} \end{aligned}$$

Find the inner tank outer surface area of the sphere.

$$A_1 = \pi D_1^2$$

Substitute 2.01 m for D_1

$$\begin{aligned} A_1 &= \pi \times 2.01^2 \\ &= 12.69\,\text{m}^2 \end{aligned}$$

Step 2 of 4

(a)

Find the rate of heat transfer to the iced water in the spherical tank by using the following equation:

$$\dot{Q}_{12} = \frac{A_1\sigma\left(T_2^4 - T_1^4\right)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)^2}$$

Here, σ is Stefan Boltzmann's constant, $\varepsilon_1, \varepsilon_2$ are the emissivity's of the inner and outer surfaces, T_1 is the inner wall temperature, and T_2 is the outer wall temperature.

Substitute $12.69\,\text{m}^2$ for A_1, 0.15 for $\varepsilon_1, \varepsilon_2$, $5.67\times10^{-8}\,\text{W/m}^2.\text{K}^4$ for σ, 2.01 m for D_1, 2.04 m for D_2, $(20+273)\,\text{K}$ for T_2, and $(0+273)\,\text{K}$ for T_1.

$$\begin{aligned} \dot{Q}_{12} &= \frac{12.69\times5.67\times10^{-8}\left(293^4 - 273^4\right)}{\frac{1}{0.15} + \frac{1-0.15}{0.15}\left(\frac{2.01}{2.04}\right)^2} \\ &= \frac{1306.2788}{12.00728} \\ &= 108.79\,\text{W} \end{aligned}$$

Therefore, heat transfer rate to the iced water is $\boxed{108.79\,\text{W}}$.

Step 3 of 4

(b)

Find the amount of ice melts at $0°\text{C}$ during a 24-h period.

$$Q = \dot{Q}\Delta t$$

Here, t is the time period.

Substitute 108.79 W for $\dot{Q}$ and $(24\times3600)\,\text{s}$ for t.

$$\begin{aligned} Q &= 108.79\times(24\times3600) \\ &= 9399456\,\text{J} \\ &= 9399.456\,\text{kJ} \end{aligned}$$

Step 4 of 4

Find the amount of ice melts during the 24 hour period.

$$Q = mL_{ice}$$

Here, m is amount of ice and L_{ice} is latent heat of ice.

Substitute $9399.456\,\text{kJ}$ for Q and 334 kJ/kg for L_{ice}

$$\begin{aligned} 9399.456 &= m\times334 \\ m &= 28.14\,\text{kg} \end{aligned}$$

Therefore, the amount of ice melts in 24 h period is $\boxed{28.14\,\text{kg}}$.

Question: 19.115P

A transistor with a height of 0.32 in and a diameter of 0.22 in is mounted on a circuit board. The transistor is cooled by air flowing over it at a velocity of 600 ft/min. If the air temperature is 120°F and the transistor case temperature is not to exceed 180°F, determine the amount of power this transistor can dissipate safely.

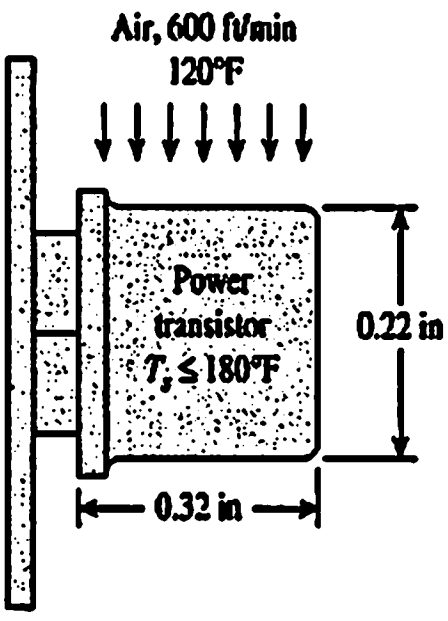

FIGURE P19–115E

Step 1 of 4

Given data:

Height of the transistor, $H = 0.32$ in.$=0.027$ft

Diameter of the transistor, $D = 0.22$ in.$=0.0183$ft

Air flow velocity, $V = 600$ ft/min

$= 10$ ft/s

Temperature of the air, $T_\infty = 120°F$

Temperature of transistor, $T_s = 180°F$

Step 2 of 4

The film temperature is determined as

$$T_f = \frac{(T_s + T_\infty)}{2}$$

$$= \frac{(180+120)}{2}$$

$$= 150°F$$

From the table, properties of air at 1 atm pressure

At $T_f = 150°F$

Thermal conductivity, $k = 0.01646$ Btu/h·ft·R

Kinematic viscosity, $\nu = 2.099\times10^{-4}$ ft^2/s

Prandtl number, $\Pr = 0.7188$

Step 3 of 4

The Reynolds number for the flow is determined as

$$\mathrm{Re} = \frac{VD}{\nu}$$

$$= \frac{10\times0.0183}{2.099\times10^{-4}}$$

$$= 871.84$$

The Nusselt number is determined from the relation given by

$$\mathrm{Nu}_{cyl} = 0.3 + \frac{0.62\mathrm{Re}^{0.5}\mathrm{Pr}^{1/3}}{\left[1+\left(\frac{0.4}{\mathrm{Pr}}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62\times(871.84)^{0.5}\times(0.7188)^{1/3}}{\left[1+\left(\frac{0.4}{0.7188}\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{871.84}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 15.02$$

Step 4 of 4

The convective heat transfer coefficient is determined from the equation given by

$$\mathrm{Nu} = \frac{hD}{k}$$

Rewrite and solve for h:

$$h = \frac{\mathrm{Nu}_{cyl}\times k}{D}$$

$$= \frac{15.02\times0.01646}{0.0183}$$

$$= 13.51 \text{ Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

The amount of power dissipated by the transistor is determined from the equation given by

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$= h\times(\pi DH)\times(T_s - T_\infty)$$

$$= 13.51\times(\pi\times0.0183\times0.027)\times(180-120)$$

$$= 1.26 \text{ Btu/h}$$

Therefore, the amount of power dissipated by the transistor is $\boxed{\dot{Q} = 1.26 \text{ Btu/h}}$

Question: 19.116P pg 1

The roof of a house consists of a 15-cm-thick concrete slab (k =2 W/m·K) that is 15 m wide and 20 m long. The convection heat transfer coefficient on the inner surface of the roof is 5 W/m2·K. On a clear winter night, the ambient air is reported to be at 10°C, while the night sky temperature is 100 K. The house and the interior surfaces of the wall are maintained at a constant temperature of 20°C. The emissivity of both surfaces of the concrete roof is 0.9. Considering both radiation and convection heat transfer, determine the rate of heat transfer through the roof when wind at 60 km/h is blowing over the roof.

If the house is heated by a furnace burning natural gas with an efficiency of 85 percent, and the price of natural gas is $1.20/therm, determine the money lost through the roof that night during a 14-h period.

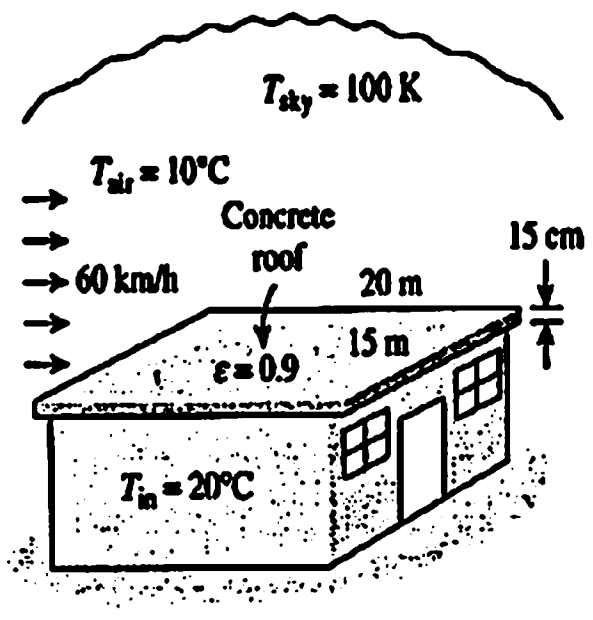

FIGURE P19–116

Step 1 of 6

Schematic diagram of solar system:

Step 2 of 6

Calculate the mean film temperature is

$$T_f = \frac{(T_1 + T_2)}{2}$$

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Substitute $80°C$ for T_1, $32°C$ for T_2

$$T_f = \frac{(T_1 + T_2)}{2}$$
$$= \frac{(80+32)}{2}$$
$$= 56°C$$

From the table the properties of air, at 1 atm and the film temperature of are

$$\text{Thermal conductivity}, k = 0.0277\ \text{W/m}\cdot\text{K}$$
$$\text{kinematic viscosity}, \nu = 1.857\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Prandtle number}, \text{Pr} = 0.7212$$

Use the conversion factor to convert the temperature from $1°C$ to $1K$ is

$$1K = 1°C + 273$$

Calculate the coefficient of volume expansion (β) is

$$\beta = \frac{1}{(56+273)}$$
$$= 0.003041\,K^{-1}$$

For $\theta = 20°$, we have horizontal rectangular enclosure. The characteristic length in this case is the distance between the two glasses $L_c = L = 0.03\,\text{m}$

Step 3 of 6

Calculate the Rayleigh number is

$$\text{Ra} = \frac{g\beta(T_1 - T_2)L^3}{\nu^2}\text{Pr}$$

Here,

Acceleration due to gravity is g

Substitute $0.003041\,K^{-1}$ for β, $80°C$ for T_1, $32°C$ for T_2 $0.03\,\text{m}$ for L, $9.81\,\text{m/s}^2$ for g, $1.857\times10^{-5}\ \text{m}^2/\text{s}$ for ν

$$\text{Ra} = \frac{g\beta(T_1 - T_2)L^3}{\nu^2}\text{Pr}$$
$$= \frac{9.81(\text{m}^2/\text{s})\times0.003041(\text{K}^{-1})\times(80\text{-}32)(\text{K})\times0.03^3(\text{m}^3)}{\left(1.857\times10^{-5}\ \text{m}^2/\text{s}\right)^2}\times0.7212$$
$$= 80857.878$$

Step 4 of 6

Calculate the Nusselt number correlation for the Natural convention is

$$\text{Nu} = 1 + 1.44\left[1 - \frac{1708}{Ra\cos\theta}\right]\times\left[1 - \frac{1708(\sin1.8\theta)^{1.6}}{Ra\cos\theta}\right] + \left[\frac{(Ra\cos\theta)^{1/3}}{18} - 1\right]$$

Here,

Tilted angle of solar collector is θ

Substitute $20°$ for θ, 80857.878 for Ra

$$\text{Nu} = 1 + 1.44\left[1 - \frac{1708}{Ra\cos\theta}\right]\times\left[1 - \frac{1708(\sin1.8\theta)^{1.6}}{Ra\cos\theta}\right] + \left[\frac{(Ra\cos\theta)^{1/3}}{18} - 1\right]$$
$$= 1 + 1.44\left[1 - \frac{1708}{}\right]\times\left[1 - \frac{1708(\sin1.8\times20)^{1.6}}{}\right.$$

$$Nu = 1+1.44\left[1-\frac{1708}{Ra\cos\theta}\right]\times\left[1-\frac{1708(\sin 1.8\theta)^{1.6}}{Ra\cos\theta}\right]+\left[\frac{(Ra\cos\theta)^{1/3}}{18}-1\right]$$

$$=1+1.44\left[1-\frac{1708}{80857.878\times\cos 20}\right]\times\left[1-\frac{1708(\sin 1.8\times 20)^{1.6}}{80857.878\times\cos 20}\right]$$

$$+\left[\frac{(80857.878\times\cos 20)^{1/3}}{18}-1\right]$$

$$=1+1.44\times 0.9775\times 0.9904+1.353$$

$$=3.747$$

Calculate the Surface is

$$A_s = H\times W$$

Here,

Height of the solar collector, H

Width of the solar collector, W

Substitute $1.5\,\text{m}$ for H , 3m for W

$$A_s = H\times W$$

$$=1.5(\text{m})\times 3(\text{m})$$

$$=4.5\,\text{m}^2$$

Since Nusselt number is

$$Nu = \frac{hL}{k}$$

$$h = \frac{k\,Nu}{L}$$

Here,

Heat transfer coefficient is h

Step 5 of 6

Calculate the rate of heat transfer due to natural convection

$$\dot{Q}_{conv} = hA_s(T_1-T_2)$$

$$=\frac{k\text{Nu}}{L}A_s(T_1-T_2)$$

Substitute $0.0277\ \text{W/m}\cdot\text{K}$ for k , 3.747 for Nu

$$\dot{Q}_{conv} = hA_s(T_1-T_2)$$

$$=\frac{kNu}{L}A_s(T_1-T_2)$$

$$=\frac{0.02779(\text{W/m}\cdot\text{K})\times 3.747}{0.03(\text{m})}\times 4.5(\text{m}^2)\times(80-32)$$

$$=750\,\text{W}$$

Therefore, the rate of heat transfer due to natural convection is $\boxed{750\,\text{W}}$

Step 6 of 6

Calculate the rate of heat transfer due to radiation

$$\dot{Q}_{rad} = \frac{\sigma A_2\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1}$$

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Emissivity of the absorber plate, ε_1

Emissivity of the glass surface, ε_2

Substitute $80°\text{C}$ for T_1 , $32°\text{C}$ for T_2 , 0.8 for ε_1 , 0.9 for ε_2

$$\dot{Q}_{rad} = \frac{\sigma A_2\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1}$$

$$=\frac{5.67\times 10^{-8}(\text{W/m}^2\cdot\text{K}^4)\times 4.5(\text{m}^2)\times(353^4-305^4)}{\frac{1}{0.9}+\frac{1}{0.8}-1}$$

$$=1289\ \text{W}$$

Therefore, rate of heat transfer due to radiation is $\boxed{1289\,\text{W}}$

Question: 19.117P pg 1

Steam at 250°C flows in a stainless steel pipe (k =15 W/m•K) whose inner and outer diameters are 4 cm and 4.6 cm, respectively. The pipe is covered with 3.5-cm-thick glass wool insulation (k = 0.038 W/m•K) whose outer surface has an emissivity of 0.3. Heat is lost to the surrounding air and surfaces at 3°C by convection and radiation. Taking the heat transfer coefficient inside the pipe to be 80 W/m2•K, determine the rate of heat loss from the steam per unit length of the pipe when air is flowing across the pipe at 4 m/s.

Step 1 of 7

Outer diameter of the insulated pipe is determined as,

$$D_3 = D_2 + 2t$$

Here, D_2 is outer diameter of the pipe and t is thickness of insulation

Substitute 4.6 cm for D_2 and 3.5 cm for t

$$D_3 = 4.6 + (2 \times 3.5)$$
$$= 11.6 \text{ cm}$$

Assume the outside surface temperature of the pipe $T_s = 12°C$

Calculate the film temperature of air by using the equation,

$$T_f = \frac{(T_s + T_\infty)}{2}$$

Here, T_∞ is temperature of the surrounding air

$$T_f = \frac{(12+3)}{2}$$
$$= 7.5°C$$

From the table, properties of air at 1 atm pressure and $T_f = 7.5°C$ by using interpolation

Thermal conductivity,

$$k = \frac{0.02439 + 0.02401}{2}$$
$$= 0.0242 \text{ W/m·K}$$

Kinematic viscosity,

$$\nu = \frac{(1.382 + 1.426) \times 10^{-5}}{2}$$
$$= 1.404 \times 10^{-5} \text{ m}^2/\text{s}$$

Prandtl number,

$$\text{Pr} = \frac{0.7350 + 0.7336}{2}$$
$$= 0.7343$$

Step 2 of 7

Calculate the Reynolds number of the flow by using the equation,

$$\text{Re} = \frac{VD_t}{\nu}$$

Here, V is velocity of air

Substitute 4 m/s for V

$$\text{Re} = \frac{4 \times \left(11.6 \times 10^{-2}\right)}{1.404 \times 10^{-5}}$$
$$= 33048.43$$

Find the Nusselt number by using the equation,

$$\text{Nu}_{cyl} = 0.3 + \frac{0.62\text{Re}^{0.5}\text{Pr}^{1/3}}{\left[1 + \left(\frac{0.4}{\text{Pr}}\right)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62 \times (33048.43)^{0.5} \times (0.7343)^{1/3}}{\left[1 + \left(\frac{0.4}{0.7343}\right)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{33048.43}{282000}\right)^{5/8}\right]^{4/5}$$

$$= 107.79$$

Step 3 of 7

Calculate the convective heat transfer coefficient by using the equation

$$\text{Nu} = \frac{hD_t}{k}$$

Rewrite and solve for h:

$$h = \frac{\text{Nu} \times k}{D_t}$$
$$= \frac{107.79 \times 0.0242}{0.116}$$
$$= 22.49 \text{ W/m}^2\text{·K}$$

Calculate heat transfer surface area per meter length of the pipe,

$$A_s = \pi D_t L$$
$$= \pi \times \left(11.6 \times 10^{-2}\right) \times 1$$
$$= 0.3644 \text{ m}^2$$

Step 4 of 7

The heat gained by the pipe from the steam per unit length is determined from the equation given by

$$\dot{Q}_{gain} = \frac{T_{in} - T_{out}}{R_{inside} + R_{pipe} + R_{ins}}$$
$$= \frac{T_{in} - T_s}{R_{inside} + R_{pipe} + R_{ins}}$$
$$= \frac{T_{in} - T_s}{\frac{1}{h_i A_i} + \frac{\ln\left(\frac{r_2}{r_1}\right)}{2\pi k_{pipe} L} + \frac{\ln\left(\frac{r_3}{r_2}\right)}{2\pi k_{ins} L}}$$

Here, T_{in} is temperature of the steam, T_s is surface temperature of the steam, h_i is heat transfer coefficient inside the pipe, k_{pipe} is thermal conductivity of the steel pipe, k_{ins} is thermal conductivity of the insulation, r_1 is inner radius of the pipe, r_2 is outer radius of the steel pipe and r_3 is outer diameter of the insulated pipe.

Step 5 of 7

Substitute 250°C for T_{in}, 80 W/m^2·°C for h_i, $\pi D_i L$ for A_i, 15 W/m·K for

Step 5 of 7

Substitute 250°C for T_{in}, 80 W/m^2·°C for h_i, $\pi D_1 L$ for A_i, 15 W/m·K for k_{pipe}, 0.038 W/m·K for k_{ins}, 0.02 m for r_1, 0.023 m for r_2, 0.058 m for r_3 and 1 m for L

$$\dot{Q}_{gain} = \frac{250 - T_s}{\frac{1}{\left(80 \times \pi \times \left(4 \times 10^{-2}\right) \times 1\right)} + \frac{\ln\left(\frac{0.023}{0.02}\right)}{(2\pi \times 15 \times 1)} + \frac{\ln\left(\frac{0.058}{0.023}\right)}{(2\pi \times 0.038 \times 1)}}$$

$$= \frac{250 - T_s}{0.0995 + \left(1.483 \times 10^{-3}\right) + 3.874}$$

$$\dot{Q}_{gain} = \frac{250 - T_s}{3.975} \qquad \text{..... (1)}$$

Step 6 of 7

Calculate the heat lost by the pipe to the surroundings per unit length of the pipe,

$$\dot{Q}_{lost} = \dot{Q}_{conv} + \dot{Q}_{rad}$$

$$= hA_s(T_s - T_\infty) + \varepsilon A_s \sigma\left(T_s^4 - T_\infty^4\right)$$

Here, ε is emissivity of insulation and σ is Stefan Boltzmann's constant.

Substitute, 0.3 for ε and 5.67×10^{-8} W/m^2·K^4 for σ

$$= 22.49 \times 0.3644(T_s - 3) + 0.3 \times 0.3644 \times 5.67 \times 10^{-8}$$

$$\times\left((T_s + 273)^4 - (3 + 273)^4\right)$$

$$\dot{Q}_{lost} = 8.199(T_s - 3) + 6.198 \times 10^{-9}\left[(T_s + 273)^4 - (276)^4\right] \qquad \text{..... (2)}$$

The heat lost by the pipe to the surroundings is nothing but the heat gained by the pipe from the steam.

So, calculate the surface temperature of the pipe, by equating the equations (1) and (2)

$$\dot{Q}_{gain} = \dot{Q}_{lost}$$

$$\frac{250 - T_s}{3.98} = 8.199(T_s - 3) + 6.198 \times 10^{-9}\left[(T_s + 273)^4 - (276)^4\right]$$

Solve the above equation,

$$T_s = 9.9°C$$

Since the obtained value is close to the assumed value. So, the assumption is correct.

Step 7 of 7

Substitute the value of T_s in equation (2) to obtain the heat loss from the steam per unit length of the pipe,

$$\dot{Q}_{lost} = 8.199(9.9 - 3) + 6.198 \times 10^{-9}\left[\left(282.9^4 - 276^4\right)\right]$$

$$= 60.325 \text{ W/m}$$

Therefore, the heat loss from the steam per unit length of the pipe $\dot{Q}_{lost}$ is $\boxed{60.325 \text{ W/m}}$

Question: 19.118P

Consider a house that is maintained at 24°C at all times. The walls of the house have *R*-3.38 insulation in SI units (i.e., an *L/k* value or a thermal resistance of 3.38 m2-C/W). During a cold winter night, the outside air temperature is 6°C and wind at 50 km/h is blowing parallel to a 4-m-high and 8-m-long wall of the house. If the heat transfer coefficient on the interior surface of the wall is 12 W/m2-K, determine the rate of heat loss from that wall of the house. Draw the thermal resistance network and disregard radiation heat transfer.

Step 1 of 5

Given data:

Temperature inside house, $T_{in} = 24°C$

Thermal resistance of the wall, $R'_{wall} = 3.38\ m^2 \cdot °C/W$

Outside air temperature, $T_{out} = 6°C$

Velocity of the wind, $V = 50\ km/h$

$= 13.89\ m/s$

Height of the wall of the house, $H = 4\ m$

Length of the wall of the house, $L = 8\ m$

Heat transfer coefficient on the interior surface of the wall, $h_i = 12\ W/m^2 \cdot K$

Step 2 of 5

Let us assume the film temperature of air as $T_f = 10°C$

From the table, properties of air at 1 atm pressure

At $T = 10°C$

Thermal conductivity, $k = 0.02439\ W/m \cdot K$

Kinematic viscosity, $\nu = 1.426 \times 10^{-5}\ m^2/s$

Prandtl number, $Pr = 0.7336$

The Reynolds number for the flow is determined from the equation given by

$$Re = \frac{VL}{\nu}$$

$$= \frac{13.89 \times 8}{1.426 \times 10^{-5}}$$

$$= 7791803$$

Since the obtained Reynolds number $Re > Re_{critical}$ i.e. 5×10^5 but less than 10^7, so the flow is a combined laminar and turbulent flow.

The Nusselt number for the combined flow is determined from the relationship given by

$$Nu = \left(0.037 Re^{0.8} - 871\right) Pr^{1/3}$$

$$= \left(0.037 \times (7791803)^{0.8} - 871\right) \times (0.7336)^{1/3}$$

$$= 10095.36$$

Step 3 of 5

The convective heat transfer coefficient of air is determined from the equation given by

$$Nu = \frac{hD}{k}$$

Rewrite and solve for h:

$$h = \frac{Nu \times k}{L}$$

$$= \frac{10095.36 \times 0.02439}{8}$$

$$= 30.78\ W/m^2 \cdot K$$

The surface area of the wall is determined as

$$A_s = H \times L$$

$$= 4 \times 8$$

$$= 32\ m^2$$

Step 4 of 5

The thermal resistance network is shown below:

Step 5 of 5

From the thermal resistance network the rate of heat loss from the wall is determined from the equation given by

$$\dot{Q} = \frac{T_{in} - T_{out}}{R_{in} + R_{wall} + R_{out}}$$

$$= \frac{T_{in} - T_{out}}{\left(\frac{1}{h_i A_s}\right) + \left(\frac{R'_{wall}}{A_s}\right) + \left(\frac{1}{hA_s}\right)}$$

$$= \frac{24 - 6}{\left(\frac{1}{12 \times 32}\right) + \left(\frac{3.38}{32}\right) + \left(\frac{1}{30.78 \times 32}\right)}$$

$$= 164.77\ W$$

Therefore, the rate of heat loss from the wall of the house is $\boxed{\dot{Q} = 164.77\ W}$

Question: 19.119P

An automotive engine can be approximated as a 0.4-m-high, 0.60-m-wide, and 0.7-m-long rectangular block. The bottom surface of the block is at a temperature of 75°C and has an emissivity of 0.92. The ambient air is at 5°C, and the road surface is at 10°C. Determine the rate of heat transfer from the bottom surface of the engine block by convection and radiation as the car travels at a velocity of 60 km/h. Assume the flow to be turbulent over the entire surface because of the constant agitation of the engine block. How will the heat transfer be affected when a 2-mm-thick gunk (k =3 W/m•K) has formed at the bottom surface as a result of the dirt and oil collected at that surface over time? Assume the metal temperature under the gunk still to be 75°C.

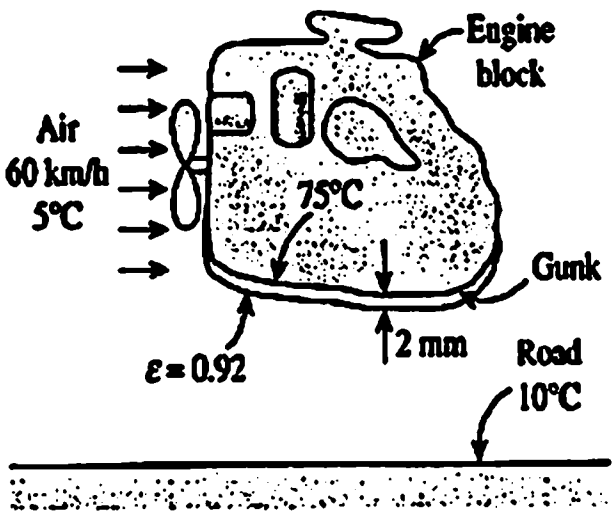

FIGURE P19–119

Step 1 of 4

Given
Height of engine block = 0.4 m
Width of engine block = 0.6 m
Length of engine block = 0.7 m
Temperature of bottom surface = 75°C
Emissivity (ε) = 0.92
Temperature of air = 5°C
Temperature of road surface = 10°C
Velocity of car = 60 km/h
Temperature of metal = 75°C
Thermal conductivity of gunk material = 3 W/m.°C

Step 2 of 4

Average film temperature $T_{avg} = \dfrac{75+5}{2}$

$$T_{avg} = 40^0\text{C}$$

From properties of air table at 1 atm and 40°C,

$k = 0.02662$ W/m.°C
$\upsilon = 1.702\times10^{-5}$ m^2/s
Pr = 0.7255

Reynolds number, $\text{Re}_L = \dfrac{VL}{\upsilon}$

$$\text{Re}_L = \frac{[(60\times1000/3600)\text{ m/s}](0.7\text{ m})}{1.702\times10^{-5}\text{ m}^2/\text{s}}$$

$$\text{Re}_L = 6.855\times10^5$$

This value is less than the critical Reynolds number value. But we assume turbulent flow due to the constant agitation of the engine block.

Nusselt number, $Nu = 0.037\text{Re}_L^{0.8}\,\text{Pr}^{1/3}$

$$Nu = 0.037(6.855\times10^5)^{0.8}(0.7255)^{1/3}$$

$$Nu = 1551$$

And $Nu = \dfrac{hL}{k}$

Heat transfer rate, $h = \dfrac{k}{L}Nu$

$$h = \frac{0.02662}{0.7}\times(1551)$$

$$h = 58.97\text{ W/m}^2.^\circ\text{C}$$

Step 3 of 4

Heat loss rate by convection, $\dot{Q}_{conv} = hA_s(T_\infty - T_s)$

$$\dot{Q}_{conv} = (58.97)\times(0.6\times0.7)\times(75-5)$$

$$\dot{Q}_{conv} = 1734\text{ W}$$

Heat loss rate by radiation, $\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s^4 - T_{surr}^4)$

$$\dot{Q}_{rad} = (0.92)(0.6\times0.7)\left(5.67\times10^{-8}\right)\left[(75+273)^4 - (10+273)^4\right]$$

$$\dot{Q}_{rad} = 181\text{ W}$$

Total heat loss rate is $\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$

$$\dot{Q}_{total} = 1734 + 181$$

$$\dot{Q}_{total} = 1915\text{ W}$$

The rate of heat transferred from the bottom surface is $\boxed{\dot{Q}_{total} = 1915\text{ W}}$

Step 4 of 4

Heat transfer rate with gunk is $\dot{Q} = \dfrac{T_\infty - T_s}{\dfrac{1}{hA_s} + \dfrac{L}{kA_s}}$

$$\dot{Q} = \frac{(75\text{-}5)^\circ\text{C}}{\dfrac{1}{58.97\times(0.6\times0.7)} + \dfrac{0.002}{3\times(0.6\times0.7)}}$$

$$\dot{Q} = 1668\text{ W}$$

Total heat loss rate with gunk is $\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$

$$\dot{Q}_{total} = 1668 + 181$$

$$\dot{Q}_{total} = 1849\text{ W}$$

The rate of heat transferred from the bottom surface with gunk is $\boxed{\dot{Q}_{total} = 1849\text{ W}}$

Question: 19.120P pg 1

The boiling temperature of nitrogen at atmospheric pressure at sea level (1 atm pressure) is −196°C. Therefore, nitrogen is commonly used in low-temperature scientific studies, since the temperature of liquid nitrogen in a tank open to the atmosphere will remain constant at -196°C until it is depleted. Any heat transfer to the tank will result in the evaporation of some liquid nitrogen, which has a heat of vaporization of 198 kJ/kg and a density of 810 kg/m3 at 1 atm.

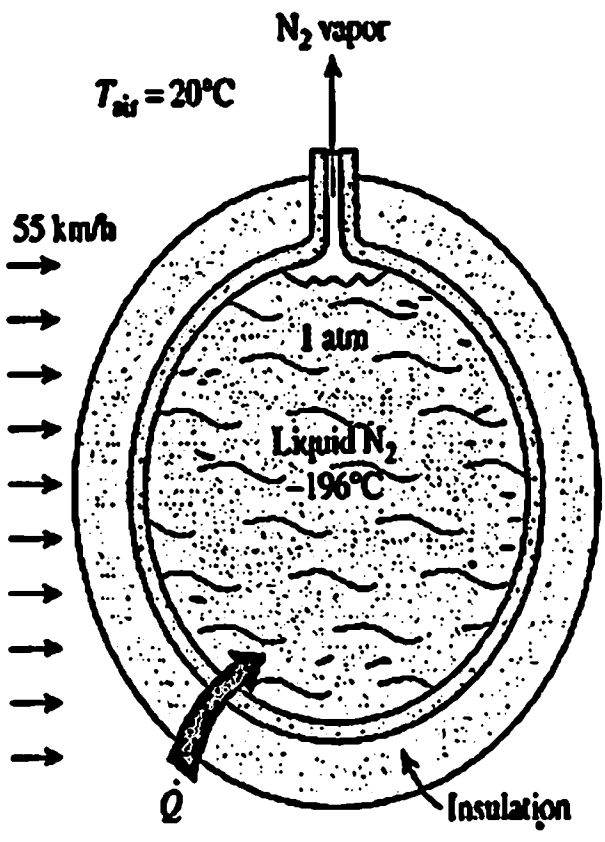

FIGURE P19–120

Consider a 4-m-diameter spherical tank that is initially filled with liquid nitrogen at 1 atm and – 196°C. The tank is exposed to 20° C ambient air and 55 km/h winds. The temperature of the thin-shelled spherical tank is observed to be almost the same as the temperature of the nitrogen inside. Disregarding any radiation heat exchange, determine the rate of evaporation of the liquid nitrogen in the tank as a result of heat transfer from the ambient air if the tank is (*a*) not insulated, (*b*) insulated with 5-cm-thick fiberglass insulation (k =0.035 W/m·K), and (*c*) insulated with 2-cm-thick superinsulation that has an effective thermal conductivity of 0.00005 W/m·K.

Step 1 of 14

Given data:

Boiling temperature of nitrogen at 1 atm T= -196°C

Heat of vaporization, h_f =198 kJ/kg

Density of nitrogen, ρ=810 kg/m^3

Diameter of spherical tank, D = 4 m

Temperature of air, T_s = 20°C

Velocity of wind, V=55 km/h

Thickness of insulation, t_1 = 5 cm

Thermal conductivity of insulation material, k_i = 0.035 W/m · °C

Thickness of super insulation, t_{supi} = 2cm

Thermal conductivity of super insulation material, k_{supi} = 0.00005 W/m · °C

Step 2 of 14

From properties of air table taking properties of air at 1 atm and free stream temperature of 20°C

Thermal conductivity, k = 0.02514 W/m.°C

Kinetic viscosity, $\upsilon = 1.516\times10^{-5}$ m^2/s

Dynamic viscosity, $\mu_\infty = 1.825\times10^{-5}$ kg/m · s

$\mu_{s@-196\,°C} = 5.023\times10^{-6}$ kg/m · s

Prandntl number, Pr = 0.7309

Step 3 of 14

(a)

When there is no insulation of the spherical tank then diameter $D = D_i = 4$ m

Reynolds number

$$\mathrm{Re} = \frac{VD}{\upsilon}$$

$$= \frac{[(55\times1000/3600)\ \mathrm{m/s}](4\ \mathrm{m})}{1.516\times10^{-5}\ \mathrm{m^2/s}}$$

$$= 4.031\times10^6$$

For flow over a sphere Nusselt number can be expressed as

$$\mathrm{Nu} = 2+\left[0.4\mathrm{Re}^{0.5}+0.06\mathrm{Re}^{2/3}\right]\mathrm{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$=2+\left[0.4\times\left(4.031\times10^6\right)^{0.5}+0.06\left(4.031\times10^6\right)^{2/3}\right]\times0.7309^{0.4}\left(\frac{1.825\times10^{-5}}{5.023\times10^{-6}}\right)^{1/4}$$

$$=2+[803.094+1519.706]\times1.2179$$

$$\mathrm{Nu} = 2830.93$$

Then heat transfer coefficient is

$$\mathrm{Nu} = \frac{hD}{k}$$

$$h = \frac{k}{D}\mathrm{Nu}$$

$$= \frac{0.02514}{4}\times2830.93$$

$$h = 17.79\ \mathrm{W/m^2\cdot K}$$

Step 4 of 14

Heat transfer rate will be

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$= h\times\pi D^2\times(T_s - T_\infty)$$

$$= 17.79\times[\pi\times4^2][(20-(-196)]$$

$$\dot{Q} = 193152.15\ \mathrm{W}$$

Step 5 of 14

Rate of evaporation of liquid nitrogen is determined as

$$\dot{Q} = \dot{m}h_f$$

$$\dot{m} = \frac{\dot{Q}}{h_f}$$

Step 5 of 14

Rate of evaporation of liquid nitrogen is determined as

$$\dot{Q} = \dot{m}h_f$$

$$\dot{m} = \frac{\dot{Q}}{h_f}$$

$$= \frac{193.152}{198}$$

$$\dot{m} = 0.9755 \text{kg/s}$$

Therefore rate of evaporation of liquid nitrogen when it is not insulated is

$$\boxed{\dot{m} = 0.9755 \text{kg/s}}$$

Step 6 of 14

(b)

The spherical tank is insulated with 5 cm thick fiberglass insulation

Then outer diameter of the sphere is

$$D_0 = D + 2 \times 0.05$$

$$= 4 + 0.1$$

$$= 4.1 \text{m}$$

As insulation is provided on the outer surface the surface temperature of the sphere changes, therefore taking Dynamic viscosity value,

$$\mu_{s,-100^\circ\text{C}} = 1.189 \times 10^{-5} \text{kg/m} \cdot s$$

Step 7 of 14

Reynolds number can be calculated as

$$\text{Re} = \frac{VD}{\upsilon}$$

$$= \frac{[(55 \times 1000/3600) \text{ m/s}](4.1 \text{ m})}{1.516 \times 10^{-5} \text{ m}^2/\text{s}}$$

$$\text{Re} = 4.131 \times 10^6$$

For flow over a sphere Nusselt number can be expressed as

$$\text{Nu} = 2 + \left[0.4\text{Re}^{0.5} + 0.06\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

$$= 2 + \left[0.4 \times \left(4.131 \times 10^6\right)^{0.5} + 0.06\left(4.131 \times 10^6\right)^{2/3}\right] \times 0.7309^{0.4}\left(\frac{1.825 \times 10^{-5}}{1.189 \times 10^{-5}}\right)^{1/4}$$

$$= 2 + [812.99 + 1544.737] \times 0.9818$$

$$\text{Nu} = 2316.81$$

Step 8 of 14

Heat transfer coefficient is

$$\text{Nu} = \frac{hD}{k}$$

$$h = \frac{k}{D}\text{Nu}$$

$$= \frac{0.02514}{4.1} \times 2316.81$$

$$h = 14.206 \text{W/m}^2 \cdot \text{K}$$

Step 9 of 14

Surface area

$$A_s = \pi D^2$$

$$= \pi(4.1 \text{ m})^2$$

$$= 52.81 \text{ m}^2$$

Rate of heat transfer

$$\dot{Q} = \frac{T_\infty - T_{s,tank}}{R_{insulation} + R_{conv}}$$

$$= \frac{T_\infty - T_{s,tank}}{\frac{r_2 - r_1}{4\pi k r_1 r_2} + \frac{1}{hA_s}}$$

$$= \frac{[20 - (-196)]^\circ\text{C}}{\frac{(2.05 - 2) \text{ m}}{4\pi(0.035 \text{ W/m.}^\circ\text{C})(2.05 \text{ m})(2 \text{ m})} + \frac{1}{(14.206 \text{ W/m}^2.^\circ\text{C})(52.81 \text{ m}^2)}}$$

$$= \frac{216}{0.02772 + 0.00133}$$

$$\dot{Q} = 7435.45 \text{W}$$

Step 10 of 14

Rate of evaporation of liquid nitrogen is determined as

$$\dot{Q} = \dot{m}h_f$$

$$\dot{m} = \frac{\dot{Q}}{h_f}$$

$$= \frac{7.435}{198}$$

$$\dot{m} = 0.0375 \text{kg/s}$$

Rate of evaporation of liquid nitrogen is $\boxed{\dot{m} = 0.0375 \text{kg/s}}$

Step 11 of 14

(c)

The spherical tank is insulated with 2 cm thick super insulation

Taking dynamic viscosity value at the new value surface temperature 0°C to be

$$\mu = 1.729 \times 10^{-5} \text{ kg/m} \cdot s$$

Then outer diameter of the sphere is

$$D_0 = D + 2 \times 0.02$$

$$= 4 + 0.04$$

$$= 4.04 \text{m}$$

Reynolds number

$$\text{Re} = \frac{VD}{\upsilon}$$

$$=4+0.04$$
$$=4.04\,\text{m}$$

Reynolds number

$$\text{Re}=\frac{VD}{\upsilon}$$
$$=\frac{[(55\times1000/3600)\,\text{m/s}](4.04\,\text{m})}{1.516\times10^{-5}\,\text{m}^2/\text{s}}$$
$$\text{Re}=4.071\times10^{6}$$

For flow over a sphere Nusselt number can be expressed as

$$\text{Nu}=2+\left[0.4\text{Re}^{0.5}+0.06\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$
$$=2+\left[0.4\times\left(4.071\times10^{6}\right)^{0.5}+0.06\left(4.071\times10^{6}\right)^{2/3}\right]\times0.7309^{0.4}\left(\frac{1.825\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4}$$
$$=2+[807.06+1529.743]\times0.894$$
$$\text{Nu}=2091.10$$

Step 12 of 14

Heat transfer coefficient

$$\text{Nu}=\frac{hD}{k}$$
$$h=\frac{k}{D}\text{Nu}$$
$$=\frac{0.02514}{4.04}\times2091.10$$
$$h=13.012\,\text{W/m}^2\cdot\text{K}$$

Step 13 of 14

Surface area

$$A_s=\pi D^2$$
$$=\pi(4.04\,\text{m})^2$$
$$=51.28\,\text{m}^2$$

Heat transfer rate for liquid nitrogen is

$$\dot{Q}=\frac{T_\infty-T_{s,\text{tank}}}{R_{\text{insulation}}+R_{\text{conv}}}$$
$$=\frac{T_\infty-T_{s,\text{tank}}}{\frac{r_2-r_1}{4\pi k r_1 r_2}+\frac{1}{hA_s}}$$
$$=\frac{[20-(-196)]^\circ\text{C}}{\frac{(2.02-2)\,\text{m}}{4\pi(0.00005\,\text{W/m.}^\circ\text{C})(2.02\,\text{m})(2\,\text{m})}+\frac{1}{(13.012\,\text{W/m}^2.^\circ\text{C})(51.28\,\text{m}^2)}}$$
$$=\frac{216}{7.878+0.00149}$$
$$\dot{Q}=27.412\,\text{W}$$

Step 14 of 14

Rate of evaporation of liquid nitrogen is determined as

$$\dot{Q}=\dot{m}h_f$$
$$\dot{m}=\frac{\dot{Q}}{h_f}$$
$$=\frac{0.027412}{198}$$
$$=1.38\times10^{-4}\,\text{kg/s}$$

Therefore, Rate of evaporation of liquid nitrogen when the sphere is insulated with super insulation is $\boxed{\dot{m}=1.38\times10^{-4}\,\text{kg/s}}$

Question:

Repeat Prob. 19-120 for liquid oxygen, which has a boiling temperature of −183°C, a heat of vaporization of 213 kJ/kg, and a density of 1140 kg/m3 at 1 atm pressure.

Step 1 of 13

Taking properties of air at 1 atm for free stream temperature of 20°C from properties of air table

Thermal conductivity, $k = 0.02514\ \text{W/m}\cdot{}^\circ\text{C}$

Kinetic viscosity, $\upsilon = 1.516\times10^{-5}\ \text{m}^2/\text{s}$

Dynamic viscosity, $\mu_\infty = 1.825\times10^{-5}\ \text{kg/m}\cdot\text{s}$

$\mu_{s,@-183^\circ C} = 6.127\times10^{-5}\ \text{kg/m-s}$

Prandntl number, $\text{Pr} = 0.7309$

Step 2 of 13

(a)

$D = D_i = 4\ \text{m}$ When no insulation is there, and

Calculate e the Reynolds number,

$$\text{Re} = \frac{VD}{\upsilon}$$

V is the velocity of the wind and

L is the diameter of the spherical tank.

Substitute 55 km/h for V, 4 m for D and $1.516\times10^{-5}\ \text{m}^2/\text{s}$ for ν in the above equation,

$$\text{Re} = \frac{\left(55\text{km/h}\times\frac{1000}{3600}\text{m/s}\right)(4\ \text{m})}{1.516\times10^{-5}\ \text{m}^2/\text{s}}$$
$$= 4.03\times10^6$$

Step 3 of 13

Calculate the Nusselt number,

$$\text{Nu} = \frac{hD}{k}$$
$$= 2+\left[0.4\text{Re}^{0.5}+0.06\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

Substitute the respective values in the above equation,

$$\text{Nu} = 2+\left[0.4\left(4.03\times10^6\right)^{0.5}+0.06\left(4.03\times10^6\right)^{2/3}\right](0.7309)^{0.4}\left(\frac{1.825\times10^{-5}}{1.05\times10^{-5}}\right)^{1/4}$$
$$= 2+[803+1519.46]1.0129$$
$$= 2354.4$$

Calculate the coefficient of convective heat transfer,

$$h = \frac{k}{D}\text{Nu}$$

Substitute the respective values in the above equation,

$$h = \frac{0.02514}{4}\times2354.4$$
$$= 14.79\ \text{W/m}^2\cdot{}^\circ\text{C}$$

Step 4 of 13

Calculate the heat transfer rate,

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$= h(\pi D^2)(T_s - T_\infty)$$

Where,

T_s is the surface temperature and

T_∞ is the boiling temperature of the oxygen at 1 atm.

Substitute 20°C for T_s, -183°C for T_∞ and the respective values in the above equation,

$$\dot{Q} = (14.79)\left(\pi\times4^2\right)(20-(-183))$$
$$= 150915.58\ \text{W}$$

Step 5 of 13

Calculate the Rate of evaporation of liquid oxygen,

$$\dot{Q} = \dot{m}h_{fg}$$
$$\dot{m} = \frac{\dot{Q}}{h_{fg}}$$

Where,

h_{fg} is the heat of vaporization.

Substitute $(213\,\text{kJ/kg})$ for h_{fg} and the respective values in the above equation,

$$\dot{m} = \frac{142.4}{213}$$
$$= 0.6685\ \text{kg/s}$$

Therefore, Rate of evaporation of liquid oxygen $\boxed{\dot{m} = 0.6685\ \text{kg/s}}$

Step 6 of 13

(b)

After insulation diameter and surface temperature will change. So $D = D_0 = 4.1$ m and surface temperature will be evaluating dynamic viscosity a -100°C .

Calculate the Reynolds number,

$$\text{Re} = \frac{VD}{\upsilon}$$
$$= \frac{\left(55\text{km/h}\times\frac{1000}{3600}\text{m/s}\right)(4.1\ \text{m})}{1.516\times10^{-5}\ \text{m}^2/\text{s}}$$
$$= 4.132\times10^6$$

Step 7 of 13

Calculate the Nusselt number,

$$\text{Nu} = \frac{hD}{k}$$

Step 7 of 13

Calculate the Nusselt number,

$$\mathrm{Nu}=\frac{hD}{k}$$

$$=2+\left[0.4\mathrm{Re}^{0.5}+0.06\mathrm{Re}^{2/3}\right]\mathrm{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

Substitute the respective values in the above equation,

$$\mathrm{Nu}=2+\left[0.4\left(4.132\times10^{6}\right)^{0.5}+0.06\left(3.005\times10^{6}\right)^{2/3}\right](0.7309)^{0.4}\left(\frac{1.825\times10^{-5}}{1.189\times10^{-5}}\right)^{1/4}$$

$$=2+[813.1+1544.97]0.982$$

$$=2317.7$$

Calculate the coefficient of convective heat transfer,

$$h=\frac{k}{D}\mathrm{Nu}$$

$$=\frac{0.02514}{4.1}\times2317.7$$

$$=14.21\ \mathrm{W/m^2\cdot{}^\circ C}$$

Step 8 of 13

Calculate the surface area of the spherical tank,

$$A_s=\pi D^2$$

$$=\pi(4.1\ \mathrm{m})^2$$

$$=52.81\ \mathrm{m^2}$$

Calculate the Heat transfer rate for liquid oxygen,

$$\dot{Q}=\frac{T_\infty-T_{s,\mathrm{tank}}}{R_{\mathrm{insulation}}+R_{\mathrm{conv}}}$$

$$=\frac{T_\infty-T_{s,\mathrm{tank}}}{\frac{r_2-r_1}{4\pi k r_1 r_2}+\frac{1}{hA_s}}$$

Where,

T_∞ is the temperature of the air,

$T_{s,\mathrm{tank}}$ is the surface temperature of the tank,

$R_{\mathrm{insulation}}$ is the co-efficient of thermal resistance of the insulation and

R_{conv} is the convective co-efficient of thermal resistance.

Substitute $20^\circ\mathrm{C}$ for T_∞, $(-183^\circ\mathrm{C})$ for $T_{s,\mathrm{Tank}}$, 2.05 m for r_1, 2 m for r_2 and the respective values in the above equation,

$$\dot{Q}=\frac{[20-(-183)]^\circ\mathrm{C}}{\frac{(2.05-2)\ \mathrm{m}}{4\pi(0.035\ \mathrm{W/m.^\circ C})(2.05\ \mathrm{m})(2\ \mathrm{m})}+\frac{1}{(14.21\ \mathrm{W/m^2.^\circ C})(52.81\ \mathrm{m^2})}}$$

$$=\frac{203}{0.0277+1.33\times10^{-3}}$$

$$=6986.186\ \mathrm{W}$$

Step 9 of 13

Calculate the Rate of evaporation of liquid oxygen,

$$\dot{Q}=\dot{m}h_{fg}$$

$$\dot{m}=\frac{\dot{Q}}{h_{fg}}$$

$$=\frac{6.986186}{213}$$

$$=0.0328\ \mathrm{kg/s}$$

Rate of evaporation of liquid oxygen is $\boxed{0.0328\mathrm{kg/s}}$

Step 10 of 13

(c)

Taking dynamic viscosity value at the new value surface temperature $0^\circ\mathrm{C}$ to be

$\mu=1.729\times10^{-5}\ \mathrm{kg/m.s}$.

Diameter will be $D=D_0=4.04$ m calculating Nusselt number

$$\mathrm{Re}=\frac{VD}{\upsilon}$$

$$=\frac{[(55\times1000/3600)\ \mathrm{m/s}](4.04\ \mathrm{m})}{1.516\times10^{-5}\ \mathrm{m^2/s}}$$

$$=4.07\times10^{6}$$

Step 11 of 13

Calculate the Nusselt number,

$$\mathrm{Nu}=\frac{hD}{k}$$

$$=2+\left[0.4\mathrm{Re}^{0.5}+0.06\mathrm{Re}^{2/3}\right]\mathrm{Pr}^{0.4}\left(\frac{\mu_\infty}{\mu_s}\right)^{1/4}$$

Substitute the respective values in the above equation,

$$\mathrm{Nu}=2+\left[0.4(4.07\times10^{6})^{0.5}+0.06(4.07\times10^{6})^{2/3}\right](0.713)^{0.4}\left(\frac{1.825\times10^{-5}}{1.729\times10^{-5}}\right)^{1/4}$$

$$=2+[806.97+1529.5]0.885$$

$$=2069.78$$

Step 12 of 13

Calculate the Convection heat transfer coefficient,

$$h=\frac{k}{D}\mathrm{Nu}$$

$$=\frac{0.02514}{4.04}2069.78$$

$$=12.88\ \mathrm{W/m^2\cdot{}^\circ C}$$

Calculate the surface area of the spherical tank,

$$A_s=\pi D^2$$

$$=\pi(4.04\ \mathrm{m})^2$$

$$=51.28\ \mathrm{m^2}$$

Calculate the heat transfer rate for liquid nitrogen

Calculate the surface area of the spherical tank.

19.1211 pg 3

$$A_s = \pi D^2$$
$$= \pi(4.04\ \text{m})^2$$
$$= 51.28\ \text{m}^2$$

Calculate the heat transfer rate for liquid nitrogen,

$$\dot{Q} = \frac{T_\infty - T_{s,tank}}{R_{insulation} + R_{conv}}$$
$$= \frac{T_\infty - T_{s,tank}}{\frac{r_2 - r_1}{4\pi k r_1 r_2} + \frac{1}{hA_s}}$$

Substitute the respective values in the above equation,

$$\dot{Q} = \frac{20-(-183)}{\frac{(2.02-2)}{4\pi(0.00005)(2.02\times 2)} + \frac{1}{(12.88)(51.28)}}$$
$$= \frac{20-(-183)}{7.87+1.514\times 10^{-3}}$$
$$= 25.759\ \text{W}$$

Step 13 of 13

Calculate the Rate of evaporation of liquid oxygen,

$$\dot{Q} = \dot{m} h_{fg}$$
$$\dot{m} = \frac{\dot{Q}}{h_{fg}}$$
$$= \frac{0.025759}{213}$$
$$= 1.21\times 10^{-4}\ \text{kg/s}$$

Therefore, Rate of evaporation of liquid oxygen is $\boxed{1.21\times 10^{-4}\ \text{kg/s}}$

Question: 19.122P

Four power transistors, each dissipating 10 W, are mounted on a thin vertical aluminum plate (k= 237 W/m·K) 22 cm × 22 cm in size. The heat generated by the transistors is to be dissipated by both surfaces of the plate to the surrounding air at 20°C, which is blown over the plate by a fan at a velocity of 5 m/s. The entire plate can be assumed to be nearly isothermal, and the exposed surface area of the transistor can be taken to be equal to its base area. Determine the temperature of the aluminum plate.

Step 1 of 5

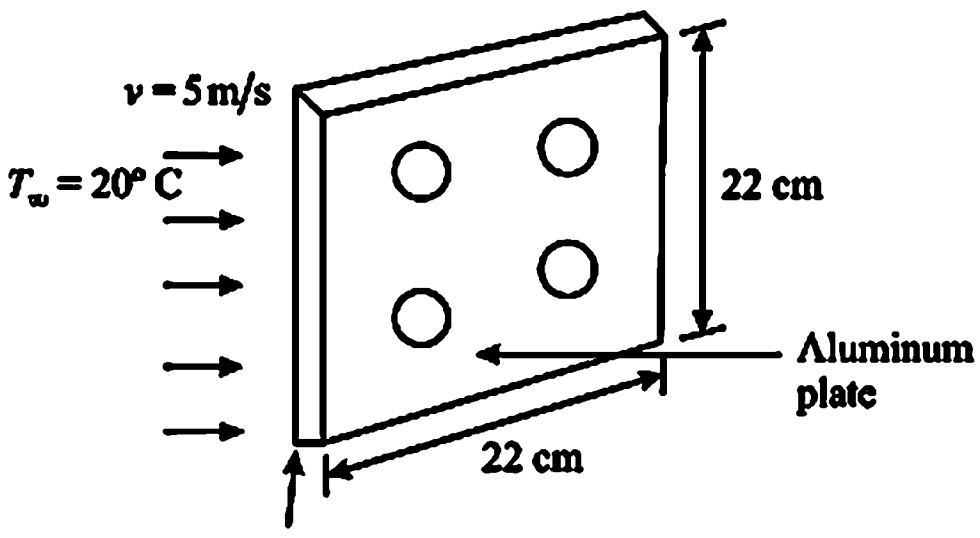
Given data:

No. of transfers, $N = 4$

Power Dissipation by each transistor, $P = 10\,\text{W}$

Thermal conductivity of the plate is $k = 237\,\text{W/m}\cdot\text{K}$

Aluminum plate dimensions $(L \times B) = 22 \times 22\,\text{cm}$ or $0.22 \times 0.22\,\text{m}$



Ambient air temperature, $T_\infty = 20^\circ\text{C}$

Velocity of air flow, $V = 5\,\text{m/s}$

Plate is isothermal.

Step 2 of 5

Figure showing the aluminum plate,

Step 3 of 5

Let's take the properties of air at files temperature say 30°C (Assuming).

Kinematic viscosity, $\nu = 1.608 \times 10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7282$

Reynolds number

$$\text{Re} = \frac{VL}{\nu}$$
$$= \frac{5 \times 0.22}{1.608 \times 10^{-5}}$$
$$= 68408$$

Since the value is less than $\text{Re}_{\text{critical}}$ that is 5×10^5 the flow is laminar here.

Step 4 of 5

Nusselt number calculation (based on Reynolds number and Prandtl number)

$$Nu = 0.664\,\text{Re}_L^{0.5}\text{Pr}^{1/3}$$
$$= 0.664 \times (68408)^{0.5}(0.7282)^{1/3}$$
$$= 156.25$$

Also we know that,

$$Nu = \frac{hL}{k}$$
$$h = \frac{k \cdot Nu}{L}$$
$$= 18.38\,\text{W/m}^2\,^\circ\text{C}$$

Step 5 of 5

Heat transfer surface area

$$A_s = (L \times B) \times \text{number of plates}$$
$$= (0.22)^2 \times 2$$
$$= 0.0968\,\text{m}^2$$

Total heat dissipation or transfer,

$$\dot{Q} = P \times N$$
$$= 40\,\text{W}$$

Heat transfer through convection is given by.

$$\dot{Q} = hA_s(T_s - T_\infty)$$
$$40 = 18.38 \times 0.0968(T_s - 20)$$
$$T_s = 42.48^\circ\text{C}$$

Therefore, Surface temperature of the aluminum plate is obtained as $\boxed{T_s = 42.5^\circ\text{C}}$

Question: 19.123P

It is well known that cold air feels much colder in windy weather than what the thermometer reading indicates because of the "chilling effect" of the wind. This effect is due to the increase in the convection heat transfer coefficient with increasing air velocities. The *equivalent temperature* in °F is given by (1993 *ASHRAE Handbook of Fundamentals,* Atlanta, GA, p. 8.15)

where *V* is the wind velocity in mph and *T*ambient air temperature in °F in calm air. which is takento a be air with light winds at speeds up to 4 mph. The constant 91.4°F in the above equation is the mean skin temperature of a resting person in a comfortable environment. Windy air at atemperature *Tambient* and velocity Vwill feel as cold as calmair at a temperature *Tequiv*. The equation above is valid for winds up to 43 mph. Winds at higher velocities produce little additional chilling effect. Determine the equivalent temperature of an environment at 10°F at wind speeds of 10, 20. 30, and 40 mph. Exposed flesh can freeze within one minute at i a temperature below −25°F in calm weather. Does a person need to be concerned about this possibility in any of the cases above?

$$T_{equiv} = 91.4 - (91.4 - T_{ambient})(0.475 - 0.0203V + 0.304\sqrt{V})$$

FIGURE P19–123E

Step 1 of 5

Given data:

Equivalent temperature, $T_{equivalent} = 91.4-(91.4-T_{ambinet})\left(0.475-0.0203V+0.304\sqrt{V}\right)$

Wind velocity is V in mph

Ambient air temperature, $T_{ambinet}$

Equation validity for winds up to 43mph

Ambient Temperature, $T_{ambient} = 10°F$

Equivalent temperature $T_{equivalent}$ for wind speed of 10, 20, 30, 40 mph.

Step 2 of 5

Equivalent temperature is given by

$$T_{equivalent} = 91.4-(91.4-T_{ambient})\left(0.475-0.0203V+0.304\sqrt{V}\right) \quad \ldots\ldots (1)$$

For $V = 10$mph

$$T_{equivalent} = 91.4-(91.4-10)\left(0.475-0.0203\times 10+0.304\sqrt{10}\right)$$

$$\boxed{T_{equivalent} = -8.99°F}$$

Step 3 of 5

For $V = 20$mph

$$T_{equivalent} = 91.4-(91.4-10)\left(0.475-0.0203\times 20+0.304\sqrt{20}\right)$$

$$\boxed{T_{equivalent} = -24.9°F}$$

Step 4 of 5

For $V = 30$mph

$$T_{equivalent} = 91.4-(91.4-10)\left(0.475-0.0203\times 30+0.304\sqrt{30}\right)$$

$$\boxed{T_{equivalent} = -33.2°F}$$

Step 5 of 5

For $V = 40$mph

$$T_{equivalent} = 91.4-(91.4-10)\left(0.475-0.0203\times 40+0.304\sqrt{40}\right)$$

$$\boxed{T_{equivalent} = -37.7°F}$$

In the second case the equivalent temperature is almost equal to given freezing temperature that is 25°C and in last two cases it is more than given. So for all these three cases person should be concerned about his possibility of freezing.

Question:

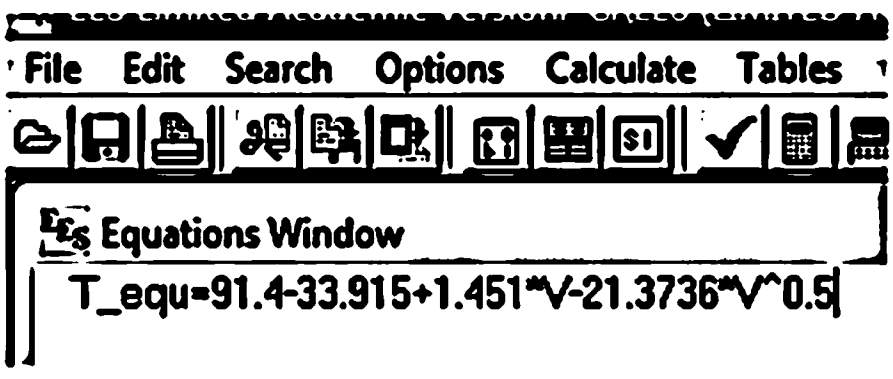
Reconsider Prob. 19-123E. Using EES (or other) software, plot the equivalent wind chill temperatures in °F as a function of wind velocity in the range of 5 mph to 50 mph for ambient temperatures of 20°F, 40°F and 60°F. Discuss the results.

Step 1 of 13

$$T_{equiv} = 91.4 - (91.4 - T_{ambient})\left(0.475 - 0.0203V + 0.304\sqrt{V}\right)$$

Step 2 of 13

Case: I

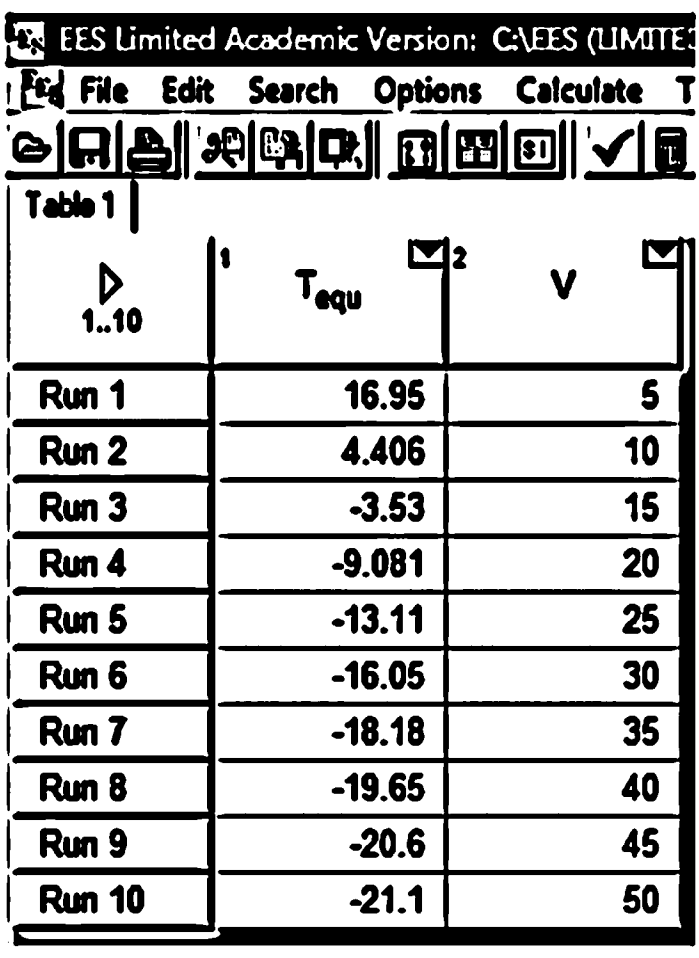


When the ambient temperature is $T_{ambient} = 20°F$

By substituting the known values in above expression, we get

$$\begin{aligned} T_{equiv} &= 91.4 - (91.4 - T_{ambient})\left(0.475 - 0.0203V + 0.304\sqrt{V}\right) \\ &= 91.4 - (91.4 - 20)\left(0.475 - 0.0203V + 0.304\sqrt{V}\right) \\ &= 91.4 - 71.4\left(0.475 - 0.0203V + 0.304\sqrt{V}\right) \\ &= 91.4 - 33.915 + 1.451V - 21.736\sqrt{V} \end{aligned}$$

Step 3 of 13

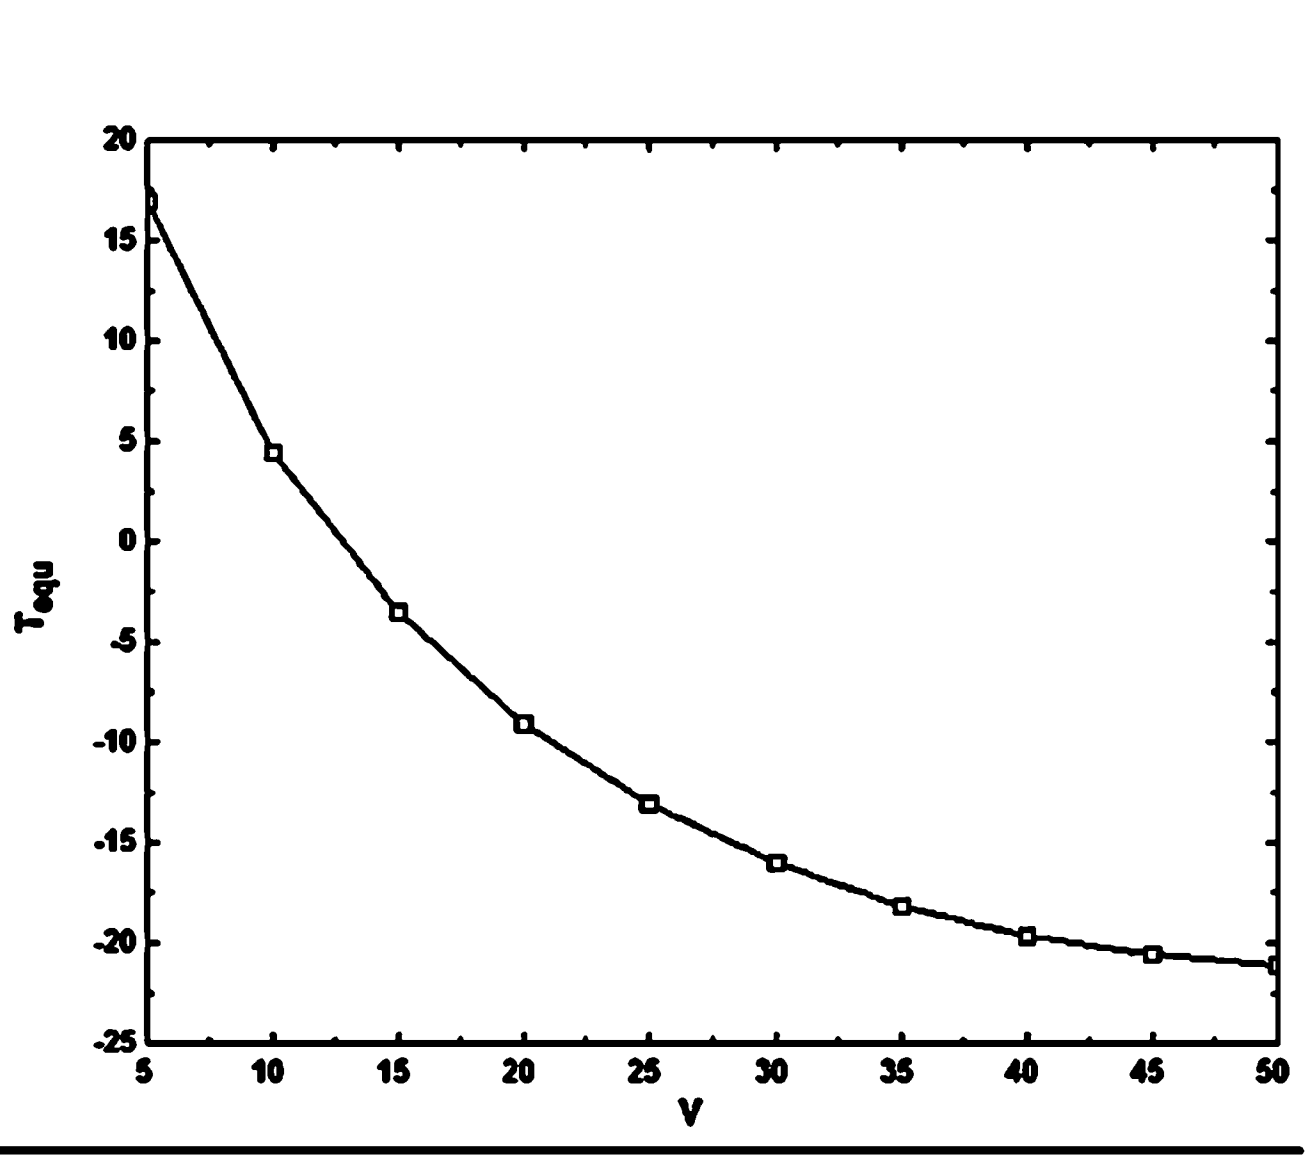


Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

Step 4 of 13

After writing the program in equation window select table on menu bar and click new parameter table. Now the dialog box will be appeared on the screen and then select the efficiency, head loss and work done by the pump. Finally click ADD, then click OK button.

<u>The following results are displayed:</u>



1..10	T_{equ} [1]	V [2]
Run 1	16.95	5
Run 2	4.406	10

Step 5 of 13

Select the plot on menu bar, then click x-y plot .Dialog box will be appeared and select variables to draw graph, then click OK button.

<u>By plotting the graph between temperature and velocity:</u>

Step 6 of 13

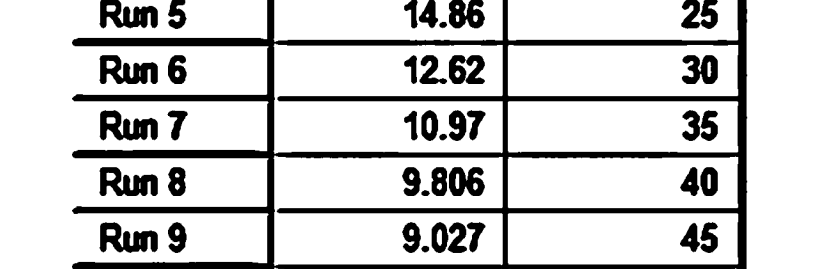
Case: 2

When the ambient temperature is $T_{ambient} = 40°F$

By substituting the known values in above expression, we get

$$\begin{aligned} T_{equiv} &= 91.4 - (91.4 - T_{ambient})\left(0.475 - 0.0203V + 0.304\sqrt{V}\right) \\ &= 91.4 - (91.4 - 40)\left(0.475 - 0.0203V + 0.304\sqrt{V}\right) \\ &= 91.4 - 51.4\left(0.475 - 0.0203V + 0.304\sqrt{V}\right) \end{aligned}$$

$$T_{equiv} = 91.4 - (91.4 - T_{ambient})\left(0.475 - 0.0203V + 0.304\sqrt{V}\right)$$

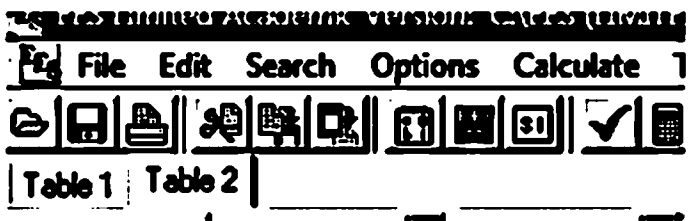


$$= 91.4 - (91.4 - 40)\left(0.475 - 0.0203V + 0.304\sqrt{V}\right)$$

$$= 91.4 - 51.4\left(0.475 - 0.0203V + 0.304\sqrt{V}\right)$$

$$= 91.4 - 24.415 + 1.045V - 15.65\sqrt{V}$$

Step 7 of 13

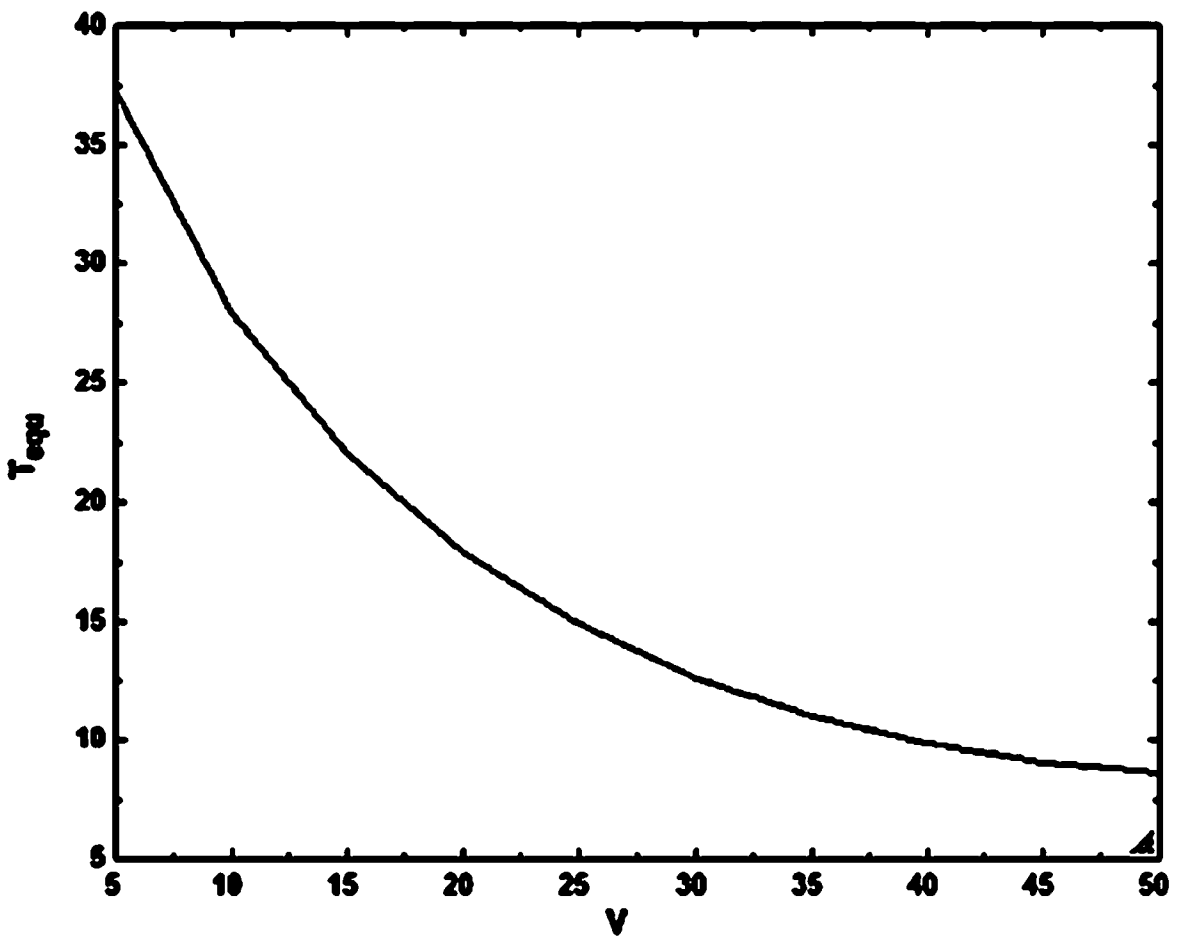


Open the EES software, then click file on menu bar and select the new file on menu bar. Then write the program in equation window.

Step 8 of 13

After writing the program in equation window select table on menu bar and click new parameter table. Now the dialog box will be appeared on the screen and then select the efficiency, head loss and work done by the pump. Finally click ADD, then click OK button.

The following results are displayed:



1..10	1 T_{equ}	2 V
Run 1	37.22	5

By plotting the graph between temperature and velocity:

Question: 19.125P

To cool a storehouse in the summer without using a conventional air-conditioning system, the owner decided to hire an engineer to design an alternative system that would make use of the water in the nearby lake. The engineer decided to How air through a thin smooth 10-cm diameter copper tube that is submerged in the nearby lake. The water in the lake is typically maintained at a constant temperature of 15°C and a convection heat transfer coefficient of 1000 W/m2•K. If air (1 atm) enters the copper tube at amean temperature of 30°C with an average velocity of 2.5 m/s, determine the necessary copper tube length so that the outlet mean temperature of the air is 20°C.

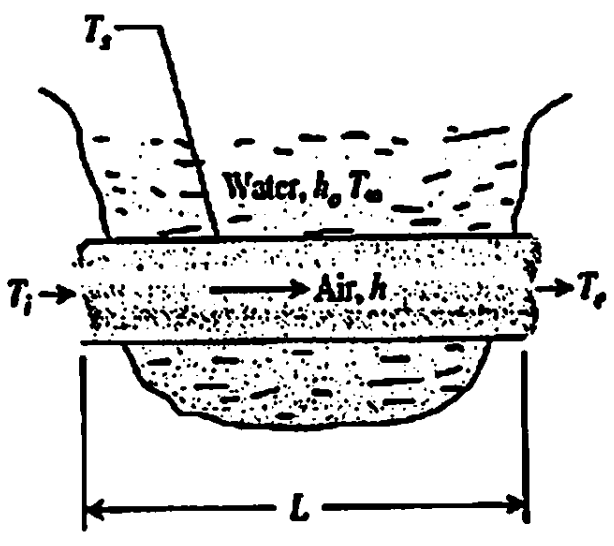

FIGURE P19–125

Step 1 of 8

Diameter of copper tube $D = 10\,\text{cm} = 0.1\text{m}$

The temperature of water, $T_\infty = 15°\text{C}$

Convection heat transfer coefficient, $h_0 = 1000\,\text{W/m}^2\cdot\text{K}$

Air inlet temperature, $T_i = 30\,°\text{C}$

Average velocity of air, $V_{avg} = 2.5\text{m/s}$

Outlet air temperature, $T_e = 20\,°\text{C}$

Step 2 of 8

Calculation of copper tube length as follows:

The average temperature is,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{30+20}{2}$$
$$= 25\,°\text{C}$$

From the properties of air at one atmospheric pressure table, at $T = 25\,°\text{C}$

Density, $\rho = 1.184\,\text{kg/m}^3$

Specific heat, $c_p = 1007\text{J/kg}\cdot\text{K}$

Thermal conductivity, $k = 0.02551\text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.562\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7296$

Step 3 of 8

Now the Reynolds number,

$$\text{Re} = \frac{V_{avg}D}{\nu}$$
$$= \frac{2.5\times0.1}{1.562\times10^{-5}}$$
$$= 16005.121$$

This value is greater than 10,000 , so the flow is turbulent.

Step 4 of 8

By using the Dittus – Boelter equation, Nusselt number can be expressed as,

$$\text{Nu} = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$
$$= 0.023\times(16005.121)^{0.8}\times(0.7296)^{0.4}$$
$$= 46.81$$

We know that Nusselt number is also expressed as,

$$\text{Nu} = \frac{hD}{k}$$
$$h = \frac{\text{Nu}\times k}{D}$$
$$= \frac{46.81\times0.02551}{0.1}$$
$$h = 11.94\,\text{W/m}^2\cdot°\text{C}$$

Step 5 of 8

We can calculate the mass flow rate as, $\dot{m} = \rho A_c V_{avg}$

Cross-sectional area of tube is, $A_c = \frac{\pi D^2}{4}$

Therefore,

$$\dot{m} = \frac{\rho\pi D^2}{4}\times V_{avg}$$
$$= \frac{1.184\times\pi\times(0.1)^2\times2.5}{4}$$
$$= 0.0232477\,\text{kg/s}$$

Step 6 of 8

Therefore, heat transfer to lower temperature,

$$\dot{Q} = \dot{m}c_p(T_i - T_e)$$
$$= 0.0232477\times1007\times(30-20)$$
$$= 234.104\,\text{W}$$

Now calculating surface temperature T_s per 1 m length of tube by the equation,

$$\dot{Q} = h_o A_s (T_s - T_\infty)$$

Heat transfer surface area,

$$A_s = \pi DL$$
$$= \pi\times0.1\times1$$
$$= 0.314\,\text{m}^2$$

Step 7 of 8

Therefore, as steady condition is,

The heat given by air = Heat transferred is water.

$$\dot{Q} = h_o A_s (T_s - T_\infty)$$
$$234.104 = 1000\times0.314(T_s - 15)$$
$$(T_s - 15) = \frac{234.104}{314}$$
$$T_s - 15 = 0.74554$$
$$T_s = 15.74\,°\text{C}$$

Now, by substituting the known values in outlet temperature equation we get,

Step 8 of 8

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{hA_s}{\dot{m}c_p}\right)$$
$$= T_s - (T_s - T_i)\exp\left(-\frac{h\pi DL}{\dot{m}c_p}\right)$$
$$20 = 15.74 - (15.74 - 30)\exp\left(\frac{-11.94\times0.314\text{L}}{0.02324\times1007}\right)$$

The above equation can be simplify as follows,

Therefore, length of the pipe is $\boxed{L = 32.60\,\text{ft}}$.

Question: 19.126P

Liquid mercury is flowing at 0.6 kg/s through a 5-cm diameter tube with inlet and outlet mean temperatures of 100°C and 200°C, respectively. The tube surface temperature is maintained constant at 250°C. Determine the tube length using (*a*) the appropriate Nusselt number relation for liquid metals and (*b*) the Dittus-Boelter equation, (*c*) Compare the results of (*a*) and (*b*).

Step 1 of 7

Given data:

Mass flow rate of mercury, $\dot{m} = 0.6\ \text{kg/s}$

Diameter of the tube, $D = 0.05\ \text{m}$

Inlet mean temperature, $T_i = 100°\text{C}$

Outlet mean temperature, $T_e = 200°\text{C}$

Surface temperature of the tube, $T_s = 250°\text{C}$

Step 2 of 7

(*a*)

From properties table of mercury,

Kinematic viscosity, $\nu = 8.514\times10^{-8}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.0152$

Dynamic viscosity at 150°C, $\mu = 1.126\times10^{-3}\ \text{kg/m-s}$

Reynolds number for the given flow is

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$

$$= \frac{4\times0.6}{\pi\times0.05\times1.126\times10^{-3}}$$

$$= 13569.16$$

As the obtained Reynolds number is greater than 10,000 the flow is turbulent flow.

Step 3 of 7

Prandtl number at T_s (250°) is $\text{Pr}_s = 0.0119$

According to the relation recommended by Sleicher and Rouse for liquid metals with the Nusselt number is

$$Nu = 4.8 + 0.0156\text{Re}^{0.85}\text{Pr}_s^{0.93}$$

$$= 4.8 + 0.0156(13569.16)^{0.85}(0.0119)^{0.93}$$

$$= 5.624$$

Heat transfer coefficient for the liquid metal is

$$h = \frac{k\cdot Nu}{D}$$

$$= \frac{10.0778\times5.624}{0.05}$$

$$= 1133.6\ \text{W/m}^2\cdot°\text{C}$$

Step 4 of 7

Calculating length, through energy balance relation,

$$L = -\frac{\dot{m}c_p}{\pi Dh}\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)$$

$$= -\frac{0.6\times136.1}{\pi\times0.05\times1133.6}\ln\left(\frac{250-200}{250-100}\right)$$

$$= 0.5038\,\text{m}$$

Therefore the length of the tube is $\boxed{L = 0.5038\,\text{m}}$

Step 5 of 7

(*b*)

According to Dittus-Boelter equation,

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$

$$= 0.023(13569.16)^{0.8}(0.0152)^{0.4}$$

$$= 8.7198$$

Therefore heat transfer coefficient for the liquid metal is

$$h = \frac{Nu\cdot k}{D}$$

$$= \frac{8.7198\times10.0778}{0.05}$$

$$= 1757.53\ \text{W/m}^2\cdot°\text{C}$$

Step 6 of 7

Calculating length, through energy balance relation,

$$L = -\frac{\dot{m}c_p}{\pi Dh}\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)$$

$$= -\frac{0.6\times136.1}{\pi\times0.05\times1757.53}\ln\left(\frac{250-200}{250-100}\right)$$

$$= 0.325\,\text{m}$$

Therefore the length of the tube is $\boxed{L = 0.325\,\text{m}}$

Step 7 of 7

(*c*)

As we can see from the calculated values, the length of the tube required for satisfying Sleicher and Rouse relation must be larger than that of the tube required for satisfying Dittus-Boelter criteria.

Question: 19.127P

In the effort to find the best way to cool a smooth thin-walled copper tube, an engineer decided to flow air either through the tube or across the outer tube surface. The tube has a diameter of 5 cm, and the surface temperature is maintained constant. Determine (*a*) the convection heat transfer coefficient when air is flowing through its inside at 25 m/s with bulk mean temperature of 50°C and (*b*) the convection heat transfer coefficient when air is flowing across its outer surface at 25 m/s with film temperature of 50°C.

Step 1 of 4

Given data:

Diameter of tube, $D = 0.05\text{m}$

Bulk mean temperature, $T = 50^\circ\text{C}$

Velocity of air flow, $V_{avg} = 25\text{m/s}$

Step 2 of 4

From the properties table for air,

Specific heat, $c_p = 1007\ \text{J/kg}\cdot\text{k}$

Thermal conductivity, $k = 0.02735\ \text{W/m -k}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

Reynolds number is expressed as

$$\text{Re} = \frac{V_{avg}D}{\nu}$$

$$= \frac{25\times0.05}{\left(1.798\times10^{-5}\right)}$$

$$= 69521.7$$

At the obtained Reynolds number is greater than 10,000 the flow is turbulent flow.

Step 3 of 4

(*a*) Air flowing inside:

Nusselt number is determined by

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$

$$= 0.023(69521.7)^{0.8}(0.7228)^{0.4}$$

$$= 151$$

Heat transfer coefficient when air is flowing through the tube is

$$h = \frac{k\cdot Nu}{D}$$

$$= \frac{0.02735\times151}{0.05}$$

$$= 82.61\ \text{W/m}^2\cdot^\circ\text{C}$$

Therefore the Heat transfer coefficient is $\boxed{h = 82.61\ \text{W/m}^2\cdot^\circ\text{C}}$

Step 4 of 4

(*b*) Air flowing outside:

When air is flowing across tube's outer surface, Nusselt number according to Zukauskas equation is

$$Nu = 0.027\text{Re}^{0.805}\text{Pr}^{1/3}$$

$$= 0.027(69521.7)^{0.805}(0.7228)^{1/3}$$

$$= 191.55$$

Heat transfer coefficient when air is flowing across its outer surface is

$$h = \frac{Nu\cdot k}{D}$$

$$= \frac{191.55\times0.02735}{0.05}$$

$$= 104.78\ \text{W/m}^2\cdot^\circ\text{C}$$

Therefore the Heat transfer coefficient is $\boxed{h = 104.78\ \text{W/m}^2\cdot^\circ\text{C}}$

Convection coefficient h is more when air is being flown across tube's outer surface.

Question: 19.128P

A silicon chip is cooled by passing water through microchannels etched in the back of the chip, as shown in Fig- P19-128. The channels are covered with a silicon cap. Consider a 12-mm × 12-mm square chip in which $N = 60$ rectangular microchannels, each of width $W = 50$ μm and height $H = 200$ μm have been etched. Water enters the microchannels at a temperature $Ti = 290$ K, and a total flow rate of 0.005 kg/s. The chip and cap are maintained at a uniform temperature of 350 K. Assuming that the flow in the channels is fully developed, all the heat generated by the circuits on the top surface of the chip is transferred to the water, and using circular tube correlations, determine:

(*a*) The water outlet temperature, *Te*

(*b*) The chip power dissipation, *We*

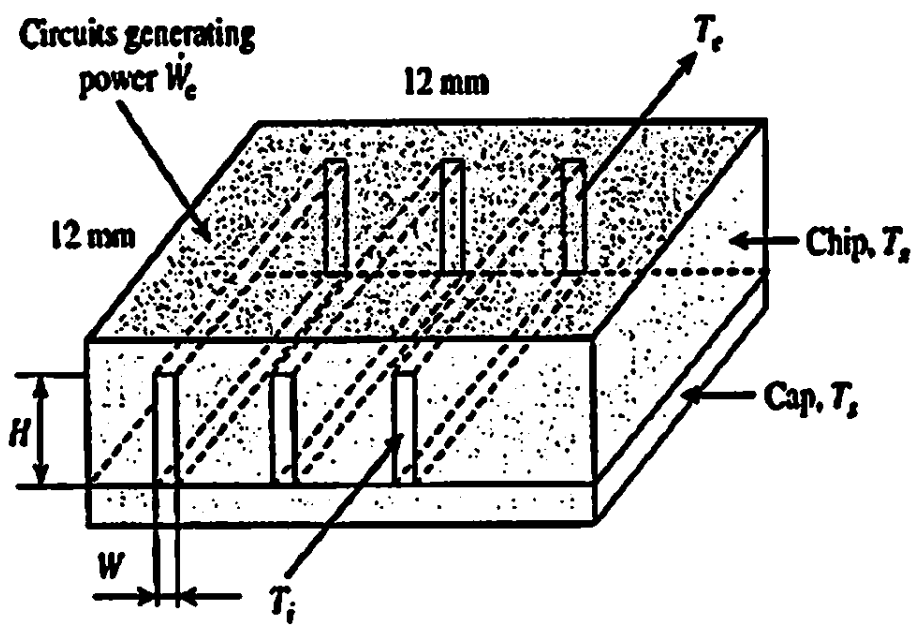

FIGURE P19–128

Step 1 of 6

Given data:

Length of chip, $L = 0.012\,\text{m}$

Width of chip, $w_c = 0.012\,\text{m}$

Number of micro-channels, $N = 60$

Height of micro channel, $H = 200\,\mu\text{m}$

Width of micro channel, $w = 50\,\mu\text{m}$

Inlet water temperature, $T_i = 290\,\text{K}$

Total flow rate, $\dot{m}_t = 0.005\,\text{kg/s}$

Uniform temperature of chip & cap, $T_s = 350\,\text{K}$

Step 2 of 6

The properties of water from properties table at assumed value of $T_{avg} = 30°\text{C}$,

Specific heat, $c_p = 4178\,\text{J/kg}\cdot\text{K}$

Thermal conductivity, $k = 0.615\,\text{W/m}\cdot\text{K}$

Dynamic viscosity, $\mu = 0.798\times10^{-3}\,\text{kg/m}\cdot\text{s}$

Density, $\rho = 996\,\text{kg/m}^3$

Mass flow rate through single channel,

$$\dot{m} = \frac{\dot{m}_t}{N}$$
$$= \frac{0.005}{60}$$
$$= 8.33\times10^{-5}\,\text{kg/s}$$

Cross sectional area,

$$A_c = H \times w$$
$$= 200\times50$$
$$= 10{,}000\,\mu\text{m}^2$$
$$= 10^{-8}\,\text{m}^2$$

Step 3 of 6

Hydraulic diameter,

$$D_h = \frac{4A_c}{p}$$
$$= \frac{4\times10000}{2(200+50)}$$
$$= 80\mu\text{m}$$

Reynolds number,

$$\text{Re} = \frac{\rho V D_h}{\mu}$$
$$= \frac{\rho(\dot{m}/\rho A_c)D_h}{\mu}$$
$$= \frac{\dot{m}D_h}{A_c\mu}$$
$$= \frac{\left(8.33\times10^{-5}\right)\times\left(80\times10^{-6}\right)}{\left(10^{-8}\right)\times\left(0.798\times10^{-3}\right)}$$
$$= 835.08$$

As the obtained Reynolds number is less than 2300, the flow is laminar.

Step 4 of 6

Therefore Nusselt number, $Nu = 3.66$

Heat transfer coefficient,

$$h = \frac{k\cdot Nu}{D_h}$$
$$= \frac{0.615\times3.66}{80\times10^{-6}}$$
$$= 28136.25\,\text{W/m}^2\,°\text{C}$$

Heat transfer surface area,

$$A_s = 2wL + 2HL$$
$$= 2\left(50\times10^{-6}\right)(0.012) + 2\left(200\times10^{-6}\right)(0.012)$$
$$= 1.2\times10^{-6} + 4.8\times10^{-6}$$
$$= 6\times10^{-6}\,\text{m}^2$$

Step 5 of 6

Exit temperature of the water is

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{hA_s}{\dot{m}C_p}\right)$$
$$= 350 - (350-290)\exp\left(-\frac{28136.25\times6\times10^{-6}}{8.33\times10^{-5}\times4178}\right)$$
$$= 350 - (60\times0.61565)$$
$$= 313\,\text{K}$$

Therefore the exit temperature is $\boxed{T_e = 313\text{K}}$

Step 6 of 6

Rate of power dissipated,

$$\dot{W}_e = NQ$$
$$= N\dot{m}c_p(T_e - T_i)$$
$$= 60\times8.333\times10^{-5}\times4178\times(350-313)$$
$$= 772.9\,\text{W}$$

Therefore total power dissipated is $\boxed{\dot{W}_e = 772.9\,\text{W}}$

Question: 19.129P

Water is heated at a rate of 10 kg/s from a temperature of 15°C to 35°C by passing it through five identical tubes, each 5.0 cm in diameter, whose surface temperature is 60.0°C. Estimate (*a*) the steady rate of heat transfer and (*b*) the length of tubes necessary to accomplish this task.

Step 1 of 6

Given data:

Mass flow rate of water in 5 tubes is 10 kg/s

Diameter of each pipe, $D = 0.05$ m

Number of pipes, $n = 5$

Surface temperature, $T_s = 60$ C

Step 2 of 6

Bulk temperature, $T_b = \dfrac{15+35}{2}$

$$T_b = 25°C$$

Properties of saturated water at 25° C (from saturated water tables) is

$\rho = 997$ kg/m^3

$k = 0.607$ W/mC

$\mu = 0.891 \times 10^{-3}$ m^2/s

$c_p = 4180$ J/kgC

$P_r = 6.14$

Step 3 of 6

Cross-sectional area of the pipe, $A_c = \dfrac{\pi}{4}(D^2)$

$$A_c = \frac{\pi}{4}(0.05)^2$$

$$A_c = 1.9635 \times 10^{-3} \text{ m}^2$$

Mass flow rate, $\dot{m} = \rho A_c V_{avg}$

So $V_{avg} = \dfrac{\dot{m}}{\rho A_c}$

$$V_{avg} = \frac{10/5}{997 \times 1.9635 \times 10^{-3}}$$

$$V_{avg} = 1.0216 \text{ m/s}$$

Step 4 of 6

Reynolds number, $\text{Re} = \dfrac{\rho V_{avg} D}{\mu}$

$$\text{Re} = \frac{997 \times 1.0216 \times 0.05}{0.891 \times 10^{-3}}$$

$$\text{Re} = 57156.86$$

This Reynolds number shows that the flow is turbulent

Nusselt number, $\text{Nu} = 0.023\text{Re}^{0.8}\text{Pr}^{0.3}$

$$= 0.023 \times (57156.86)^{0.8} \times (6.14)^{0.3}$$

$$= 253.415$$

But $\text{Nu} = \dfrac{hD}{k}$

so $h = \dfrac{\text{Nu} \times k}{D}$

$$h = \frac{253.415 \times 0.607}{0.05}$$

$$h = 3076.458 \text{ W/m}^2\text{sec}$$

Step 5 of 6

(a) Heat transfer is $\dot{Q} = \dot{m}C_p(T_e - T_i)$

$$\dot{Q} = 10 \times 4180 \times (35-15)$$

$$\dot{Q} = 836000 \text{ W}$$

Hence steady rate of heat transfer, $\boxed{\dot{Q} = 836000 \text{ W}}$

Step 6 of 6

(b) Using the relation for convective heat transfer, $Q = hA_s(T_s - T_b)$

Hence $A_s = \dfrac{Q}{h \times (T_s - T_b)}$

$$A_s = \frac{836000}{3076.458 \times (60-25)}$$

$$A_s = 7.764 \text{ m}^2$$

But surface area is $A_s = n \times \pi DL$

So $L = \dfrac{A_s}{n \times \pi D}$

$$L = \frac{7.764}{5 \times \pi \times 0.05}$$

$$L = 9.88 \text{ m}$$

Hence the length of each tube has to be $\boxed{L = 9.88 \text{ m}}$

Question: 19.130P

Repeat Prob. 19-129 for a flow rate of 20 kg/s.

Step 1 of 6

Given data:

Mass flow rate of water in 5 tubes is 20 kg/s

Diameter of each pipe, $D = 0.05$ m

Number of pipes, $n = 5$

Surface temperature, $T_s = 60$ C

Step 2 of 6

Bulk temperature, $T_b = \dfrac{15+35}{2}$

$T_b = 25°C$

Properties of saturated water at 25° C (from saturated water tables) is

$\rho = 997$ kg/m^3

$k = 0.607$ W/mC

$\mu = 0.891 \times 10^{-3}$ m^2/s

$c_p = 4180$ J/kgC

$P_r = 6.14$

Step 3 of 6

Cross-sectional area of the pipe is $A_c = \dfrac{\pi}{4}(D^2)$

$A_c = \dfrac{\pi}{4}(0.05)^2$

$A_c = 1.9635 \times 10^{-3}$ m^2

Mass flow rate, $\dot{m} = \rho A_c V_{avg}$

So $V_{avg} = \dfrac{\dot{m}}{\rho A_c}$

$V_{avg} = \dfrac{20/5}{997 \times 1.9635 \times 10^{-3}}$

$V_{avg} = 2.0432$ m/s

Step 4 of 6

Reynolds number, $\mathrm{Re} = \dfrac{\rho V_{avg} D}{\mu}$

$\mathrm{Re} = \dfrac{997 \times 2.0432 \times 0.05}{0.891 \times 10^{-3}}$

$\mathrm{Re} = 114313.715$

This Reynolds number value shows that the flow is turbulent

Nusselt number, $\mathrm{Nu} = 0.023\mathrm{Re}^{0.8}\mathrm{Pr}^{0.3}$

$= 0.023 \times (114313.715)^{0.8} \times (6.14)^{0.3}$

$= 441.222$

But $\mathrm{Nu} = \dfrac{hD}{k}$ so $h = \dfrac{\mathrm{Nu} \times k}{D}$

$h = \dfrac{441.222 \times 0.607}{0.05}$

$h = 5356.435$ W/m^{2}sec

Step 5 of 6

(a) Heat transfer is $\dot{Q} = \dot{m} C_p (T_e - T_i)$

$\dot{Q} = 20 \times 4180 \times (35 - 15)$

$\dot{Q} = 1672000$ W

Hence steady rate of heat transfer, $\boxed{\dot{Q} = 1672000 \text{ W}}$

Step 6 of 6

(b) Using the relation for convective heat transfer, $Q = hA_s(T_s - T_b)$

Hence $A_s = \dfrac{Q}{h \times (T_s - T_b)}$

$A_s = \dfrac{1672000}{5356.435 \times (60 - 25)}$

$A_s = 8.918$ m^2

But surface area is $A_s = n \times \pi DL$

So $L = \dfrac{A_s}{n \times \pi D}$

$L = \dfrac{8.918}{5 \times \pi \times 0.05}$

$L = 11.35$ m

Hence the length of each tube has to be $\boxed{L = 11.35 \text{ m}}$

Question: 19.131P

Water at 1800 kg/h and 10°C enters a 10-mm diameter smooth tube whose wall temperature is maintained al 49°C. Calculate (*a*) the tube length necessary to heat the water to 40°C. and (*b*) the water outlet temperature if the tube length is doubled, Assume average water properties to be the same as in (*a*).

Step 1 of 8

Given data:

Mass flow rate, $\dot{m} = 1800 \text{kg/h}$

Inlet temperature of water $T_i = 10°\text{C}$

Outlet temperature of water, $T_e = 40°\text{C}$

Surface temperature of tube, $T_s = 49°\text{C}$

Diameter of the tube, $D = 0.01\text{m}$

Step 2 of 8

(*a*)

Average temperature,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{10+40}{2}$$
$$= 25°\text{C}$$

Properties of water at average temperature,

Specific heat, $c_p = 4180 \text{J/kgK}$

Density, $\rho = 997.0 \text{kg/m}^3$

Thermal conductivity, $k = 0.607 \text{ W/m} \cdot \text{K}$

Dynamic viscosity, $\mu = 0.891 \times 10^{-3} \text{kg/m} \cdot s$

Prandtl number, $\text{Pr} = 6.14$

Step 3 of 8

Average velocity at which the water flows is

$$V_{avg} = \frac{4\dot{m}}{\rho \pi D^2}$$
$$= \frac{4 \times 0.5}{997 \times \pi (0.01)^2}$$
$$= 6.385 \text{ m/s}$$

Rate of heat transfer of the water is

$$\dot{Q} = \dot{m} C_p (T_e - T_i)$$
$$= 0.5 \times 4180 \times (40 - 10)$$
$$= 62700 \text{W}$$

Step 4 of 8

Reynolds number for the flow is

$$\text{Re} = \frac{\rho V_{avg} D}{\mu}$$
$$= \frac{997 \times 6.385 \times 0.01}{0.891 \times 10^{-3}}$$
$$= 71446.07$$

As the Reynolds number is greater than 10,000 the flow is turbulent flow.

$$Nu = 0.023 \times \text{Re}^{0.8} \times \text{Pr}^{0.4}$$
$$= 0.023 (71446.07)^{0.8} (6.14)^{0.4}$$
$$= 363.23$$

Heat transfer coefficient for the water flowing through the tube is

$$h = \frac{k \cdot Nu}{D}$$
$$= \frac{0.607 \times 363.23}{0.01}$$
$$= 22047.86 \text{W/m}^2 °\text{C}$$

Step 5 of 8

Logarithmic mean temperature,

$$\Delta T_{lm} = \frac{T_i - T_e}{\ln\left[\frac{T_s - T_e}{T_s - T_i}\right]}$$
$$= \frac{10-40}{\ln\left[\frac{49-40}{49-10}\right]}$$
$$= 20.46°\text{C}$$

Surface area along which the heat transfer takes place is

$$A_s = \pi D L$$
$$= \pi (0.01) L$$
$$= 0.03142\, L$$

Step 6 of 8

Thus the heat transfer rate is expressed by using the following relation,

$$\dot{Q} = h A_s \Delta T_{lm}$$
$$62700 = 22047.86 \times 0.03142\, L \times 20.46$$
$$L = \frac{62700}{14173.537}$$
$$L = 4.42 \text{ m}$$

Therefore the length of the tube is $\boxed{L = 4.42\text{m}}$

Step 7 of 8

(*b*)

By considering double the length,

$$L = 4.42 \times 2$$
$$= 8.84\text{m}$$

Surface area along which the heat transfer takes place is

$$A_s = \pi D L$$
$$= \pi (0.01) \times 8.84$$
$$= 0.278\text{m}^2$$

Step 8 of 8

Thus the heat transfer rate is expressed by using the following relation,

$$\dot{Q} = h A_s \Delta T_{lm}$$
$$\dot{m} c_p (T_e - T_i) = h A_s \Delta T_{lm}$$
$$(T_e - T_i) = \frac{h A_s}{\dot{m} c_p} \Delta T_{lm}$$
$$(T_e - T_i) = \frac{22047.86 \times 0.278}{0.5 \times 4180} \times \left[\frac{T_e - 10}{\ln\left(\frac{49 - T_e}{49 - 10}\right)}\right]$$
$$(T_e - 10) = \frac{6129.3}{2090} \left[\frac{T_e - 10}{\ln\left(\frac{49 - T_e}{49 - 10}\right)}\right]$$

The solution of the above equation shows that $T_e = -683.37°\text{C}$, which is not practically feasible. So increasing the length is not necessary.

Question: 19.132P

Liquid water enters a 10-m-long smooth rectangular tube with a =50 mm and b= 25 mm. The surface temperature is maintained constant, and water enters the tube at 20°C with a mass How rate of 0.25 kg/s. Determine the tube surface temperature necessary to heat the water to the desired outlet temperature of 80°C.

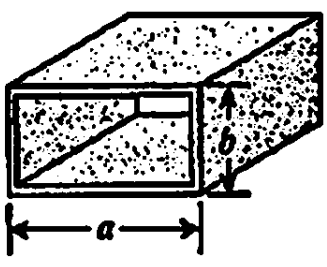

FIGURE P19–132

Step 1 of 5

Given data:

Length of smooth rectangular tube, $L = 10\,\text{m}$

Width of the tube $a = 50\,\text{mm} = 0.05\text{m}$

Height of the tube $b = 25\,\text{mm} = 0.025\text{m}$

Water Inlet temperature, $T_i = 20°\text{C}$

Mass flow rate, $\dot{m} = 0.25\,\text{kg/s}$

Outlet temperature, $T_e = 80°\text{C}$

Step 2 of 5

Average temperature,

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{20+80}{2}$$
$$= 50°\text{C}$$

Properties of water at average temperature from properties table,

Density, $\rho = 988.1\,\text{kg/m}^3$

Specific heat, $c_p = 4181\,\text{J/kg}\cdot\text{K}$

Thermal conductivity, $k = 0.644\,\text{W/m}\cdot\text{K}$

Dynamic viscosity, $\mu = 0.547\times10^{-3}\,\text{kg/m}\cdot\text{s}$

Prandtl number, $\text{Pr} = 3.55$

Step 3 of 5

Hydraulic Diameter of the tube is

$$D_h = \frac{4A_c}{p}$$
$$= \frac{4ab}{2(a+b)}$$
$$= \frac{4\times0.05\times0.025}{2(0.05+0.025)}$$
$$= 0.0333\text{m}$$

Reynolds number for the flow is

$$\text{Re} = \frac{\rho V_{avg} D_h}{\mu}$$
$$= \frac{\rho(\dot{m}/\rho A_c)D_h}{\mu}$$
$$= \frac{\dot{m}\times D_h}{A_c\times\mu}$$
$$= \frac{0.25\times0.0333}{(0.05\times0.025)\times\left(0.547\times10^{-3}\right)}$$
$$= 12187.7$$

Step 4 of 5

The calculated value of Reynolds number is greater than 10000 therefore it is a turbulent flow. Now the entry length is determined by

$$L_h \approx L_t$$
$$\approx 10D_h$$
$$= 10\times0.0333$$
$$= 0.333\text{m}$$

As the entry length is less than given length, the flow is fully developed turbulent flow. Thus by Dittus-Boelter equation, Nusselt number is

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$
$$= 0.023(12187.7)^{0.8}(3.55)^{0.4}$$
$$= 70.89$$

Heat transfer coefficient for the flow is

$$h = \frac{k\cdot Nu}{D_h}$$
$$= \frac{0.644\times70.89}{0.0333}$$
$$= 1370.87\,\text{W/m}^2°\text{C}$$

Step 5 of 5

Surface area along which the heat transfer takes place is

$$A_s = 2\times L\times(a+b)$$
$$= 2\times10(0.05+0.025)$$
$$= 1.5\text{m}^2$$

Therefore from the relation for exit temperature,

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{hA_s}{\dot{m}c_p}\right)$$
$$80 = T_s - (T_s - 20)\exp\left(-\frac{1370.87\times1.5}{0.25\times4181}\right)$$
$$80 = T_s - 0.1398T_s + 2.7967$$
$$T_s = 89.75°\text{C}$$

Therefore the tube surface temperature is $\boxed{T_s = 89.75°\text{C}}$

Question: 19.133P

Air is flowing through a smooth thin-walled 4-in diameter copper tube that is submerged in water. The water maintains a constant temperature of 60°F and a convection heat transfer coefficient of 176 Btu/h-ft2•R. If air (1 atm) enters the copper tube at a mean temperature of 90°F with an average velocity of 8 ft/s, determine the necessary copper tube length so that the outlet mean temperature of the air is 70°F.

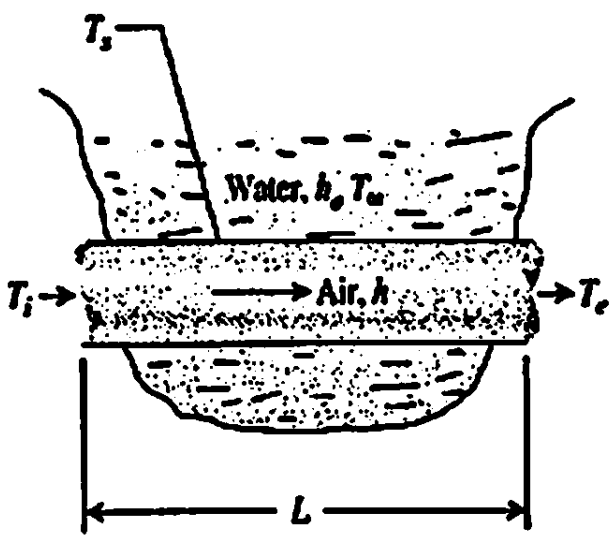

FIGURE P19–133E

Step 1 of 7

Given data:

Diameter of copper tube, $D = 4\,\text{inch} = 0.333\,\text{ft}$

Water temperature, $T_\infty = 60°\text{F}$

Convection coefficient, $h_0 = 176\,\text{Btu}/\text{ft}^2 \cdot \text{R}$

Air inlet temperature, $T_i = 90°\text{F}$

Velocity average, $V_{avg} = 8\,\text{ft}/s$

Outlet air temperature, $T_e = 70°\text{F}$

Step 2 of 7

Mean temperature is

$$T_{avg} = \frac{T_i + T_e}{2}$$
$$= \frac{90+70}{2}$$
$$= 80°\text{F}$$

From the properties of the various gases at atmospheric pressure

Density, $\rho = 0.07350\,\text{lbm}/\text{ft}^3$

Specific heat, $c_p = 0.2404\,\text{Btu}/\text{lbm} \cdot \text{R}$

Thermal conductivity, $k = 0.01481\,\text{Btu}/\text{h} \cdot \text{ft} \cdot \text{R}$

Kinematic viscosity, $\nu = 1.697 \times 10^{-4}\,\text{ft}^2/s$

Prandtl number, $\text{Pr} = 0.7290$

Step 3 of 7

Reynolds number,

$$\text{Re} = \frac{V_{avg} \cdot D}{\nu}$$
$$= \frac{8 \times 0.333}{1.697 \times 10^{-4}}$$
$$= 15714$$

This is greater than 10,000 , so the flow is turbulent and also assumes that the flow is a fully developed one.

Step 4 of 7

By using the Dittus – Boelter equation, Nusselt number can be expressed as,

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$
$$= 0.023 \times (15714)^{0.8} \cdot (0.7290)^{0.4}$$
$$= 46.11$$

Thus the Nusselt number (Nu) is expressed as

$$Nu = \frac{hD}{k}$$
$$h = \frac{Nu \times k}{D}$$
$$= \frac{46.11 \times 0.01481}{0.333}$$
$$h = 2.051\,\text{Btu}/\text{h} \cdot \text{ft}^2 \cdot °\text{F}$$

Step 5 of 7

Calculating mass flow rate, $\dot{m} = \rho A_c V_{avg}$

Where,

A_c – Cross-sectional area of tube, $\frac{\pi D^2}{4}$

Thus the mass flow rate is

$$\dot{m} = \rho \times \frac{\pi D^2}{4} \times V_{avg}$$
$$= \frac{0.07350 \times \pi \times (0.333)^2 \times 8}{4}$$
$$= 0.0512\,\text{lbm}/s$$

Converting the mass flow rate per hour,

$$\dot{m} = 0.0573 \times 3600\,\text{lbm}/\text{hour}$$
$$= 184.36\,\text{lbm}/\text{h}$$

Step 6 of 7

Therefore heat transfer to lower temperature,

$$\dot{Q} = \dot{m}C_p(T_i - T_e)$$
$$= 184.36 \times 0.2404 \times (90-70)$$
$$= 886.39\,\text{Btu}/\text{hr}$$

Now calculating surface temperature T_s per 1 ft length of tube by the equation

$$\dot{Q} = h_o A_s (T_s - T_\infty)$$

Surface area along which the heat transfer takes place is

$$A_s = \pi DL$$
$$= \pi \times 0.333 \times 1$$
$$= 1.047\,\text{ft}^2$$

Step 7 of 7

Thus from the steady conditions we get the heat given by air will be equal to the heat transferred to water.

$$\dot{Q} = h_o A_s (T_s - T_\infty)$$
$$886.39 = 176 \times 1.047 (T_s - 60)$$
$$T_s - 60 = 4.81$$
$$T_s = 64.81°\text{F}$$

Now, putting the value of T_s & all other quantities in the equation

$$T_e = T_s - (T_s - T_i)\exp\left(-\frac{h\pi DL}{\dot{m}C_p}\right)$$

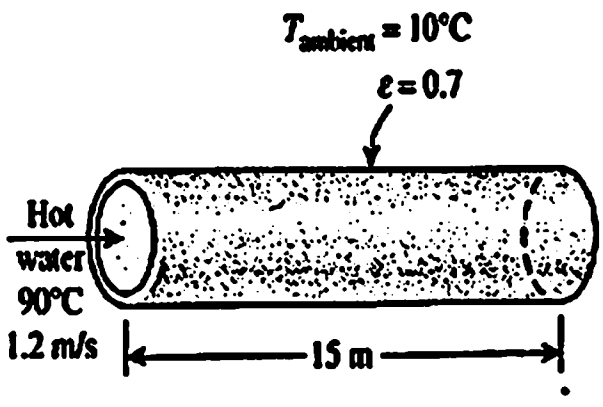
$$70 = 64.81 - (64.81-90)\exp\left(\frac{-2.051 \times 1.047\,L}{184.36 \times 0.2404}\right) \qquad [\because A_s = \pi DL]$$

$$L = 32.60\,\text{ft}$$

Therefore, length of the pipe is $\boxed{L = 32.60\,\text{ft}}$

Question: 19.134P pg 1

Hot water at 90°C enters a 15-m section of a cast iron pipe (k= 52 W/m·K) whose inner and outer diameters are 4 and 4.6 cm, respectively, at an average velocity of 1.2m/s. The outer surface of the pipe, whose emissivity is 0.7, is exposed to the cold air at 10°C in a basement, with a convection heat transfer coefficient of 12 W/m2•K. Taking the walls of the basement to be at 10°C also, determine (*a*) the rate of heat loss from the water and (*b*) the temperature at which the water leaves the basement.



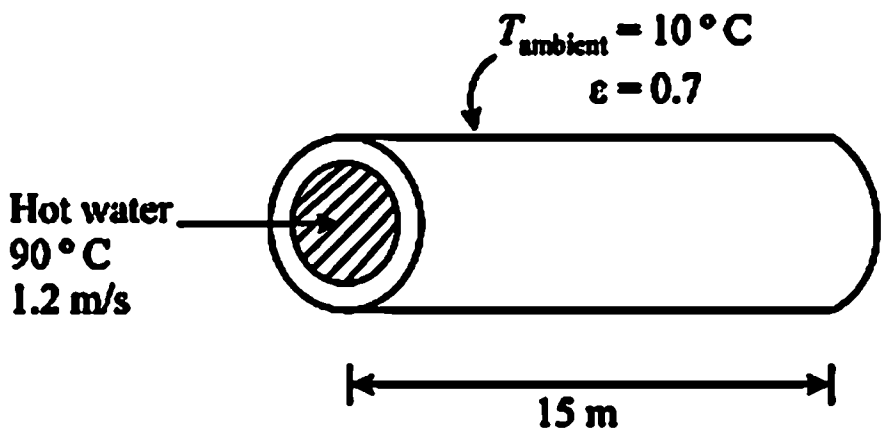


FIGURE P19–134

Step 1 of 13

The schematic diagram shows, hot water flows through cast iron pipe, and exposed to ambient temperature.

Step 2 of 13

Assume average temperature of the water is $T_{avg} = 90°C$.

Take properties of water from the table, 'properties of saturated water' at $T_{avg} = 90°C$

Density, $\rho = 965.3 kg/m^3$

Specific heat, $c_p = 4206 J/kg \cdot K$

Thermal conductivity, $k = 0.675 W/m \cdot K$

Dynamic viscosity, $\mu = 0.315 \times 10^{-3} N \cdot sec/m^2$

Prandtl number, $Pr = 1.96$

Step 3 of 13

Calculate kinematic viscosity of water by using the expression,

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{0.315 \times 10^{-3}}{965.3}$$
$$= 3.263 \times 10^{-7} m^2/s$$

Step 4 of 13

Calculate the Reynolds number by using the expression,

$$Re = \frac{V_{avg} D_i}{\nu}$$

Here, V_{avg} is average velocity of water flows in a pipe and D_i is inside diameter of cast iron pipe.

Substitute $1.2 m/s$ for V_{avg} and $0.04 m$ for D_i

$$Re = \frac{1.2 \times 0.04}{3.263 \times 10^{-7}}$$
$$= 147093.33$$

This is greater than $10,000$, therefore, the flow of water is turbulent flow.

Step 5 of 13

Check the entry length of hydrodynamic and turbulent boundary length by using the expression,

$$L_h \approx L_t$$
$$\approx 10 D_i$$
$$= 10 \times 0.04$$
$$= 0.4 m$$

This is much smaller than the given length $L = 15 m$

Therefore, it is a fully developed turbulent flow.

Step 6 of 13

From the table of 'equivalent roughness values for the new commercial pipes'
The roughness factor of cast iron pipe is,

$$\varepsilon = 0.26 mm$$
$$= 0.26 \times 10^{-3} m$$

Calculate the roughness ratio by using the equation,

$$\frac{\varepsilon}{D_i} = \frac{0.26 \times 10^{-3}}{0.04}$$
$$= 6.5 \times 10^{-3}$$

Step 7 of 13

Take friction factor f, from Moody's chart by interpolating the values between $(0.005 - 0.01)$

$$f = 0.0305 + \frac{0.0380 - 0.0305}{(0.01 - 0.005)}(0.0065 - 0.005)$$
$$= 0.03275$$

Calculate Nusselt number by using Chilton – Colburn analogy expression for rough tubes,

$$Nu = \frac{hD_i}{k} = 0.125 f . Re . Pr^{1/3}$$

$=0.03275$

Calculate Nusselt number by using Chilton – Colburn analogy expression for rough tubes,

$$\mathrm{Nu}=\frac{hD_i}{k}=0.125\,f.\mathrm{Re}.\mathrm{Pr}^{1/3}$$
$$=0.125\times0.03275\times147093.33\times(1.96)^{1/3}$$
$$=751.896$$

Step 8 of 13

Then calculate the heat transfer coefficient by using Nusselt number,

$$\mathrm{Nu}=\frac{hD_i}{k}$$
$$h=\frac{k\cdot\mathrm{Nu}}{D_i}$$
$$=\frac{0.675\times751.896}{0.04}$$
$$=12688.245\,\mathrm{w/m^2\cdot{}^\circ C}$$

Step 9 of 13

Calculate thermal conduction resistance in this pipe,

$$R=\frac{\ln(D_o/D_i)}{2\pi k_{CI}L}$$

Here, D_o is outer diameter of the pipe, L is length of the pipe and k_{CI} is thermal conductivity of cast iron pipe.

Substitute $0.046\,\mathrm{m}$ for D_o, $15\,\mathrm{m}$ for L and $52\,\mathrm{W/m\text{-}K}$ for k_{CI}

$$R=\frac{\ln(0.046/0.04)}{2\pi\times52\times15}$$
$$=2.85\times10^{-5}\,^\circ\mathrm{C/W}$$

Thermal conduction resistance is very less; therefore, so outer and inner temperature will be almost equal.

Therefore, assume the surface temperature is $T_s=90^\circ\mathrm{C}$

Step 10 of 13

Calculate the heat transfer surface area by using the equation,

$$A_s=\pi D_oL$$
$$=\pi\times0.046\times15$$
$$=2.168\,\mathrm{m^2}$$

Step 11 of 13

(a)

Calculate the total heat transfer due to convection and radiation to atmosphere from outer pipe surface.

$$Q_{\text{total}}=Q_{\text{conv}}+Q_{\text{rad}}$$
$$=h_oA_s(T_s-T_{\text{amb}})+\varepsilon A_s\sigma\left[T_s^4-T_{\text{surr}}^4\right]$$

Here, h_o is convection heat transfer coefficient, T_{amb} is ambient temperature of air, T_{surr} is surrounding temperature of walls, ε is emissivity of pipe surface and σ is Stefan Boltzmann's constant,

Substitute $10^\circ\mathrm{C}$ for T_{surr}, T_{amb}, 0.7 for ε, $12\,\mathrm{W/m^2\cdot K}$ for h_o and $5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}$ for σ

$$Q_{total}=12\times2.168(90-10)+0.7\times2.168\times5.67\times10^{-8}\left[(90+273)^4-(10+273)^4\right]$$
$$=2081.28+942.12$$
$$=3023.4\,\mathrm{W}$$

Therefore, total heat loss from the water Q_{total} is $\boxed{3023.4\,\mathrm{W}}$

Step 12 of 13

(b)

Calculate mass flow rate of water by using the equation,

$$\dot{m}=\rho A_cV_{avg}$$

Here, A_c cross sectional area

Substitute $\frac{\pi D_i^2}{4}$ for A_c

$$\dot{m}=\frac{\rho\times\pi D_i^2}{4}\times V_{avg}$$
$$=\frac{965.3\times\pi\times(0.04)^2\times1.2}{4}$$
$$=1.456\,\mathrm{kg/s}$$

Step 13 of 13

Apply energy balance equation by equating; Total heat lost by pipe is equal to the heat gain by water flows through the pipe, $\dot{Q}$

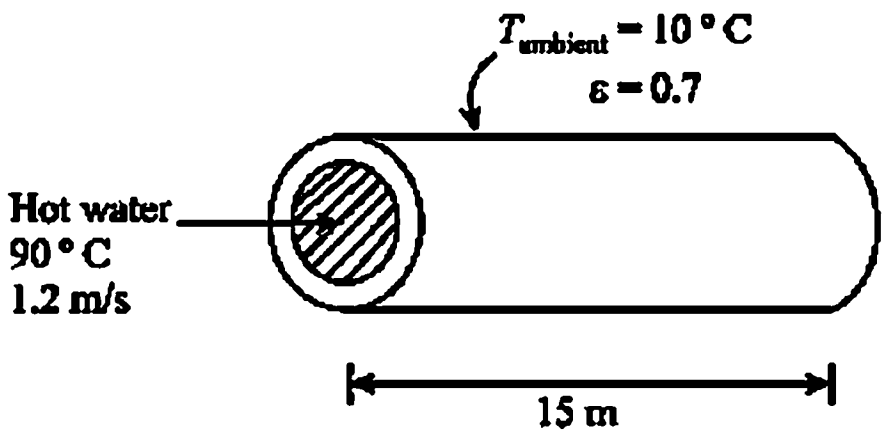
$$Q_{total}=mc_p(T_i-T_e)$$

Here, T_i is water inlet temperature and T_e is water exit temperature.

Substitute $90^\circ\mathrm{C}$ for T_i

$$3023.4=1.456\times4206(90-T_e)$$
$$T_e=89.51^\circ\mathrm{C}$$

Therefore, exit temperature of the water T_e is $\boxed{89.51^\circ\mathrm{C}}$



Also our assumed mean temperature is right as there is not much difference between inlet and outlet temperature.

Question: 19.135P pg 1

Repeat Prob. 19-134 for a pipe made of copper (k =386 W/m·K) instead of cast iron.

Step 1 of 12

The schematic diagram shows, hot water flows through cast iron pipe, and exposed to ambient temperature.

Step 2 of 12

Assume average temperature of the water is $T_{avg} = 90°C$.

Take properties of water from the table 'properties of saturated water' at $T_{avg} = 90°C$

Density, $\rho = 965.3 kg/m^3$

Specific heat, $c_p = 4206 J/kg \cdot K$

Thermal conductivity, $k = 0.675 W/m \cdot K$

Dynamic viscosity, $\mu = 0.315 \times 10^{-3} N \cdot sec/m^2$

Prandtl number, $Pr = 1.96$

Step 3 of 12

Calculate kinematic of viscosity of water by using the expression,

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{0.315 \times 10^{-3}}{965.3}$$
$$= 3.263 \times 10^{-7}\ m^2/s$$

Step 4 of 12

Calculate the Reynolds number by using the expression,

$$\mathrm{Re} = \frac{V_{avg} D_i}{\nu}$$

Here V_{avg} is average velocity of water flows in a pipe and D_i is inside diameter of cast iron pipe.

Substitute $1.2 m/s$ for V_{avg} and $0.04 m$ for D_i

$$\mathrm{Re} = \frac{1.2 \times 0.04}{3.263 \times 10^{-7}}$$
$$= 147093.33$$

This is greater than $10,000$, Therefore, the flow of water is turbulent flow.

Step 5 of 12

Check the entry length of hydrodynamic and turbulent boundary length by using the expression,

$$L_h \approx L_t$$
$$\approx 10 D_i$$
$$= 10 \times 0.04$$
$$= 0.4 m$$

This is much smaller than the given length $L = 15 m$

Therefore, it is a fully developed turbulent flow.

Step 6 of 12

From the table of 'equivalent roughness values for the new commercial pipes'
The roughness factor of cast iron pipe is,

$$\varepsilon = 0.0015 mm$$
$$= 1.5 \times 10^{-6} m$$

Calculate the roughness ratio by using the equation,

$$\frac{\varepsilon}{D_i} = \frac{1.5 \times 10^{-6}}{0.04}$$
$$= 3.75 \times 10^{-5}$$

Step 7 of 12

Take friction factor f, from Moody's chart at $\varepsilon / D = 3.75 \times 10^{-5}$

$f = 0.0119$

Calculate Nusselt number by using Chilton – Colburn analogy expression for rough tubes,

$$\mathrm{Nu} = \frac{hD_i}{k} = 0.125 f . \mathrm{Re} . \mathrm{Pr}^{1/3}$$
$$= 0.125 \times 0.0119 \times 147093.33 \times (1.96)^{1/3}$$
$$= 273.208$$

Then calculate the heat transfer coefficient by using Nusselt number,

$$\mathrm{Nu} = \frac{hD_i}{k}$$
$$h = \frac{k \cdot \mathrm{Nu}}{D_i}$$
$$= \frac{0.675 \times 273.208}{0.04}$$
$$= 4610.385\ W/m^2 \cdot {}^{\circ}C$$

Step 8 of 12

Calculate thermal conduction resistance in this pipe,

$$R = \frac{\ln(D_o/D_i)}{}$$

Step 8 of 12

Calculate thermal conduction resistance in this pipe,

$$R = \frac{\ln(D_o/D_i)}{2\pi k_{copper} L}$$

Here, D_o is outer diameter of the pipe, k_{copper} is thermal conductivity of copper and L is length of the pipe.

Substitute 0.046 m for D_o, 386 W/m·K for k_{copper} and 15 m for L

$$R = \frac{\ln(0.046/0.04)}{2\pi \times 386 \times 15}$$
$$= 3.84 \times 10^{-6}\ ^\circ\text{C/W}$$

Thermal conduction resistance is very less; therefore, so outer and inner temperature will be almost equal.

Therefore, assume the surface temperature is $T_s = 90^\circ\text{C}$

Step 9 of 12

Calculate the heat transfer surface area by using the equation,

$$A_s = \pi D_o L$$
$$= \pi \times 0.046 \times 15$$
$$= 2.168\ \text{m}^2$$

Step 10 of 12

(a)

Calculate the total heat transfer due to convection and radiation to atmosphere from outer pipe surface.

$$Q_{\text{total}} = Q_{\text{conv}} + Q_{\text{rad}}$$
$$= h_o A_s (T_s - T_{\text{amb}}) + \varepsilon A_s \sigma \left[T_s^4 - T_{\text{surr}}^4\right]$$

Here, h_o is convection heat transfer coefficient, T_{amb} is ambient temperature of air, T_{surr} is surrounding temperature of walls, ε is emissivity of pipe surface and σ is Stefan Boltzmann's constant,

Substitute 10°C for T_{surr}, T_{amb}, 0.7 for ε, 12 W/m²·K for h_o and 5.67×10^{-8} W/m²·K⁴ for σ

$$Q_{total} = 12 \times 2.168(90-10) + 0.7 \times 2.168 \times 5.67 \times 10^{-8} \left[(90+273)^4 - (10+273)^4\right]$$
$$= 2081.28 + 942.12$$
$$= 3023.4\ \text{W}$$

Therefore, total heat loss from the water Q_{total} is $\boxed{3023.4\ \text{W}}$

Step 11 of 12

(b)

Calculate mass flow rate of water by using the equation,

$$\dot{m} = \rho A_c V_{avg}$$

Here, A_c cross sectional area

Substitute $\frac{\pi D_i^2}{4}$ for A_c

$$\dot{m} = \frac{\rho \times \pi D_i^2}{4} \times V_{avg}$$
$$= \frac{965.3 \times \pi \times (0.04)^2 \times 1.2}{4}$$
$$= 1.456\ \text{kg/s}$$

Step 12 of 12

Apply energy balance equation by equating; Total heat lost by pipe is equal to the heat gain by water flows through the pipe, $\dot{Q}$

$$Q_{total} = mc_p(T_i - T_e)$$

Here, T_i is water inlet temperature and T_e is water exit temperature.

Substitute 90°C for T_i

$$3023.4 = 1.456 \times 4206(90 - T_e)$$
$$T_e = 89.51^\circ\text{C}$$

Therefore, exit temperature of the water T_e is $\boxed{89.51^\circ\text{C}}$

Also our assumed mean temperature is right as there is not much difference between inlet and outlet temperature.

Question: 19.136P

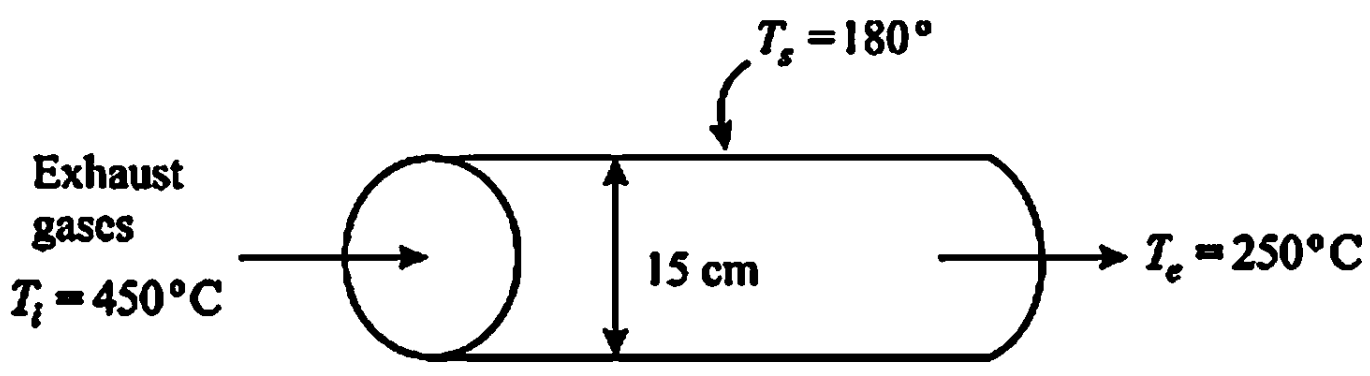
Hot exhaust gases leaving a stationary diesel engine at 450°C enter a 15-cm-diameter pipe at an average velocity of 7.2 m/s. The surface temperature of the pipe is 180°C. Determine the pipe length if the exhaust gases are to leave the pipe at 250°C after transferring heat to water in a heat recovery unit. Use properties of air for exhaust gases.

Step 1 of 9

Given data:

Diameter of the pipe, $D = 15\,\text{cm} = 0.15\,\text{m}$

Inlet temperature of gas, $T_i = 450°\text{C}$



Outlet temperature of gas, $T_e = 250°\text{C}$

Average entrance velocity, $V_{avg} = 7.2\,\text{m/s}$

Surface temperature of tube, $T_s = 180°\text{C}$

Step 2 of 9

Schematic diagram of pipe flow:

Step 3 of 9

Mean film temperature of the air is

$$T_{avg} = (T_i + T_e)/2$$
$$= (450+250)/2$$
$$= 350°\text{C}$$

From the properties of the air table

Density, $\rho = 0.5664\,\text{kg/m}^3$

Specific heat at constant pressure, $c_p = 1056\,\text{J/kg}\cdot\text{k}$

Thermal conductivity, $k = 0.04721\,\text{W/m}\cdot\text{k}$

Kinematic viscosity, $\nu = 5.475\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.6937$

Step 4 of 9

Thus the Reynolds number for the flow is

$$\text{Re} = \frac{V_{avg}\cdot D}{\nu}$$
$$= \frac{7.2\times0.15}{5.475\times10^{-5}}$$
$$= 19726.03$$

Since it is greater than 10,000 , therefore it is turbulent flow

Therefore assuming it is a fully developed one.

Step 5 of 9

By Dittus – Boelter equation.

Nusselt number,

$$Nu = \frac{hD}{k} = 0.023\text{Re}^{0.8}\text{Pr}^{0.3}$$
$$= 0.023(19726.03)^{0.8}(0.6937)^{033}$$
$$= 55.63$$

Then, Heat transfer coefficient is

$$Nu = \frac{hD}{k}$$
$$h = \frac{k\cdot Nu}{D}$$
$$= \frac{0.04721\times55.63}{0.15}$$
$$= 17.50\,\text{W/m}^2\cdot°\text{C}$$

Step 6 of 9

Therefore logarithmic mean temperature,

$$\Delta T_{lm} = \frac{T_e - T_i}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)}$$
$$= \frac{250-450}{\ln\left(\frac{180-250}{180-450}\right)}$$
$$= 148.16°\text{C}$$

Step 7 of 9

Heat transfer surface Area per meter length,

$$A_s = \pi DL$$
$$= \pi\times0.15\times1$$
$$= 0.4712\,\text{m}^2$$

Heat transfer per meter length of tube,

$$Q_m = hA_s\Delta T_{lm}$$
$$= 17.50\times0.4712\times148.16$$
$$= 1221..727\,\text{W}$$

Step 8 of 9

Now we will calculate total heat transfer in pipe by the expression

$$Q_t = \dot{m}C_p(T_i - T_e) \qquad \ldots\ldots (1)$$

Where,

Mass flow rate is $\dot{m} = \rho A_c V_{avg}$

A_c – Cross section area of pipe $= \frac{\pi D^2}{4}$

Then the mass flow rate is expressed as

$$\dot{m} = \frac{\rho\times\pi D^2\times V_{avg}}{4}$$

Step 9 of 9

Thus substituting the known values in equation (1) we get the heat transfer rate as

$$Q_t = \frac{\rho\times\pi D^2\times V_{avg}}{4}\times c_p\times(T_i - T_e)$$
$$= \frac{0.5664\times\pi\times(0.15)^2\times7.2\times1056\times(450-250)}{4}$$
$$= 15220.26\,\text{W}$$

Thus the length of the pipe is determined by

$$L = \frac{\text{Total heat transfer, } Q_t}{\text{heat transfer/m, } Q_m}$$
$$= \frac{15220.26}{1235.79}$$
$$= 12.31\text{m}$$

Therefore, length of the pipe is $\boxed{L = 12.31\text{m}}$

Question: 19.137P

Geothermal steam at 165°C condenses in the shell side of a heat exchanger over the tubes through which water flows. Water enters the 4-cm-diameter, 14-m-long tubes at 20°C at a rate of 0.8 kg/s. Determine the exit temperature of water and the rate of condensation of geothermal steam.

Step 1 of 10

Given data:

Diameter of tube, $D = 4\,\text{cm}$

Length of tube, $L = 14\,\text{m}$

Inlet temperature of water, $T_i = 20°\text{C}$

Mass flow rate, $\dot{m} = 0.8\,\text{kg/s}$

Steam temperature, $T_s = 165°\text{C}$

Step 2 of 10

As given, the steam at 165°C is condensing over the tubes.

Therefore assuming the surface temperature of tube is also 165°C

Therefore $T_s = 165°\text{C}$

Therefore as tube surface $T_s = 165°\text{C}$ & entrance temperature of water is 20°C

Therefore assuming mean temperature as 90°C

Taking properties of water at 90°C

Density of the water, $\rho = 965.3\,\text{kg/m}^3$

Specific heat of the water, $C_p = 4206\,\text{J/kg}\cdot\text{k}$

Thermal conductivity, $k = 0.675\,\text{w/m}\cdot\text{k}$

Dynamic viscosity, $\mu = 0.315\times10^{-3}\,\text{kg/m}\cdot\text{s}$

Prandtl number, $\text{Pr} = 1.96$

Step 3 of 10

As we know kinematic viscosity,

$$\nu = \frac{\mu}{\rho}$$

$$= \frac{0.315\times10^{-3}}{965.3}$$

$$= 3.263\times10^{-7}\,\text{m}^2/\text{s}$$

Step 4 of 10

Now average velocity,

$$V_{avg} = \frac{\dot{m}}{\rho A_c}$$

Mass flow rate, $\dot{m} = \rho A_c V_{avg}$

Cross sectional area of pipe, $A_c = \frac{\pi D^2}{4}$

Then,

$$V_{avg} = \frac{4\dot{m}}{\rho\pi D^2}$$

$$= \frac{4\times0.8}{965.3\times\pi\times(0.04)^2}$$

$$= 0.6595\,\text{m/s}$$

Step 5 of 10

Therefore, Reynolds number,

$$\text{Re} = \frac{VD}{\nu}$$

$$= \frac{0.6595\times0.04}{3.263\times10^{-7}}$$

$$= 80845.84$$

This is larger than 10,000

Step 6 of 10

Let's check entry length

Therefore

$$L_h \approx L_t$$

$$\approx 10\text{D}$$

$$\approx 10\times0.04$$

$$\approx 0.4\,\text{m}$$

This is less than the given length, $L = 14\,\text{m}$

Therefore flow is a fully developed turbulent flow.

By the Dietus-Boelter equation,

Nusselt number,

$$Nu = 0.023\text{Re}^{0.8}\text{Pr}^{0.4}$$

$$= 0.023(80845.84)^{0.8}(1.96)^{0.4}$$

$$= 253.96$$

Step 7 of 10

Also,

$$Nu = \frac{hD}{k}$$

Therefore heat transfer coefficient,

$$h = \frac{k\cdot Nu}{D}$$

$$= \frac{0.675\times253.96}{0.04}$$

$$= 4285.49\,\text{W/m}^2\,°\text{C}$$

Step 8 of 10

Heat transfer surface area,

$$A_s = \pi DL$$

$$= \pi\times0.04\times14$$

$$= 1.7593\,\text{m}^2$$

Now by the energy balance relation,

$$T_e = T_s - (T_s - T_i)\exp\left(\frac{-hA_s}{\dot{m}C_p}\right)$$

$$= 165 - (165-20)\exp\left(\frac{-4285.49\times1.7593}{0.8\times4206}\right)$$

$$= 149.57°\text{C}$$

Therefore, the exit temperature of the water, $\boxed{T_e = 149.57°\text{C}}$

Step 9 of 10

Therefore assumed mean temperature is nearly equal.

As we know rate of condensation,

$$m_R = \frac{\text{Total heat transfer to steam}}{\text{Enthalpy of vapourisation}}$$

$$= \frac{\dot{Q}}{h_{fg}}$$

Calculating $\dot{Q}$ from the expression,

$$\dot{Q} = \dot{m}C_p(T_e - T_i)$$

$$= 0.8\times4206\times(149.57-20°\text{C})$$

$$= 435977.136\,\text{W}$$

Step 10 of 10

Taking value of h_{fg} at 165°C from water properties table,

Therefore

$$h_{fg} = \frac{2083+2050}{2}$$

$$= \frac{4133}{2}$$

$$= 2066.5\,\text{kJ/kg}$$

Therefore

$$\dot{Q} = 435.977\,\text{KW}$$

Now,

$$\dot{m}_R = \frac{435.977}{2066.5}$$

Therefore, the rate of condensation of geothermal steam, $\boxed{\dot{m}_R = 0.2109\,\text{kg/s}}$

Question: 19.138P

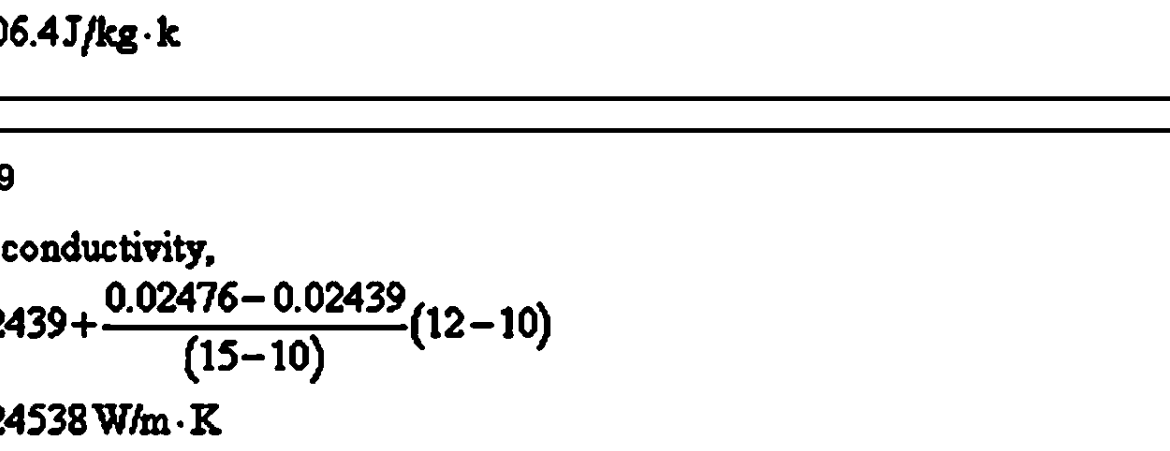
Cold air at 5°C enters a 12-cm-diameter 20-m-long isothermal pipe at a velocity of 2.5 m/s and leaves at 19°C. Estimate the surface temperature of the pipe.

Step 1 of 9

Given data:

Diameter of pipe, $D = 12\,\text{cm}$

Length of the pipe, $L = 20\,\text{m}$



Inlet temperature of air, $T_{inlet} = 5^\circ\text{C}$

Outlet temperature of air, $T_{exit} = 19^\circ\text{C}$

Average velocity, $V_{avg} = 2.5\,\text{m/s}$

Step 2 of 9

Schematic diagram of pipe flow:

Step 3 of 9

Mean film temperature is

$$T_{avg} = \frac{(T_i + T_e)}{2} = \frac{(5+19)}{2} = 12^\circ\text{C}$$

From the properties of ideal gas of air at $T_{avg} = 12^\circ\text{C}$

Density,

$$\rho = 1.246 + \frac{1.225 - 1.246}{15 - 10} \times (12 - 10) = 1.2376\,\text{kg/m}^3$$

Specific heat,

$$C_p = 1006 + \frac{1007 - 1006}{15 - 10} \times (12 - 10) = 1006.4\,\text{J/kg}\cdot\text{k}$$

Step 4 of 9

Thermal conductivity,

$$k = 0.02439 + \frac{0.02476 - 0.02439}{(15 - 10)}(12 - 10) = 0.024538\,\text{W/m}\cdot\text{K}$$

Kinematic viscosity,

$$\nu = 1.426 \times 10^{-5} + \frac{(1.470 - 1.426)10^{-5}}{(15 - 10)}(12 - 10) = 1.4436 \times 10^{-5}\,\text{m}^2/\text{s}$$

Prandtl number,

$$\text{Pr} = 0.7336 + \frac{0.7323 - 0.7336}{15 - 10}(12 - 10) = 0.73308$$

Step 5 of 9

Calculating Reynolds number,

$$\text{Re} = \frac{V_{avg} D}{\nu} = \frac{2.5 \times 0.12}{1.4436 \times 10^{-5}} = 20781.38$$

Which is greater than 10,000.

Let us check the entry lengths

$$L_h \approx L_t \approx 10\text{D} \approx 10 \times 0.12 = 1.2\,\text{m}$$

This is shorter than the given length of $L = 20\,\text{m}$

Therefore flow is a fully developed turbulent flow.

Step 6 of 9

By Dietus – Boelter equation,

Nusselt number,

$$Nu = 0.023(\text{Re})^{0.8}(\text{Pr})^{0.4} = 0.023(20781.38)^{0.8}(0.73308)^{0.4} = 57.8$$

Also we know, $Nu = \frac{hD}{k}$

Therefore, heat transfer coefficient,

$$h = \frac{k \cdot Nu}{D} = \frac{0.024538 \times 57.8}{0.12} = 11.819\,\text{W/m}^2{}^\circ\text{C}$$

Step 7 of 9

Mass flow rate of the air, $\dot{m} = \rho A_c V_{avg}$

Cross sectional area of pipe, $A_c = \frac{\pi D^2}{4}$

$$\dot{m} = p \times \frac{\pi D^2}{4} \times V_{avg} = \frac{1.2376 \times \pi \times (0.12)^2 \times 2.5}{4} = 0.03499\,\text{kg/s}$$

Step 8 of 9

The rate of heat transfer for air,

$$\dot{Q} = \dot{m} C_p (T_e - T_i) = 0.03499 \times 1006.4 \times (19 - 5) = 493.03\,\text{W}$$

Therefore heat transfer surface area,

$$A_s = \pi DL = \pi \times 0.12 \times 20 = 7.54\,\text{m}^2$$

We know that,

Heat lost by cold air is equal to the heat gain by the surface of the pipe.

$$Q = hA\Delta T_m$$

$$493.03 = 11.819 \times 7.54 \times \Delta T_m$$

$$\Delta T_m = 5.53^\circ\text{C}$$

Step 9 of 9

Then, log mean temperature difference,

$$\Delta T_m = \frac{T_{exit} - T_{inlet}}{\ln\left(\frac{T_s - T_{exit}}{T_s - T_{inlet}}\right)}$$

$$5.53 = \frac{19 - 5}{\ln\left(\frac{T_s - 19}{T_s - 5}\right)}$$

$$T_s = 3.99^\circ\text{C}$$

Therefore, the surface temperature of the pipe, $\boxed{T_s = 3.99^\circ\text{C}}$

Question:

Oil at 15°C is to be heated by saturated steam at 1 atm in a double-pipe heat exchanger to a temperature of 25°C. The inner and outer diameters of the annular space are 3 cm and 5 cm, respectively, and oil enters at with a mean velocity of 1.2 m/s. The inner tube may be assumed to be isothermal at 100°C, and the outer tube is well insulated. Assuming fully developed (low for oil, determine the tube length required to heat the oil to the indicated temperature. In reality, will you need a shorter or longer lube? Explain.

Step 1 of 7

Calculate the average temperature of the oil using the following equation

$$T_{avg} = (T_i + T_e)/2$$

Here, T_i is the inlet temperature of the oil and T_e is the exit temperature of the oil.

Substitute $15°C$ for T_i and $25°C$ for T_e

$$T_{avg} = \frac{(15+25)}{2}$$
$$= 20° C$$

Obtain the properties of engine oil at temperature $T_{avg} = 20°C$ from the table: "Properties of liquids – Engine oil (unused)".

Density, $\rho = 888.1\ kg/m^3$

Specific heat, $C_p = 1881\ J/kg \cdot K$

Thermal conductivity, $k = 0.1450\ w/m \cdot K$

Kinematic viscosity, $\nu = 9.429 \times 10^{-4}\ m^2/s$

Prandtl number, $Pr = 10,863$

Step 2 of 7

Calculate the hydraulic diameter using the following equation

$$D_h = \frac{4A_c}{P}$$
$$= \frac{4 \times \frac{\pi}{4}\left(D_o^2 - D_i^2\right)}{\pi(D_o + D_i)}$$
$$= D_o - D_i$$

Here, A_c is the cross-sectional area of the annulus, P is the perimeter of the annulus and D_o, D_i are the outer and inner diameters of the annular space respectively.

Substitute 0.05 m for D_o and 0.03 for D_i

$$D_h = 0.05 - 0.03$$
$$= 0.02\ m$$

Step 3 of 7

Calculate the Reynolds number using the following equation

$$Re = \frac{V_{avg} \times D_h}{\nu}$$

Here, V_{avg} is the mean velocity.

Substitute $1.2\ m/s$ for V_{avg} and

$$Re = \frac{1.2 \times 0.02}{9.429 \times 10^{-4}}$$
$$= 25.45$$

Therefore, the flow of oil is laminar.

Calculate the Hydrodynamic entry length using the following equation

$$L_h = 0.05(Re)(D_h)$$
$$= (0.05)(25.45)(0.02)$$
$$= 0.025\ m$$

Calculate the thermal boundary entry length using the following relation

$$L_t = L_h \cdot Pr$$
$$= 0.025 \times 10,863$$
$$= 271.5\ m$$

Step 4 of 7

The oil is flowing through the inner pipe.

Calculate the cross – sectional area of oil flow

$$A_c = \frac{\pi D_i^2}{4}$$
$$= \frac{\pi (0.03)^2}{4}$$
$$= 7.06 \times 10^{-4}\ m^2$$

Calculate the mass flow rate using the following equation

$$\dot{m} = \rho A_c V_{avg}$$
$$= 888.1 \times 7.06 \times 10^{-4} \times 1.2$$
$$= 0.7533\ kg/s$$

Step 5 of 7

Calculate the heat transferred rate using the following equation

$$\dot{Q} = \dot{m} C_p (T_e - T_i)$$
$$= 0.7533 \times 1881(25 - 15)$$

Calculate the heat transferred rate using the following equation

$$\begin{aligned}\dot{Q} &= \dot{m}C_p(T_e - T_i)\\ &= 0.7533\times 1881(25-15)\\ &= 14169.573\,\text{W}\end{aligned}$$

Calculate the heat transfer surface area using the following equation

$$\begin{aligned}A_s &= \pi D_i L\\ &= \pi\times 0.03\times L\\ &= 0.0942\,\text{L}\end{aligned}$$

Calculate the logarithmic mean temperature using the following equation

$$\begin{aligned}\Delta T_{lm} &= \frac{T_i - T_e}{\ln\left(\frac{T_s - T_e}{T_s - T_i}\right)}\\ &= \frac{15-25}{\ln\left(\frac{100-25}{100-15}\right)}\\ &= 79.9^\circ\text{C}\end{aligned}$$

Calculate the ratio $\frac{D_i}{D_o}$

$$\begin{aligned}\frac{D_i}{D_o} &= \frac{0.03}{0.05}\\ &= 0.6\end{aligned}$$

Step 6 of 7

Obtain the value of Nusselt number from the table, "Nusselt number for fully developed laminar flow in an annulus with one surface isothermal and the other adiabatic - Nu_i " at $\frac{D_i}{D_o} = 0.6$.

Nusselt number, $\text{Nu} = 5.564$

Consider the equation for Nusselt number.

$$\text{Nu} = \frac{hD_h}{k}$$

$$h = \frac{\text{Nu}\cdot k}{D_h}$$

Here, h is the convective heat transfer coefficient.

$$\begin{aligned}h &= \frac{5.564\times 0.1450}{0.02}\\ &= 40.339\,\text{W/m}^2\,^\circ\text{C}\end{aligned}$$

Step 7 of 7

Consider the equation for heat transfer

$$Q = hA_s DT_{lm}$$

$$14169.573 = 40.339\times 0.0942\,L\times(79.9)$$

$$L = 46.66\,\text{m}$$

Here, the length of the pipe (46.66 m) is less than the thermal boundary entry length (271.5). Hence, the length of the pipe should be longer for the flow to be fully developed.

Question: 19.140P

100 kg/s of a crude oil is heated from 20°C to 40°C through the tube side of a multitube heat exchanger. The crude oil flow is divided evenly among all 100 tubes in the tube bundle. The ID of each tube is 10 mm, and the inside tube-wall temperature is maintained at 100°C. Average properties of the crude oil are ρ =950 kg/m3, cp =1.9 kJ/kg·K, k= 0.25 W/m·K, μ =12 mPa·s, and μw= 4 mPa·s. Estimate the rate of heat transfer and the tube length.

Step 1 of 7

Given data:

Internal Diameter of tube, $D = 10\,\text{mm}$

Inlet temperature of crude oil, $T_i = 20°\text{C}$

Outlet temperature of crude oil, $T_e = 40°\text{C}$

Wall temperature of tube, $T_s = 100°\text{C}$

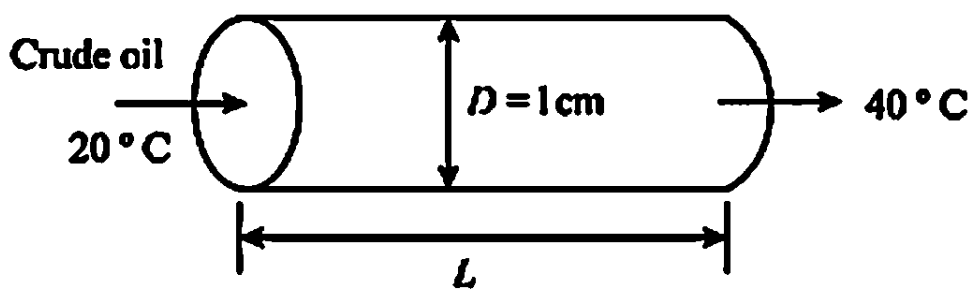
Mass flow rate, $\dot{m} = 100\,\text{kg/s}$ i.e. for $N = 100$

Average properties of crude oil:

Density, $\rho = 950\,\text{kg/m}^3$

Specific heat, $C_p = 1.9\,\text{kJ/kg°k}$

Thermal conductivity, $k = 0.25\,\text{w/m} - \text{k}$



Dynamic viscosity, $\mu = 12\,\text{mPa} \cdot \text{s}$

Dynamic viscosity water $\mu_w = 4\,\text{mP}_a \cdot \text{s}$

$\mu_w = 4 \times 10^{-3}\,\text{kg/m} - \text{s}$

Step 2 of 7

Schematic diagram of pipe flow:

Step 3 of 7

As we know the rate of heat transfer can be expressed as:

$$\dot{Q} = \dot{m}C_p(T_e - T_i)$$
$$= 100 \times 1900(40 - 20)$$
$$= 38 \times 10^5\,\text{W}$$

Therefore, rate of heat transfer, $\boxed{\dot{Q} = 3.8 \times 10^6\,\text{W}}$

Step 4 of 7

As mass flow rate for tube is

$$\dot{m} = \frac{m}{N}$$
$$= \frac{100}{100}$$
$$= 1\,\text{kg/m} - \text{s}$$

Therefore,

$$\text{Re} = \frac{4\dot{m}}{\pi D\mu}$$
$$= \frac{4 \times 1}{\pi \times 0.01 \times 0.012}$$
$$= 10610.33$$

Since it is more than 10,000 Therefore it is a turbulent flow.

Step 5 of 7

By the Dittus – Boelter equation

$$Nu = 0.23\text{Re}^{0.8}\text{Pr}^{0.4}$$

As P_r is not known calculating Prandtl number from

$$\text{Pr} = \frac{\mu C_p}{k}$$
$$= \frac{0.012 \times 1900}{0.25}$$
$$= 91.2$$

Therefore,

$$Nu = \frac{hD}{k} = 0.023(\text{Re})^{0.8}(\text{Pr})^{0.4}$$
$$= 0.023(10610.33)^{0.8}(91.2)^{0.4}$$
$$= 232.44$$

Step 6 of 7

Also, nusselt number

$$Nu = \frac{hD}{k}$$

Heat transfer coefficient,

$$h = \frac{k \cdot Nu}{D}$$
$$= \frac{0.25 \times 232.44}{0.01}$$
$$= 5811\,\text{W/m}^2 \cdot °\text{C}$$

Step 7 of 7

By the Newton's law of cooling

$$Q = hA_s(T_s - T_b)$$

Where

$$T_b = \frac{T_i + T_e}{2}$$
$$= \frac{40 + 20}{2}$$
$$= 30°\text{C}$$

Therefore putting the values in equation above, we get

$$3.8 \times 10^6 = 5811 \times \pi \times 0.01 \times L \times (100 - 30°)$$

$$\boxed{L = 297.36\,\text{m}}$$

This length L is the total length of tube bunch as the total calculated heat transfer was for all 100 tubes.

Therefore, length of each tube, $L = 2.97\,\text{m}$

Question: 19.141P

A fluid (ρ =1000 kg/m3. μ = 1.4 ×10−3 kg/m·s, cp = 4.2 kJ/kg·K, and k =0.58 W/m·K) flows with an average velocity of 0.3 m/s through a 14-m long tube with inside diameter of 0.01 m. Heat is uniformly added to the entire tube at the rate of 1500 W/m2. Determine (*a*) the value of convection heat transfer coefficient at the exit, (*b*) the value of $Ts - Tm$, and (*c*) the value of $Te - Ti$.

Step 1 of 7

Given data:

Average velocity of fluid flow, $V_{avg} = 0.3\,\text{m/s}$

Length of tube, $L = 14\,\text{m}$

Inside diameter of tube, $D_i = 0.01\,\text{m}$

Heat flux rate, $\dot{q}_s = 1500\ \text{W/m}^2$

Fluid properties:

Density, $\rho = 1000\ \text{kg/m}^3$

Dynamic viscosity, $\mu = 1.4\times10^{-3}\ \text{kg/m}\cdot\text{s}$

Specific heat, $c_p = 4.2\ \text{kJ/kg}\cdot\text{K}$

Thermal conductivity, $k = 0.58\ \text{W/m}\cdot\text{K}$

Step 2 of 7

(a) The Reynolds number for the flow,

$$\text{Re} = \frac{\rho V_{avg} D}{\mu}$$

$$= \frac{1000\times0.3\times0.01}{1.4\times10^{-3}}$$

$$\text{Re} = 2142.8$$

Since the Reynolds number is less than 2300 the flow is said to be laminar flow.

Therefore it's a laminar flow.

The prandtl number ,

$$\text{Pr} = \frac{\mu c_p}{k}$$

$$= \frac{1.4\times10^{-3}\times4200}{0.58}$$

$$\text{Pr} = 10.14$$

Step 3 of 7

The hydrodynamic entry length,

$$L_h = 0.05\,\text{Re}\,D$$

$$= 0.05\times2142.8\times0.01$$

$$L_h = 1.071\,\text{m}$$

The thermal entry length,

$$L_t = L_h \times \text{Pr}$$

$$= 1.071\times10.14$$

$$L_t = 10.85$$

Since both the thermal entry lengths L_h and L_t are less than given length $L = 14\,\text{m}$

The flow is said to be fully developed laminar flow.

Step 4 of 7

From the graph named Local Nusselt numbers in the entry and fully developed regions for laminar flow in a circular tube for hydro dynamically developed and thermally developing flow.

For constant surface heat flux,

Nusselt number, $Nu = 4.36$

The heat transfer coefficient is determined as

$$Nu = \frac{hD}{k}$$

$$4.36 = \frac{h\times0.01}{0.58}$$

$$h = 252.88\ \text{W/m}^2\cdot\text{K}$$

Therefore, the value of convective heat transfer coefficient at the exit,

$$\boxed{h = 252.88\ \text{W/m}^2\cdot\text{K}}$$

Step 5 of 7

(b) From the Newton's law of cooling the heat flux ,

$$\dot{q} = h(T_s - T_m)$$

$$1500 = 252.88(T_s - T_m)$$

$$(T_s - T_m) = 5.93^\circ\text{C}$$

Therefore, the value of the temperature difference, $\boxed{T_s - T_m = 5.93^\circ\text{C}}$

Step 6 of 7

(c) surface area of the heat flow,

$$A_s = \pi DL$$

$$= \pi\times0.01\times14$$

$$A_s = 0.4398\ \text{m}^2$$

The mass flow rate of the fluid is determined as

$$\dot{m} = \rho V_{avg} A_c$$

$$= \rho\times V_{avg}\times\frac{\pi D^2}{4}$$

$$= \frac{1000\times0.3\times\pi\times(0.01)^2}{4}$$

$$\dot{m} = 0.02356\ \text{kg/s}$$

Step 7 of 7

The heat transfer rate can be expressed by

$$\dot{Q} = \dot{m}c_p(T_e - T_i)$$

$$\dot{q}\times A_s = 0.02356\times4.2\times10^3\times(T_e - T_i)$$

$$1500\times0.4398 = 0.02356\times4.2\times(T_e - T_i)$$

$$(T_e - T_i) = 6.67^\circ\text{C}$$

Therefore, the value of the temperature difference, $\boxed{(T_e - T_i) = 6.67^\circ\text{C}}$

Question: 19.142P

Air (1 atm) entered into a 5-mm diameter circular tube at an average velocity of 5 m/s. The tube wall is maintained at a constant surface temperature. Determine the convection heat transfer coefficient for (*a*) a 10-cm long tube and (*b*) a 50-cm long tube. Evaluate the air properties at 50°C.

Step 1 of 5

Given data:

Diameter of circular tube, $D = 5\,\text{mm}$

Average velocity of air, $V_{avg} = 5\ \text{m/s}$

Pressure of the air, $P = 1\,\text{atm}$

Temperature of the air, $T = 50°\text{C}$

Step 2 of 5

The properties of air table, at $P = 1\,\text{atm}$ and $T = 50°\text{C}$

Density, $\rho = 1.092\,\text{kg/m}^3$

Specific heat, $c_p = 1007\ \text{J/kg}\cdot\text{K}$

Thermal conductivity, $k = 0.02735\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

The Reynolds number for the flow is determined as

$$\text{Re} = \frac{V_{avg}D}{\nu}$$

$$= \frac{5\times5\times10^{-3}}{\left(1.798\times10^{-5}\right)}$$

$$\text{Re} = 1390.43$$

Since the Reynolds number is less than 2300, the flow is said to laminar flow.

Step 3 of 5

(a) For a tube length, $L = 10\ \text{cm}$

The thermal entry lengths are determined as

$$L_h = 0.05\,\text{Re}\times D$$

$$= 0.05\times1390.43\times5\times10^{-3}$$

$$L_h = 0.348\,\text{m}$$

$$L_t = L_h\times\text{Pr}$$

$$= 0.348\times0.7228$$

$$L_t = 0.2515\ \text{m}$$

Since the thermal entry lengths L_h and L_t are greater than the given length $L = 0.1\,\text{m}$,

The flow is fully developed laminar flow.

Step 4 of 5

The Nusselt number for the laminar flow in a circular tube,

$$Nu = 1.86\left(\frac{\text{Re}\cdot\text{Pr}\cdot D}{L}\right)\left(\frac{\mu_b}{\mu_s}\right)^{0.14}$$

From the Dynamic viscosity tables at $T = 50°\text{C}$

$\mu_b = 1.963\times10^{-5}\ \text{kg/m}\cdot\text{s}$

At surface temperature $T_s = 160°\text{C}$

$\mu_s = 2.420\times10^{-5}\ \text{kg/m}\cdot\text{s}$

The Nusselt number is determined as

$$Nu = 1.86\left(\frac{1390.43\times0.7228\times5\times10^{-3}}{0.1}\right)^{1/3}\left(\frac{1.963\times10^{-5}}{2.420\times10^{-5}}\right)^{0.14}$$

$$= 6.6655$$

The convective heat transfer coefficient is determined as

$$h = \frac{k\times Nu}{D}$$

$$= \frac{0.02735\times6.6655}{5\times10^{-3}}$$

$$= 36.46\ \text{W/m}^2\cdot\text{K}$$

Therefore, the convective heat transfer coefficient of air, $\boxed{h = 36.46\ \text{W/m}^2\cdot\text{K}}$

Step 5 of 5

(b) For a tube length, $L = 50\ \text{cm}$

Since both the thermal entry lengths L_h and L_t are less than given length $L = 0.5\text{m}$

The flow is said to be fully developed laminar flow.

From the graph named Local Nusselt numbers in the entry and fully developed regions for laminar flow in a circular tube for hydro dynamically developed and thermally developing flow.

For constant surface temperature,

$Nu = 3.66$

The convective heat transfer coefficient is determined as

$$h = \frac{k\times Nu}{D}$$

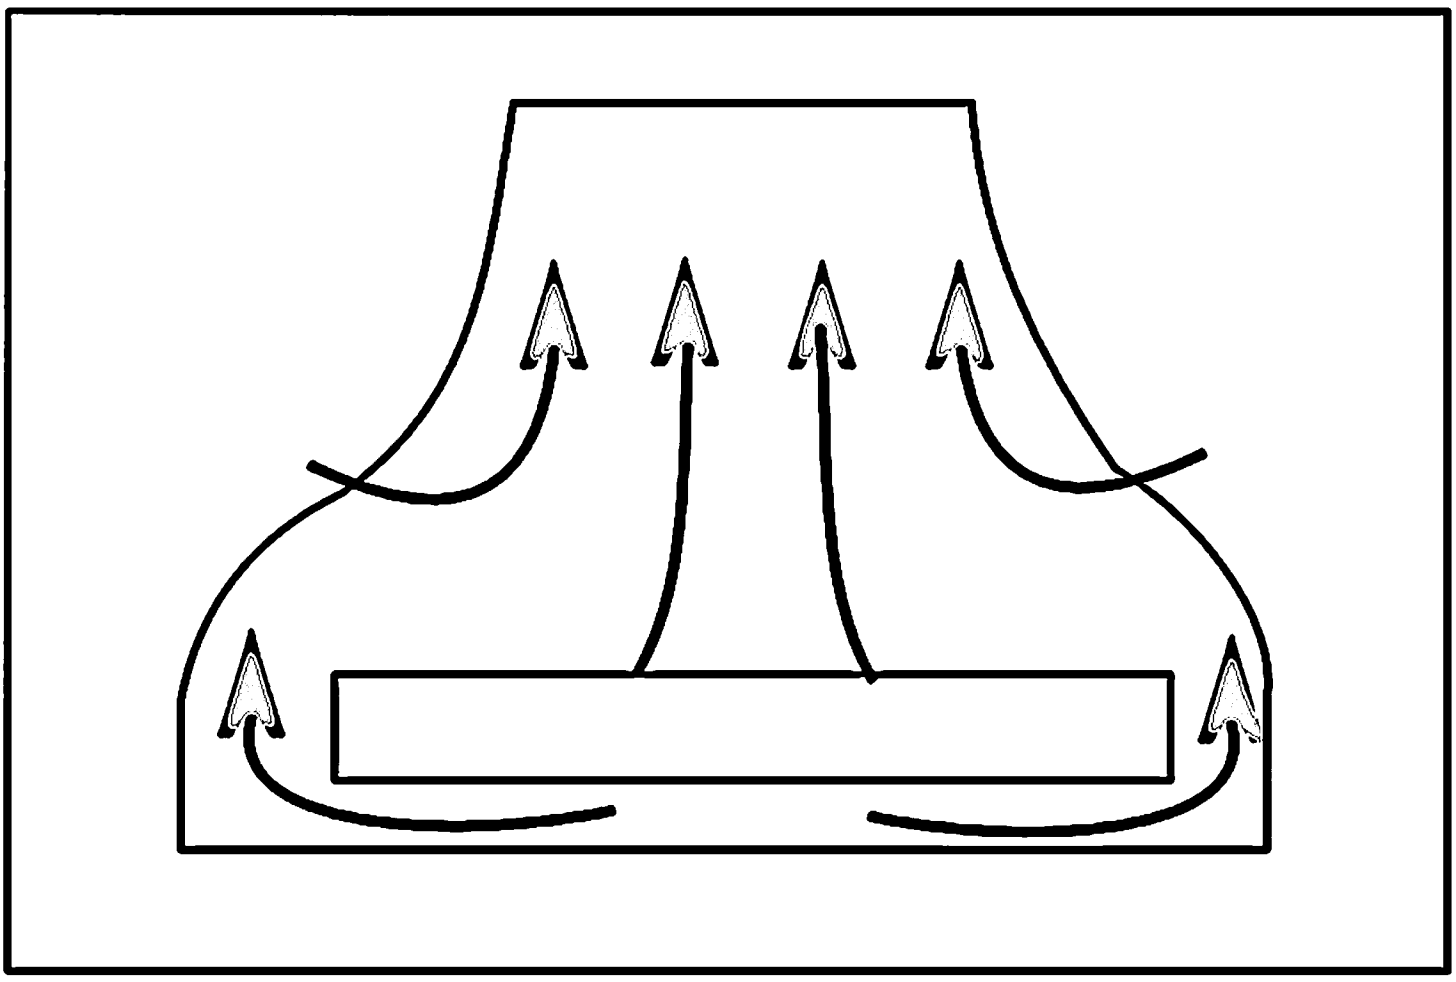
$$= \frac{0.02735\times3.66}{5\times10^{-3}}$$

$$h = 20.02\ \text{W/m}^2\cdot\text{K}$$

Therefore, the convective heat transfer coefficient of air is $\boxed{h = 20.02\ \text{W/m}^2\cdot\text{K}}$

CHAPTER 21

SOLUTIONS



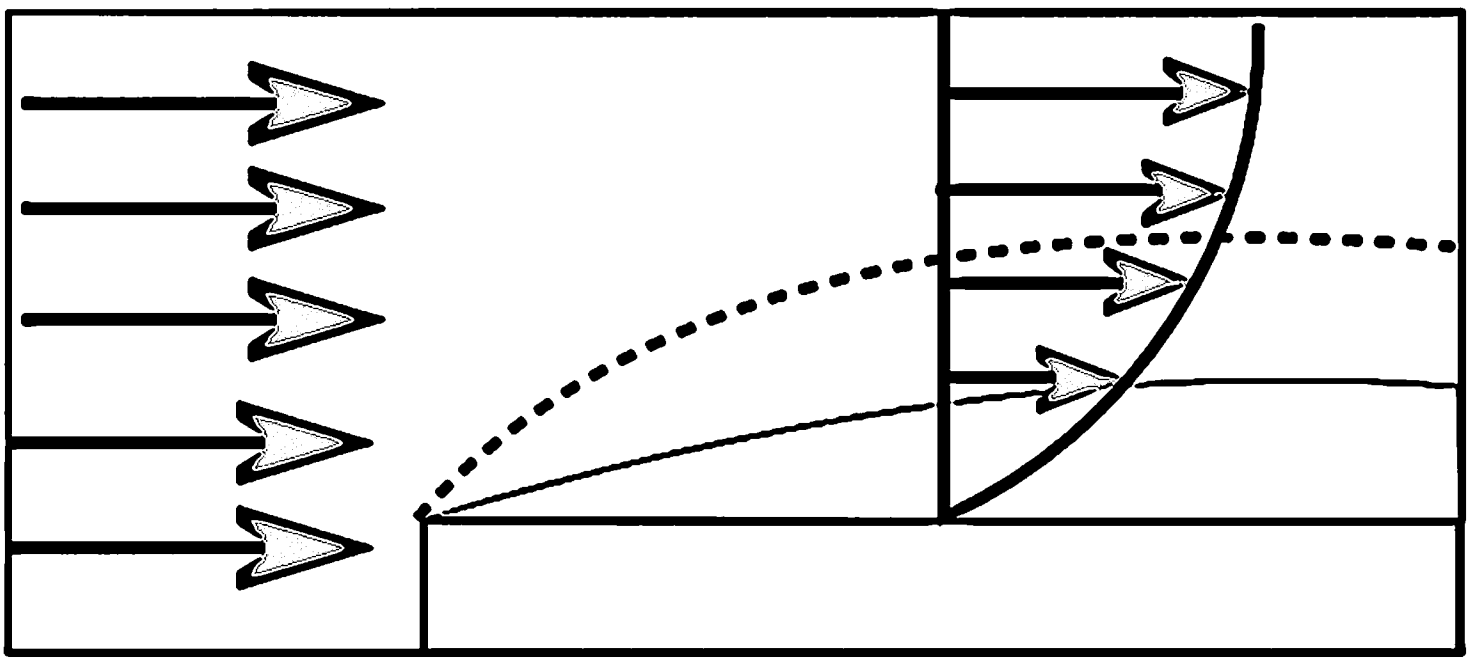
Question: 20.001P

What is natural convection? How does it differ from forced convection? What force causes natural convection currents?

Step 1 of 2

When a temperature difference produces density variations which results in mass movement of fluids, then the process is called free or natural convection.

The following sketch shows the free convection currents around a horizontal plate:



The natural convection occurs, when a free flowing air air sorrounded by a hot plate passes over it and rises from the plate .

Step 2 of 2

When the mass motion of the fluid is caused by an external device like a pump, compressor, blower or fan, the process is called forced convection.

The following sketch shows the forced convection currents:

The figure represents the relation between flow velocity, direction, and temperature for a hot, horizontal surface under forced convection.

Forced convection is generally more efficient than natural convection due to the rapid velocity of the currents. In forced convection, buoyancy has small effect on the direction of flow. Thus buoyancy force causes natural convection currents.

Question: 20.002P

In which mode of heat transfer is the convection heat transfer coefficient usually higher, natural convection or forced convection? Why?

Step 1 of 1

Velocity magnitude of forced convection is greater than that of the natural convection so that the heat transfer coefficient of forced convection is higher.

Question: 20.003P

What is buoyancy force? Compare the relative magnitudes of the buoyancy force acting on a body immersed in these mediums; (*a*) air, (*b*) water, (*c*) mercury, and (*d*) an evacuated chamber.

Step 1 of 1

The upward force exerted by a fluid on a body completely or partially immersed in it is called the buoyancy. The buoyancy force is proportional to the density of the medium. Therefore, the buoyancy force is the largest in mercury, followed by in water, air, and the evacuated chamber. Note that in an evacuated chamber there will be no buoyancy force because of absence of any fluid in the medium.

Question: 20.004P

Consider a hot boiled egg in a spacecraft that is filled with air at atmospheric pressure and temperature at all times. Will the egg cool faster or slower when the spacecraft is in space instead of on the ground? Explain.

Step 1 of 1

Natural convection is mainly based on buoyancy force which is due to the gravity effect. In case of boiled egg in the aircraft which is at space, there is no gravity effect acting on the egg, which means there is no buoyancy effect on egg. So the egg takes more time to cool down in the space. Hence egg cools faster when the spacecraft is on ground.

Question: 20.005P

When will the hull of a ship sink in water deeper: when the ship is sailing in fresh water or in seawater? Why?

Step 1 of 1

The buoyancy force is proportional to the density of the medium, and thus is larger in sea water than it is in fresh water. Therefore, the hull of a ship will sink deeper in fresh water because of the smaller buoyancy force acting upwards.

Question: 20.006P

Consider two fluids, one with a large coefficient of volume expansion and the other with a small one. In what fluid will a hot surface initiate stronger natural convection currents? Why? Assume the viscosity of the fluids to be the same.

Step 1 of 1

The greater the volume expansion coefficient, greater will be the change in density with temperature. And with greater change in density, the buoyancy force will be greater, and thus the natural convection currents are greater. So for the fluid with greater volume expansion coefficient, the natural convection currents are greater.

Question: 20.007P

Physically, what does the Grashof number represent? How does the Grashof number differ from the Reynolds number?

Step 1 of 1

Physically, Grashof number represents the ratio of the buoyancy force to the viscous force acting on a fluid. In Reynolds number, if the inertia force is replaced by the buoyancy forces then it becomes Grashof number.

Question: 20.008P

Show that the volume expansion coefficient of an ideal gas is $\beta = 1/T$, where T is the absolute temperature.

Step 1 of 1

The volume expansion coefficient is $\beta = \frac{-1}{\rho}\left(\frac{\partial \rho}{\partial T}\right)_p$

But for an ideal gas, $P = \rho RT$ or

$$\rho = \frac{P}{RT}$$

Then the volume expansion coefficient becomes

$$\beta = -\frac{1}{\rho}\left(\frac{\partial}{\partial T}(P/RT)\right)_p$$

$$\beta = -\frac{1}{\rho}\left(\frac{P}{R} \times \frac{\partial}{\partial T}\left(\frac{1}{T}\right)\right)_p$$

$$\beta = \frac{-1}{\rho}\left(\frac{P}{R} \times \frac{-1}{T^2}\right)$$

$$\beta = \frac{-1}{\rho}\left(\frac{-P}{RT^2}\right)$$

$$\beta = \frac{1}{\rho T}\left(\frac{P}{RT}\right)$$

$$\beta = \frac{1}{\rho T}(\rho)$$

Hence volume expansion coefficient of ideal gas is $\boxed{\beta = \frac{1}{T}}$

Question: 20.009P

Using its definition and the values listed in Table A -15.determine the volume expression coefficient of saturated liquid water at 70°C. Compare the result with the value tabulated in Table A-15.

Step 1 of 3

Given data:

Temperature of water, $T = 70°C$

We assume that density is dependent upon temperature only.

Consider the density of the water to be ρ

A property that represents the variations of density of a fluid with temperature at constant pressure, is volume expansion co-efficient (β) is given as;

$$\beta = \frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_p$$

$$= -\frac{1}{\rho}\left(\frac{\partial \rho}{\partial T}\right)_p$$

$$\beta = -\frac{1}{\rho}\left(\frac{\rho_1 - \rho_2}{T_1 - T_2}\right) \qquad \ldots\ldots (1)$$

Step 2 of 3

Let us take variation of temperature between 65 °C to 75 °C and respective densities values from the table Properties of saturated water

At temperature, $T_1 = 65°C$

Density, $\rho_1 = 980.4 kg/m^3$

At temperature, $T_2 = 75°C$

Density, $\rho_2 = 974.7 kg/m^3$

At temperature, $T = 70°C$

Average Density, $\rho = 977.5 kg/m^3$

Step 3 of 3

Now substituting the above values in the equation (1),

$$\beta = -\frac{1}{\rho}\left(\frac{\rho_1 - \rho_2}{T_1 - T_2}\right)$$

$$= -\frac{1}{977.5}\left(\frac{980.4 - 974.7}{65 - 75}\right)$$

$$= 5.83 \times 10^{-4} K^{-1}$$

Therefore, the volume expansion coefficient is $\boxed{\beta = 5.83 \times 10^{-4} K^{-1}}$

From the Properties of saturated water table, at $T = 70°C$

Volume expansion coefficient value, $\beta = 5.78 \times 10^{-4} K^{-1}$

By comparing both the values, approximately the calculated value is 1% higher than tabular value.

Question: 20.010P

The density of liquid water can be correlated as $\rho(T) = 1000 - 0.0736T - 0.00355T2$ where ρ and T are in kg/m and °C, respectively. Determine the volume expansion coefficient at 70°C. Compare the result with the value tabulated in Table A–15.

Step 1 of 3

Given data:

Density of the liquid water relation with the temperature,

$\rho(T) = 1000 - 0.0736T - 0.00355T^2$

Density units, ρ kg/m^3

Temperature units, T°C

Volume expansion co-efficient, β

Step 2 of 3

Volume expansion co-efficient relationship is written as

$$\beta = -\frac{1}{\rho}\left(\frac{\partial \rho}{\partial T}\right)_p \qquad \ldots\ldots (1)$$

By substituting the density relation in the equation (1) and differentiating with respective to the T;

$$\beta = -\frac{1}{\rho}\left(\frac{\partial \rho}{\partial T}\right)_p$$

$$= -\frac{1}{\rho}\left[\frac{\partial}{\partial T}\left(1000 - 0.0736T - 0.00355T^2\right)\right]_p$$

$$= \frac{1}{\rho}\left(-0.0736 - 0.0071T\right)_p$$

$$= \frac{\left(-0.0736 - 0.0071T\right)_p}{1000 - 0.0736T - 0.00355T^2}$$

Step 3 of 3

Now at $T = 70°C$, the volume expansion co-efficient β is given by

$$\beta = -\frac{\left(-0.0736 - 0.0071T\right)}{\left(1000 - 0.0736T - 0.00355T^2\right)}$$

$$\beta_{T=70°C} = -\frac{\left(-0.0736 - 0.0071\times 70\right)}{\left[1000 - 0.0736\times 70 - 0.00355\times(70)^2\right]}$$

$$= \frac{0.5733}{977.453}$$

$$= 5.86\times 10^{-4}\,\mathrm{K}^{-1}$$

Therefore, the volume expansion co-efficient β is $\boxed{\beta_{T=70°C} = 5.86\times 10^{-4}\,\mathrm{K}^{-1}}$

From the Properties of saturated water table, at $T = 70°C$

Volume expansion coefficient value, $\beta = 5.78\times 10^{-4}\,\mathrm{K}^{-1}$

By comparing both the values, approximately the calculated value is 1% higher than tabular value.

Question: 20.011P

A 10 cm × 10cm plate has a constant surface temperature of 150°C. Determine the Grashof number if the chip is placed in the following fluids: air (1 atm, 30°C), liquid water (30°C), engine oil (10°C). Discuss how the Grashof number affects the natural convection flow.

Step 1 of 7

Given data:

Plate dimensions $= 10\,\text{cm} \times 10\,\text{cm}$

$= 0.1 \times 0.1\ \text{m}^2$

Surface temperature of plate, $T_s = 150°\text{C}$

Step 2 of 7

When chip is placed in air $(1\text{atm}, T_\infty = 30°\text{C})$:

As fluid properties are to be evaluated at film temperature T_f;

$$T_f = \frac{(T_s + T_\infty)}{2}$$
$$= \frac{(150+30)}{2}$$
$$= 90°\text{C}$$

Density, $\rho = 0.9718\ \text{kg/m}^3$

Volume expansion coefficient, $\beta = 2.755 \times 10^{-3}\ \text{K}^{-1}$

Dynamic viscosity, $\mu = 2.139 \times 10^{-5}\ \text{kg/m} \cdot s$

Characteristic length from plate dimension, $L_c = 0.1\text{m}$

Gravitational constant, $g = 9.81\ \text{m/s}^2$

Step 3 of 7

Now calculating the kinematic viscosity of the air,

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{2.139 \times 10^{-5}}{0.9718}$$
$$= 2.201 \times 10^{-5}\ \text{m}^2/s$$

Grashof number is given by

$$(\text{Gr}_L)_{air} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$
$$= \frac{9.81 \times 2.755 \times 10^{-3}(150-30)(0.1)^3}{\left(2.201 \times 10^{-5}\right)^2}$$
$$= 6694710$$

Thus, Grashof number when chip is placed in air is $\boxed{(\text{Gr}_L)_{air} = 6694710}$

Step 4 of 7

When chip is placed in Liquid water $(T_\infty = 30°\text{C})$:

By calculating fluid properties at film temperature,

$$T_f = \frac{(T_s + T_\infty)}{2}$$
$$= \frac{(150+30)}{2}$$
$$= 90°\text{C}$$

Density, $\rho = 965.3\text{kg/m}^3$

Volume expansion coefficient, $\beta = 0.702 \times 10^{-3}\text{K}^{-1}$

Dynamic viscosity, $\mu = 0.315 \times 10^{-3}\ \text{kg/m} \cdot s$

Step 5 of 7

By calculating the kinematic viscosity of the liquid:

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{0.315 \times 10^{-3}}{965.3}$$
$$= 3.263 \times 10^{-7}\ \text{m}^2/s$$

So, Grashof number is calculated as

$$(\text{Gr}_L)_w = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$
$$= \frac{9.81 \times 0.702 \times 10^{-3} \times (150-30)(0.1)^3}{\left(3.263 \times 10^{-7}\right)^2}$$
$$= 7761635041$$

Hence, Grashof number when chip is placed in liquid is $\boxed{(\text{Gr}_L)_w = 7761635041}$

Step 6 of 7

When chip is placed in Liquid water Engine oil $(T_\infty = 10°\text{C})$

Properties of engine oil at film temperature T_f

$$T_f = (T_s + T_\infty)/2$$
$$= (150+10)/2$$
$$= 80°\text{C}$$

Density, $\rho = 852\text{kg/m}^3$

Volume expansion coefficient, $\beta = 0.700 \times 10^{-3}\text{K}^{-1}$

Dynamic viscosity, $\mu = 3.232 \times 10^{-2}\ \text{kg/m} \cdot s$

Kinematic viscosity,
kinematic viscosity

$$\nu = \frac{\mu}{\rho}$$
$$= 3.793 \times 10^{-3}\ \text{m}^2/s$$

Step 7 of 7

Grashof number is given by

$$(Gr_L)_O = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$
$$= \frac{9.81 \times 0.7 \times 10^{-3} \times (150-10) \times (0.1)^3}{\left(3.793 \times 10^{-5}\right)^2}$$
$$= 668235$$

Hence, Grashof number when chip is placed in oil is $\boxed{(Gr_L)_O = 668235}$

Question:

A long 2-in.-diameter rod with surface temperature of 200°F is submerged in a bath of fluid. Determine the Grashof and Raylcigh numbers if the fluid is (*a*) liquid water at 40°F, (*b*) liquid ammonia at 40°F, (*c*) engine oil at 50°F, and (*d*) air at 40°F(1 atm).

Step 1 of 14

Given data:-

A long rod is submerged in a bath of fluid

Diameter of rod, $D = 2\text{in.}$

Surface temperature of rod, $T_s = 200\,^\circ\text{F}$

Step 2 of 14

Let us consider the following parameters;

g – Acceleration due to gravity, ft/s^2

β – Co-efficient of volume expansion, R^{-1}

T_∞ – Temperature of fluid, °F

ν – Kinematic viscosity, ft^2/s

L_c – Characteristic length, ft

Step 3 of 14

(a) If the fluid is Liquid water at $T_\infty = 40^\circ\text{F}$

By calculating properties of liquid water at film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{200+40}{2}$$

$$= 120^\circ\text{F}$$

Acceleration due to gravity, $g = 32.2\,\text{ft}/s^2$

Density, $\rho = 61.71\,\text{lbm}/\text{ft}^3$

Dynamic viscosity, $\mu = 3.744\times10^{-4}\,\text{lbm}/\text{ft}\cdot s$

Prandtl number, $\text{Pr} = 3.63$

Co-efficient of volume expansion, $\beta = 0.246\times10^{-3}\,\text{R}^{-1}$

Step 4 of 14

By calculating kinematic viscosity:

$$\nu = \frac{\mu}{\rho}$$

$$= \frac{3.744\times10^{-4}}{61.71}$$

$$= 6.067\times10^{-6}\,\text{ft}^2/s$$

As the rod is placed horizontally, characteristic length becomes:

L_c = Diameter of rod

$D = 0.1667\,\text{ft}$

Step 5 of 14

Now substituting the values in the Grashof and Rayleigh number then

$$\text{Gr} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$

$$= \frac{32.2\times0.246\times10^{-3}\times(200-40)\times(0.1667)^3}{\left(6.067\times10^{-6}\right)^2}$$

$$= 1.60\times10^8$$

$$\text{Ra} = \text{Gr}\cdot\text{Pr}$$

$$= 1.60\times10^8\times3.63$$

$$= 5.79\times10^8$$

Thus, Grashof and Rayleigh number are

$\boxed{\text{Gr} = 1.60\times10^8}$

and

$\boxed{\text{Ra} = 5.79\times10^8}$

Step 6 of 14

(b) If the fluid is Liquid Ammonia at $T_\infty = 40\,^\circ\text{F}$

By taking properties of Ammonia at film temperature;

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{200+40}{2}$$

$$= 120\,^\circ\text{F}$$

Density, $\rho = 35.26\,\text{lbm}/\text{ft}^3$

Dynamic viscosity, $\mu = 7.444\times10^{-5}\,\text{lbm}/\text{ft}\cdot s$

Prandtl number, $\text{Pr} = 1.313$

Co-efficient of volume expansion, $\beta = 1.74\times10^{-3}\,\text{R}^{-1}$

Step 7 of 14

By calculating kinematic viscosity:

$$\nu = \frac{\mu}{\rho}$$

$$= \frac{7.444\times10^{-5}}{35.26}$$

$$= 2.11\times10^{-6}\,\text{ft}^2/s$$

As the rod is placed horizontally, characteristic length becomes:

L_c = Diameter of rod

$D = 0.1667\,\text{ft}$

Step 8 of 14

Now substituting the values in the Grashof and Rayleigh number then

$$\text{Gr} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$

Step 8 of 14

Now substituting the values in the Grashof and Rayleigh number then

$$Gr = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$

$$= \frac{32.2 \times 0.174 \times 10^{-4} \times (200-40) \times (0.1667)^3}{(2.11 \times 10^{-6})^2}$$

$$= 9.33 \times 10^7$$

$$Ra = Gr \cdot Pr$$

$$= 1.968 \times 10^8 \times 1.313$$

$$= 1.22 \times 10^9$$

Thus, Grashof and Rayleigh number are

$$\boxed{Gr = 9.33 \times 10^7}$$

and

$$\boxed{Ra = 1.22 \times 10^9}$$

Step 9 of 14

(c) If the fluid is Engine oil at $T_\infty = 50°F$

By taking properties of engine oil at film temperature;

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{200+50}{2}$$

$$= 125°F$$

Density, $\rho = 54.24 \text{ lbm/ft}^3$

Dynamic viscosity, $\mu = 7.617 \times 10^{-2} \text{ lbm/ft} \cdot s$

Prandtl number, $Pr = 1607$

Co-efficient of volume expansion, $\beta = 0.389 \times 10^{-3} R^{-1}$

Step 10 of 14

By calculating kinematic viscosity:

$$\nu = \frac{\mu}{\rho}$$

$$= \frac{7.617 \times 10^{-2}}{54.24}$$

$$= 1.404 \times 10^{-3} \text{ ft}^2/s$$

As the rod is placed horizontally, characteristic length becomes:

L_c = Diameter of rod

$D = 0.1667 \text{ ft}$

Step 11 of 14

Now substituting the values in the Grashof and Rayleigh number then

$$Gr = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$

$$= \frac{32.2 \times 0.389 \times 10^{-3} \times (200-50) \times (0.1667)^3}{(1.404 \times 10^{-3})^2}$$

$$= 4.42 \times 10^3$$

$$Ra = Gr \cdot Pr$$

$$= 6.619 \times 10^3 \times 1607$$

$$= 7.71 \times 10^6$$

Thus, Grashof and Rayleigh number are

$$\boxed{Gr = 4.42 \times 10^3}$$

and

$$\boxed{Ra = 7.1 \times 10^6}$$

Step 12 of 14

(d) If the fluid is Air at $T_\infty = 40°F$

By taking properties of air at film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{200+40}{2}$$

$$= 120°F$$

Density, $\rho = 0.06843 \text{ lbm/ft}^3$

Dynamic viscosity, $\mu = 1.316 \times 10^{-5} \text{ lbm/ft} \cdot s$

Prandtl number, $Pr = 0.723$

Co-efficient of volume expansion, $\beta = 1.72 \times 10^{-3} R^{-1}$

Step 13 of 14

By calculating kinematic viscosity:

$$\nu = \frac{\mu}{\rho}$$

$$= \frac{1.316 \times 10^{-5}}{0.06843}$$

$$= 1.923 \times 10^{-4} \text{ ft}^2/s$$

As the rod is placed horizontally, characteristic length becomes:

L_c = Diameter of rod

$D = 0.1667 \text{ ft}$

Step 14 of 14

Now substituting the values in the Grashof and Rayleigh number then

$$Gr = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$

$$= \frac{32.2 \times 1.72 \times 10^{-3} \times (200-40) \times (0.1667)^3}{}$$

Now substituting the values in the Grashof and Rayleigh number then

$$\mathrm{Gr} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}$$

$$= \frac{32.2 \times 1.72 \times 10^{-3} \times (200-40) \times (0.1667)^3}{\left(1.923 \times 10^{-4}\right)^2}$$

$$= 1.11 \times 10^6$$

$$\mathrm{Ra} = \mathrm{Gr} \cdot \mathrm{Pr}$$

$$= 2.13 \times 10^6 \times 0.723$$

$$= 8.03 \times 10^5$$

Thus, Grashof and Rayleigh number are

$$\boxed{\mathrm{Gr} = 1.11 \times 10^6}$$

and

$$\boxed{\mathrm{Ra} = 8.03 \times 10^5}$$

Question: 20.013P

Consider laminar natural convection from a vertical hot-plate. Will the heat flux be higher at the top or at the bottom of the plate? Why?

Step 1 of 1

For a vertical hot plate, the boundary layer is thinner at the bottom than at the top. As the boundary layer thickness represents thermal resistance, the resistance at bottom is less so the plate has higher heat flux at bottom.

Question: 20.014P

Under what conditions can the outer surface of a vertical cylinder be treated as a vertical plate in natural convection calculations?

Step 1 of 1

In natural convection calculations, the vertical cylinder can be treated as a vertical plate if the diameter of the cylinder is large. The curvature effects are negligible if the diameter of the cylinder is large. The dimeter of the cylinder should satisfy the following relation:

$$D \geq \frac{35L}{\mathrm{Gr}^{1/4}}$$

Here, D is the diameter of the cylinder, L is the length of the cylinder, and Gr is the Grashof number.

Question: 20.015P

Will a hot horizontal plate whose back side is insulated cool faster or slower when its hot surface is facing down instead of up?

Step 1 of 1

A hot horizontal plate surface will not cool faster when the un-insulated surface is facing down. The reason is that the warmer air cannot rise and escape easily if the plate is faced down.

Question: 20.016P

An aluminum soda can of 150-mm in length and 60-mm in diameter is placed horizontally inside a refrigerator compartment that maintains a temperature of 4°C. If the surface temperature of the can is 36°C, estimate heat transfer rate from the can. Neglect the heat transfer from the ends of the can.

Step 1 of 6

Given data:-

Aluminum soda can placed horizontally inside a refrigerator.

Diameter of aluminum soda can, $D = 60\,\text{mm}$

Length of soda can, $L = 150\,\text{mm}$

Surface temperature of can, $T_s = 36\,^\circ\text{C}$

Refrigerator compartment temperature, $T_\infty = 4\,^\circ\text{C}$

Step 2 of 6

Heat transfer rate from the soda-can can be calculated by

$$\dot{Q} = hA_s\left(T_s - T_\infty\right)$$

Heat transfer co-efficient is given by the formula:

$$h = \frac{k}{D}N_u$$

Calculating film temperature:

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{36+4}{2}$$

$$= 20^\circ\text{C}$$

Step 3 of 6

By taking properties of the air from table at film temperature T_f:

Thermal conductivity, $k = 0.02514\,\text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.516\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7309$

Expansion co-efficient, $\beta = 0.003413\,\text{K}^{-1}$

Acceleration due to gravity, $g = 9.81\,\text{m/s}^2$

Surface area of the soda-can is calculated as:

$$A_s = \pi DL$$

$$= 3.142\times0.06\times0.15$$

$$= 0.02827\,\text{m}^2$$

Step 4 of 6

Using the above values, the Rayleigh number is calculated as;

$$\text{Ra}_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu^2}.\text{Pr}$$

$$= \frac{9.81\times0.003413(36-4)(0.06)^3}{\left(1.516\times10^{-5}\right)^2}\times(0.7309)$$

$$= \frac{1.69\times10^{-4}}{1.516\times10^{-10}}$$

$$= 735984.4$$

Step 5 of 6

Using the Rayleigh number, by calculating Nu (Nusselt number) for horizontal plate:

$$\text{Nu} = \left[0.6 + \frac{0.387\,\text{Ra}_D^{\frac{1}{6}}}{\left[1+\left(\frac{0.559}{\text{Pr}}\right)^{\frac{9}{16}}\right]^{\frac{8}{27}}}\right]^2$$

$$= \left[0.6 + \frac{0.387(735984.4)^{\frac{1}{6}}}{\left[1+(0.559/0.7309)^{\frac{9}{16}}\right]^{\frac{8}{27}}}\right]^2$$

$$= [0.6+3.059]^2$$

$$= 13.391$$

Step 6 of 6

By calculating heat transfer co-efficient:

$$h = \frac{k}{D}\text{Nu}$$

$$= \frac{0.02514}{0.06}\times13.391$$

$$= 5.61\,\text{W/m}^2\cdot\text{K}$$

Now the heat transfer rate is calculated as;

$$\dot{Q} = hA_s\left(T_s - T_\infty\right)$$

$$= 5.61\times0.02827(36-4)$$

$$= 5.0757\,\text{W}$$

Hence, the heat transfer rate of the soda-can is $\boxed{\dot{Q} = 5.0757\,\text{W}}$

Question: 20.017P

A can of engine oil with a length of 150 mm and a diameter of 100 mm is placed vertically in the trunk of a car. In a hot summer day, the temperature in the trunk is 43°C. If the surface temperature of the can is 17°C, determine heat transfer rate from the can surface. Neglect the heat transfer from the ends of the can.

Step 1 of 5

Given data:

A can of engine oil is placed vertically.

Length of the can, $L = 150\,\text{mm}$

Diameter of can, $D = 100\,\text{mm}$

Temperature of trunk, $T_\infty = 43°\text{C}$

Surface temperature of can, $T_s = 17°\text{C}$

Step 2 of 5

Calculating film temperature:

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{43+17}{2}$$
$$= 30°\text{C}$$

By taking the air properties at film temperature,

Thermal conductivity, $k = 0.02588\,\text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.608\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7282$

Volume expansion co-efficient, $\beta = 0.0033\,\text{K}^{-1}$

Acceleration due to gravity, $g = 9.81\,\text{m/s}^2$

Step 3 of 5

Surface area of the can is calculated as:

$$A_s = \pi DL$$
$$= \pi\times0.1\times0.15$$
$$= 0.047\,\text{m}^2$$

Using the above values, the Rayleigh number is given by,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)D^3}{\nu^2}\text{Pr}$$
$$= \frac{9.81\times0.0033(43-17)(0.15)^3}{\left(1.608\times10^{-5}\right)^2}\times0.7282$$
$$= \frac{2.0686\times10^{-3}}{\left(1.608\times10^{-5}\right)^2}$$
$$= 8000343.94$$

Step 4 of 5

From table of empirical correlations for the average Nusselt number for natural convection over surfaces, the Nusselt number for vertical plate is given by

$$\text{Nu} = 0.59\,\text{Ra}_L^{1/4}$$
$$= 0.59\times(8000343.94)^{0.25}$$
$$= 31.378$$

Heat transfer co-efficient is calculated as:

$$h = \frac{k}{D}\text{Nu}$$
$$= \frac{0.02588}{0.15}\times31.378$$
$$= 5.4137\ \text{W/m}^2\cdot\text{K}$$

Step 5 of 5

Heat transfer rate is calculated as:

$$\dot{Q} = hA_s(T_\infty - T_s)$$
$$= 5.4138\times0.047\times(43-17)$$
$$= 6.6156\,\text{W}$$

Hence, the rate of heat transfer is $\boxed{\dot{Q} = 6.633\,\text{W}}$

Question: 20.018P pg 1

Consider a thin 24-cm-long and 20-cm-wide horizontal plate suspended in air at 20°C. The plate is equipped with electric resistance heating elements with a rating of 20 W. Now the heater is turned on and the plate temperature rises. Determine the temperature of the plate when steady operating conditions are reached. The plate has an emissivity of 0.90 and the surrounding surfaces arc at 17°C.

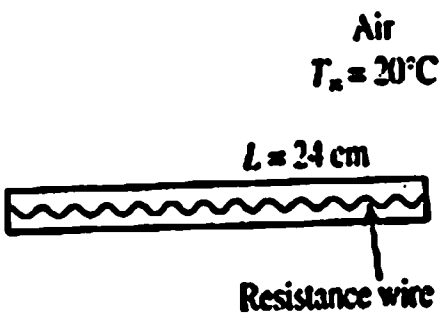


FIGURE P20–18

Step 1 of 10

Assume surface temperature of the plate is $T_s = 40°C$

Find the film temperature of air.

$$T_f = \frac{T_s + T_\infty}{2}$$

Here, T_s is surface temperature of the plate, and T_∞ is surrounding air temperature.

Substitute $40°C$ for T_s and $20°C$ for T_∞

$$T_f = \frac{40+20}{2}$$
$$= 30°C$$

Now take the properties of air at film temperature, $T_f = 30°C$ from table A-22, "properties of air" in the text book.

Thermal conductivity, $k = 0.02588\ \mathrm{W/m°C}$

Prandtl number, $\mathrm{Pr} = 0.7282$

Kinematic viscosity, $v = 1.608\times10^{-5}\ \mathrm{m^2/s}$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{30+273}$$
$$= 3.3\times10^{-3}\ \mathrm{K^{-1}}$$

Step 2 of 10

Find the characteristic length.

$$L_c = \frac{A_s}{p}$$

Here, A_s is surface area and p is perimeter.

Substitute $(0.24\times0.2)\mathrm{m^2}$ for A_s and $2(0.24+0.2)$ for p.

$$L_c = \frac{0.24\times0.20}{2(0.24+0.20)}$$
$$= 0.05455\ \mathrm{m}$$

Step 3 of 10

Find the Rayleigh number by using the following equation:

$$\mathrm{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{v^2}\cdot\mathrm{Pr}$$

Here, g is acceleration due to gravity.

Substitute $9.81\ \mathrm{m/s^2}$ for g, $3.3\times10^{-3}\ \mathrm{K^{-1}}$ for β, $40°C$ for T_s, $20°C$ for T_∞, 0.05455 m for L_c, $1.608\times10^{-5}\ \mathrm{m^2/s}$ for v, and 0.7282 for Pr.

$$\mathrm{Ra} = \frac{9.81\times3.3\times10^{-3}(40-20)(0.05455)^3}{\left(1.608\times10^{-5}\right)^2}\times0.7282$$
$$= 2.959\times10^5$$

Step 4 of 10

Find the heat transfer from the top surface.

Find the Nusselt number by using the following equation:

$$\mathrm{Nu} = 0.54\,\mathrm{Ra}^{0.25}$$

Substitute 2.959×10^5 for Ra.

$$\mathrm{Nu} = 0.54\left(2.959\times10^5\right)^{0.25}$$
$$= 12.5944$$

Find the heat transfer coefficient by using the following equation:

$$\mathrm{Nu} = \frac{h_{top}L_c}{k}$$
$$h_{top} = \frac{k\cdot\mathrm{Nu}}{L_c}$$

Substitute 12.5944 for Nu, 0.05455 m for L_c, and $0.02588\ \mathrm{W/m°C}$ for k.

$$h_{top} = \frac{0.02588\times12.594}{0.05455}$$
$$= 5.9749\ \mathrm{W/m^2.K}$$

$$h_{top} = \frac{0.02588 \times 12.394}{0.05455}$$
$$= 5.9749\ \text{W/m}^2\text{.K}$$

Step 5 of 10

Find the heat transfer from the top surface.

$$\dot{Q}_{top} = h A_s (T_s - T_\infty)$$

Substitute $5.9749\ \text{W/m}^2\text{.K}$ for h, $(0.24 \times 0.2)\text{m}^2$ for A_s, and $20°\text{C}$ for T_∞

$$\dot{Q}_{top} = 5.9749 \times 0.24 \times 0.2 (T_s - 20)$$
$$= 0.28679 (T_s - 20)$$

Step 6 of 10

Calculate the heat transfer from bottom surface:

Find the Nusselt number by using the following relation:

$$\text{Nu} = 0.27\,\text{Ra}^{0.25}$$

Substitute 2.959×10^5 for Ra.

$$\text{Nu} = 0.27 \left(2.959 \times 10^5\right)^{0.25}$$
$$= 6.297$$

Step 7 of 10

Find the heat transfer coefficient at bottom of the surface by using the following equation:

$$\text{Nu} = \frac{h_{bottom} L_c}{k}$$
$$h_{bottom} = \frac{k \cdot \text{Nu}}{L_c}$$

Substitute 6.297 for Nu, 0.05455 m for L_c, and $0.02588\ \text{W/m}°\text{C}$ for k.

$$h_{bottom} = \frac{0.02588 \times 6.297}{0.05455}$$
$$= 2.987\ \text{W/m}^2\text{.K}$$

Step 8 of 10

Find the heat transfer from the bottom surface.

$$\dot{Q}_{bottom} = h_{bottom} A_s (T_s - T_\infty)$$

Substitute $2.987\ \text{W/m}^2\text{.K}$ for h_{bottom}, $(0.24 \times 0.2)\text{m}^2$ for A_s, and $20°\text{C}$ for T_∞

$$\dot{Q}_{bottom} = 2.987 \times 0.24 \times 0.2 (T_s - 20)$$
$$= 0.14337 (T_s - 20)$$

Step 9 of 10

Write the expression for heat transfer due to radiation,

$$\dot{Q}_{rad} = \varepsilon (2A_s) \sigma \left(T_s^4 - T_{amb}^4\right)$$

Here, ε is emissivity of the plate and σ is Stefan Boltzmann's constant.

Here, $2A_s$ indicates radiation heat loss from top and bottom surfaces.

Substitute 0.9 for ε, (0.24×0.2) for A_s, $5.67 \times 10^{-8}\ \text{W/m}^2\text{.K}^4$ for σ, and $(17 + 273)\text{K}$ for T_{amb}

$$Q_{rad} = 0.9 \times 2 \times 0.24 \times 0.2 \times 5.67 \times 10^{-8} \left((T_s + 273)^4 - (17 + 273)^4\right)$$
$$= 0.4898 \times 10^{-8} \left((T_s + 273)^4 - (17 + 273)^4\right)$$

Step 10 of 10

Apply energy balance.

$$\dot{Q} = \dot{Q}_{rad} + \dot{Q}_{top} + \dot{Q}_{bottom}$$

Substitute 20W for $\dot{Q}$, $0.28679(T_s - 20)$ for $\dot{Q}_{top}$, $0.14337(T_s - 20)$ for $\dot{Q}_{bottom}$, and $0.4898 \times 10^{-8} \left((T_s + 273)^4 - (17 + 273)^4\right)$ for $\dot{Q}_{rad}$

$$20 = 0.4898 \times 10^{-9} \left[(T_s + 273)^4 - (290)^4\right] + (T_s - 20)[0.28679 + 0.14337]$$
$$T_s = 39.05°\text{C}$$

The surface temperature is approximately equal to $40°\text{C}$. So, our assumption of surface temperature is correct.

Therefore, the surface temperature of the plate is $\boxed{39.05°\text{C}}$

Question: 20.019P

Flue gases from an incinerator are released to atmosphere using a stack that is 0.6 m in diameter and 10.0 m high. The outer surface of the stack is at 40°C and the surrounding air 1 is at 10°C. Determine the rate of heat transfer from the stack I assuming (*a*) there is no wind and (*b*) the stack is exposed to 20 km/h winds.

Step 1 of 7

Diameter of the stack, $D = 0.6\text{m}$

Height of the stack, $H = 10\text{m}$

Temperature outside of stack, $T_s = 40°\text{C}$

Temperature of surrounding air, $T_{air} = 10°\text{C}$

Step 2 of 7

(a) The heat convected by the stack can be calculated only if the heat transfer coefficient is known. The heat transfer coefficient is determined from the Nusselt number. For determining the Nusselt number, we need the Rayleigh number and the Raleigh number can be calculated if the properties of the surrounding medium are known at film temperature.

The film temperature is given by the formula

$$T_f = \frac{T_s + T_{air}}{2}$$
$$= \frac{40+10}{2}$$
$$= 25°\text{C}$$

The properties of the air at 25°C are

Thermal conductivity, $k = 0.02551\text{W/m°C}$

Prandtl number, $\text{Pr} = 0.7296$

Kinematic viscosity, $\nu = 1.562\times10^{-5}\text{m}^2/\text{s}$

Step 3 of 7

The Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{25+273}$$
$$= 3.356\times10^{-3}\text{K}^{-1}$$

The characteristic length of the plate is

$$L_c = \frac{A_s}{p}$$
$$= \frac{\pi DH}{\pi D}$$
$$= H$$
$$= 10\text{m}$$

Step 4 of 7

The formula for Rayleigh number is

$$\text{Ra} = \frac{g\beta(T_s - T_{air})L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{(9.81)\left(3.356\times10^{-3}\right)(40-10)(10)^3}{\left(1.562\times10^{-5}\right)^2}(0.7296)$$
$$= 2.953\times10^{12}$$

Let us check if the stack can be assumed as a vertical plate. In-order to treat the stack as vertical plate, the condition that should be satisfied is $\frac{35L}{Gr^{0.25}} < 0.6$

$$\frac{35L_c}{Gr^{0.25}} = \frac{35\times L_c}{(\text{Ra}/\text{Pr})^{0.25}}$$
$$= \frac{35\times10}{\left(2.953\times10^{12}/0.7296\right)^{0.25}}$$
$$= 0.246$$

Since the obtained value of ratio is less than 0.6, we can treat the stack as vertical plate.

Step 5 of 7

Now calculate the Nusselt number using the relation for vertical plate

$$\text{Nu} = 0.1\text{Ra}^{1/3}$$
$$= 0.1\left(2.953\times10^{12}\right)^{1/3}$$
$$= 1433.3$$

The heat transfer coefficient is calculated using the formula

$$h = \frac{\text{Nu}\times k}{L_c}$$
$$= \frac{1433.3\times0.02551}{10}$$
$$= 3.656\ \text{W/m}^2\text{K}$$

The heat convected from the plate is given by

$$Q_{conv} = hA_s(T_s - T_{air})$$
$$= 3.656\times(\pi\times0.6\times10)\times(40-10)$$
$$= 2067.6\ \text{W}$$

Thus the heat convected from the stack is $\boxed{Q_{conv} = 2067.6\ \text{W}}$

Step 6 of 7

(b) When the stack is exposed to wind at 20 km/hr (5.55 m/s), the heat transfer from stack is due to forced convection. For forced convection, the heat transfer coefficient is determined from the Nusselt number which in turn is determined depending on the value of Reynolds number.

The formula for Reynolds number is

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{(5.55)(0.6)}{\left(1.562\times10^{-5}\right)}$$
$$= 2.134\times10^5$$

Now calculate the Nusselt number using the relation

$$\text{Nu} = 0.027(\text{Re})^{0.805}(\text{Pr})^{0.333}$$
$$= 0.027\left(2.134\times10^5\right)^{0.805}(0.7296)^{0.333}$$
$$= 474$$

Step 7 of 7

The heat transfer coefficient is calculated using the formula

$$h = \frac{\text{Nu}\times k}{D}$$
$$= \frac{474\times0.02551}{0.6}$$
$$= 20.153\ \text{W/m}^2\text{K}$$

The heat convected from the plate is given by

$$Q_{conv} = hA_s(T_s - T_{air})$$
$$= 20.153\times(\pi\times0.6\times10)\times(40-10)$$
$$= 11396.2\ \text{W}$$

Thus the heat convected from the stack when the wind blows is $\boxed{Q_{conv} = 11396.2\ \text{W}}$

Question: 20.020P

Thermal energy generated by the electrical resistance of a 5-mm-diameter and 4-m-long bare cable is dissipated to the surrounding air at 20°C. The voltage drop and the electric current across the cable in steady operation are measured to be 60 V and 1.5 A, respectively. Disregarding radiation, estimate the surface temperature of the cable.

Step 1 of 5

Thermal energy generated by electric resistance of cable

Diameter of cable $D = 5\text{ mm} = 5\times10^{-3}\text{ m}$

Length of cable $L = 4\text{ m}$

Voltage drop across the cable $dV = 60\text{ V}$

Electric current across the cable $I = 1.5\text{ A}$

Surrounding temperature $T_\infty = 20°\text{C}$

Step 2 of 5

The surface temperature of the cable can be determined by considering the heat convected by the cable. This can be calculated only if the heat transfer coefficient is known. The heat transfer coefficient is determined from the Nusselt number. For determining the Nusselt number, we need the Rayleigh number and the Raleigh number can be calculated if the properties of the surrounding medium are known at film temperature.

Let us assume the surface temperature as 100°C for calculating the film temperature

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{100+20}{2}$$
$$= 60°\text{C}$$

The properties of the air at 60°C are

Thermal conductivity, $k = 0.02808\text{ W/m°C}$

Prandtl number, $\text{Pr} = 0.7202$

Kinematic viscosity, $\nu = 1.896\times10^{-5}\text{ m}^2/\text{s}$

Step 3 of 5

The Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{60+273}$$
$$= 3.003\times10^{-3}\text{ K}^{-1}$$

The characteristic length is

$$L_c = D$$
$$= 5\times10^{-3}\text{ m}$$

Step 4 of 5

The formula for Rayleigh number is

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times\left(3.003\times10^{-3}\right)(100-20)\left(5\times10^{-3}\right)^3}{\left(1.896\times10^{-5}\right)^2}\times0.7202$$
$$= 590.202$$

Nusselt number can be calculated using

$$\text{Nu} = \left(0.6 + \frac{0.387\text{Ra}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right)^2$$
$$= \left(0.6 + \frac{0.387(590.202)^{1/6}}{\left[1+(0.559/0.7202)^{9/16}\right]^{8/27}}\right)^2$$
$$= 2.3456$$

Step 5 of 5

The heat transfer coefficient is calculated using the formula

$$h = \frac{\text{Nu}\times k}{D}$$
$$= \frac{2.3456\times0.02808}{0.005}$$
$$= 13.173\text{ W/m}^2\text{K}$$

The heat convected from the cable is given by

$$Q = hA_s(T_s - T_\infty)$$
$$T_s = \frac{Q}{hA_s} + T_\infty$$
$$= \frac{dV\times I}{hA_s} + T_\infty$$
$$= \frac{60\times1.5}{13.173\times\left(\pi\times5\times10^{-3}\times4\right)} + 20$$
$$= 128.74°\text{C}$$

Thus the surface temperature of the cable is $\boxed{T_s = 128.74°\text{C}}$

Question: 20.021P

A 12-m-long section of a 5-cm-diameter horizontal hot-water pipe passes through a large room whose temperature is 27°C. If the temperature and the emissivity of the outer surface of the pipe are 73°C and 0.8. respectively, determine the rate of heat loss from the pipe by (*a*) natural convection and (*b*) radiation.

Step 1 of 6

Given data:

Heat loss through the pipe is due to the convection and radiation.

Length of the pipe section, $L = 12\,\text{m}$

Diameter of pipe section, $D = 5\,\text{cm}$

Ambient (Room) temperature, $T_\infty = 27\,^\circ\text{C}$

Surface temperature of pipe, $T_s = 73^\circ\text{C}$

Emissivity, $\varepsilon = 0.8$

Step 2 of 6

(a) Heat transfer by natural convection:

Heat transfer coefficient can be calculated after finding the Rayleigh and Nusselt number.

By taking properties from the table at film temperature;

$$T_f = \frac{(T_s + T_\infty)}{2}$$

$$= \frac{(73+27)}{2}$$

$$= 50^\circ\text{C}$$

Prandlt number, $\text{Pr} = 0.7228$

Thermal conductivity, $k = 0.02735\,\text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\,\text{m/s}$

Step 3 of 6

Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{(50+273)}$$

$$= 3.0959\times10^{-3}\,\text{K}^{-1}$$

Also characteristic length;

$$L_C = D$$

$$= 0.05\,\text{m}$$

Step 4 of 6

Now calculating the Rayleigh,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)D^3}{\nu^2}\cdot\text{Pr}$$

$$= \frac{9.81\times3.0959\times10^{-3}\times(73-27)\times(0.05)^3}{\left(1.798\times10^{-5}\right)^2}\times0.7228$$

$$= 390456.9$$

As pipe is placed horizontally, the Nusselt number is calculated as

$$\text{Nu} = \left[0.6+\frac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.6+\frac{0.387(390456.9)^{\frac{1}{6}}}{\left[1+\left(\frac{0.559}{0.7228}\right)^{\frac{9}{16}}\right]^{\frac{8}{27}}}\right]^2$$

$$= 11.2257$$

Step 5 of 6

Now, heat transfer co-efficient is calculated as,

$$h = \frac{k}{D}\text{Nu}$$

$$= \frac{0.02735}{0.05}\times11.2257$$

$$= 6.1405\,\text{W/m}^2\cdot\text{K}$$

So, heat transfer by natural convection is calculated as,

$$\dot{Q} = hA(T_s - T_\infty)$$

$$= h\times\pi\times D\times L(T_s - T_\infty)$$

$$= 6.1405\times\pi\times0.05\times12(73-27)$$

$$= 532.43\,\text{W}$$

Hence, heat transfer by natural convection is $\boxed{\dot{Q} = 532.43\,\text{W}}$

Step 6 of 6

(b) Heat transfer by radiation is given by

$$Q_{rad} = EA\sigma\left(T_s^4 - T_\infty^4\right)$$

$$= 0.8\times\pi\times0.05\times12\times5.67\times10^{-8}\left[(346)^4-(300)^4\right]$$

$$= 8.55\times10^{-8}\left(6.2319\times10^9\right)$$

$$= 532.83\,\text{W}$$

Hence, heat transfer by radiation is $\boxed{Q_{rad} = 532.83\,\text{W}}$

Question: 20.022P

An average person generates heat at a rate of 240 Btu/h while resting in a room at 70°F. Assuming one-quarter of this heat is lost from the head and taking the emissivity of the skin to be 0.9, determine the average surface temperature of the head when it is not covered. The head can be approximated as a 12-in-diameter sphere, and the interior surfaces of the room can be assumed to be at the room temperature.

Step 1 of 6

Heat generated by person $\dot{Q} = 240\,\text{Btu/h}$

Room temperature $T_\infty = 70°\text{F}$

Heat lost from head $\dot{Q}_{\text{lost}} = 0.25\dot{Q} = 60\,\text{Btu/h}$

Emissivity of the skin $\varepsilon = 0.9$

Diameter of head $D = 12\text{in} = 1\text{ft}$

Temperature of room surface $T_{\text{amb}} = 70°\text{F}$

Step 2 of 6

Assume that the average surface temperature is $T_S = 85°\text{F}$

Calculate film temperature T_f,

$$T_f = (T_S + T_\infty)/2$$
$$= (85+70)/2$$
$$= 77.5°\text{F}$$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{77.5+460}$$
$$= 1.86\times10^{-3}\,\text{R}^{-1}$$

Step 3 of 6

Now take the properties of Air at 1atm and film temperature T_f,

Thermal conductivity,

$$k = 0.01457 + \frac{0.01481-0.01457}{(80-70)}(77.5-70)$$
$$= 0.01475\,\text{Btu/h}\cdot\text{ft}\cdot°\text{F}$$

Prandtl number,

$$\text{Pr} = 0.7306 + \frac{0.7290-0.7306}{(80-70)}(77.5-70)$$
$$= 0.7294$$

Kinematic viscosity,

$$\nu = 1.643\times10^{-4} + \frac{(1.697-1.643)10^{-4}}{(80-70)}(77.5-70)$$
$$= 1.6835\times10^{-4}\,\text{ft}^2/\text{s}$$

Step 4 of 6

Characteristic length,

$$L_c = D$$
$$= 1\text{ft}$$

Calculate the Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_S-T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{32.2\times1.86\times10^{-3}(85-70)(1)^3}{\left(1.6835\times10^{-4}\right)^2}\times(0.7294)$$
$$= 2.312\times10^7$$

Step 5 of 6

Nusselt number for sphere,

$$\text{Nu} = 2 + \frac{0.589\text{Ra}^{0.25}}{\left[1+(0.69/\text{Pr})^{9/16}\right]^{4/9}}$$
$$= 2 + \frac{0.589\left(2.312\times10^7\right)^{0.25}}{\left[1+(0.69/0.7294)^{9/16}\right]^{4/9}}$$
$$= 33.609$$

Neat transfer coefficient,

$$h = \frac{k}{L_c}\cdot\text{Nu}$$
$$= \frac{0.01475}{1}\times33.609$$
$$= 0.496\,\text{Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

Step 6 of 6

Surface Area,

$$A_S = \pi D^2$$
$$= \pi(1)^2$$
$$= 3.142\,\text{ft}^2$$

The total heat loss is due to both convection and radiation.

As, we know that the heat transfer rate by convection and radiation can be expressed as

$$\dot{Q}_{\text{lost}} = Q_{\text{conv}} + Q_{\text{rad}}$$
$$60 = hA_S(T_S-T_\infty) + \varepsilon A_S\sigma\left(T_S^4 - T_{\text{amb}}^4\right)$$
$$60 = 0.496(3.142)(T_S-70) + 0.9(3.142)\left(0.1714\times10^{-8}\right)\left[(T_S+460)^4-(70+460)^4\right]$$
$$60 = (1.558)(T_S-70) + \left(4.847\times10^{-9}\right)\left[(T_S+460)^4-(530)^4\right]$$

The temperature from the above equation is $T_S = 85°\text{F}$

Therefore the average surface temperature of the head when it is not covered is

$$\boxed{T_S = 83.18°\text{F}}$$

Question: 20.023P

An incandescent lightbulb is an inexpensive but highly inefficient device that converts electrical energy into light. It converts about 5 percent of the electrical energy it consumes into light while converting the remaining 95 percent into heat. The glass bulb of the lamp heats up very quickly as a result of absorbing all that heat and dissipating it to the surroundings by

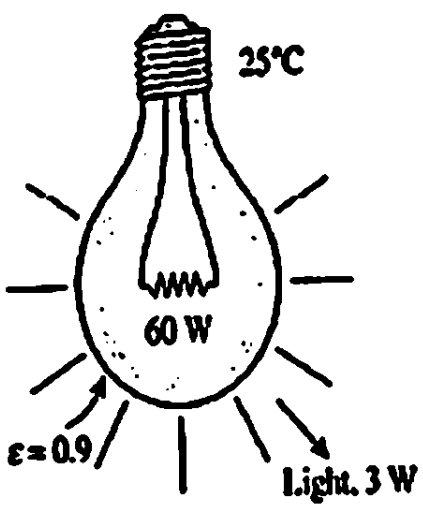

FIGURE P20–23

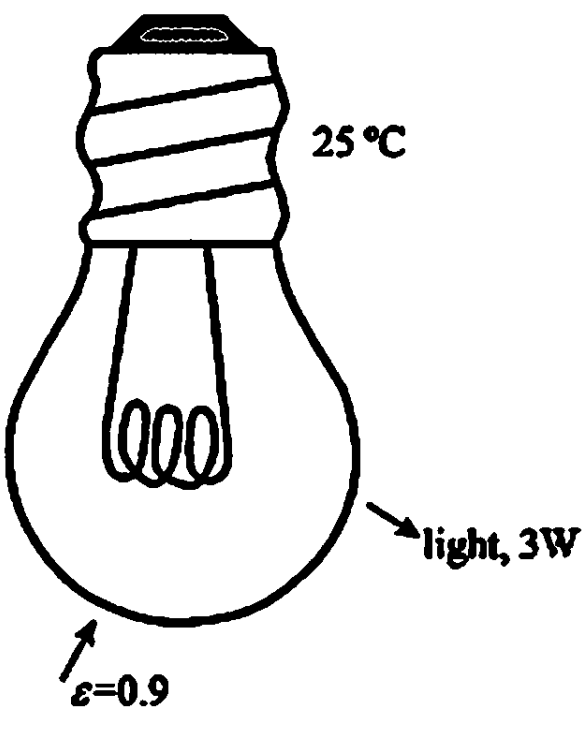
convection and radiation. Consider an 8-cm-diameter 60-W lightbulb in a room at 25°C. The emissivity of the glass is 0.9. Assuming that 5 percent of the energy passes through the glass bulb as light with negligible absorption and the rest of the energy is absorbed and dissipated by the bulb itself by natural convection and radiation, determine the equilibrium temperature of the glass bulb. Assume the interior surfaces of the room lo be at room temperature.

Step 1 of 7

Given data:

Diameter of bulb, $D = 8\text{cm}$



Wattage of bulb, $\dot{Q}_e = 60\,\text{W}$

Ambient temperature, $T_\infty = 25°\text{C}$

Emissivity of the glass, $\varepsilon = 0.9$

Step 2 of 7

Given figure:

Step 3 of 7

As it is converting 95% in to heat energy under steady condition heat generated,

Heat loss,

$\dot{Q} = 0.95 \times 60$

$\dot{Q} = 57\,\text{W}$

Assumptions:

(i) Steady conditions

(ii) Properties take at 1atm pressure.

(iii) Radiation and convection considered.

(iv) Assuming $T_S = 175°\text{C}$

To find T_s from the relation $\dot{Q} = hA(T_s - T_\infty)$ we need to calculate heat transfer Co-efficient (h)

By calculating Rayleigh and Nusselt number, we get

Film temperature of the given system,

$$T_f = \frac{(T_S + T_\infty)}{2}$$

$$= \frac{(175+25)}{2}$$

$$T_f = 100°\text{C}$$

Step 4 of 7

Taking properties from the table at $T_f = 100°\text{C}$

Prandtl number, $\text{Pr} = 0.7111$

Thermal conductivity, $k = 0.03095\ \text{W/m}\cdot°\text{C}$

Kinematic viscosity, $\nu = 2.306\times10^{-5}\,\text{m}^2/\text{s}$

Volume expansion coefficient,

$$\beta = 1/T_f$$

$$= \frac{1}{273+100}$$

$$= 2.6809\times10^{-3}$$

Characteristic length = Diameter of the bulb

= 0.08m

Step 5 of 7

Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_S - T_\infty)D^3}{\nu^2}\times\text{Pr}$$

$$= \frac{9.81\times2.6809\times10^{-3}\times(175-25)\times(0.08)^3}{(2.306\times10^{-5})^2}\times0.7111$$

$$= 2701055.25$$

Nusselt number considering sphere from the table,

Nusselt number,

$$\text{Nu} = 2 + \frac{0.589\text{Ra}^{1/4}}{\left(1+(0.469/\text{Pr})^{9/16}\right)^{4/9}}$$

$$= 2 + \frac{0.589\times(2701055.25)^{1/4}}{\left(1+\left(\frac{0.469}{0.7111}\right)^{9/16}\right)^{4/9}}$$

$$= 20.428$$

Step 6 of 7

Heat transfer coefficient,

$$h = \frac{k}{D}\text{Nu}$$

$$= \frac{0.03095\times20.428}{0.08}$$

$$= 7.903\,\text{W/m}^2\cdot°\text{C}$$

Surface area,

$$A_s = \pi D^2$$

$$= \pi(0.08)^2$$

$$= 0.02011\text{m}^2$$

Step 7 of 7

From the relation of the heat transfer, we get

$\dot{Q} = hA_S(T_S - T_\infty) + \varepsilon.A_S.\sigma\left(T_S^4 - T_\infty^4\right)$ (Because Radiation is also considered)

$$57 = 7.903\times0.02011(T_S - 25) + 0.9\times0.02011$$

$$\times5.67\times10^{-8}\left[(T_S+273)^4 - (298)^4\right]$$

$$57 = 0.15893(T_S - 25) + 1.0262\times10^{-9}\left[(T_S+273)^4 - (298)^4\right]$$

$$T_S = 174.84°\text{C}$$

This is approximately equal to assumed T_S that is 175°C

Therefore the equilibrium temperature of the glass tube, $\boxed{T_S = 174.84°\text{C}}$

Question:

A 450-W cylindrical resistance heater is 0.75 m long and 0.5 cm in diameter. The resistance wire is placed horizontally in a fluid at 20°C. Determine the outer surface temperature of the resistance wire in steady operation if the fluid is (*a*) air and (*b*) water. Ignore any heat transfer by radiation. Use properties at 500°C for air and 40°C for water.

Step 1 of 7

a) Calculate the surface temperature of the wire if the fluid is air:

Obtain the properties for air from properties of air table as follows:

Consider the properties of air are taken at $T_f = 500°C$.

At $T_f = 500°C$;

The thermal conductivity k is $0.05572\ W/m \cdot K$.

The kinematic viscosity ν is $7.806 \times 10^{-5}\ m^2/s$.

The Prandtl number Pr is 0.6986.

Calculate the value for expansion coefficient β:

$$\beta = \frac{1}{T_f}$$

Here, T_f is the average temperature.

Substitute 773 K $(500+273)$ K for T_f

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{(500+273)}$$
$$= 0.001294\ K^{-1}$$

Step 2 of 7

Calculate the Rayleigh Number:

Obtain the surface area of the heater as follows;

$$A_s = \pi DL$$

Here, *D* is the diameter of the heater and *L* is the length of the heater.

Substitute 0.005 m for *D* and 0.75 m for *L*

$$= \pi \times 0.005 \times 0.75$$
$$= 0.01178\ m^2$$

Obtain the characteristic length of the wire as follows.

$$L_c = D = 0.005\ m.$$

Assume the surface temperature to be $T_s = 1680°C$

Rayleigh Number,

$$Ra = \frac{g\beta(T_s - T_\infty)D^3}{\nu^2} Pr$$

Here, g is the acceleration due to gravity, β is the expansion coefficient, T_s is the surface temperature, T_∞ is the temperature of the fluid, D is the diameter of the heater, ν is the kinematic viscosity and Pr is the Prandtl number.

Substitute, $9.81\ m/s$ for *g*, 0.001294 for β, $1680°C$ for T_s, $20°C$ for T_∞, $0.005\ m$ for *D*, $7.806 \times 10^{-5}\ m^2/s$ for *v* and 0.6986 for Pr.

$$Ra = \frac{9.81 \times 0.001294 \times (1680-20) \times 0.005^3}{(7.806 \times 10^{-5})^2}(0.6986)$$
$$= \frac{2.634 \times 10^{-6}}{6.09 \times 10^{-9}}(0.6986)$$
$$= 302.153$$

Step 3 of 7

Calculate the Nusselt number by using the formula as follows:

$$Nu = \left\{0.6 + \frac{0.387 Ra^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2$$

Here, Ra is the Rayleigh number and Pr is the Prandtl number.

Substitute 302.153 for Ra and 0.6986 for Pr

$$= \left\{0.6 + \frac{0.387(302.153)^{1/6}}{\left[1+(0.559/0.6986)^{9/16}\right]^{8/27}}\right\}^2$$
$$= \left\{0.6 + \frac{1.0024}{1.20608}\right\}^2$$
$$= 2.048$$

Calculate the heat transfer coefficient using the formula as follows:

$$Nu = \frac{hD}{k}$$

Here, *h* is the heat transfer coefficient, *D* ids the diameter of the heater and Nu is the Nusselt number.

Substitute $0.05572\ W/m \cdot K$ for *k*, 0.005 m for *d* and 2.048 for Nu.

$$h = \frac{k}{D} Nu$$
$$= \frac{0.05572}{0.005} \times 2.048$$
$$= 22.822\ W/m^2 \cdot K$$

$$h = \frac{k}{D}\text{Nu}$$
$$= \frac{0.05572}{0.005} \times 2.048$$
$$= 22.822\ \text{W/m}^2 \cdot \text{K}$$

Calculate the heat transfer:

$$\dot{Q} = hA_s(T_s - T_\infty)$$

Here, T_s is the surface temperature, T_∞ is the temperature of the fluid, A_s is the surface area and h is the heat transfer coefficient.

Substitute $1680°C$ for T_s, $20°C$ for T_∞, $22.822\ \text{W/m}^2 \cdot \text{K}$ for h and $0.01178\,\text{m}^2$ for A_s.

$$450 = 22.822 \times 0.01178 \times (T_s - 20)$$

$$T_s = 1693.83°\text{C}$$

Since assumed surface temperature is approximately equal to the obtained value.

Hence the outer surface temperature T_s of the wire if the fluid is air is $\boxed{1693.83°\text{C}}$.

Step 4 of 7

b) Calculate the surface temperature of the wire if the fluid is water:

Obtain the properties for water from properties of saturated water table:

Consider the properties of air are taken at $T_f = 500°\text{C}$.

At $T_f = 40°\text{C}$;

The thermal conductivity k is $0.631\ \text{W/m} \cdot \text{K}$.

The kinematic viscosity ν is follows.

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{0.653 \times 10^{-3}}{992.1}$$
$$= 0.6582 \times 10^{-6}\ \text{m}^2/\text{s}$$

The Prandtl number Pr is 4.32.

Calculate the value for expansion coefficient β:

$$\beta = \frac{1}{T_f}$$

Here, T_f is the average temperature.

Substitute $313\ \text{K}(40 + 273)\ \text{K}$ for T_f

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{40 + 273}$$
$$= 0.00319\ \text{K}^{-1}$$

Step 5 of 7

Calculate the Rayleigh Number:

Obtain the surface area of the heater as follows;

$$A_s = \pi DL$$

Here, D is the diameter of the heater and L is the length of the heater.

Substitute 0.005 m for D and 0.75 m for L

$$= \pi \times 0.005 \times 0.75$$
$$= 0.01178\,\text{m}^2$$

Obtain the characteristic length of the wire as follows.

$$L_c = D = 0.005\ \text{m}.$$

Assume the surface temperature to be $T_s = 40°\text{C}$

Rayleigh Number,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)D^3}{\nu^2}\text{Pr}$$

Here, g is the acceleration due to gravity, β is the expansion coefficient, T_s is the surface temperature, T_∞ is the temperature of the fluid, D is the diameter of the heater, ν is the kinematic viscosity and Pr is the Prandtl number.

Substitute, $9.81\,\text{m/s}$ for g, 0.00319 for β, $40°C$ for T_s, $20°C$ for T_∞, $0.005\ \text{m}$ for D, $0.6582 \times 10^{-6}\,\text{m}^2/\text{s}$ for ν and 4.32 for Pr.

$$= \frac{9.81 \times 0.00319(40 - 20) \times 0.005^3}{(0.6582 \times 10^{-6})^2} \times 4.32$$
$$= \frac{78.23 \times 10^{-9}}{4.3323 \times 10^{-13}} \times 4.32$$
$$= 780078.94$$

Step 6 of 7

Calculate the Nusselt number by using the formula as follows:

$$\text{Nu} = \left\{0.6 + \frac{0.387\text{Ra}^{1/6}}{\left[1 + (0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2$$

Here, Ra is the Rayleigh number and Pr is the Prandtl number.

Substitute 780078.94 for Ra and 4.32 for Pr

$$\mathrm{Nu}=\left\{0.6+\frac{0.387\mathrm{Ra}^{1/6}}{\left[1+(0.559/\mathrm{Pr})^{9/16}\right]^{8/27}}\right\}^2$$

.024P pg 3

Here, Ra is the Rayleigh number and Pr is the Prandtl number.

Substitute 780078.94 for Ra and 4.32 for Pr

$$=\left\{0.6+\frac{0.387\times780078.94^{1/6}}{\left[1+(0.559/4.32)^{9/16}\right]^{8/27}}\right\}^2$$

$$=\left\{0.6+\frac{3.713}{1.085}\right\}^2$$

$$=16.177$$

Calculate the heat transfer coefficient using the formula as follows:

$$\mathrm{Nu}=\frac{hD}{k}$$

Here, h is the heat transfer coefficient, D ids the diameter of the heater and Nu is the Nusselt number.

Substitute $2041.53\ \mathrm{W/m\cdot K}$ for k, 0.005 m for d and 16.177 for Nu.

$$h=\frac{k}{D}\mathrm{Nu}$$

$$=\frac{0.631}{0.005}\times16.177$$

$$=2041.53\ \mathrm{W/m^2\cdot K}$$

Step 7 of 7

Calculate the heat transfer:

$$\dot{Q}=hA_s(T_s-T_\infty)$$

Here, T_s is the surface temperature, T_∞ is the temperature of the fluid, A_s is the surface area and h is the heat transfer coefficient.

Substitute $20°C$ for T_∞, $22.822\ \mathrm{W/m^2\cdot K}$ for h and $0.01178\ \mathrm{m^2}$ for A_s.

$$450=2041.53\times0.01178\times(T_s-20)$$

$$=\frac{450}{24.049}+20$$

$$T_s=38.711°\mathrm{C}$$

Since assumed surface temperature is approximately equal to the obtained value.

Hence the outer surface temperature T_s of the wire if the fluid is water is $\boxed{38.711°\mathrm{C}}$.

Question: 20.025P

In a plant that manufactures canned aerosol paints, the cans are temperature-tested in water baths at 60°C before they are shipped to ensure that they withstand temperatures up to 55°C during transportation and shelving. The cans, moving on a conveyor, enter the open hot water bath, which is 0.5 m deep, 1 m wide, and 3.5 m long, and move slowly in the hot water toward the other end. Some of the cans fail the test and explode in the water bath. The water container is made of sheet metal, and the entire container is at about the same temperature as the hot water. The emissivity of the outer surface of the container is 0.7. If the temperature of the surrounding air and surfaces is 20°C, determine the rate of heat loss from the four side surfaces of the container (disregard the top surface, which is open).

The water is heated electrically by resistance heaters, and the cost of electricity is $0.085/kWh. If the plant operates 24 h a day 365 days a year and thus 8760 h a year, determine the annual cost of the heat losses from the container for this facility.

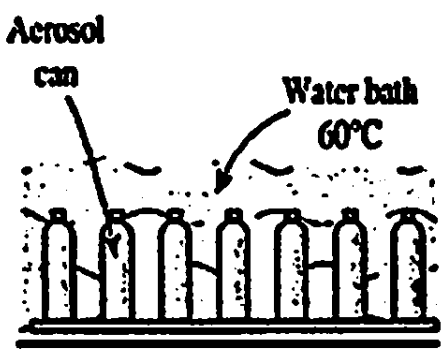


FIGURE P20–25

Step 1 of 7

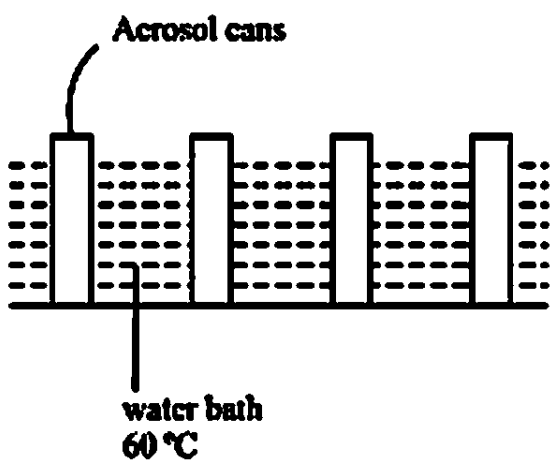
Given data:

Water bath temperature, $T_s = 60°C$

Depth of water bath, $L = 0.5m$

Surrounding air temperature, $T_\infty = 20°C$

Emissivity, $\varepsilon = 0.7$



Container dimensions, $3.5m \times 1m$

Cost of electricity is $\$0.085/kwh$

Operations hours, $t = 8760h$

Step 2 of 7

Schematic representation of the given system,

Step 3 of 7

Heat transfer rate of the given system,

$$\dot{Q} = hA_s(T_s - T_\infty)$$

h And A_s are unknown here, so that find the heat transfer coefficient

Taking properties of air at film temperature,

$$T_f = \frac{60+20}{2}$$

$$= 40°C$$

Thermal conductivity, $k = 0.02662 W/m \cdot °C$

Prandtl number, $Pr = 0.7255$

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{(273+40)}$$

$$= 3.19488 \times 10^{-3} K^{-1}$$

Kinematic viscosity, $\nu = 1.702 \times 10^{-5} m^2/s$

Characteristic length, $L_c = 0.5m$

Step 4 of 7

Rayleigh number,

$$Ra_L = \frac{g\beta(T_s - T_\infty)D^3}{\nu^2} \times Pr$$

$$= \frac{9.81 \times 3.19488 \times 10^{-3} \times (60-20) \times (0.5)^3}{(1.702 \times 10^{-5})^2} \times 0.7255$$

$$= 3.9247 \times 10^8$$

Considering vertical plate,

Nusselt number,

$$Nu = \left(0.825 + \frac{0.387 Ra^{1/6}}{(1+(0.492/Pr)^{9/16})^{8/27}}\right)^2$$

$$= \left(0.825 + \frac{0.387(3.9247 \times 10^8)^{1/6}}{\left(1+\left(\frac{0.492}{0.7255}\right)^{9/16}\right)^{8/27}}\right)^2$$

$$= 92.495$$

Step 5 of 7

Heat transfer co-efficient of the given system,

$$h = \frac{k}{L_c} Nu$$

$$= \frac{0.02662}{0.5} \times 92.495$$

$$= 4.9244 W/m^2 \cdot °C$$

Surface area of container with the given dimensions,

$$A_s = 2[(3.5 \times 0.5) + (1 \times 0.5)]$$

$$= 4.5m^2$$

Step 6 of 7

Heat lost by Convection,

$$\dot{Q}_{conv} = hA(T_s - T_\infty)$$

$$= 4.9244 \times 4.5 \times (60-20)$$

$$= 886.392 W$$

Heat lost by Radiation,

$$Q_{rad} = EA\sigma(T_s^4 - T_\infty^4)$$

$$= 0.7 \times 4.5 \times 5.67 \times 10^{-8}[(333)^4 - (293)^4]$$

$$= 879.865W$$

Step 7 of 7

Total heat loss of the given system,

$$Q_{total} = Q_{conv} + Q_{rad}$$

$$= 886.392 + 879.865$$

$$= 1766.26 W$$

$$= 1.7662 kW$$

Total Heat lost in a year,

$$Q = Q_{total} \times 8760$$

$$= 1.7662 \times 8760$$

$$= 15471.91 kW \cdot h$$

Total annual cost of the heat lost

cost = Heat lost in a year × cost of electricity

$$= 15471.91 \times 0.085$$

$$= \$1315.11$$

Therefore total annual cost of the heat lost, $\boxed{\text{cost} = \$1315.11}$

Question: 20.026P

Reconsider Prob. 20-25. In order to reduce the heating cost of the hot water, it is proposed to insulate the side and bottom surfaces of the container with 5-cm-thick fiberglass insulation (k= 0.035 W/m·K) and to wrap the insulation with aluminum foil (ε = 0.1) in order to minimize the heat loss by radiation. An estimate is obtained from a local insulation contractor, who proposes to do the insulation job for $350, including materials and labor. Would you support this proposal? How long will it take for the insulation to pay for itself from the energy it saves?

Step 1 of 8

Calculate heat transfer rate

$$\dot{Q}=hA_s\left(T_s-T_\infty\right)$$

Here,

The Convection heat coefficient is h

The cross-section area is A_s

Taking the properties by interpolation

At film temperature $T_f=22.5^\circ\text{C}$, take the properties of air,

Thermal conductivity,

$$k=0.02514+\frac{(0.02551-0.02514)}{(25-20)}(22.5-20)$$

$$=0.025325\,\text{W/m}^\circ\text{C}$$

Step 2 of 8

Kinematic viscosity,

$$\nu=1.516\times10^{-5}+\frac{10^{-5}(1.562-1.516)}{(25-20)}(22.5-20)$$

$$=1.539\times10^{-5}\,\text{m}^2/\text{s}$$

Prandtl number,

$$\text{Pr}=0.7309+\frac{(0.7296-0.7309)}{(25-20)}(22.5-20)$$

$$=0.73025$$

And

$$\beta=\frac{1}{T_f}$$

$$=\frac{1}{(22.5+273)}$$

$$=3.3841\times10^{-3}\text{K}^{-1}$$

Step 3 of 8

Calculate Rayleigh number,

$$Ra_L=\frac{g\beta(T_s-T_\infty)L_c^{\,3}}{\nu^2}\cdot\text{Pr}$$

$$=\frac{9.81\times3.841\times10^{-3}(25.0-20)(0.5)^3}{\left(1.539\times10^{-5}\right)^2}$$

$$=6.395\times10^7$$

Calculate Nusselt number,

$$Nu=\left[0.825+\frac{0.387(Ra)^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$=\left[0.825+\frac{0.387\left(6.397\times10^7\right)^{1/6}}{\left[1+\left(\frac{0.492}{0.73025}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$=53.68$$

Step 4 of 8

Calculate Heat transfer coefficient,

$$h=\frac{k}{L_c}Nu$$

$$=\frac{0.025325}{0.5}\times53.68$$

$$=2.72\,\text{W/m}^2{}^\circ\text{C}$$

Calculate the area of container,

$$A_s=2(0.5\times3.6+0.5\times1.1)$$

$$=4.7\,\text{m}^2$$

Calculate Heat loss rate by convection

$$Q_{conv}=hA_s\left(T_s-T_\infty\right)$$

$$=2.72\times4.7(25-20)$$

$$=63.89\,\text{W}$$

Step 5 of 8

Calculate Heat lost by Radiation

$$Q_{rad}=\varepsilon\sigma\text{A}\left(T_s^4-T_\infty^4\right)$$

$$=0.1\times5.67\times10^{-8}\times4.7\left((25+273)^4-(20+273)^4\right)$$

$$=13.753\,\text{w}$$

Calculate total heat loss,

$$Q_{total}=Q_{conv}+Q_{rad}$$

$$=63.89+13.753$$

$$Q_{total}=77.64\,\text{W}$$

Step 6 of 8

Now to verify that the assumed surface temperature (T_s) is now much accurate we till find T_s by conduction between tank and insulation and that is equal to Heat loss by insulation exposed surface under steady conditions.

Conduction between hot tank and insulation = Total heat loss by outer surface

$$kA_s\frac{T_{hot\,bath}-T_s}{L}=77.64$$

$$\frac{0.035\times4.7(60-T_s)}{0.05}=77.64$$

$$T_s=36.4^\circ\text{C}$$

Not very close but ok.

Step 7 of 8

Now calculate heat loss in year

$$Q_{year}=Q_{total}\times hrs\,in\,year$$

$$=77.64\times8760$$

$$=680126\,\text{W-h}$$

The cost of the power, $cost=0.085/\text{kWh}$

Therefore,

$$\text{Totalcost}=680.126\times0.085$$

$$=\$57.81$$

Money saved in one year $=1315-57.81$

$$=\$1257.189$$

Money to be spent to insulation $=\$350$

Step 8 of 8

Clear from figures obtained that pay back will take less than one year.

$$\text{Pay back duration}=\frac{350}{1257.189}\times365$$

$$=101.61\text{Days}$$

Therefore, the Payback period is $\boxed{101.61\text{Days}}$

I would support the proposal.

Question: 20.027P pg 1

Consider a 15-cm × 20-cm printed circuit board (PCB) that has electronic components on one side. The board is placed in a room at 20°C. The heat loss from the back surface of the board is negligible. If the circuit board is dissipating 8 W of power in steady operation, determine the average temperature of the hot surface of the board, assuming the board is (*a*) vertical; (*b*) horizontal with hot surface facing up; and (c) horizontal with hot surface facing down. Take the emissivity of the surface of the board to be 0.8 and assume the surrounding surfaces to be at the same temperature as the air in the room.

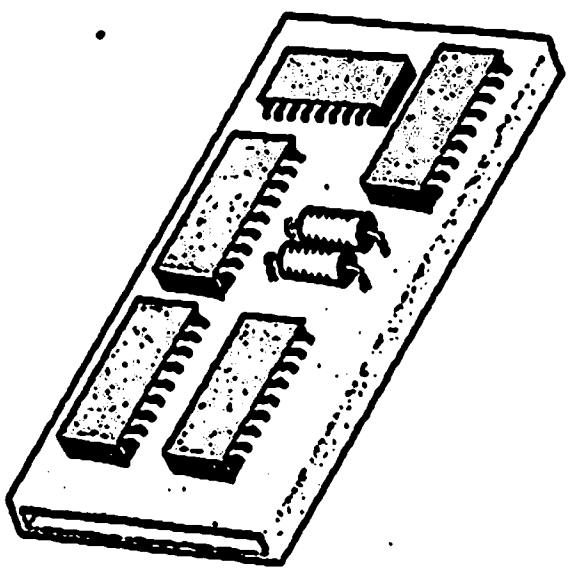


FIGURE P20–27

Step 1 of 12

Length of the Pinned circuit board, $L = 20\text{cm} = 0.2\text{m}$

Width of the Pinned circuit $W = 15\text{cm} = 0.15\text{m}$

Room temperature, $T_\infty = 20°\text{C}$

Heat dissipated, $\dot{Q} = 8\text{W}$

Emissivity $\varepsilon = 0.8$

Ambient temperature $T_{amb} = 20°\text{C}$

Step 2 of 12

Assuming the air temperature in the room as $T_s = 45$, calculate mean film temperature of the air

$$T_f = \frac{45+20}{2}$$
$$= 32.5°\text{C}$$

From the properties of air at 1 atm pressure and $T_f = 32.5°\text{C}$

By using the method of interpolation,

Thermal conductivity is

$$k = 0.02588 + \frac{(0.02625-0.02588)}{(35-30)}(32.5-30)$$
$$= 0.026065\ \text{W/m}\cdot°\text{C}$$

Prandtl number is

$$\text{Pr} = 0.7282 + \frac{0.7268-0.7282}{(35-30)}(32.5-30)$$
$$= 0.7275$$

Kinematic viscosity is

$$\nu = 1.608\times10^{-5} + \frac{(1.655-1.608)^{10^{-5}}}{(35-30)}\times(32.5-30)$$
$$= 1.6315\times10^{-5}\ \text{m}^2/\text{s}$$

Step 3 of 12

Volume expansion coefficient is

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{(273+32.5)}$$
$$= 3.273\times10^{-3}\text{K}^{-1}$$

Characteristic length

$$(L_c) = L$$
$$= 0.2\text{m}$$

Calculation Rayleigh number

$$\text{Ra}_L = \frac{g\beta(T_s-T_\infty)L_c^3}{\nu^2}\times\text{Pr}$$
$$= \frac{9.81\times3.273\times10^{-3}(45-20)(0.2)^3}{\left(1.6315\times10^{-5}\right)^2}\times0.7275$$
$$= 175.528\times10^5$$

Step 4 of 12

(a) Now Nusselt N_g for vertical printed circuit board is

$$\text{Nu} = \left[0.825 + \frac{0.387(\text{Ra}_L)^{1/6}}{\left[1+(0.492/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{0.387(175.528)^{1/6}}{\left[1+(0.492/0.7275)^{9/16}\right]^{8/27}}\right]^2$$
$$= 36.777$$

Heat transfer co-efficient,

$$h = \frac{k\times\text{Nu}}{L_c}$$
$$= \frac{0.026065}{0.2}\times36.777$$
$$= 4.7931\ \text{W/m}^2\cdot°\text{C}$$

Step 5 of 12

$= 4.7931\ \text{W/m}^2\cdot^\circ\text{C}$

Step 5 of 12

Total heat transfer by convection and radiation,

$$Q = Q_{conv} + Q_{rad}$$

$$Q = hA_s(T_s - T_\infty) + \varepsilon\sigma A_s\left(T_s^4 - T_{amb}^4\right)$$

$$8 = 4.7931(0.03)(T_s - 20) + 0.8\left(5.67\times10^{-8}\right)(0.03)\left[(T_s + 273)^4 - (20+273)^4\right]$$

By solving the above expression, we get $T_s = 46^\circ\text{C}$

Therefore average temperature of the hot surface board is $\boxed{T_s = 46^\circ\text{C}}$

Step 6 of 12

(b) Horizontal circuit board with hot surface facing up

Characteristic length in this set up

$$L_c = \frac{A_s}{p}$$

$$= \frac{(0.20\times0.15)}{2(0.2+0.15)}$$

$$= 0.04285\text{m}$$

Therefore calculate Rayleigh number.

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$

$$= \frac{9.81\times3.273\times10^{-3}\times(45-20)(0.04285)^3}{\left(1.6315\times10^{-5}\right)^2}\times0.7275$$

$$= 172696.48$$

Step 7 of 12

Calculate the Nusselt number by using the below equation

$$\text{Nu} = 0.54\text{Ra}^{1/4}$$

$$= 0.54(172696.48)^{1/4}$$

$$= 11.008$$

Therefore heat transfer coefficient,

$$h = \frac{k\times\text{Nu}}{L_c}$$

$$= \frac{0.026065\times11.008}{0.04285}$$

$$= 6.696\ \text{W/m}^2\cdot^\circ\text{C}$$

Step 8 of 12

Total heat transfer by convection and radiation,

$$Q = Q_{conv} + Q_{rad}$$

$$Q = hA_s(T_s - T_\infty) + \varepsilon\sigma A_s\left(T_s^4 - T_{amb}^4\right)$$

$$8 = 6.696(0.03)(T_s - 20) + 0.8\left(5.67\times10^{-8}\right)(0.03)\left[(T_s + 273)^4 - (20+273)^4\right]$$

By solving the above expression, we get $T_s = 42^\circ\text{C}$

Therefore average temperature of the hot surface when board facing up is $\boxed{T_s = 42^\circ\text{C}}$

Step 9 of 12

(c) Horizontal circuit board with hot surface facing down

Calculation made by assuming $T_s = 45^\circ\text{C}$ Are not sufficiently accurate for this set up so assuming $T_s = 50^\circ\text{C}$ In this case, calculate mean film temperature of the air.

$$T_f = (T_s + T_\infty)/2$$

$$= (50+20)/2$$

$$= 35^\circ\text{C}$$

From the properties of air at 1 atm pressure and $T_f = 35^\circ\text{C}$

Thermal conductivity is $k = 0.02625\ \text{W/m}\cdot^\circ\text{C}$

Prandtl number is $\text{Pr} = 0.7268$

Kinematic viscosity is $\nu = 1.655\times10^{-5}\ \text{m}^2/\text{s}$

Step 10 of 12

Volume expansion coefficient is

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{(50+273)}$$

$$= 3.2467\times10^{-3}\ \text{K}^{-1}$$

Characteristic length

$$L_c = \frac{A_s}{p}$$

$$= \frac{(0.20\times0.15)}{2(0.2+0.15)}$$

$$= 0.04285\text{m}$$

Step 11 of 12

Calculate the Rayleigh number.

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$

$$= \frac{9.81\left(3.2467\times10^{-3}\right)(50-20)(0.04285)^3}{\left(1.655\times10^{-5}\right)^2}\times0.7268$$

$$\mathrm{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot \mathrm{Pr}$$

$$= \frac{9.81\left(3.2467\times10^{-3}\right)(50-20)(0.04285)^3}{\left(1.655\times10^{-5}\right)^2}\times 0.7268$$

$$= 199482$$

Calculate the Nusselt number.

$$\mathrm{Nu} = 0.27(\mathrm{Ra}_L)^{0.25}$$

$$= 0.27(199482)^{0.25}$$

$$= 5.706$$

Step 12 of 12

Heat transfer co-efficient,

$$h = \frac{k}{L_c}\mathrm{Nu}$$

$$= \frac{0.02625}{0.04285}\times 5.706$$

$$= 3.496\,\mathrm{W/m^2\cdot^\circ C}$$

Total heat transfer by convection and radiation,

$$Q = Q_{conv} + Q_{rad}$$

$$Q = hA_s(T_s - T_\infty) + \varepsilon\sigma A_s\left(T_s^4 - T_{amb}^4\right)$$

$$8 = 3.496(0.03)(T_s - 20) + 0.8\left(5.67\times10^{-8}\right)(0.03)\left[(T_s+273)^4 - (20+273)^4\right]$$

By solving the above expression, we get $T_s = 50.3^\circ C$

Therefore average temperature of the hot surface when board faces down is $\boxed{T_s = 50.3^\circ C}$

Question: 20.028P

Reconsider Prob. 20-27. Using EES (or other) software, investigate the effects of the room temperature and the emissivity of the board on the temperature of the hot surface of the board for different orientations of the board. Let the room temperature vary from 5°C to 35°C and the emissivity from 0.1 to 1.0. Plot the hot surface temperature for different orientations of the board as the functions of the room temperature and the emissivity, and discuss the results.

Step 1 of 1

Given

Power dissipation is maintained constant at 60 W

Calculate the Convection heat transfer coefficient,

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$h = \frac{\dot{Q}}{A_s(T_s - T_\infty)}$$

Here,

Where heat transfer surface area is calculated as

$$A = \pi DL$$

$$= \pi(0.02\text{ m})(0.8\text{ m})$$

$$= 0.05027\text{ m}^2$$

Therefore heat transfer coefficient becomes

$$h = \frac{60\text{ W}}{(0.05027\text{ m}^2)(120-20)^\circ\text{C}}$$

$$\therefore h = 11.9355\text{ W/m}^2.^\circ\text{C}$$

The radiation heat loss from the cylinder is

$$\dot{Q}_{rad} = \varepsilon A_s\sigma(T_s^4 - T_{surr}^4)$$

$$= (0.1)(0.05027\text{ m}^2)(5.67\times10^{-8}\text{ W/m}^2.\text{K}^4)[(120+273\text{ K})^4 - (20+273\text{ K})^4]$$

$$= 4.7\text{ W}$$

Therefore, the fraction of heat loss by radiation is

$$\text{Radiation fraction} = \frac{\dot{Q}_{radiation}}{\dot{Q}_{total}}$$

$$= \frac{4.7\text{ W}}{60\text{ W}}$$

$$= 0.07833$$

$$= 7.833\%$$

This is greater than 5%. Therefore, the radiation effect is still more than acceptable, and corrections must be made for the radiation effect.

Question: 20.029P

Consider a vertical plate with length L, placed in quiescent air. If the Him temperature is 20°C and the average Nusselt number in natural convection is of the form $\mathrm{Nu} = \mathrm{CR}_L^n$, show that the average heat transfer coefficient can be expressed as

$h = 1.51(\Delta T/L)^{1/4}$ $\quad 10^4 < \mathrm{Ra}_L < 10^9$

$h = 1.19\Delta T^{1/3}$ $\quad 10^{10} < \mathrm{Ra}_L < 10^{13}$

Step 1 of 7

Given data:

Length of vertical plate is L

Mean film temperature, $T_f = 20°\mathrm{C}$

Nusselt number, $\mathrm{Nu} = C \times \mathrm{Ra}_L^n$

Step 2 of 7

From the ideal gas properties of the air at 1atm pressure,

At $T_f = 20°\mathrm{C}$

Thermal conductivity, $k = 0.02514\,\mathrm{w/m{\cdot}°C}$

Prandtl number, $\mathrm{Pr} = 0.7309$

Kinematic viscosity, $\nu = 1.516\times10^{-5}\,\mathrm{m^2/s}$

Volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{298}$$

$$= 3.413\times10^{-3}\mathrm{k}^{-1}$$

Characteristic length is the length of vertical plate (L)

Step 3 of 7

Rayleigh number,

$$\mathrm{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\times\mathrm{Pr}$$

$$= \frac{9.81\times3.413\times10^{-3}\times\Delta T\times L^3}{\left(1.516\times10^{-5}\right)^2}\times0.7309$$

$$= 1.0648\times10^8\,\Delta T\times L^3$$

where,

$\Delta T = T_s - T_\infty$ is the temperature difference

Step 4 of 7

From the empirical correlation for the average Nusselt number for natural convention over surfaces

For vertical plate,

Nusselt number for range of $\mathrm{Ra}\left(10^4 - 10^9\right)$

As given Nu in form of $C\times\mathrm{Ra}_L^n$

$$\mathrm{Nu} = 0.59\times\mathrm{Ra}_L^{0.25}$$

$$= 0.59\left(1.0648\times10^8\,\Delta T\times L^3\right)^{0.25}$$

Step 5 of 7

Now heat transfer coefficient,

$$h = \frac{k}{L_c}\mathrm{Nu}$$

$$= \frac{0.02514}{L}\times\left(0.59\left(1.0648\times10^8\,\Delta T\times L^3\right)^{0.25}\right)$$

$$= 1.51\left(\frac{\Delta T}{L}\right)^{1/4}$$

Therefore average heat transfer coefficient is $\boxed{h = 1.51\left(\frac{\Delta T}{L}\right)^{1/4}}$

Step 6 of 7

From the empirical correlation for the average Nusselt number for natural convention over surfaces

For vertical plate

Nusselt number for range of $\mathrm{Ra}\left(10^{10} - 10^{13}\right)$

$$\mathrm{Nu} = 0.1\times\mathrm{Ra}_L^{1/3}$$

$$= 0.1\times\left(1.0648\times10^8\,\Delta T\times L^3\right)^{1/3}$$

$$= 47.398\left(\Delta T\times L^3\right)^{1/3}$$

Step 7 of 7

Heat transfer co-efficient,

$$h = \frac{k}{L_c}\mathrm{Nu}$$

$$= \frac{0.02514}{L}\times\left(47.398\left(\Delta T\times L^3\right)^{1/3}\right)$$

$$= 1.19(\Delta T)^{1/3}$$

Therefore average heat transfer coefficient is $\boxed{h = 1.19(\Delta T)^{1/3}}$

Question: 20.030P

A circular grill of diameter 0.25 m has an emissivity of 0.8. If the surface temperature is maintained at 150°C, determine the required electrical power when the room air and surroundings are at 30°C.

Step 1 of 8

Given data:

Grill diameter, $d = 0.25\text{m}$

$$r = \frac{0.25}{2}$$

$$= 0.125\text{m}$$

Emissivity, $\varepsilon = 0.8$

Surface temperature, $T_s = 150°\text{C}$

Surrounding Ambient air Temperature, $T_\infty = 30°\text{C}$

Step 2 of 8

Considering the grill as a horizontal plate, we have

Mean film temperature of the air,

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{150+30}{2}$$

$$= 90°\text{C}$$

From the ideal gas properties of the air 1 atm pressure

At $T_f = 90°\text{C}$

Thermal conductivity, $k = 0.03024\,\text{w/m}\,°\text{k}$

Prandtl number, $\text{Pr} = 0.7132$

Kinematic viscosity, $\nu = 2.201\times10^{-5}\,\text{m}^2/\text{s}$

Step 3 of 8

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{363}$$

$$= 2.7548\times10^{-3}\text{K}^{-1}$$

Step 4 of 8

Characteristic length for horizontal plate

$$L_c = \frac{A_s}{p}$$

$$= \frac{\pi r^2}{2\pi r}$$

where

p is the perimeter

Therefore,

$L_c = r/2$

$= 0.0625\text{m}$

Step 5 of 8

Rayleigh number,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\times\text{Pr}$$

$$= \frac{9.81\times2.7548\times10^{-3}\times(150-30)(0.0625)^3}{\left(2.201\times10^{-5}\right)^2}\times0.7132$$

$$= 1.166\times10^6$$

Step 6 of 8

From the empirical correlation for the average Nusselt number for natural convention over surfaces

For horizontal plate:

Nusselt number,

$$\text{Nu} = 0.54\,\text{Ra}_L^{0.25}$$

$$= 0.54\times\left(1.166\times10^6\right)^{0.25}$$

$$= 17.743$$

Step 7 of 8

Now heat transfer co-efficient,

$$h = \frac{k}{L_c}\text{Nu}$$

$$= \frac{0.03024}{0.0625}\times17.743$$

$$= 8.585\,\text{W/m}^2.°\text{C}$$

Step 8 of 8

Total rate of heat transfer,

$$Q_{total} = Q_{conv} + Q_{rad}$$

$$= hA_s(T_s - T_\infty) + \varepsilon\sigma A_s\left(T_s^4 - T_{Amb}^4\right)$$

$$= 8.585\times\pi\times(0.125)^2\times(150-30)$$

$$+0.8\times5.67\times10^{-8}\times\pi\times(0.125)^2\left((423)^4-(303)^4\right)$$

$$= 103.08\,\text{W}$$

Therefore total rate of heat transfer, $\boxed{Q_{total} = 103.08\,\text{W}}$

Question:

A manufacturer makes absorber plates that are 1.2 m × 0.8 m in size for use in solar collectors. The back side of the plate is heavily insulated, while its front surface is coated with black chrome, which has an absorptivity of 0.87 for solar radiation and an emissivity of 0.09. Consider such a plate placed horizontally outdoors in

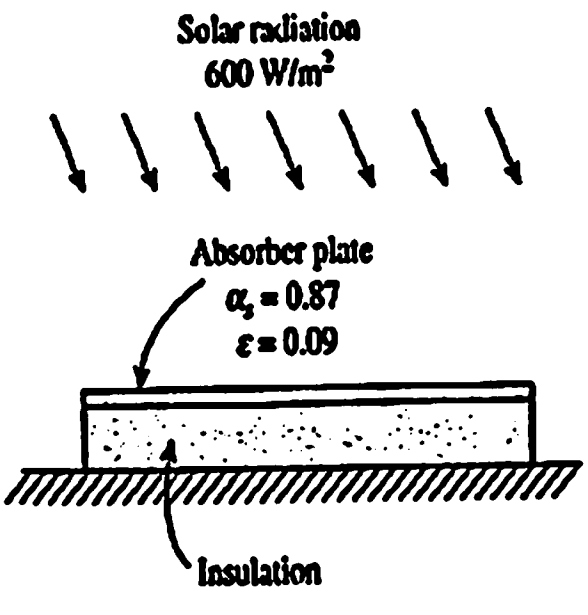

FIGURE P20–31

calm air at 25°C. Solar radiation is incident on the plate at a rate of 600 W/m2. Taking the effective sky temperature to be 10°C, determine the equilibrium temperature of the absorber plate. What would your answer be if the absorber plate is made of ordinary aluminum plate that has a solar absorptivity of 0.28 and an emissivity of 0.07?

Step 1 of 14

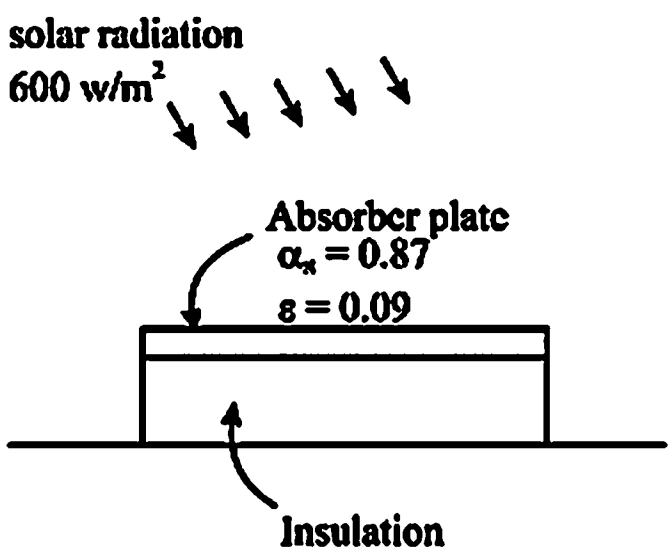
Given data:

Length of absorber plate, $L = 1.2\text{m}$

Width of absorber plate, $W = 0.8\text{m}$

Absorptivity of front side, $(\alpha_s) = 0.87$

Emissivity of the plate, $\varepsilon = 0.09$



Ambient air temperature, $T_\infty = 25°\text{C}$

Solar radiation rate, $\dot{q} = 600\,\text{w/m}^2$

Effect sky temperature, $(T_{amb}) = 10°\text{C}$

Step 2 of 14

Schematic representation of the given system,

Step 3 of 14

Let us assume the surface temperature of the plate is $T_s = 100°\text{C}$

Therefore mean film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= 62.5°\text{C}$$

Step 4 of 14

From the ideal gas properties of the air 1 atm pressure,

At $T_f = 62.5°\text{C}$

By Using the Method of Interpolation

Thermal conductivity,

$$k = 0.02808 + \frac{0.02881 - 0.02808}{(70 - 60)}(62.5 - 60)$$

$$= 0.0282625\,\text{w/m}\cdot°\text{C}$$

Prandtl number,

$$\text{Pr} = 0.7202 + \frac{0.7177 - 0.7202}{(70 - 60)}(62.5 - 60)$$

$$= 0.719575$$

Kinematic viscosity,

$$\nu = 1.896 \times 10^{-5} + \frac{(1.995 - 1.896)10^{-5}}{(70 - 60)} \times (62.5 - 60)$$

$$= 1.92075 \times 10^{-5}\,\text{m}^2/\text{s}$$

Step 5 of 14

Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= 2.9806 \times 10^{-3}\,\text{K}^{-1}$$

Characterize length = length of the plate

$$= A_s / p$$

where

p = Perimeter of plate

A_s = Area of plate

Therefore characteristic length,

$$L_c = \frac{1.2 \times 0.8}{2(1.2 + 0.8)}$$

$$= 0.24\,\text{m}$$

Step 6 of 14

Rayleigh number,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2} \times \text{Pr}$$

$$9.81 \times 2.9806 \times 10^{-3}(100 - 25)(0.24)^3$$

Rayleigh number,

$$\mathrm{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2} \times \mathrm{Pr}$$

$$= \frac{9.81 \times 2.9806 \times 10^{-3}(100-25)(0.24)^3}{\left(1.92075 \times 10^{-5}\right)^2}$$

$$= 5.9129 \times 10^7$$

From the empirical correlation for the average Nusselt number for natural convention over surfaces

For horizontal plate of upper surface

Nusselt number for range $\left(10^7 - 10^{11}\right)$

$$\mathrm{Nu} = 0.15\left(\mathrm{Ra}_L\right)^{1/3}$$

$$= 0.15 \times \left(5.9129 \times 10^7\right)^{1/3}$$

$$= 58.44$$

Step 7 of 14

Heat transfer co-efficient,

$$h = \frac{k}{L_c} \times Nu$$

$$= \frac{0.028265}{0.24} \times 58.44$$

$$= 6.882 \mathrm{w/m^2 \cdot ^\circ C}$$

Surface area of the plate,

$$A_s = 0.12 \times 0.8$$

$$= 0.96 \mathrm{m^2}$$

Step 8 of 14

Heat again = heat lost by convection and radiation

Heat gain by solar radiation,

$$\dot{Q} = \alpha_s \cdot \dot{q} \cdot A_s$$

$$= 0.87 \times 600 \times 0.96$$

$$\dot{Q} = 501.12 \mathrm{w}$$

Step 9 of 14

To calculate temperature (T_s), we will use heat transfer equation

$$Q_{total} = h A_s (T_s - T_\infty) + \varepsilon A \sigma \left(T_s^4 - T_{Amb}^4\right)$$

$$501.12 = hA(T_s - T_\infty) + \sigma A E \left(T_s^4 - T_{amb}^4\right)$$

$$= 6.882 \times 0.96 (T_s - 25) + 5.67 \times 10^{-8} \times 0.96 \times 0.09$$

$$\left((T_s + 273)^4 283^4\right)$$

$$501.12 = 6.607(T_s - 25) + 4.9 \times 10^{-9}\left((T_s + 273)^4 - (283)^4\right)$$

$$T_s = 92.38^\circ \mathrm{C}$$

Step 10 of 14

If solar absorptivity, $\alpha_s = 0.28$

And emissivity, $\varepsilon = 0.07$

Then heat gain by solar radiation,

$$\dot{Q} = \alpha_s \cdot \dot{q} \cdot A_s$$

$$= 0.28 \times 600 \times 0.96$$

$$= 161.28 \mathrm{W}$$

Step 11 of 14

On substituting the known values in the above equation Q_{total}, we get

$$161.28 = 6.882 \times 0.96 (T_s - 25) + 5.67 \times 10^{-8}$$

$$\times 0.96 \times 0.07\left((T_s + 273)^4 - (283)^4\right)$$

$$161.28 = 6.6067(T_s - 25) + 3.81024 \times 10^{-9}\left((T_s + 273)^4 - (283)^4\right)$$

$$T_s = 47.058^\circ \mathrm{C}$$

This is not close to assumed one i.e. 100°C

Step 12 of 14

We need to assume T_s again for calculation near 50 say.

Assuming the surface temperature of the plate, $T_s = 55^\circ$

Mean film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= 40^\circ \mathrm{C}$$

Thermal conductivity, $k = 0.02662 \mathrm{W/m \cdot ^\circ C}$

Prandtl number, $\mathrm{Pr} = 0.7255$

Kinematic viscosity, $\nu = 1.702 \times 10^{-5} \mathrm{m^2/s}$

Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= 3.1949 \times 10^{-3} \mathrm{K^{-1}}$$

Step 13 of 14

Nusselt, Rayleigh numbers and heat transfer co-efficient, h

$$\mathrm{Ra}_L = \frac{9.81 \times 3.1949 \times 10^{-3}(55-25)(0.24)^3}{\left(1.702 \times 10^{-5}\right)^2} \times 0.7255$$

$$= 3.255 \times 10^{-7}$$

Nusselt number,

$$\mathrm{Nu} = 0.15\left(3.255 \times 10^7\right)^{1/3}$$

$$= 47.895$$

$= 3.255 \times 10^{-7}$

Nusselt number,

$$Nu = 0.15\left(3.255 \times 10^{7}\right)^{1/3}$$

$$= 47.895$$

Heat transfer co-efficient,

$$h = \frac{0.02662}{0.24} \times 47.895$$

$$= 5.312\ W/m^2 \cdot K$$

Step 14 of 14

Now putting the values in the heat transfer rate equation

$$\dot{Q} = h A_s (T_s - T_\infty) + E A_s \sigma \left(T_s^4 - T_{amb}^4\right)$$

$$161.28 = 5.312 \times 0.96 (T_s - 25) + 5.67 \times 10^{-8} \times 0.96 \times 0.07 \left((T_s + 273)^4 - (283)^4\right)$$

$$161.28 = 5.0999 (T_s - 25) + 3.31024 \times 10^{-9} \left((T_s + 273)^4 - (283)^4\right)$$

$$T_s = 53.418^\circ C$$

Therefore the surface temperature of the plate, $\boxed{T_s = 53.418^\circ C}$

Question:

Repeat Prob. 20-31 for an aluminum plate painted flat black (solar absorptivity 0.98 and emissivity 0.98) and also for a plate painted white (solar absorptivity 0.26 and emissivity 0.90).

Step 1 of 12

Let us assume the surface temperature of the plate is $T_s = 70°C$

Then,

Mean film temperature is

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{70+25}{2}$$
$$= 47.5°C$$

Step 2 of 12

From the ideal gas properties of the air 1 atm pressure,

At $T_f = 47.5°C$

Calculate the thermal conductivity of the system,

$$k = 0.2699 + \frac{0.02735 - 0.02699}{(50-45)}(47.5-45)$$
$$= 0.02717\ W/m\cdot°C$$

Step 3 of 12

Calculate the Prandtl number,

$$Pr = 0.7241 + \frac{0.7228 - 0.7241}{(50-45)}(47.5-45)$$
$$= 0.7235$$

Calculate the Kinematic viscosity,

$$\nu = 1.750\times10^{-5} + \frac{(1.798-1.750)10^{-5}}{(50-45)}\times(47.5-45)$$
$$= 1.774\times10^{-5}\ m^2/s$$

Step 4 of 12

Calculate the Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

Where,

T_f is the mean film temperature

Substitute the respective values in the above equation,

$$\beta = \frac{1}{(47.5+273)}$$
$$= 3.1201\times10^{-3}\ k^{-1}$$

Step 5 of 12

Characterize length = length of the plate

$$L_c = \frac{A_s}{p}$$

Where as,

p = Perimeter of plate

A_s = Area of plate

$$L_c = \frac{1.2\times0.8}{2(1.2+0.8)}$$
$$= 0.24\ m$$

Step 6 of 12

Calculate the Rayleigh number,

$$Ra_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}Pr$$

Where,

T_∞ is Ambient air temperature and

g is acceleration due to gravity.

Substitute the respective values in the above equation,

$$Ra_L = \frac{9.81\times3.1201\times10^{-3}(70-25)(0.24)^3}{\left(1.774\times10^{-5}\right)^2}\times0.7235$$
$$= 4.379\times10^7$$

Step 7 of 12

For horizontal plate of upper surface, the Nusselt number,

$$Nu = 0.15\left(Ra_L\right)^{1/4}$$
$$= 0.54\times\left(4.379\times10^7\right)^{1/4}$$
$$= 43.93$$

Step 8 of 12

Calculate the Heat transfer co-efficient,

$$h = \frac{k}{L_c}\times Nu$$
$$= \frac{0.02717}{0.24}\times43.93$$
$$= 4.973\ W/m^2\cdot°C$$

Calculate the Surface area of the plate,

$$A_s = 0.12\times0.8$$
$$= 0.96\ m^2$$

Step 9 of 12

$A_s = 0.12 \times 0.8$

$= 0.96\text{m}^2$

Step 9 of 12

As it's a steady operation,
Heat gain = heat lost by convection and radiation
Heat gain by solar radiation

$$\dot{Q} = \alpha_s \dot{q} A_s$$

Where,
$\dot{q}$ is the Solar radiation rate and
α_s is the Absorbivity of front side

Substitute $\left(600\text{w/m}^2\right)$ for $\dot{q}$, 0.98 for α_s and the respective values in the above equation,

$$\dot{Q} = 0.98 \times 600 \times 0.96$$
$$= 564.48\text{W}$$

Step 10 of 12

To calculate temperature (T_s), we can use heat transfer equation,

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A \sigma\left(T_s^4 - T_{amb}^4\right)$$

Where,
T_{amb} is the Effect sky temperature,
ε is the Emissivity of the plate,

Substitute 10°C for T_{amb}, 0.98 for ε and the respective values in the above equation,

$$564.48 = hA(T_s - T_\infty) + \sigma AE\left(T_s^4 - T_{amb}^4\right)$$
$$= 4.973 \times 0.96(T_s - 25) + 5.67 \times 10^{-8} \times 0.96 \times 0.98\left[(T_s + 273)^4 - (10 + 273)^4\right]$$
$$T_s = 66.4886°\text{C}$$

The temperature of the absorber plate is close to the assumed value,
Therefore, the temperature of the black colored absorber plate is $\boxed{66.4886°\text{C}}$.

Step 11 of 12

If the plate is painted with white color, then the solar absorptivity is $\alpha_s = 0.26$ and emissivity is $\varepsilon = 0.9$
Then heat gain by solar radiation,

$$\dot{Q} = \alpha_s \dot{q} A_s$$

Substitute the respective values in the above equation,

$$\dot{Q} = 0.26 \times 600 \times 0.96$$
$$= 149.76\text{W}$$

Step 12 of 12

To calculate temperature (T_s), we can use heat transfer equation,

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A \sigma\left(T_s^4 - T_{amb}^4\right)$$
$$149.76 = 4.973 \times 0.96 \times (T_s - 25) + 5.67 \times 10^{-8} \times 0.96 \times 0.9 \times \left[(T_s + 273)^4 - (10 + 273)^4\right]$$
$$T_s = 32.6411°\text{C}$$

Therefore, the temperature of the white colored absorber plate is $\boxed{32.6411°\text{C}}$.

Question: 20.033P

A room is to be heated by a coal-burning stove, which is a cylindrical cavity with an outer diameter of 50 cm and a height of 120 cm. The rate of heat loss from the room is estimated to be 1.5 kW when the air temperature in the room is maintained constant at 24°C. The emissivity of the stove surface is 0.85, and the average temperature of the surrounding wall surfaces is 14°C. Determine the surface temperature of the stove. Neglect the heat transfer from the bottom surface and take the heat transfer coefficient at the top surface to be the same as that on the side surface.

The heating value of the coal is 30,000 kJ/kg, and the combustion efficiency is 65 percent. Determine the amount of coal burned a day if the stove operates 14 h a day.

Step 1 of 9

Given data:

Outer diameter of stove, $D = 50\,\text{cm} = 0.5\,\text{m}$

Height of stove, $L = 120\,\text{cm} = 1.2\,\text{m}$

Air temperature in room, $T_\infty = 24°\text{C}$

Surrounding wall temperature, $T_{amb} = 14°\text{C}$

Emissivity of stove surface, $\varepsilon = 0.85$

Heating value of coal $= 30000\,\text{kJ/kg}$

Combustion efficiency, $\eta = 65\% = 0.65$

Operations hours $= 14$

Rate of heat loss, $Q_{total} = 1.5\text{kW}$

Step 2 of 9

Let us assume the surface temperature of the cylinder, $T_s = 76°\text{C}$

Then mean film temperature,

$$T_f = \frac{(T_s + T_\infty)}{2}$$

$$= \frac{(76+24)}{2}$$

$$= 50°\text{C}$$

From the properties of air at 1 atm pressure table, the properties of air at 50°C,

Thermal conductivity, $k = 0.02735\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7228$

Step 3 of 9

Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{(273+50)}$$

$$= 3.0960\times10^{-3}\,\text{k}^{-1}$$

Characteristic length = height of vertical cylinder

$$L_c = L$$

$$= 1.2\,\text{m}$$

Step 4 of 9

Rayleigh number,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\times\text{Pr}$$

$$= \frac{9.81\times3.096\times10^{-3}(76-24)(1.2)^3}{\left(1.793\times10^{-5}\right)^2}\times0.7228$$

$$= 6.101\times10^9$$

Step 5 of 9

By using the condition for checking if we can treat cylinder as a vertical plate or not, we have

$$D \geq \frac{35L}{\text{Gr}_L^{0.25}}$$

$$\geq \frac{35L}{\left(\frac{\text{Ra}_L}{\text{Pr}}\right)^{0.25}} \qquad \left(\text{since, } \text{Gr}_L = \frac{\text{Ra}_L}{\text{Pr}}\right)$$

$$\geq \frac{35L}{\left(\frac{6.101\times10^9}{0.7228}\right)^{0.25}}$$

$$\geq \frac{35\times1.2}{303.115}$$

$$D \geq 0.13856$$

Given that, $D = 0.5\text{m}$

As it is satisfying the equation, we will treat the outer curvature as a vertical plate.

Step 6 of 9

By using empirical correlations for the average Nusselt number for vertical plate, we get

$$\text{Nu} = \left[0.825 + \frac{0.387\left(R_{a_L}\right)^{1/6}}{\left[1+\left(\frac{0.492}{p_r}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.825 + \frac{0.387\left(6.101\times10^9\right)^{1/6}}{\left[1+\left(\frac{0.492}{0.7228}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= 216.42$$

Step 7 of 9

Using formula for heat transfer co-efficient, we get

$$h = \frac{k}{L_c}\text{Nu}$$

$$= \frac{0.02735}{1.2}\times216.42$$

$$= 4.9326\,\text{W/m}^2\cdot\text{k}$$

Step 8 of 9

By using heat loss rate equation (considering both convection and radiation), we get

$$Q_{total} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma\left(T_s^4 - T_{amb}^4\right)$$

$$1500 = 4.9326\times2.081\times(T_s - 24) + 0.85\times2.081$$

$$\times5.67\times10^{-8}\times\left((T_s+273)^4 - (287)^4\right)$$

$$1500 = 10.265(T_s - 24) + 1.003\times10^{-7}\left((T_s+273)^4 - (287)^4\right)$$

$$T_s = 81.72°\text{C}$$

Therefore, surface temperature of stove is $\boxed{T_s = 81.72°\text{C}}$.

Step 9 of 9

Total heat production $= 1.5\text{kW} = 1.5\text{kJ/s}$

14 operating hours per day is given

Therefore,

Amount of heat produced,

$$Q = 1.5\times14\times3600$$

$$Q = 75600\,\text{kJ}$$

Now heat value of coal $= 30000\,\text{kJ/kg}$

By using the formula for coal consumed, we get

$$m = \frac{Q/\eta}{\text{heating value}}$$

$$= \frac{75600/0.65}{30000}$$

$$= 3.88\,\text{kg}$$

Therefore, amount of cola burned per day is $\boxed{m = 3.88\,\text{kg}}$.

Question:

Thick fluids such as asphalt and waxes and the pipes in which they flow are often heated in order to reduce the viscosity of the fluids and thus to reduce the pumping costs. Consider the flow of such a fluid through a 100-m-long pipe of outer diameter 30 cm in calm ambient air at 0°C. The pipe is heated electrically, and a thermostat keeps the outer surface temperature of the pipe constant at 25°C. The emissivity of the outer surface of the pipe is 0.8, and the effective sky temperature is –30°C. Determine the power rating of the electric resistance heater, in kW, that needs to be used. Also, determine the cost of electricity associated with heating the pipe during a 15-h period under the above conditions if the price of electricity is $0.09/kWh.

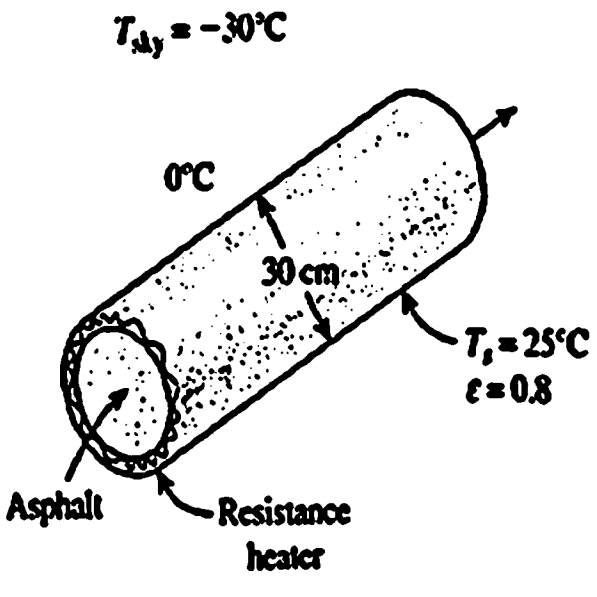


FIGURE P20–34

Step 1 of 9

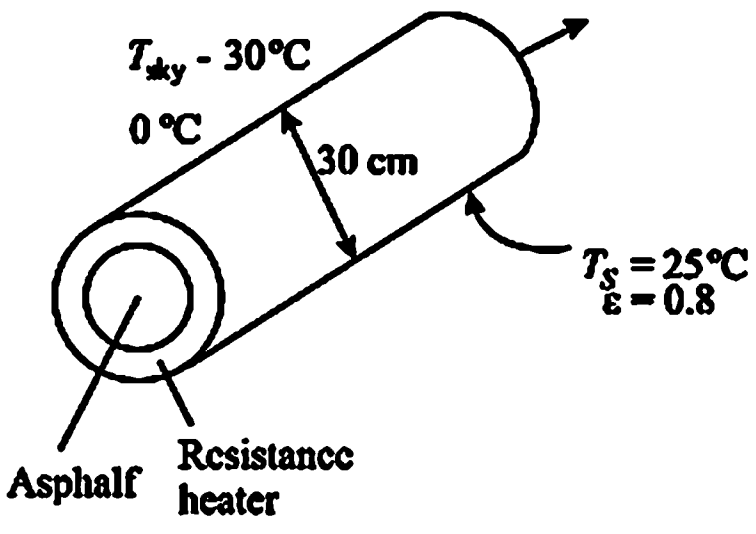
Given data:

Length of the pipe, $L = 100\,\text{m}$

Diameter of the pipe, $D = 30\,\text{cm} = 0.3\text{m}$

Ambient air, $T_\infty = 0°C$

Surface temperature of pipe, $T_s = 25°C$



Emissivity, $\varepsilon = 0.8$

Effective sky temperature, $T_{amb} = -30°C$

Price of electricity $= \$0.09/\text{kWh}$

Step 2 of 9

The pipe is as shown in figure,

Step 3 of 9

By using Mean film temperature formula, we get

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= 12.5°C$$

From the properties of air at mean film temperature and 1 atm pressure by using the method of interpolation,

The thermal conductivity,

$$k = (0.02476 + 0.02439)/2$$

$$= 0.024575\,\text{W/m}\cdot\text{K}$$

The Prandtl number,

$$\text{Pr} = (0.7323 + 0.7336)/2$$

$$= 0.73295$$

Kinematic viscosity

$$\nu = (1.470 + 1.426)/2 \times 10^{-5}$$

$$= 1.448 \times 10^{-5}\,\text{m}^2/\text{s}$$

Step 4 of 9

Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{285.5}$$

$$= 3.5026 \times 10^{-3}\,\text{K}^{-1}$$

Characteristic length = diameter of pipe

$$L_c = D$$

$$= 0.3\text{m}$$

Step 5 of 9

Now, Rayleigh number,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2} \times \text{Pr}$$

$$= \frac{9.81 \times 3.5026 \times 10^{-3}(25-0)(0.3)^3}{(1.448 \times 10^{-5})^2} \times (0.73295)$$

$$= 8.108 \times 10^7$$

Step 6 of 9

By using Nusselt number formula, we get

$$\text{Nu} = \left[0.6 + \frac{0.387(\text{Ra}_L)^{1/6}}{\left[1 + \left(\frac{0.559}{\text{Pr}}\right)^{9/16}\right]^{8/27}} \right]^2$$

$$= \left[0.6 + \frac{0.387(8.108 \times 10^7)^{1/6}}{\left[1 + \left(\frac{0.559}{0.73295}\right)^{9/16}\right]^{8/27}} \right]^2$$

$$\left[1+\left(\frac{0.559}{\mathrm{Pr}}\right)^{9/16}\right]^{20}\Bigg] \quad \text{034P pg 2}$$

$$= \left[0.6+\frac{0.387\left(8.108\times10^{7}\right)^{1/6}}{\left[1+\left(\frac{0.559}{0.73295}\right)^{9/16}\right]^{8/27}}\right]^{2}$$

$$= 53.296$$

Step 7 of 9

Heat transfer co-efficient,

$$h = \frac{k}{L_c}\mathrm{N_u}$$

$$= \frac{0.024575}{0.3}\times(53.296)$$

$$= 4.366\,\mathrm{W/m^2\cdot K}$$

Surface area of the plate,

$$A_s = \pi\Delta L$$

$$= \pi\times0.3\times100$$

$$= 94.248\,\mathrm{m^2}$$

Step 8 of 9

Power rating of electric resistance heater = heat loss rate from cylinder by convection and radiation

$$\dot{Q} = hA_s\left(T_s - T_\infty\right) + \varepsilon A_s\sigma\left(T_s^4 - T_{amb}^4\right)$$

$$= 4.366\times94.28\times(25-0) + 0.8\times94.248 \times5.67\times10^{-8}\left(298^4 - 243^4\right)$$

$$= 29098.344\,\mathrm{W}$$

Therefore, power rating of the electrical resistance is $\boxed{\dot{Q} = 29.098\,\mathrm{kW}}$.

Step 9 of 9

During 15 hours period heat loss will be

$$Q = \dot{Q}\times\text{number of hours}$$

$$= 29.098\times15$$

$$Q = 436.48\ \mathrm{kWh}$$

The cost of electricity,

$$\text{cost} = Q\times\text{cost/hour}$$

$$= 436.48\times0.09$$

$$= \$39.282$$

Therefore, cost of the electricity is $\boxed{\text{cost} = \$39.282}$

Question:

Reconsider Prob. 20-34. To reduce the heating cost I of the pipe, it is proposed to insulate it with sufficiently thick fiberglass insulation (k= 0.035 W/m·K) wrapped with aluminum foil (ε = 0.1) to cut down the heat losses by 85 percent. Assuming the pipe temperature to remain constant at 25°C, determine the thickness of the insulation that needs to be used. How much money will the insulation save during this 15-h period?

Step 1 of 13

Loading solution. Please wait ...

Step 2 of 13

Loading solution. Please wait ...

Step 3 of 13

From the properties of air at 1 atm pressure table, the properties of air at 12.5°C by using interpolation,

Thermal conductivity,

$$\frac{12.5-10}{15-10}=\frac{k-0.02439}{0.02476-0.02439}$$

$$k=0.02458\ \text{W/m}\cdot\text{K}$$

Kinematic viscosity,

$$\frac{12.5-10}{15-10}=\frac{v-1.426\times10^{-5}}{1.47\times10^{-5}-1.426\times10^{-5}}$$

$$v=1.448\times10^{-5}\ \text{m/s}$$

Step 4 of 13

Prandtl number,

$$\frac{12.5-10}{15-10}=\frac{\text{Pr}-0.7336}{0.7326-0.7336}$$

$$\text{Pr}=0.7331$$

Rayleigh's number,

$$\text{Ra}=\frac{g\beta(T_s-T_\infty)L_c^3}{v^2}\times\text{Pr}$$

$$=\frac{9.81\times0.003503\times(25-0)\times0.3^3}{(1.448\times10^{-5})^2}\times0.7330$$

$$=8.106\times10^7$$

Step 5 of 13

$$\text{Pr}=0.7331$$

Rayleigh's number,

$$\text{Ra}=\frac{g\beta(T_s-T_\infty)L_c^3}{v^2}\times\text{Pr}$$

$$=\frac{9.81\times0.003503\times(25-0)\times0.3^3}{(1.448\times10^{-5})^2}\times0.7330$$

$$=8.106\times10^7$$

Step 5 of 13

Nusselt number,

$$\text{Nu}=\left\{0.6+\frac{0.387\text{Ra}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2$$

$$=\left\{0.6+\frac{0.387(8.106\times10^7)^{1/6}}{\left[1+(0.559/0.7330)^{9/16}\right]^{8/27}}\right\}^2$$

$$=53.29$$

But $\text{Nu}=\frac{hL_c}{k}$, so heat transfer coefficient is

$$h=\frac{k}{L_c}\text{Nu}$$

$$=\frac{0.02458}{0.3\ \text{m}}\times(53.29)$$

$$=4.366\ \text{W/m}^2\cdot\text{K}$$

Step 6 of 13

Calculate the Convection heat transfer rate,

$$\dot{Q}_{conv}=hA_s(T_s-T_\infty)$$

$$=4.366\times94.25\times(25-0)$$

$$=10{,}287\ \text{W}$$

Calculate the Radiation heat transfer rate,

$$\dot{Q}_{rad}=\varepsilon A_s\sigma\left(T_s^4-T_{sur}^4\right)$$

Where,

ε is the Emissivity of the outer surface of pipe,

T_{sur} is the Surrounding temperature,

Step 7 of 13

Substitute $T_{sur}=-30°\text{C}$, $\varepsilon=0.8$ and the respective values in the above equation,

$$\dot{Q}_{rad}=0.8\times94.25\times5.67\times10^{-8}\times[(25+273)^4-(-30+273)^4]$$

$$=18{,}808\ \text{W}$$

Calculate the total hear transfer rate,

$$\dot{Q}_{total}=\dot{Q}_{conv}+\dot{Q}_{rad}$$

$$=10{,}287+18{,}808$$

$$=29.094\ \text{kW}$$

Step 8 of 13

After insulation, the heat losses gets reduced by 85%, so

$$\dot{Q}=(1-0.85)\times\dot{Q}_{\text{no insulation}}$$

Step 8 of 13

After insulation, the heat losses gets reduced by 85%, so

$$\dot{Q} = (1-0.85)\times \dot{Q}_{\text{no insulation}}$$
$$= 0.15\times 29,094$$
$$= 4364 \text{ W}$$

Calculate the average film temperature,

$$T_f = 5^\circ\text{C}$$
$$= 5+273$$
$$= 278^\circ\text{K}$$

Step 9 of 13

From properties of air table, the properties of air at 5°C are

$k = 0.02401 \text{ W/m}\cdot\text{K}$

$\upsilon = 1.382\times 10^{-5} \text{ m}^2/\text{s}$

$\text{Pr} = 0.7350$

$$\beta = \frac{1}{T_f} = 0.003597 \text{ K}^{-1}$$

Calculate the Surface area of the pipe,

$$A_s = \pi D_0 L$$
$$= \pi(0.3+2t_{ins})\times 100$$

Calculate the characteristic length after insulation,

$$L_c = D+2t_{ins}$$
$$= 0.3+2t_{ins}$$

Step 10 of 13

Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_s-T_\infty)L_c^3}{\upsilon^2}\text{Pr}$$
$$= \frac{9.81\times 0.003597\times[(T_s-273)](0.3+2t_{ins})^3}{(1.382\times 10^{-5})^2}(0.7350)$$

Nusselt number,

$$\text{Nu} = \left\{0.6+\frac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2$$
$$= \left\{0.6+\frac{0.387Ra^{1/6}}{\left[1+(0.559/0.7350)^{9/16}\right]^{8/27}}\right\}^2$$

Step 11 of 13

But $\text{Nu} = \frac{hL_c}{k}$ so heat transfer coefficient is

$$h = \frac{k}{L_c}\text{Nu}$$
$$= \frac{0.02401}{L_c}\text{Nu}$$

Calculate the total hear transfer rate,

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}}$$
$$= hA_s(T_s-T_\infty)+\varepsilon A_s\sigma(T_s^4-T_{\text{sur}}^4)$$
$$4364 = \{h\times A_s\times(T_s-273)\}+\{0.1\times A_s\times 5.67\times 10^{-8}\times[T_s^4-(-30+273)^4]\} \quad \ldots\ldots (1)$$

Step 12 of 13

In steady state operation, the heat lost by the side surfaces of the pipe must be equal to the heat lost from the exposed surface of the insulation by convection and radiation, therefore,

$$\dot{Q}_{\text{ins}} = \frac{2\pi kL(T_{\text{sink}}-T_s)}{\ln(D_o/D)}$$
$$4364 = \frac{2\pi\times 0.035\times 100\times(298-T_s)}{\ln\left(\frac{0.3+2t_{\text{ins}}}{0.3}\right)} \quad \ldots\ldots (2)$$

Solve equations (1) and (2) by using equation solver, we get

$T_s = 281.5 \text{ K} = 8.5^\circ\text{C}$

$t_{\text{ins}} = 1.3 \text{ cm}$

Therefore, the final insulation has thickness is $\boxed{t_{\text{ins}} = 1.3 \text{ cm}}$

Step 13 of 13

Calculate the amount money insulation will save during a 10 hr period,

$$Q_{\text{saved, total}} = \dot{Q}_{\text{saved}}\Delta t$$
$$= (0.85\times 29.094 \text{ kW})(15 \text{ h})$$
$$= 370.948 \text{ kWh}$$

Money saved = (Energy saved)(Unit cost of energy)

$$= (370.948 \text{ kWh})(\$0.09/\text{kWh})$$
$$= \$33.385$$

Therefore, the total money saved due to insulation is $\boxed{\text{Money saved} = \$33.385}$

Question: 20.036P pg 1

Consider a 1.2-m-high and 2-m-wide glass window with a thickness of 6 mm, thermal conductivity k =0.78 W/m-K, and emissivity ε = 0.9. The room and the walls that face the window are maintained at 25°C, and the average temperature of the inner surface of the window is measured to be 5°C. If the temperature of the outdoors is –5°C, determine (*a*) the convection heat transfer coefficient on the inner surface of the window, (*b*) the rate of total heat transfer through the window, and (*c*) the combined natural convection and radiation heat transfer coefficient on the outer surface of the window. Is it reasonable to neglect the thermal resistance of the glass in this case?

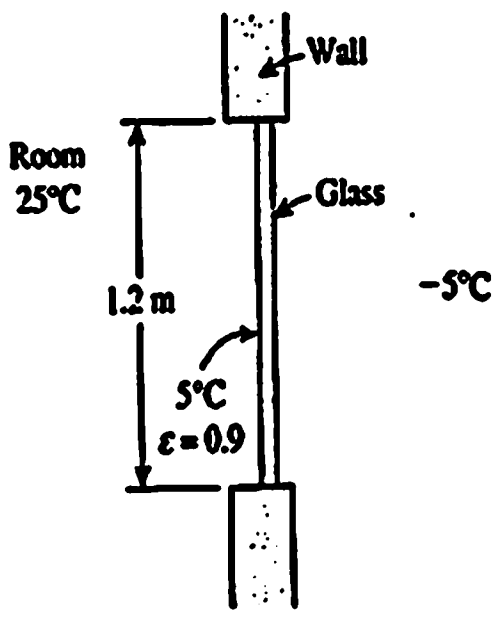


FIGURE P20–36

Step 1 of 12

Find the average film temperature.

$$T_f = \frac{T_s + T_\infty}{2}$$

Here, T_s is average inner surface temperature and T_∞ is ambient temperature.

Step 2 of 12

Step 3 of 12

Substitute $5°C$ for T_s and $25°C$ for T_∞.

$$T_f = \frac{5+25}{2}$$
$$= 15°C$$
$$= 288\,K$$

Obtain the following properties of the air from the table A-22 "properties of air at 1 atm pressure "at $15°C$.

Step 4 of 12

Thermal concavity, $k = 0.02476\ W/m°C$

Kinematic viscosity, $\upsilon = 1.471\times10^{-5}\ m^2/s$

Prandit number, $Pr = 0.7323$

Step 5 of 12

a)

Find the co-efficient of volume expansion.

$$\beta = \frac{1}{T_f}$$

Substitute $288\,K$ for T_f.

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{288}$$
$$= 0.003472\ K^{-1}$$

Find the surface area of the window.

$$A_s = (1.2\ m \times 2\ m)$$
$$= 2.4\ m^2$$

Find the characteristic length.

$$L_c = L$$
$$= 1.2\ m$$

Step 6 of 12

Find the Rayleigh number using the equation.

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2} Pr$$

Substitute $0.003472\ K^{-1}$ for β, $9.81\ m/s^2$ for g, 0.7323 for Pr, $1.2\ m$ for L, $1.471\times10^{-5}\ m^2/s$ for υ, $5°C$ for T_s and $25°C$ for T_∞.

$$Ra = \frac{g\beta(T_s - T_\infty)L^3}{\upsilon^2} Pr$$
$$= \frac{9.81\times0.003472\times(25-5)\times1.2^3}{(1.417\times10^{-5})^2}\times(0.7323)$$
$$= 3.986\times10^9$$

Find the Nusselt number using the number.

$$Nu = \left\{0.825 + \frac{0.387Ra^{1/6}}{\left[1+\left(\frac{0.492}{Pr}\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$Nu=\left\{0.825+\frac{0.387Ra^{1/6}}{\left[1+\left(\frac{0.492}{Pr}\right)^{9/16}\right]^{8/27}}\right\}$$

Substitute 0.7323 for Pr, and 3.986×10^9 for Ra.

$$Nu=\left\{0.825+\frac{0.387\times\left(3.986\times10^9\right)^{1/6}}{\left[1+\left(\frac{0.492}{0.7323}\right)^{9/16}\right]^{8/27}}\right\}^2$$
$$=189.7$$

Step 7 of 12

Find the heat transfer coefficient of inner surface using the equation.

$$Nu=\frac{hL_c}{k}$$

$$h=\frac{k}{L_c}Nu$$

Substitute $0.02476\ W/m°C$ for k, $1.2\ m$ for L_c and 189.7 for Nu.

$$h=\frac{k}{L_c}Nu$$
$$=\frac{0.02476}{1.2}\times189.7$$
$$=3.915\ W/m^2°C$$

Therefore, the heat transfer coefficient of inner surface is $\boxed{3.915\ W/m^2°C}$.

Step 8 of 12

b)

Find the convection heat transfer rate using the equation.

$$\dot{Q}_{conv}=hA_s(T_\infty-T_s)$$

Substitute $3.915\ W/m^2°C$ for h, $2.4\ m^2$ for A_s, $5°C$ for T_s and $25°C$ for T_∞.

$$\dot{Q}_{conv}=3.915\times2.4\times(25-5)$$
$$=187.9\ W$$

Find the radiation heat transfer rate using the equation.

$$\dot{Q}_{rad}=\varepsilon A_s\sigma\left(T_{surr}^4-T_s^4\right)$$

Here. ε is emissivity and σ is the Stefan-Boltzmann constant.

Substitute

$$\dot{Q}_{rad}=0.9\times2.4\times5.67\times10^{-8}\times\left[(25+273)^4-(5+273)^4\right]$$
$$=234.3\ W$$

Find the total heat transfer rate using the equation.

$$\dot{Q}_{total}=\dot{Q}_{conv}+\dot{Q}_{rad}$$

Substitute $234.3\ W$ for $\dot{Q}_{conv}$ and 234.3 W for $\dot{Q}_{rad}$.

$$\dot{Q}_{total}=187.9+234.3$$
$$=422.2\ W$$

Therefore, the rate of heat transfer through window is $\boxed{422.2\ W}$.

Step 9 of 12

c)

Find the temperature using conduction heat transfer through the window glass.

$$\dot{Q}_{cond}=\frac{k_gA_s}{t}\left(T_{s,i}-T_{s,o}\right)$$

$$T_{s,o}=T_{s,i}-\left(\frac{\dot{Q}_{total}t}{k_gA_s}\right)$$

Here, t is thickness and k_g is the thermal conductivity of glass.

Substitute $422.2\ W$ for $\dot{Q}_{total}$, $2.4\ m^2$ for A_s, $5°C$ for $T_{s,i}$, $0.78\ W/m°C$ for k_g, and 0.006 m for t.

$$T_{s,o}=T_{s,i}-\left(\frac{\dot{Q}_{total}t}{k_gA_s}\right)$$
$$=5-\left(\frac{422.2\times0.006}{0.78\times2.4}\right)$$
$$=3.65°C$$

Step 10 of 12

Find the heat transfer due to conduction is equal to the heat transfer due to combined effect of convection and radiation.

$$\dot{Q}_{cond}=h_{combined}A_s\left(T_{s,o}-T_{\infty,o}\right)$$

$$h_{combined}=\frac{\dot{Q}_{total}}{A_s\left(T_{s,o}-T_{\infty,o}\right)}$$

$$h_{combined}=\frac{\dot{Q}_{total}}{A_s(T_{s,o}-T_{\infty,o})}$$

$$h_{combined}=\frac{346}{2.4\times[3.65-(-5)]}$$

$$h_{combined}=20.35\ W/m^2°C$$

Hence coefficient of heat transfer due to combined effect of radiation and convection is

$$h_{combined} = \frac{346}{2.4\times[3.65-(-5)]}$$

20.036P pg 3

$$h_{combined} = 20.35\ \text{W/m}^2\text{°C}$$

Hence coefficient of heat transfer due to combined effect of radiation and convection is

$$\boxed{h_{combined} = 20.35\ \text{W/m}^2\text{°C}}$$

Step 11 of 12

Note that $\Delta T = \dot{Q}R$ and thus the thermal resistance R of a layer is proportional to the temperature drop across that layer. Therefore, the fraction of thermal resistance of the glass is equal to the ratio of the temperature drop across the glass to the overall temperature difference,

$$\frac{R_{glass}}{R_{total}} = \frac{\Delta T_{glass}}{\Delta T_{total}} = \frac{5-3.65}{25-(-5)} = 0.045 \quad \text{(or 4.5\%)}$$

Step 12 of 12

It is reasonable to neglect the thermal resistance of the glass.

Question: 20.037P

A 3-mm-diameter and 12-m-long electric wire is tightly wrapped with a 1.5-mm-thick plastic cover whose thermal conductivity and emissivity are k = 0.20 W/m·K and ε = 0.9. Electrical measurements indicate that a current of 10 A passes through the wire and there is a voltage drop of 7 V along the wire. If the insulated wire is exposed to calm atmospheric air at T_∞ = 30°C, determine the temperature at the interface of the wire and the plastic cover in steady operation. Take the surrounding surfaces to be at about the same temperature as the air.

Step 1 of 6

Given

Length of the electric wire, $L = 12\text{ m}$

Diameter of the electric wire, $d = 0.003\text{ m}$

Thickness of the electric wire, $t = 0.0015\text{ m}$

Emissivity of the plastic cover is $\varepsilon = 0.9$

Ambient temperature $T_\infty = 30^0\text{C}$

Step 2 of 6

Assuming the surface temperature as $T_s = 55^0\text{C}$

Average film temperature, $T_f = \dfrac{T_s + T_\infty}{2}$

$$T_f = \frac{55+30}{2}$$

$$T_f = 42.5^0\text{C}$$

$$T_f = 315.5^0\text{K}$$

Properties of the air at 42.5^0C

$k = 0.02892\text{ W/m.°C}$

$\upsilon = 1.752\times10^{-5}\text{ m}^2/s$

$\text{Pr} = 0.73$

$$\beta = \frac{1}{T_f} = 0.0031695\text{ K}^{-1}$$

Step 3 of 6

Rate of heat transfer, $\dot{Q} = VI$

$$\dot{Q} = (7\text{ V})(10\text{ A})$$

$$\dot{Q} = 70\text{ W}$$

Surface area of the electric wire, $A_s = \pi DL$

$$A_s = \pi(0.003\text{ m})(12\text{ m})$$

$$A_s = 0.1131\text{ m}^2$$

Characteristic length, $L_c = D = 0.003\text{ m}$

Rayleighs number, $Ra = \dfrac{g\beta(T_s - T_\infty)D^3}{\upsilon^2}\text{Pr}$

$$Ra = \frac{9.81\times0.0031695\times(55-30)\times0.003^3}{(1.752\times10^{-5})^2}(0.73)$$

$$Ra = 56.3888$$

Step 4 of 6

Nusselt number, $Nu = \left\{0.6 + \dfrac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2$

$$Nu = \left\{0.6 + \frac{0.387(56.3888)^{1/6}}{\left[1+(0.559/0.73)^{9/16}\right]^{8/27}}\right\}^2$$

$$Nu = 1.72$$

But $Nu = \dfrac{hL_c}{k}$ So heat transfer coefficient is

$$h = \frac{k}{D}Nu$$

$$h = \frac{0.02892}{0.003}(1.72)$$

$$h = 15.897\text{ W/m}^2\text{°C}$$

Step 5 of 6

Total heat transfer rate,

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^4 - T_{surr}^4)$$

$$70 = \{15.897\times0.1131\times(T_s - 30)\}$$

$$+\left\{0.9\times0.1131\times5.67\times10^{-8}\times[(T_s+273)^4 - (30+273)^4]\right\}$$

$$70 = \{1.79795\times(T_s - 30)\} + \left\{5.7715\times10^{-9}\times[(T_s+273)^4 - (303)^4]\right\}$$

$$T_s = 56.6°\text{C}$$

Step 6 of 6

Conduction heat transfer through the wire is

$$\dot{Q} = \frac{2\pi kL}{\ln(D_2/D_1)}(T_i - T_s)$$

$$T_i = T_s + \frac{\dot{Q}\ln(D_2/D_1)}{2\pi kL}$$

$$T_i = 56.6 + \frac{70\times\ln(3/1.5)}{2\pi\times0.2\times12}$$

$$T_i = 59.8^0\text{C}$$

Temperature at interface, $\boxed{T_i = 59.8^0\text{C}}$

Question:

During a visit to a plastic sheeting plant, it was observed that a 45-m-long section of a 2-in nominal (6.03-em-outer-diameter) steam pipe extended from one end of the plant to the other with no insulation on it. The temperature measurements at several locations revealed that the average temperature of the exposed surfaces of the steam pipe was 170°C, while the temperature of the surrounding air was 20°C. The outer surface of the pipe appeared to be oxidized, and its emissivity can be taken to be 0.7. Taking the temperature of the surrounding surfaces to be 20°C also, determine the rate of heat loss from the steam pipe.

Steam is generated in a gas furnace that has an efficiency of 84 percent, and the plant pays $1.10 per therm (1 therm = 105,500 kJ) of natural gas. The plant operates 24 h a day 365 days a year, and thus 8760 h a year. Determine the annual cost of the heat losses from the steam pipe for this facility.

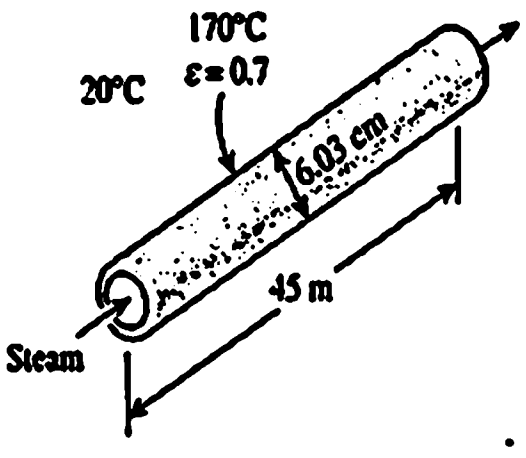

FIGURE P20–38

Step 1 of 11

Given data:

Length of steam pipe, $L = 45\text{m}$

Diameter of steam pipe, $D_0 = 6.03\text{cm} = 0.0603\text{m}$

Average surface temperature, $T_s = 170°\text{C}$

Air temperature, $T_\infty = 20°\text{C}$

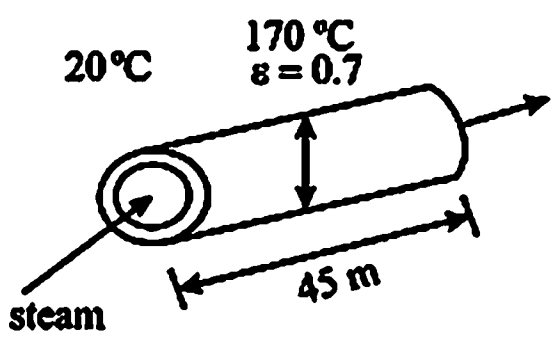
Emissivity of surface, $\varepsilon = 0.7$

Surrounding surface Temperature, $T_{amb} = 20°\text{C}$

Efficiency of the gas furnace, $\eta_{gasfurnace} = 84\%$

Operations hours,

$t = 8760\,\text{hours}$



$= 8760 \times 3600$

$= 31536000\,\text{sec}$

Amount paid = $1.10 per therm

Step 2 of 11

The steam pipe is as shown in figure,

Step 3 of 11

Mean film temperature,

$$T_f = (T_s + T_\infty)/2$$

$$= (170+20)/2$$

$$= 95°\text{C}$$

Step 4 of 11

From the properties of the ideal gas of air at 1 atm pressure and mean film temperature,

Thermal conductivity,

$$k = (0.03095+0.03024)/2$$

$$= 0.030595$$

Prandtl number,

$$\text{Pr} = (0.7132+0.7111)/2$$

$$= 0.71215$$

Kinematic viscosity,

$$\nu = (2.201+2.306)/2\times10^{-5}$$

$$= 2.2535\times10^{-5}\,\text{m}^2/\text{s}$$

Step 5 of 11

Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{368}$$

$$= 2.7174\times10^{-3}\,\text{K}^{-1}$$

Characteristic length for horizontal = diameter of cylinder

$L_c = 0.0603\text{m}$

Step 6 of 11

Rayleigh number,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\times\text{Pr}$$

$$= \frac{9.81\times2.7174\times10^{-3}(170-20)(0.0603)^3}{(2.254\times10^{-5})^2}\times0.71215$$

$$= 1.229\times10^6$$

Step 7 of 11

Nusselt number,

$$\text{Nu} = \left\{0.6 + \frac{0.387(R_{a_L})^{1/6}}{\left[\left(0.559\right)^{9/16}\right]^{8/27}}\right.$$

Nusselt number,

$$\mathrm{Nu}=\left[0.6+\frac{0.387\left(R_{a_L}\right)^{1/6}}{\left[1+\left(\frac{0.559}{P_r}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$=\left[0.6+\frac{0.387\left(1.229\times10^{6}\right)^{1/6}}{\left[1+\left(\frac{0.559}{0.71215}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$=15.412$$

Step 8 of 11

Heat transfer co-efficient,

$$h=\frac{k}{L_c}\mathrm{Nu}$$

$$=\frac{0.030595}{0.0603}\times15.412$$

$$=7.82\,\mathrm{W/m^2\cdot K}$$

Surface Area of the cylinder,

$$A_s=\pi DL$$

$$=\pi\times0.0603\times45$$

$$=8.525\,\mathrm{m^2}$$

Step 9 of 11

By using total heat losses formula, we get

$$\dot{Q}=hA_s\left(T_s-T_\infty\right)+\varepsilon A_s\sigma\left(T_s^4-T_{amb}^4\right)$$

$$=7.82\times8.525(170-20)+0.7\times8.525$$

$$\times5.67\times10^{-8}\left(443^4-293^4\right)$$

$$=20537.49\,\mathrm{W}$$

Therefore, the total heat loss from the pipe is $\boxed{\dot{Q}=20537.49\,\mathrm{W}}$.

Step 10 of 11

Total heat consumption from gas,

$$Q_{gas}=Q\times\text{operations hours}$$

$$=20537.49\times31536000$$

$$=6.47\times10^{11}\,\mathrm{J/s}$$

$$=6.47\times10^{8}\,\mathrm{kJ/s}$$

As efficiency is 84%

Therefore, actual heat transfer is

$$Q_{gas}=\frac{6.47\times10^{8}}{\eta_{\text{gas furnance}}}$$

$$=\frac{6.47\times10^{8}}{0.84}$$

$$=7.7\times10^{8}\,\mathrm{kJ/s}$$

Step 11 of 11

Note: $1\text{therm}=105500\,\mathrm{kJ}$

Let us convert into therms,

Therefore

$$Q_{gas}=\frac{7.7\times10^{8}}{105500}$$

$$=7298.57\,\text{therms}$$

$\text{cost/therm}=\$1.10$

Then, Total cost (annual) of heat loses

$$\text{Total cost}=\text{cost/therm}\times Q_{gas}$$

$$=1.10\times7298.57$$

$$=\$8028.427$$

Therefore, annual cost of heat losses is $\boxed{\text{total cost}=\$8028.427}$.

Question: 20.039P

Reconsider Prob. 20-38. Using EES (or other) software, investigate the effect of the surface temperature of the steam pipe on the rate of heat loss from the pipe and the annual cost of this heat loss. Let the surface temperature vary from 100°C to 200°C. Plot the rate of heat loss and the annual cost as a function of the surface temperature, and discuss the results.

Step 1 of 5

```
"GIVEN"
L=45 "[m]"
D=0.0603 "[m]"
"T_s=170 [C], parameter to be varied from 100[C] to 200[C]"

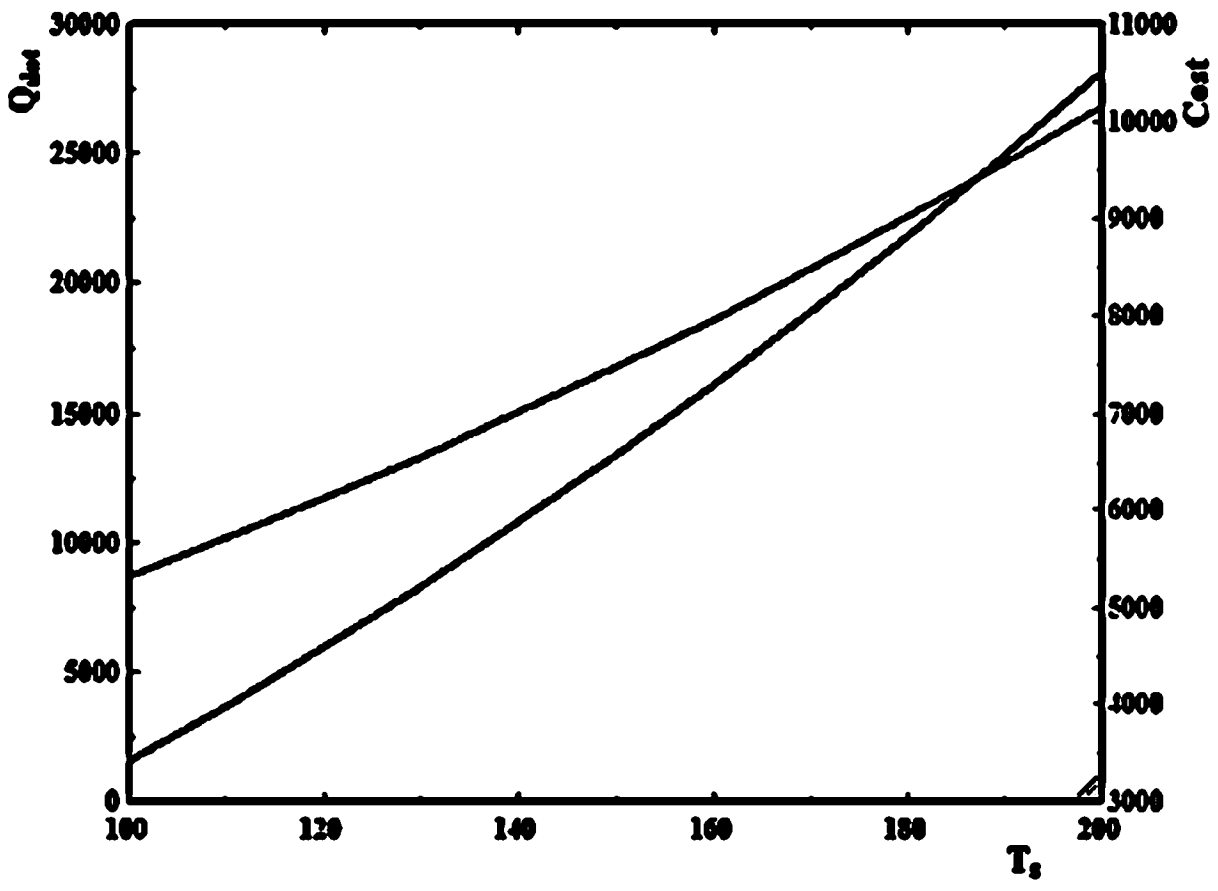
Q_gas=(Q_dot*time)/eta_furnace*Convert(h, s)*Convert(J, kJ)*Convert(kJ, therm)
Cost=Q_gas*UnitCost
```



Step 4 of 5

The variation of heat loss and annual cost with surface temperature is as shown below.

▷ 1..11	1 T_s	2 $\dot{Q}$	3 Cost
Run 1	100	8726	3416
Run 2	110	10183	3986
Run 3	120	11714	4585
Run 4	130	13320	5214
Run 5	140	15005	5873
Run 6	150	16768	6563
Run 7	160	18613	7286
Run 8	170	20542	8041
Run 9	180	22558	8830
Run 10	190	24664	9654
Run 11	200	26862	10514

Step 5 of 5

Plot showing the variation of heat loss and annual cost with surface temperature:

Thus both the heat loss and annual cost increases with increase in the surface temperature.

Question:

Reconsider Prob. 20-38. In order to reduce heat losses, it is proposed to insulate the steam pipe with 5-cm-thick fiberglass insulation (k =0.038 W/m·K) and to wrap it with aluminum foil ($\varepsilon = 0.1$) in order to minimize the radiation losses. Also, an estimate is obtained from a local insulation contractor, who proposed to do the insulation job for $750. including materials and labor. Would you support this proposal? How long will it take for the insulation to pay for itself from the energy it saves? Assume the temperature of the steam pipe to remain constant at 170°C.

Step 1 of 11

Before insulation,

Calculate the mean film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

Where,

T_s is the pipe outer surface temperature,

T_∞ is the ambient temperature,

Substitute $T_s = 170°C$ and $T_\infty = 20°C$ in the above equation,

$$T_f = \frac{170+20}{2}$$
$$= 95°C$$
$$= 368\ K$$

Step 2 of 11

From properties of air table, the properties of at 95°C

$$k = 0.0306\ W/m\cdot K$$
$$\upsilon = 2.252\times10^{-5}\ m^2/s$$
$$Pr = 0.7121$$
$$\beta = \frac{1}{T_f} = 0.002717\ K^{-1}$$

Step 3 of 11

Surface area of the pan,

$$A_s = \pi D_1 L$$

Where,

D_1 is the diameter of the steam pipe before insulation,

L is the Length of the steam pipe,

Substitute $D_1 = 0.0603\ m$ and $L = 45\ m$ in the above equation,

$$A_s = \pi(0.0603\ m)(45\ m)$$
$$= 8.524\ m^2$$

Characteristic length, $L_c = D = 0.0603\ m$

Rayleigh number,

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\times Pr$$
$$= \frac{9.81\times0.002717\times(170-20)\times0.0603^3}{(2.252\times10^{-5})^2}(0.7121)$$
$$= 1.231\times10^6$$

Step 4 of 11

Nusselt number,

$$Nu = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2$$
$$= \left\{0.6 + \frac{0.387(1.231\times10^6)^{1/6}}{\left[1+(0.559/0.7121)^{9/16}\right]^{8/27}}\right\}^2$$
$$= 15.42$$

Step 5 of 11

But, $Nu = \frac{hL_c}{k}$, so heat transfer coefficient is

$$h = \frac{k}{D_1}Nu$$
$$= \frac{0.0306}{0.0603}\times(15.42)$$
$$= 7.823\ W/m^2\cdot K$$

Calculate the total heat loss,

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^4 - T_\infty^4)$$

Where,

ε is the emissivity of surface of pipe,

Substitute $\varepsilon = 0.7$ and the respective values in the above equation,

$$\dot{Q} = \{7.823\times8.524\times(170-20)\}$$
$$+\left\{0.7\times8.524\times5.67\times10^{-8}\times[(170+273)^4-(20+273)^4]\right\}$$
$$= 20538.921\ W$$
$$= 20.538\ kW$$

Step 6 of 11

After insulation, let the surface temperature be assumed to 35°C, therefore $T_s = 35°C$

Then the mean film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{35+20}{2}$$
$$= 27.5°C$$
$$= 300.5\ K$$

Step 7 of 11

From properties of air table, the properties of at 27.5°C

$$k = 0.0257\ W/m\cdot K$$
$$\upsilon = 1.584\times10^{-5}\ m^2/s$$

Step 7 of 11

From properties of air table, the properties of at 27.5°C

$k = 0.0257 \text{ W/m-K}$

$\upsilon = 1.584\times10^{-5} \text{ m}^2/\text{s}$

$\text{Pr} = 0.7289$

$$\beta = \frac{1}{T_f} = 0.003328 \text{ K}^{-1}$$

Surface area of the pan,

$$A_s = \pi D_2 L$$

Where,

D_2 is the diameter of the steam pipe after insulation,

Substitute $D_2 = 0.1603$ m and the respective values in the above equation,

$$A_s = \pi(0.1603 \text{ m})(45 \text{ m})$$
$$= 22.661 \text{ m}^2$$

Step 8 of 11

Characteristic length, $L_c = D = 0.1603$ m.

Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\text{Pr}$$
$$= \frac{9.81\times0.003328\times(35-20)\times0.1603^3}{(1.584\times10^{-5})^2}(0.7289)$$
$$= 5.856\times10^6$$

Nusselt number,

$$\text{Nu} = \left\{0.6 + \frac{0.387\text{Ra}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2$$
$$= \left\{0.6 + \frac{0.387(5.856\times10^6)^{1/6}}{\left[1+(0.559/0.7289)^{9/16}\right]^{8/27}}\right\}^2$$
$$= 24.23$$

Step 9 of 11

But $\text{Nu} = \frac{hL_c}{k}$, so heat transfer coefficient is

$$h = \frac{k}{D}\text{Nu}$$
$$= \frac{0.0257}{0.1603}\times(24.23)$$
$$= 3.884 \text{ W/m}^2\text{-K}$$

Calculate the Total heat loss,

$$\dot{Q} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$= hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^4 - T_{sur}^4)$$
$$= \{3.884\times22.661\times(35-20)\} +$$
$$\{0.1\times22.661\times5.67\times10^{-8}\times[(35+273)^4 - (20+273)^4]\}$$
$$= 1529.553 \text{ W}$$
$$= 1.529 \text{ kW}$$

Step 10 of 11

In steady state operation, the heat lost by the side surfaces of the pipe must be equal to the heat lost from the exposed surface of the insulation by convection and radiation, which must be equal to the heat conducted through the insulation.

$T_{s,1}$ is the temperature on the surface of the pipe, and $T_{s,1} = 170°\text{C}$

T_s is the temperature on the surface of the insulation.

$$\dot{Q}_{ins} = \frac{T_{s,1} - T_s}{R_{ins}}$$

$$\dot{Q}_{ins} = \frac{T_{s,1} - T_s}{\frac{\ln(D_2/D_1)}{2\pi kL}}$$

$$1529.553 = \frac{(170 - T_s)}{\left[\frac{\ln(16.03/6.03)}{2\pi\times0.038\times45}\right]}$$

$$170 - T_s = 1529.553\times0.091$$

$$T_s = 30.812°\text{C}$$

Calculate the reduction heat loss,

$$\dot{Q}_{saved} = 20.538 - 1.529$$
$$= 19.009 \text{ kW}$$

Calculate the annual cost of the container from the heat loss,

$$Q_{gas} = \frac{\dot{Q}\Delta t}{\eta}$$
$$= \frac{19.009 \text{ kJ/s}}{0.84}\left(\frac{1 \text{ therm}}{105{,}500 \text{ kJ}}\right)(8760 \text{ h/yr}\times3600 \text{ s/h})$$
$$= 6764.475 \text{ therms/yr}$$

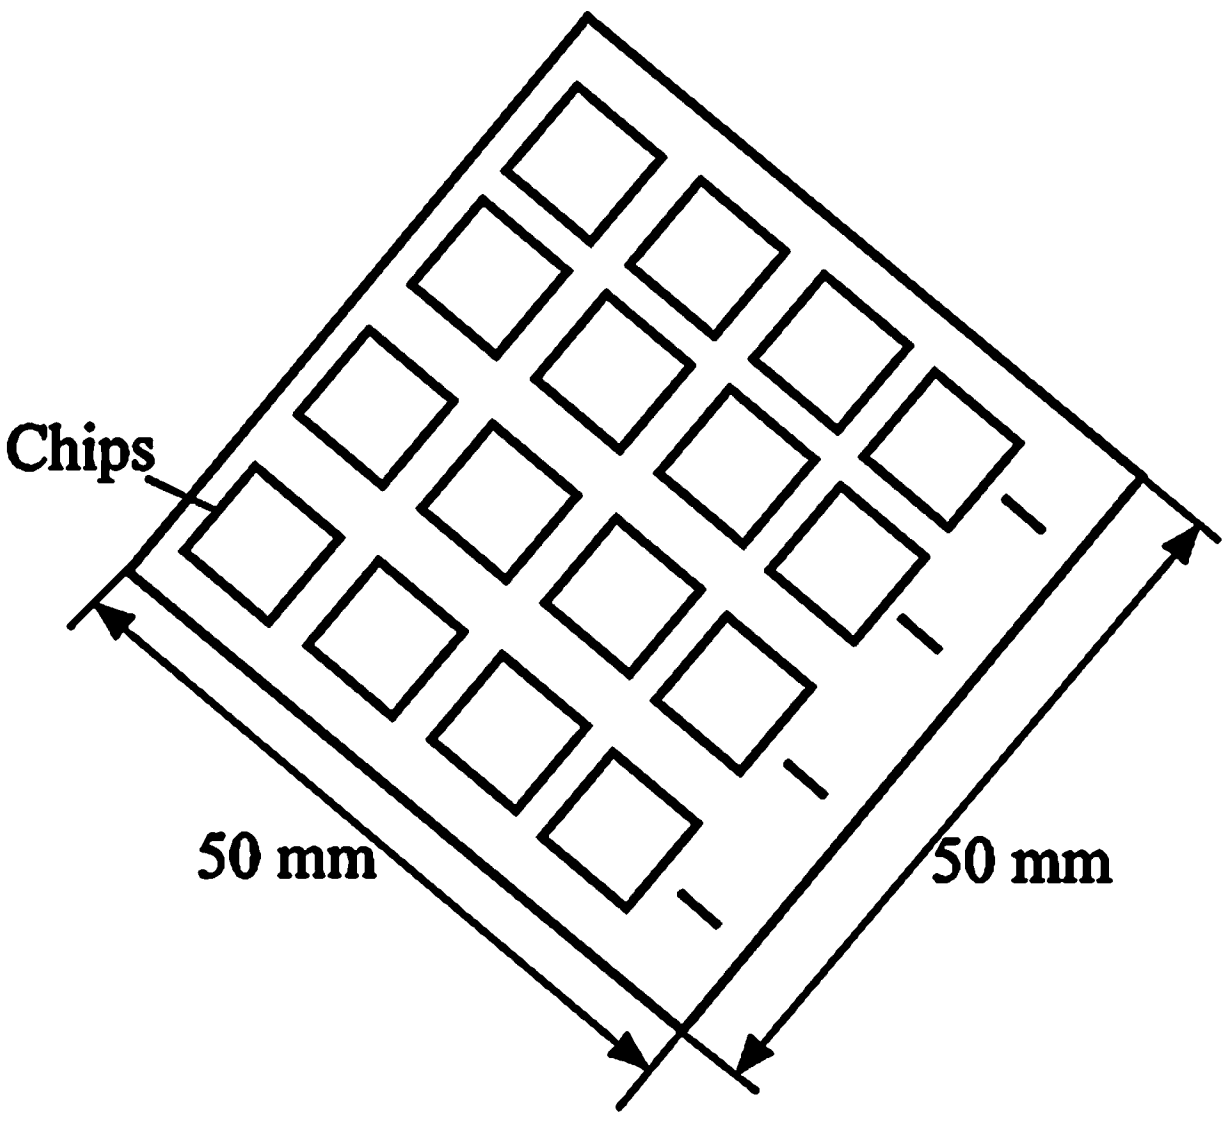
$$\text{Cost} = (6764.475 \text{ therms/yr})\times(\$1.10/\text{therm})$$
$$\text{Cost} = \$\,7440.922 \text{ per yr}$$

Step 11 of 11

Calculate the time required for the insulation to pay for itself from the energy it saves is

$$t = \frac{\$750}{\$7440.992 \text{ per yr}}$$
$$= 0.1432\times365 \text{ days}$$
$$= 36.78 \text{ days}$$

Therefore, in $\boxed{36.78 \text{ days}}$ cost of insulation gets paid by itself.



Therefore, in 36.78 days cost of [illegible] gets paid by itself.

Question:

A 50-cm × 50-cm circuit board that contains 121 square chips on one side is to be cooled by combined natural convection and radiation by mounting it on a vertical surface in a room at 25°C. Each chip dissipates 0.18 W of power, and the emissivity of the chip surfaces is 0.7. Assuming the heat transfer from the back side of the circuit board to be negligible, and the temperature of the surrounding surfaces to be the same as the air temperature of the room, determine the surface temperature of the chips.

Step 1 of 9

Sketch the circuit board with square chips cooled by natural convection as follows:

Step 2 of 9

Assume the surface temperature of the circuit board as $35°C$.

$$T_s = 35°C$$

Calculate the mean flam temperature of the air as follows:

$$T_f = \frac{T_s + T_\infty}{2}$$

Substitute $35°C$ for T_s and $25°C$ for T_∞.

$$T_f = \frac{35+25}{2}$$
$$= 30°C$$

Step 3 of 9

Calculate the coefficient of volume expansion as follows:

$$\beta = \frac{1}{T_f}$$

Substitute $30°C$ for T_f.

$$\beta = \frac{1}{30}$$
$$= \frac{1}{(30+273)\ \mathrm{K}}$$
$$= 3.3\times10^{-3}\mathrm{K}^{-1}$$

Obtain the properties of air from table A-15, "Properties of air at 1 atm pressure" at $T = 30°C$ as follows:

Thermal conductivity, $k = 0.02588\ \mathrm{w/m°C}$

Kinematic viscosity, $\nu = 1.608\times10^{-5}\ \mathrm{m^2/s}$

Prandtl number, $\mathrm{Pr} = 0.7282$

Step 4 of 9

Calculate the characteristic length L_c.

$$L_c = \frac{A_s}{p}$$

Here, A_s is the surface area of the board, and p is the parameter of the board.

Substitute $(L\times w)$ for A_s and $2(L+w)$ for p.

$$L_c = \frac{(L\times w)}{2(L+w)}$$

Here, L and w is the length and width of the board.

Substitute 50 mm for L and 50 mm for w .

$$L_c = \frac{(50\times50)\ \mathrm{mm^2}}{2(50+50)\ \mathrm{mm}}$$
$$= \frac{\left(2500\times10^{-6}\right)\ \mathrm{m^2}}{2\left(100\times10^{-3}\right)\mathrm{m}}$$
$$= 0.125\,\mathrm{m}$$

Step 5 of 9

Calculate the Rayleigh number as follows:

$$\mathrm{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\mathrm{Pr}$$

Calculate the Rayleigh number as follows:

$$\mathrm{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot \mathrm{Pr}$$

Here, g is the acceleration due gravity, T_s is the surface temperature, T_∞ is the ambient temperature, Pr is the Prandtl number, ν is the kinematic viscosity.

Substitute $9.81\ \mathrm{m/s^2}$ for g, $3.3\times10^{-3}\mathrm{K^{-1}}$ for β, $35°\mathrm{C}$ for T_s, $25°\mathrm{C}$ for T_∞, $0.125\,\mathrm{m}$ for L_c, $1.608\times10^{-5}\ \mathrm{m^2/s}$ for ν and 0.7282 for Pr.

$$\mathrm{Ra}_L = \frac{9.81\times3.3\times10^{-3}(35-25)(0.125)^3}{\left(1.608\times10^{-5}\right)^2}(0.7282)$$

$$= 178.07\times10^4$$

Step 6 of 9

Calculate the Nusselt number as follows:

From the empirical correlation for the average Nusselt number for natural convention over surfaces, as it is a upper surface hot plate and lies in rang $\left(10^4 - 10^7\right)$, hence the relation for Nusselt number becomes as follows:

$$\mathrm{Nu} = 0.54\left(\mathrm{Ra}_L\right)^{0.25}$$

Substitute 178.07×10^4 for Ra_L.

$$\mathrm{Nu} = 0.54\times\left(178.07\times10^4\right)^{0.25}$$

$$= 19.726$$

Calculate the heat transfer coefficient h.

$$h = \frac{k}{L_c}\times\mathrm{Nu}$$

Substitute $0.02588\,\mathrm{w/m°C}$ for k, $0.125\,\mathrm{m}$ for L_c, and 19.726 for Nu.

$$h = \frac{0.02588}{0.125}\times19.726$$

$$= 4.084\,\mathrm{w/m^2°C}$$

Step 7 of 9

Calculate the total heat transfer dissipated from the board.

$$\dot{Q} = \text{heat dissipated by one chip} \times \text{number of chips}$$

$$= 0.18\ \mathrm{W}\times121$$

$$= 21.78\ \mathrm{W}$$

a)

Calculate the surface temperature of the chip, if the chips are facing up as follows:

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon\sigma A\left((T_s)^4 - \left(T_\infty^4\right)\right)$$

Here, ε is the emissivity, σ is the Stephen Boltzmann's constant.

Substitute 21.78 W for $\dot{Q}$, $4.084\,\mathrm{w/m^2°C}$ for h, $25°\mathrm{C}$ for T_∞, $5.67\times10^{-8}\ \mathrm{W/m^2\cdot K}$ for σ, 0.7 for ε.

$$21.78 = 4.084\times0.25(T_s - 25) + 0.7\times5.67\times10^{-8}\times0.25\left((T_s+273)^4 - (298)^4\right)$$

$$21.78 = 1.01(T_s - 25) + 9.9225\times10^{-9}\left((T_s+273)^4 - (298)^4\right)$$

$$21.78 = 1.01T_s - 25.25 + 9.9225\times10^{-9}(T_s+273)^4 - 78.25$$

$$125.28 = 1.01T_s + 9.9225\times10^{-9}(T_s+273)^4$$

$$T_s = 35.675°\mathrm{C}$$

Therefore, the surface temperature of the chip, if the chips are facing up is $\boxed{35.675°\mathrm{C}}$.

Step 8 of 9

b)

If the chips are facing down as follows:

Calculate the Nusselt number as follows:

From the empirical correlation for the average Nusselt number for natural convention over surfaces, as it is downward with hot surface down range $\left(10^5 - 10^{11}\right)$, hence the relation for Nusselt number becomes as follows:

$$\mathrm{Nu} = 0.27\left(\mathrm{Ra}_L\right)^{1/4}$$

Substitute 178.07×10^4 for Ra_L.

$$\mathrm{Nu} = 0.27\times\left(178.07\times10^4\right)^{0.25}$$

$$= 9.3631$$

Calculate the heat transfer coefficient h.

$$h = \frac{k}{L_c}\times\mathrm{Nu}$$

Substitute $0.02588\,\mathrm{w/m°C}$ for k, $0.125\,\mathrm{m}$ for L_c, and 9.3631 for Nu.

$$h = \frac{0.02588}{0.125}\times9.8631$$

$$= 2.042\,\mathrm{w/m^2°C}$$

Step 9 of 9

Calculate the surface temperature of the chip, if the chips are facing downward as follows:

Step 9 of 9

Calculate the surface temperature of the chip, if the chips are facing downward as follows:

$$\dot{Q} = h A_s (T_s - T_\infty) + \varepsilon \sigma A \left((T_s)^4 - (T_\infty^4) \right)$$

Substitute 21.78 W for $\dot{Q}$, $2.042\,\mathrm{w/m^2{}^\circ C}$ for h, 25°C for T_∞, $5.67\times10^{-8}\ \mathrm{W/m^2 \cdot K}$ for σ, 0.7 for ε.

$$21.78 = 2.042\times0.25(T_s - 25) + 0.7\times5.67\times10^{-8}\times0.25\left((T_s+273)^4 - (298)^4\right)$$

$$21.78 = 0.5105(x-25) + 9.9225\times10^{-9}\left((x+273)^4 - (298)^4\right)$$

$$21.78 = 0.5105T_s - 12.76 + 9.9225\times10^{-9}(T_s+273)^4 - 78.25$$

$$112.8 = 1.01T_s + 9.9225\times10^{-9}(T_s+273)^4$$

$$T_s = 38.33^\circ C$$

Therefore, the surface temperature of the chip, if the chips are facing up is **38.33°C**.

Question: 20.042P

Repeat Prob. 20–41 assuming the circuit board to be positioned horizontally with (*a*) chips facing up and (*b*) chips facing down.

Step 1 of 8

Length of circuit board, $L = 50\text{cm} = 0.5\text{m}$

Breadth of circuit board, $w = 50\text{cm} = 0.5\text{m}$

Room temperature, $T_\infty = 25°\text{C}$

Emissivity of chip surface, $\varepsilon = 0.7$

Temperature of surrounding surface is, $T_{amb} = 25°\text{C}$

Step 2 of 8

a) Assuming the surface temperature of the circuit board is $T_s = 30°\text{C}$, calculate the mean film temperature of the air.

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{30+25}{2}$$
$$= 30°\text{C}$$

From the properties of air,

Thermal conductivity, $k = 0.02588\ \text{W/m-°C}$

Kinematic viscosity, $\nu = 1.608\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7282$

Step 3 of 8

Coefficient of volume expansion is

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{303}$$
$$= 3.3\times10^{-3}\text{K}^{-1}$$

Characteristic length,

$$L_c = \frac{A_s}{p}$$
$$= \frac{L\times w}{2(L+w)}$$
$$= \frac{(0.5)^2}{2(0.5+0.5)}$$
$$= 0.125\text{m}$$

Step 4 of 8

Calculate the Rayleigh number

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.3\times10^{-3}(35-25)(0.125)^3}{\left(1.608\times10^{-5}\right)^2}(0.7282)$$
$$= 178.07\times10^4$$

From the empirical correlation for the average Nusselt number for natural convention over surfaces,

$$\text{Nu} = 0.54(\text{Ra})^{0.25}$$
$$= 0.54\times\left(178.07\times10^4\right)^{0.25}$$
$$= 19.726$$

Step 5 of 8

Heat transfer co-efficient,

$$h = \frac{k}{L_c}\cdot\text{Nu}$$
$$= \frac{0.02588}{0.125}\times19.726$$
$$= 4.084\ \text{W/m}^2\text{-°C}$$

Therefore total heat transfer here will be

$$\dot{Q} = (\text{heat dissipated per chip})\times(\text{number of chips})$$
$$= 0.18\times121$$
$$= 21.78$$

Step 6 of 8

Now consider the total heat transfer as the sum of convection and radiation heat transfers.

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon\sigma A\left[(T_s)^4 - \left(T_{amb}^4\right)\right]$$

$$21.78 = 4.084(0.25)(T_s - 25) + 0.7\left(5.67\times10^{-8}\right)(0.25)\left[(T_s+273)^4 - (298)^4\right]$$

$$21.78 = 1.01(T_s - 25) + 9.9225\times10^{-9}\left[(T_s+273)^4 - (298)^4\right]$$

The value of temperature obtained by solving the above equation is $T_s = 35.675°\text{C}$

Therefore surface temperature of the circuit board is $\boxed{T_s = 35.675°\text{C}}$

Step 7 of 8

(b) Hot surface down facing. Consider the Rayleigh number which is calculated in above case.

$$\text{Ra}_L = 178.07\times10^4$$

Calculate the Nusselt number form the equation

$$\text{Nu} = 0.27\text{Ra}^{1/4}$$
$$= 0.27\times\left(178.07\times10^4\right)^{0.25}$$
$$= 9.3631$$

Heat transfer co-efficient

$$h = \frac{k}{L_c}\cdot\text{Nu}$$
$$= \frac{0.02588}{0.125}\times9.8631$$
$$= 2.042\ \text{W/m}^2\text{-°C}$$

Step 8 of 8

Now consider the total heat transfer as the sum of convection and radiation heat transfers.

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon\sigma A\left[(T_s)^4 - \left(T_{amb}^4\right)\right]$$

$$21.78 = 2.042(0.25)(T_s - 25) + 0.7\left(5.67\times10^{-8}\right)(0.25)\left[(T_s+273)^4 - (298)^4\right]$$

$$21.78 = 1.01(T_s - 25) + 9.9225\times10^{-9}\left[(T_s+273)^4 - (298)^4\right]$$

The value of temperature obtained by solving the above equation is $T_s = 38.33°\text{C}$

Therefore surface temperature of the circuit board when facing down is $\boxed{T_s = 38.33°\text{C}}$

Question:

The side surfaces of a 3-m-high cubic industrial furnace burning natural gas are not insulated, and the temperature at the outer surface of this section is measured to be 110°C. The temperature of the furnace room, including its surfaces, is 30°C, and the emissivity of the outer surface of the furnace is 0.7. It is proposed that this section of the furnace wall be insulate with glass wool insulation (k= 0.038 W/m·K) wrapped by a reflective sheet (ε = 0.2) in order to reduce the heat loss by 90 percent. Assuming the outer surface temperature of the metal section still remains at about 110°C, determine the thickness of the insulation that needs to be used.

The furnace operates continuously throughout the year and has an efficiency of 78 percent. The price of the natural gas is $1.10/therm (1 therm = 105,500 kJ of energy content). If the installation of the insulation will cost $550 for materials and labor, determine how long it will take for the insulation to pay for itself from the energy it saves.

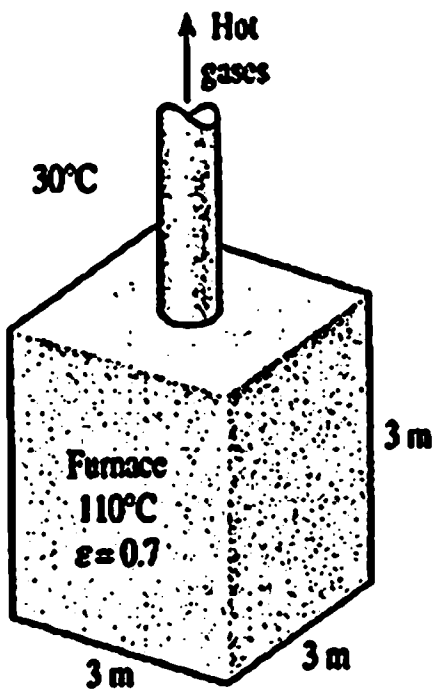


FIGURE P20–43

Step 1 of 10

Calculate the film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

Where,

T_s is the outer surface temperature of the furnace wall,

T_∞ is the temperature of the room.

Substitute $T_\infty = 303\,\text{K}$ and $T_s = 383\,\text{K}$ in the above equation,

$$T_f = \frac{110^\circ\text{C} + 30^\circ\text{C}}{2}$$
$$= 70^\circ\text{C}$$
$$\beta = \frac{1}{T_f + 273}$$
$$= \frac{1}{70 + 273}$$
$$= 0.002915\,\text{K}^{-1}$$

The properties of air at film temperature and atmospheric pressure are

Thermal conductivity, $k = 0.02881\,\text{W/m}^\circ\text{C}$

Kinematic viscosity, $\nu = 1.995 \times 10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7177$

Step 2 of 10

The Rayleigh number is given by

$$\text{Ra} = \text{Gr} \times \text{Pr}$$
$$= \frac{g\beta(T_s - T_\infty)L^3}{\nu^2} \times \text{Pr}$$

Where,

L is the side of the cube shaped furnace,

g is the acceleration due to gravity.

Subtitute $g = 9.81\,\text{m/s}^2$ and 3 m for L in the above equation,

$$\text{Ra} = \frac{9.81 \times 0.002915(110 - 30)(3)^3}{\left(1.995 \times 10^{-5}\right)^2} \times 0.7177$$
$$= 1.1138 \times 10^{11}$$

The relation for Nusselt number,

$$\text{Nu} = \left[0.825 + \frac{0.387 \times \text{Ra}^{1/6}}{\left(1 + (0.492/\text{Pr})^{9/16}\right)^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{0.387 \times \left(1.1138 \times 10^{11}\right)^{1/6}}{\left(1 + (0.492/0.7177)^{9/16}\right)^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{26.844}{1.192}\right]^2$$
$$= 544.99$$

Step 3 of 10

Calculate the heat transfer coefficient,

$$h = \frac{\text{Nu} \times k}{L}$$
$$= \frac{544.99 \times 0.02881}{3}$$
$$= 5.234\ \text{W/m}^2\text{C}$$

Calculate the lateral surface area of the furnace,

$$A_s = 4 \times \left(L^2\right)$$
$$= 4 \times 3^2$$
$$= 36\ \text{m}^2$$

Step 4 of 10

Calculate the total heat of the given system,

$$\dot{Q} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$= hA_s(T_s - T_\infty) + \varepsilon A_s \sigma\left(T_s^4 - T_\infty^4\right)$$

Step 4 of 10

Calculate the total heat of the given system,

$$\begin{aligned}\dot{Q} &= \dot{Q}_{conv} + \dot{Q}_{rad} \\ &= hA_s(T_s - T_\infty) + \varepsilon A_s \sigma\left(T_s^4 - T_\infty^4\right) \\ &= \left[5.234 \times 36(383-303)\right] + \left[0.7 \times 36 \times \left(5.67 \times 10^{-8}\right)\left(383^4 - 303^4\right)\right] \\ &= 33.77\ \text{kW}\end{aligned}$$

Calculate the quantity of heat lost,

$$\begin{aligned}\dot{Q}_{lost} &= (1-0.9)\dot{Q} \\ &= (0.1)(33.77\ \text{kW}) \\ &= 3.377\ \text{kJ/s}\end{aligned}$$

Calculate the quantity of heat saves,

$$\begin{aligned}\dot{Q}_{saved} &= 0.9\dot{Q} \\ &= (0.9)(33.77\ \text{kW}) \\ &= 30.39\ \text{kJ/s}\end{aligned}$$

Step 5 of 10

The cost of energy saved by controlling the heat loss is given by

$$\begin{aligned}\text{Cost} &= \left(\frac{\dot{Q}_{saved}}{\eta_f}\right) \times (\Delta t) \times (\text{Unit cost}) \\ &= \left(\frac{30.39}{0.78}\ \text{kJ/s} \times \frac{1\ \text{therm}}{105500\ \text{kJ}}\right) \times (365 \times 24 \times 60 \times 60\ \text{s/yr}) \times (\$1.1/\text{therm}) \\ &= \$12811\end{aligned}$$

The duration in which the saved energy repays the installation cost is given by

$$\begin{aligned}\text{time} &= \frac{\text{installation cost}}{\text{Cost saved per yr}} \\ &= \frac{\$550}{\$12811/\text{yr}} \\ &= 0.0429\ \text{yr} \\ &= 15.67\ \text{days}\end{aligned}$$

Therefore the time required for the saved cost to repay its installation charges is

$\boxed{15.67\ \text{days}}$

Step 6 of 10

Now by considering the insulation, the calculation should be repeated for determining the surface temperature T_{ins} of the insulation.

Consider the surface temperature of the insulation as $T_{ins} = 50^\circ\text{C}$

Calculate the film temperature,

$$\begin{aligned}T_f &= \frac{T_{ins} + T_\infty}{2} \\ &= \frac{50^\circ\text{C} + 30^\circ\text{C}}{2} \\ &= 40^\circ\text{C} \\ \beta &= \frac{1}{T_f + 273} \\ &= \frac{1}{40 + 273} \\ &= 0.003195\ \text{K}^{-1}\end{aligned}$$

The properties of air at film temperature and atmospheric pressure are

Thermal conductivity, $k = 0.02662\ \text{W/m}^\circ\text{C}$

Kinematic viscosity, $\nu = 1.702 \times 10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7255$

Step 7 of 10

The Rayleigh number is given by

$$\begin{aligned}\text{Ra} &= \text{Gr} \times \text{Pr} \\ &= \frac{g\beta(T_s - T_\infty)L^3}{\nu^2} \times \text{Pr} \\ &= \frac{9.81 \times 0.003195(50-30)(3)^3}{\left(1.702 \times 10^{-5}\right)^2} \times 0.7255 \\ &= 4.2388 \times 10^{10}\end{aligned}$$

The relation for Nusselt number is

$$\begin{aligned}\text{Nu} &= \left[0.825 + \frac{0.387 \times Ra^{1/6}}{\left(1 + (0.492/\text{Pr})^{9/16}\right)^{8/27}}\right]^2 \\ &= \left[0.825 + \frac{0.387 \times \left(4.2388 \times 10^{10}\right)^{1/6}}{\left(1 + (0.492/0.7255)^{9/16}\right)^{8/27}}\right]^2 \\ &= \left[0.825 + \frac{22.8517}{1.191}\right]^2 \\ &= 400.479\end{aligned}$$

Step 8 of 10

Calculate the heat transfer coefficient,

$$\begin{aligned}h &= \frac{\text{Nu} \times k}{L} \\ &= \frac{400.479 \times 0.02662}{3} \\ &= 3.55\ \text{W/m}^2\text{C}\end{aligned}$$

Calculate the total surface area of the insulation,

$$\begin{aligned}A_s &= 4 \times (L)(L + 2t_{ins}) \\ &= 4 \times (3)(3 + 2t_{ins}) \\ &= 12(3 + 2t_{ins})\ \text{m}^2\end{aligned}$$

Calculate the total surface area of the insulation,

20.043P pg 3

$$A_s = 4\times(L)(L+2t_{ins})$$
$$= 4\times(3)(3+2t_{ins})$$
$$= 12(3+2t_{ins})\,\text{m}^2$$

Step 9 of 10

Calculate the quantity of heat lost,

$$\dot{Q}_{lost} = \frac{k_{ins}A_{ins}(T_s - T_{ins})}{t_{ins}}$$

$$t_{ins} = \frac{k_{ins}A_{ins}(T_s - T_{ins})}{\dot{Q}_{lost}}$$
$$= \frac{0.038\times\left[12(3+2t_{ins})\right](110-T_{ins})}{3.377\ \text{kJ/s}}$$
$$= 0.135(3+2t_{ins})(110-T_{ins}) \qquad \ldots\ldots (1)$$

Step 10 of 10

Calculate the total heat loss of the given system by the energy balance equation,

$$\dot{Q}_{lost} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$3.377 = hA_{ins}(T_{ins} - T_\infty) + \varepsilon_r A_{ins}\sigma\left(T_{ins}^4 - T_\infty^4\right)$$
$$3.377 = \left[3.55\left[12(3+2t_{ins})\right](T_{ins}-303)\right]$$
$$+\left[0.2\left[12(3+2t_{ins})\right]\left(5.67\times10^{-8}\right)\left(T_{ins}^4 - 303^4\right)\right]$$
$$3.377 = \left[42.6(T_{ins}-303) + \left(13.608\times10^{-8}\right)\left(T_{ins}^4 - 303^4\right)\right](3+2t_{ins}) \ldots\ldots (2)$$

solve the equations (1) and (2),

$$t_s = 3.18\ \text{cm}$$

Therefore the thickness of the insulation is $\boxed{3.18\text{cm}}$

Question: 20.044P

A 1.5-m-diameter, 4-m-long cylindrical propane tank is initially filled with liquid propane, whose density is 581 kg/m3. The tank is exposed to the ambient air at 25°C in calm weather. The outer surface of the tank is polished so that the radiation heat transfer is negligible. Now a crack develops at the top of the tank, and the pressure inside drops to 1 atm while the temperature drops to –42°C. which is the boiling temperature of propane at 1 atm. The heat of vaporization of propane at 1 atm is 425 kJ/kg. The propane is slowly vaporized as a result of the heat transfer from the ambient air into the tank, and the propane vapor escapes the tank at –42°C through the crack. Assuming the propane tank to be at about the same temperature as the propane inside at all times, determine how long it will take for the tank to empty if it is not insulated.

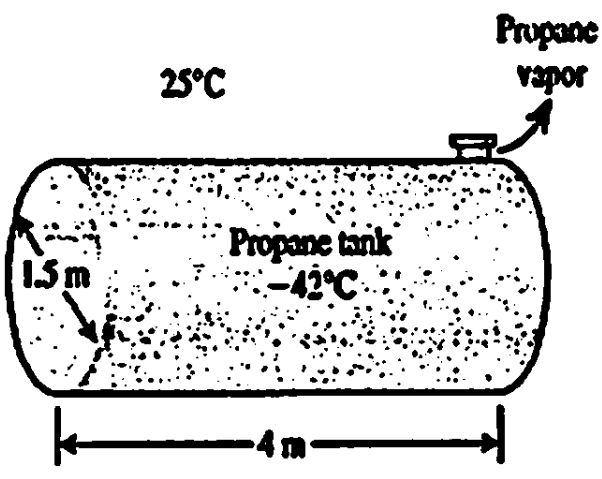

FIGURE P20–44

Step 1 of 4

The time for emptying the tank can be determined by finding the time for heating all the propane to its vapor state. In-order to find the time for heating the propane, determine the convectional heat input by considering the properties of air at film temperature.

The average film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

Substitute 25°C for T_∞ and –42°C for T_S

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{-42 + 25}{2}$$
$$= -8.5°C$$

The volume expansion coefficient,

$$\beta = \frac{1}{T_f + 273}$$
$$= \frac{1}{-8.5 + 273}$$
$$= 0.003781\ K^{-1}$$

Step 2 of 4

The properties of air at –8.5°C are

$$k = 0.02299\ W/m \cdot °C$$
$$\nu = 1.265 \times 10^{-5}\ m^2/s$$
$$Pr = 0.7383$$

Calculate the Rayleigh number. Substitute $9.81\ m/s^2$ for g, $0.003781 K^{-1}$ for β, –42°C for T_s, 25°C for T_∞, 1.5 m for D, $1.265 \times 10^{-5}\ m^2/s$ for ν and 0.7383 for Pr

$$Ra = \frac{g\beta(T_\infty - T_s)D^3}{\nu^2} Pr$$
$$= \frac{9.81 \times 0.003781 \times (25 + 42) \times 1.5^3}{\left(1.265 \times 10^{-5}\right)^2} \times 0.7383$$
$$= 3.869 \times 10^{10}$$

Now determine the Nusselt number. Substitute 3.869×10^{10} for Ra and 0.7383 for Pr

$$Nu = \left[0.6 + \frac{0.387 \times Ra^{1/6}}{\left(1 + (0.559/Pr)^{9/16}\right)^{8/27}}\right]^2$$
$$= \left[0.6 + \frac{0.387 \times \left(3.869 \times 10^{10}\right)^{1/6}}{\left(1 + (0.559/0.7383)^{9/16}\right)^{8/27}}\right]^2$$
$$= 374.1$$

Step 3 of 4

Estimate the heat transfer coefficient from the Nusselt number. Substitute 374.1 for Nu, 4 m for L and 0.02299 W/m·°C for k

$$h = \frac{Nu \times k}{L}$$
$$= \frac{374.1 \times 0.02299}{4}$$
$$= 5.733\ W/m^2 \cdot K$$

Determine the surface area. Substitute 1.5 m for D and 4 m for L

$$A_s = (\pi \times D \times L) + 2\left(\frac{\pi}{4} \times D^2\right)$$
$$= (\pi \times 1.5 \times 4) + 2\left(\frac{\pi}{4} \times 1.5^2\right)$$
$$= 22.38\ m^2$$

Determine the total heat transfer from the circuit board. Substitute $5.733\ W/m^2 \cdot K$ for h, $22.38\ m^2$ for A_s, –42°C for T_s and 25°C for T_∞

$$\dot{Q} = hA_s(T_\infty - T_s)$$
$$= 374.1 \times 22.38 \times (25 - 42)$$
$$= 8598\ W$$
$$= 8.598\ kW$$

Step 4 of 4

Find the total mass of propane. Substitute $581\ kg/m^3$ for ρ, 1.5 m for D and 4 m for L

$$m = \rho \times V$$
$$= \rho \times \left(\frac{\pi}{4} \times D^2 \times L\right)$$
$$= 581 \times \left(\frac{\pi}{4} \times 1.5^2 \times 4\right)$$
$$= 4107\ kg$$

Determine the heat required for heating all the propane to its vapor state.

$$Q = m \times h_{fg}$$
$$= 4107 \times 425$$
$$= 1745475\ kJ$$

Calculate the time for emptying the tank. Substitute 1745475 kJ for Q and 8.598 kW for $\dot{Q}$

$$t = \frac{Q}{\dot{Q}}$$
$$= \frac{1745475\ kJ}{8.598\ kJ/s}$$
$$= 203009.42\ s$$
$$= 56.39\ hr$$

Thus the time for emptying the tank is **56.39 hr**

Question:

Consider a 2-ft · 2-ft thin square plate in a room at 75°F. One side of the plate is maintained at a temperature of 130°F, while the other side is insulated. Determine the rate of heat transfer from the plate by natural convection if the plate is (*a*) vertical; (*b*) horizontal with hot surface facing up: and (*c*) horizontal with hot surface facing down.

Step 1 of 9

Given

Ambient temperature $T_\infty = 75^0\text{F}$

Pipe outer surface temperature is $T_s = 130^0\text{F}$

Step 2 of 9

Average film temperature, $T_f = \dfrac{T_s + T_\infty}{2}$

$$T_f = \frac{75+130}{2}$$

$$T_f = 102.5^0\text{F} = 562.5^0\text{R}$$

Properties of the air at 102.5^0F, $k = 0.01535$ Btu/h.ft.°F

$\upsilon = 0.1823\times10^{-3}$ ft²/s

$\text{Pr} = 0.7256$

$$\beta = \frac{1}{T_f} = 0.001778\ \text{R}^{-1}$$

Step 3 of 9

a)

Surface area of the plate is $A_s = L^2$

$= (2\text{ ft})^2$

$= 4\text{ ft}^2$

Characteristic length is the height of the plate so $L_c = L = 2$ ft.

Rayleigh Number, $Ra = \dfrac{g\beta(T_s - T_\infty)L^3}{\upsilon^2}\text{Pr}$

$$Ra = \frac{32.2\times0.001778\times(130-75)\times2^3}{(0.1823\times10^{-3})^2}(0.7256)$$

$$Ra = \frac{25.19\times0.7256}{3.323329\times10^{-8}}$$

$$Ra = 5.503\times10^8$$

Step 4 of 9

Nusselt number, $Nu = \left\{0.825 + \dfrac{0.387\text{Ra}^{1/6}}{\left[1+\left(\dfrac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2$

$$Nu = \left\{0.825 + \frac{0.387(5.503\times10^8)^{1/6}}{\left[1+\left(\frac{0.492}{0.7256}\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$Nu = \left\{0.825 + \frac{11.078}{1.190967}\right\}^2$$

$$Nu = 102.6$$

Step 5 of 9

But $Nu = \dfrac{hL}{k}$ So heat transfer coefficient,

$$h = \frac{k}{L}Nu$$

$$h = \frac{0.01535}{2}(102.6)$$

$h = 0.7869$ Btu/h.ft²°F

Heat transfer rate, $\dot{Q} = hA_s(T_s - T_\infty)$

$$\dot{Q} = 0.7869\times4\times(130-75)$$

$$\dot{Q} = 173.1\text{ Btu/hr}$$

$\boxed{\dot{Q} = 173.1\text{ Btu/hr}}$

Step 6 of 9

b)

the characteristic length, $L_s = \dfrac{A_s}{P}$

$$L_s = \frac{L}{4}$$

$$L_s = 0.5\text{ ft}$$

Rayleigh Number, $Ra = \dfrac{g\beta(T_s - T_\infty)L_s^3}{\upsilon^2}\text{Pr}$

$$Ra = \frac{32.2\times0.001778\times(130-75)\times(0.5)^3}{\left(0.1823\times10^{-3}\right)^2}(0.7256)$$

$$Ra = \frac{0.3936}{3.32333\times10^{-8}}(0.7256)$$

$$Ra = 8.598\times10^6$$

Nusselt number, $Nu = 0.54Ra^{1/4}$

$$Nu = 0.54(8.598\times10^6)^{1/4}$$

$$Nu = 29.24$$

Step 7 of 9

But $Nu = \dfrac{hL}{k}$ So transfer coefficient,

$$h = \frac{k}{L_c}Nu$$

$$h = \frac{0.01535}{(29.24)}$$

But $Nu = \frac{hL}{k}$ So transfer coefficient,

$$h = \frac{k}{L_c} Nu$$

$$h = \frac{0.01535}{0.5}(29.24)$$

$$h = 0.8975 \text{ Btu/h.ft}^2.^\circ\text{F}$$

Heat transfer rate, $\dot{Q} = hA_s(T_s - T_\infty)$

$$\dot{Q} = 0.8975 \times 4 \times (130 - 75)$$

$$\dot{Q} = 197.4 \text{ btu/hr}$$

$$\boxed{\dot{Q} = 197.4 \text{ btu/hr}}$$

Step 8 of 9

c)

the characteristic length, $L_s = \frac{A_s}{P}$

$$L_s = \frac{L}{4}$$

$$L_s = 0.5 \text{ ft}$$

Rayleigh Number, $Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\text{Pr}$

$$Ra = \frac{32.2 \times 0.001778 \times (130 - 75) \times (0.5)^3}{\left(0.1823 \times 10^{-3}\right)^2}(0.7256)$$

$$Ra = \frac{0.3936}{3.32333 \times 10^{-8}}(0.7256)$$

$$Ra = 8.598 \times 10^6$$

Nusselt number, $Nu = 0.27Ra^{1/4}$

$$Nu = 0.54(8.598 \times 10^6)^{1/4}$$

$$Nu = 14.62$$

Step 9 of 9

But $Nu = \frac{hL}{k}$ So transfer coefficient,

$$h = \frac{k}{L_c} Nu$$

$$h = \frac{0.01535}{0.5}(14.62)$$

$$h = 0.4487 \text{ Btu/h.ft}^2{}^\circ\text{F}$$

Heat transfer rate, $\dot{Q} = hA_s(T_s - T_\infty)$

$$\dot{Q} = 0.4487 \times 4 \text{ ft}^2 \times (130 - 75)$$

$$\dot{Q} = 98.7 \text{ Btu/h}$$

$$\boxed{\dot{Q} = 98.7 \text{ Btu/h}}$$

Question:

Reconsider Prob. 20–45E. Using EES (or other) software, plot the rate of natural convection heat transfer for different orientations of the plate as a function of the plate temperature as the temperature varies from 80°F to 180°F, and discuss the results.

Step 1 of 7

Side length of the thin square plate, $s = 2\,\text{ft}$

Outside room temperature, $T_\infty = 75°\text{F}$

Higher surface temperature, $T_s = 130°\text{F}$

Step 2 of 7

This given problem is solved in EES "Engineering Equation Solver" in the following method.

Open a new window in the EES software by ceasing " File > New " and type the program as shown below.

Equations Window

```
P_1=1 [atm]

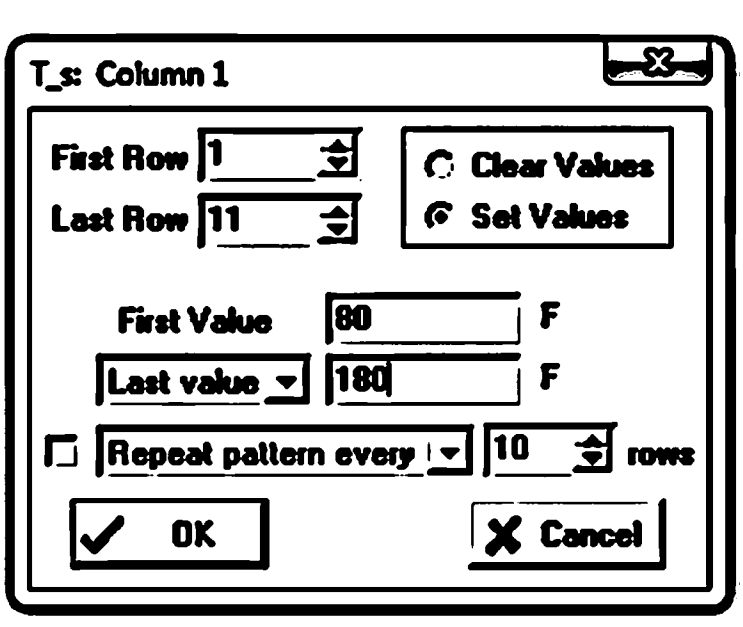
```



Step 3 of 7

Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

Step 4 of 7

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Step 5 of 7

Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Parametric Table

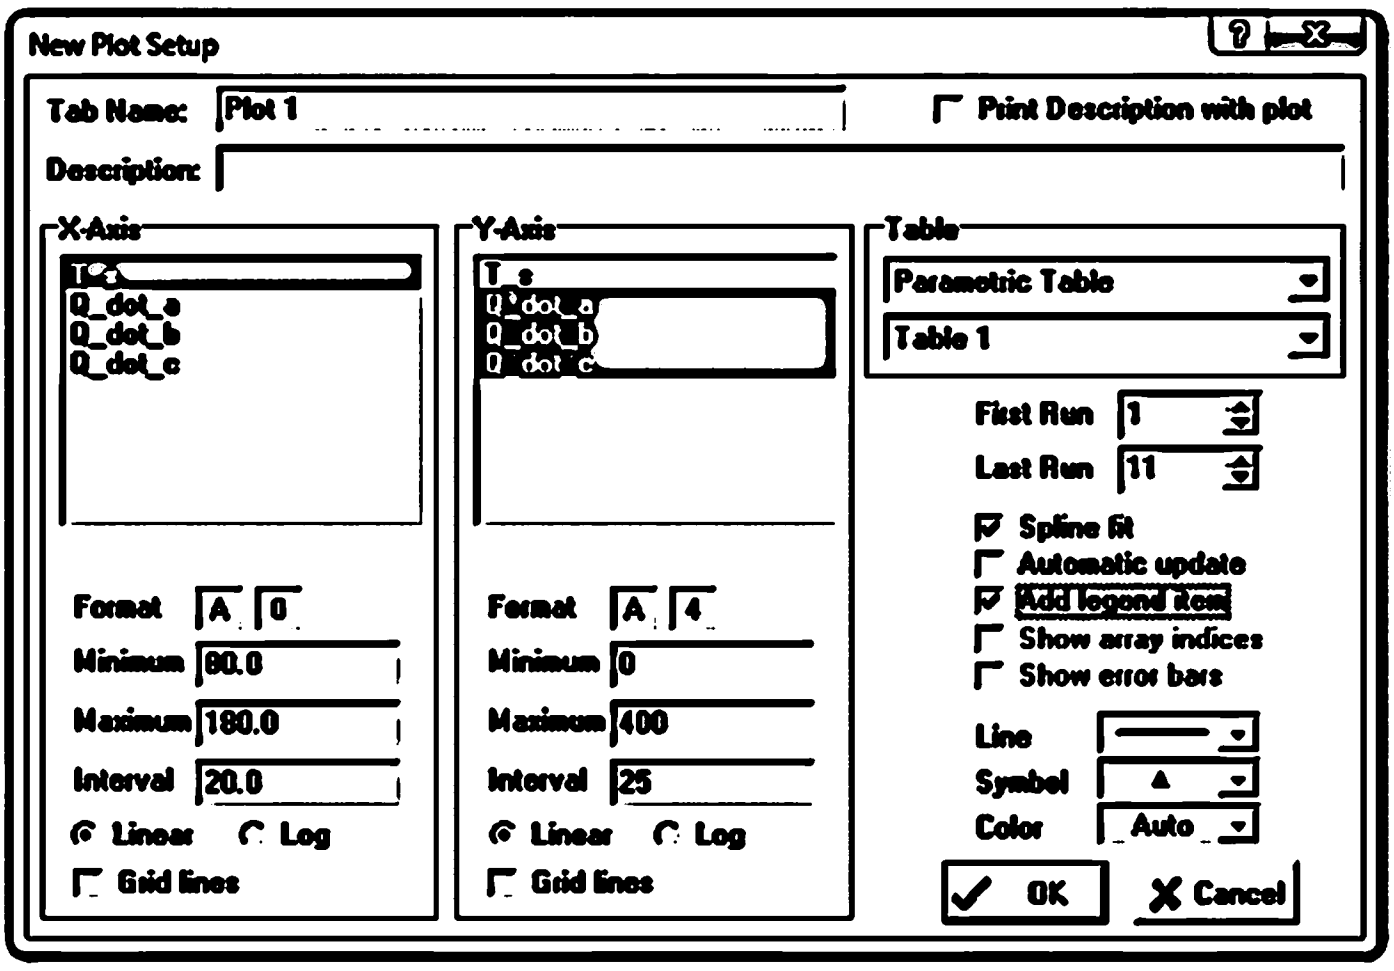


Table 1

1..11	T_s [F]	$\dot{Q}_a$	$\dot{Q}_b$	$\dot{Q}_c$
Run 1	80	7.825	2.495	1.247

Step 6 of 7

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 7 of 7

By clicking on OK the graph will be generated as shown,

Question: 20.047P

A 28-cm-high, 18-cm-long, and 18-cm-wide rectangular container suspended in a room at 24°C is initially filled with cold water at 2°C. The surface temperature of the container is observed to be nearly the same as the water temperature inside. The emissivity of the container surface is 0.6, and the temperature of the surrounding surfaces is about the same as the air temperature. Determine the water temperature in the container after 3 h, and the average rate of heat transfer to the water. Assume the heat transfer coefficient on the top and bottom surfaces to be the same as that on the side surfaces.

Step 1 of 7

Height of container, $H = 28\text{cm} = 0.28\text{m}$

Length of container, $L = 18\text{cm} = 0.18\text{m}$

Width of container, $w = 18\text{cm} = 0.18\text{m}$

Temperature outside the room, $T_\infty = 24°\text{C}$

Emissivity of container surface $\varepsilon = 0.6$

Outside surface temperature $T_{amb} = 24°\text{C}$

Cold water temperature $T_1 = 2°\text{C}$

Step 2 of 7

Assume the surface temperature as 6°C. Now the film temperature is

$$T_f = (T_s + T_\infty)/2$$
$$= (6+24)/2$$
$$= 15°\text{C}$$

Volume expansion Co-efficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{15+273}$$
$$= 3.472\times10^{-3}\text{K}^{-1}$$

Characteristic length,

$$L_c = H$$
$$= 0.28\text{m}$$

Step 3 of 7

Take the properties of air at 1 atm and temperature, 15°C

Thermal conductivity, $k = 0.02476\,\text{W/m}\cdot°\text{C}$

Prandtl Number, $\text{Pr} = 0.7323$

Kinematic Viscosity, $\nu = 1.470\times10^{-5}\,\text{m}^2/\text{s}$

Rayleigh number

$$\text{Ra} = \frac{g\beta(T_\infty - T_s)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.472\times10^{-3}(24-6)(0.28)^3}{\left(1.470\times10^{-5}\right)^2}(0.7323)$$
$$= 4.56\times10^7$$

Step 4 of 7

Nusselt number for entire range

$$\text{Nu} = \left[0.825 + \frac{0.387\,Ra^{1/6}}{\left[1+(0.492/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{0.387\left(4.56\times10^7\right)^{1/6}}{\left[1+(0.492/0.7323)^{9/16}\right]^{8/27}}\right]^2$$
$$= 48.596$$

Heat transfer co-efficient,

$$h = \frac{k}{L_c}\cdot\text{Nu}$$
$$= \frac{0.02476}{0.28}\times48.596$$
$$= 4.297\,\text{W/m}^2\cdot\text{K}$$

Step 5 of 7

Calculate the surface area.

$$A_s = 4(0.28\times0.18) + 2(0.18\times0.18)$$
$$= 0.2664\,\text{m}^2$$

Rate of heat transfer $\dot{Q}$ can be written as (radiation considered),

$$\dot{Q} = hA_s\left(T_\infty - \frac{T_1+T_2}{2}\right) + \varepsilon\sigma A_s\left(T_{amb}{}^4 - \left(\frac{T_1+T_2}{2}\right)^4\right)$$

$$\dot{Q} = 4.297(0.2664)\left(297 - \left(\frac{275+T_2}{2}\right)\right) + 0.6\left(5.67\times10^{-8}\right)0.2664\left(297^4 - \left(\frac{275+T_2}{2}\right)^4\right)$$

$$\dot{Q} = 1.1447\left(297 - \left(\frac{275+T_2}{2}\right)\right) + 9.0629\times10^{-9}\left(297^4 - \left(\frac{275+T_2}{2}\right)^4\right) \quad \text{..... (1)}$$

Step 6 of 7

Mass of water,

$$m = \rho v$$
$$= 1000\times(0.28\times0.18\times0.18)$$
$$= 9.072\,\text{kg}$$

Specific heat of water, $c_p = 4214\,\text{J/kg}°\text{C}$

Heat transfer to water,

$$Q = mc_p(T_2 - T_1)$$
$$= 9.072\times4214(T_2 - 275)$$
$$= 38229.41(T_2 - 275)$$

Average rate of heat transfer after 3 hours,

$$\dot{Q} = \frac{Q}{\Delta t}$$
$$\dot{Q} = \frac{38229.41}{3\times3600}(T_2 - 275)$$
$$\dot{Q} = 3.54(T_2 - 275) \quad \text{..... (2)}$$

Step 7 of 7

Consider equations (1) and (2). And calculate the final temperature.

By solving the temperatures, the final temperature becomes. $T_2 = 11.75°\text{C}$

Hence water temperature after 3 hours, is $\boxed{T_2 = 11.75°\text{C}}$

Average rate of heat transfer to water is obtained by substituting the value of T_2 in equation (2)

$$\dot{Q} = 3.54(284.75 - 275)$$
$$= 34.514\ \text{W}$$

The average rate of heat transfer to the water is $\boxed{\dot{Q} = 34.514\ \text{W}}$

Question:

Reconsider Prob. 20–47. Using EES (or other) software, plot the water temperature in the container as a function of the heating time as the time varies from 30 min to 10 h. and discuss the results.

Step 1 of 6

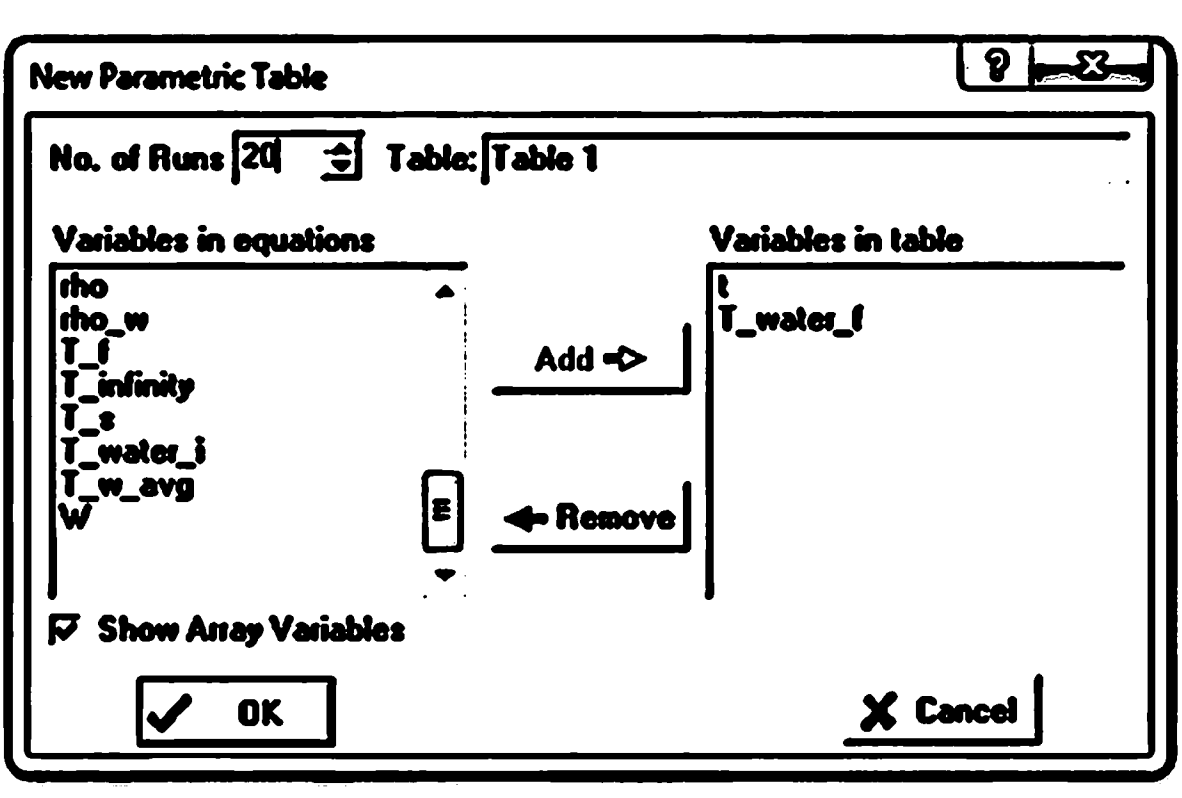
Loading solution. Please wait ...

Step 2 of 6

This given problem is solved in EES "Engineering Equation Solver" in the following method.
Open a new window in the EES software by ceasing " File > New " and type the program as shown below,

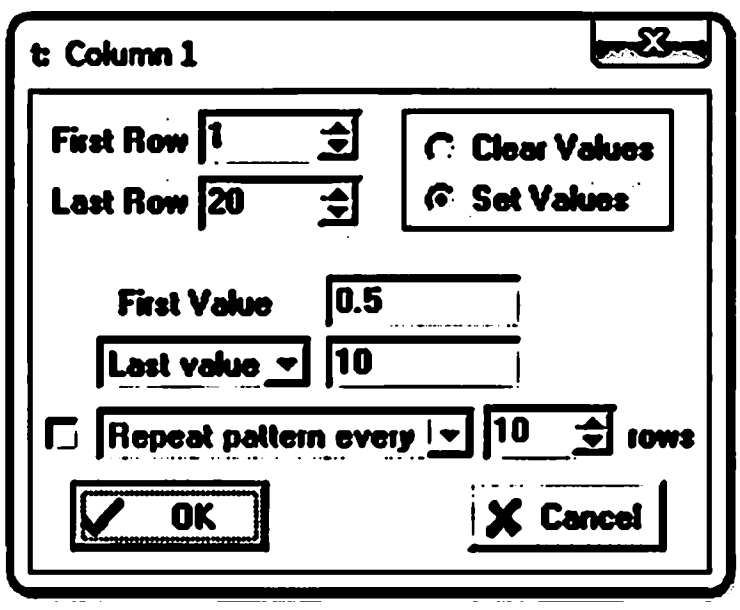
```
"Given data"
H=0.28 [m]
L=0.18 [m]
W=0.18 [m]
T_infinity=297 [K]
epsilon=0.6
T_water_i=275[K]
L_c=0.28 [m]
P_1=101.3 [kPa]
T_s=279 [K]                                   "Assumption of film temprature"
t=3 [hour]*convert(hour,second)

"Properties of air and water at given conditions"
A_s=2*((H*L)+(W*H)+(W*L))
T_f=(T_s+T_infinity)/2
T_w_avg=(T_water_i+T_water_f)
k=Conductivity(Air,T=T_f)
Pr=Prandtl(Air,T=T_f)
mu=Viscosity(Air,T=T_f)
cp=Cp(water,T=T_water_i,P=P_1)
rho=Density(Air,T=T_f,P=P_1)
nu=mu/rho
rho_w=density(water,T=T_water_i,P=P_1)



beta=1/T_f                                    "Co-efficient of Volume expansion "

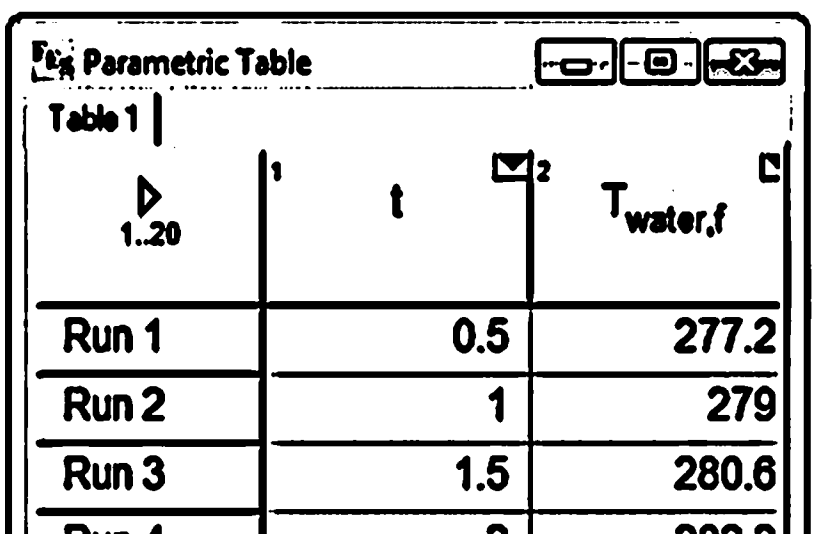
Ra=(g)*beta*(T_infinity-T_s)*L_c^3)/nu^2*Pr
Nus=(0.825+((0.387*Ra^(1/6))/(1+(0.492/Pr)^(9/16)^(8/27))))   "Nusselt number "
h_bar=(k/L_c)*Nus



"Rate of heat transfer "
Q_dot=h_bar*A_s*(T_infinity- T_w_avg)+(epsilon*sigma#*A_s*((T_s)^4)-( T_w_avg)^4)
m=rho_w*(H*L*W)                               "Mass of water "
Q=m*cp*( T_water_f- T_water_i)                "Heat transfer to water"
Q_dot=Q/t                                     "Average rate of heat transfer after 3 hours"
```

Step 3 of 6

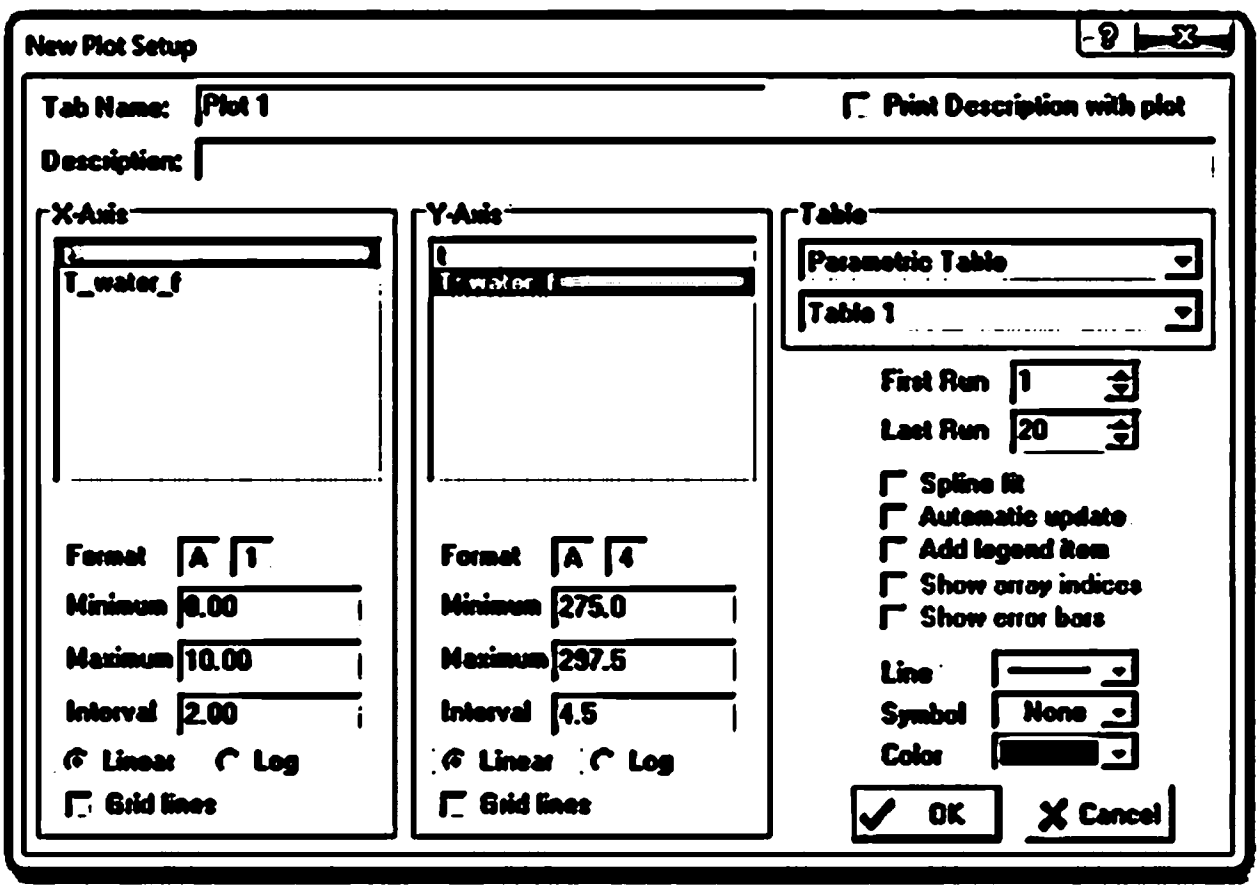
Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,



To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

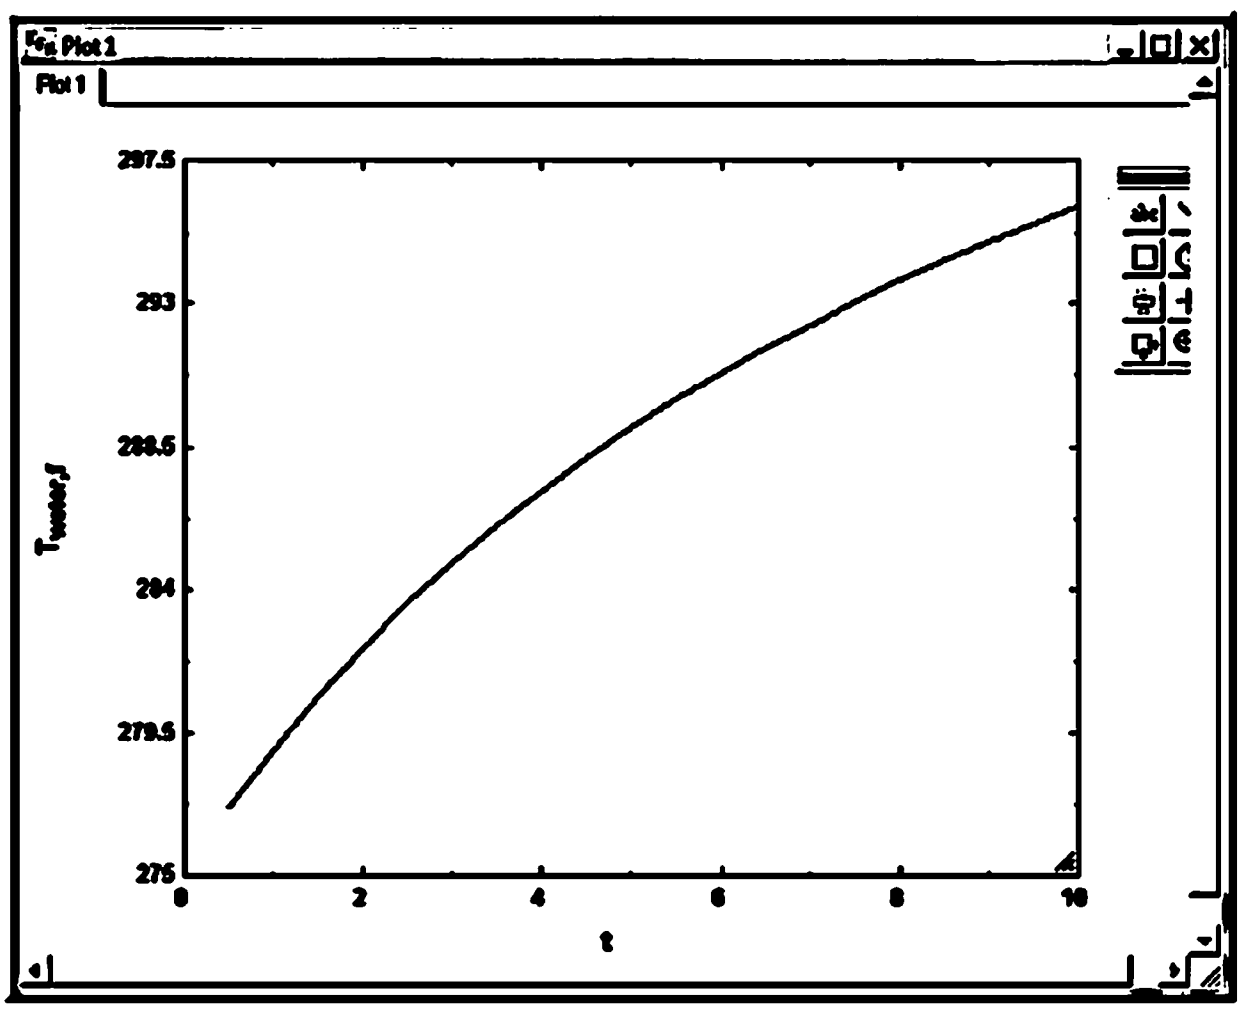
Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Step 4 of 6



1..20	t	$T_{water,f}$
Run 1	0.5	277.2
Run 2	1	279
Run 3	1.5	280.6

Run 1	0.5	277.2
Run 2	1	279
Run 3	1.5	280.6
Run 4	2	282.2
Run 5	2.5	283.6
Run 6	3	284.8
Run 7	3.5	286
Run 8	4	287.1
Run 9	4.5	288.2
Run 10	5	289.1
Run 11	5.5	290
Run 12	6	290.8
Run 13	6.5	291.6
Run 14	7	292.3
Run 15	7.5	293.1
Run 16	8	293.7
Run 17	8.5	294.4
Run 18	9	295
Run 19	9.5	295.5
Run 20	10	296.1



Step 5 of 6

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 6 of 6

By clicking on OK the graph will be generated as shown,

Question: 20.049P

The following experiment is conducted to determine the natural convection heat transfer coefficient for a horizontal cylinder that is 80 cm long and 2 cm in diameter. A 8 cm long resistance heater is placed along the centerline of the cylinder, and the surfaces of the cylinder are polished to minimize the radiation effect. The two circular side surfaces of the cylinder are well insulated. The resistance heater is turned on and the power dissipation is maintained constant at 60 W. If:; the average surface temperature of the cylinder is measured to 1 be 120°C in the 20°C room air when steady operation is I reached, determine the natural convection heat transfer coefficient. If the emissivity of the outer surface of the cylinder is 0.1 and a 5 percent error is acceptable, do you think we used to do any correction for the radiation effect? Assume the surrounding surfaces to be at 20°C also.

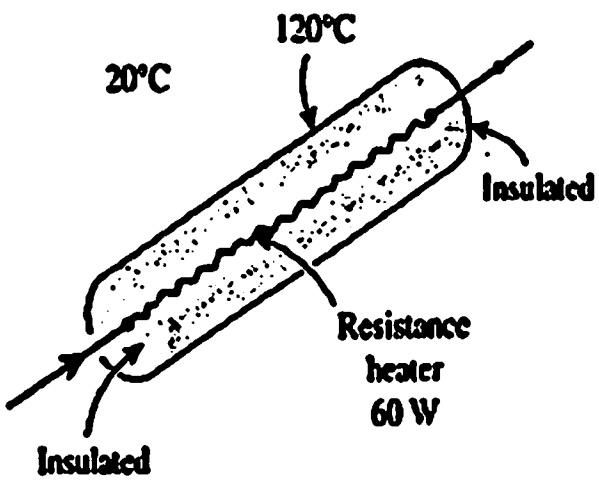


FIGURE P20–49

Step 1 of 3

Loading solution. Please wait ...

Step 2 of 3

Surface area, $A = \pi DL$

$A = \pi(0.02\ \text{m})(0.8\ \text{m})$

$A = 0.05027\ \text{m}^2$

Heat transfer due to convection, $\dot{Q} = hA_s(T_s - T_\infty)$

Now $h = \dfrac{\dot{Q}}{A_s(T_s - T_\infty)}$

$h = \dfrac{60\ \text{W}}{0.05027 \times (120 - 20)}$

$h = 11.9355\ \text{W/m}^2\text{C}$

Step 3 of 3

Radiation heat loss from the cylinder,

$\dot{Q}_{rad} = \varepsilon A_s \sigma(T_s^4 - T_{surr}^4)$

$\dot{Q}_{rad} = 0.1 \times 0.05027 \times 5.67 \times 10^{-8} \times [(120+273)^4 - (20+273)^4]$

$\dot{Q}_{rad} = 4.7\ \text{W}$

The fraction of heat loss by radiation,

Radiation fraction $= \dfrac{\dot{Q}_{radiation}}{\dot{Q}_{total}}$

$= \dfrac{4.7\ \text{W}}{60\ \text{W}}$

$= 0.07833$

$= 7.833\%$

This is greater than 5%. Therefore, the radiation effect is still considerable and necessary corrections must be made to control the radiation effect.

Question: 20.050P

The water in a 40-L tank is to be heated from 15°C to 45°C by a 6-cm-diameter spherical heater whose surface temperature is maintained at 85°C. Determine how long the heater should be kept on.

Step 1 of 7

Loading solution. Please wait ...

Step 2 of 7

Average temperature of water,

$$T_\infty = \frac{T_1 + T_2}{2}$$
$$= \frac{15+45}{2}$$
$$= 30°C$$

Mean film temperature of water

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{(85+30)}{2}$$
$$= 57.5°C$$

Step 3 of 7

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{57.5+273}$$
$$= 3.026\times10^{-3}\,K^{-1}$$

Take the properties of water by interpolating the values between $(55-60)°C$

Thermal conductivity, $k = 0.6515\,W/m\cdot°C$

Prandtl number, $Pr = 3.12$

Kinematic viscosity, $\nu = 4.933\times10^{-7}\,m^2/s$

Step 4 of 7

Properties of water at 30°C (Average temperature)

Density, $\rho = 996\,kg/m^3$

Specific heat, $c_p = 4178\,J/kg\,°C$

Characteristic length,

$$L_c = D$$
$$= 0.06\,m$$

Calculate the Rayleigh

$$Ra_D = \frac{g\beta(T_s - T_\infty)L_c^3}{(\nu)^2}\cdot Pr$$
$$= \frac{9.81\times\left(3.026\times10^{-3}\right)(85-30)(0.06)^3}{\left(4.933\times10^{-7}\right)^2}\times(3.12)$$
$$= 45.211\times10^8$$

Step 5 of 7

Calculate the Nusselt number for sphere $\left(Ra_D \le 10^{11} \text{ and } Pr \ge 0.7\right)$

$$Nu = 2 + \frac{0.589\,Ra_D^{1/4}}{\left[1+(0.469/Pr)^{9/16}\right]^{4/9}}$$
$$= 2 + \frac{0.589\left(45.211\times10^8\right)^{1/4}}{\left[1+(0.469/3.12)^{9/16}\right]^{4/9}}$$
$$= 136$$

Heat transfer co-efficient,

$$h = \frac{k}{L_c}\cdot Nu$$
$$= \frac{0.6515}{0.06}\times136$$
$$= 1475.72\,W/m^2\cdot°C$$

Step 6 of 7

Rate of heat transfer by convection

$$Q_{conv} = hA_s(T_s - T_\infty)$$
$$= h\left(\pi D^2\right)(T_s - T_\infty)$$
$$= 1475.72\left(\pi0.06^2\right)(85-30)$$
$$= 917.95\,W$$

Total amount of heat transfer to water:

$$Q = mc_p(T_2 - T_1)$$
$$= (\rho V)c_p(T_2 - T_1)$$
$$= (996\times0.04)\times4178\times(45-15)$$
$$= 4993545.6\,J$$

$$= (\rho V)c_p(T_2 - T_1)$$
$$= (996\times0.04)\times4178\times(45-15)$$
$$= 4993545.6\,J$$

Step 7 of 7

Time taken by the heater,

$$t = \frac{\text{amount of heat needed}}{\text{Rate of heat transfer}}$$
$$= \frac{Q}{Q_{conv}}$$
$$= \frac{4993545.6}{917.95}$$
$$= 5439.88\,sec$$
$$= 1.51\,h$$

The heater should be kept on for $\boxed{t = 1.51\,hours}$

Question: 20.052P

The upper and lower compartments of a well-insulated container are separated by two parallel sheets of glass with an air space between them. One of the compartments is to be filled with a hot fluid and the other with a cold fluid. If it is desired that heat transfer between the two compartments be minimal, would you recommend putting the hot fluid into the upper or the lower compartment of the container? Why?

Step 1 of 1

The convection currents get developed if the hotter fluid (lighter) is below the colder (denser) fluid. Hence it is better to have colder fluid in the bottom compartment and the hotter fluid in the upper compartment of a well-insulated container.

Question: 20.053P

Someone claims that the air space in a double-pane window enhances the heat transfer from a house because of the natural convection currents that occur in the air space and recommends that the double-pane window be replaced by a single sheet of glass whose thickness is equal to the sum of the thicknesses of the two glasses of the double-pane Window to save energy. Do you agree with this claim?

Step 1 of 1

By removing the air space and replacing the double pane with a single glass sheet, we eliminate the resistance offered by the air. As air has low thermal conductivity, the resistance offered by the air to flow of heat is more. Hence by removing the air space and by providing a single glass sheet, the heat transfer gets enhanced.

Question: 20.054P

Consider a double-pane window consisting of two glass sheets separated by a 1-cm-wide air space. Someone suggests inserting a thin vinyl sheet in the middle of the two glasses to form two 0.5-cm-wide compartments in the window in order to reduce natural convection heat transfer through the window. From a heat transfer point of view, would you be in favor of this idea to reduce heat losses through the window?

Step 1 of 1

Dividing the air space into thinner compartments would reduce the convection currents of the air. Hence by placing a thin vinyl sheet in the middle of two glasses to divide the air compartment into thinner compartments, heat losses from the window can be reduced.

Question: 20.055P

What does the effective conductivity of an enclosure represent? How is the ratio of the effective conductivity to thermal conductivity related to the Nusselt number?

Step 1 of 3

The rate of heat transfer through the enclosure is

$$\dot{Q} = hA_s(T - T_2)$$

$$= kNuA_s\left(\frac{T_1 - T_2}{L_c}\right) \qquad \text{.....(1)}$$

Since $h = \frac{kNu}{L}$

The rate of steady heat conduction across the layer of thickness L_c and A_s, and thermal conductivity k is expressed as

$$\dot{Q} = kA_s\left(\frac{T_1 - T_2}{L_c}\right) \qquad \text{.....(2)}$$

Where

T_1 and T_2 Is the temperature on the both sides of the layer.

Step 2 of 3

A compression the relation 2 with 1 is reveals that the convention heat transfer in an enclosure is analogue to heat conduction across the fluid layer in the enclosure provided that the thermal conductivity k is replaces with kNu .it is due to convention currents. So the quantity kNu is called effective thermal conductivity.

Step 3 of 3

The effective thermal conductivity of the rectangular enclosure represents the product of the thermal conductivity and the Nusselt number as a result of convection currents.
The ratio of effective thermal conductivity to thermal conductivity equals to the Nusselt number.

$$\frac{k_{eff}}{k} = Nu$$

Question: 20.056P

Consider a 3-m high rectangular enclosure consisting of two surfaces separated by a 0.1-m air gap at 1 atm. If the surface temperatures across the air gap are 30°C and -10°C, determine the ratio of the heat transfer rate for the horizontal orientation (with hotter surface at the bottom) to that for vertical orientation.

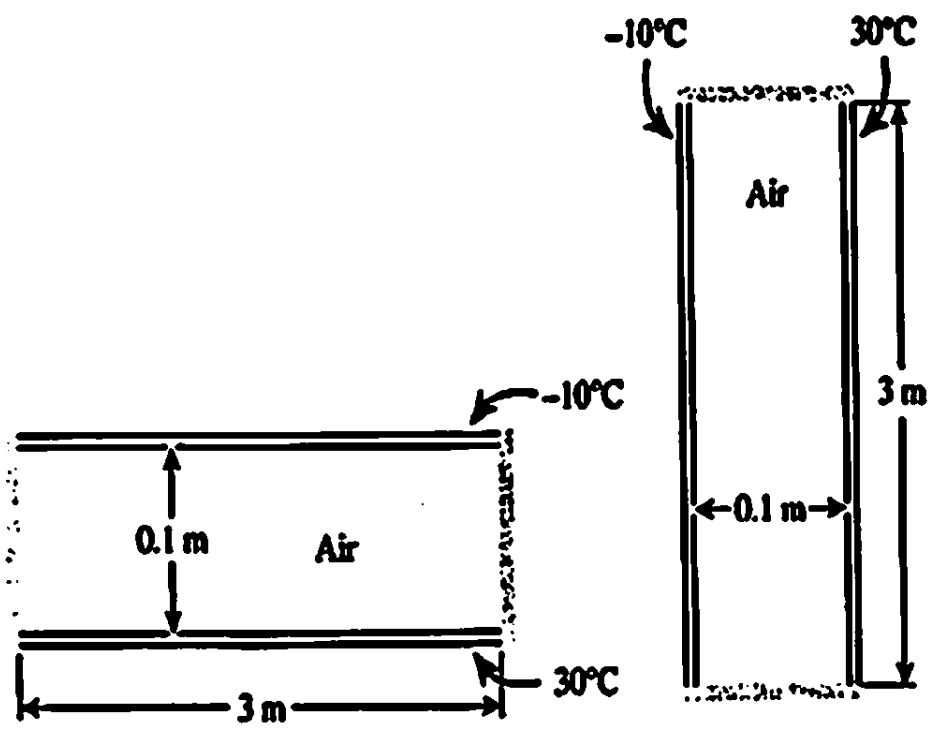

FIGURE P20–56

Step 1 of 5

Calculate the average temperature of two surfaces by using the equation,

$$T_f = \frac{T_{s1} + T_{s2}}{2}$$

Here, T_{s1} and T_{s2} are the surface temperatures.

Substitute $30°C$ for T_{s1} and $-10°C$ for T_{s2}

$$T_f = \frac{-10+30}{2}$$
$$= 10°C$$

Find coefficient of volume expansion by using the equation,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{10+273}$$
$$= 0.00353$$

Obtain the properties of air at 1atm and $10°C$ from properties of air table,

Thermal conductivity, $k = 0.02288\ \text{W/m°·C}$

Prandtl number, $\text{Pr} = 0.7387$

Kinematic viscosity, $\nu = 1.252\times10^{-5}\ \text{m}^2/\text{s}$

Step 2 of 5

Find the Rayleigh number when the plates are placed in horizontal position,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$

Here, β is coefficient of volume expansion, L_c is characteristic length

Substitute 0.1 m for L_c . 9.81m/s^2 for g

$$\text{Ra}_L = \frac{g\beta\Delta T L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times0.00353\times[30-(-10)]\times0.1^3}{(1.252\times10^{-5})^2}\times0.7387$$
$$= 6.5277\times10^6\ (<10^8)$$

For horizontal position, calculate the Nusselt number by using the expression,

$$\text{Nu}_h = 1+1.44\left[1-\frac{1708}{\text{Ra}_L}\right]^+ + \left[\frac{\text{Ra}_L^{1/3}}{18}-1\right]^+$$
$$= 1+1.44\left[1-\frac{1708}{6.5277\times10^6}\right]^+ + \left[\frac{(6.5277\times10^6)^{1/3}}{18}-1\right]^+$$
$$= 1+1.44\times0.999+9.377$$
$$= 11.81$$

Step 3 of 5

For vertical orientation, find the aspect ratio,

$$\frac{H}{L}$$

Here, H is height of the vertical plate and L is distance between two plates.

Substitute 3 m for H and 0.1 m for L

$$\frac{H}{L} = \frac{3}{0.1}$$
$$= 30$$

For vertical position, find the Nusselt number at the aspect ratio $\frac{H}{L} = 30$

$$\text{Nu} = 0.42\text{Ra}_L^{1/4}\,\text{Pr}^{0.012}\left(\frac{H}{L}\right)^{-0.3}$$
$$= 0.42\times(6.5277\times10^6)^{1/4}\times0.7387^{0.012}\times30^{-0.3}$$
$$= 7.624$$

Step 4 of 5

Find the heat transfer coefficient in horizontal position,

$$h_h = \frac{\text{Nu}_h\times k}{L_c}$$
$$= \frac{11.81\times0.02288}{0.1}$$
$$= 2.7021\ \text{W/m}^2\cdot°\text{C}$$

Heat transfer coefficient for vertical position,

$$h_v = \frac{\text{Nu}_v\times k}{L_C}$$
$$= \frac{7.624\times0.02288}{0.1}$$
$$= 1.744\ \text{W/m}^2\cdot°\text{C}$$

Find the heat transfer in horizontal position by using the equation,

$$Q_h = h_h A_s(T_{s1}-T_{s2})$$
$$= 2.7021\times A_s(30-(-10))$$
$$= 108.084A_s\ \text{W}$$

Find the heat transfer in vertical position by using the equation,

$$Q_v = h_v A_s(T_{s1}-T_{s2})$$
$$= 1.744\times A_s(30-(-10))$$
$$= 69.76A_s$$

Step 5 of 5

Find the ratio of heat transfer between horizontal orientations to the vertical orientation of the surfaces,

$$\frac{\dot{Q}_h}{\dot{Q}_v} = \frac{108.084A_s}{69.76A_s}$$
$$= 1.54$$

Hence the ratio of heat transfer rate for horizontal to vertical is $\boxed{\frac{\dot{Q}_h}{\dot{Q}_v} = 1.54}$

Question: 20.057P

Two concentric spheres with radii of 5 cm and 10 cm are having the surface temperatures maintained at 100°C and 200°C, respectively. The enclosure between the two concentric spherical surfaces is filled with nitrogen gas at 1 atm. Determine the rate of heat transfer through the enclosure.

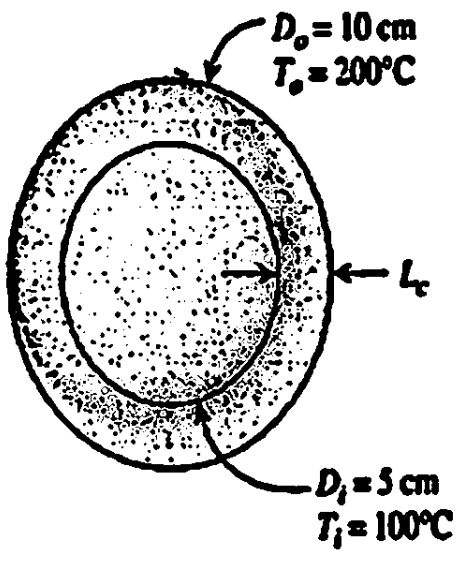

FIGURE P20–57

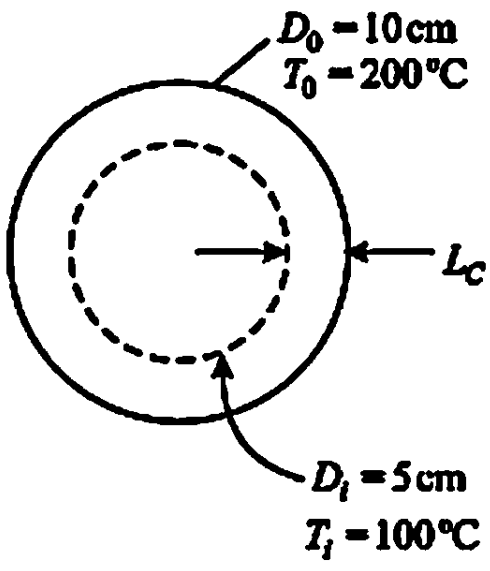
Step 1 of 6

Given data:

Diameter of outer sphere, $D_0 = 10\,\text{cm} = 0.1\text{m}$

Diameter of inner sphere, $D_i = 5\,\text{cm} = 0.05\text{m}$



Temperature of outer surface, $T_o = 200°\text{C}$

Temperature of inner surface, $T_i = 100°\text{C}$

Pressure of Nitrogen filled in the sphere, $P = 1\,\text{atm}$

Step 2 of 6

Given figure:

Step 3 of 6

Characteristic length,

$$L_C = \frac{D_0 - D_i}{2}$$
$$= \frac{10-5}{2}$$
$$= 2.5\,\text{cm}$$
$$= 0.025\text{m}$$

Film temperature of Nitrogen,

$$T_f = \frac{T_o + T_i}{2}$$
$$= \frac{200+100}{2}$$
$$= 150°\text{C}$$

Step 4 of 6

Properties of Nitrogen at 1 atm and 150°C

Thermal conductivity, $k = 0.03416\,\text{w/m °C}$

Kinematic viscosity, $v = 2.851\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7025$

Now Rayleigh number,

$$Ra_L = \frac{g\beta(T_o - T_i)L_C^3}{v^2}\cdot\text{Pr}$$
$$= \frac{g(1/T_f)(T_o - T_i)L_C^3}{v^2}\cdot\text{Pr}$$
$$= \frac{9.81(200-100)\times0.025^3}{(150+273)\left(2.851\times10^{-5}\right)^2}\times(0.7025)$$
$$= 3.1317\times10^4$$

Step 5 of 6

Effective thermal conductivity,

$$F_{sph} = \frac{L_C}{(D_iD_0)^4\left(D_i^{-7/5} + D_0^{-7/5}\right)^5}$$
$$= \frac{0.025}{(0.1\times0.05)^4\left((0.05)^{-7/5} + (0.1)^{-7/5}\right)^5}$$
$$= 6.2682\times10^{-3}$$
$$k_{eff} = 0.74k\left(\frac{\text{Pr}}{0.861+\text{Pr}}\right)^{1/4}\left(F_{sph}Ra_L\right)^{1/4}$$
$$= 0.74\times0.03416\left(\frac{0.7025}{0.861+0.7025}\right)^{1/4}(6.2682\times3.1317\times10)^{1/4}$$
$$= 0.07747\,\text{W/m}\cdot\text{K}$$

Step 6 of 6

For concentric spheres, heat transfer through gap by natural convection is

$$\dot{Q} = k_{eff}\left(\frac{\pi D_iD_0}{L_C}\right)(T_o - T_i)$$
$$= 0.07747\times\left(\frac{\pi\times0.05\times0.1}{0.025}\right)(200-100)$$
$$= 4.867\ \text{W}$$

Hence the heat transfer through gap is $\boxed{\dot{Q} = 4.867\ \text{W}}$

Question: 20.058P

Show that the thermal resistance of a rectangular enclosure can be expressed as $R = L_c/(Ak\,\mathrm{Nu})$, where k is the thermal conductivity of the fluid in the enclosure.

Step 1 of 2

The rate of heat transfer through the enclosure is

$$\dot{Q} = hA_s(T - T_2)$$

$$= kNuA_s\left(\frac{T_1 - T_2}{L_c}\right) \qquad \ldots\ldots(1)$$

Since $h = \frac{kNu}{L}$

The rate of steady heat conduction across the layer of thickness L_c and A_s, and thermal conductivity k is expressed as

$$\dot{Q} = kA_s\left(\frac{T_1 - T_2}{L_c}\right) \qquad \ldots\ldots(2)$$

Where

T_1 and T_2 Is the temperature on the both sides of the layer.

Step 2 of 2

A compression the relation 2 with 1 is reveals that the convention heat transfer in an enclosure is analogue to heat conduction across the fluid layer in the enclosure provided that the thermal conductivity k is replaces with kNu .it is due to convention currents.

$$\dot{Q} = hA_s(T_s - T_\infty)$$

$$= kNuA_s\frac{(T_s - T_\infty)}{L_c}$$

$$= \frac{(T_s - T_\infty)}{\left(\frac{L_c}{kNuA_s}\right)}$$

From the above relation thermal resistance through enclosure is

$$R = \left(\frac{L_c}{kNuA_s}\right)$$

$$\boxed{R = \left(\frac{L_c}{kNuA_s}\right)}$$

Question: 20.059P

A vertical 1.5-m-high and 3.0-m-wide enclosure consists of two surfaces separated by a 0.4-m air gap at atmospheric pressure. If the surface temperatures across the air gap are measured to be 280 K and 336 K and the surface emissivities to be 0.15 and 0.90. determine the fraction of heat transferred through the enclosure by radiation.

Step 1 of 7

Height of enclosure, $H = 1.5\,\text{m}$

Width of enclosure, $w = 3.0\,\text{m}$

Air gap between surfaces, $L_C = 0.4\,\text{m}$

Temperature of surface-1, $T_1 = 336\,\text{K}$

Temperature of surface-2, $T_2 = 280\,\text{K}$

Emissivity of surface-1, $\varepsilon_1 = 0.90$

Emissivity of surface-2, $\varepsilon_2 = 0.15$

Step 2 of 7

The average temperature,

$$T_{avg} = \frac{(T_1 + T_2)}{2}$$
$$= \frac{(336 + 280)}{2}$$
$$= 308\,\text{K}$$

Considering the properties of Air at 1atm and 308 K,

Thermal conductivity, $k = 0.02625\ \text{W/m}^\circ\text{C}$

Prandtl number, $\text{Pr} = 0.7268$

Kinematic viscosity, $v = 1.655 \times 10^{-5}\ \text{m}^2/\text{s}$

Characteristic length, L_C = Distance between two surfaces $= 0.4\,\text{m}$

Step 3 of 7

Now Rayleigh number,

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{v^2} \cdot \text{Pr}$$
$$= \frac{g(T_s - T_\infty)L_c^3}{(T_f) \times (v^2)} \cdot \text{Pr}$$
$$= \frac{9.81 \times (336 - 280)(0.4)^3}{308 \times \left(1.655 \times 10^{-5}\right)^2} \times (0.7268)$$
$$= 3.029 \times 10^8$$

Step 4 of 7

As $\text{Ra}_L < 10^{10}$, the relation for Nusselt number will be

$$\text{Nu} = 0.22\left(\frac{\text{Pr}}{0.22 + \text{Pr}} \times \text{Ra}_L\right)^{0.28}\left(\frac{H}{2}\right)^{-1/4}$$
$$= 0.22\left(\frac{0.7268}{0.22 + 0.7268} \times 3.029 \times 10^8\right)^{0.28}(3.75)^{-0.25}$$
$$= 34.795$$

Heat transfer coefficient,

$$h = \frac{k}{L_C} \times \text{Nu}$$
$$= \frac{0.02625}{0.4} \times 34.795$$
$$= 2.283\ \text{W/m}^2 \cdot ^\circ\text{C}$$

Step 5 of 7

Surface area,

$$A_S = H \times w$$
$$= 1.5 \times 3.0$$
$$= 4.5\ \text{m}^2$$

Rate of Heat transfer by convection,

$$Q_{conv} = hA_S(T_1 - T_2)$$
$$= 2.283 \times 4.5(336 - 280)$$
$$= 575.32\ \text{W}$$

Step 6 of 7

Effective emissivity,

$$\varepsilon_{eff} = \frac{1}{(1/\varepsilon_1) + (1/\varepsilon_2) - 1}$$
$$= \frac{1}{(1/0.9) + (1/0.15) - 1}$$
$$= 0.1475$$

Rate of Heat transfer by Radiation,

$$Q_{rad} = \varepsilon_{eff}\sigma A_S\left(T_1^4 - T_2^4\right)$$
$$= 0.1475 \times \left(5.67 \times 10^{-8}\right) \times 4.5\left(336^4 - 280^4\right)$$
$$= 248.35\ \text{W}$$

Step 7 of 7

Total heat transfer,

$$Q_{tot} = Q_{conv} + Q_{rad}$$
$$= 575.32 + 248.35$$
$$= 823.67\ \text{W}$$

Radiation heat transfer fraction in total heat transfer,

$$\text{Fraction} = \frac{Q_{rad}}{Q_{tot}}$$
$$= \frac{248.35}{823.67}$$
$$= 0.3015$$

Hence fraction of radiation heat transfer in total heat transfer is $\boxed{\text{Fraction} = 0.3015}$

Question:

A vertical 1.5-m-high, 2.8-m-wide double-pane window consists of two layers of glass separated by a 2.0-cm air gap at atmospheric pressure. The room temperature is 26°C while the inner glass temperature is 18°C. Disregarding radiation heat transfer, determine the temperature of the outer glass layer and the rate of heat loss through the window by natural convection.

Step 1 of 9

Given data:

Height of enclosure, $H = 1.5\text{m}$

Width of enclosure, $w = 2.8\text{ m}$

Air gap between surfaces, $L_c = 20\text{ cm} = 0.02\text{m}$

Temperature of the inner glass, $T_1 = 18°\text{C}$

Temperature of room, $T_\infty = 26°\text{C}$

Step 2 of 9

Film temperature,

$$T_f = \frac{T_1 + T_\infty}{2}$$
$$= \frac{18+26}{2}$$
$$= 22°\text{C}$$

The volume expansion coefficient is given by,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{22+273}$$
$$= 3.390\times10^{-3}\,\text{K}^{-1}$$

Characteristic length,

$$L_c = H$$
$$= 1.5\text{m}$$

Step 3 of 9

Properties of air at 1atm and film temperature, by interpolation,

Thermal conductivity,

$$k = 0.02514 + \frac{0.02551-0.02514}{25-20}(22-20)$$
$$= 0.025288\ \text{W/m}\cdot\text{K}$$

Prandtl Number,

$$\text{Pr} = 0.7309 + \frac{0.7296-0.7309}{25-20}(22-20)$$
$$= 0.7305$$

Kinematic viscosity,

$$\nu = 1.516\times10^{-5} + \frac{(1.562-1.516)10^{-5}}{(25-20)}(22-20)$$
$$= 1.5344\times10^{-5}\,\text{m}^2/\text{s}$$

Step 4 of 9

Rayleigh number id given by,

$$\text{Ra}_L = \frac{g\beta(T_S - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.390\times10^{-3}(26-18)(1.5)^3}{\left(1.5344\times10^{-5}\right)^2}\times0.7305$$
$$= 2.786\times10^9$$

Nusselt Number is given by,

$$\text{Nu} = \left[0.825 + \frac{0.387\left(\text{Ra}_L\right)^{1/6}}{\left[1+\left(0.492/\text{Pr}\right)^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{0.387\left(2.786\times10^9\right)^{1/6}}{\left[1+\left(0.492/0.7305\right)^{9/16}\right]^{8/27}}\right]^2$$
$$= 169.524$$

Step 5 of 9

Heat transfer coefficient is given by,

$$h = \frac{k}{L_c}\text{Nu}$$
$$= \frac{0.025288}{1.5}\times169.524$$
$$= 2.858\ \text{W/m}^2\cdot\text{K}$$

Surface area of the plate is given by,

$$A_s = H\times w$$
$$= 1.5\times2.8$$
$$= 4.2\,\text{m}^2$$

Rate of heat transfer from room to inner glass surface is given by,

$$\dot{Q}_{conv} = hA_s(T_1 - T_\infty)$$
$$= 2.858\times(4.2)(26-18)$$
$$= 96.028\,\text{W}$$

Step 6 of 9

Now, considering convection between two glass surfaces,

Let us assume the outer glass temperature, $T_2 = 2°\text{C}$,

The properties of Air, at pressure 1 atm and average temperature,

Thermal conductivity, $k = 0.02439\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.426\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7336$

Characteristic length, $L_c = L = 0.020\text{m}$

The properties of Air, at pressure 1 atm and average temperature,

Thermal conductivity, $k = 0.02439\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 1.426\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7336$

Characteristic length, $L_C = L = 0.020\text{m}$

Average temperature is given by,

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{18+2}{2}$$
$$= 10^\circ\text{C}$$

Step 7 of 9

The volume expansion coefficient is given by,

$$\beta = \frac{1}{T_{avg}}$$
$$= \frac{1}{273+10}$$
$$= 3.534\times10^{-3}\ \text{K}^{-1}$$

Rayleigh number is given by,

$$\text{Ra}_L = \frac{g\beta(T_1 - T_2)L_C^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.534\times10^{-3}(18-2)(0.020)^3}{\left(1.426\times10^{-5}\right)^2}(0.7336)$$
$$= 16009.06$$

Step 8 of 9

Nusselt Number is given by,

$$\text{Nu} = 0.42\ \text{Ra}_L^{1/4}\ \text{Pr}^{0.012}\left(\frac{H}{L}\right)^{-0.3}$$
$$= 0.42\times(16009.06)^{0.25}\times(0.7336)^{0.012}\times\left(\frac{1.5}{0.020}\right)^{-0.3}$$
$$= 1.2888$$

Heat transfer coefficient is given by,

$$h = \frac{k}{L_C}\times\text{Nu}$$
$$= \frac{0.02439}{0.02}\times1.2888$$
$$= 1.572\ \text{W/m}^2{}^\circ\text{C}$$

Step 9 of 9

Rate of heat transfer between two glass surfaces is given by,

$$\dot{Q} = hA_s(T_1 - T_2)$$
$$\dot{Q} = 1.572\times4.2(18 - T_2)$$

As the heat transfer rate between room and inner glass surface is equal to heat transfer rate between glass surfaces. Therefore,

$$\dot{Q}_{conv} = \dot{Q}$$
$$96.028 = 1.572\times4.2(18 - T_2)$$
$$T_2 = 3.456^\circ\text{C}$$

Therefore, the outer glass surface temperature is $\boxed{T_2 = 3..456^\circ\text{C}}$

Question: 20.061P

Two concentric spheres of diameters 15 cm and 25 cm are separated by air at 1 atm pressure. The surface temperatures of the two spheres enclosing the air are $T1$, = 350 K and $T2$ =275 K, respectively. Determine the rate of heat transfer from the inner sphere to the outer sphere by natural convection.

Step 1 of 6

Diameter of outer sphere, $D_0 = 25\text{cm} = 0.25\text{m}$

Diameter of inner sphere, $D_i = 15\text{cm} = 0.15\text{m}$

Temperature of inner sphere, $T_1 = 350\text{ K}$

Temperature of Outer sphere, $T_2 = 275\text{ K}$

Step 2 of 6

Average temperature is given by,

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{350 + 275}{2}$$
$$= 312.5\text{ K}$$
$$= 39.5^\circ\text{C}$$

The volume expansion coefficient is given by,

$$\beta = \frac{1}{T_{avg}}$$
$$= \frac{1}{312.5}$$
$$= 3.2\times10^{-3}\text{ K}^{-1}$$

Step 3 of 6

Properties of air at pressure 1 atm and average temperature by interpolation,

Thermal conductivity,

$$k = (0.02625) + \left(\frac{0.02662 - 0.02625}{40 - 35}\right)(39.5 - 35)$$
$$= 0.026583\text{ W/m}^\circ\text{C}$$

Prandtl Number,

$$\text{Pr} = (0.7268) + \left(\frac{0.7255 - 0.7268}{40 - 35}\right)(39.5 - 35)$$
$$= 0.72563$$

Kinematic viscosity,

$$\nu = \left(1.655\times10^{-5}\right) + \frac{(1.702 - 1.655)10^{-5}}{(40 - 35)}(39.5 - 35)$$
$$= 1.6973\times10^{-5}\text{ m}^2/\text{s}$$

Step 4 of 6

Characteristic length is given by,

$$L_C = \frac{D_0 - D_i}{2}$$
$$= \frac{0.25 - 0.15}{2}$$
$$= 0.05\text{ m}$$

Rayleigh Number is given by,

$$\text{Ra}_L = \frac{g\beta(T_1 - T_2)L_C^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.2\times10^{-3}(350 - 275)(0.05)^3}{\left(1.6973\times10^{-5}\right)^2}\times0.72563$$
$$= 741290.218$$

Step 5 of 6

Geometric factor is given by,

$$F_{sph} = \frac{L_C}{(D_i D_0)^4\left(D_i^{-7/5} + D_0^{-7/5}\right)^5}$$
$$= \frac{0.05}{(0.15\times0.25)^4\left(0.15^{-7/5} + 0.25^{-7/5}\right)^5}$$
$$= 0.0058998$$

Effective heat transfer coefficient is given by,

$$k_{eff} = 0.74\left(\frac{\text{Pr}}{0.861 + \text{Pr}}\right)^{1/4}\left(F_{sph}\text{Ra}_L\right)^{1/4}\cdot k$$
$$= 0.74\left(\frac{0.72563}{0.861 + 0.72563}\right)^{0.25}\times\left[(0.0058998)\times(741290.218)\right]^{0.25}\times0.026583$$
$$= 0.1315\text{ W/m}^2{}^\circ\text{C}$$

Step 6 of 6

Rate of heat transfer from inner to outer sphere can be expressed by the equation.

$$\dot{Q}_{conv} = k_{eff}\frac{\pi D_i D_0}{L_C}(T_1 - T_2)$$
$$= 0.1315\frac{(\pi\times0.25\times0.15)}{0.05}(350 - 275)$$
$$= 23.24\text{ W}$$

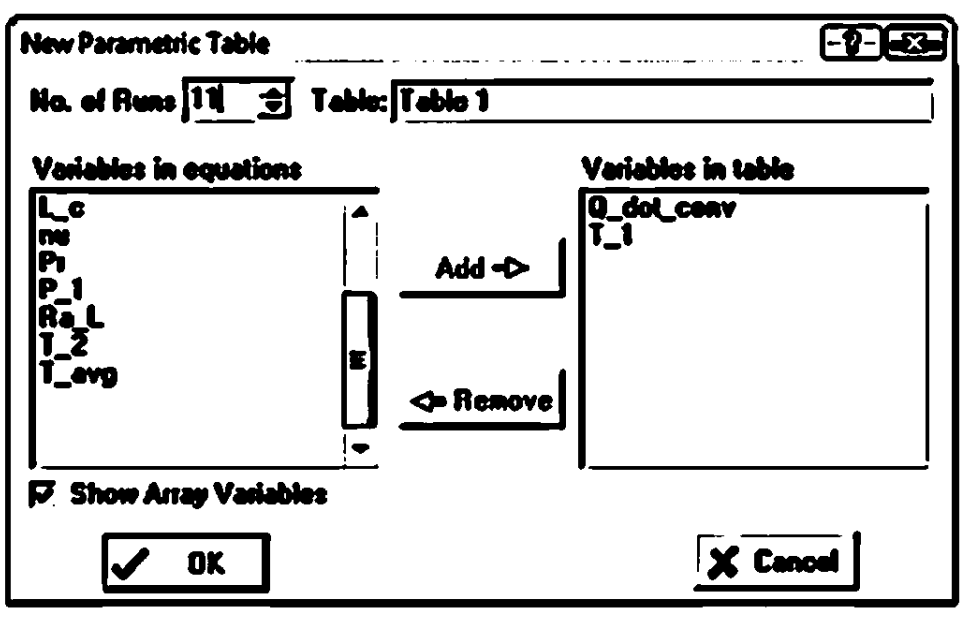
Therefore, the rate of heat transfer is $\boxed{\dot{Q}_{conv} = 23.24\text{ W}}$

Question: 20.062P

Reconsider Prob. 20–61. Using EES (or other) software, plot the rate of natural convection heat transfer as a function of the hot surface temperature of the sphere as the temperature varies from 250 K to 450 K, and discuss the results.

Step 1 of 5

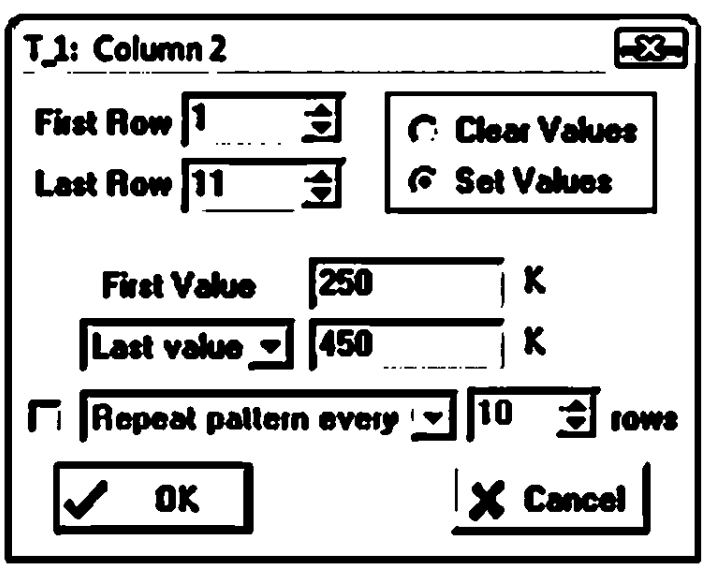
The given problem can be solved using EES software by following the below steps.



1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
"Given Data"
D_o=0.25[m]                          "Diameter of outer sphere"
D_i=0.15[m]                          "Diameter of inner sphere"
"T_1=350[K]"                         "Temperature of inner sphere"
T_2=275[K]                           "Temperature of outer sphere"
P_1=1[atm]*convert(atm,kPa)          "Pressure of air"

T_avg=converttemp(K,C,((T_1)+(T_2))/2)
                                     "Average Temperature"
beta=1/(converttemp(C,K,T_avg))      "Volume expansion"
k=Conductivity(Air,T=T_avg)          "properties of air at T_avg temperature"
nu= Viscosity(Air,T=T_avg)/ Density(Air,T=T_avg,P=P_1)
Pr=Prandtl(Air,T=T_avg)
L_c=(D_o-D_i)/2                      "Characteristic Length"
Ra_L=g#*beta*abs(T_1-T_2)*L_c^3*Pr/nu^2
                                     "Rayleigh Number"
F_sph=L_c/((D_i*D_o)^4*(D_i^(-7/5)+D_o^(-7/5))^5)
                                     "Geometric Factor"
k_eff=0.74*(Pr/(0.861+Pr))^0.25*(F_sph*Ra_L)^0.25*k
                                     "Effective heat transfre coefficient"
Q_dot_conv=k_eff*pi*D_i*D_o*(T_1-T_2)/L_c
                                     "Rate of heat Transfer"
```



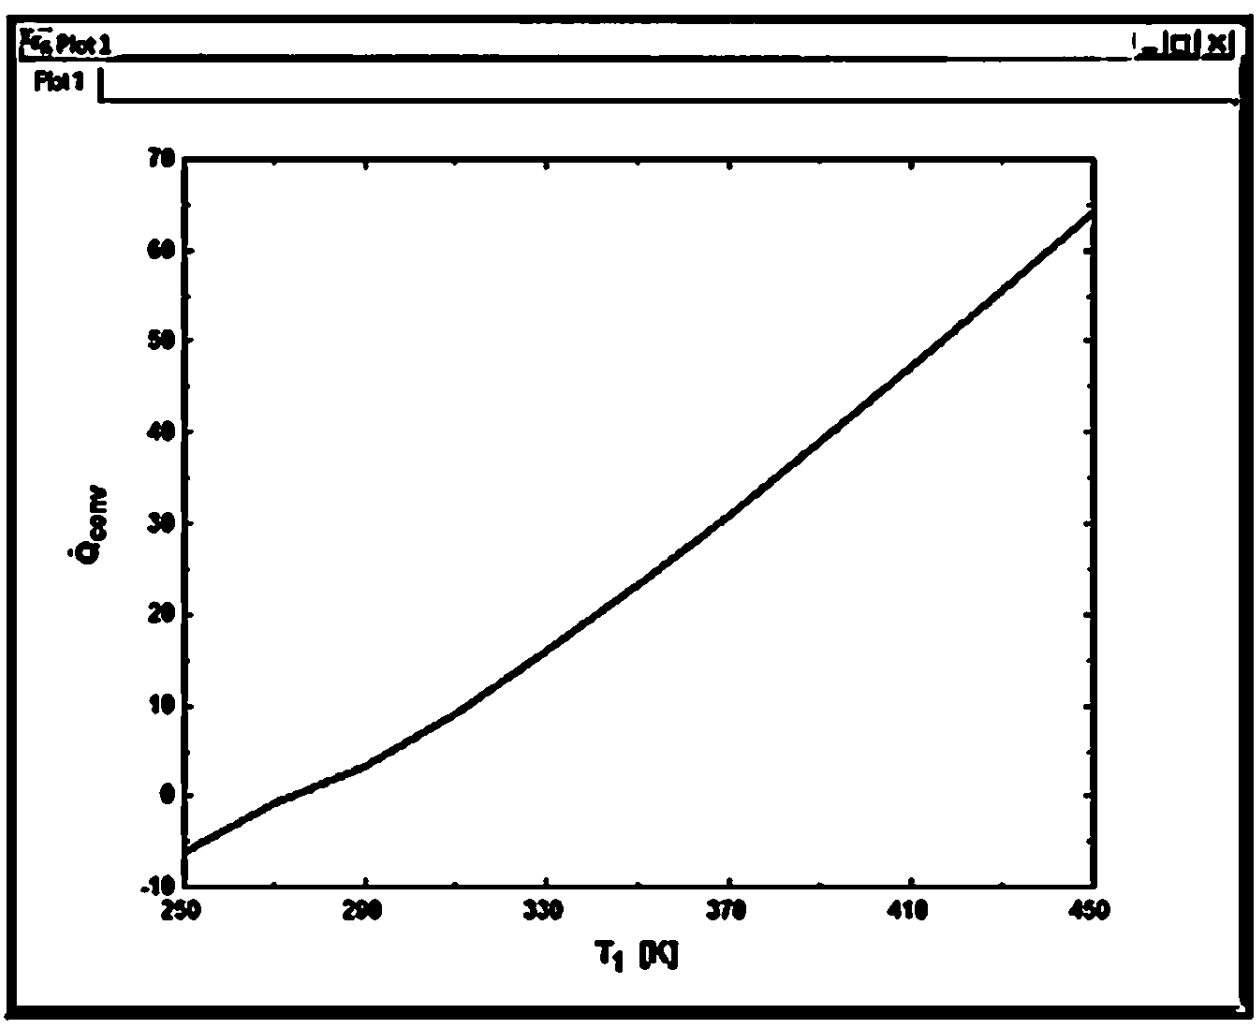
Step 2 of 5

Now to solve the equation for a range of hot surface temperature values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "Q_dot_conv" and "T_1" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 5

To enter the values in the "T_1" column click on the drop tab in "T_1" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 5



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	$\dot{Q}_{conv}$ [1]	T_1 [K] [2]
Run 1	-6.198	250
Run 2	-0.8198	270
Run 3	3.202	290
Run 4	9.14	310
Run 5	15.92	330
Run 6	23.24	350
Run 7	30.94	370
Run 8	38.93	390
Run 9	47.15	410
Run 10	55.57	430
Run 11	64.14	450

Step 5 of 5

Inorder to plot the rate of natural convection heat transfer as a function of hot surface temperature, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Select X-axis as "T_1" and Y-axis as "Q_dot_conv" and press 'OK'
The Graph will be plotted as shown below:

From the above graph we can interpret that as the temperature of the hot surface increases, the rate of convection heat transfer also increases.

Question: 20.063P

Flat-plate solar collectors are often tilted up toward the sun in order to intercept a greater amount of direct solar radiation, The tilt angle from the horizontal also affects the rate of heat loss from the collector. Consider a 1.5-m-high and 3-m-wide solar collector that is tilted at an angle θ from the horizontal. The back side of the absorber is heavily insulated. The absorber plate and the glass cover, which are spaced 2.5 cm from each other, are maintained at temperatures of 80°C and 40°C, respectively. Determine the rate of heat loss from the absorber plate by natural convection for θ =0°, 30°, and 90°.

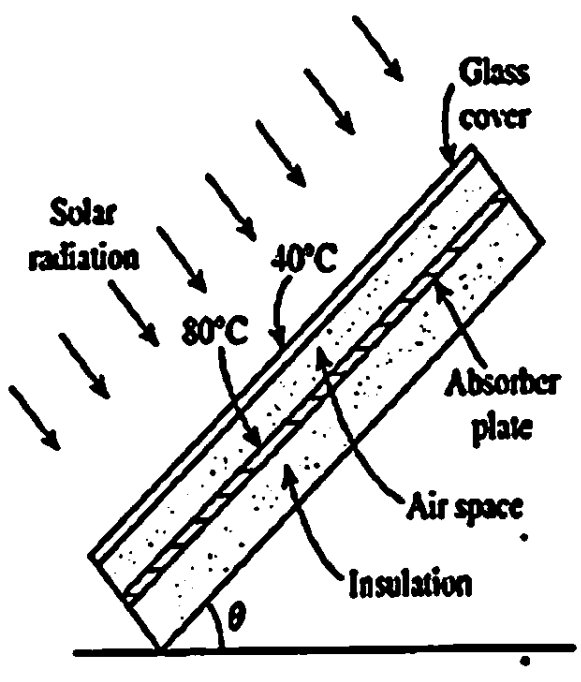


FIGURE P20-63

Step 1 of 8

Height of collector, $H = 1.5\text{m}$

Width of collector, $w = 3\text{m}$

Temperature of absorber plate, $T_1 = 80°\text{C}$

Temperature of Glass plate, $T_2 = 40°\text{C}$

Space between the plates, $L = 2.5\text{ cm} = 0.025\text{m}$

Step 2 of 8

At inclination of $\theta = 0°$:

The set up will become horizontal enclosure.

Average temperature,

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{40 + 80}{2}$$
$$= 60^0\text{C}$$

Inverse of temperature,

$$\beta = \frac{1}{T_{avg}}$$
$$= \frac{1}{60 + 273}$$
$$= 3.003 \times 10^{-3}\ \text{K}^{-1}$$

Step 3 of 8

Properties of Air at 1atm & average temperature,

Thermal conductivity, $k = 0.02808\ \text{w/m°C}$

Prandtl number, $P_r = 0.7202$

Kinematic viscosity, $v = 1.896 \times 10^{-5}\ \text{m}^2/\text{s}$

Characteristic length $L_C = 0.025\text{m}$

Area of the surface,

$$(A_S) = H \times w$$
$$= 1.5 \times 3$$
$$= 4.5\ \text{m}^2$$

Step 4 of 8

Rayleigh number,

$$Ra_L = \frac{g\beta(T_1 - T_2)L_C^3}{v^2} \cdot \text{Pr}$$
$$= \frac{9.81 \times 3.003 \times 10^{-3} \times (80 - 40) \times (0.025)^3}{\left(1.896 \times 10^{-5}\right)^2} \times (0.7202)$$
$$= 36887.63$$

Nusselt number,

$$Nu = 1 + 1.44\left[1 - \frac{1708}{Ra_L}\right]^+ + \left[\frac{Ra_L^{1/3}}{18} - 1\right]^+$$
$$= 1 + 1.44\left[1 - \frac{1708}{36887.63}\right]^+ + \left[\frac{(36887.63)^{1/3}}{18} - 1\right]^+$$
$$= 3.223$$

Step 5 of 8

Now heat transfer,

$$\dot{Q}_{conv} = k\,Nu\,A_S\frac{T_1 - T_2}{L_C}$$
$$= \frac{0.02808 \times 3.223 \times 4.5 \times (80 - 40)}{0.025}$$
$$= 651.5\ \text{W}$$

Hence the rate of heat loss is $\boxed{Q_{conv} = 651.5\ \text{W}}$

Step 6 of 8

At inclination of $\theta^o = 30°$:

Nusselt number,

$$Nu = 1 + 1.44\left[1 - \frac{1708}{R_{a_L}\cos\theta}\right]^+\left(1 - \frac{1708(\sin 1.8\theta)^{1.6}}{R_{a_L}\cos\theta}\right) + \left[\frac{(R_{a_L}\cos\theta)^{1/3}}{18} - 1\right]^+$$
$$= 1 + 1.44\left[1 - \frac{1708}{36887.6\cos 30°}\right]\left(1 - \frac{1708(\sin 1.8 \times 30)^{1.6}}{36887.6\cos 30°}\right) + \left[\frac{(36887.6\cos 30°)^{1/3}}{18} - 1\right]$$
$$= 3.092$$

Step 7 of 8

Now heat transfer,

$$\dot{Q}_{conv} = k\,Nu\,A_S\frac{T_1 - T_2}{L_C}$$
$$= \frac{0.02808 \times 3.092 \times 4.5 \times (80 - 40)}{0.025}$$
$$= 625.2\ \text{W}$$

Hence the rate of heat loss is $\boxed{Q_{conv} = 625.2\ \text{W}}$

Step 8 of 8

At inclination of $\theta = 90°$:

Set up will be vertical rectangular enclosure. Therefore Nusselt number, Nu for vertical enclosure based on Ra_L calculated is

$$Nu = 0.42R_{a_L^{0.25}}P_r^{0.012}\left(\frac{H}{C}\right)^{-0.3}$$
$$= 0.42Ra_L^{0.25}P_r^{0.012}\left(\frac{1.5}{0.025}\right)^{-0.3}$$
$$= 1.6975$$

Now heat transfer,

$$\dot{Q}_{conv} = k\,Nu\,A_S\frac{T_1 - T_2}{L_C}$$
$$= \frac{0.02808 \times 1.6975 \times 4.5 \times (80 - 40)}{0.025}$$
$$= 343.2\ \text{W}$$

Hence the rate of heat loss is $\boxed{Q_{conv} = 343.2\ \text{W}}$

Question:

A simple solar collector is built by placing a 5-cm-diameter clear plastic lube around a garden hose whose outer diameter is 1.6 cm. The hose is painted black to maximize solar absorption, and some plastic rings are used to keep the spacing between the hose and the clear plastic cover constant. During a clear day, the temperature of the hose is measured to be 65°C, while the ambient air temperature is 26°C. Determine the rate of heat loss from the water in the hose per meter of its length by natural convection. Also, discuss how the performance of this solar collector can be improved.

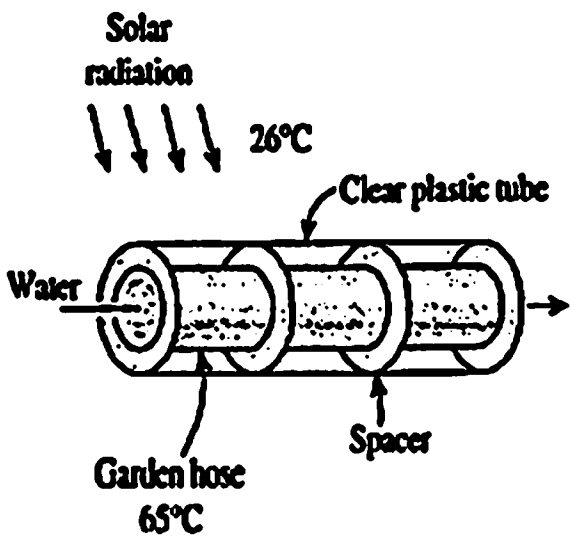

FIGURE P20–64

Step 1 of 10

Diameter of plastic tube, $D_0 = 5\text{cm} = 0.05\text{m}$

Diameter of garden Hose, $D_i = 1.6\text{cm} = 0.016\text{m}$

Ambient Air temperature, $T_\infty = 26°\text{C}$

Temperature of Garden Hose, $T_1 = 65°\text{C}$

Step 2 of 10

Let us assume the temperature of clear plastic tube to be $T_2 = 35°$

Average temperature,

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{65+35}{2}$$
$$= 50°\text{C}$$

Inverse of temperature,

$$\beta = \frac{1}{T_{avg}}$$
$$= \frac{1}{323}$$
$$= 3.0960\times10^{-3}\,\text{K}^{-1}$$

Step 3 of 10

The properties of air at average temperature,

Thermal conductivity, $k = 0.02735\,\text{w/m}°\text{C}$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\,\text{m}^2/\text{s}$

Prandtl number, $P_r = 0.7228$

Rayleigh number,

$$Ra_L = \frac{g\beta(T_1 - T_2)L_C^3}{\nu^2}.\text{Pr}$$
$$= \frac{9.81\times3.096\times10^{-3}(65.35)(0.017)^3}{\left(1.798\times10^{-5}\right)^2}\times(0.7228)$$
$$= 10008.6$$

Step 4 of 10

Characteristic length

$$L_C = \frac{\Delta_0 - \Delta_i}{2}$$
$$= \frac{0.05 - 0.016}{2}$$
$$= 0.017\,\text{m}$$

Geometric factor,

$$F_{cyl} = \frac{\left[\ln(\Delta_0/\Delta_i)\right]^4}{L_C^3\left(\Delta_i^{-3/5} + \Delta_0^{-3/5}\right)^2}$$
$$= \frac{\left[\ln(0.05/0.016)\right]^4}{(0.017)^3\left[(0.016)^{-3/5} + (0.05)^{-3/5}\right]^5}$$
$$= 0.1821$$

Step 5 of 10

Effective thermal conductivity,

$$k_{eff} = 0.386\left(\frac{P_r}{0.861+P_r}\right)^{0.25}\left(F_{cyl}\cdot Ra_L\right)^{0.25}\times k$$
$$= 0.386\left(\frac{0.7228}{0.861+0.7228}\right)^{0.25}\times(0.1821\times10008.6)^{0.25}\times0.02735$$
$$= 0.31726\times6.5339\times0.02735$$
$$= 0.0567\ \text{W/m}^0\text{C}$$

Rate of heat loss through concentric cylinders can be expressed as

$$\dot{Q} = \frac{2\pi k_{eff}}{\ln(\Delta_0/\Delta_i)}(T_i - T_2)$$
$$\dot{Q} = \frac{2\pi\times0.0567}{\ln(0.05/0.016)}(65 - T_2)$$
$$\dot{Q} = 0.3126(65 - T_2) \qquad \ldots\ldots (1)$$

Step 6 of 10

Heat transfer from garden hose to plastic will be equal to heat transfer from plastic pipe to martinet air. So

By assuming the surface temperature to be $T_S = 35°$

Film temperature,

Heat transfer from garden hose to plastic will be equal to heat transfer from plastic pipe to martinet air. So

By assuming the surface temperature to be $T_S = 35°$

Film temperature,

$$T_f = \frac{T_S + T_\infty}{2}$$
$$= \frac{35+26}{2}$$
$$= 30.5°C$$

Temperature inverse,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{273+30.5}$$
$$= 3.2948\times10^{-3}\ K^{-1}$$

Step 7 of 10

At film temperature, the properties using interpolation are

Thermal conductivity

$$k = 0.02588 + \frac{0.02625-0.02588}{(35-30)}\times(30.5-30)$$
$$= 0.025917\ W/m°C$$

Prandtl number,

$$P_r = 0.7282 + \frac{0.7268-0.7282}{35-30}\times(30.5-30)$$
$$= 0.72806$$

Kinematic viscosity,

$$\nu = \left(1.608\times10^{-5}\right) + \frac{(1.655-1.608)10^{-5}}{35-30}\times(30.5-30)$$
$$= 1.6127\times10^{-5}\ m^2/s$$

Characteristic length, $L_C = D_0 = 0.05m$

Step 8 of 10

Rayleigh number

$$Ra_L = \frac{g\beta(T_S-T_\infty)L_C^3}{\nu^2}\cdot P_r$$
$$= \frac{9.81\times3.2948\times10^{-3}(35-26)(0.05)^3}{\left(1.6127\times10^{-5}\right)^2}\times(0.72806)$$
$$= 1.0179\times10^5$$

Nusselt number for horizontal cylinder,

$$Nu = \left[0.6 + \frac{0.387R_a^{1/6}}{\left[1+(0.559/P_r)^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.6 + \frac{0.387\left(1.0179\times10^5\right)^{1/6}}{\left[1+(0.559/0.72806)^{9/16}\right]^{8/27}}\right]^2$$
$$= 7.8377$$

Step 9 of 10

Heat transfer coefficient,

$$h = \frac{k}{L_C}Nu$$
$$= \frac{0.025917}{0.05}\times7.8377$$
$$= 4.0626\ W/m^2°C$$

Surface area,

$$A_S = \pi\Delta_0 L$$
$$= \pi\times0.05\times1$$
$$= 0.15708\ m^2$$

Step 10 of 10

Now rate of heat transfer from pipe to outside air is

$$\dot{Q} = hA_S(T_S-T_\infty)$$
$$\dot{Q} = 4.0626\times0.15708(T_S-26)$$
$$\dot{Q} = 0.6382(T_S-26) \qquad \text{..... (2)}$$

From equations (1) and (2), we get

$$0.3126(65-T_2) = 0.6382(T_2-26)$$
$$(65-T_2) = \frac{0.6382}{0.3126}(T_2-26)$$
$$65-T_2 = 2.0416T_2 - 53.08$$
$$T_2 = 38.82°C$$

As the obtained temperature is very close to the assumed value, we can consider the heat transfer according to equation (1) as

$$\dot{Q} = 0.3126(65-38.82)$$
$$\dot{Q} = 8.183\ W$$

Hence the rate of heat loss is $\boxed{\dot{Q} = 8.183\ W}$

Question: 20.065P

Reconsider Prob. 20-64. Using EES (or other) eHsoftware, plot the rate of heat loss from the water by natural convection as a function of the ambient air temperature as the temperature varies from 4°C to 40°C, and discuss the results.

Step 1 of 3

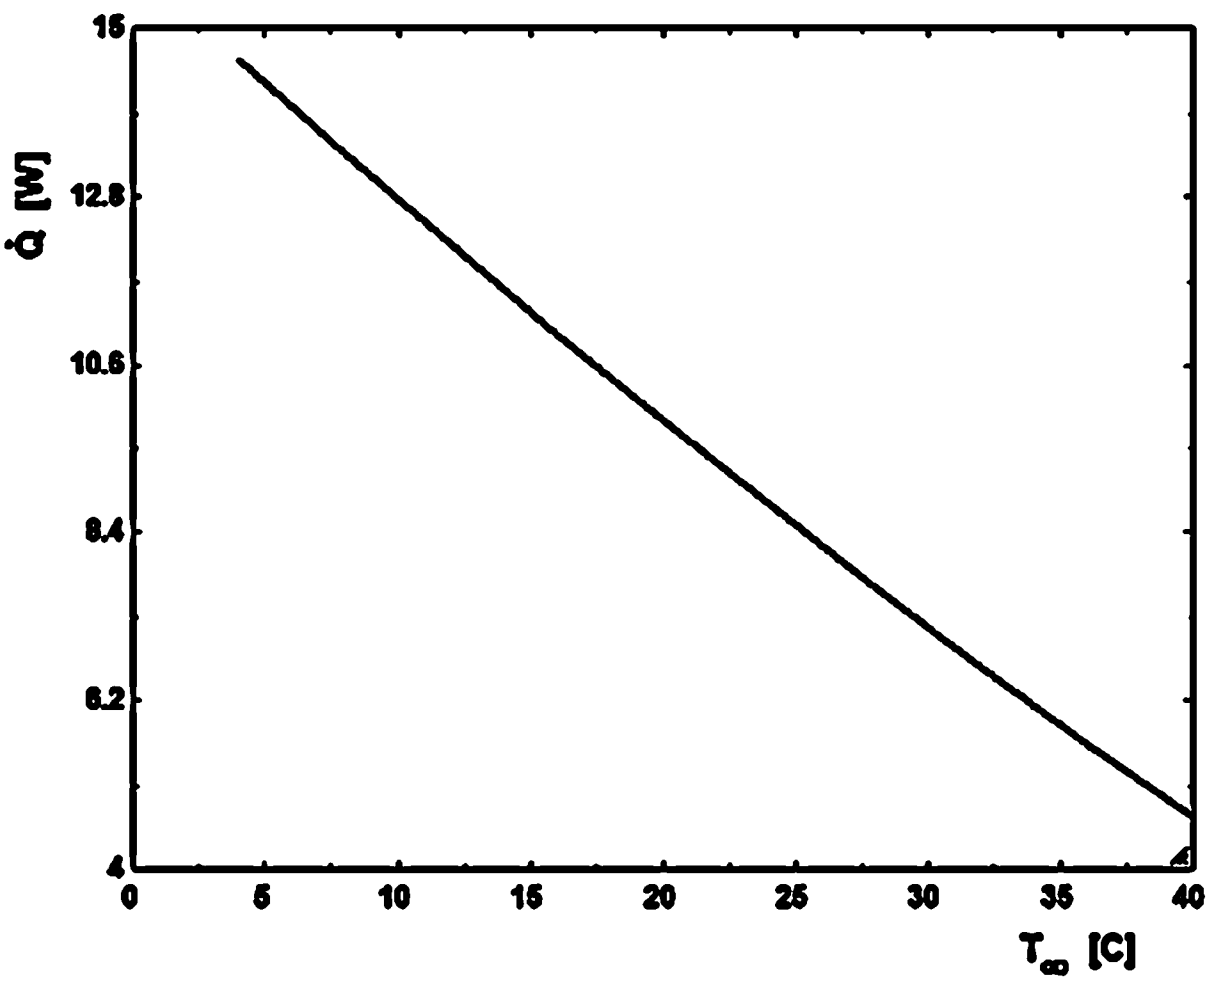
Solve the problem with EES software by following the below steps.

1. **Open EES software**
2. **Crease a new file by clicking on the 'New' of the 'File menu'**
3. **Now type the following code in the new window.**

```
"GIVEN DATA"
D_1=0.016 [m]
D_2=0.05 [m]
T_1=65 "[C]"
"T_infinity=26 [C]"
Length=1 [m] " consider unit length of the tube"

"PROPERTIES for enclosure"
Fluid$='air'
k_1=Conductivity(Fluid$, T=T_ave)
Pr_1=Prandtl(Fluid$, T=T_ave)
rho_1=Density(Fluid$, T=T_ave, P=101.3)
mu_1=Viscosity(Fluid$, T=T_ave)
nu_1=mu_1/rho_1
beta_1=1/(T_ave+273)
T_ave=1/2*(T_1+T_2)
g=9.807 [m/s^2]
"ANALYSIS for enclosure"
L=(D_2-D_1)/2
Ra_1=(g*beta_1*(T_1-T_2)*L^3)/nu_1^2*Pr_1
F_cyl=(ln(D_2/D_1))^4/(L^3*(D_1^(-3/5)+D_2^(-3/5))^5)
k_eff=0.386*k_1*(Pr_1/(0.861+Pr_1))^0.25*(F_cyl*Ra_1)^0.25
Q_dot=(2*pi*k_eff)/ln(D_2/D_1)*(T_1-T_2)

"PROPERTIES for convection on the outer surface"
k_2=Conductivity(Fluid$, T=T_film)
Pr_2=Prandtl(Fluid$, T=T_film)
rho_2=Density(Fluid$, T=T_film, P=101.3)
mu_2=Viscosity(Fluid$, T=T_film)
nu_2=mu_2/rho_2
beta_2=1/(T_film+273)
T_film=1/2*(T_2+T_infinity)
"ANALYSIS for convection on the outer surface"
delta=D_2
Ra_2=(g*beta_2*(T_2-T_infinity)*delta^3)/nu_2^2*Pr_2
Nusselt=(0.6+(0.387*Ra_2^(1/6))/(1+(0.559/Pr_2)^(9/16))^(8/27))^2
h=k_2/delta*Nusselt
A=pi*D_2*Length
Q_dot=h*A*(T_2-T_infinity)
```



Step 2 of 3

Now to solve the equation for a range of 'temperature' values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 10
Select variables in equations as 'T_infinity' and 'Q_dot' press 'Add' and then press 'ok'
A table will appear and enter the values of "T_ infinity" as 4, 8,....40 in runs 1 to 10
Then from click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below

▷ 1..10	1 T_∞ [C]	2 $\dot{Q}$ [W]
Run 1	4	14.6
Run 2	8	13.37
Run 3	12	12.18
Run 4	16	11.01
Run 5	20	9.871
Run 6	24	8.764
Run 7	28	7.688
Run 8	32	6.647
Run 9	36	5.641
Run 10	40	4.675

Step 3 of 3

Then click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Select X-axis as 'T_infinity' and Y-axis as 'Q_dot'. Press OK
The Graph will be plotted as shown below.

This graph represents that by increasing the ambient temperature, heat transfer rate will decrease.

Question:

A vertical 5-ft-high and 6-ft-wide double-pane window consists of two sheets of glass separated by a 0.8-in air gap at atmospheric pressure. If the glass surface temperatures across the air gap are measured to be 65°F and 40°F, determine the rate of heat transfer through the window by (*a*) natural convection and (*b*) radiation. Also, determine the *R*-value of insulation of this window such that multiplying the

.

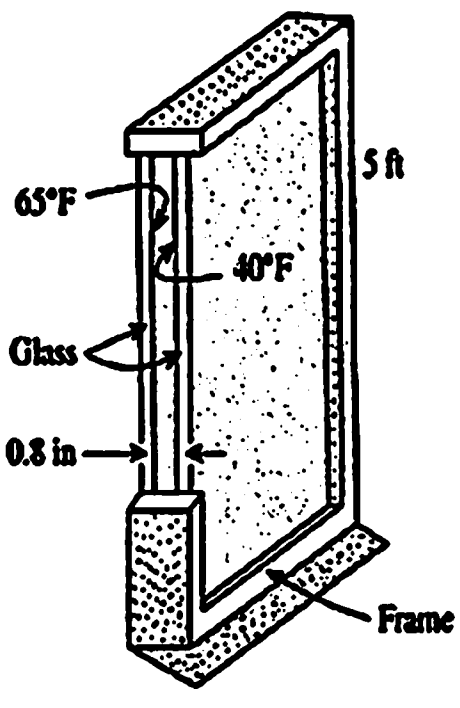


FIGURE P20–66E

inverse of the *R*-value by the surface area and the temperature difference gives the total rate of heat transfer through the window. The effective emissivity for use in radiation calculations between two large parallel glass plates can be taken to be 0.82.

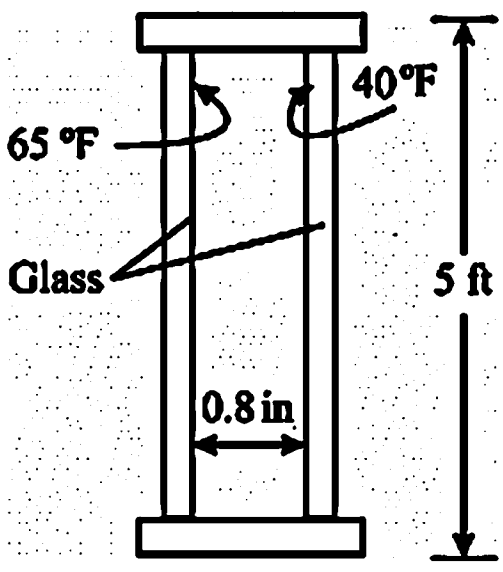
Step 1 of 9

Given data:

Height of window, $H = 5\text{ft}$

Width of window, $W = 6\text{ ft}$

Glass separation gap $L = 0.8\text{in} = 0.0667\text{ft}$



Temperature of inner glass surface, $T_i = 65°\text{F}$

Temperature of outer glass surface, $T_o = 40°\text{F}$

Effective emissivity, $\varepsilon = 0.82$

Step 2 of 9

Figure showing the double pane window:

Step 3 of 9

Average temperature is given by,

$$T_{avg} = \frac{T_i + T_o}{2}$$
$$= \frac{65+40}{2}$$
$$= 52.5°\text{F}$$

Volume expansion co-efficient is given by,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{(52.5+460)}$$
$$= 1.9512\times10^{-3}\ \text{R}^{-1}$$

Characteristic length is given by,

$$L_c = L$$
$$= 0.8\text{in}$$
$$= 0.0667\text{ft}$$

Step 4 of 9

From properties table of air, at 1 atm and average temperature by interpolation,

Thermal conductivity,

$$k = (0.01409) + \left(\frac{0.01433-0.01409}{60-50}\right)(52.5-50)$$
$$= 0.01415\ \text{Btu/h}\cdot\text{ft}\cdot\text{R}$$

Kinematic viscosity,

$$\nu = \left(1.535\times10^{-4}\right) + \left(\frac{1.588\times10^{-4}-1.535\times10^{-4}}{60-50}\right)(52.5-50)$$
$$= 0.1548\times10^{-3}\ \text{ft}^2/\text{s}$$

Prandtl number,

$$\text{Pr} = (0.7336) + \left(\frac{0.7321-0.7336}{60-50}\right)(52.5-50)$$
$$= 0.7332$$

Step 5 of 9

Rayleigh number is given by,

$$Ra_L = \frac{g\beta(T_i-T_o)L_c^3}{\nu^2}\times\text{Pr}$$
$$= \frac{32.2\left(1.9512\times10^{-3}\right)(65-40)(0.0667)^3}{\left(0.1548\times10^{-3}\right)^2}(0.7332)$$
$$= 14261.188$$

The aspect ratio is given by,

$$(H/L) = \frac{5}{}$$

$$= 14261.188$$

The aspect ratio is given by,

$$(H/L) = \frac{5}{0.0667}$$
$$= 75$$

Step 6 of 9

From the Rayleigh number and aspect ratio, the appropriate relation for Nusselt number is given by,

$$\mathrm{Nu} = 0.42 Ra_L^{0.25} \mathrm{Pr}^{0.012} \left(\frac{H}{L}\right)^{-0.3}$$

$$= 0.42(14261.188)^{0.25} (0.7332)^{0.012} \left(\frac{5}{0.0667}\right)^{-0.3}$$

$$= 1.2523$$

The surface area is given by,

$$A_s = H \times W$$
$$= 5 \times 6$$
$$= 30 \text{ ft}^2$$

Step 7 of 9

(a)

Rate of heat transfer by convection is given by,

$$\dot{Q}_{conv} = k \,\mathrm{Nu}\, A_s \frac{(T_i - T_o)}{L_c}$$

$$= 0.01415 \times 1.2523 \times 30 \times \left(\frac{65-40}{0.0667}\right)$$

$$= 199.25 \text{ Btu/h}$$

Therefore, the rate of heat transfer by convection is $\boxed{\dot{Q}_{conv} = 199.25 \text{ Btu/h}}$

Step 8 of 9

(b)

Rate of heat transfer by radiation is given by,

$$\dot{Q}_{rad} = \varepsilon A_s \sigma \left(T_i^4 - T_o^4\right)$$

$$= 0.82 \times 30 \times \left(0.1714 \times 10^{-8}\right)\left[(65+460)^4 - (40+460)^4\right]$$

$$= 4.21644 \times 10^{-8}\left(525^4 - 500^4\right)$$

$$= 567.92 \text{ Btu/h}$$

Therefore, the rate of heat transfer by radiation is $\boxed{\dot{Q}_{rad} = 567.92 \text{ Btu/h}}$

Step 9 of 9

Total heat transfer rate,

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$= 199.25 + 567.92$$
$$= 767.17 \text{ Btu/h}$$

As per given condition,

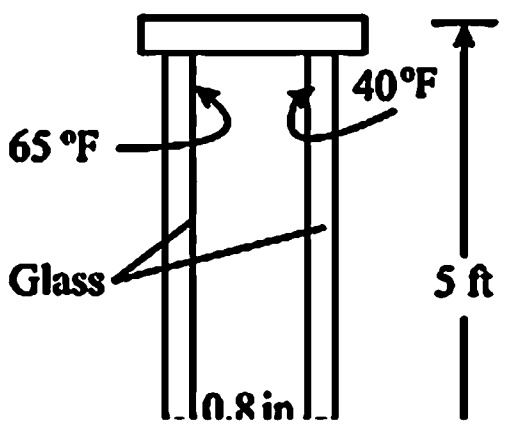
$$\dot{Q}_{total} = R_{value}^{-1} \times A_s \times (T_i - T_o)$$

$$\dot{Q}_{total} = \frac{A_s \times (T_i - T_o)}{R_{value}}$$

$$R_{value} = \frac{A_s (T_i - T_o)}{\dot{Q}_{total}}$$

$$R_{value} = \frac{30 \times (65-40)}{767.17}$$

$$R_{value} = 0.978 \text{ ft}^2 \cdot \text{hr} \cdot \text{R/Btu}$$



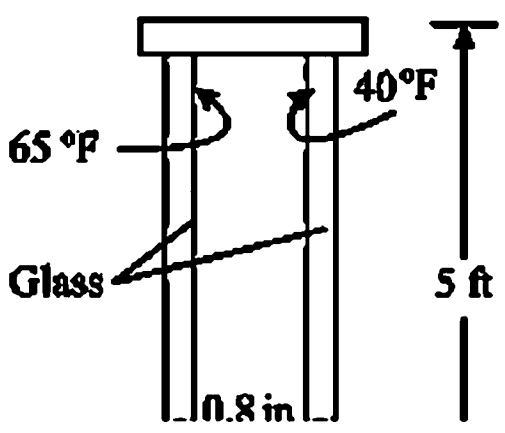
Therefore, the R-value of insulation of the window is $\boxed{R_{value} = 0.978 \text{ ft}^2 \cdot \text{hr} \cdot \text{R/Btu}}$

Question: 20.067P pg 1

Reconsider Prob. 20–66E. Using EES (or other) software, investigate the effect of the air gap thickness on the rates of heat transfer by natural convection and radiation, and the *R*-value of insulation. Let the air gap thickness vary from 0.2 in to 2.0 in. Plot the rates of I heat transfer by natural convection and radiation, and the value of insulation as a function of the air gap thickness, and discuss the results.

Step 1 of 8

Draw the figure of double pane window:

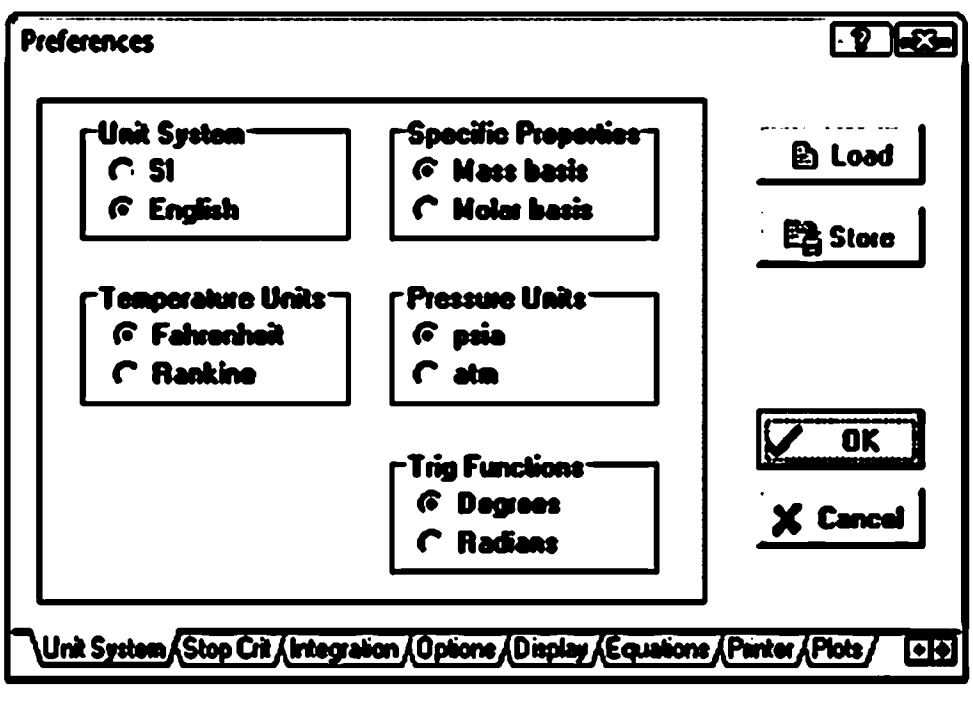


Question:

Reconsider Prob. 20–66E. Using EES (or other) software, investigate the effect of the air gap thickness on the rates of heat transfer by natural convection and radiation, and the *R*-value of insulation. Let the air gap thickness vary from 0.2 in to 2.0 in. Plot the rates of I heat transfer by natural convection and radiation, and the value of insulation as a function of the air gap thickness, and discuss the results.

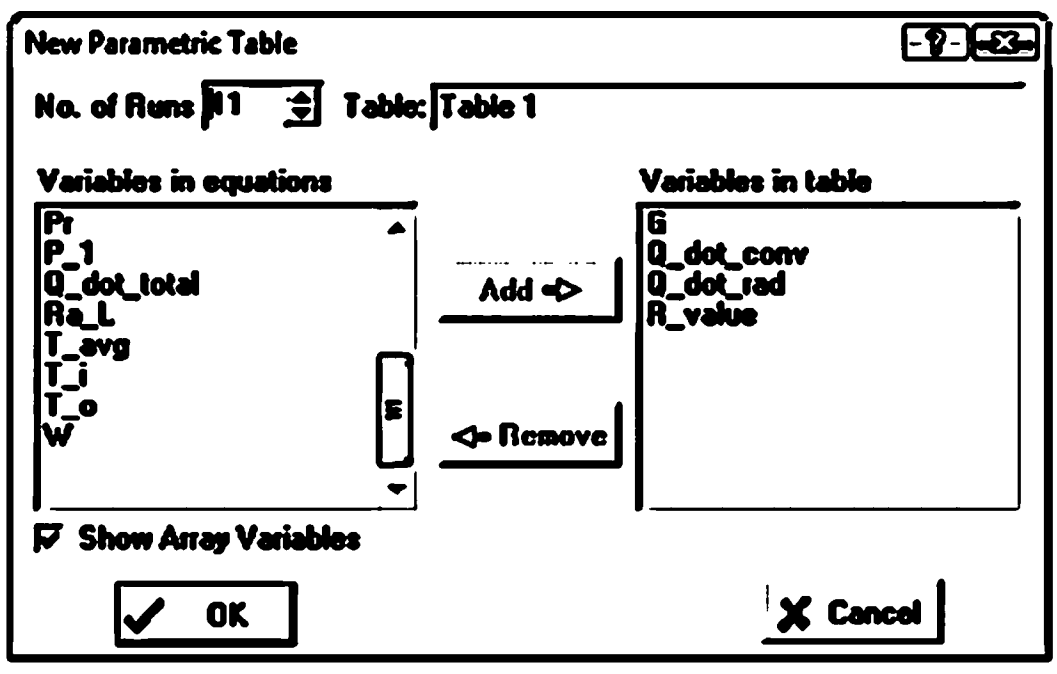
Step 1 of 8

Draw the figure of double pane window:



```
Ra_L=g#*beta*(T_i-T_o)*L_c^3*Pr/nu^2"Rayleigh number"
Nus=0.42*Ra_L^0.25*Pr^0.012*(H/L)^(-0.3)
                                        "Nusselt Number"
A_s=H*W                                 "Surface area"

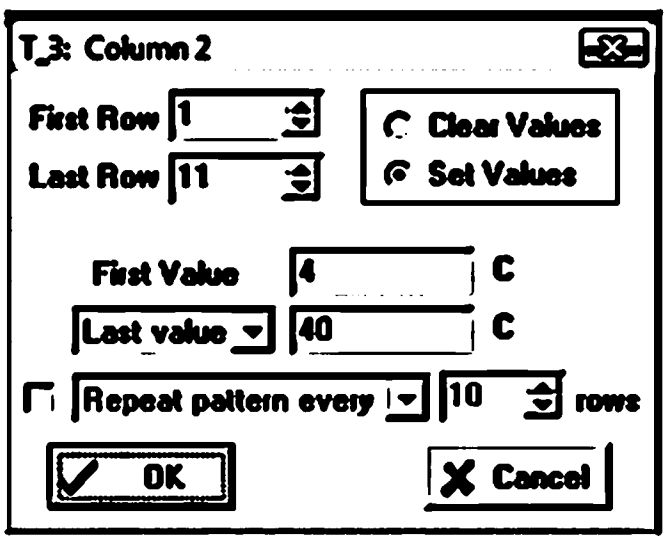
Q_dot_conv=k*Nus*A_s*(T_i-T_o)/L_c"Rate of heat transfer due to convection"
Q_dot_rad=epsilon*A_s*sigma#*(T_i^4-T_o^4)
                                        "Rate of heat transfer due to radiation"
Q_dot_total=Q_dot_conv+Q_dot_rad
Q_dot_total=R_value^(-1)*A_s*(T_i-T_o)
```



Step 3 of 8

Since, the units are in english system. Therefore, the unit system must be changed to english system by clicking on the 'Unit system' of 'Options' menu and change the radio button to English. The screenshot of the 'Preferences' window is shown below:

Step 4 of 8



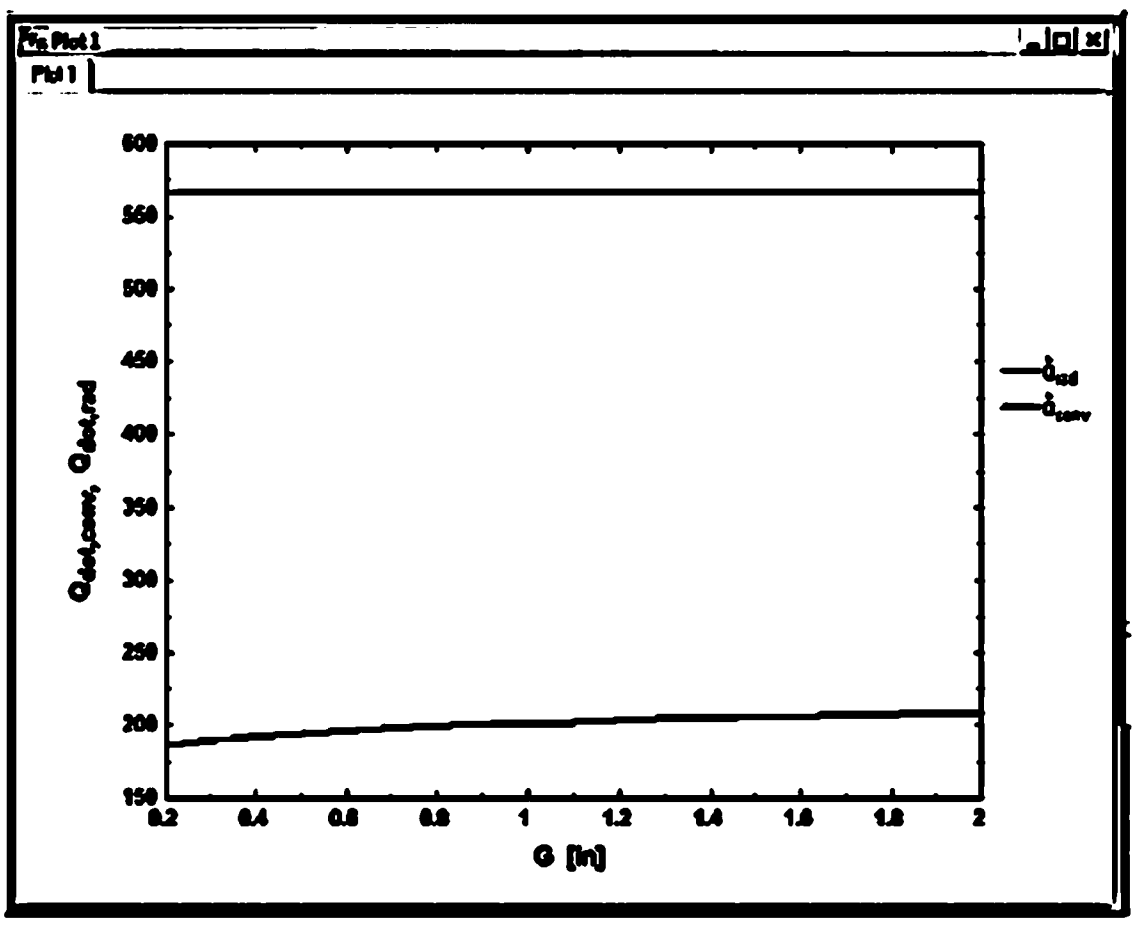
Now to solve the equation for a range of air gap values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "G", "Q_dot_conv", "Q_dot_rad" and "R_value" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 5 of 8

To enter the values in the "G" column, click on the drop tab in "G" column. A new windows pops up, fill in the details as shown below and then press 'OK'

To enter the values in the "G" column, click on the drop tab in "G" column. A new windows pops up, fill in the details as shown below and then press 'OK'

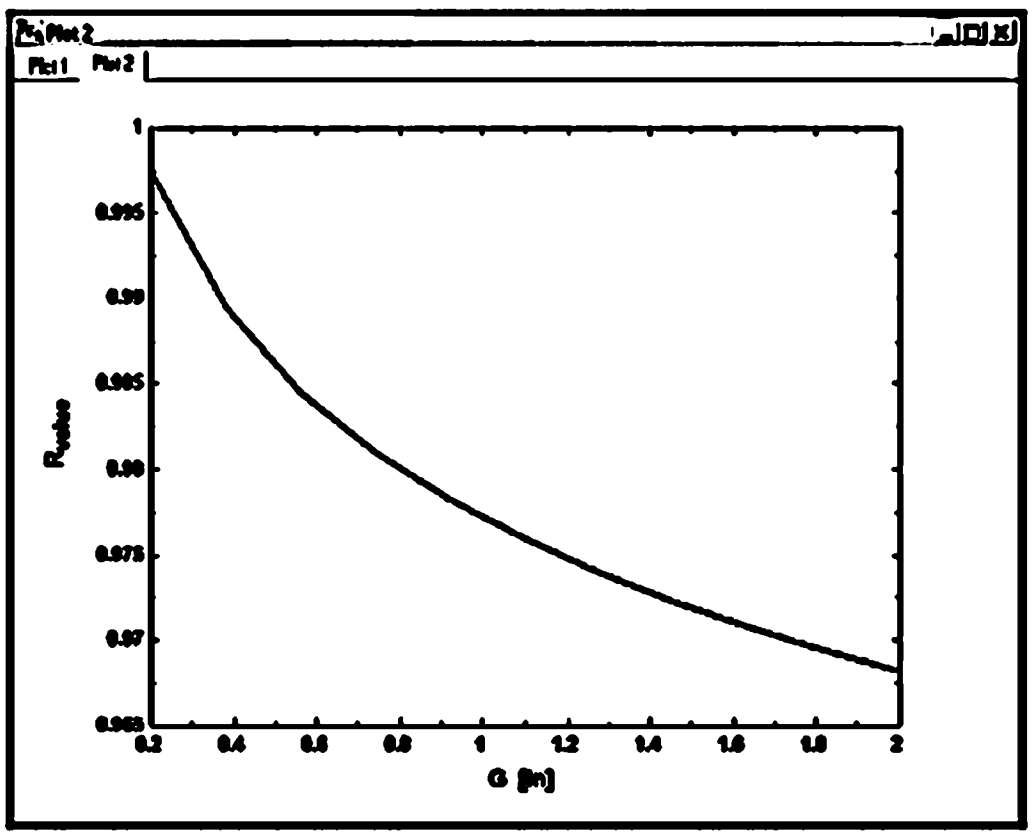
Step 6 of 8



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	G [in]	$\dot{Q}_{conv}$	$\dot{Q}_{rad}$	R_{value}
Run 1	0.2	185.8	566.2	0.9974
Run 2	0.38	191.9	566.2	0.9894
Run 3	0.56	195.6	566.2	0.9845
Run 4	0.74	198.4	566.2	0.981
Run 5	0.92	200.5	566.2	0.9782
Run 6	1.1	202.3	566.2	0.9759
Run 7	1.28	203.9	566.2	0.9739
Run 8	1.46	205.2	566.2	0.9722
Run 9	1.64	206.4	566.2	0.9707
Run 10	1.82	207.5	566.2	0.9694
Run 11	2	208.5	566.2	0.9682



Step 7 of 8

Inorder to plot the rate of heat loss from water by natural convection as a function of ambient air temperature, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Select X-axis as "G" and Y-axis as "Q_dot_conv","Q_dot_rad" and press 'OK'
The Graph will be plotted as shown below:

Step 8 of 8

Now to plot a graph for "G" and "R_value", select X-axis as "G" and Y-axis as "R_value" and press 'OK'
The Graph will be plotted as shown below:

From the above graph we can interpret that as the air gap thickness increases, the rate of heat transfer by convection (Q_{conv}) increases and the R_{value} decreases.

Question:

Consider two concentric horizontal cylinders of diameters 55 cm and 65 cm, and length 125 cm. The surfaces of the inner and outer cylinders are maintained at 54°C and 106°C, respectively. Determine the rate of heat transfer between the cylinders by natural convection if the annular space is filled with (*a*) water and (*b*) air.

Step 1 of 9

The diameter of inner cylinder, $D_i = 55 \text{ cm} = 0.55 \text{ m}$

The diameter of outer cylinder, $D_o = 65 \text{ cm} = 0.65 \text{ m}$

Length of cylinders, $L = 125 \text{ cm} = 1.25 \text{ m}$

Step 2 of 9

(*a*)

The average temperature is given by,

$$T_{avg} = \frac{T_i + T_o}{2}$$
$$= \frac{54 + 106}{2}$$
$$= 80°\text{C}$$

Characteristic length is given by,

$$L_c = \frac{D_o - D_i}{2}$$
$$= \frac{65 - 55}{2}$$
$$= 0.05 \text{ m}$$

Step 3 of 9

The annular space is filled with water:

From properties of saturated water tables, considering the properties of water at average temperature, $T_{avg} = 80°\text{C}$

Thermal conductivity, $k = 0.670 \text{ W/m-K}$

Density, $\rho = 971.8 \text{ kg/m}^3$

Dynamic viscosity, $\mu = 0.355 \times 10^{-3} \text{ kg/m-s}$

Prandtl number, $\text{Pr} = 2.22$

Volume expansion co-efficient, $\beta = 0.653 \times 10^{-3} \text{ K}^{-1}$

Kinematic viscosity is given by,

$$\nu = \frac{\mu}{\rho}$$
$$= \frac{0.355 \times 10^{-3}}{971.8}$$
$$= 3.653 \times 10^{-7} \text{ m}^2/\text{s}$$

Step 4 of 9

Rayleigh numbers is given by,

$$\text{Ra}_L = \frac{g\beta(T_o - T_i)L_c^3}{\nu^2} \cdot \text{Pr}$$
$$= \frac{9.81 \times 0.653 \times 10^{-3} \times (106 - 54) \times (0.05)^3}{\left(3.653 \times 10^{-7}\right)^2}(2.22)$$
$$= 6.927 \times 10^8$$

Geometric factor is given by,

$$F_{cyl} = \frac{\left[\ln(D_o / D_i)\right]^4}{L_c^3\left(D_i^{-3/5} + D_o^{-3/5}\right)^5}$$
$$= \frac{\left[\ln(0.65/0.55)\right]^4}{(0.05)^3\left((0.55)^{-3/5} + (0.65)^{-3/5}\right)^5}$$
$$= 0.041358$$

Step 5 of 9

Effective thermal conductivity is given by,

$$k_{eff} = 0.386k\left(\frac{\text{Pr}}{0.861 + \text{Pr}}\right)^{1/4}\left(F_{cyl} \times \text{Ra}_L\right)^{1/4}$$
$$= 0.386 \times 0.670 \times \left(\frac{2.22}{0.861 + 2.22}\right)^{1/4}\left(0.041357 \times 6.927 \times 10^8\right)^{1/4}$$
$$= 0.386 \times 0.670 \times \left(\frac{2.22}{3.081}\right)^{1/4}(28{,}647{,}994)^{1/4}$$
$$= 17.43 \text{ W/m} \cdot \text{K}$$

Step 6 of 9

Rate of heat transfer when fluid is water,

$$\dot{Q}_{water} = \frac{2\pi \times k_{eff}}{\ln(D_o / D_i)}(T_o - T_i)$$
$$= \frac{2\pi \times 17.43}{\ln(0.65/0.55)}(106 - 54)$$
$$= 34.09 \times 10^3 \text{ W}$$
$$= 34.09 \text{ kW}$$

Therefore, rate of heat transfer when fluid is water is $\boxed{\dot{Q}_{water} = 34.09 \text{ kW}}$

Step 7 of 9

(*b*)

From properties of air tables, considering the properties of air at pressure of 1 atm and average temperature, $T_{avg} = 80°\text{C}$

Thermal conductivity, $k = 0.02953 \text{ W/m} \cdot \text{K}$

Kinematic viscosity, $\nu = 2.097 \times 10^{-5} \text{ m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7154$

From properties of air tables, considering the properties of air at pressure of 1 atm and average temperature, $T_{avg} = 80°C$

Thermal conductivity, $k = 0.02953\ \text{W/m}\cdot\text{K}$

Kinematic viscosity, $\nu = 2.097\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7154$

Volume expansion co-efficient is given by,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{353}$$
$$= 2.833\times10^{-3}\ \text{K}^{-1}$$

Step 8 of 9

Rayleigh number is given by,

$$\text{Ra}_L = \frac{g\beta(T_o - T_i)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times2.833\times10^{-3}\times(106-54)\times(0.05)^3}{\left(2.097\times10^{-5}\right)^2}\times(0.7154)$$
$$= 2.94\times10^5$$

Geometric factor is given by,

$$F_{cyl} = \frac{\left[\ln(D_o/D_i)\right]^4}{L_c^3\left(D_i^{-3/5} + D_o^{-3/5}\right)^5}$$
$$= \frac{\left[\ln(0.65/0.55)\right]^4}{(0.05)^3\left((0.55)^{-3/5} + (0.65)^{-3/5}\right)^5}$$
$$= 0.041358$$

Step 9 of 9

Effective thermal conductivity is given by,

$$k_{eff} = 0.386k\left(\frac{\text{Pr}}{0.861+\text{Pr}}\right)^{0.25}\left(F_{cyl}\cdot\text{Ra}_L\right)^{1/4}$$
$$= 0.386\times0.02953\left(\frac{0.7154}{0.861+0.7154}\right)^{0.25}\left(0.041358\times2.94\times10^5\right)^{1/4}$$
$$= 0.09824\ \text{W/m}\,°\text{C}$$

Rate of heat transfer when the fluid is air is given by,

$$\dot{Q}_{Air} = \frac{2\pi k_{eff}}{\ln(D_o/D_i)}(T_o - T_i)$$
$$= \frac{2\pi\times0.09824}{\ln(0.65/0.55)}(106-54)$$
$$= 192.14\ \text{W}$$

Therefore, rate of heat transfer when fluid is air, $\boxed{\dot{Q}_{\text{Air}} = 192.14\,\text{W}}$

Question: 20.069P

Consider an $L\times L$ horizontal plate that is placed in quiescent air with the hot surface facing up. If the film temperature is 20°C and the average Nusselt number in natural convection is of the form $\mathrm{Nu} = C\mathrm{Ra}_L^n$, show that the average heat transfer coefficient can be expressed as

$h = 1.95(\Delta T/L)^{1/4} \quad 10^4 < \mathrm{Ra}_L < 10^7$

$h = 1.79\Delta T^{1/3} \quad 10^7 < \mathrm{Ra}_L < 10^{11}$

Step 1 of 4

Given data:

Length of horizontal plate is L

Width of horizontal plate is L

Film temperature, $T_f = 20°\mathrm{C}$

Step 2 of 4

The properties of air at the given film temperature,

Thermal conductivity, $k = 0.02514\ \mathrm{W/m\text{-}°C}$

Prandtl number, $\mathrm{Pr} = 0.7309$

Kinematic viscosity, $\nu = 1.516\times10^{-5}\ \mathrm{m^2/s}$

Inverse of film temperature,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{298}$$
$$= 3.413\times10^{-3}\ \mathrm{K^{-1}}$$

Step 3 of 4

Characteristic length,

$$(L_c) = \frac{A_s}{P}$$
$$= \frac{L\times L}{2(L+L)}$$
$$= \frac{L}{4}$$

The expression for Rayleigh number,

$$\mathrm{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot \mathrm{Pr}$$
$$= \frac{9.81\times3.413\times10^{-3}(\Delta T)L^3}{64\nu^2}\times0.7309$$
$$= 1.664\times10^6(\Delta T)L^3$$

Step 4 of 4

From empirical correlations table, Nusselt number for range $\left(10^4 - 10^7\right)$

$$Nu = 0.54\mathrm{Ra}_L^{0.25}$$
$$= 0.54\left(1.664\times10^6(\Delta T)L^3\right)^{0.25}$$

Now heat transfer co-efficient,

$$h = \frac{k}{L_c}Nu$$
$$= \frac{0.02514\times4}{L}\left[0.54\left(1.664\times10^6(\Delta T)L^3\right)^{0.25}\right]$$
$$= \frac{1.95025}{L}\left(\Delta T L^3\right)^{0.25}$$
$$= 1.95\left(\frac{\Delta T}{L}\right)^{1/4}$$

Hence heat transfer co-efficient for range $\left(10^4 - 10^7\right)$ is $\boxed{h = 1.95\left(\frac{\Delta T}{L}\right)^{1/4}}$

From empirical correlations table, Nusselt number for range $\left(10^7 - 10^{11}\right)$

$$Nu = 0.15\mathrm{Ra}_L^{1/3}$$
$$= 0.15\left(1.664\times10^6(\Delta T)L^3\right)^{1/3}$$
$$= 17.775\left((\Delta T)L^3\right)^{1/3}$$

Now heat transfer co-efficient,

$$h = \frac{k}{L_c}\cdot Nu$$
$$= \frac{0.02514\times4}{L}\times17.775\left(\Delta T L^3\right)^{1/3}$$
$$= 1.787(\Delta T)^{1/3}$$

Hence heat transfer co-efficient for range $\left(10^7 - 10^{11}\right)$ is $\boxed{h = 1.79(\Delta T)^{1/3}}$

Question: 20.070P

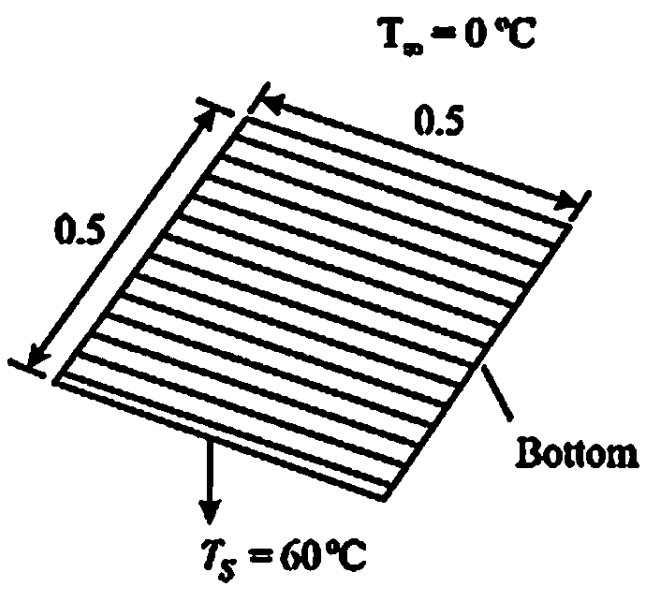
A plate (0.5 m × 0.5 m) is inclined at an angle of 30°. The top surface of the plate is well insulated. Estimate the rate of heat loss from the plate when the bottom surface is maintained at 60°C and the surrounding atmospheric quiescent air is at 0°C.

Step 1 of 6

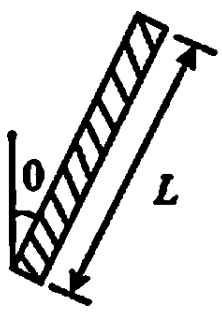
Given data:

Length of Plate, $L = 0.5\text{m}$

Width of Plate, $W = 0.5\text{m}$



Therefore outside, $T_\infty = 0°\text{C}$



Surface temperature of plate, $T_S = 60°\text{C}$

Inclination angle, $\theta = 30°\text{C}$

Step 2 of 6

Figure showing the inclined plate:

Step 3 of 6

Film temperature,

$$T_f = (T_S + T_\infty)/2$$
$$= (60+0)/2$$
$$= 30°\text{C}$$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{303}$$
$$= 3.3\times10^{-3}\ \text{K}^{-1}$$

Characteristic length,

$$L_C = L$$
$$= 0.5\text{m}$$

Step 4 of 6

From the properties of air at 1atm pressure and film temperature

Thermal conductivity, $k = 0.02588\ \text{W/m-°C}$

Kinematics viscosity, $\nu = 1.608\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7282$

Now Rayleigh Number,

$$Ra_L = \frac{g\cos\theta\beta(T_S - T_\infty)L_C^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times\cos30°\times3.3\times10^{-3}(60-0)(0.5)^3}{\left(1.608\times10^{-5}\right)^2}\times(0.7282)$$
$$= 5.92\times10^8$$

Step 5 of 6

Therefore using vertical plate & Ra_L entre range, Nusselt number,

$$Nu = \left[0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+(0.492/\text{Pr})^{9/16}\right]^{8/27}}\right]$$

$$Nu = \left[0.825 + \frac{0.387\left(5.92\times10^8\right)^{1/6}}{\left[1+(0.492/0.728)^{9/16}\right]^{8/27}}\right]^2$$

$$Nu = 104.94$$

Heat transfer coefficient,

$$h = \frac{k}{L_C}\cdot Nu$$
$$= \frac{0.02588}{0.5}\times104.94$$
$$= 5.432\ \text{W/m}^2\text{-°C}$$

Step 6 of 6

Area of surface,

$$A_S = L\times W$$
$$= 0.5\times0.5$$
$$= 0.25\ \text{m}^2$$

The rate of Heat loss,

$$\dot{Q} = hA_S(T_S - T_\infty)$$
$$= 5.432\times0.25\times(60-0)$$
$$= 5.432\times0.25\times60$$
$$= 81.47\ \text{W}$$

Hence the rate of Heat loss is $\boxed{\dot{Q} = 81.47\ \text{W}}$

Question: 20.071P

A 12-cm-diameter and 15-m-long cylinder with a surface temperature of 10°C is placed horizontally in air at 40°C. Calculate the steady rate of heat transfer for the cases of (*a*) free-stream air velocity of 10 m/s due to normal winds and (*b*) no winds and thus a free stream velocity of zero.

Step 1 of 8

Given data:

Diameter of cylinder, $D = 0.12\,\text{m}$

Length of cylinder, $L = 15\,\text{m}$

Outside air temperature, $T_\infty = 40°\text{C}$

Surface temperature of cylinder, $T_S = 10°\text{C}$

Step 2 of 8

Figure showing the Cylinder:

Step 3 of 8

(*a*)

The free stream air velocity, $V = 10\,\text{m/s}$

Area of cylinder surface,

$$A = \pi DL$$
$$= \pi \times 0.12 \times 15$$
$$= 5.65\,\text{m}^2$$

Film temperature,

$$T_f = \frac{T_S + T_\infty}{2}$$
$$= \frac{10+40}{2}$$
$$= 25°\text{C}$$

Step 4 of 8

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{298}$$
$$= 3.356 \times 10^{-3}\,\text{K}^{-1}$$

Characteristic length

$$L_C = D$$
$$= 0.12\,\text{m}$$

Properties of air at 1atm and film temperature,

Thermal conductivity, $k = 0.02551\,\text{W/m}\,°\text{C}$

Prandtl number, $\text{Pr} = 0.7296$

Kinematic viscosity, $\nu = 1.562 \times 10^{-5}\,\text{m}^2/\text{s}$

Step 5 of 8

Reynolds number,

$$\text{Re} = \frac{VD}{\nu}$$
$$= \frac{10 \times 0.12}{1.562 \times 10^{-5}}$$
$$= 76824.58$$

Therefore Nusselt number,

$$Nu = 0.027.\text{Re}^{0.805}.\text{Pr}^{1/3}$$
$$= 0.027 \times (76824.58)^{0.805} \times (0.7296)^{1/3}$$
$$= 208.23$$

Step 6 of 8

Heat transfer coefficient,

$$h = \frac{k \times Nu}{L_C}$$
$$= \frac{0.02551 \times 208.23}{0.12}$$
$$= 44.27\,\text{W/m}^2\,°\text{C}$$

The heat transfer rate,

$$\dot{Q}_{FC} = hA(T_\infty - T_S)$$
$$= 44.27 \times 5.65(40-10)$$
$$= 7503.29\,\text{W}$$

Hence the heat transfer rate by forced convection is $\boxed{\dot{Q}_{FC} = 7503.29\,\text{W}}$

Step 7 of 8

(*b*)

Rayleigh number,

$$Ra_D = \frac{g\beta(T_\infty - T_S)}{\nu^2} \cdot \text{Pr}$$
$$= \frac{9.81 \times 3.356 \times 10^{-3} \times (40-10) \times (0.12)^3}{(1.562 \times 10^{-5})^2} \times (0.7296)$$
$$= 5.104 \times 10^6$$

Therefore Nusselt number for horizontal cylinder for obtained Nusselt number range,

$$Nu = \left[0.6 + \frac{0.387\,Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.6 + \frac{0.387 \times (5.104 \times 10^6)^{1/6}}{\left[1+(0.559/0.7296)^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.6 + \frac{5.078}{1.2}\right]^2$$
$$= 23.345$$

Step 8 of 8

Heat transfer coefficient,

$$h = \frac{k}{L_C} \cdot Nu$$
$$= \frac{0.02551}{0.12} \times (23.345)$$
$$= 4.963\,\text{W/m}^2\,{}^0\text{C}$$

Heat transfer rate by natural convection,

$$\dot{Q}_{NC} = hA(T_\infty - T_S)$$
$$= 4.948 \times 5.65 \times (40-10)$$
$$= 838.71\,\text{W}$$

Hence the heat transfer rate by natural convection is $\boxed{\dot{Q}_{NC} = 838.71\,\text{W}}$

Question: 20.072P pg 1

A spherical vessel, with 30.0-cm outside diameter, is used as a reactor for a slow endothermic reaction. The vessel is completely submerged in a large water-filled tank, held at a constant temperature of 30°C. The outside surface temperature of the vessel is 20°C. Calculate the rate of heat transfer in steady operation for the following cases: (*a*) the water in the tank is still, (*b*) the water in the tank is still (as in a part a), however, the buoyancy force caused by the difference in water density is assumed to be negligible, and (*c*) the water in the lank is circulated at an average velocity of 20 cm/s.

Step 1 of 9

Determine the Film temperature,

$$T_f = \frac{T_S + T_\infty}{2}$$
$$= \frac{30+20}{2}$$
$$= 25°C$$

The properties of water at film temperature,

Thermal conductivity, $k = 0.607\,W/m°C$

Dynamic viscosity, $\mu = 0.891\times10^{-3}\,kg/m-s$

Prandtl number, $Pr = 6.14$

Volume expansion coefficient, $\beta = 0.247\times10^{-3}\,K^{-1}$

Density, $\rho = 997.0 kg/m^3$

Step 2 of 9

Therefore kinematic viscosity,

$$v = \mu/\rho$$
$$= \frac{0.891\times10^{-3}}{997}$$
$$= 8.94\times10^{-7}\,m^2/s$$

Characteristic length,

$$L_C = D$$
$$= 0.3\,m$$

Step 3 of 9

(*a*)

When water in the tank is still, only Natural convection prevails.

Rayleigh number,

$$Ra_D = \frac{g\beta(T_\infty - T_S)L_C^3}{v^2}.Pr$$
$$= \frac{9.81\times0.247\times10^{-3}\times(30-20)\times(0.3)^3}{\left(8.94\times10^{-7}\right)^2}\times(6.14)$$
$$= 5.026\times10^9$$

Nusselt number for the obtained range of Raleigh's number is,

$$Nu = 2 + \frac{0.589Ra_D^{1/4}}{\left[1+\left(\frac{0.469}{Pr}\right)^{9/16}\right]^{4/9}}$$
$$= 2 + \frac{0.589\times\left(5.026\times10^9\right)^{0.25}}{\left[1+\left(\frac{0.469}{6.14}\right)^{9/16}\right]^{4/9}}$$
$$= 144.77$$

Step 4 of 9

Heat transfer coefficient,

$$h = \frac{k\cdot Nu}{L_C}$$
$$= \frac{0.607\times144.77}{0.3}$$
$$= 293\ W/m^2°C$$

Now heat transfer rate by natural convection,

$$Q_{NC} = hA_S(T_\infty - T_S)$$
$$= h\pi D^2(T_\infty - T_S)$$
$$= 293\times\pi\times0.3^2\times(30-20)$$
$$= 828.44\,W$$

Hence heat transfer rate by natural convection is $\boxed{Q_{NC} = 828.44\,W}$

Step 5 of 9

(b)

If the Buoyancy force due to difference in water density is negligible, then the Rayleigh number can be neglected $\left(Ra_D = 0\right)$.

Thus Nusselt number is

$$Nu = 2 + \frac{0.589\,Ra_D^{1/4}}{\left[1+(0.469/Pr)^{9/16}\right]^{4/9}}$$
$$= 2 + \frac{0.589\times(0)^{1/4}}{\left[1+(0.469/Pr)^{9/16}\right]^{4/9}}$$
$$= 2$$

Step 6 of 9

Heat transfer coefficient,

$$= h\pi D^2(T_\infty - T_S)$$
$$= 293\times\pi\times0.3^2\times(30-20)$$
$$= 828.44\,W$$

Hence heat transfer rate by natural convection is $\boxed{Q_{NC} = 828.44\,W}$

20.072P pg 2

$= 828.44\,\text{W}$

Hence heat transfer rate by natural convection is $\boxed{Q_{NC} = 828.44\,\text{W}}$

Step 5 of 9

(b)

If the Buoyancy force due to difference in water density is negligible, then the Rayleigh number can be neglected $\left(Ra_D = 0\right)$.

Thus Nusselt number is

$$Nu = 2 + \frac{0.589\,Ra_D^{1/4}}{\left[1 + \left(0.469/\text{Pr}\right)^{9/16}\right]^{4/9}}$$

$$= 2 + \frac{0.589 \times (0)^{1/4}}{\left[1 + \left(0.469/\text{Pr}\right)^{9/16}\right]^{4/9}}$$

$$= 2$$

Step 6 of 9

Heat transfer coefficient,

$$\mu_\infty = 0.798 \times 10^{-3}\,\text{kg/m-s}$$

Step 8 of 9

Now Reynolds number,

$$\text{Re} = \frac{VD}{\nu}$$

$$= \frac{VD\rho}{\mu}$$

$$= \frac{0.2 \times 0.3 \times 998}{\left(1.002 \times 10^{-3}\right)}$$

$$= 59760.96$$

Nusselt number,

$$Nu = 2 + \left[0.4\text{Re}^{0.5} + 0.06\text{Re}^{2/3}\right]\text{Pr}^{0.4}\left(\frac{\mu_s}{\mu_\infty}\right)^{0.25}$$

$$= 2 + \left[0.4(59760.96)^{0.5} + 0.06(59760.96)^{2/3}\right](7.01)^{0.4}\left(\frac{1.002 \times 10^{-3}}{0.798 \times 10^{-3}}\right)^{0.25}$$

$$= 2 + [189.49 \times 2.179 \times 1.059]$$

$$= 439.27$$

Step 9 of 9

Heat transfer coefficient,

$$h = \frac{k \cdot Nu}{D}$$

$$= \frac{0.598 \times 439.27}{0.3}$$

$$= 875.61\,\text{W/m}^2\,^\circ\text{C}$$

Rate of heat transfer by forced convection,

$$Q = hA_S\left(T_\infty - T_S\right)$$

$$= 875.61 \times 0.283 \times (30 - 20)$$

$$= 2477.98\,\text{W}$$

Therefore rate of heat transfer by forced convection, $\boxed{Q = 2477.98\,\text{W}}$

Question:

Hot water is flowing at an average velocity of 4 ft/s through a cast iron pipe (k= 30 Btu/h·ft·°F) whose inner and outer diameters are 1.0 in and 1.2 in, respectively. The pipe passes through a 50-ft-long section of a basement whose temperature is 60°F. The emissivity of the outer surface of the pipe is 0.5, and the walls of the basement are also at about 60°F. If the inlet temperature of the water is 150°F and the heat transfer coefficient on the inner surface of the pipe is 30 Btu/h ·°F, determine the temperature drop of water as it passes through the basement.

Step 1 of 7

Length of pipe, $L = 50\,\text{ft}$

Emissivity of pipe surface, $\varepsilon = 0.5$

Temperature of basement, $T_\infty = 60°\text{F}$

Inlet water flow temperature, $T_w = 150°\text{F}$

Average velocity of water flow, $V = 4\ \text{ft/s}$

Inside Diameter of pipe, $D_i = 1.0\,\text{in} = 0.083\,\text{ft}$

Outside Diameter of pipe, $D_o = 1.2\,\text{in} = 0.1\,\text{ft}$

Temperature of outside surfaces, $T_{amb} = 60°\text{F}$

Thermal conductivity of pipe, $k = 30\ \text{Btu/h}\cdot\text{ft}°\text{F}$

Heat transfer coefficient for inner pipe surface, $h_i = 30\,\text{Btu/h}\cdot\text{ft}^2°\text{F}$

Step 2 of 7

Calculate the Film temperature,

$$T_f = \frac{T_S + T_\infty}{2}$$
$$= \frac{150+60}{2}$$
$$= 105°\text{F}$$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{460+105}$$
$$= 1.77\times10^{-3}\ \text{R}^{-1}$$

Step 3 of 7

Take properties of air at 1atm pressure and film temperature,

Thermal conductivity, $k = 0.015405\,\text{Btu/h}-\text{ft}°\text{F}$

Prandtl number, $\text{Pr} = 0.72525$

Kinematic viscosity, $\nu = 1.8375\times10^{-4}\ \text{ft}^2/\text{s}$

Characteristic length, $L_C = 0.1\ \text{ft}$

Inner surface Area,

$$A_i = \pi D_i L$$
$$= \pi\times0.083\times50$$
$$= 13.04\ \text{ft}^2$$

Outer surface Area,

$$A_o = \pi D_o L$$
$$= \pi\times0.1\times50$$
$$= 15.71\ \text{ft}^2$$

Step 4 of 7

Calculate Rayleigh number,

$$Ra = \frac{g\beta(T_\infty - T_S)L_C^3}{\nu^2}\times\text{Pr}$$
$$= \frac{32.2\times\left(1.77\times10^{-3}\right)\times(150-60)\times(0.1)^3}{\left(1.8375\times10^{-4}\right)^2}\times(0.72525)$$
$$= 1.102\times10^5$$

Calculate Nusselt number,

$$Nu = \left[0.6 + \frac{0.387\text{Ra}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.6 + \frac{0.387(1.102\times10^5)\text{Ra}^{1/6}}{\left[1+(0.559/0.72525)^{9/16}\right]^{8/27}}\right]^2$$
$$= 7.998$$

Step 5 of 7

Heat transfer coefficient for outside surface,

$$h_o = \frac{k}{L_C}\cdot Nu$$
$$= \frac{0.015405}{0.1}\times7.998$$
$$= 1.232\ \text{Btu/h-ft}^2\text{-°F}$$

Calculating heat transfer coefficient for radiation from outside surface,

$$h_{rad} = \varepsilon\sigma(T_S + T_{amb})\left(T_S^2 + T_{amb}^2\right)$$
$$= 0.5\times\left(0.1714\times10^{-8}\right)\left[(150+460)+(60+460)\right]$$
$$\left[(150+460)^2+(60+460)^2\right]$$
$$= 0.6222\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}$$

Step 6 of 7

Therefore combined heat transfer coefficient,

$$h_{com} = h_0 + h_{rad}$$
$$= 1.232 + 0.6222$$

Step 6 of 7

Therefore combined heat transfer coefficient,

$$h_{com} = h_0 + h_{rad}$$
$$= 1.232 + 0.6222$$
$$= 1.854 \text{ Btu/h-ft}^2\text{-R}$$

Overall resistance to heat transfer,

$$R_{tot} = \frac{1}{h_i A_i} + \frac{\ln(D_o/D_i)}{4\pi kL} + \frac{1}{h_o A_o}$$
$$= \frac{1}{(30)(13.04)} + \frac{\ln(0.1/0.0833)}{4\pi(30)(50)} + \frac{1}{(1.854)(15.71)}$$
$$= \left(2.56\times10^{-3}\right) + \left(9.69\times10^{-6}\right) + (0.0343)$$
$$= 0.03687 \ ^0\text{R-h/Btu}$$

Heat transfer due to convection and radiation,

$$\dot{Q} = \frac{T_w - T_\infty}{R_{tot}}$$
$$= \frac{150 - 60}{0.03687}$$
$$= 2441.28 \text{Btu/h}$$

Step 7 of 7

Density of water from property table, at 150°F, is $\rho = 61.2 \text{lbm/ft}^3$

Now calculate mass flow rate,

$$\dot{m} = \rho \times A_i \times V$$
$$= 61.21 \times 13.04 \times 4$$
$$= 1.3245 \text{ lbm/s}$$
$$= 4768.2 \text{ lbm/hour}$$

Calculate heat transfer rate,

$$\dot{Q} = \dot{m} c_p (\Delta T)$$

$$\Delta T = \frac{\dot{Q}}{\dot{m} c_p}$$
$$= \frac{2441.28}{4768.2 \times 1.0}$$
$$= 0.512$$

Hence the temperature Drop across pipe is, $\boxed{\Delta T = 0.512°\text{F}}$

$$= 2441.28 \text{Btu/h}$$

Step 7 of 7

Question: 20.074P

Consider a flat-plate solar collector placed horizontally on the flat roof of a house. The collector is 1.5 m wide and 4.5 m long, and the average temperature of the exposed surface of the collector is 42°C. Determine the rate of heat loss from the collector by natural convection during a calm day when the ambient air temperature is 8°C. Also, determine the heat loss by radiation by taking the emissivity of the collector surface to be 0.85 and the effective sky temperature to be –15°C.

Step 1 of 7

Given data:

Length of collector, $L = 4.5\text{m}$

Width of collector $w = 1.5\text{m}$

Temperature of collector surface $T_s = 42°\text{C}$

Ambient air temperature $T_\infty = 8°\text{C}$

Effective sky temperature $T_{sky} = -15°\text{C}$

Emissivity of the collector surface $\varepsilon = 0.85$

Step 2 of 7

(a)Rate of heat transfer by convection, $\dot{Q}_{conv}$ is expressed as:-

$$Q_{conv} = hA_s\left(T_s - T_\infty\right) \quad \ldots\ldots (1)$$

Let us find the unknown quantities

Heat transfer surface Area,

$$A_s = L \times W$$
$$= 4.5 \times 1.5$$
$$= 6.75\text{m}^2$$

The average temperature of air

$$T_f = \left(T_s + T_\infty\right)/2$$
$$T_f = (42+8)/2$$
$$T_f = 25°\text{C}$$

Step 3 of 7

The properties of air at 1atm and average temperature at $T_f = 25°\text{C}$ are

Thermal conductivity, $k = 0.02551\,\text{W/m}\cdot\text{k}$

Prandtl Number, $\text{Pr} = 0.7296$

Kinematic viscosity, $v = 1.562\times10^{-5}\,\text{m}^2/\text{s}$

Volume expansion coefficient

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{298}$$
$$= 3.36\times10^{-3}\,\text{K}^{-1}$$

Step 4 of 7

The characteristic length for horizontal surface is calculated as,

$$L_c = \frac{A_s}{p}$$

Where A_s – Surface area

p = Perimeter of surface

$$L_c = \frac{A_s}{2(L+w)}$$
$$= \frac{6.75}{2(1.5+4.5)}$$
$$= 0.5625\text{m}$$

Step 5 of 7

The Rayleigh number becomes

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{v^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.36\times10^{-3}\times(42-8)\times(0.5625)^3}{\quad}\times(0.7296)$$
$$= \frac{1}{298}$$
$$= 3.36\times10^{-3}\,\text{K}^{-1}$$

Step 4 of 7

The characteristic length for horizontal surface is calculated as,

$$L_c = \frac{A_s}{p}$$

Where A_s – Surface area

p = Perimeter of surface

$$L_c = \frac{A_s}{2(L+w)}$$
$$= \frac{6.75}{2(1.5+4.5)}$$
$$= 0.5625\text{m}$$

Step 5 of 7

The Rayleigh number becomes

$$\text{Ra}_L = \frac{g\beta(T_s - T_\infty)L_c^3}{v^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.36\times10^{-3}\times(42-8)\times(0.5625)^3}{\quad}\times(0.7296)$$

(b)Rate of heat transfer by radiation, $\dot{Q}_{rad}$ can be calculated as

$$\dot{Q}_{rad} = \varepsilon A_s\sigma\left(T_s^4 - T_{sky}^4\right)$$

Where

Stefan Boltzmann constant $\sigma = 5.67\times10^{-8}\,\text{W/m}^2\text{K}^4$

Then

$$\dot{Q}_{rad} = 0.85\times6.75\times5.67\times10^{-8}\left((42+273)^4 - (-15+273)^4\right)$$
$$= 1761.53\,\text{W}$$

Question: 20.076P

A 6-m-internal-diameter spherical tank made of 1.5-cm-thick stainless steel (k =15 W/m·K) is used to store iced water at 0°C in a room at 20°C. The walls of the room are also at 20°C. The outer surface of the tank is black (emissivity ε= 1), and heat transfer between the outer surface of the tank and the surroundings is by natural convection and radiation. Assuming the entire steel tank to be at 0°C and thus the thermal resistance of the tank to be negligible, determine (*a*) the rate of heat transfer to the iced water in the tank and (*b*) the amount of ice at 0°C that melts during a 24-h period. The heat of fusion of water is 333.7 kJ/kg.

Step 1 of 6

As given the heat transfer is by convection and radiation both, therefore

$$Q_{total} = Q_{conv} + Q_{rad}$$

$$Q_{total} = hA_s(T_s - T_\infty) + \sigma A_s \varepsilon\left(T_s^4 - T_w^4\right) \quad \text{..... (1)}$$

The average temperature of air is

$$T_f = (T_s + T_\infty)/2$$
$$= (0+20)/2$$
$$= 10°C$$

Taking properties of air at 1 atm and T_f =10°C is

Thermal conductivity, $k = 0.02439\,W/m°C$

Prandtl number, $Pr = 0.7336$

Kinematic viscosity, $\nu = 1.426\times10^{-5}\,m^2/s$

Step 2 of 6

Determine the Volume expansion,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{10+273}$$
$$= 3.534\times10^{-3}K^{-1}$$

Characteristic length of spherical tank is equal to the diameter of the spherical tank

$$L_c = D_o = 6.03\,m$$

Step 3 of 6

Therefore Rayleigh number

$$Ra_L = \frac{g\beta(T_\infty - T_s)L_c^3}{\nu^2}\cdot Pr$$
$$= \frac{9.81\times3.534\times10^{-3}(20-0)(6.03)^3}{\left(1.426\times10^{-5}\right)^2}\times(0.7336)$$
$$= 5.4845\times10^{11}$$

From table "Empirical correlations for the average Nusselt number for natural convection" in case of spheres Nusselt number is

$$Nu = 2 + \frac{0.589Ra_L^{0.25}}{\left[1+\left(\frac{0.469}{Pr}\right)^{9/16}\right]^{4/9}}$$
$$= 2 + \frac{0.589\times\left(5.4845\times10^{11}\right)^{0.25}}{\left[1+\left(\frac{0.469}{0.7336}\right)^{9/16}\right]^{4/9}}$$
$$= 394.53$$

Step 4 of 6

Heat transfer coefficient,

$$h = \frac{Nu\cdot k}{L_c}$$
$$= \frac{394.53\times0.02439}{6.03}$$
$$= 1.596\,W/m^2°C$$

Area of spherical surface,

$$A_s = \pi D_0^2$$
$$= \pi(6.03)^2$$
$$= 114.23\,m^2$$

Step 5 of 6

(a) Substituting known values in equation (1)

$$Q_{total} = hA_s(T_s - T_\infty) + \sigma A_s\varepsilon\left(T_s^4 - T_w^4\right)$$
$$= 1.596\times114.23(20-0) + 5.67\times10^{-8}\times114.23\times1\left(293^4 - 273^4\right)$$
$$= 3646.2216 + 11758.568$$
$$= 15404.789\,W$$

Therefore heat transfer to the iced water in the tank is $\boxed{15.404\,kW}$

Step 6 of 6

(b) Heat transfer per second Q_{total} =15404.789 J/s

Therefore heat transfer in 24 hours,

$$Q = 15404.789\times3600\times24$$
$$Q = 1330.97\times10^3\,kJ$$

Amount of ice melt,

$$m = \frac{\text{Total heat transfer in 24 hours}}{\text{Heat of fusion of water, } h_f}$$
$$m = \frac{1330.97\times10^3}{333.7}$$

Thus the mass of ice melt is $\boxed{3988.522\,kg}$

Question: 20.077P

Consider a 1.2-m-high and 2-m-wide double-pane window consisting of two 3-mm-thick layers of glass (k =0.78 W/m · K} separated by a 2.5-cm-wide air space. Determine the steady rate of heat transfer through this window and the temperature of its inner surface for a day during which the room is maintained at 20°C while the temperature of the outdoors is 0°C. Take the heat transfer coefficients on the inner and outer surfaces of the window to be $h1$, = 10 W/m K and $h2$ =25 W/m2.K and disregard any heat transfer by radiation.

Step 1 of 7

Loading solution. Please wait ...

Step 2 of 7

Assumptions:

(i) Steady state heat transfer

(ii) Radiation effects are neglected

(iii) Inner glass temperature, $T_1 = 18°C$

(iv) Outer glass surface temperature, $T_2 = 2°C$

(v) Let us take the air properties at 1atm and at average temperature T_{avg}

Average temperature of air is

$$T_{avg} = \frac{T_1 + T_2}{2}$$

$$= \frac{18+2}{2}$$

$$T_{avg} = 10°C$$

Thermal conductivity, $k = 0.02439\,w/m°C$

Prandtl number, $Pr = 0.7336$

Kinematic viscosity, $\nu = 1.426\times10^{-5}\,m^2/s$

Step 3 of 7

Volume expansion coefficient,

$$\beta = \frac{1}{T_{avg}}$$

$$= \frac{1}{(273+10)}$$

$$= 3.534\times10^{-3}\,K^{-1}$$

Heat transfer through window, Q can be expressed as

$$Q = hA_s(T_1 - T_2) \qquad \ldots\ldots (1)$$

Heat transfer rate $\dot{Q}$ is also given by.

$$\dot{Q} = \frac{T_{\infty_i} - T_{\infty_o}}{R_{inside} + R_{Glass} + R_{airspace} + R_{outside}} \qquad \ldots\ldots (2)$$

Step 4 of 7

Characteristic length L_c = Airspace between Glasses,

$$L_c = L = 0.025\,m$$

Calculating Rayleigh and Nusselt number for heat transfer coefficient h,
Rayleigh number,

$$Ra = \frac{g\beta(T_1 - T_2)L_c^3}{\nu^2}\cdot Pr$$

$$= \frac{9.81\times3.534\times10^{-3}(18-2)(0.025)^3}{(1.426\times10^{-5})^2}\times(0.7336)$$

$$= 31267.7$$

Nusselt number

$$Nu = 0.42Ra^{0.25}Pr^{0.012}\left(\frac{H}{L}\right)^{-0.3}$$

$$= 0.42\times(31267.7)^{0.25}\times(0.7336)^{0.012}\times\left(\frac{1.2}{0.025}\right)^{-0.3}$$

$$= 1.742$$

Step 5 of 7

Heat transfer coefficient,

$$h_{air} = \frac{k}{L_c}\cdot Nu$$

$$= \frac{0.02439}{0.025}\times1.742$$

$$= 1.7\,W/m^2°C$$

Cross sectional area of the Glass,

$$A_s = H\times W$$

$$= 1.2\times2$$

$$= 2.4\,m^2$$

Step 6 of 7

Substituting the known values in equation (2)

$$\dot{Q} = \frac{T_{\infty_i} - T_{\infty_o}}{R_{inside} + R_{Glass} + R_{airspace} + R_{outside}}$$

$$= \frac{T_{\infty_i} - T_{\infty_o}}{\frac{1}{h_1A_s} + \frac{2L_g}{k_gA_s} + \frac{1}{h_{air}A_s} + \frac{1}{h_2\cdot A}}$$

$$= \frac{20-0}{\frac{1}{10\times2.4} + \frac{2\times0.003}{0.78\times2.4} + \frac{1}{1.7\times2.4} + \frac{1}{25\times2.4}}$$

$$= \frac{20}{0.3066}$$

$$= 65.22\,W$$

Step 7 of 7

Now putting the values in equation (1) to check whether the assumed values are correct or not

$$Q = hA_s(T_1 - T_2)$$

$$65.22 = 1.7\times2.4(T_1 - T_2)$$

$$T_1 - T_2 = 15.98°C$$

$T_1 - T_2 = 16°C$ This is exactly same as we assumed.

Question: 20.078P pg 1

An electric resistance space heater is designed such that it resembles a rectangular box 50 cm high, 80 cm long, and 15 cm wide filled with 45 kg of oil. The heater is to be placed against a wall, and thus heat transfer from its back surface is negligible. The surface temperature of the heater is not to exceed 75°C in a room at 25°C for safety considerations. Disregarding heat transfer from the bottom and top surfaces of the heater in anticipation that the top surface will be used as a shelf, determine the power rating of the heater in W. Take the emissivity of the outer surface of the heater to be 0.8 and the average temperature of the ceiling and wall surfaces to be the same as the room air temperature.

Also, determine how long it will take for the heater to reach steady operation when it is first turned on (i.e., for the oil temperature to rise from 25°C to 75°C). State your assumptions in the calculations.

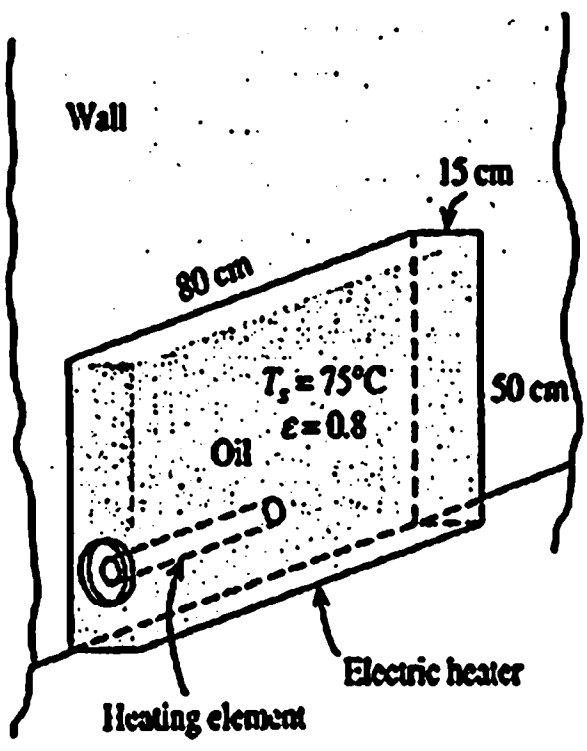


FIGURE P20–78

Step 1 of 7

Height of rectangular box, $H = 50\text{cm} = 0.5\text{m}$

Width of rectangular box, $W = 15\text{cm} = 0.15\text{m}$

Length of rectangular box, $L = 80\text{cm} = 0.8\text{m}$

Quantity of oil, $m = 45\text{kg}$

Surface temperature of heater, $T_s = 75°\text{C}$

Room temperature $T_\infty = 25°\text{C}$

Emissivity of Heater surface, $\varepsilon = 0.8$

Outside wall temperature, $T_w = 25°\text{C}$

Step 2 of 7

The heat loss is due to both convection and radiation. Therefore heat transfer rate will be expressed as

$$\dot{Q} = hA_s\left(T_s - T_\infty\right) + \varepsilon A_s \sigma\left(T_s^4 - T_w^4\right) \qquad \ldots\ldots (1)$$

Let us take average temperature of air for determining the properties of air

$$T_f = \left(T_s + T_\infty\right)/2$$
$$= (75+25)/2$$
$$= 50°\text{C}$$

Taking air properties at 1atm pressure and average temperature $T_f = 50°\text{C}$

Thermal conductivity, $k = 0.02735\,\text{W/m}°\text{C}$

Prandtl number, $\text{Pr} = 0.7228$

Kinematic viscosity, $\nu = 1.798\times10^{-5}\,\text{m}^2/\text{s}$

Step 3 of 7

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{50+273}$$
$$= \frac{1}{323}$$
$$= 3.0960\times10^{-3}\,\text{K}^{-1}$$

Characteristic length is height of vertical side of box

$L_c = 0.5\text{m}$

Step 4 of 7

Calculating the Rayleigh number,

$$\text{Ra} = \frac{g\beta\left(T_s - T_\infty\right)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.0960\times10^{-3}\times(75-25)\times(0.5)^3}{\left(1.798\times10^{-5}\right)^2}\times(0.7228)$$
$$= 4.244\times10^8$$

Nusselt number for vertical plate and complete range of Ra

$$\text{Nu} = \left[0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+(0.492/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{0.387\left(4.244\times10^8\right)^{1/6}}{\left[1+(0.492/0.7228)^{9/16}\right]^{8/27}}\right]^2$$
$$= 94.68$$

Step 5 of 7

Therefore Heat transfer coefficient,

$$h = \frac{k\times\text{Nu}}{L_c}$$
$$= \frac{0.02735\times94.68}{0.5}$$
$$= 5.179\,\text{W/m}^2°\text{C}$$

$$= \frac{0.02735 \times 94.68}{0.5}$$

$$= 5.179\ \text{W/m}^2\,^\circ\text{C}$$

The heat transfer takes place from side surfaces of the rectangular box and the front surface of the rectangular box. Thus the surface Area of heat flow is

$$A_s = (0.5 \times 0.8) + 2(0.15 \times 0.5)$$

$$= 0.55\ \text{m}^2$$

From equation (1), the total heat loss is

$$\dot{Q} = hA_s(T_s - T_\infty) + \varepsilon A_s \sigma\left(T_s^4 - T_w^4\right)$$

$$= 5.179(0.55)(75-25) + 0.8(0.55)\left(5.67 \times 10^{-8}\right)\left[(75+273)^4 - (25+273)^4\right]$$

$$= 142.4225 + 169.148$$

Thus the total heat loss is $\boxed{\dot{Q} = 311.57\ \text{W}}$

Step 6 of 7

Time taken to raise oil temperature from 25°C to 75°C:

Let us calculate the heat required to raise the oil temperature. It can be expressed as

$$Q_T = mc_p(T_2 - T_1)$$

Assuming specific heat of oil as $c_p = 2006\ \text{J/kg.°C}$

$T_2 = T_s$ = Surface temperature of heater

$T_1 = T_\infty$ = Ambient room temperature

Therefore

$$Q_T = 45 \times 2006 \times (75-25)$$

$$= 4.5135 \times 10^6\ \text{J}$$

Step 7 of 7

And the heat generated is power rating of the heater

$$\dot{Q} = 311.57\ \text{W}$$

$$= 311.57\ \text{J/s}$$

Therefore time taken to rise the oil temperature from 25°C to 75°C

$$t = \frac{\text{Heat required to rise temperature}}{\text{Heat generated}}$$

$$= \frac{Q_T}{\dot{Q}}$$

$$= \frac{4.5135 \times 10^6}{311.57}$$

$$= 14486.31\ \text{seconds}$$

$$= 4.024\ \text{hours}$$

Therefore time taken to rise the oil temperature is $\boxed{t = 4.024\ \text{hours}}$

Question: 20.079P pg 1

During a plant visit, it was observed that a 2-m-high and 1-m-wide section of the vertical front section of a natural gas furnace wall was too hot to touch. The temperature measurements on the surface revealed that the average temperature of the exposed hot surface was 110°C, while the temperature of the surrounding air was 25°C. The surface appeared to be oxidized, and its emissivity can be taken to be 0.6. Taking the temperature of the surrounding surfaces to be 25°C also, determine the rate of heat loss from, this furnace.

The furnace has an efficiency of 79 percent, and the plant pays $ 1.20 per therm of natural gas. If the plant operates 10 h a day, 310 days a year, and thus 3100 h a year, determine the annual cost of the heat loss from this vertical hot surface on the front section of the furnace wall.

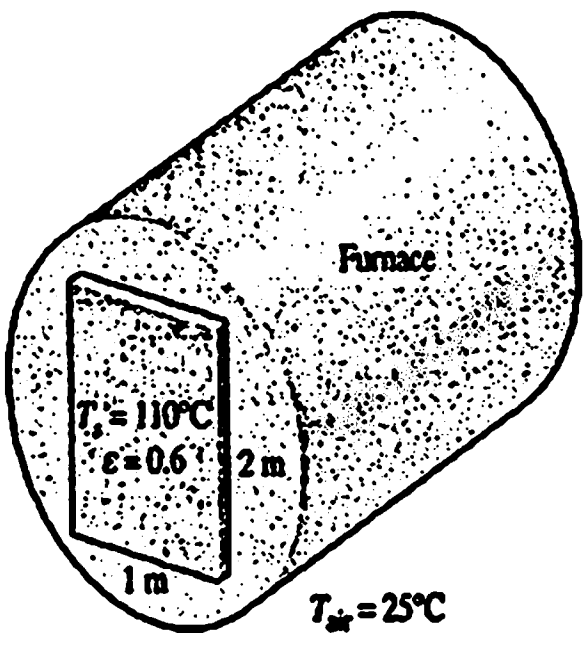

FIGURE P20–79

Step 1 of 8

Given data:

Height of section, $H = 2\text{m}$

Width of section, $W = 1\text{m}$

Temperature of hot surface, $T_s = 110°C$

Temperature of surrounding air, $T_\infty = 25°C$

Emissivity of surface, $\varepsilon = 0.6$

Surrounding surface temperature, $T_w = 25°C$

Furnace efficiency

$\eta_{\text{furnace}} = 79\%$

$= 0.79$

Operating Hours, $N = 3100\text{h}$

Cost of natural gas, $C_N = \$1.20/\text{therm}$

Step 2 of 8

The total rate of heat loss,

$$Q_T = hA_s(T_s - T_\infty) + \varepsilon\sigma A_s\left(T_s^4 - T_w^4\right) \quad \ldots\ldots (1)$$

The average film temperature of air,

$T_f = (T_s + T_\infty)/2$

$= (110 + 25)/2$

$T_f = 67.5°C$

Taking air properties at 1atm pressure and film temperature $T_f = 67.5°C$

Interpolating air properties between $(60 - 70)°C$

Thermal conductivity,

$$k = 0.02808 + \frac{(0.02881 - 0.02808)}{(70 - 60)}(67.5 - 60)$$

$k = 0.02863\text{w/m} \cdot \text{K}$

Prandtl number, $\text{Pr} = 0.71833$

Step 3 of 8

Kinematic viscosity,

$$\nu = 1.896\times10^{-5} + \frac{(1.995 - 1.896)\times10^{-5}}{(70 - 60)} \times (67.5 - 60)$$

$\nu = 1.97025\times10^{-5}\,\text{m}^2/\text{s}$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{273 + 67.5}$$

$\beta = 2.937\times10^{-3}\,\text{K}^{-1}$

Step 4 of 8

Characteristic length is Height of section, $L_C = H = 2\text{m}$

Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2} \cdot \text{Pr}$$

$$= \frac{9.81\times2.937\times10^{-3}\times(110 - 25)\times(2)^3}{\left(1.97025\times10^{-5}\right)^2} \times (0.71833)$$

$\text{Ra} = 3.626\times10^{10}$

Nusselt number for vertical plate and entire range of Ra,

$$\text{Nu} = \left[0.825 + \frac{0.387\,Ra^{1/6}}{\left[1 + \left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.825 + \frac{0.387\left(3.626\times10^{10}\right)^{1/6}}{\left[1 + \left(\frac{0.492}{0.71833}\right)^{9/16}\right]^{8/27}}\right]^2$$

$\text{Nu} = 380.44$

Step 5 of 8

$$\left[\left(\frac{}{0.71833}\right)^{}\right]^{}$$ 20.079P pg 2

$\mathrm{Nu} = 380.44$

Step 5 of 8

Heat transfer coefficient,

$$h = \frac{k}{L_c} \times \mathrm{Nu}$$

$$= \frac{0.02863}{2} \times 380.44$$

$$h = 5.45\,\mathrm{W/m^2.^oC}$$

Surface Area of the heat transfer

$$A_s = H \times W$$

$$= 2 \times 1$$

$$A_s = 2\,\mathrm{m^2}$$

Step 6 of 8

On substituting the known values in the equation (1), we get

$$Q_T = hA_s(T_s - T_\infty) + \varepsilon\sigma A_s\left(T_s^4 - T_w^4\right)$$

$$= 5.45 \times 2 \times (110-25) + 0.6 \times 2 \times 5.67 \times 10^{-8}\left[(273+110)^4 - (273+25)^2\right]$$

$$Q_T = 926.5 + 927.488$$

Therefore the rate of heat loss from this furnace, $\boxed{Q_T = 1853.988\,\mathrm{W}}$

Step 7 of 8

Annual cost of heat loss (C_A)

Rate of heat loss, $Q_T = 1853.32\,\mathrm{J/s}$

Total heat loss in a year

$$Q_{year} = \frac{Q_T \times N}{\eta_{furnance}}$$

$$= \frac{1853.988 \times 3100 \times 3600}{0.79}$$

$$Q_{year} = 2.619 \times 10^{10}\,\mathrm{J}$$

$$Q_{year} = 2.619 \times 10^{7}\,\mathrm{kJ}$$

Step 8 of 8

Let us convert into therm of natural gas

We know $1\mathrm{therm} = 105500\,\mathrm{kJ}$

Therefore,

$$Q_{year} = \frac{2.619 \times 10^7}{105500}$$

$$Q_{year} = 248.246\,\mathrm{therms}$$

The annual cost,

$$C_A = Q_{year} \times C_N$$

$$= 248.246 \times 1.20$$

$$C_A = \$297.895$$

Therefore the annual cost, $\boxed{C_A = \$297.8}$

Question: 20.080P

A solar collector consists of a horizontal copper tube of outer diameter 5 cm enclosed in a concentric thin glass tube of 9 cm diameter. Water is heated as it flows through the tube, and the annular space between the copper and glass tube is filled with air at 1 atm pressure. During a clear day, the temperatures of the tube surface and the glass cover are measured to be 60°C and 32°C, respectively. Determine the rate of heat loss from the collector by natural convection per meter length of the tube.

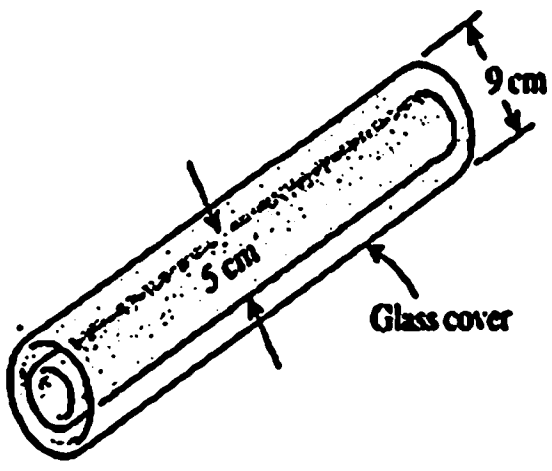

FIGURE P20–80

Step 1 of 3

The rate of heat loss from the collector due to convection is determined by estimating the effective thermal conductivity. In order to determine the effective thermal conductivity, first take the properties at average temperature and calculate the Rayleigh number then use the relation for shape factor.

Calculate the average temperature. Substitute 60°C for T_1 and 32°C for T_2

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{60+32}{2}$$
$$= 46°C$$

Determine the volume expansion coefficient.

$$\beta = \frac{1}{T_{avg} + 273}$$
$$= \frac{1}{46+273}$$
$$= 0.003135\ K^{-1}$$

Step 2 of 3

Calculate the characteristic length. Substitute 0.09 m for D_2 and 0.05 m for D_1

$$L_c = \frac{D_1 - D_2}{2}$$
$$= \frac{0.09-0.05}{2}$$
$$= 0.02\ m$$

Calculate the shape factor. Substitute 0.02 m for L_c, 0.09 m for D_2 and 0.05 m for D_1

$$F = \frac{\left[\ln(D_1/D_2)\right]^4}{L_c^3\left[D_1^{-3/5} + D_2^{-3/5}\right]^5}$$
$$= \frac{\left[\ln(0.09/0.05)\right]^4}{0.02^3\left[0.09^{-3/5} + 0.05^{-3/5}\right]^5}$$
$$= 0.1303$$

Step 3 of 3

Calculate the Rayleigh number. Substitute 9.81 m/s^2 for g, 0.7238 for Pr, 0.003135 K^{-1} for β, 0.02 m for L, 1.76×10^{-5} m^2/s for v, 60°C for T_1 and 32°C for T_2

$$\text{Ra} = \frac{g\beta(T_1 - T_2)D^3}{v^2} \times \text{Pr}$$
$$= \frac{9.81\times0.003135\times(60-32)(0.02)^3}{\left(1.76\times10^{-5}\right)^2} \times 0.7238$$
$$= 16100$$

Determine the effective thermal conductivity. Substitute 0.1303 for F, 0.7238 for Pr, 16100 for Ra and 0.02706 W/m·°C for k

$$k_{eff} = 0.386\times k\times\left(\frac{\text{Pr}}{0.861+\text{Pr}}\right)^{0.25}(F\times\text{Ra})^{0.25}$$
$$= 0.386\times0.02706\left(\frac{0.7238}{0.861+0.7238}\right)^{0.25}(0.1303\times16100)^{0.25}$$
$$= 0.05811\ \text{W/m}\cdot°C$$

Calculate the heat loss from the collector. Substitute 0.05811 W/m·°C for k_{eff}, 0.09 m for D_2, 0.05 m for D_1, 60°C for T_1 and 32°C for T_2

$$\dot{Q} = \frac{2\pi k_{eff}(T_1 - T_2)}{\ln(D_2/D_1)}$$
$$= \frac{2\pi(0.05811)(60-32)}{\ln(0.09/0.05)}$$
$$= 17.4\ \text{W}$$

Thus the heat loss from the collector is **17.4 W**

Question:

A solar collector consists of a horizontal aluminum tube of outer diameter 5 cm enclosed in a concentric thin glass tube of 7 cm diameter. Water is heated as it flows through the aluminum tube, and the annular space between the aluminum and glass tubes is filled with air at 1 atm pressure. The pump circulating the water fails during a clear day, and the water temperature in the tube starts rising. The aluminum tube absorbs solar radiation at a rate of 20 W per meter length, and the temperature of the ambient air outside is 30°C. Approximating the surfaces of the tube and the glass cover as being black (emissivity $\varepsilon = 1$) in radiation calculations and taking the effective sky temperature to be 20°C, determine the temperature of the aluminum tube when equilibrium is established (i.e., when the net heat loss from the tube by convection and radiation equals the amount of solar energy absorbed by the tube).

Step 1 of 13

Let assume the outside surface temperature of glass tube, $T_s = 35°C$

Calculate the Mean film temperature of the air,

$$T_f = (T_s + T_\infty)/2$$

Here,

Outside air temperature, T_∞

Substitute $30°C$ for T_∞ $35°C$ for T_s

$$T_f = (T_s + T_\infty)/2$$

$$= (35 + 30)/2$$

$$= 32.5°C$$

Step 2 of 13

From the properties of the air,

At $T_f = 32.5°C$

Use the method of interpolating properties between $(30 - 35)°C$

Thermal conductivity,

$$k = \frac{0.02588 + 0.02625}{2}$$

$$= 0.026065\ W/m \cdot °C$$

Prandtl number,

$$Pr = \frac{0.7268 + 0.7282}{2}$$

$$= 0.7275$$

Kinematic viscosity,

$$\nu = \frac{(1.608 + 1.655)10^{-5}}{2}$$

$$= 1.6315 \times 10^{-5}\ m^2/s$$

Calculate the Coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{32.5 + 273}$$

$$\beta = 3.273 \times 10^{-3}\ K^{-1}$$

Step 3 of 13

Characteristic length (L_c) = Diameter of Horizontal cylinder

$$L_c = 0.07\ m$$

Calculate Rayleigh number,

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2} \cdot Pr$$

Here,

Acceleration due gravity is g

Substitute $9.81\ m/s^2$ for g, $3.273 \times 10^{-3}\ K^{-1}$ for β, $0.07\ m$ for L_c 0.7275 for Pr, $1.6315 \times 10^{-5}\ m^2/s$ for ν

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2} \cdot Pr$$

$$= \frac{9.81 \times 3.273 \times 10^{-3} \times (35 - 30)(0.07)^3}{(1.6315 \times 10^{-5})^2} \times (0.7275)$$

$$Ra = 150500.512$$

Step 4 of 13

From table "empirical correlations for the average Nusselt number for natural convection over surfaces" Nusselt number for horizontal cylinders is

$$Nu = \left[0.6 + \frac{0.387\,Ra^{1/6}}{\left[1 + \left(\frac{0.559}{Pr}\right)^{9/16}\right]^{8/27}}\right]^2$$

Substitute 150500.512 for Ra

$$Nu = \left[0.6 + \frac{0.387\,Ra^{1/6}}{\left[1 + \left(\frac{0.559}{Pr}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$Nu = \left[0.6 + \frac{0.387\,Ra^{1/6}}{\left[1+\left(\frac{0.559}{Pr}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.6 + \frac{0.387(150500.512)^{1/6}}{\left[1+\left(\frac{0.559}{0.7275}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.6 + \frac{2.8225}{1.2022}\right]^2$$

$$Nu = 8.689$$

Calculate Heat transfer coefficient,

$$h = \frac{k}{L_c} Nu$$

Here,

Heat transfer coefficient is h

Substitute 8.689 for Nu, $0.07\,m$ for L_c, $0.026065\,W/m \cdot K$ for k

$$h = \frac{k}{L_c} Nu$$

$$= \frac{0.026065 \times 8.689}{0.07}$$

$$h = 3.235\,W/m^2 \cdot {}^\circ C$$

Step 5 of 13

Use the conversion factor to convert the temperature from $1°C$ to $1K$ is

$$1K = 1°C + 273$$

Calculate the rate of heat loss,

$$Q = Q_{conv} + Q_{rad}$$

$$= hA_s(T_s - T_\infty) + \varepsilon A_s \sigma\left(T_s^4 - T_{eff}^4\right)$$

$$= h(\pi DL)(T_s - T_\infty) + \varepsilon(\pi DL)\sigma\left(T_s^4 - T_{eff}^4\right)$$

Here,

Rate of solar radiation, Q_{rad}

Outside air temperature, T_∞

Emissivity of surface, ε

Effective sky temperature, T_{eff}

Substitute $20°C$ for T_{eff}, $30°C$ for T_∞, 1 for ε, $20\,W/m$ for Q_{rad}

$$20 = 3.235 \times \pi \times 0.07 \times 1 \times (T_s - 30)$$

$$+ (1)(\pi \times 0.07 \times 1) \times 5.67 \times 10^{-8} \times \left[(T_s + 273)^4 - (30 + 273)^4\right]$$

$$20 = 0.7114(T_s - 30) + 1.25 \times 10^{-8}\left[(T_s + 273)^4 - (303)^4\right]$$

$$T_s = 39.23°C$$

Therefore surface temperature of the glass tube, $T_s = 39.23°C$.

Step 6 of 13

Therefore temperature of glass tube surface,

$$T_s = T_2 = 39.23°C$$

Now calculating heat transfer through the air space between Aluminum tube and glass cover

Assuming Aluminum tube surface temperature,

$$T_1 = 45°C$$

Calculate the Mean film temperature of the aluminum,

$$T_{avg} = (T_1 + T_2)/2$$

$$= (45 + 39.23)/2$$

$$= 42.115°C$$

Step 7 of 13

From properties of air table at $T_{avg} = 42.115°C$

Thermal conductivity,

$$k = 0.02662 + \frac{0.02699 - 0.02662}{(45 - 40)}(42.115 - 40)$$

$$= 0.02678\,W/m \cdot {}^\circ C$$

Prandtl number,

$$Pr = 0.7255 + \frac{0.7241 - 0.7255}{(45 - 40)}(42.115 - 40)$$

$$= 0.7249$$

Kinematic viscosity,

$$v = 1.702 \times 10^{-5} + \frac{(1.750 - 1.702) \times 10^{-5}}{(45 - 40)}(42.115 - 40)$$

$$= 1.7224 \times 10^{-5}\,m^2/s$$

Step 8 of 13

$$=1.7224\times10^{-5}\ \mathrm{m^2/s}$$

Step 8 of 13

Calculate the Coefficient of volume expansion,

$$\beta=\frac{1}{T_{avg}}$$
$$=\frac{1}{273+42.115}$$
$$=3.1734\times10^{-3}\ \mathrm{K^{-1}}$$

Step 9 of 13

Find the Characteristic length,

$$(L_C)=(D_o-D_i)/2$$
$$=(0.07-0.05)/2$$
$$=0.01\mathrm{m}$$

Calculate Rayleigh number,

$$\mathrm{Ra}=\frac{g\beta(T_1-T_2)L_C^3}{\nu^2}\times\mathrm{Pr}$$
$$=\frac{9.81\times3.1734\times10^{-3}(45-39.23)(0.01)^3}{\left(1.7224\times10^{-5}\right)^2}\times(0.7249)$$
$$=438.914$$

Calculate the geometric factor for concentric cylinders,

$$F_{cyl}=\frac{\left[\ln\frac{D_o}{D_i}\right]^4}{L_C^3\left[D_i^{-3/5}+D_o^{-3/5}\right]^5}$$

Here,

Geometric factor for concentric cylinders are F_{cyl}

Substitute $0.07\,\mathrm{m}$ for D_0, $0.05\,\mathrm{m}$ for D_i, $0.01\,\mathrm{m}$ for L_c

$$F_{cyl}=\frac{\left[\ln\frac{D_o}{D_i}\right]^4}{L_C^3\left[D_i^{-3/5}+D_o^{-3/5}\right]^5}$$
$$=\frac{\left(\ln\frac{0.07}{0.05}\right)^4}{(0.01)^3\left[(0.05)^{-3/5}+(0.07)^{-3/5}\right]^5}$$
$$=\frac{0.012817}{0.1585}$$
$$=0.08086$$

Step 10 of 13

Calculate effective thermal conductivity,

$$k_{eff}=0.386k\left[\frac{\mathrm{Pr}}{0.861+\mathrm{Pr}}\right]^{0.25}\left(F_{cyl}\cdot\mathrm{Ra}\right)^{0.25}$$

Substitute 0.7249 for Pr, $0.02678\,\mathrm{W/m\cdot K}$ for k, 438.914 for Ra, 0.08086 for F_{cyl}

$$k_{eff}=0.386k\left[\frac{\mathrm{Pr}}{0.861+\mathrm{Pr}}\right]^{0.25}\left(F_{cyl}\cdot\mathrm{Ra}\right)^{0.25}$$
$$=0.386\times(0.02678)\left[\frac{0.7249}{0.861+0.7249}\right]^{0.25}\times(0.08086\times438.914)^{1/4}$$
$$=0.00849\times2.4407$$
$$=0.02072\,\mathrm{W/m\cdot{}^\circ C}$$

Step 11 of 13

Calculate the heat transfer due to convection between the cylinders is

$$Q_{conv}=\frac{2\pi k_{eff}}{\ln\left(\frac{D_o}{D_i}\right)}(T_1-T_2)$$
$$=\frac{2\pi\times0.02072}{0.33647}(T_1-39.23)$$
$$=0.386(T_1-39.23)$$

Step 12 of 13

Calculate Surface area of the plate per unit length of the tube,

$$A_s=\pi D_iL$$

Here,

Length of the plate is L

Substitute $1\,\mathrm{m}$ for L

$$A_s=\pi D_iL$$
$$=\pi\times(0.05)\times1$$
$$A_s=0.1571\,\mathrm{m^2}$$

Calculate Heat transfer through radiation,

$$Q_{rad}=\varepsilon A_s\sigma\left(T_s^4-T_{amb}^4\right)$$

Here,

Emissivity is ε

$$Q_{rad} = \varepsilon A_s \sigma \left(T_s^4 - T_{amb}^4 \right)$$

Here,

Emissivity is ε

Stefan Boltzmann constant is σ

substitute $5.67 \times 10^{-8}\ \mathrm{W/m^2 \cdot K^4}$ for σ, 1 for ε

$$Q_{rad} = 1 \times 0.1571 \times 5.67 \times 10^{-8} \left[(T_1 + 273)^4 - (273 + 39.23)^4 \right]$$

$$= 8.91 \times 10^{-9} \left[(T_1 + 273)^4 - (312.23)^4 \right]$$

Step 13 of 13

Calculate the total heat transfer,

$$Q = Q_{conv} + Q_{rad}$$

$$20 = 0.386 (T_1 - 39.23) + 8.91 \times 10^{-9} \left[(T_1 + 273)^4 - (312.23)^4 \right]$$

Solve for T_1

$$T_1 = 52.2137^\circ\mathrm{C}$$

Therefore temperature of the aluminum tube when equilibrium is established, $\boxed{52.2137^\circ\mathrm{C}}$

Question:

The components of an electronic system dissipating 150 W are located in a 5-ft-long horizontal duct whose J cross section is 6 in × 6 in. The components in the duct are J cooled by forced air, which enters at 85°F at a rate of 22 cfm and leaves at 100°F. The surfaces of the sheet metal duct are 1 not painted, and thus radiation heat transfer from the outer surfaces is negligible. If the ambient air temperature is 80°F determine (*a*) the heat transfer from the outer surfaces of the 1 duct to the ambient air by natural convection and (*b*) the average temperature of the duct.

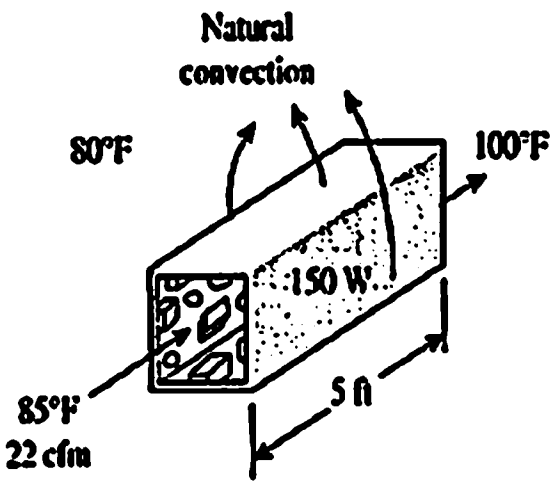

FIGURE P20–82E

Step 1 of 11

Given data:

Heat dissipation by system, $Q = 150\,\text{W}$

Length of Horizontal duct, $L = 5\,\text{ft}$

Width of duct, $W = 6\,\text{in} = 0.5\,\text{ft}$

Height of duct, $H = 6\,\text{in} = 0.5\,\text{ft}$

Forced air temperature, $T_{in} = 85°\text{F}$

Flow rate of air, $V = 22\,\text{cfm}\left(\text{ft}^3/\text{min}\right)$

Exit temperature of air, $T_{exit} = 100°\text{F}$

Ambient air temperature, $T_\infty = 80°\text{F}$

Step 2 of 11

Assuming surface temperature of the duct is $T_s = 90°\text{F}$

Film temperature,

$$T_f = (T_s + T_\infty)/2$$

$$= (90+80)/2$$

$$T_f = 85°\text{F}$$

Heat transfer by natural convection,

$$Q_{conv} = hA_s(T_s - T_\infty) \qquad \ldots\ldots (1)$$

Taking properties of air at 1atm and at temperature $T_f = 85°\text{F}$

Thermal conductivity, $k = 0.01493\,\text{Btu/h}\cdot\text{ft}\cdot°\text{F}$

Prandtl number, $\text{Pr} = 0.72825$

Kinematic viscosity, $\nu = 1.725\times10^{-4}\,\text{ft}^2/\text{s}$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{85+460}$$

$$\beta = 1.835\times10^{-3}\,\text{R}^{-1}$$

Step 3 of 11

Considering Horizontal top surface:

Characteristic length,

$$L_c = \frac{A_s}{p}$$

where, A_s – Surface Area

p = Perimeter of surface

$$L_c = \frac{5\times0.5}{2(5+0.5)}$$

$$L_c = 0.2273\,\text{ft}$$

Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$

$$= \frac{32.2\times1.835\times10^{-3}\times(90-80)\times(0.2273)^3}{\left(1.725\times10^{-4}\right)^2}(0.72825)$$

$$\text{Ra} = 1.698\times10^5$$

Step 4 of 11

Nusselt number,

$$\text{Nu} = 0.54\,\text{Ra}^{0.25}$$

$$= 0.54\left(1.698\times10^5\right)^{0.25}$$

$$\text{Nu} = 10.96$$

Heat transfer coefficient on top surface,

$$h_{top} = \frac{k}{L_c}\cdot\text{Nu}$$

$$= \frac{0.01493\times10.96}{0.2273}$$

$$h_{top} = 0.72\,\text{Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

Surface Area,

$$A_s = 5\times0.5$$

$$A_s = 2.5\,\text{ft}^2$$

$$Q_{top} = h_{top}A_s(T_s - T_\infty)$$

$$Q_{top} = 0.72\times2.5(T_s - 80)$$

$$Q_{top} = 1.8(T_s - 80) \qquad \ldots\ldots (2)$$

Step 5 of 11

Considering Horizontal bottom surface:

The Nusselt number in case of Horizontal bottom hot surface

Step 5 of 11

Considering Horizontal bottom surface:
The Nusselt number in case of Horizontal bottom hot surface,

$$\mathrm{Nu} = 0.27(\mathrm{Ra})^{0.25}$$

$$= 0.27\left(1.698\times10^{5}\right)^{0.25}$$

$$\mathrm{Nu} = 5.48$$

Step 6 of 11

Heat transfer coefficient on bottom surface:-

$$h_{\text{bottom}} = \frac{k}{L_c}\times\mathrm{Nu}$$

$$= \frac{0.01493\times5.48}{0.2273}$$

$$h_{\text{bottom}} = 0.36\,\mathrm{Btu/h\cdot ft^2\cdot{}^oF}$$

Heat transfer through bottom surface by natural convection,

$$Q_{\text{bottom}} = h_{\text{bottom}} A_s (T_s - T_\infty)$$

$$= 0.36\times2.5(T_s - 80)$$

$$Q_{\text{bottom}} = 0.9(T_s - 80) \qquad \text{..... (3)}$$

Step 7 of 11

Considering vertical side surface (Right, left):
The characteristic length $L_c = H = 0.5\,\mathrm{ft}$
Rayleigh number,

$$\mathrm{Ra} = \frac{g\beta(T_s - T_\infty)L_C^3}{\nu^2}\cdot\mathrm{Pr}$$

$$= \frac{32.2\times1.835\times10^{-3}(90-80)(0.5)^3}{\left(1.725\times10^{-4}\right)^2}(0.72825)$$

$$\mathrm{Ra} = 1.808\times10^{6}$$

Nusselt number in case of vertical surfaces,

$$\mathrm{Nu} = \left[0.825 + \frac{0.387\mathrm{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\mathrm{Pr}}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.825 + \frac{0.387\times\left(1.808\times10^{6}\right)^{1/6}}{\left[1+\left(\frac{0.492}{0.72825}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$\mathrm{Nu} = 19.47$$

Step 8 of 11

Therefore heat transfer coefficient on vertical sides,

$$h_{\text{vertical}} = \frac{k}{L_c}\times\mathrm{Nu}$$

$$= \frac{0.01493}{0.2273}(19.47)$$

$$h_{\text{vertical}} = 1.2788\,\mathrm{Btu/h\cdot ft^2\cdot{}^oF}$$

Surface Area of the vertical surface,

$$A_s = 2\times5\times0.5$$

$$= 5\,\mathrm{ft^2}$$

Heat transfer by vertical sides by natural convection, Q_{vertical}.

$$Q_{\text{vertical}} = h_{\text{vertical}}\cdot A_s(T_s - T_\infty)$$

$$= 1.2788\times5(T_s - 80)$$

$$Q_{\text{vertical}} = 6.394(T_s - 80) \qquad \text{..... (4)}$$

The amount of energy dissipated,

$$\dot{Q}_{\text{total}} = 150\,\mathrm{W}$$

$$= 150\times3.412\,\mathrm{Btu/h}$$

$$\dot{Q}_{\text{total}} = 511.8\,\mathrm{Btu/h}$$

Step 9 of 11

(a)Calculating heat transfer by forced air flow,

$$Q_{\text{forced}} = \dot{m}c_p(T_{\text{out}} - T_{\text{in}})$$

Properties of air taken at average temperature

$$T_{avg} = \frac{T_{\text{in}} + T_{\text{out}}}{2}$$

$$= \frac{85+100}{2}$$

$$T_{avg} = 92.5^\circ\mathrm{F}$$

At this average temperature properties of air,

$$\rho = 0.07217 + (0.07088 - 0.07217)\left(\frac{92.5-90}{100-90}\right)$$

$$\rho = 0.07184\,\mathrm{lbm/ft^3}$$

$$c_p = 0.2404\,\mathrm{Btu/lbm^\circ F}$$

Mass flow rate of air,

$$\dot{m} = \rho V$$

$$= 0.07184\times22$$

$$\dot{m} = 1.58048\,\mathrm{lbm/min}$$

Step 10 of 11

Therefore forced convection heat transfer is

$$Q_{\text{forced}} = \dot{m}c_p(T_{\text{out}} - T_{\text{in}})$$

$$= 1.58048\times0.2404(100-85)$$

$$Q_{\text{forced}} = 5.6992\,\mathrm{Btu/min}$$

Therefore forced convection heat transfer is

$$Q_{forced} = \dot{m} c_p (T_{out} - T_{in})$$

$$= 1.58048 \times 0.2404 (100 - 85)$$

$$Q_{forced} = 5.6992 \text{ Btu/min}$$

$$Q_{forced} = 341.952 \text{ Btu/h}$$

Total heat transfer,

$$Q_{total} = Q_{forced} + Q_{conv}$$

$$Q_{conv} = Q_{total} - Q_{forced}$$

$$= 511.8 - 341.952$$

$$Q_{conv} = 169.848 \text{ Btu/h}$$

Therefore heat transfer due to convection, $\boxed{Q_{conv} = 169.848 \text{ Btu/h}}$

Step 11 of 11

(b)

The average temperature of the duct

$$Q_{conv} = Q_{top} + Q_{bottom} + Q_{vertical}$$

$$169.848 = 1.8(T_s - 80) + 0.9(T_s - 80) + 6.394(T_s - 80)$$

$$169.848 = (T_s - 80)[9.094]$$

$$T_s = 98.676^\circ\text{F}$$

The value obtained is closer to the assumed value.

Therefore the surface temperature of the duct, $\boxed{T_s = 98.676^\circ\text{F}}$

Question: 20.083P

Repeat Prob. 20–82E for a circular horizontal duct of diameter 4 in.

Step 1 of 9

Given data:

Dissipation of heat from the system, $Q = 150\,\text{W}$

Diameter of duct,

$D = 4\,\text{in.}$

$= 0.333\,\text{ft}$

Length of the duct, $L = 5\,\text{ft}$

Temperature of air entering into the duct, $T_{in} = 85°\text{F}$

Exit temperature of air from the duct, $T_{exit} = 100°\text{F}$

Flow rate of air, $V = 22\,\text{cfm}$

Ambient air temperature, $T_\infty = 80°\text{F}$

Step 2 of 9

Assume surface temperature of the duct is $T_s = 120°\text{F}$

Then film temperature of air,

$T_f = (T_s + T_\infty)/2$

$= 120 + 80/2$

$T_f = 100°\text{F}$

From properties of air table at 1atm and $T_f = 100°\text{F}$

Thermal conductivity

$k = 0.01529\,\text{Btu/h-ft-°F}$

Prandtl number,

$\text{Pr} = 0.7260$

Kinematic viscosity,

$\nu = 1.809\times10^{-4}\,\text{ft}^2/\text{s}$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{100+460}$$

$\beta = 1.786\times10^{-3}\,\text{R}^{-1}$

Step 3 of 9

Heat transfer by natural convection,

$Q_{conv} = hA_s(T_s - T_\infty)$ ..... (1)

As given, total heat dissipation from the system,

$\dot{Q}_{total} = 150\,\text{W}$

$= 150\times3.412$

$\dot{Q}_{total} = 511.8\,\text{Btu/h}$

Heat transfer by forced air flow,

$Q_{forced} = \dot{m}c_p(T_{out} - T_{in})$

Step 4 of 9

Mass flow rate of air,

$\dot{m} = \rho v$

Taking Density, ρ at average temperature of air,

$T_{avg} = (T_{in} + T_{out})/2$

$= 85 + 100/2$

$T_{avg} = 92.5°\text{F}$

From properties of air table,

$$\rho_{92.5°\text{C}} = 0.07217 + (0.07088 - 0.07217)\left(\frac{92.5-90}{100-90}\right)$$

$\rho_{92.5°\text{C}} = 0.07184\,\text{lbm/ft}^3$

Step 5 of 9

The mass flow rate of air,

$\dot{m} = \rho V$

$= 0.07184\times22$

$\dot{m} = 1.58048\,\text{lbm/min}$

$\dot{m} = 94.828\,\text{lbm/h}$

Specific heat at constant pressure, $c_p = 0.2404\,\text{Btu/lbm°F}$

Step 6 of 9

Heat transfer by forced air flow,

$Q_{forced} = \dot{m}c_p(T_{out} - T_{in})$

$= 94.828\times0.2404\times(100-85)$

$= 341.949\,\text{Btu./h}$

Total heat transfer,

$Q_{total} = Q_{conv} + Q_{forced}$

$Q_{conv} = Q_{total} - Q_{forced}$

$= 511.8 - 341.949$

$= 169.851\,\text{Btu/h}$

Therefore convection heat transfer, $\boxed{Q_{conv} = 169.85\,\text{Btu/h}}$

Step 7 of 9

(b)

Calculating Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)L_C^3}{\nu^2}\times\text{Pr}$$

$$= \frac{32.2\times1.786\times10^{-3}(120-80)(0.33)^3}{(1.809\times10^{-4})^2}(0.7260)$$

$= 1.833\times10^6$

Nusselt number for circular duct

$$\text{Nu} = \left[0.6 + \frac{0.387\,\text{Ra}^{1/6}}{\left[1+\left(\frac{0.559}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.6 + \frac{0.387(1.833\times10^6)^{1/6}}{\left[1+\left(\frac{0.559}{0.7260}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.6 + \frac{4.2808}{1.202}\right]^2$$

$= 17.31$

Step 8 of 9

Heat transfer coefficient,

$$h = \frac{k}{L_C}\times\text{Nu}$$

$$= \frac{0.01529\times17.31}{0.33}$$

$h = 0.802\,\text{Btu/h-ft}^2\text{-°F}$

Surface Area,

$A_s = \pi DL$

$= \pi\times0.33\times5$

$A_s = 5.184\,\text{ft}^2$

Step 9 of 9

Then from the equation (1), we have

Convective heat transfer,

$Q_{conv} = hA_s(T_s - T_\infty)$

$169.85 = 0.802\times5.184(T_s - 80)$

$T_s = 120.8532°\text{F}$

The surface temperature is approximately equal to the assumed value.

Therefore the actual surface temperature of the duct, $\boxed{T_s = 120.8532°\text{F}}$

Question:

Repeat Prob. 20–82E assuming the fan fails and thus the entire heat generated inside the duel must be rejected to the ambient air by natural convection through the outer surfaces of the duel.

Step 1 of 10

Consider that the surface temperature of the duct (T_s) is $135°F$.

Calculate the mean film temperature (T_f) by using the following relation:

$$T_f = \frac{T_s + T_\infty}{2}$$

Here, T_∞ is the temperature of the surrounding air and T_s is the surface temperature of the duct.

Substitute $135°F$ for T_s, and $80°F$ for T_∞.

$$T_f = \frac{135+80}{2}$$
$$= 107.5°F$$

Calculate the volume expansion coefficient (β).

$$\beta = \frac{1}{t_f}$$

Substitute $(107.5+460)\ R$ for t_f.

$$\beta = \frac{1}{107.5+460}$$
$$= 0.001680\ R^{-1}$$

Step 2 of 10

Use interpolation technique and obtain the following properties of air at $1\ atm$ and $107.5°F$ from table A-15E (Properties of air at $1\ atm$) in the text book.

Interpolate the Thermal conductivity.

$$k = 0.01529 + \frac{0.01552-0.01529}{110-100}(107.5-100)$$
$$= 0.01546\ Btu/h \cdot ft \cdot R$$

Interpolate the Kinematic viscosity.

$$\nu = 1.809\times10^{-4} + \frac{1.866\times10^{-4}-1.809\times10^{-4}}{110-100}(107.5-100)$$
$$= 1.8517\times10^{-4}\ ft^2/s$$

Interpolate the Prandtl number.

$$Pr = 0.7260 - \frac{0.7260-0.7245}{110-100}(107.5-100)$$
$$= 0.7848$$

Step 3 of 10

a)

As the heat transferred through radiation is negligible, and because of the failure of the fan, the total heat generated must be dissipated by natural convection only.

Therefore, the amount of heat dissipated by natural convection $(Q_{natural})$ is $\boxed{150\ W}$.

Step 4 of 10

b)

Calculate the horizontal top surface area of the duct from the geometry of the duct.

$$A_{top} = 5\times\frac{6}{12}$$
$$= 2.5\ ft^2$$

Calculate the perimeter of the top surface of the duct from the geometry of the duct.

$$P_{top} = 2\times\left(5+\frac{6}{12}\right)$$
$$= 11\ ft$$

Calculate the characteristic length for horizontal surface of the duct.

$$L_c = \frac{A_{top}}{P_{top}}$$

Here, A is the area of horizontal surface and P is the perimeter of horizontal surface.

Substitute $2.5\ ft^2$ for A_{top}, and $11\ ft$ for P_{top}.

$$L_c = \frac{2.5}{11}$$
$$= 0.2273\ ft$$

Step 5 of 10

Calculate the Rayleigh number for horizontal surface of the duct.

$$Ra = \frac{g\beta(T_s-T_\infty)L_c^3}{\nu^2}Pr$$

Here, g is the acceleration due to gravity, volume expansion coefficient is, and characteristic length of the duct is L_c.

Substitute $32.2\ ft/s^2$ for g, $0.001680\ R^{-1}$ for β, $135°F$ for T_s, $80°F$ for T_∞, $0.2273\ ft$ for L_c, $1.8517\times10^{-4}\ ft^2/s$ for ν, and 0.7848 for Pr.

$$Ra = \frac{32.2\times0.001680(135-80)\times0.2273^3}{\left(1.8517\times10^{-4}\right)^2}\times0.7848$$

1.8517×10^{-4} ft^2/s for ν, and 0.7848 for Pr.

$$\text{Ra} = \frac{32.2\times0.001680(135-80)\times0.2273^3}{\left(1.8517\times10^{-4}\right)^2}\times0.7848$$
$$= 7.99\times10^5$$

Calculate the Nusselt number for horizontal top surface by using the following relation:

$$\text{Nu}_{top} = 0.54\text{Ra}^{1/4}$$

Substitute 7.99×10^5 for Ra.

$$\text{Nu}_{top} = 0.54\times\left(7.99\times10^5\right)^{1/4}$$
$$= 16.144$$

Step 6 of 10

Calculate the heat transfer coefficient for top surface of the duct by using the following relation:

$$h_{top} = \frac{k}{L_c}\text{Nu}_{top}$$

Substitute 0.01546 $\text{Btu/h}\cdot\text{ft}\cdot\text{R}$ for k, 16.144 for Nu_{top}, and 0.2273 ft for L_c.

$$h_{top} = \frac{0.01546}{0.2273}\times16.144$$
$$= 1.098 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

Calculate the Nusselt number for horizontal bottom surface by using the following relation:

$$\text{Nu}_{bot} = 0.27Ra^{1/4}$$

Substitute 7.99×10^5 for Ra.

$$\text{Nu}_{bot} = 0.27\times\left(7.99\times10^5\right)^{1/4}$$
$$= 8.072$$

Step 7 of 10

Calculate the heat transfer coefficient for bottom surface of the duct by using the following relation:

$$h_{bot} = \frac{k}{L_c}\text{Nu}_{bot}$$

Substitute 0.01546 $\text{Btu/h}\cdot\text{ft}\cdot\text{R}$ for k, 8.072 for Nu_{bot}, and 0.2273 ft for L_c.

$$h_{bot} = \frac{0.01546}{0.2273}\times8.072$$
$$= 0.549 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

The horizontal bottom surface area of the duct is equal to the top surface.

$$A_{bot} = A_{top}$$

Substitute 2.5 ft^2 for A_{top}.

$$A_{bot} = 2.5 \text{ ft}^2$$

Step 8 of 10

Calculate the characteristic length for vertical surface of the duct.

$$L_c = L$$

Here, length of the vertical surface is L.

Substitute $\frac{6}{12}$ ft for L.

$$L_c = \frac{6}{12}$$
$$= 0.5 \text{ ft}$$

Calculate the Rayleigh number for vertical side surfaces of the duct.

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\text{Pr}$$

Here, acceleration due to gravity is g, volume expansion coefficient is β, and characteristic length for the vertical surface of the duct is L_c.

Substitute 32.2 ft/s^2 for g, 0.001680 R^{-1} for β, $135°\text{F}$ for T_s, $80°\text{F}$ for T_∞, 0.5 ft for L_c, 1.8517×10^{-4} ft^2/s for ν, and 0.7848 for Pr.

$$\text{Ra} = \frac{32.2\times0.001680(135-80)\times0.5^3}{\left(1.8517\times10^{-4}\right)^2}\times0.7848$$
$$= 8.512\times10^6$$

Step 9 of 10

Calculate the Nusselt number for vertical side surfaces by using the following relation:

$$\text{Nu}_{side} = \left\{0.825 + \frac{0.387Ra^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right\}^2$$

Substitute 8.512×10^6 for Ra, and 0.7848 for Pr.

$$\text{Nu}_{side} = \left\{0.825 + \frac{0.387\times\left(8.512\times10^6\right)^{1/6}}{\left[1+\left(\frac{0.492}{0.7848}\right)^{9/16}\right]^{8/27}}\right\}^2$$
$$= 30.1948$$

$$\mathrm{Nu}_{side}=\left\{0.825+\frac{\left(\quad\right)^{2}}{\left[1+\left(\frac{0.492}{0.7848}\right)^{9/16}\right]^{8/27}}\right\}^{2}$$

20384P pg 3

$$=30.1948$$

Calculate the heat transfer coefficient for side surfaces of the duct by using the following relation:

$$h_{side}=\frac{k}{L_c}\mathrm{Nu}_{side}$$

Substitute $0.01546\ \mathrm{Btu/h\cdot ft\cdot R}$ for k, 30.1948 for Nu_{side}, and $0.5\ \mathrm{ft}$ for L_c.

$$h_{side}=\frac{0.01546}{0.5}\times 30.1948$$
$$=0.9336\ \mathrm{Btu/h\cdot ft^2\cdot ^\circ F}$$

Calculate the vertical side surface area of the duct.

$$A_{side}=2\times 5\times 0.5$$
$$=5\ \mathrm{ft^2}$$

Step 10 of 10

Calculate the average temperature of the duct by using the following relation:

$$Q_{total}=Q_{top}+Q_{bottom}+Q_{side}$$
$$=\left(h_{top}A_{top}+h_{bot}A_{bot}+h_{side}A_{side}\right)\left(T_s-T_\infty\right)$$

Substitute $150\ \mathrm{W}$ for Q_{total}, $1.098\ \mathrm{Btu/h\cdot ft^2\cdot ^\circ F}$ for h_{top}, $2.5\ \mathrm{ft^2}$ for A_{top}, $0.549\ \mathrm{Btu/h\cdot ft^2\cdot ^\circ F}$ for h_{bot}, $2.5\ \mathrm{ft^2}$ for A_{bot}, $0.9336\ \mathrm{Btu/h\cdot ft^2\cdot ^\circ F}$ for h_{side}, $5\ \mathrm{ft^2}$ for A_{side}, and $80^\circ\mathrm{F}$ for T_∞.

$$150\times 3.41214=\left(1.098\times 2.5+0.549\times 2.5+0.9336\times 5\right)\left(T_s-80\right)$$
$$150\times 3.41214=\left(1.098\times 2.5+0.549\times 2.5+0.9336\times 5\right)\left(x-80\right)$$
$$T_s=138.257^\circ\mathrm{F}$$

The calculated average temperature of the duct is very close to the assumed temperature and hence there is no need to repeat the calculation.

Therefore, the average temperature of the duct is $\boxed{138.257^\circ\mathrm{F}}$.

Question:

Consider a cold aluminum canned drink that is initially at a uniform temperature of 5°C. The can is 12.5 cm high and has a diameter of 6 cm. The emissivity of the outer surface of the can is 0.6. Disregarding any heat transfer from the bottom surface of the can, determine how long will take for the average temperature of the drink to rise to 7°C if the surrounding air and surfaces are at 25°C.

Step 1 of 9

Diameter of can, $D = 6\,\text{cm} = 0.06\,\text{m}$

Ambient air temperature, $T_\infty = 25^\circ\text{C}$

Ambient surface temperature, $T_{amb} = 25^\circ\text{C}$

Emissivity of the outer surface of the can, $\varepsilon = 0.6$

Cold drink temperature, $T_1 = 5^\circ\text{C}$

Temperature rise of the drink, $T_2 = 7^\circ\text{C}$

Height of can,

$$H = 12.5\,\text{cm}$$
$$= 0.125\,\text{m}$$

Step 2 of 9

The average surface temperature of can surface,

$$T_s = \frac{5+7}{2}$$
$$T_s = 6^\circ\text{C}$$

The film temperature,

$$T_f = (T_s + T_\infty)/2$$
$$= (6+25)/2$$
$$T_f = 15.5^\circ\text{C}$$

The heat transfer rate,

$$Q = hA_s(T_\infty - T_s) + \varepsilon A_s \sigma\left(T_{amb}^4 - T_s^4\right) \quad \ldots\ldots (1)$$

From properties of air table the properties of air at 1atm and at film temperature,

Thermal conductivity,

$$k = 0.02476 + \frac{0.02514 - 0.02476}{(20-15)}(15.5-15)$$
$$k = 0.024798\,\text{W/m}^\circ\text{C}$$

Step 3 of 9

Prandtl number,

$$\text{Pr} = 0.7323 + \frac{0.7309 - 0.7323}{(20-15)}(15.5-15)$$
$$\text{Pr} = 0.73216$$

Kinematic viscosity,

$$\nu = 1.470\times10^{-5} + \frac{(1.516-1.470)\times10^{-5}}{(20-15)}(15.5-15)$$
$$\nu = 1.4746\times10^{-5}\,\text{m}^2/\text{s}$$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{15.5+273}$$
$$\beta = 3.46\times10^{-3}\,\text{K}^{-1}$$

Step 4 of 9

Characteristic length L_c = Height of can, $H = 0.125\,\text{m}$

Calculating Rayleigh number

$$\text{Ra} = \frac{g\beta(T_\infty - T_s)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.46\times10^{-3}(25-6)(0.125)^3}{\left(1.4746\times10^{-5}\right)^2}\times0.73216$$
$$\text{Ra} = 4.25\times10^6$$

Grashoff number,

$$\text{Gr} = \frac{\text{Ra}}{\text{Pr}}$$
$$= \frac{4.25\times10^6}{0.73216}$$
$$\text{Gr} = 5.8047\times10^6$$

Step 5 of 9

Checking whether the cylindrical can be treated as vertical plate,

If

$$D \geq \frac{35L}{\text{Gr}^{0.25}}$$

$$\frac{35L}{\text{Gr}^{0.25}} = \frac{35\times(0.125)}{\left(5.8047\times10^6\right)^{0.25}}$$

$$\frac{35L}{\text{Gr}^{0.25}} = 0.08913$$

As $D = 0.125$

Therefore,

$D \geq \frac{35L}{\text{Gr}^{0.25}}$ We can treat it as vertical plate.

Step 6 of 9

Therefore Nusselt number in case of vertical plates,

$$\text{Nu} = \left[0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right]^2$$

$$Nu=\left[0.825+\frac{0.387Ra^{1/6}}{\left[1+\left(\frac{0.492}{Pr}\right)^{9/16}\right]^{8/27}}\right]^{2}$$ 085P pg 2

$$=\left[0.825+\frac{0.387\left(4.25\times10^{6}\right)^{1/6}}{\left[1+\left(\frac{0.492}{0.73216}\right)^{9/16}\right]^{8/27}}\right]^{2}$$

$Nu=24.64$

Heat transfer coefficient,

$$h=\frac{k}{L_c}Nu$$

$$=\frac{0.024798\times24.64}{0.125}$$

$$h=4.89\,W/m^2{}^\circ C$$

Step 7 of 9

Area, A_s = Area of cylindrical surface + Area of top of the can

$$A_s=\pi DH+\frac{\pi D^2}{4}$$

$$=\pi\left(0.06\times0.125+\frac{(0.06)^2}{4}\right)$$

$$A_s=0.02639\,m^2$$

On substituting the known values in equation (1), we get

$$Q=hA_s\left(T_\infty-T_s\right)+\varepsilon A_s\sigma\left(T_{amb}^4-T_s^4\right)$$

$$=\left[4.89\times0.02639(25-6)\right]+\left[0.6\times(0.02639)\times\left(5.67\times10^{-8}\right)\times\left[(25+273)^4-(6+273)^4\right]\right]$$

$$=2.45189+1.64019$$

$$\dot{Q}=4.092\,W$$

Step 8 of 9

Heat required raising temperature from 5°C to 7°C

$$Q_{req}=mc_p\left(T_2-T_1\right)$$

Let us take average temperature of water $T_{av}=6°C$

At $T_{av}=6°C$ from saturated properties of water

$$c_p=4203\,J/kg\cdot K$$

$$\rho=999.9\,kg/m^3$$

Mass of water,

$$m=\rho V$$

$$=999.9\times\frac{\pi D^2}{4}\times L$$

$$=\frac{999.9\times\pi\times(0.06)^2\times0.125}{4}$$

$$m=0.3534\,kg$$

Step 9 of 9

Heat required raising temperature from 5°C to 7°C,

$$Q_{req}=mc_p\left(T_2-T_1\right)$$

$$=0.3534\times4203\times(7-5)$$

$$Q_{req}=2970.7\,W$$

Time taken to increase the temperature of water from 5°C to 7°C,

$$t=\frac{Q_{req}}{Q}$$

$$=\frac{2970.7}{4.092}$$

$$t=725.97\,s$$

$$t=725.97\times\frac{1}{60}$$

$$t=12.099\,min$$

Therefore time taken to increase the temperature of water from 5°C to 7°C,

$$\boxed{t=12.099\,min}$$

Question: 20.086P

A group of 25 power transistors, dissipating 1.5 W each, are to be cooled by attaching them to a black-anodized square aluminum plate and mounting the plate on the wall of a room at 30°C. The emissivity of the transistor and the plate surfaces is 0.9. Assuming the heat transfer from the back side of the plate to be negligible and the temperature of the surrounding surfaces to be the same as the air temperature of the room, determine the size of the plate if the average surface temperature of the plate is not to exceed 50°C.

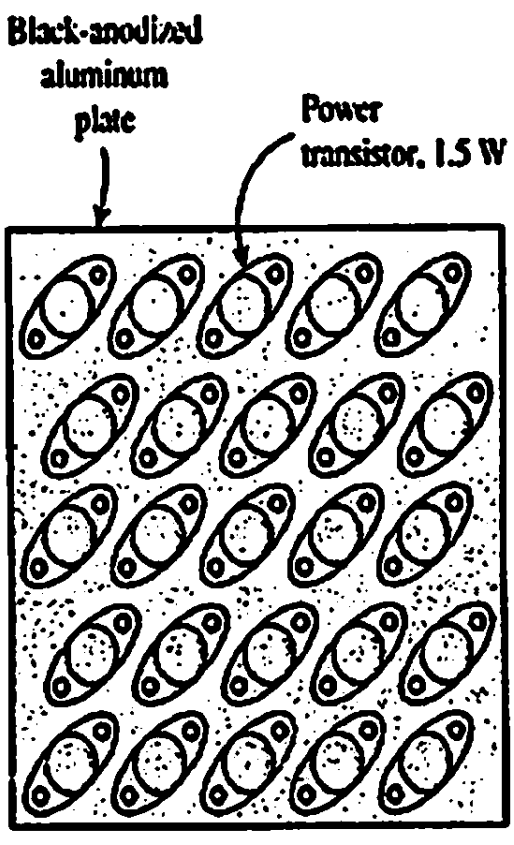

FIGURE P20–86

Step 1 of 8

Number of power transistors, $N = 25$
Dissipation of heat by a transistor, $Q = 1.5\,\text{W}$
Room temperature, $T_\infty = 30^\circ\text{C}$
Emissivity of transistor surface $\varepsilon = 0.9$
Temperature of surrounding $T_{amb} = 30^\circ\text{C}$
Average surface temperature of the plate, $T_s = 50^\circ\text{C}$

Step 2 of 8

The total heat transfer rate $\dot{Q}_t$ is given by.

$$\dot{Q}_t = hA_s(T_s - T_\infty) + \varepsilon A_s \sigma\left(T_s^4 - T_\infty^4\right) \quad \ldots\ldots (1)$$

Taking the properties of air at 1atm and film temperature T_f,

$$T_f = (T_s + T_\infty)/2$$
$$= (30+50)/2$$
$$T_f = 40^\circ\text{C}$$

Step 3 of 8

Thermal conductivity,
$k = 0.02662\,\text{W/m}^\circ\text{K}$
Prandtl number, $\text{Pr} = 0.7255$
Kinematic viscosity, $\nu = 1.702\times10^{-5}\,\text{m}^2/\text{s}$
The coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{273+40}$$
$$\beta = 3.195\times10^{-3}\,\text{K}^{-1}$$

Step 4 of 8

Characteristic length, L_c = length of plate $= L$
Therefore Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.195\times10^{-3}(50-30)L^3}{\left(1.702\times10^{-5}\right)^2}\cdot(0.7255)$$
$$\text{Ra} = 1.57\times10^9\,L^3$$

Step 5 of 8

The Nusselt number for vertical plate is given by,

$$\text{Nu} = \left[0.825 + \frac{0.387(\text{Ra})^{1/6}}{\left[1+\left(\frac{0.492}{\text{Pr}}\right)^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{0.387\left(1.57\times10^9\,L^3\right)^{1/6}}{\left[1+\left(\frac{0.492}{0.7255}\right)^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.825 + \frac{13.19L^{1/2}}{1.19}\right]^2$$
$$\text{Nu} = \left(0.825 + 11.08L^{1/2}\right)^2$$

Heat transfer coefficient,

$$h = \frac{k}{L_c}\cdot\text{Nu}$$
$$h = \frac{0.02662}{L}\left(0.825+11.08\sqrt{L}\right)^2$$

Step 6 of 8

Surface Area of the square plate is
$A_s = L^2$
Now substituting values in equation (1)

$$\dot{Q}_t = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma\left(T_s^4 - T_\infty^4\right)$$
$$= \frac{0.02662}{L}\left(0.825+11.08\sqrt{L}\right)^2\times L^2\times(50-30)$$
$$+0.9\times L^2\times5.67\times10^{-8}\left[(273+50)^4 - (273+30)^4\right]$$
$$= 0.02662\left(0.825+11.08\sqrt{L}\right)^2 20L + 125.3L^2$$
$$\dot{Q}_t = 0.5324L\left(0.825+11.08\sqrt{L}\right)^2 + 125.3L^2 \quad \ldots\ldots (2)$$

Step 7 of 8

We know
$\dot{Q}_t = N\times Q$
Where
N =Number of transistor
Q =power dissipated by each transistor
Then,
$\dot{Q}_t = 25\times1.5\,\text{W}$

Step 8 of 8

Then substituting in equation (2),

$$\dot{Q}_t = 0.5324L\left(0.825+11.08\sqrt{L}\right)^2 + 125.3L^2$$
$$25\times1.5 = 0.5324L\left(0.825+11.07\sqrt{L}\right)^2 + 125.3L^2$$
$$37.5 = 0.5324L\left(0.825+11.07\sqrt{L}\right)^2 + 125.3L^2$$

By solving the above equation
$L = 0.4264\,\text{m}$
Therefore, size of the square aluminum plate is $\boxed{42.64\,\text{cm}\times42.64\,\text{cm}}$

Question: 20.087P

Repeat Prob. 20-86 assuming the plate to be positioned horizontally with (*a*) transistors facing up and (*b*) transistors facing down.

Step 1 of 7

Number of power transistors, $N = 25$
Dissipation of heat by a transistor, $Q = 1.5\,\text{W}$
Room temperature, $T_\infty = 30^\circ\text{C}$
Emissivity of transistor surface, $\varepsilon = 0.9$
Temperature of surrounding, $T_{\text{surr}} = 30^\circ\text{C}$
Average surface temperature of the plate, $T_s = 50^\circ\text{C}$

Step 2 of 7

The total heat transfer rate $\dot{Q}_t$ is given by.

$$\dot{Q}_t = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma\left(T_s^4 - T_\infty^4\right) \quad \ldots\ldots (1)$$

Taking the properties of air at 1atm and film temperature T_f, we have,

$$T_f = (T_s + T_\infty)/2$$
$$= (30+50)/2$$
$$T_f = 40^\circ\text{C}$$

Thermal conductivity, $k = 0.02662\,\text{W/m}^\circ\text{K}$
Prandtl number, $\text{Pr} = 0.7255$
Kinematic viscosity, $\nu = 1.702\times10^{-5}\,\text{m}^2/\text{s}$
The coefficient of volume expansion,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{273+40}$$
$$= 3.195\times10^{-3}\,\text{K}^{-1}$$

Step 3 of 7

Characteristic length, L_C for a Horizontal plate:

$$L_c = \frac{A_s}{p}$$
$$= \frac{L^2}{4L}$$
$$= \frac{L}{4}$$

Total heat dissipated by transistors,

$$\dot{Q}_t = N\times Q$$

where N is the number of transistor
Q is the power dissipated by each transistor
Hence,

$$\dot{Q}_t = 25\times1.5\,\text{W}$$

Step 4 of 7

(i) Plate to be positioned horizontally with transistors facing up.
Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.195\times10^{-3}(50-30)\left(\frac{L}{4}\right)^3}{\left(1.702\times10^{-5}\right)^2}\cdot(0.7255)$$
$$= 2.453\times10^7\,L^3$$

Assuming Rayleigh number ranges as $Ra = 10^4 \sim 10^7$, from empirical correlations of the Nusselt number,

$$\text{Nu} = 0.54\,\text{Ra}^{1/4}$$
$$= 0.54\left(2.453\times10^7\,L^3\right)^{1/4}$$
$$= 38L^{3/4}$$

Step 5 of 7

Heat transfer coefficient,

$$h = \frac{k}{L_c}\text{Nu}$$
$$= \frac{0.02662}{L/4}\times38L^{3/4}$$
$$= \frac{4.05}{L^{1/4}}$$

Surface Area of the square plate is

$$A_s = L^2$$

Substitute the known values in equation (1).

$$\dot{Q}_t = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma\left(T_s^4 - T_\infty^4\right)$$
$$= 4.05L^{-0.25}\times L^2(50-30) + 0.9\times5.67\times10^{-8}\times L^2\left[(273+50)^4 - (273+30)^4\right]$$
$$\dot{Q}_t = 81L^{1.75} + 125.311L^2$$
$$25\times15 = 81L^{1.75} + 125.311L^2$$
$$37.5 = 81L^{1.75} + 125.311L^2$$

By solving the above equation

$$L = 0.4066\,\text{m}$$

Therefore, the size of the square aluminum plate is $\boxed{40.66\times40.66\ \text{cm}^2}$.

Step 6 of 7

(ii) Plate to be positioned horizontally with transistors facing down.
Rewriting the above calculated values, we have,

$$\text{Ra} = 2.453\times10^7\,L^3$$

Then from empirical correlations of the Nusselt number,

$$\text{Nu} = 0.27\,\text{Ra}^{0.25}$$
$$= 0.27\left(2.453\times10^7\,L^3\right)^{1/4}$$
$$= 19.0L^{3/4}$$

Then heat transfer coefficient,

$$h = \frac{k}{L_c}\cdot\text{Nu}$$
$$= \frac{0.02662}{L/4}\left(19.0L^{3/4}\right)$$
$$h = 2.023L^{-1/4}$$

Step 7 of 7

Substitute the known values in equation (1).

$$\dot{Q}_t = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma\left(T_s^4 - T_\infty^4\right)$$
$$37.5 = 2.023L^{-1/4}\cdot L^2(50-30) + 0.9\times5.67\times10^{-8}\times L^2\left[(273+50)^4 - (273+30)^4\right]$$
$$37.5 = 40.46L^{1.75} + 125.3L^2$$

By solving the above equation,

$$L = 0.4638\,\text{m}$$

Therefore size of the square aluminum plate is $\boxed{46.38\times46.38\ \text{cm}^2}$.

Question: 20.088P

A 0.1-W small cylindrical resistor mounted on a lower part of a vertical circuit board is 0.3 in long and has a diameter of 0.2 in. The view of the resistor is largely blocked by another circuit board facing it, and the heat transfer through the connecting wires is negligible. The air is free to flow through the large parallel flow passages between the boards as a result of natural convection currents. If the air temperature at the vicinity of the resistor is 120°F, determine the approximate surface temperature of the resistor.

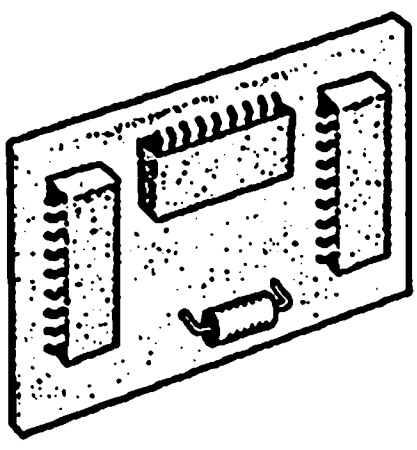

FIGURE P20–88E

Step 1 of 4

The cooling of the resistor is due to the natural convective heat transfer. In order to find the surface temperature of the resistor from the energy balance equation, we first need to find the Rayleigh's number and then the Nusselt number and heat transfer coefficient. But to find the Rayleigh number, we need the properties of air at mean film temperature. So assume the surface temperature to be 220°F. Now substitute 220°F for T_s and 120°F for T_∞

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{220+120}{2}$$
$$= 170°\text{F}$$

Step 2 of 4

The properties of air at mean film temperature are
Thermal conductivity, $k = 0.01692$ Btu/h·ft·°F
Prandtl number, $\text{Pr} = 0.7161$
Kinematic viscosity, $\nu = 0.222\times10^{-3}$ ft^2/s
Volume expansion coefficient,

$$\beta = \frac{1}{T_f + 273}$$
$$= \frac{1}{170+460}$$
$$= 0.001587\ \text{R}^{-1}$$

Step 3 of 4

Calculate the Rayleigh number. Substitute 32.2 ft/s^2 for g, 0.001587 R^{-1} for β, 220°F for T_s, 120°F for T_∞, 0.2/12 ft for D, 0.222×10^{-3} ft^2/s for ν and 0.7161 for Pr

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)D^3}{\nu^2}\times\text{Pr}$$
$$= \frac{32.2\times0.001587\times(220-120)(0.2/12)^3}{\left(0.222\times10^{-3}\right)^2}\times0.7161$$
$$= 343.8$$

Determine the Nusselt number. Substitute 343.8 for Ra and 0.7161 for Pr

$$\text{Nu} = \left[0.6 + \frac{0.387\,\text{Ra}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$
$$= \left[0.6 + \frac{0.387(343.8)^{1/6}}{\left[1+(0.559/0.7161)^{9/16}\right]^{8/27}}\right]^2$$
$$= 2.105$$

Step 4 of 4

Estimate the heat transfer coefficient. Substitute 2.105 for Nu, 0.01692 Btu/h·ft·°F for k, and 0.2/12 ft for D

$$h = \frac{\text{Nu}\times k}{D}$$
$$= \frac{2.105\times0.01692}{0.2/12}$$
$$= 2.138\ \text{Btu/h}\cdot\text{ft}^2\cdot°\text{F}$$

Determine the heat transfer rate. Substitute 2.138 Btu/h·ft^2·°F for h, 0.2/12 ft for D, 0.3/12 ft for L, (0.1×3.412) Btu/h for $\dot{Q}$ and 120°F for T_∞

$$\dot{Q} = h\left(\pi DL + 2\frac{\pi D^2}{4}\right)(T_s - T_\infty)$$

$$T_s = T_\infty + \frac{\dot{Q}}{h\left(\pi DL + 2\frac{\pi D^2}{4}\right)}$$
$$= 120 + \frac{0.1\times3.412}{2.138\left(\pi\times\frac{0.2}{12}\times\frac{0.3}{12} + 2\frac{\pi(0.2/12)^2}{4}\right)}$$
$$= 211°\text{F}$$

Thus the surface temperature of the resistor is $\boxed{211°\text{F}}$

Question: 20.089P pg 1

An ice chest whose outer dimensions are 30 cm X 40 cm × 40 cm is made of 2-cm-thick Styrofoam (k =0.033 W/m · K). Initially, the chest is filled with 35 kg of ice at 0°C, and the inner surface temperature of the ice chest can be taken to be 0°C at all times. The heat of fusion of water at 0°C is 337.7 kJ/kg, and the surrounding ambient air is at 20CC. Disregarding any heat transfer from the 40 cm × 40 cm base of the ice chest, determine how long it will take for the ice in the chest to melt completely if the ice chest is subjected to (*a*) calm air and (*b*) winds at 50 km/h. Assume the heat transfer coefficient on the front, back, and lop surfaces to be the same as that on the side surfaces.

Step 1 of 13

Given data:

Mass of ice, $m = 35\,\text{kg}$

Heat of fusion, $h_f = 337.7\,\text{kJ/kg}$

Surface temperature inside, $T_{in} = 0°\text{C}$

Surrounding Air temperature, $T_\infty = 20°\text{C}$

Length of the ice-chest,

$L = 40\,\text{cm}$

$= 0.4\,\text{m}$

Breadth of the ice-chest,

$B = 40\,\text{cm}$

$= 0.4\,\text{m}$

Width of the ice-chest,

$W = 30\,\text{cm}$

$= 0.3\,\text{m}$

Thermal conductivity of Styrofoam, $k_s = 0.033\,\text{W/m} \cdot \text{K}$

Step 2 of 13

(*a*)

Let us assume the surface temperature as $T_s = 12°\text{C}$

Film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$

$$= \frac{12+20}{2}$$

$$= 16°\text{C}$$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{16+273}$$

$$= 3.46\times10^{-3}\ \text{K}^{-1}$$

Step 3 of 13

Taking properties from the table of air, at 1atm and at film temperature $T_f = 16°\text{C}$

Thermal conductivity, $k = 0.02484\ \text{W/m°C}$

Prandtl number, $\text{Pr} = 0.73202$

Kinematic viscosity, $\nu = 1.4792\times10^{-5}\,\text{m}^2/\text{s}$

Characteristic length $L_C = H = 0.3\text{m}$

Rayleigh Number,

$$Ra = \frac{g\beta(T_s - T_\infty)L_C^3}{\nu^2}.\text{Pr}$$

$$= \frac{9.81\times3.46\times10^{-3}(20-12)(0.3)^3}{\left(1.4792\times10^{-5}\right)^2}(0.73202)$$

$$= 2.45\times10^7$$

Step 4 of 13

Nusselt number,

$$Nu = \left[0.825 + \frac{0.387\text{Ra}^{1/6}}{\left[1+(0.492/\text{Pr})^{9/16}\right]^{8/27}}\right]^2$$

$$= \left[0.825 + \frac{0.387\left(2.45\times10^7\right)^{1/6}}{\left[1+(0.492/0.73202)^{9/16}\right]^{8/27}}\right]^2$$

$$= 40.53$$

Heat transfer coefficient,

$$h = \frac{k}{L_C}\cdot\text{Nu}$$

$$= \frac{0.0.2484\times40.53}{0.3}$$

$$= 3.356\ \text{W/m}^2\text{°C}$$

Step 5 of 13

Surface Area of chest,

$$A_s = 4[0.3\times0.4]+[0.4\times0.4]$$

$$= 0.64\text{m}^2$$

Total resistance to heat transfer,

$$R_{total} = R_{cond} + R_{conv}$$

$$= \frac{t}{kA_s} + \frac{1}{hA_s}$$

$$= \frac{0.02}{(0.033\times0.64)} + \frac{1}{(3.356\times0.64)}$$

$$= 1.41255\ \text{K/W}$$

Step 6 of 13

The heat transfer rate is,

$$\dot{Q} = \frac{T_\infty - T_{in}}{R_{total}}$$

$$= \frac{20-0}{}$$

The heat transfer rate is,

$$\dot{Q} = \frac{T_\infty - T_{in}}{R_{total}}$$
$$= \frac{20-0}{1.41255}$$
$$= 14.158\,\text{W}$$

The relation for heat transfer due to convection is

$$\dot{Q} = hA_s(T_\infty - T_s)$$
$$14.158 = 3.356\times 0.64(20 - T_s)$$
$$T_s = 20 - \frac{14.158}{3.356\times 0.64}$$
$$= 13.40^\circ\text{C}$$

Step 7 of 13

As the obtained value of surface temperature is very close to assumed value, our assumptions are valid and heat transfer calculated can be used for obtaining rate of melting. So the Rate of ice melting is

$$\dot{m} = \frac{\dot{Q}}{h_f}$$
$$= \frac{14.158\times 10^{-3}}{337.7}$$
$$= 4.243\times 10^{-5}\ \text{kg/s}$$

Time taken for melting,

$$t = \frac{m}{\dot{m}}$$
$$= \frac{35}{4.243\times 10^{-5}}$$
$$= 824937\,\text{sec}$$
$$= 229.15\ \text{h}$$

Hence, the time taken for melting the ice is $\boxed{t = 229.15\ \text{h}}$

Step 8 of 13

(b)

When chest is subjected to winds at 50 km/hr, the forced convection prevails.

Let us assume the surface temperature as $T_s = 19^\circ\text{C}$

Now film temperature becomes,

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{20+19}{2}$$
$$= 19.5^\circ\text{C}$$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{(2730+19.5)}$$
$$= 3.419\times 10^{-3}\,\text{K}^{-1}$$

Step 9 of 13

Taking properties from the table of air, at 1atm and at film temperature $T_f = 19.5^\circ\text{C}$

Thermal conductivity, $k = 0.025102\,\text{W/m}^\circ\text{C}$

Prandtl number, $\text{Pr} = 0.73104$

Kinematic viscosity, $\nu = 1.5114\times 10^{-5}\,\text{m}^2/\text{s}$

Characteristic length, $L_C = W = 0.4\,\text{m}$

Reynolds number

$$R_e = V\frac{L}{\nu}$$
$$= \left(50\times\frac{1000}{3600}\right)\frac{0.4}{1.5114\times 10^{-5}}$$
$$= 367576.8$$

The calculated value of Reynolds number is less than the critical Reynolds number so the flow is laminar.

Step 10 of 13

Nusselt number,

$$Nu = 0.664\times \text{R}_e^{0.5}\times p_r^{1/3}$$
$$= 0.664\times(367576.8)^{0.5}(0.73104)^{1/3}$$
$$= 362.65$$

Heat transfer coefficient,

$$h = \frac{k}{L_C}\times Nu$$
$$= \frac{0.025102}{0.4}\times 362.65$$
$$= 22.758\ \text{W/m}^2{}^\circ\text{C}$$

Step 11 of 13

Rate of heat transfer,

$$\dot{Q} = \frac{T_\infty - T_{in}}{R_{chestwall} + R_{conv}}$$
$$= \frac{T_\infty - T_{in}}{\left(\frac{t}{kA_s}\right)+\left(\frac{1}{hA_s}\right)}$$
$$= \frac{(20-0)}{\left(\frac{0.02}{0.033\times 0.64}\right)+\left(\frac{1}{22.76\times 0.64}\right)}$$
$$= 19.69\ \text{W}$$

Step 12 of 13

$= 19.69\ \text{W}$

Step 12 of 13

The relation for heat transfer due to convection is

$$\dot{Q} = hA_s(T_\infty - T_s)$$

$$19.69 = 22.758 \times 0.64(20 - T_s)$$

$$T_s = 20 - \frac{19.69}{22.758 \times 0.64}$$

$$= 18.65^\circ\text{C}$$

As the obtained value of surface temperature is very close to assumed value, our assumptions are valid and heat transfer calculated can be used for obtaining rate of melting. So the Rate of ice melting is

$$\dot{m} = \frac{\dot{Q}}{h_f}$$

$$= \frac{19.69 \times 10^{-3}}{337.7}$$

$$= 5.8306 \times 10^{-5}\ \text{kg/s}$$

Step 13 of 13

Time taken for melting the ice,

$$t = \frac{m}{\dot{m}}$$

$$= \frac{35}{5.8306 \times 10^{-5}}$$

$$= 600279.3\ \text{sec}$$

$$= 166.74\ \text{h}$$

Hence, the time taken for melting the ice is $\boxed{t = 166.74\ \text{h}}$

Question: 20.090P pg 1

Solar radiation is incident on the glass cover of a solar collector at a rate of 650 W/m2. The glass transmits 88 percent of the incident radiation and has an emissivity of 0.90. The hot water needs of a family in summer can be met completely by a collector 1.5 m high and 2 m wide, and tilted 40° from the horizontal. The temperature of the glass cover is measured to be 40°C on a calm day when the surrounding air temperature is 20°C. The effective sky temperature for radiation exchange between the glass cover and the open sky is −40°C. Water enters the tubes attached to the absorber plate at a rate of 1 kg/min. Assuming the back surface of the absorber plate to be heavily insulated and the only heat loss occurs through the glass cover, determine (*a*) the total rate of heat loss from the collector; (*b*) the collector efficiency, which is the ratio of the amount of heat transferred to the water to the solar energy incident on the collector; and (*c*) the temperature rise of water as it flows through the collector.

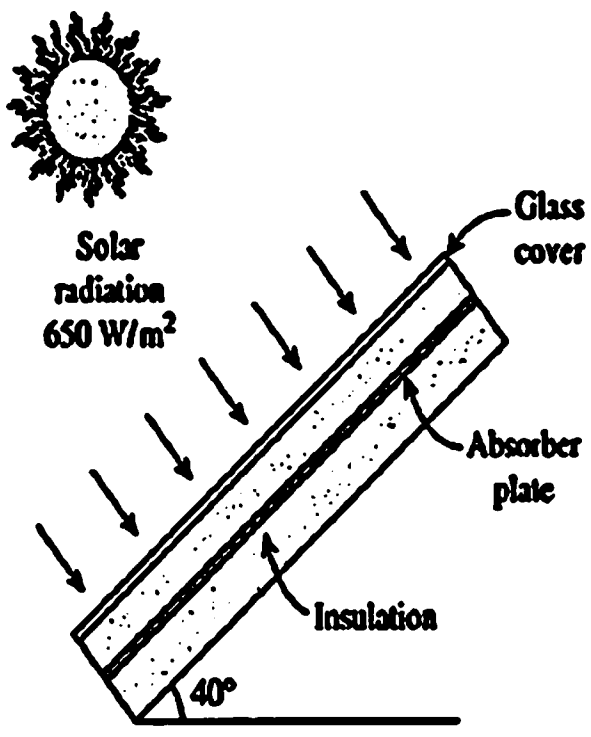

FIGURE P20–90

Step 1 of 8

Solar radiation incident rate, $\dot{q} = 650\ \text{W/m}^2$

Emissivity of the glass, $\varepsilon = 0.9$

Transmissivity of the glass, $\tau = 0.88$

Height of the collector, $H = 1.5\text{m}$

Width of the collector, $W = 2\text{m}$

Angle of tilt, $\theta = 40°$

Temperature of glass cover, $T_s = 40°\text{C}$

Surrounding air temperature, $T_\infty = 20°\text{C}$

Open sky temperature $T_{sky} = -40°\text{C}$

Water flow rate, $\dot{m} = 1\ \text{kg/min}$

Step 2 of 8

Film temperature,

$$T_f = \frac{T_s + T_\infty}{2}$$
$$= \frac{40+20}{2}$$
$$= 30°\text{C}$$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$
$$= \frac{1}{273+30}$$
$$= 3.3\times10^{-3}\ \text{K}^{-1}$$

Step 3 of 8

Take air properties at 1atm pressure and film temperature T_f

Thermal conductivity, $k = 0.02588\ \text{W/m°C}$

Prandtl number, $\text{Pr} = 0.7282$

Kinematic viscosity, $\nu = 1.608\times10^{-5}\ \text{m}^2/\text{s}$

Characteristic length,

$$L_C = \frac{A_s}{p}$$
$$= \frac{(1.5\times2)}{2(1.5+2)}$$
$$= 0.429\text{m}$$

Surface Area,

$$A_s = 1.5\times2$$
$$= 3\text{m}^2$$

Step 4 of 8

Rayleigh number,

$$\text{Ra} = \frac{g\beta\cos\theta(T_s - T_\infty)L_C^3}{\nu^2}\cdot\text{Pr}$$
$$= \frac{9.81\times3.3\times10^{-3}\times\cos40°(40-20)(0.429)^3}{\left(1.608\times10^{-5}\right)^2}$$
$$= 1.103\times10^8$$

Nusselt number,

$$Nu = 0.15\text{Ra}^{1/3}$$
$$= 0.15\left(1.103\times10^8\right)^{1/3}$$
$$= 71.93$$

Step 5 of 8

Heat transfer coefficient,

$$h = \frac{k}{L_C}\cdot Nu$$
$$= \frac{0.02588}{0.429}\times71.93$$
$$= 4.34\ \text{W/m}^2\text{°C}$$

$$h = \frac{k}{L_C} \cdot Nu$$
$$= \frac{0.02588}{0.429} \times 71.93$$
$$= 4.34\ \text{W/m}^2\,^\circ\text{C}$$

Heat transfer rate by convection,

$$\dot{Q}_{conv} = hA_s(T_s - T_\infty)$$
$$= 4.34 \times 3 \times (40 - 20)$$
$$= 260.4\ \text{W}$$

Step 6 of 8

Heat transfer rate by radiation,

$$\dot{Q}_{rad} = \sigma \varepsilon A_s \left(T_s^4 - T_{amb}^4\right)$$
$$= 0.9 \times 5.67 \times 10^{-8} \times 3\left((273+40)^4 - (273-40)^4\right)$$
$$= 1018.14\ \text{W}$$

Total heat transfer rate,

$$\dot{Q}_{tot} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$= 260.4 + 1018.14$$
$$= 1278.5\ \text{W}$$

Hence the total heat transfer rate is $\boxed{\dot{Q} = 1278.5\ \text{W}}$

Step 7 of 8

(b)

Heat transmitted by the glass,

$$Q_{in} = \tau \dot{q} A_s$$
$$= 0.88 \times 650 \times 3$$
$$= 1716\ \text{W}$$

Heat transferred to water,

$$Q_w = Q_{in} - Q$$
$$= 1716 - 1278.5$$
$$= 437.5\ \text{W}$$

Step 8 of 8

Collector efficiency,

$$\eta_C = \frac{Q_w}{Q_{in}} \times 100$$
$$= \frac{437.5}{1716} \times 100$$
$$= 25.5\%$$

Therefore the collector efficiency is $\boxed{\eta_C = 25.5\%}$

Heat required to raise temperature is given by

$$Q_w = mc_p(\Delta T)$$
$$437.5 = \frac{1}{60} \times 4180(\Delta T)$$
$$\Delta T = \frac{437.5 \times 60}{4180}$$
$$= 6.28^0\text{C}$$

Hence the temperature difference is $\boxed{\Delta T = 6.28^\circ\text{C}}$

Question: 20.091P

Two concentric spheres with radii of 5 cm and 10 cm are having the surface temperatures maintained at 200°C and 100°C, respectively. The enclosure between the two concentric spherical surfaces is filled with nitrogen gas at 1 atm. If both concentric sphere surfaces tire black (ε= 1), determine the rate of heat transfer on the inner surface.

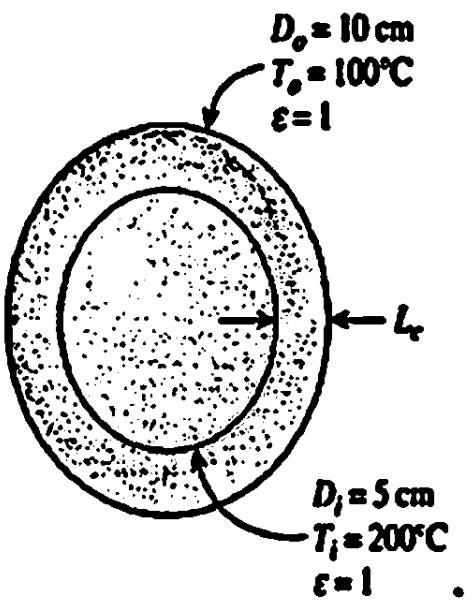

FIGURE P20–91

Step 1 of 6

Diameter of the outer cylinder, $D_0 = 10\text{cm} = 0.1\text{m}$

Temperature of the outer cylinder, $T_0 = 100°\text{C}$

Diameter of the inner cylinder, $D_i = 5\text{cm} = 0.05\text{m}$

Temperature of the inner cylinder, $T = 200°\text{C}$

Pressure, $P = 1\text{atm}$

Step 2 of 6

Mean film temperature of the concentric cylinder is

$$T_{avg} = \frac{T_i + T_0}{2}$$
$$= \frac{100+200}{2}$$
$$= 150°\text{C}$$

From the table of "properties of air at 1atm pressure "

At $T_{avg} = 150°\text{C}$

Thermal conductivity

$$k = 0.03374 + \frac{(150-140)(0.03511-0.03374)}{160-140}$$
$$= 0.034425$$

Prandtl number is

$$\text{Pr} = 0.7041 + \frac{(150-140)(0.7014-0.7041)}{(160-140)}$$
$$= 0.70275$$

Kinematic viscosity

$$\nu = 2.745\times10^{-5} + \frac{(150-140)\left((2.975-2.745)10^{-5}\right)}{160-140}$$
$$= 2.86\times10^{-5}\ \text{m}^2/\text{s}$$

And

$$\beta = \frac{1}{T_{avg}}$$
$$= \frac{1}{(150+273\text{K})}$$
$$= \frac{1}{423\text{K}}$$

Step 3 of 6

Characteristic length of the spherical enclosure is

$$L_C = \frac{D_0 - D_i}{2}$$
$$= \frac{0.1-0.05}{2}$$
$$= 0.025\,\text{m}$$

The Rayleigh number is

$$\text{Ra}_L = \frac{g\beta(T_i - T_0)L_c^3}{\nu^2}\text{Pr}$$
$$= \frac{9.81\times\frac{1}{423}(200-100)(0.025)^3(0.70275)}{\left(2.86\times10^{-5}\right)^2}$$
$$= 31.132\times10^3$$

Step 4 of 6

$$F_{sph} = \frac{L_c}{(D_iD_o)^4\left(D_i^{-7/5} + D_0^{-7/5}\right)^5}$$
$$= \frac{0.025}{(0.05\times0.1)^4\left(0.05^{-7/5} + 0.1^{-7/5}\right)^5}$$
$$= \frac{0.025}{6.25\times10^{-10}(6381455116)}$$
$$= 0.006268$$

Step 5 of 6

Then, effective thermal conductivity is

$$k_{eff} = (0.74)k\left(\frac{\text{Pr}}{0.861+\text{Pr}}\right)^{1/4}\left(F_{sph}\text{Ra}_L\right)^{1/4}$$
$$= 0.74\times0.034425\left(\frac{0.70275}{0.861+0.70275}\right)^{1/4}\left(31.132\times10^3\times0.006268\right)^{1/4}$$
$$= 0.02085\times3.737$$
$$= 0.0779\,\text{W/m}\cdot\text{K}$$

Step 6 of 6

The rate of heat transfer becomes

$$\dot{Q} = k_{eff}\frac{\pi D_0 D_i}{L_c}(T_i - T_0)$$
$$= 0.0779\frac{\pi\times0.05\times0.1}{0.025}(200-100)$$
$$= 4.8\,\text{kW}$$

Therefore, Heat Transfer Rate is $\boxed{\dot{Q} = 4.8\,\text{kW}}$

Question: 20.092P

Exhaust gases from a manufacturing plant are being discharged through a 10-m tall exhaust stack with outer diameter of i m. The exhaust gases are discharged at a rate of 0.125 kg/s, while temperature drop between inlet and exit of the exhaust stack is 30°C, and the constant pressure-specific heat of the exhaust gases is 1600 J/kg·K. On a particular calm day, the surrounding quiescent air temperature is 33°C. Solar radiation

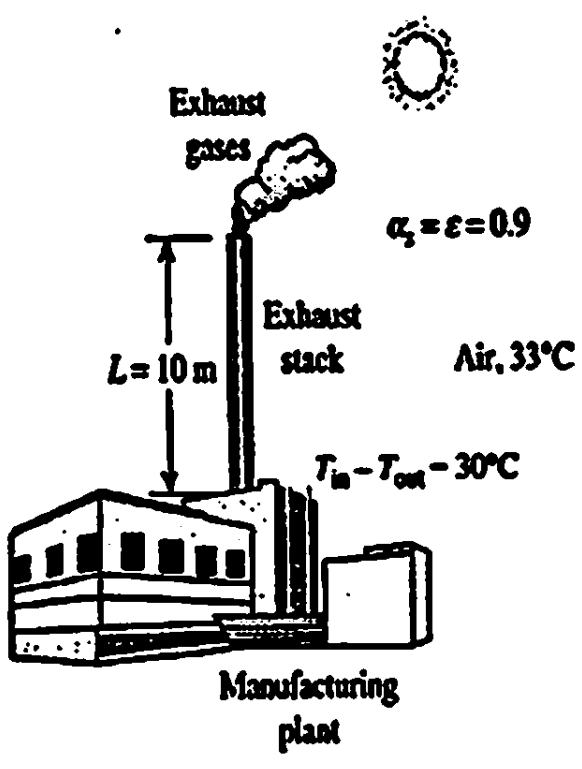

FIGURE P20–92

is incident on the exhaust stack outer surface at a rate of 500W/m2, and both the emissivity and solar absorptivity 0f the outer surface are 0.9. Determine the exhaust stack outer surface temperature. Assume the film temperature is 60°C.

Step 1 of 8

Given data:

Height of exhaust stack, $L = 10\,\text{m}$

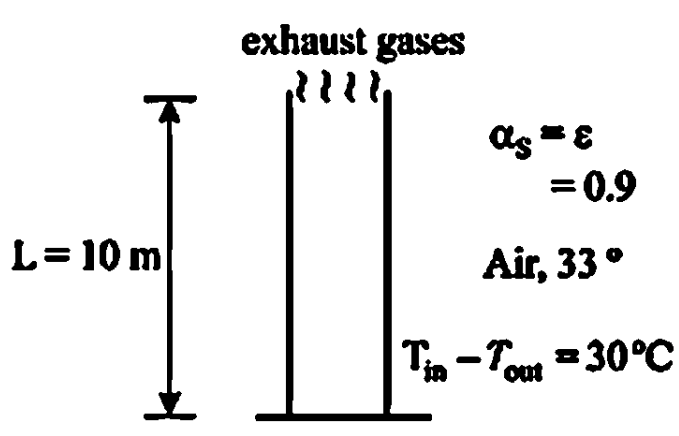
Diameter of stack, $D = 1\,\text{m}$

Discharge rate of gases, $m = 0.125\,\text{kg/s}$

Temperature drop, $(T_{in} - T_{out}) = 30°C$

Specific heat of gas, $c_p = 1600\,\text{J/kg}\cdot\text{K}$

Ambient air temperature, $T_\infty = 33°C$



Solar radiation incidence $\dot{q} = 500\,\text{W/m}^2$

Emissivity of stack surface, $\varepsilon = 0.9$

Film temperature, $T_f = 60°C$

Step 2 of 8

Figure showing the exhaust stack:

Step 3 of 8

Film temperature, $T_f = 60°C$

Volume expansion coefficient,

$$\beta = \frac{1}{T_f}$$

$$= \frac{1}{273+60}$$

$$= 3.0\times10^{-3}\ \text{K}^{-1}$$

Taking properties from the table of air at film temperature $T_f = 60°C$ and 1 atm pressure

Thermal conductivity, $k = 0.02808\,\text{W/m}\,°C$

Prandtl number, $\text{Pr} = 0.7202$

Kinematic viscosity, $\nu = 1.896\times10^{-5}$

Characteristic length, $L_C = L = 10\,\text{m}$

Step 4 of 8

Calculating Rayleigh number,

$$Ra = \frac{g\beta(T_s - T_\infty)L_C^3}{\nu^2}\cdot\text{Pr}$$

$$= \frac{9.81\times\left(3.0\times10^{-3}\right)(T_s - 306)(10)^3}{\left(1.896\times10^{-5}\right)^2}(0.7202)$$

$$= 5.896\times10^{10}(T_s - 306)$$

Therefore as per calculation Ra value seems to be in the range $10^{10} - 10^{13}$

Therefore Nusselt number,

$$Nu = 0.1\text{Ra}^{1/3}$$

$$= 0.1\left(5.86\times10^{10}(T_s - 306)\right)^{1/3}$$

$$= 389.2(T_s - 306)^{1/3}$$

Step 5 of 8

Convective heat transfer coefficient,

$$h = \frac{k}{L_C}\cdot Nu$$

$$= \frac{0.02808}{10}\times389.2(T_s - 306)^{1/3}$$

$$= 1.093(T_s - 306)^{1/3}$$

Surface area of the stack,

$$A_s = \pi DL$$

$$= \pi\times1\times10$$

$$= 31.42\,\text{m}^2$$

Step 6 of 8

Convective heat transfer rate,

$$Q_{conv} = hA_s(T_s - T_\infty)$$

$$= 1.093(T_s - 306)^{1/3}\times31.42\times(T_s - 306)$$

$$= 34.342(T_s - 306)^{4/3}$$

Rate of heat loss from exhaust gases

$$Q_{exhaust} = m\times c_p\times(T_1 - T_2)$$

$$= 0.125\times1600\times30$$

$$= 6000\,\text{W}$$

Total heat gain from solar radiation,

$$Q_{total} = \alpha\times\dot{q}\times A_s$$

$$= 500\times0.9\times31.42$$

$$= 14139\ \text{W}$$

Step 7 of 8

Radiation heat transfer rate,

$$\dot{Q}_{rad} = \varepsilon\times A_s\times\sigma$$

$$= 0.9\times31.42\times\left(5.67\times10^{-8}\right)\times\left[(T_s + 273)^4 - (33+273)^4\right]$$

$$= 1.6\times10^{-6}\times\left((T_s + 273)^4 - (33+273)^4\right)$$

Step 8 of 8

Now total heat transfer rate is

$$Q_{total} = Q_{exhaust} + Q_{conv} + Q_{rad}$$

$$14139 = [6000] + \left[34.342(T_s - 306)^{4/3}\right] + \left[1.6\times10^{-6}\times\left(T_s^4 - 306^4\right)\right]$$

By solving the above expression,

The temperature is close to,

$$T_s = 360.5\ \text{K}$$

$$= 87.5°C$$

As this is near to assumed value, our assumption is valid and the surface temperature is

$$\boxed{T_s = 87.5°C}$$

CHAPTER 22

SOLUTIONS

Question: 21.001P

By what properties is an electromagnetic wave characterized? How are these properties related to each other?

Step 1 of 1

Electromagnetic waves are characterized by their frequency ν or wavelength λ.
These two properties in a medium are related by

$$\lambda = \frac{c}{\nu}$$

Where c is the speed of propagation of a wave in that medium, $c = \frac{c_0}{n}$

c_0 is the speed of light in a vacuum

n is the index of refraction of that medium.

Question: 21.002P

What is visible light? How does it differ from the other forms of electromagnetic radiation?

Step 1 of 1

Light is the visible portion of the electromagnetic spectrum that lies between 0.4 μm and 0.76 μm. Light is characteristically not different from other electromagnetic radiations, except that it triggers the sensation of seeing in the human eye. Light, or the visible spectrum, consists of narrow bands of color from violet (0.40 to 0.44 μm) to red (0.63 to 0.76 μm).

Question: 21.003P

How does microwave cooking differ from conventional cooking?

Step 1 of 1

Microwave ovens utilize electromagnetic radiation in the microwave region of the spectrum generated by microwave tubes called magnetrons. Microwaves in the range $10^2 - 10^5\ \mu m$ are very suitable for use in cooking since they are reflected by metals, transmitted by glass and plastics, and absorbed by food molecules. Thus in a microwave oven, the electrical energy is directly converted to radiation that is useful for cooking. But in conventional cooking, a considerable amount of supplied heat is lost to surroundings due conduction, convection and radiation. Hence the time for cooking also increases in conventional cooking.

Question: 21.004P

What is thermal radiation? How does it differ from the other forms of electromagnetic radiation?

Step 1 of 1

Thermal radiation emitted as a result of energy transitions of molecules, atoms, and electrons of a substance. Thermal radiation is also defined as the portion of the electromagnetic spectrum that extends from about 0.1 to 100 μm. Unlike other forms of electromagnetic radiation thermal radiation is continuously emitted by all matter whose temperature is above absolute zero.

Question: 21.005P

What is the cause of color? Why do some objects appear blue to the eye while others appear red? Is the color of a surface at room temperature related to the radiation it emits?

Step 1 of 1

The color of a surface depends on the absorption and reflection characteristics of the surface and is due to selective absorption and reflection of the incident visible radiation coming from a light source such as the sun or incandescent light bulb. For example, a surface that reflects radiation in the wavelength range 0.63 μm - 0.76c μm while absorbing the rest appears red to the eye. A surface that reflects all of the light appears white, while a surface that absorbs the entire light incident on it appears black.

Question: 21.006P

Why is radiation usually treated as a surface phenomenon?

Step 1 of 1

For opaque solids such as metals, wood, and rocks, radiation is considered to be a surface phenomenon, since the radiation emitted by the interior regions can never reach the surface, and the radiation incident on such bodies is usually absorbed within a few microns from the surface.

Question: 21.007P

How do ultraviolet and infrared radiation differ? Do you think your body emits any radiation in the ultraviolet range? Explain.

Step 1 of 1

The radiation emitted by bodies at room temperature falls into the infrared region of the spectrum, which extends from 0.76 to 100 μm.

The ultraviolet radiation includes the low wavelength end of the thermal radiation spectrum and lies between the wavelengths 0.01 and 0.4 μm.

Since the human body at room temperature emits radiation in the infrared region only so that it is not possible to emits radiation in the ultraviolet region.

Question: 21.008P

A cordless telephone is designed to operate at a frequency of 8.5 ×108 Hz. Determine the wavelength of these telephone waves.

Step 1 of 1

Given frequency of the cordless telephone, $\nu = 8.5 \times 10^8$ Hz

Wavelength of the cordless telephone is determined by using $\lambda = \frac{c}{\nu}$

Where λ is the wavelength in m

ν is the frequency of the waves in Hz

c is the speed of light in medium $= 3 \times 10^8$ m/s

Hence $\lambda = \frac{3 \times 10^8 \text{ m/s}}{8.5 \times 10^8 \text{ Hz}}$

$\lambda = 0.353$ m

Therefore wavelength is $\boxed{\lambda = 0.353 \text{ m}}$

Question: 21.009P

Electricity is generated and transmitted in power lines at a frequency of 50 Hz (1 Hz = 1 cycle per second). Determine the wavelength of the electromagnetic waves generated by the passage of electricity in power lines.

Step 1 of 1

Given data:

Frequency of power lines $\nu = 50$ Hz.

Question: 21.010P

A microwave oven is designed to operate at a frequency of 2.2 ×109 Hz. Determine the wavelength of these microwaves and the energy of each microwave.

Step 1 of 2

Given frequency of microwaves is $2.2\times10^{9}\ \text{Hz}$

The wavelength of these microwaves is determined by using,

$$\lambda = \frac{c}{\nu}$$

$$\lambda = \frac{2.9979\times10^{8}\ \text{m/s}}{2.2\times10^{9}\ \text{Hz}}$$

$$\lambda = 0.136\ \text{m}$$

Hence wavelength of these microwaves is $\boxed{\lambda = 0.136\ \text{m}}$

Step 2 of 2

The energy of each microwave is determined by using $e = h\nu$

Where e is the energy in Joules (J)

h is the Planck's constant $(6.626\times10^{-34}\ \text{J.s})$

ν is the frequency of the wave $(2.2\times10^{9}\ \text{Hz})$

Hence $e = h\nu$

$$e = (6.626\times10^{-34}\ \text{J.s})(2.2\times10^{9}\ \text{Hz})$$

$$e = 1.457\times10^{-24}\ \text{J}$$

Hence energy of each microwave is $\boxed{e = 1.457\times10^{-24}\ \text{J}}$

Question: 21.011P

A radio station is broadcasting radio waves at a wavelength of 150 m. Determine the frequency of these waves.

Step 1 of 1

Given data:

The wavelength of the radio waves is $\lambda = 150$ m.

Question: 21.012P

The speed of light in vacuum is given to be 3.0 ×108 m/s. Determine the speed of light in air (n = 1), in water (n = 1.33), and in glass (n = 1.5).

Step 1 of 2

Given

Speed of light in the vacuum is $c_0 = 3\times10^8$ m/s

Speed of light in medium is $c = \frac{c_0}{n}$

For air, $n = 1$

Hence, $c = \frac{c_0}{n}$

$$c = \frac{3\times10^8 \text{ m/s}}{1}$$

$$c = 3\times10^8 \text{ m/s}$$

Speed of light in air is $\boxed{c = 3\times10^8 \text{ m/s}}$

Step 2 of 2

For water, $n = 1.5$

Hence, $c = \frac{c_0}{n}$

$$c = \frac{3\times10^8 \text{ m/s}}{1.5}$$

$$c = 2\times10^8 \text{ m/s}$$

Speed of light in water is $\boxed{c = 2\times10^8 \text{ m/s}}$

Question: 21.013P

What is a blackbody? Does a blackbody actually exist?

Step 1 of 1

A black body is a perfect emitter and absorber of radiation. Black body is an ideal body and hence it does not actually exist.

Question: 21.014P

Why did we define the blackbody radiation function? What does it represent? For what is it used?

Step 1 of 1

The radiation energy emitted by a blackbody per unit area over a wavelength band from $\lambda = 0$ to λ is determined from

$$E_b = \sum_0^\infty E_{b\lambda}(\lambda, T)\, d\lambda \qquad (W/m^2)$$

But this summation does not have a simple closed form solution, and performing a numerical integration each time we need a value of $E_{b0-\lambda}$ is not practically feasible.

Therefore, a dimensionless quantity f_λ called the blackbody radiation function is introduced to represent the fraction of radiation emitted from a blackbody at temperature T in the wavelength band from $\lambda = 0$ to λ.

This function is used to determine the fraction of radiation in a wavelength range between λ_1 and λ_2.

Question: 21.015P

Define the total and spectral blackbody emissive powers. How are they related to each other? How do they differ?

Step 1 of 1

Total body emissive power (E_b) is the sum of the radiation emitted over entire range of wavelengths. Whereas Spectral body emissive power is the amount of radiation energy emitted by a blackbody at a thermodynamic temperature (T) per unit time, per unit surface area, and per unit wavelength about the specific wavelength λ.

The spectral body emissive power ($E_{b\lambda}$) over the entire wavelength spectrum gives the total blackbody emissive power (E_b).

$$E_b = \sum_0^\infty E_{b\lambda}(\lambda, T)\, d\lambda \qquad (W/m^2)$$

Total emissive power of the blackbody doesn't vary with wavelength. Spectral blackbody emissive power varies with wavelength.

Question: 21.016P

The temperature of the filament of an incandescent lightbulb is 2500 K. Assuming the filament to be a blackbody, determine the fraction of the radiant energy emitted by the filament that falls in the visible range. Also, determine the wavelength at which the emission of radiation from the filament peaks.

Step 1 of 4

Given data:

The temperature of the incandescent bulb $T = 2500\ \text{K}$.

Step 2 of 4

The visible range of the electromagnetic spectrum extends from $\lambda_1 = 0.4\ \mu\text{m}$ to $\lambda_2 = 0.76\ \mu\text{m}$.

Hence $\lambda_1 = 0.4\ \mu\text{m}$

$\lambda_2 = 0.76\ \mu\text{m}$

$$\lambda_1 T = (0.4\ \mu\text{m})(2500\ \text{K})$$
$$= 1000\ \mu\text{m}\cdot\text{K}$$

From blackbody radiation functions table at $\lambda_1 T = 1000\ \mu\text{m}\cdot\text{K}$, the radiation function is $f_{\lambda_1} = 0.000321$

$$\lambda_2 T = (0.76\ \mu\text{m})(2500\ \text{K})$$
$$= 1900\ \mu\text{mK}$$

From blackbody radiation functions table at $\lambda_2 T = 1900\ \mu\text{m}\cdot\text{K}$, the radiation function is $f_{\lambda_2} = 0.053035$

Step 3 of 4

Fraction of radiant energy emitted in the given range of wavelengths is given by,

$$f_{\lambda_2} - f_{\lambda_1} = 0.053035 - 0.000321$$
$$f_{\lambda_2} - f_{\lambda_1} = 0.05272$$
$$\boxed{f_{\lambda_2} - f_{\lambda_1} = 0.05272}$$

About 5% of the radiation emitted by the filament of the lightbulb falls in the visible range.

Step 4 of 4

The wavelength at which the emission of radiation from the filament peaks is easily determined from Wien's displacement law, which is given below.

$$(\lambda_1 T)_{\text{max_power}} = 2897.8\ \mu\text{m}\cdot\text{K}$$
$$(\lambda_1)_{\text{max_power}} = \frac{2897.8\ \mu\text{m}\cdot\text{K}}{2500\ \text{K}}$$
$$(\lambda_1)_{\text{max_power}} = 1.16\ \mu\text{m}$$

Therefore, the displacement of the wave form is determined to be $\boxed{(\lambda_1)_{\text{max_power}} = 1.16\ \mu\text{m}}$.

Question: 21.017P

Consider a black surface at 2060°F. Determine the radiation energy emitted by the black surface per unit area (in Btu/h•ft2) for ($\lambda \geq 4\ \mu m$.)

Step 1 of 1

Substitute $0.1714\times10^{-8}\,BTu/h\cdot ft^2\cdot R^4$ for σ and $(2060+460)$ for T.

$$E_b(T)=\sigma T^4$$

$$E_b(T)=0.1714\times10^{-8}\,BTu/h\cdot ft^2\cdot R^4(2060+460)^4$$

$$E_b=6.912\times10^4\ BTu/h\cdot ft^2$$

Therefore, radiation of energy emitted from the black surface is $\boxed{6.912\times10^4\ BTu/h\cdot ft^2}$.

Question: 21.018P

Consider a surface at a uniform temperature of 1000 K. Determine the maximum rate of thermal radiation that can be emitted by this surface, in W/m2.

Step 1 of 2

Given

The temperature of the surface $T = 1000\ \text{K}$.

Step 2 of 2

Maximum rate of thermal radiation emitted by the surface at temperature 1000 K can be determined by

$$E_b(T) = \sigma T^4 \ (\text{W/m}^2)$$

Where

Stefan-boltzmann constant $\sigma = 5.67 \times 10^{-8}\ \text{W/m}^2.\text{K}^4$

$$E_b(T) = (5.67 \times 10^{-8}\ \text{W/m}^2.\text{K}^4)(1000\ \text{K})^4$$
$$= 56700\ \text{W/m}^2$$

Therefore, maximum rate of thermal radiation emitted by the surface is $\boxed{E_b(T) = 56,700\ \text{W/m}^2}$.

Question: 21.019P

An incandescent lightbulb is desired to emit at least 15 percent of its energy at wavelengths shorter than 0.8 μm. Determine the minimum temperature to which the filament of the lightbulb must be heated.

Step 1 of 2

Given that the fraction of radiation for the light bulb is 15%

Hence $f_\lambda = 0.15$

Wavelength range of light bulb is from $0.0\,\mu m$ to $0.8\,\mu m$

Hence $\lambda_1 = 0.0\,\mu m$

$\lambda_2 = 0.8\,\mu m$

Step 2 of 2

From blackbody radiation functions table at $f_\lambda = 0.15$,

$\lambda T = 2445\,\mu m\text{K}$

For the wavelength range $\lambda_1 = 0.0\,\mu m$ to $\lambda_2 = 0.8\,\mu m$,

The minimum temperature to which the filament of the light bulb must be heated is

$$\lambda T = 2445\,\mu m\text{K}$$

$$T = \frac{2445\,\mu m\text{K}}{0.8\,\mu m}$$

$$T = 3056.25\,\text{K}$$

The minimum temperature is $\boxed{T = 3056.25\,\text{K}}$

Question: 21.020P

The sun can be treated as a blackbody at an effective surface temperature of 10,400 R. Determine the rate at which infrared radiation energy (λ = 0.76-100 μm) is emitted by the sun, in Btu/h·ft2.

Step 1 of 3

Given

Effective temperature Sun surface is $(T) = 10400\ \text{R}$
$= 5778\ \text{K}$

Let wavelength range be from λ_1 to λ_2

$\lambda_1 = 0.76\ \mu m$

$\lambda_2 = 100\ \mu m$

Step 2 of 3

Considering the product of the minimum wavelength and temperature,

$\lambda_1 T = (0.76\ \mu\text{m})(5778\ \text{K})$

$\lambda_1 T = 4391.3\ \mu\text{mK}$

From blackbody radiation functions table at $\lambda T = 4391.3$,

$f_{\lambda_1} = 0.547370$

Considering the product of the maximum wavelength and temperature,

$\lambda_2 T = (100\ \mu\text{m})(5778\ \text{K})$

$\lambda_2 T = 577{,}800\ \mu\text{mK}$

From blackbody radiation functions table at $\lambda T = 577800$,

$f_{\lambda_2} = 1.0$

Step 3 of 3

Fraction of radiation emitted between these two wavelengths becomes

$f_{\lambda_2} - f_{\lambda_1} = 1.0 - 0.547$

$= 0.453$

From the Stefan-Boltzmann law the total blackbody emissive power of the sun is

$E_b = \sigma T^4$

$= (0.1714 \times 10^{-8}\ \text{Btu/h.ft}^2\text{.R}^4)(10{,}400\ \text{R})^4$

$= 2.005 \times 10^7\ \text{Btu/h.ft}^2$

Then the infrared radiation energy emitted by the sun is

$E_{\text{infrared}} = (0.451) E_b$

$= (0.453)(2.005 \times 10^7\ \text{Btu/h.ft}^2)$

$= 9.08 \times 10^6\ \text{Btu/h.ft}^2$

$\boxed{E_{\text{infrared}} = 9.08 \times 10^6\ \text{Btu/h.ft}^2}$

Question: 21.021P

The sun can be treated as a blackbody at 5780 K. Using EES (or other) software, calculate and plot the spectral blackbody emissive power $E_{b\lambda}$ of the sun versus wavelength in the range of 0.01 μm to 1000 μm. Discuss the results.

Step 1 of 3

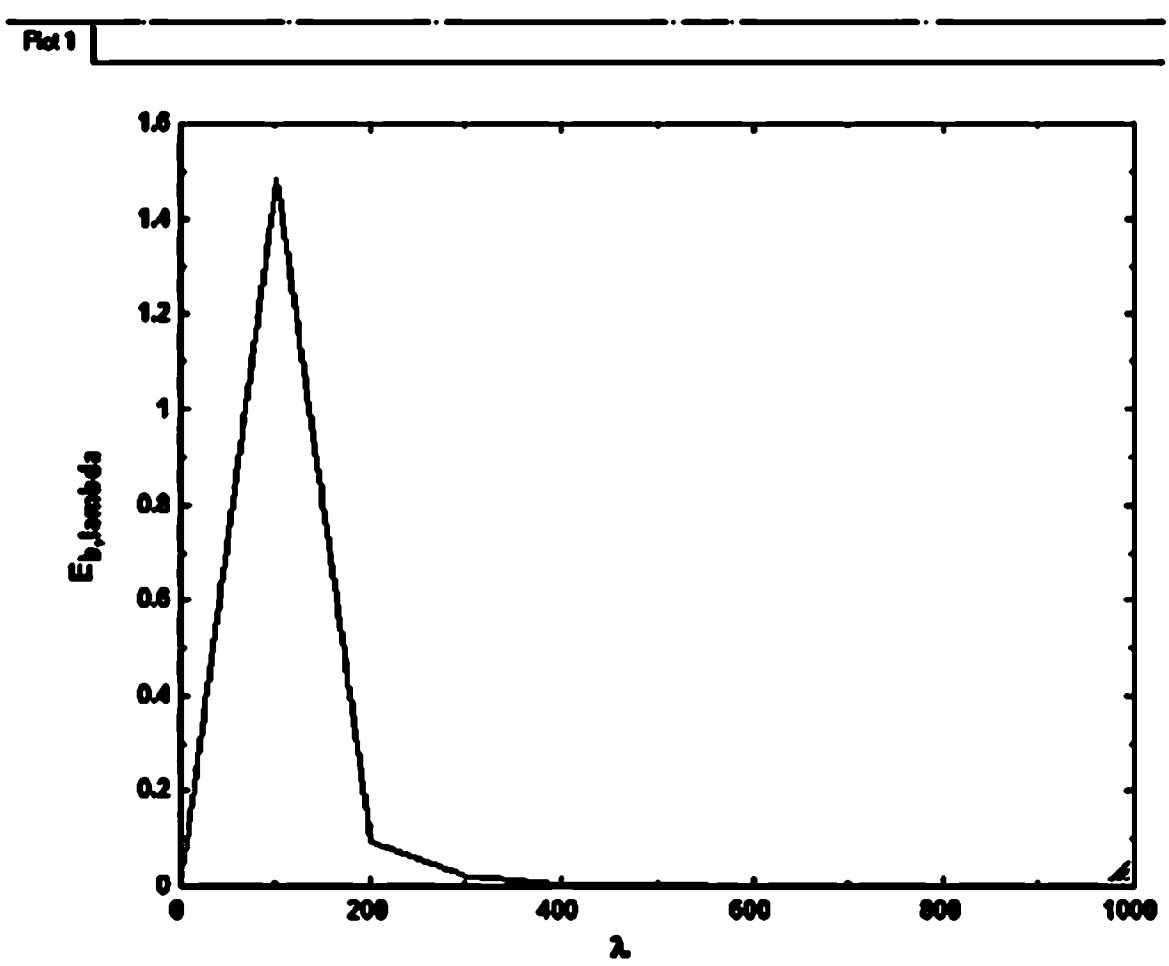
The given problem can be solved using EES software by following the below steps.

1. **Open EES software**
2. **Create a new file by clicking on the 'New' of the 'File menu'**

```
Equations Window
  "GIVEN"
  T=5780 "[K]"
  "lambda=0.01[micrometer],
..parameter to be varied"

  "ANALYSIS"
  E_b_lambda=C_1/(lambda^5*(exp
..(C_2/(lambda*T))-1))
  C_1=3.742E8 "[W-micrometer^4/m^
..2]"
  C_2=1.439E4 "[micrometer-K]"
```

Step 2 of 3



From the above code generate the parametric table.

Table 1

1..11	1 $E_{b,\lambda}$	2 λ
Run 1	2.820E-90	0.01
Run 2	1.484	100

Step 3 of 3

Plot the graph

Question: 21.022P

The temperature of the filament of an incandescent lightbulb is 2800 K. Treating the filament as a blackbody, determine the fraction of the radiant energy emitted by the filament that falls in the visible range. Also, determine the wavelength at which the emission of radiation from the filament peaks.

Step 1 of 3

Given data:

The temperature of the incandescent bulb $T = 2800$ K.

Step 2 of 3

We know that,

The visible range of the electromagnetic spectrum extends from $\lambda_1 = 0.4$ μm to $\lambda_2 = 0.76$ μm

Hence $\lambda_1 = 0.4$ μm

$\lambda_2 = 0.76$ μm

$\lambda_1 T = (0.4\ \mu m)(2800\ K)$

$= 1120\ \mu mK$

From blackbody radiation functions table at $\lambda_1 T = 1120\ \mu mK$

Radiation function is $f_{\lambda_1} = 0.0014088$

$\lambda_2 T = (0.76\ \mu m)(2800\ K)$

$= 2128\ \mu mK$

From blackbody radiation functions table at $\lambda_2 T = 2128\ \mu mK$

Radiation function is $f_{\lambda_2} = 0.0885904$

Fraction of radiation emitted between these two wavelengths becomes

$f_{\lambda_2} - f_{\lambda_1} = 0.0885904 - 0.0014088$

$f_{\lambda_2} - f_{\lambda_1} = 0.0872$

$\boxed{f_{\lambda_2} - f_{\lambda_1} = 0.0872}$

About 8% of the radiation emitted by the filament of the lightbulb falls in the visible range.

Step 3 of 3

The wavelength at which the emission of radiation from the filament peaks is easily determined from Wien's displacement law to be

$(\lambda_1 T)_{max_power} = 2897.8\ \mu m.K$

$(\lambda_1)_{max_power} = \dfrac{2897.8\ \mu m.K}{2800}$

$(\lambda_1)_{max_power} = 1.035\ \mu m$

Therefore, the length wave length is $\boxed{(\lambda_1)_{max_power} = 1.035\ \mu m}$.

Question: 21.023P

Reconsider Prob. 21-22. Using EES (or other) software, investigate the effect of temperature on the fraction of radiation emitted in the visible range. Let the surface temperature vary from 1000 K to 4000 K, and plot fraction of radiation emitted in the visible range versus the surface temperature.

Step 1 of 3

The given problem can be solved using EES software by following the below steps.

1. **Open EES software**
2. **Create a new file by clicking on the 'New' of the 'File menu'**

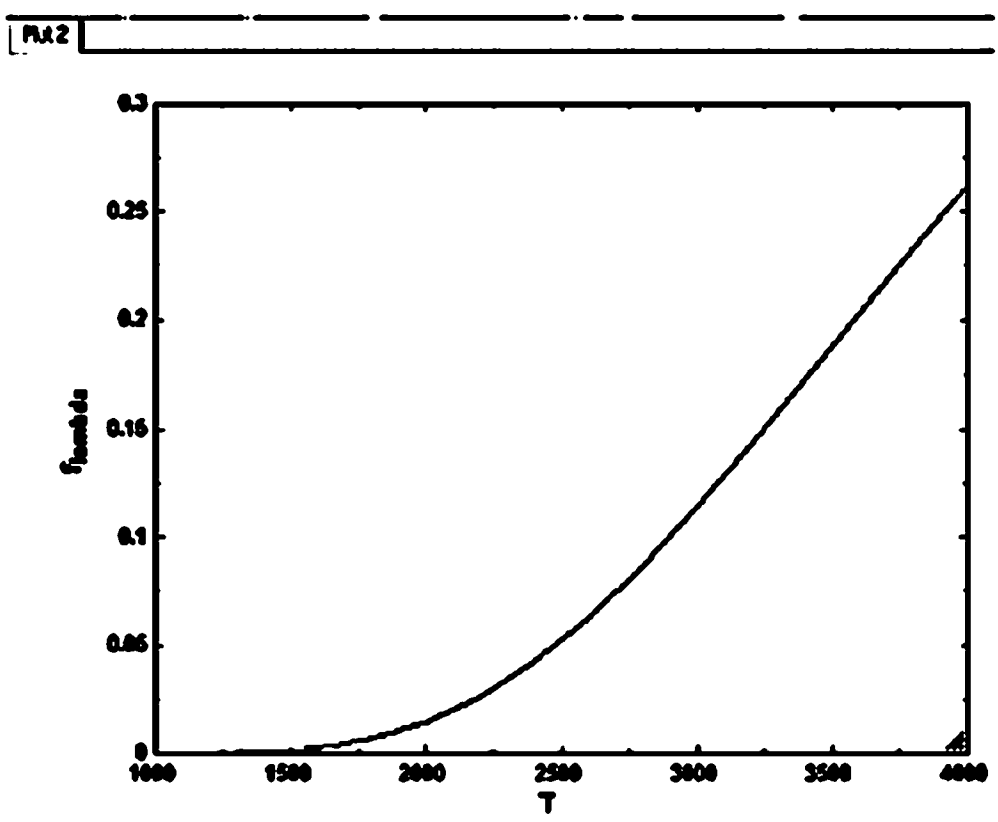
Equations Window

```
"GIVEN"
"T=2800 [K], parameter to be varied"
lambda_1=0.40 "[micrometer]"
lambda_2=0.76 "[micrometer]"

"ANALYSIS"
E_b_lambda=C_1/(lambda^5*(exp(C_2/(lambda*T))-1))
C_1=3.742E8 "[W-micrometer^4/m^2]"
C_2=1.439E4 "[micrometer-K]"

f_lambda=integral(E_b_lambda, lambda, lambda_1, lambda_2)/E_b
E_b=sigma*T^4
sigma=5.67E-8 "[W/m^2-K^4], Stefan-Boltzmann constant"
```

Step 2 of 3



From the above code generate the parametric table.

Table 2

Step 3 of 3

Plot the graph

Question: 21.024P

It is desired that the radiation energy emitted by a light source reach a maximum in the blue range (λ = 0.47 μm).Determine the temperature of this light source and the fraction of radiation it emits in the visible range (λ = 0.40–0.76 μm).

Step 1 of 3

Given that the radiation energy emitted by a light source reach a maximum in the blue range i.e. at $\lambda = 0.47\ \mu m$

The standard value for the maximum, $(\lambda T)_{max\ power} = 2897.8\ \mu m \cdot K$

The temperature of this light source is determined by using the relation,

$$T = \frac{(\lambda T)_{max\ power}}{\lambda}$$

$$T = \frac{2897.8\ \mu m \cdot K}{0.47\ \mu m}$$

$$T = 6167\ K$$

Temperature of this light source is $\boxed{T = 6167\ K}$

Step 2 of 3

Visible range of electromagnetic spectrum extends from $\lambda_1 = 0.4\ \mu m$ to $\lambda_2 = 0.76\ \mu m$

Considering the product of the minimum wavelength and temperature,

$\lambda_1 T = (0.4\ \mu m)(6167\ K)$

$\lambda_1 T = 2466\ \mu mK$

From blackbody radiation functions table at $\lambda T = 2466$,

$f_{\lambda_1} = 0.15444$

Considering the product of the maximum wavelength and temperature,

$\lambda_2 T = (0.76\ \mu m)(6167\ K)$

$\lambda_2 T = 4686\ \mu mK$

From blackbody radiation functions table at $\lambda T = 4686$,

$f_{\lambda_2} = 0.59141$

Step 3 of 3

Fraction of radiation emitted between these two wavelengths becomes

$$f_{\lambda_2} - f_{\lambda_1} = 0.59141 - 0.15444$$

$$f_{\lambda_2} - f_{\lambda_1} = 0.437$$

Fraction of radiation emitted is $\boxed{43.7\ \%}$

Question: 21.025P

A 3-mm-thick glass window transmits 90 percent of the radiation between λ = 0.3 and 3.0 μm and is essentially opaque for radiation at other wavelengths. Determine the rate of radiation transmitted through a 3-m × 3-m glass window from blackbody sources at (*a*) 5800 K and (*b*) 1000 K.

Step 1 of 5

(a)

Temperature of the plate is, $T = 5800\ \text{K}$

Take the product of the minimum wavelength, λ_1 and temperature *T*,

Substitute $0.3\ \mu\text{m}$ for λ_1 and 5800 K for *T*,

$$\begin{aligned}\lambda_1 T &= (0.3\ \mu\text{m})(5800\ \text{K})\\ &= 1740\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 1740$, find the value of fraction of radiation emitted from a black body at temperature *T* by using interpolation method,

$$\frac{1800-1600}{1800-1740} = \frac{0.039341-0.019718}{0.039341-f_{\lambda_1}}$$

$$f_{\lambda_1} = 0.03345$$

Take the product of the maximum wavelength and temperature,

Substitute $3\ \mu\text{m}$ for λ_1 and 5800 K for *T*,

$$\begin{aligned}\lambda_2 T &= (3.0\ \mu\text{m})(5800\ \text{K})\\ &= 17400\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 17400$, find the value of fraction of radiation emitted from a black body at temperature *T* by using interpolation method,

$$\frac{18000-16000}{18000-17400} = \frac{0.980860-0.973814}{0.980860-f_{\lambda_2}}$$ 00.

$$f_{\lambda_2} = 0.97875$$

Step 2 of 5

Find the fraction of radiation emitted between these two wavelengths,

$$\begin{aligned}f_{\lambda_2} - f_{\lambda_1} &= 0.97875-0.03345\\ \Delta f &= 0.9453\end{aligned}$$

Calculating the total blackbody radiation emission,

$$E_b(T) = \sigma T^4 A_s$$

Here, area of the square plate,

$$\begin{aligned}A_s &= 3\text{m}\times 3\text{m}\\ &= 9\text{m}^2\end{aligned}$$

Substitute $5.67\times10^{-8}\ \text{W/m}^2.\text{K}$ for σ

$$\begin{aligned}E_b(T) &= \sigma T^4 A_s\\ &= \left(5.67\times10^{-8}\right)(5800)^4(9)\\ &= 5.774\times10^5\ \text{kW}\end{aligned}$$

Step 3 of 5

Find the rate of radiation transmitted,

$$E_{\text{transmit}} = \varepsilon\times\Delta f\times E_b(T)$$

Here, ε is emissivity

Substitute 0.9 for ε

$$\begin{aligned}E_{\text{transmit}} &= 0.9\times0.9453\times5.774\times10^5\\ &= 491{,}234.598\ \text{kW}\end{aligned}$$

Therefore, the rate of radiation transmitted through a glass window is $\boxed{491{,}234.598\ \text{kW}}$

Step 4 of 5

(b)

Temperature of the plate is, $T = 1000\ \text{K}$

Take the product of the minimum wavelength, λ_1 and temperature *T*,

Substitute $0.3\ \mu\text{m}$ for λ_1 and 1000 K for *T*,

$$\begin{aligned}\lambda_1 T &= (0.3\ \mu\text{m})(1000\ \text{K})\\ &= 300\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 300$

$$f_{\lambda_1} = 0.0$$

Take the product of the maximum wavelength and temperature,

Substitute $3\ \mu\text{m}$ for λ_1 and 5800 K for *T*,

$$\begin{aligned}\lambda_2 T &= (3.0\ \mu\text{m})(1000\ \text{K})\\ &= 3000\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 3000$

$$f_{\lambda_2} = 0.273232$$

Step 5 of 5

Fraction of radiation emitted between these two wavelengths becomes

$$\begin{aligned}f_{\lambda_2} - f_{\lambda_1} &= 0.273232-0.0\\ \Delta f &= 0.273232\end{aligned}$$

Calculating the total blackbody radiation emission,

$$\begin{aligned}E_b(T) &= \sigma T^4 A_s\\ &= \left(5.67\times10^{-8}\right)(1000)^4(9)\\ &= 510.3\ \text{kW}\end{aligned}$$

Find the rate of radiation transmitted,

$$\begin{aligned}E_{\text{transmit}} &= \varepsilon\times\Delta f\times E_b(T)\\ &= 0.9\times0.273232\times510.3\\ &= 125.47\ \text{kW}\end{aligned}$$

Therefore, the rate of radiation transmitted through a glass window is $\boxed{125.47\ \text{kW}}$

Question: 21.026P

Daylight and candlelight may be approximated as a blackbody at the effective surface temperatures of 5800 K and 1800 K, respectively. Determine the radiation energy (in W/m2) emitted by both lighting sources (daylight and candlelight) within the visible light region (0.40 to 0.76 μm).

Step 1 of 6

Given data:

Effective surface temperature of daylight, $T = 5800\ \text{K}$

Effective surface temperature of candle light, $T_l = 1800\ \text{K}$

For daylight:

The visible range of the electromagnetic spectrum extends from $\lambda_1 = 0.4\ \mu\text{m}$ to $\lambda_2 = 0.76\ \mu\text{m}$.

For candlelight:

The visible range of the electromagnetic spectrum extends from $\lambda_1 = 0.4\ \mu\text{m}$ to $\lambda_2 = 0.76\ \mu\text{m}$.

Step 2 of 6

Considering the product of the wavelength and temperature,

$$\begin{aligned}\lambda_1 T &= (0.4\ \mu\text{m})(5800)\ \text{K}\\ &= 2320\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 2320\ \mu\text{m}\cdot\text{K}$

By using interpolation method,

Fraction of radiation emitted,

$$\frac{2400-2000}{2400-2320} = \frac{0.140256-0.100888}{0.140256-f_{\lambda_1}}$$

$$f_{\lambda_1} = 0.13382$$

Step 3 of 6

Considering the product of the wavelength and temperature,

$$\begin{aligned}\lambda_2 T &= (0.76\ \mu\text{m})(5800)\ \text{K}\\ &= 4408\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 4408\ \mu\text{m}\cdot\text{K}$

By using interpolation method,

Fraction of radiation emitted,

$$\frac{4600-4400}{4600-4408} = \frac{0.579280-0.516014}{0.579280-f_{\lambda_2}}$$

$$f_{\lambda_2} = 0.5185$$

Fraction of radiation emitted between these two wavelengths becomes

$$f_{\lambda_2} - f_{\lambda_1} = 0.5185 - 0.13382$$

$$\Delta f = 0.3846$$

Step 4 of 6

The total blackbody emissive power of the sun is determined from Stefan-Boltzmann Law to be

$$E_b(T) = \sigma T^4 \quad \ldots\ldots (1)$$

Where,

Stefan Boltzman constant is, $\sigma = 5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4$

Substituting the values $T = 5800\ \text{K}$ and σ in equation (1), we get

$$\begin{aligned}E_b(T) &= \sigma T^4\\ &= 5.67\times10^{-8}\times5800^4\\ &= 6.416\times10^7\ \text{W/m}^2\end{aligned}$$

Radiation energy of daylight,

$$\begin{aligned}E_{\text{Daylight}} &= \Delta f E_b(T)\\ &= (0.3846)\left(6.416\times10^7\right)\ \text{W/m}^2\\ &= 2.467\times10^7\ \text{W/m}^2\end{aligned}$$

Therefore, radiation energy of daylight is $\boxed{E_{\text{Daylight}} = 2.467\times10^7\ \text{W/m}^2}$

Step 5 of 6

Considering the product of the wavelength and temperature,

$$\begin{aligned}\lambda_1 T &= (0.4\ \mu\text{m})(1800)\ \text{K}\\ &= 720\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 720\ \mu\text{m}\cdot\text{K}$

By using interpolation method,

Fraction of radiation emitted,

$$\frac{800-600}{800-720} = \frac{0.000016-0}{0.000016-f_{\lambda_1}}$$

$$f_{\lambda_1} = 0.0000096$$

Step 6 of 6

Considering the product of the wavelength and temperature,

$$\begin{aligned}\lambda_2 T &= (0.76\ \mu\text{m})(1800)\ \text{K}\\ &= 1368\ \mu\text{m}\cdot\text{K}\end{aligned}$$

From blackbody radiation functions table, at $\lambda T = 1368\ \mu\text{m}\cdot\text{K}$

By using interpolation method,

Fraction of radiation emitted,

$$\frac{1400-1200}{1400-1368} = \frac{0.007790-0.002134}{0.007790-f_{\lambda_2}}$$

$$f_{\lambda_2} = 0.006885$$

Fraction of radiation emitted between these two wavelengths becomes

$$f_{\lambda_2} - f_{\lambda_1} = 0.0068854 - 0.0000096$$

$$\Delta f = 0.0068754$$

The total blackbody emissive power of the sun is determined from Stefan-Boltzmann Law to be

$$E_b(T) = \sigma T^4 \quad \ldots\ldots (2)$$

Where,

Stefan Boltzman constant is, $\sigma = 5.67\times10^{-8}\ \text{W/m}^2.\text{K}^4$

Substituting the values $T = T_l = 1800\ \text{K}$ and σ in equation (2), we get

$$\begin{aligned}E_b(T) &= \sigma T^4\\ &= 5.67\times10^{-8}\times1800^4\\ &= 5.5952\times10^5\ \text{W/m}^2\end{aligned}$$

Radiation energy of daylight,

$$\begin{aligned}E_{\text{candlelight}} &= \Delta f E_b(T)\\ &= (0.006885)5.952\times10^5\ \text{W/m}^2\\ &= 4097.9\ \text{W/m}^2\end{aligned}$$

Therefore, radiation energy of daylight is $\boxed{E_{\text{candlelight}} = 4097.9\ \text{W/m}^2}$

Question: 21.027P

A flame from a match may be approximated as a blackbody at the effective surface temperature of 1700 K, while moonlight may be approximated as a blackbody at the effective surface temperature of 4000 K, respectively. Determine the peak spectral blackbody emissive power for both lighting sources (match flame and moonlight).

Step 1 of 4

Effective surface temperature of the match flame, $T_1 = 1700\ \text{K}$

Effective surface temperature of the moonlight, $T_2 = 4000\ \text{K}$

Step 2 of 4

The relation for the spectral blackbody emissive power $E_{b\lambda}$ is determined by the Planck's law which is expressed as

$$E_{b\lambda T}(\lambda, T) = \frac{C_1}{\lambda^5\left[\exp(C_2/\lambda T) - 1\right]} \qquad \ldots\ldots (1)$$

Where the value of the constants are,

$C_1 = 3.742\times10^8\ \text{W}\cdot\mu\text{m}^4/\text{m}^2$

$C_2 = 1.439\times10^4\ \mu\text{m}\cdot\text{K}$

Step 3 of 4

Now the value of the wavelength (λ) for the match flame is determined by using the Wien's displacement law which is expressed as

$(\lambda T)_{\text{max power}} = 2897.8\ \mu\text{m}\cdot\text{K}$

Re-arranging the above relation for wavelength we get

$$\lambda = \frac{2897.8}{T}$$
$$= \frac{2897.8}{1700}$$
$$= 1.704\ \mu\text{m} \qquad \ldots\ldots (2)$$

Similarly the value of the wavelength (λ) for the moon light is determined by using the Wien's displacement law

$$\lambda = \frac{2897.8}{T}$$
$$= \frac{2897.8}{4000}$$
$$= 0.724\ \mu\text{m} \qquad \ldots\ldots (3)$$

Step 4 of 4

Now substituting the value of λ for the match flame from equation (2) and the constants C_1, C_2 in equation (1) we get

$$E_{b\lambda T}(\lambda, T) = \frac{C_1}{\lambda^5\left[\exp(C_2/\lambda T) - 1\right]}$$
$$= \frac{3.742\times10^8}{1.704^5\left[\exp\left(1.439\times10^4/1.704\times1700\right) - 1\right]}$$
$$= \frac{3.742\times10^8}{2049.71}$$
$$= 0.182\times10^6\ \text{W}/\text{m}^2\cdot\mu\text{m}$$

Similarly substituting the value of λ for the moon light from equation (3) and the constants C_1, C_2 in equation (1) we get

$$E_{b\lambda T}(\lambda, T) = \frac{C_1}{\lambda^5\left[\exp(C_2/\lambda T) - 1\right]}$$
$$= \frac{3.742\times10^8}{0.724^5\left[\exp\left(1.439\times10^4/0.724\times4000\right) - 1\right]}$$
$$= \frac{3.742\times10^8}{28.421}$$
$$= 13.16\times10^6\ \text{W}/\text{m}^2\cdot\mu\text{m}$$

Therefore the peak spectral blackbody emissive power for the match flame is $\boxed{0.182\times10^6\ \text{W}/\text{m}^2\cdot\mu\text{m}}$ and for the moon light is $\boxed{13.16\times10^6\ \text{W}/\text{m}^2\cdot\mu\text{m}}$

Question: 21.028P

What is a graybody? How does it differ from a blackbody? What is a diffuse gray surface?

Step 1 of 1

A body whose surface properties i.e. emissivity and abosrptivity are independent of wavelength is said to be a graybody. The emissivity of a blackbody is one for all wavelengths; the emissivity of a graybody is between zero and one.

A surface for which emissivity and absorptivity are directional (θ) independent and wavelength (λ) independent are termed as diffusive gray surface.

Question: 21.029P

Define the properties emissivity and absorptivity. When are these two properties equal to each other?

Step 1 of 1

Emissivity of a surface represents the ratio of the radiation emitted by the surface at a given temperature to the radiation emitted by a blackbody at the same temperature. The fraction of irradiation absorbed by the surface is called the absorptivity. Both emissivity and absorptivity are equal under the condition that the surface temperature is equal to the temperature of the source of irradiation.

Question: 21.030P

What is the greenhouse effect? Why is it a matter of great concern among atmospheric scientists?

Step 1 of 1

Earth receives energy from the sun as radiation and gets heated. At nights, the earth's surface gets cooled by radiating this energy into deep space as Infrared radiation. But due to the presence of materials that are of non-gray characteristics, the Infrared radiation is reflected back to the surface and this eventually cause global warming. And this Heating effect is known as greenhouse effect. There is a great concern for this effect among atmospheric scientists, as this effect would bring drastic changes in weather patterns.

Question: 21.031P

Consider an opaque horizontal plate that is well insulated on the edges and the lower surface. The plate is maintained at 500 K, has a total hemispherical absorptivity of 0.51 and the following spectral emissivity function:

$$\varepsilon_\lambda = \begin{cases} \varepsilon_1 = 0.4, & 0 \le \lambda < 4\ \mu\text{m} \\ \varepsilon_2 = 0.8, & 4\ \mu\text{m} \le \lambda < \infty \end{cases}$$

If the plate is subjected to an irradiation of 5600 W/m2, determine (*a*) the total hemispherical emissivity and (*b*) the radiosity of the plate surface.

Step 1 of 4

Temperature of the plate, $T = 500\ \text{K}$
Absorptivity of the plate, $\alpha = 0.51$
Irradiation on the plate, $G = 5600\ \text{W/m}^2$
The emissivity of the plate for $0 < \lambda < 4\ \mu\text{m}$ is $\varepsilon_1 = 0.4$
The emissivity of the plate for $4\ \mu\text{m} < \lambda < \infty$ is $\varepsilon_2 = 0.8$

Step 2 of 4

(a)
Radiation function corresponding to the temperature of 500K,

$$\lambda T = (4)(500)$$
$$= 2000\ \mu\text{m}\cdot\text{K}$$

From the black body radiation function, at $\lambda T = 2000\ \mu\text{m}\cdot\text{K}$

$$f_\lambda = 0.066728$$

The emissivity of the plate is

$$\varepsilon = \varepsilon_1 f_\lambda + \varepsilon_2 (1 - f_\lambda)$$
$$= (0.4)(0.066728) + (0.8)(1 - 0.066728)$$
$$= 0.7733$$

Hence the emissivity of the plate is $\boxed{\varepsilon = 0.7733}$

Step 3 of 4

(b)
The radiation emitted by the plate is

$$E_{\text{emitted}} = \varepsilon \sigma T^4$$
$$= 0.7733 \times \left(5.67 \times 10^{-8}\right) \times 500^4$$
$$= 2740.38\ \text{W/m}^2$$

The energy reflected by the plate is

$$E_{\text{reflected}} = \rho G$$
$$= (1 - \alpha) G$$
$$= (1 - 0.51)5600$$
$$= 2744\ \text{W/m}^2$$

Step 4 of 4

The radiosity of the plate is

$$J = E_{\text{emitted}} + E_{\text{reflected}}$$
$$= 2740.38 + 2744$$
$$= 5484.38\ \text{W/m}^2$$

Thus the radiosity of the plate is $\boxed{J = 5484.38\ \text{W/m}^2}$

Question: 21.032P

The spectral emissivity function of an opaque surface at 1000 K is approximated as

$$\varepsilon_\lambda = \begin{cases} \varepsilon_1 = 0.4, & 0 \le \lambda < 3\ \mu m \\ \varepsilon_2 = 0.7, & 3\ \mu m \le \lambda < 6\ \mu m \\ \varepsilon_3 = 0.3, & 6\ \mu m \le \lambda < \infty \end{cases}$$

Determine the average emissivity of the surface and the rate of radiation emission from the surface, in W/m2.

Step 1 of 4

Given data:

The temperature of the surface $T = 1000\ \text{K}$

In order to find the average emissivity of the surface, the fraction of radiation is determined.

The fraction of radiation in the range of $3\mu m$ to $6\mu m$ is

$$\lambda_1 T = (3\ \mu\text{m})(1000\ \text{K})$$
$$= 3000\ \mu\text{m} \cdot \text{K}$$

From the blackbody radiation function f_λ

At $\lambda_1 T = 3000\ \mu\text{m} \cdot \text{K}$

$$f_{\lambda_1} = 0.273232$$

Step 2 of 4

$$\lambda_2 T = (6\ \mu\text{m})(1000\ \text{K})$$
$$= 6000\ \mu\text{m} \cdot \text{K}$$

From the blackbody radiation function f_λ

At $\lambda_2 T = 6000\ \mu\text{m} \cdot \text{K}$

$$f_{\lambda_2} = 0.737818$$

Step 3 of 4

The average emissivity of the surface is determined using the formula,

$$\varepsilon(T) = \varepsilon_1 f_{\lambda_1} + \varepsilon_2 \left(f_{\lambda_2} - f_{\lambda_1}\right) + \varepsilon_3 \left(1 - f_{\lambda_2}\right)$$

Substituting the known values in the above relation, we have,

$$\varepsilon(T) = (0.4)(0.273232) + (0.7)(0.737818 - 0.273232) + 0.3(1 - 0.737818)$$
$$= 0.1092928 + 0.3252102 + 0.0786546$$
$$= 0.5131$$

Therefore, the average rate of emissivity of the given opaque surface is $\boxed{\varepsilon(T) = 0.513}$.

Step 4 of 4

The rate of emission from the surface is expressed as,

$$E = \varepsilon \sigma T^4$$

$$E = (0.513)\left(5.67 \times 10^{-8}\right)(1000)^4$$
$$= 29{,}096\ \text{W/m}^2$$
$$\approx 29.1\ \text{W/m}^2$$

Therefore, rate of radiation emission form the surface is $\boxed{E = 29.1\ \text{kW/m}^2}$.

Question: 21.033P

A 5-in-diameter spherical ball is known to emit radiation at a rate of 480 Btu/h when its surface temperature is 950 R. Determine the average emissivity of the ball at this temperature.

Step 1 of 2

Given

Diameter of the spherical ball $D = 5$ in

$= 5/12$ ft

Emit radiation rate $E = 480$ Btu/h

Surface temperature $T = 950$ R

Step 2 of 2

Surface area of the spherical ball is

$$A = \pi D^2$$

$$= \pi(5/12 \text{ ft})^2$$

$$= 0.5454 \text{ ft}^2$$

The average emissivity of the ball at this temperature is determined by

$$\varepsilon_{avg} = \frac{E}{A\sigma T^4}$$

$$= \frac{480 \text{ Btu/h}}{(0.5454 \text{ ft}^2)(0.1714 \times 10^{-8} \text{ Btu/h.ft}^2 \cdot \text{R}^4)(950 \text{ R})^4}$$

$$= 0.63$$

Therefore, average emissivity of the ball is $\boxed{\varepsilon_{avg} = 0.63}$.

Question: 21.034P

A furnace that has a 40-cm ×40-cm glass window can he considered to be a blackbody at 1200 K. If the transmissivity of the glass is 0.7 for radiation at wavelengths less than 3 μm and zero for radiation at wavelengths greater than 3 μm, determine the fraction and the rate of radiation coming from the furnace and transmitted through the window.

Step 1 of 3

Given

Glass window at temperature $T = 1200\ \text{K}$

Transmissivity of surface at wavelength less than $3\ \mu\text{m}$ is $\tau_1 = 0.7$

Transmissivity of surface at wavelength greater than $3\ \mu\text{m}$ is $\tau_2 = 0$

Surface area of the glass window $A_s = a^2$

$$= (0.4)^2$$

$$= 0.16\ \text{m}^2$$

Step 2 of 3

Considering the product of the wavelength and temperature,

$$\lambda T = (3\ \mu\text{m})(1200\ \text{K})$$

$$\lambda T = 3600\ \mu\text{mK}$$

From blackbody radiation functions table at $\lambda T = 3600$,

$f_{\lambda_1} = 0.403607$

Step 3 of 3

The fraction of radiation coming from the furnace and transmitted through the window is

$$\tau(T) = \tau_1 f_\lambda + \tau_2(1 - f_\lambda)$$

$$\tau(T) = (0.7)(0.403607) + (0)(1 - 0.403607)$$

$$\tau(T) = 0.283$$

The rate of radiation is $G_w = \tau A \sigma T^4$

$$G_w = 0.283(0.4 \times 0.4\ \text{m}^2)(5.67 \times 10^{-8}\ \text{W/m}^2.\text{K}^4)(1200\ \text{K})^4$$

$$G_w = 5323.7\ \text{W}$$

Rate of radiation coming from the furnace and transmitted through the window is

$\boxed{G_w = 5323.7\ \text{W}}$

Question: 21.035P

The emissivity of a tungsten filament can be approximated to be 0.5 for radiation at wavelengths less than 1 μm and 0.15 for radiation at greater than 1 μm. Determine the average emissivity of the filament at (*a*) 1500 K and (*b*) 2500 K. Also, determine the absorptivity and reflectivity of the filament at both temperatures.

Step 1 of 5

Given

The emissivity $\varepsilon_1 = 0.5$ for wavelength less than $1\ \mu m$

The emissivity $\varepsilon_2 = 0.15$ for wavelength greater than $1\ \mu m$

Step 2 of 5

(a) At $T = 1500\ K$

Average emissivity of the surface for the radiation at $T = 1500\ K$ is determined as follows

Fraction of radiation at wavelength less than 5 μm is calculated by

$$\lambda T = (1\ \mu m)(1500\ K)$$
$$= 1500\ \mu mK$$

From Blackbody radiation function f_λ

$$\lambda T = 1500\ \mu mK$$

$$f_\lambda = 0.01375$$

Average emissivity of the surface is determined by

$$\varepsilon(T) = \varepsilon_1 f_\lambda + \varepsilon_2(1 - f_\lambda)$$
$$\varepsilon(T) = (0.5)(0.01375) + (0.15)(1 - 0.01375)$$
$$\boxed{\varepsilon(T) = 0.155}$$

From Kirchhoff's law the absorptivity of the surface becomes $\boxed{\therefore \alpha = \varepsilon = 0.155}$

Step 3 of 5

Then the reflectivity of the surface is determined by

$$\alpha + \rho = 1$$

$$\rho = 1 - \alpha$$

$$= 1 - 0.155$$

$$\boxed{\rho = 0.854}$$

Step 4 of 5

(b) $T = 2500\ K$

Average emissivity of the surface for the radiation at $T = 1500\ K$ is determined as follows

Fraction of radiation at wavelength less than 5 μm is calculated by

$$\lambda T = (1\ \mu m)(2500\ K)$$
$$= 2500\ \mu mK$$

From Blackbody radiation function f_λ

At $\lambda T = 2500\ \mu mK$

$$f_\lambda = 0.1617$$

Average emissivity of the surface is determined by

$$\varepsilon(T) = \varepsilon_1 f_\lambda + \varepsilon_2(1 - f_\lambda)$$
$$\varepsilon(T) = (0.5)(0.1617) + (0.15)(1 - 0.1617)$$
$$\boxed{\varepsilon(T) = 0.2066}$$

From Kirchhoff's law the absorptivity of the surface becomes $\boxed{\alpha = \varepsilon = 0.2066}$

Step 5 of 5

Then the reflectivity of the surface is determined by

$$\alpha + \rho = 1$$

$$\rho = 1 - \alpha$$

$$= 1 - 0.2066$$

$$\boxed{\rho = 0.7934}$$

Question: 21.036P

The variations of the spectral emissivity of two surfaces are as given in Fig. P21-36. Determine the average emissivity of each surface at $T = 3000$ K. Also, determine the average absorptivity and reflectivity of each surface for radiation coming from a source at 3000 K. Which surface is more suitable to serve as a solar absorber?

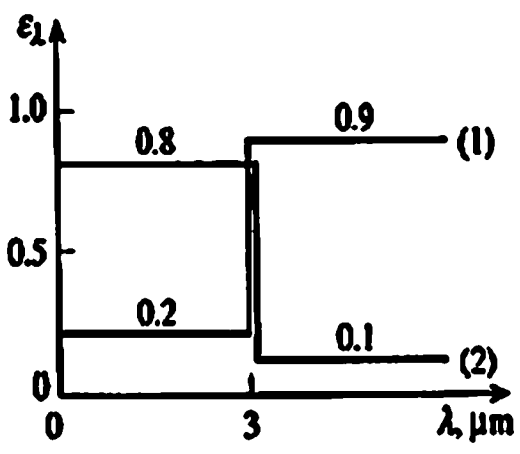

FIGURE P21–36

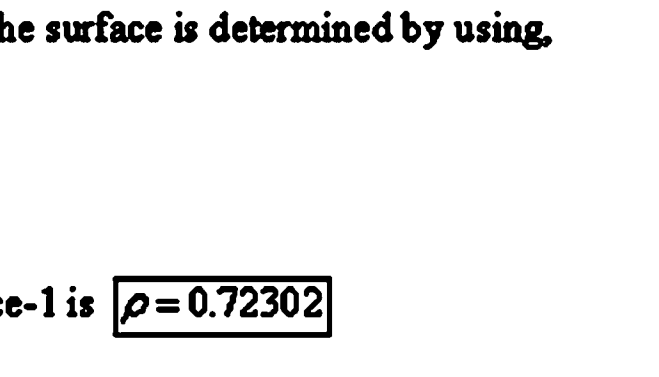
Step 1 of 9

Given temperature of the surface, $T = 3000$ K



Emissivity of the surface-1 at wavelength less than 3 μm , $\varepsilon_{1a} = 0.2$

Emissivity of the surface-1 at wavelength greater than 3 μm , $\varepsilon_{1b} = 0.9$

Emissivity of the surface-2 at wavelength less than 3 μm , $\varepsilon_{2a} = 0.8$

Emissivity of the surface-2 at wavelength greater than 3 μm , $\varepsilon_{2b} = 0.1$

Step 2 of 9

Step 3 of 9

For the surface-1,

Considering the product of the wavelength and temperature,

$\lambda T = (3\ \mu m)(3000\ K)$

$\lambda T = 9{,}000\ \mu mK$

From blackbody radiation functions table at $\lambda T = 9000$,

$f_{\lambda 1} = 0.890029$

Step 4 of 9

Average emissivity of the surface is determined by using,

$$\varepsilon(T) = \varepsilon_{1a} f_{\lambda 1} + \varepsilon_{1b}(1 - f_{\lambda 1})$$

$$\varepsilon(T) = (0.2)(0.890029) + (0.9)(1 - 0.890029)$$

$$\varepsilon(T) = 0.27698$$

Hence emissivity of the surface-1, $\boxed{\varepsilon = 0.27698}$

From Kirchhoff's law, the absorptivity of the surface is $\boxed{\alpha = \varepsilon = 0.27698}$

Step 5 of 9

Then the reflectivity of the surface is determined by using,

$$\alpha + \rho = 1$$

$$\rho = 1 - \alpha$$

$$\rho = 1 - 0.27698$$

$$\rho = 0.72302$$

Reflectivity of the surface-1 is $\boxed{\rho = 0.72302}$

Step 6 of 9

For the surface-2,

Considering the product of the wavelength and temperature,

$\lambda T = (3\ \mu m)(3000\ K)$

$\lambda T = 9{,}000\ \mu mK$

From blackbody radiation functions table at $\lambda T = 9000$,

$f_{\lambda 2} = 0.890029$

Step 7 of 9

Average emissivity of the surface is determined by using,

$$\varepsilon(T) = \varepsilon_{2a} f_{\lambda 2} + \varepsilon_{2b}(1 - f_{\lambda 2})$$

$$\varepsilon(T) = (0.8)(0.890029) + (0.1)(1 - 0.890029)$$

$$\varepsilon(T) = 0.72302$$

Hence emissivity of the surface-2, $\boxed{\varepsilon = 0.72302}$

From Kirchhoff's law, the absorptivity of the surface is $\boxed{\alpha = \varepsilon = 0.72302}$

Step 8 of 9

Then the reflectivity of the surface is determined by using,

$$\alpha + \rho = 1$$

$$\rho = 1 - \alpha$$

$$\rho = 1 - 0.72302$$

$$\rho = 0.27698$$

Reflectivity of the surface-2 is $\boxed{\rho = 0.27698}$

Step 9 of 9

The second surface is more suitable to serve as a solar absorber since its absorptivity for short wavelength radiation (typical of radiation emitted by a high-temperature source such as the sun) is high, and its emissivity for long wavelength radiation (typical of emitted radiation from the absorber plate) is low.

Question: 21.037P

The emissivity of a surface coated with aluminum oxide can be approximated to be 0.15 for radiation at wavelengths less than 5 μm and 0.9 for radiation at wavelengths greater than 5 μm. Determine the average emissivity of this surface at (*a*) 5800 K and (*b*) 300 K. What can you say about the absorptivity of this surface for radiation coming from sources at 5800 K and 300 K?

Step 1 of 5

Given data:

The emissivity for the wave lengths less than $5\,\mu m$ is $\varepsilon_1 = 0.15$

The emissivity for the wave lengths greater than $5\,\mu m$ is $\varepsilon_2 = 0.9$

Step 2 of 5

a)

Average emissivity of the surface for the radiation at $T = 5800\ \text{K}$ is determined as

Fraction of radiation at wavelength $5\,\mu\text{m}$ is calculated by

$$\lambda T = (5\ \mu\text{m})(5800\ \text{K})$$
$$= 29{,}000\ \mu\text{mK}$$

From the black body radiation function f_λ table

To the corresponding λT value take black body radiation functions

$$f_\lambda = 0.992215 + (0.995340 - 0.992215)\left[\frac{29000 - 25000}{30000 - 25000}\right]$$

$$f_\lambda = 0.994715$$

Step 3 of 5

Average emissivity of the surface is determined by

$$\varepsilon(T) = \varepsilon_1 f_\lambda + \varepsilon_2 (1 - f_\lambda)$$
$$= (0.15)(0.994715) + (0.9)(1 - 0.994715)$$
$$= 0.153$$

$\therefore$ The average emissivity is $\boxed{\varepsilon(T) = 0.153}$

From Kirchhoff's law the absorptivity of the surface becomes $\boxed{\therefore\ \alpha = \varepsilon = 0.153}$

Step 4 of 5

b)

Average emissivity of the surface for the radiation at $T = 300\ \text{K}$ is determined as follows

Fraction of radiation at wavelength $5\ \mu\text{m}$ is calculated by

$$\lambda T = (5\ \mu\text{m})(300\ \text{K})$$
$$= 1500\ \mu\text{mK}$$

From the black body radiation function f_λ table

To the corresponding λT value take black body radiation functions

$$f_\lambda = 0.007790 + (0.019718 - 0.007790)\left[\frac{1500 - 1400}{1600 - 1400}\right]$$

$$f_\lambda = 0.013754$$

Step 5 of 5

Average emissivity of the surface is determined by

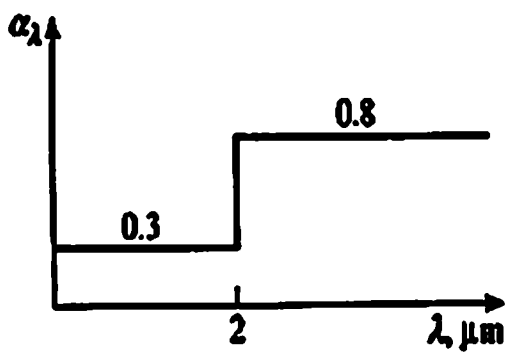
$$\varepsilon(T) = \varepsilon_1 f_\lambda + \varepsilon_2 (1 - f_\lambda)$$
$$= (0.15)(0.013754) + (0.9)(1 - 0.013754)$$

$\therefore$ The average emissivity is $\boxed{\varepsilon(T) = 0.889}$

From Kirchhoff's law the absorptivity of the surface becomes $\boxed{\therefore\ \alpha = \varepsilon = 0.889}$

Question: 21.038P

The variation of the spectral absorptivity of a surface is as given in Fig. P21-38. Determine the average absorptivity and reflectivity of the surface for radiation that originates from a source at $T = 2500$ K. Also, determine the average emissivity of this surface at 3000 K.



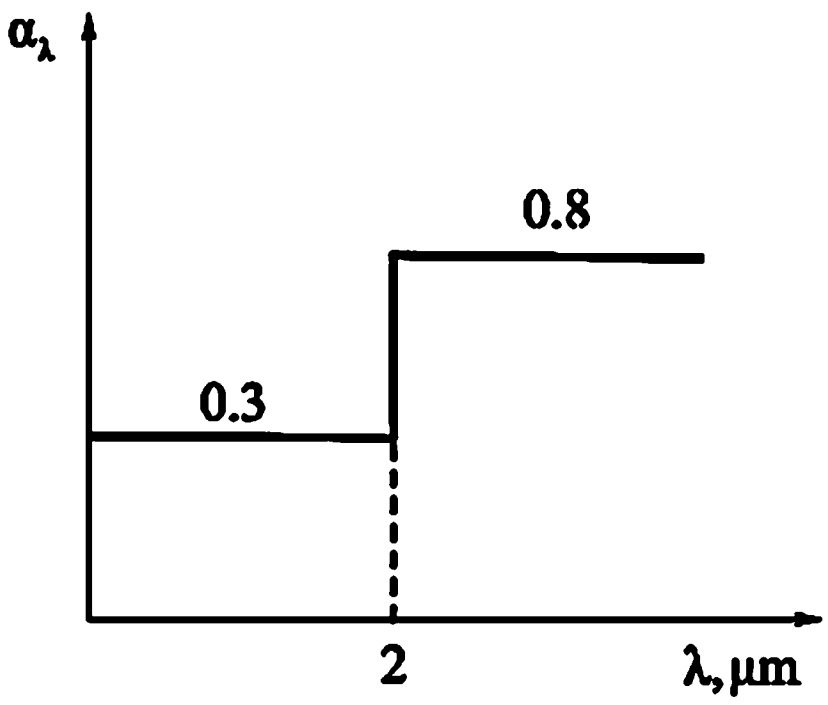


FIGURE P21–38

Step 1 of 4

Step 2 of 4

Considering the figure to determine the average absorptivity and reflectivity of the surface for radiation at T= 2500 K calculated as follows

Fraction of radiation at wavelength less than 2 μm is calculated by

$\lambda_1 T = (2\ \mu m)(2500\ K)$

$= 5000\ \mu mK$

From Blackbody radiation function f_λ

At $\lambda_1 T = 5000\ \mu mK$

$f_{\lambda_1} = 0.633747$

Average absorptivity of the surface is determined by

$$\alpha(T) = \alpha_1 f_\lambda + \alpha_2 (1 - f_\lambda)$$
$$= (0.3)(0.633747) + (0.8)(1 - 0.633747)$$
$$= 0.48$$

Therefore, average absorptivity of the surface is $\boxed{\alpha(T) = 0.48}$

Step 3 of 4

Then the reflectivity of the surface is determined by

$$\alpha + \rho = 1$$
$$\rho = 1 - \alpha$$
$$= 1 - 0.48$$
$$= 0.52$$

Therefore, average reflectivity of the surface is $\boxed{\rho = 0.52}$

Step 4 of 4

The average emissivity of the surface at T= 3000 K is determined using Kirchhoff's law i.e. $\alpha = \varepsilon$

$\lambda T = (2\ \mu m)(3000\ K)$

$= 6000\ \mu mK$

From Blackbody radiation function f_λ

At $\lambda T = 6000\ \mu mK$

$f_\lambda = 0.737818$

Average absorptivity of the surface is determined by

$$\varepsilon(T) = \varepsilon_1 f_\lambda + \varepsilon_2 (1 - f_\lambda)$$
$$= (0.3)(0.737818) + (0.8)(1 - 0.737818)$$
$$= 0.43$$

Therefore, average emissivity of the surface is $\boxed{\varepsilon(T) = 0.43}$.

Question: 21.039P

The reflectivity of aluminum coated with lead sulfate is 0.35 for radiation at wavelengths less than 3 μm and 0.95 for radiation greater than 3 μm. Determine the average reflectivity of this surface for solar radiation (T ≈5800 K) and radiation coming from surfaces at room temperature (T ≈ 300 K). Also, determine the emissivity and absorptivity of this surface at both temperatures. Do you think this material is suitable for use in solar collectors?

Step 1 of 7

Given

Reflectivity of surface at wavelength less than $3\,\mu m$ is $\rho_1 = 0.35$

Reflectivity of surface at wavelength greater than $3\,\mu m$ is $\rho_2 = 0.95$

Temperature of the solar radiation is $T = 5800\ K$

Considering the product of the wavelength and temperature,

$\lambda_1 T = (3\ \mu m)(5800\ K)$

$\lambda_1 T = 17400\ \mu mK$

From blackbody radiation functions table at $\lambda T = 17400$,

$f_{\lambda 1} = 0.978746$

Step 2 of 7

Average emissivity of the surface is determined by using,

$$\rho(T) = \rho_1 f_{\lambda 1} + \rho_2 (1 - f_{\lambda 1})$$
$$\rho(T) = (0.35)(0.978746) + (0.95)(1 - 0.978746)$$
$$\rho(T) = 0.362$$

$\boxed{\rho(T) = 0.362}$

Step 3 of 7

The reflectivity of the surface is determined by using,

$$\alpha + \rho = 1$$
$$\alpha = 1 - \rho$$
$$\alpha = 1 - 0.362$$
$$\alpha = 0.638$$

absorptivity of the surface, $\boxed{\alpha = 0.638}$

From Kirchhoff's law the emissivity of the surface becomes $\boxed{\alpha = \varepsilon = 0.638}$

Step 4 of 7

Temperature of the room is $T = 300\ K$

Considering the product of the wavelength and temperature,

$\lambda_1 T = (3\ \mu m)(300\ K)$

$\lambda_1 T = 900\ \mu mK$

From blackbody radiation functions table at $\lambda T = 900$,

$f_{\lambda 1} = 0.0001685$

Step 5 of 7

Average emissivity of the surface is determined by

$$\rho(T) = \rho_1 f_\lambda + \rho_2 (1 - f_\lambda)$$
$$\rho(T) = (0.35)(0.0001685) + (0.95)(1 - 0.0001685)$$
$$\rho(T) = 0.95$$

$\boxed{\rho(T) = 0.95}$

Step 6 of 7

Then the reflectivity of the surface is determined by

$$\alpha + \rho = 1$$
$$\alpha = 1 - \rho$$
$$\alpha = 1 - 0.95$$
$$\alpha = 0.05$$

absorptivity of the surface, $\boxed{\alpha = 0.05}$

From Kirchhoff's law the emissivity of the surface becomes $\boxed{\alpha = \varepsilon = 0.05}$

Step 7 of 7

The temperature of the aluminum plate is close to room temperature, and thus emissivity of the plate will be equal to its absorptivity at room temperature. That is,

$$\varepsilon = \varepsilon_{room} = 0.05$$
$$\alpha = \alpha_s = 0.638$$

This makes it suitable for using it as solar collector. ($\alpha_s = 1$ and $\varepsilon_{room} = 0$ for an ideal solar collector)

Question: 21.040P

The variation of the spectral transmissivity of a 0.6-cm-thick glass window is as given in Fig. P21-40. Determine the average transmissivity of this window for solar radiation ($T \approx 5800$ K) and radiation coming from surfaces at room temperature ($T \approx 300$ K). Also, determine the amount of solar radiation transmitted through the window for incident solar radiation of 650 W/m2.

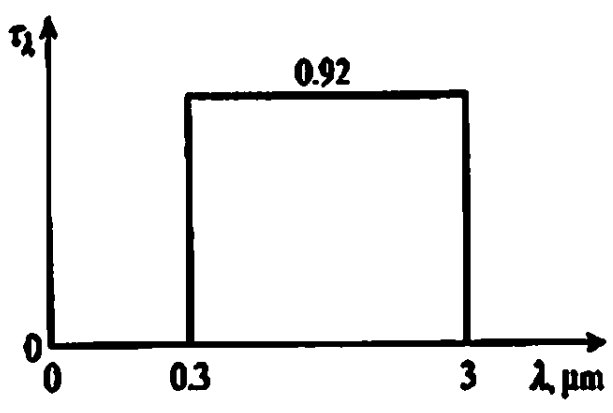

FIGURE P21–40

Step 1 of 7

Calculate the value of the λT for surface at temperature $5800\ \text{K}$ and wavelength $0.3\ \mu\text{m}$.

Substitute $0.3\ \mu\text{m}$ for λ and $5800\ \text{K}$ for T.

$$\lambda_1 T_1 = (0.3\ \mu\text{m})(5800\ \text{K})$$
$$\lambda_1 T_1 = 1740\ \mu\text{mK}$$

Determine the black body radiation function, f_{λ_1} of the window for $1740\ \mu\text{mK}$.

Take the black body radiation function by linear interpolating the value between $1600\ \mu\text{mK}$ and $1800\ \mu\text{mK}$.

$$f_{\lambda_1} = 0.019718 + (0.039341 - 0.019718)\left[\frac{1740-1600}{1800-1600}\right]$$
$$f_{\lambda_1} = 0.03345$$

Step 2 of 7

Calculate the value of the λT for surface at temperature $5800\ \text{K}$ and wavelength $3\ \mu\text{m}$.

Substitute $3\ \mu\text{m}$ for λ and $5800\ \text{K}$ for T.

$$\lambda_2 T_2 = (3\ \mu\text{m})(5800\ \text{K})$$
$$\lambda_2 T_2 = 17400\ \mu\text{mK}$$

Determine the black body radiation function, f_{λ_2} of the window for $17400\ \mu\text{mK}$.

Take the black body radiation function by linear interpolating the value between $16000\ \mu\text{mK}$ and $18000\ \mu\text{mK}$.

$$f_{\lambda 2} = 0.973814 + (0.980860 - 0.973814)\left[\frac{17400-16000}{18000-16000}\right]$$
$$f_{\lambda 2} = 0.9787462$$

Step 3 of 7

Calculate the average transmissivity of the surface at $5800\ \text{K}$.

$$\tau(T) = \tau_1\left(f_{\lambda_2} - f_{\lambda_1}\right)$$

Here, $\tau(T)$ is the average transmissivity of the surface and τ_1 is the transmissivity of the surface.

Substitute 0.9787462 for f_{λ_2} , 0.03345 for f_{λ_1} and 0.92 for τ_1

$$\tau(T) = (0.92)(0.9787462 - 0.03345)$$
$$\tau(T) = 0.87$$

Thus the transmissivity is $\boxed{0.87}$.

Step 4 of 7

Calculate the value of the λT for surface at temperature $300\ \text{K}$ and wavelength $0.3\ \mu\text{m}$.

Substitute $0.3\ \mu\text{m}$ for λ and $300\ \text{K}$ for T.

$$\lambda_1 T_1 = (0.3\ \mu\text{m})(300\ \text{K})$$
$$\lambda_1 T_1 = 90\ \mu\text{mK}$$

Determine the black body radiation function, $f_{\lambda 1}$ of the window for $90\ \mu\text{mK}$.

$$f_{\lambda 1} = 0$$

Step 5 of 7

Calculate the value of the λT for surface at temperature $300\ \text{K}$ and wavelength $0.3\ \mu\text{m}$.

Substitute $3\ \mu\text{m}$ for λ and $300\ \text{K}$ for T.

$$\lambda_2 T_2 = (3\ \mu\text{m})(300\ \text{K})$$
$$\lambda_2 T_2 = 900\ \mu\text{mK}$$

Determine the black body radiation function, $f_{\lambda 2}$ of the window for $900\ \mu\text{mK}$.

Take the black body radiation function by linear interpolating the value between $800\ \mu\text{mK}$ and $1000\ \mu\text{mK}$.

$$f_{\lambda_2} = 0.000016 + (0.000321 - 0.000016)\left[\frac{900-800}{1000-800}\right]$$
$$f_{\lambda_2} = 0.00001685$$

Step 6 of 7

Calculate the average transmissivity of the surface at $300\ \text{K}$.

$$\tau(T) = \tau_1\left(f_{\lambda_2} - f_{\lambda_1}\right)$$

Substitute 0.00001685 for f_{λ_2} , 0 for f_{λ_1} and 0.92 for τ_1

$$\tau(T) = (0.92)(0.00001685 - 0)$$
$$\tau(T) = 0.000016$$

Thus the transmissivity is $\boxed{0.000016}$.

Step 7 of 7

Calculate the amount of solar radiation transmitted through this glass.

$$G_{tr} = \tau G_{\text{incident}}$$

Here, G_{incident} is the incident solar radiation and τ is transmissivity of surface.

Substitute $650\ \text{W/m}^2$ for G_{incident} and 0.87 for τ

$$G_{tr} = 0.87(650\ \text{W/m}^2)$$
$$G_{tr} = 566\ \text{W/m}^2$$

Thus, the amount of solar radiation transmitted is $\boxed{566\ \text{W/m}^2}$.

Question: 21.041P

An opaque horizontal plate is well insulated on the edges and the lower surface. The irradiation on the plate is 3000 W/m2, of which 500 W/m2 is reflected. The plate has a uniform temperature of 700 K and has an emissive power of 5000 W/m2. Determine the total emissivity and absorptivity of the plate.

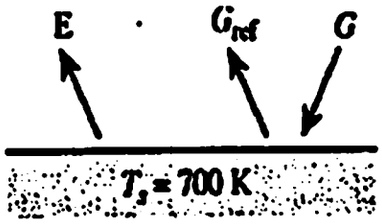

FIGURE P21-41

Step 1 of 3

Irradiation on the plate, $G = 3000\ \text{W/m}^2$

Reflected irradiation, $G_{ref} = 500\ \text{W/m}^2$

Temperature of the plate, $T = 700\ \text{K}$

Emissive power of the plate, $E = 5000\ \text{W/m}^2$

Step 2 of 3

The emissivity of the plate is given by

$$\varepsilon = \frac{E}{E_b}$$
$$= \frac{E}{\sigma T^4}$$
$$= \frac{5000}{\left(5.67\times10^{-8}\right)700^4}$$
$$= 0.367$$

Thus the emissivity of the plate is $\boxed{\varepsilon = 0.367}$

Step 3 of 3

The absorptivity of the plate is

$$\alpha = \frac{G_{abs}}{G}$$
$$= \frac{G - G_{ref}}{G}$$
$$= \frac{3000 - 500}{3000}$$
$$= 0.833$$

Thus the absorptivity of the plate is $\boxed{\alpha = 0.833}$

Question: 21.042P

A horizontal plate is experiencing uniform irradiation on the both upper and lower surfaces. The ambient air temperature surrounding the plate is 290 K with a convection heat

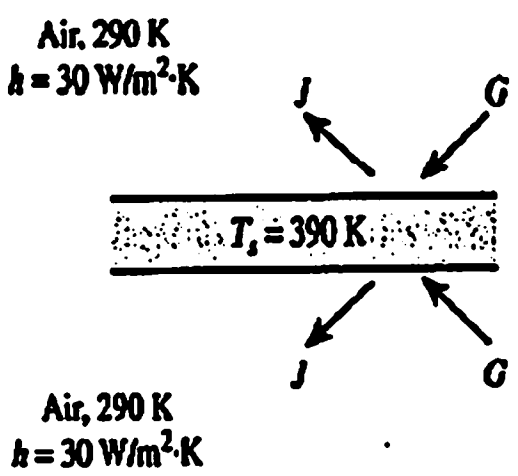

FIGURE P21–42

transfer coefficient of 30 W/m2•K. Both upper and lower surfaces of the plate have a radiosity of 4000 W/m2, and the plate temperature is maintained uniformly at 390 K. If the plate is not opaque and has an absorptivity of 0.527, determine the irradiation and emissivity of the plate.

Step 1 of 5

Temperature of the plate, $T = 390$ K
Temperature of the air, $T_\infty = 290$ K

The convective coefficient of air is $h = 30$ W/m^{2}K

Radiocity of the plate, $J = 4000$ W/m^2
Absorptivity of the plate, $\alpha = 0.527$
Let the irradiation on the plate be G
Let the Emissive power of the plate be E

Step 2 of 5

The upper and lower surfaces of the plate are subjected to similar conditions. Hence it is sufficient to consider either of the surfaces for energy balance. By considering the energy balance on upper surface of the plate, we get

$$Q_{abs} = Q_{con} + E$$
$$\alpha G = h(T - T_\infty) + E$$
$$E = (0.527 \times G) - 30(390 - 290)$$
$$E = (0.527 \times G) - 3000 \quad \text{..... (1)}$$

Step 3 of 5

From the definition of the radiocity, we have

$$J = Q_{ref} + E$$
$$E = J - Q_{ref}$$
$$E = J - \rho G$$
$$E = J - (1 - \alpha)G$$
$$E = 4000 - (1 - 0.527)G$$
$$E = 4000 - (0.473 \times G) \quad \text{..... (2)}$$

Step 4 of 5

By considering equations (1) and (2), we get

$$(0.527 \times G) - 3000 = 4000 - (0.473 \times G)$$
$$(0.527 + 0.473)G = 4000 + 3000$$
$$G = 7000 \text{ W/m}^2$$

Thus the irradiation on the surface is $\boxed{G = 7000 \text{ W/m}^2}$

Step 5 of 5

Substituting the values is equation (2), we get

$$E = 4000 - (0.473 \times G)$$
$$\varepsilon E = 4000 - (0.473 \times 7000)$$
$$\varepsilon = \frac{4000 - 3311}{E}$$
$$= \frac{4000 - 3311}{(5.67 \times 10^{-8})390^4}$$
$$= 0.525$$

Thus the emissivity of the plate is $\boxed{\varepsilon = 0.525}$

Question: 21.043P

What does the view factor represent? When is the view factor from a surface to itself not zero?

Step 1 of 1

View Factor is a geometric quantity. It does not depend on surface properties and temperature. The other names for view factor are shape factor, configuration factor, and angle factor.

The view factor is denoted as $F_{i \to j}$ or F_{ij} . It indicates the fraction of the radiation leaving surface *i* that strikes surface *j*.

For **concave surfaces**, view factor from a surface to itself not zero.

Question: 21.044P

What is the crossed-strings method? For what kind of geometries is the crossed-strings method applicable?

Step 1 of 1

Crossed strings method is applicable for the channels and ducts that are very long in one direction relative to the other directions. Such geometries can conveniently be considered to be two-dimensional, since any radiation interaction through their end surface is negligible. These geometries can subsequently be modeled as being infinitely long

View factor for the crossed strings method is expressed as

$$F_{i\to j}=\frac{\sum(\text{Crossed strings})-\sum(\text{Uncrossed strings})}{2\times(\text{String on surface } i)}$$

The crossed-string method is applicable even when the two surfaces considered share a common edge, as in a triangle. I such cases, the common edge can be treated as an imaginary string of zero length. The method can also be applied to surfaces that are partially blocked by other surfaces by allowing the strings to bend around the blocking surfaces

Question: 21.045P

What are the summation rule and the superposition rule for view factors?

Step 1 of 1

The sum of the view factors from surface i of an enclosure to all surfaces of the enclosure, including to itself, must equal unity. This is known as the summation rule for an enclosure and it is expressed as

$$\sum_{j=1}^{N} F_{i \to j} = 1$$

Superposition rule can be expressed as the view factor from a surface i to a surface j is equal to the sum of the view factors from surface i to the parts of surface j.

Question: 21.046P

How can you determine the view factor *F*12 when the view factor *F*21 and the surface areas are available?

Step 1 of 1

The view factors $F_{i\to j}$ and $F_{j\to i}$ are not equal to each other unless the areas of the two surfaces are. That is

$F_{j\to i} = F_{i\to j}$ when $A_i = A_j$

$F_{j\to i} \neq F_{i\to j}$ when $A_i \neq A_j$

The pair of view factors $F_{i\to j}$ and $F_{j\to i}$ are related to each other by the reciprocity rule

$A_i F_{ij} = A_j F_{ji}$

Where A_i is the area of the surface i and A_j is the area of the surface j.

Therefore,

$A_1 F_{12} = A_2 F_{21}$

$$F_{12} = \frac{A_2}{A_1} F_{21}$$

Question: 21.047P

Consider an enclosure consisting of five surfaces. How many view factors does this geometry involve? How many of these view factors can be determined by the application of the reciprocity and summation rules?

Step 1 of 1

An enclosure consisting of eight surfaces involves view factors are

$$N^2 = 5^2$$
$$= 25$$

The total number of view factors that need to be evaluated directly for the N- surfaces enclosure becomes

$$\frac{N(N-1)}{2} = \frac{5(5-1)}{2}$$
$$= 10$$

The remaining $25-10=15$ the view factors can be determined from the 15 equations that are obtained by the application of the reciprocity and summation rules.

Question: 21.048P

Consider a cylindrical enclosure with *A*1, *A*2, and *A*3 representing the internal base, top, and side surfaces, respectively. Using the length to diameter ratio, $K = L/D$, determine (*a*) the expression for the view factor between the base and the side surface *F*13 in terms of *K* and (*b*) the value of the view factor *F*13 for $L = D$.

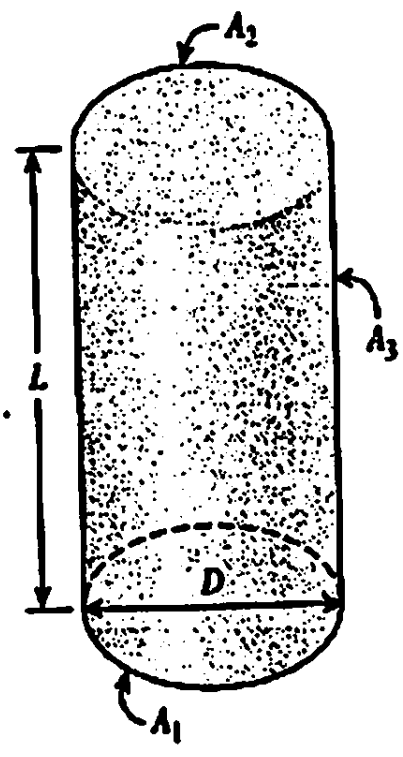

FIGURE P21–48

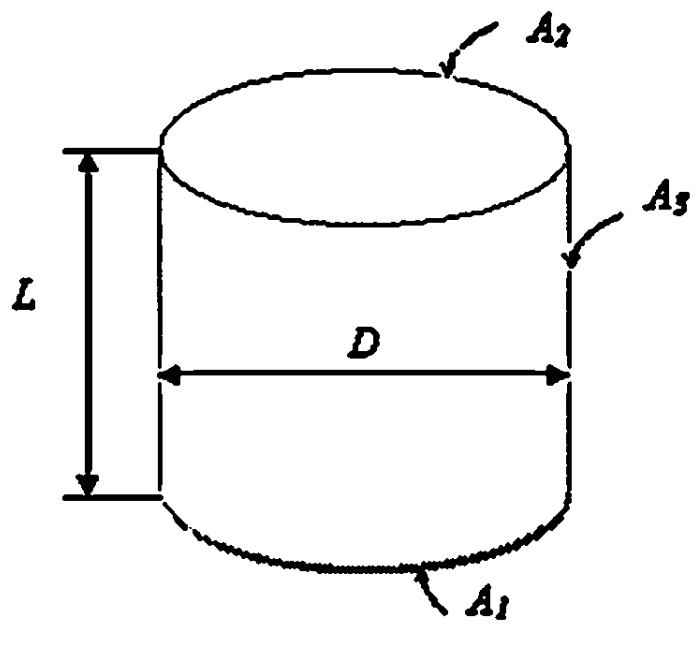
Step 1 of 5

Given data:

Number of surfaces in an enclosure, $N = 13$



Surface area of the base, $A_1 = \frac{\pi}{4}D^2$

Surface area of the top, $A_2 = \frac{\pi}{4}D^2$

Surface area of the side surface, $A_3 = \pi DL$

Length to diameter ratio, $K = \frac{L}{D}$

Step 2 of 5

Step 3 of 5

a) The view factor from the base to the top can be determined from the table view factor expressions for common geometries

$$F_{12} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

Where, $R = \frac{D}{2L}$

By rewriting the R in terms of K, $R = \frac{1}{2K}$

Therefore, the view factor from the base to the top written as

$$F_{12} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

$$= 1 + \frac{1 - \sqrt{4(1/2K)^2 + 1}}{2(1/2K)^2}$$

$$= 1 + \frac{1 - \sqrt{1/K^2 + 1}}{1/2K^2}$$

$$= 1 + 2K\left(K - \sqrt{K^2 + 1}\right)$$

Step 4 of 5

The view factor from the base to the side surface is determined by applying the summation rule to be

$$F_{11} + F_{12} + F_{13} = 1$$

$$F_{13} = 1 - F_{11} - F_{12}$$

Since the base surface is flat and thus $F_{11} = 0$

Therefore substituting the known values in the above expression the view factor from the base to the side surface can be expressed as

$$F_{13} = 1 - F_{11} - F_{12}$$

$$= 1 - 0 - \left(1 + 2K\left(K - \sqrt{K^2 + 1}\right)\right)$$

$$= 2K\sqrt{K^2 + 1} - 2K^2$$

$$\boxed{F_{13} = 2K\sqrt{K^2 + 1} - 2K^2}$$

Step 5 of 5

b) The value of the view factor from the base to the side surface for $L = D$ can be determined as

For $L = D$ the value of K is

$$K = \frac{L}{D}$$

$$= \frac{D}{D}$$

$$K = 1$$

And by substituting the value of K, the view factor F_{13} can be calculated as

$$F_{13} = 2K\sqrt{K^2 + 1} - 2K^2$$

$$= 2 \times 1 \times \sqrt{1^2 + 1} - 2 \times 1^2$$

$$F_{13} = 0.828$$

$$\boxed{F_{13} = 0.828}$$

Question: 21.049P

Two infinitely long parallel plates of width *w* are located at *w* distance apart, as shown in the figure. Using the Hottel's crossed-strings method, determine the view factor *F*12.

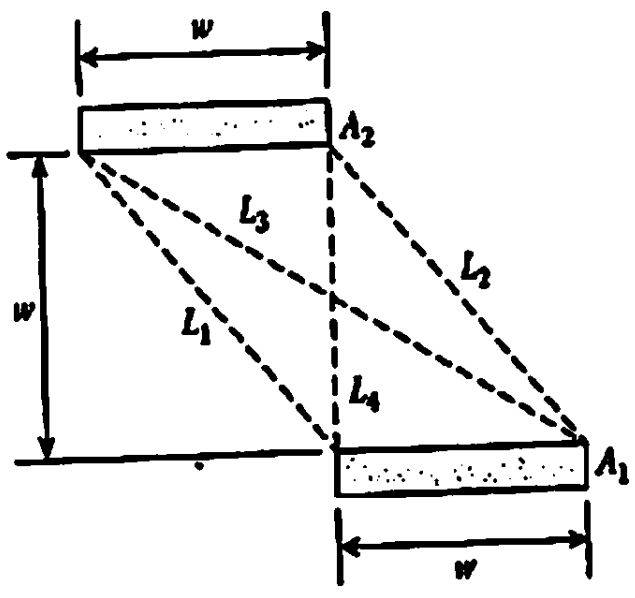


FIGURE P21–49

Step 1 of 10

Given data:

Width of the two plates is w and the view factors between two infinitely long parallel plates are to be determined using the Hottel's crossed-strings method.

Step 2 of 10

Assumptions:

The surfaces are diffuse emitters and reflectors.

Step 3 of 10

L_2

L_3

Step 4 of 10

w

L_1

Step 5 of 10

L_4

Step 6 of 10

Step 7 of 10

Step 8 of 10

Step 9 of 10

The view factor from the base plate to the top plate can be determined using the Hottel's cross-strings method as

$$F_{12} = \frac{\sum(\text{Crossed strings}) - \sum(\text{Uncrossed strings})}{2 \times (\text{String on surface 1})}$$

$$= \frac{(L_3 + L_4) - (L_1 + L_2)}{2w}$$

Where

$$L_4 = w$$

$$L_2 = \sqrt{L_4^2 + w^2}$$

$$= \sqrt{w^2 + w^2}$$

$$= \sqrt{2}w$$

$$L_1 = \sqrt{L_4^2 + w^2}$$

$$= \sqrt{w^2 + w^2}$$

$$= \sqrt{2}w$$

$$L_3 = \sqrt{(2w)^2 + (w)^2}$$

$$= \sqrt{5}w$$

Step 10 of 10

Substituting the known values in F_{12}

$$F_{12} = \frac{(L_3 + L_4) - (L_1 + L_2)}{2w}$$

$$= \frac{(\sqrt{5}w + w) - (\sqrt{2}w + \sqrt{2}w)}{2w}$$

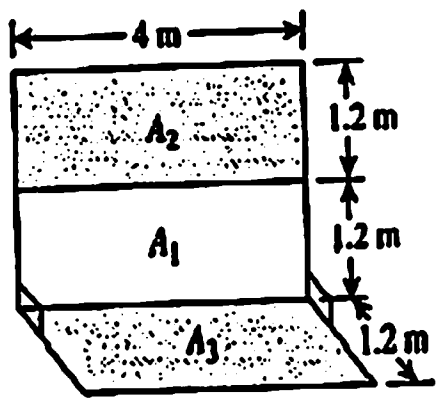
$$= \frac{w\left[(\sqrt{5} + 1) - (\sqrt{2} + \sqrt{2})\right]}{2w}$$

$$= 0.204$$

$$\boxed{F_{13} = 0.204}$$

Question: 21.050P

Determine the view factors *F*13 and *F*23 between the rectangular surfaces shown in Fig. P21-50.



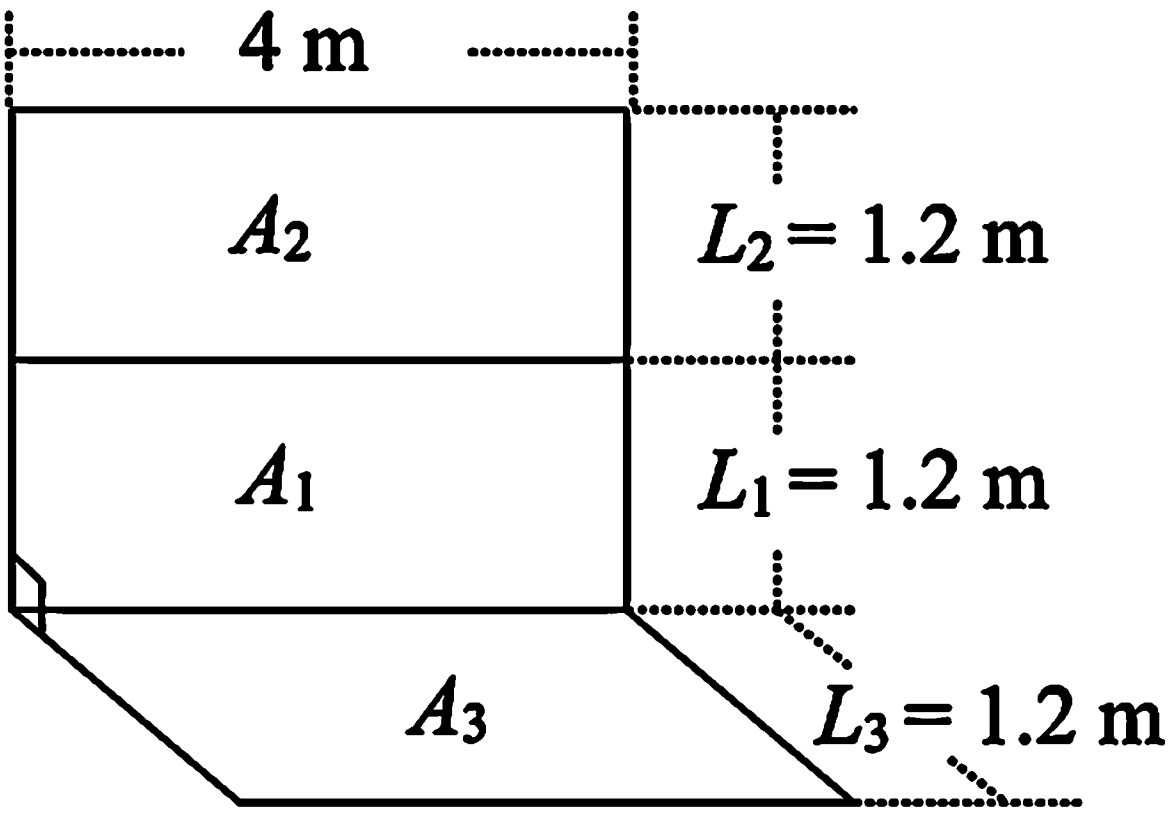


FIGURE P21–50

Step 1 of 4

Figure showing the geometry of the surfaces

Step 2 of 4

From the figure, the length to width ratio for surfaces 3 and 1 are

$$\frac{L_3}{w} = \frac{1.2}{4} = 0.3$$
$$\frac{L_1}{w} = \frac{1.2}{4} = 0.3$$

Where L_3 and L_1 are the lengths, and w is the width of surfaces 3 and 1 respectively

From the table of view factor between two perpendicular rectangles, at $(L_3/w) = 0.3$ and $(L_1/w) = 0.3$, the shape factor is

$$F_{31} = 0.26$$

Step 3 of 4

From the figure, the length to width ratio for entire vertical surface (surface-1 and surface-2) and horizontal surface (surface-3) is

$$\frac{L_1 + L_2}{w} = \frac{2.4}{4}$$
$$= 0.6$$

From the table of view factor between two perpendicular rectangles, at $(L_3/w) = 0.3$ and $(L_1 + L_2)/w = 0.6$, the shape factor is

$$F_{3\to(1+2)} = 0.32$$

Apply the reciprocity rule to the surfaces 1 and 3

$$A_1 F_{13} = A_3 F_{31}$$
$$A \times F_{13} = A \times F_{31}$$
$$F_{13} = F_{31}$$
$$= 0.26$$

Therefore the view factor $\boxed{F_{13} = 0.26}$

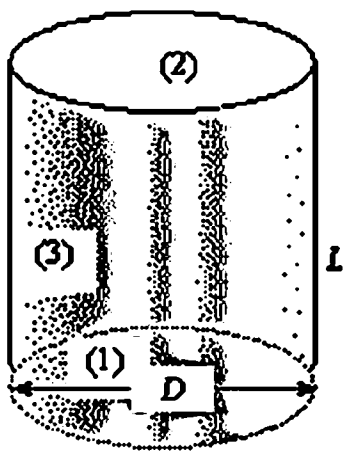
Step 4 of 4

Apply the superposition rule to the surfaces

$$F_{3\to(1+2)} = F_{31} + F_{32}$$
$$0.32 = 0.26 + F_{32}$$
$$F_{32} = 0.06$$

Apply the reciprocity rule to the surfaces 2 and 3

$$A_2 F_{23} = A_3 F_{32}$$
$$A \times F_{23} = A \times F_{32}$$
$$F_{23} = F_{32}$$
$$= 0.06$$



Therefore the view factor $\boxed{F_{23} = 0.06}$

Question: 21.051P

Consider a cylindrical enclosure whose height is twice the diameter of its base. Determine the view factor from the side surface of this cylindrical enclosure to its base surface.

Step 1 of 5

Given that,
Height is twice the diameter $L = 2D$

Step 2 of 5

The view factor from the side surface of this cylindrical enclosure can be calculated by using the table of view factor expressions for some common geometries of finite size (3-D)

$$R_1 = \frac{r_1}{L}$$
$$= \frac{r_1}{r_1}$$
$$= 1$$
$$\& R_2 = \frac{r_2}{L}$$
$$= \frac{r_2}{r_2}$$
$$= 1$$
$$S = 1 + \frac{1 + R_2^2}{R_1^2}$$
$$= 1 + \frac{1 + 1^2}{1^2}$$
$$= 3$$

Step 3 of 5

The view factor from surface 1-2 is given by

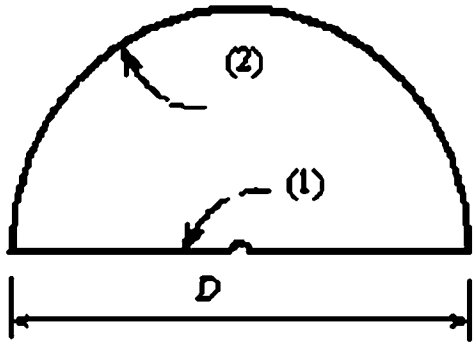
$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{R_2}{R_1}\right)^2\right]^{0.5}\right\}$$
$$= \frac{1}{2}\left\{3 - \left[3^2 - 4\left(\frac{1}{1}\right)^2\right]^{0.5}\right\}$$
$$= 0.3819$$

Step 4 of 5

From the summation rule
$F_{11} + F_{12} + F_{13} = 1$
$F_{11} = 0$
$0 + 0.3819 + F_{13} = 1$
$F_{13} = 0.618$

Step 5 of 5

From the reciprocity rule
$A_1 F_{13} = A_3 F_{31}$



$$F_{31} = \frac{A_1}{A_3} F_{13}$$
$$= \frac{\pi r_1^2}{2\pi r_1 L} F_{13}$$
$$= \frac{\pi r_1^2}{2\pi r_1 (r_1)} F_{13}$$
$$= \frac{1}{2}(0.618)$$
$$= 0.309$$

∴ The view factor from the side surface to its base surface, $\boxed{F_{31} = 0.309}$

Question: 21.052P

Consider a hemispherical furnace with a flat circular base of diameter *D*. Determine the view factor from the dome of this furnace to its base.

Step 1 of 3

Step 2 of 3

From the reciprocity rule

$F_{11}+F_{12}=1$

View factor for the surface 1 it self is $F_{11}=0$

$0+F_{12}=1$

$F_{12}=1$

Step 3 of 3

From the reciprocity rule

$$A_1F_{12}=A_2F_{21}$$

$$F_{21}=\frac{A_1}{A_2}F_{12}$$

$$=\frac{\pi r^2}{2\pi r^2}F_{12}$$

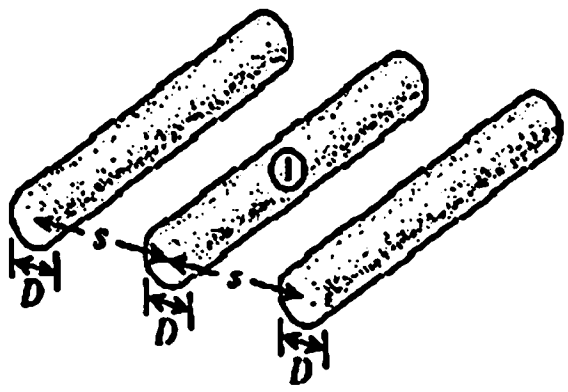
$$=\frac{1}{2}(1)$$

$$=0.5$$

∴ The view factor from the dome of this surface to its base $\boxed{F_{21}=0.5}$

Question: 21.053P

Three infinitely long parallel cylinders of diameter D are located a distance s apart from each other. Determine the view factor between the cylinder in the middle and the surroundings.



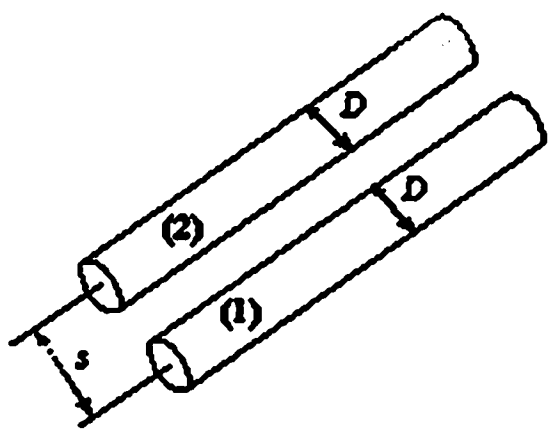


FIGURE P21–53

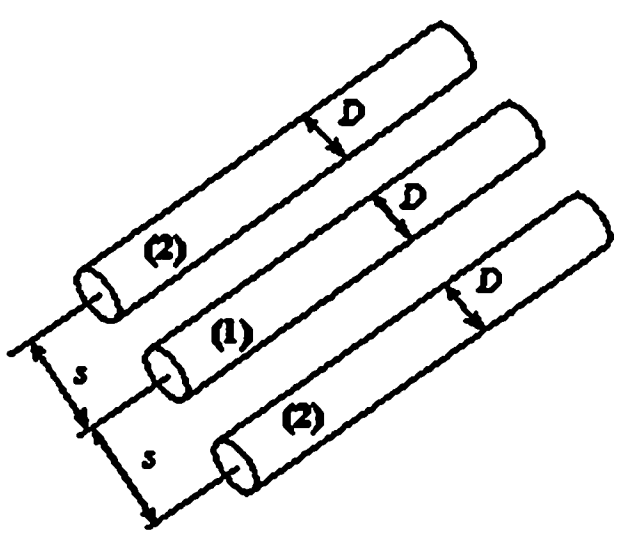
Step 1 of 4

Step 2 of 4

Using cross string method



$$F_{1-2} = \frac{\sum \text{Crossed strings} - \sum \text{Uncrossed strings}}{2 \times \text{String on surface 1}}$$

$$= \frac{2\sqrt{s^2 + D^2} - 2s}{2(\pi D / 2)}$$

∴ The view factor between two cylinders facing each other is

$$F_{1-2} = \frac{2\left(\sqrt{s^2 + D^2} - s\right)}{\pi D}$$

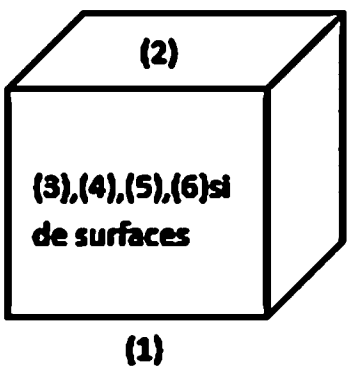
Step 3 of 4

Step 4 of 4

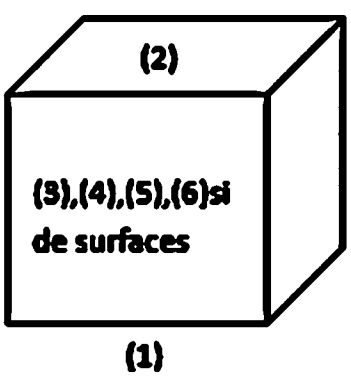
Noting that the radiation leaving cylinder 1 that does not strike the cylinder will strike the surroundings, and this is also the case for the other half of the cylinder, the view factor between the cylinder in the middle and the surroundings becomes

$$F_{1-surr} = 1 - 2F_{1-2}$$

$$F_{1-surr} = 1 - 2\left(\frac{2\left(\sqrt{s^2 + D^2} - s\right)}{\pi D}\right)$$



$$\therefore \boxed{F_{1-surr} = 1 - \frac{4\left(\sqrt{s^2 + D^2} - s\right)}{\pi D}}$$



Question: 21.054P

Determine the view factors from the base of a cube to each of the other five surfaces.

Step 1 of 3

Draw the cubic box and indicate the sides of cube with numbers.

Step 2 of 3

From the figure the base of cube is side-1.

Side-2 is aligned parallel to the side-1, and the sides 3, 4, 5, and 6 are aligned perpendicular to the side-1.

Calculate the view factor side-2 from the base.

Obtain the ratio $\frac{L_1}{D}$ and the ratio $\frac{L_2}{D}$.

Here, L_1 is the length of cube, L_2 is the width of cube, and D is the height of cube.

For cubic box all sides are equal, $L_1 = L_2 = D$.

$$\frac{L_1}{D} = 1$$

$$\frac{L_2}{D} = 1$$

Obtain the view factor F_{12} at $\frac{L_1}{D} = 1$ and $\frac{L_2}{D} = 1$ from the plot " view factor between two aligned parallel rectangles of equal size" of the text book.

$$F_{12} = 0.2$$

Therefore, the view factor of side-2 from the base of cube is, $\boxed{0.2}$.

Step 3 of 3

Calculate the view factor side-3 from the base.

Obtain the ratio $\frac{L_1}{W}$ and $\frac{L_2}{W}$.

Here, L_1 is the length of cube, L_2 is the height of cube, and W is the width of cube.

For cubic box all sides are equal, $L_1 = L_2 = W$.

$$\frac{L_1}{W} = 1$$

$$\frac{L_2}{W} = 1$$

Obtain the view factor F_{12} at $\frac{L_1}{W} = 1$ and $\frac{L_2}{W} = 1$ from the plot " view factor between two aligned parallel rectangles of equal size" of the text book.

$$F_{13} = 0.2$$

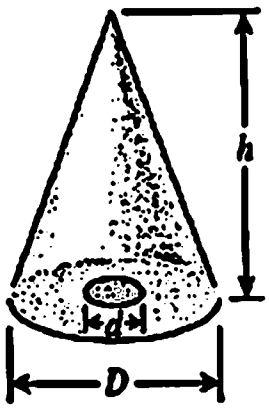
Therefore, the view factor of side-3 from the base of cube is, $\boxed{0.2}$.

The sides 4, 5, and 6 are perpendicular to the base (side-1) as like side-3.

Therefore, the view factors of sides4, 5, and 6 from base are, $\boxed{F_{14} = F_{15} = F_{16} = 0.2}$.

Question: 21.055P

Consider a conical enclosure of height h and base diameter D. Determine the view factor from the conical side surface to a hole of diameter d located at the center of the base.



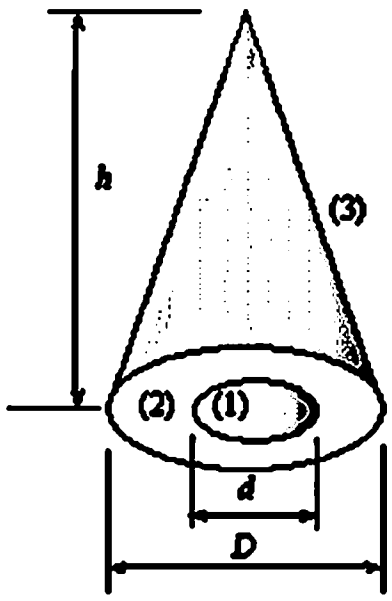


FIGURE P21–55

Step 1 of 3

Step 2 of 3

Surfaces 1 and 2 are flat, and they have no direct view of each other. Therefore,

$$F_{11} = F_{22} = F_{12} = F_{21} = 0$$

From the summation rule

$$F_{11} + F_{12} + F_{13} = 1$$

$$F_{13} = 1$$

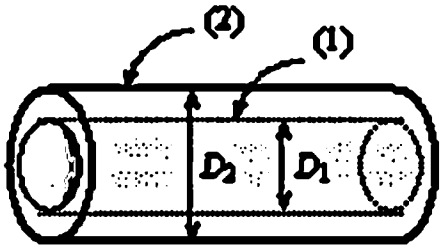
Step 3 of 3

From the reciprocity rule

$$A_1 F_{13} = A_3 F_{31}$$

$$F_{31} = \frac{A_1}{A_3} F_{13}$$

$$= \frac{\pi \frac{d^2}{4}}{\frac{\pi D h}{2}} \times (1)$$



$$= \frac{d^2}{2dh}$$

∴ The view factor from the conical side surface to a hole of diameter d $\boxed{F_{31} = \frac{d^2}{2dh}}$

Question: 21.056P

Determine the four view factors associated with an enclosure formed by two very long concentric cylinders of radii $r1$ and $r2$. Neglect the end effects.

Step 1 of 3

Step 2 of 3

No radiation leaving surface 1 strikes itself and thus $\therefore F_{11} = 0$

All radiation leaving surface 1 strikes surface 2 and thus $\therefore F_{12} = 1$

From the reciprocity rule

$$A_1 F_{12} = A_2 F_{21}$$

$$F_{21} = \frac{A_1}{A_2} F_{12}$$

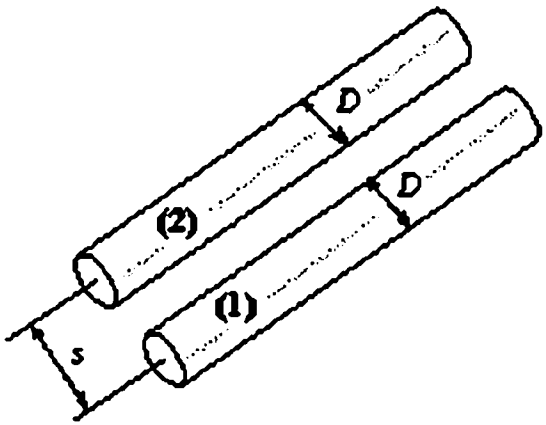
$$= \frac{2\pi r_1 h}{2\pi r_2 h} (1)$$

$\therefore$ The view factor for the surface 1 to 2 is $\boxed{F_{21} = \frac{r_1}{r_2}}$

Step 3 of 3

From the reciprocity rule

$$F_{21} + F_{22} = 1$$



$$F_{22} = 1 - F_{21}$$

$\therefore$ The view factor for the surface 2 itself $\boxed{F_{22} = 1 - \frac{r_1}{r_2}}$

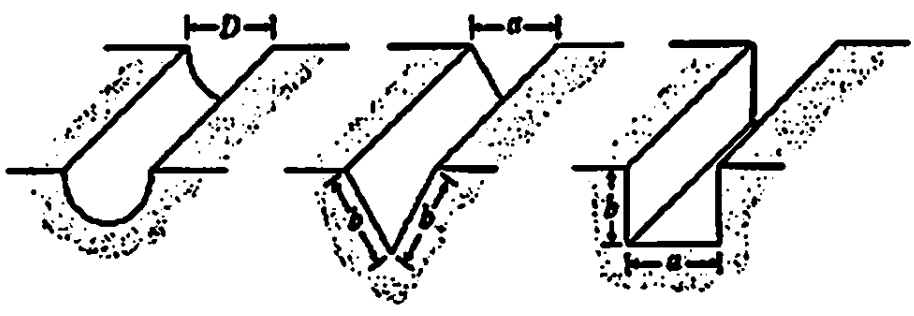
Question: 21.057P

Two infinitely long parallel cylinders of diameter D are located a distance s apart from each other. Determine the view factor $F12$ between these two cylinders.

Step 1 of 2

Step 2 of 2

Using cross string method



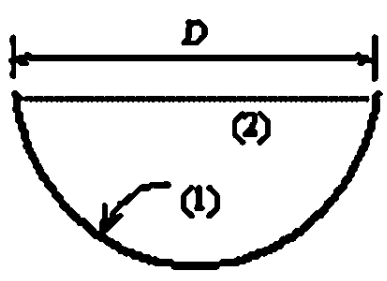
$$F_{1-2} = \frac{\sum \text{Crossed strings} - \sum \text{Uncrossed strings}}{2 \times \text{String on surface 1}}$$

$$= \frac{2\sqrt{s^2 + D^2} - 2s}{2(\pi D / 2)}$$

$\therefore$ The view factor between two long cylinders is $\boxed{F_{1-2} = \frac{2\sqrt{s^2 + D^2} - 2s}{\pi D}}$

Question: 21.058P

Determine the view factors from the very long grooves shown in Fig. P21-58 to the surroundings without using any view factor tables or charts. Neglect end effects.



(a) Semicylindrical (b) Triangular groove (c) Rectangular groove

FIGURE P21–58

Step 1 of 7

a)

Step 2 of 7

From the reciprocity rule

$F_{21} + F_{22} = 1$

$F_{22} = 0$

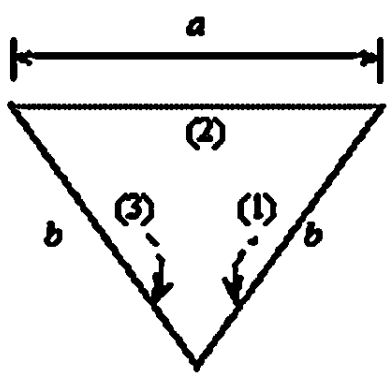
Therefore $F_{21} = 1$

From the reciprocity rule

$A_1 F_{12} = A_2 F_{21}$

$$F_{12} = \frac{A_2}{A_1} F_{21}$$

$$= \frac{D}{\frac{\pi D}{2}} (1)$$



$$= \frac{2}{\pi}$$

$$= 0.636$$

∴ The view factor for the long circular groove is $\boxed{F_{12} = 0.636}$

Step 3 of 7

b)

Step 4 of 7

From the summation rule

$F_{21} + F_{22} + F_{23} = 1$

View factor for the surface itself $F_{22} = 0$

$0 + F_{21} + F_{23} = 1$

$F_{21} = F_{23}$ Because of symmetry

$F_{21} = F_{23} = 0.5$

Step 5 of 7

From the summation rule

$F_{22} + F_{2\to(1+3)} = 1$

$F_{2\to(1+3)} = 1$

From the reciprocity rule

$A_2 F_{2\to(1+3)} = A_{(1+3)} F_{(1+3)\to 2}$

$$F_{(1+3)} = \frac{A_2}{A_{(1+3)}} (1)$$

$$= \frac{a}{2b}$$

∴ The view factor for the long groove is $\boxed{F_{(1+3)} = \frac{a}{2b}}$

Step 6 of 7

c)

Step 7 of 7

From the summation rule

$F_{44} + F_{4\to(1+2+3)} = 1$

View factor for the surface itself $F_{44} = 0$

$F_{4\to(1+2+3)} = 1$

From the reciprocity rule

$A_4 F_{4\to(1+2+3)} = A_{(1+2+3)} F_{(1+2+3)\to 4}$

$$F_{(1+2+3)} = \frac{A_4}{A_{(1+2+3)}} (1)$$

$$= \frac{a}{a+2b}$$

∴ The view factor for the long rectangular groove is $\boxed{F_{(1+2+3)} = \frac{a}{a+2b}}$

Question: 21.059P

A circular cone of diameter D is positioned on a common axis with a circular disk, also of diameter, D, at a distance L, as shown in the figure. With a hypothetical area ($A3$) corresponding to the opening of the cone, determine the values of $F11$ and $F12$ for $L = D = 100$ mm.

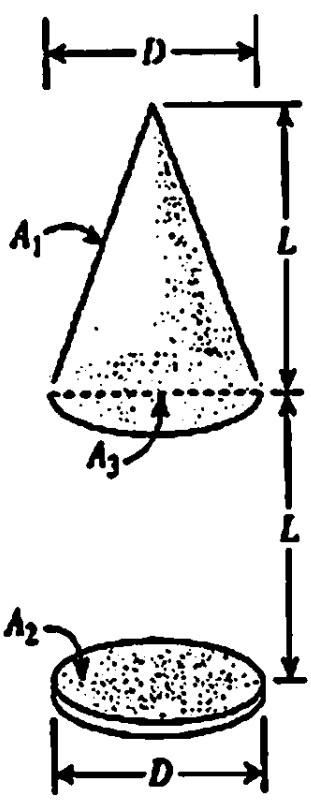


FIGURE P21-59

Step 1 of 5

Consider the surfaces 1 and 3 as enclosure.

So, use summation rule as follows:

$$F_{11} + F_{13} = 1$$
$$F_{11} = 1 - F_{13} \quad \text{..... (1)}$$

Here, F_{11} is the view factor for 1-1 surfaces, and F_{13} is the view factor for 1-3 surfaces.

Apply reciprocity relation between A_1 and A_3 as follows.

$$A_1F_{13} = A_3F_{31}$$
$$F_{13} = \left(\frac{A_3}{A_1}\right)F_{31}$$

Substitute $\left(\frac{A_3}{A_1}\right)F_{31}$ for F_{13} in equation (1).

$$F_{11} = 1 - F_{13}$$
$$F_{11} = 1 - \left(\frac{A_3}{A_1}\right)F_{31} \quad \text{..... (2)}$$
$$= 1 - \left(\frac{7853.89}{17562.0}\right)F_{31}$$
$$F_{11} = 1 - 0.44F_{31}$$

Step 2 of 5

Consider the following relation between view factors.

$$F_{31} + F_{33} = 1$$

Since, $F_{33} = 0$

Substitute 0 for F_{33} .

$$F_{31} + 0 = 1$$
$$F_{31} = 1$$

Substitute 1 for F_{31} in equation (2).

$$F_{11} = 1 - 0.44F_{31}$$
$$= 1 - 0.44$$
$$= 0.55$$

Therefore, the view factor 11 is $\boxed{0.55}$.

Step 3 of 5

The radiation leaving from surface A_2 is intercepted by A_1 and A_2 equally.

$$F_{21} = F_{23}$$

Apply reciprocity relation between A_1 and A_2 as follows.

$$A_1F_{12} = A_2F_{21}$$
$$F_{12} = \left(\frac{A_2}{A_1}\right)F_{21} \quad \text{..... (3)}$$
$$= \left(\frac{7853.89}{17562.0}\right)F_{21}$$
$$F_{12} = 0.44F_{21}$$

Step 4 of 5

Consider that coaxial parallel disks,
Obtain the view factor F_{23} from table 13-1 as follows.

$$F_{23} = \frac{1}{2}\left\{S - \left(S^2 - 4\left(\frac{D_3}{D_2}\right)^2\right)^{\frac{1}{2}}\right\}$$
$$F_{23} = \frac{1}{2}\left(S - \left(S^2 - 4\right)^{\frac{1}{2}}\right)$$

Here, R and S are constants.

Calculate the values of constants as follows:

$$R = \frac{D}{2L}$$
$$= \frac{100}{2(100)}$$
$$= 0.5$$

$$S = 1 + \frac{1 + R^2}{R^2}$$
$$= 2 + \frac{1}{R^2}$$
$$= 2 + 4$$
$$= 6$$

Step 5 of 5

Substitute 0.5 for R and 6 for S .

$$F_{23} = \frac{1}{2}\left(S - \left(S^2 - 4\right)^{\frac{1}{2}}\right)$$
$$= \frac{1}{2}\left(6 - \left(6^2 - 4\right)^{\frac{1}{2}}\right)$$
$$= 0.1716$$

Substitute 0.1716 for F_{23} in equation (3).

$$F_{12} = 0.44F_{21}$$
$$= 0.44 \times (0.1716)$$
$$= 0.0755$$

Therefore, the view factor 11 is $\boxed{0.755}$.

Question: 21.060P

Consider a cylindrical surface and a disk oriented coaxially as shown in the figure. The cylinder has a diameter D and a length L. The disk of diameter D is placed coaxially with the cylinder at a distance L. If $L = 2D$, determine the view factor $F12$ between the cylindrical surface (1) and the disk (2) facing it.

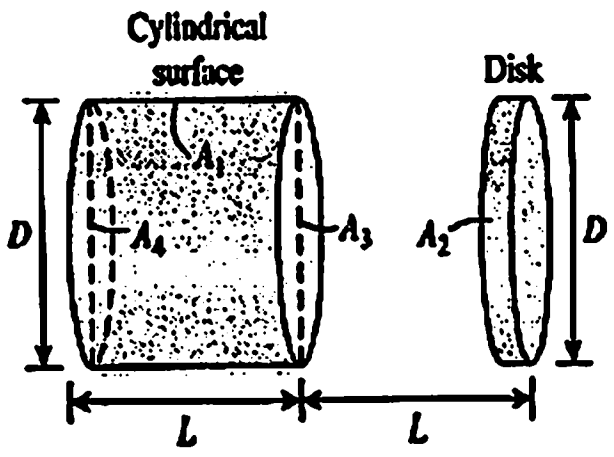

FIGURE P21-60

Step 1 of 5

Given data:

Length of the cylinder, $L = 2D$

Distance between the cylinder and the disc, $L = 2D$

Step 2 of 5

Given diagram:

Step 3 of 5

From the tables of the view factors of finite geometries, the view factor from the disc to the surface A_3 is given by,

$$F_{23} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

where,

$$R = \frac{D}{2L}$$
$$= \frac{D}{2 \times 2D}$$
$$= 0.25$$

Substituting the value of R, we have,

$$F_{23} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$
$$= 1 + \frac{1 - \sqrt{\left(4 \times 0.25^2\right) + 1}}{2 \times 0.25^2}$$
$$= 0.05573$$

Step 4 of 5

Similarly, the view factor from the surface A_2 to the surface A_4 is,

$$F_{24} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

where,

$$R = \frac{D}{2 \times 2L}$$
$$= \frac{D}{2 \times (2 \times 2D)}$$
$$= 0.125$$

By substituting the value of R, we have,

$$F_{24} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$
$$= 1 + \frac{1 - \sqrt{\left(4 \times 0.125^2\right) + 1}}{2 \times 0.125^2}$$
$$= 0.015155$$

Step 5 of 5

By using the summation rule, we have,

$$F_{21} + F_{22} + F_{23} + F_{24} = 1$$
$$F_{21} + 0 + 0.05573 + 0.015155 = 1$$
$$F_{21} = 0.93$$

By using the reciprocity rule, the view factor from the cylindrical surface, A_1 to the disc, A_2 can be determined as follows.

$$A_1 F_{12} = A_2 F_{21}$$

Therefore, the view factor F_{12} is given by,

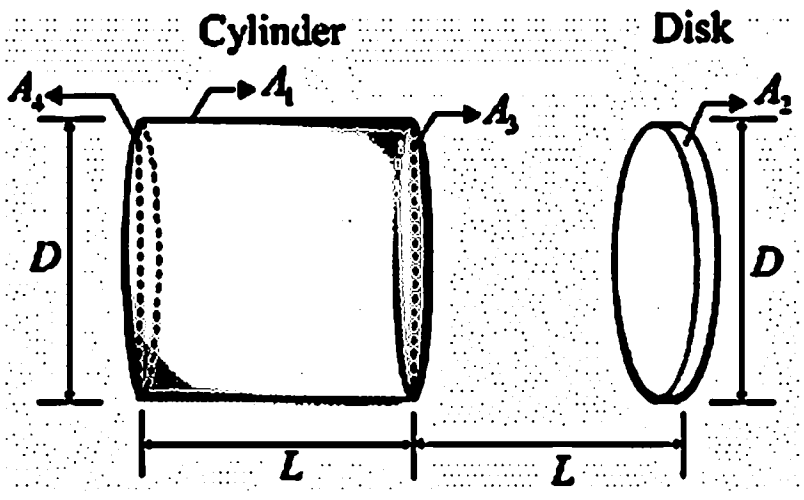
$$F_{12} = \frac{A_2}{A_1} F_{21}$$
$$= \frac{(\pi/4)D^2}{\pi D \times 2D} \times 0.93$$
$$= 0.11625$$
$$F_{12} = 0.11625$$

The view factor F_{12} between the cylindrical surface and the disc facing is $\boxed{F_{12} = 0.11625}$

Question: 21.061P

Repeat Prob. 21-60 with $L = D$.

Step 1 of 5



Given data:

Length of the cylinder, $L = 2D$

Distance between the cylinder and the disc, $L = 2D$

Step 2 of 5

Given diagram:

Step 3 of 5

From the tables of the view factors of finite geometries, the view factor from the disc to the surface A_3 is given by,

$$F_{23} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

where,

$$R = \frac{D}{2L}$$
$$= \frac{D}{2 \times D}$$
$$= 0.5$$

Substituting the value of R, we have,

$$F_{23} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$
$$= 1 + \frac{1 - \sqrt{\left(4 \times 0.5^2\right) + 1}}{2 \times 0.5^2}$$
$$= 0.1715$$

Step 4 of 5

Similarly, the view factor from the surface A_2 to the surface A_4 is,

$$F_{24} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

where,

$$R = \frac{D}{2 \times 2L}$$
$$= \frac{D}{2 \times (2 \times D)}$$
$$= 0.25$$

Substituting the value of R, we get

$$F_{24} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$
$$= 1 + \frac{1 - \sqrt{\left(4 \times 0.25^2\right) + 1}}{2 \times 0.25^2}$$
$$= 0.05573$$

Step 5 of 5

By using the summation rule, we have,

$$F_{21} + F_{22} + F_{23} + F_{24} = 1$$
$$F_{21} + 0 + 0.1715 + 0.05573 = 1$$
$$F_{21} = 0.772772$$

By using the reciprocity rule, the view factor from the cylindrical surface, A_1 to the disc, A_2 can be determined as follows.

$$A_1 F_{12} = A_2 F_{21}$$

Therefore, the view factor F_{12} is given by,

$$F_{12} = \frac{A_2}{A_1} F_{21}$$
$$= \frac{(\pi/4)D^2}{\pi D \times D} \times 0.772772$$
$$= 0.1932$$

$$\boxed{F_{12} = 0.1932}$$

The view factor F_{12} between the cylindrical surface and the disc facing is $F_{12} = 0.1932$.

Question: 21.062P

What are the two methods used in radiation analysis? How do these two methods differ?

Step 1 of 2

The two methods used in radiation analysis are the matrix and network methods. In matrix method, equations

Surface with specified net heat transfer rate $\dot{Q}_i = A_i \sum_{j=1}^{N} F_{i \to j}(J_i - J_j)$

Surface with specified temperature $\sigma T_i^4 = J_i + \frac{1-\varepsilon_i}{\varepsilon_i} \sum_{j=1}^{N} F_{i \to j}(J_i - J_j)$

Give N linear algebraic equations for the determination of the N unknown radiosities for an N-surface enclosure. Once the radiosities are available, the unknown surface temperatures and heat transfer rates can be determined from these equations respectively. This method involves the use of matrices especially when there are a large number of surfaces. Therefore this method requires some knowledge of linear algebra.

Step 2 of 2

The network method involves drawing a surface resistance associated with each surface of an enclosure and connecting them with space resistances. Then the radiation problem is solved by treating it as an electrical network problem where the radiation heat transfer replaces the current and the radiosity replaces the potential. The network method is not practical for enclosures with more than three or four surfaces due to the increased complexity of the network.

Question: 21.063P

How does radiosity for a surface differ from the emitted energy? For what kind of surfaces are these two quantities identical?

Step 1 of 1

Radiosity is defined as the total radiation energy leaving a surface per unit time per unit area. It is denoted by *J*. Radiosity includes the emitted radiation energy as well as the reflected energy.

Radiosity can be expressed through the following relation:

$$\begin{aligned} J_i &= \left(\text{Radiation emitted by surface } i\right) + \left(\text{Radiation reflected by surface } i\right) \\ &= \varepsilon_i E_{bi} + \rho_i G_i \end{aligned}$$

For a black body, $\left(\text{emissivity}: \varepsilon_i = 1 \text{ and reflectivity}: \rho_i = 0\right)$

Substituting it in the radiosity expression, we obtain

$$\begin{aligned} J_i &= (1) E_{bi} + (0) G_i \\ &= E_{bi} \\ &= \sigma T_i^4 \end{aligned}$$

Radiosity of a blackbody is equal to its emissive power since a blackbody does not reflect any radiation.

Therefore, radiosity and emitted energy are identical for black bodies.

Question: 21.064P

What are the radiation surface and space resistances? How are they expressed? For what kind of surfaces is the radiation surface resistance zero?

Step 1 of 1

During a surface interaction, a surface losses energy by emitting radiation and gains energy by absorbing radiation emitted by other surfaces. The surface resistance to radiation is expressed as

$$R_i = \frac{1-\varepsilon_i}{A_i \varepsilon_i}$$

It is zero for black surfaces.

The space resistance is the radiation resistance between two surfaces and is expressed as

$$R_{i \to j} = \frac{1}{A_i F_{i \to j}}$$

Question: 21.065P

Why is the radiation analysis of enclosures that consist of black surfaces relatively easy? How is the rate of radiation heat transfer between two surfaces expressed in this case?

Step 1 of 1

A blackbody is defined as a perfect emitter and absorber of radiation. Because of the absence of the reflection analysis of radiation exchange between black surfaces is relatively easy. Rate of radiation heat transfer between two surfaces expressed as

$$\dot{Q} = A_1 F_{12} \sigma \left(T_1^4 - T_2^4 \right)$$

Where A_1 is the surface area,
F_{12} is the view factor,
And T_1 and T_2 are the temperatures of two surfaces.

Question: 21.066P

What is a reradiating surface? What simplifications does a reradiating surface offer in the radiation analysis?

Step 1 of 1

A reradiating surface is insulated on one side and all the heat transfer it receives through radiation is emitted by radiation and convection. The net $\dot{Q}_i$ from a reradiating surface is zero. Approximated by surfaces that are well insulated on one side and for which convection is negligible on the opposite (radiating) side

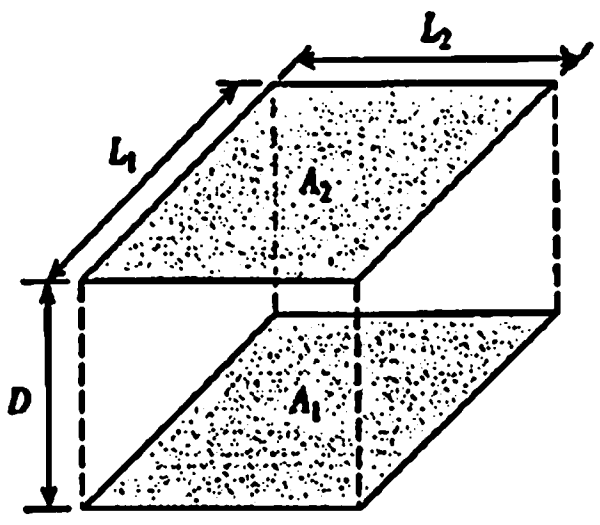
Some surfaces encountered in numerous practical heat transfer applications are modeled as being adiabatic as the back sides of these surfaces are well insulated and net heat transfer through these surfaces is zero. When the convection effects on the front (heat transfer) side of such a surface is negligible and steady-state conditions are reached, the surface must lose as much radiation energy as it receives. Such a surface is called reradiating surface. In radiation analysis, the surface resistance of a reradiating surface is taken to be zero since there is no heat transfer through it.

Setting $\dot{Q}_i = 0$ yields

$$J_i = E_{bi} = \sigma T_i^4 \left(\mathrm{W/m^2}\right)$$

Question: 21.067P pg 1

Two aligned parallel rectangles with dimensions 6 m × 8 m are spaced apart by a distance of 2 m. If the two parallel rectangles are experiencing radiation heat transfer as black surfaces, determine the percentage of change in radiation heat transfer rate when the rectangles are moved 8 m apart.



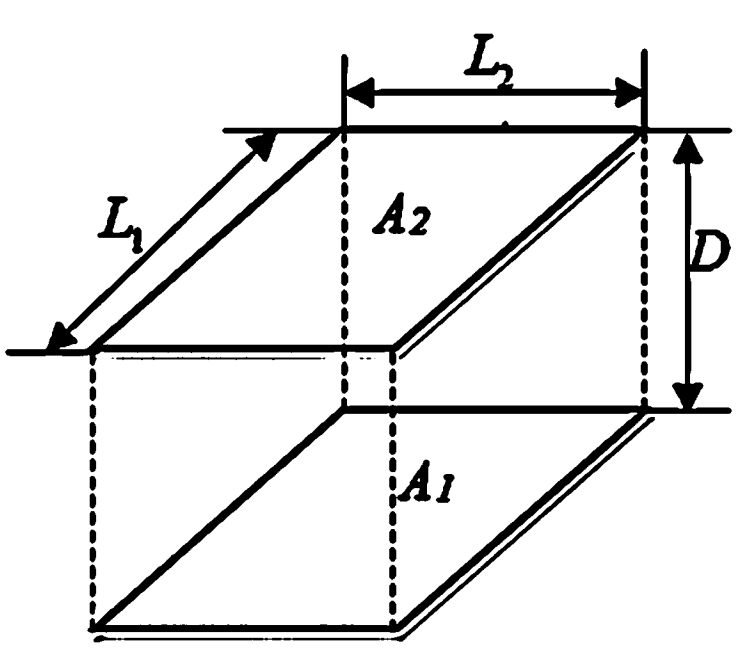


FIGURE P21–67

Step 1 of 7

The surfaces are diffuse emitters and reflectors.

Step 2 of 7

Given data:

Length of the rectangle, $L_1 = 8\,\text{m}$

Width of the rectangle, $L_2 = 6\,\text{m}$

Distance between the two rectangles, $D = 2\,\text{m}$

Find the *L/D* ratio of upper plate.

$$x = \frac{L_2}{D}$$

Here, Length of the rectangle L_1 and Distance between two rectangles is *D*.

Substitute, 8 m for L_1 and 2 m for *D*.

$$\begin{aligned} x &= \frac{L_2}{D} \\ &= \frac{6}{2} \\ &= 3 \end{aligned}$$

Step 3 of 7

Find the *L/D* ratio of upper plate.

$$y = \frac{L_1}{D}$$

Substitute, 8 m for L_1 and 2 m for *D*.

$$\begin{aligned} y &= \frac{L_1}{D} \\ &= \frac{8}{2} \\ &= 4 \end{aligned}$$

Step 4 of 7

Find the view factor of bottom surface to the top surface from the figure.

$$(F_{12})_{D=2\text{m}} = \frac{2}{\pi \times x \times y}\left\{\begin{array}{l} \ln\left(\sqrt{\frac{(1+x^2)(1+y^2)}{1+x^2+y^2}}\right) + x\sqrt{1+y^2}\tan^{-1}\left(\frac{x}{\sqrt{1+y^2}}\right) \\ +y\sqrt{1+x^2}\tan^{-1}\left(\frac{y}{\sqrt{1+x^2}}\right) - x\tan^{-1}(x) - y\tan^{-1}(y) \end{array}\right\}$$

Substitute, 3 for *x* and 4 for *y*.

$$\begin{aligned} (F_{12})_{D=2\text{m}} &= \frac{2}{\pi \times 3 \times 4}\left\{\begin{array}{l} \ln\left(\sqrt{\frac{(1+3^2)(1+4^2)}{1+3^2+4^2}}\right) + 3\sqrt{1+4^2}\tan^{-1}\left(\frac{3}{\sqrt{1+4^2}}\right) \\ +4\sqrt{1+3^2}\tan^{-1}\left(\frac{4}{\sqrt{1+3^2}}\right) - 3\tan^{-1}(3) - 4\tan^{-1}(4) \end{array}\right\} \\ &= \frac{2}{\pi \times 3 \times 4}\left\{\begin{array}{l} \ln(2.557) + 3\sqrt{1+4^2}\tan^{-1}(0.7276) \\ +4\sqrt{1+3^2}\tan^{-1}(1.265) - 3\tan^{-1}(3) - 4\tan^{-1}(4) \end{array}\right\} \\ &= \frac{2}{\pi \times 3 \times 4}(0.9388 + 7.78 + 11.384 - 3.747 - 5.303) \\ &= 0.586 \end{aligned}$$

Find the *L/D* ratio of upper plate.

$$x_2 = \frac{L_2}{D_2}$$

Here, Distance between two rectangles is *D*.

Find the *L/D* ratio of upper plate. 21.067P pg 2

$$x_2 = \frac{L_2}{D_2}$$

Here, Distance between two rectangles is D_2 .

Substitute, 8 m for L_1 and 8 m for *D*.

$$\begin{aligned} x_2 &= \frac{L_2}{D_2} \\ &= \frac{6}{8} \\ &= 0.75 \end{aligned}$$

Step 5 of 7

Find the *L/D* ratio of upper plate.

$$y_2 = \frac{L_1}{D_2}$$

Substitute, 8 m for L_1 and 8 m for D_2 .

$$\begin{aligned} y &= \frac{L_1}{D_2} \\ &= \frac{8}{8} \\ &= 1 \end{aligned}$$

Step 6 of 7

Find the view factor of bottom surface to the top surface from the figure.

$$(F_{12})_{D=8m} = \frac{2}{\pi \times x_2 \times y_2}\left\{\begin{array}{l} \ln\left(\sqrt{\frac{(1+x_2^2)(1+y_2^2)}{1+x_2^2+y_2^2}}\right)+x_2\sqrt{1+y_2^2}\tan^{-1}\left(\frac{x_2}{\sqrt{1+y_2^2}}\right) \\ +y_2\sqrt{1+x_2^2}\tan^{-1}\left(\frac{y_2}{\sqrt{1+x_2^2}}\right)-x_2\tan^{-1}(x_2)-y\tan^{-1}(y_2) \end{array}\right\}$$

Substitute, 0.75 for x_2 and 1 for y_2.

$$\begin{aligned} (F_{12}')_{D=8m} &= \frac{2}{\pi \times 0.75 \times 1}\left\{\begin{array}{l} \ln\left(\sqrt{\frac{(1+0.75^2)(1+1^2)}{1+0.75^2+1^2}}\right)+0.75\sqrt{1+1^2}\tan^{-1}\left(\frac{0.75}{\sqrt{1+1^2}}\right) \\ +1\sqrt{1+0.75^2}\tan^{-1}\left(\frac{1}{\sqrt{1+0.75^2}}\right)-0.75\tan^{-1}(0.75)-1\tan^{-1}(1) \end{array}\right\} \\ &= \frac{2}{\pi \times 0.75 \times 1}(0.099+0.5171+0.8895-0.9316-0.785) \\ &= 0.17 \end{aligned}$$

Step 7 of 7

Find the percentage change in radiation heat transfer rate can be determined using the radiation equation.

$$\dot{Q} = F_{12} A\sigma\left(T_1^4 - T_2^4\right)$$

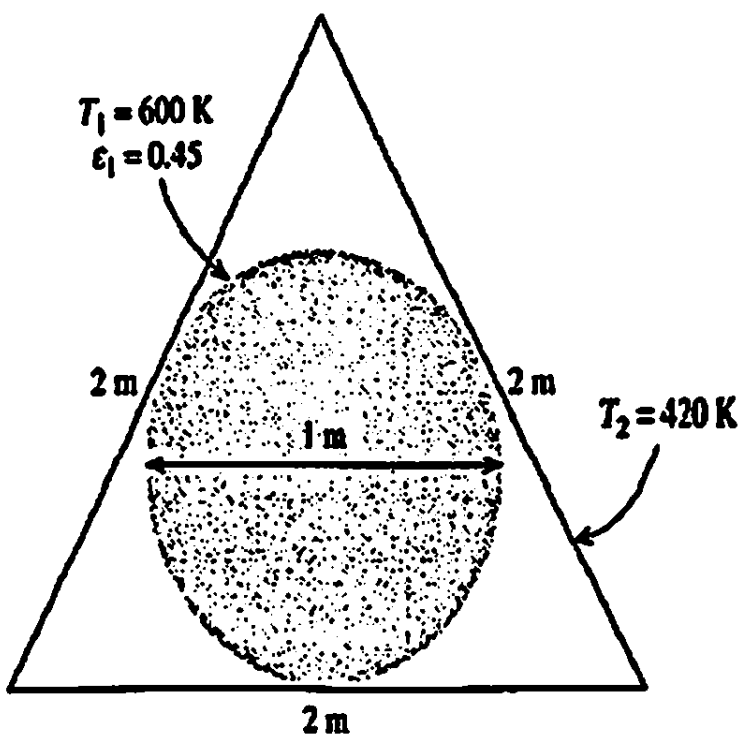
Since the surface area, Stefan Boltzmann constant and the temperatures are remains same, the change in radiation heat transfer rate is mainly due to change in shape factor.

$$\begin{aligned} \%\text{change} &= \frac{\left(F_{12} - F_{12}'\right)}{F_{12}} \times 100 \\ &= \frac{(0.6-0.17)}{0.6} \times 100 \\ &= 71.6\% \end{aligned}$$

Due to increase in distance between the two surfaces from 2 to 8 m, the view factor has been reduced from 0.6 to 0.17 and hence the radiation heat transfer between two surfaces reduced by **71.6%**

Question: 21.068P

A solid sphere of 1 m diameter at 600 K is kept in an evacuated, long, equilateral triangular enclosure whose sides are 2 m long. The emissivity of the sphere is 0.45 and the temperature of the enclosure is 420 K. If heat is generated uniformly within the sphere at a rate of 3100 W, determine (*a*) the view factor from the enclosure to the sphere and (*b*) the emissivity of the enclosure.



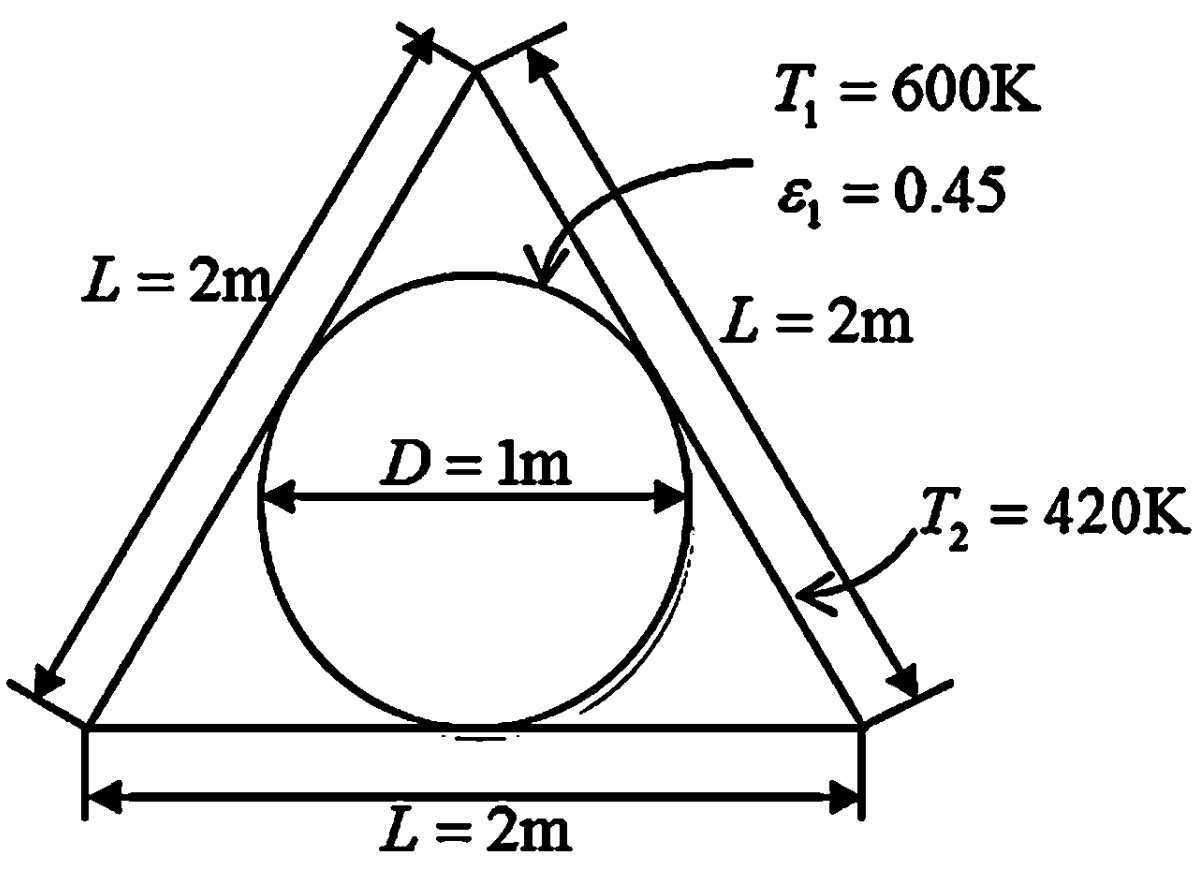


FIGURE P21–68

Step 1 of 3

Figure shows a solid sphere is kept in evacuated equilateral triangle enclosure:

Step 2 of 3

(a)

Find the cross sectional area sphere surface 1.

$$A_1 = \pi D^2$$

Here, D is the diameter of the sphere.

Substitute 1 m for D.

$$\begin{aligned} A_1 &= \pi D^2 \\ &= \pi \times 1^2 \\ &= 3.141\ \text{m}^2 \end{aligned}$$

Find the cross sectional area of equilateral triangular enclosure is 2.

$$A_2 = 3 \times \frac{L}{2}\sqrt{L^2 - D^2}$$

Here, L is the side of equilateral triangular enclosure.

Substitute 2 m for L.

$$\begin{aligned} A_2 &= 3 \times \frac{L}{2}\sqrt{L^2 - D^2} \\ &= 3 \times \frac{2}{2}\sqrt{2^2 - 1^2} \\ &= 5.196\ \text{m}^2 \end{aligned}$$

Since, the view factor for sphere surface with respect to equilateral triangular enclosure surface is unity because sphere is enclosed in equilateral triangular enclosure.

$$F_{12} = 1$$

Find the view factor for equilateral triangular enclosure 2 with respect to a sphere surface 1 by using the reciprocity relation.

$$\begin{aligned} A_1 F_{12} &= A_2 F_{21} \\ F_{21} &= \frac{A_1 F_{12}}{A_2} \end{aligned}$$

Substitute 1 for F_{12}, $5.196\ \text{m}^2$ for A_2, and $3.141\ \text{m}^2$ for A_1.

$$\begin{aligned} F_{21} &= \frac{A_1 F_{12}}{A_2} \\ &= \frac{3.141 \times 1}{5.196} \\ &= 0.604 \end{aligned}$$

Therefore, the view factor for equilateral triangular enclosure 2 with respect to a sphere surface 1 is $\boxed{0.604}$.

Step 3 of 3

(b)

Find the emissivity of the enclosure using net rate of radiation heat transfer for the two-surface enclosure.

$$\dot{Q} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1-\varepsilon_1}{A_1\varepsilon_1} + \frac{1}{A_1 F_{12}} + \frac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

Here, T_2 is temperature of the enclosure, T_1 is the temperature of the sphere, ε_1 is emissivity of sphere, ε_2 is emissivity triangular, σ is Stefan Boltzmann constant and $\dot{Q}$ is net radiation heat transfer.

Substitute $5.67 \times 10^{-8} \times \text{W/m}^2 \cdot \text{K}^4$ for σ, 600 K for T_1, 420 K for T_2, 0.604 for F_{21}, ε_1

$$\dot{Q} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1-\varepsilon_1}{A_1\varepsilon_1} + \frac{1}{A_1 F_{12}} + \frac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

$$3100\,\text{W} = \frac{5.67 \times 10^{-8} \times \left(600^4 - 420^4\right)}{\frac{1-0.45}{3.141 \times 0.45} + \frac{1}{3.141 \times 1} + \frac{1-\varepsilon_2}{5.196 \times \varepsilon_2}}$$

$$3100 = \frac{5583.98}{0.389 + 0.3183 + \left(\frac{1-\varepsilon_2}{5.196\varepsilon_2}\right)}$$

$$\frac{1-\varepsilon_2}{5.196\varepsilon_2} = 1.09398$$

$$\varepsilon_2 = 0.15$$

Therefore, the emissivity of the enclosure is $\boxed{0.15}$.

Question:

Consider a 10-ft ×10-ft ×10-ft cubical furnace whose top and side surfaces closely approximate black surfaces and whose base surface has an emissivity ε = 0.4. The base, top, and side surfaces of the furnace are maintained at uniform temperatures of 800 R, 1600 R, and 2400 R, respectively. Determine the net rate of radiation heat transfer between (*a*) the base and the side surfaces and (*b*) the base and the top surfaces. Also, determine the net rate of radiation heat transfer to the base surface.

Step 1 of 11

Given data:

Size of the cubical furnace, $L = 10\,\text{ft}$

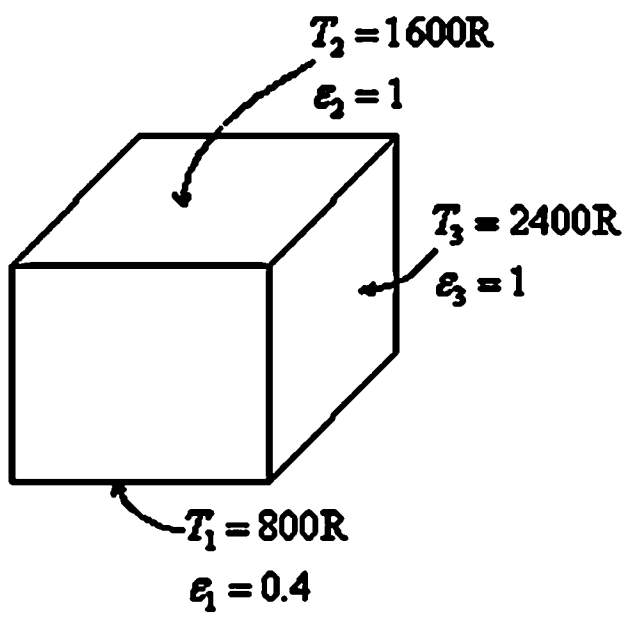
Emissivity of the base surface, $\varepsilon_1 = 0.4$

Emissivity of the top surface, $\varepsilon_2 = 1$

Emissivity of the side surfaces, $\varepsilon_3 = 1$

Temperature of the base surface, $T_1 = 800\,\text{R}$

Temperature of the top surface, $T_2 = 1600\,\text{R}$



Temperature of the side surfaces, $T_3 = 2400\,\text{R}$

Step 2 of 11

Assumptions:

1. The surfaces are diffuse, gray and opaque
2. Steady operating conditions exist
3. Heat transfer from and to the surfaces is only due to Radiation

Step 3 of 11

Step 4 of 11

Consider the base surface to be surface 1, the top surface to be surface 2 and the side surfaces to be surface 3. The cubical furnace can be considered to be three-surface enclosure. The areas and blackbody emissive powers of surfaces can be calculated as

$$A_1 = 10\times10\,(\text{ft})^2$$
$$= 100\,\text{ft}^2$$
$$A_2 = 10\times10\,(\text{ft})^2$$
$$= 100\,\text{ft}^2$$
$$A_3 = 4\times10\times10\,(\text{ft})^2$$
$$= 400\,\text{ft}^2$$

Step 5 of 11

Emissive powers on each surface

$$E_{b1} = \sigma T_1^4$$
$$= 0.1714\times10^{-8}\,(\text{Btu/h-ft}^2\text{-R}^4)\times800^4\,(\text{R})^4$$
$$= 702.0544\,\text{Btu/h-ft}^2$$
$$E_{b2} = \sigma T_2^4$$
$$= 0.1714\times10^{-8}\,(\text{Btu/h-ft}^2\text{-R}^4)\times1600^4\,(\text{R})^4$$
$$= 11232.8704\,\text{Btu/h-ft}^2$$
$$E_{b3} = \sigma T_3^4$$
$$= 0.1714\times10^{-8}\,(\text{Btu/h-ft}^2\text{-R}^4)\times2400^4\,(\text{R})^4$$
$$= 56866.4064\,\text{Btu/h-ft}^2$$

Step 6 of 11

From figure, the view factor from the base to the top surface of the cube can be determined as

$$\frac{L_1}{D} = \frac{10(\text{ft})}{10(\text{ft})} = 1$$
$$\frac{L_2}{D} = \frac{10(\text{ft})}{10(\text{ft})} = 1$$
$$F_{12} = 0.2$$

By using the summation rule, the view factor from the base or top to the side surfaces can be determined as

$$F_{11} + F_{12} + F_{13} = 1$$

Since the base surface is flat and thus the view factor $F_{11} = 0$

Therefore, by rewriting the above equation we will get

$$F_{13} = 1 - F_{11} - F_{12}$$
$$= 1 - 0 - 0.2$$
$$= 0.8$$

Step 7 of 11

In order to calculate the radiation heat transfer, we need to determine the thermal resistances and these can be calculated as

$$R_1 = \frac{1-\varepsilon_1}{A_1\varepsilon_1}$$
$$= \frac{1-0.4}{100(\text{ft}^2)\times0.4}$$
$$= 0.015\,\text{ft}^{-2}$$
$$R_{12} = \frac{1}{A_1F_{12}}$$

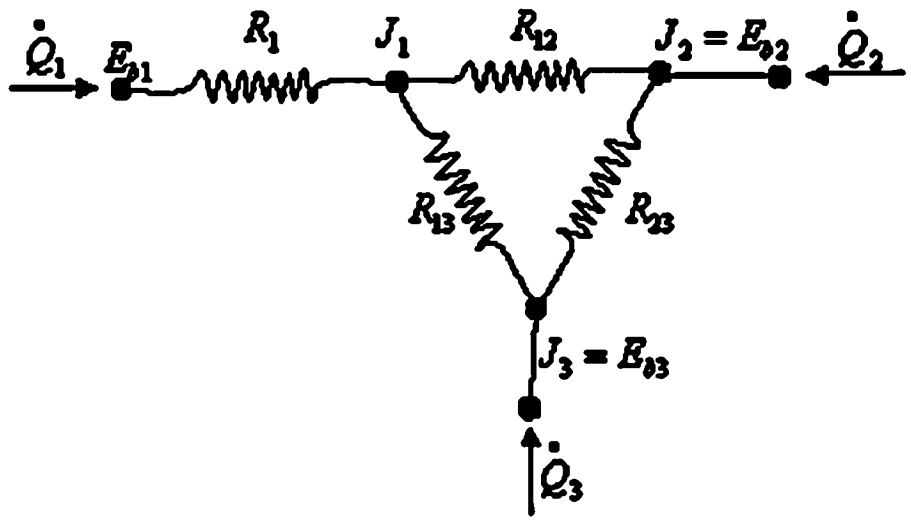
$$= \frac{1}{100(\text{ft}^2)\times 0.4}$$

$$= 0.015\text{ft}^{-2}$$

$$R_{12} = \frac{1}{A_1 F_{12}}$$

$$= \frac{1}{100(\text{ft}^2)\times 0.2}$$

$$= 0.05\text{ft}^{-2}$$



$$R_{13} = \frac{1}{A_1 F_{13}}$$

$$= \frac{1}{100(\text{ft}^2)\times 0.8}$$

$$= 0.0125\text{ft}^{-2}$$

Step 8 of 11

Since the side and the top surfaces are black, and thus their radiosities are equal to their emissive powers. The radiosity of the base surface is determined by using electrical network analogy that the algebraic sum of the currents (net radiation heat transfer) at each node must be equal to zero.

$$\frac{E_{b1}-J_1}{R_1}+\frac{E_{b2}-J_1}{R_{12}}+\frac{E_{b3}-J_1}{R_{13}}=0$$

$$\frac{702.0544-J_1}{0.015}+\frac{11232.8704-J_1}{0.05}+\frac{56866.4064-J_1}{0.0125}=0$$

$$J_1 = 28924.6413\text{Btu/h-ft}^2$$

Step 9 of 11

a) The net rate of radiation heat transfer between the base and the side surfaces can be determined as

$$\dot{Q}_{31} = \frac{E_{b3}-J_1}{R_{13}}$$

$$= \frac{56866.4064\,(\text{Btu/h-ft}^2)-28924.6413(\text{Btu/h-ft}^2)}{0.0125(\text{ft}^{-2})}$$

$$= 2.235\times 10^6\text{Btu/h}$$

$$\boxed{\dot{Q}_{31} = 2.235\times 10^6\text{Btu/h}}$$

Step 10 of 11

b) The net rate of radiation heat transfer between the base and the top surfaces is

$$\dot{Q}_{12} = \frac{J_1-E_{b2}}{R_{12}}$$

$$= \frac{28924.6413(\text{Btu/h-ft}^2)-11232.8704\,(\text{Btu/h-ft}^2)}{0.05\,(\text{ft}^{-2})}$$

$$= 3.538\times 10^5\text{Btu/h}$$

$$\boxed{\dot{Q}_{12} = 3.538\times 10^5\text{Btu/h}}$$

Step 11 of 11

c) The net rate of radiation heat transfer to the base surface can be determined as

$$\dot{Q}_1 = \dot{Q}_{12}+\dot{Q}_{13}$$

$$= 3.538\times 10^5(\text{Btu/h})+2.235\times 10^6\,(\text{Btu/h})$$

$$= 2.589\times 10^6\text{Btu/h}$$

$$\boxed{\dot{Q}_1 = 2.589\times 10^6\text{Btu/h}}$$

Question:

Reconsider Prob. 21-69E. Using EES (or other) software, investigate the effect of base surface emissivity on the net rates of radiation heat transfer between the base and the side surfaces, between the base and top surfaces, and to the base surface. Let the emissivity vary from 0.1 to 0.9. Plot the rates of heat transfer as a function of emissivity, and discuss the results.

Step 1 of 13

Given data:

Size of the cubical furnace, $L = 10\,\text{ft}$

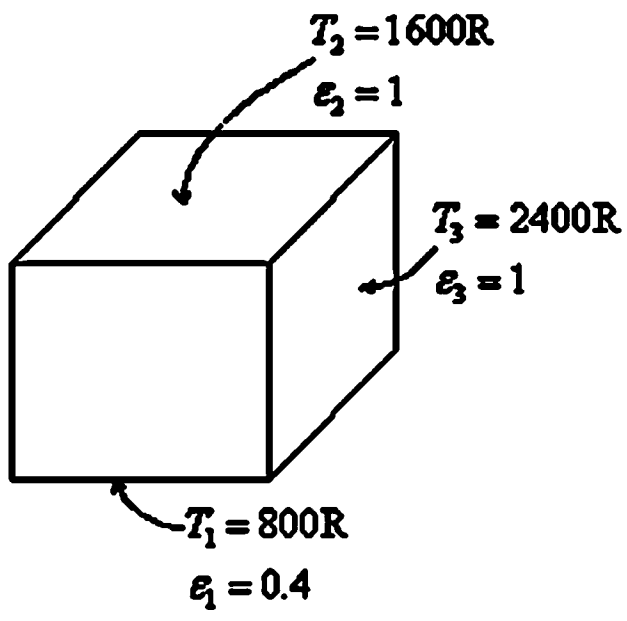
Emissivity of the base surface, $\varepsilon_1 = 0.4$

Emissivity of the top surface, $\varepsilon_2 = 1$

Emissivity of the side surfaces, $\varepsilon_3 = 1$

Temperature of the base surface, $T_1 = 800\,\text{R}$

Temperature of the top surface, $T_2 = 1600\,\text{R}$



Temperature of the side surfaces, $T_3 = 2400\,\text{R}$

Step 2 of 13

Assumptions:

1. The surfaces are diffuse, gray and opaque
2. Steady operating conditions exist
3. Heat transfer from and to the surfaces is only due to Radiation

Step 3 of 13

Step 4 of 13

Consider the base surface to be surface 1, the top surface to be surface 2 and the side surfaces to be surface 3. The cubical furnace can be considered to be three-surface enclosure. The areas and blackbody emissive powers of surfaces can be calculated as

$$A_1 = 10\times10\,(\text{ft})^2$$
$$= 100\,\text{ft}^2$$
$$A_2 = 10\times10\,(\text{ft})^2$$
$$= 100\,\text{ft}^2$$
$$A_3 = 4\times10\times10\,(\text{ft})^2$$
$$= 400\,\text{ft}^2$$

Step 5 of 13

Emissive powers on each surface

$$E_{b1} = \sigma T_1^4$$
$$= 0.1714\times10^{-8}\,(\text{Btu/h-ft}^2\text{-R}^4)\times800^4\,(\text{R})^4$$
$$= 702.0544\,\text{Btu/h-ft}^2$$
$$E_{b2} = \sigma T_2^4$$
$$= 0.1714\times10^{-8}\,(\text{Btu/h-ft}^2\text{-R}^4)\times1600^4\,(\text{R})^4$$
$$= 11232.8704\,\text{Btu/h-ft}^2$$
$$E_{b3} = \sigma T_3^4$$
$$= 0.1714\times10^{-8}\,(\text{Btu/h-ft}^2\text{-R}^4)\times2400^4\,(\text{R})^4$$
$$= 56866.4064\,\text{Btu/h-ft}^2$$

Step 6 of 13

From figure, the view factor from the base to the top surface of the cube can be determined as

$$\frac{L_1}{D} = \frac{10(\text{ft})}{10(\text{ft})} = 1$$
$$\frac{L_2}{D} = \frac{10(\text{ft})}{10(\text{ft})} = 1$$
$$F_{12} = 0.2$$

By using the summation rule, the view factor from the base or top to the side surfaces can be determined as

$$F_{11} + F_{12} + F_{13} = 1$$

Since the base surface is flat and thus the view factor $F_{11} = 0$

Therefore, by rewriting the above equation we will get

$$F_{13} = 1 - F_{11} - F_{12}$$
$$= 1 - 0 - 0.2$$
$$= 0.8$$

Step 7 of 13

In order to calculate the radiation heat transfer, we need to determine the thermal resistances and these can be calculated as

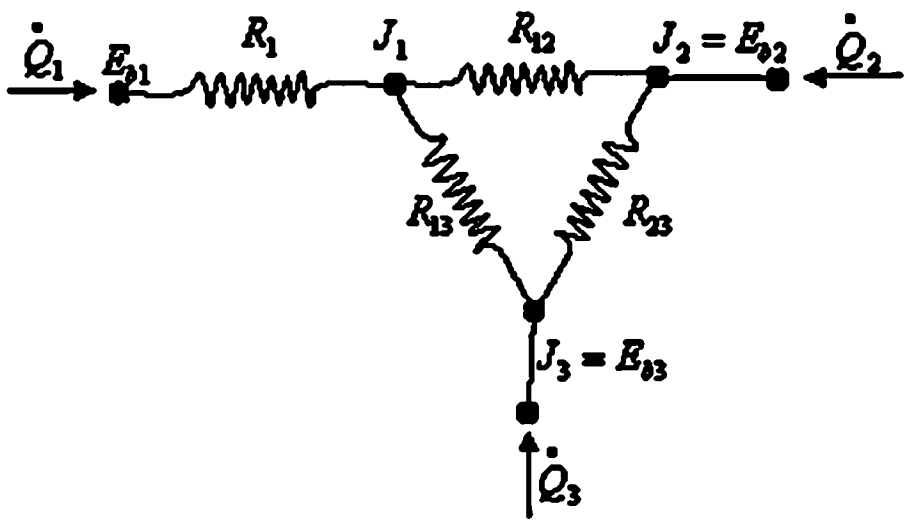
$$R_1 = \frac{1-\varepsilon_1}{A_1\varepsilon_1}$$
$$= \frac{1-\varepsilon_1}{100(\text{ft}^2)\times\varepsilon_1}$$
$$R_{12} = \frac{1}{A_1 F_{12}}$$

$$= \frac{1-\varepsilon_1}{100(\text{ft}^2)\times\varepsilon_1}$$

$$R_{12} = \frac{1}{A_1 F_{12}}$$

$$= \frac{1}{100(\text{ft}^2)\times 0.2}$$

$$= 0.05\text{ft}^{-2}$$



$$R_{13} = \frac{1}{A_1 F_{13}}$$

$$= \frac{1}{100(\text{ft}^2)\times 0.8}$$

$$= 0.0125\text{ft}^{-2}$$

Step 8 of 13

Since the side and the top surfaces are black, and thus their radiosities are equal to their emissive powers. The radiosity of the base surface is determined by using electrical network analogy that the algebraic sum of the currents (net radiation heat transfer) at each node must be equal to zero.

$$\frac{E_{b1}-J_1}{R_1}+\frac{E_{b2}-J_1}{R_{12}}+\frac{E_{b3}-J_1}{R_{13}}=0$$

$$\frac{702.0544-J_1}{R_1}+\frac{11232.8704-J_1}{0.05}+\frac{56866.4064-J_1}{0.0125}=0$$

By varying the emissivity of the bas surface, the thermal resistance of the base surface will vary and hence the radiosity of the base surface.

Step 9 of 13

a) The net rate of radiation heat transfer between the base and the side surfaces can be expressed as

$$\dot{Q}_{31} = \frac{E_{b3}-J_1}{R_{13}}$$

$$= \frac{56866.4064\,(\text{Btu/h-ft}^2)-J_1\,(\text{Btu/h-ft}^2)}{0.0125(\text{ft}^2)}$$

Step 10 of 13

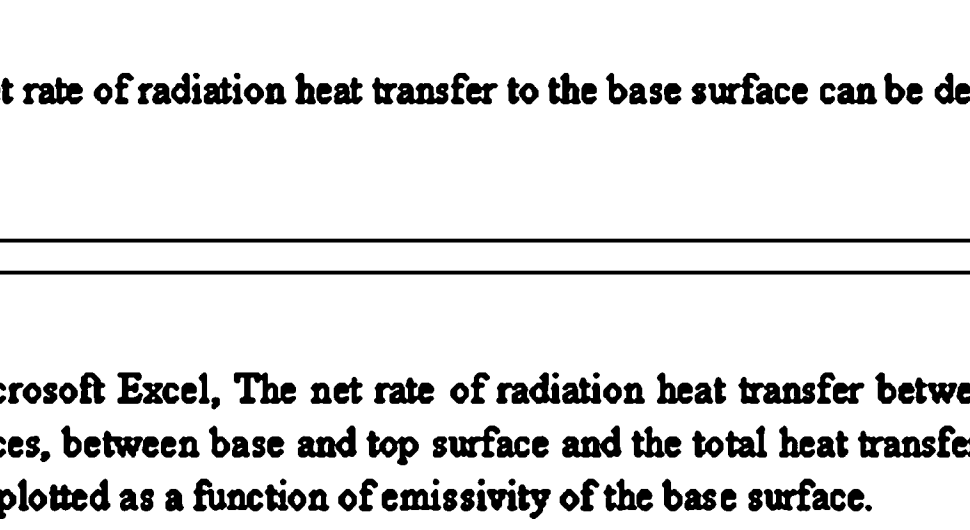
b) The net rate of radiation heat transfer between the base and the top surfaces can be expressed as

$$\dot{Q}_{12} = \frac{J_1-E_{b2}}{R_{12}}$$

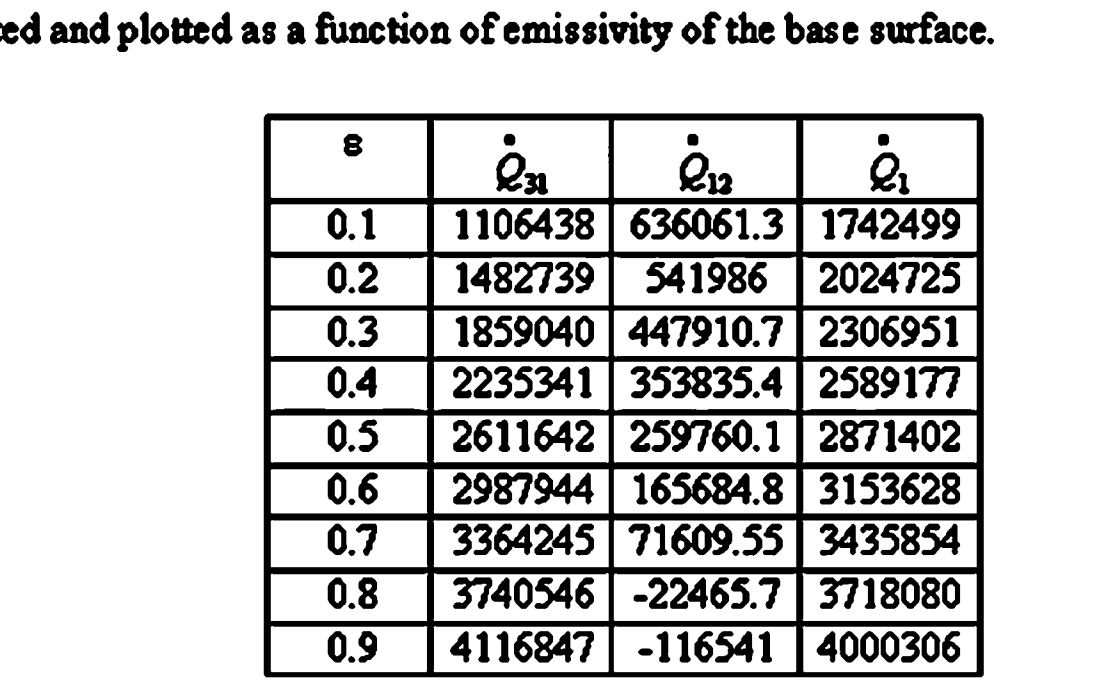
$$= \frac{J_1\,(\text{Btu/h-ft}^2)-11232.8704\,(\text{Btu/h-ft}^2)}{0.05\,(\text{ft}^2)}$$

Step 11 of 13

c) The net rate of radiation heat transfer to the base surface can be determined as

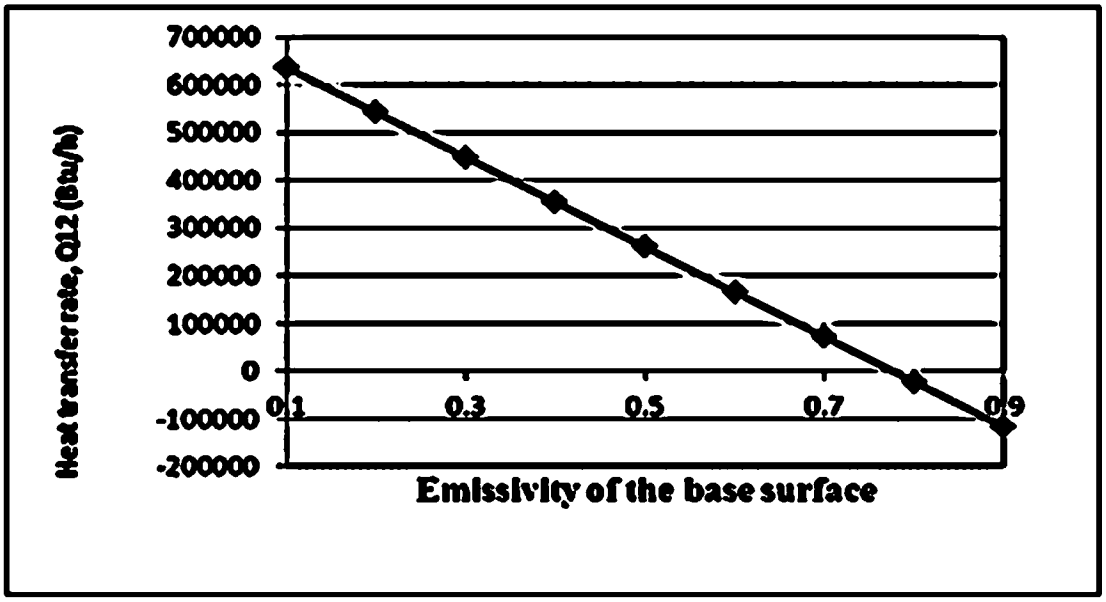


$$\dot{Q}_1 = \dot{Q}_{12}+\dot{Q}_{13}$$

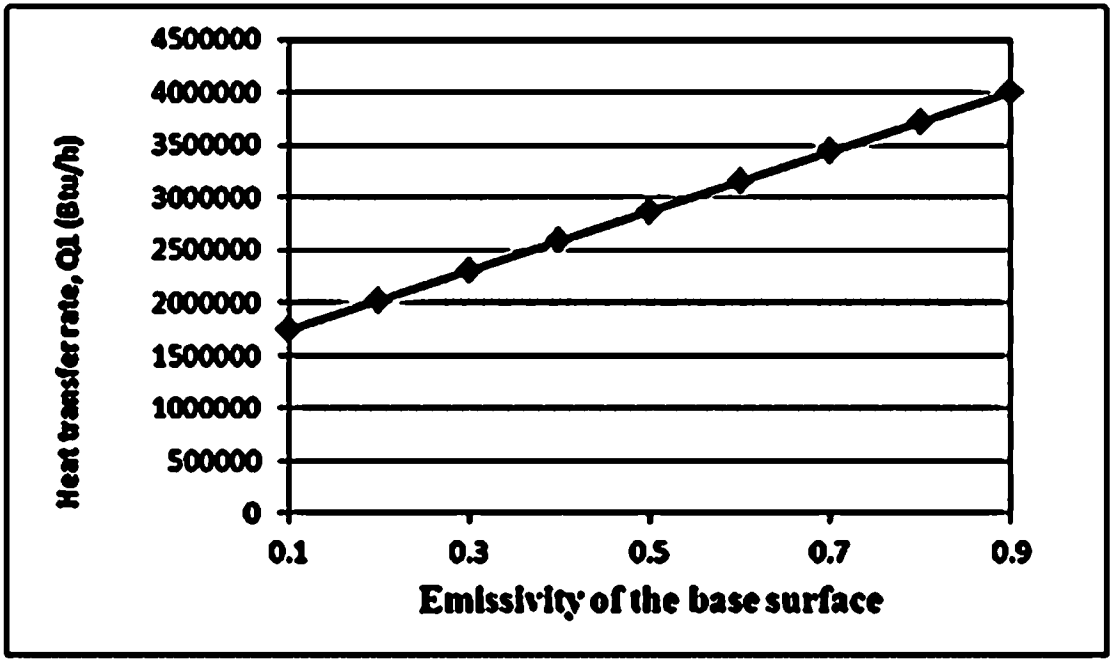


Step 12 of 13

Using the Microsoft Excel, The net rate of radiation heat transfer between the base and the side surfaces, between base and top surface and the total heat transfer to the base are tabulated and plotted as a function of emissivity of the base surface.



ε	$\dot{Q}_{31}$	$\dot{Q}_{12}$	$\dot{Q}_1$
0.1	1106438	636061.3	1742499
0.2	1482739	541986	2024725
0.3	1859040	447910.7	2306951
0.4	2235341	353835.4	2589177
0.5	2611642	259760.1	2871402
0.6	2987944	165684.8	3153628
0.7	3364245	71609.55	3435854
0.8	3740546	-22465.7	3718080
0.9	4116847	-116541	4000306



Step 13 of 13

Emissivity of the base surface

By increasing the emissivity of the base surface, the net rate of heat transfer between base and side surface increases, where as between base and top surface it is decreases and the total net rate of heat transfer to the base is increases.

Question: 21.071P

Two very large parallel plates are maintained at uniform temperatures of $T1 = 600$ K and $T2 = 400$ K and have emissivities $\varepsilon 1 = 0.5$ and $\varepsilon 2 = 0.9$, respectively. Determine the net rate of radiation heat transfer between the two surfaces per unit area of the plates.

Step 1 of 2

Given

Two plates maintained at temperatures $T_1 = 600\ K$

and $T_2 = 400\ \text{K}$

Emissivity of the two plates was $\varepsilon_1 = 0.5$

$\varepsilon_2 = 0.9$

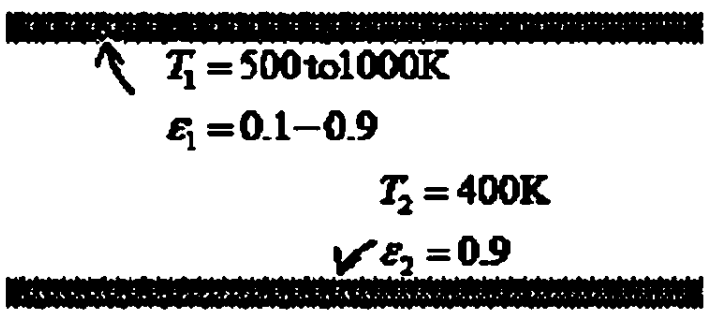
Step 2 of 2

The net rate of radiation heat transfer is calculated as

$$\dot{Q}_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1}$$

$$= \frac{5.67 \times 10^{-8} \times \left(600^4 - 400^4\right)}{\frac{1}{0.5} + \frac{1}{0.9} - 1}$$

$$= 2793.2\ \text{W/m}^2$$



Net rate of radiation heat transfer per unit area, $\boxed{\dot{Q}_{12} = 2793.2\ \text{W/m}^2}$

Question: 21.072P

Reconsider Prob. 21-71. Using EES (or other) software, investigate the effects of the temperature and the emissivity of the hot plate on the net rate of radiation heat transfer between the plates. Let the temperature vary from 500 K to 1000 K and the emissivity from 0.1 to 0.9. Plot the net rate of radiation heat transfer as functions of temperature and emissivity, and discuss the results.

Step 1 of 6

The surfaces are diffuse, gray and opaque. Steady operating conditions exist. Heat transfer from and to the surfaces is only due to radiation.

Step 2 of 6

The net rate of radiation heat transfer between the two surfaces per unit area of the plates is determined by the expression,

$$\dot{Q}_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1}$$

T_1 is the temperature of the top plate

T_2 is the temperature of the bottom plate

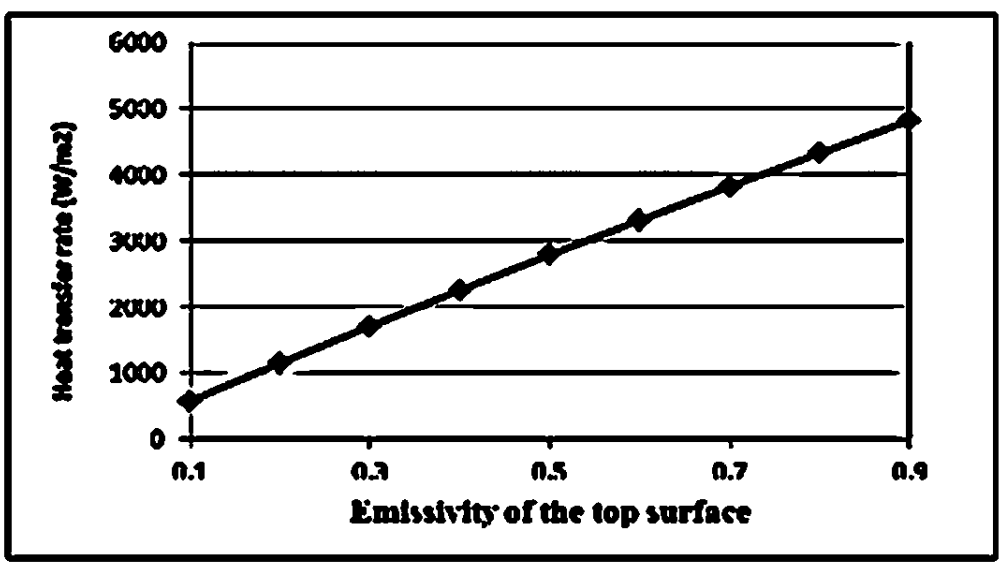
ε_1 is the emissivity of the top plate

ε_2 is the emissivity of the bottom plate

Now, substitute 400K for T_2 , 0.9 for ε_2

Then the expression becomes,

$$\dot{Q}_{12} = \frac{5.67\times10^{-8}\,(\text{W/m}^2\cdot\text{K}^4)\times(T_1^4 - 400^4)(\text{K}^4)}{\frac{1}{\varepsilon_1} + \frac{1}{0.9} - 1}$$



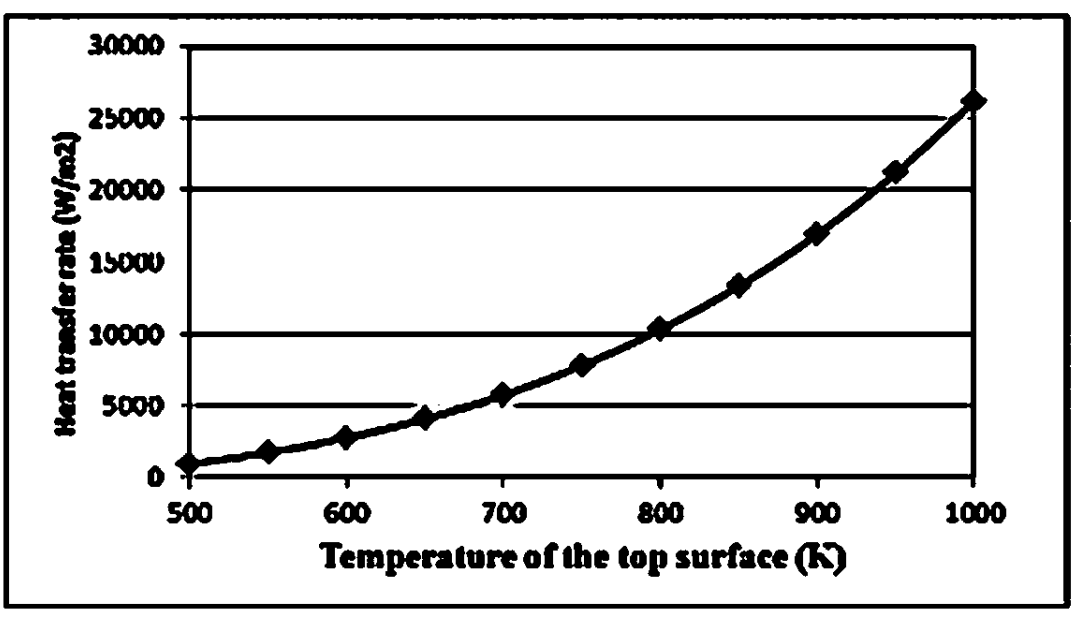
Step 3 of 6

By varying the emissivity of the top plate varied from 0.1 and 0.9, the EES software is developed the table for ε_1 corresponding to the $\dot{Q}_{12}$ values that are shown below,

ε_1	$\dot{Q}_{12}$
0.1	583.2
0.2	1153.722
0.3	1711.974
0.4	2258.349
0.5	2793.221
0.6	3316.95
0.7	3829.88
0.8	4332.343
0.9	4824.655

Step 4 of 6

The EES software is developing the graph between $\dot{Q}_{12}$ and ε_1 is as shown below,



Step 5 of 6

When the temperature varied from 500 K and 1000 K, the EES software is developing the table for T corresponding to the $\dot{Q}_{12}$ values is as shown below,

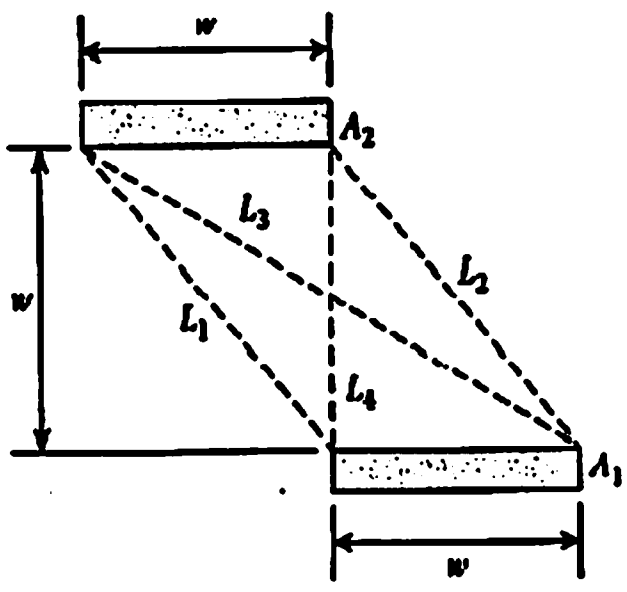
T	$\dot{Q}_{12}$
500	991.0563
550	1770.103
600	2793.221
650	4106.74
700	5761.018
750	7810.444
800	10313.43
850	13332.43
900	16933.9
950	21188.36
1000	26170.33

Step 6 of 6

The EES software is developing the graph between $\dot{Q}_{12}$ and T is as shown below,

Question: 21.073P

Two infinitely long parallel plates of width w are located at w distance apart, as shown in the figure. The two plates behave as black surfaces, where surface $A1$ has a temperature of 700 K and surface $A2$ has a temperature of 300 K. Determine the radiation heat flux between the two surfaces.



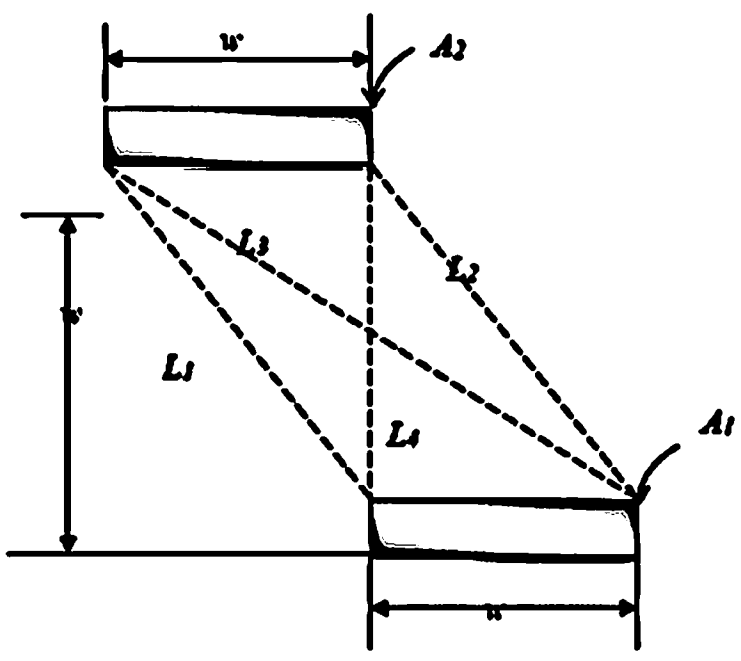


FIGURE P21–73

Step 1 of 4

Draw the schematic diagram of long parallel plates.

Step 2 of 4

Use Pythagoras theorem to calculate the crossed and uncrossed strings lengths.

$$L_4 = w$$

$$L_2 = \sqrt{L_4^2 + w^2}$$
$$= \sqrt{w^2 + w^2}$$
$$= \sqrt{2}w$$

$$L_1 = \sqrt{L_4^2 + w^2}$$
$$= \sqrt{w^2 + w^2}$$
$$= \sqrt{2}w$$

$$L_3 = \sqrt{(2w)^2 + (w)^2}$$
$$= \sqrt{5}w$$

Step 3 of 4

The view factor from the base plate to the top plate can be calculate by using the Hottel's cross-strings method.

$$F_{12} = \frac{\sum(\text{Crossed strings}) - \sum(\text{Uncrossed strings})}{2 \times (\text{String on surface 1})}$$
$$= \frac{(L_3 + L_4) - (L_1 + L_2)}{2w}$$

$$F_{12} = \frac{(L_3 + L_4) - (L_1 + L_2)}{2w}$$
$$= \frac{\left(\sqrt{5}w + w\right) - \left(\sqrt{2}w + \sqrt{2}w\right)}{2w}$$
$$= \frac{w\left[\left(\sqrt{5}+1\right) - \left(\sqrt{2}+\sqrt{2}\right)\right]}{2w}$$
$$= 0.204$$

Step 4 of 4

The net rate of heat flux $\dot{q}_{1\to 2}$ from surface 1 to surface 2 can be Calculate using the radiation equation.

$$\dot{q}_{1\to 2} = F_{1\to 2}\sigma\left(T_1^4 - T_2^4\right)$$

Here, $F_{1\to 2}$ is the view factor, σ is the Stefan Boltzmann constant, T_1 is the Temperature of the surface A_1 and T_2 is the temperature of the surface A_2.

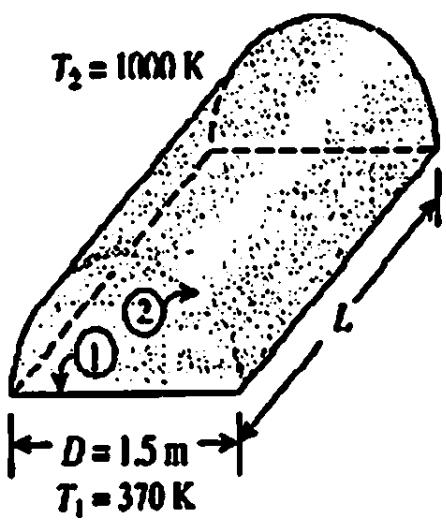
Substitute 0.204 for $F_{1\to 2}$, $5.67\times10^{-8}\ \text{W/m}^2\text{-K}^4$ for σ, 700K for T_1 and 300K for T_2.

$$\dot{q}_{1\to 2} = F_{1\to 2}\sigma\left(T_1^4 - T_2^4\right)$$
$$= 0.204\times5.67\times10^{-8}(\text{W/m}^2\text{-K}^4)\times\left[(700\text{K})^4 - (300\text{K})^4\right]$$
$$= 2683.5\ \text{W/m}^2$$

Therefore, the net rate of heat flux is $\boxed{2683.5\ \text{W/m}^2}$.

Question: 21.074P

A dryer is shaped like a long semi-cylindrical duct of diameter 1.5 m. The base of the dryer is occupied with water soaked materials to be dried. The base is maintained at



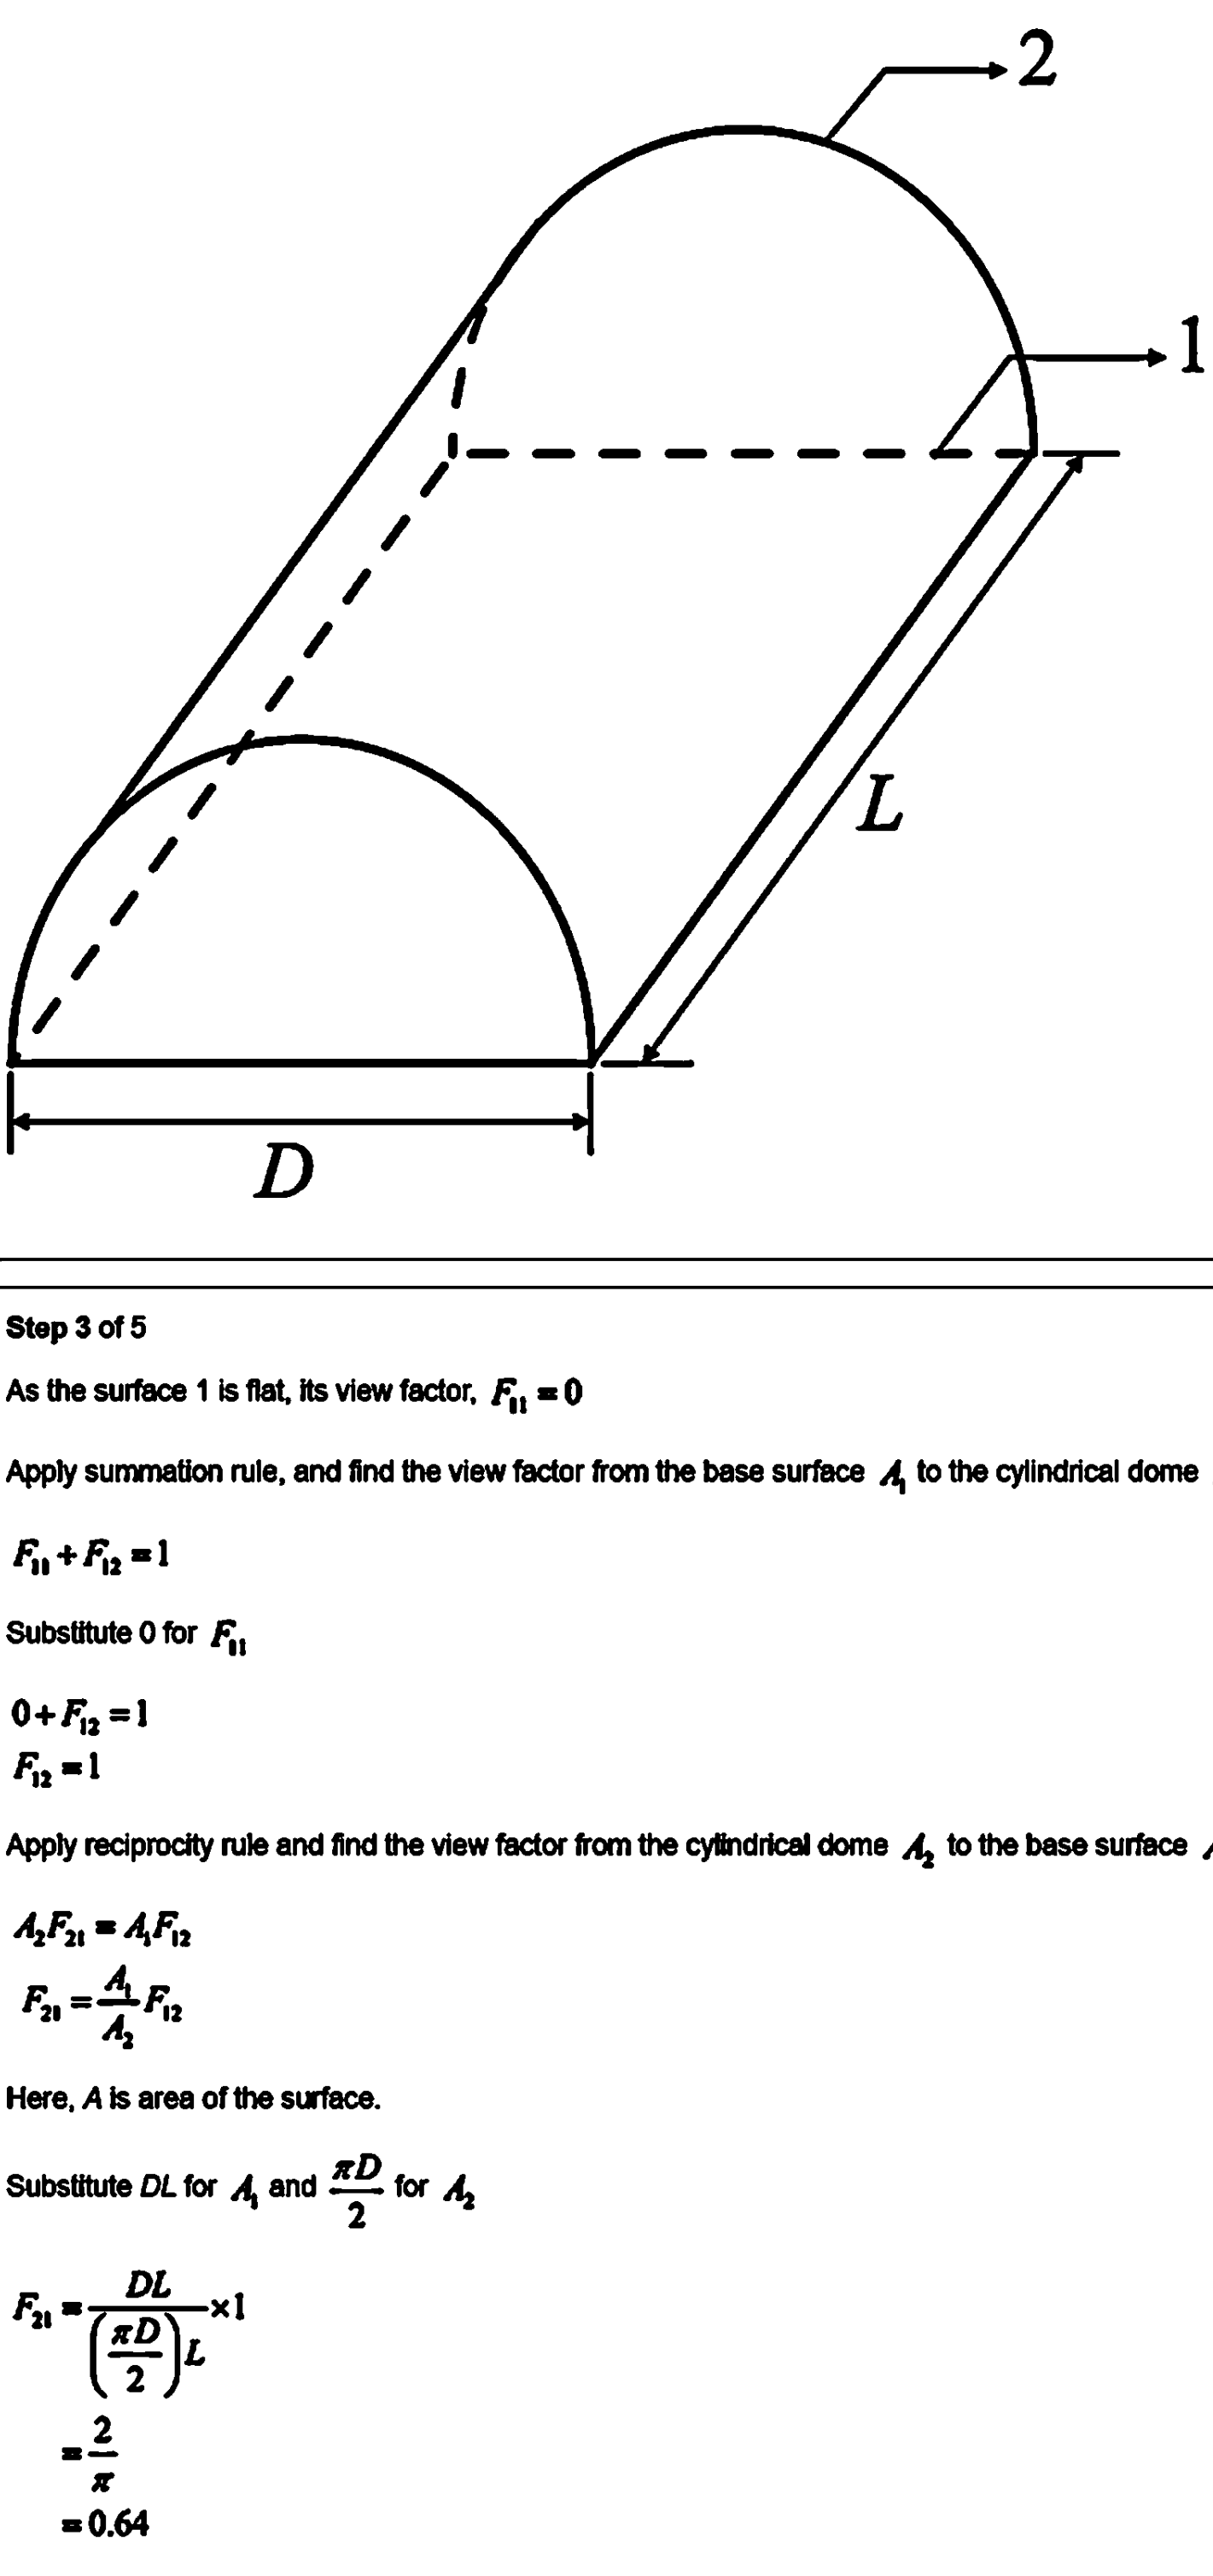


FIGURE P21–74

a temperature of 370 K, while the dome of the dryer is maintained at 1000 K. If both surfaces behave as blackbody, determine the drying rate per unit length experienced by the wet materials.

Step 1 of 5

Draw the semi cylindrical duct as shown:

Step 2 of 5

Step 3 of 5

As the surface 1 is flat, its view factor, $F_{11} = 0$

Apply summation rule, and find the view factor from the base surface A_1 to the cylindrical dome A_2

$$F_{11} + F_{12} = 1$$

Substitute 0 for F_{11}

$$0 + F_{12} = 1$$
$$F_{12} = 1$$

Apply reciprocity rule and find the view factor from the cylindrical dome A_2 to the base surface A_1.

$$A_2 F_{21} = A_1 F_{12}$$
$$F_{21} = \frac{A_1}{A_2} F_{12}$$

Here, *A* is area of the surface.

Substitute *DL* for A_1 and $\frac{\pi D}{2}$ for A_2

$$F_{21} = \frac{DL}{\left(\frac{\pi D}{2}\right)L} \times 1$$
$$= \frac{2}{\pi}$$
$$= 0.64$$

Step 4 of 5

Apply energy balance equation to the dryer.

$$\dot{Q}_{21} = \dot{Q}_{evap}$$

Calculate the radiation heat exchange between the dome and the base surface per unit length by using the following equation:

$$\dot{Q}_{21} = F_{21} A_2 \sigma \left(T_2^4 - T_1^4\right)$$
$$\dot{Q}_{21} = F_{21} \times \frac{\pi D}{2} \sigma \left(T_2^4 - T_1^4\right)$$

Here, σ is Stefan Boltzmann's constant, T_1 is base temperature and T_2 is temperature of the dome.

Substitute 0.64 for F_{21}, 1.5 m for *D*, $5.67 \times 10^{-8}\ \text{W/m}^2.\text{K}^4$ for σ, 370 K for T_1, and 1000 K for T_2

$$\dot{Q}_{21} = 0.64 \times \left(\frac{\pi}{2} \times 1.5\right) \times 5.67 \times 10^{-8} \times \left(1000^4 - 370^4\right)$$
$$= 83899.15\ \text{W/m}$$

Step 5 of 5

Find the mass flow rate of water by using amount of heat required for drying.

$$\dot{Q}_{21} = \dot{Q}_{evap}$$
$$\dot{Q}_{evap} = \dot{m} h_{fg}$$

Here, h_{fg} is enthalpy of vaporization and $\dot{m}$ is mass flow rate of water.

Substitute $83899.15\ \text{W/m}$ for $\dot{Q}_{evap}$ and $2257 \times 10^3\ \text{J/kg}$ for h_{fg}

$$83899.15 = \dot{m} \times 2257 \times 10^3$$
$$\dot{m} = 0.0371\ \text{kg/s.m}$$

Therefore, the drying rate per unit length is $\boxed{0.0371\ \text{kg/s} \cdot \text{m}}$.

Question: 21.075P

A furnace is of cylindrical shape with $R = H = 3$ m. The base, top, and side surfaces of the furnace are all black and are maintained at uniform temperatures of 500,700, and 1400 K, respectively. Determine the net rate of radiation heat transfer to or from the top surface during steady operation.

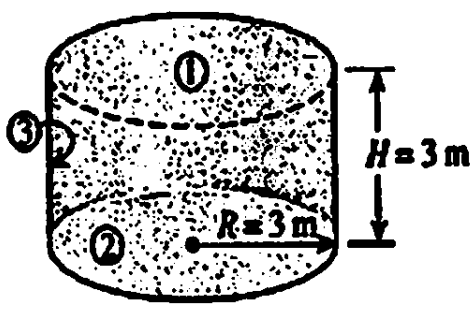

FIGURE P21–75

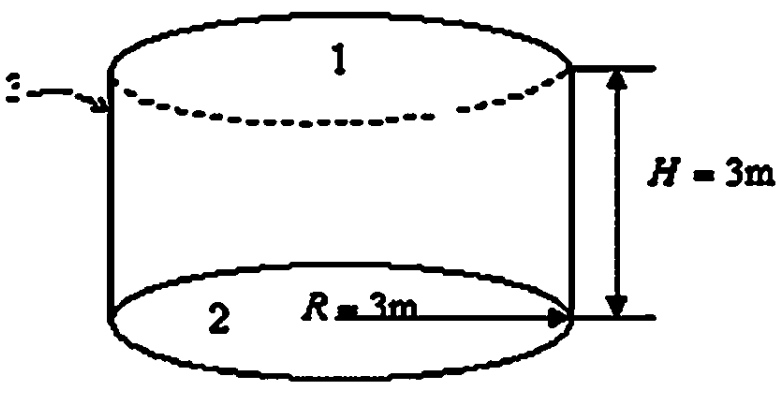
Step 1 of 6

Given data:

Radius of the furnace, $R = 3\,\text{m}$

Height of the furnace, $H = 3\text{m}$

Emissivity of the all furnace surfaces, $\varepsilon = 1$



Temperature of the base surface, $T_2 = 500\,\text{K}$

Temperature of the top surface, $T_1 = 700\,\text{K}$

Temperature of the side surface, $T_3 = 1400\,\text{K}$

Step 2 of 6

Given figure:

Step 3 of 6

Consider the top surface to be surface 1, the base surface to be surface 2 and the side surface to be surface 3.

The area of the top surface is given by,

$$A_1 = \pi R^2$$
$$= \pi \times 3^2$$
$$= 28.27\,\text{m}^2$$

From the figure, the view factor from the base to the top surface is determined as

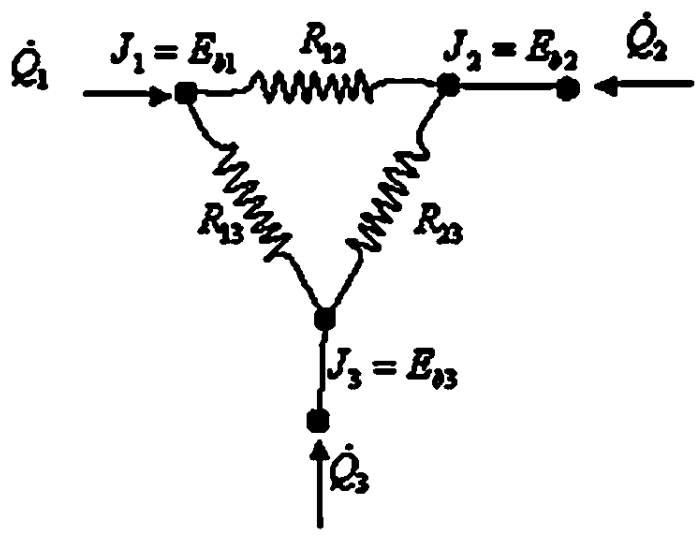
$$F_{12} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

where,

$$R = \frac{L_1}{R_1}$$
$$= \frac{3}{3}$$
$$= 1$$

Substituting the value of R, we have,

$$F_{12} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$
$$= 1 + \frac{1 - \sqrt{\left(4 \times 1^2\right) + 1}}{2 \times 1^2}$$
$$F_{12} = 0.38$$



Step 4 of 6

The view factor from the base to the side surfaces is determined by applying the summation rule to be

$$F_{11} + F_{12} + F_{13} = 1$$
$$0 + 0.38 + F_{13} = 1$$
$$F_{13} = 1 - 0.38$$
$$= 0.62$$

Step 5 of 6

The cylindrical furnace can be considered to be three-surface enclosure. We assume that steady-state conditions exist. Since all the surfaces are black, the radiosities are equal to the emissive powers of surfaces, and the net rate of radiation heat transfer from the top surface can be determined by using electrical network analogy that the algebraic sum of the currents (net radiation heat transfer) at each node must be equal to zero.

Step 6 of 6

The net rate of radiation heat transfer from the top surface can be expressed as,

$$\dot{Q} = A_1 F_{12} \sigma\left(T_1^4 - T_2^4\right) + A_1 F_{13} \sigma\left(T_1^4 - T_3^4\right)$$
$$= 28.27\left(\text{m}^2\right) \times 0.38 \times 5.67 \times 10^{-8}\left(\text{W/m}^2 \cdot \text{K}^4\right)\left(700^4 - 500^4\right)\left(\text{K}^4\right)$$
$$+ 28.27\left(\text{m}^2\right) \times 0.62 \times 5.67 \times 10^{-8}\left(\text{W/m}^2 \cdot \text{K}^4\right)\left(700^4 - 1400^4\right)\left(\text{K}^4\right)$$
$$= -3471\,\text{kW}$$

$$\boxed{\dot{Q} = -3471\,\text{kW}}$$

The negative sign indicates that the net heat transfer is towards the top surface.

Therefore, the net rate of radiation heat transfer to the top surface is determined to be 3471 kW.

Question: 21.076P

A 9-ft-high room with a base area of 12 ft × 12 ft is to be heated by electric resistance heaters placed on the ceiling, which is maintained at a uniform temperature of 90°F at all times. The floor of the room is at 65°F and has an emissivity of 0.8. The side surfaces are well insulated. Treating the ceiling as a blackbody, determine the rate of heat loss from the room through the floor.

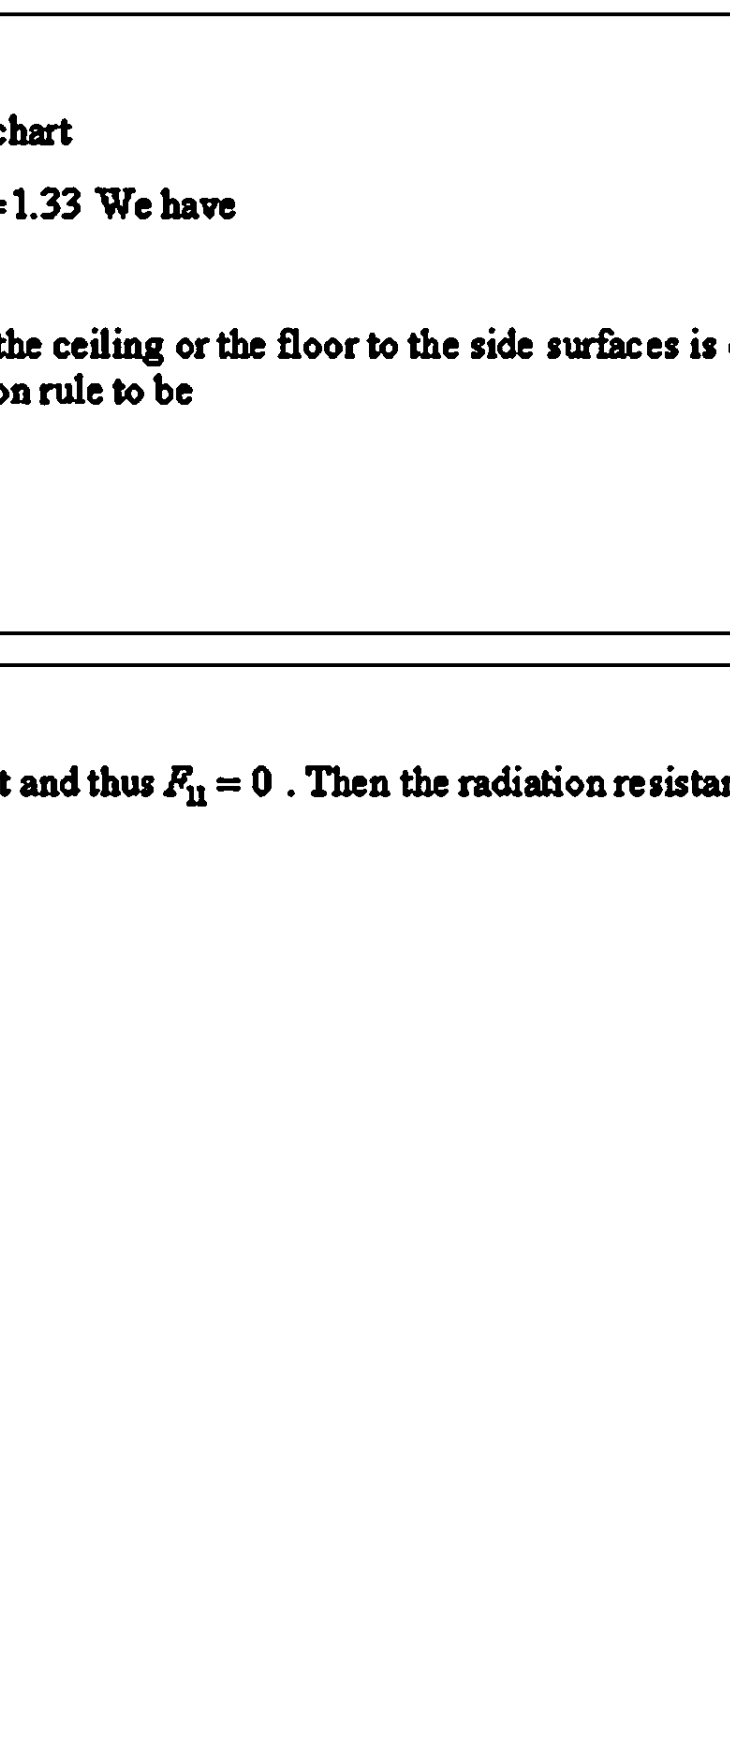
Step 1 of 7

Given data:

Base area of the room, $A_2 = A_1 = 12\text{ft} \times 12\text{ft}$

Height of the room, $D = 9\text{ft}$

Emissivity of the base surface, $\varepsilon_2 = 0.8$



Emissivity of the top surface, $\varepsilon_1 = 1$

Temperature of the base surface, $T_2 = 65\,^{\circ}\text{F}$

Temperature of the top surface, $T_1 = 90^{\circ}\text{F}$

Step 2 of 7

Ceiling temperature and floor temperature of the room is as shown in figure:

Step 3 of 7

Consider the base surface to be surface 1, the top surface to be surface 2 and the side surfaces to be surface 3. The furnace can be considered to be three-surface enclosure. The areas and blackbody emissive powers of surfaces can be calculated as

$$A_1 = 12 \times 12$$
$$= 144\text{ft}^2$$
$$A_2 = 12 \times 12$$
$$= 144\text{ft}^2$$

From the figure, the view factor from the floor to the ceiling of the room is

$$\frac{L_1}{D} = \frac{12}{9}$$
$$= 1.33$$
$$\frac{L_2}{D} = \frac{12}{9}$$
$$= 1.33$$

Step 4 of 7

From the view factor chart

At $\frac{L_1}{D} = 1.33$ and $\frac{L_2}{D} = 1.33$ We have

$$F_{12} = 0.27$$

The view factor from the ceiling or the floor to the side surfaces is determined by applying the summation rule to be

$$F_{11} + F_{12} + F_{13} = 1$$
$$0 + 0.27 + F_{13} = 1$$
$$F_{13} = 0.73$$

Step 5 of 7

Since the ceiling is flat and thus $F_{11} = 0$. Then the radiation resistances are calculated as

$$R_2 = \frac{1-\varepsilon_2}{A_2\varepsilon_2}$$
$$= \frac{1-0.8}{144 \times 0.8}$$
$$= 0.001736\,\text{ft}^{-2}$$
$$R_{12} = \frac{1}{A_1 F_{12}}$$
$$= \frac{1}{144 \times 0.27}$$
$$= 0.0257\text{ft}^{-2}$$
$$R_{13} = R_{23}$$
$$= \frac{1}{A_1 F_{13}}$$
$$= \frac{1}{144 \times 0.73}$$
$$= 0.009513\text{ft}^{-2}$$

Step 6 of 7

The emissive powers of the ceiling and base surface are calculated as

$$E_{b1} = \sigma T_1^4$$
$$= 0.1714 \times 10^{-8} \times 550^4$$
$$= 156.84\ \text{Btu/h} \cdot \text{ft}^2$$
$$E_{b2} = \sigma T_2^4$$
$$= 0.1714 \times 10^{-8} \times 525^4$$
$$= 130.211\text{Btu/h} \cdot \text{ft}^2$$

Step 7 of 7

Since the side surfaces are reradiating, there is no heat transfer through them, and the entire heat lost by the ceiling must be gained by the floor. Then the rate of heat loss from the room through its floor can be determined as

$$\dot{Q}_{12} = \frac{E_{b1} - E_{b2}}{\left(\frac{1}{R_{12}} + \frac{1}{R_{13} + R_{23}}\right)^{-1} + R_2}$$
$$= \frac{156.84 - 130.211}{\left(\frac{1}{0.0257} + \frac{1}{2 \times 0.009513}\right)^{-1} + 0.001736}$$
$$= 2102\ \text{Btu/h}$$

Therefore, the rate of heat loss from the floor is $\boxed{\dot{Q}_{12} = 2102\text{Btu/h}}$.

Question: 21.077P

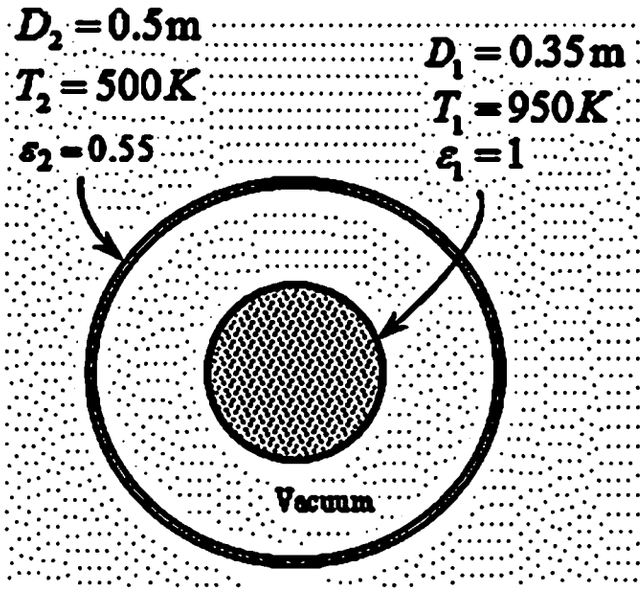
Two very long concentric cylinders of diameters $D1 = 0.35$ m and $D2 = 0.5$ m are maintained at uniform temperatures of $T1 = 950$ K and $T2 = 500$ K and have emissivities $\varepsilon 1 = 1$ and $\varepsilon 2 = 0.55$, respectively. Determine the net rate of radiation heat transfer between the two cylinders per unit length of the cylinders.

Step 1 of 3

Given data:

Diameter of inner cylinder, $D_1 = 0.35$ m

Diameter of outer cylinder, $D_2 = 0.5$ m



Temperature of inner cylinder, $T_1 = 950\ K$

Temperature of outer cylinder, $T_2 = 500$ K

Emissivities of the two cylinders are $\varepsilon_1 = 1$

And $\varepsilon_2 = 0.55$

Step 2 of 3

Step 3 of 3

Rate of radiation heat transfer between two cylinders per unit length is

$$\dot{Q}_{12} = \frac{A_1\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \left(\frac{1-\varepsilon_2}{\varepsilon_2}\right)\left(\frac{r_1}{r_2}\right)}$$

$$\frac{\dot{Q}_{12}}{L} = \frac{\pi \times 0.35 \times 5.67 \times 10^{-8} \times \left(950^4 - 500^4\right)}{\frac{1}{1} + \left(\frac{1-0.55}{0.55}\right)\left(\frac{0.35}{0.5}\right)}$$

$$= \frac{46883.76}{1.572}$$

$$= 29810.48\ \text{W}$$

Net rate radiation heat transfer per unit length, $\boxed{\dot{Q} = 29.81\ \text{kW}}$

Question: 21.078P pg 1

This question deals with steady-state radiation heat transfer between a sphere ($r1$ = 30 cm) and a circular disk ($r2$ = 120 cm), which are separated by a center-to-center distance h = 60 cm. When the normal to the center of disk passes through the center of the sphere, the radiation view factor is given by

$$F_{12} = 0.5\left\{1 - \left[1 + \left(\frac{r_2}{h}\right)^2\right]^{-0.5}\right\}$$

Surface temperatures of the sphere and the disk are 600°C and 200°C, respectively; and their emissivities are 0.9 and 0.5, respectively.

(*a*) Calculate the view factors *F*12 and *F*2l.

(*b*) Calculate the net rate of radiation heat exchange between the sphere and the disk.

(*c*) For the given radii and temperatures of the sphere and the disk, the following four possible modifications could increase the net rate of radiation heat exchange: paint each of the two surfaces to alter their emissivities, adjust the distance between them, and provide an (refractory) enclosure. Calculate the net rate of radiation heat exchange between the two bodies if the *best values* are selected for each of the above modifications.

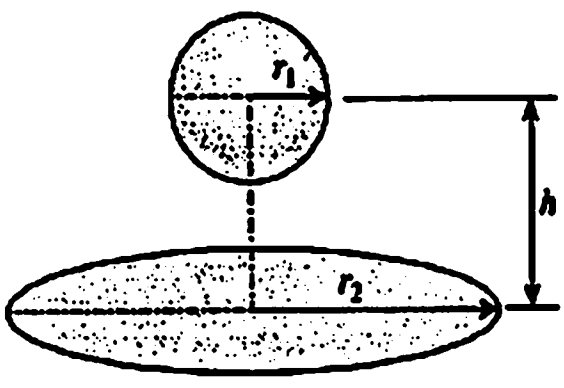


FIGURE P21–78

Step 1 of 10

(a) The radiation view factor from surface 1 to surface 2 is given as,

$$F_{12} = 0.5\left\{1-\left[1+\left(\frac{r_2}{h}\right)^2\right]^{-0.5}\right\}$$

Radius of disc is r_2

Center to center distance is h

Now, Substitute 120 cm for r_2 and 60 cm for h

$$F_{12} = 0.5\left\{1-\left[1+\left(\frac{120}{60}\right)^2\right]^{-0.5}\right\}$$
$$= 0.5\times 0.5527$$
$$= 0.27635$$

Therefore, the radiation view factor from surface 1 to surface 2 is $\boxed{F_{12} = 0.2764}$

Step 2 of 10

The view factor from surface 2 to surface 1 can be calculated using the reciprocity rule,

$$A_2F_{21} = A_1F_{12}$$

The area of the sphere is A_1

The area of the disc surface is A_2

Therefore, the view factor F_{21} calculated as,

$$F_{21} = \frac{A_1}{A_2}F_{12}$$
$$= \frac{\pi\times 0.6^2}{\frac{\pi}{4}\times 2.4^2}\times 0.2764$$
$$= 0.0691$$

Therefore, the view factor from 2 to 1 is $\boxed{0.0691}$

Step 3 of 10

(b) The net rate of radiation heat transfer between the surfaces can be determined by the expression,

$$\dot{Q}_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1-\varepsilon_1}{A_1\varepsilon_1} + \frac{1}{A_1F_{12}} + \frac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

Now substitute 5.67×10^{-8} W/m^2-K for σ , 873K for T_1 , 473K for T_2 , and 0.9 for ε_1 , 0.5 for ε_2

$$\dot{Q}_{12} = \frac{5.67\times10^{-8}\times(873^4 - 473^4)}{\frac{1-0.9}{1.131\times0.9} + \frac{1}{1.131\times0.2764} + \frac{1-0.5}{4.524\times0.5}}$$
$$= \frac{30095.56}{3.518}$$
$$= 8554.73\,\text{W}$$

Therefore, the net rate of radiation heat exchange between the sphere and the disk is $\boxed{8554.73\,\text{W}}$

Step 4 of 10

(c)The given two modifications could increase the net rate of radiation heat exchange, which are

1) Emissivity of the surfaces should be 1.
   It can be achieved by paint each of the two surfaces to alter their emissivities, and get maximum possible heat exchange.
2) By adjusting the distance between the two bodies which means that for $h = 0$ the maximum possible heat exchange will happen.

In this case, the view factor becomes,

$$F_{12} = 0.5\left\{1-\left[1+\left(\frac{r_2}{h}\right)^2\right]^{-0.5}\right\}$$

Now substitute, $h = 0$ and 120 cm for r_2

$$F_{12} = 0.5\left\{1-\left[1+\left(\frac{120}{0}\right)^2\right]^{-0.5}\right\}$$
$$= 0.5$$

$$F_{12}=0.5\left\{1-\left[1+\left(\frac{120}{0}\right)^2\right]^{-0.5}\right\}$$
$$=0.5$$

Step 5 of 10

The view factor F_{21} calculated as using the reciprocity rule as follows,

$$A_2F_{21}=A_1F_{12}$$
$$F_{21}=\frac{A_1}{A_2}F_{12}$$

Now substitute, $A_1=\pi\times0.6^2$, $A_2=\frac{\pi}{4}\times2.4^2$ and $F_{12}=0.5$

$$F_{21}=\frac{1.131}{4.524}\times0.5$$
$$=0.125$$

Step 6 of 10

(3) By providing a refractory enclosure and let us assume the enclosure surface is 3,

By using the summation rule,

$$F_{11}+F_{12}+F_{13}=1$$
$$F_{21}+F_{22}+F_{23}=1$$

Since the view factor with respect to the sphere surface and disc itself, $F_{11}=0$ and $F_{22}=0$

Therefore,

$$F_{11}+F_{12}+F_{13}=1$$
$$0+F_{12}+F_{13}=1$$
$$F_{13}=1-F_{12}$$

Substitute, 0.5 for F_{12}

$$F_{13}=1-F_{12}$$
$$=1-0.5$$
$$=0.5$$

Step 7 of 10

And for the surface 2

$$F_{21}+F_{22}+F_{23}=1$$
$$F_{21}+0+F_{23}=1$$
$$F_{23}=1-F_{21}$$

Now substitute 0.5 for F_{12}

$$F_{23}=1-F_{21}$$
$$=1-0.125$$
$$=0.875$$

Step 8 of 10

The surface resistance of the circular disk can be calculated as

$$R_2=\frac{1-\varepsilon_2}{A_2\varepsilon_2}$$

Now, substitute 0.5 for ε_2, $A_2=\frac{\pi}{4}\times2.4^2$

$$R_2=\frac{1-1}{\frac{\pi}{4}\times2.4^2\times1}$$
$$=0$$

The space resistance for surfaces $1\to2$ can be calculated as

$$R_{12}=\frac{1}{A_1F_{12}}$$

Now, substitute 0.5 for F_{12}, $A_1=\pi\times0.6^2$

$$R_{12}=\frac{1}{\left(\pi\times0.6^2\right)\times0.5}$$
$$=1.768\ \text{m}^{-2}$$

Step 9 of 10

The space resistance for surfaces $1\to3$ can be calculated as

$$R_{13}=\frac{1}{A_1F_{13}}$$

Now, substitute 0.5 for F_{13}, $A_1=\pi\times0.6^2$

$$R_{13}=\frac{1}{1.131\times0.5}$$
$$=1.768\ \text{m}^{-2}$$

The space resistance for surfaces $2\to3$ can be calculated as

$$R_{23}=\frac{1}{A_2F_{23}}$$

Now, substitute 0.875 for F_{23}, $A_2=\frac{\pi}{4}\times2.4^2$

$$R_{23}=\frac{1}{4.524\times0.875}$$
$$=0.25262\ \text{m}^{-2}$$

Step 10 of 10

Therefore, the net rate of radiation heat exchange can be calculated as,

$$\dot{Q}_{12}=\frac{E_{b1}-E_{b2}}{\left(\frac{1}{R_{12}}+\frac{1}{R_{13}+R_{23}}\right)^{-1}+R_2}$$

Emissive power of the surface 1 E_{b1}

Emissive power of the surface 1 E_{b2}

$$\dot{Q}_{12}=\frac{\sigma T_1^4-\sigma T_2^4}{}$$

Emissive power of the surface 1 E_{b1}

Emissive power of the surface 1 E_{b2}

$$\dot{Q}_{12} = \frac{\sigma T_1^4 - \sigma T_2^4}{\left(\frac{1}{R_{12}} + \frac{1}{R_{13}+R_{23}}\right)^{-1} + R_2}$$

Now substitute, 0 for R_2 1.768 m^{-2} for R_{12} 1.768 m^{-2} for R_{13} 0.25262 m^{-2} for R_{23} and $5.67\times10^{-8}\ W/m^2\cdot K$ for σ , 873K for T_1 , 473K for T_2

$$\dot{Q}_{12} = \frac{5.67\times10^{-8}\times(873^4 - 473^4)}{\left(\frac{1}{1.768} + \frac{1}{(1.768+0.25262)}\right)^{-1} + 0}$$

$$= \frac{30095.56}{0.9429}$$

$$= 31916.59\ W$$

The net rate of radiation heat exchange between the two bodies, $\boxed{\dot{Q}_{12} = 31916.6\,W}$

Hence, the net rate of heat transfer is higher in part (c) which is almost 3 times higher than part 2 by using the best values.

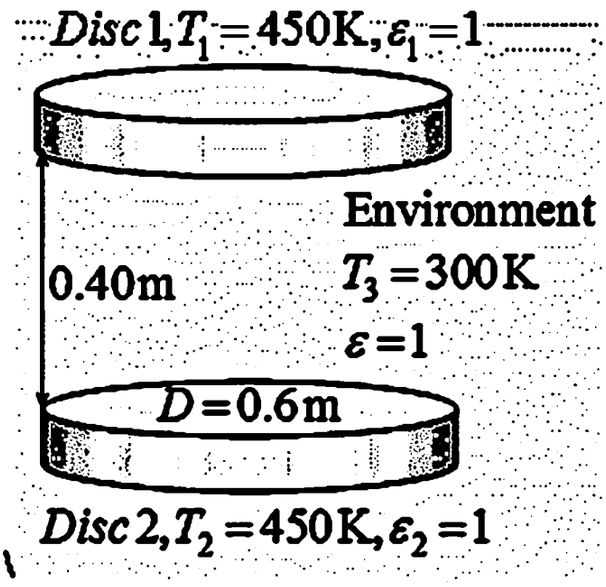
Question: 21.079P

Two parallel disks of diameter $D = 0.6$ m separated by $L = 0.4$ m are located directly on top of each other. Both disks are black and are maintained at a temperature of 450 K. The back sides of the disks are insulated, and the environment that the disks are in can be considered to be a blackbody at 300 K. Determine the net rate of radiation heat transfer from the disks to the environment.

Step 1 of 4

Given

Diameter of the disk, $D = 0.6\text{ m}$



Distance between two discs, $L = 0.4\text{m}$

Temperatures of each disc 1, $T_1 = 450\text{K}$

Temperatures of each disc 2, $T_2 = 450\text{K}$

Environment temperature, $T_3 = 300\text{K}$

Step 2 of 4

Step 3 of 4

From figure, view factor between two coaxial parallel disks

For $L/r_1 = 1.33$

And $r_2/L = 0.75$

So view factor between base to top surface of the cylinder becomes $F_{12} = 0.26$ From the summation rule

$$F_{13} = 1 - 0.26$$
$$= 0.74$$

Step 4 of 4

The net rate of radiation heat transfer from the discs to the environment is calculated as

$$\dot{Q}_3 = \dot{Q}_{13} + \dot{Q}_{23}$$
$$= 2\dot{Q}_{13}$$
$$\dot{Q}_3 = 2F_{13}A_1\sigma(T_1^4 - T_3^4)$$
$$= 2 \times 0.74 \times \left(\pi \times 0.3^2\right) \times 5.67 \times 10^{-8} \times \left(450^4 - 300^4\right)$$
$$= 780.76\text{ W}$$

Net rate heat radiation, $\boxed{\dot{Q}_3 = 780.76\text{ W}}$

Question: 21.080P

Two black parallel rectangles with dimensions 3 ft × 5 ft are spaced apart by a distance of 1 ft. The two parallel rectangles are experiencing radiation heat transfer as black surfaces, where the top rectangle receives a total of 180,000 Btu/h radiation heat transfer rate from the bottom rectangle. If the top rectangle has a uniform temperature of 60°F, determine the temperature of the bottom rectangle.

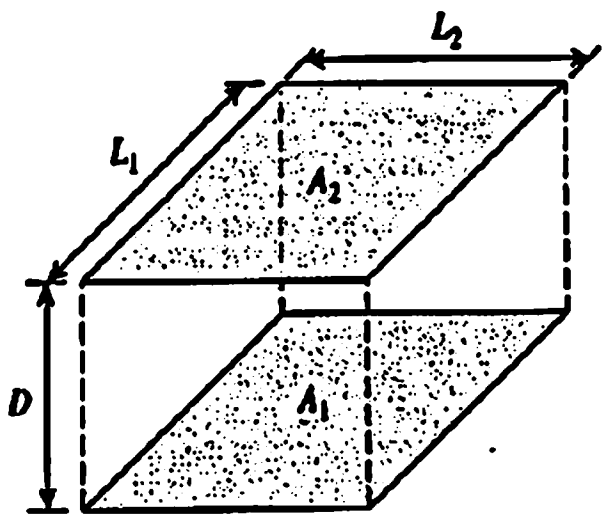


FIGURE P21–80E

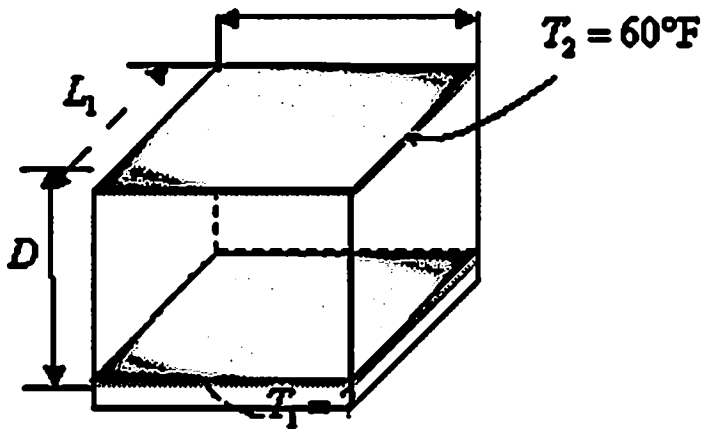
Step 1 of 4

Size of the rectangle, $L_1 = 5\text{ft}$

Size of the rectangle, $L_2 = 3\text{ft}$



Distance between two rectangles, $D = 1\text{ft}$

The net rate of radiation heat transfer from surface A_1 to A_2 is, $\dot{Q}_{12} = 180,000\ \text{Btu/h}$

Temperature of the top rectangle, $T_2 = 60°\text{F}$

Step 2 of 4

Two black parallel rectangles with all dimensions as shown in figure:

Step 3 of 4

Consider the base surface to be surface 1 and the top surface to be surface 2.
From the figure, the view factor from the base surface to the top surface is

$$\frac{L_1}{D} = \frac{5}{1}$$
$$= 5$$
$$\frac{L_2}{D} = \frac{3}{1}$$
$$= 3$$

From the view factor chart

At $\frac{L_1}{D} = 5$ and $\frac{L_2}{D} = 5$ we have

$F_{12} = 0.6$

Step 4 of 4

Since the top and bottom surfaces are blackbody, the net rate of radiation heat transfer can be expressed as

$$\dot{Q}_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4)$$

$$180,000 = 15 \times 0.6 \times 0.1714 \times 10^{-8} \times \left(T_1^4 - (60+460)^4\right)$$

By rewriting the above equation for the temperature of the bottom rectangle, we will get

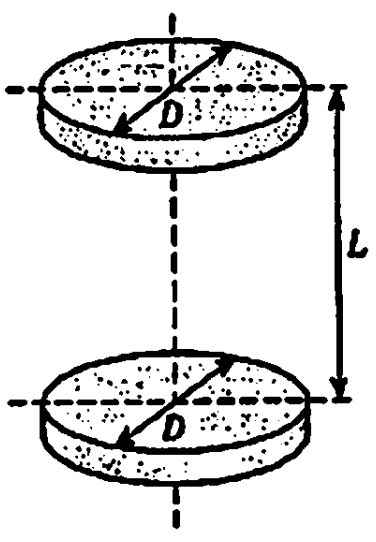
$T_1 = 1851\text{ R}$

$T_1 = 1391°\text{F}$

Therefore, the temperature of the bottom rectangle is $\boxed{T_1 = 1391°\text{F}}$.

Question: 21.081P

Two coaxial parallel disks of equal diameter 1 m are originally placed at a distance of 1 m apart. If both disks behave as black surfaces, determine the new distance between the disks such that there is a 75% reduction in radiation heat transfer rate from the original distance of 1 m.



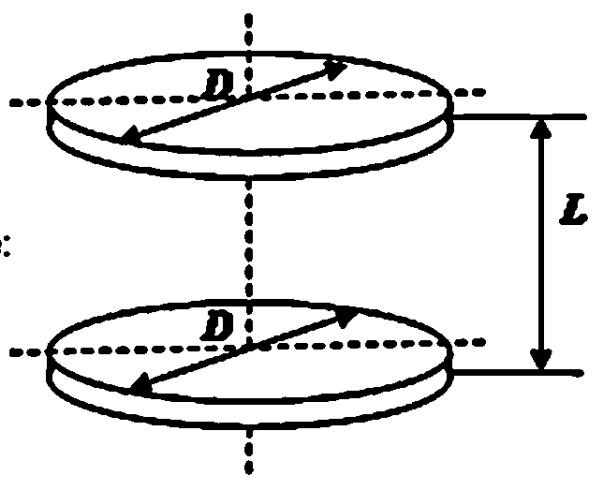


FIGURE P21–81

Step 1 of 5

Draw two coaxial parallel disks

I

of equal diameter and placed at a distance as shown in figure:

Step 2 of 5

Find the view factor from surface 1 to surface 2 by using the equation,

$$F_{12}=1+\frac{1-\sqrt{4R^2+1}}{2R^2}$$

Calculate R value as shown below:

$$R=\frac{D}{2L}$$

Substitute 1 m for D and 1 m for L

$$R=\frac{1}{2\times 1}$$
$$=0.5$$

Now substitute the known values in view factor

$$F_{12}=1+\frac{1-\sqrt{4R^2+1}}{2R^2}$$
$$=1+\frac{1-\sqrt{\left(4\times 0.5^2\right)+1}}{2\times 0.5^2}$$
$$=0.1715$$

Step 3 of 5

Express the net rate of radiation heat transfer between the surfaces by using the expression,

$$\dot{Q}_{12}=A_1F_{12}\sigma\left(T_1^4-T_2^4\right)$$

Since the area of the two discs and the temperature of two discs unchanged, the radiation heat transfer is directly proportional to the view factor, F_{12}

Since 75% reduction in radiation heat transfer rate from the original distance of

1 m will be resulted in the 75% reduction in view factor. Hence the new distance can be determined as a result of 75% reduction in view factor.

Then find the new view factor,

$$F_{12}=0.1715\times 0.25$$
$$=0.043$$

Step 4 of 5

Find the R value by using the equation,

$$F_{12}=1+\frac{1-\sqrt{4R^2+1}}{2R^2}$$
$$0.043=1+\frac{1-\sqrt{\left(4\times R^2\right)+1}}{2R^2}$$
$$\frac{1-\sqrt{\left(4\times R^2\right)+1}}{2R^2}=0.043-1$$
$$\frac{1-\sqrt{\left(4\times R^2\right)+1}}{2R^2}=-0.957$$
$$1-\sqrt{\left(4\times R^2\right)+1}=(-0.957)2R^2$$
$$1-\sqrt{\left(4\times R^2\right)+1}=-1.914R^2$$
$$1+1.914R^2=\sqrt{\left(4\times R^2\right)+1}$$
$$\left(1+1.914R^2\right)^2=\left(\sqrt{\left(4\times R^2\right)+1}\right)^2$$

Step 5 of 5

Squaring on both sides

$$1^2+\left(1.914R^2\right)^2+2\left(1.914R^2\right)=\left(4R^2\right)+1$$
$$1+3.663R^4+3.828R^2=\left(4R^2\right)+1$$
$$3.663R^4+3.828R^2-\left(4R^2\right)=0$$
$$3.663R^4-0.172R^2=0$$
$$\left(3.663R^2-0.172\right)R^2=0$$
$$3.663R^2-0.172=0$$
$$R^2=\frac{0.172}{3.663}$$
$$=0.04695$$
$$R=\pm 0.2166$$

Consider the positive value $R=0.2166$

Find the new distance between discs by using the equation,

$$R=\frac{D}{2L}$$
$$0.2166=\frac{1}{2\times L}$$
$$L=2.3084\,\text{m}$$

Therefore, the new distance between the discs is $\boxed{2.3084\,\text{m}}$

Question: 21.082P

A furnace is shaped like a long equilateral-triangular duct where the width of each side is 2 m. Heat is supplied from the base surface, whose emissivity is ε1 = 0.8, at a rate of 800 W/m2 while the side surfaces, whose emissivities are 0.4, are maintained at 600 K. Neglecting the end effects, determine the temperature of the base surface. Can you treat this geometry as a two-surface enclosure?

Step 1 of 1

The furnace duct acts like a two surface enclosure because the two surfaces of duct having similar properties. Thus consider base surface to be surface 1 and the remaining two surfaces to be surface 2.

Write the expression for heat transfer from the base surface 1 to the surface 2.

$$\dot{Q}_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1-\varepsilon_1}{A_1\varepsilon_1} + \frac{1}{A_1F_{12}} + \frac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

$$\frac{\dot{Q}_{12}}{A} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1-\varepsilon_1}{\varepsilon_1} + \frac{1}{F_{12}} + \frac{1-\varepsilon_2}{\varepsilon_2}}$$

Here, σ is Stefan Boltzmann's constant, T_1 is temperature of base surface, T_2 is temperature of surface 2, ε_1 is emissivity of surface 1, ε_2 is emissivity of surface 2, A is area of the surface, and F_{12} is shape factor.

Substitute $800\,\text{W/m}^2$ for $\dot{Q}_{12}/A$, $5.67\times10^{-8}\,\text{W/m}^2\text{K}^4$ for σ, 0.8 for ε_1, 0.4 for ε_2, 1 for F_{12}, and 600 K for T_2.

$$800 = \frac{5.67\times10^{-8}(T_1^4 - 600^4)}{\left(\frac{1-0.8}{0.8}\right) + \left(\frac{1}{1}\right) + \left(\frac{1-0.4}{0.4}\right)}$$

$$800 = \frac{5.67\times10^{-8}\left(T_1^4 - 600^4\right)}{0.25+1+1.5}$$

$$T_1 = 640.598\,\text{K}$$

Therefore, the base temperature is $\boxed{640.598\,\text{K}}$.

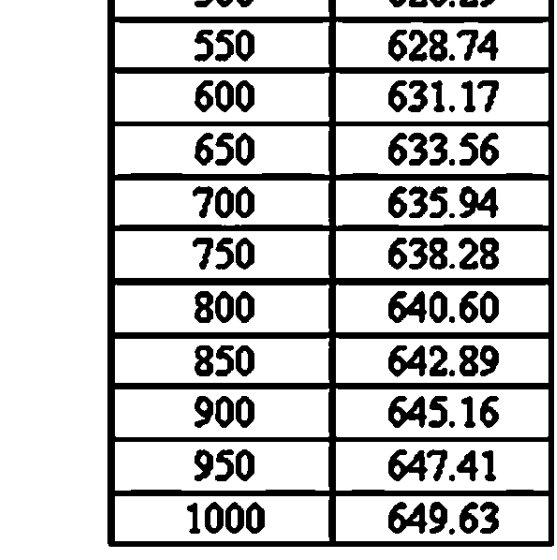
Question: 21.083P

Reconsider Prob. 21-82. Using EES (or other) software, investigate the effects of the rate of the heat transfer at the base surface and the temperature of the side surfaces on the temperature of the base surface. Let the rate of heat transfer vary from 500 W/m2 to 1000 W/m2 and the temperature from 300 K to 700 K. Plot the temperature of the base surface as functions of the rate of heat transfer and the temperature of the side surfaces, and discuss the results.

Step 1 of 7

Given data:

Width of the equilateral triangular duct, $w = 2\text{m}$



Heat supplied from the base surface, $\dot{Q}_{12} = 800\ \text{W/m}^2$

Emissivity of the base surface, $\varepsilon_1 = 0.8$

Emissivity of the side surfaces, $\varepsilon_2 = 0.4$

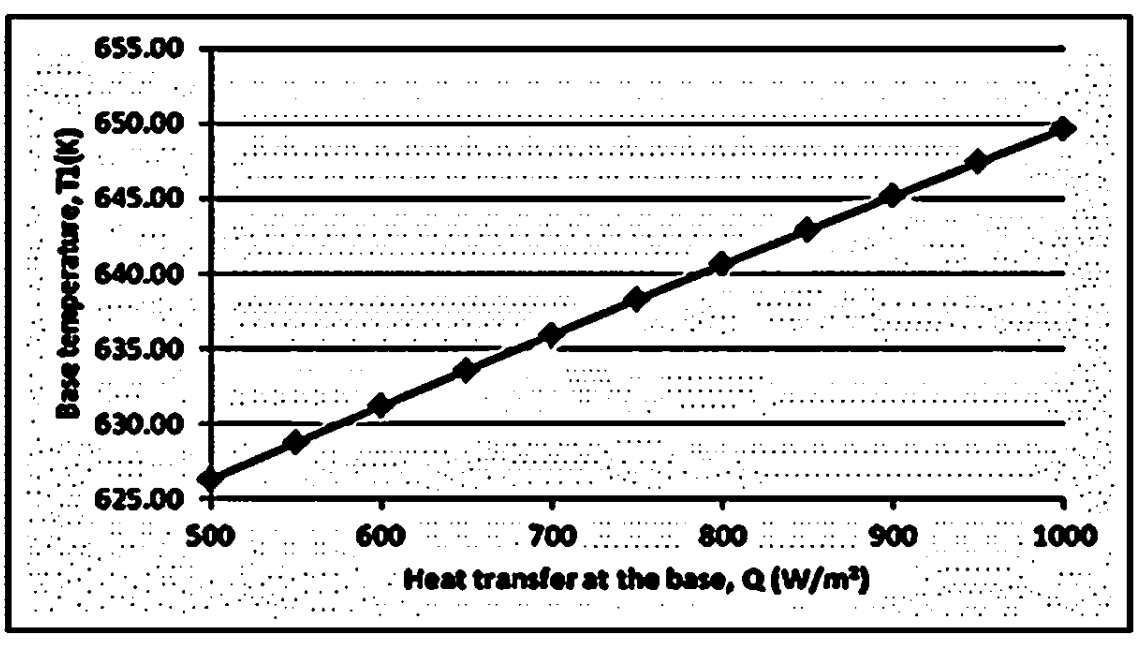
Temperature of the side surfaces, $T_2 = 600\text{K}$

Step 2 of 7

Step 3 of 7

This geometry can be treated as a two surface enclosure since two surfaces have identical properties. We consider base surface to be surface 1 and other two surfaces to be surface 2. Then the view factor between the two becomes $F_{12} = 1$. The temperature of the base surface is determined from

$$\dot{Q}_{12} = \frac{\sigma(T_1^4 - T_2^4)}{\frac{1-\varepsilon_1}{A_1\varepsilon_1} + \frac{1}{A_1F_{12}} + \frac{1-\varepsilon_2}{A_2\varepsilon_2}}$$



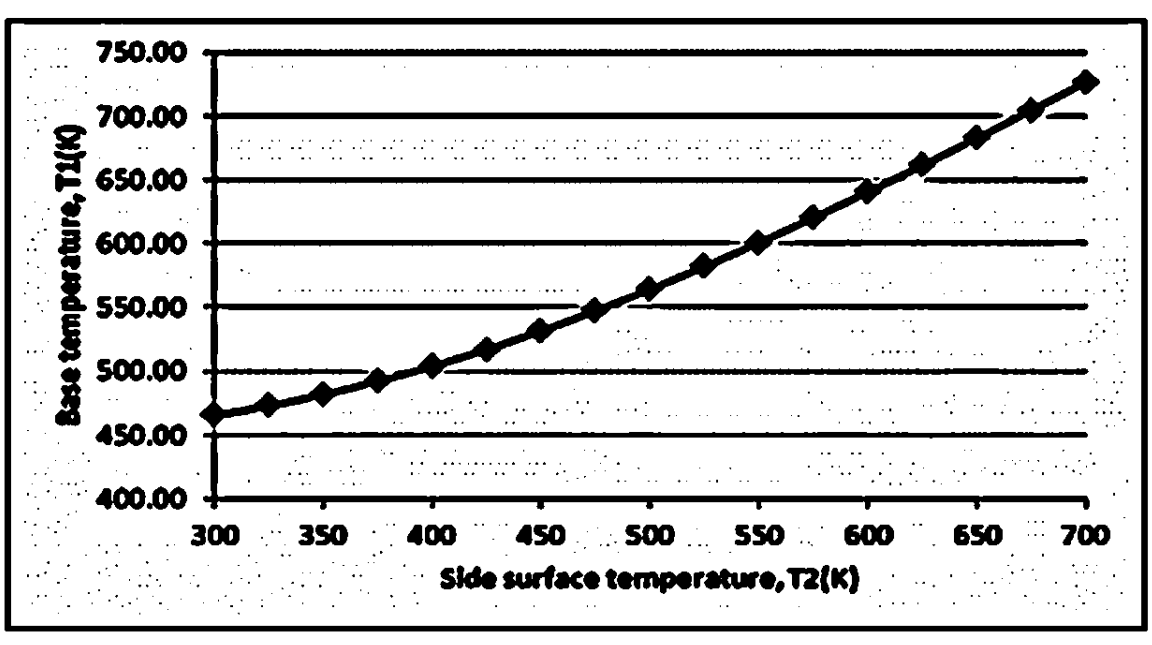
$$\dot{Q}_{12} = \frac{5.67\times10^{-8}(T_1^4 - 600^4)}{\left(\frac{1-0.8}{1\times0.8}\right) + \left(\frac{1}{1\times1}\right) + \left(\frac{1-0.4}{1\times0.4}\right)} \qquad \ldots\ldots (1)$$

Step 4 of 7

Using the Microsoft Excel sheet, from the equation(1) by varying the heat transfer at the base from 500 to the 1000 W/m^2, the variation in temperature of the base calculated and results are tabulated and plotted below.

$\dot{Q}_{12}$ (W/m^2)	T_1(K)
500	626.29
550	628.74
600	631.17
650	633.56
700	635.94
750	638.28
800	640.60
850	642.89
900	645.16
950	647.41
1000	649.63

Step 5 of 7



Step 6 of 7

By using equation (1) varying the side surfaces temperature from 300 K to 700 K, the variation in temperature of the base calculated and results are tabulated and plotted below.

T_2 (K)	T_1(K)
300	465.37
325	472.77
350	481.63
375	491.96
400	503.76
425	516.97
450	531.51
475	547.28
500	564.16
525	582.05
550	600.82
575	620.37
600	640.60
625	661.42
650	682.76
675	704.54
700	726.71

Step 7 of 7

Question: 21.084P

Consider a 4-m × 4-m × 4-m cubical furnace whose floor and ceiling are black and whose side surfaces are reradiating. The floor and the ceiling of the furnace are maintained at temperatures of 550 K and 1100 K, respectively. Determine the net rate of radiation heat transfer between the floor and the ceiling of the furnace.

Step 1 of 4

Given

Side of the cubical furnace, $a = 4\,\text{m}$

Temperatures of ceiling $T_1 = 1100\,\text{K}$

Temperature of floor $T_2 = 550\,\text{K}$

Step 2 of 4

Consider the ceiling surface to be surface 1, floor to be surface 2 and side surfaces to be surface 3.

From figure, view factor between two aligned rectangles of equal size

For $\frac{L_2}{D} = 1$

And $\frac{L_1}{D} = 1$

View factor from ceiling to floor, $F_{12} = 0.2$

And we know that, $F_{11} + F_{12} + F_{13} = 1$

$$\Rightarrow 0 + 0.2 + F_{13} = 1$$

$$\Rightarrow F_{13} = 0.8$$

Surface areas of the floor and ceiling are $A_1 = A_2$

$$= 4^2$$

$$= 16\,\text{m}^2$$

Step 3 of 4

Space resistances are $R_{12} = \frac{1}{A_1 F_{12}}$

$$= \frac{1}{16 \times 0.2}$$

$$= 0.3125\,\text{m}^{-2}$$

And $R_{13} = R_{23} = \frac{1}{A_1 F_{13}}$

$$= \frac{1}{16 \times .8}$$

$$= 0.07812\,\text{m}^{-2}$$

Emissive powers are $E_{b1} = \sigma T_1^4$

$$= 5.67 \times 10^{-8} \times 1100^4$$

$$= 83015\ \text{W/m}^2$$

And $E_{b2} = \sigma T_2^4$

$$= 5.67 \times 10^{-8} \times 550^4$$

$$= 5188\ \text{W/m}^2$$

Step 4 of 4

Net rate of radiation heat transfer between floor and ceiling is determined as follows

The net rate heat transfer, $\dot{Q}_1 = \frac{E_{b1} - E_{b2}}{\left(\frac{1}{R_{12}} + \frac{1}{R_{13} + R_{23}}\right)^{-1}}$

$$= \frac{83015 - 5188}{\left(\frac{1}{0.3125} + \frac{1}{2 \times 0.07812}\right)^{-1}}$$

$$= \frac{77827}{0.1042}$$

$$= 746900.2\,\text{W}$$

Net rate heat radiation, $\boxed{\dot{Q} = 746.9\,\text{kW}}$

Question: 21.085P

Two concentric spheres of diameters $D1$, = 0.3 m and $D2$ = 0.6 m are maintained at uniform temperatures $T1$, = 800 K and $T2$ = 500 K and have emissivities ε1 = 0.5 and ε2 = 0.7, respectively. Determine the net rate of radiation heat transfer between the two spheres. Also, determine the convection heat transfer coefficient at the outer surface if both the surrounding medium and the surrounding surfaces are at 30°C. Assume the emissivity of the outer surface is 0.35.

Step 1 of 5

Given data:

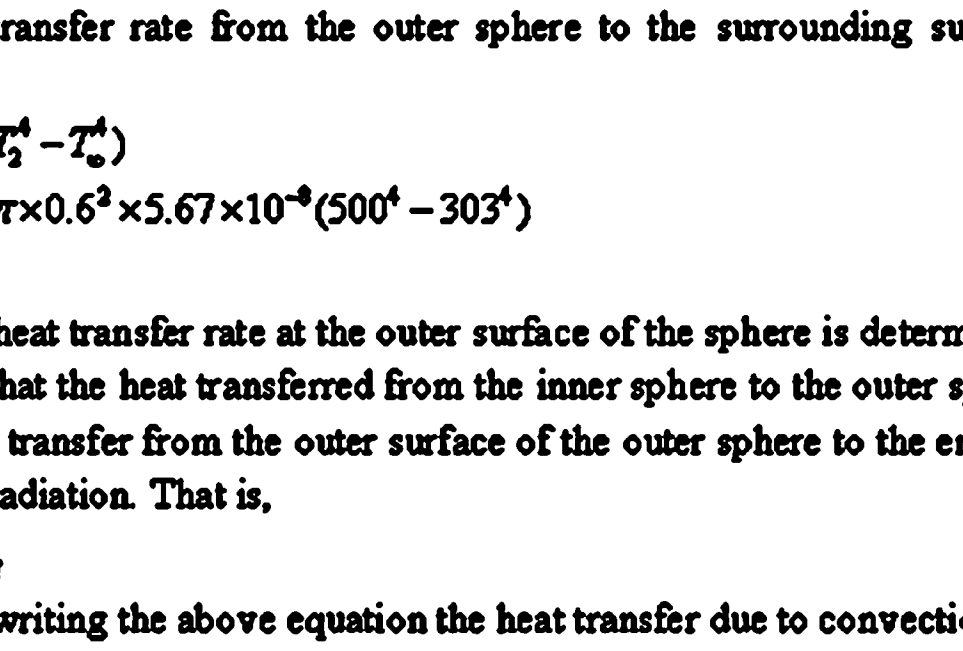
Diameter of the inner sphere, $D_1 = 0.3\,\text{m}$

Diameter of the outer sphere, $D_2 = 0.6\,\text{m}$

Surface temperature of the inner sphere, $T_1 = 800\,\text{K}$

Surface temperature of the outer sphere, $T_2 = 500\,\text{K}$

Emissivity of the inner sphere outer surface, $\varepsilon_1 = 0.5$



Emissivity of the outer sphere inner surface, $\varepsilon_2 = 0.7$

Emissivity of the outer sphere outer surface, $\varepsilon_3 = 0.35$

Temperature of the surrounding medium, $T_\infty = 303\,\text{K}$

Step 2 of 5

Two concentric spheres of different diameters are maintained at uniform temperatures as shown below.

Step 3 of 5

The net rate of radiation heat transfer between the two spheres can be calculated as

$$\dot{Q}_{12} = \frac{A_1\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{r_1^2}{r_2^2}\right)}$$

$$= \frac{\pi \times 0.3^2 \times 5.67\times10^{-8}(800^4 - 500^4)}{\frac{1}{0.5} + \frac{1-0.7}{0.7}\left(\frac{0.15^2}{0.3^2}\right)}$$

$$= \frac{5564.55}{2 + 0.428(0.25)}$$

$$= 2640.8\,\text{W}$$

The net rate of heat transfer between the two spheres is $\boxed{\dot{Q}_{12} = 2640.8\,\text{W}}$.

Step 4 of 5

Radiation heat transfer rate from the outer sphere to the surrounding surfaces can be calculated as

$$\dot{Q}_{rad} = \varepsilon F_{23} A_2 \sigma(T_2^4 - T_\infty^4)$$

$$= 0.35 \times 1 \times \pi \times 0.6^2 \times 5.67\times10^{-8}(500^4 - 303^4)$$

$$= 1213.6\,\text{W}$$

The convection heat transfer rate at the outer surface of the sphere is determined by using energy balance that the heat transferred from the inner sphere to the outer sphere must be equal to the heat transfer from the outer surface of the outer sphere to the environment by convection and radiation. That is,

$$\dot{Q}_{12} = \dot{Q}_{conv} + \dot{Q}_{rad}$$

Therefore, by rewriting the above equation the heat transfer due to convection becomes,

$$\dot{Q}_{conv} = \dot{Q}_{12} - \dot{Q}_{rad}$$

$$= 2640.8 - 1213.6$$

$$= 1427.2\,\text{W}$$

Step 5 of 5

Then the convection heat transfer coefficient can be expressed as

$$\dot{Q}_{conv} = hA_2(T_2 - T_\infty)$$

By rewriting the above equation for the convection heat transfer coefficient, the equation becomes,

$$h = \frac{\dot{Q}_{conv}}{A_2(T_2 - T_\infty)}$$

$$= \frac{1427.2}{\pi \times 0.6^2 \times (500 - 303)}$$

$$= 6.4\,\text{W/m}^2\cdot\text{K}$$

Therefore, the convection heat transfer coefficient at the outer surface is $\boxed{h = 6.4\,\text{W/m}^2\cdot\text{K}}$.

Question: 21.086P

A spherical tank of diameter $D = 2$ m that is filled with liquid nitrogen at 100 K is kept in an evacuated cubic enclosure whose sides are 3 m long. The emissivities of the spherical tank and the enclosure are $\varepsilon 1 = 0.1$ and $\varepsilon 2 = 0.8$, respectively. If the temperature of the cubic enclosure is measured to be 240 K, determine the net rate of radiation heat transfer to the liquid nitrogen.

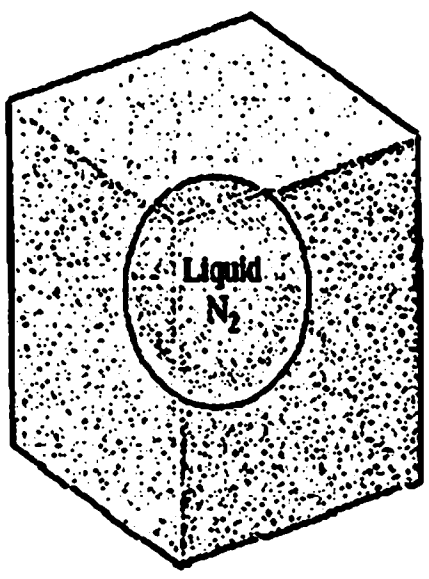


FIGURE P21–86

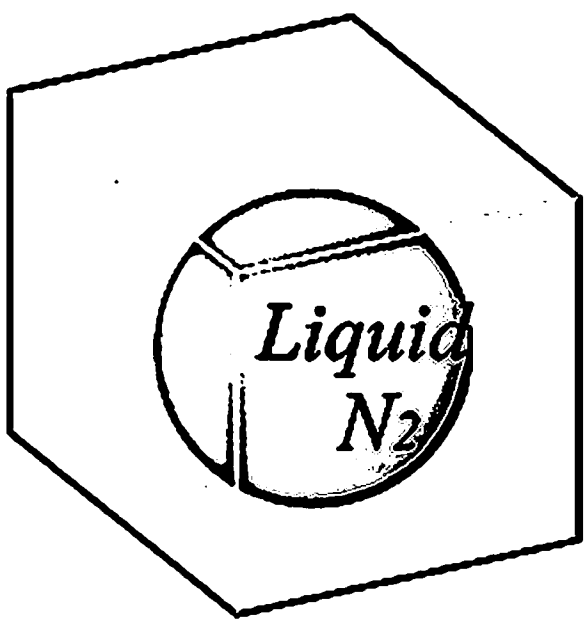
Step 1 of 4

Given

Diameter of spherical tank, $D = 2$ m

Emissivity of the spherical tank, $\varepsilon_1 = 0.1$



Emissivity of cube surface, $\varepsilon_2 = 0.8$

Side of the cube, $a = 3$m

Temperature of tank, $T_1 = 100\ K$

Temperature of cube surface, $T_2 = 240$ K

Step 2 of 4

Step 3 of 4

Surface area of spherical tank, $A_1 = \pi D^2$

$= \pi \times 2^2$

$= 12.57\,\text{m}^2$

Surface area of cube, $A_2 = 6a^2$

$= 6 \times 3^2$

$= 54\,\text{m}^2$

Step 4 of 4

Rate of radiation heat transfer to the liquid nitrogen is

$$\dot{Q}_{21} = -\dot{Q}_{12}$$

$$= -\frac{\sigma A_1 \left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \left(\frac{1-\varepsilon_2}{\varepsilon_2}\right)\left(\frac{A_1}{A_2}\right)}$$

$$= -\frac{5.67 \times 10^{-8} \times 12.57 \times \left(100^4 - 240^4\right)}{\frac{1}{0.1} + \frac{1-0.8}{0.8}\left(\frac{12.57}{54}\right)}$$

$$= \frac{2293.36}{10.058}$$

$$= 228\,\text{W}$$

Net rate of radiation heat transfer, $\boxed{\dot{Q} = 228\,\text{W}}$

Question: 21.087P

Repeat Prob. 21-86 by replacing the cubic enclosure by a spherical enclosure whose diameter is 3 m.

Step 1 of 2

Given

Diameter of inner sphere, $D_1 = 2\ \text{m}$

Diameter of outer sphere, $D_2 = 3\ \text{m}$

Emissivity of inner sphere surface, $\varepsilon_1 = 0.1$

Emissivity of outer sphere surface, $\varepsilon_2 = 0.8$

Temperature of inner sphere, $T_1 = 100\ K$

Temperature of outer surface, $T_2 = 240\ \text{K}$

Step 2 of 2

Rate of radiation heat transfer to the liquid nitrogen is

$$\dot{Q}_{21} = -\dot{Q}_{12}$$

$$= -\frac{A_1\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \left(\frac{1-\varepsilon_2}{\varepsilon_2}\right)\frac{A_1}{A_2}}$$

Surface area of the sphere, $A = \pi D^2$

$$= -\frac{\left(\pi \times 2^2\right) \times 5.67 \times 10^{-8} \times \left(100^4 - 240^4\right)}{\frac{1}{0.1} + \left(\frac{1-0.8}{0.8}\right)\left[\frac{\pi \times 2^2}{\pi \times 3^2}\right]}$$

$$= \frac{2292.7}{10.11}$$

$$= 226.8\ \text{W}$$

Net rate heat radiation, $\boxed{\dot{Q} = 226.8\ \text{W}}$

Question:

Reconsider Prob. 21-86. Using EES (or other) software, investigate the effects of the side length and the emissivity of the cubic enclosure, and the emissivity of the spherical tank on the net rate of radiation heat transfer. Let the side length vary from 2 m to 12 m and both emissivities from 0.1 to 0.9. Plot the net rate of radiation heat transfer as functions of side length and emissivities, and discuss the results.

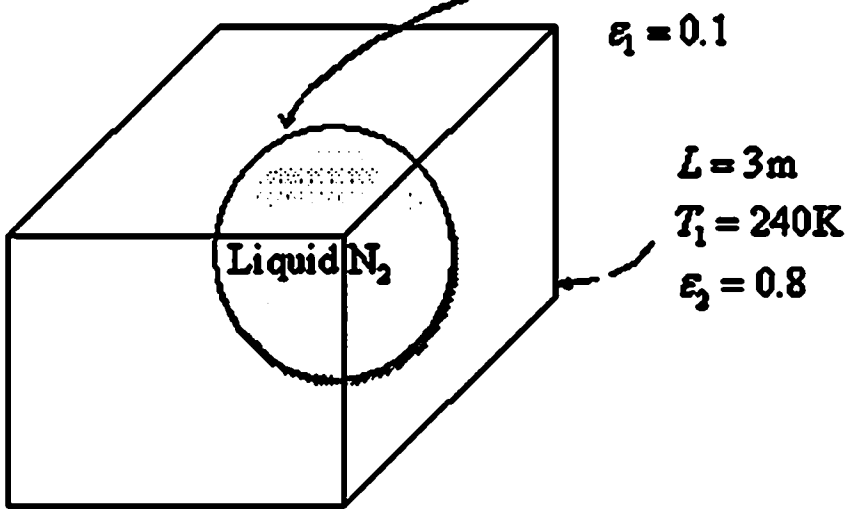
Step 1 of 9

Given data:

Diameter of the spherical tank, $D = 2\,\text{m}$

Size of the cubical enclosure, $L = 3\,\text{m}$

Temperature of the liquid oxygen, $T_1 = 100\,\text{K}$



Temperature of the cubical enclosure, $T_2 = 240\,\text{K}$

Emissivity of the spherical tank, $\varepsilon_1 = 0.1$

Emissivity of the cubical enclosure, $\varepsilon_2 = 0.8$

Step 2 of 9

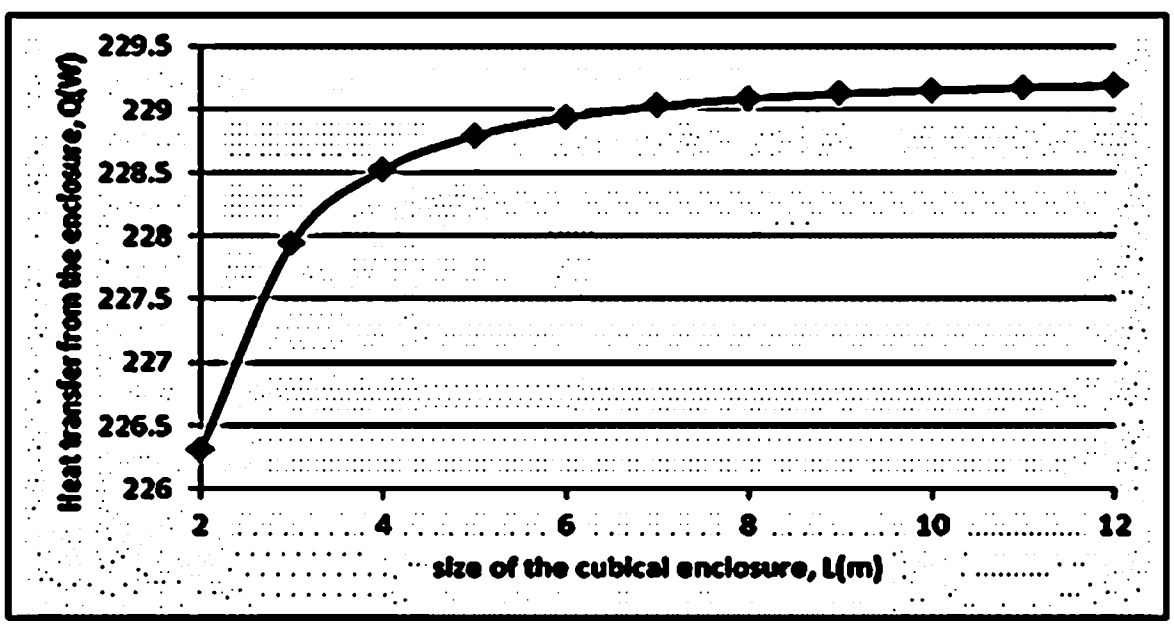
A spherical tank of diameter filled with liquid nitrogen is as shown below:

Step 3 of 9

The net rate of radiation heat transfer to liquid nitrogen can be expressed as

$$\dot{Q}_{12} = \frac{A_1\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{A_1}{A_2}\right)}$$

$$\dot{Q}_{12} = \frac{\pi \times 2^2 \times 5.67\times10^{-8}(100^4 - 240^4)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{\pi \times 2^2}{6 \times L^2}\right)} \qquad \ldots\ldots (1)$$



Step 4 of 9

Using equation (1) vary the size of the cubical enclosure from 2 m to 12 m, the variation in net rate of radiation heat transfer is calculated and results are tabulated.

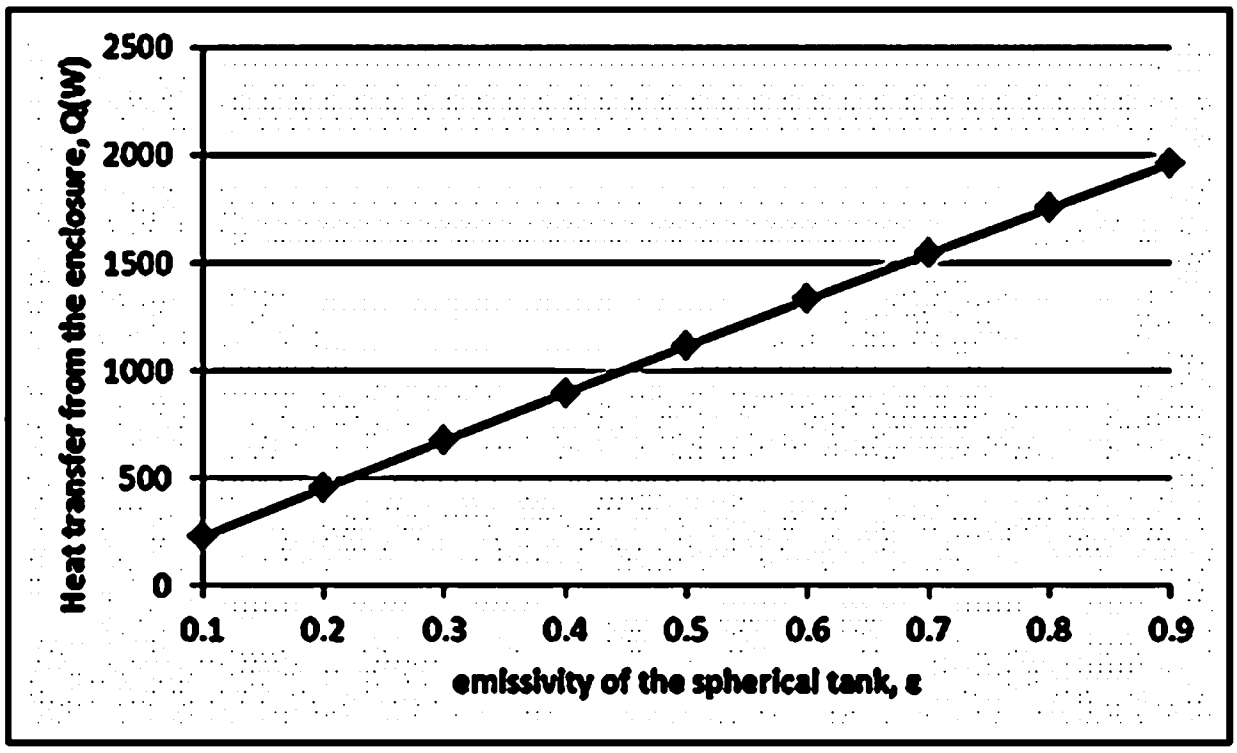
L,m	Q,W
2	226.3073
3	227.9435
4	228.5218
5o	228.7905
6	228.9367
7	229.0249
8	229.0822
9	229.1215
10	229.1497
11	229.1705
12	229.1863

Step 5 of 9

Plotting the size of the cubical enclosure and net rate of radiation heat transfer:

Step 6 of 9

From equation (1) vary the emissivity of the spherical tank from 0.1 to 0.9, the variation in net rate of radiation heat transfer is calculated and results are tabulated.



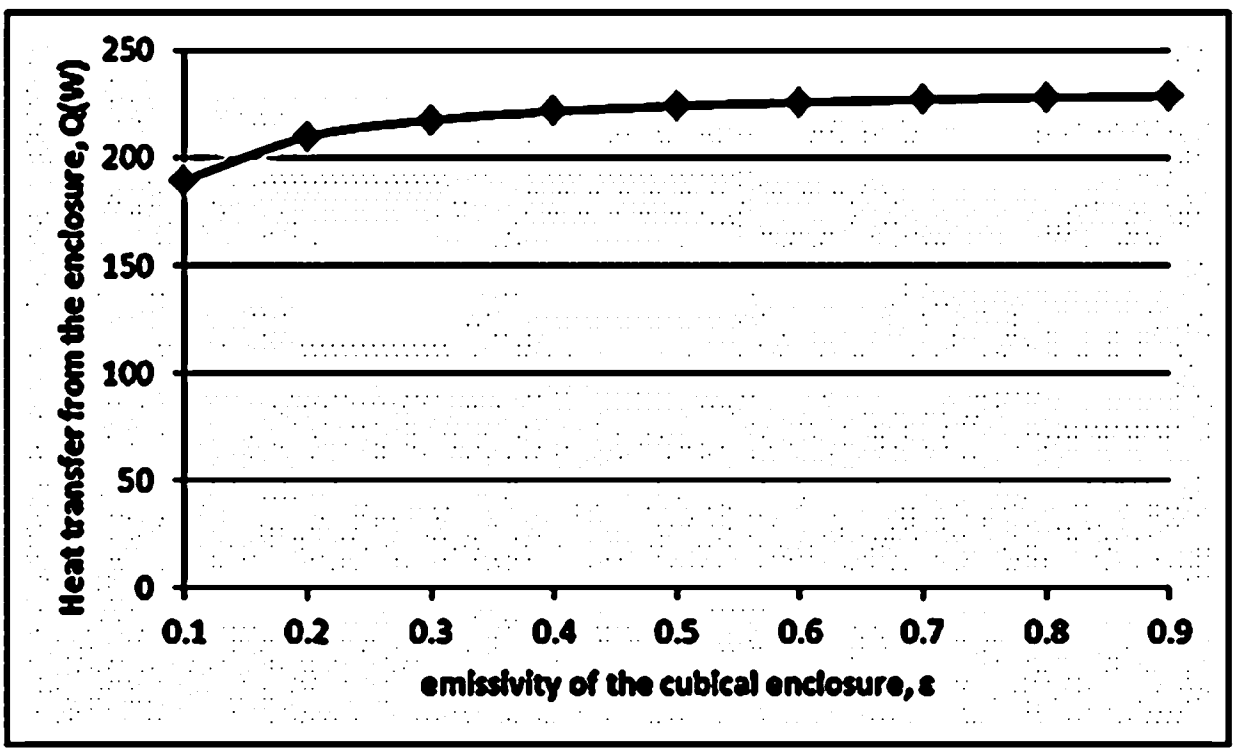
ε_1	Q(W)
0.1	227.9435
0.2	453.2653
0.3	676.0103
0.4	896.2226
0.5	1113.945
0.6	1329.219
0.7	1542.087
0.8	1752.588
0.9	1960.762

Step 7 of 9

Plotting the size of the cubical enclosure and net rate of radiation heat transfer:

Step 7 of 9

Plotting the size of the cubical enclosure and net rate of radiation heat transfer:



Step 8 of 9

From equation (1) vary the emissivity of the cubical enclosure from 0.1 to 0.9, the variation in net rate of radiation heat transfer is calculated and results are tabulated.

ε_2	Q(W)
0.1	189.5669
0.2	209.7456
0.3	217.4617
0.4	221.5366
0.5	224.0556
0.6	225.7671
0.7	227.0057
0.8	227.9435
0.9	228.6784

Step 9 of 9

Plotting the emissivity of the cubical enclosure and net rate of radiation heat transfer:

Question: 21.089P

Consider a circular grill whose diameter is 0.3 m. The bottom of the grill is covered with hot coal bricks at 950 K, while the wire mesh on top of the grill is covered with steaks initially at 5°C. The distance between the coal bricks and the steaks is 0.20 m. Treating both the steaks and the coal bricks as blackbodies, determine the initial rate of radiation heat transfer from the coal bricks to the steaks. Also, determine the initial rate of radiation heat transfer to the steaks if the side opening of the grill is covered by aluminum foil, which can be approximated as a reradiating surface.

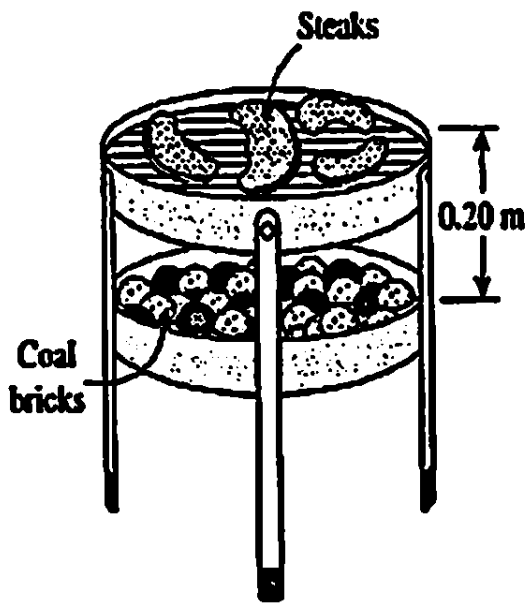


FIGURE P21–89

Step 1 of 5

Given

Diameter of circular grill, $D = 0.3\ \text{m}$

Distance between the coal bricks and the steaks, $L = 0.2\ \text{m}$

Temperatures of the hot coal bricks, $T_1 = 950\ K$

Temperatures of the steaks, $T_2 = 5°\text{c}$

Step 2 of 5

(a) First we have to find view factor F_{12}

$$R_{12} = F_{ij} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{R_j}{R_i}\right)^2\right]^{1/2}\right\}$$

Where $R_i = R_j$

$$= \frac{r_1}{L}$$
$$= \frac{0.15}{0.20}$$
$$= 0.75$$

And $S = 1 + \frac{1 + R_j^2}{R_i^2}$

$$= 1 + \frac{1 + 0.75^2}{0.75^2}$$
$$= 3.778$$

Step 3 of 5

$\therefore$ View factor, $F_{12} = \frac{1}{2}\left\{3.778 - \left[3.778^2 - 4\left(\frac{0.75}{0.75}\right)^2\right]^{1/2}\right\}$

$$= \frac{1}{2}(3.778 - 3.205)$$
$$= 0.2864$$

Initial rate of radiation heat transfer from the coal bricks to the steaks is determined as

$$\dot{Q}_{12} = F_{12}A_1\sigma\left(T_1^4 - T_2^4\right)$$
$$= 0.2864 \times \left(\pi \times 0.3^2/4\right) \times 5.67 \times 10^{-8} \times \left(950^4 - 278^4\right)$$
$$= 928\ \text{W}$$

The net rate heat transfer, $\boxed{\dot{Q} = 928\ \text{W}}$

Step 4 of 5

(b) Initial rate of radiation heat transfer to steaks if the side opening of the grill is covered by aluminum foil, which can be approximated as reradiating surface.

Emissivities of the reradiating surfaces are $\varepsilon = 1$

Surface area of the grills is $A_1 = A_2$

$$= \frac{\pi \times 0.3^2}{4}$$
$$= 0.0707\ \text{m}^2$$

The emissive powers are

$$E_{b1} = \varepsilon\sigma T_1^4$$
$$= 1 \times 5.67 \times 10^{-8} \times 950^4$$
$$= 46182.5\ \text{W/m}^2$$

And $E_{b2} = \varepsilon\sigma T_2^4$

$$= 1 \times 5.67 \times 10^{-8} \times 278^4$$
$$= 339\ \text{W/m}^2$$

Step 5 of 5

Space resistances are

$$R_{12} = \frac{1}{A_1 F_{12}}$$
$$= \frac{1}{0.0707 \times 0.2864}$$
$$= 49.39\ \text{m}^{-2}$$

And $R_{13} = R_{2B}$

$$= \frac{1}{A_1 F_{13}}$$
$$= \frac{1}{0.0707 \times (1 - 0.2864)}$$
$$= 19.81\ \text{m}^{-2}$$

Then heat transfer rate becomes

$$\dot{Q}_{12} = \frac{46182.5 - 339}{\left(\frac{1}{49.39} + \frac{1}{2 \times 19.81}\right)^{-1}}$$
$$= \frac{45843.5}{21.98}$$
$$= 2085.7\ \text{W}$$

Initial rate of radiation heat transfer to steaks, $\boxed{\dot{Q}_{12} = 2085.7\ \text{W}}$

Question: 21.090P

Consider a hemispherical furnace of diameter D = 5 m with a flat base. The dome of the furnace is black, and the base has an emissivity of 0.7. The base and the dome of the furnace are maintained at uniform temperatures of 400 and 1000 K, respectively. Determine the net rate of radiation heat transfer from the dome to the base surface during steady operation.

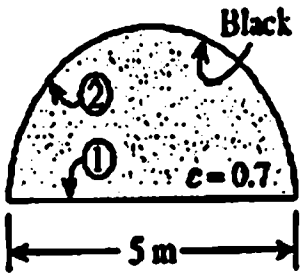

FIGURE P21–90

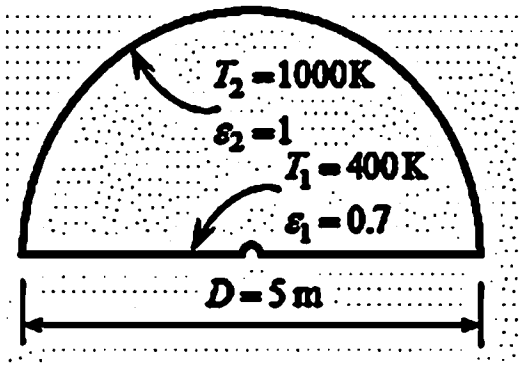
Step 1 of 4

Given



Diameter of hemispherical surface, $D = 5\ \text{m}$

Emissivity of flat base, $\varepsilon = 0.7$

Temperature of the flat base, $T_1 = 400\ K$

Temperature of dome surface, $T_2 = 1000\ \text{K}$

Step 2 of 4

Step 3 of 4

Net rate radiation heat transfer from the dome to base surface during the steady operation determined by

$$\dot{Q}_{21} = -\dot{Q}_{12}$$
$$= -\varepsilon A_1 F_{12} \sigma (T_1^4 - T_2^4)$$

Where view factor F_{12} calculated as follows

For the flat surface $F_{11} = 0$

From the summation rule

$$F_{11} + F_{12} = 1$$
$$\Rightarrow F_{12} = 1$$

Step 4 of 4

Then the heat transfer rate becomes

$$\dot{Q}_{21} = -\varepsilon A_1 F_{12} \sigma (T_1^4 - T_2^4)$$
$$= -0.7 \times \left(\pi \times \frac{5^2}{4} \right) \times 1 \times \left(5.67 \times 10^{-8}\right)\left(400^4 - 1000^4\right)$$
$$= 7.594 \times 10^5\ \text{W}$$
$$= 759.4\ \text{kW}$$

Net heat transfer, $\boxed{\dot{Q} = 759.4\ \text{kW}}$

Question: 21.091P pg 1

Consider two rectangular surfaces perpendicular to each other with a common edge which is 1.6 m long. The horizontal surface is 0.8 m wide and the vertical surface is 1.2 m high. The horizontal surface has an emissivity of 0.75 and is maintained at 450 K. The vertical surface is black and is maintained at 700 K. The back sides of the surfaces are insulated. The surrounding surfaces are at 290 K, and can be considered to have an emissivity of 0.85. Determine the net rate of radiation heat transfers between the two surfaces, and between the horizontal surface and the surroundings.

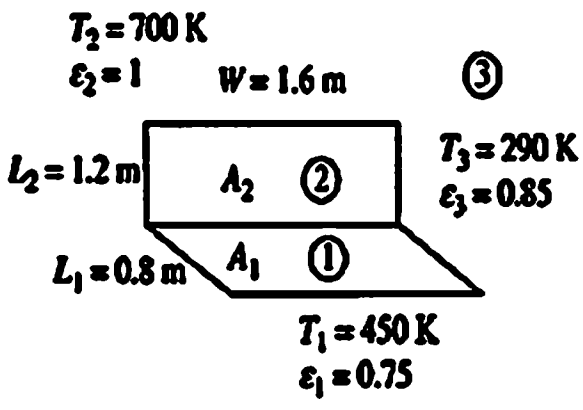


FIGURE P21-91

Step 1 of 8

Given data:

Length of the two rectangular surfaces, $W = 1.6\,\text{m}$

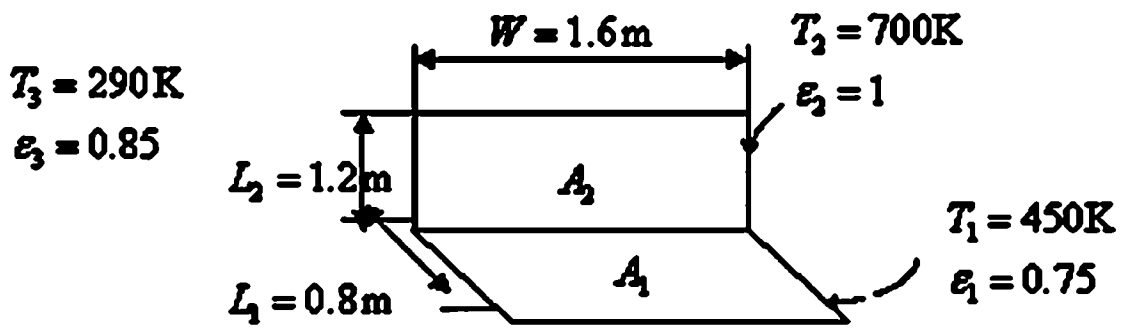
Width of the horizontal surface, $L_1 = 0.8\,\text{m}$

Width of the vertical surface, $L_2 = 1.2\,\text{m}$

Temperature of the horizontal surface, $T_1 = 450\,\text{K}$

Temperature of the vertical surface, $T_2 = 700\,\text{K}$

Emissivity of the horizontal surface, $\varepsilon_1 = 0.75$



Emissivity of the vertical surface, $\varepsilon_2 = 1$

Emissivity of the surroundings, $\varepsilon_3 = 0.85$

Temperature of the surrounding medium, $T_3 = T_\infty = 290\,\text{K}$

Step 2 of 8

Two rectangular surfaces perpendicular to each other is as shown in figure:

Step 3 of 8

Consider the horizontal rectangle to be surface 1, the vertical rectangle to be surface 2 and the surroundings to be surface 3. This system can be considered to be a three-surface enclosure. The view factor from surface 1 to surface 2 is determined as

$$\frac{L_1}{W} = \frac{0.8}{1.6}$$
$$= 0.5$$
$$\frac{L_2}{W} = \frac{1.2}{1.6}$$
$$= 0.75$$

From the view factor chart

At $\frac{L_1}{W} = 0.5$ and $\frac{L_2}{W} = 0.75$ We have

$$F_{12} = 0.27$$

The surface areas can be calculated as

$$A_1 = 0.8 \times 1.6$$
$$= 1.28\,\text{m}^2$$
$$A_2 = 1.2 \times 1.6$$
$$= 1.92\,\text{m}^2$$
$$A_3 = 2 \times \left(\frac{1.2 \times 0.8}{2}\right) + \sqrt{0.8^2 + 1.2^2} \times 1.6$$
$$= 3.267\,\text{m}^2$$

Step 4 of 8

The surface area of the surroundings is determined assuming that surroundings form flat surfaces at all openings to form an enclosure. Then other view factors are determined to be

By using the reciprocity rule,

$$A_2 F_{21} = A_1 F_{12}$$
$$F_{21} = \frac{A_1}{A_2} \times F_{12}$$
$$= \frac{1.28}{1.98} \times 0.27$$
$$= 0.175$$

By using the summation rule,

$$F_{11} + F_{12} + F_{13} = 1$$
$$0 + 0.27 + F_{13} = 1$$
$$F_{13} = 1 - 0.27$$
$$F_{13} = 0.73$$

By suing the summation rule,

$$F_{21} + F_{22} + F_{23} = 1$$
$$0.175 + 0 + F_{23} = 1$$
$$F_{23} = 1 - 0.175$$
$$F_{23} = 0.825$$

Step 5 of 8

By using the reciprocity rule,

$$A_3 F_{31} = A_1 F_{13}$$
$$F_{31} = \frac{A_1}{A_3} \times F_{13}$$
$$= \frac{1.28}{} \times 0.73$$

$$A_3F_{31} = A_1F_{12}$$

$$F_{31} = \frac{A_1}{A_3} \times F_{12}$$

$$= \frac{1.28}{3.267} \times 0.73$$

$$= 0.286$$

Step 6 of 8

By using the reciprocity rule,

$$A_3F_{32} = A_2F_{23}$$

$$F_{32} = \frac{A_2}{A_3} \times F_{23}$$

$$= \frac{1.98}{3.267} \times 0.825$$

$$= 0.5$$

Step 7 of 8

To determine radiosity for each surface with specified temperature can be expressed as,
For surface 1, the equation can be written as

$$\sigma T_1^4 = J_1 + \frac{1-\varepsilon_1}{\varepsilon_1}\left[F_{12}(J_1 - J_2) + F_{13}(J_1 - J_3)\right]$$

$$5.67 \times 10^{-8} \times 450^4 = J_1 + \frac{1-0.75}{0.75}\left[0.27(J_1 - J_2) + 0.73(J_1 - J_3)\right]$$

For surface 2, the equation can be written as

$$\sigma T_2^4 = J_2$$

$$5.67 \times 10^{-8} \times 700^4 = J_2$$

For surface 3, the equation can be written as

$$\sigma T_3^4 = J_3 + \frac{1-\varepsilon_3}{\varepsilon_3}\left[F_{31}(J_3 - J_1) + F_{32}(J_3 - J_2)\right]$$

$$5.67 \times 10^{-8} \times 290^4 = J_3 + \frac{1-0.85}{0.85}\left[0.286(J_3 - J_1) + 0.5(J_3 - J_2)\right]$$

Solving the above three equations we will get,

$$J_1 = 2943.82\ \text{W/m}^2$$

$$J_2 = 13613.67\ \text{W/m}^2$$

$$J_3 = 1534.65\ \text{W/m}^2$$

Step 8 of 8

Therefore, the net rate of radiation heat transfers between the two surfaces and between the horizontal surface and the surroundings are determined to be

$$\dot{Q}_{21} = -\dot{Q}_{12}$$

$$= -A_1F_{12}(J_1 - J_2)$$

$$= -1.28 \times 0.27 \times (2943.82 - 13613.67)$$

$$= 3687.5\ \text{W}$$

Therefore, the net rate of radiation heat transfer between the two surfaces is

$$\boxed{\dot{Q}_{21} = 3687.5\ \text{W}}$$

The net rate of heat transfer between the horizontal surface and the surroundings is given by

$$\dot{Q}_{13} = A_1F_{13}(J_1 - J_3)$$

$$= 1.28 \times 0.73 \times (2943.82 - 1534.65)$$

$$= 1316.73\ \text{W}$$

Therefore, the net rate of heat transfer between the horizontal surface and the surroundings is $\boxed{\dot{Q}_{13} = 1316.73\ \text{W}}$

Question: 21.092P

Two long parallel 20-cm-diameter cylinders are located 30 cm apart from each other. Both cylinders are black, and are maintained at temperatures 425 K and 275 K. The surroundings can be treated as a blackbody at 300 K. For a 1-m-long section of the cylinders, determine the rates of radiation heat transfer between the cylinders and between the hot cylinder and the surroundings.

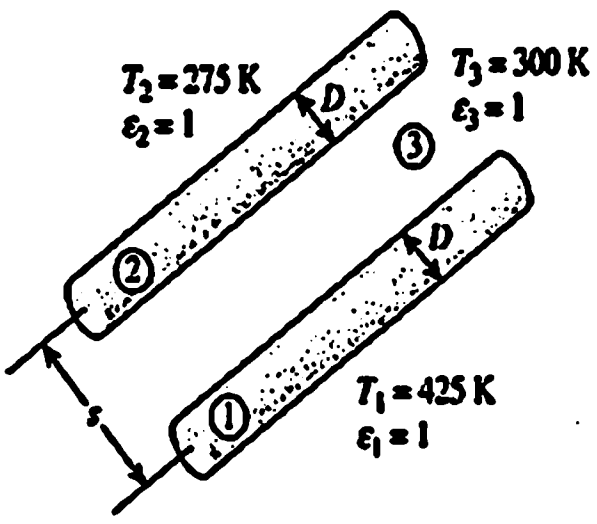


FIGURE P21–92

Step 1 of 3

Given

Diameter of each cylinder, $D = 20$ cm

Distance between both cylinders, $s = 30$ cm

Length of the each cylinder, $L = 1$m

Temperature of cylinder 1, $T_1 = 425$ K

Temperature of cylinder 2, $T_2 = 275$ K

Surrounding temperature, $T_3 = 300$ K

All are black bodies

So, emissivities are $\varepsilon_1 = 1$

$\varepsilon_2 = 1$

$\varepsilon_3 = 1$

Step 2 of 3

(a) Surface area of the cylinder which is face to the other cylinder, $A = \pi DL/2$

$$= \frac{\pi \times 0.2 \times 1}{2}$$

$$= 0.314 \text{ m}^2$$

Where the view factor between two cylinders F_{12} is given by

From crossed strings method, $F_{12} = \dfrac{\sum \text{Crossed strings} - \sum \text{Uncrossed strings}}{2 \times \text{String on surface 1}}$

$$= \frac{2\sqrt{s^2 + L^2} - 2s}{2L}$$

$$= \frac{\left(\sqrt{s^2 + L^2} - s\right)}{L}$$

$$= \frac{\left(\sqrt{0.3^2 + 1^2} - 0.3\right)}{1}$$

$$= 0.744$$

Then the heat transfer rate becomes

$$\dot{Q}_{12} = AF_{12}\sigma(T_1^4 - T_2^4)$$

$$= 0.314 \times 0.744 \times \left(5.67 \times 10^{-8}\right) \times \left(425^4 - 275^4\right)$$

$$= 356.4 \text{ W}$$

Rate of radiation heat transfer between cylinders, $\boxed{\dot{Q}_{12} = 356.4 \text{ W}}$

Step 3 of 3

(b) Rate of radiation heat transfer between the hot cylinder and the surroundings is

Surface area becomes $A_1 = \pi DL$

$$= \pi \times 0.2 \times 1$$

$$= 0.628 \text{ m}^2$$

View factor between hot cylinder and surroundings by summation rule is

$$F_{13} = 1 - F_{12}$$

$$= 1 - 0.744$$

$$= 0.256$$

Rate of heat loss becomes

$$\dot{Q}_{13} = A_1 F_{13}\sigma(T_1^4 - T_3^4)$$

$$= 0.628 \times 0.256 \times \left(5.67 \times 10^{-8}\right) \times \left(425^4 - 300^4\right)$$

$$= 223.6 \text{ W}$$

Rate of radiation heat transfer between hot cylinder and surroundings,

$\boxed{\dot{Q}_{13} = 223.6 \text{ W}}$

Question: 21.093P

Consider a long semicylindrical duct of diameter 1.0 m. Heat is supplied from the base surface, which is black, at a rate of 1200 W/m2, while the side surface with an emissivity of 0.4 is maintained at 650 K. Neglecting the end effects, determine the temperature of the base surface.

Step 1 of 5

Given

Diameter of semi cylindrical duct is $D = 1\,\text{m}$

Rate of heat supplied, $\dot{Q} = 1200\ \text{W/m}^2$

Emissivity of base surface, $\varepsilon_1 = 1$

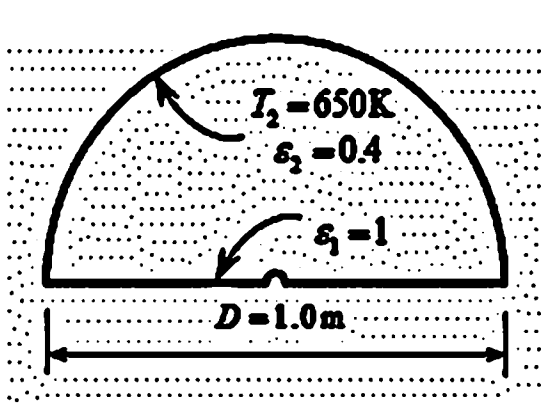
Emissivity of side surface, $\varepsilon_2 = 0.4$

Temperature of side surface, $T_2 = 650\,\text{K}$

Step 2 of 5

Consider base surface to be surface 1 and side surface to be surface 2

Base surface area, $A_1 = 1 \times 1$



$$= 1\,\text{m}^2$$

Side surface area, $A_2 = \dfrac{\pi DL}{2}$

$$= \frac{\pi \times 1 \times 1}{2}$$

$$= 1.571\,\text{m}^2$$

Step 3 of 5

Step 4 of 5

View factor for the surface 1 with respect to itself is zero.

Then by summation rule,

$$F_{11} + F_{12} = 1$$

$$\Rightarrow 0 + F_{12} = 1$$

$$\Rightarrow F_{12} = 1$$

Step 5 of 5

Temperature of the base surface is determined by

$$\dot{Q}_{12} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\dfrac{1}{A_1 F_{12}} + \dfrac{1-\varepsilon_2}{A_2 \varepsilon_2}}$$

$$\Rightarrow 1200 = \frac{5.67 \times 10^{-8}\left(T_1^4 - 650^4\right)}{\dfrac{1}{1 \times 1} + \dfrac{1-0.4}{1.571 \times 0.4}}$$

$$\Rightarrow 2345.77 = 5.67 \times 10^{-8}\left(T_1^4 - 650^4\right)$$

$$\Rightarrow T_1^4 - 650^4 = 413.7 \times 10^8$$

$$\Rightarrow T_1 = 684.78\text{K}$$

Temperature of base surface, $\boxed{T_1 = 684.78\text{K}}$

Question: 21.094P

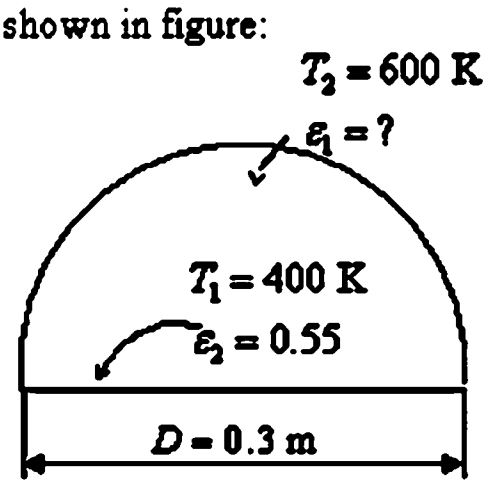
Consider a 30-cm-diameter hemispherical enclosure. The dome is maintained at 600 K and heat is supplied from the dome at a rate of 65 W while the base surface with an emissivity of 0.55 is maintained at 400 K. Determine the emissivity of the dome.

Step 1 of 4

Given data:

Diameter of the hemispherical enclosure, $D = 30$ cm

Temperature of the base surface, $T_1 = 400$ K



Temperature of the dome, $T_2 = 600$ K

Emissivity of the base surface, $\varepsilon_1 = 0.55$

Heat supplied from the dome, $\dot{Q}_{21} = 65$ W

Step 2 of 4

A hemispherical dome is as shown in figure:

Step 3 of 4

Consider the base surface to be surface 1, the side surface to be surface 2. This system is a two-surface enclosure. The surface areas and the view factor are determined as

$$A_1 = \frac{\pi}{4}D^2$$

$$= \frac{\pi}{4}\times 0.3^2$$

$$= 0.07069\ \text{m}^2$$

$$A_2 = \frac{\pi}{2}D^2$$

$$= \frac{\pi}{2}\times 0.3^2$$

$$= 0.1413\ \text{m}^2$$

Step 4 of 4

By using the summation rule,

$$F_{11} + F_{12} = 1$$

$$0 + F_{12} = 1$$

$$F_{12} = 1$$

The emissivity of the dome can be determined as;

$$\dot{Q}_{21} = -\dot{Q}_{12}$$

$$= -\frac{\sigma(T_1^4 - T_2^4)}{\frac{1-\varepsilon_1}{A_1\varepsilon_1} + \frac{1}{A_1F_{12}} + \frac{1-\varepsilon_2}{A_2\varepsilon_2}}$$

$$65 = -\frac{5.67\times 10^{-8}(400^4 - 600^4)}{\frac{1-0.55}{0.07069\times 0.55} + \frac{1}{0.07069} + \frac{1-\varepsilon_2}{0.1413\times\varepsilon_2}}$$

$$\varepsilon_2 = 0.0982$$

Therefore, the emissivity of the dome is $\boxed{\varepsilon_2 = 0.0982}$.

Question: 21.095P

Consider a hot cylindrical surface and a disk oriented as shown in the figure. Both the cylindrical surface and the disk behave as blackbody. The cylinder has a diameter D and a length L of 0.2 m. The disk of diameter D = 0.2 m is placed coaxially with the cylinder at a distance of L = 0.2 m apart. The cylindrical surface and the disk are maintained at uniform temperatures of 1000 K and 300 K, respectively. Determine the rate of heat transfer by radiation from cylindrical surface to the disk.

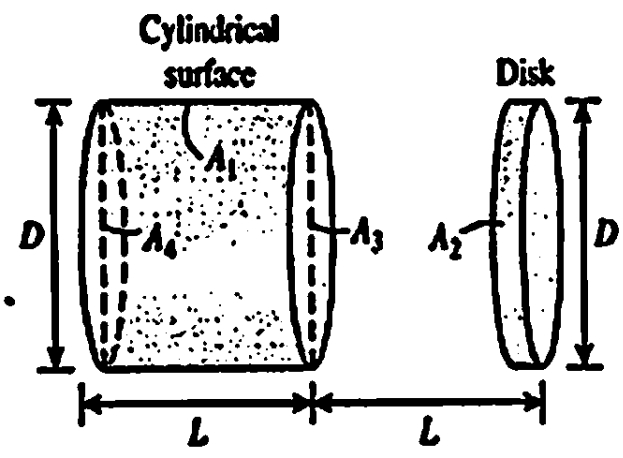


FIGURE P21–95

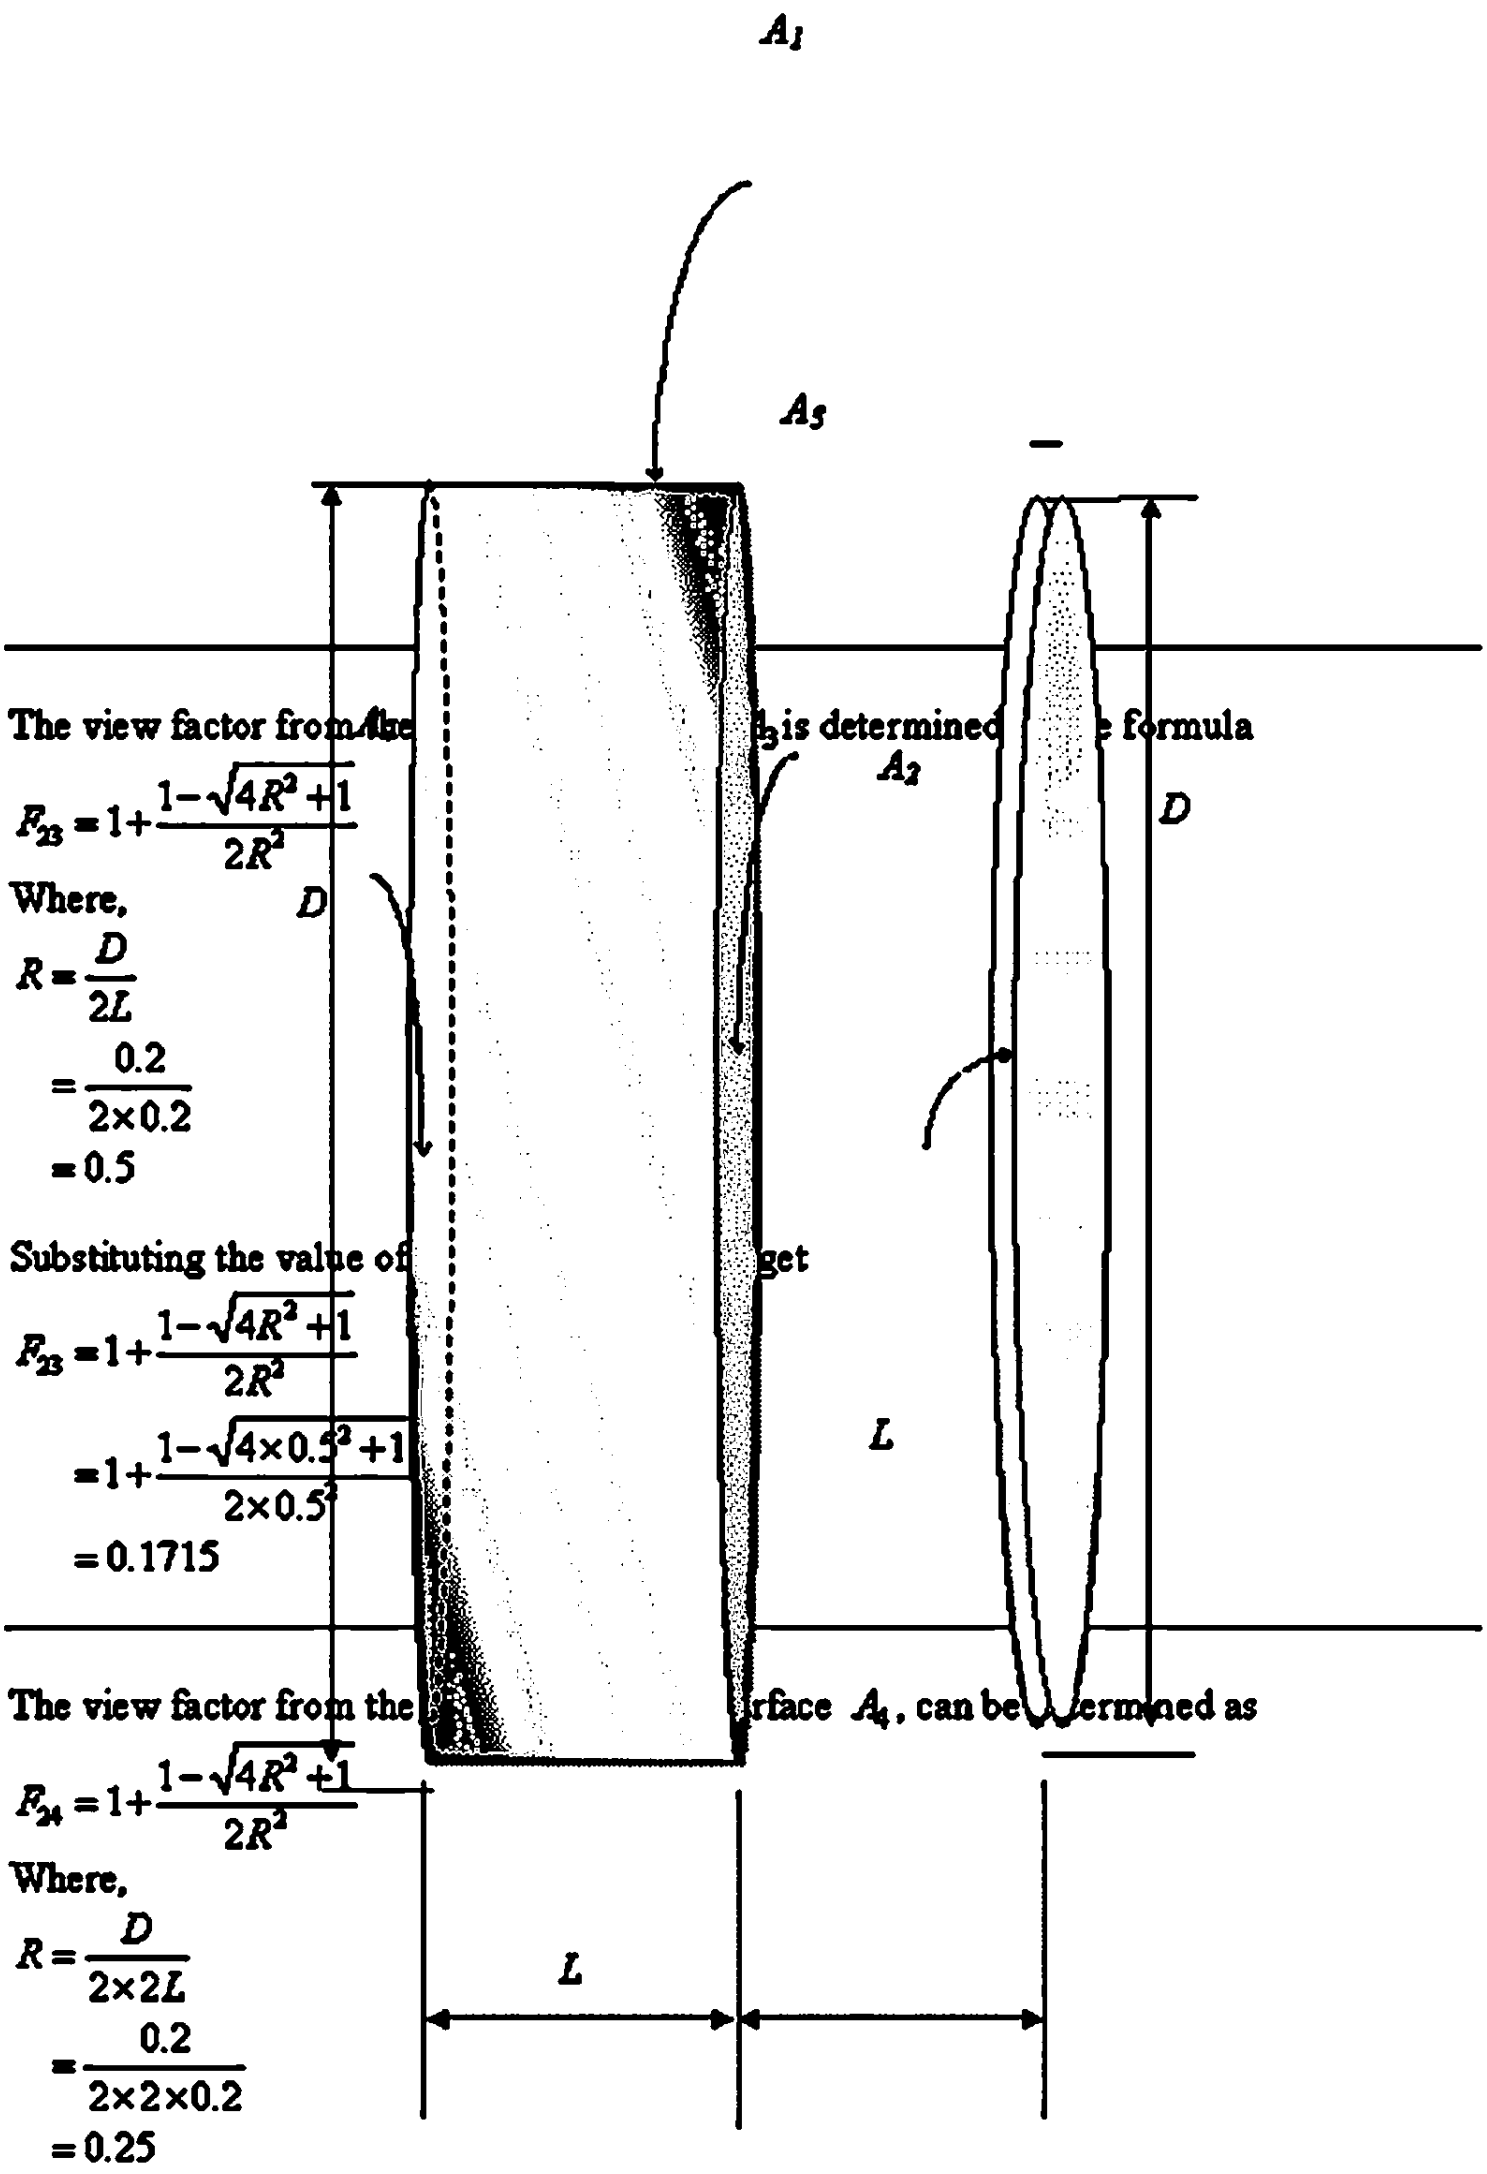
Step 1 of 4

Given data:

Diameter of the disk, $D = 0.2$ m

Cylinder length, $L = 0.2$ m

Distance between cylinder and disc, $L = 0.2$ m



Temperature of the cylindrical surface, $T_1 = 1000$ K

Temperature of the disk, $T_2 = 300$ K

Emissivity of the cylindrical surface and the disc, $\varepsilon_1 = \varepsilon_2 = 1$

Step 2 of 4

The geometrical parameters are as shown in the figure.

The view factor from the A_3 is determined e formula

$$F_{23} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

Where,

$$R = \frac{D}{2L}$$
$$= \frac{0.2}{2 \times 0.2}$$
$$= 0.5$$

Substituting the value of get

$$F_{23} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$
$$= 1 + \frac{1 - \sqrt{4 \times 0.5^2 + 1}}{2 \times 0.5^2}$$
$$= 0.1715$$

The view factor from the rface A_4, can be ermined as

$$F_{24} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

Where,

$$R = \frac{D}{2 \times 2L}$$
$$= \frac{0.2}{2 \times 2 \times 0.2}$$
$$= 0.25$$

Substituting the value of R in view factor, we get

$$F_{24} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$
$$= 1 + \frac{1 - \sqrt{4 \times 0.25^2 + 1}}{2 \times 0.25^2}$$
$$= 0.05573$$

Step 3 of 4

From the summation rule,

$$1 = F_{21} + F_{22} + F_{23} + F_{24}$$
$$1 = F_{21} + 0 + 0.1715 + 0.05573$$
$$F_{21} = 0.772772$$

From the reciprocity rule,

$$A_1 F_{12} = A_2 F_{21}$$
$$F_{12} = \frac{A_2}{A_1} F_{21}$$
$$= \frac{(\pi/4) D^2}{\pi D \times D} \times 0.772772$$
$$= 0.1932$$

Step 4 of 4

The net rate of radiation heat transfer from the cylindrical surface to the disc:

$$\dot{Q}_{12} = \sigma A_1 F_{12} \left(T_1^4 - T_2^4 \right)$$
$$= \left(5.67 \times 10^{-8} \right) (\pi 0.2 \times 0.2)(0.1932) \left(1000^4 - 300^4 \right)$$
$$= 1365.425 \text{ W}$$

Thus, the rate of heat transfer by radiation from the cylindrical surface to the disk is

$$\boxed{\dot{Q}_{12} = 1365.425 \text{ W}}$$

Question: 21.096P

Two parallel black disks are positioned coaxially with a distance of 0.25 m apart in a surrounding with a constant temperature of 300 K. The lower disk is 0.2 m is diameter and the upper disk is 0.4 m in diameter. If the lower disk is heated electrically at 100 W to maintain a uniform temperature of 500 K, determine the temperature of the upper disk.

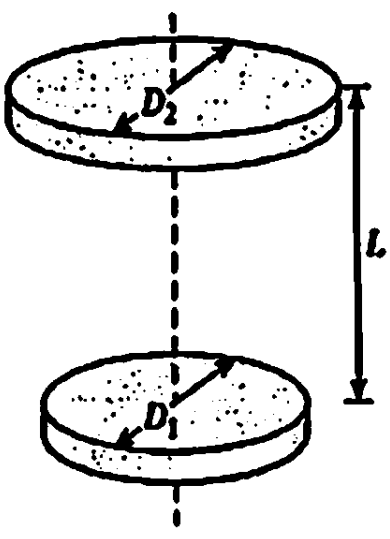


FIGURE P21–96

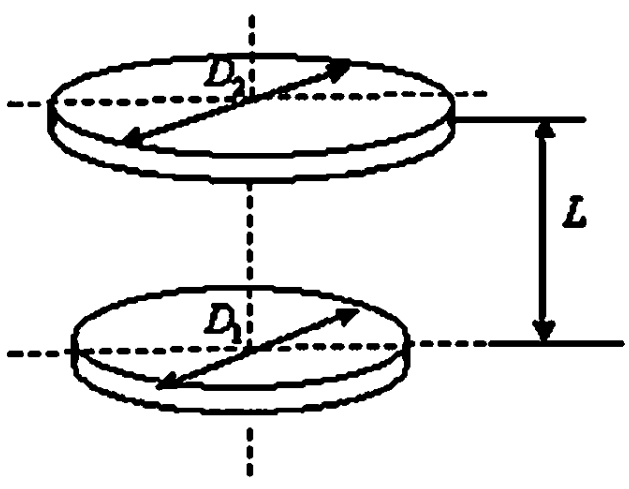
Step 1 of 6

Given data:

Distance between two plates, $L = 0.25$ m

Diameter of the lower disc, $D_1 = 0.2$ m

Diameter of the upper disc, $D_2 = 0.4$ m



Surrounding Temperature, $T_\infty = 300$ K

Temperature of the lower disc, $T_1 = 500$ K

Heat supplied to the lower disc, $\dot{Q} = 100$ W

Step 2 of 6

The geometrical parameters are as shown in the figure:

Step 3 of 6

By considering the bottom plate as surface-1, top plate as surface-2 and the ambient as surface-3, the view factor for surface-2 from surface-1 is given by the formula

$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{r_2}{r_1}\right)^2\right]^{1/2}\right\}$$

Where

$$S = 1 + \frac{1 + R_2^2}{R_1^2}$$

$$R_1 = \frac{r_1}{L}$$
$$= \frac{0.1}{0.25}$$
$$= 0.4$$
$$R_2 = \frac{r_2}{L}$$
$$= \frac{0.2}{0.25}$$
$$= 0.8$$

Step 4 of 6

By substituting the values in equation for S, we get

$$S = 1 + \frac{1 + R_2^2}{R_1^2}$$
$$= 1 + \frac{1 + 0.8^2}{0.4^2}$$
$$= 11.25$$

The view factor can now be calculated as

$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{r_2}{r_1}\right)^2\right]^{1/2}\right\}$$
$$= \frac{1}{2}\left\{11.25 - \left[11.25^2 - 4\left(\frac{0.2}{0.1}\right)^2\right]^{1/2}\right\}$$
$$= 0.3675$$

Step 5 of 6

From the summation rule,

$$1 = F_{11} + F_{12} + F_{13}$$
$$1 = 0 + 0.3675 + F_{13}$$
$$F_{13} = 0.6325$$

The rate of radiation heat transfer from the lower plate to the ambient can be expressed as

$$\dot{Q}_{13} = A_1 F_{13} \sigma (T_1^4 - T_3^4)$$
$$= \left(\frac{\pi}{4} \times 0.2^2\right)(0.6325)\left(5.67 \times 10^{-8}\right)\left(500^4 - 300^4\right)$$
$$= 61.3\text{W}$$

The rate of radiation heat transfer from the lower plate to the upper plate is determined as

$$\dot{Q}_{12} = \dot{Q} - \dot{Q}_{13}$$
$$= 100 - 61.3$$
$$= 38.7 \text{ W}$$

Step 6 of 6

The temperature of the upper plate can be determined by using the heat transfer rate.

$$\dot{Q}_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4)$$
$$38.7 = \left(\frac{\pi}{4} \times 0.2^2\right)(0.3675)\left(5.67 \times 10^{-8}\right)\left(500^4 - T_2^4\right)$$
$$T_2^4 = \left(500^4\right) - \left(5.912 \times 10^{10}\right)$$
$$T_2 = 241.2 \text{ K}$$

Thus, the temperature of the upper plate is $\boxed{T_2 = 241.2 \text{ K}}$

Question: 21.097P

Two-phase gas-liquid oxygen is stored in a spherical tank of 1-m diameter, where it is maintained at its normal boiling point. The spherical tank is enclosed by a 1.6-m diameter concentric spherical surface at 273 K. Both spherical surfaces have an emissivity of 0.01, and the gap between the inner sphere and outer sphere is vacuumed. Assuming that the spherical tank surface has the same temperature as the oxygen, determined the heat transfer rate at the spherical tank surface.

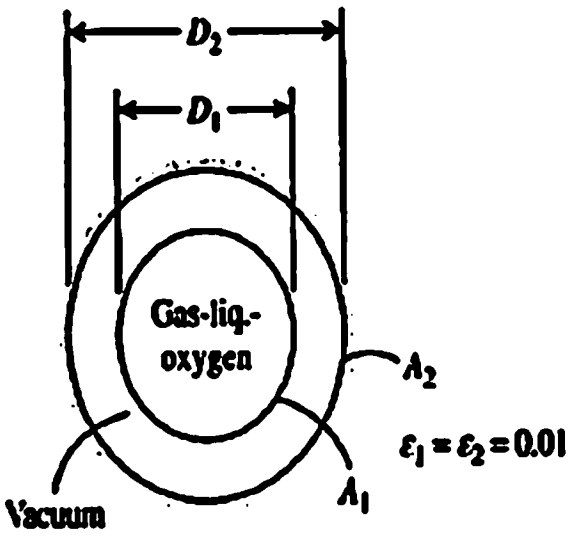


FIGURE P21-97

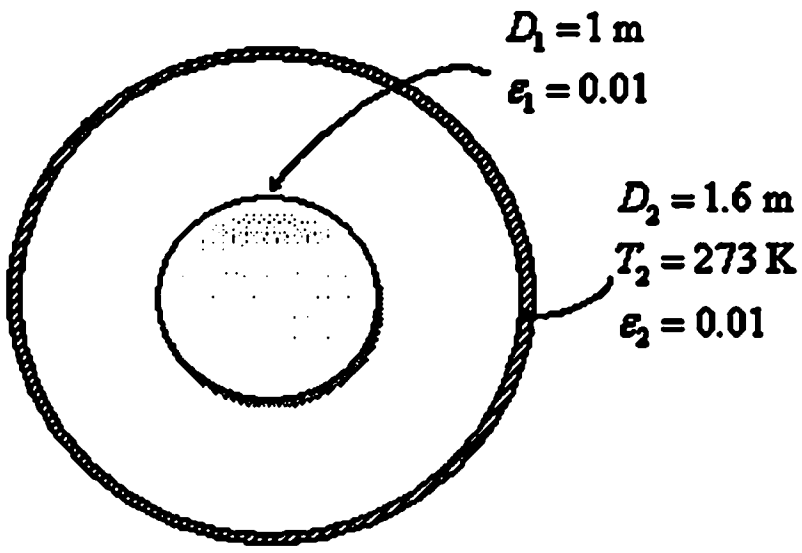
Step 1 of 3

Given data:

Diameter of the spherical tank, $D_1 = 1\ \text{m}$

Diameter of the concentric spherical surface, $D_2 = 1.6\ \text{m}$



Surface temperature of the spherical tank (Boiling point), $T_1 = 241\ \text{K}$

Surface temperature of the concentric spherical surface, $T_2 = 273\ \text{K}$

Emissivity of the inner and outer spherical surfaces, $\varepsilon_1 = \varepsilon_2 = 0.01$

Step 2 of 3

The geometrical parameters are as shown in the figure:

Step 3 of 3

The radiation heat transfer rate at the spherical tank surface is given by the formula

$$\dot{Q}_{12} = \frac{A_1\sigma(T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{r_1^2}{r_2^2}\right)}$$

$$= \frac{(\pi \times 1^2)(5.67\times10^{-8})(241^4 - 273^4)}{\frac{1}{0.01} + \frac{1-0.01}{0.01}\left(\frac{0.5^2}{0.8^2}\right)}$$

$$= \frac{-388.53}{100 + 38.672}$$

$$= -2.8\ \text{W}$$

Thus the heat transfer rate at the spherical tank surface is $\boxed{\dot{Q}_{12} = -2.8\ \text{W}}$

Question: 21.098P

Daylight and incandescent light may be approximated as a blackbody at the effective surface temperatures of 5800 K and 2800 K, respectively. Determine the wavelength at maximum emission of radiation for each of the lighting sources.

Step 1 of 3

Given data:

The temperature of daylight, $T_d = 5800\ \text{K}$

Incandescent light, $T_i = 2800\ \text{K}$

Step 2 of 3

The wavelength at which the emission of radiation takes a peak value can be determined from Wien's displacement.

For a daylight

$$(\lambda_1 T_d)_{max_power} = 2897.8\ \mu\text{m.K}$$

$$(\lambda_1)_{max_power} = \frac{2897.8\ \mu\text{m.K}}{5800}$$

$$= 0.5\ \mu\text{m}$$

Thus, the maximum power in daylight is observed at $\boxed{(\lambda_1)_{max_power} = 0.5\ \mu\text{m}}$

Step 3 of 3

For an incandescent light $T_i = 2800\ \text{K}$

$$(\lambda_1 T_i)_{max_power} = 2897.8\ \mu\text{m.K}$$

$$(\lambda_1)_{max_power} = \frac{2897.8\ \mu\text{m.K}}{2800}$$

$$= 1.035\ \mu\text{m}$$

Thus, the maximum power in incandescent light is observed at $\boxed{(\lambda_1)_{max_power} = 1.035\ \mu\text{m}}$

Question: 21.099P

A horizontal opaque flat plate is well insulated on the edges and the lower surface. The top surface has an area of 5 m2, and it experiences uniform irradiation at a rate of 5000 W. The plate absorbs 4000 W of the irradiation, and the surface is losing heat at a rate of 500 W by convection. If the plate maintains a uniform temperature of 350 K, determine the absorptivity, reflectivity, and emissivity of the plate.

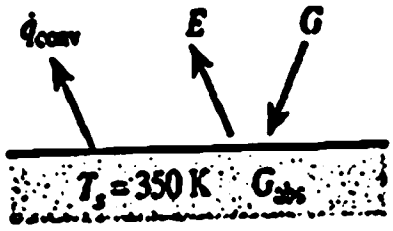


FIGURE P21-99

Step 1 of 3

Given data:

The surface area of the plate, $A = 5\,\text{m}^2$

The irradiation on the surface, $G = 5000$ W

The irradiation absorbed by the surface, $G_{abs} = 4000$ W

Heat lost by convection, $\dot{q}_{conv} = 500$ W

Surface temperature of the plate, $T_s = 350$ K

For opaque surfaces, the transmissivity is zero ($\tau = 0$)

Step 2 of 3

The absorptivity of the surface is the ratio of energy absorbed by the surface to the energy incident on the surface.

$$\alpha = \frac{G_{abs}}{G}$$
$$= \frac{4000}{5000}$$
$$= 0.8$$

Hence the absorptivity of the surface is $\boxed{\alpha = 0.8}$

The sum of the absorbed, reflected and transmitted energies is unity. Hence

$$1 = \alpha + \rho + \tau$$
$$1 = 0.8 + \rho + 0$$
$$\rho = 0.2$$

Hence the reflectivity of the surface is $\boxed{\rho = 0.2}$

Step 3 of 3

From energy balance,

$$G_{abs} = \dot{q}_{conv} + \dot{q}_{rad}$$
$$G_{abs} = \dot{q}_{conv} + \varepsilon A \sigma T_s^4$$
$$\varepsilon = \frac{G_{abs} - \dot{q}_{conv}}{A \sigma T_s^4}$$
$$= \frac{4000 - 500}{5 \times \left(5.67 \times 10^{-8}\right) \times 350^4}$$
$$= 0.8227$$

Hence the emissivity of the surface is $\boxed{\varepsilon = 0.8227}$

Question: 21.100P

The spectral emissivity of an opaque surface at 1200 K is approximated as

$\varepsilon_1 = 0 \quad \text{for} \quad \lambda < 2\,\mu\text{m}$
$\varepsilon_2 = 0.85 \quad \text{for} \quad 2 \le \lambda \le 6\,\mu\text{m}$
$\varepsilon_3 = 0 \quad \text{for} \quad \lambda > 6\,\mu\text{m}$

Determine the total emissivity and the emissive flux of the surface.

Step 1 of 4

Given
Spectral Emissivity of an opaque surface can be expressed as
$\varepsilon_1 = 0 \quad \text{for} \quad \lambda < 2\mu\text{m}$
$\varepsilon_2 = 0.85 \text{ for} \quad 2 \le \lambda \le 6\ \mu\text{m}$
$\varepsilon_3 = 0 \quad \text{for} \quad \lambda > 6\mu\text{m}$
Temperature of opaque surface, $T = 1500\,\text{K}$

Step 2 of 4

The emissivity of the surface is calculated as follows
$\lambda_1 T = 2 \times 1200$
$= 2400\,\mu\text{mK}$
$\lambda_2 T = 6 \times 1200$
$= 7200\,\mu\text{mK}$
From table, Black body radiation functions
The blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$ are determined as
$f_{\lambda_1} = 0.140256$
$f_{\lambda_2} = 0.819217$

Step 3 of 4

Total emissivity of the surface becomes
$$\varepsilon(T) = \varepsilon_1 f_{\lambda_1} + \varepsilon_2 \left(f_{\lambda_2} - f_{\lambda_1}\right) + \varepsilon_3 \left(1 - f_{\lambda_2}\right)$$
$$= 0.0 \times 0.140256 + 0.85(0.819217 - 0.140256) + 0.0(1 - 0.819217)$$
$$= 0 + 0.57712 + 0$$
$$= 0.57712$$
Total emissivity of the surface, $\boxed{\varepsilon(T) = 0.57712}$

Step 4 of 4

Emissive flux of the surface is given by
$$E = \varepsilon \sigma T^4$$
$$= 0.57712 \times \left(5.67 \times 10^{-8}\right) \times 1200^4$$
$$= 67853.8\,\text{W/m}^2$$
Emissive flux of the surface, $\boxed{E = 67853.8\,\text{W/m}^2}$

Question: 21.101P

The spectral transmissivity of a glass cover used in a solar collector is given as

$\tau_1 = 0$ for $\lambda < 0.3\ \mu m$
$\tau_2 = 0.9$ for $0.3 < \lambda < 3\ \mu m$
$\tau_3 = 0$ for $\lambda > 3\ \mu m$

Solar radiation is incident at a rate of 950 W/m2, and the absorber plate, which can be considered to be black, is maintained at 340 K by the cooling water. Determine (*a*) the solar flux incident on the absorber plate, (*b*) the transmissivity of the glass cover for radiation emitted by the absorber plate, and (*c*) the rate of heat transfer to the cooling water if the glass cover temperature is also 340 K.

Step 1 of 6

Given data:

The temperature of the surface $T = 340\ K$

Incident radiation is $q = 950\ W/m^2$

The transmissivity of the cover for $\lambda < 0.3\ \mu m$, $\tau_1 = 0$

The transmissivity of the cover for $0.3\ \mu m < \lambda < 3\ \mu m$, $\tau_2 = 0.9$

The transmissivity of the cover for $\lambda > 3\ \mu m$, $\tau_3 = 0$

Step 2 of 6

a)

The temperature of solar radiation is $T = 5800\ K$

Radiation function corresponding to the temperature of 5800K,

$$\lambda_1 T = (0.3)(5800)$$
$$= 1740\ \mu m \cdot K$$
$$\lambda_2 T = (3)(5800)$$
$$= 17400\ \mu m \cdot K$$

From the black body radiation function, at $\lambda_1 T = 1740\ \mu m \cdot K$

$f_{\lambda_1} = 0.033454$

From the black body radiation function, at $\lambda_2 T = 17400\ \mu m \cdot K$

$f_{\lambda_2} = 0.97874$

Step 3 of 6

The average transmissivity of the surface is

$$\tau_s = \tau_1 f_{\lambda_1} + \tau_2 (f_{\lambda_2} - f_{\lambda_1}) + \tau_3 (1 - f_{\lambda_2})$$
$$= (0)(0.033454) + (0.9)(0.97874 - 0.033454) + (0.0)(1 - 0.97874)$$
$$= 0.851$$

Now radiation absorbed by the plate is

$$E_{abs} = 0.851 \times 950$$
$$= 808.45\ W/m^2$$

Therefore, solar flux incident on absorber plate is $\boxed{E_{abs} = 808.45\ W/m^2}$

Step 4 of 6

b)

The radiation emitted by the absorber plate is $T = 340\ K$

Radiation function corresponding to the temperature of 340K

$$\lambda_1 T = (0.3)(340)$$
$$= 102\ \mu m K$$
$$\lambda_2 T = (3)(340)$$
$$= 1020\ \mu m K$$

From the black body radiation function, at $\lambda_1 T = 102\ \mu m \cdot K$

$f_{\lambda_1} = 0.0$

From the black body radiation function, at $\lambda_2 T = 1020\ \mu m \cdot K$

$f_{\lambda_2} = 0.0005023$

Step 5 of 6

The average transmissivity of the surface is

$$\tau(T) = \tau_1 f_{\lambda_1} + \tau_2 (f_{\lambda_2} - f_{\lambda_1}) + \tau_3 (1 - f_{\lambda_2})$$
$$= (0)(0.0) + (0.9)(0.0005023 - 0.0) + (0.0)(1 - 0.0005023)$$
$$= 0.0004520$$

Therefore, the transmissivity of the glass cover for the radiation emitted by the absorber plate is $\boxed{\tau_r = 0.0004520}$

Step 6 of 6

c)

The rate of heat transfer to the cooling water is the difference between the radiation absorbed by the absorber plate and radiation emitted by the absorber plate.

$$Q_{cw} = (\tau_s - \tau_r) q$$
$$= (0.851 - 0.0004520)950$$
$$= 808.02\ W/m^2$$

Therefore, rate of heat transfer to the cooling water is $\boxed{Q_{cw} = 808.02\ W/m^2}$

Question: 21.102P

The spectral absorptivity of an opaque surface is as shown on the graph. Determine the absorptivity of the surface for radiation emitted by a source at (a) 1000 K and (b) 3000 K.

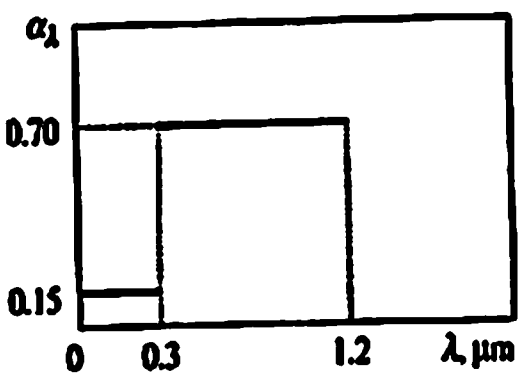

FIGURE P21-102

Step 1 of 5

Given data:

(a) T = 1000 K

Average absorptivity of the surface for radiation at calculated as follows

From Blackbody radiation function f_λ

The fraction of radiation in the range of 0.3 to 1.2 μm is

$\lambda_1 T = (0.3\ \mu m)(1000\ K)$

$=300\ \mu mK$

Step 2 of 5

From Blackbody radiation function f_λ

At $\lambda_1 T = 300\ \mu mK$

$f_{\lambda_1} = 0$

$\lambda_2 T = (1.2\ \mu m)(1000\ K)$

$=1200\ \mu mK$

From Blackbody radiation function f_λ

$\lambda_2 T = 1200\ \mu mK$

$f_{\lambda_2} = 0.002134$

Step 3 of 5

Average absorptivity of the surface is determined by

$$\alpha(T) = \alpha_1 f_{\lambda 1} + \alpha_2 (f_{\lambda 2} - f_{\lambda 1}) + \alpha_3 (1 - f_{\lambda 2})$$

$$= (0.15)(0) + (0.7)(0.002134 - 0) + (0)(1 - 0.002134)$$

$\alpha(T) = 0.0015$

Therefore, Average absorptivity of the surface is $\alpha(T) = 0.0015$

Step 4 of 5

(b) T = 3000 K

Similarly the absorptivity of the surface is determined as

From Table 12-2 Blackbody radiation function f_λ

The fraction of radiation in the range of 0.3 to 1.2 μm is

$\lambda_1 T = (0.3\ \mu m)(3000\ K)$

$=900\ \mu mK$

From Blackbody radiation function f_λ

At $\lambda_1 T = 900\ \mu mK$

$f_{\lambda_1} = 0.00017$

Step 5 of 5

The fraction of radiation is 1.2 μm

$\lambda_2 T = (1.2\ \mu m)(3000\ K)$

$=3600\ \mu mK$

From Blackbody radiation function f_λ

$\lambda_2 T = 3600\ \mu mK$

$f_{\lambda_2} = 0.403607$

Question: 21.103P

The surface in Prob. 21–102 receives solar radiation at a rate of 470 W/m2. Determine the solar absorptivity of the surface and the rate of absorption of solar radiation.

Step 1 of 3

Given

The solar radiation on the surface $I = 470\ \text{W/m}^2$

We know the surface of the sun is $T = 5800\ \text{K}$

Step 2 of 3

Average absorptivity of the surface for radiation at calculated as follows

The fraction of radiation in the range of 0.3 to 1.2 μm is

$\lambda_1 T = (0.3\ \mu\text{m})(5800\ \text{K})$

$= 1740\ \mu\text{mK}$

From Blackbody radiation function f_λ

$f_{\lambda_1} = 0.0335$

$\lambda_2 T = (1.2\ \mu\text{m})(5800\ \text{K})$

$= 6960\ \mu\text{mK}$

From Blackbody radiation function f_λ

$f_{\lambda_2} = 0.806$

Step 3 of 3

Average absorptivity of the surface is determined by

$$\alpha(T) = \alpha_1 f_{\lambda 1} + \alpha_2 (f_{\lambda 2} - f_{\lambda 1}) + \alpha_3 (1 - f_{\lambda 2})$$

$$= (0.15)(0.0335) + (0.7)(0.806 - 0.0335) + (0)(1 - 0.806)$$

$$= \alpha(T) = 0.546$$

Therefore, Average absorptivity of the surface is $\boxed{\alpha(T) = 0.546}$

Question: 21.104P

The spectral transmissivity of a 3-mm-thick regular glass can be expressed as

$\tau_1 = 0$ for $\lambda < 0.35\ \mu m$
$\tau_2 = 0.85$ for $0.35 < \lambda < 2.5\ \mu m$
$\tau_3 = 0$ for $\lambda > 2.5\ \mu m$

Determine the transmissivity of this glass for solar radiation. What is the transmissivity of this glass for light?

Step 1 of 5

Given
Thickness of glass, $t = 3mm$
Spectral transmissivity of glass can be expressed as
$\tau_1 = 0$ for $\lambda < 0.35\mu m$
$\tau_2 = 0.85$ for $0.35 \le \lambda \le 2.5\ \mu m$
$\tau_3 = 0$ for $\lambda > 2.5\mu m$

Step 2 of 5

The transmissivity of this glass for the solar radiation at $T = 5800K$ calculated as follows
$\lambda_1 T = 0.35 \times 5800$
$= 2030\mu mK$
$\lambda_2 T = 2.5 \times 5800$
$= 14500\mu mK$
From table, Black body radiation functions
The blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$ are determined as
$f_{\lambda_1} = 0.071852$
$f_{\lambda_2} = 0.966440$

Step 3 of 5

Transmissivity of this glass,
$$\tau(T) = \tau_1 f_{\lambda_1} + \tau_2 \left(f_{\lambda_2} - f_{\lambda_1}\right) + \tau_3 \left(1 - f_{\lambda_2}\right)$$
$$= 0.0 \times 0.071852 + 0.85(0.966440 - 0.071852) + 0.0(1 - 0.966440)$$
$$= 0 + 0.7604 + 0$$
$$= 0.7604$$
Transmissivity of this glass for solar radiation, $\boxed{\tau(T) = 0.7604}$

Step 4 of 5

The transmissivity of this glass for the light at $T = 300K$ calculated as follows
$\lambda_1 T = 0.35 \times 300$
$= 105\mu mK$
$\lambda_2 T = 2.5 \times 300$
$= 750\mu mK$
From table, Black body radiation functions
The blackbody radiation functions corresponding to $\lambda_1 T$ and $\lambda_2 T$ are determined as
$f_{\lambda_1} = 0.00$
$f_{\lambda_2} = 0.000012$

Step 5 of 5

Transmissivity of this glass,
$$\tau(T) = \tau_1 f_{\lambda_1} + \tau_2 \left(f_{\lambda_2} - f_{\lambda_1}\right) + \tau_3 \left(1 - f_{\lambda_2}\right)$$
$$= 0.0 \times 0.00 + 0.85(0.000012 - 0.00) + 0.0(1 - 0.000012)$$
$$= 0 + 0.0000102 + 0$$
$$= 0.0000102$$
Transmissivity of this glass for light, $\boxed{\tau(T) = 0.0000102}$

Question: 21.105P

A 1-m-diameter spherical cavity is maintained at a uniform temperature of 600 K. Now a 5-mm-diameter hole is drilled. Determine the maximum rate of radiation energy streaming through the hole. What would your answer be if the diameter of the cavity were 3 m?

Step 1 of 3

Given

Diameter of spherical cavity, $D = 1\text{m}$

Diameter of the drilled hole, $d = 5\text{mm}$

Temperature of cavity, $T = 600\text{ K}$

Step 2 of 3

Area of the hole, $A = \dfrac{\pi d^2}{4}$

$$= \frac{\pi \times 0.005^2}{4}$$

$$= 1.96 \times 10^{-5}\text{ m}^2$$

Maximum rate of radiation energy streaming through the hole is given by

$$E = A\sigma T^4 \text{ -------(1)}$$

$$= 1.96 \times 10^{-5} \times \left(5.67 \times 10^{-8}\right) \times 600^4$$

$$= 0.144\text{ W}$$

Maximum rate of radiation energy streaming through the hole, $\boxed{E = 0.144\text{ W}}$

Step 3 of 3

Now, diameter of spherical cavity, $D = 3\text{m}$

From equation (1)

Rate of radiation energy doesn't depend up on diameter of spherical cavity but, depend on diameter of the drilled hole because of we require radiation energy through hole.

So, we get the same answer.

Maximum rate of radiation energy streaming through the hole, $\boxed{E = 0.144\text{ W}}$

Question: 21.106P

The human skin is "selective" when it comes to the absorption of the solar radiation that strikes it perpendicularly. The skin absorbs only 50 percent of the incident radiation with wavelengths between λ1 =0.517 μm and λ2 = 1.552 . The radiation with wavelengths shorter than λ1 and longer than λ2 is fully absorbed. The solar surface may be modeled as a blackbody with effective surface temperature of 5800 K. Calculate the fraction of the incident solar radiation that is absorbed by the human skin.

Step 1 of 3

Given data:

The surface of the sun is $T = 5800\ \text{K}$

The absorptivity of the skin for $\lambda < 0.517\ \mu\text{m}$, $\alpha_1 = 1$

The absorptivity of the skin for $0.517\ \mu\text{m} < \lambda < 1.552\ \mu\text{m}$, $\alpha_2 = 0.5$

The absorptivity of the skin for $\lambda > 1.552\ \mu\text{m}$, $\alpha_3 = 1$

Step 2 of 3

Radiation function corresponding to the temperature of 5800 K,

$$\lambda_1 T = (0.517)(5800)$$
$$= 2998.6\ \mu\text{m}\cdot\text{K}$$
$$\lambda_2 T = (1.552)(5800)$$
$$= 9001.6\ \mu\text{m}\cdot\text{K}$$

From the black body radiation function, at $\lambda_1 T = 2998.6\ \mu\text{m}\cdot\text{K}$

$f_{\lambda 1} = 0.273232$

From the black body radiation function, at $\lambda_2 T = 9001.6\ \mu\text{m}\cdot\text{K}$

$f_{\lambda 2} = 0.890029$

Step 3 of 3

The average absorptivity of the skin is

$$\alpha(T) = \alpha_1 f_{\lambda 1} + \alpha_2 (f_{\lambda 2} - f_{\lambda 1}) + \alpha_3 (1 - f_{\lambda 2})$$
$$= (1)(0.273232) + (0.5)(0.890029 - 0.273232) + (1)(1 - 0.890029)$$
$$= 0.6916$$

Therefore, the average absorptivity of the skin is $\boxed{\alpha(T) = 0.6916}$

Question: 21.107P

Consider a cylindrical enclosure with *A*1, *A*2 and *A*3 representing the internal base, top, and, side surfaces, respectively. Using the length to diameter ratio, *K* = L/D, determine (*a*) the expression for the view factor from the side surface to itself F33 in terms of K and (*b*) the value of the view factor *F*33 for *L* = *D*.

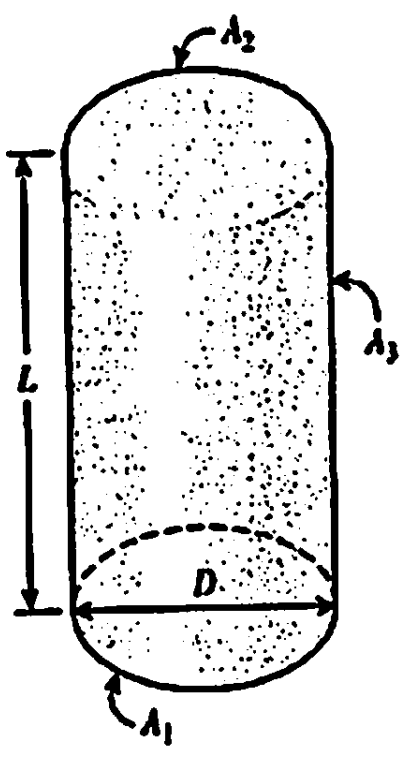

FIGURE P21–107

Step 1 of 8

Given data:

The internal base area of the cylinder is A_1

The top surface area of the cylinder is A_2

The side surface area of the cylinder is A_3

Length to diameter ratio is $K = \frac{L}{D}$

Step 2 of 8

a) For coaxial parallel disks from the table of 'view factor expressions for some common geometrics of finite size', the expression for view factor is

$$F_{12} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

Where,

$$R = \frac{D}{2L}$$

$$= \frac{1}{2K}$$

Step 3 of 8

Therefore, the view factor from the base to the top is written as

$$F_{12} = 1 + \frac{1 - \sqrt{4R^2 + 1}}{2R^2}$$

$$= 1 + \frac{1 - \sqrt{4(1/2K)^2 + 1}}{2(1/2K)^2}$$

$$= 1 + \frac{1 - \sqrt{1/K^2 + 1}}{1/2K^2}$$

$$= 1 + 2K\left(K - \sqrt{K^2 + 1}\right)$$

Step 4 of 8

By using the reciprocity relation, the view factor from the top surface to the base surface can be expressed as

$$F_{21} = \frac{A_1}{A_2} F_{12}$$

$$= \frac{A_1}{A_1} \times \left[1 + 2K\left(K - \sqrt{K^2 + 1}\right)\right]$$

$$= 1 + 2K\left(K - \sqrt{K^2 + 1}\right)$$

As the surface-1 is flat, by consider the view factor of surface-1 with respect to itself, we get

$$F_{11} = 0$$

Step 5 of 8

The view factor from the base to the side surface is determined by applying the summation rule.

$$1 = F_{11} + F_{12} + F_{13}$$

$$F_{13} = 1 - F_{11} - F_{12}$$

$$= 1 - 0 - \left(1 + 2K\left(K - \sqrt{K^2 + 1}\right)\right)$$

$$= 2K\sqrt{K^2 + 1} - 2K^2$$

Step 6 of 8

By using the reciprocity rule, the view factor from the side surface to the base surface/top surface can be expressed as

$$F_{31} = \frac{A_3}{A_3} F_{13}$$

$$= \frac{\pi D^2/4}{\pi DL} \times \left(2K\sqrt{K^2 + 1} - 2K^2\right)$$

$$= \frac{1}{4K} \times \left(2K\sqrt{K^2 + 1} - 2K^2\right)$$

$$= \frac{1}{2}\left(\sqrt{K^2 + 1} - K\right)$$

Step 7 of 8

The view factor from the side surface to itself is determined by applying the summation.

$$1 = F_{31} + F_{32} + F_{33}$$

$$1 = F_{31} + F_{31} + F_{33}$$

$$F_{33} = 1 - 2F_{31}$$

$$= 1 - 2\left(\frac{1}{2}\right)\left(\sqrt{K^2 + 1} - K\right)$$

$$= 1 - \left(\sqrt{K^2 + 1} - K\right)$$

Thus the expression for view factor from side surface to itself is $\boxed{F_{33} = 1 - \left(\sqrt{K^2 + 1} - K\right)}$

Step 8 of 8

b)

The relation between the length and diameter is given as $L = D$

Thus the value of K becomes,

$$K = \frac{L}{D}$$

$$= \frac{D}{D}$$

$$= 1$$

The expression for view factor from side surface to itself is

$$F_{33} = 1 - \left(\sqrt{K^2 + 1} - K\right)$$

$$= 1 - \left(\sqrt{1^2 + 1} - 1\right)$$

$$= 1.414$$

Thus the view factor from side surface to itself is $\boxed{F_{33} = 1.414}$

Question: 21.108P

A long cylindrical black surface fuel rod of diameter 25 mm is shielded by a surface concentric to the rod. The shield has diameter of 50 mm and a constant surface temperature of 320 K. Both inner and outer surfaces of the shield have an emissivity of 0.05, and the gap between the fuel rod and the shield is a vacuum. If the fuel rod is generating 0.5 MW/m3 of heat per unit length, determine the surface temperature of the fuel rod.

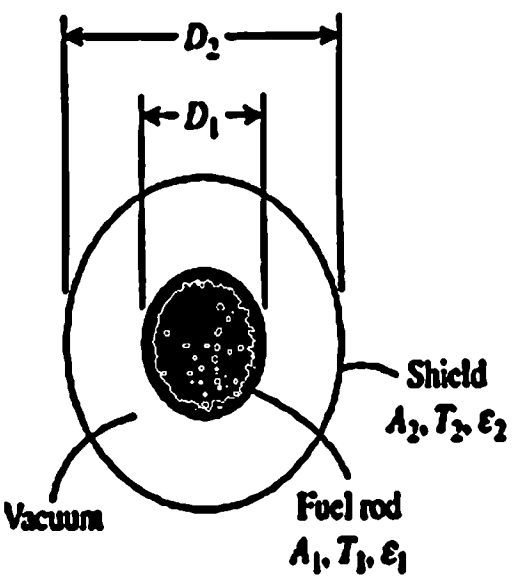

FIGURE P21–108

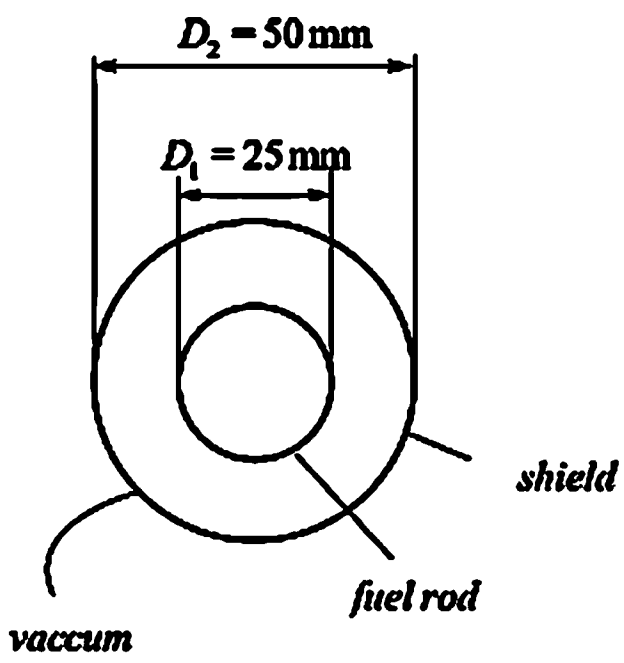
Suppose another (infinitely) large disk *c*, of negligible thickness and $s = 0.7$, is inserted between disks *a* and *b* such that it is parallel and equidistant to both disks. Calculate the net rate of radiation heat exchange between disks *a* and *c* and disks *c* and *b* in steady operation.

Step 1 of 3

Given data:

Diameter of the fuel rod, $D_1 = 25\,\text{mm}$

Diameter of the outer shield, $D_2 = 50\,\text{mm}$



Temperature of the outer shield, $T_2 = 320\ \text{K}$

Emissivity of the radiation shield on inner and outer surfaces, $\varepsilon_2 = 0.05$

Heat generation by the fuel rod, $\dot{q}_{gen} = 0.5\ \text{MW/m}^3$

Step 2 of 3

Given figure:

Step 3 of 3

Calculation of surface temperature of fuel rod

By applying the energy balance at the surface of the fuel rod, we get,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0$$

$$\dot{Q}_{rad\ from\ shield} - \dot{Q}_{rad\ from\ fuelrod} + \dot{Q}_{gen} = 0$$

$$\varepsilon_2 A_2 \sigma T_2^4 - A_1 \sigma T_1^4 + A_1 L \dot{q}_{gen} = 0 \qquad (\because \varepsilon_1 = 1)$$

Therefore, the surface temperature of the fuel rod can be expressed as

$$T_1^4 = \frac{\varepsilon_2 A_2 \sigma T_2^4 + A_1 L \dot{q}_{gen}}{A_1 \sigma}$$

$$T_1^4 = \frac{\left[0.05 \times (\pi \times 0.05) \times 5.67 \times 10^{-8} \times 320^4\right] + \left[\left(\frac{\pi}{4} \times 0.025^2\right) \times 0.5 \times 10^6\right]}{(\pi \times 0.025) \times 5.67 \times 10^{-8}}$$

$$T_1^4 = \frac{4.6695 + 245.43}{4.453 \times 10^{-9}}$$

$$T_1^4 = 5.616 \times 10^{10}$$

$$T_1 = 486.816\ \text{K}$$

Therefore, the surface temperature of the fuel rod is $\boxed{T_1 = 487\ \text{K}}$

Question: 21.109P

A dryer is shaped like a long semi-cylindrical duct of diameter 1.5 m. The base of the dryer is occupied with water soaked materials to be dried, and maintained at a temperature of 370 K and emissivity of 0.5. The dome of the dryer is maintained at 1000 K with emissivity of 0.8. Determine the drying rate per unit length experienced by the wet materials.

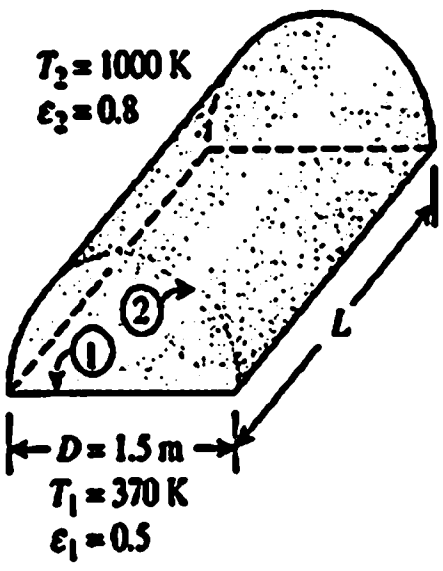


FIGURE P21–109

Step 1 of 4

Given data:

Diameter of the duct, $D = 1.5$ m

Base temperature, $T_1 = 370$ K

Dome temperature, $T_2 = 1000$ K

Emissivity of the base surface, $\varepsilon_1 = 0.5$

Emissivity of the dome surface, $\varepsilon_2 = 0.8$

Step 2 of 4

Calculation of drying rate per unit length:

The drying rate per unit length can be calculated as follows,

From the properties of saturated water,

By interpolating the values of latent heat of vaporization at $T = 95$ °C $T = 100$ °C, we get the latent heat of vaporization at $T = 97$ °C as follows,

$$h_{fg\ at\ 97^\circ C} = h_{fg\ at\ 95^\circ C} + \left(h_{fg\ at\ 100^\circ C} - h_{fg\ at\ 95^\circ C}\right)\left(\frac{97-95}{100-95}\right)$$

$$= 2269.6 + \left[(2256.4 - 2269.6) \times 0.4\right]$$

$$= 2269.6 - 5.28$$

$$= 2264.32 \text{ kJ/kg}$$

Therefore, the Latent heat of vaporization at $T_1 = 370$ K is, $h_{fg} = 2256$ kJ/kg

Since, Surface 1 is flat, $F_{11} = 0$

The view factor from the base surface A_1 to the cylindrical dome A_2 can be determined by using the summation rule as,

$$F_{11} + F_{12} = 1$$

$$0 + F_{12} = 1$$

$$F_{12} = 1$$

Step 3 of 4

The radiation heat exchange between the dome and the base surface per unit length can be determined as,

$$\dot{Q}_{12} = -\frac{\sigma\left(T_1^4 - T_2^4\right)}{\left(\frac{1-\varepsilon_1}{A_1\varepsilon_1} + \frac{1}{F_{12}A_1} + \frac{1-\varepsilon_2}{A_2\varepsilon_2}\right)}$$

$$= -\frac{5.67\times10^{-8}\times\left(370^4 - 1000^4\right)}{\left(\frac{1-0.5}{1.5\times1\times0.5} + \frac{1}{1\times1.5\times1} + \frac{1-0.8}{\frac{\pi}{2}\times1.5\times1\times0.8}\right)}$$

$$= \frac{55.63\times10^3}{1.4394}$$

$$= 38209.39 \text{ W/m}$$

$$\dot{Q}_{12} = 38209.39 \text{ W/m} \qquad \ldots\ldots (1)$$

Step 4 of 4

The amount of heat required for drying can be expressed as,

$$\dot{Q} = \dot{m}h_{fg} \qquad \ldots\ldots (2)$$

The drying rate per unit length can be determined by equating the equations (1) and (2) as,

$$\dot{Q}_{12} = \dot{Q}$$

$$38209.39 = \dot{m}h_{fg}$$

$$\dot{m} = \frac{38209.39}{h_{fg}}$$

$$= \frac{38209.39}{2256\times10^3}$$

$$\dot{m} = 0.0169 \text{ kg/s-m}$$

The drying rate per unit length experienced by the wet material is $\boxed{\dot{m} = 0.0169 \text{ kg/s-m}}$

Question: 21.110P

Two concentric spheres of diameters $D1$ = 15 cm and $D2$ = 25 cm are separated by air at 1 atm pressure. The surface temperatures of the two spheres enclosing the air are $T1$ = 350 K and $T2$ = 275 K, respectively, and their emissivities are 0.75. Determine the rate of heat transfer from the inner sphere to the outer sphere by (*a*) natural convection and (*b*) radiation.

Step 1 of 8

Given

Diameter of inner sphere, $D_1 = 15$ cm

Diameter of outer sphere, $D_2 = 25$ cm

Surface temperature of inner sphere, $T_1 = 350$ K

Surface temperature of outer sphere, $T_2 = 275$ K

Emissivity of each surface, $\varepsilon = 0.75$

Step 2 of 8

(a) The characteristic length, $L_c = \frac{1}{2}(D_2 - D_1)$

$$= \frac{1}{2}(0.25 - 0.15)$$

$$= 0.05\text{m}$$

Film temperature, $T_f = \frac{T_1 + T_2}{2}$

$$= \frac{350 + 275}{2}$$

$$= 312.5\text{K}$$

Step 3 of 8

From table, Properties of air at 1 atm pressure

At $T_f = 312.5$K

Kinematic viscosity of air, $\upsilon = 1.697 \times 10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7256$

Thermal conductivity, $k = 0.02658$ W/m.K

Now, $\beta = \frac{1}{T_f}$

$$= \frac{1}{312.5}$$

$$= 0.0032\text{K}^{-1}$$

Step 4 of 8

Rayleigh number is given by

$$Ra = \frac{g\beta(T_s - T_\infty)L_c^3}{\upsilon^2}\text{Pr}$$

$$= \frac{9.81 \times 0.0032 \times (350 - 275) \times 0.05^3 \times 0.7256}{\left(1.697 \times 10^{-5}\right)^2}$$

$$= \frac{2.13 \times 10^{-4}}{\left(1.697 \times 10^{-5}\right)^2}$$

$$= 7.41 \times 10^5$$

Step 5 of 8

The geometric factor for concentric spheres is given by

$$F_{sph} = \frac{L_c}{(D_1 D_2)^4 \left(D_1^{-3/5} + D_2^{-3/5}\right)^5}$$

$$= \frac{0.05}{[0.15 \times 0.25]^4 \left[0.15^{-3/5} + 0.25^{-3/5}\right]^5}$$

$$= \frac{0.05}{8.47}$$

$$= 5.9 \times 10^{-3}$$

Step 6 of 8

The effective thermal conductivity is given by

$$k_{eff} = 0.74k\left(\frac{\text{Pr}}{0.861 + \text{Pr}}\right)^{1/4}(F_{sph}Ra)^{1/4}$$

$$= 0.74 \times 0.02658\left(\frac{0.7256}{0.861 + 0.7256}\right)^{1/4}\left[0.0059 \times 7.41 \times 10^5\right]^{1/4}$$

$$= 0.1315\ \text{W/m.K}$$

Then the rate oh heat transfer becomes

$$\dot{Q} = k_{eff}\pi\left(\frac{D_1 D_2}{L_c}\right)(T_1 - T_2)$$

$$= 0.1315 \times \pi\left[\frac{0.15 \times 0.25}{0.05}\right](350 - 275)$$

$$= 23.24\,\text{W}$$

Rate of heat transfer by natural convection, $\boxed{\dot{Q} = 23.24\,\text{W}}$

Step 7 of 8

(b) Surface area of the inner sphere, $A_1 = \pi D_1^2$

$$= \pi \times 0.15^2$$

$$= 0.0707\ \text{m}^2$$

Step 8 of 8

Rate of heat transfer is given by

$$\dot{Q}_{12} = \frac{A_1\sigma\left(T_2^4 - T_1^4\right)}{\frac{1}{\varepsilon_1} + \frac{1 - \varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)^2}$$

$$= \frac{0.0707 \times 5.67 \times 10^{-8} \times \left(350^4 - 275^4\right)}{\frac{1}{0.75} + \frac{1 - 0.75}{0.75}\left(\frac{0.15}{0.25}\right)^2}$$

$$= \frac{37.23}{1.453}$$

$$= 25.6\,\text{W}$$

Rate of heat transfer by radiation, $\boxed{\dot{Q}_{12} = 25.6\,\text{W}}$

Question: 21.111P pg 1

Consider the two parallel coaxial disks of diameters *a* and *b*, shown in Fig. P21–111. For this geometry, the view factor from the smaller disk to the larger disk can be calculated from

$$F_{ij} = 0.5\left(\frac{B}{A}\right)^2\left\{C - \left[C^2 - 4\left(\frac{A}{B}\right)^2\right]^{0.5}\right\}$$

Where , $A = a/2L$, $B = b/2L$, and $C = 1 + [(1 + A^2)/B^2]$.. The diameter, emissivity and temperature are 20 cm , and 600°C, respectively, for disk *a*, and 40 cm, 0.80 and 200°C for disk *b*. The distance between the two disks is *L* = 10 cm.

(a) Calculate *Fab* and *Fba*.

(b) Calculate the net rate of radiation heat exchange between disks *a*and *b* in steady operation.

(c) Suppose another (infinity) large disk *c*,of negligible thickness and ε = 0.7, is inserted between disks *a* and *b* such that it is parallel and equidistant to both disks. Calculate the net rate of radiation heat exchange between disks *a*and *c* and disks *c* and *b* in steady operation.

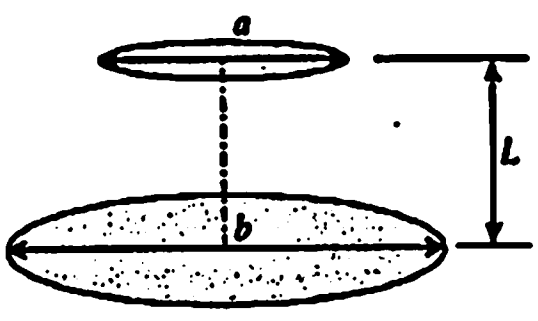

FIGURE P21–111

Step 1 of 9

Given data:

Diameter of the disk a, $a = 20\,\text{cm}$

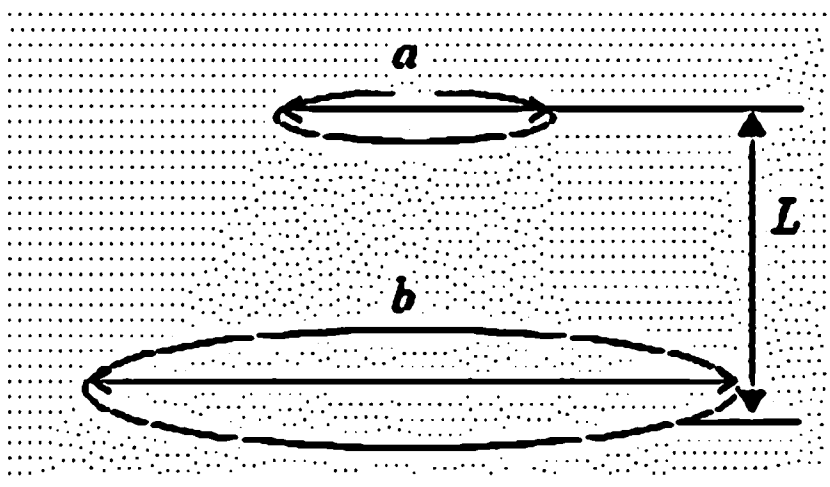
Emissivity of the disk a, $\varepsilon_a = 0.6$

Surface temperature of the disk a, $T_a = 600\,^\circ\text{C}$

Diameter of the disk b, $b = 40\,\text{cm}$

Emissivity of the disk b , $\varepsilon_b = 0.8$

Surface temperature of the disc b, $T_b = 200\,^\circ\text{C}$



Center to center distance, $L = 10\,\text{cm}$

View factor from the smaller disk to larger disk is given by,

$$F_{ij} = 0.5\left(\frac{B}{A}\right)^2\left\{C - \left[C^2 - 4\left(\frac{A}{B}\right)^2\right]^{0.5}\right\}$$

Step 2 of 9

Given figure:

Step 3 of 9

a) Calculation of view factors from a to b and b to a:

The view factor from surface a to surface b is given as

$$F_{ab} = 0.5\left(\frac{B}{A}\right)^2\left\{C - \left[C^2 - 4\left(\frac{A}{B}\right)^2\right]^{0.5}\right\}$$

Where,

$$A = \frac{a}{2L}$$
$$= \frac{0.2}{2\times 0.1}$$
$$= 1$$
$$B = \frac{b}{2L}$$
$$= \frac{0.4}{2\times 0.1}$$
$$= 2$$
$$C = 1 + \left[\left(1 + A^2\right)/B^2\right]$$
$$= 1 + \left[\left(1 + 1^2\right)/2^2\right]$$
$$= 1.5$$

Step 4 of 9

Therefore, the view factor F_{12} can be calculated as,

$$F_{ab} = 0.5\left(\frac{B}{A}\right)^2\left\{C - \left[C^2 - 4\left(\frac{A}{B}\right)^2\right]^{0.5}\right\}$$
$$= 0.5\left(\frac{2}{1}\right)^2\left\{1.5 - \left[1.5^2 - 4\left(\frac{1}{2}\right)^2\right]^{0.5}\right\}$$
$$= 0.5\times 4\times 0.3819$$
$$= 0.7639$$

Step 5 of 9

The view factor from surface b to surface a can be calculated using the reciprocity rule.

The area of the disk 'a' and the disk 'b' can be calculated as,

$$A_a = \frac{\pi}{4}a^2$$
$$= \frac{\pi}{4}\times 0.2^2$$
$$= 0.031416\,\text{m}^2$$
$$A_b = \frac{\pi}{4}b^2$$

$$= \frac{\pi}{4} \times 0.2^2$$

$$= 0.031416 \text{m}^2$$

$$A_b = \frac{\pi}{4} b^2$$

$$= \frac{\pi}{4} \times 0.4^2$$

$$= 0.1256 \text{m}^2$$

Step 6 of 9

Therefore, the view factor F_{ba} calculated as,

$$A_b F_{ba} = A_a F_{ab}$$

$$F_{ba} = \frac{A_a}{A_b} F_{ab}$$

$$= \frac{0.031416}{0.1256} \times 0.764$$

$$= 0.191$$

Therefore, the view factor from a to b and from b to a is, $\boxed{F_{ab} = 0.764}$ and $\boxed{F_{ba} = 0.191}$

Step 7 of 9

(b)Calculation of total rate of radiation heat exchange between the disks a and b:
The net rate of radiation heat transfer between the surfaces can be determined as,

$$\dot{Q}_{ab} = \frac{\sigma(T_a^4 - T_b^4)}{\frac{1-\varepsilon_a}{A_a \varepsilon_a} + \frac{1}{A_a F_{ab}} + \frac{1-\varepsilon_b}{A_b \varepsilon_b}}$$

$$= \frac{5.67 \times 10^{-8}(873^4 - 473^4)}{\frac{1-0.6}{0.031416 \times 0.6} + \frac{1}{0.031416 \times 0.764} + \frac{1-0.8}{0.1256 \times 0.8}}$$

$$= \frac{30095.56}{64.874}$$

$$= 463.902 \text{ W}$$

$$\boxed{\dot{Q}_{ab} = 463.902 \text{W}}$$

Step 8 of 9

c) In order to calculate the net rate of radiation heat exchange, let us calculate the temperature of disk c as follows:
In this case we have an infinitely large disc; it represents that $A_c = \infty$ and the emissivity of the disk c is $\varepsilon_c = 0.7$. Since the disc is infinitely large, the view factors $F_{ac} = F_{bc} = 1$. Therefore, $\dot{Q}_{ac} = \dot{Q}_{cb} = \dot{Q}_{bc}$ by applying an Energy balance, we get,

$$\frac{\sigma(T_a^4 - T_c^4)}{\frac{1-\varepsilon_a}{A_a \varepsilon_a} + \frac{1}{A_a F_{ac}} + \frac{1-\varepsilon_c}{A_c \varepsilon_c}} = \frac{\sigma(T_b^4 - T_c^4)}{\frac{1-\varepsilon_c}{A_c \varepsilon_c} + \frac{1}{A_c F_{cb}} + \frac{1-\varepsilon_b}{A_b \varepsilon_b}}$$

By substituting the known values in the above equation (1), we get,

$$\frac{5.67 \times 10^{-8}(873^4 - T_c^4)}{\left(\frac{1-0.6}{0.031416 \times 0.6} + \frac{1}{0.031416 \times 1} + 0\right)} = \frac{5.67 \times 10^{-8}(T_c^4 - 473^4)}{\left(0 + \frac{1}{(0.1256)(1)} + \frac{1-0.8}{0.1256 \times 0.8}\right)}$$

$$\frac{(873^4 - T_c^4)}{53.0515} = \frac{(T_c^4 - 473^4)}{9.9522}$$

$$57.8 \times 10^{11} - 9.9522 T_c^4 = 53.0515 T_c^4 - 26.55 \times 10^{11}$$

$$21.303 T_c^4 = 31.25 \times 10^{11}$$

$$T_c^4 = 14.66 \times 10^{10}$$

$$T_c = 618.87 \text{K}$$

Step 9 of 9

Therefore,

$$\dot{Q}_{ac} = \dot{Q}_{cb}$$

$$= \frac{\sigma(T_a^4 - T_c^4)}{\frac{1-\varepsilon_a}{A_a \varepsilon_a} + \frac{1}{A_a F_{ac}} + \frac{1-\varepsilon_c}{A_c \varepsilon_c}}$$

$$= \frac{5.67 \times 10^{-8}(873^4 - 605^4)}{\left(\frac{1-0.6}{0.031416 \times 0.6} + \frac{1}{0.031416 \times 1} + \frac{1-0.7}{\infty \times 0.7}\right)}$$

$$= \frac{25.333 \times 10^3}{21.22 + 31.83 + 0}$$

$$= \frac{25.333 \times 10^3}{53.0509}$$

$$= 477.46 \text{ W}$$

The net rate of radiation heat exchange between disks a and c and disks c and b, $\boxed{\dot{Q}_{ac} = \dot{Q}_{cb} = 477.46 \text{ W}}$

The rate of heat transfer is higher in part (c) because the large disk c is able to collect all radiation emitted by disk a. Hence it is not acting as a radiation shield.

Question: 21.112P pg 1

A large number of long tubes, each of diameter *D*, are placed parallel to each other and at a center-to-center distance of *s*. Since all of the tubes are geometrically similar and at the same temperature, these could be treated collectively as one surface (*Aj*) for radiation heat transfer calculations. As shown in Fig. P21-112, the tube-bank (*Aj*) is placed opposite a large flat wall (*Ai*) such that the tube-bank is parallel to the wall. The radiation view factor, *Fij*, for this arrangement is given by

$$F_{ij} = 1 - \left[1 - \left(\frac{D}{s}\right)^2\right]^{0.5} + \frac{D}{s}\left\{\tan^{-1}\left[\left(\frac{s}{D}\right)^2 - 1\right]^{0.5}\right\}$$

(*a*) Calculate the view factors *Fij* and *Fji* for $s = 3.0$ cm and $D = 1.5$ cm.

(*b*) Calculate the net rate of radiation heat transfer between the wall and the tube-bank per unit area of the wall when $Ti = 900°C$, $Tj = 60°C$, $\varepsilon i = 0.8$, and $\varepsilon j = 0.9$.

(c) A fluid flows through the tubes at an average temperature of 40°C, resulting in a heat transfer coefficient of 2.0 kW/m2·K. Assuming $Ti = 900°C$, $\varepsilon i = 0.8$ and $\varepsilon j = 0.9$ (as above) and neglecting the tube wall thickness and convection from the outer surface, calculate the temperature of the tube surface in steady operation.

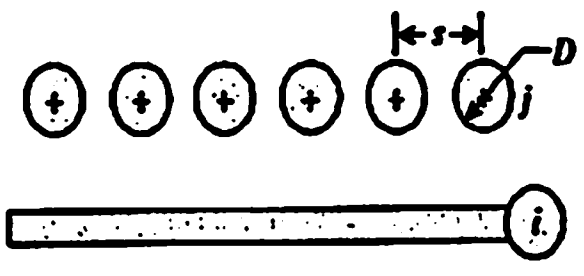


FIGURE P21-112

Step 1 of 6

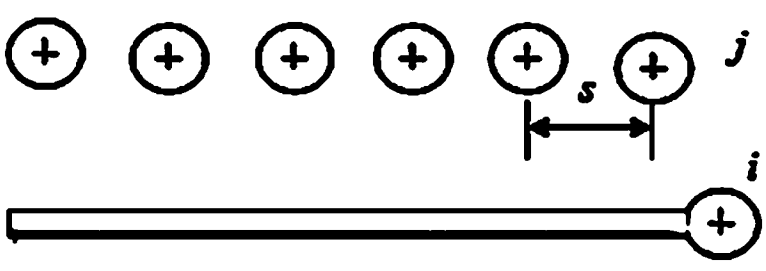
Given data:

Diameter of the tubes, $D = 1.5$ cm

Center to center distance, $s = 3$ cm

Surface temperature of the tubes, $T_j = 60°C$

Emissivity of the wall, $\varepsilon_i = 0.8$



Average fluid temperature, $T_\infty = 40°C$

Heat transfer coefficient,

$$h_{conv} = 2 \text{ kW/m}^2\cdot\text{K}$$
$$= 2000 \text{ W/m}^2\cdot\text{K}$$

Step 2 of 6

Given diagram:

Step 3 of 6

(a)

Calculate the view factor from surface i to surface j is

$$F_{ij} = 1 - \left[1 - \left(\frac{D}{s}\right)^2\right]^{0.5} + \frac{D}{s}\left\{\tan^{-1}\left[\left(\frac{s}{D}\right)^2 - 1\right]^{0.5}\right\}$$

Here,

Diameter of the tubes, D

Center to center distance, s

Substitute 1.5 cm for D, 3 cm for s.

$$F_{ij} = 1 - \left[1 - \left(\frac{D}{s}\right)^2\right]^{0.5} + \frac{D}{s}\left\{\tan^{-1}\left[\left(\frac{s}{D}\right)^2 - 1\right]^{0.5}\right\}$$
$$= 1 - \left[1 - \left(\frac{1.5}{3}\right)^2\right]^{0.5} + \frac{1.5}{3}\left\{\tan^{-1}\left[\left(\frac{3}{1.5}\right)^2 - 1\right]^{0.5} \times \frac{\pi}{180}\right\}$$
$$= 0.658$$

Therefore, the view factor from surface i to j is $\boxed{0.658}$

Calculate the view factor from surface j to surface i is

By apply summation rule

$$F_{ij} + F_{ji} = 1$$

Here,

the view factor from surface j to surface i is F_{ji}

Substitute 0.658 for F_{ij}

$$F_{ij} + F_{ji} = 1$$
$$0.658 + F_{ji} = 1$$
$$F_{ji} = 0.342$$

Step 4 of 6

Therefore, the view factor from surface j to i is $\boxed{0.342}$

Step 5 of 6

(b)

Calculate the net rate of radiation heat transfer between the surfaces per unit area of the wall

$$\left[\right.$$

(b)

Calculate the net rate of radiation heat transfer between the surfaces per unit area of the wall

$$\dot{Q}_{ij} = \frac{1}{A_i}\left[\frac{\sigma(T_i^4 - T_j^4)}{\frac{1-\varepsilon_i}{A_i\varepsilon_i} + \frac{1}{A_iF_{ij}} + \frac{1-\varepsilon_j}{A_j\varepsilon_j}}\right]$$

$$= \frac{\sigma(T_i^4 - T_j^4)}{\frac{1-\varepsilon_i}{\varepsilon_i} + \frac{1}{F_{ij}} + \frac{1-\varepsilon_j}{\varepsilon_j}\left(\frac{A_i}{A_j}\right)}$$

Here,

Stefan Boltzmann constant is σ

Surface temperature of the tubes, T_j

Surface temperature of the wall, T_i

Emissivity of the tubes, ε_j

Emissivity of the wall, ε_i

Use the conversion factor to convert the temperature from $1°C$ to $1K$ is

$1K = 1°C + 273$

Substitute $60°C$ for T_j, $900°C$ for T_i, 0.9 for ε_j, 0.8 for ε_i

$$\dot{Q}_{ij} = \frac{\sigma(T_i^4 - T_j^4)}{\frac{1-\varepsilon_i}{\varepsilon_i} + \frac{1}{F_{ij}} + \frac{1-\varepsilon_j}{\varepsilon_j}\left(\frac{A_i}{A_j}\right)}$$

$$= \frac{5.67\times10^{-8}\times((900+273)^4 - (60+273)^4)}{\left(\frac{1-0.8}{0.8}\right) + \left(\frac{1}{0.658}\right) + \frac{1-0.9}{0.9}\left(\frac{0.03}{\pi\times0.015}\right)}$$

$$= 57944.4\ \text{W/m}^2$$

Therefore, the net rate of radiation heat transfer between the wall and the tube-bank per unit area is

$\boxed{57944.4\ \text{W/m}^2}$

Step 6 of 6

(c)

Under steady conditions, the rate of radiation heat transfer from the wall to the tube surface is equal to the rate of convection heat transfer from the tube wall to the fluid.

Calculate the rate of heat transfer due to convention is

$$\dot{Q}_{rad} = \dot{Q}_{conv}$$

$$\frac{\sigma(T_i^4 - T_j^4)}{\frac{1-\varepsilon_i}{\varepsilon_i} + \frac{1}{F_{ij}} + \frac{1-\varepsilon_j}{\varepsilon_j}\left(\frac{A_i}{A_j}\right)} = h_{conv}\frac{A_j}{A_i}(T_j - T_\infty)$$

Here,

Heat transfer coefficient, h_{conv}

Average fluid temperature, T_∞

Substitute $2\ \text{kW/m}^2\cdot\text{K}$ for h_{conv}, $40°C$ for T_∞.

$$\frac{\sigma(T_i^4 - T_j^4)}{\frac{1-\varepsilon_i}{\varepsilon_i} + \frac{1}{F_{ij}} + \frac{1-\varepsilon_j}{\varepsilon_j}\left(\frac{A_i}{A_j}\right)} = h_{conv}\frac{A_j}{A_i}(T_j - T_\infty)$$

$$\frac{5.67\times10^{-8}(1173^4 - T_j^4)}{\left(\frac{1-0.8}{0.8}\right) + \left(\frac{1}{0.658}\right) + \frac{1-0.9}{0.9}\left(\frac{0.03}{\pi\times0.015}\right)} = 2000\times\frac{\pi\times0.015}{0.03}\times(T_j - 313)$$

$$T_j = 331.6\ \text{K}$$

$$= 58.6°C$$

Therefore, the temperature of the tube in steady state is $\boxed{58.6°C}$

Question: 21.113P pg 1

A simple solar collector is built by placing a 6-cm-diameter clear plastic tube around a garden hose whose outer diameter is 2 cm. The hose is painted black to maximize solar absorption, and some plastic rings are used to keep the spacing between the hose and the clear plastic cover constant. The emissivities of the hose surface and the glass cover are 0.9, and the effective sky temperature is estimated to be 15°C. The temperature of the plastic tube is measured to be 40°C, while the ambient air temperature is 25°C. Determine the rate of heat loss from the water in the hose by natural convection and radiation per meter of its length under steady conditions. *Answers:* 12.7 W, 26.1 W

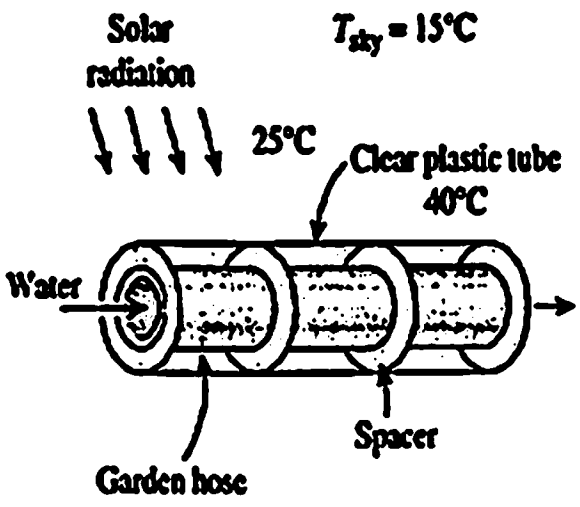


FIGURE P21–113

Step 1 of 6

Calculate the mean film temperature

$$T_f = \frac{(T_s + T_\infty)}{2}$$

Here,

Temperature of the plastic tube, T_s

Ambient air temperature, T_∞

Substitute $40°C$ for T_s, $25°C$ for T_∞

$$T_f = \frac{(T_s + T_\infty)}{2}$$
$$= \frac{(40+25)}{2}$$
$$= 32.5°C$$

Step 2 of 6

From the table the properties of air at 1 atm and the film temperature

At $T_f = 32.5°C$

$$\text{Thermal conductivity}, k = 0.02607\ \text{W/m}\cdot\text{K}$$
$$\text{kinematic viscosity}, \nu = 1.632\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Prandtle number}, \text{Pr} = 0.7275$$

Calculate the coefficient of volume expansion

$$\beta = \frac{1}{T_f + 273\text{K}}$$
$$= \frac{1}{(32.5+273)}$$
$$= 0.003273\ \text{K}^{-1}$$

The characteristic length in this case is the diameter of the plastic tube, $L_c = D_2 = 0.06\ \text{m}$

Step 3 of 6

Calculate the non-dimensional Rayleigh number

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)D_2^3}{\upsilon^2}\text{Pr}$$

Here,

Acceleration due gravity is g

Substitute $9.81\ \text{m/s}^2$ for g, $1.632\times10^{-5}\ \text{m}^2/\text{s}$ for v, $0.06\ \text{m}$ for D_2, 0.7275 for Pr

$$\text{Ra} = \frac{g\beta(T_s - T_\infty)D_2^3}{\upsilon^2}\text{Pr}$$
$$= \frac{9.81\times0.003273\times(40-25)\times0.06^3}{\left(1.632\times10^{-5}\right)^2}\times0.7275$$
$$= 284153.305$$

Step 4 of 6

Calculate the Nusselt number correlation for the Natural convention is

$$\text{Nu} = \left\{0.6 + \frac{0.387Ra^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2$$

Substitute 284153.305 for Ra , 0.7275 for Pr

$$\text{Nu} = \left\{0.6 + \frac{0.387\text{Ra}^{1/6}}{\left[1+(0.559/\text{Pr})^{9/16}\right]^{8/27}}\right\}^2$$
$$= \left\{0.6 + \frac{0.387\times(284153.305)^{1/6}}{\left[1+(0.559/0.7275)^{9/16}\right]^{8/27}}\right\}^2$$
$$= 10.3035$$

Step 5 of 6

$= 10.3035$

Step 5 of 6

Calculate the heat transfer coefficient

$$h_{conv} = \mathrm{Nu}\frac{k}{L_c}$$
$$= 10.3035 \times \frac{0.02607}{0.06}$$
$$= 4.5\,\mathrm{W/m^2 \cdot K}$$

Find the Surface area of the plastic tube

$$A_{plastic} = A_2$$
$$= \pi D_2 L$$

Here Length of the tube is L

Substitute $1\,\mathrm{m}$ for L, $0.06\,\mathrm{m}$ for D_2

$$A_{plastic} = \pi D_2 L$$
$$= \pi \times 0.06 \times 1$$
$$= 0.1885\,\mathrm{m^2}$$

Calculate the rate of heat transfer from the outer surface of the plastic tube by natural convection

$$\dot{Q}_{conv} = h_{conv} A_2 (T_s - T_\infty)$$

Substitute $4.5\,\mathrm{W/m^2 \cdot K}$ for h_{conv}, $0.1885\mathrm{m^2}$ for A_2

$$\dot{Q}_{conv} = h_{conv} A_2 (T_s - T_\infty)$$
$$= 4.5(\mathrm{W/m^2 \cdot K}) \times 0.1885(\mathrm{m^2}) \times (40 - 25)$$
$$= 12.72\,\mathrm{W}$$

Therefore, the *rate* of heat transfer by natural convection is $\boxed{12.72\,\mathrm{W}}$

Step 6 of 6

Use the conversion factor to convert the temperature from $1°\mathrm{C}$ to $1\mathrm{K}$ is

$1\mathrm{K} = 1°\mathrm{C} + 273$

Calculate the rate of heat transfer by radiation from the outer surface of the plastic tube

$$\dot{Q}_{rad} = \varepsilon \sigma A_2 (T_s^4 - T_\infty^4)$$

Here,

Emissivity of the hose surface and the glass cover, ε

Substitute 0.9 for ε, $5.67 \times 10^{-8}\,\mathrm{W/m^2 \cdot K^4}$ for σ

$$\dot{Q}_{rad} = \varepsilon \sigma A_2 (T_s^4 - T_\infty^4)$$
$$= 0.9 \times 5.67 \times 10^{-8} \times 0.1885 \times \left((40 + 273\mathrm{K})^4 - (15 + 273\mathrm{K})^4\right)$$
$$= 26.15\,\mathrm{W}$$

Therefore, the rate of heat transfer by radiation is $\boxed{26.15\,\mathrm{W}}$

Question: 21.114P pg 1

Consider a 1.5-m-high and 3-m-wide solar collector that is tilted at an angle 20° from the horizontal. The distance between the glass cover and the absorber plate is 3 cm, and the back side of the absorber is heavily insulated. The absorber plate and the glass cover are maintained at temperatures of 80°C and 32°C, respectively. The emissivity of the glass surface is 0.9 and that of the absorber plate is 0.8. Determine the rate of heat loss from the absorber plate by natural convection and radiation. *Answers:* 750 W, 1289 W

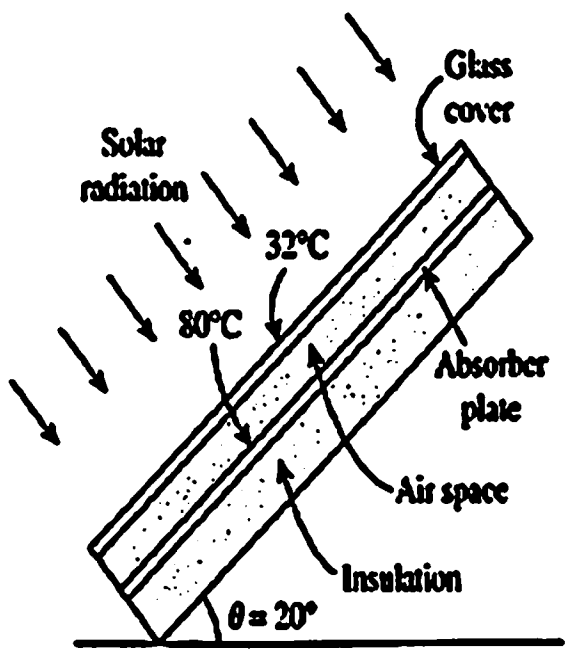

FIGURE P21–114

Step 1 of 6

Schematic diagram of solar system:

Step 2 of 6

Calculate the mean film temperature is

$$T_f = \frac{(T_1 + T_2)}{2}$$

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Substitute $80°C$ for T_1, $32°C$ for T_2

$$T_f = \frac{(T_1 + T_2)}{2}$$
$$= \frac{(80+32)}{2}$$
$$= 56°C$$

From the table the properties of air, at 1 atm and the film temperature of are

$$\text{Thermal conductivity}, k = 0.0277\ \text{W/m}\cdot\text{K}$$
$$\text{kinematic viscosity}, \nu = 1.857\times10^{-5}\ \text{m}^2/\text{s}$$
$$\text{Prandtle number}, \text{Pr} = 0.7212$$

Use the conversion factor to convert the temperature from $1°C$ to $1K$ is

$$1K = 1°C + 273$$

Calculate the coefficient of volume expansion (β) is

$$\beta = \frac{1}{(56+273)}$$
$$= 0.003041\,K^{-1}$$

For $\theta = 20°$, we have horizontal rectangular enclosure. The characteristic length in this case is the distance between the two glasses $L_c = L = 0.03\,\text{m}$

Step 3 of 6

Calculate the Rayleigh number is

$$\text{Ra} = \frac{g\beta(T_1 - T_2)L^3}{\nu^2}\text{Pr}$$

Here,

Acceleration due to gravity is g

Substitute $0.003041\,K^{-1}$ for β, $80°C$ for T_1, $32°C$ for T_2 $0.03\,\text{m}$ for L, $9.81\,\text{m/s}^2$ for g, $1.857\times10^{-5}\ \text{m}^2/\text{s}$ for ν

$$\text{Ra} = \frac{g\beta(T_1 - T_2)L^3}{\nu^2}\text{Pr}$$
$$= \frac{9.81(\text{m}^2/\text{s})\times0.003041(\text{K}^{-1})\times(80\text{-}32)(\text{K})\times0.03^3(\text{m}^3)}{\left(1.857\times10^{-5}\ \text{m}^2/\text{s}\right)^2}\times0.7212$$
$$= 80857.878$$

Step 4 of 6

Calculate the Nusselt number correlation for the Natural convention is

$$\text{Nu} = 1 + 1.44\left[1 - \frac{1708}{Ra\cos\theta}\right]\times\left[1 - \frac{1708(\sin1.8\theta)^{1.6}}{Ra\cos\theta}\right] + \left[\frac{(Ra\cos\theta)^{1/3}}{18} - 1\right]$$

Here,

Tilted angle of solar collector is θ

Substitute $20°$ for θ, 80857.878 for Ra

$$\text{Nu} = 1 + 1.44\left[1 - \frac{1708}{Ra\cos\theta}\right]\times\left[1 - \frac{1708(\sin1.8\theta)^{1.6}}{Ra\cos\theta}\right] + \left[\frac{(Ra\cos\theta)^{1/3}}{18} - 1\right]$$
$$= 1 + 1.44\left[1 - \frac{1708}{80857.878\times\cos20}\right]\times\left[1 - \frac{1708(\sin1.8\times20)^{1.6}}{80857.878\times\cos20}\right]$$
$$\left[\frac{(80857.878\times\cos20)^{1/3}}{}\right.$$

$$\left[Ra\cos\theta\right]\left[21.114P\ \text{pg}\ 2^{18}\right]$$

$$=1+1.44\left[1-\frac{1708}{80857.878\times\cos 20}\right]\times\left[1-\frac{1708(\sin 1.8\times 20)^{1.6}}{80857.878\times\cos 20}\right]+\left[\frac{(80857.878\times\cos 20)^{1/3}}{18}-1\right]$$

$$=1+1.44\times 0.9775\times 0.9904+1.353$$

$$=3.747$$

Calculate the Surface is

$$A_s=H\times W$$

Here,

Height of the solar collector, H

Width of the solar collector, W

Substitute $1.5\,\text{m}$ for H . 3m for W

$$A_s=H\times W$$
$$=1.5(\text{m})\times 3(\text{m})$$
$$=4.5\,\text{m}^2$$

Since Nusselt number is

$$Nu=\frac{hL}{k}$$

$$h=\frac{k\,Nu}{L}$$

Here,

Heat transfer coefficient is h

Step 5 of 6

Calculate the rate of heat transfer due to natural convection

$$\dot{Q}_{conv}=hA_s(T_1-T_2)$$
$$=\frac{k\text{Nu}}{L}A_s(T_1-T_2)$$

Substitute $0.0277\ \text{W/m}\cdot\text{K}$ for k . 3.747 for Nu

$$\dot{Q}_{conv}=hA_s(T_1-T_2)$$
$$=\frac{kNu}{L}A_s(T_1-T_2)$$
$$=\frac{0.02779(\text{W/m}\cdot\text{K})\times 3.747}{0.03(\text{m})}\times 4.5(\text{m}^2)\times(80-32)$$
$$=750\,\text{W}$$

Therefore, the rate of heat transfer due to natural convection is $\boxed{750\,\text{W}}$

Step 6 of 6

Calculate the rate of heat transfer due to radiation

$$\dot{Q}_{rad}=\frac{\sigma A_2\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1}$$

Here,

Temperature of the absorber plate, T_1

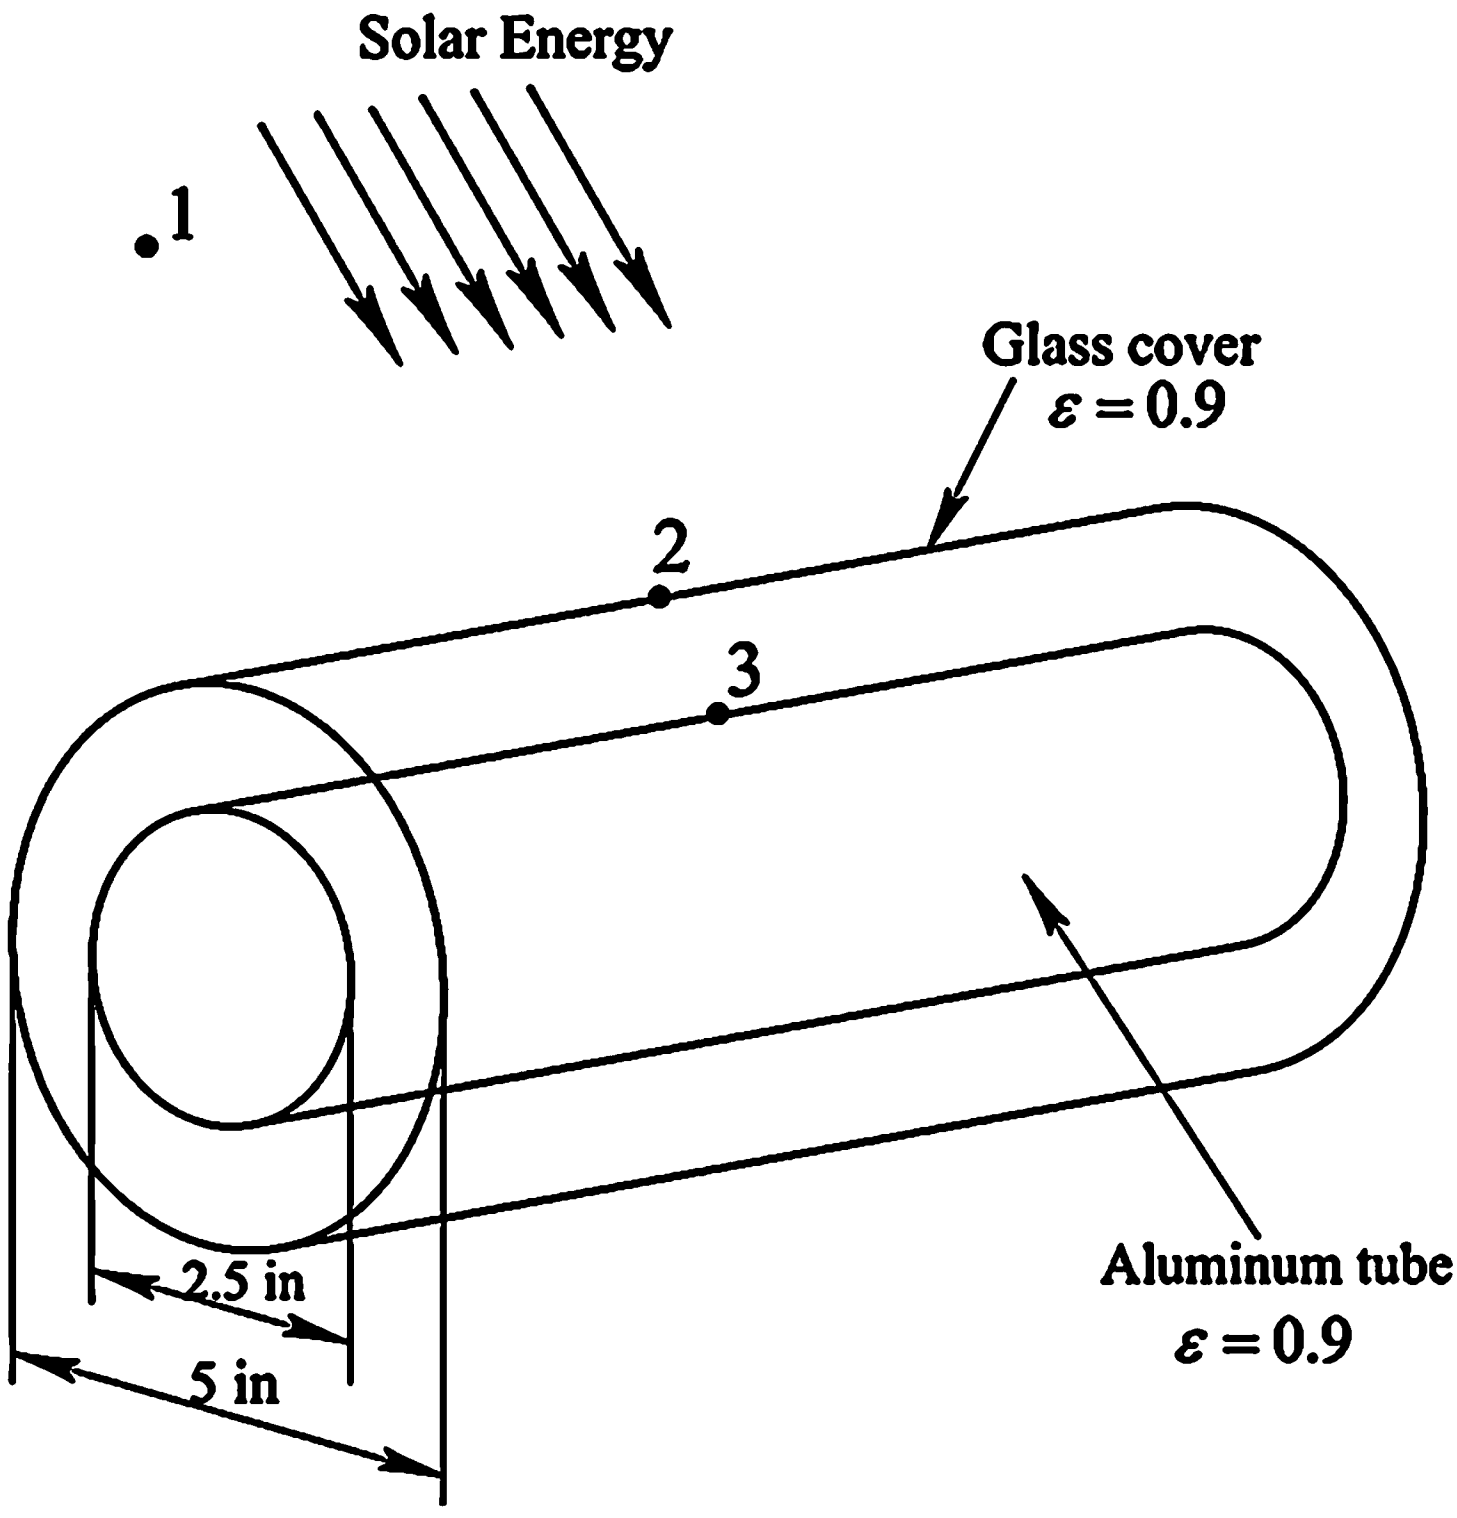
Temperature of the glass cover, T_2

Emissivity of the absorber plate, ε_1

Emissivity of the glass surface, ε_2

Substitute $80°\text{C}$ for T_1 . $32°\text{C}$ for T_2 . 0.8 for ε_1 . 0.9 for ε_2

$$\dot{Q}_{rad}=\frac{\sigma A_2\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1}$$
$$=\frac{5.67\times 10^{-8}(\text{W/m}^2\cdot\text{K}^4)\times 4.5(\text{m}^2)\times(353^4-305^4)}{\frac{1}{0.9}+\frac{1}{0.8}-1}$$
$$=1289\ \text{W}$$



Therefore, rate of heat transfer due to radiation is $\boxed{1289\,\text{W}}$

Question: 21.115P pg 1

A solar collector consists of a horizontal aluminum tube having an outer diameter of 2.5 in enclosed in a concentric thin glass tube of diameter 5 in. Water is heated as it flows through the tube, and the annular space between the aluminum and the glass tube is filled with air at 0.5 atm pressure. The pump circulating the water fails during a clear day, and the water temperature in the tube starts rising. The aluminum tube absorbs solar radiation at a rate of 40 Btu/h per foot length, and the temperature of the ambient air outside is 75°F. The emissivities of the tube and the glass cover are 0.9. Taking the effective sky temperature to be 60°F, determine the temperature of the aluminum tube when thermal equilibrium is established (i.e., when the rate of heat loss from the tube equals the amount of solar energy gained by the tube).

Step 1 of 23

Consider the aluminum tube and the glass cover as shown in the following figure:

Step 2 of 23

Consider the heat transfer between the points 1 and 2.

Assume the exit temperature of air in the duct to be $85°F$, because the exit temperature of the air is required to evaluate the properties of air.

Calculate the average temperature.

$$T_{avg} = \frac{T_e + T_\infty}{2}$$

Here, T_{avg} is the average temperature, T_e is the exit temperature of air, and T_∞ is the temperature of the surroundings.

Substitute $85°F$ for T_e and $75°F$ for T_∞ .

$$T_{avg} = \frac{85+75}{2}$$
$$= 80°F$$

Step 3 of 23

Take the properties of air from the table A-15E 'Properties of air at 1 atm pressure'.

$$\nu = 1.697 \times 10^{-4} \ ft^2/s$$
$$Pr = 0.729$$
$$k = 0.01481 \ Btu/h \cdot ft \cdot R$$

Here, ν is the kinematic viscosity, Pr is the Prandtl number, and k is the coefficient of thermal conductivity.

Calculate the coefficient of thermal expansion.

$$\beta = \frac{1}{T_{avg}}$$

Here, β is the coefficient of thermal expansion.

Substitute $(80+460)R$ for T_{avg} .

$$\beta = \frac{1}{(80+460)}$$
$$= \frac{1}{540}$$
$$= 1.8518 \times 10^{-3}/R$$

Step 4 of 23

Calculate the surface area of the glass cover.

$$A = \pi D_o L$$

Here, A is the surface area, D_o is the outer diameter, and L is the length of the tube.

Substitute $\left(\frac{5}{12}\right)ft$ for D_o and 1 ft for L.

$$A = \pi \times \left(\frac{5}{12}\right) \times 1$$
$$= 1.30899 \ ft^2$$

$$A=\pi\times\left(\frac{5}{12}\right)\times 1$$
$$=1.30899\ \text{ft}^2$$

Step 5 of 23

Calculate the Rayleigh number as follows:

$$\text{Ra}=\frac{g\beta(T_0-T_\infty)D_0^3}{\nu^2}$$

Here, Ra is the Rayleigh number and g is the acceleration due to gravity.

Substitute $9.81\ \text{m/s}^2$ for g, $1.8518\times10^{-3}/\text{R}$ for β, $\left(5/12\right)\text{ft}$ for D_0, $1.697\times10^{-4}\ \text{ft}^2/\text{s}$ for ν, $85°\text{F}$ for T_0, and $75°\text{F}$ for T_∞.

$$\text{Ra}=\frac{9.81\times1.8518\times10^{-3}(85-75)\left(5/12\right)^3}{\left(1.697\times10^{-4}\right)^2}$$
$$=\frac{0.01314}{2.8798\times10^{-8}}$$
$$=456280.26$$

Step 6 of 23

Calculate the Nusselt number as follows:

$$\text{Nu}=\left[0.6+\frac{0.387\times(\text{Ra})^{(1/6)}}{\left(1+\left(\frac{0.559}{\text{Pr}}\right)^{(9/16)}\right)^{(8/27)}}\right]^2$$

Here, Nu is the Nusselt number.

Substitute 456280.26 for Ra and 0.7302 for Pr.

$$\text{Nu}=\left[0.6+\frac{0.387\times(456280.26)^{(1/6)}}{\left(1+\left(\frac{0.559}{0.7302}\right)^{(9/16)}\right)^{(8/27)}}\right]^2$$
$$=\left[0.6+\frac{3.3956}{1.2019}\right]^2$$
$$=11.7319$$

Step 7 of 23

Calculate the convective heat transfer coefficient as follows:

$$h=\frac{k}{D_0}\text{Nu}$$

Here, h is the convective heat transfer coefficient.

Substitute $0.01481\ \text{Btu/h}\cdot\text{ft}\cdot\text{R}$ for k, $\left(5/12\right)\text{ft}$ for D_0, and 11.7319 for Nu.

$$h=\frac{0.01481}{\left(\frac{5}{12}\right)}\times11.7319$$
$$=0.41699\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}$$

Step 8 of 23

Calculate the heat transfer due to convection as follows:

$$Q_C=hA(T_0-T_\infty)$$

Here, Q_C is the heat transfer due to convection.

Substitute $0.41699\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}$ for h, $1.30899\ \text{ft}^2$ for A, $85°\text{F}$ for T_0, and $75°\text{F}$ for T_∞.

$$Q_C=0.41699\times1.30899\times(85-75)$$
$$=5.458\ \text{Btu/h}$$

Step 9 of 23

Convert the temperatures into Rankine scale.

$$T_0(\text{R})=T_0(\text{F})+460$$
$$=85+460$$
$$=545\ \text{R}$$

Similarly, for the exit temperature,

$$T_\infty(\text{R})=T_\infty(\text{F})+460$$
$$=75+460$$
$$=535\ \text{R}$$

Similarly, for the effective temperature,

$$T_e(\text{R})=T_e(\text{F})+460$$
$$=60+460$$
$$=520\ \text{R}$$

Step 10 of 23

Calculate the heat transfer due to radiation as follows:

$$Q_R=\varepsilon\sigma A\left(T_0^4-T_e^4\right)$$

Here, Q_R is the heat transfer due to radiation, ε is the emissivity of the glass cover, and σ is the Stefan-Boltzmann constant.

$$Q_R = \varepsilon\sigma A\left(T_0^4 - T_c^4\right)$$

Here, Q_R is the heat transfer due to radiation, ε is the emissivity of the glass cover, and σ is the Stefan-Boltzmann constant.

Substitute 0.9 for ε, $0.1714\times10^{-8}\ \text{Btu/h}\cdot\text{ft}^2\cdot\text{R}^4$ for σ, $1.30899\ \text{ft}^2$ for A, 545 R for T_0, and 520 R for T_c.

$$\begin{aligned} Q_R &= 0.9\times0.1714\times10^{-8}\times1.30899\times\left(545^4 - 520^4\right) \\ &= 30.506\ \text{Btu/h} \end{aligned}$$

Step 11 of 23

Calculate the total heat transferred.

$$Q_G = Q_C + Q_R$$

Here, Q_G is the total heat transferred from glass to ambient air.

Substitute $5.458\ \text{Btu/h}$ for Q_C and $30.506\ \text{Btu/h}$ for Q_R.

$$\begin{aligned} Q_G &= 5.458 + 30.506 \\ &= 35.964\ \text{Btu/h} \end{aligned}$$

The total heat transfer is equal to $40\ \text{Btu/h}$ in the equilibrium condition. So, the temperature of the exit of air is greater than the assumed temperature. Since, the value obtained is very near to the required value, consider the exit temperature of air in the duct to be approximately equal to $87°\text{F}$

$$T_0 = 87°\text{F}$$

Step 12 of 23

Consider the heat transfer between the points 2 and 3.
Assume the temperature of the aluminum tube to be $130°\text{F}$, because the exit temperature of the air is required to evaluate the properties of air.

Calculate the average temperature.

$$T_{avg} = \frac{T_i + T_0}{2}$$

Here, T_{avg} is the average temperature, T_0 is the exit temperature of air, and T_i is the temperature of the aluminum tube.

Substitute $87°\text{F}$ for T_0 and $130°\text{F}$ for T_i.

$$\begin{aligned} T_{avg} &= \frac{87 + 130}{2} \\ &= 108.5°\text{F} \end{aligned}$$

Step 13 of 23

Take the properties of air at $108.5°\text{F}$ from the table A-15E 'Properties of air at 1 atm pressure'.

$$\begin{aligned} \nu_0 &= 1.857\times10^{-4}\ \text{ft}^2/\text{s} \\ \text{Pr} &= 0.724725 \\ k &= 0.0154855\ \text{Btu/h}\cdot\text{ft}\cdot\text{R} \end{aligned}$$

Here, ν_0 is the kinematic viscosity, Pr is the Prandtl number, and k is the coefficient of thermal conductivity.

But the pressure in the enclosed region is 0.5 bar. So, the parameters k and Pr remain unchanged, but, the kinematic viscosity changes as follows:

$$\nu = \frac{\nu_0}{P}$$

Here, ν is the kinematic viscosity at 0.5 bar and P is the pressure.

Substitute $1.857\times10^{-4}\ \text{ft}^2/\text{s}$ for ν_0 and 0.5 bar for P.

$$\begin{aligned} \nu &= \frac{1.857\times10^{-4}}{0.5} \\ &= 3.714\times10^{-4}\ \text{ft}^2/\text{s} \end{aligned}$$

Step 14 of 23

Calculate the coefficient of thermal expansion.

$$\beta = \frac{1}{T_{avg}}$$

Here, β is the coefficient of thermal expansion.

Substitute $(108.5+460)\text{R}$ for T_{avg}.

$$\begin{aligned} \beta &= \frac{1}{(108.5+460)} \\ &= \frac{1}{568.5} \\ &= 1.759\times10^{-3}/\text{R} \end{aligned}$$

Step 15 of 23

Calculate the characteristic length as follows:

$$L_C = \frac{(D_0 - D_i)}{2}$$

Here, L_C is the characteristic length.

Substitute $\left(5/12\right)\text{ft}$ for D_0 and $\left(2.5/12\right)\text{ft}$ for D_i.

$$\begin{aligned} L_C &= \frac{\left(\left(5/12\right) - \left(2.5/12\right)\right)}{2} \\ &= \left(1.25/12\right)\text{ft} \end{aligned}$$

$$L_c = \frac{\left(\left(5/12\right) - \left(2.5/12\right)\right)}{2}$$
$$= \left(1.25/12\right)\text{ft}$$

Step 16 of 23

Calculate the surface area of the glass cover.

$$A = \pi D_i L$$

Here, A is the surface area, D_i is the inner diameter, and L is the length of the tube.

Substitute $\left(2.5/12\right)\text{ft}$ for D_o and 1 ft for L.

$$A = \pi \times \left(\frac{2.5}{12}\right) \times 1$$
$$= 0.65449\ \text{ft}^2$$

Step 17 of 23

Calculate the Rayleigh number as follows:

$$\text{Ra}_l = \frac{g\beta\left(T_i - T_0\right)L_C^3}{\nu^2}$$

Here, Ra_l is the Rayleigh number and g is the acceleration due to gravity.

Substitute $9.81\ \text{m/s}^2$ for g, $1.759\times10^{-3}/\text{R}$ for β, $\left(1.25/12\right)\text{ft}$ for L_c, $3.714\times10^{-4}\ \text{ft}^2/\text{s}$ for ν, $87°\text{F}$ for T_0, and $130°\text{F}$ for T_i.

$$\text{Ra}_l = \frac{9.81\times1.759\times10^{-3}\left(130-87\right)\left(1.25/12\right)^3}{\left(3.714\times10^{-4}\right)^2}$$
$$= \frac{0.00083867}{13.7938\times10^{-8}}$$
$$= 6080.05$$

Step 18 of 23

Calculate the geometric factor as follows:

$$F_{cyl} = \frac{\left(\ln\left(D_o/D_i\right)\right)^4}{L_C^3\left(D_i^{(-3/5)} + D_o^{(-3/5)}\right)^5}$$

Here, F_{cyl} is the geometric factor.

Substitute $\left(1.25/12\right)\text{ft}$ for L_c, $\left(5/12\right)\text{ft}$ for D_o, and $\left(2.5/12\right)\text{ft}$ for D_i.

$$F_{cyl} = \frac{\left(\ln\left(\left(5/12\right)/\left(2.5/12\right)\right)\right)^4}{\left(1.25/12\right)^3\left(\left(2.5/12\right)^{(-3/5)} + \left(5/12\right)^{(-3/5)}\right)^5}$$
$$= \frac{0.2308}{1.5738}$$
$$= 0.1466$$

Step 19 of 23

Calculate the effective thermal conductivity as follows:

$$k_{eff} = 0.386k\left(\frac{\text{Pr}}{0.861+\text{Pr}}\right)^{(1/4)}\left(F_{cyl}\text{Ra}_l\right)^{(1/4)}$$

Here, k_{eff} is the effective thermal conductivity.

Substitute $0.0154855\ \text{Btu/h}\cdot\text{ft}\cdot\text{R}$ for k, 6080.05 for Ra_l, 0.724725 for Pr, and 0.1466 for F_{cyl}.

$$k_{eff} = 0.386\times0.0154855\times\left(\frac{0.724725}{0.861+0.724725}\right)^{\left(\frac{1}{4}\right)}\left(0.1466\times6080.05\right)^{\left(\frac{1}{4}\right)}$$
$$= 0.005977\times0.8222\times5.46399$$
$$= 0.02685\ \text{Btu/h}\cdot\text{ft}\cdot\text{R}$$

Step 20 of 23

Calculate the heat transfer due to convection as follows:

$$Q_C = \frac{2\pi k_{eff}\left(T_i - T_0\right)}{\ln\left(D_o/D_i\right)}$$

Here, Q_C is the heat transfer due to convection.

Substitute $0.02685\ \text{Btu/h}\cdot\text{ft}\cdot\text{R}$ for k_{eff}, $87°\text{F}$ for T_0, $130°\text{F}$ for T_i, $\left(5/12\right)\text{ft}$ for D_o, and $\left(2.5/12\right)\text{ft}$ for D_i.

$$Q_C = \frac{2\pi\times0.02685\times\left(130-87\right)}{\ln\left(\left(5/12\right)/\left(2.5/12\right)\right)}$$
$$= \frac{7.2542}{0.693}$$
$$= 10.4678\ \text{Btu/h}$$

Step 21 of 23

$$= 10.4678 \text{ Btu/h}$$

Step 21 of 23

Convert the temperatures into Rankine scale.

$$\begin{aligned} T_o(\text{R}) &= T_o(\text{F}) + 460 \\ &= 87 + 460 \\ &= 547 \text{ R} \end{aligned}$$

Similarly, for the surface temperature of the aluminum tube,

$$\begin{aligned} T_i(\text{R}) &= T_i(\text{F}) + 460 \\ &= 130 + 460 \\ &= 590 \text{ R} \end{aligned}$$

Step 22 of 23

Calculate the heat transfer due to radiation as follows:

$$Q_R = \frac{\sigma A\left(T_i^4 - T_o^4\right)}{\frac{1}{\varepsilon} + \frac{1-\varepsilon}{\varepsilon}\left(\frac{D_i}{D_o}\right)}$$

Here, Q_R is the heat transfer due to radiation, ε is the emissivity of the glass cover, and σ is the Stefan-Boltzmann constant.

Substitute 0.9 for ε, 0.1714×10^{-8} Btu/h·ft²·R⁴ for σ, 1.30899 ft² for A, 547 R for T_o, 590 R for T_i, $\left(\frac{5}{12}\right)$ft for D_o, and $\left(\frac{2.5}{12}\right)$ft for D_i.

$$Q_R = \frac{0.1714\times10^{-8}\times0.65449\times\left(590^4 - 547^4\right)}{\frac{1}{0.9} + \frac{1-0.9}{0.9}\left(\frac{\left(\frac{2.5}{12}\right)}{\left(\frac{5}{12}\right)}\right)}$$

$$\begin{aligned} &= \frac{35.5024}{1.1667} \\ &= 30.429 \text{ Btu/h} \end{aligned}$$

Step 23 of 23

Calculate the total heat transferred.

$$Q_G = Q_C + Q_R$$

Here, Q_G is the total heat transferred from glass to ambient air.

Substitute 10.4678 Btu/h for Q_C and 30.429 Btu/h for Q_R.

$$\begin{aligned} Q_G &= 10.4678 + 30.429 \\ &= 40.8968 \text{ Btu/h} \end{aligned}$$

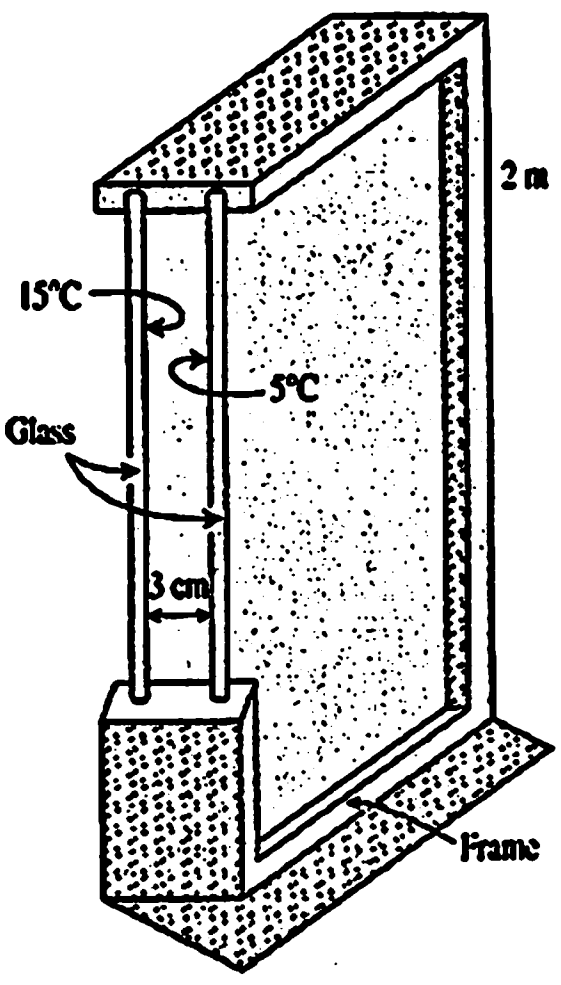
The total heat transfer is equal to 40 Btu/h in the equilibrium condition. And the total heat transfer that is obtained is very close to the required value. So, the temperature of the aluminum tube surface is approximately equal to the assumed value.

$$T_i = 130°\text{F}$$

Hence, the temperature of the surface of the aluminum tube during the equilibrium condition is $\boxed{130°\text{F}}$.

Question: 21.116P pg 1

A vertical 2-m-high and 5-m-wide double-pane window consists of two sheets of glass separated by a 3-cm-thick air gap. In order to reduce heat transfer through the window, the air space between the two glasses is partially evacuated to 0.3 atm pressure. The emissivities of the glass surfaces are 0.9. Taking the glass surface temperatures across the air gap to be 15°C and 5°C, determine the rate of heat transfer through the window by natural convection and radiation.



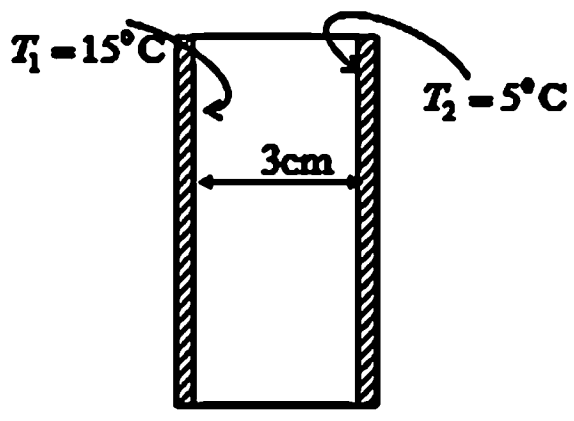


FIGURE P21–116

Step 1 of 7

The representation of vertical double pane window consists of two sheets of glass separated by an air gap is as shown below:

Step 2 of 7

Calculate the average temperature

$$T_f = \frac{(T_1 + T_2)}{2}$$

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Substitute 15°C for T_1, 5°C for T_2

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{15+5}{2}$$
$$= 10°C$$

From the properties of air at $p = 1\text{atm}$ and average temperature $T_{avg} = 10°C$ the properties of air are

Thermal conductivity, $k = 0.02439\ \text{W/m}\cdot\text{K}$

kinematic viscosity, $\nu = 1.426\times10^{-5}\ \text{m}^2/\text{s}$

Prandtl number, $\text{Pr} = 0.7336$

Step 3 of 7

Since thermal conductivity and Prandtl number are independent of pressure these properties remain constant at $p = 1\text{atm}$ or 0.3atm

The Kinematic viscosity of air at $p = 0.3\text{atm}$ becomes

$$\nu = 1.426\times10^{-5}\ \text{m}^2/\text{s}$$
$$= \frac{1.426\times10^{-5}}{0.3}$$
$$= 4.75\times10^{-5}\ \text{m}^2/\text{s}$$

Use the conversion factor to convert the temperature from 1°C to 1K is

$$1\text{K} = 1°\text{C} + 273$$

Find the Coefficient of volume expansion

$$\beta = \frac{1}{T_{avg}}$$
$$= \frac{1}{(10+273)}$$
$$= (1/283)\text{K}^{-1}$$

Step 4 of 7

Calculate the characteristic length in this case is the distance between the two cylinders,

$$L_c = 3\text{cm}$$
$$= \frac{3}{100}\ \text{m}$$
$$= 0.03\ \text{m}$$

Calculate the Surface area

$$A_s = H \times W$$

Here,

Height of the solar collector, H

Width of the solar collector, W

Substitute 2m for H, 5m for W

Here,

Height of the solar collector, H

Width of the solar collector, W

Substitute 2m for H, 5m for W

$$A_s = H \times W$$
$$= 2 \times 5(\text{m}^2)$$
$$= 10\,\text{m}^2$$

Step 5 of 7

Calculate the Rayleigh number,

$$\text{Ra} = \frac{g\beta(T_1 - T_2)L_c^3}{\nu^2}\text{Pr}$$

Here,

Acceleration due to gravity is g

Substitute $1/283\,\text{K}^{-1}$ for β, 15°C for T_1, 5°C for T_2, 0.03m for L, $9.81\,\text{m/s}^2$ for g, $4.753\times10^{-5}\,\text{m}^2/\text{s}$ for ν

$$\text{Ra} = \frac{g\beta(T_1 - T_2)L_c^3}{\nu^2}\text{Pr}$$
$$= \frac{9.81(\text{m/s}^2)\times(1/283)(\text{K}^{-1})\times(15-5)(\text{K})\times(0.03)^3(\text{m}^3)}{\left(4.753\times10^{-5}\,\text{m}^2/\text{s}\right)^2}\times 0.7336$$
$$= 3039.275$$

Step 6 of 7

Calculate the Nussult number,

$$Nu = 0.197 Ra^{1/4}\left(\frac{H}{L}\right)^{-1/9}$$
$$= 0.197\times(3039.275)^{1/4}\left(\frac{2}{0.03}\right)^{-1/9}$$
$$= 0.9173$$

Find the rate of heat transfer between the glass surfaces by convection

$$\dot{Q}_{conv} = kNuA_s\frac{(T_1 - T_2)}{L}$$
$$= 0.02439\times0.917\times10\frac{(15-5)}{0.03}$$
$$= 74.55\,\text{W}$$

Calculate the net rate of heat transfer due to radiation

$$\dot{Q}_{rad} = \frac{\sigma A_s\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1}$$

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Emissivity of the absorber plate, ε_1

Emissivity of the glass surface, ε_2

Substitute, 288K for T_1, 278K for T_2, 0.9 for ε_1, 0.9 for ε_2

$$\dot{Q}_{rad} = \frac{\sigma A_s\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1}$$
$$= \frac{5.67\times10^{-8}(\text{W/m}^2\cdot\text{K}^4)\times10(\text{m}^2)\times(288^4 - 278^4)}{\frac{1}{0.9}+\frac{1}{0.9}-1}$$
$$= 420.71\,\text{W}$$

Step 7 of 7

Calculate the total rate of heat transfer

$$\dot{Q}_{total} = \dot{Q}_{conv} + \dot{Q}_{rad}$$
$$= 74.55(\text{W}) + 420.71(\text{W})$$
$$= 495.26\,\text{W}$$

Therefore the total rate of heat transfer through the window by natural convection and radiation is $\boxed{495.26\,\text{W}}$ and the heat transfer through the window is mostly by radiation.

Question: 21.117P

A 2-m-internal-diameter double-walled spherical tank is used to store iced water at 0°C. Each wall is 0.5 cm thick, and the 1.5-cm-thick air space between the two walls of the tank is evacuated in order to minimize heat transfer. The surfaces surrounding the evacuated space are polished so that each surface has an emissivity of 0.15. The temperature of the outer wall of the tank is measured to be 20°C. Assuming the inner wall of the steel tank to be at 0°C, determine (*a*) the rate of heat transfer to the iced water in the tank and (*b*) the amount of ice at 0°C that melts during a 24-h period.

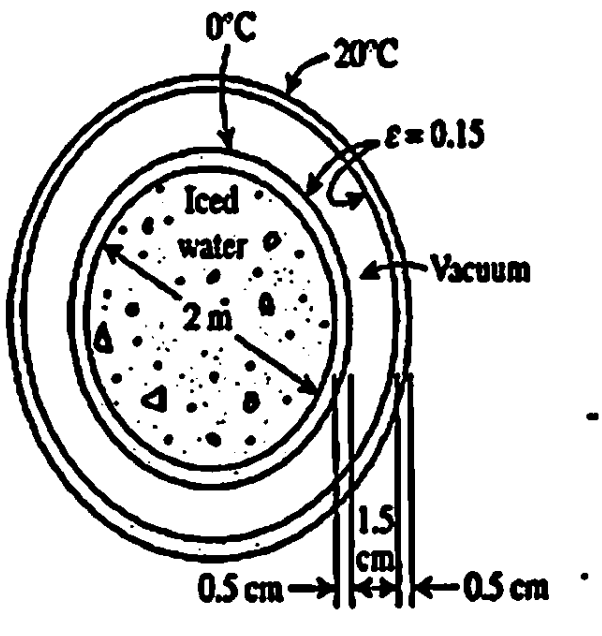

FIGURE P21–117

Step 1 of 4

Assume outer surface of the inner tank to be surface 1 and inner surface of outer tank to be surface 2.

Find the inner diameter of the spherical tank,

$$D_1 = D_i + 2t$$

Here, D_i is inner diameter of the sphere and t is thickness of the wall.

Substitute 2 m for D_i and 0.005 m for t

$$D_1 = 2 + 2\times 0.005$$
$$= 2.01\,\text{m}$$

Find the inner diameter of the outer tank,

$$D_2 = D_1 + 2l_{air}$$

Here, l_{air} is thickness of air space between two walls.

Substitute 2.01 m for D_1 and 0.015 m for l_{air}

$$D_2 = 2.01 + 2\times 0.015$$
$$= 2.04\,\text{m}$$

Find the inner tank outer surface area of the sphere.

$$A_1 = \pi D_1^2$$

Substitute 2.01 m for D_1

$$A_1 = \pi \times 2.01^2$$
$$= 12.69\,\text{m}^2$$

Step 2 of 4

(a)

Find the rate of heat transfer to the iced water in the spherical tank by using the following equation:

$$\dot{Q}_{12} = \frac{A_1\sigma\left(T_2^4 - T_1^4\right)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)^2}$$

Here, σ is Stefan Boltzmann's constant, $\varepsilon_1, \varepsilon_2$ are the emissivity's of the inner and outer surfaces, T_1 is the inner wall temperature, and T_2 is the outer wall temperature.

Substitute $12.69\,\text{m}^2$ for A_1, 0.15 for $\varepsilon_1, \varepsilon_2$, $5.67\times10^{-8}\,\text{W/m}^2.\text{K}^4$ for σ, 2.01 m for D_1, 2.04 m for D_2, $(20+273)\,\text{K}$ for T_2, and $(0+273)\,\text{K}$ for T_1.

$$\dot{Q}_{12} = \frac{12.69\times5.67\times10^{-8}\left(293^4 - 273^4\right)}{\frac{1}{0.15} + \frac{1-0.15}{0.15}\left(\frac{2.01}{2.04}\right)^2}$$
$$= \frac{1306.2788}{12.00728}$$
$$= 108.79\,\text{W}$$

Therefore, heat transfer rate to the iced water is $\boxed{108.79\,\text{W}}$.

Step 3 of 4

(b)

Find the amount of ice melts at $0°\text{C}$ during a 24-h period.

$$Q = \dot{Q}\Delta t$$

Here, t is the time period.

Substitute 108.79 W for $\dot{Q}$ and $(24\times3600)\,\text{s}$ for t.

$$Q = 108.79\times(24\times3600)$$
$$= 9399456\,\text{J}$$
$$= 9399.456\,\text{kJ}$$

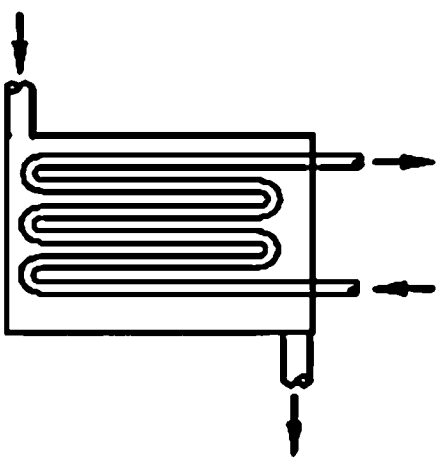
Step 4 of 4

Find the amount of ice melts during the 24 hour period.

$$Q = mL_{ice}$$

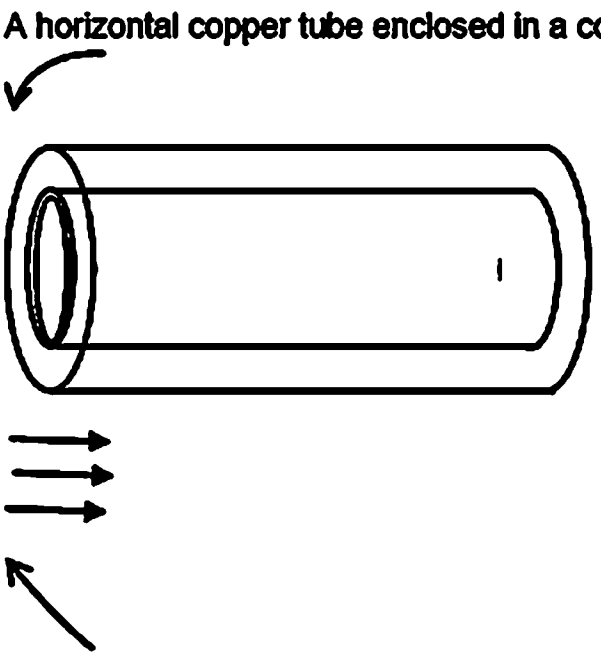
Here, m is amount of ice and L_{ice} is latent heat of ice.

Substitute $9399.456\,\text{kJ}$ for Q and 334 kJ/kg for L_{ice}



$$9399.456 = m\times334$$
$$m = 28.14\,\text{kg}$$

Therefore, the amount of ice melts in 24 h period is $\boxed{28.14\,\text{kg}}$.



Question:

A solar collector consists of a horizontal copper tube of outer diameter 5 cm enclosed in a concentric thin glass tube of diameter 12 cm. Water is heated as it flows through the tube, and the annular space between the copper and the glass tubes is filled with air at 1 atm pressure. The emissivities of the tube surface and the glass cover are 0.85 and 0.9, respectively. During a clear day, the temperatures of the tube surface and the glass cover are measured to be 60°C and 40°C, respectively. Determine the rate of heat loss from the collector by natural convection and radiation per meter length of the tube.

Step 1 of 8

A horizontal copper tube enclosed in a concentric thin glass tube is as shown in figure,

Step 2 of 8

Calculate the average temperature

$$T_f = \frac{(T_1 + T_2)}{2}$$

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Substitute $60°C$ for T_1, $40°C$ for T_2

$$T_{avg} = \frac{T_1 + T_2}{2}$$
$$= \frac{60 + 40}{2}$$
$$= 50°C$$

From table properties of air at 1atm and the average temperature $T_{avg} = 50°C$ the properties of air are

Thermal conductivity, $k = 0.02735\ W/m \cdot K$

kinematic viscosity, $\nu = 1.798 \times 10^{-5}\ m^2/s$

Prandtle number, $Pr = 0.7228$

Step 3 of 8

Use the conversion factor to convert the temperature from $1°C$ to $1K$ is

$$1K = 1°C + 273$$

Find the Coefficient of volume expansion

$$\beta = \frac{1}{T_{avg}}$$
$$= \frac{1}{(50 + 273)}$$
$$= 3.0959 \times 10^{-3}\ K^{-1}$$

Calculate the characteristic length in this case is the distance between the two cylinders,

$$L_c = \frac{(D_2 - D_1)}{2}$$

Here,

Outer diameter of the solar collector, D_1

Diameter of the glass tube, D_2

Substitute $5\,cm$ for D_1, $12\,cm$ for D_2

$$L_c = \frac{(D_2 - D_1)}{2}$$
$$= \frac{(0.12 - 0.05)}{2}$$
$$= 0.035\,m$$

Step 4 of 8

Calculate the Rayleigh number

$$Ra = \frac{g\beta(T_1 - T_2)L_c^3}{\nu^2} Pr$$

Here,

Acceleration due to gravity is g

Substitute $3.0959\,K^{-1}$ for β, $60°C$ for T_1, $40°C$ for T_2, $0.035\,m$ for L, $9.81\,m/s^2$ for g, $1.798 \times 10^{-5}\ m^2/s$ for ν

$$\frac{g\beta(T_1 - T_2)L_c^3}{\nu^2}$$

Acceleration due to gravity is g

Substitute $3.0959\,K^{-1}$ for β, $60°C$ for T_1, $40°C$ for T_2, $0.035\,m$ for L, $9.81\,m/s^2$ for g, $1.798\times10^{-5}\ m^2/s$ for ν

$$Ra = \frac{g\beta(T_1-T_2)L_c^3}{\nu^2}Pr$$

$$= \frac{9.81(m/s^2)\times3.0959\times10^{-3}(K^{-1})\times(60-40)(K)\times(0.035)^3(m^3)}{(1.798\times10^{-5}\,m^2/s)^2}\times0.7228$$

$$= 58229$$

Calculate the effective thermal conductivity

$$F_{cyc} = \frac{\left[\ln\left(\frac{D_2}{D_1}\right)\right]^4}{L_c^3\left(D_1^{-3/5}+D_2^{-3/5}\right)^5}$$

$$= \frac{\left[\ln\left(\frac{0.12}{0.05}\right)\right]^4}{(0.035)^3\left[(0.05\,m)^{-3/5}+(0.12\,m)^{-3/5}\right]^5}$$

$$= \frac{0.5874}{3.5008}$$

$$= 0.1678$$

Step 5 of 8

Calculate the Further calculation,

$$k_{eff} = 0.386k\left(\frac{Pr}{0.861+Pr}\right)^{1/4}\left(F_{cyc}Ra_L\right)^{1/4}$$

Substitute 0.7228 for Pr, 0.1678 for F_{cyl}

$$k_{eff} = 0.386k\left(\frac{Pr}{0.861+Pr}\right)^{1/4}\left(F_{cyc}Ra_L\right)^{1/4}$$

$$= 0.386\times0.02735(W/m\cdot K)\times\left(\frac{0.7228}{0.861+0.7228}\right)^{1/4}\times(0.1678\times58229)^{1/4}$$

$$= 0.01055\times0.8219\times9.942$$

$$= 0.086207\ W/m\cdot K$$

Step 6 of 8

Calculate the rate of heat transfer between the cylinders by convection

$$\dot{Q}_{conv} = \frac{2\pi k_{eff}}{\ln\left(\frac{D_2}{D_1}\right)}(T_1-T_2)$$

$$= \frac{2\pi\times0.08620}{\ln\left(\frac{12}{5}\right)}(60-40)$$

$$= 12.374\,W$$

Step 7 of 8

Calculate the rate of heat transfer by radiation is

$$\dot{Q}_{rad} = \frac{\sigma A_1\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)}$$

Here,

Here,

Temperature of the absorber plate, T_1

Temperature of the glass cover, T_2

Emissivity of the absorber plate, ε_1

Emissivity of the glass surface, ε_2

Substitute, $333\,K$ for T_1, $313\,K$ for T_2, 0.85 for ε_1, $5.67\times10^{-8}\,W/m^2K^4$ for σ, 0.9 for ε_2

$$\dot{Q}_{rad} = \frac{\sigma A_1\left(T_1^4-T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{D_1}{D_2}\right)}$$

$$= \frac{5.67\times10^{-8}(W/m^2\text{-}K^4)\times\pi\times0.05(m)\times1(m)\times(333^4-313^4)}{\frac{1}{0.85}+\frac{1-0.9}{0.9}\left(\frac{5}{12}\right)}$$

$$= \frac{24.033}{1.2227}$$

$$= 19.655\,W$$

Step 8 of 8

Calculate the total rate of heat loss from the glass cover becomes

$$\dot{Q}_{total} = \dot{Q}_{conv}+\dot{Q}_{rad}$$

$$= 12.374(W)+19.655(W)$$

$$= 32.029\,W$$

Therefore, the rate of heat loss from the collector by natural convection and radiation per meter length of the tube is $\boxed{32.029\,W}$

Question: 21.119P pg 1

Two parallel concentric disks, 20 cm and 40 cm in diameter, are separated by a distance of 10 cm. The smaller disk ($\varepsilon = 0.80$) is at a temperature of 300°C. The larger disk ($\varepsilon = 0.60$) is at a temperature of 800°C.

(*a*) Calculate the radiation view factors.

(*b*) Determine the rate of radiation heat exchange between the two disks.

(c) Suppose that the space between the two disks is completely surrounded by a reflective surface. Estimate the rate of radiation heat exchange between the two disks.

Step 1 of 7

(a)

From table, the view factor for coaxial parallel disks is given as

$$F_{i\to j} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{r_j}{r_i}\right)^2\right]^{1/2}\right\}$$

$$F_{ba} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{r_a}{r_b}\right)^2\right]^{1/2}\right\}$$

Here,

Radius of the disk *a* is r_a

Radius of the disk *b* is r_b

Shape factor is *S*

Step 2 of 7

Find the radius of disk *a*,

$$r_a = \frac{d_a}{2}$$

Here,

Diameter of disk a, d_a

Substitute $20\,\text{cm}$ for d_a.

$$\begin{aligned} r_a &= \frac{d_a}{2} \\ &= \frac{20}{2} \\ &= 10\,\text{cm} \end{aligned}$$

Calculate the radius of disk *b*,

$$r_b = \frac{d_b}{2}$$

Here,

Diameter of the disk b, d_b

Substitute $40\,\text{cm}$ for d_b

$$\begin{aligned} r_b &= \frac{d_b}{2} \\ &= \frac{40}{2} \\ &= 20\,\text{cm} \end{aligned}$$

Step 3 of 7

Calculate the R_a by using the formula for R_a.

$$R_a = \frac{r_a}{L}$$

Here,

Center to center distance, L

Su8bstitute $10\,\text{cm}$ for L, 10 cm for r_a

$$\begin{aligned} R_a &= \frac{r_a}{L} \\ &= \frac{10}{10} \\ &= 1 \end{aligned}$$

Calculate the R_b by using the formula for R_b.

$$\begin{aligned} R_b &= \frac{r_b}{L} \\ &= \frac{20}{10} \\ &= 2 \end{aligned}$$

Step 4 of 7

Find the value of S.

$$\begin{aligned} S &= 1 + \left[\frac{1 + R_a^2}{R_b^2}\right] \\ &= 1 + \left[\frac{1 + 1^2}{2^2}\right] \\ &= 1.5 \end{aligned}$$

Calculate the view factor F_{ab}

$$F_{ba} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{r_a}{r_b}\right)^2\right]^{1/2}\right\}$$

Calculate the view factor F_{ab}

$$F_{ba}=\frac{1}{2}\left\{S-\left[S^2-4\left(\frac{r_a}{r_b}\right)^2\right]^{1/2}\right\}$$

Substitute 1.5 for S, $10\,\text{cm}$ for r_a, $20\,\text{cm}$ for r_b

$$\begin{aligned}F_{ba}&=\frac{1}{2}\left\{S-\left[S^2-4\left(\frac{r_a}{r_b}\right)^2\right]^{1/2}\right\}\\&=\frac{1}{2}\left\{1.5-\left[1.5^2-4\left(\frac{10}{20}\right)^2\right]^{1/2}\right\}\\&=0.191\end{aligned}$$

The view factor from surface b to surface a can be calculated using the reciprocity rule. Calculate the area of the disk 'a'

$$A_a=\frac{\pi}{4}d_a^2$$

Substitute $0.2\,\text{m}$ for d_a

$$\begin{aligned}A_a&=\frac{\pi}{4}d_a^2\\&=\frac{\pi}{4}\times 0.2^2\,(\text{m})^2\\&=0.031416\,\text{m}^2\end{aligned}$$

Calculate the area of the disk '*b*'

$$A_b=\frac{\pi}{4}d_b^2$$

Substitute $0.4\,\text{m}$ for d_b

$$\begin{aligned}A_b&=\frac{\pi}{4}d_b^2\\&=\frac{\pi}{4}\times 0.4^2\,(\text{m})^2\\&=0.1256\,\text{m}^2\end{aligned}$$

Step 5 of 7

Calculate the view factor F_{ab}

$$A_aF_{ab}=A_bF_{ba}$$

$$F_{ab}=\frac{A_b}{A_a}F_{ba}$$

Substitute 0.1256 for A_b, 0.031416 for A_a, 0.191 for F_{ba}

$$\begin{aligned}A_aF_{ab}&=A_bF_{ba}\\F_{ab}&=\frac{A_b}{A_a}F_{ba}\\&=\frac{0.1256}{0.031416}\times 0.191\\&=0.764\end{aligned}$$

Therefore, the view factor of ab is $\boxed{0.764}$.

Step 6 of 7

(b)

The net rate of radiation heat transfer between the surfaces can be determined as

$$\dot{Q}_{ab}=-\frac{\sigma\left(T_a^4-T_b^4\right)}{\frac{1-\varepsilon_a}{A_a\varepsilon_a}+\frac{1}{A_aF_{ab}}+\frac{1-\varepsilon_b}{A_b\varepsilon_b}}$$

Here,

Stefan Boltzmann constant is σ

Emissivity of the disk b, ε_b

Surface temperature of the disc b, T_b

Surface temperature of the disk a, T_a

Emissivity of the disk a, ε_a

Substitute 0.8 for ε_a, 0.6 for ε_b $800\,^\circ\text{C}$ for T_b, $300\,^\circ\text{C}$ for T_a, $5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4$ for σ

$$\begin{aligned}\dot{Q}_{ab}&=-\frac{\sigma\left(T_a^4-T_b^4\right)}{\frac{1-\varepsilon_a}{A_a\varepsilon_a}+\frac{1}{A_aF_{ab}}+\frac{1-\varepsilon_b}{A_b\varepsilon_b}}\\&=-\frac{5.67\times10^{-8}\times573^4-1073^4}{\frac{1-0.8}{0.031416\times0.8}+\frac{1}{0.031416\times0.764}+\frac{1-0.6}{0.1256\times0.6}}\\&=1257\,\text{W}\end{aligned}$$

Therefore, the net rate of radiation heat transfer between the surfaces is $\boxed{1257\,\text{W}}$.

Step 7 of 7

(c)

When the space between the disks is completely surrounded by a refractory surface, the net rate of radiation heat transfer can be determined as

$$\dot{Q}_{ab}=\frac{A_b\sigma\left(T_b^4-T_a^4\right)}{\left(\frac{1}{\varepsilon_b}-1\right)+\frac{A_b}{A_a}\left(\frac{1}{\varepsilon_a}-1\right)+\frac{A_a+A_b-2A_bF_{ba}}{A_a-A_bF_{ba}^2}}$$

Therefore, the net rate

radiation heat transfer can be determined as

21.119P pg 3

$$\dot{Q}_{ab} = \frac{A_b\sigma\left(T_b^4 - T_a^4\right)}{\left(\frac{1}{\varepsilon_b}-1\right)+\frac{A_b}{A_a}\left(\frac{1}{\varepsilon_a}-1\right)+\frac{A_a+A_b-2A_bF_{ba}}{A_a-A_bF_{ba}^2}}$$

$$= \frac{0.1256\times 5.67\times 10^{-8}\times 1073^4 - 573^4}{\left(\frac{1}{0.6}-1\right)+\frac{0.1256}{0.031416}\left(\frac{1}{0.8}-1\right)+\frac{0.031416+0.1256-2\times 0.1256\times 0.191}{0.031416-0.1256\times 0.191^2}}$$

$$= 1506\,\text{W}$$

Therefore, the net rate of radiation heat transfer is $\boxed{1506\text{W}}$

Question: 21.120P

Two parallel back disks are positioned coaxially with a distance of 0.25 m apart. The lower disk is 0.2 m in diameter and the upper disk is 0.4 m in diameter. If the lower disk is heated electrically at 20 W to maintain a uniform temperature of 500 K, determine the temperature of the upper disk. Answer. 423 K

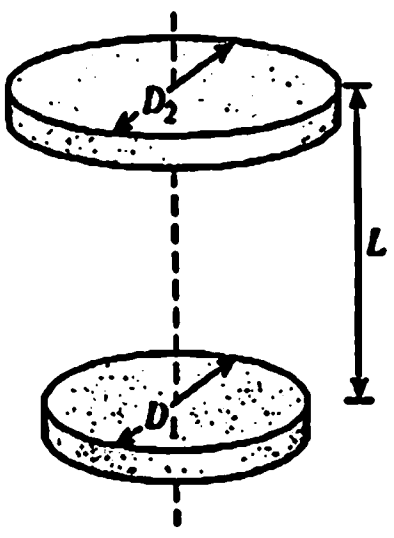


FIGURE P21–120

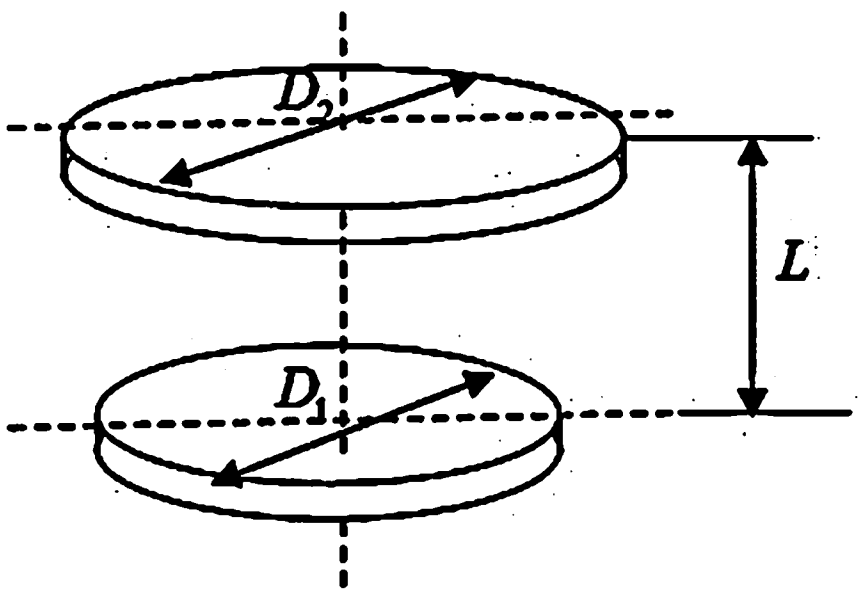
Step 1 of 6

Given data:

Distance between two plates, $L = 0.25\,\text{m}$

Diameter of the lower disc, $D_1 = 0.2\,\text{m}$



Diameter of the upper disc, $D_2 = 0.4\,\text{m}$

Temperature of the lower disc, $T_1 = 500\,\text{K}$

Heat supplied to the lower disc, $\dot{Q} = 20\,\text{W}$

Step 2 of 6

Schematic diagram of disc system:

Step 3 of 6

From the view factor expression for common geometrics of finite size

For Coaxial parallel disks

Assume, the lower plate is denoted as1 and upper plate is denoted as 2, the view factor from plate 1 to plate 2 can be expressed as

$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{r_2}{r_1}\right)^2\right]^{1/2}\right\}$$

where

$$S = 1 + \frac{1 + R_2^2}{R_1^2}$$

Step 4 of 6

The values of R_1 and R_2 can be calculated as

$$R_1 = \frac{r_1}{L}$$
$$= \frac{0.1}{0.25}$$
$$= 0.4$$
$$R_2 = \frac{r_2}{L}$$
$$= \frac{0.2}{0.25}$$
$$= 0.8$$

Step 5 of 6

Therefore,

$$S = 1 + \frac{1 + R_2^2}{R_1^2}$$
$$= 1 + \frac{1 + 0.8^2}{0.4^2}$$
$$= 11.25$$

The view factor can be calculated as

$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(\frac{r_2}{r_1}\right)^2\right]^{1/2}\right\}$$
$$= \frac{1}{2}\left\{11.25 - \left[11.25^2 - 4\left(\frac{0.2}{0.1}\right)^2\right]^{1/2}\right\}$$
$$= 0.3675$$

Step 6 of 6

The net rate of radiation heat transfer from the lower plate to the upper plate can be expressed as

$$\dot{Q}_{12} = A_1 F_{12} \sigma (T_1^4 - T_2^4)$$

Therefore, the temperature of the upper plate can be calculated as

$$20\,(\text{W}) = \frac{\pi}{4} \times 0.2^2\,(\text{m}^2) \times 0.3675 \times 5.67 \times 10^{-8}\,(\text{W/m}^2\text{-K}^4) \times (500^4 - T_2^4)\,(\text{K}^4)$$

$$T_2 = 423\,\text{K}$$

Therefore, the temperature of the upper plate is $\boxed{T_2 = 423\,\text{K}}$.

CHAPTER 23
SOLUTIONS

Question: 22.001P

Classify heat exchangers according to flow type and explain the characteristics of each type.

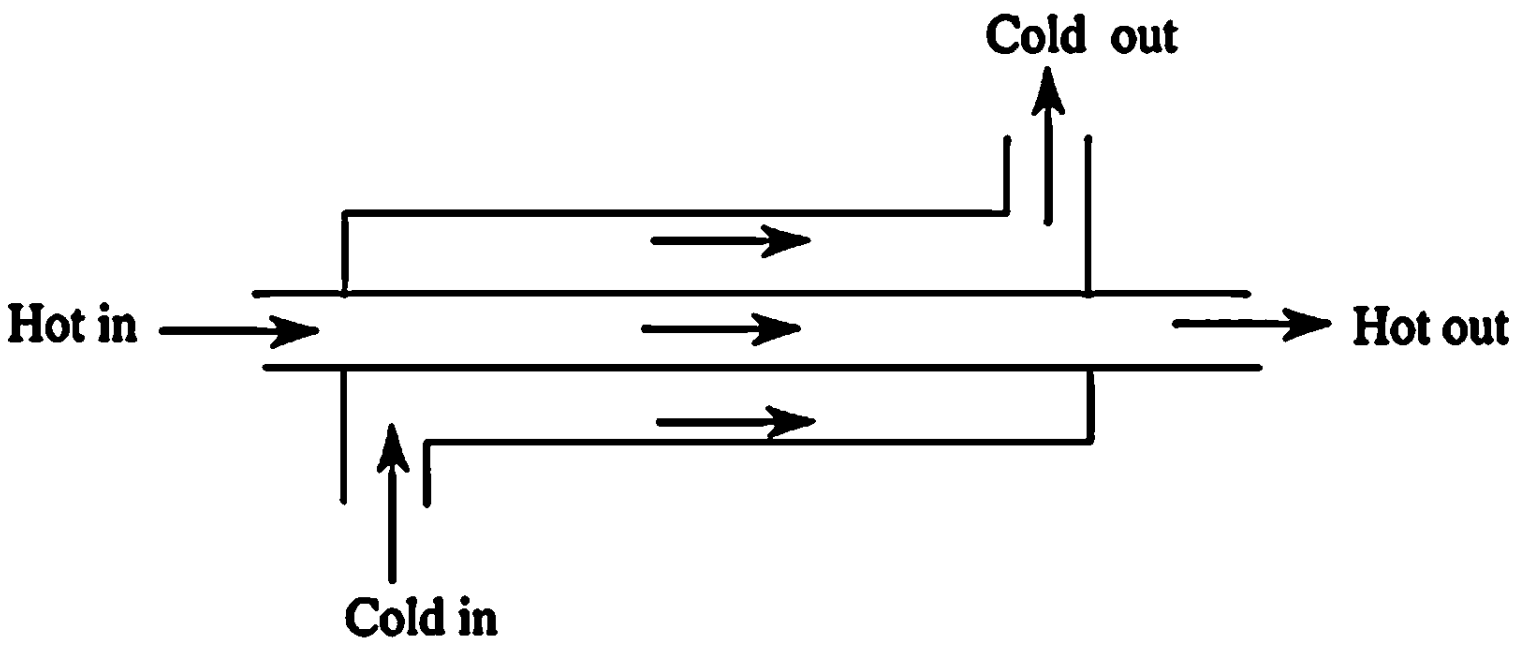
Step 1 of 8

Classification of heat exchangers on the basis of flow type is as follows.

a) Parallel flow heat exchangers

b) Counter flow heat exchangers

c) Cross flow heat exchangers



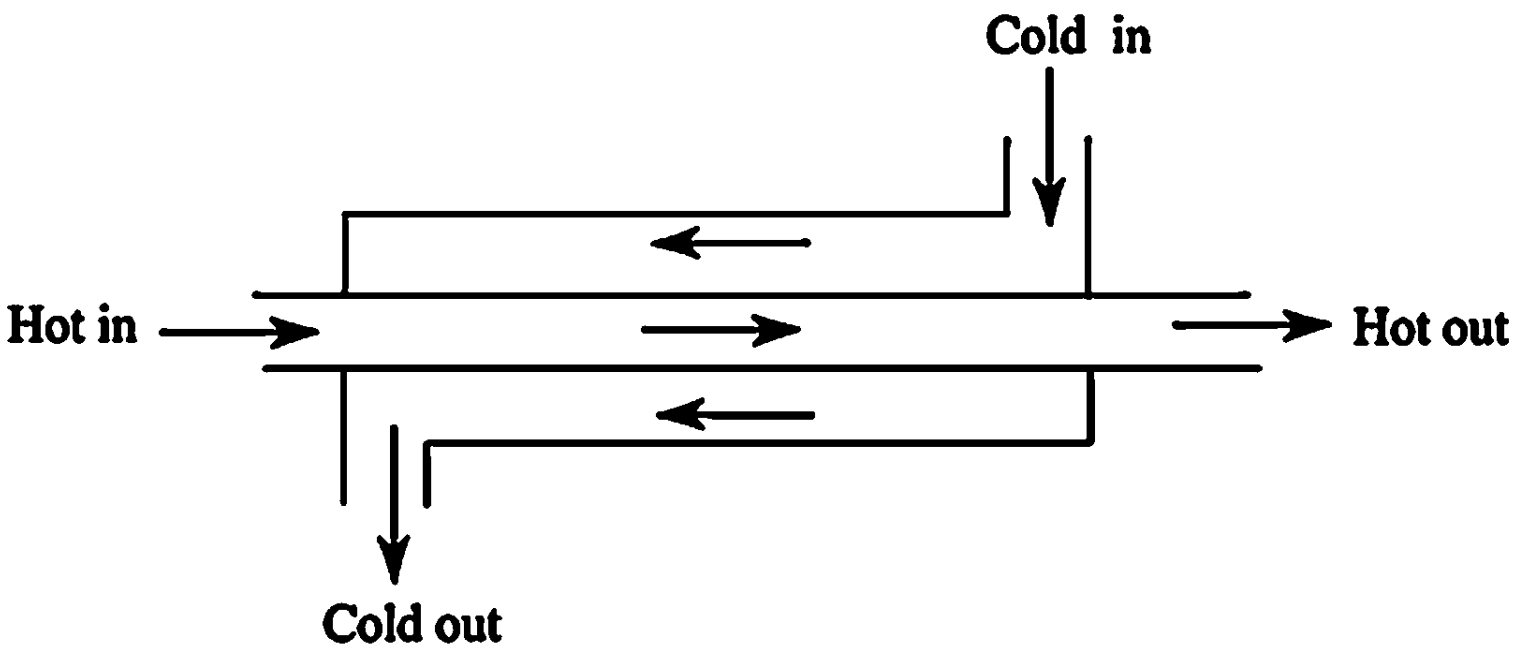
Step 2 of 8

Parallel flow:

In parallel flow arrangement, the hot and cold fluids enters at the same end, flow in the same direction, and leave at the same end.

Step 3 of 8

Draw the diagram of parallel flow heat exchanger.



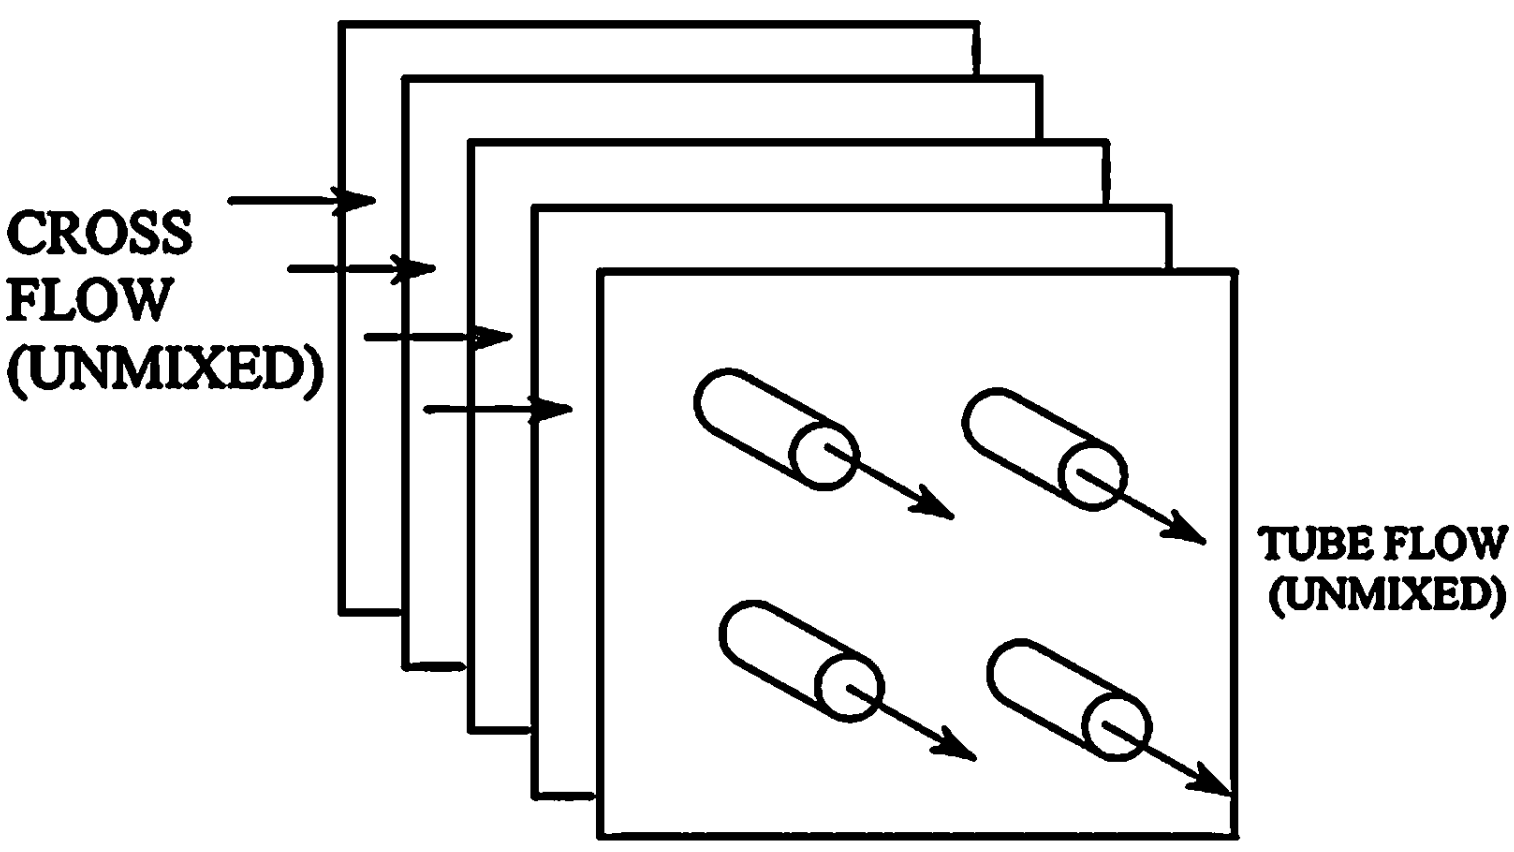
Step 4 of 8

Counter flow:

In counter flow arrangement, the hot and cold fluids enter the heat exchanger at opposite ends, flow in opposite directions.

Step 5 of 8

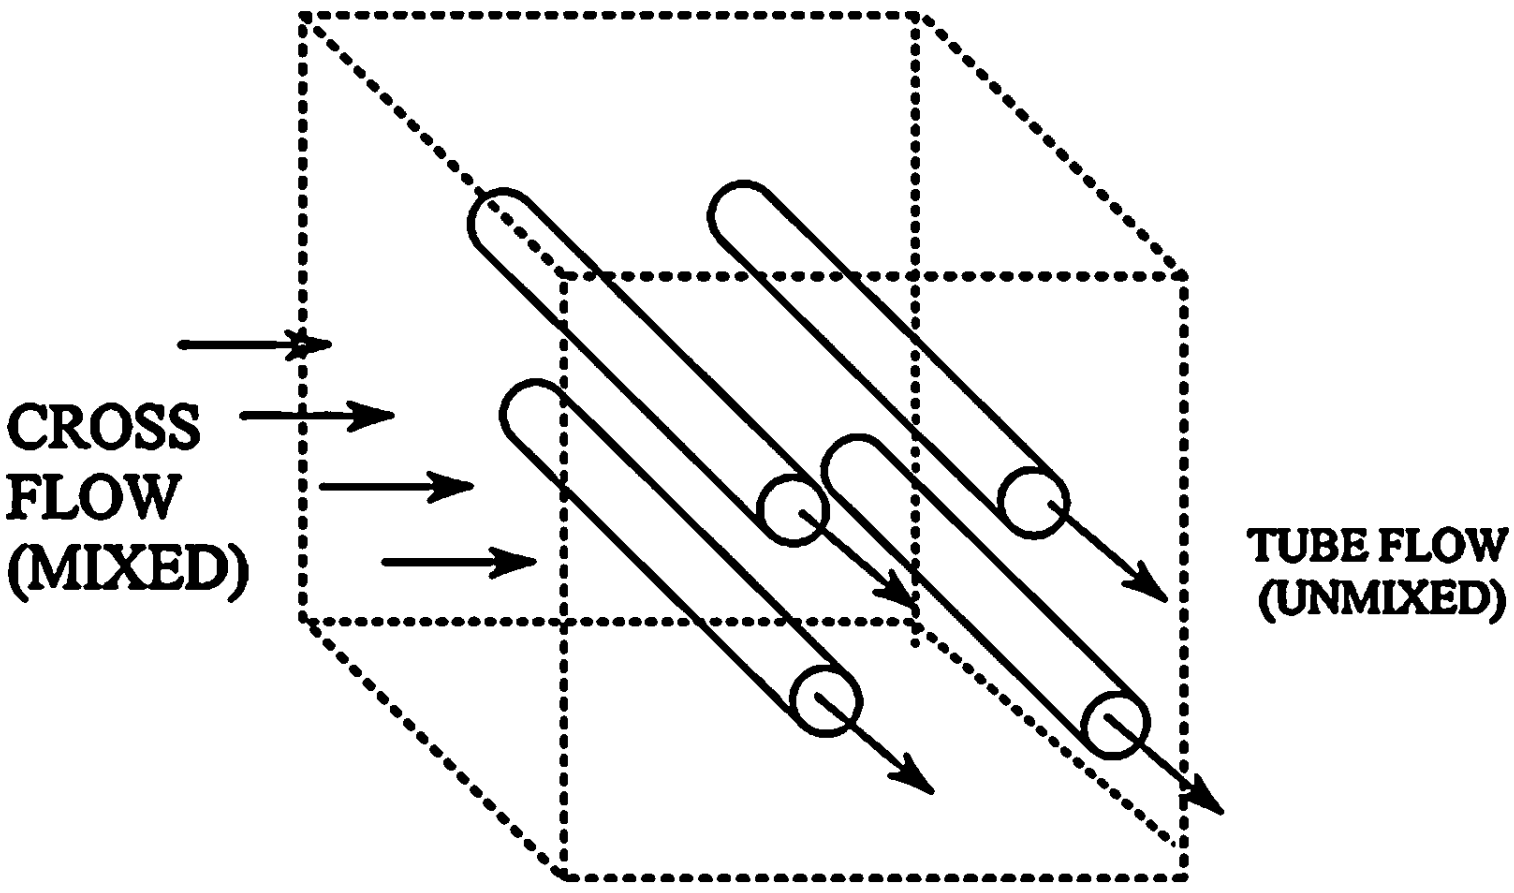
Draw the diagram of counter flow heat exchanger.



Step 6 of 8

Cross flow:

In cross flow arrangement, hot and cold fluids move in the perpendicular direction. Cross flow is further classified as unmixed and mixed flow depending on flow configuration.



Step 7 of 8

Draw the diagram showing "both fluids unmixed".

Step 8 of 8

Draw the diagram showing "one fluid mixed and other fluid unmixed".

Question: 22.002P

When is a heat exchanger classified as being compact? Do you think a double-pipe heat exchanger can be classified as a compact heat exchanger?

Step 1 of 2

The ratio of surface area through which heat transfer takes place in a heat exchanger to its volume is called the area density (β) .Being compact of a heat exchanger depends on the area density of the heat exchanger.

Step 2 of 2

If the area density (β) of a heat exchanger is greater than $(700\ \mathrm{m^2/m^3})$ or $(200\ \mathrm{ft^2/ft^3})$ then the heat exchanger is called as compact heat exchanger.

Car radiator $(\beta \simeq 1000\mathrm{m^2/m^3})$ and glass ceramic gas turbine $(\beta \simeq 6000\mathrm{m^2/m^3})$ are best examples of compact heat exchangers.

The area density for a double pipe heat exchanger cannot be more than $700\ \mathrm{m^2/m^3}$. Therefore double pipe heat exchanger is not considered as compact heat exchanger.

Question: 22.003P

What is a regenerative heat exchanger? How does a static type of regenerative heat exchanger differ from a dynamic type?

Step 1 of 2

The ratio of surface area through which heat transfer takes place in a heat exchanger to its volume is called the area density (β) .Being compact of a heat exchanger depends on the area density of the heat exchanger.

Step 2 of 2

If the area density (β) of a heat exchanger is greater than $(700\ \mathrm{m^2/m^3})$ or $(200\ \mathrm{ft^2/ft^3})$ then the heat exchanger is called as compact heat exchanger.

Car radiator $(\beta \simeq 1000\mathrm{m^2/m^3})$ and glass ceramic gas turbine $(\beta \simeq 6000\mathrm{m^2/m^3})$ are best examples of compact heat exchangers.

The area density for a double pipe heat exchanger cannot be more than $700\ \mathrm{m^2/m^3}$. Therefore double pipe heat exchanger is not considered as compact heat exchanger.

Question: 22.004P

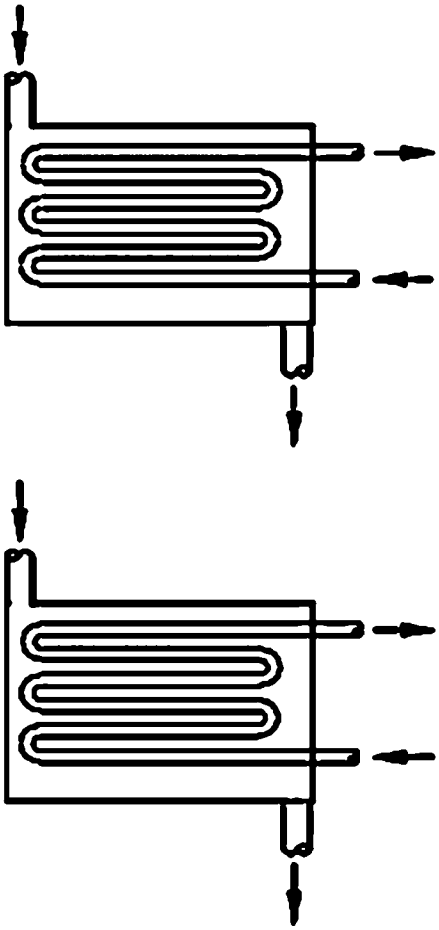
What is the role of the baffles in a shell-and-tube heat exchanger? How does the presence of baffles affect the heat transfer and the pumping power requirements? Explain.

Step 1 of 1

Baffles are commonly placed in the shell to force the shell-side fluid to flow across the shell to enhance heat transfer and to maintain uniform spacing between the tubes.

Baffles are usually installed to increase the convection coefficient of the shell-side fluid by inducing turbulence and a cross flow velocity component.

In addition, the baffles physically support the tubes, reducing flow induced tube vibration.



And an increased pumping power will be needed to maintain.

Question: 22.005P

How does a cross-flow heat exchanger differ from a counter-flow one? What is the difference between mixed and unmixed fluids in cross-flow?

Step 1 of 1

Draw the 1 shell and 6 tube passes arrangement as follows:

Advantages:

The heat transfer surface area is more by using 6 tube passes. If surface area increases, the heat transfer rate increases. Hence, for the same pipe diameter, the heat transfer rate is more by using six tube passes instead of two tube passes.

Disadvantages:

Despite their wide spread use, shell-and-tube heat exchangers are not suitable for use in automotive and aircraft applications because of their relatively large size and weight. The manufacturing cost increases due to increased area in case of six tube arrangement.

Question: 22.006P

What are the heat transfer mechanisms involved during heat transfer in a liquid-to-liquid heat exchanger from the hot to the cold fluid?

Step 1 of 1

The mechanism involved during heat transfer in a liquid to liquid heat exchanger from the hot fluid to the cold fluid is due to convection and conduction.
Heat is transferred from hot fluid to wall is due to convection, heat transfer through the wall is by conduction and finally from the wall to the cold fluid is due to convection

If the difference in temperature between the hot and cold fluid are too large, radiation heat transfer will come into picture.
The total thermal resistance during the heat transfer becomes

$R = R_i + R_{wall} + R_o$

Question: 22.007P

Under what conditions is the thermal resistance of the tube in a heat exchanger negligible?

Step 1 of 1

When the wall thickness of the tube is small and the thermal conductivity of the tube material high, as is usually the case, the thermal resistance of the tube is negligible.

Question: 22.008P

Consider a double-pipe parallel-flow heat exchanger of length *L*. The inner and outer diameters of the inner tube are *D*1 and *D*2, respectively, and the inner diameter of the outer tube is *D*3. Explain how you would determine the two heat transfer surface areas *Ai* and *AO*. When is it reasonable to assume *Ai* ≈ *Ao* ≈ *As*?

Step 1 of 1

A_i and A_o are surface areas of the separating wall wetted by the inner and outer fluids respectively. The surface areas can be calculated by

$$A_i = \pi D_1 L$$

$$A_o = \pi D_2 L$$

When the wall thickness of the tube is small then we can consider $A_i \cong A_o \cong A_s$

Question: 22.009P

How is the thermal resistance due to fouling in a heat exchanger accounted for? How do the fluid velocity and temperature affect fouling?

Step 1 of 1

The layer of deposits represents additional resistance to heat transfer and causes the rate of heat transfer in a heat exchanger to decrease. The net effect of these accumulations on heat transfer is represented by a fouling factor R_f, which is a measure of the thermal resistance introduced by fouling.

Fouling increases with increasing temperature and by decreasing fluid velocity.

Question: 22.010P

In a thin-walled double-pipe heat exchanger, when is the approximation $U = h_i$,- a reasonable one? Here U is the overall heat transfer coefficient and h_i is the convection heat transfer coefficient inside the tube.

Step 1 of 1

In a thin-walled double-pipe heat exchanger, the relation $U \cong h_i$ is valid only when the overall heat transfer coefficient U is dominated by the smaller convective coefficient, since the inverse of a large number is small. When one of the convection coefficients is smaller than the other (say $h_i << h_0$), we have $\frac{1}{h_i} >> \frac{1}{h_0}$ and thus $U \approx h_i$

Question: 22.011P

What are the common causes of fouling in a heat exchanger? How does fouling affect heat transfer and pressure drop?

Step 1 of 1

The layer of deposits represents additional resistance to heat transfer and causes the rate of heat transfer in a heat exchanger to decrease. The net effect of these accumulations on heat transfer is represented by a fouling factor R_f, which is a measure of the thermal resistance introduced by fouling.

Fouling increases with increasing temperature and by decreasing fluid velocity.

Question: 22.012P

Under what conditions can the overall heat transfer coefficient of a heat exchanger be determined from $U = (1/hi + VhO)-1$?

Step 1 of 1

When the wall thickness of the tube is small and the thermal conductivity of the tube material high, as is usually the case, the thermal resistance of the tube is negligible and the inner and outer surfaces of the tube are almost identical then the overall heat transfer coefficient can be calculated by

$$\frac{1}{U}=\frac{1}{h_i}+\frac{1}{h_o}$$

Question: 22.013P

Water at an average temperature of 180°F and an average velocity of 4 ft/s flows through a thin-walled $\frac{3}{4}$-in- diameter tube. The water is cooled by air that flows across the tube with a velocity of 12 ft/s at an average temperature of 80°F. Determine the overall heat transfer coefficient.

Step 1 of 6

Calculate the overall heat transfer coefficient.

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_o}} \quad \text{..... (1)}$$

Here, h_i is the inside heat transfer coefficient and h_o is the outside heat transfer coefficient.

Obtain the properties of water from properties of saturated water table in the text book, at $180°\text{F}$.

Dynamic viscosity is $\mu = 2.317 \times 10^{-4}\ \text{lbm/ft-s}$.

Density is $\rho = 60.57\ \text{lbm/ft}^3$.

Thermal conductivity is $k = 0.388\ \text{Btu/h.ft.°F}$.

Prandtl number is $\text{Pr} = 2.15$.

Step 2 of 6

Calculate the Reynolds number of water.

$$\text{Re} = \frac{\rho V_m D_h}{\mu}$$

Here, V_m is the average velocity of water and D_h is the diameter of thin walled tube.

Substitute $60.57\ \text{lbm/ft}^3$ for ρ, $8\ \text{ft/s}$ for V_m, $0.75\ \text{in.}$ for D_h, and $2.317 \times 10^{-4}\ \text{lbm/ft-s}$ for μ.

$$\text{Re} = \frac{(60.57\ \text{lbm/ft}^3)(8\ \text{ft/s})\left(\frac{0.75}{12}\ \text{ft}\right)}{2.317 \times 10^{-4}\ \text{lbm/ft-s}}$$
$$= 130707.81$$

Since, $\text{Re} > 10000$, the flow of water is turbulent.

Step 3 of 6

Calculate the Nusselt number for the fully developed flow in tube.

$$Nu = 0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.4}$$

Substitute 130707.81 for Re and 2.15 for Pr.

$$Nu = 0.023(130707.81)^{0.8}(2.15)^{0.4}$$
$$= 387.03$$

Calculate the inside heat transfer coefficient using the relation.

$$h_i = \frac{k}{D_h} Nu$$

Substitute $0.388\ \text{Btu/h-ft-°F}$ for k, $0.75\ \text{in.}$ for D_h, and 387.03 for Nu.

$$h_i = \frac{0.388\ \text{Btu/h-ft-°F}}{\frac{0.75}{12}\ \text{ft}}(387.03)$$
$$= 2402.7\ \text{Btu/h-ft}^2\text{-°F}$$

Step 4 of 6

Obtain the properties of air from properties of air table in the text book, at $80°\text{F}$.

Kinematic viscosity is $\nu = 1.697 \times 10^{-4}\ \text{ft}^2/\text{s}$.

Thermal conductivity of air is $k = 0.01481\ \text{Btu/h.ft.°F}$.

Prandtl number of air is $\text{Pr} = 0.729$.

Calculate the Reynolds number of air.

$$\text{Re} = \frac{V_{air} D}{\nu}$$

Substitute $12\ \text{ft/s}$ for V_{air}, $0.75\ \text{in.}$ for D_h, and $1.697 \times 10^{-4}\ \text{ft}^2/\text{s}$ for ν.

$$\text{Re} = \frac{(12\ \text{ft/s})\left(\frac{0.75}{12}\ \text{ft}\right)}{0.1697 \times 10^{-3}\ \text{ft}^2/\text{s}}$$
$$= 4419.56$$

Step 5 of 6

Calculate the Nusselt number.

$$Nu = 0.3 + \frac{0.62\,\text{Re}^{0.5}\,\text{Pr}^{1/3}}{[1 + (0.4)\text{Pr}^{2/3}]^{1/4}} + \left[1 + \left(\frac{\text{Re}}{282000}\right)^{5/8}\right]^{4/5}$$

Substitute 4419.56 for Re and 0.729 for Pr.

$$Nu = 0.3 + \frac{0.62(4419.56)^{0.5}(0.729)^{1/3}}{\left[1 + (0.4)(0.729)^{2/3}\right]^{1/4}} + \left[1 + \left(\frac{4419.56}{282000}\right)^{5/8}\right]^{4/5}$$
$$= 0.3 + 34.582 + 1.059$$
$$= 35.94$$

Step 6 of 6

Calculate the outside heat transfer coefficient using the relation.

$$h_o = \frac{k}{D_h} Nu$$

Substitute $0.01481\ \text{Btu/h-ft-°F}$ for k, $0.75\ \text{in.}$ for D_h, and 35.94 for Nu.

$$h_o = \frac{0.01481\ \text{Btu/h-ft-°F}}{\frac{0.75}{12}\ \text{ft}}(35.94)$$
$$= 8.516\ \text{Btu/h-ft}^2\text{-°F}$$

Substitute $8.516\ \text{Btu/h-ft}^2\text{-°F}$ for h_o and $2402.7\ \text{Btu/h-ft}^2\text{-°F}$ for h_i in equation (1).

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_o}}$$
$$= \frac{1}{\frac{1}{2402.7} + \frac{1}{8.516}}$$
$$= 8.486\ \text{Btu/h-ft}^2\text{-°F}$$

Therefore, the overall heat transfer coefficient is $\boxed{8.486\ \text{Btu/h-ft}^2\text{-°F}}$.

Question: 22.014P

Water at an average temperature of 110°C and an average velocity of 3.5 m/s flows through a 7-m-long stainless steel tube (k = 14.2 W/m·K) in a boiler. The inner and outer diameters of the tube are Di = 1.0 cm and DO = 1.4 cm, respectively. If the convection heat transfer coefficient at the outer surface of the tube where boiling is taking place is $h0$ = 7200 W/m2·K, determine the overall heat transfer coefficient Ui of this boiler based on the inner surface area of the tube.

Step 1 of 4

Given

Average velocity of water is $V_m = 3.5$ m/s

Average temperature of water $T = 110°C$

Length of the stainless steel tube $L = 7$ m

Thermal conductivity of the stainless steel tube $k_{ss} = 14.2$ W/m · °C

Inner and outer diameter of the tube are $D_i = 0.01$ m and $D_o = 0.014$ m

The convection heat transfer coefficient at the outer surface of the tube is $h_o = 7200$ W/m^2 · K

Step 2 of 4

From properties of saturated water tables the properties of water at $T = 110°C$ are

$\nu = 0.268\times10^{-6}$ m^2/s

k=0.682 W/m · K

Pr=1.58

The overall heat transfer coefficient U_i of this boiler based on the inner surface area of the tube is calculated by

$$R = \frac{1}{U_i A_i}$$

$$U_i = \frac{1}{R A_i}$$

Where

$$R = R_i + R_{wall} + R_o$$

$$R = \frac{1}{h_i A_i} + \frac{\ln(D_o/D_i)}{2\pi k L} + \frac{1}{h_o A_o}$$

Step 3 of 4

The Reynolds number is

$$\mathrm{Re} = \frac{V_m D_i}{\nu}$$

$$\mathrm{Re} = \frac{(3.5\ \text{m/s})(0.01\ \text{m})}{0.268\times10^{-6}\ \text{m}^2/\text{s}}$$

Re=130597.01

Re >10,000 the flow is turbulent. Assume the flow is fully developed flow.

$$Nu = 0.023\,\mathrm{Re}^{0.8}\,\mathrm{Pr}^{0.4}$$

$$= 0.023(130597.01)^{0.8}(1.58)^{0.4}$$

$$Nu = 341.93$$

And we know

$$Nu = \frac{hD_i}{k}$$

$$h_i = \frac{k}{D_i} Nu$$

$$= \frac{0.682\ \text{W/m}\cdot\text{K}}{0.01\ \text{m}}(341.93)$$

$$h_i = 23319.626\ \text{W/m}^2\cdot°\text{C}$$

Step 4 of 4

Therefore total resistance of this heat exchanger is then determined substituting all the known values

$$R = \frac{1}{h_i A_i} + \frac{\ln(D_o/D_i)}{2\pi k L} + \frac{1}{h_o A_o}$$

$$R = \frac{1}{(23319.626)[\pi(0.01)(7)]} + \frac{\ln\left(0.014/0.01\right)}{[2\pi(14.2)(7)]} + \frac{1}{(7200)[\pi(0.014)(7)]}$$

$$= 0.000194 + 0.0005387 + 0.000451$$

$$R = 0.0011837°\text{C/W}$$

Then

$$U_i = \frac{1}{R A_i}$$

$$U_i = \frac{1}{(0.0011837°\text{C/W})[\pi(0.01\ \text{m})(7\ \text{m})]}$$

$$\boxed{U_i = 3841.584\ \text{W/m}^2\cdot°\text{C}}$$

Question: 22.015P

Repeat Prob. 22-14, assuming a fouling factor Rf,i =0.0005 m2·K/W on the inner surface of the tube.

Step 1 of 4

Given

Average velocity of water is $V_m = 3.5$ m/s

Average temperature of water $T = 110°C$

Length of the stainless steel tube $L = 7$ m

Thermal conductivity of the stainless steel tube $k_{ss} = 14.2$ W/m · °C

Inner and outer diameter of the tube are $D_i = 0.01$ m and $D_o = 0.014$ m

The convection heat transfer coefficient at the outer surface of the tube is $h_o = 7200$ W/m^2 · K

Fouling factor on the inner surface of the tube is $R_{f,i} = 0.0005$ m^2.K/W

Step 2 of 4

From properties of saturated water tables the properties of water at $T = 110°C$ are

$\nu = 0.268\times10^{-6}$ m^2/s

k=0.682 W/m · K

Pr=1.58

The overall heat transfer coefficient U_i of this boiler based on the inner surface area of the tube is calculated by

$$R = \frac{1}{U_i A_i}$$

$$U_i = \frac{1}{RA_i}$$

Where

$$R = R_i + R_{wall} + R_o$$

$$R = \frac{1}{h_i A_i} + \frac{R_{f,i}}{A_i} + \frac{\ln(D_o/D_i)}{2\pi KL} + \frac{1}{h_o A_o}$$

Step 3 of 4

The Reynolds number is

$$\mathrm{Re} = \frac{V_m D_i}{\nu}$$

$$\mathrm{Re} = \frac{(3.5\ \text{m/s})(0.01\ \text{m})}{0.268\times10^{-6}\ \text{m}^2/\text{s}}$$

Re=130597.01

Re >10,000 the flow is turbulent. Assume the flow is fully developed flow.

$$Nu = 0.023\mathrm{Re}^{0.8}\mathrm{Pr}^{0.4}$$

$$= 0.023(130597.01)^{0.8}(1.58)^{0.4}$$

$$Nu = 341.93$$

And we know

$$Nu = \frac{hD_i}{k}$$

$$h_i = \frac{k}{D_i}Nu$$

$$= \frac{0.682\ \text{W/m}\cdot\text{K}}{0.01\ \text{m}}(341.93)$$

$$h_i = 23319.626\ \text{W/m}^2\cdot°\text{C}$$

Step 4 of 4

Therefore total resistance of this heat exchanger is then determined substituting all the known values

$$R = \frac{1}{h_i A_i} + \frac{R_{f,i}}{A_i} + \frac{\ln(D_o/D_i)}{2\pi KL} + \frac{1}{h_o A_o}$$

$$R = \frac{1}{(23319.626)[\pi(0.01)(7)]} + \frac{(0.0005)}{\pi(0.01)(7)} + \frac{\ln\left(0.014/0.01\right)}{[2\pi(14.2)(7)]} + \frac{1}{(7200)[\pi(0.014)(7)]}$$

$$= 0.000194 + 0.00227 + 0.0005387 + 0.000451$$

$$R = 0.003453°\text{C/W}$$

Then

$$U_i = \frac{1}{RA_i}$$

$$U_i = \frac{1}{(0.003453°\text{C/W})[\pi(0.01\ \text{m})(7\ \text{m})]}$$

$$\boxed{U_i = 1316.908\ \text{W/m}^2\cdot°\text{C}}$$

Therefore the overall heat transfer coefficient of this boiler based on the inner surface area of the tube is $U_i = 1316.908$ W/m^2 · °C

Question: 22.016P

Reconsider Prob. 22-15. Using EES (or other) software, plot the overall heat transfer coefficient based on the inner surface as a function of fouling factor as it varies from 0.0001 m2·K/W to 0.0008 m2·K/W, and discuss the results.

Step 1 of 4

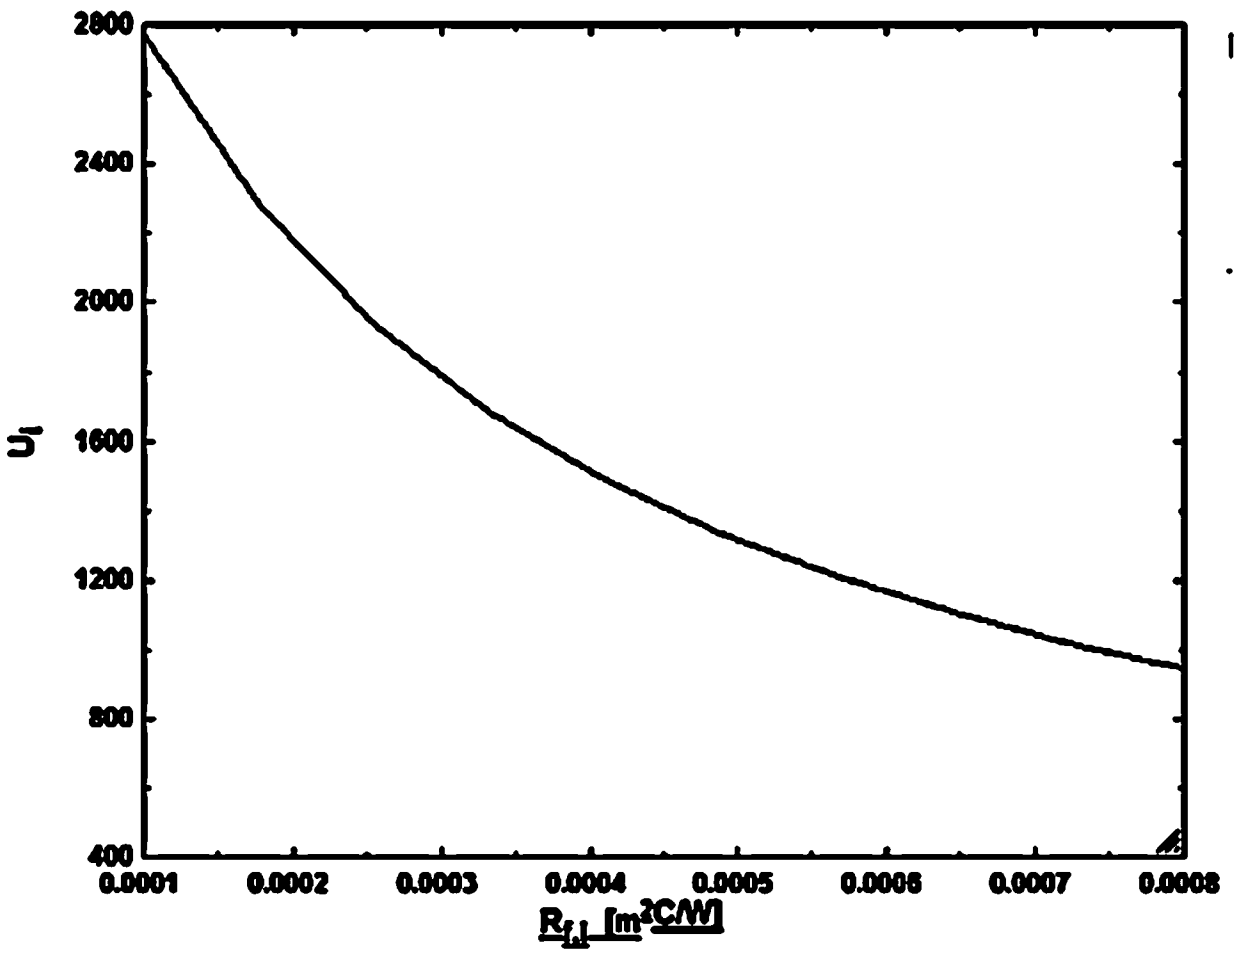
The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
"GIVEN"
T_w=110 [C]
Vel=3.5 [m/s]
L=7 [m]
k_pipe=14.2 [W/m-C]
D_i=0.010 [m]
D_o=0.014 [m]
h_o=7200 [W/m^2-C]
"R_f_i=0.0005 [m^2-C/W] "
"PROPERTIES"
k=conductivity (Water, T=T_w, P=300)
Pr=Prandtl (Water, T=T_w, P=300)
Rho=density (Water, T=T_w, P=300)
Mu=viscosity (Water, T=T_w, P=300)
Nu=mu/rho
"ANALYSIS"
Re=(Vel*D_i)/nu "Re is calculated to be greater than 10,000. Therefore, the flow is turbulent."
Nusselt=0.023*Re^0.8*Pr^0.4
h_i=k/D_i*Nusselt
A_i=pi*D_i*L
A_o=pi*D_o*L
R=1/(h_i*A_i)+R_f_i/A_i+ln(D_o/D_i)/(2*pi*k_pipe*L)+1/(h_o*A_o)
U_i=1/(R*A_i)
```

Step 2 of 4

Now to solve the equation for a range of length values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 10
Select variables in equations as R_{fi} and U_i press 'Add' and then press 'ok'
A table will appear and enter the values of length under ' R_{fi} ' as
0.0001,0.0001778.....0 .0008in runs 1 to 10
Then from click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below



Step 3 of 4

The following results are displayed:

1..10	$R_{f,i}$ [m2-C/W]	U_i
Run 1	0.0001	2769
Run 2	0.0001778	2279
Run 3	0.0002556	1936
Run 4	0.0003333	1682
Run 5	0.0004111	1488
Run 6	0.0004889	1333
Run 7	0.0005667	1208
Run 8	0.0006444	1104
Run 9	0.0007222	1017
Run 10	0.0008	942.4

Step 4 of 4

Select the plot on menu bar, and then click x-y plot .Dialog box will be appeared.
Select X-axis as R_{fi} and Y-axis as U_i .Press OK
The Graph will be plotted as shown below.
By plotting the graph between fouling factor and heat transfer coefficient:

This graph represents that by increasing the fouling factor, the overall heat transfer coefficient decreases.

Question: 22.017P

A counter-flow heat exchanger is stated to have an overall heat transfer coefficient, based on outside tube area of 50 Btu/h·ft2·°F when operating at design and clean conditions. After a period of use, scale built-up in the heat exchanger gives a fouling factor of 0.002 h·ft2·°F/Btu. Determine (*a*) the overall heat transfer coefficient of the heat exchanger and (*b*) the percentage change in the overall heat transfer coefficient due to the scale built-up.

Step 1 of 2

a)

From the equation of overall heat transfer coefficient with fouling factor

$$\frac{1}{UA_0}=\frac{1}{U_0A_0}+\frac{R_{f,0}}{A_0} \qquad \text{..... (1)}$$

Here

Overall heat transfer coefficient based on outside tube area, U_0

Fouling factor for outside tube, $R_{f,0}$

Outer surface area, A_0

Simplify the equation (1) and substitute 50 $\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ for U_0, 0.002 $\text{h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}$ for R_0 in the equation (1) to determine overall heat transfer coefficient

$$\frac{1}{UA_0}=\frac{1}{U_0A_0}+\frac{R_{f,0}}{A_0}$$

$$\frac{1}{U}=\frac{1}{50}+0.002$$

$$=0.022$$

$$U=45.45\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

Therefore, overall heat transfer coefficient of the heat exchanger is $\boxed{45.45\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}}$

Step 2 of 2

b)

Percentage change of overall heat transfer coefficient due to scale built up is

$$\%U_c=\frac{U_0-U}{U_0}$$

Substitute 45.45 $\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ for U, 50 $\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ for U_0 in the above equation

$$\%U_c=\frac{50-45.45}{50}$$

$$=0.091$$

$$=9.1\%$$

Therefore, percentage change of overall heat transfer coefficient U_c is $\boxed{9.1\%}$.

Question: 22.018P

The tube in a heat exchanger has a 2-in. inner diameter and a 3-in. outer diameter. The thermal conductivity of the tube material is 0.5 Btu/h·ft·°F, while the inner surface heat transfer coefficient is 50 Btu/h·ft2·°F and the outer surface heat transfer coefficient is 10 Btu/h·ft2·°F. Determine the overall heat transfer coefficients based on the outer and inner surfaces.

Step 1 of 3

Total thermal resistance of the heat exchanger is

$$R=\frac{1}{h_i A_i}+\frac{\ln\left(\frac{D_o}{D_i}\right)}{2\pi kL}+\frac{1}{h_0 A_o}$$

Here

Inner diameter of tube in heat exchanger, D_i

Outer diameter of tube I heat exchanger, D_o

Thermal conductivity tube material, k

Heat transfer coefficient at inner side of heat exchanger, h_i

Heat transfer coefficient at outer side of heat exchanger, h_0

Inner surface area, A_i and Outer surface area A_o

Inner surface area, $A_i=\pi D_i L$

Outer surface area, $A_o=\pi D_o L$

Substitute 2in. for D_i, 3in. for D_o, $0.5\text{Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$ for k, $50\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ for h_i, $10\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ for h_0, 1 ft. for L in the below equation

$$R=\frac{1}{h_i A_i}+\frac{\ln\left(\frac{D_o}{D_i}\right)}{2\pi kL}+\frac{1}{h_0 A_o}$$

$$=\frac{1}{h_i(\pi D_i L)}+\frac{\ln\left(\frac{D_o}{D_i}\right)}{2\pi kL}+\frac{1}{h_0(\pi D_o L)}$$

$$=\frac{1}{50\left(\pi\left(2\text{in.}\times\frac{1\text{ft}}{12\text{in.}}\right)1\right)}+\frac{\ln\left(\frac{3}{2}\right)}{2\pi\times0.5\times1}+\frac{1}{10\left(\pi\times3\text{in.}\times\frac{1\text{ft}}{12\text{in.}}1\right)}$$

$$=0.03819+0.1290+0.127$$

$$=0.2945\ {}^\circ\text{F/Btu}$$

Step 2 of 3

Overall heat transfer coefficient based on outer surface is

$$U_o=\frac{1}{RA_0}$$

Substitute $0.2945\ {}^\circ\text{F/Btu}$ for R, 1 ft. for L in the below equation

$$U_o=\frac{1}{RA_0}$$

$$=\frac{1}{0.2945\times(\pi D_o L)}$$

$$=\frac{1}{0.2945\times\pi\times3\text{in.}\times\frac{1\text{ft}}{12\text{in.}}\times1}$$

$$=4.323\ \text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

Therefore, Overall heat transfer coefficient based on outer surface is $\boxed{4.323\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}}$

Step 3 of 3

Overall heat transfer coefficient based on inner surface is

$$U_i=\frac{1}{RA_i}$$

Substitute $0.2945\ {}^\circ\text{F/Btu}$ for R, 1 ft. for L in the below equation

$$U_i=\frac{1}{RA_i}$$

$$=\frac{1}{0.2945\times(\pi D_i L)}$$

$$=\frac{1}{0.2945\times\pi\times2\text{in.}\times\frac{1\text{ft}}{12\text{in.}}\times1}$$

$$=6.485\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$$

Therefore, Overall heat transfer coefficient based on inner surface is $\boxed{6.485\ \text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}}$

Question: 22.019P

A long thin-walled double-pipe heat exchanger with tube and shell diameters of 1.0 cm and 2.5 cm, respectively, is used to condense refrigerant-134a by water at 20°C. The refrigerant flows through the tube, with a convection heat transfer coefficient of *hi* = 4100 W/m2·K. Water flows through the shell at a rate of 0.3 kg/s. Determine the overall heat transfer coefficient of this heat exchanger.

Step 1 of 5

Given

Heat exchanger with tube and shell diameters are $D_o = 0.01\ \text{m}$ and $D_s = 0.025\ \text{m}$

Temperature of water $T = 20°\text{C}$

Mass flow rates of water is $\dot{m} = 0.3\ \text{kg/s}$

Convection heat transfer coefficient $h_i = 4100\ \text{W/m}^2 \cdot \text{K}$

Step 2 of 5

From saturated properties of water the properties of water at $T = 20°\text{C}$ are

$\nu = 1.004 \times 10^{-6}\ \text{m}^2/\text{s}$

$k = 0.598\ \text{W/m.°C}$

$\rho = 998\ \text{kg/m}^3$

$\text{Pr} = 7.01$

The overall heat transfer coefficient is determined by using the expression

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_o}}$$

The average velocity of water in the tube

$$V_m = \frac{\dot{m}}{\rho A_c}$$

$$V_m = \frac{\dot{m}}{\rho\left(\pi\left(\frac{D_o^2 - D_i^2}{4}\right)\right)}$$

$$V_m = \frac{0.3}{998\left(\pi\left(\frac{0.025^2 - 0.01^2}{4}\right)\right)}$$

$$V_m = 0.729\ \text{m/s}$$

Step 3 of 5

Reynolds number for the flow is expressed as

$$\text{Re} = \frac{V_m D_h}{\nu}$$

Where D_h = hydraulic diameter

$$D_h = D_o - D_i$$

$$D_h = 0.025\ \text{m} - 0.01\ \text{m}$$

$$D_h = 0.015\ \text{m}$$

Then Reynolds number is

$$\text{Re} = \frac{(0.729\ \text{m/s})(0.015\ \text{m})}{1.004 \times 10^{-6}\ \text{m}^2/\text{s}}$$

$$\text{Re} = 10891.434$$

Re >10,000 the flow is turbulent. Assume the flow is fully developed flow.

Step 4 of 5

Nusselt number is

$$Nu = \frac{hD_h}{k}$$

$$Nu = 0.023\text{Re}^{0.8}\,\text{Pr}^{0.4}$$

$$= 0.023(10891.434)^{0.8}(7.01)^{0.4}$$

$$Nu = 85.0517$$

And

$$h_o = \frac{k}{D_h} Nu$$

$$= \frac{0.598}{0.015} \times 85.0517$$

$$h_o = 3390.727\ \text{W/m}^2 \cdot °\text{C}$$

Step 5 of 5

By substituting h_o and h_i overall heat transfer coefficient becomes

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_o}}$$

$$U = \frac{1}{\frac{1}{4100} + \frac{1}{3390.727}}$$

$$\boxed{U = 1855.89\ \text{W/m}^2 \cdot °\text{C}}$$

Therefore the overall heat transfer coefficient of this heat exchanger is

$$U = 1855.89\ \text{W/m}^2 \cdot °\text{C}$$

Question: 22.020P

Repeat Prob. 22–19 by assuming a 2-mm-thick layer of limestone (k = 1.3 W/m·K) forms on the outer surface of the inner tube.

Step 1 of 5

Given

Heat exchanger with tube and shell diameters are $D_o = 0.01\ \text{m}$ and $D_s = 0.025\ \text{m}$

Temperature of water $T = 20°\text{C}$

Mass flow rates of water is $\dot{m} = 0.3\ \text{kg/s}$

Convection heat transfer coefficient $h_i = 4100\ \text{W/m}^2 \cdot \text{K}$

Thickness of the layer $L = 2\,\text{mm}$

Thermal conductivity of the limestone $k = 1.3\ \text{W/m.°C}$

Step 2 of 5

From saturated properties of water the properties of water at $T = 20°\text{C}$ are

$\nu = 1.004 \times 10^{-6}\ \text{m}^2/\text{s}$

$k = 0.598\ \text{W/m.°C}$

$\rho = 998\ \text{kg/m}^3$

$\text{Pr} = 7.01$

The overall heat transfer coefficient is determined by using the expression

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_o}}$$

The average velocity of water in the tube

$$V_m = \frac{\dot{m}}{\rho A_c}$$

$$V_m = \frac{\dot{m}}{\rho\left(\pi\left(\frac{D_o^2 - D_i^2}{4}\right)\right)}$$

$$V_m = \frac{0.3}{998\left(\pi\left(\frac{0.025^2 - 0.01^2}{4}\right)\right)}$$

$$V_m = 0.729\ \text{m/s}$$

Step 3 of 5

Reynolds number for the flow is expressed as

$$\text{Re} = \frac{V_m D_h}{\nu}$$

Where D_h = hydraulic diameter

$$D_h = D_o - D_i$$

$$D_h = 0.025\ \text{m} - 0.01\ \text{m}$$

$$D_h = 0.015\ \text{m}$$

Then Reynolds number is

$$\text{Re} = \frac{(0.729\ \text{m/s})(0.015\ \text{m})}{1.004 \times 10^{-6}\ \text{m}^2/\text{s}}$$

$$\text{Re} = 10891.434$$

Re >10,000 the flow is turbulent. Assume the flow is fully developed flow.

Step 4 of 5

Nusselt number is

$$Nu = \frac{hD_h}{k}$$

$$Nu = 0.023\text{Re}^{0.8}\,\text{Pr}^{0.4}$$

$$= 0.023(10891.434)^{0.8}(7.01)^{0.4}$$

$$Nu = 85.0517$$

And

$$h_o = \frac{k}{D_h} Nu$$

$$= \frac{0.598}{0.015} \times 85.0517$$

$$h_o = 3390.727\ \text{W/m}^2 \cdot °\text{C}$$

Step 5 of 5

By substituting h_o, h_i and lime stone k overall heat transfer coefficient becomes

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_o} + \left(\frac{L}{k}\right)}$$

$$U = \frac{1}{\frac{1}{4100} + \frac{1}{3390.727} + \frac{2 \times 10^{-3}}{1.3}}$$

$$\boxed{U = 481.397\ \text{W/m}^2 \cdot °\text{C}}$$

Therefore the overall heat transfer coefficient of this heat exchanger is

$U = 481.397\ \text{W/m}^2 \cdot °\text{C}$

Question: 22.021P

Reconsider Prob. 22–20. Using EES (or other) software, plot the overall heat transfer coefficient as a function of the limestone thickness as it varies from 1 mm to 3 mm, and discuss the results.

Step 1 of 3

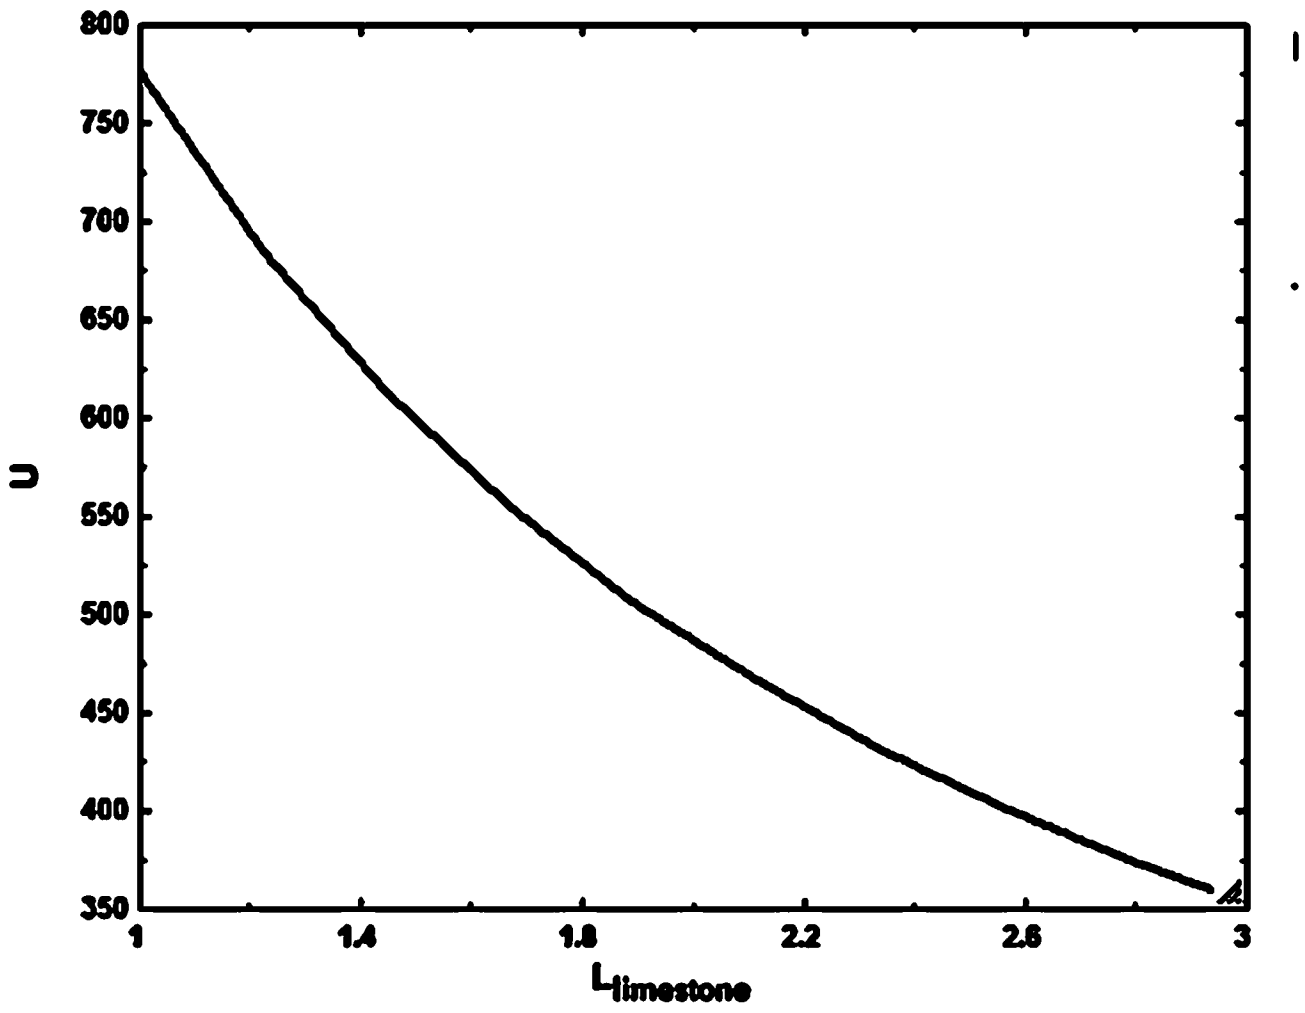
The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box.

```
"GIVEN"
D_i=0.010[m]
D_o=0.025[m]
T_w=20[C]
h_i=4100[W/m^2-C]
m_dot=0.3[kg/s]
""L_limestone=2[mm]""
k_limestone=1.3[W/m-C]
"PROPERTIES"
k=conductivity (Water, T=T_w, P=100)
Pr=Prandtl (Water, T=T_w, P=100)
Rho=density (Water, T=T_w, P=100)
Mu=viscosity (Water, T=T_w, P=100)
Nu=mu/rho
"ANALYSIS"
D_h=D_o-D_i
Vel=m_dot/(rho*A_c)
A_c=pi*(D_o^2-D_i^2)/4
Re=(Vel*D_i)/nu
"Re is calculated to be greater than 10,000. Therefore, the flow is turbulent."
Nusselt=0.023*Re^0.8*Pr^0.4
h_o=k/D_i*Nusselt
U=1/(1/h_i+(L_limestone*Convert(mm,m))/k_limestone+1/h_o)
```

Step 2 of 3

Now to solve the equation for a range of length values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select number of runs = 10
Select variables in equations as R_g and U_i press 'Add' and then press 'ok'
A table will appear and enter the values of length under ' R_g ' as 1,1.222,....2.778,3in runs 1 to 10
Then from click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below



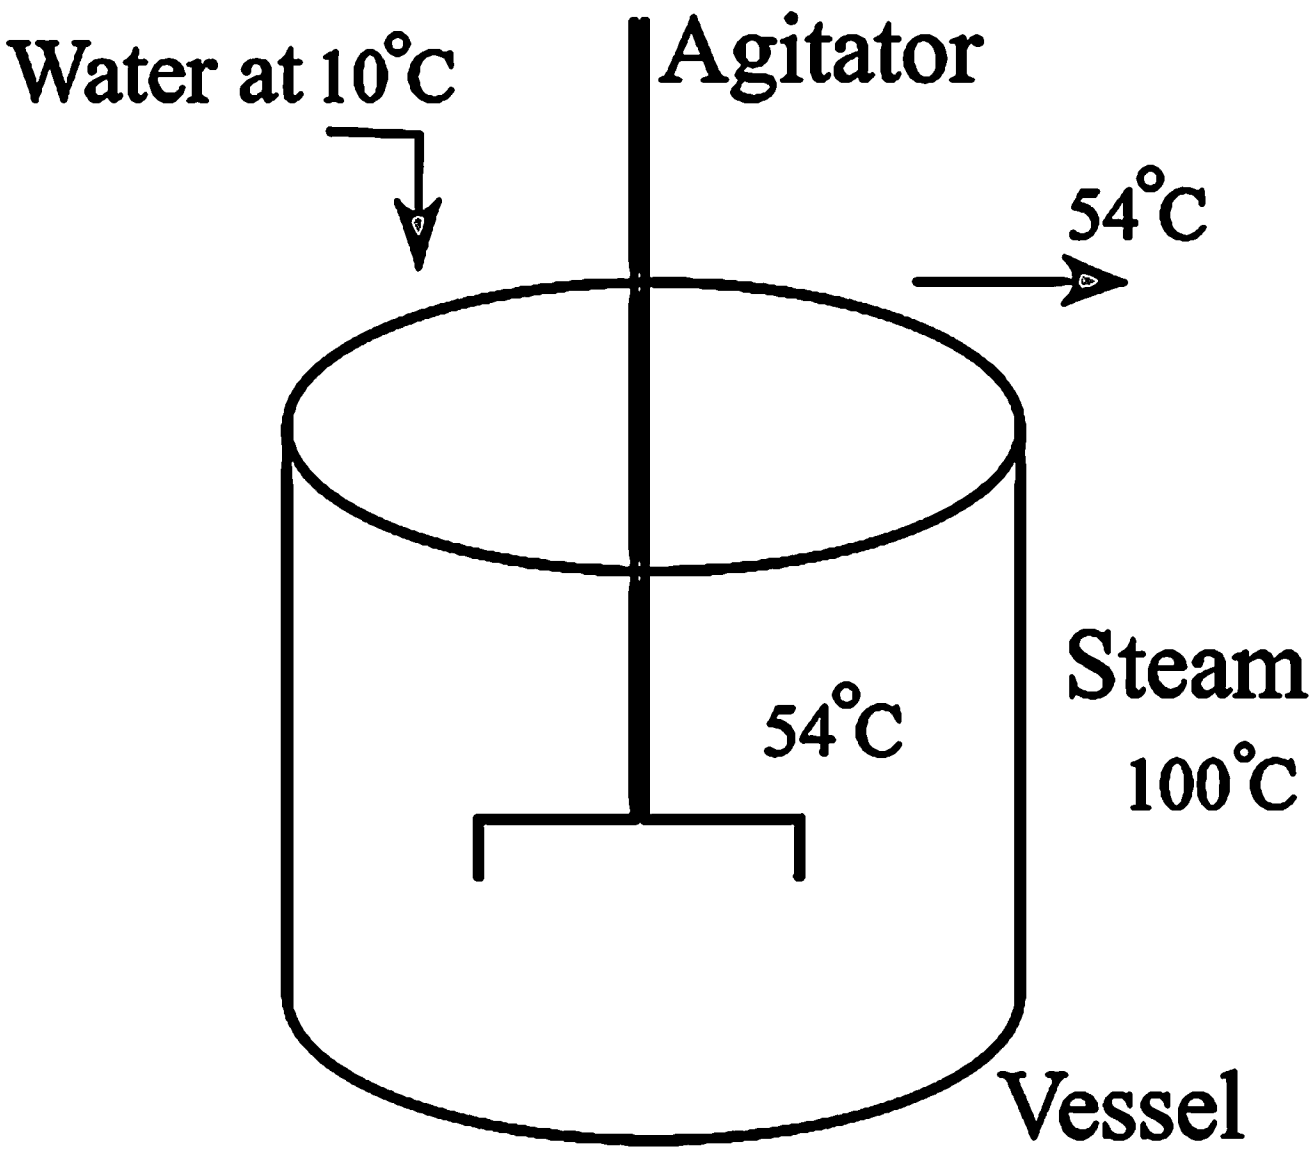
The following results are displayed:

1..10	1 $L_{limestone}$	2 U
Run 1	1	776.2
Run 2	1.222	685.2
Run 3	1.444	613.4
Run 4	1.667	555.2
Run 5	1.889	507.1
Run 6	2.111	466.6
Run 7	2.333	432.1
Run 8	2.556	402.4
Run 9	2.778	376.5
Run 10	3	353.7

Step 3 of 3

Select the plot on menu bar, and then click x-y plot .Dialog box will be appeared.
Select X-axis as $L_{limestone}$ and Y-axis as U .Press OK
The Graph will be plotted as shown below.

By plotting the graph between overall heat transfer and Length:



Question: 22.022P pg 1

A jacketted-agitated vessel, fitted with a turbine agitator, is used for heating a water stream from 10°C to 54°C. The average heat transfer coefficient for water at the vessel's inner-wall can be estimated from Nu = 0.76Re2/3 Re1/3. Saturated steam at 100°C condenses in the jacket, for which the average heat transfer coefficient in kW/m2·K is: *hO* = 13.1(*Tg* − *Tw*)−*0.25*. The vessel dimensions are: *Dt* = 0.6 m, *H* = 0.6 m and *Da* =0.2 m. The agitator speed is 60 rpm. Calculate the mass rate of water that can be heated in this agitated vessel steadily.

Step 1 of 9

Draw the diagram of jacketed-agitated vessel.

Step 2 of 9

Obtain the following properties of water at $54°C$ from table A-9, "properties of saturated water" in the text book.

Thermal conductivity, $k = 0.648\ W/m \cdot °C$

Density, $\rho = 985.8\ kg/m^3$

Absolute viscosity, $\mu = 0.513 \times 10^{-3}\ kg/m \cdot s$

Prandtl number, $Pr = 3.31$

Step 3 of 9

Calculate the average temperature of water.

$$T_m = \left(\frac{T_i + T_f}{2}\right)$$

Here, T_i is the initial temperature of water and T_f is the final temperature of water.

Substitute $10°C$ for T_i and $54°C$ for T_f .

$$T_m = \left(\frac{10+54}{2}\right)$$
$$= 32°C$$

Step 4 of 9

Obtain the specific heat at the average temperature of water at $32°C$ from Table A-9 "properties of saturated water" in the text book.

$$c_{pw} = 4178\ J/kg \cdot °C$$

Calculate the Reynolds number using the following relation:

$$Re = \frac{\rho n D_a^2}{\mu}$$

Substitute $985.8\ kg/m^3$ for ρ, 0.2 m for D_a, and $0.513 \times 10^{-3}\ kg/m \cdot s$ for μ .

$$Re = \frac{(985.8)\left(\frac{60}{60}\right)(0.2)^2}{0.513 \times 10^{-3}}$$
$$= 76865$$

Step 5 of 9

Calculate the Nusselts number using the following relation:

$$Nu = 0.76\, Re^{2/3}\, Pr^{1/3}$$

Substitute 76865 for Re and 3.31 for Pr .

$$Nu = 0.76\left[(76865)^{2/3} \times (3.31)^{1/3}\right]$$
$$= 2048$$

Step 6 of 9

Calculate the convective heat transfer coefficient on the inner wall of the vessel using the following relation:

$$h_i = \frac{k}{D_t} Nu$$

Substitute $0.6\ m$ for D_t, 2048 for Nu , and $0.648\ W/m \cdot °C$ for k .

$$h_i = \frac{0.648}{0.6} \times 2048$$

Substitute $0.6\,\text{m}$ for D_i, 2048 for Nu, and $0.648\,\text{W/m}^\circ\text{C}$ for k.

$$h_i = \frac{0.648}{0.6} \times 2048$$
$$= 2211\ \text{W/m}^2 \cdot ^\circ\text{C}$$

Step 7 of 9

Calculate the convective heat transfer coefficient on the outer side using the following relation:

$$h_o = 13100\left(T_s - T_w\right)^{-0.25}$$

Here, saturation steam temperature is T_s.

Substitute 100°C for T_s.

$$h_o = 13100\left(100 - T_w\right)^{-0.25} \quad \text{..... (1)}$$

Determine T_w using the following relation:

$$h_o\left(T_s - T_w\right) = h_i\left(T_w - 54\right)$$

Substitute $13100\left(100 - T_w\right)^{-0.25}$ for h_o, 100°C for T_s, and $2211\ \text{W/m}^2 \cdot ^\circ\text{C}$ for h_i.

$$\left[13100\left(100 - T_w\right)^{-0.25}\right]\left(100 - T_w\right) = 2211\left(T_w - 54\right)$$
$$13100\left(100 - T_w\right)^{0.75} = 2211\left(T_w - 54\right)$$
$$T_w = 89.2^\circ\text{C}$$

Substitute 89.2°C for T_w in equation (1).

$$h_o = 13100\left(100 - T_w\right)^{-0.25}$$
$$= 13100\left(100 - 89.2\right)$$
$$= 7226\ \text{W/m}^2 \cdot ^\circ\text{C}$$

Step 8 of 9

Calculate the overall heat transfer co-efficient using the following relation:

$$\frac{1}{U} = \frac{1}{h_i} + \frac{1}{h_o}$$

Substitute $2211\ \text{W/m}^2 \cdot ^\circ\text{C}$ for h_i and $7226\ \text{W/m}^2 \cdot ^\circ\text{C}$ for h_o.

$$\frac{1}{U} = \frac{1}{2211} + \frac{1}{7226}$$
$$U = 1694\ \text{W/m}^2 \cdot ^\circ\text{C}$$

Step 9 of 9

Write the energy balance equation to calculate the mass flow rate of water.

$$\dot{m}_w c_{pw}\left(T_{out} - T_{in}\right)_{water} = UA_s\Delta T$$
$$\dot{m}_w c_{pw}\left(T_{out} - T_{in}\right)_{water} = U\left(\pi D_i H\right)\left(T_s - T_{out}\right)$$

Substitute $4178\ \text{J/kg} \cdot ^\circ\text{C}$ for c_{pw}, 54°C for T_{out}, 10°C for T_i, $1694\ \text{W/m}^2 \cdot ^\circ\text{C}$ for U,

0.6 m for D_i, 0.6 m for H, 100°C for T_s.

$$\dot{m}_w(4178)(54 - 10) = 1694 \times \pi \times 0.6 \times 0.6(100 - 54)$$
$$\dot{m}_w = 0.479\ \text{kg/s}$$
$$= 1725\ \text{kg/hr}$$

Therefore, the mass rate of water that can be heated in the agitated vessel steadily is $\boxed{1725\ \text{kg/hr}}$.

Question: 22.023P

What are the common approximations made in the analysis of heat exchangers?

Step 1 of 4

A heat exchanger to be selected should achieve a specified temperature change in a fluid stream of known mass flow rate, or to predict the outlet temperatures of the hot and cold fluid streams in a specified heat exchanger.

Step 2 of 4

Methods used in the analysis:

- LMTD Method(log mean temperature difference)
- Effectiveness-NTU Method

Step 3 of 4

Approximations made in the analysis:

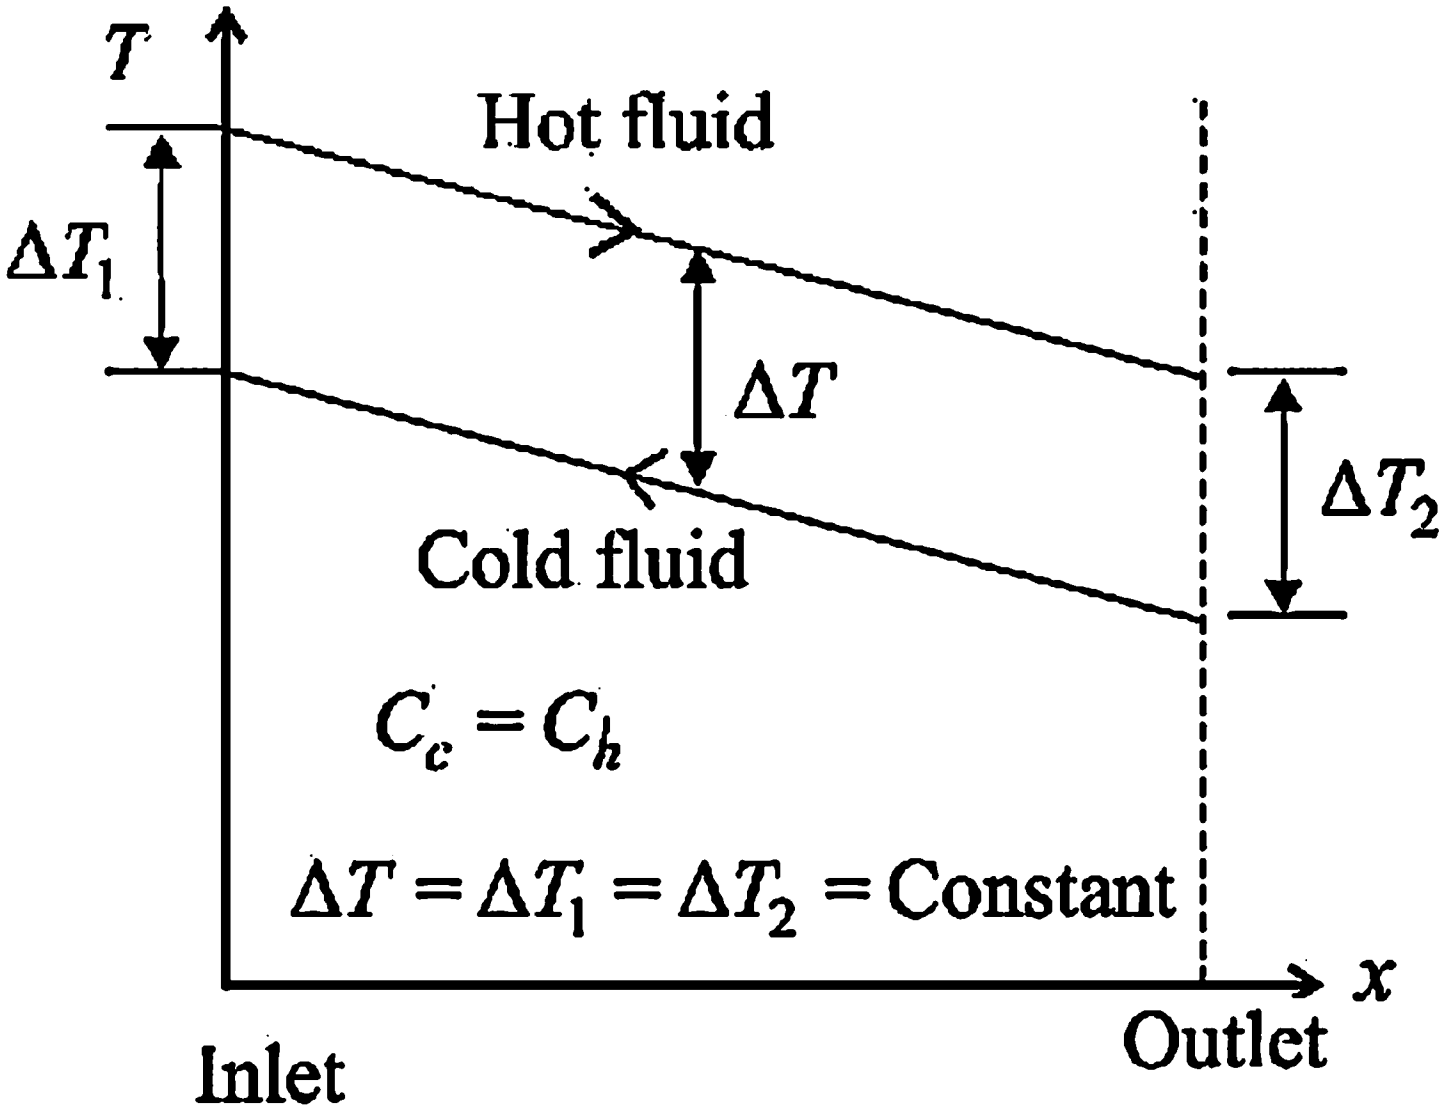
- Heat exchangers usually operate for long periods of time with no change in their operating conditions, and then they can be modeled as steady-flow devices.
- As such, the mass flow rate of each fluid remains constant and the fluid properties such as temperature and velocity at any inlet and outlet remain the same.
- The fluid streams experience little or no change in their velocities and elevations, and thus the kinetic and potential energy changes are negligible.

Step 4 of 4

- The specific heat of a fluid can be treated as constant for a specified temperature range.
- Axial heat conduction along the tube can be considered negligible.
- The outer surface of the heat exchanger is assumed to be perfectly insulated, so that there is no heat loss to the surrounding medium, and any heat transfer thus occurs is between the two fluids only.

Question: 22.024P

Under what conditions will the temperature rise of the cold fluid in a heat exchanger be equal to the temperature drop of the hot fluid?



Step 1 of 1

$$\dot{Q} = C_c(T_{c,out} - T_{c,in}) = C_h(T_{h,in} - T_{h,out})$$

That is, the heat transfer rate in a heat exchanger is equal to the heat capacity rate of either fluid multiplied by the temperature change of that fluid.

The only time the temperature rise of a cold fluid is equal to the temperature drop of the hot fluid is when the heat capacity rates of the two fluids are equal to each other.

When $C_c = C_h$, $\Delta T_1 = \Delta T_1$

Question:

22.025P

What is the heat capacity rate? What can you say about the temperature changes of the hot and cold fluids in a heat exchanger if both fluids have the same capacity rate? What does a heat capacity of infinity for a fluid in a heat exchanger mean?

Step 1 of 3

The product of mass flow rate and specific heat of fluid is called as heat capacity rate.

Heat capacity rate for hot fluids is given by $C_h = \dot{m}_h c_{ph}$

Heat capacity rate for hot fluids is given by $C_c = \dot{m}_c c_{pc}$

Step 2 of 3

$$\dot{Q} = \dot{m}_c c_{pc}(T_{c,out} - T_{c,in}) = \dot{m}_h c_{ph}(T_{h,in} - T_{h,out})$$

When $\dot{m}_c c_{pc} = \dot{m}_h c_{ph}$ then $\Delta T_c = \Delta T_h$

If the hot and cold fluids have the same heat capacity rate, it means that temperature difference of hot and cold fluids are equal. Then the temperature profiles of hot and cold fluids are straight lines.

Step 3 of 3

The heat capacity rate of the fluid during the phase change process must be infinity since the temperature change is practically zero.

That is $C = \dot{m}c_p \to \infty$ when $\Delta T \to 0$, so that heat transfer rate $Q = \dot{m}c_p \Delta T$ is an infinite quantity.

Question: 22.026P

Consider a condenser in which steam at a specified temperature is condensed by rejecting heat to the cooling water. If the heat transfer rate in the condenser and the temperature rise of the cooling water is known, explain how the rate of condensation of the steam and the mass flow rate of the cooling water can be determined. *Also,* explain how the total thermal resistance *R* of this condenser can be evaluated in this case.

Step 1 of 3

The mass flow rate of the cooling water is determined by

$$\dot{Q} = [\dot{m} C_p (\Delta T)]_{cooling\ water}$$

Here $(\Delta T)_{cooling\ water}$ & $\dot{Q}$ are given.

$$\dot{m}_{cooling\ water} = \frac{\dot{Q}}{c_p [T_{out} - T_{in}]}$$

Step 2 of 3

The rate of condensation of the steam is determined by

$$\dot{Q} = [\dot{m} h_{fg}]_{steam}$$

$$\dot{m}_{steam} = \frac{\dot{Q}}{h_{fg}}$$

Step 3 of 3

The total resistance of the condenser is

$$R = \frac{\dot{Q}}{\Delta T_{cooling\ water}}$$

Question: 22.027P

Under what conditions is the heat transfer relation

$$\dot{Q} = \dot{m}_c c_{pc}(T_{c,\text{out}} - T_{c,\text{in}}) = \dot{m}_h c_{ph}(T_{h,\text{in}} - T_{h,\text{out}})$$

valid for a heat exchanger?

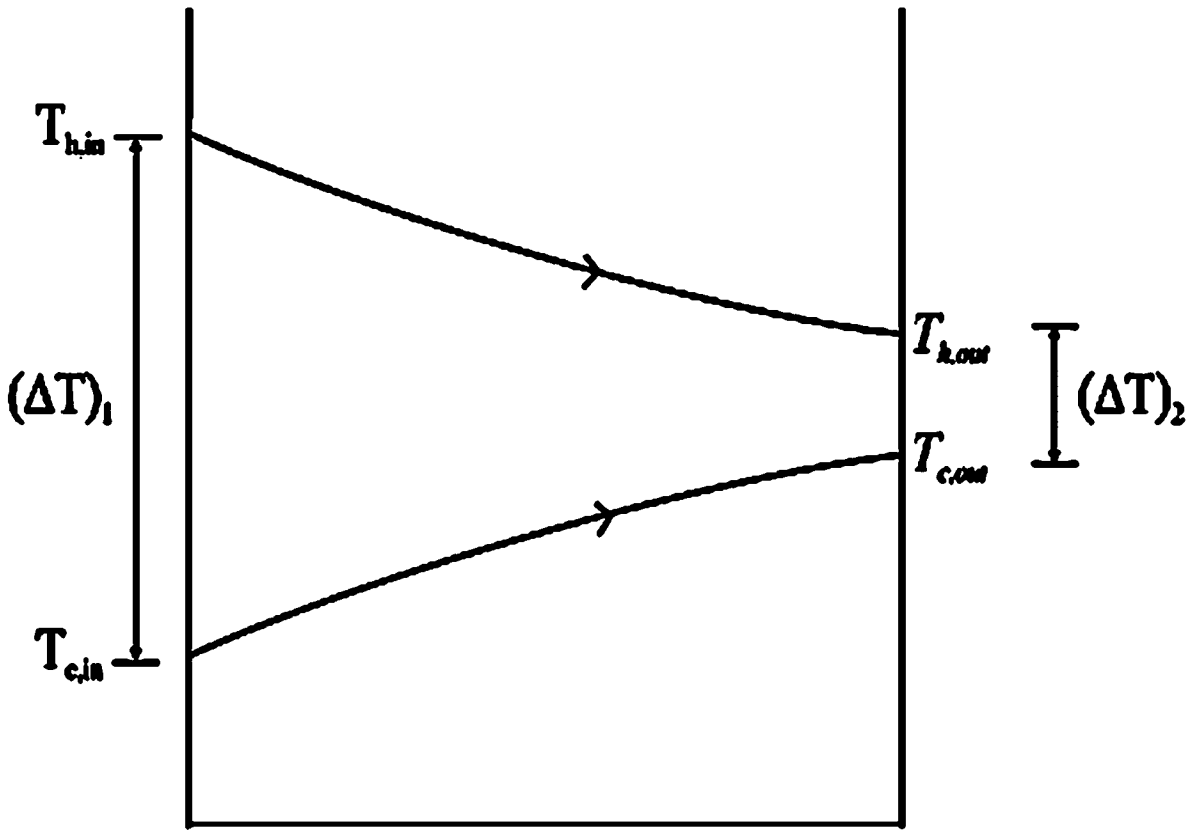
Step 1 of 1

The heat transfer relation $\dot{Q} = \dot{m}_c c_{pc}(T_{c,out} - T_{c,in}) = \dot{m}_h c_{ph}(T_{h,in} - T_{h,out})$ is valid under the following conditions.

1. The heat exchanger is insulated from its surroundings in which case the only heat exchange is between the hot and cold fluids.
2. Axial conduction along the tubes is negligible.
3. Potential and kinetic energy changes are negligible.
4. The fluid specific heats are constants.
5. The overall heat transfer coefficient is constant.

Question: 22.028P

In the heat transfer relation $\dot{Q}$ = UAsΔTlm for a heat exchanger, what is ΔTlm called? How is it calculated for a parallel-flow and counter-flow heat exchanger?



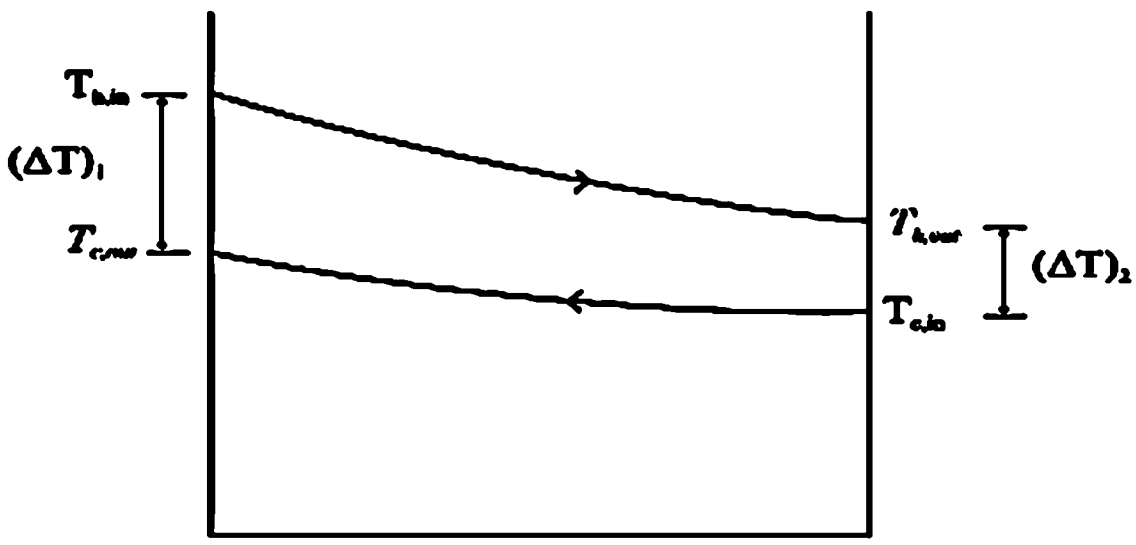
Step 1 of 2

In the heat transfer relation $\dot{Q} = UA_s\Delta T_{lm}$ where ΔT_{lm} is the log mean temperature difference.

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln \frac{\Delta T_1}{\Delta T_2}}$$

For parallel flow

$$\Delta T_1 = T_{h,in} - T_{c,in}$$
$$\Delta T_2 = T_{h,out} - T_{c,out}$$



Parallel flow

Step 2 of 2

For counter flow

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$

Counter flow

Question: 22.029P

How does the log mean temperature difference for a heat exchanger differ from the arithmetic mean *temperature* difference? For specified inlet and outlet temperatures, which one of these two quantities is larger?

Step 1 of 3

The arithmetic mean temperature difference:

$$\Delta T_{am} = \frac{\Delta T_1 - \Delta T_2}{2}$$

Step 2 of 3

The logarithmic mean temperature difference ΔT_{lm} is obtained by tracing the actual temperature profile of the fluids along the heat exchanger and is an exact representation of the average temperature difference between the hot and cold fluids. It truly reflects the exponential decay of the local temperature difference.

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)}$$

Step 3 of 3

Log mean temperature difference ΔT_{lm} is always less than arithmetic temperature difference ΔT_{am}.

Using ΔT_{am} in calculations instead of ΔT_{lm} will overestimate the rate of heat transfer in a heat exchanger between the two fluids.

Therefore, we should always use logarithmic mean temperature difference ΔT_{lm} when determining the rate of heat transfer in a heat exchanger.

Question: 22.030P

The temperature difference between the hot and cold fluids in a heat exchanger is given to be $\Delta T1$, at one end and $\Delta T2$, at the other end. Can the logarithmic temperature difference $\Delta T1m$ of this heat exchanger be greater than both $\Delta T1$, and $\Delta T2$? Explain.

Step 1 of 1

ΔT_{lm} Cannot be greater than both ΔT_1 and ΔT_2 because ΔT_{lm} gives the exact representation of the mean temperature difference between the hot and cold fluids.

Question: 22.031P

Can the outlet temperature of the cold fluid in a heat exchanger be higher than the outlet temperature of the hot fluid in a parallel-flow heat exchanger? How about in a counter-flow heat exchanger? Explain.

Step 1 of 1

In case of parallel flow heat exchanger hot and cold fluids are in the same direction and the temperature of the hot fluid decreases and the temperature of the cold fluid increases across the heat exchanger, but the temperature of the cold fluid never exceed that of the hot fluid no matter how long the heat exchanger is.

In case of the counter flow heat exchanger hot and cold fluids enter the heat exchanger from opposite ends, and the outlet temperature of the cold fluid in this case may exceed the outlet temperature of the hot fluid. In the limiting case, the cold fluid will be heated to the inlet temperature of the hot fluid. However, the outlet temperature of the cold fluid never exceeds the inlet temperature of the hot fluid, since this would be a violation of the 2^{nd} law of thermodynamics.

Question: 22.032P

Explain how the LMTD method can be used to determine the heat transfer surface area of a multipass shell-and-tube heat exchanger when all the necessary information, including the outlet temperatures, is given.

Step 1 of 1

Basic relation to determine the heat transfer surface area is

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

Since $\dot{Q} = UA_sF\Delta T_{lm}$

Overall heat transfer coefficient U will be given.

So in order to calculate A_s, correction factor F, ΔT_{lm} must be calculated as follows.

For F:

We have to find $P = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$ and $R = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$.

At this P & R, F can be found from table-correction factor F for common shell and tube and cross flow heat exchangers

For ΔT_{lm}:

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

Question: 22.033P

In the heat transfer relation $\dot{Q} = UA_s F \Delta T_{lm}$ for a heat exchanger, what is the quantity *F* called? What does it represent? Can *F* be greater than one?

Step 1 of 1

In the heat transfer relation $\dot{Q} = [\dot{m} C_p (\Delta T)]_{cooling\ water}$

F is called correction factor, which depends on the geometry of the heat exchanger and the inlet and outlet temperature of the hot and cold fluid streams.

The correction factor is less than unity for a cross-flow and multipass shell-and-tube heat exchanger. That is, $F \leq 1$.

The limiting value of $F = 1$ corresponds to the counter-flow heat exchanger.

Thus correction factor F is a measure of deviation of the ΔT_{lm} from the corresponding values for the counter flow.

Question: 22.034P

When the outlet temperatures of the fluids in a heat exchanger are not known, is it still practical to *use* the LMTD method? Explain.

Step 1 of 1

The LMTD method could still be used when outlet temperatures of the hot and cold fluids are not given, but the procedure would require tedious iterations, and thus it is not practical. In an attempt to eliminate the iterations from the solution of such problems, it is preferable to use NTU method.

Question: 22.035P

For specified inlet and outlet temperatures, for what kind of heat exchanger will the ΔT_{lm} be greatest: double-pipe parallel-flow, double-pipe counter-flow, cross-flow, or multipass shell-and-tube heat exchanger?

Step 1 of 1

For specified inlet and outlet temperature ΔT_{lm} will be more for double-pipe counter flow heat exchanger.

Question: 22.036P

A counter-flow heat exchanger is stated to have an overall heat transfer coefficient of 284 W/m2·K when operating at design and clean conditions. Hot fluid enters the tube side at 93°C and exits at 71°C, while cold fluid enters the shell side at 27°C and exits at 38°C. After a period of use, built-up scale in the heat exchanger gives a fouling factor of 0.0004 m2·K/W. If the surface area is 93 m2, determine (*a*) the rate of heat transfer in the heat exchanger and (*b*) the mass flow rates of both hot and cold fluids. Assume both hot and cold fluids have a spe*cific* heat of 4.2 kJ/kg·K.

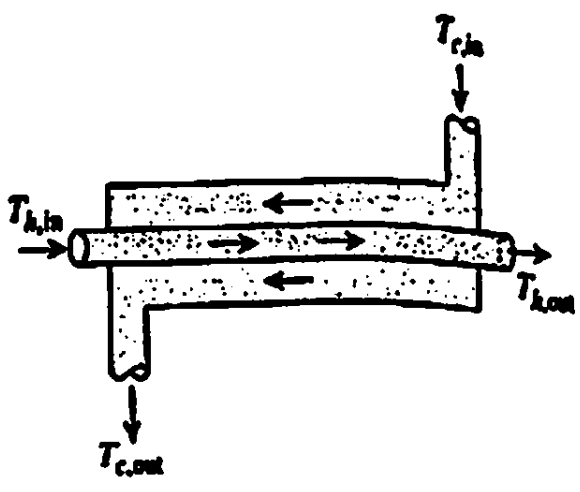


FIGURE P22–36

Step 1 of 5

(*a*)

Calculate the overall heat transfer coefficient, $U_{\text{W/scale}}$ after a period of use due to scale build up from the following relation.

$$\frac{1}{U_{\text{W/scale}}} = R_f + \frac{1}{U_{\text{W/No scale}}}$$

Here, $U_{\text{W/No scale}}$ is the overall heat transfer coefficient at design and clean conditions and

R_f is the fouling factor.

Substitute $284\ \text{W/m}^2\cdot\text{K}$ for $U_{\text{W/No scale}}$ and $0.0004\ \text{m}^2\cdot\text{K/W}$ for R_f.

$$\frac{1}{U_{\text{W/scale}}} = 0.0004\ \text{m}^2\cdot\text{K/W} + \frac{1}{284\ \text{W/m}^2\cdot\text{K}}$$

$$\frac{1}{U_{\text{W/scale}}} = 0.00392\ \text{W/m}^2\cdot\text{K}$$

$$U_{\text{W/scale}} = 255\ \text{W/m}^2\cdot\text{K}$$

Step 2 of 5

Calculate the temperature difference, ΔT_1.

$$\Delta T_1 = T_{h,i} - T_{c,o}$$

Here, $T_{h,i}$ is the inlet temperature of the hot fluid and $T_{c,o}$ is the outlet temperature of cold fluid.

Substitute $93°\text{C}$ for $T_{h,i}$ and $38°\text{C}$ for $T_{c,o}$.

$$\Delta T_1 = 93°\text{C} - 38°\text{C}$$
$$= 55°\text{C}$$

Calculate the temperature difference, ΔT_2.

$$\Delta T_2 = T_{h,o} - T_{c,i}$$

Here, $T_{h,o}$ is the outlet temperature of hot fluid and $T_{c,i}$ is the inlet temperature of the cold fluid.

Substitute $71°\text{C}$ for $T_{h,o}$ and $27°\text{C}$ for $T_{c,i}$.

$$\Delta T_2 = 71°\text{C} - 27°\text{C}$$
$$= 44°\text{C}$$

Step 3 of 5

Calculate the log mean temperature difference of the heat exchanger from the following relation.

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)}$$

Substitute $55°\text{C}$ for ΔT_1 and $44°\text{C}$ for ΔT_2.

$$\Delta T_{lm} = \frac{55°\text{C} - 44°\text{C}}{\ln(55°\text{C}/44°\text{C})}$$
$$= 49.295\ \text{K}$$

Step 4 of 5

Calculate the rate of heat transfer in the heat exchanger from the following relation.

$$\dot{Q} = U_{\text{W/scale}} A_s (\Delta T_{lm})$$

Here, surface area of the heat exchanger is A_s.

Substitute $255\ \text{W/m}^2\cdot\text{K}$ for $U_{\text{W/scale}}$, $93\ \text{m}^2$ for A_s, and $49.295\ \text{K}$ for ΔT_{lm}.

$$\dot{Q} = (255\ \text{W/m}^2\cdot\text{K}) \times (93\ \text{m}^2) \times (49.295\ \text{K})$$
$$= 1.169\times10^6\ \text{W}$$

Therefore, the rate of heat transfer in the heat exchanger is $\boxed{1.169\times10^6\ \text{W}}$.

Step 5 of 5

(*b*)

Calculate the mass flow rate of hot fluid from the following heat transfer rate relation.

$$\dot{Q} = (\dot{m} c_p \Delta T)_h$$
$$= \dot{m}_h c_p (\Delta T)_h$$
$$= \dot{m}_h c_p (T_{h,i} - T_{h,o})$$

Here, c_p is the heat transfer coefficient, $\dot{m}_h$ is the mass flow rate of the hot fluid, and $(\Delta T)_h$ is the temperature difference between inlet and outlet of hot fluid.

Substitute $1.17\times10^6\ \text{W}$ for $\dot{Q}$, $4.2\times1000\ \text{J/kg·K}$ for c_p, $93°\text{C}$ for $T_{h,i}$, and $71°\text{C}$ for $T_{h,o}$.

$$1.17\times10^6\ \text{W} = m_h \times (4.2\times1000\ \text{J/kg·K}) \times (93-71)\text{K}$$

$$m_h = \frac{1.17\times10^6\ \text{W}}{(4{,}200\ \text{J/kg·K}) \times (22\text{K})}$$
$$= 12.66\ \text{kg/s}$$

Therefore, the mass flow rate of hot fluid is $\boxed{12.66\ \text{kg/s}}$.

Calculate the mass flow rate of cold fluid from the following heat transfer rate relation.

$$\dot{Q} = (\dot{m} c_p \Delta T)_c$$
$$= \dot{m}_c c_p (\Delta T)_C$$
$$= \dot{m}_c c_p (T_{c,o} - T_{c,i})$$

Here, c_p is the heat transfer coefficient, $\dot{m}_c$ is the mass flow rate of cold fluid, and $(\Delta T)_c$ is the temperature difference between outlet and inlet of cold fluid.

Substitute $1.17\times10^6\ \text{W}$ for $\dot{Q}$, $4.2\times1000\ \text{J/kg·K}$ for c_p, $38°\text{C}$ for $T_{c,o}$, and $27°\text{C}$ for $T_{c,i}$.

$$1.17\times10^6\ \text{W} = \dot{m}_c \times (4.2\times1000\ \text{J/kg·K}) \times (38-27)\text{K}$$

$$\dot{m}_c = \frac{1.17\times10^6\ \text{W}}{(4{,}200\ \text{J/kg·K}) \times (11\text{K})}$$
$$= 25.32\ \text{kg/s}$$

Therefore, the mass flow rate of cold fluid is $\boxed{25.32\ \text{kg/s}}$.

Question: 22.037P

A single-pass cross-flow heat exchanger is used to cool jacket water (cp = 1.0 Btu/lbm·°F) of a diesel engine from 190°F to 140°F, using air (cp = 0.245 Btu/lbm·°F) with inlet temperature of 90°F. Both air flow and water flow are unmixed. If the water and air mass flow rates are 92,000 lbm/h and 400,000 lbm/h, respectively, determine the log mean temperature difference for this heat exchanger.

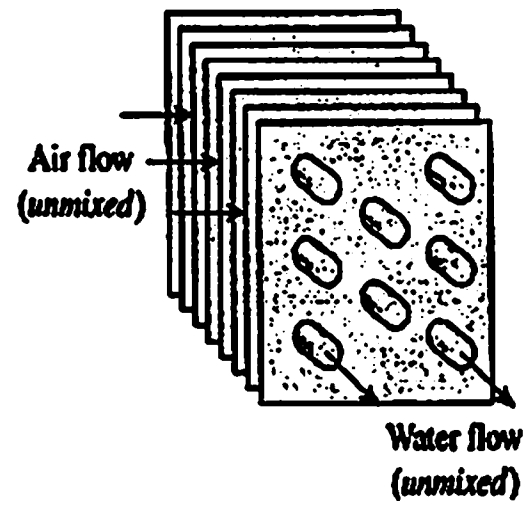

FIGURE P22–37E

Step 1 of 5

The specific heat of water, $c_{p,h} = 1 \text{ Btu/lbm} \cdot °\text{F}$

The specific heat of air, $c_{p,c} = 0.245 \text{ Btu/lbm} \cdot °\text{F}$

Inlet temperature of water, $T_{h,i} = 190°\text{F}$

Exit temperature of water, $T_{h,e} = 140°\text{F}$

Inlet temperature of air, $T_{c,i} = 90°\text{F}$

Mass flow rate of water, $\dot{m}_h = 92{,}000 \text{ lbm/h}$

Mass flow rate of air, $\dot{m}_c = 400{,}000 \text{ lbm/h}$

Step 2 of 5

Heat given out by the jacket water:

$$\begin{aligned}\dot{Q} &= \left(\dot{m}c_p\right)_h \left(T_{h,i} - T_{h,e}\right) \\ &= 92{,}000 \times 1 \times (190 - 140) \\ &= 4{,}600{,}000 \text{ Btu/h}\end{aligned}$$

Step 3 of 5

This amount of heat is absorbed by the air. Therefore, the expression for heat transfer is given by,

$$\begin{aligned}\dot{Q} &= \left(\dot{m}c_p\right)_c \left(T_{c,e} - T_{c,i}\right) \\ &= 400{,}000 \times 0.245 \times \left(T_{c,e} - 90\right) \\ T_{c,e} &= \frac{4{,}600{,}000}{400{,}000 \times 0.245} + 90 \\ &= 136.938°\text{F}\end{aligned}$$

Step 4 of 5

Determination of Log Mean Temperature Difference:

$$\begin{aligned}\Delta T_1 &= T_{h,i} - T_{c,e} \\ &= 190 - 136.938 \\ &= 53.061°\text{C}\end{aligned}$$

$$\begin{aligned}\Delta T_2 &= T_{h,e} - T_{c,i} \\ &= 140 - 90 \\ &= 50°\text{C}\end{aligned}$$

Step 5 of 5

The log mean temperature difference of the given heat exchanger is given by,

$$\begin{aligned}\Delta T_{lm} &= \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)} \\ &= \frac{53.061 - 50}{\ln\left(53.061/50\right)} \\ &= 51.515 \text{ °F}\end{aligned}$$

Therefore, the log mean temperature difference is found to be $\boxed{\Delta T_{lm} = 51.515 \text{ °F}}$.

Question:

Ethylene glycol is heated from 25°C to 40°C at a rate of 1.5 kg/s in a horizontal copper tube (k = 386 W/m·K) with an inner diameter of 2.0 cm and an outer diameter of 2.5 cm. A saturated vapor (Tg = 110°C) condenses on the outside-tube surface with the heat transfer coefficient (in kW/m2·K) given by $9.2/(Tg - Tw)0.25$, where Tw is the average outside-tube wall temperature. What tube length must be used? Take the properties of ethylene glycol to be ρ = 1109 kg/m3, cp = 2428 kJ/kg·K, k = 0.253 W/m·K, μ = 0.01545 kg/m·s, and Pr = 148.5.

Step 1 of 10

Initial temperature of the ethylene glycol, $T_i = 25°C$

Final temperature of the ethylene glycol, $T_f = 40°C$

Mass flow rate is given by, $m = 1.5\ kg/s$

Thermal conductivity of copper, $k = 386\ W/m \cdot K$

Inner diameter of the copper tube, $D_i = 2.0cm = 0.2m$

Outer diameter of the copper tube, $D_o = 2.5cm = 0.25m$

Saturated waster temperature, $T_g = 110°C$

Let L be the length of tube.

Step 2 of 10

Heat transfer coefficient of the condenser,

$$h_o = 9.2/(T_g - T_w)^{0.25}\ kW/m^2 \cdot K$$
$$= 9200/(T_g - T_w)^{0.25}\ W/m^2 \cdot K$$

Average temperature of the ethylene glycol, $T_{b,av} = 30°C$

Properties of ethylene glycol,

Density of ethylene glycol, $\rho = 1109\ kg/m^3$

Specific heat at constant pressure, $c_p = 2428\ kJ/kg \cdot K$

Thermal conductivity of ethylene glycol, $k_g = 0.253\ W/m \cdot K$

Viscosity of ethylene glycol, $\mu = 0.01545\ kg/m \cdot s$

Prandtl number, $Pr = 148.5$

Step 3 of 10

The heat transfer coefficient,

$$\frac{1}{U_o A_o} = \frac{1}{h_0 A_o} + \frac{\ln(D_o/D_i)}{2\pi kL} + \frac{1}{h_i A_i}$$ (since surface area of a cylinder, $A = \pi DL$)

$$\frac{1}{U_o \pi D_o L} = \frac{1}{h_o \pi D_o L} + \frac{\ln(D_o/D_i)}{2\pi kL} + \frac{1}{h_i \pi D_i L}$$

$$\frac{1}{U_o} = \frac{1}{h_0} + \frac{\pi D_o L \ln(D_o/D_i)}{2\pi kL} + \frac{\pi D_o L}{h_i \pi D_i L}$$

$$= \frac{1}{h_0} + \frac{D_o \ln(D_o/D_i)}{2k} + \frac{D_o}{h_i D_i} \quad \text{..... (1)}$$

Step 4 of 10

Heat lost to the condenser must be equal to the heat transfer from the ethylene glycol to the outer tube wall. We have,

$$\dot{Q} = h_o A_o (T_g - T_w)$$
$$h_o A_o (T_g - T_w) = \dot{Q}$$

$$h_o A_o (T_g - T_w) = \frac{T_w - T_{b,av}}{\left[\frac{\ln(D_o/D_i)}{2\pi kL} + \frac{1}{h_i A_i}\right]}$$ (but its know, $h_o = 9.2/(T_g - T_w)^{0.25}$)

$$\left[\frac{9200}{(T_g - T_w)^{0.25}}\right] \pi D_o L (T_g - T_w) = \frac{T_w - T_{b,av}}{\left[\frac{\ln(D_o/D_i)}{2\pi kL} + \frac{1}{h_i \pi D_i L}\right]}$$

$$9200(T_g - T_w)^{0.75} = \frac{T_w - T_{b,av}}{\left[\frac{\pi D_o L \ln(D_o/D_i)}{2\pi kL} + \frac{\pi D_o L}{h_i \pi D_i L}\right]}$$

$$= \frac{T_w - T_{b,av}}{\frac{D_o \ln(D_o/D_i)}{2k} + \frac{D_o}{h_i D_i}} \quad \text{..... (2)}$$

Step 5 of 10

The velocity of flow is given by,

$$V = \frac{\dot{m}}{\rho A}$$
$$= \frac{\dot{m}}{\rho(\pi D_i^2/4)}$$
$$= \frac{1}{1109\frac{\pi}{4}(0.02)^2}$$
$$= 2.870\ m/s$$

Step 6 of 10

Reynolds number is given by,

$$Re = \frac{\rho V D}{\mu}$$

Step 6 of 10

Reynolds number is given by,

$$\begin{aligned}\mathrm{Re} &= \frac{\rho V D}{\mu}\\ &= \frac{11092.870(0.02)}{0.01545}\\ &= 4120.16\end{aligned}$$

This is a transition flow we will use the equation for fully developed turbulent flow in this case.

Nusselt number is given by,

$$\begin{aligned}Nu &= 0.023\,\mathrm{Re}^{0.8}\,\mathrm{Pr}^{0.4}\\ &= 0.023(4120.16)^{0.8}(148.5)^{0.4}\\ &= 132.54\end{aligned}$$

Heat transfer coefficient of inner surface,

$$\begin{aligned}h_i &= \frac{kNu}{D_i}\\ &= \frac{132.54\times 0.253}{0.02}\\ &= 1676.64\ \mathrm{W/m^2\cdot K}\end{aligned}$$

Step 7 of 10

Substituting the value of heat transfer coefficient h_i and other parameters in equation (2) we have,

$$9200(T_g - T_w)^{0.75} = \frac{T_w - T_{b,mix}}{\frac{D_o \ln(D_o/D_i)}{2k} + \frac{D_o}{h_i D_i}}$$

$$\begin{aligned}9200(110 - T_w)^{0.75} &= \frac{T_w - 30^\circ}{\frac{0.025\ln[0.025/0.02]}{2\times 385} + \frac{0.025}{1677\times 0.02}}\\ &= \frac{T_w - 30}{7.24\times 10^{-6} + 745.4\times 10^{-6}}\\ &= \frac{T_w - 30}{752.65\times 10^{-6}}\\ T_w &= 91.58^\circ\mathrm{C}\end{aligned}$$

Step 8 of 10

The overall heat transfer coefficient from equation (1),

$$\begin{aligned}\frac{1}{U_o} &= \frac{1}{h_o} + \frac{D_o \ln(D_o/D_i)}{2k} + \frac{D_o}{h_i D_i}\\ &= \frac{(T_g - T_w)^{0.25}}{9200} + \frac{D_o \ln(D_o/D_i)}{2k} + \frac{D_o}{h_i D_i}\\ &= \frac{(110 - 91.58)^{0.25}}{9200} + \frac{0.025\ln[0.025/0.02]}{2\times 385} + \frac{0.025}{1677\times 0.02}\\ &= 9.706\times 10^{-4}\\ U_o &= 1030.3\ \mathrm{W/m^2.^\circ C}\end{aligned}$$

Step 9 of 10

Heat transfer is given by,

$$\begin{aligned}\dot{Q} &= \dot{m} c_p (T_f - T_i)\\ &= 1\times 2428(40 - 20)\\ &= 48560\ W\end{aligned}$$

The log-mean temperature difference for this heat exchanger,

$$\begin{aligned}\Delta T_{lm} &= \frac{(T_g - T_i) - (T_g - T_f)}{\ln\left(\frac{T_g - T_i}{T_g - T_f}\right)}\\ &= \frac{(110^\circ - 20^\circ) - (110^\circ - 40^\circ)}{\ln\left(\frac{110^\circ - 20^\circ}{110^\circ - 40^\circ}\right)}\\ &= 79.58^\circ\mathrm{C}\end{aligned}$$

Step 10 of 10

The length of the heat exchange can be calculated as,

$$\begin{aligned}\dot{Q} &= U_o A_o \Delta T_{lm}\\ &= U_o \pi D_o L \Delta T_{lm}\\ L &= \frac{\dot{Q}}{U_o \pi D_o \Delta T_{lm}}\\ &= \frac{48560}{1030\times \pi \times 0.025\times 79.58^\circ}\\ &= 7.54\end{aligned}$$

Therefore the length of the heat exchanger is obtained as $\boxed{7.54\,\mathrm{m}}$

Question: 22.039P

A test is conducted to determine the overall heat transfer coefficient in a shell-and-tube oil-to-water heat exchanger that has 24 tubes of internal diameter 1.2 cm and length 2 m in a single shell. Cold water (*cp* = 4180 J/kg·K) enters the tubes at 20°C at a rate of 3 kg/s and leaves at 55°C. Oil (*cp* = 2150 J/kg·K) flows through the shell and is cooled from 120°C to 45°C. Determine the overall heat transfer coefficient *Ui* of this heat exchanger based on the inner surface area of the tubes.

Step 1 of 10

Given

Number of tubes $N = 24$

Internal diameter $D_i = 1.2\text{cm}$

$$D_i = 0.012\text{m}$$

Length of shell $L = 2\text{m}$

For water:

$$T_{c,in} = 20^0\text{C}$$

$$T_{c,out} = 55^0\text{C}$$

$$\dot{m} = 3\text{kg/s}$$

The specific heat of water, $c_p = 4180\ \text{J/kg.}^\circ\text{C}$

For oil:

$$T_{h,in} = 120^0\text{C}$$

$$T_{h,out} = 45^0\text{C}$$

Step 2 of 10

The rate of heat transfer in this radiator from the cold water to the oil is determined by an energy balance.

$$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{water}$$

$$= (3\ \text{kg/s})(4180\ \text{J/kg.}^\circ\text{C})[55\text{-}20]^\circ\text{C}$$

$$\dot{Q} = 438.9\ \text{kW}$$

Step 3 of 10

The total surface area of tube:

$$A_i = N\pi D_i L$$

$$= (24)(\pi)(.012\ \text{m})(2\ \text{m})$$

$$A_i = 1.8096\ \text{m}^2$$

Step 4 of 10

The overall heat transfer coefficient can be found using the relation

$$\dot{Q} = U_i A_i F \Delta T_{lm}\ \text{kW}$$

$$U_i = \frac{\dot{Q}}{A_i F \Delta T_{lm}}\ \text{W/m}^2\text{.}^\circ\text{C}$$

Where F is the correction factor and

ΔT_{lm} is the log mean temperature difference of the heat exchanger.

Step 5 of 10

$$\Delta T_1 = (T_{h,in} - T_{c,out})$$

$$= (120 - 55)$$

$$\Delta T_1 = 65^\circ\text{C}$$

Step 6 of 10

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= 45 - 20$$

$$\Delta T_2 = 25^\circ\text{C}$$

Step 7 of 10

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined by

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$= \frac{65 - 25}{\ln\left(\frac{65}{25}\right)}$$

$$\Delta T_{lm} = 41.862^\circ\text{C}$$

Step 8 of 10

And

$$P = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$$

$$= \frac{55 - 20}{120 - 20}$$

$$P = 0.35$$

Step 9 of 10

$$R = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$$

$$= \frac{120 - 45}{55 - 20}$$

$$R = 2.15$$

Step 10 of 10

At these P and R values $F = 0.7$ (From correction factor F charts for common shell and tube and cross flow heat exchangers (a))

By substituting the values overall heat transfer coefficient become

$$U_i = \frac{\dot{Q}}{A_i F \Delta T_{lm}}\ \text{W/m}^2\text{°C}$$

$$= \frac{438.9\ \text{W}}{(1.80956\ \text{m}^2)(0.7)(41.862^\circ\text{C})}$$

$$\therefore U_i = 8.277\ \text{kW/m}^2\text{°C}$$

Question: 22.040P

A stream of hydrocarbon (*cp* = 2.2 kJ/kg·K) is cooled at a rate of 720 kg/h from 150°C to 40°C in the tube side of a double-pipe counter-flow heat exchanger. Water (*cp* =4.18 kJ/kg·K) enters the heat exchanger at 10°C at a rate of 540 kg/h. The outside diameter of the inner tube is 2.5 cm, and its length is 6.0 m. Calculate the overall heat transfer coefficient.

Step 1 of 5

Flow rate of hydrocarbon,

$$\begin{aligned}\dot{m}_h &= 720 \text{ kg/h} \\ &= \frac{720}{3600} \\ &= 0.2 \text{ kg/s}\end{aligned}$$

Flow rate of water,

$$\begin{aligned}\dot{m}_w &= 540 \text{ kg/h} \\ &= \frac{540}{3600} \\ &= 0.15 \text{ kg/s}\end{aligned}$$

Step 2 of 5

The rate of heat transfer from the hydrocarbon,

$$\dot{Q} = \dot{m} c_{p,h} (T_{out} - T_{in})$$

Here T_{in} is the inlet temperature of hydrocarbon, T_{out} is the outlet temperature of hydrocarbon, $c_{p,h}$ Specific heat of hydrocarbon, and $c_{p,w}$ Specific heat of water

Substitute 150°C for T_{in}, 40°C for T_{out}, 2.2 kJ/kg·K for $c_{p,h}$, 4.18 kJ/kg·K for $c_{p,w}$

$$\begin{aligned}\dot{Q} &= 0.2 \times (2.2) \times (150 - 40) \\ &= 48.4 \text{ kW}\end{aligned}$$

The heat transfer from the hydrocarbon to water,

$$\dot{Q} = \left(\dot{m} c_p (T_{out} - T_{in})\right)_w$$

The temperature of the heat exchanger, $T_{w_in} = 10°C$

$$\begin{aligned}48.4 &= 0.15 \times (4.18) \times (T_{w_out} - 10) \\ T_{w_out} &= 87.19°C\end{aligned}$$

Step 3 of 5

Since it is a counter flow heat exchanger the temperature difference between the hydrocarbon and the water at the two ends of the condenser is

$$\begin{aligned}\Delta T_1 &= T_{h,in} - T_{w,out} \\ &= (150 - 87.19) \\ &= 62.81°C \\ \Delta T_2 &= T_{h,out} - T_{w,in} \\ &= 40 - 10 \\ &= 30°C\end{aligned}$$

Step 4 of 5

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which can be determined by using below formula,

$$\begin{aligned}\Delta T_{lm} &= \frac{\Delta T_1 - \Delta T_2}{\ln \frac{\Delta T_1}{\Delta T_2}} \\ &= \frac{62.81 - 30}{\ln\left(\frac{62.81}{30}\right)} \\ &= 44.4°C\end{aligned}$$

Step 5 of 5

The overall heat transfer coefficient can be determined as

$$\begin{aligned}\dot{Q} &= U A_s \Delta T_{lm} \\ &= U(\pi D L) \Delta T_{lm}\end{aligned}$$

Here D is the Diameter of the tube, and L is Length of the tube

Substitute 2.5 cm for D for, 6 m for L

$$\begin{aligned}48.4 &= U(\pi(0.025)6)44.4 \\ U &= 2.313 \text{ kW/m}^2\text{·K}\end{aligned}$$

Therefore, the overall heat transfer coefficient is $\boxed{U = 2.313 \text{ kW/m}^2\text{·K}}$.

Question: 22.041P

A shell-and-tube heat exchanger is used for heating 14 kg/s of oil (*cp* = 2.0 kJ/kg·K) from 20°C to 46°C. The heat exchanger has 1-shell pass and 6-tube passes. Water enters the shell side at 80°C and leaves at 60°C. The overall heat transfer coefficient is estimated to be 1000 W/m2·K. Calculate the rate of heat transfer and the heat transfer area.

Step 1 of 4

Type of heat exchanger: shell and tube

Mass flow rate of oil, $m_o = 14\text{kg/s}$

Specific heat of oil, $c_{po} = 2\text{kJ/kg-K}$

Inlet of temperature of the oil, $T_{i,o} = 20°\text{C}$

Outlet temperature of the oil, $T_{o,o} = 46°\text{C}$

Number of tubes, $n = 6$

Inlet temperature of the water, $T_{w,i} = 80°\text{C}$

Outlet temperature of the water, $T_{w,o} = 60°\text{C}$

Overall heat transfer coefficient, $U = 1000\,\text{W/m}^2\text{-K}$

Step 2 of 4

Rate of heat transfer for oil is

$$\begin{aligned} Q_0 &= m_o c_{po}\left(T_{0,o} - T_{i,o}\right) \\ &= 14 \times 2(46-20) \\ &= 728\,\text{kW} \end{aligned}$$

From the energy balance equation,

Rate of heat loss by water is equal to rate of heat gain by oil.

Hence, rate of heat transfer is $\boxed{\dot{Q} = Q_0 = 728\,\text{kW}}$

Step 3 of 4

From the equation of Log mean temperature difference, we have

$$\begin{aligned} \Delta T_{lm} &= \frac{\left(T_{w,i} - T_{i,o}\right) - \left(T_{w,o} - T_{o,o}\right)}{\ln\left(\frac{\left(T_{w,i} - T_{i,o}\right)}{\left(T_{w,o} - T_{o,o}\right)}\right)} \\ &= \frac{(80-20)-(60-40)}{\ln\left(\frac{80-20}{60-40}\right)} \\ &= \frac{40}{1.098640} \\ &= 36.408°\text{C} \end{aligned}$$

Step 4 of 4

Now, rate of heat transfer in heat exchanger can be determined by

$$\dot{Q} = Q_o = UA_s\left(\Delta T_{lm}\right)$$

$$728 \times 10^3\,\text{W} = 1000 \times A_s(36.408)$$

$$A_s = 19.99\,\text{m}^2$$

Therefore, heat transfer surface area is $\boxed{A_s = 19.99\,\text{m}^2}$.

Question: 22.042P

A double-pipe parallel-flow heat exchanger is to heat water *(cp* = 4180 J/kg·K) from 25°C to 60°C at a rate of 0.2 kg/s. The heating is to be accomplished by geothermal water *(cp* =4310 J/kg·K) available at 140°C at a mass flow rate of 0.3 kg/s. The inner tube is thin-walled and has a diameter of 0.8 cm. If the overall heat transfer coefficient of the heat exchanger is 550 W/m2·K, determine the length of the tube required to achieve the desired heating.

Step 1 of 7

Given data:

Specific heat of water, $c_p = 4180\ \text{J/kg}^\circ\text{C}$

Specific heat of geothermal water, $c_p = 4310\ \text{J/kg}^\circ\text{C}$

Mass flow rates of water, $\dot{m} = 0.2\ \text{kg/s}$

Mass flow rates of geothermal water, $\dot{m} = 0.3\ \text{kg/s}$

Overall heat transfer coefficient, $U = 550\ \text{W/m}^2\cdot^\circ\text{C}$

Step 2 of 7

The rate of heat transfer from the water is determined by an energy balance.

$$\dot{Q} = \left[\dot{m}c_p\left(T_{out} - T_{in}\right)\right]_{water}$$

$$= (0.2\ \text{kJ/s})(4180\ \text{J/kg}^\circ\text{C})[60\text{-}25]^\circ\text{C}$$

$$= 29260\ \text{kW}$$

$$= 29.26\ \text{kW}$$

Step 3 of 7

The rate of heat transfer from the geothermal water is determined by

$$\dot{Q} = \left[\dot{m}c_p\left(T_{in} - T_{out}\right)\right]_{Geothermal\ water}$$

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}_{max}}{\dot{m}c_p}$$

$$= 140^\circ\text{C} - \frac{29260\ \text{W}}{(0.3\ \text{kg/s})(4.31\ \text{kJ/kg}^\circ\text{C})}$$

$$\therefore T_{h,out} = 117.4^\circ\text{C}$$

Step 4 of 7

For this parallel- flow heat exchanger LMTD determined to be

$$\Delta T_1 = T_{h,in} - T_{c,in}$$

$$= (140 - 25)$$

$$= 115^\circ\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= (117.4 - 60)$$

$$= 57.4^\circ\text{C}$$

Step 5 of 7

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined from

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$= \frac{115 - 57.4}{\ln\left(115/57.4\right)}$$

$$= 82.9^\circ\text{C}$$

Step 6 of 7

Heat transfer surface area on the tube side is determined to be

$$\dot{Q} = UA_s\Delta T_{lm}$$

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

By substituting all values heat transfer surface area becomes

$$A_s = \frac{29260\ \text{W}}{(550\ \text{W/m}^2.^\circ\text{C})(82.9^\circ\text{C})}$$

$$\therefore A_s = 0.6418\ \text{m}^2$$

Step 7 of 7

Length of the tube required to achieve the desired heating is calculated by

$$A_s = \pi DL$$

$$L = \frac{A_s}{\pi D}$$

$$= \frac{0.6418\ \text{m}^2}{\pi(0.008\ \text{m})}$$

$\therefore$ The length of the tube $\boxed{L = 25.5\ \text{m}}$

Question: 22.043P

Reconsider Prob. 22–42. Using EES (or other) software, investigate the effects of temperature and mass flow rate of geothermal water on the length of the tube. Let the temperature vary from 100°C to 200°C, and the mass flow rate from 0.1 kg/s to 0.5 kg/s. Plot the length of the tube as functions of temperature and mass flow rate, and discuss the results.

Step 1 of 5

The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box.

```
"GIVEN"
c_pc=4180[J/kg-K]
T_c_in=25[C]
T_c_out=60[C]
"T_h_out=200[C]"
m_dot_c=0.2[kg/s]
c_ph=4310[J/kg-K]
"T_h_in is varied from 100 [C] to 200 [C]"
"m_dot_h is varied from 0.1 [kg/s] to 0.5 [kg/s]"
D=0.8[cm]
U=550[W/m^2-K]
"Analysis"
Q_dot= m_dot_c* c_pc*(T_c_out- T_c_in)
Q_dot = m_dot_h* c_ph*(T_h_in- T_h_out)
DELTAT_1=T_h_in-T_c_in
DELTAT_2=T_h_out-T_c_out
DELTAT_lm=( DELTAT_1- DELTAT_2)/ln(DELTAT_1/ DELTAT_2)
Q_dot=U*A_s* DELTAT_lm
A_s=pi*D*L
```

Step 2 of 5

Now to solve the equation for a range of geothermal water inlet temperature and mass flow rates, use parametric table by clicking on the "New parametric table" of 'table' menu.

A dialog box will open
Select number of runs=11
Select variables equations as 'L', 'm_dot_h' and 'T_h_in' and press 'Add' and then press 'OK'.
The screenshot of the "New parametric table"

First the inlet temperature of geothermal water is varied at constant flow rate of $\dot{m}_h = 0.3$ kg/s
To Enter the values in the "T_h_in" column click on the drop tab in "T_h_in" column.
New window pops up opens, fill in the details as shown and then press "OK"

Step 3 of 5

Now click on the 'solve table' of 'Calculate' menu

The solution will appear as shown below:

Parametric Table

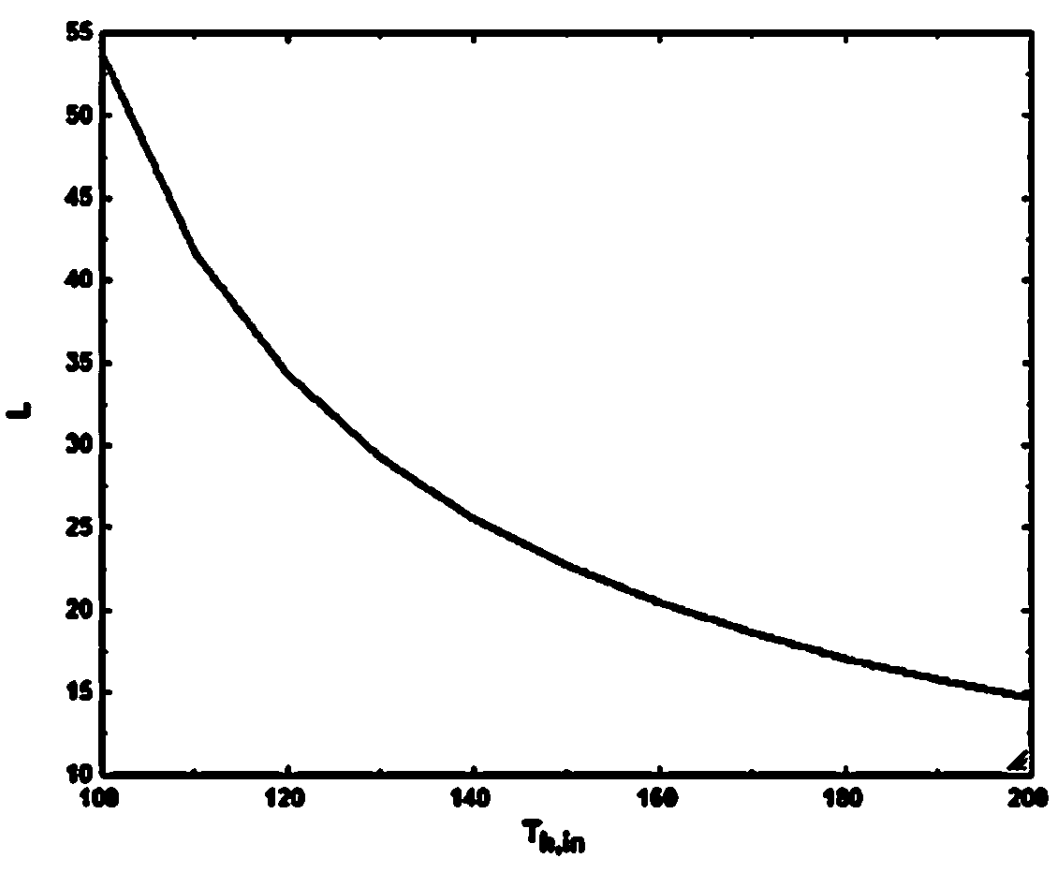

Table 2

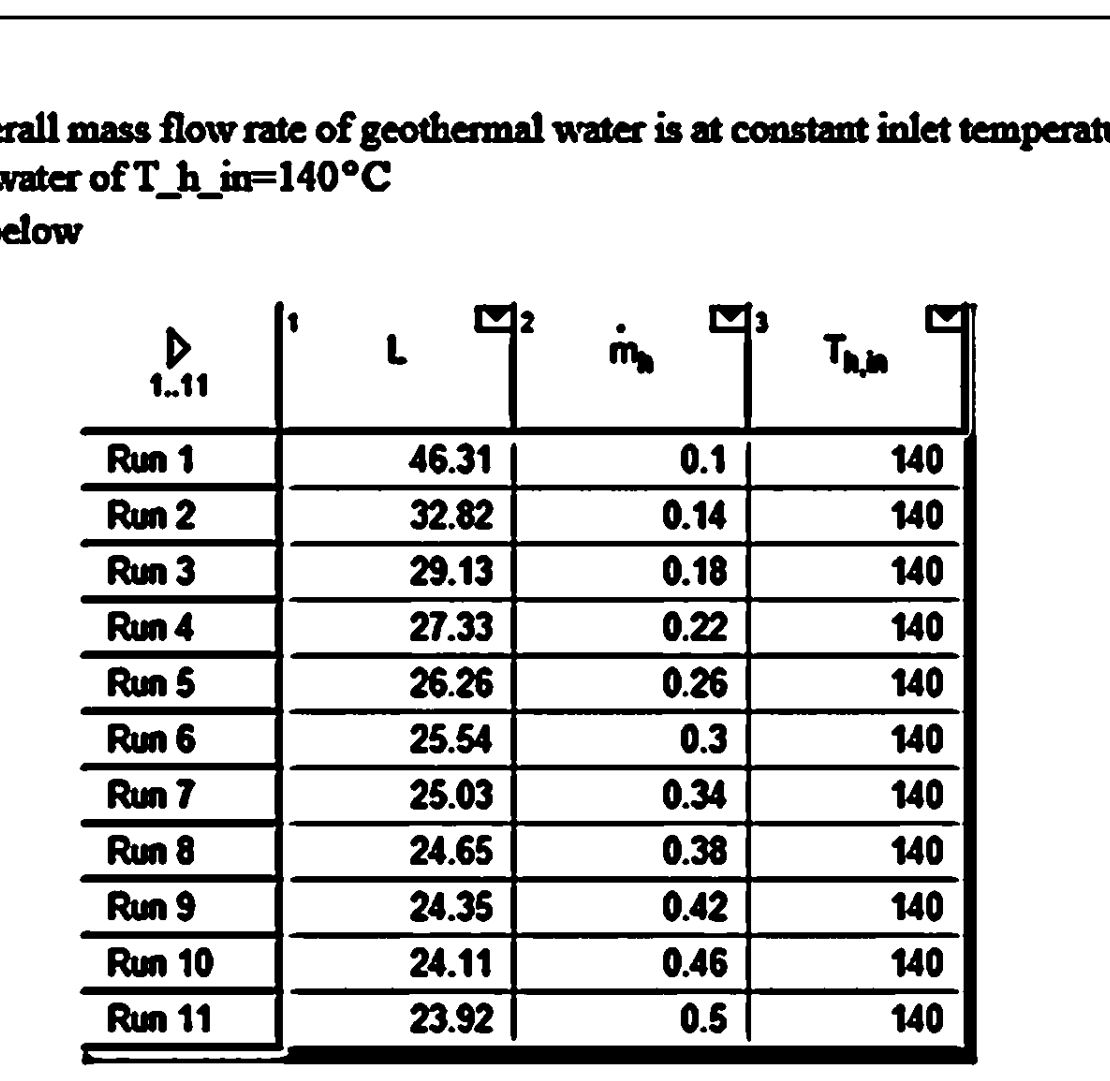
1..11	L	$\dot{m}_h$	$T_{h,in}$
Run 1	53.73	0.3	100
Run 2	41.62	0.3	110
Run 3	34.27	0.3	120
Run 4	29.24	0.3	130
Run 5	25.54	0.3	140
Run 6	22.7	0.3	150
Run 7	20.45	0.3	160
Run 8	18.61	0.3	170
Run 9	17.08	0.3	180
Run 10	15.78	0.3	190
Run 11	14.67	0.3	200

Step 4 of 5

In order to plot length of the tube as function of inlet temperature of geothermal water, click on the 'X-Y' plot of "New Plot window" from plot menu.

Screen Shot of the plot showing the length of the tube as function of the inlet temperature of the geothermal water.

From the above plot we can interpert that as the inlet temperture of the geothermal water increases, the length of the tube decreases.



Step 5 of 5

Now the overall mass flow rate of geothermal water is at constant inlet temperature of the geothermal water of T_h_in=140°C
Proceed as below

1..11	L	$\dot{m}_h$	$T_{h,in}$
Run 1	46.31	0.1	140
Run 2	32.82	0.14	140
Run 3	29.13	0.18	140
Run 4	27.33	0.22	140
Run 5	26.26	0.26	140
Run 6	25.54	0.3	140
Run 7	25.03	0.34	140
Run 8	24.65	0.38	140
Run 9	24.35	0.42	140
Run 10	24.11	0.46	140
Run 11	23.92	0.5	140

In order to plot length of the tube as function of inlet temperature of geothermal water, click on the 'X-Y' plot of "New Plot window" from plot menu

Screen Shot of the plot showing the length of the tube as function of the mass flow rate of the geothermal water.

Question: 22.044P

A 1-shell-pass and 8-tube-passes heat exchanger is used to heat glycerin (*cp* = 0.60 Btu/lbm·°F) from 80°F to 140°F by hot water (*cp* = 1.0 Btu/lbm·°F) that enters the thin- walled 0.5-in-diameter tubes at 175°F and leaves at 120°F. The total length of the tubes in the heat exchanger is 400 ft. The convection heat transfer coefficient is 4 Btu/h·ft2·°F on the glycerin (shell) side and 50 Btu/h·ft2·°F on the water (tube) side. Determine the rate of heat transfer in the heat exchanger (*a*) before any fouling occurs and (*b*) after fouling with a fouling factor of 0.002 h·ft2·°F/Btu on the outer surfaces of the tubes.

Step 1 of 7

Number of tubes $N = 8$

Specific heat of glycerin, $c_p = 0.60\,\text{Btu/lbm}\cdot{}^\circ\text{F}$

Inlet temperature of the glycerin, $T_{in,g} = 80^\circ\text{F}$

Exit temperature of the glycerin, $T_{out,g} = 140^\circ\text{F}$

Specific heat of the hot water, $c_{pw} = 1.0\,\text{Btu/lbm}\cdot{}^\circ\text{F}$

Inlet temperature of the hot water, $T_{in,w} = 175^\circ\text{F}$

Outlet temperature of the hot water, $T_{out,w} = 120^\circ\text{F}$

Diameter of the tube $D = 0.5\,\text{in.}$

Length of the tube $L = 400\,\text{ft}$

Heat transfer coefficient for glycerin, $h_g = 4\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$

Heat transfer coefficient for water, $h_w = 50\,\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$

Fouling factor, $R_0 = 0.002\,\text{h}\cdot\text{ft}^2\cdot\text{F/Btu}$

Step 2 of 7

Overall heat transfer coefficient is given as

$$\frac{1}{U} = \frac{1}{h_g} + \frac{1}{h_w}$$

$$= \frac{1}{4} + \frac{1}{50}$$

$$= 0.27$$

$$U = 3.703\,\text{Btu/ft}^2\cdot{}^\circ\text{F}$$

Step 3 of 7

Surface area of the heat exchanger is

$$A_s = N\pi DL$$

$$= 8\pi\left(0.5\,\text{in.}\times\frac{1\,\text{ft}}{12\,\text{in.}}\right)400$$

$$= 418.879\,ft^2$$

Step 4 of 7

Log mean temperature difference of the counter flow heat exchanger is

$$\Delta t_{lm} = \frac{\left(T_{out,w} - T_{in,g}\right) - \left(T_{in,w} - T_{out,g}\right)}{\ln\left(\frac{T_{out,w} - T_{in,g}}{T_{in,w} - T_{out,g}}\right)}$$

$$= \frac{(120-80)-(175-140)}{\ln\left(\frac{120-80}{175-140}\right)}$$

$$= \frac{5}{0.133}$$

$$= 37.593^\circ\text{F}$$

Step 5 of 7

a)

Rate of heat transfer without fouling factor is

$$\dot{Q} = UA_s\Delta t_{lm}$$

$$= 3.703\times 418.879\times 37.593$$

$$= 58310.838\,\text{Btu}$$

Therefore, Rate of heat transfer without fouling factor is $\boxed{\dot{Q} = 58310.838\,\text{Btu}}$.

Step 6 of 7

b)

Overall heat transfer coefficient with fouling factor is given as

$$\frac{1}{U} = \frac{1}{h_g} + \frac{1}{h_w} + R_{f0}$$

$$= \frac{1}{4} + \frac{1}{50} + 0.002$$

$$= 0.27 + 0.002$$

$$= 0.272$$

$$U = 3.676\,\text{Btu/ft}^2\cdot{}^\circ\text{F}$$

Step 7 of 7

Rate of heat transfer without fouling factor is

$$\dot{Q} = UA_s\Delta t_{lm}$$

$$= 3.676\times 418.879\times 37.593$$

$$= 57893.081\,\text{Btu}$$

Therefore, Rate of heat transfer without fouling factor is $\boxed{\dot{Q} = 57893.081\,\text{Btu}}$.

Question: 22.045P

A double-pipe parallel-flow heat exchanger is used to heat cold tap water with hot water. Hot water (*cp* = 4.25 kJ/kg·K) enters the tube at 85°C at a rate of 1.4 kg/s and leaves at 50°C. The heat exchanger is not well insulated, and it is estimated that 3 percent of the heat given up by the hot fluid is lost from the heat exchanger. If the overall heat transfer coefficient and the surface area of the heat exchanger are 1150 W/m2·K and 4 m2, respectively, determine the rate of heat transfer to the cold water and the log mean temperature difference for this heat exchanger.

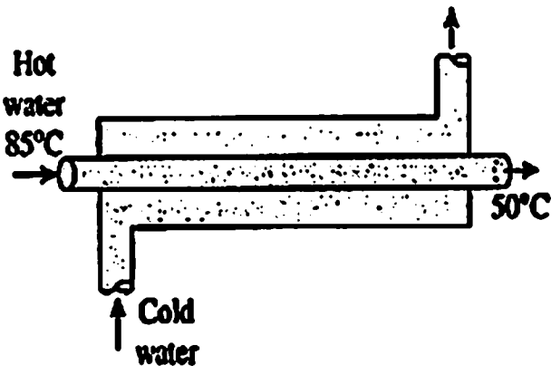


FIGURE P22–45

Step 1 of 2

The rate of heat transfer from hot water,

$$\dot{Q}_{hot_water} = [\dot{m}C_p(T_{out} - T_{in})]_{hot_water}$$

Here $\dot{m}$ is the Flow rate of hot water, c_p is The specific heat of hot water at average temperature, T_{out} is the Exit temperature of hot water and T_{in} is the Inlet temperature of hot water

Substitute 1.4 kg/s for $\dot{m}$, 4.25 kJ/kg·K for c_p, 50°C for T_{out} for and 85°C for T_{in}.

$$\begin{aligned}\dot{Q}_{hot_water} &= (1.4\ \text{kg/s})\times(4.25\ \text{kJ/kg}\cdot°\text{C})\times(85\text{-}50)°\text{C}\\ &= 208.3\ \text{kW}\end{aligned}$$

The rate of heat transfer in this radiator from the hot water to the cold water is determined by energy balance.

Since heat exchanger is not well insulated there is 3 percent of the heat given up by the hot fluid is lost from the heat exchanger then the rate of heat gain by the cold water is

$$\begin{aligned}\dot{Q}_{cold_water} &= (1-0.03)\dot{Q}_{hot_water}\\ &= (1-0.03)\times 208.3\\ &= 202.051\text{kW}\end{aligned}$$

Therefore, the rate of heat gain by the cold water is $\boxed{\dot{Q}_{cold_water} = 202.051\ \text{kW}}$.

Step 2 of 2

The logarithmic mean temperature difference for this heat exchanger,

$$\dot{Q}_{cold_water} = UA_i\Delta T_{lm}$$

Here U is the overall heat transfer coefficient, and A_i is the Area of the heat exchanger

Substitute 1150 W/m^2·K for U, and 4.25 kJ/kg·K for c_p.

$$\begin{aligned}\Delta T_{lm} &= \frac{202.051\times 10^3}{(1150)\times(4)}\\ &= 43.924°\text{C}\end{aligned}$$

Therefore, the logarithmic mean temperature difference for this heat exchanger is $\boxed{43.924°\text{C}}$.

Question: 22.046P

A thin-walled double-pipe counter-flow heat exchanger is to be used to cool oil (*cp* = 2200 J/kg·K) from 150°C to 50°C at a rate of 2.5 kg/s by water (*cp* = 4180 J/kg·K) that enters at 22°C at a rate of 1.5 kg/s. The diameter of the tube is 2.5 cm, and its length is 6 m. Determine the overall heat transfer coefficient of this heat exchanger.

Step 1 of 4

Specific heat of oil, $c_{po} = 2200\,\text{J/kg-K}$

Inlet temperature of the oil, $T_{io} = 150°\text{C}$

Exit temperature of the oil, $T_{eo} = 50°\text{C}$

Mass flow rate of oil, $m_o = 2.5\,\text{kg/s}$

Specific heat of water, $c_{pw} = 4180\,\text{J/kg-K}$

Inlet temperature of the water, $T_{wi} = 22°\text{C}$

Mass flow rate of water, $m_w = 1.5\,\text{kg/s}$

Diameter of the tube, $D = 2.5\,\text{cm} = 0.025\,\text{m}$

Length of the tube, $L = 6\,\text{m}$

Step 2 of 4

Heat transfer area of the counter flow heat exchanger is

$$A_s = \pi DL$$
$$= \pi(0.025)(6)$$
$$= 0.471\,\text{m}^2$$

Rate of heat transfer of oil is

$$Q_o = m_o c_{po}(T_{io} - T_{eo})$$
$$= 2.5 \times 2200(150 - 50)$$
$$= 550000\,\text{W}$$

From the energy balance equation

Rate of heat transfer loss by oil is equal to rate of heat gain by the water.

$$\dot{Q} = Q_0 = 550000\,\text{W} = m_w c_{pw}(T_{w0} - T_{wi})$$
$$550000 = 1.5 \times 4180(T_{wo} - 22)$$
$$T_{wo} = 109.719°\text{C}$$

Step 3 of 4

Log mean temperature difference for counter flow heat exchanger is

$$\Delta T_{lm} = \frac{(T_{io} - T_{wo}) - (T_{eo} - T_{wi})}{\ln\left(\frac{(T_{io} - T_{wo})}{(T_{eo} - T_{wi})}\right)}$$
$$= \frac{(150 - 109.719) - (50 - 22)}{\ln\left(\frac{150 - 109.719}{50 - 22}\right)}$$
$$= \frac{12.281}{0.3636}$$
$$= 33.769°\text{C}$$

Step 4 of 4

Then, overall heat transfer coefficient is

$$\dot{Q} = UA_s(\Delta T_{lm})$$
$$550000 = U \times 0.471 \times 33.769$$
$$U = 34579.88\,\text{W/m}^2\cdot\text{K}$$

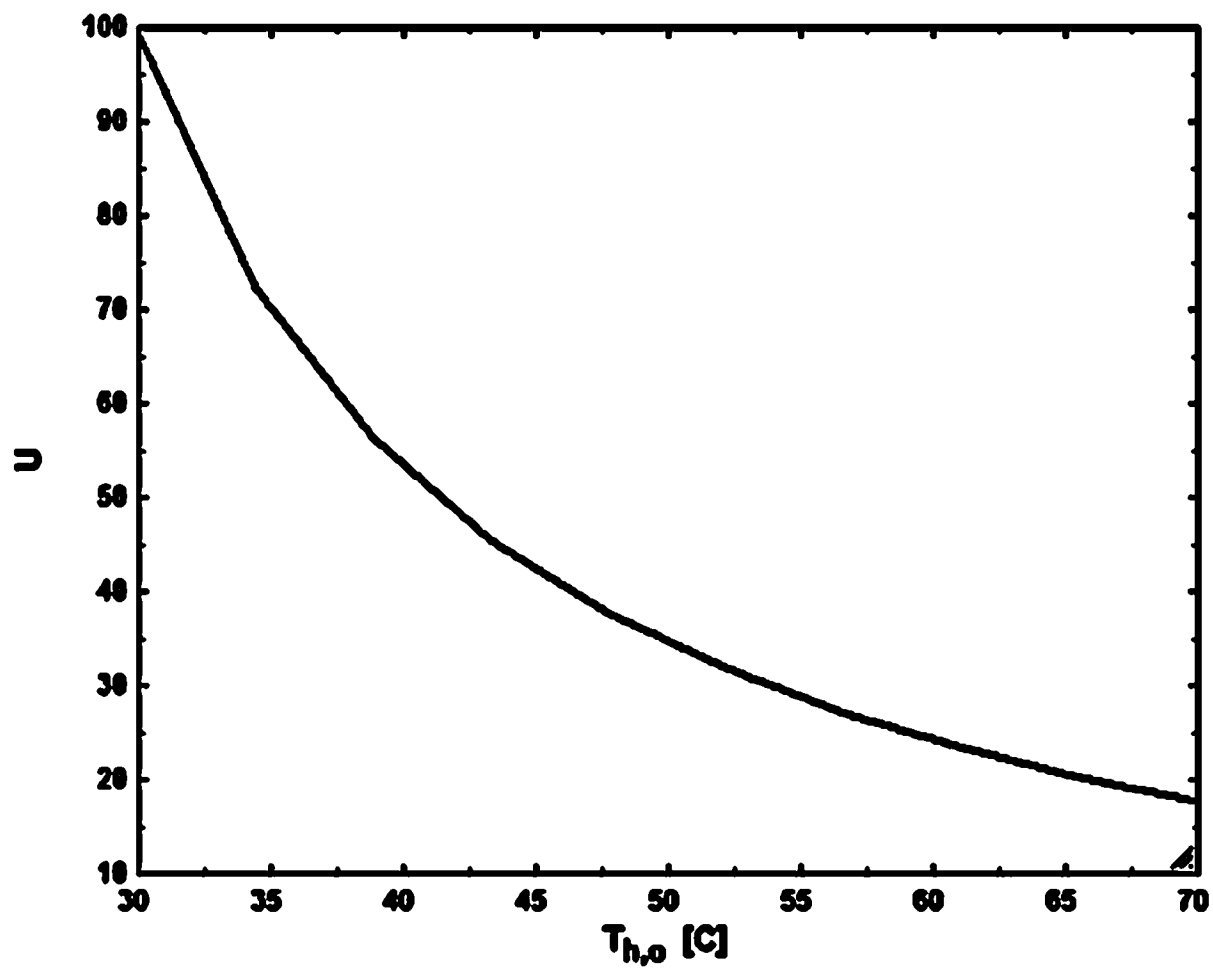
Therefore, overall heat transfer coefficient is $\boxed{U = 34579.88\,\text{W/m}^2\cdot\text{K}}$

Question: 22.047P

Reconsider Prob. 22–46. Using EES (or other) software, investigate the effects of oil exit temperature and water inlet temperature on the overall heat transfer coefficient of the heat exchanger. Let the oil exit temperature vary from 30°C to 70°C and the water inlet temperature from 5°C to 25°C. Plot the overall heat transfer coefficient as functions of the two temperatures, and discuss the results.

Step 1 of 3

The given problem can be solved using EES software by following the below steps.

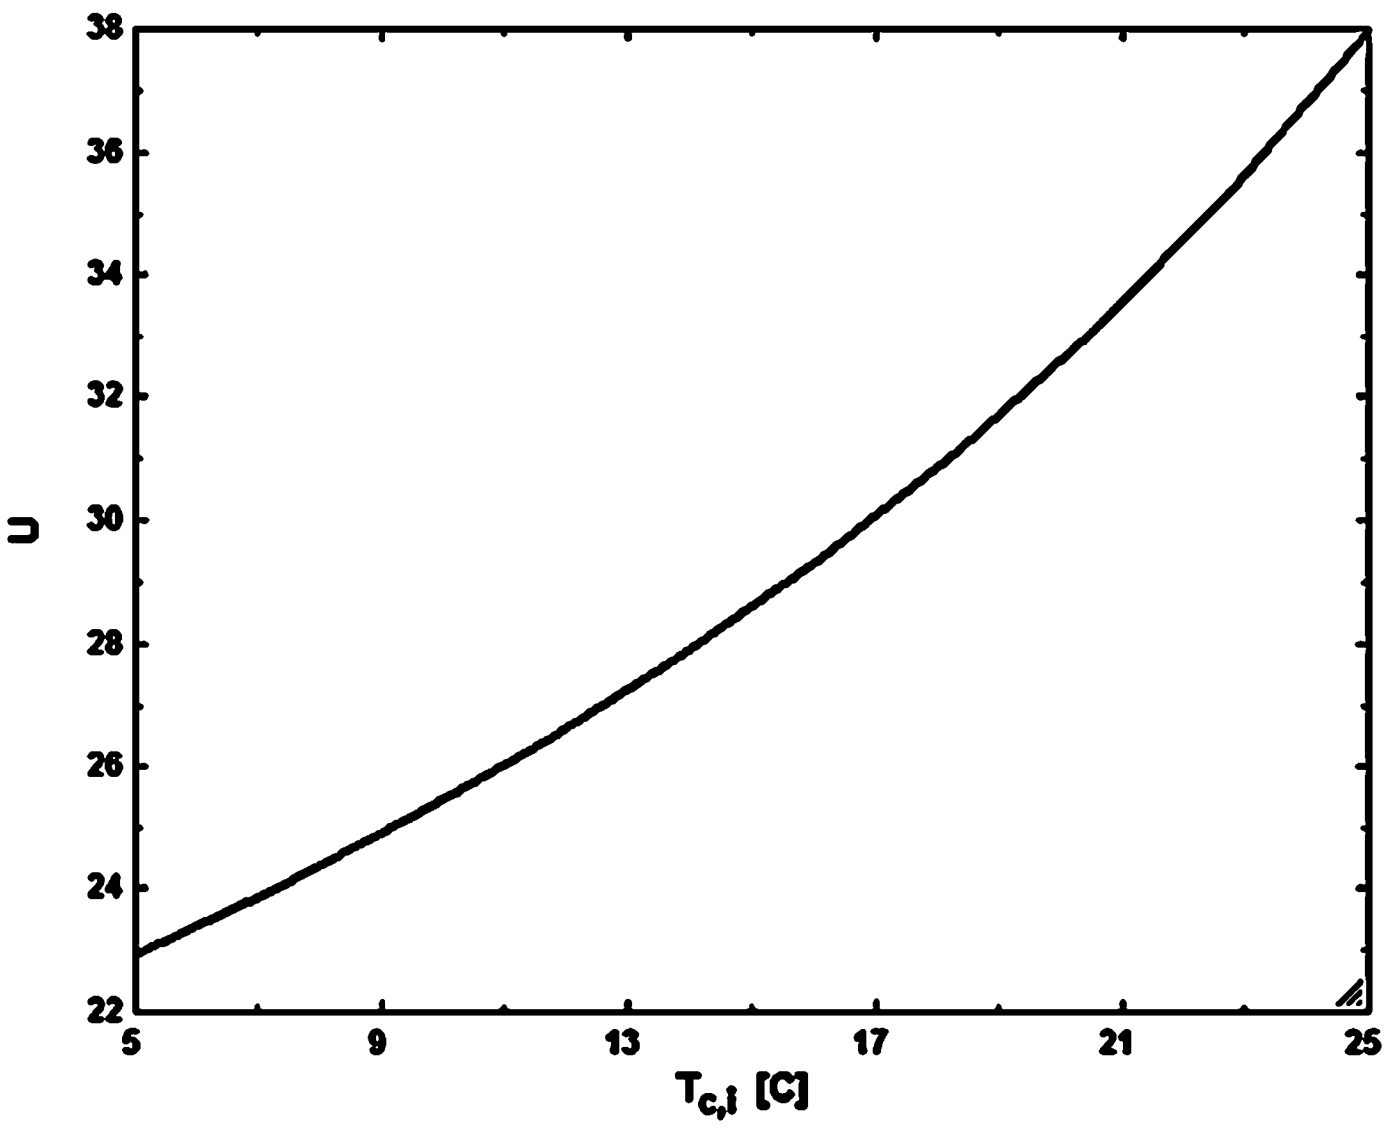


1. **Open EES software**
2. **Crease a new file by clicking on the 'New' of the 'File menu'**
3. **Now type the following code in dailog box.**

```
"GIVEN"
T_h_i=150[C]
T_h_o=50[C]
m_dot_h=2.5[kg/s]
c_p_h=2.2[kJ/kg-K]
T_c_i=22[C]
m_dot_c=1.5[kg/s]
c_p_c=4.18[kJ/kg-K]
D=0.025[m]
L=6[m]
"Determination for overall heat transfer coefficient"
Q_dot= m_dot_h* c_p_h*(T_h_i- T_h_o)
Q_dot = m_dot_c* c_p_c*(T_c_o- T_c_i)
DeltaT_1=T_h_i-T_c_o
DeltaT_2=T_h_o-T_c_i
DeltaT_lm=(DeltaT_1-DeltaT_2)/ln(DeltaT_1/DeltaT_2)
A=pi*D*L
Q_dot=U*A*DeltaT_lm
```

Step 2 of 3

Now to solve the equation for a range of length values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 10
Select variables in equations as $T_{h,o}$ and U press 'Add' and then press 'ok'



On executing the program by giving the range of the oil exit temperature, the variation in the overall heat transfer coefficient is known.

Step 3 of 3

Now to solve the equation for a range of length values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 10
Select variables in equations as $T_{c,i}$ and U press 'Add' and then press 'ok'

For the given range of water inlet temperature from 5°C to 25°C the variation in the overall heat transfer coefficient is plotted on an XY graph.

Question: 22.048P

A shell-and-tube heat exchanger with 2-shell passes and 12-tube passes is used to heat water (cp = 4180 J/kg·K) with ethylene glycol (cp = 2680 J/kg·K). Water enters the tubes at 22°C at a rate of 0.8 kg/s and leaves at 70°C. Ethylene glycol enters the shell at 110°C and leaves at 60°C. If the overall heat transfer coefficient based on the tube side is 280 W/m2·K, determine the rate of heat transfer and the heat transfer surface area on the tube side.

Step 1 of 5

Find the heat transfer rate by using the following equation:

$$\dot{Q} = \dot{m}_c c_p \left(T_{c,out} - T_{c,in}\right)$$

Here, $\dot{m}_c$ is mass flow rate of cold water, c_p is specific heat of water, $T_{c,out}$ is exit temperature of cold water, and $T_{c,in}$ is inlet temperature of cold water.

Substitute 0.8 kg/s for $\dot{m}_c$, $4180\,\text{J/kg.K}$ for c_p, $22°\text{C}$ for $T_{c,in}$, and $70°\text{C}$ for $T_{c,out}$.

$$\begin{aligned}\dot{Q} &= 0.8\times 4180(70-22)\\ &= 160512\,\text{W}\\ &= 160.512\,\text{kW}\end{aligned}$$

Therefore, heat transfer rate is $\boxed{160.512\,\text{W}}$

Step 2 of 5

Find the heat transfer surface area by using the following equation:

$$\dot{Q} = FUA_s\Delta T_{lm} \quad \text{..... (1)}$$

Here, F is correction factor, U is overall heat transfer coefficient, and ΔT_{lm} is log mean temperature difference.

Find the correction factor as follows:

Find the parameter P and R.

$$P = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$$

Substitute $22°\text{C}$ for $T_{c,in}$, $70°\text{C}$ for $T_{c,out}$, and $110°\text{C}$ for $T_{h,in}$

$$\begin{aligned}P &= \frac{70-22}{110-22}\\ &= 0.5454\end{aligned}$$

$$R = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$$

Substitute $22°\text{C}$ for $T_{c,in}$, $70°\text{C}$ for $T_{c,out}$, $110°\text{C}$ for $T_{h,in}$, and $60°\text{C}$ for $T_{h,out}$

$$\begin{aligned}R &= \frac{110-60}{70-22}\\ &= 1.0416\end{aligned}$$

Obtain correction factor at P=0.5454 and R=1.0416 from the figure 11-9, "correction factor charts" in the text book.

$F = 0.94$

Step 3 of 5

Find log mean temperature difference by using the following equation:

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

Find temperature differences $\Delta T_1, \Delta T_2$

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

Substitute $70°\text{C}$ for $T_{c,out}$, and $110°\text{C}$ for $T_{h,in}$

$$\begin{aligned}\Delta T_1 &= (110-70)\\ &= 40°\text{C}\end{aligned}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

Substitute $22°\text{C}$ for $T_{c,in}$ and $60°\text{C}$ for $T_{h,out}$

$$\begin{aligned}\Delta T_2 &= (60-22)\\ &= 38°\text{C}\end{aligned}$$

Step 4 of 5

Substitute $40°\text{C}$ for ΔT_1 and $38°\text{C}$ for ΔT_2 in log mean temperature difference.

$$\begin{aligned}\Delta T_{lm} &= \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}\\ &= \frac{40-38}{\ln\left(\frac{40}{38}\right)}\\ &= 38.99°\text{C}\end{aligned}$$

Step 5 of 5

Substitute 0.94 for F, $280\,\text{W/m}^2\text{.K}$ for U, $38.99°\text{C}$ for ΔT_{lm}, and 160512 W for $\dot{Q}$ in equation (1).

$$\begin{aligned}&\dot{Q} = FUA_s\Delta T_{lm}\\ &160512 = 0.94\times 280\times A_s\times 38.99\\ &A_s = 15.64\,\text{m}^2\end{aligned}$$

Therefore, the total surface area on the tube side is $\boxed{15.64\ \text{m}^2}$.

Question: 22.049P

Reconsider Prob. 22–48. Using EES (or other) software, investigate the effect of the mass flow rate of water on the rate of heat transfer and the tube-side surface area. Let the mass flow rate vary from 0.4 kg/s to 2.2 kg/s. Plot the rate of heat transfer and the surface area as a function of the mass flow rate, and discuss the results.

Step 1 of 3

The given problem can be solved using EES software by following the below steps.

1. **Open EES software**
2. **Crease a new file by clicking on the 'New' of the 'File menu'**
3. **Now type the following code in dailog box**

```
"GIVEN"
T_w_in=22 "[C]"
T_w_out=70 "[C]"
"m_dot_w=0.8 [kg/s], parameter to be varied"
C_p_w=4.18 "[kJ/kg-C]"
T_glycol_in=110 "[C]"
T_glycol_out=60 "[C]"
C_p_glycol=2.68 "[kJ/kg-C]"
U=0.28 "[kW/m^2-C]"

"ANALYSIS"
Q_dot=m_dot_w*C_p_w*(T_w_out-T_w_in)
Q_dot=m_dot_glycol*C_p_glycol*(T_glycol_in-T_glycol_out)
DELTAT_1=T_glycol_in-T_w_out
DELTAT_2=T_glycol_out-T_w_in
DELTAT_lm_CF=(DELTAT_1-DELTAT_2)/ln(DELTAT_1/DELTAT_2)
P=(T_glycol_out-T_glycol_in)/(T_w_in-T_glycol_in)
R=(T_w_in-T_w_out)/(T_glycol_out-T_glycol_in)
F=0.94 "from Fig. 13-18b of the text at the calculated P and R"
Q_dot=U*A*F*DELTAT_lm_CF
```

Step 2 of 3

Now to solve the equation for a range of length values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 10
Select variables in equations as m_w, $\dot{Q}$,and A press 'Add' and then press 'ok'
A table will appear and enter the values of length under 'm_w ' varing fro 0.4 kg/s to 2.2 kg/s
Then from click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below

Parametric Table

Table 1

1..10	$\dot{m}_w$	$\dot{Q}$	A
Run 1	0.4	80.26	7.82
Run 2	0.6	120.4	11.73
Run 3	0.8	160.5	15.64
Run 4	1	200.6	19.55
Run 5	1.2	240.8	23.46
Run 6	1.4	280.9	27.37
Run 7	1.6	321	31.28
Run 8	1.8	361.2	35.19
Run 9	2	401.3	39.1
Run 10	2.2	441.4	43.01

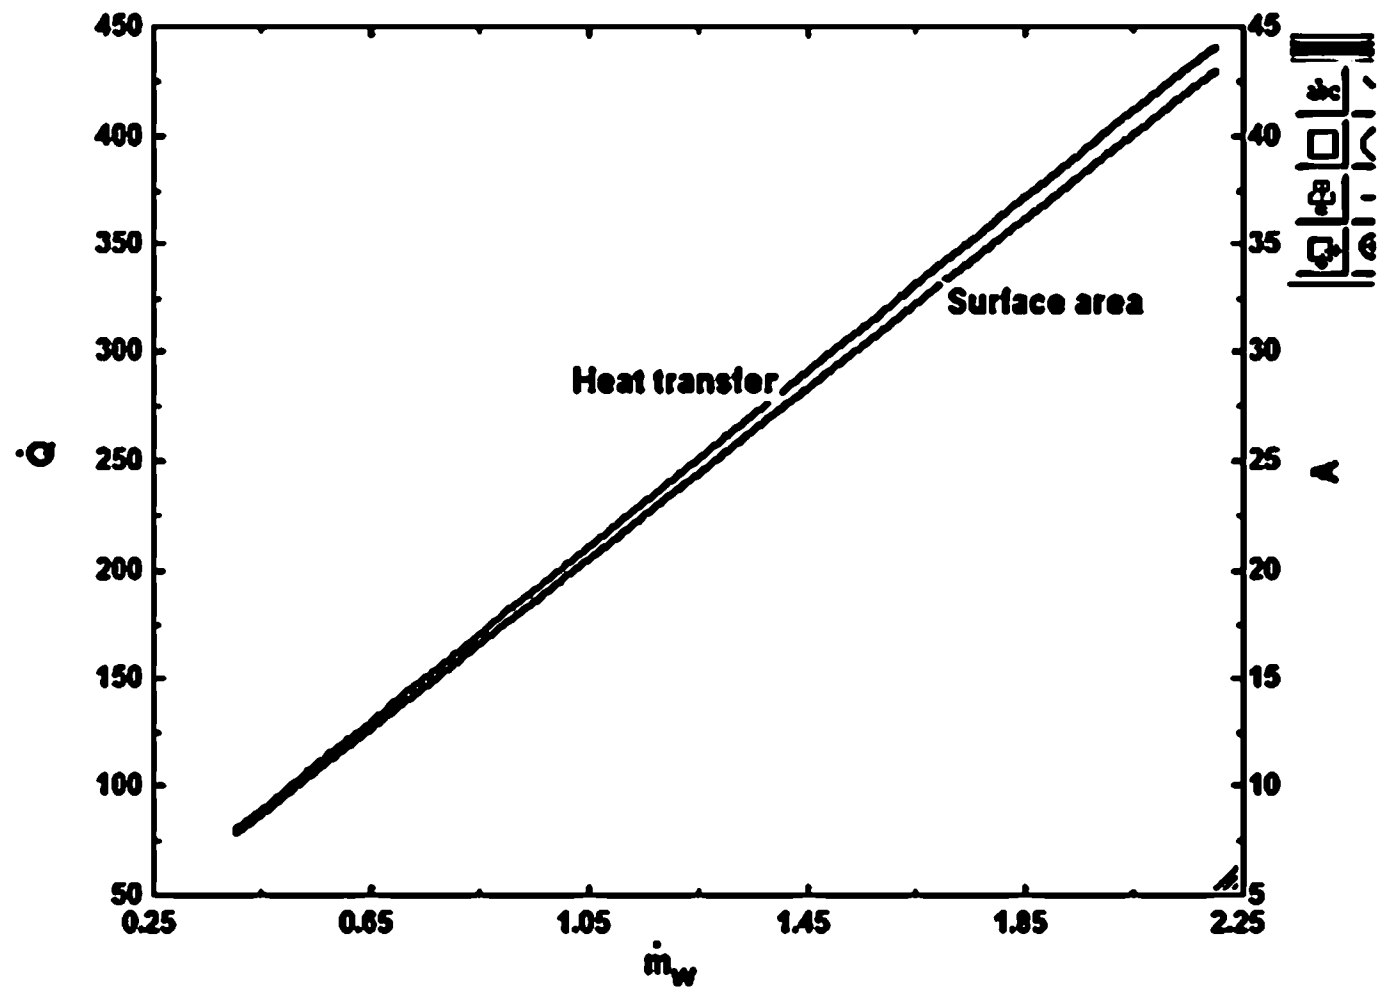
Step 3 of 3

For graph between mass flow rate and heat transfer

Select the plot on menu bar, and then click X-Y plot .Dialog box will be appeared.

Select X-axis as m_w and Y-axis as $\dot{Q}$ .Press OK

A graph indicated in red color will be plotted as shown below.



For graph between mass flow rate and surface area

Select the plot on menu bar, and then click overlay plot .Dialog box will be appeared

Select X-axis as m_w and Y-axis as A .Press OK

A graph indicated in blue color will be plotted as shown below.

Plot the graph between mass flow rate and heat transfer, surface area:

Question: 22.050P

Glycerin (*cp* = 2400 J/kg·K) at 20°C and 0.5 kg/s is to be heated by ethylene glycol (*cp* = 2500 J/kg·K) at 70°C in a thin-walled double-pipe parallel-flow heat exchanger. The temperature difference between the two fluids is 15°C at the outlet of the heat exchanger. If the overall heat transfer coefficient is 240 W/m2·K and the heat transfer surface area is 3.2 m2, determine (*a*) the rate of heat transfer, (*b*) the outlet temperature of the glycerin, and (*c*) the mass flow rate of the ethylene glycol.

Step 1 of 5

Given

The specific heat of Glycerin is $c_p = 2400\ \text{J/kg}\cdot\text{K}$

The specific heat of Ethylene glycol is $c_p = 2500\ \text{J/kg}\cdot\text{K}$

Inlet temperature of glycerin is $T_{c,in} = 20°\text{C}$

Inlet temperature of ethylene glycol is $T_{h,in} = 70°\text{C}$

Overall heat transfer coefficient $U = 240\ \text{W/m}^2\cdot\text{K}$

Heat transfer surface area is $A = 3.2\ \text{m}^2$

Mass flow rate of Glycerin $\dot{m}_{Glycerin} = 0.5\ \text{kg/s}$

The temperature difference between the two fluids at the outlet of the heat exchanger is $\Delta T_2 = 15°\text{C}$

Step 2 of 5

LMTD of the parallel flow heat exchanger is

$$\Delta T_1 = T_{h,in} - T_{c,in}$$
$$= 70 - 20$$
$$\Delta T_1 = 50°\text{C}$$

Then

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln \Delta T_1 / \Delta T_2}$$
$$\Delta T_{lm} = \frac{50 - 15}{\ln 50/15}$$
$$\Delta T_{lm} = 29.07°\text{C}$$

Step 3 of 5

(a) The rate of heat transfer can be calculated as

$$\dot{Q} = UA_s\Delta T_{lm}$$
$$\dot{Q} = (240\ \text{W/m}^2\cdot°\text{C})(3.2\ \text{m}^2)(29.07°\text{C})$$
$$\boxed{\dot{Q} = 22325.76\ \text{W}}$$
$$\boxed{\dot{Q} = 22.32576\text{kW}}$$

Step 4 of 5

(b)The outlet temperature of the Glycerin is calculated by the relation

$$\dot{Q} = [\dot{m}c_p(T_{out} - T_{in})]_{Glycerin}$$
$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{\dot{m}c_p}$$
$$= 20°\text{C} + \frac{22325.76\ \text{W}}{(0.5\ \text{kg/s})(2400\ \text{kJ/kg}\cdot°\text{C})}$$
$$\boxed{T_{c,out} = 38.6°\text{C}}$$

Step 5 of 5

(c)

The mass flow rate of ethylene glycol can be calculated as

$$\dot{Q} = [\dot{m}c_p(T_{out} - T_{in})]_{Ethylene\ glycol}$$

Where exit temperature of ethylene glycol is

$$\Delta T_2 = T_{h_out} - T_{c_out} = 15$$
$$T_{h_out} = 15 + T_{c_out}$$
$$= 15 + 38.6$$
$$T_{h_out} = 53.6°\text{C}$$
$$\dot{m}_{Ethylene\ glycol} = \left(\frac{\dot{Q}}{c_p[T_{out} - T_{in}]}\right)_{Ethylene\ glycol}$$
$$\dot{m}_{Ethylene\ glycol} = \frac{22.32576}{(2.5)(70 - 53.6)}$$
$$\boxed{\dot{m}_{Ethylene\ glycol} = 0.5445\ \text{kg/s}}$$

Question: 22.051P

Air (cp = 1005 J/kg·K) is to be preheated by hot exhaust gases in a cross-flow heat exchanger before it enters the furnace. Air enters the heat exchanger at 95 kPa and 20°C at a rate of 0.8 m3/s. The combustion gases (cp = 1100 J/kg·K) enter at 180°C at a rate of 1.1 kg/s and leave at 95°C. The product of the overall heat transfer coefficient and the heat transfer surface area is UAS = 1200 W/K. Assuming both fluids to be unmixed, determine the rate of heat transfer and the outlet temperature of the air.

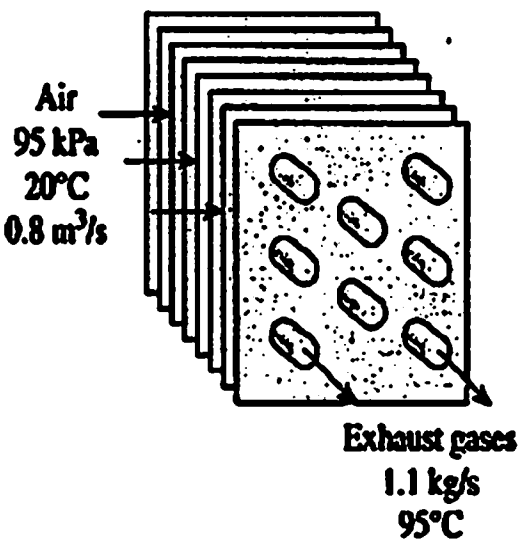


FIGURE P22–51

Step 1 of 3

Given

The specific heat of exhaust gases is $c_{p_gas} = 1100\ \text{J/kg}\cdot\text{K}$

The specific heat of air is $c_{p_air} = 1005\ \text{J/kg}\cdot\text{K}$

Mass flow rate of exhaust gases is $\dot{m}_g = 1.1\ \text{kg/s}$

The product of the overall heat transfer coefficient and the heat transfer surface area is $UA_s = 1200\ \text{W/°C}$

Air enters at pressure $P = 95\text{kPa}$

Temperature of air at inlet $T = 20°\text{C}$

Volumetric flow rate of air at inlet is $\dot{V}_1 = 0.8\,\text{m}^3/\text{s}$

Step 2 of 3

Mass flow rate of air can be calculated by using the ideal gas equation

$$\dot{m}_{air} = \frac{P_1 \dot{V}_1}{RT_1}$$

$$= \frac{(95\ \text{kPa})(0.8\ \text{m}^3/\text{s})}{(0.287\ \text{kPa.m}^3/\text{kg.K})(293\ \text{K})}$$

$$\dot{m}_{air} = 0.9038\ \text{kg/s}$$

The rate of heat transfer can be calculated by using the relation

$$\dot{Q} = [\dot{m}_h c_{ph}(T_{out} - T_{in})]_{\text{combustion gases}}$$

$$\dot{Q} = (1.1\ \text{kg/s})(1100\ \text{J/kg}\cdot\text{K})(180 - 95)°\text{C}$$

$$\dot{Q} = 102.85\ \text{kJ/s}$$

Step 3 of 3

Therefore the outlet temperature of the air is

$$\dot{Q} = \left[\dot{m}_c c_{pc}(T_{out} - T_{in})\right]_{air}$$

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{\dot{m}_c c_{pc}}$$

$$T_{out_air} = 20 + \frac{102.85}{0.9038 \times 1.005}$$

$$\boxed{T_{out_air} = 133.23°\text{C}}$$

Question: 22.052P

A shell-and-tube heat exchanger with 2-shell passes and 12-tube passes is used to heat water *(cp* = 4180 J/kg·K) in the tubes from 20°C to 70°C at a rate of 4.5 kg/s. Heat is supplied by hot oil *(cp* = 2300 J/kg·K) that enters the shell side at 170°C at a rate of 10 kg/s. For a tube-side overall heat transfer coefficient of 350 W/m2·K, determine the heat transfer surface area on the tube side.

Step 1 of 9

Given

Type: 2shell and 12 tube passes

Specific heats of water $c_{pc} = 4180$ J/kg.°C

Specific heats of oil $c_{ph} = 2300$ J/kg.°C

Mass flow rates of water $\dot{m}_c = 4.5$ kg/s

Mass flow rates of oil $\dot{m}_h = 10$ kg/s

$T_{c,in} = 20^0$C

$T_{c,out} = 70^0$C

$T_{h,in} = 170^0$C

Tube side overall heat transfer coefficient $U_{c,w} = 350$ W/m^2°C

Step 2 of 9

Heat transfer surface area on the tube side:

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

$\dot{Q}$, F &ΔT_{lm} are calculated by the following relations

Step 3 of 9

Heat transfer rate is $\dot{Q} = [\dot{m}_c c_{pc}(T_{c,out} - T_{c,in})]_{water}$

$$= (4.5 \text{ kg/s})(4180 \text{ J/kg.°C})(65\text{-}25)\text{°C}$$

$$\dot{Q} = 940.5 \text{ kW}$$

Step 4 of 9

Then the outlet temperature of the oil is

$$\dot{Q} = [\dot{m}_h c_{ph}(T_{h,out} - T_{h,in})]_{oil}$$

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}}{\dot{m}_h c_{ph}}$$

$$= 170\text{°C} - \frac{940500 \text{ W}}{(10 \text{ kg/s})(2300 \text{ J/kg.°C})}$$

$$T_{h,out} = 129.108\text{°C}$$

Step 5 of 9

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$= (170 - 70)\text{°C}$$

$$\Delta T_1 = 100\text{°C}$$

Step 6 of 9

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= (129.108 - 20)\text{°C}$$

$$\Delta T_2 = 109.108\text{°C}$$

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$= \frac{100 - 109.108}{\ln\left(\frac{100}{109.108}\right)}$$

$$\therefore \Delta T_{lm} = 104.4878\text{°C}$$

Step 7 of 9

And $$P = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$$

$$= \frac{129.108 - 170}{20 - 170}$$

$$P = 0.27$$

Step 8 of 9

$$R = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$$

$$= \frac{20 - 70}{129.108 - 170}$$

$$R = 1.2$$

At these P and R values $F = 1$

(From correction factor F charts for common shell and tube and cross flow heat exchangers (b))

Step 9 of 9

By substituting all values heat transfer surface area becomes

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

$$A_s = \frac{940500}{(350)(1)(104.435)}$$

$$\therefore A_s = 25.73 \text{ m}^2$$

Question: 22.053P

Repeat Prob. 22–52 for a mass flow rate of 3 kg/s for water.

Step 1 of 6

Given

Type: 2shell and 12 tube passes

Specific heats of water $c_{pc} = 4180$ J/kg.°C

Specific heats of oil $c_{ph} = 2300$ J/kg.°C

Mass flow rates of water $\dot{m}_c = 3$ kg/s

Mass flow rates of oil $\dot{m}_h = 10$ kg/s

Inlet temperature of water in the tube $T_{c,in} = 20^0$C

Exit temperature of water in the tube $T_{c,out} = 70^0$C

Inlet temperature of hot oil in the shell side $T_{h,in} = 170^0$C

Tube side overall heat transfer coefficient $U_{c,w} = 350$ W/m$^2 \cdot$K

Step 2 of 6

Heat transfer surface area on the tube side:

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

Heat transfer rate is

$$\dot{Q} = [\dot{m}_c c_{pc}(T_{c,out} - T_{c,in})]_{water}$$

$$= (3 \text{ kg/s})(4180 \text{ J/kg} \cdot \text{K})(70 - 20)^\circ\text{C}$$

$$\dot{Q} = 627000 \text{ W}$$

Step 3 of 6

Then the outlet temperature of the oil is

$$\dot{Q} = [\dot{m}_h c_{ph}(T_{h,out} - T_{h,in})]_{oil}$$

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}}{\dot{m}_h c_{ph}}$$

$$= 170^\circ\text{C} - \frac{627000 \text{ W}}{(10 \text{ kg/s})(2300 \text{ J/kg} \cdot ^\circ\text{C})}$$

$$T_{h,out} = 142.739^\circ\text{C}$$

Step 4 of 6

The log mean temperature difference of the counter flow heat exchanger is

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$= 170 - 70$$

$$\Delta T_1 = 100^\circ\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= 142.739 - 20$$

$$\Delta T_2 = 122.739^\circ\text{C}$$

Then LMTD is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$= \frac{100 - 122.739}{\ln\left(\frac{100}{122.739}\right)}$$

$$\Delta T_{lm} = 110.981^\circ\text{C}$$

Step 5 of 6

The correction factor for two shell and 12 tube pass can be determined as follows

$$P = \frac{t_2 - t_1}{T_1 - t_1} = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$$

$$= \frac{70 - 20}{170 - 20}$$

$$P = 0.333$$

$$R = \frac{T_1 - T_2}{t_2 - t_1} = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$$

$$= \frac{170 - 142.739}{70 - 20}$$

$$R = 0.545$$

At these P and R values from correction factor F charts for two shell and 12tube passes and cross flow heat exchangers (b)

$$F = 1$$

Step 6 of 6

By substituting all values heat transfer surface area becomes

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

$$= \frac{627000}{(350)(1)(110.981)}$$

$$\boxed{A_s = 16.14 \text{ m}^2}$$

Therefore the heat transfer surface area on the tube side is $A_s = 16.14$ m^2

Question: 22.054P

A shell-and-tube heat exchanger with 2-shell passes and 8-tube passes is used to heat ethyl alcohol *(cp* = 2670 J/kg·K) in the tubes from 25°C to 70°C at a rate of 2.1 kg/s. The heating is to be done by water *(cp* = 4190 J/kg·K) that enters the shell side at 95°C and leaves at 45°C. If the overall heat transfer coefficient is 950 W/m2·K, determine the heat transfer surface area of the heat exchanger.

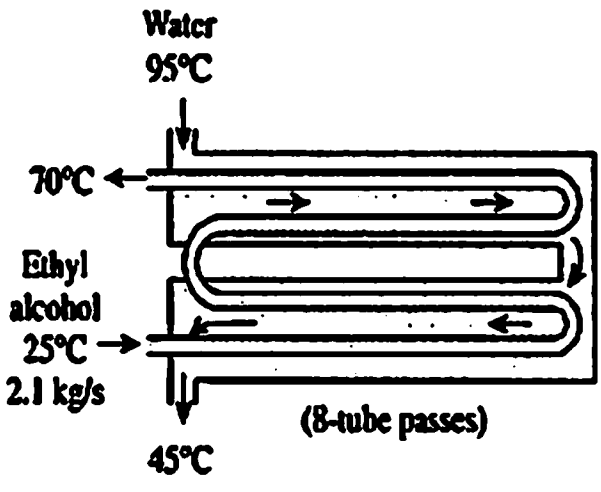

FIGURE P22–54

Step 1 of 6

Given data:

Specific heats of water $c_{ph} = 4190$ J/kg.°C

Specific heats of ethyl alcohol $c_{pc} = 2670$ J/kg.°C

Overall heat transfer coefficient $U = 950$ W/m^2.°C

Step 2 of 6

Heat transfer rate is

$$\dot{Q} = [\dot{m}_c c_{pc}(T_{out} - T_{in})]_{\text{Ethyl alcohol}}$$
$$= (2.1)(2670)(70-25)$$
$$= 252.315 \text{ kW}$$

Step 3 of 6

And

$$P = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$$
$$= \frac{45-95}{25-95}$$
$$= 0.7$$
$$R = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$$
$$= \frac{25-70}{45-95}$$
$$= 0.9$$

Step 4 of 6

From the correction chart
At these P and R values $F = 0.77$
For this counter flow heat exchanger LMTD determined to be

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= (95-70)$$
$$= 25°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= (45-25)$$
$$= 20°\text{C}$$

Step 5 of 6

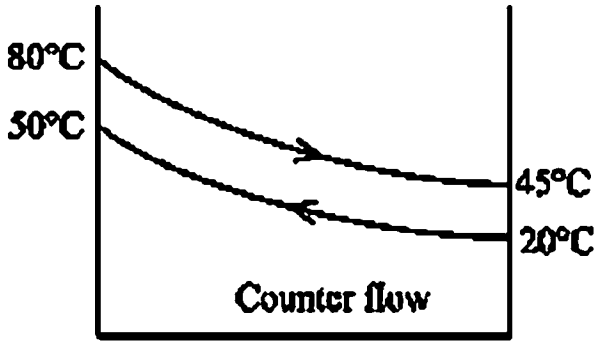
Log mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$
$$= \frac{25-20}{\ln\left(\frac{25}{20}\right)}$$
$$= 22.407°\text{C}$$

Step 6 of 6

Heat transfer surface area is determined to be

$$\dot{Q} = UA_s\Delta T_{lm}$$
$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$
$$A_s = \frac{252315}{(950)(0.77)(22.407)}$$
$$= 15.3937 \text{ m}^2$$



$$\therefore A_s = 15.3937 \text{ m}^2$$

Question: 22.055P

Consider a water-to-water double-pipe heat exchanger whose flow arrangement is not known. The temperature measurements indicate that the cold water enters at 20°C and leaves at 50°C, while the hot water enters at 80°C and leaves at 45°C.Do you think this is a parallel-flow or counter-flow heat exchanger? Explain.

Step 1 of 1

In parallel-flow heat exchangers, the temperature of the cold water can never exceed that of the hot fluid. In this case $T_{\text{cold out}} = 50°C$ which is greater than $T_{\text{hot out}} = 45°C$. Therefore this must be a counter-flow heat exchanger

Question: 22.056P

Cold water *(cp* = 4180 J/kg·K) leading to a shower enters a thin-walled double-pipe counter-flow heat exchanger at 15°C at a rate of 1.25 kg/s and is heated to 60°C by hot water *(cp* = 4190 J/kg·K) that enters at 100°C at a rate of 4 kg/s. If the overall heat transfer coefficient is 880 W/m2·K, determine the rate of heat transfer and the heat transfer surface area of the heat exchanger.

Step 1 of 7

Using NTU method heat transfer surface area is determined as follows

The heat capacity rate of cold fluid is,

$$C_c = \dot{m}_c C_{pc}$$

Here

Specific heat of cold water, $c_{pc} = 4180$ J/kg-K

Mass flow rate of cold water, $\dot{m}_c = 1.25$ kg/s

Substitute 4180 J/kg-K for c_{pc}, 1.25 kg/s for $\dot{m}_c$ in the above equation

$$\begin{aligned} C_c &= \dot{m}_c C_{pc} \\ &= (1.25 \text{ kg/s})(4180 \text{ J/kg-K}) \\ &= 5225 \text{ W/K} \end{aligned}$$

Step 2 of 7

The heat capacity rate of hot fluid is,

$$C_h = \dot{m}_h C_{ph}$$

Here

Specific heat of hot water, $c_{ph} = 4190$ J/kg-K

Mass flow rate of hot water, $\dot{m}_h = 4$ kg/s

Substitute 4190 J/kg-K for c_{ph}, 4 kg/s for $\dot{m}_h$ in the above equation

$$\begin{aligned} C_h &= \dot{m}_h C_{ph} \\ &= (4 \text{ kg/s})(4190 \text{ J/kg-K}) \\ &= 16760 \text{ W/K} \end{aligned}$$

Step 3 of 7

Therefore the minimum heat capacity is

$$C_{min} = C_c = 5225 \text{ W/K}$$

And

$$\begin{aligned} C &= \frac{C_{min}}{C_{max}} \\ &= \frac{5225}{16760} \\ &= 0.31 \end{aligned}$$

Step 4 of 7

The maximum heat transfer rate is,

$$\dot{Q}_{max} = C_{min}\left(T_{h,in} - T_{c,in}\right)$$

Temperature at inlet of cold fluid, $T_{c,in}$

Temperature at inlet of hot fluid, $T_{h,in}$

Substitute 15°C for $T_{c,in}$, 100°C for $T_{h,in}$, 5225 W/K for C_{min} in the above equation

$$\begin{aligned} \dot{Q}_{max} &= C_{min}\left(T_{h,in} - T_{c,in}\right) \\ &= 5225 \text{ W/K}(100°\text{C} - 15°\text{C}) \\ &= 444125 \text{ W} \\ &= 444.125 \text{ kW} \end{aligned}$$

Step 5 of 7

Actual heat transfer is

$$\dot{Q} = C_c(T_{c,out} - T_{c,in})$$

Here

Temperature at outlet of cold fluid, $T_{h,in}$

Substitute 15°C for $T_{c,in}$, 60°C for $T_{h,in}$, 5225 W/K for C_c in the above equation

$$\begin{aligned} \dot{Q} &= C_c(T_{c,out} - T_{c,in}) \\ &= (5225 \text{ W/K})(60°\text{C} - 15°\text{C}) \\ &= 235125 \text{ W} \\ &= 235.125 \text{ kW} \end{aligned}$$

Therefore, the actual rate of heat transfer $\dot{Q}$ is $\boxed{235.125 \text{ kW}}$

Step 6 of 7

Then effectiveness of the heat exchanger is

$$\begin{aligned} \varepsilon &= \frac{\dot{Q}}{\dot{Q}_{max}} \\ &= \frac{235.125}{444.125} \\ &= 0.52 \end{aligned}$$

NTU of the heat exchanger is,

$$\begin{aligned} NTU &= \frac{1}{C-1}\ln\left(\frac{\varepsilon - 1}{\varepsilon C - 1}\right) \\ &= \frac{1}{0.31-1}\ln\left(\frac{0.52-1}{0.52\times 0.31-1}\right) \\ &= 0.808 \end{aligned}$$

Step 7 of 7

Heat transfer surface area is,

$$NTU = \frac{UA_s}{C_{min}}$$

Overall heat transfer coefficient, U

Substitute 950 W/m^2·K for U, 0.808 for NTU, 5225 W/K for C_{min} in the above equation.

$$\begin{aligned} NTU &= \frac{UA_s}{C_{min}} \\ A_s &= \frac{NTU(C_{min})}{U} \\ &= \frac{(0.808)(5225 \text{ W/K})}{880 \text{ W/m}^2\text{·K}} \\ &= 4.79 \text{ m}^2 \end{aligned}$$

Therefore, the heat transfer surface area A_s is $\boxed{4.79 \text{ m}^2}$

Question: 22.057P

Steam is to be condensed on the shell side of a 1 -shell- pass and 8-tube-passes condenser, with 60 tubes in each pass at 90°F *(hfg* = 1043 Btu/lbm). Cooling water *(cp* = 1.0 Btu/lbm·°F) enters the tubes at 55°F and leaves at 70°F. The tubes are thin walled and have a diameter of 3/4 in and length of 5 ft per pass. If the overall heat transfer coefficient is 600 Btu/h·ft2·°F, determine (*a*) the rate of heat transfer, *(b)* the rate of condensation of steam, and (*c*) the mass flow rate of cold water.

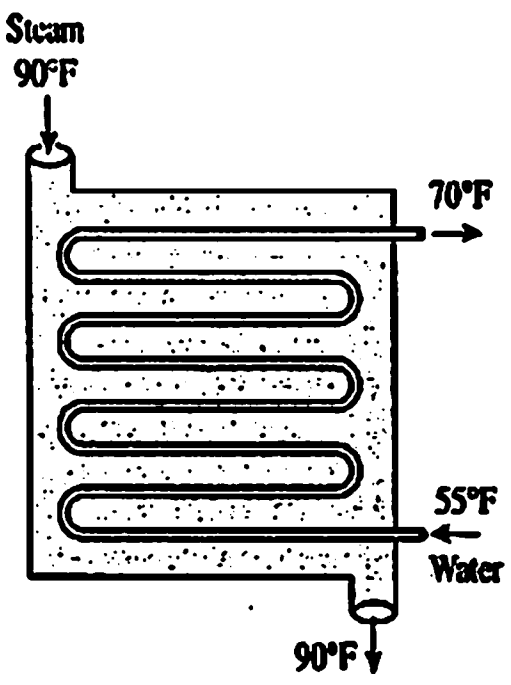


FIGURE P22–57E

Step 1 of 5

Given

The heat of vaporization of water at 90°F is $h_{fg} = 1043$ Btu/lbm

Specific heat of cold water is $c_p = 1$ Btu/lbm · °F

Overall heat transfer coefficient is $U = 600$ Btu/h.ft^2 · °F

The diameter of the tube

$$D = \frac{3}{4}\text{in}$$

$$D = 0.0625 \text{ ft}$$

Length of the tube is $L = 5$ ft

Cooling water enters the tubes at temperature $T_{c,in} = 55°F$

Cooling water exits the tubes at temperature $T_{c,out} = 70°F$

Condenser temperature $T_{h,in} = T_{h,out} = 90°F$

Step 2 of 5

Heat transfer surface area is

$$A_s = n\pi DL$$
$$= 8(50)(\pi)(0.0625 \text{ ft})(5 \text{ ft})$$
$$A_s = 471.238 \text{ ft}^2$$

The log mean temperature difference of the heat exchanger is calculated as

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$\Delta T_1 = (90 - 70)°F$$
$$\Delta T_1 = 20°F$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= (90 - 55)$$
$$\Delta T_2 = 35°F$$

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined as

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln \Delta T_1 / \Delta T_2}$$
$$= \frac{20 - 35}{\ln 20/35}$$
$$\Delta T_{lm} = 26.8°F$$

Step 3 of 5

(a) The rate of heat transfer becomes

$$\dot{Q} = UA_s \Delta T_{lm}$$

$$\dot{Q} = (600 \text{ Btu/h.ft}^2\text{.°F})(471.238 \text{ ft}^2)(26.8°F)$$

$$\boxed{\dot{Q} = 7.577 \times 10^6 \text{ Btu/h}}$$

Step 4 of 5

b) The rate of condensation of the steam

$$\dot{Q} = (\dot{m} h_{fg})_{steam}$$

$$\dot{m}_{steam} = \frac{\dot{Q}}{h_{fg}}$$
$$= \frac{7.577 \times 10^6 \text{ Btu/h}}{1043 \text{ Btu/lbm}}$$
$$= 7264.62 \text{lbm/h}$$

$$\boxed{\dot{m}_{steam} = 2.0179 \text{lbm/s}}$$

Step 5 of 5

c) The mass flow rate of the cold water is

$$\dot{Q} = [\dot{m} c_p (T_{out} - T_{in})]_{cold\ water}$$

$$\dot{m}_{cold\ water} = \frac{\dot{Q}}{c_p (T_{out} - T_{in})}$$
$$= \frac{7.577 \times 10^6 \text{ Btu/h}}{(1.0 \text{ Btu/lbm} \cdot °F)(70°F - 55°F)}$$
$$= 0.5051 \times 10^6 \text{ lbm/h}$$

$$\boxed{\dot{m}_{cold\ water} = 140.305 \text{ lbm/s}}$$

Question:

Reconsider Prob. 22–57E. Using EES (or other) software, investigate the effect of the condensing steam temperature on the rate of heat transfer, the rate of condensation of steam, and the mass flow rate of cold water. Let the steam temperature vary from 80°F to 120°F. Plot the rate of heat transfer, the condensation rate of steam, and the mass flow rate of cold water as a function of steam temperature, and discuss the results.

Step 1 of 8

This given problem is solved in EES "Engineering Equation Solver" in the following method.
Open a new window in the EES software by ceasing " File > New " and type the program as shown below.

Equations Window

```
"Given data"
n=8*60
h_fg=1043 [Btu/lbm]
cp=1 [Btu/lbm-F]
D=(3/4) [in]*convert(in,ft)
L=5 [ft]
T_c_in=55 [F]
T_c_out=70 [F]
"T_h_in=90 [F]"
T_h_in=T_h_out
U=600 [Btu/h-ft^2]

A_s=n*pi*D*L                              "Surface area "
"Log mean temperature difference of the heat exchanger"
DELTAT_lm=(DELTAT_1-DELTAT_2)/ln(DELTAT_1/DELTAT_2)
DELTAT_1=T_h_in-T_c_out
DELTAT_2=T_h_out-T_c_in

"The rate of heat transfer "
Q_dot=U*A_s*DELTAT_lm

"The rate of condensation of the steam"
Q_dot=m_dot_steam*h_fg

"Mass flow rate of the cold water "
Q_dot=m_dot_water*cp*(T_c_out-T_c_in)*convert(lb_m/hr,lb_m/s)
```

Step 2 of 8

To check weather the program typed is in correct mathematical format or not go to "Options > Function info" a window opens as show below.

Formatted Equations

Given data

$n = 8 \cdot 60$

$h_{fg} = 1043 \quad [Btu/lbm]$

$cp = 1 \quad [Btu/lbm\text{-}F]$

$D = 3 / 4 \cdot 1 \quad [in] \cdot \left| 0.083333 \cdot \frac{ft}{in} \right|$

$L = 5 \quad [ft]$

$T_{c,in} = 55 \quad [F]$

$T_{c,out} = 70 \quad [F]$

$T_{h,in} = 90 \quad [F]$

$T_{h,in} = T_{h,out}$

$U = 600 \quad [Btu/h\text{-}ft^2]$

$A_s = n \cdot \pi \cdot D \cdot L$ Surface area

Log mean temperature difference of the heat exchanger

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left[\frac{\Delta T_1}{\Delta T_2}\right]}$$

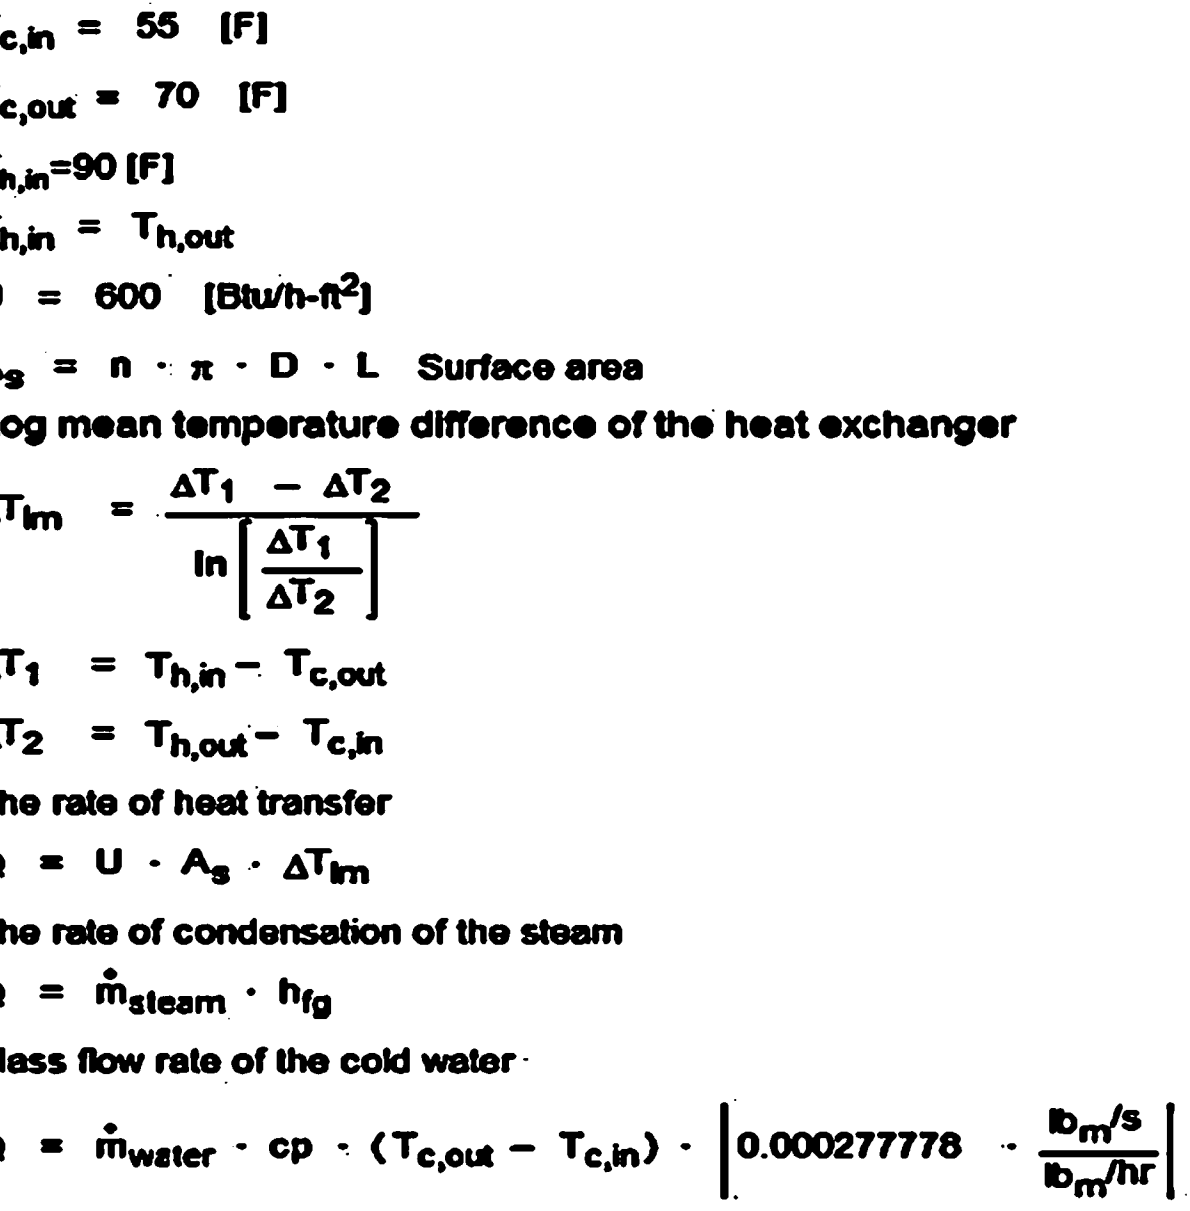
$\Delta T_1 = T_{h,in} - T_{c,out}$

$\Delta T_2 = T_{h,out} - T_{c,in}$

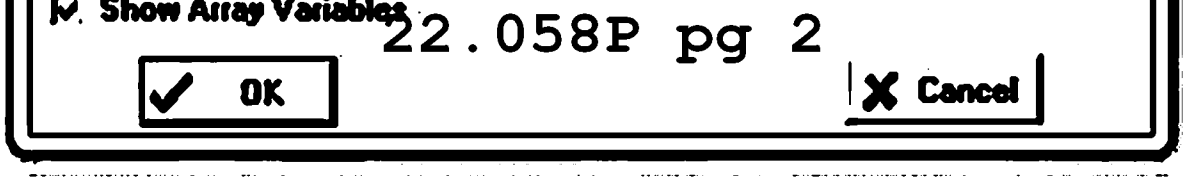
The rate of heat transfer

$\dot{Q} = U \cdot A_s \cdot \Delta T_{lm}$

The rate of condensation of the steam

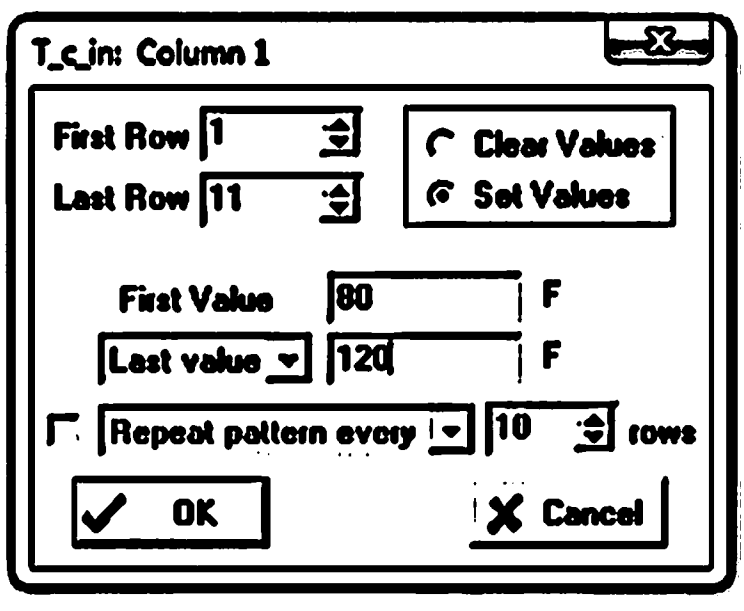


$\dot{Q} = \dot{m}_{steam} \cdot h_{fg}$



Mass flow rate of the cold water

$$\dot{Q} = \dot{m}_{water} \cdot cp \cdot (T_{c,out} - T_{c,in}) \cdot \left| 0.000277778 \cdot \frac{lb_m/s}{lb_m/hr} \right|$$



Step 3 of 8

Now to create a tabulated result go to "Tables > New Parametric Tables". Fill in the details as shown below,

To enter the values in the velocity column click on the drop tab in velocity column. A new windows opens fill in the details as shown below,

Step 4 of 8

Click on the run button which is symbolized as a green icon on the left side your results will be displayed as shown,

Parametric Table

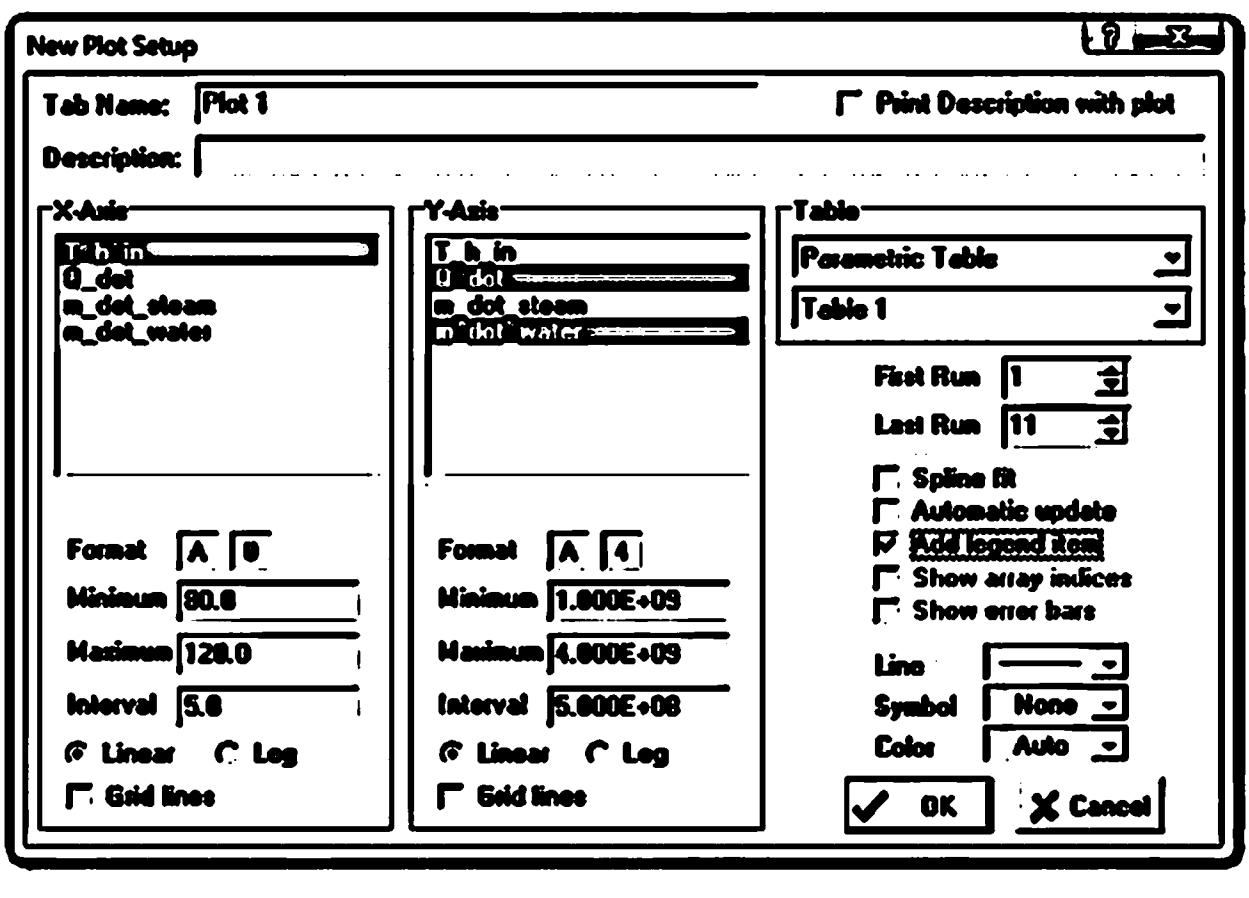


Table 1

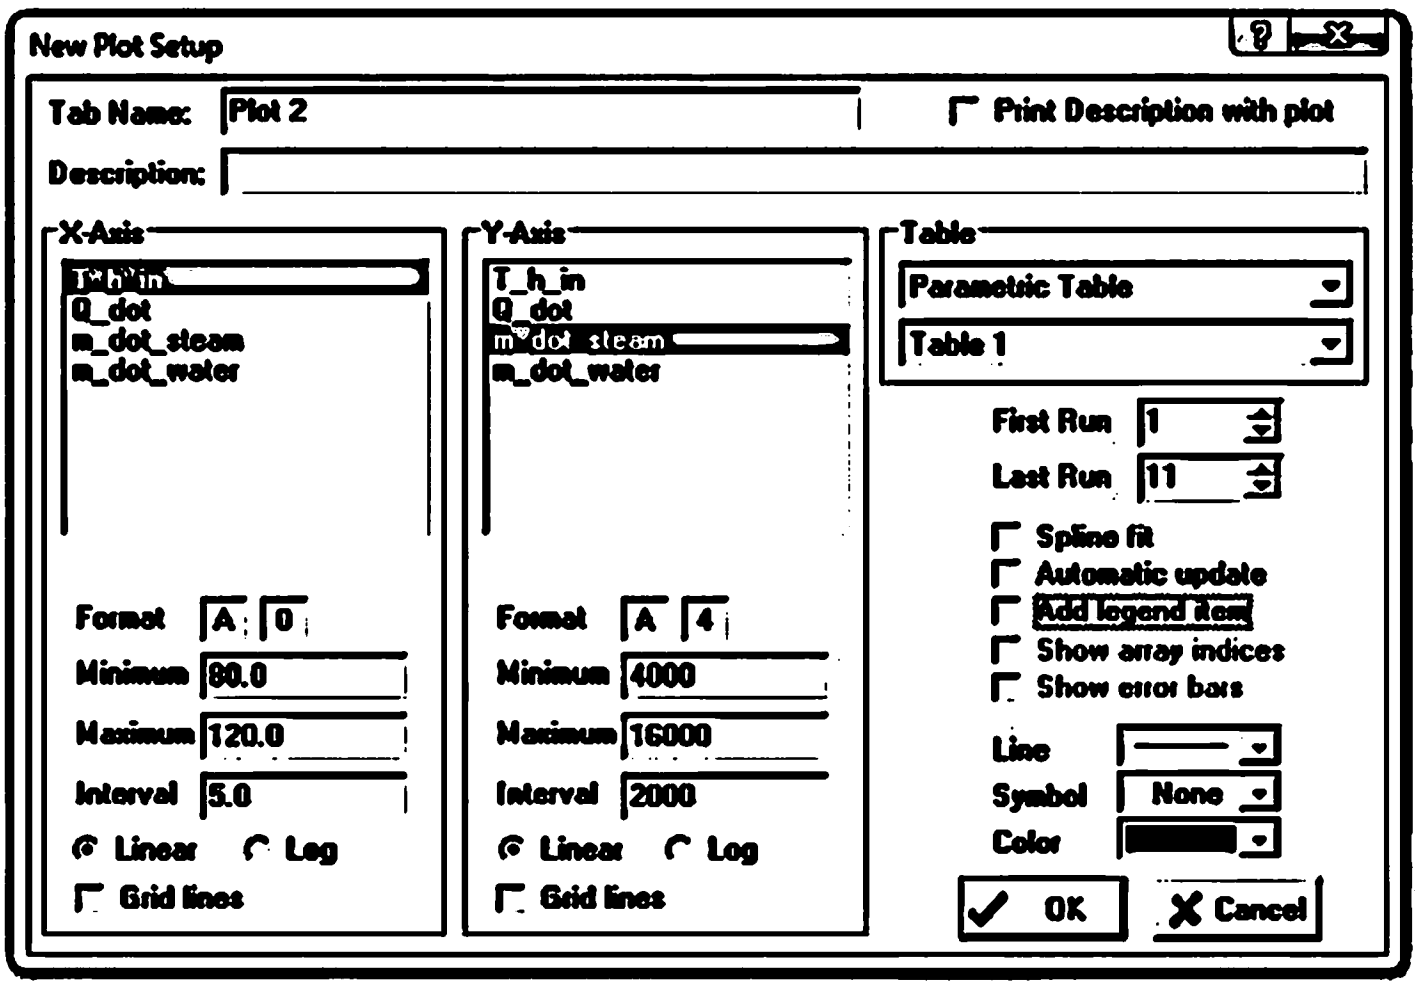
	1 $T_{h,in}$ [F]	2 $\dot{Q}$ [Btu/hr]	3 $\dot{m}_{steam}$ [lbm/hr]	4 $\dot{m}_{water}$ [lbm/hr]
Run 1	80	4.629E+06	4438	1.111E+09
Run 2	84	5.824E+06	5584	1.398E+09
Run 3	88	6.997E+06	6709	1.679E+09
Run 4	92	8.158E+06	7822	1.958E+09
Run 5	96	9.311E+06	8928	2.235E+09
Run 6	100	1.046E+07	10029	2.510E+09
Run 7	104	1.160E+07	11126	2.785E+09
Run 8	108	1.274E+07	12222	3.059E+09
Run 9	112	1.388E+07	13315	3.333E+09
Run 10	116	1.502E+07	14408	3.606E+09
Run 11	120	1.617E+07	15499	3.880E+09

Step 5 of 8

Due to the difference in range of values of the variables we draw the plot twice. Fist for $T_{h,in}$ Vs $\dot{Q}, \dot{m}_{water}$.

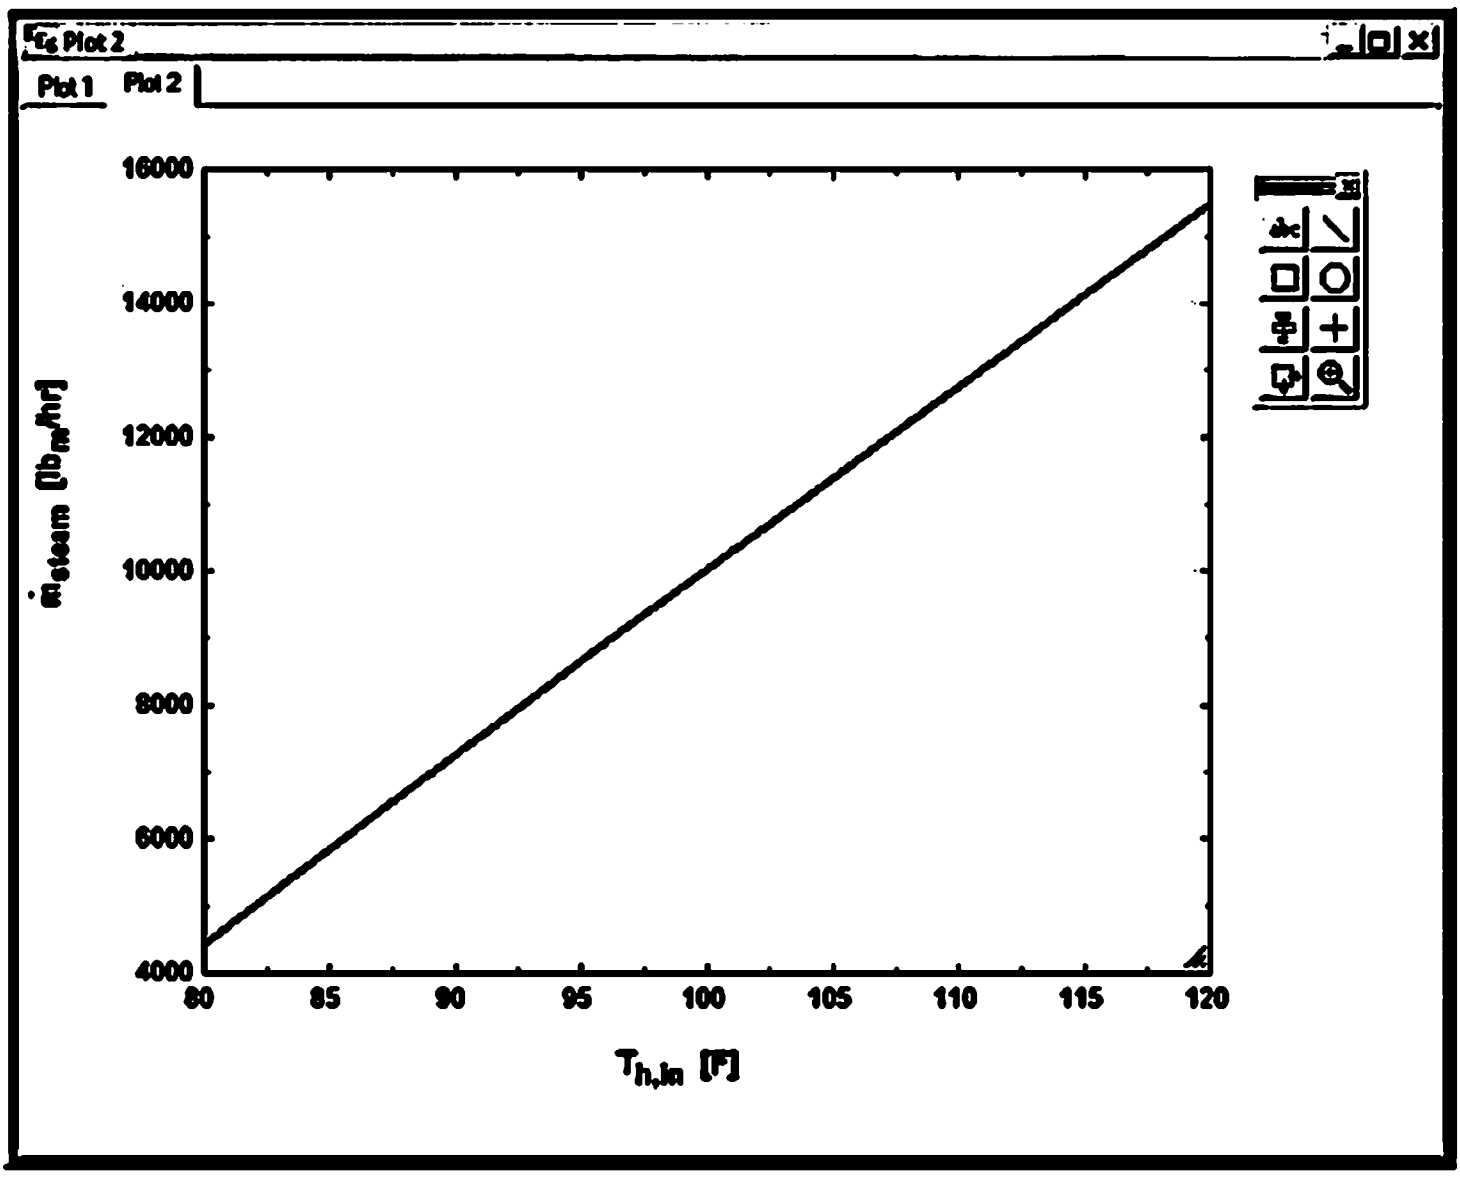
Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 6 of 8



By clicking on OK the graph will be generated as shown,

Step 7 of 8



Step 7 of 8

The plot for $T_{h,in}$ Vs $\dot{m}_{steam}$

Now to generate a graph go to " Plots > New Plot window > X-Y Plot ", verify the settings as shown below,

Step 8 of 8

Question: 22.059P

Hot exhaust gases of a stationary diesel engine are to be used to generate steam in an evaporator. Exhaust gases (*cp* = 1051 J/kg·K) enter the heat exchanger at 550°C at a rate of 0.25 kg/s while water enters as saturated liquid and evaporates at 200°C (*hfg* = 1941 kJ/kg). The heat transfer surface area of the heat exchanger based on water side is 0.5 m2 and overall heat transfer coefficient is 1780 W/m2·K. Determine the rate of heat transfer, the exit temperature of exhaust gases, and the rate of evaporation of water.

Step 1 of 5

Given

The specific heat of exhaust gases, $c_{ph} = 1051\ \text{J/kg}^\circ\text{C}$

The heat of vaporization of exhaust gases is $h_{fg} = 1941\ \text{kJ/kg}$

Mass flow rate of exhaust gases $\dot{m}_h = 0.25\ \text{kg/s}$

Heat transfer surface area based on water side, $A_s = 0.5\ \text{m}^2$

Overall heat transfer coefficient $U = 1780\ \text{W/m}^2{}^\circ\text{C}$

Inlet temperature of exhaust gases, $T_{h,in} = 550^\circ\text{C}$

Temperature of evaporator liquid, $T_{c,in} = T_{c,out} = 200^\circ\text{C}$

Step 2 of 5

The LMTD between the steam and the exhaust gases:

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= (550 - 200)^\circ\text{C}$$
$$\Delta T = 350^\circ\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$\Delta T_2 = (T_{h,out} - 200)^\circ\text{C}$$
$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$\Delta T_{lm} = \frac{350 - (T_{h,out} - 200)}{\ln\left[\frac{350}{(T_{h,out} - 200)}\right]}$$

Step 3 of 5

The rate of heat transfer is expressed as

$$\dot{Q} = UA_s \Delta T_{lm}$$

And $\dot{Q} = [\dot{m}_h C_{hp} (T_{h,out} - T_{h,in})]_{\text{exhaust gases}}$

Therefore

$$UA_s \Delta T_{lm} = [\dot{m}_h C_{ph} (T_{h,in} - T_{h,out})]_{\text{exhaust gases}}$$

$$1780 \times 0.5 \times \left\{\frac{350 - (T_{h,out} - 200)}{\ln\left[\frac{350}{(T_{h,out} - 200)}\right]}\right\} = 0.25 \times 1051 \times \left(550 - T_{h,out}\right)$$

$$\therefore T_{out} = 211.8^\circ\text{C}$$

Step 4 of 5

Heat transfer rate is determined by

$$\dot{Q} = [\dot{m}_h C_{hp} (T_{h,out} - T_{h,in})]_{\text{exhaust gases}}$$
$$= (0.25)(1051) \times (550\text{-}211.8)$$

$$\therefore \dot{Q} = 88.9\ \text{kW}$$

Step 5 of 5

Rate of vaporization of water can be calculated by

$$\dot{m}_{water} = \frac{\dot{Q}}{h_{fg}}$$
$$= \frac{88.9\ \text{kJ/s}}{1941\ \text{kJ/kg}}$$

$$\therefore \dot{m}_{water} = 0.0458\ \text{kg/s}$$

Question: 22.060P

Reconsider Prob. 22–59. Using EES (or other) software, investigate the effect of the exhaust gas inlet temperature on the rate of heat transfer, the exit temperature of exhaust gases, and the rate of evaporation of water. Let the temperature of exhaust gases vary from 300°C to 600°C. Plot the rate of heat transfer, the exit temperature of exhaust gases, and the rate of evaporation of water as a function of the temperature of the exhaust gases, and discuss the results.

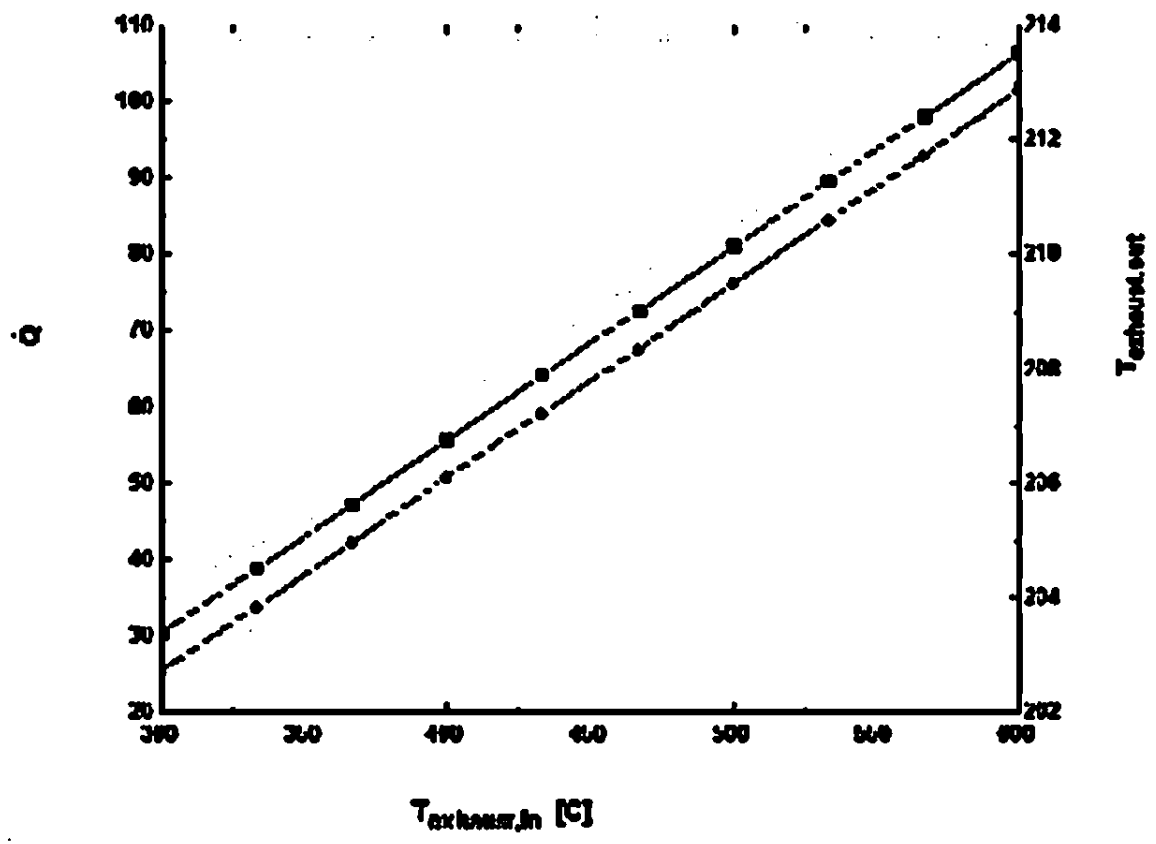
Step 1 of 4

The given problem can be solved using EES software by following the below steps.

1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
"GIVEN"
"T_exhaust_in=550 [C]"
C_p_exhaust=1.051 [kJ/kg-C]
m_dot_exhaust=0.25 [kg/s]
T_w=200 [C]
h_fg_w=1941 [kJ/kg]
A=0.5 [m^2]
U=1.780 [kW/m^2-C]
"ANALYSIS"
DELTAT_1=T_exhaust_in-T_w
DELTAT_2=T_exhaust_out-T_w
DELTAT_lm=(DELTAT_1-DELTAT_2)/ln(DELTAT_1/DELTAT_2)
Q_dot=U*A*DELTAT_lm
Q_dot=m_dot_exhaust*C_p_exhaust*(T_exhaust_in-T_exhaust_out)
Q_dot=m_dot_w*h_fg_w
```

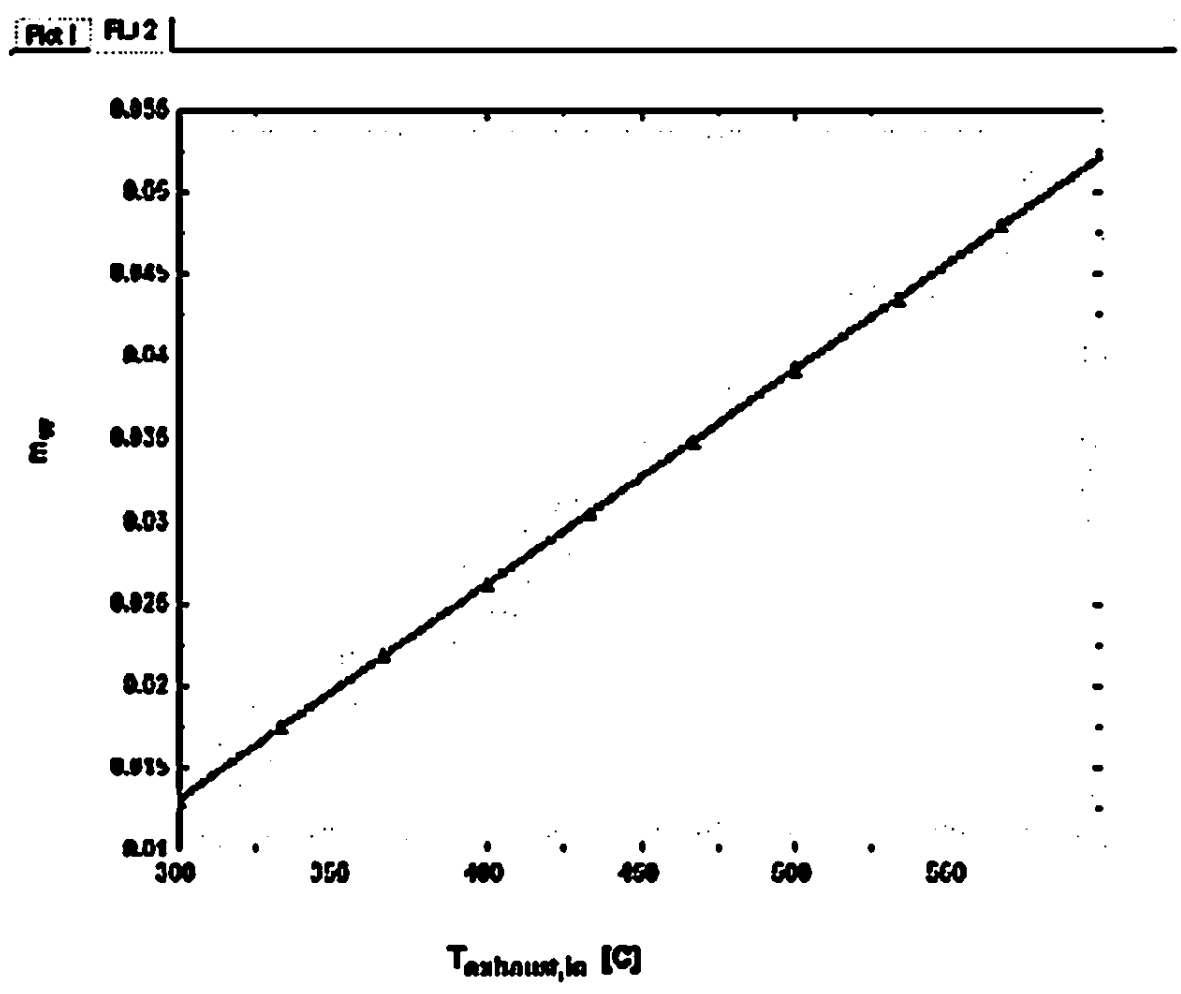
Step 2 of 4



After writing the equations in the Equation window then click on table in menu bar. Then select new parameter table. The temperature of exhaust gases the varying from the value $T_{exhaust,in} = 300°C$ to $600°C$ we get

Table 1

	$\dot{m}_w$	$\dot{Q}$	$T_{exhaust,in}$ [C]	$T_{exhaust,out}$
Run 1	0.01308	25.39	300	203.4
Run 2	0.01744	33.85	333.3	204.5
Run 3	0.0218	42.31	366.7	205.6
Run 4	0.02615	50.77	400	206.8
Run 5	0.03052	59.24	433.3	207.9
Run 6	0.03488	67.7	466.7	209
Run 7	0.03921	76.16	500	210.1
Run 8	0.0435	84.62	533.3	211.3
Run 9	0.04795	93.09	566.7	212.4
Run 10	0.05232	101.5	600	213.5



Step 3 of 4

To plot the rate of heat transfer, the exist temperature of the exhaust gases and the rate of evaporation of water as a function of the exhaust gases, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu. Now specify the X and Y parameters as $T_{exhaust,in}$ and $\dot{Q}$ and click OK. Now from the 'New Plot window' select overlay and specify the second parameters on the X-Y as $T_{exhaust,in}$ and $T_{exhaust,out}$.

Step 4 of 4

To plot the the rate of evaporation of water as a function of the exhaust gases, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu. Now specify the X and Y parameters as $T_{exhaust,in}$ and $\dot{m}_w$ and click OK.

Question: 22.061P

In a textile manufacturing plant, the waste dyeing water (cp = 4295 J/kg·K) at 80°C is to be used to preheat fresh water (cp = 4180 J/kg·K) at 10°C at the same flow rate in a double-pipe counter-flow heat exchanger. The heat transfer surface area of the heat exchanger is 1.65 m2 and the overall heat transfer coefficient is 625 W/m2·K. If the rate of heat transfer in the heat exchanger is 35 kW, determine the outlet temperature and the mass flow rate of each fluid stream.

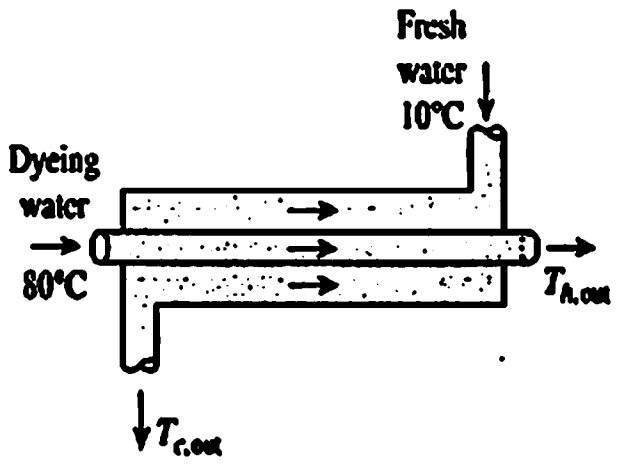


FIGURE P22–61

Step 1 of 5

Specific heat of waste dyeing water, $c_p = 4295\ \text{J/kg}\cdot\text{K}$

Specific heat of fresh water, $c_{pw} = 4180\ \text{J/kg}\cdot\text{K}$

Inlet temperature of waste dyeing water, $T_{h_in} = 80°\text{C}$

Inlet temperature of fresh water, $T_{c_in} = 10°\text{C}$

Overall heat transfer coefficient, $U = 625\ \text{W/m}^2\cdot\text{K}$

Surface area of the heat exchanger, $A_s = 1.65\ \text{m}^2$

The rate of heat transfer in the heat exchanger, $\dot{Q} = 35\ \text{kW}$

Step 2 of 5

The mass flow rate of waste dyeing water and fresh water are same and let it be $\dot{m}$

The temperature differences between the dyeing water and the fresh water at the two ends of the heat exchanger are

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$\Delta T_1 = 80 - T_{c,out}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$\Delta T_2 = T_{h,out} - 10$$

Step 3 of 5

Therefore the LMTD of the heat exchanger is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$= \frac{\left(80 - T_{c,out}\right) - \left(T_{h,out} - 10\right)}{\ln\left[\frac{\left(80 - T_{c,out}\right)}{\left(T_{h,out} - 10\right)}\right]}$$

Step 4 of 5

The rate of heat transfer can be expressed as

$$\dot{Q} = UA_s\Delta T_{lm}$$

$$35 = 0.625 \times 1.65 \times \frac{\left(80 - T_{c,out}\right) - \left(T_{h,out} - 10\right)}{\ln\left[\frac{\left(80 - T_{c,out}\right)}{\left(T_{h,out} - 10\right)}\right]} \qquad \ldots\ldots (1)$$

The rate of heat transfer can also be expressed for dyeing water

$$\dot{Q} = \dot{m}c_p\left(T_{h,in} - T_{h,out}\right)$$

$$35 = \dot{m} \times 4.295\left(80 - T_{h,out}\right) \qquad \ldots\ldots (2)$$

Step 5 of 5

And the rate of heat transfer for fresh cooling water,

$$\dot{Q} = \dot{m}c_{pw}\left(T_{c,out} - T_{c,in}\right)$$

$$35 = \dot{m} \times 4.18\left(T_{c,out} - 10\right) \qquad \ldots\ldots (3)$$

Solving equations (1), (2) and (3) by using an equation solver such as EES, the unknowns are determined to be

Outlet temperature of fresh water is $\boxed{T_{c,out} = 40.6°\text{C}}$

Outlet temperature of waste dyeing water is $\boxed{T_{h,out} = 50.2°\text{C}}$

Mass flow rate is $\boxed{\dot{m} = 0.278\ \text{kg/s}}$.

Question: 22.062P

A heat exchanger contains 400 tubes with inner diameter of 23 mm and outer diameter of 25 mm. The length of each tube is 3.7 m. The corrected log mean temperature difference is 23°C, while the inner surface convection heat transfer coefficient is 3410 W/m2·K and the outer surface convection heat transfer coefficient is 6820 W/m2·K. If the thermal resistance of the tubes is negligible, determine the heat transfer rate.

Step 1 of 4

Perimeter of the inner surface,

$$p_i = \pi D_i$$

Here, inner diameter of tube, D_i

Substitute $23\,\text{mm}$ for D_i in the above equation

$$\begin{aligned} p_i &= \pi D_i \\ &= \pi \times 0.023 \\ &= 0.07226\,\text{m} \end{aligned}$$

Total inner surface area is,

$$A_i = p_i \times L \times n$$

Here, Length of the tube, L,

Number of tubes in the heat exchanger, n

Substitute $3.7\,\text{m}$ for L, 400 for n, $0.07226\,\text{m}$ for p_i in the below equation

$$\begin{aligned} A_i &= p_i \times L \times n \\ &= 0.07226 \times 3.7 \times 400 \\ &= 106.94\,\text{m} \end{aligned}$$

Step 2 of 4

Perimeter of the outer surface,

$$p_o = \pi D_o$$

Here, Outer diameter of tube, D_o

Substitute $25\,\text{mm}$ for D_o in the above equation

$$\begin{aligned} p_o &= \pi D_o \\ &= \pi \times 0.025 \\ &= 0.07854\,\text{m} \end{aligned}$$

Total outer surface area is;

$$A_o = p_o \times L \times n$$

Here, Length of the tube, L,

Number of tubes in the heat exchanger, n

Substitute $3.7\,\text{m}$ for L, 400 for n, $0.07854\,\text{m}$ for p_o in the below equation

$$\begin{aligned} A_o &= p_o \times L \times n \\ &= 0.07854 \times 3.7 \times 400 \\ &= 116.24\,\text{m} \end{aligned}$$

Step 3 of 4

Overall heat transfer coefficient is,

$$\frac{1}{UA_s} = \frac{1}{h_i A_i} + R_{wall} + \frac{1}{h_o A_o}$$

Here

Inner surface heat transfer coefficient, h_i

Outer surface heat transfer coefficient, h_o

Substitute $3410\ \text{W/m}^2\cdot\text{K}$ for h_i, $6820\ \text{W/m}^2\cdot\text{K}$ for h_o, $116.24\,\text{m}$ for A_o, $106.94\,\text{m}$ for A_i in the above equation

$$\begin{aligned} \frac{1}{UA_s} &= \frac{1}{h_i A_i} + R_{wall} + \frac{1}{h_o A_o} \\ &= \frac{1}{h_i A_i} + \frac{1}{h_o A_o} \qquad \text{(Negleting wall thickness, } R_{wall} = 0) \\ &= \frac{1}{3410 \times 106.94} + \frac{1}{6820 \times 116.24} \\ &= 249771.41\,\text{W/m}^2\cdot\text{K} \end{aligned}$$

Step 4 of 4

Heat transfer rate is,

$$\dot{Q} = UA_s \Delta T_{lm}$$

Here, Corrected log mean temperature difference, ΔT_{lm}

Substitute $23°\text{C}$ for ΔT_{lm}, $249771.41\,\text{W/m}^2\cdot\text{K}$ for (UA_s) in the above equation

$$\begin{aligned} \dot{Q} &= UA_s \Delta T_{lm} \\ &= 249771.41 \times 23 \\ &= 5744742\,\text{W/m}^2 \\ &= 5744.71\ \text{kW/m}^2 \end{aligned}$$

The total heat transfer rate is obtained as $\boxed{5744.71\text{kW/m}^2}$

Question: 22.063P

A single pass heat exchanger is to be designed to heat 100,000 lbm of water in an hour from 60°F to 100°F by condensation of water vapor at 230°F on the shell side. Each tube has an inner diameter of 1.2 in. and a wall thickness of 0.12 in. The inner surface convection heat transfer coefficient is 480 Btu/h·ft2·°F and the outer surface convection heat transfer coefficient is 2000 Btu/h·ft2·°F. If the inlet velocity of water (*cpc* = 1 Btu/lbm·°F and ρ = 62.3 lbm/ft3) on the tube side is 4 ft/s, determine the required number of tubes and length of tubes. Assume the thermal resistance of the tubes is negligible.

Step 1 of 6

Mass flow rate of cold water,

$$\dot{m}_c = A \times V \times \rho \times N$$

$$= \frac{\pi}{4} \times d_i^2 \times V \times \rho \times N$$

Here, Number of tubes in the heat exchanger, N, Length of the tube, L, Velocity of the water, V ,Density of water, ρ , Mass flow rate of the water to be heated, $\dot{m}_c$, Inner diameter of the tube, d_i

$$\dot{m}_c = 10000 \text{ lbm/hr}$$

$$= 27.78 \text{ lbm/s}$$

Substitute 27.78 lbm/s for $\dot{m}_c$, 62.3 lbm/ft^3 for ρ, 4 ft/s for V, 1.2 in. for d_i in the above equation.

$$\dot{m}_c = \frac{\pi}{4} \times d_i^2 \times V \times \rho \times N$$

$$27.78 = \frac{\pi}{4} \times \left(\frac{1.2}{12}\right)^2 \times 4 \times 62.3 \times N$$

$$N = 14.2$$

The number of tubes required is $\boxed{N = 14.2}$

Step 2 of 6

Logarithmic mean temperature is,

$$\Delta T_{lm} = \frac{(T_{h,i} - T_{c,i}) - (T_{h,o} - T_{c,o})}{\ln\left(\frac{(T_{h,i} - T_{c,i})}{(T_{h,o} - T_{c,o})}\right)}$$

Initial temperature of the water to be heated, $T_{c,i}$

Final temperature of the water after heated, $T_{c,o}$

Condensation water temperature, $T_{h,i} = T_{h,o}$

$$= T_{con}$$

Substitute 60°F for $T_{c,i}$, 100°F for $T_{c,o}$, 230°F for $T_{h,i}$ and $T_{h,o}$ in the above equation

$$\Delta T_{lm} = \frac{(T_{h,i} - T_{c,i}) - (T_{h,o} - T_{c,o})}{\ln\left(\frac{(T_{h,i} - T_{c,i})}{(T_{h,o} - T_{c,o})}\right)}$$

$$= \frac{(230 - 60) - (230 - 100)}{\ln\left(\frac{(230 - 60)}{(230 - 100)}\right)}$$

$$= 149.1°\text{F}$$

Step 3 of 6

Perimeter of the inner surface,

$$p_i = \pi d_i$$

Here, inner diameter of tube, d_i

Substitute 1.2 in. for d_i in the above equation

$$p_i = \pi d_i$$

$$= \pi \times 1.2$$

$$= 3.77 \text{ in.}$$

$$= 0.314 \text{ ft}$$

Total inner surface area is,

$$A_i = p_i \times L \times n$$

Here, Length of the tube, L,
Number of tubes in the heat exchanger, N

Substitute 14.2 for N, 0.314 ft for p_i in the below equation

$$A_i = p_i \times L \times N$$

$$= 0.314 \times L \times 14.2$$

$$= 4.46L$$

Step 4 of 6

Perimeter of the outer surface,

$$p_o = \pi d_o$$

$$= \pi(d_i + t)$$

Here, Thickness of the pipe, t

Substitute 1.2 in. for d_i, 0.12 in. for t in the above equation;

$$p_o = \pi(d_i + t)$$

$$= \pi(1.2 + 0.12)$$

$$= 4.146 \text{ in.}$$

$$= 0.3455 \text{ ft}$$

Total outer surface area is,

$$A_o = p_o \times L \times N$$

Substitute 14.2 for N, 0.3455 ft for p_o in the above equation

$$A_o = p_o \times L \times N$$

$$= 0.3455 \times L \times 14.2$$

$$= 4.91L$$

Step 5 of 6

Overall heat transfer coefficient is,

$$\frac{1}{UA_s} = \frac{1}{h_i A_i} + R_{wall} + \frac{1}{h_o A_o}$$

Here

Inner surface heat transfer coefficient, h_i

Outer surface heat transfer coefficient,

(Negleting wall thickness, $R_{wall} = 0$)

$$\frac{1}{UA_s} = \frac{1}{h_i A_i} + R_{wall} + \frac{1}{h_o A_o}$$

$$= \frac{1}{h_i A_i} + \frac{1}{h_o A_o}$$

Substitute 480 Btu/h·ft^2·°F for h_i, 2000 Btu/h·ft^2·°F for h_o, $4.91L$ for A_o, $4.46L$ for A_i in the above equation

$$\frac{1}{UA_s} = \frac{1}{h_i A_i} + \frac{1}{h_o A_o}$$

$$= \frac{1}{480 \times [4.46L]} + \frac{1}{2000 \times [4.91L]}$$

$$UA_s = 1757.63L \text{ Btu/h·ft}^2\text{·°F}$$

Step 6 of 6

Heat transfer rate is,

$$\dot{Q} = UA_s \Delta T_{lm}$$

Here, Corrected log mean temperature difference, ΔT_{lm}

Substitute 149.1 for ΔT_{lm}, $1757.63L$ Btu/h·ft^2·°F for (UA_s) in the above equation

$$\dot{Q} = UA_s \Delta T_{lm}$$

$$\dot{m} c_p (T_{c,o} - T_{c,i}) = UA_s \Delta T_{lm}$$

$$100000 \times 1 \times (100 - 60) = (1757.63L) \times 149.1$$

$$L = 1.53 \text{ ft}$$

$$= 18.32 \text{ in.}$$

There for the each of length is $\boxed{L = 18.32 \text{ in}}$.

Question: 22.064P

What does the effectiveness of a heat exchanger represent? Can effectiveness be greater than one? On what factors does the effectiveness of a heat exchanger depend?

Step 1 of 1

Effectiveness of heat exchanger is defined as the ratio of actual heat transfer rate to the maximum possible heat transfer rate.

$$\varepsilon = \frac{\dot{Q}}{Q_{max}}$$

Since the actual heat transfer is always less than maximum possible heat transfer effectiveness is always less than one.

Effectiveness of heat exchanger depends on the **geometry** of the heat exchanger as well as **flow arrangement**.

Question: 22.065P

For a specified fluid pair, inlet temperatures, and mass flow rates, what kind of heat exchanger will have the highest effectiveness: double-pipe parallel-flow, double-pipe counter-flow, cross-flow, or multipass shell-and-tube heat exchanger?

Step 1 of 1

Double-pipe counter-flow heat exchanger has high effectiveness for a specified fluid pair, inlet temperature and mass flow rate.

Question: 22.066P

Explain how you can evaluate the outlet temperatures of the cold and hot fluids in a heat exchanger after its effectiveness is determined.

Step 1 of 1

Effectiveness can be found by $\varepsilon = \dfrac{\dot{Q}_{act}}{\dot{Q}_{max}}$

$$\dot{Q}_{act} = \varepsilon \dot{Q}_{max}$$

Outlet temperatures of hot fluid:

$$\dot{m}_h C_{p,h}(T_{h,in} - T_{h,out}) = \varepsilon C_{min}(T_{h,in} - T_{c,in})$$

$$\therefore T_{h,out} = T_{h,in} + \frac{(\varepsilon)(C_{min})(T_{h,in} - T_{c,in})}{\dot{m}_h C_{p,h}}$$

On substituting all values on right hand side we can find $T_{h,out}$

Outlet temperatures of cold fluid:

$$\dot{m}_c C_{p,c}(T_{c,in} - T_{c,out}) = \varepsilon C_{min}(T_{h,in} - T_{c,in})$$

$$\therefore T_{c,out} = T_{c,in} - \frac{(\varepsilon)(C_{min})(T_{h,in} - T_{c,in})}{\dot{m}_c C_{p,c}}$$

On substituting all values on right hand side we can find $T_{c,out}$

Question: 22.067P

Can the temperature of the cold fluid rise above the inlet temperature of the hot fluid at any location in a heat exchanger? Explain.

Step 1 of 1

While exchanging the heat from cold fluid to the hot fluid, temperature of the cold fluid rises and may reach to the maximum temperature i.e. inlet temperature of the hot fluid.

The temperature of the cold fluid will not rise above the inlet temperature of hot fluid at any location.

Question: 22.068P

Consider a heat exchanger in which both fluids have the same specific heats but different mass flow rates. Which fluid will experience a larger temperature change: the one with the lower or higher mass flow rate?

Step 1 of 1

By energy balance is given by

$$\dot{Q} = \dot{m}_c c_{p,c} \Delta T_{cold} = \dot{m}_h c_{p,h} \Delta T_{hot}$$

Since both fluids have same specific heats

i.e., $c_{p,c} = c_{p,h}$

$$\dot{m}_c \Delta T_{cold} = \dot{m}_h \Delta T_{hot}$$

From this relation it is clearly understood that the fluid with lower mass flow rate will experience a larger temperature change.

Question: 22.069P

Explain how the maximum possible heat transfer rate $\dot{Q}$max in a heat exchanger can be determined when the mass flow rates, specific heats, and the inlet temperatures of the two fluids are specified. Does the value of $\dot{Q}$max depend on the type of the heat exchanger?

Step 1 of 1

The rate of heat transfer for a given mass flow rates, specific heats and inlet temperatures of the two fluids can be determined as follows

$$C_h = \dot{m} c_{ph}$$

$$C_c = \dot{m}_c c_{pc}$$

$$C_{min} = \text{min of } (C_h, C_c)$$

The fluid with smaller heat capacity rate will experience a larger temperature change, and thus it will be the first to experience the maximum temperature

Therefore, maximum possible heat transfer rate in a heat exchanger is

$$\therefore \dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$

$\dot{Q}_{max}$ is same for all heat exchangers. It is independent of type of heat exchanger.

Question: 22.070P

Under what conditions can a counter-flow heat exchanger have an effectiveness of one? What would your answer be for a parallel-flow heat exchanger?

Step 1 of 1

Effectiveness for a counter flow heat exchanger is given by

$$\varepsilon = \frac{1-\exp\left[-NTU(1-c)\right]}{1-c\exp\left[-NTU(1-c)\right]}$$

For $\varepsilon = 1$

$$1-\exp\left[-NTU(1-c)\right] = 1-c\exp\left[-NTU(1-c)\right]$$

$$c = 1$$

When capacity ratio c is equal to one and NTU value is very large then the counter flow heat exchanger will have an effectiveness of one i.e. 100% effectiveness.

In this case parallel flow heat exchanger will have 50% effectiveness.

Question: 22.071P

Consider a double-pipe counter-flow heat exchanger. In order to enhance heat transfer, the length of the heat exchanger is now doubled. Do you think its effectiveness will also double?

Step 1 of 1

NTU is expressed by $NTU = \frac{UA_s}{C_{min}}$

Where A_s : heat transfer surface area

$A_s \propto$ Length of heat exchanger

By increasing length of the heat exchanger NTU of heat exchanger will be increased.

Effectiveness for double pipe counter flow heat exchanger is given by

$$\varepsilon = \frac{1-\exp\left[-NTU(1-c)\right]}{1-c\exp\left[-NTU(1-c)\right]}$$

Effectiveness increases rapidly with NTU for small values but rather slowly for larger values.

Therefore effectiveness of the heat exchanger will not be double when the length of the heat exchanger is doubled.

Question: 22.072P

Consider two double-pipe counter-flow heat exchangers that are identical except that one is twice as long as the other one. Which heat exchanger is more likely to have a higher effectiveness?

Step 1 of 1

NTU is expressed by $NTU = \frac{UA_s}{C_{min}}$

Where A_s : heat transfer surface area

$A_s \propto$ Length of heat exchanger

By increasing length of the heat exchanger NTU of heat exchanger will be increased.

Effectiveness for double pipe counter flow heat exchanger is given by

$$\varepsilon = \frac{1-\exp[-NTU(1-c)]}{1-c\exp[-NTU(1-c)]}$$

Effectiveness increases rapidly with NTU for small values (up to about NTU=1.5) but rather slowly for larger values.

Therefore double-pipe counter-flow heat exchanger with double length will have the higher effectiveness.

Question: 22.073P

How is the NTU of a heat exchanger defined? What does it represent? Is a heat exchanger with a very large NTU (say, 10) necessarily a good one to buy?

Step 1 of 1

NTU of the heat exchanger is a dimensionless group and is represented as

$$NTU = \frac{UA_s}{C_{min}}$$

Where U is the overall heat transfer coefficient and A_s is heat transfer surface area of heat exchanger.

For specified values of U and C_{min}, the value of NTU is a measure of the heat transfer surface area A_s. Thus, the longer the NTU, the larger the heat exchanger.

Effectiveness of heat exchanger increase slowly for large value of NTU. So large value of NTU in a heat exchanger is not economically justified. Therefore it is not necessarily a good one to buy.

Question: 22.074P

Consider a heat exchanger that has an NTU of 4. Someone proposes to double the size of the heat exchanger and thus double the NTU to 8 in order to increase the effectiveness of the heat exchanger and thus save energy. Would you support this proposal?

Step 1 of 1

Effectiveness increases rapidly with NTU for small values (up to about NTU=1.5) but rather slowly for larger values. Therefore the use of heat exchanger with a large NTU (usually larger than 3) and thus a large size cannot be justified.

Large increase in NTU corresponds to small increase in effectiveness.

So it is not desirable to double the size of the heat exchanger and thus double the NTU in order to increase the effectiveness of heat exchanger and thus save the energy.

Question: 22.075P

Consider a heat exchanger that has an NTU of 0.1. Someone proposes to triple the size of the heat exchanger and thus triple the NTU to 0.3 in order to increase the effectiveness of the heat exchanger and thus save energy. Would you support this proposal?

Step 1 of 1

Effectiveness increases rapidly with NTU for small values (up to about NTU=1.5) but rather slowly for larger values. Therefore the use of heat exchanger with a large NTU (usually larger than 3) and thus a large size cannot be justified.

Small increase in NTU corresponds to large increase in effectiveness.

Therefore the proposal of small increase in NTU (from 0.1 to 0.3) in order to increase the effectiveness can be supported.

Question: 22.076P

A 1-shell and 2-tube type heat exchanger has an overall heat transfer coefficient of 300 Btu/h-ft2·°F. The shell side fluid has a heat capacity rate of 20,000 Btu/h·°F, while the tube side fluid has a heat capacity rate of 40,000 Btu/h·°F. The inlet temperatures on the shell side and tube side are 200°F and 90°F, respectively. If the total heat transfer area is 100 ft2, determine (*a*) the heat transfer effectiveness and (*b*) the actual heat transfer rate in the heat exchanger.

Step 1 of 4

Given data:

The overall heat transfer coefficient, $U = 300\ \text{Btu/h.ft}^2\text{.°F}$

Heat capacity on shell and tube side,

$C_{shell} = 20,000\ \text{Btu/h.°F}$

$C_{tube} = 40,000\ \text{Btu/h.°F}$

Inlet temperatures of shell and tube side are

$T_{shell,in} = 200°\text{F}$

$T_{tube,in} = 90°\text{F}$

The heat transfer surface area, $A_s = 100\ \text{ft}^2$

Step 2 of 4

The smaller of two heat capacities are

$C_{min} = C_{shell} = 20,000\ \text{Btu/h.°F}$

The maximum rate of heat transfer in the shell and tube heat exchanger is

$$\dot{Q} = C_{min}\left(T_{shell,in} - T_{tube,in}\right)$$
$$= 20000(200-90)$$
$$= 2200000\ \text{Btu/h}$$

$$\dot{Q}_{max} = 2200000 \times \frac{1}{3600}$$
$$= 611.1\ \text{Btu/s}$$

Step 3 of 4

The NTU of heat exchanger is expressed as

$$NTU = \frac{UA_s}{C_{min}}$$
$$= \frac{(300)100}{20000}$$
$$= 1.5$$

Also

$$c = \frac{C_{min}}{C_{max}}$$
$$= \frac{20000}{40000}$$
$$= 0.5$$

From graph Effectiveness of heat exchangers for 1 shell pass and two tube passes at $NTU = 1.5$ and $c = 0.5$ the value of effectiveness is determined as

$\boxed{\varepsilon = 0.64}$

Therefore heat transfer effectiveness is $\varepsilon = 0.64$

Step 4 of 4

(b)

The actual heat transfer rate of the heat exchanger is

$$\dot{Q} = \varepsilon \dot{Q}_{max}$$
$$= (0.64)(611.1)$$
$$= 391.104\ \text{Btu/s}$$

$\boxed{\dot{Q} = 391.104\ \text{Btu/s}}$

Therefore, the actual heat transfer rate of the heat exchanger is $\dot{Q} = 391.104\ \text{Btu/s}$

Question: 22.077P

A cross-flow heat exchanger with both fluids unmixed has an overall heat transfer coefficient of 200 W/m2·K, and a heat transfer surface area of 400 m2. The hot fluid has a heat capacity of 40,000 W/K, while the cold fluid has a heat capacity of 80,000 W/K. If the inlet temperatures of both hot and cold fluids are 80°C and 20°C, respectively, determine the exit temperature of the cold fluid.

Step 1 of 4

Given data:

The overall heat transfer coefficient $U = 200\,\mathrm{W/m^2\text{-}K}$

Heat capacity on hot and cold fluids is

$C_h = 40,000\,\mathrm{W/K}$

$C_c = 80,000\,\mathrm{W/K}$

Inlet temperatures of on hot and cold fluids are

$T_{h,in} = 80°\mathrm{C}$

$T_{c,in} = 20°\mathrm{C}$

The surface area $A_s = 400\,\mathrm{m^2}$

Step 2 of 4

The smaller of two heat capacities are

$C_{min} = C_h = 40,000\,\mathrm{W/K}$

The maximum rate of heat transfer in a cross flow heat exchanger is

$$\dot{Q} = C_{min}\left(T_{h,in} - T_{c,in}\right)$$

$$\dot{Q} = 40000(80-20)$$

$$\dot{Q}_{max} = 2400\ \mathrm{kW}$$

The NTU of heat exchanger is expressed as

$$NTU = \frac{UA_s}{C_{min}}$$

$$= \frac{(200)400}{40000}$$

$$NTU = 2$$

Step 3 of 4

Also

$$c = \frac{C_{min}}{C_{max}}$$

$$= \frac{40000}{80000}$$

$$c = 0.5$$

From graph effectiveness for heat exchangers at $c = 0.5$ and $NTU = 2$ the value of effectiveness is determined as

$\varepsilon = 0.74$

The actual heat transfer rate of the heat exchanger is

$$\dot{Q} = \varepsilon \dot{Q}_{max}$$

$$\dot{Q} = (0.74)(2400)$$

$$\dot{Q} = 1776\ \mathrm{kW}$$

Step 4 of 4

The exit temperature of the cold side is determined as

$$\dot{Q} = C_c\left(T_{c,out} - T_{c,in}\right)$$

$$1776\times10^3 = 80000\left(T_{c,out} - 20\right)$$

$$T_{c,out} = 42.2°\mathrm{C}$$

The exit temperature of the cold side $\boxed{T_{c,out} = 42.2°\mathrm{C}}$

Question: 22.078P

In a 1 -shell and 2-tube heat exchanger, cold water with inlet temperature of 20°C is heated by hot water supplied at the inlet at 80°C. The cold and hot water flow rates are 5000 kg/h and 10,000 kg/h, respectively. If the shell-and-tube heat exchanger has a *UAS* value of 11,600 W/K, determine the cold water and hot water outlet temperatures. Assume *cpc* = 4178 J/kg·K and *cph* = 4188 J/kg·K.

Step 1 of 6

The ratio of the heat capacities is,

$$c = \frac{C_{min}}{C_{max}} = \frac{(\dot{m}c_p)_c}{(\dot{m}c_p)_h}$$

Here,

Mass flow rate of cold fluid, $\dot{m}_c$

Mass flow rate of hot fluid, $\dot{m}_h$

Specific heat of cold fluid, $c_{p,c}$

Specific heat of hot fluid, $c_{p,h}$

Substitute 5,000 kg/hr for $\dot{m}_h$, 10,000 kg/hr for $\dot{m}_c$, 4,178 J/kg·K for $c_{p,c}$ 4,188 J/kg-K for $c_{p,h}$ in the above equation

$$c = \frac{(\dot{m}c_p)_c}{(\dot{m}c_p)_h} = \frac{5,000 \times 4,178}{10,000 \times 4,188} = 0.498$$

Step 2 of 6

The smaller of the two heat capacities,

$$C_{min} = C_c = (\dot{m}c_p)_c = \frac{5,000}{60 \times 60}\text{kg/s} \times 4,178 = 5,802.778 \text{ W/K}$$

The NTU of heat exchanger is;

$$\text{NTU} = \frac{UA_s}{C_{min}}$$

Here,

The product of the overall heat transfer coefficient and the area of the 1-shell, 2-tube heat exchanger, UA_s

Substitute 11,600 W/K for UA_s, 5,802.778 W/K for C_{min}, in the above equation

$$\text{NTU} = \frac{UA_s}{C_{min}} = \frac{11,600}{5,802.778} = 1.99$$

Step 3 of 6

The maximum heat transfer rate is,

$$\dot{Q}_{max} = C_{min}(T_{h,i} - T_{c,i})$$

Here,

Inlet temperature of cold fluid, $T_{c,i}$

Inlet temperature of hot fluid, $T_{h,i}$

Substitute 20°C for $T_{c,i}$, 80°C for $T_{h,i}$, 5,802.778 W/K for C_{min}, in the above equation

$$\dot{Q}_{max} = C_{min}(T_{h,i} - T_{c,i}) = 5,802.778 \times (80 - 20) = 5,802.778 \times 60 = 348,166.667 \text{ W}$$

Step 4 of 6

From the graph containing effectiveness and NTU, at $c = 0.498$ and $\text{NTU} = 1.99$ the value of effectiveness is determined to be

$$\varepsilon = 0.68$$

The actual rate is,

$$\dot{Q} = \varepsilon \dot{Q}_{max} = 0.68 \times 348,166.667 = 236,753.334 \text{ W}$$

Step 5 of 6

Determine the exit temperatures of the cold and hot fluids as follows.
Consider the expression for the actual heat transfer rate in terms of cold fluid temperatures.

$$\dot{Q} = C_c(T_{c,o} - T_{c,i}) = (\dot{m}c_p)_c(T_{c,o} - T_{c,i})$$

Here, exit temperature of cold fluid, $T_{c,o}$

Substitute, 10,000 kg/hr for $\dot{m}_c$, 4,178 J/kg-K for $c_{p,c}$, 20°C for $T_{c,i}$, 236,753.334 W for $\dot{Q}$ in the above equation

$$\dot{Q} = (\dot{m}c_p)_c(T_{c,o} - T_{c,i})$$

$$236,753.334 = \left(\frac{5,000}{60 \times 60} \times 4,178\right)(T_{c,o} - 20)$$

$$T_{c,o} = \frac{236,753.334 \times 60 \times 60}{5,000 \times 4,178} + 20 = 60.8°\text{C}$$

Therefore the exit temperatures of the cold fluid is **60.8°C**

Step 6 of 6

Similarly, the heat transfer rate in terms of hot fluid temperatures is,

$$\dot{Q} = C_h(T_{h,i} - T_{h,o}) = (\dot{m}c_p)_h(T_{h,i} - T_{h,o})$$

Here, Exit temperature of hot fluid, $T_{h,o}$

Substitute, 10,000 kg/hr for $\dot{m}_c$, 4,188 J/kg·K for $c_{p,h}$, 20°C for $T_{c,i}$, 236,753.334 W for $\dot{Q}$ in the above equation

$$\dot{Q} = (\dot{m}c_p)_h(T_{h,i} - T_{h,o})$$

$$236,753.334 = \left(\frac{10,000}{60 \times 60} \times 4,188\right)(80 - T_{h,o})$$

$$T_{h,o} = 80 - \frac{236,753.334 \times 60 \times 60}{10,000 \times 4,188} = 59.64°\text{C}$$

Therefore the exit temperatures of hot fluid is **59.64°C**.

Question: 22.079P

The radiator in an automobile is a cross-flow heat exchanger (*UAS* = 10 kW/K) that uses air (*cp* = 1.00 kJ/kg·K) to cool the engine-coolant fluid (*cp* = 4.00 kJ/kg-K). The engine fan draws 22°C air through this radiator at a rate of 8 kg/s while the coolant pump circulates the engine coolant at a rate of 5 kg/s. The coolant enters this radiator at 80°C. Under these conditions, the effectiveness of the radiator is 0.4. Determine (*a*) the outlet temperature of the air and (*b*) the rate of heat transfer between the two fluids.

Step 1 of 3

The ratio of the heat capacities is,

$$c = \frac{C_{min}}{C_{max}}$$
$$= \frac{(\dot{m}c_p)_c}{(\dot{m}c_p)_h}$$

Here,

Mass flow rate of cold fluid, $\dot{m}_c$

Mass flow rate of hot fluid, $\dot{m}_h$

Specific heat of cold fluid, $c_{p,c}$

Specific heat of hot fluid, $c_{p,h}$

Substitute 5 kg/s for $\dot{m}_h$, 8 kg/s for $\dot{m}_c$, 1,000 J/kg·K for $c_{p,c}$ 4,000 J/kg·K for $c_{p,h}$ in the above equation

$$c = \frac{(\dot{m}c_p)_c}{(\dot{m}c_p)_h}$$
$$= \frac{8\times1{,}000}{5\times4{,}000}$$
$$= 0.4$$

The smaller of the two heat capacities,

$$C_{min} = C_c$$
$$= (\dot{m}c_p)_c$$
$$= 8\times1{,}000$$
$$= 8{,}000 \text{ W/K}$$

Step 2 of 3

b)

For the ease of calculation, first determine the heat transfer rate between the fluids is.

The maximum heat transfer rate is,

$$\dot{Q}_{max} = C_{min}(T_{h,i} - T_{c,i})$$

Here,

Inlet temperature of cold fluid, $T_{c,i}$

Inlet temperature of hot fluid, $T_{h,i}$

Substitute 22°C for $T_{c,i}$, 80°C for $T_{h,i}$, 8,000 W/K for C_{min}, in the above equation

$$\dot{Q}_{max} = C_{min}(T_{h,i} - T_{c,i})$$
$$= 8{,}000\times(80-22)$$
$$= 8{,}000\times58$$
$$= 464{,}000 \text{ W}$$

The actual heat transfer rate between the two fluids is,

$$\dot{Q} = \varepsilon\dot{Q}_{max}$$

Here, The effectiveness of the of the radiator, $\varepsilon = 0.4$

$$\dot{Q} = \varepsilon\dot{Q}_{max}$$
$$= 0.4\times464{,}000$$
$$= 185{,}600 \text{ W}$$

Therefore, the amount of heat transferred from the

Step 3 of 3

a)

Determine the exit temperature of the cold fluid is as follows.

The product of the overall heat transfer coefficient and the area of the cross flow heat exchanger, $UA_s = 10{,}000$ W/K

Consider the expression for the actual heat transfer rate in terms of cold fluid temperatures.

$$\dot{Q} = C_c(T_{c,o} - T_{c,i})$$
$$= (\dot{m}c_p)_c(T_{c,o} - T_{c,i})$$

Here, exit temperature of cold fluid, $T_{c,o}$

$$\dot{Q} = C_c(T_{c,o} - T_{c,i})$$
$$= (\dot{m}c_p)_c(T_{c,o} - T_{c,i})$$
$$185{,}600 = (8\times1{,}000)(T_{c,o} - 22)$$
$$T_{c,o} = \frac{185{,}600}{8{,}000} + 22$$
$$= 45.2°\text{C}$$

Therefore the exit temperature of the air or the cold fluid is $\boxed{45.2°\text{C}}$.

Question: 22.080P

Water (*cp* = 4180 J/kg·K) enters the 2.5-cm-internal diameter tube of a double-pipe counter-flow heat exchanger at 20°C at a rate of 2.2 kg/s. Water is heated by steam condensing at 120°C (*hfg* = 2203 kJ/kg) in the shell. If the overall heat transfer coefficient of the heat exchanger is 700 W/m2·K, determine the length of the tube required in order to heat the water to 80°C using (*a*) the LMTD method and (*b*) the ε-NTU method.

Step 1 of 6

Given data:

Diameter of the tube, $D = 2.5\,\text{cm}$

Specific heat water, $c_p = 4180\ \text{J/kg}\cdot\text{K}$

Mass flow rate of water, $\dot{m}_w = 2.2\ \text{kg/s}$

Initial temperature of water, $T_{in} = 20\,^\circ\text{C}$

Exit temperature of water, $T_{out} = 80\,^\circ\text{C}$

Steam temperature $T = 120\,^\circ\text{C}$

Overall heat transfer coefficient, $U = 700\ \text{W/m}^2\cdot\text{K}$

Enthalpy of the steam, $h_{fg} = 2203\ \text{kJ/kg}$

Step 2 of 6

a) Determination of length of the tube by Log Mean Temperature Difference method:

The heat transfer rate is given by,

$$\dot{Q} = [\dot{m}_c c_{pc}(T_{out} - T_{in})]_{water}$$
$$= 2.2\times4180\times(80-20)$$
$$= 551.76\ \text{kW}$$

Calculation of LMTD for the given counter flow heat exchanger:

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= (120-80)$$
$$= 40^\circ\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= (120-20)$$
$$\Delta T_2 = 100^\circ\text{C}$$

Now, LMTD is,

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)}$$
$$= \frac{40-100}{\ln\left(40/100\right)}$$
$$= 65.48\,^\circ\text{C}$$

Step 3 of 6

The heat transfer surface area is calculated using the formula,

$$\dot{Q} = UA_s\Delta T_{lm}$$
$$A_s = \frac{\dot{Q}}{U\Delta T_{lm}}$$
$$= \frac{551.76\times10^3}{(700)(65.48)}$$
$$= 12.04\ \text{m}^2$$

Length of the tube is calculated using the formula,

$$A_s = \pi DL$$
$$L = \frac{A_s}{\pi D}$$
$$= \frac{12.04\ \text{m}^2}{\pi(0.025\ \text{m})}$$
$$\boxed{L = 153.298\ \text{m}}$$

Step 4 of 6

b) Calculation of the length of the tube by Effectiveness-Number of Transfer Units method:

The maximum rate of heat transfer is given by,

$$\dot{Q} = \dot{m}_c c_{pc}\left(T_{h,out} - T_{w,in}\right)$$
$$= 2.2\times4180\times(120-20)$$
$$= 919.6\ \text{kW}$$

Effectiveness of the heat exchanger is calculated using the formula,

$$\varepsilon = \frac{Q}{Q_{max}}$$
$$= \frac{551.76}{919.6}$$
$$= 0.6$$

The NTU of this heat exchanger is determined using the relation in the table containing NTU relations for heat exchangers.

$$\text{NTU} = -\ln(1-\varepsilon)$$
$$= -\ln(1-0.6)$$
$$= 0.9163$$

Step 5 of 6

Using the value of NTU, the area of the heat exchanger is calculated.

$$\text{NTU} = \frac{UA_s}{C_{min}}$$
$$A_s = \frac{\text{NTU}\,C_{min}}{U}$$
$$= \frac{(0.9163)(2.2\times4.18)}{0.7}$$
$$= 12.037\ \text{m}^2$$

Step 6 of 6

The length of the tube is therefore,

$$A_s = \pi DL$$
$$L = \frac{A_s}{\pi D}$$
$$= \frac{12.037}{\pi\times0.025}$$
$$\boxed{L = 153.26\ \text{m}}$$

Hence, the length of the tube required in order to heat the water from 20 ℃ to 80 ℃ is $L = 153.26\ \text{m}$.

Question:

Ethanol is vaporized at 78°C (h_{fg} = 846 kJ/kg) in a double-pipe parallel-flow heat exchanger at a rate of 0.04 kg/s by hot oil (cp = 2200 J/kg·K) that enters at 115°C. If the heat transfer surface area and the overall heat transfer coefficients are 6.2 m2 and 320 W/m2·K, respectively, determine the outlet temperature and the mass flow rate of oil using (*a*) the LMTD method and (*b*) the ε-NTU method.

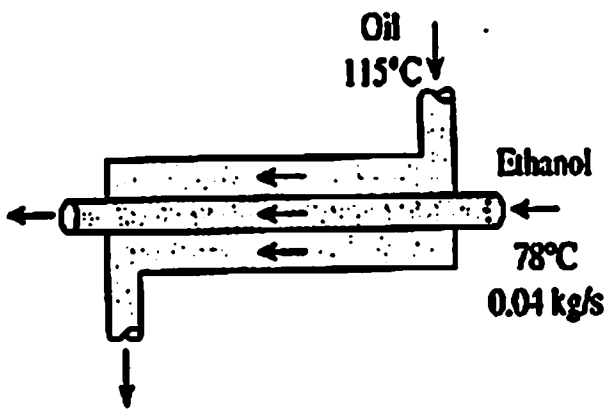

FIGURE P22–81

Step 1 of 5

Given

Specific heats of hot oil is $c_p = 2200\ \text{J/kg.°C}$

Mass flow rates of hot oil is $\dot{m}_{hot\,oil} = 0.04\ \text{kg/s}$

Temperature of Ethanol $T_{Ethanol} = 78°\text{C}$

Enthalpy of vaporization $h_{fg} = 846\ \text{kJ/kg}$

Inlet temperature of hot oil $T_{h,in} = 115°\text{C}$

Heat transfer surface area is $A_s = 6.2\ \text{m}^2$

Overall heat transfer coefficient $U = 320\ \text{W/m}^2.°\text{C}$

Step 2 of 5

a) Using LMTD method

Mass flow rate of the oil is determined as

$$\dot{Q} = \dot{m}_h C_p (T_{h,in} - T_{h,out})$$

$$\dot{m}_h = \frac{\dot{Q}}{C_p (T_{h,in} - T_{h,out})} \quad \text{..... (1)}$$

Where heat transfer rate and hot oil outlet temperature can be calculated as follows

The rate of heat transfer is

$$\dot{Q} = \left(\dot{m} h_{fg}\right)_{Ethanol}$$

$$\dot{Q} = 0.04(846)$$

$$\dot{Q} = 33.84\ \text{kW}$$

Step 3 of 5

LMTD for this heat exchanger is

$$\dot{Q} = U A_s \Delta T_{lm}$$

$$\Delta T_{lm} = \frac{\dot{Q}}{U A_s}$$

$$\Delta T_{lm} = \frac{33.84 \times 10^3}{320 \times 6.2}$$

$$\Delta T_{lm} = 17.056°\text{C}$$

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$= 115 - 78$$

$$\Delta T = 37°\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$\Delta T_2 = T_{h,out} - 78$$

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined from

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)}$$

$$17.06 = \frac{37 - \left(T_{h,out} - 78\right)}{\ln\left(37 / \left(T_{h,out} - 78\right)\right)}$$

by solving the above equation

$$\boxed{T_{h,out} = 84°\text{C}}$$

By substituting the values in equation (1) the mass flow rate of hot oil becomes

$$\dot{m}_h = \frac{\dot{Q}}{C_p (T_{h,in} - T_{h,out})}$$

$$\dot{m}_h = \frac{33.84}{2.2(115 - 84)}$$

$$\boxed{\dot{m}_h = 0.496\ \text{kg/s}}$$

Step 4 of 5

b) Using NTU method

For the condensing and evaporating type of heat exchangers

$$C = C_{min} / C_{max}$$

$$C = 0$$

Effectiveness of the heat exchanger is

For the condensing and evaporating type of heat exchangers

$$C = C_{min} / C_{max}$$

$$C = 0$$

Effectiveness of the heat exchanger is

$$\varepsilon = \frac{Q}{Q_{max}}$$

$$\varepsilon = \frac{C_{min}(T_{h,in} - T_{c,in})}{C_{min}(T_{h,in} - T_{c,in})}$$

$$\varepsilon = \frac{115 - T_{h,out}}{115 - 78}$$

But in case of condenser or evaporator type of heat exchangers effectiveness is

$$\varepsilon = 1 - e^{-NTU}$$

Therefore

$$\frac{115 - T_{h,out}}{115 - 78} = 1 - e^{-NTU} \quad \text{..... (2)}$$

Where NTU is

$$NTU = \frac{UA_s}{C_{min}}$$

$$= \frac{320 \times 6.2}{\dot{m}_h \times 2200}$$

$$NTU = \frac{0.9018}{\dot{m}_h}$$

Then substituting NTU in equation (2)

$$\frac{115 - T_{h,out}}{115 - 78} = 1 - e^{-NTU}$$

$$\frac{115 - T_{h,out}}{115 - 78} = 1 - e^{\frac{0.9018}{\dot{m}_h}} \quad \text{..... (3)}$$

Step 5 of 5

And heat transfer rate is

$$\dot{Q} = C_h(T_{h,in} - T_{h,out})$$

$$\dot{Q} = \dot{m}_h \times 2200(115 - T_{h,out})$$

$$33840 = \dot{m}_h \times 2200(115 - T_{h,out})$$

$$\dot{m}_h = \frac{33480}{2200(115 - T_{h,out})}$$

$$\dot{m}_h = \frac{15.218}{(115 - T_{h,out})}$$

By substituting $\dot{m}_h$ in equation (3)

$$\frac{115 - T_{h,out}}{115 - 78} = 1 - e^{\frac{-0.9018}{\dot{m}_h}}$$

$$\frac{115 - T_{h,out}}{115 - 78} = 1 - e^{\frac{-0.9018}{\frac{15.218}{115 - T_{h,out}}}}$$

$$\frac{115 - T_{h,out}}{115 - 78} = 1 - e^{-0.0592(115 - T_{h,out})}$$

By solving the above expression

$$\boxed{T_{h,out} = 83.8°C}$$

And the mass flow rate can be obtained by using the above relation

$$\dot{m}_h = \frac{15.218}{(115 - T_{h,out})}$$

$$= \frac{15.218}{115 - 83.8}$$

$$\boxed{\dot{m}_h = 0.487 \text{ kg/s}}$$

Question: 22.082P

Air (*cp* = 1005 J/kg-K) enters a cross-flow heat exchanger at 20°C at a rate of 3 kg/s, where it is heated by a hot water stream (*cp* = 4190 J/kg·K) that enters the heal exchanger at 70°C at a rate of 1 kg/s. Determine the maximum heat transfer rate and the outlet temperatures of both fluids for that case.

Step 1 of 5

Given data:

Specific heat of air, $c_{pc} = 1005\ \text{J/kg} \cdot {}^\circ\text{C}$

Specific heat of water, $c_{ph} = 4190\ \text{J/kg} \cdot {}^\circ\text{C}$

Mass flow rate of water, $\dot{m}_h = 1\ \text{kg/s}$

Mass flow rate of air, $\dot{m}_c = 3\ \text{kg/s}$

Inlet temperature of the air, $T_{c,in} = 20°\text{C}$

Inlet temperature of the water, $T_{h,in} = 70°\text{C}$

Step 2 of 5

Maximum possible heat transfer rate is determined as

$$\dot{Q}_{max} = C_{min}\left(T_{h,in} - T_{c,in}\right)$$

Where C_{min} is calculated as follows

The heat capacity rates of hot and cold fluids are calculated as

$$C_h = \dot{m}_h C_{ph}$$
$$= (1\ \text{kg/s})(4190\ \text{J/kg} \cdot °\text{C})$$
$$= 4190\ \text{W/°C}$$
$$C_c = \dot{m}_c C_{pc}$$
$$= (3\ \text{kg/s})(1005\ \text{J/kg} \cdot °\text{C})$$
$$= 3015\ \text{W/°C}$$
$$\therefore C_{min} = C_c = 3015\ \text{W/°C}$$

Step 3 of 5

By substituting the value of C_{min} heat transfer rate becomes

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$
$$= (3015\ \text{W/°C})(70°\text{C} - 20°\text{C})$$
$$= 150750\ \text{W}$$
$$= 150.75\text{kW}$$

$\therefore$ Maximum heat transfer rate is $\boxed{\dot{Q}_{max} = 150.75\text{kW}}$

Step 4 of 5

Then the outlet temperature of the air calculated by the relation

$$\dot{Q} = \left[C_c\left(T_{out} - T_{in}\right)\right]_{air}$$

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}_{max}}{C_c}$$
$$= 20°\text{C} + \frac{150750\ \text{W}}{3015\ \text{W/°C}}$$
$$= 70°\text{C}$$

$\therefore$ The outlet temperature of the air is $\boxed{T_{c,out} = 70°\text{C}}$

Step 5 of 5

Then the outlet temperature of the water calculated by the relation

$$\dot{Q} = \left[C_h\left(\left(T_{out} - T_{in}\right)\right]_{water}\right.$$

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}_{max}}{C_h}$$
$$= 70°\text{C} - \frac{150750\ \text{W}}{4190\ \text{W/°C}}$$
$$= 34°\text{C}$$

$\therefore$ The outlet temperature of the water is $\boxed{T_{h,out} = 34°\text{C}}$

Question: 22.083P

Hot oil (cp = 2200 J/kg·K) is to be cooled by water (cp = 4180 J/kg·K) in a 2-shell-passes and 12-tube-passes heat exchanger. The tubes are thin-walled and are made of copper with a diameter of 1.8 cm. The length of each tube pass in the heat exchanger is 3 m, and the overall heat transfer coefficient is 340 W/m2-K. Water flows through the tubes at a total rate of 0.1 kg/s, and the oil through the shell at a rate of 0.2 kg/s. The water and the oil enter at temperatures 18°C and 160°C, respectively. Determine the rate of heat transfer in the heat exchanger and the outlet temperatures of the water and the oil.

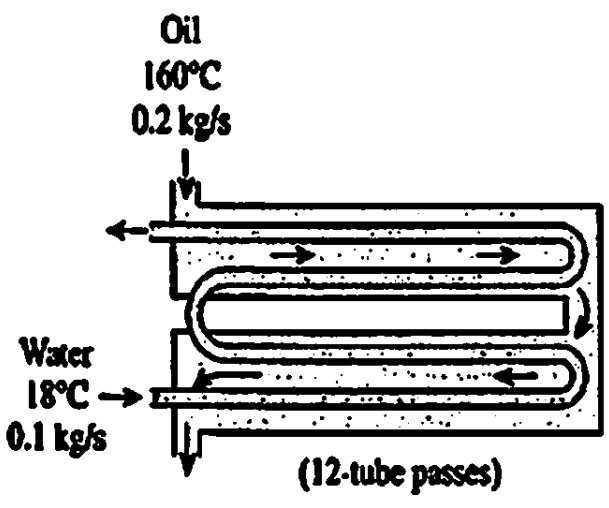

FIGURE P22–83

Step 1 of 11

Given

Type: 2shell passes and 12 tube passes

Specific heats of hot oil $c_{ph} = 2200\ \text{J/kg}^\circ\text{C}$

Specific heats of water $c_{pc} = 4810\ \text{J/kg}^\circ\text{C}$

Diameter of thin walled tubes: $D = 1.8\text{cm}$

$D = 0.018\ \text{m}$

Length of thin walled tubes $L = 3\ \text{m}$

Overall heat transfer coefficient $U = 340\ \text{W/m}^2{}^\circ\text{C}$

Mass flow rates of hot oil $\dot{m}_h = 0.2\ \text{kg/s}$

Mass flow rates of water $\dot{m}_c = 0.1\ \text{kg/s}$

Water inlet temperature, $T_{c,in} = 18^\circ\text{C}$

Hot oil inlet temperature $T_{h,in} = 160^\circ\text{C}$

Step 2 of 11

Heat capacity rate of the hot fluid:

$$C_h = \dot{m}_h c_{ph}$$
$$= (0.2\ \text{kg/s})(2200\ \text{J/kg}^\circ\text{C})$$
$$C_h = 440\ \text{W/}^\circ\text{C}$$

Step 3 of 11

Heat capacity rate of the cold fluid:

$$C_c = \dot{m}_c c_{pc}$$
$$= (0.1\ \text{kg/s})(4180\ \text{J/kg}^\circ\text{C})$$
$$C_c = 418\ \text{W/}^\circ\text{C}$$

Step 4 of 11

$$C_c(418) < C_h(440)$$
$$\therefore C_{min} = C_c$$
$$C_{min} = 418\ \text{W/}^\circ\text{C}$$

Step 5 of 11

Ratio of capacity rates:

$$C = \frac{C_{min}}{C_{max}}$$
$$= \frac{418\ \text{W/}^\circ\text{C}}{440\ \text{W/}^\circ\text{C}}$$
$$C = 0.95$$

Step 6 of 11

Fluid with smaller value of capacity rate experience the greater change in temperature so that the maximum heat transfer rate becomes

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$
$$= (418\ \text{W/}^\circ\text{C})(160\text{-}18)^\circ\text{C}$$
$$\dot{Q}_{max} = 59.356\ \text{kW}$$

Step 7 of 11

Heat exchange surface area is

$$A = n\pi DL$$
$$= (12)(\pi)(.018\ \text{m})(3\ \text{m})$$
$$A = 2.0357\ \text{m}^2$$

Step 8 of 11

NTU of this heat exchanger:

$$NTU = \frac{UA_i}{C_{min}}$$
$$= \frac{(340\ \text{W/m}^2{}^\circ\text{C})(2.0357\ \text{m}^2)}{418\ \text{W/}^\circ\text{C}}$$
$$NTU = 1.656$$

Step 9 of 11

Corresponding to $C = 0.95$ and NTU=1.656 Effectiveness $\varepsilon = 0.61$ (from Fig. (d) Effectiveness of the heat exchanger)

Actual heat transfer rate:

$$\dot{Q}_{act} = \varepsilon \dot{Q}_{max}$$
$$= (0.61)(59.356)$$
$$\boxed{\dot{Q}_{act} = 36.2\ \text{kW}}$$

Step 10 of 11

Outlet temperatures of the cold fluid stream:

$$\dot{Q}_{act} = C_c(T_{c,out} - T_{c,in})$$
$$T_{c,out} = T_{c,in} + \frac{\dot{Q}_{act}}{C_c}$$
$$= 18 + \frac{36200}{418}$$
$$\boxed{\therefore T_{c,out} = 104.602^\circ\text{C}}$$

Step 11 of 11

Outlet temperatures of the hot fluid stream:

$$\dot{Q}_{act} = C_h(T_{h,in} - T_{h,out})$$
$$T_{h,out} = T_{h,in} - \frac{\dot{Q}_{act}}{C_c}$$
$$= 160 - \frac{36200}{440}$$
$$\boxed{\therefore T_{h,out} = 77.727^\circ\text{C}}$$

Question: 22.084P

Consider an oil-to-oil double-pipe heat exchanger whose flow arrangement is not known. The temperature measurements indicate that the cold oil enters at 15°C and leaves at 55°C, while the hot oil enters at 80°C and leaves at 40°C. Do you think this is a parallel-flow or counter-flow heat exchanger? Why? Assuming the mass flow rates of both fluids to be identical, determine the effectiveness of this heat exchanger.

Step 1 of 2

Given data:

Inlet temperature of cold oil $T_{c,in} = 15°C$

Exit temperature of cold oil $T_{c,out} = 55°C$

Inlet temperature of hot oil $T_{h,in} = 80°C$

Exit temperature of hot oil $T_{h,out} = 40°C$

Step 2 of 2

In case of the parallel-flow heat exchangers the outlet temperature of the cold fluid $(T_{c,out})$ cannot exceed the outlet temperature of the hot fluid $(T_{h,out})$

But in this present problem $(T_{c,out} = 55°C) > (T_{h,out} = 40°C)$

Therefore the given heat exchanger is counter - flow heat exchanger.

Effectiveness of the heat exchanger is determined as follows

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$

$$= \frac{C_h(T_{h,in} - T_{h,out})}{C_{min}(T_{h,in} - T_{c,in})}$$

But mass flow rates are same $C_h = C_c = C_{min}$

$$\varepsilon = \frac{C_h(T_{h,in} - T_{h,out})}{C_h(T_{h,in} - T_{c,in})}$$

$$= \frac{80-40}{80-15}$$

$$\boxed{\varepsilon = 0.6154}$$

Question: 22.085P

Hot water enters a double-pipe counter-flow water- to-oil heat exchanger at 190°F and leaves at 100°F. Oil enters at 70°F and leaves at 130°F. Determine which fluid has the smaller heat capacity rate and calculate the effectiveness of this heat exchanger.

Step 1 of 2

Given data:

Cold oil inlet temperature, $T_{c,in} = 70°F$

Cold oil outlet temperature, $T_{c,out} = 130°F$

Hot water inlet temperature, $T_{h,in} = 190°F$

Hot water outlet temperature, $T_{h,out} = 100°F$

Step 2 of 2

Hot water has the smaller heat capacity rate since it experiences a more temperature difference when compared to cold water.

Effectiveness of the heat exchanger is determined as follows

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$

$$= \frac{C_h\left(T_{h,in} - T_{h,out}\right)}{C_{min}\left(T_{h,in} - T_{c,in}\right)}$$

But mass flow rates are same $\therefore C_h = C_{min}$

$$\varepsilon = \frac{C_h\left(T_{h,in} - T_{h,out}\right)}{C_h\left(T_{h,in} - T_{c,in}\right)}$$

$$= \frac{190°F - 100°F}{190°F - 70°F}$$

$$= 0.75$$

$\therefore$ The effectiveness of the heat exchanger is $\boxed{\varepsilon = 0.75}$

Question: 22.086P

Saturated water vapor at 100°C condenses in a 1 -shell and 2-tube heat exchanger with a surface area of 0.5 m2 and an overall heat transfer coefficient of 2000 W/m2-K. Cold water (*cpc* = 4179 J/kg·K) flowing at 0.5 kg/s enters the tube side at 15°C, determine (*a*) the heat transfer effectiveness, (*b*) the outlet temperature of the cold water, and (*c*) the heat transfer rate for the heat exchanger.

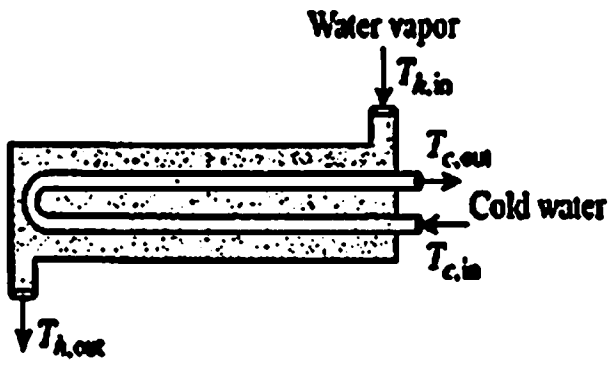

FIGURE P22–86

Step 1 of 5

Given data:

Temperature of saturated water $T_{h,in} = 100°C$

Mass flow rates of water is $\dot{m}_{water} = 0.5 kg/s$

Heat transfer surface area is $A_s = 0.5 m^2$

Overall heat transfer coefficient $U = 2000 W/m^2\text{-}K$

Temperature of cold water $T_{c,in} = 15°C$

Step 2 of 5

Heat capacity rate of the cold water is

$$C_c = \dot{m} c_{pc}$$

$$C_c = 0.5 \times 4179$$

$$C_{min} = C_c = 2089.5 \text{ W/K}$$

And $C = 0$

The maximum heat transfer rate becomes

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$

$$= (2.0895 \text{ kW/°C})(100°C - 15°C)$$

$$\dot{Q}_{max} = 177.6 \text{ kW}$$

NTU of the heat exchanger is

$$NTU = \frac{UA_s}{C_{min}}$$

$$= \frac{(2 kW/m^2.°C)(0.5 m^2)}{2.0895 \text{ kW/°C}}$$

$$NTU = 0.478$$

Step 3 of 5

(a) Effectiveness of this heat exchanger

$$\varepsilon = 1 - \exp(-NTU)$$

$$= 1 - \exp(-0.478)$$

$$\boxed{\varepsilon = 0.38}$$

Step 4 of 5

(b) The outlet temperature of cold water

The actual heat transfer rate calculated as

$$\dot{Q} = \varepsilon \dot{Q}_{max}$$

$$\dot{m} c_p (T_{c,out} - T_{c,in}) = \varepsilon \dot{Q}_{max}$$

$$0.5(4.179)(T_{c,out} - 15) = 0.38(177.6)$$

$$\boxed{T_{c,out} = 47.3°C}$$

Step 5 of 5

(c) The actual heat transfer rate calculated as

$$\dot{Q} = \varepsilon \dot{Q}_{max}$$

$$\dot{Q} = 0.38(177.6)$$

$$\boxed{\dot{Q} = 67.49 kW}$$

Question:

Hot water (*cph* = 4188 J/kg·K) with mass flow rate of 2.5 kg/s at 100°C enters a thin-walled concentric tube counter- flow heat exchanger with a surface area of 23 m2 and an overall heat transfer coefficient of 1000 W/m2-K. Cold water (*cpc* =4178 J/kg·K) with mass flow rate of 5 kg/s enters the heat exchanger at 20°C, determine (*a*) the heat transfer rate for the heat exchanger and (*b*) the outlet temperatures of the cold and hot fluids. After a period of operation, the overall heat transfer coefficient is reduced to 500 W/m2-K, determine (*c*) the fouling factor that caused the reduction in the overall heat transfer coefficient.

Step 1 of 7

(a)

Heat transfer rate for the heat exchanger:

Calculate the ratio of the heat capacities.

$$c = \frac{C_{min}}{C_{max}} = \frac{(\dot{m}c_p)_c}{(\dot{m}c_p)_h}$$

Here, $\dot{m}_c$ is the mass flow rate of cold fluid, $\dot{m}_h$ is the mass flow rate of hot fluid, $c_{p,c}$ is the specific heat of cold fluid, and $c_{p,h}$ is the specific heat of hot fluid.

Substitute $2.5\,\text{kg/hr}$ for $\dot{m}_h$. $5\ \text{kg/s}$ for $\dot{m}_c$. $4{,}178\ \text{J/kg·K}$ for $c_{p,c}$, and $4{,}188\ \text{J/kg·K}$ for $c_{p,h}$.

$$c = \frac{2.5\times4{,}188}{5\times4{,}178} = 0.501$$

Calculate the smaller of the two heat capacities.

$$C_{min} = C_h = (\dot{m}c_p)_h = 2.5\times4{,}188 = 10{,}470\ \text{W/K}$$

Step 2 of 7

Calculate the NTU of heat exchanger.

$$\text{NTU} = \frac{UA_s}{C_{min}}$$

Here, U is the overall heat transfer coefficient of the counter flow heat exchanger and A_s is the surface area of the heat exchanger.

Substitute $1{,}000\ \text{W/m}^2\text{·K}$ for U . $23\ \text{m}^2$ for A_s , and $10{,}470\ \text{W/K}$ for C_{min} .

$$\text{NTU} = \frac{1{,}000\times23}{10{,}470} = 2.196$$

Determine, from the graph containing effectiveness and NTU, at $c = 0.501$ and $\text{NTU} = 2.196$ the value of effectiveness is $\varepsilon = 0.78$.

Step 3 of 7

Calculate the heat transfer rate in terms of hot fluid temperatures.

$$\dot{Q} = C_{min}\left(T_{h,i} - T_{h,o}\right)$$

Here, $T_{h,o}$ is the exit temperature of hot fluid.

Substitute $10{,}470\ \text{W/K}$ for C_{min} , 100 for $T_{h,i}$, and 20 for $T_{c,i}$.

$$\dot{Q}_{max} = 10{,}470\times(100-20) = 10{,}470\times80 = 837{,}600\ \text{W}$$

Calculate the actual heat transfer rate between the two fluids.

$$\dot{Q} = \varepsilon\dot{Q}_{max} = 0.78\times837{,}600 = 653{,}328\ \text{W}$$

Therefore, the actual heat transfer rate between the two fluids is $\boxed{653{,}328\ \text{W}}$.

Step 4 of 7

(b)

The exit temperatures of the cold and hot fluids are determined as follows.

Consider the expression for the actual heat transfer rate in terms of cold fluid temperatures.

$$\dot{Q} = C_c\left(T_{c,o} - T_{c,i}\right) = (\dot{m}c_p)_c\left(T_{c,o} - T_{c,i}\right)$$

Substitute $5\ \text{kg/s}$ for $\dot{m}_c$. $4{,}178\ \text{J/kg·K}$ for $c_{p,c}$.$(653{,}328\ \text{W})$ for $\dot{Q}$, and $20°\text{C}$ for $T_{c,i}$.

$$653{,}328 = (5\times4{,}178)\left(T_{c,o} - 20\right)$$

$$T_{c,o} = \frac{653{,}328}{20{,}890} + 20 = 31.27°\text{C}$$

Therefore, the exit temperatures of the cold is $\boxed{31.27°\text{C}}$.

Step 5 of 7

Calculate the actual heat transfer rate in terms of hot fluid temperatures.

$$\dot{Q} = C_h\left(T_{h,i} - T_{h,o}\right)$$

Step 5 of 7

Calculate the actual heat transfer rate in terms of hot fluid temperatures.

$$\dot{Q} = C_h\left(T_{h,i} - T_{h,o}\right)$$
$$= \left(\dot{m}c_p\right)_h\left(T_{h,i} - T_{h,o}\right)$$

Substitute $2.5\,\text{kg/hr}$ for $\dot{m}_h$, $4{,}188\ \text{J/kg}\cdot\text{K}$ for $c_{p,h}$, $(653{,}328\ \text{W})$ for $\dot{Q}$, and $100°\text{C}$ for $T_{h,i}$.

$$653{,}328 = (2.5\times 4{,}188)(100 - T_{h,o})$$
$$T_{h,o} = 100 - \frac{653{,}328}{10{,}470}$$
$$= 37.6°\text{C}$$

Therefore, the exit temperature of hot fluid is $\boxed{37.6°\text{C}}$.

Step 6 of 7

(c)

Determination of fouling factor F :

The overall heat transfer coefficient of the heat exchanger falls to $U' = 500\ \text{W/m}^2\cdot\text{K}$.

$$\text{NTU}' = \frac{U'A_s}{C_{\min}}$$
$$= \frac{500\times 23}{10{,}470}$$
$$\text{NTU}' = 1.098$$

From the graph containing effectiveness and NTU, at $c = 0.501$ and $\text{NTU}' = 1.098$ the value of effectiveness is determined to be $\varepsilon' = 0.57$.

Calculate the maximum heat transfer rate using the relation,

$$\dot{Q}'_{\max} = C_{\min}\left(T_{h,i} - T_{c,i}\right)$$

Substitute 10470 for $C_{\min}$, $100°\text{C}$ for $T_{h,i}$, and $20°\text{C}$ for $T_{c,i}$.

$$\dot{Q}'_{\max} = 10{,}470\times(100 - 20)$$
$$= 10{,}470\times 80$$
$$= 837{,}600\ \text{W}$$

Step 7 of 7

Calculate the actual heat transfer rate between the two fluids.

$$\dot{Q}' = \varepsilon'\dot{Q}'_{\max}$$
$$= 0.57\times 837{,}600$$
$$= 477{,}432\ \text{W}$$

Calculate the Fouling factor which refers to the ratio of the heat transfer rate due to fouling, to the actual rate of heat transfer.

$$F = \frac{\dot{Q}'}{\dot{Q}}$$
$$= \frac{477{,}432}{653{,}328}$$
$$= 0.73$$

Therefore, the fouling factor that caused reduction in the overall heat transfer coefficient is found to be $\boxed{0.73}$.

Question: 22.088P

A cross-flow air-to-water heat exchanger with an effectiveness of 0.65 is used to heat water (cp = 4180 J/kg·K) with hot air (cp = 1010 J/kg-K). Water enters the heat exchanger at 20°C at a rate of 4 kg/s, while air enters at 100°C at a rate of 9 kg/s. If the overall heat transfer coefficient based on the water side is 260 W/m2-K, determine the heat transfer surface area of the heat exchanger on the water side. Assume both fluids are unmixed.

Step 1 of 4

Given data:

Effectiveness of the cross-flow heat exchanger, $\varepsilon = 0.65$

Specific heat of hot air, $c_{ph} = 1010\ \text{J/kg}\cdot\text{°C}$

Specific heat of water, $c_{pc} = 4180\ \text{J/kg}\cdot\text{°C}$

Mass flow rate of hot air, $\dot{m}_h = 9\ \text{kg/s}$

Mass flow rate water, $\dot{m}_c = 4\ \text{kg/s}$

Overall heat transfer coefficient $U = 260\ \text{W/m}^2\cdot\text{°C}$

Inlet temperature of the water, $T_{c,in} = 20\text{°C}$

Inlet temperature of the hot air, $T_{h,in} = 100\text{°C}$

Step 2 of 4

Heat capacity rate of the hot and cold fluids are

$$C_c = \dot{m}_c c_{pc}$$
$$= (4\ \text{kg/s})(4180\ \text{J/kg}\cdot\text{°C})$$
$$= 16720\ \text{W/°C}$$
$$C_h = \dot{m}_h c_{ph}$$
$$= (9\ \text{kg/s})(1010\ \text{J/kg}\cdot\text{°C})$$
$$= 9090\ \text{W/°C}$$
$$C_{min} = c_h$$
$$\therefore C_{min} = 9090\ \text{W/°C}$$

Step 3 of 4

Ratio of capacity rates become

$$C = \frac{C_{min}}{C_{max}}$$
$$= \frac{9090\ \text{W/°C}}{16720\ \text{W/°C}}$$
$$= 0.544$$

Step 4 of 4

Then the NTU of this heat exchanger corresponding to $C = 0.544$ and $\varepsilon = 0.65$ is determined from the effectiveness for heat exchangers of cross-flow with both fluids unmixed is $NTU = 1.5$

Then the surface area of this heat exchanger becomes

$$NTU = \frac{UA_s}{C_{min}}$$
$$A_s = \frac{NTU\ C_{min}}{U}$$
$$= \frac{(1.5)(9090\ \text{W/°C})}{260\ \text{W/m}^2\cdot\text{°C}}$$
$$= 52.4\ \text{m}^2$$

$\therefore$ The heat transfer surface are of the heat exchanger is $\boxed{A_s = 52.4\ \text{m}^2}$

Question: 22.089P

Cold water (cp = 4.18 kJ/kg·K) enters a cross-flow heat exchanger at 14°C at a rate of 0.35 kg/s where it is heated by hot air (cp = 1.0 kJ/kg·K) that enters the heat exchanger at 65°C at a rate of 0.8 kg/s and leaves at 25°C. Determine the maximum outlet temperature of the cold water and the effectiveness of this heat exchanger.

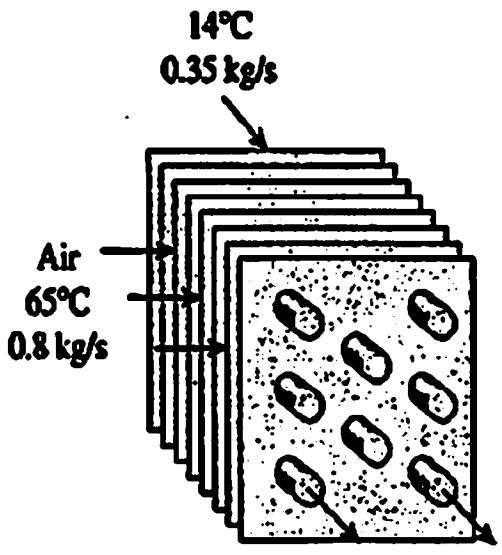

FIGURE P22–89

Step 1 of 5

Given

Type: cross flow heat exchanger

The specific heat of cold water, $c_{pc} = 4.180\ \text{kJ/kg}^\circ\text{C}$

Inlet temperature of coldwater $T_{c,in} = 14^\circ\text{C}$

Mass flow rate of cold water $\dot{m}_c = 0.35\ \text{kg/s}$

The specific heat of hot air, $c_{ph} = 1.0\ \text{kJ/kg}^\circ\text{C}$

Inlet temperature of hot air $T_{h,in} = 65^\circ\text{C}$

Outlet temperature of hot air $T_{h,out} = 25^\circ\text{C}$

Mass flow rate of hot air $\dot{m}_h = 0.8\ \text{kg/s}$

Step 2 of 5

Heat capacity rate of the hot fluid:

$$C_h = \dot{m}_h c_{ph}$$
$$= (0.8\ \text{kg/s})(1.0\ \text{kJ/kg}^\circ\text{C})$$
$$C_h = 0.8\ \text{kW/}^\circ\text{C}$$

Heat capacity rate of the cold fluid:

$$C_c = \dot{m}_c c_{pc}$$
$$= (0.35\ \text{kg/s})(4.18\ \text{kJ/kg}^\circ\text{C})$$
$$C_c = 1.463\ \text{kW/}^\circ\text{C}$$
$$C_h > C_c$$
$$\therefore C_{min} = C_c$$
$$C_{min} = 0.8\ \text{kW/}^\circ\text{C}$$

Step 3 of 5

The maximum heat transfer rate:

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$
$$= (0.8)(65-14)$$
$$\dot{Q}_{max} = 40.8\ \text{kW}$$

Outlet temperature of the cold water:

$$\dot{Q}_{max} = C_c(T_{c,out} - T_{c,in})]$$
$$T_{c,out} = T_{c,in} + \frac{\dot{Q}_{max}}{C_c}$$
$$= 14 + \frac{40.8}{1.463}$$
$$\boxed{T_{c,out} = 41.89\ ^\circ\text{C}}$$

Step 4 of 5

Effectiveness of this heat exchanger:

$$\varepsilon = \frac{\dot{Q}_{act}}{\dot{Q}_{max}}$$

Actual rate of heat transfer is

$$\dot{Q}_{act} = [C_{ph}(T_{h,out} - T_{h,in})]$$
$$= (0.8\ \text{kW/}^\circ\text{C})(65\text{-}25)^\circ\text{C}$$
$$\dot{Q}_{act} = 32\ \text{kW}$$

Step 5 of 5

Effectiveness becomes $\varepsilon = \frac{32}{40.8}$

$$\boxed{\therefore\ \varepsilon = 0.78}$$

Question: 22.090P

Water from a lake is used as the cooling agent in a power plant. To achieve condensation of 3.2 kg/s of steam exiting the turbine, a shell-and-tube heat exchanger is used, which has a single shell and 220 thin-walled, 25-mm-diameter tubes, each tube making two passes. Steam flows through the shell, while cooling water flows through the tubes. Steam enters as saturated vapor at 60°C and leaves as saturated liquid. Cooling water at 20°C is available at a rate of 200 kg/s. The convection coefficient at the outer surface of the tubes is 8500 W/m2·K. Determine (*a*) the temperature of the cooling water leaving the condenser and (*b*) the required tube length per pass. (Use the following average properties for water: *cp* =4180 J/kg·K, μ = 8 × 10−4 N·s/m2, *k* = 0.6 W/m·K, Pr = 6).

Step 1 of 7

Given data:

Mass flow rates of water is $\dot{m} = 3.2\text{kg/s}$

Number of tubes $n = 220$

Diameter of the tube $D_i = 25\text{ mm}$

Steam enters as saturated vapor and leaves as saturated liquid at temperature $T_{steam} = 60°\text{C}$

Inlet temperature of cooling water $T_{c,in} = 20°\text{C}$

The convection coefficient at the outer surface is $h_o = 8500\text{ W/m}^2\text{-K}$

The properties of water are

Dynamic viscosity $\mu = 8\times10^{-4}\text{ N.s/m}^2$

Thermal conductivity $k = 0.6\text{ W/m.°C}$

Specific heat $c_p = 4180\text{J/kgK}$

Prandtl number $\text{Pr} = 6$

Enthalpy of vaporization at $T_{steam} = 60°\text{C}$ is $h_{fg} = 2359\text{kJ/kg}$

Step 2 of 7

(a) The temperature of the cooling water leaving the condenser is

The amount of heat transfer rate is

$$\dot{Q} = \dot{m}h_{fg}$$
$$= 3.2(2359)$$
$$= 7548.8\text{ kW}$$

And we know

$$\dot{Q} = \dot{m}_c c_c\left(T_{c,out} - T_{c,in}\right)$$
$$7548.8 = 200(4.18)\left(T_{c,out} - 20\right)$$
$$\boxed{T_{c,out} = 29.03°\text{C}}$$

Step 3 of 7

(b) The length of the tube

Reynolds number for the flow is expressed as

$$\text{Re} = \frac{4\dot{m}}{n\pi D\mu}$$
$$= \frac{4\times200}{220\times\pi\times(0.025)8\times10^{-4}}$$
$$\text{Re} = 57874.5$$

Re >10,000 the flow is turbulent and assuming fully developed flow.

Step 4 of 7

Nusselt number

$$\text{Nu} = 0.023\text{Re}^{0.8}\,\text{Pr}^{0.4}$$
$$= 0.023(57874.5)^{0.8}(6)^{0.4}$$
$$\text{Nu} = 304.07$$

And

$$\text{Nu} = \frac{h_i D}{k}$$
$$h_i = \frac{k}{D}\text{Nu}$$
$$= \frac{0.6}{0.025}\times304.07$$
$$h_i = 7297.68\text{ W/m}^2\cdot°\text{C}$$

Step 5 of 7

Then the overall heat transfer coefficient is

$$U = \frac{1}{\frac{1}{h_i}+\frac{1}{h_o}}$$
$$= \frac{1}{\frac{1}{7297.68\text{ W/m}^2\cdot°\text{C}}+\frac{1}{8500\text{ W/m}^2\cdot°\text{C}}}$$
$$= 3926.54\text{ W/m}^2\cdot°\text{C}$$

Temperature differences in counter flow heat exchanger is

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= 60 - 29.03$$
$$\Delta T_1 = 30.97°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= 60 - 20$$
$$\Delta T_2 = 40°\text{C}$$

Step 6 of 7

Therefore the LMTD is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1/\Delta T_2\right)}$$
$$= \frac{30.97 - 40}{\ln[30.97/40]}$$
$$\Delta T_{lm} = 35.3°\text{C}$$

Step 7 of 7

Since the phase change on the shell side the correction factor for this case is

$$F = 1$$

Then the tube length per pass is determined to be

$$\dot{Q} = UA_s F\Delta T_{lm}$$
$$\dot{Q} = U(\pi DL)F\Delta T_{lm}$$
$$7548.8 = (3926.54)(\pi\times(0.025)L)(1)(35.3)$$
$$\boxed{L = 0.693\text{ m}}$$

Question: 22.091P

Water (cp = 4180 J/kg·K) is to be heated by solar- heated hot air (cp = 1010 J/kg·K) in a double-pipe counter- flow heat exchanger. Air enters the heat exchanger at 90°C at a rate of 0.3 kg/s, while water enters at 22°C at a rate of 0.1 kg/s. The overall heat transfer coefficient based on the inner side of the tube is given to be 80 W/m2·K. The length of the tube is 12 m and the internal diameter of the tube is 1.2 cm. Determine the outlet temperatures of the water and the air.

Step 1 of 8

Given data:

Specific heat of hot air $c_{ph} = 1010$ J/kg°C

Specific heat of water $c_{pc} = 4180$ J/kg°C

Mass flow rate of hot air, $\dot{m}_h = 0.3$ kg/s

Mass flow rate of water, $\dot{m}_c = 0.1$ kg/s

Overall heat transfer coefficient $U = 80$ W/m^2°C

The diameter of the tube, $D = 0.012$ m

The length of the tube, $L = 12$ m

Step 2 of 8

Outlet temperatures of the hot and cold fluids are determined as

Heat transfer rate of each fluid is given by

$$\dot{Q} = C_h\left(T_{h,in} - T_{h,out}\right)$$

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h}$$

The heat capacity rate of the hot fluid is

$$C_h = \dot{m}_h C_{ph}$$
$$= (0.3\text{kg/s})(1010\ \text{J/kg.°C})$$
$$= 303\ \text{W/°C}$$

Step 3 of 8

$$\dot{Q} = C_c\left(T_{c,out} - T_{c,in}\right)$$

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c}$$

The heat capacity rate of the cold fluid is

$$C_c = \dot{m}_c C_{pc}$$
$$= (0.1\ \text{kg/s})(4180\ \text{J/kg.°C})$$
$$= 418\ \text{W/°C}$$

Step 4 of 8

Therefore $C_{min} = C_c = 303$ W/°C

And $C = \frac{C_{min}}{C_{max}} = \frac{303}{418} = 0.725$

The maximum heat transfer rate is

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$
$$= (303\ \text{W/°C})(90°\text{C} - 22°\text{C})$$
$$= 20,604\ \text{kW}$$

Step 5 of 8

Hear transfer surface area is

$$A_s = \pi DL$$
$$= (\pi)(0.012\ \text{m})(12\ \text{m})$$
$$= 0.45\ \text{m}^2$$

NTU for this heat exchanger is

$$NTU = \frac{UA_s}{C_{min}}$$
$$= \frac{(80\ \text{W/m}^2\text{.°C})\ (0.45\ \text{m}^2)}{303\ \text{W/°C}}$$
$$= 0.1188$$

Step 6 of 8

Effectiveness for this heat exchanger is calculated as

$$\varepsilon = \frac{1 - \exp[-NTU(1-C)]}{1 - C\exp[-NTU(1-C)]}$$
$$= \frac{1 - \exp[-0.1188(1-0.725)]}{1 - 0.725\exp[-0.1188(1-0.725)]}$$
$$= \frac{0.03214}{0.2983}$$
$$= 0.1077$$

Step 7 of 8

Then the actual heat transfer rate is

$$\dot{Q} = \varepsilon\dot{Q}_{max}$$
$$= (0.108)(20{,}604\ \text{W})$$
$$= 2219.93\ \text{W}$$

By substituting the heat transfer rate outlet temperatures of the hot and cold fluids are

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h}$$
$$= 90°\text{C} - \frac{2219.93\ \text{W}}{303\ \text{W/°C}}$$
$$= 82.67°\text{C}$$

∴ The outlet temperature of the water, $\boxed{T_{h,out} = 82.67°\text{C}}$

Step 8 of 8

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c}$$
$$= 22°\text{C} + \frac{2219.93\ \text{W}}{418\ \text{W/°C}}$$
$$= 27.31°\text{C}$$

∴ The outlet temperature of the hot air, $\boxed{T_{c,out} = 27.31°\text{C}}$

Question: 22.092P

Reconsider Prob. 22-91. Using EES (or other) software, investigate the effects of the mass flow rate of water and the tube length on the outlet temperatures of water and air. Let the mass flow rate vary from 0.05 kg/s to 1.0 kg/s and the tube length from 5 m to 25 m. Plot the outlet temperatures of the water and the air as func-tions of the mass flow rate and the tube length, and discuss the results.

Step 1 of 4

Procedure:

Double click on the EES icon then click new command on menu bar.

Now new window will be appeared, then type equation in a new window.

Then Click table on menu bar, select the new parameter table.

And run the table for now values.

Then click ok.

Now again select the plot command on menu bar .then select the required variables from the list, then click okay.

Step 2 of 4

Equation window:

```
"GIVEN"
T_air_in=90 "[C]"
m_dot_air=0.3 "[kg/s]"
C_p_air=1.01 "[kJ/kg-C]"
T_w_in=22 "[C]"
m_dot_w=0.1
C_p_w=4.18 "[kJ/kg-C]"
U=0.080 "[kW/m^2-C]"
"L=12 [m]"
D=0.012 "[m]"

"ANALYSIS"
DELTAT_1=T_air_in-T_w_out
DELTAT_2=T_air_out-T_w_in
DELTAT_lm=(DELTAT_1-DELTAT_2)/ln(DELTAT_1/DELTAT_2)
A=pi*D*L
Q_dot=U*A*DELTAT_lm
Q_dot=m_dot_air*C_p_air*(T_air_in-T_air_out)
Q_dot=m_dot_w*C_p_w*(T_w_out-T_w_in)
```

Step 3 of 4

Step 4 of 4

Graph between Temperature of water and air out Vs. mass flow rate :

Graph between Temperature of water and air out Vs. Length:

Question: 22.093P

A thin-walled double-pipe, counter-flow heat exchanger is to be used to cool oil (cp = 0.525 Btu/lbm·°F) from 300°F to 105°F at a rate of 5 lbm/s by water (cp = 1.0 Btu/lbm·°F) that enters at 70°F at a rate of 3 lbm/s. The diameter of the tube is 5 in and its length is 200 ft. Determine the overall heat transfer coefficient of this heat exchanger using (*a*) the LMTD method and (*b*) the ε-NTU method.

Step 1 of 13

Given

Specific heat of water, $c_{pc} = 1$ Btu/lbm °F

Specific heat of oil, $c_{ph} = 0.525$ Btu/lbm °F

Mass flow rate of oil $m_h = 5$ lbm/s

Mass flow rate of water, $m_c = 3$ lbm/s

The diameter of the tube is $D = 5$ in

The total length of the tube is $L = 200$ ft

Step 2 of 13

a) Using LMTD method overall heat transfer coefficient is determined as follows

Heat transfer rate determined to be

$$\dot{Q} = [\dot{m}_h c_{hc}(T_{out} - T_{in})]_{oil}$$

$$= (5 \text{ lbm/s})(0.525 \text{ Btu/lbm °F})(300-105)°\text{F}$$

$$= 511.9 \text{ Btu/s}$$

Step 3 of 13

The mass flow rate of glycerin is determined to be

$$\dot{Q} = [\dot{m} C_p (T_{out} - T_{in})]_{water}$$

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c}$$

$$= 70°\text{F} + \frac{511.9 \text{ Btu/s}}{(3 \text{ lbm/s})(1.0 \text{ Btu/lbm.°F})}$$

$$= 240.6°\text{F}$$

Step 4 of 13

For this counter flow heat exchanger LMTD determined to be

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$= (300-240.6)°\text{F}$$

$$= 59.4°\text{F}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= (105-70)°\text{F}$$

$$= 35°\text{F}$$

Step 5 of 13

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined from

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$= \frac{59.4-35}{\ln(59.4/35)}$$

$$= 46.1°\text{F}$$

Step 6 of 13

Overall heat transfer coefficient of the heat exchanger is determined to be

$$U_i = \frac{\dot{Q}}{A_i \Delta T_{lm}}$$

$$= \frac{511.9 \text{ Btu/s}}{\pi(5/12 \text{ ft})(200 \text{ ft})(46.1°\text{F})}$$

$$= 0.0424 \text{Btu/s} \cdot \text{ft}^2 \cdot °\text{F}$$

∴ The Overall heat transfer coefficient $\boxed{U_i = 0.0424 \text{Btu/s} \cdot \text{ft}^2 \cdot °\text{F}}$

Step 7 of 13

b) Using NTU method overall heat transfer coefficient is determined as follows

Heat transfer rate of each fluid is given by

$$\dot{Q} = C_h (T_{h,in} - T_{h,out})$$

The heat capacity rate of the hot fluid is

$$C_h = \dot{m}_h C_{ph}$$

$$= (5 \text{ lbm/s})(0.525 \text{ Btu/lbm.°F})$$

$$= 2.625 \text{ Btu/s.°F}$$

Step 8 of 13

$$\dot{Q} = C_c (T_{c,out} - T_{c,in})$$

The heat capacity rate of the cold fluid is

$$C_c = \dot{m}_c C_{pc}$$

$$= (3 \text{ lbm/s})(1.0 \text{ Btu/lbm.°F})$$

$$= 3.0 \text{ Btu/s.°F}$$

Step 9 of 13

Therefore $C_{min} = C_h = 2.625$ Btu/s.°F

And $C = \frac{C_{min}}{C_{max}} = \frac{2.625}{3.0} = 0.875$

The maximum heat transfer rate is

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$

$$= (2.625 \text{ Btu/s.°F})(300°\text{F} - 70°\text{F})$$

$$= 603.75 \text{ Btu/s}$$

Step 10 of 13

Actual heat transfer is calculated by

$$\dot{Q} = C_h (T_{h,in} - T_{h,out})$$

$$= (2.625 \text{ Btu/s.°F})(300°\text{F-}105°\text{F})$$

$$= 511.9 \text{ Btu/s}$$

Step 11 of 13

Then effectiveness of the heat exchanger is

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$

$$= \frac{511.9}{603.75}$$

$$= 0.85$$

Step 12 of 13

NTU of the heat exchanger is

$$NTU = \frac{1}{C-1}\ln\left(\frac{\varepsilon - 1}{\varepsilon C - 1}\right)$$

$$= \frac{1}{0.875-1}\ln\left(\frac{0.85-1}{0.85 \times 0.875-1}\right)$$

$$= 4.28$$

Step 13 of 13

Surface area of the heat exchanger is

$$A_s = \pi DL$$

$$= \pi(5/12 \text{ ft})(200 \text{ ft})$$

$$= 261.799 \text{ ft}^2$$

Overall heat transfer coefficient becomes

$$NTU = \frac{UA_s}{C_{min}}$$

$$U = \frac{NTU \, C_{min}}{A_s}$$

$$= \frac{(4.28)(2.625 \text{ Btu/s.°F})}{261.799 \text{ ft}^2}$$

$$= 0.0429 \text{Btu/s} \cdot \text{ft}^2 \cdot °\text{F}$$

∴ The Overall heat transfer coefficient $\boxed{U_i = 0.0429 \text{Btu/s} \cdot \text{ft}^2 \cdot °\text{F}}$

Question: 22.094P

A shell-and-tube heat exchanger with 2-shell passes and 8-tube passes is used to heat ethyl alcohol (cp = 2670 J/kg·K) in the tubes from 25°C to 70°C at a rate of 2.1 kg/s. The heating is to be done by water (cp = 4190 J/kg·K) that enters the shell at 95°C and leaves at 60°C. If the overall heat transfer coefficient is 800 W/m2·K, determine the heat transfer surface area of the heat exchanger using (*a*) the LMTD method and (*b*) the ε-NTU method.

Step 1 of 13

Given data:

Specific heat of water, $c_{ph} = 4190\ \text{J/kg°C}$

Specific heat of ethyl alcohol, $c_{pc} = 2670\ \text{J/kg°C}$

Mass flow rates of ethyl alcohol is $\dot{m}_c = 2.1\ \text{kg/s}$

Overall heat transfer coefficient $U = 800\ \text{W/m}^2\text{°C}$

Step 2 of 13

a) Using LMTD method

Temperature difference between two fluids at two ends of the heat exchanger is

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= 95°C - 70°C$$
$$= 25°C$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= 60°C - 25°C$$
$$= 35°C$$

Step 3 of 13

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined from

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$
$$= \frac{25-35}{\ln(25/35)}$$
$$= 29.7°C$$

Step 4 of 13

For shell and tube heat exchanger computing the parameters P & R

$$P = \frac{t_2 - t_1}{T_1 - t_1}$$
$$= \frac{70-25}{95-25}$$
$$= 0.64$$
$$R = \frac{T_1 - T_2}{t_2 - t_1}$$
$$= \frac{95-60}{70-25}$$
$$= 0.78$$

Step 5 of 13

At these P and R values F= 0.93 (Fig. 16-18c)

Heat transfer rate determined to be

$$\dot{Q} = \left[\dot{m}_c c_{pc}(T_{out} - T_{in})\right]_{\text{ethyl alcohol}}$$
$$= (2.1\ \text{kg/s})(2.67\ \text{kJ/kg.°C})(70°C - 25°C)$$
$$= 252.3\ \text{kW}$$

Step 6 of 13

Heat transfer surface area is

$$\dot{Q} = UA_s\Delta T_{lm}$$
$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$
$$= \frac{252.3\ \text{kW}}{(0.8\ \text{kW/m}^2\cdot°C)(0.93)(29.7°C)}$$
$$= 11.4\ \text{m}^2$$

∴ The heat transfer surface area, $\boxed{A_s = 11.4\ \text{m}^2}$

Step 7 of 13

b) Using NTU method

Heat transfer rate determined to be

$$\dot{Q} = \left[\dot{m}_c c_{pc}(T_{out} - T_{in})\right]_{\text{ethyl alcohol}}$$
$$= (2.1\ \text{kg/s})(2.67\ \text{kJ/kg}\cdot°C)(70°C - 25°C)$$
$$= 252.3\ \text{kW}$$

Step 8 of 13

Mass flow rate of the hot fluid is

$$\dot{Q} = \dot{m}_h C_{ph}(T_{h,in} - T_{h,out})$$
$$\dot{m}_h = \frac{\dot{Q}}{C_{ph}(T_{h,in} - T_{h,out})}$$
$$= \frac{252.3\ \text{kW}}{(4.19\ \text{kJ/kg.°C})(95°C - 60°C)}$$
$$= 1.72\ \text{kg/s}$$

Step 9 of 13

The heat capacity rates of the hot and cold fluids are

$$C_c = \dot{m}_c C_{pc}$$
$$= (2.1\ \text{kg/s})(2.67\ \text{kJ/kg}\cdot°C)$$
$$= 5.61\ \text{kW/°C}$$
$$C_h = \dot{m}_h C_{ph}$$
$$= (1.72\ \text{kg/s})(4.19\ \text{kJ/kg}\cdot°C)$$
$$= 7.21\ \text{kW/°C}$$

Step 10 of 13

Therefore the minimum heat capacity

$$C_{min} = C_c = 5.61\ \text{kW/°C}$$

And $$C = \frac{C_{min}}{C_{max}}$$
$$= \frac{5.61}{7.21}$$
$$= 0.78$$

Step 11 of 13

Maximum heat transfer rate becomes

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$
$$= (5.61\ \text{W/°C})(95°C - 25°C)$$
$$= 392.7\ \text{kW}$$

Step 12 of 13

Effectiveness of the heat exchanger is

$$\varepsilon = \frac{Q}{Q_{max}}$$
$$= \frac{252.3}{392.7}$$
$$= 0.64$$

Step 13 of 13

Heat transfer surface area of the heat exchanger determined as

$$NTU = \frac{UA_s}{C_{min}}$$
$$A_s = \frac{NTU\ C_{min}}{U}$$
$$= \frac{(1.7)(5.61\ \text{kW/°C})}{0.8\ \text{kW/m}^2\text{.°C}}$$
$$= 11.9\ \text{m}^2$$

∴ The heat transfer surface area, $\boxed{A_s = 11.9\ \text{m}^2}$

Question: 22.095P

Steam is to be condensed on the shell side of a 1-shell- pass and 8-tube-passes condenser, with 50 tubes in each pass, at 30°C (*hfg* = 2431 kJ/kg). Cooling water (*cp* = 4180 J/kg·K) enters the tubes at 18°C at a rate of 2200 kg/h. The tubes are thin-walled, and have a diameter of 1.5 cm and length of 2 m per pass. If the overall heat transfer coefficient is 3000 W/m2·K, determine (*a*) the rate of heat transfer and (*b*) the rate of condensation of steam.

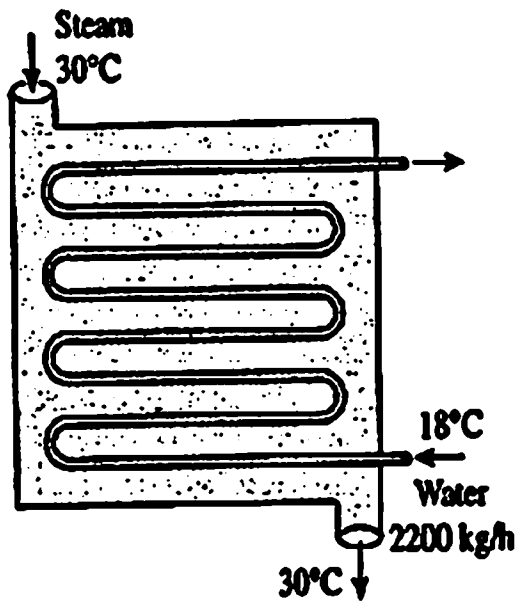

FIGURE P22–95

Step 1 of 4

Given data:

The specific heat of water is $c_p = 4180 \text{J/kg.°C}$

Inlet temperature of saturated vapor $T_{steam} = 30°\text{C}$

The heat of vaporization of steam is $h_{fg} = 2431 \text{kJ/kg}$

Mass flow rate of water

$\dot{m}_{water} = 2200 \text{ kg/h}$

$= \frac{2200}{3600}$

$\dot{m}_{water} = 0.611 \text{ kg/s}$

Overall heat transfer coefficient $U = 3000 \text{ W/m}^2\text{.°C}$

Step 2 of 4

The heat capacity rate for the condensing type heat exchanger is infinity

So

$C_{min} = C_c$

$= \dot{m}_c C_{pc}$

$= 0.611(4.18)$

$C_{min} = 2.55 \text{ kW/°C}$

And $C = 0$

The maximum heat transfer rate becomes

$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$

$= (2.55 \text{ kW/°C})(30°\text{C} - 18°\text{C})$

$\dot{Q}_{max} = 30.654 \text{ kW}$

Hat transfer surface area calculated as

$A_s = 8n\pi DL$

$= 8 \times 50\pi(0.015 \text{ m})(2 \text{ m})$

$A_s = 37.7 \text{ m}^2$

Step 3 of 4

NTU of the heat exchanger is

$\text{NTU} = \frac{UA_s}{C_{min}}$

$= \frac{(3\text{kW/m}^2\text{.°C})(37.7\text{m}^2)}{2.55 \text{ kW/°C}}$

$\text{NTU} = 44.353$

Effectiveness for this heat exchanger becomes

$\varepsilon = 1 - \exp(-\text{NTU})$

$= 1 - \exp(-44.353)$

$= 1$

Then the actual heat transfer rate calculated as

$\dot{Q} = \varepsilon \dot{Q}_{max}$

$= (1)(30.654 \text{ kW})$

$\boxed{\dot{Q} = 30.654 \text{ kW}}$

Step 4 of 4

b) Condensation steam rate is calculated as

$\dot{Q} = \dot{m} h_{fg}$

$\dot{m} = \frac{\dot{Q}}{h_{fg}}$

$= \frac{30.654 \text{ kJ/s}}{2431 \text{ kJ/kg}}$

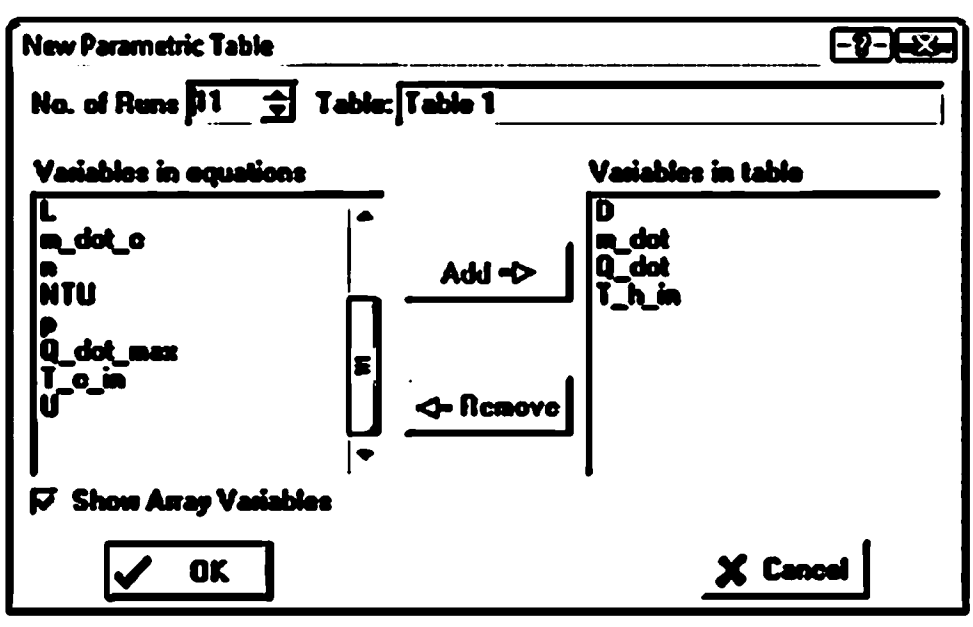
$\boxed{\dot{m} = 0.0126 \text{kg/s}}$

Question: 22.096P pg 1

Reconsider Prob. 22-95.Using EES (or other) software, investigate the effects of the condensing steam temprature and the tube diameter on the rate of heat transfer and the rate of condensation of steam. Let the steam temprature vary from 20°C to 70°C the tube diameter from 1.0 cm to 2.0 cm. Plot the rate of heat transfer and the rate of condensation as functions of steam temperature and diameter, and discuss the results.

Step 1 of 8

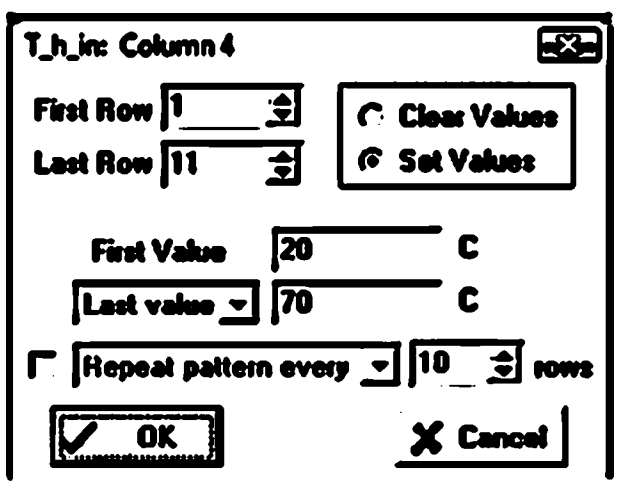
The given problem can be solved using EES software by following the below steps.



1. Open EES software
2. Create a new file by clicking on the 'New' of the 'File menu'
3. Now type the following code in dailog box

```
p=8                                          "Number of passes"
n=50                                         "Number of tubes"
"T_h_in is varied from 20[C] to 70[C]"       "Temperature of steam"
h_fg=2431[kJ/kg K]                           "Heat of vapourization of steam"
c_pc=4180[J/ kg K]                           "Specific heat of cooling water"
T_c_in=18[C]                                 "Inlet temperature of cooling water"
m_dot_c=2200[kg/h]*convert(kg/h,kg/s)        "Mass flow rate of cooling water"
"D is varied from 1.0[cm] to 2.0[cm]"        "Diameter of tube"
L=2[m]                                       "Lenght of tube"
U=3000[W/m^2 K]                              "Overall heat transfer coefficient"

C_min=m_dot_c*c_pc                           "Specific heat of cold water"
Q_dot_max=C_min*(T_h_in-T_c_in)              "Maximum rate of heat transfer"
A_s=p*n*pi*D*L                               "Heat transfer surface area"
NTU=U*A_s/C_min
epsilon=1-exp(-NTU)
Q_dot=epsilon*Q_dot_max*convert(J/s,KJ/s)
Q_dot=m_dot*h_fg
```



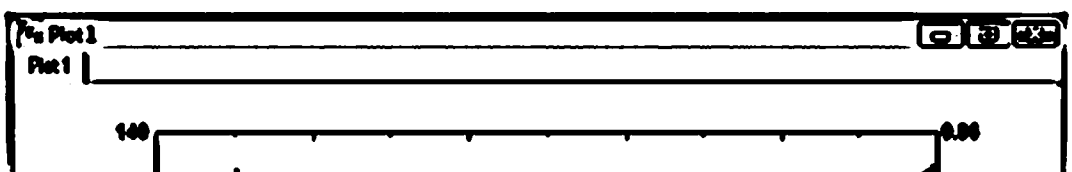
Step 2 of 8

Now to solve the equation for a range of condensing steam temperature and tube diameters, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open.
Select no of runs = 11.
Select variables in equations as "D", "m_dot", "Q_dot" and "T_h_in" press 'Add' and then press 'OK'. The screenshot of the "New Parametric Table" is shown:

Step 3 of 8

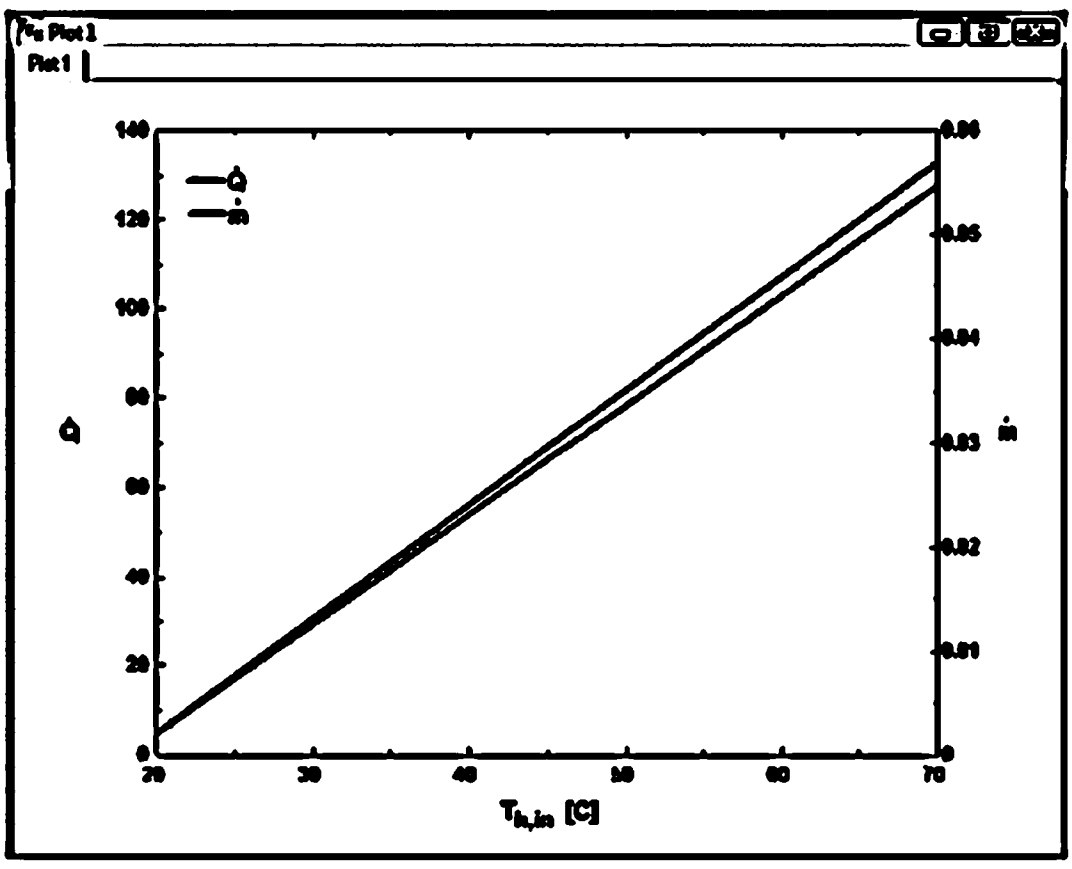
First the condensing steam temperature is varied at constant diameter of the tube of $D = 0.015\,m$.
To enter the values in the "T_h_in" column, click on the drop tab in "T_h_in" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 4 of 8



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

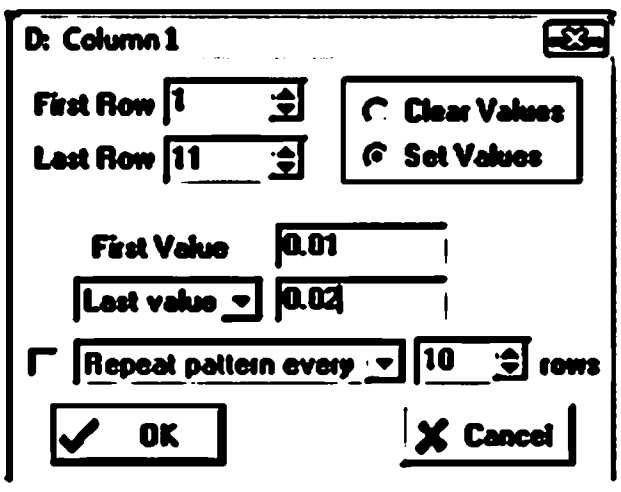
Table 1



$\triangleright_{1..11}$	1 D	2 $\dot{m}$	3 $\dot{Q}$	4 $T_{h,in}$ [C]
Run 1	0.015	0.002102	5.109	20
Run 2	0.015	0.007355	17.88	25
Run 3	0.015	0.01261	30.65	30
Run 4	0.015	0.01786	43.43	35
Run 5	0.015	0.02312	56.2	40
Run 6	0.015	0.02837	68.97	45
Run 7	0.015	0.03362	81.74	50
Run 8	0.015	0.03888	94.51	55
Run 9	0.015	0.04413	107.3	60
Run 10	0.015	0.04939	120.1	65
Run 11	0.015	0.05464	132.8	70

Step 5 of 8

Inorder to plot the heat transfer and rate of condensation as function of steam temperature, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the plot showing the heat transfer and rate of condensation as function of steam temperature is shown:



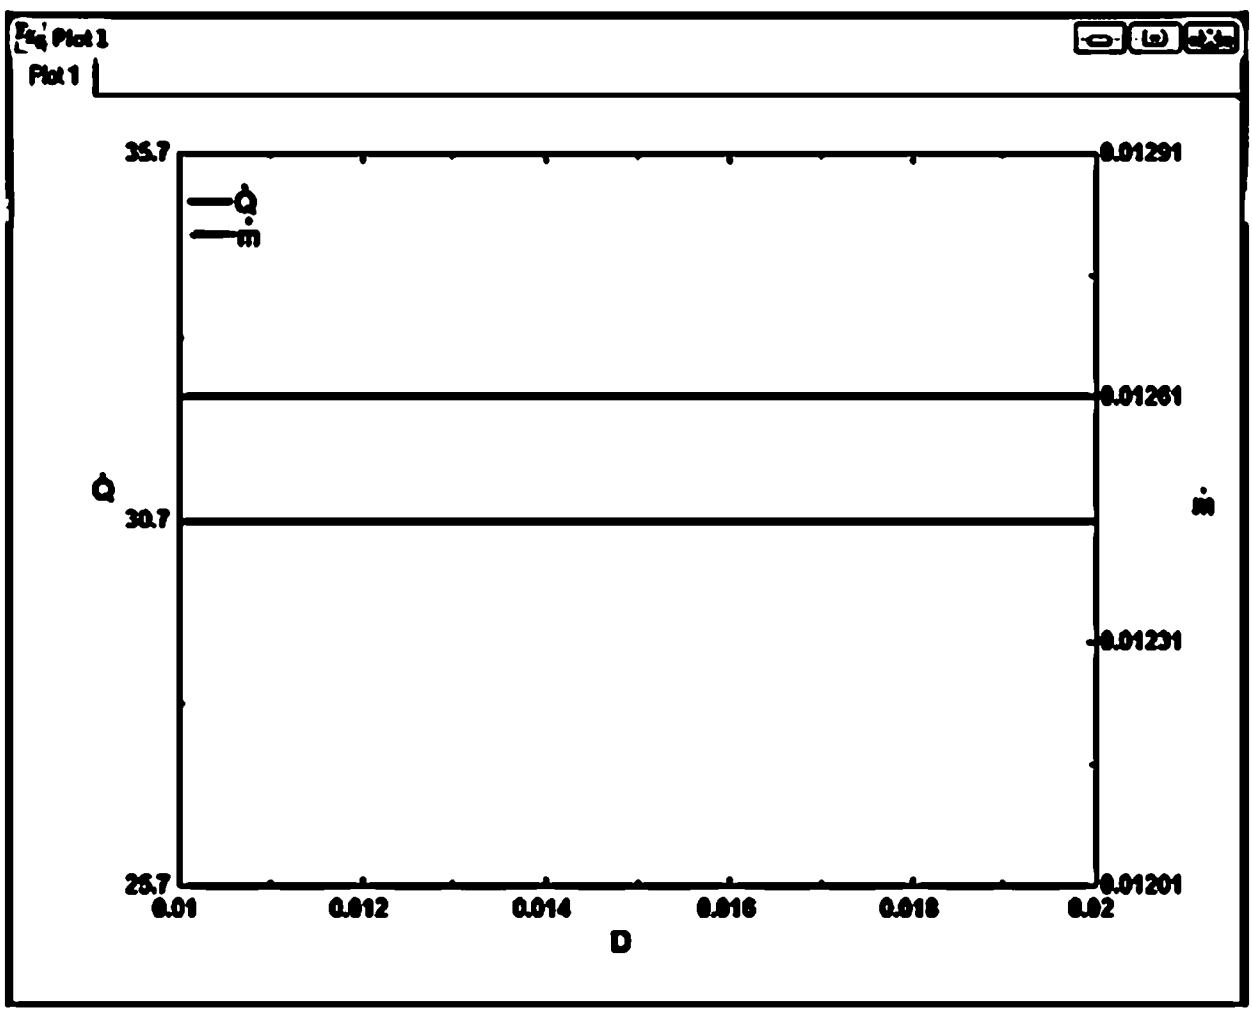
steam temperature is shown: 22.096P pg 2

From the above plot we can interpret as the steam temperature increases, the heat transfer and rate of condensation also increases.

Step 6 of 8

Now the diameter of the tube is varied at constant condensing steam temperature of T = 30°C.
To enter the values in the "D" column, click on the drop tab in "D" column. A new windows pops up, fill in the details as shown below and then press 'OK'

Step 7 of 8



Now click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below:

Table 1

1..11	1 D	2 ṁ	3 Q̇	4 $T_{h,in}$
Run 1	0.01	0.01261	30.65	30
Run 2	0.011	0.01261	30.65	30
Run 3	0.012	0.01261	30.65	30
Run 4	0.013	0.01261	30.65	30
Run 5	0.014	0.01261	30.65	30
Run 6	0.015	0.01261	30.65	30
Run 7	0.016	0.01261	30.65	30
Run 8	0.017	0.01261	30.65	30
Run 9	0.018	0.01261	30.65	30
Run 10	0.019	0.01261	30.65	30
Run 11	0.02	0.01261	30.65	30

Step 8 of 8

Inorder to plot the heat transfer and rate of condensation as function of diameter of the tube, click on the 'X-Y Plot' of 'New Plot window' from 'Plots' menu.
Screenshot of the plot showing the heat transfer and rate of condensation as function of diameter of the tube is shown:

From the above plot we can interpret as the diameter of the tube increases, there will be no effect on the heat transfer and rate of condensation.

Question: 22.097P

Cold water (cp = 4180 J/kg·K) leading to a shower enters a thin-walled double-pipe counter-flow heat exchanger at 15°C at a rate of 0.25 kg/s and is heated to 45°C by hot water (cp = 4190 J/kg·K) that enters at 100°C at a rate of 3 kg/s. If the overall heat transfer coefficient is 950 W/m2·K, determine the rate of heat transfer and the heat transfer surface area of the heat exchanger using the ε-NTU method.

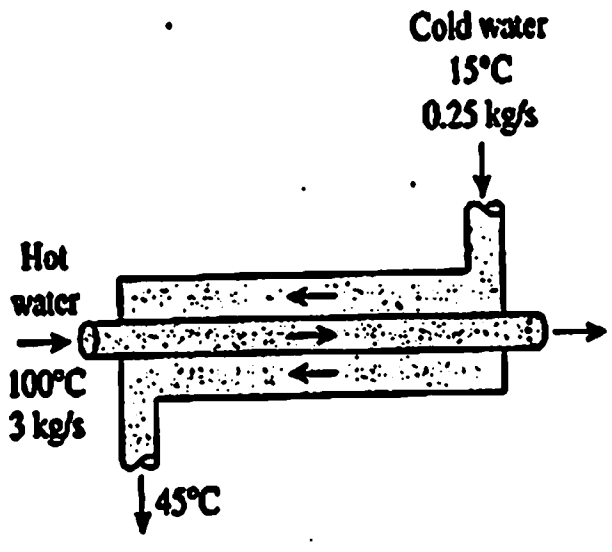


FIGURE P22–97

Step 1 of 8

Given data:

Specific heat of hot water, $c_{ph} = 4190$ J/kg°C

Specific heat of cold water, $c_{pc} = 4180$ J/kg°C

Mass flow rate of cold water, $\dot{m}_h = 0.25$ kg/s

Mass flow rate of hot water, $\dot{m}_c = 3$ kg/s

Overall heat transfer coefficient $U = 950$ W/m^2°C

Step 2 of 8

Using NTU method heat transfer surface area is determined as follows

The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph}$$
$$= (0.25 \text{ kg/s})(4180 \text{ J/kg°C})$$
$$= 1045 \text{ W/°C}$$
$$C_c = \dot{m}_c C_{pc}$$
$$= (3 \text{ kg/s})(4190 \text{ J/kg°C})$$
$$= 12,570 \text{ W/°C}$$

Step 3 of 8

Therefore the minimum heat capacity is

$$C_{min} = C_c = 1045 \text{ W/°C}$$

$$\text{And } C = \frac{C_{min}}{C_{max}}$$
$$= \frac{1045}{12,570}$$
$$= 0.083$$

Step 4 of 8

The maximum heat transfer rate is

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$
$$= (1045 \text{ W/°C})(100°C\text{-}15°C)$$
$$= 88,825 \text{ W}$$

Step 5 of 8

Actual heat transfer is calculated by

$$\dot{Q} = C_h(T_{h,in} - T_{h,out})$$
$$= (1045 \text{ W/°C})(45°C - 15°C)$$
$$= 31350 \text{ W}$$

∴ The Actual rate of heat transfer is $\boxed{\dot{Q} = 31.35 \text{kW}}$

Step 6 of 8

Then effectiveness of the heat exchanger is

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$
$$= \frac{31,350}{88,825}$$
$$= 0.35$$

Step 7 of 8

NTU of the heat exchanger is

$$NTU = \frac{1}{C-1}\ln\left(\frac{\varepsilon - 1}{\varepsilon C - 1}\right)$$
$$= \frac{1}{0.083-1}\ln\left(\frac{0.35-1}{0.35\times 0.083-1}\right)$$
$$= 0.438$$

Step 8 of 8

Heat transfer surface area is calculated as

$$NTU = \frac{UA_s}{C_{min}}$$
$$A_s = \frac{NTU(C_{min})}{U}$$
$$= \frac{(0.438)(1045 \text{ W/°C})}{950 \text{ W/m}^2\text{.°C}}$$
$$= 0.4818 \text{m}^2$$

∴ The heat transfer surface area $\boxed{A_s = 0.4818 \text{m}^2}$

Question: 22.098P pg 1

Reconsider Prob. 22-97. Using EES (or other) software, investigate the effects of the inlet temperature of hot water and the heat transfer coeffi-cient on the rate of heat transfer and the surface area. Let the inlet temperature vary from 60°C to 120°C and the overall heat transfer coefficient from 750 W/m2·K to 1250 W/m2-K. Plot the rate of heat transfer and surface area as functions of the inlet temperature and the heat transfer coefficient, and discuss the results.

Step 1 of 7

The given problem can be solved using EES software by following the below steps.

1. **Open EES software**
2. **Crease a new file by clicking on the 'New' of the 'File menu'**
3. **Now type the following code in dailog box**

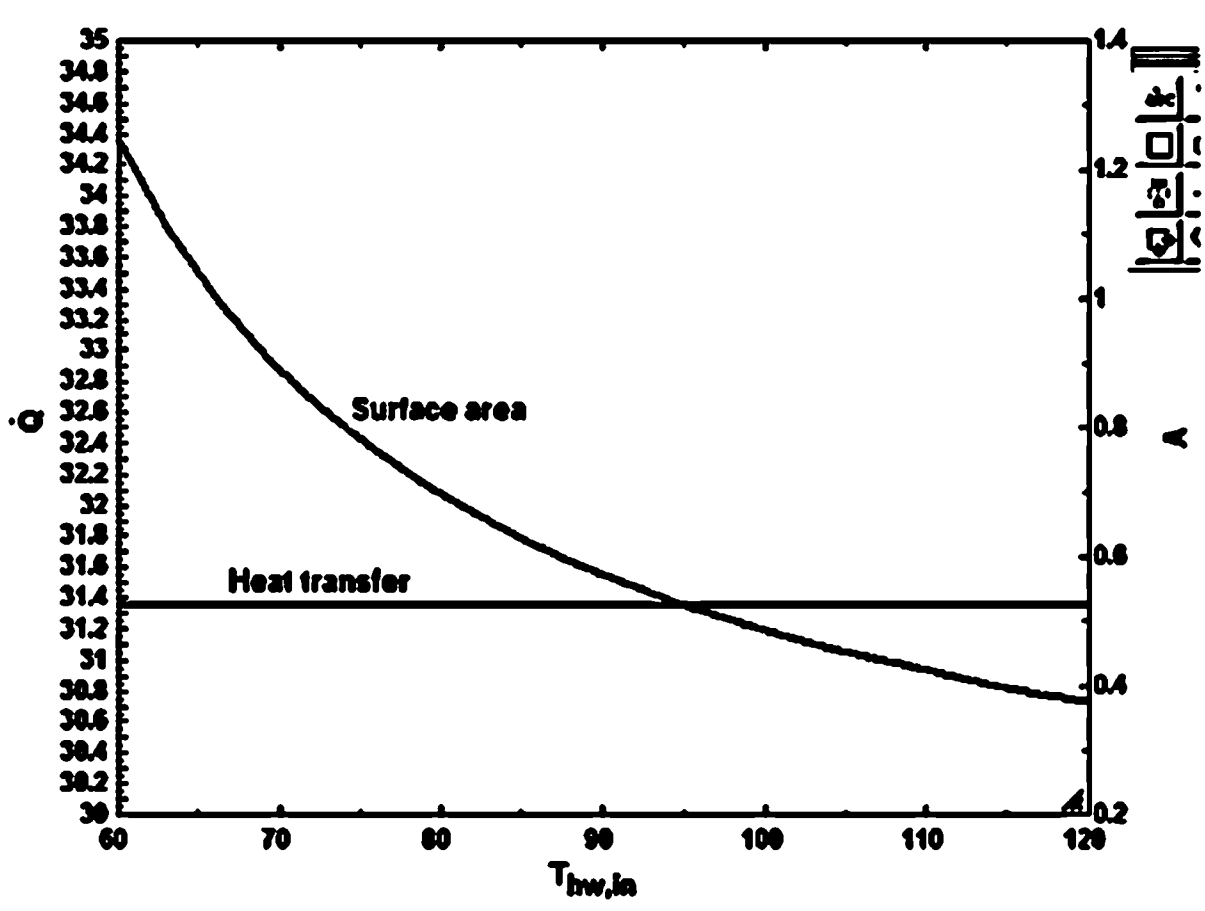
```
"GIVEN"
T_cw_in=15[C]
T_cw_out=45[C]
m_dot_cw=0.25 [kg/s]
C_p_cw=4.18 [kJ/kg-C]
T_hw_in=100[C], "Vary this parameter "
m_dot_hw=3[kg/s]
C_p_hw=4.19 [kJ/kg-C]
"U=0.95 [kW/m^2-C], "Vary this parameter "

"ANALYSIS"
" Solve this problem using LMTD method than NTU method its would be easier by
EES. Below, Use LMTD method. Both methods give the same results."
DELTAT_1=T_hw_in-T_cw_out
DELTAT_2=T_hw_out-T_cw_in
DELTAT_lm=(DELTAT_1-DELTAT_2)/ln(DELTAT_1/DELTAT_2)
Q_dot=U*A*DELTAT_lm
Q_dot=m_dot_hw*C_p_hw*(T_hw_in-T_hw_out)
Q_dot=m_dot_cw*C_p_cw*(T_cw_out-T_cw_in)
```

Step 2 of 7

Now to solve the equation for a range of length values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 10
Select variables in equations as $T_{hw,in}$ and Q ,A press 'Add' and then press 'ok'
A table will appear and enter the values of length under '$T_{hw,in}$ ' vary from 60°C to 120°C
Then from click on 'Solve table' of 'Calculate' menu.
The Solution will appear as shown below

Step 3 of 7



The following results are displayed:

Table 1

1..10	$T_{hw,in}$	$\dot{Q}$	A
Run 1	60	31.35	1.25
Run 2	66.67	31.35	0.9833
Run 3	73.33	31.35	0.814
Run 4	80	31.35	0.6957
Run 5	86.67	31.35	0.6082
Run 6	93.33	31.35	0.5405
Run 7	100	31.35	0.4865
Run 8	106.7	31.35	0.4425
Run 9	113.3	31.35	0.4058
Run 10	120	31.35	0.3748

Step 4 of 7

Select the plot on menu bar, and then click x-y plot .Dialog box will be appeared.
Select X-axis as $T_{hw,in}$ and Y-axis as $\dot{Q}$, A .Press OK
The Graph will be plotted as shown below.
By plotting the graph of heat transfer, surface area as function of inlet temperature:

This graph represents that by increasing the inlet temperature; the heat transfer remains constant and surface decreases.

Step 5 of 7

Now to solve the equation for a range of length values, use parametric table by clicking on the 'New parametric table' of 'Tables' menu.
A dailog box will open. Now
Select no of runs = 20
Select variables in equations as U and Q ,A press 'Add' and then press 'ok'
A table will appear and enter the values of length under 'U ' vary from 0.75 kW/m^2·K to 1250 kW/m^2·K
Then from click on 'Solve table' of 'Calculate' menu.

Select no of runs = 20 22.098P pg 2

Select variables in equations as U and Q, A press 'Add' and then press 'ok'

A table will appear and enter the values of length under 'U' vary from

$0.75\ kW/m^2 \cdot K$ to $1250\ kW/m^2 \cdot K$

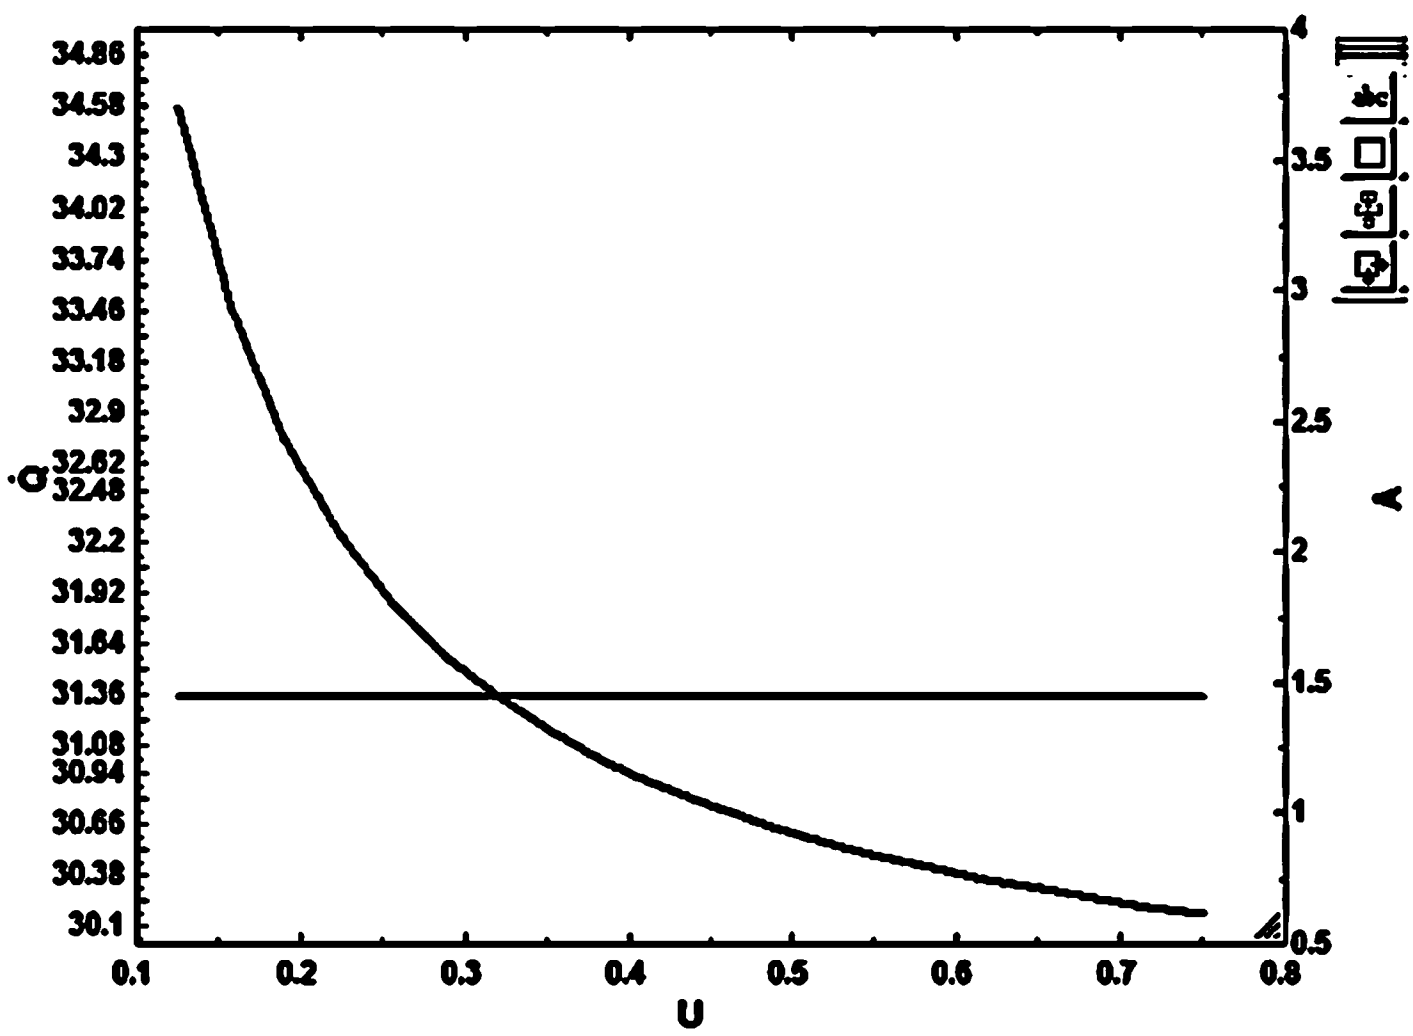
Then from click on 'Solve table' of 'Calculate' menu.

The Solution will appear as shown below

Step 6 of 7

The following results are displayed:

1..20	U	Q̇	A
Run 1	0.75	31.35	0.6163
Run 2	0.7171	31.35	0.6446
Run 3	0.6842	31.35	0.6755
Run 4	0.6513	31.35	0.7097
Run 5	0.6184	31.35	0.7474
Run 6	0.5855	31.35	0.7894
Run 7	0.5526	31.35	0.8364
Run 8	0.5197	31.35	0.8893
Run 9	0.4868	31.35	0.9494
Run 10	0.4539	31.35	1.018
Run 11	0.4211	31.35	1.098
Run 12	0.3882	31.35	1.191
Run 13	0.3553	31.35	1.301
Run 14	0.3224	31.35	1.434
Run 15	0.2895	31.35	1.597
Run 16	0.2566	31.35	1.801
Run 17	0.2237	31.35	2.066
Run 18	0.1908	31.35	2.423
Run 19	0.1579	31.35	2.927
Run 20	0.125	31.35	3.698



Step 7 of 7

Select the plot on menu bar, and then click x-y plot .Dialog box will be appeared.

Select X-axis as $T_{hot,in}$ and Y-axis as $\dot{Q}, A$ .Press OK

The Graph will be plotted as shown below.

By plotting the graph of heat transfer, surface area as function of overall heat transfer coefficient:

This graph represents that by increasing overall heat transfer coefficient; the heat transfer remains constant and surface decreases.

Question: 22.099P

Oil is being cooled from 180°F to 120°F in a 1-shell and 2-tube heat exchanger with an overall heat transfer coefficient of 40 Btu/h·ft2·°F. Water (*cpc* = 1.0 Btu/lbm·°F) enters at 80°F and exits at 100°F with a mass flow rate of 20,000 lbm/h, determine (*a*) the NTU value and (*b*) the surface area of the heat exchanger.

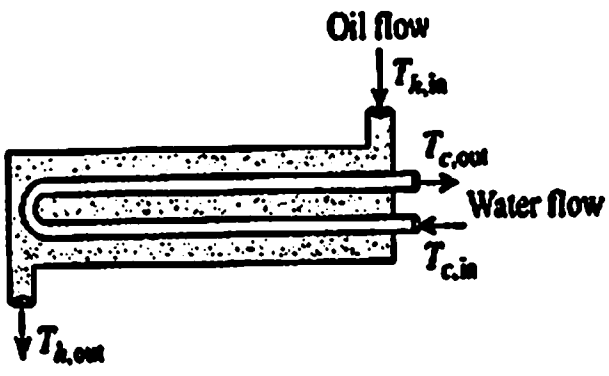


FIGURE P22–99E

Step 1 of 4

a)

NTU method:

Calculate the rate of heat transfer

$$\dot{Q} = \dot{m} c_p (T_{out} - T_{in})$$

Here,

Mass flow rate of Ethylene glycol is $\dot{m}$

Specific heat is c_p

Outlet temperature is T_{out}

Inlet temperature is T_{in}

Substitute 5.56 lbm/s for $\dot{m}$, 1 kJ/kg.K for c_p, 100°F for T_{out}, 80°F for T_{in}

$$\dot{Q} = 5.56(1)(100-80)$$

$$\dot{Q} = 111.2 \text{ Btu/s}$$

Step 2 of 4

Calculate the C_{min} for heat exchanger is

$$\dot{Q} = mc_p (T_o - T_{io})$$

$$111.2 = mc_p (180-120)$$

$$mc_p = 1.853 \text{ Btu/°F}$$

Here,

Oil inlet temperature is T_o

Oil exit temperature is T_{io}

Here,

$$C_{max} = mc_{pc}$$
$$= 5.56 \times 1$$
$$= 5.56 \text{ Btu/s·°F}$$
$$C_{min} = mc_p$$
$$= 1.853 \text{ Btu/°F}$$

Calculate the maximum rate of heat transfer is

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$

Substitute 1.853 Btu/°F for C_{min}, 180°F for T_o, 120°F for T_{io}

$$\dot{Q} = 1.852(180-80)$$

$$\dot{Q} = 185.2 \text{ Btu/s}$$

Step 3 of 4

Calculate the Effectiveness of the heat exchanger is

$$\varepsilon = \frac{Q}{Q_{max}}$$

Substitute 111.2 Btu/s for $\dot{Q}$, 185.2 Btu/s for $\dot{Q}_{max}$

$$\varepsilon = \frac{111.2}{185.2}$$
$$= 0.67$$

Calculate The NTU of this heat exchanger

$$NTU = -\ln(1-\varepsilon)$$

$$NTU = -\ln(1-0.67)$$

$$NTU = 1.11$$

Hence, number of tubes is $\boxed{1.11}$

Step 4 of 4

(b)

Calculate the surface area of this heat exchanger becomes

$$NTU = \frac{UA_s}{C_{min}}$$

$$A_s = \frac{NTU\, C_{min}}{U}$$

Here,

Overall heat transfer coefficient is U

Substitute 1.11 for NTU, 6670.8 Btu/hr.°F for C_{min} 40 Btu/h·ft^2·F for U

$$A_s = \frac{(1.11)(6670.8)}{40}$$
$$= 185.11 \text{ ft}^2$$

Hence, surface area is $\boxed{185 \text{ ft}^2}$

Question: 22.100P

Oil in an engine is being cooled by air in a cross-flow heat exchanger, where both fluids are unmixed. Oil (*cph* = 2047 J/kg·K) flowing with a flow rate of 0.026 kg/s enters the heat exchanger at 75°C, while air (*cpc* = 1007 J/kg·K) enters at 30°C with a flow rate of 0.21 kg/s. The overall heat transfer coefficient of the heat exchanger is 53 W/m2·K and the total surface area is 1 m2. Determine (*a*) the heat transfer effectiveness and (*b*) the outlet temperature of the oil.

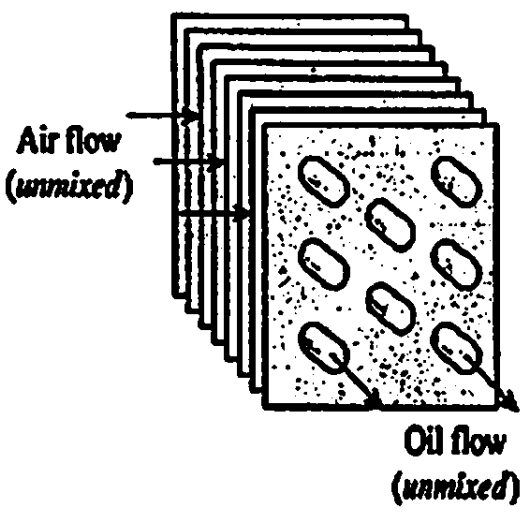

FIGURE P22–100

Step 1 of 5

Given

The specific heat of oil $c_{ph} = 2047\ \text{J/kg.°C}$

The specific heat of air $c_{pc} = 1007\ \text{J/kg.°C}$

Mass flow rate of oil is $\dot{m}_{oil} = 0.026\ \text{kg/s}$

Mass flow rate of air is $\dot{m}_{air} = 0.21\ \text{kg/s}$

Inlet temperature of oil $T_{h,in} = 75°\text{C}$

Inlet temperature of air $T_{c,in} = 30°\text{C}$

Overall heat transfer coefficient is $U = 53\ \text{W/m}^2\text{.K}$

Step 2 of 5

Heat capacity rate of the hot and cold fluids are

$$C_h = \dot{m} c_{ph}$$
$$= 0.026 \times 2047$$
$$C_h = 53.222\ \text{W/°C}$$

$$C_c = \dot{m}_c c_{pc}$$
$$= 0.21 \times 1007$$
$$C_c = 211.47\ \text{W/°C}$$

Step 3 of 5

Then

$$C_{min} = C_h = 53.22\ \text{W/°C}$$

And capacity ratio

$$c = \frac{C_{min}}{C_{max}}$$
$$= \frac{53.22}{211.47}$$
$$c = 0.25166$$

Step 4 of 5

(a) Heat transfer effectiveness

The maximum heat transfer rate becomes

$$\dot{Q}_{max} = C_{min}\left(T_{h,in} - T_{c,in}\right)$$

$$\dot{Q}_{max} = 53.22(75-30)$$

$$\dot{Q}_{max} = 2394.9\ \text{W}$$

NTU of the heat exchanger is

$$\text{NTU} = \frac{UA_s}{C_{min}}$$
$$= \frac{53 \times 1}{53.22\ \text{W/°C}}$$
$$\text{NTU} = 0.9958$$

Then the effectiveness of the heat exchanger for unmixed cross flow heat exchanger is

$$\varepsilon = 1 - \exp\left[-\frac{1}{c}\left(1 - \exp(-c\,\text{NTU})\right)\right]$$

$$\varepsilon = 1 - \exp\left[-\frac{1}{0.25166}\left(1 - \exp(-0.25166 \times 0.9958)\right)\right]$$

$$\boxed{\varepsilon = 0.585}$$

Step 5 of 5

(b)

Outlet temperature of the cold water determined to be

$$\dot{Q}_{max} = C_h\left(T_{h,in} - T_{h,out}\right)$$

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}_{max}}{C_h}$$

$$T_{h,out} = 75 - \frac{2394.9}{53.222}$$

$$\boxed{T_{h,out} = 30°\text{C}}$$

Question: 22.101P

A cross-flow heat exchanger with both fluids unmixed has an overall heat transfer coefficient of 200 W/m2·K, and a heat transfer surface area of 400 m2. The hot fluid has a heat capacity of 40,000 W/K, while the cold fluid has a heat capacity of 80,000 W/K. If the inlet temperatures of both hot and cold fluids are 80°C and 20°C, respectively, determine (*a*) the exit temperature of the hot fluid and (*b*) the rate of heat transfer in the heat exchanger.

Step 1 of 5

Given data:

The overall heat transfer coefficient $U = 200\ \text{W/m}^2\text{K}$

Heat capacity of hot and cold fluids is

$C_h = 40,000\ \text{W/K}$

$C_c = 80,000\ \text{W/K}$

Inlet temperatures of hot and cold fluids are

$T_{h,in} = 80°\text{C}$

$T_{c,in} = 20°\text{C}$

The heat transfer surface area $A_s = 400\ \text{m}^2$

Step 2 of 5

The smaller of two heat capacities is

$C_{min} = C_h = 40,000\ \text{W/K}$

The maximum rate of heat transfer rate in a cross flow exchanger is

$$\dot{Q}_{max} = C_{min}\left(T_{h,in} - T_{c,in}\right)$$

$$\dot{Q}_{max} = 40000(80-20)$$

$$= 2400000\ \text{W}$$

$$\dot{Q}_{max} = 2400\ \text{kW}$$

Step 3 of 5

The NTU of heat exchanger is expressed as

$$\text{NTU} = \frac{UA_s}{C_{min}}$$

$$= \frac{(200)400}{40000}$$

$$\text{NTU} = 2$$

Also

$$c = \frac{C_{min}}{C_{max}}$$

$$= \frac{40000}{80000}$$

$$c = 0.5$$

From table Effectiveness for heat exchangers, the value of effectiveness is determined as

At $\text{NTU} = 2$ and $c = 0.5$

The heat exchanger effectiveness is

$\varepsilon = 0.74$

Step 4 of 5

(a) The exit temperature of hot fluid

$$\dot{Q}_h = \varepsilon\dot{Q}_{max} = C_h\left(T_{h,in} - T_{h,out}\right)$$

$$0.74\times2400\times10^3 = 80000\left(80 - T_{h,out}\right)$$

$$\boxed{T_{h,out} = 57.8°\text{C}}$$

Therefore the exit temperature of the hot fluid, $T_{h,out} = 57.8°\text{C}$

Step 5 of 5

(b)The actual heat transfer rate of the heat exchanger is

$$\dot{Q} = \varepsilon\dot{Q}_{max}$$

$$\dot{Q} = (0.74)(2400)$$

$$\boxed{\dot{Q} = 1776\ \text{kW}}$$

Therefore, the actual heat transfer rate of heat exchanger, $\dot{Q} = 1776\ \text{kW}$

Question: 22.102P

A single-pass cross-flow heat exchanger uses hot air (mixed) to heat water (unmixed), flowing with a mass flow rate of 3 kg/s, from 30°C to 80°C. The hot air enters and exits the heat exchanger at 220°C and 100°C, respectively. If the overall heat transfer coefficient is 200 W/m2·K, determine the required surface area.

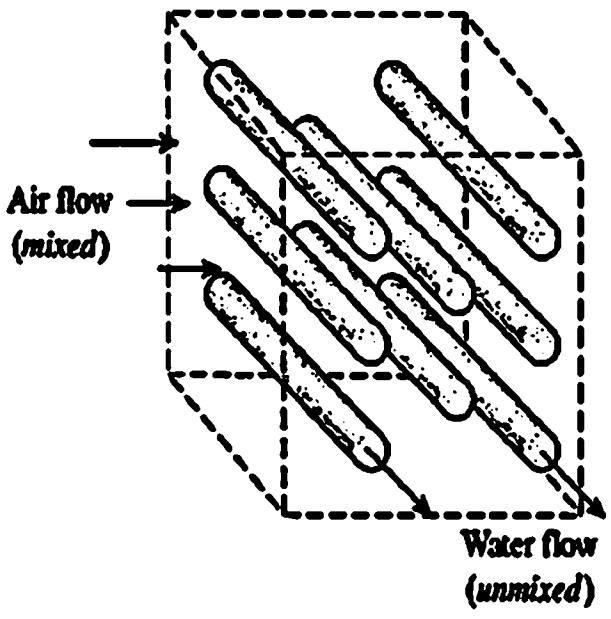

FIGURE P22–102

Step 1 of 4

Given data:

Mass flow rate of water $\dot{m}_{water} = 3\ \text{kg/s}$

Inlet and outlet temperature of water

$T_{c,in} = 30°\text{C}$

$T_{c,out} = 80°\text{C}$

Inlet and outlet temperature of hot air

$T_{h,in} = 220°\text{C}$

$T_{h,out} = 100°\text{C}$

Overall heat transfer coefficient $U = 200\ \text{W/m}^2\cdot\text{K}$

Step 2 of 4

Temperature difference between two fluids at two ends of the heat exchanger is

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= 220 - 80$$
$$= 140°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= 100 - 30$$
$$= 70°\text{C}$$

Therefore the LMTD is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)}$$
$$= \frac{140 - 70}{\ln[140/70]}$$
$$\Delta T_{lm} = 101°\text{C}$$

The specific heat of water is $c_{pc} = 4.18\ \text{kJ/kg.K}$

Heat transfer rate determined to be

$$\dot{Q} = \left[\dot{m}_c c_{pc}(T_{out} - T_{in})\right]_{water}$$
$$= 3(4.18)(80 - 30)$$
$$= 627\ \text{kW}$$

Step 3 of 4

The correction factor can be obtained as

$$P = \frac{t_2 - t_1}{T_1 - t_1}$$
$$= \frac{T_{h,out} - T_{h,in}}{T_{c,in} - T_{h,in}}$$
$$= \frac{100 - 220}{30 - 220}$$
$$P = 0.63$$
$$R = \frac{T_1 - T_2}{t_2 - t_1}$$
$$= \frac{T_{c,in} - T_{c,out}}{T_{h,out} - T_{h,in}}$$
$$= \frac{30 - 80}{100 - 220}$$
$$R = 0.416$$

At $P = 0.63$ and $R = 0.416$ from correction factor F charts for single pass cross flow with one fluid mixed and other unmixed the correction factor is

$F = 0.9$

Step 4 of 4

Heat transfer surface area is

$$\dot{Q} = UA_s F \Delta T_{lm}$$
$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$
$$A_s = \frac{627 \times 10^3\ \text{W}}{(200\ \text{W/m}^2\cdot°\text{C}) \times 0.9 \times (101°\text{C})}$$

$$\boxed{A_s = 34.48\ \text{m}^2}$$

Therefore, the surface area, $A_s = 34.48\ \text{m}^2$

Question:

The mass flow rate, specific heat, and inlet temperature of the tube-side stream in a double-pipe, parallel-flow heat exchanger are 3200 kg/h, 2.0 kJ/kg·K, and 120°C, respectively. The mass flow rate, specific heat, and inlet temperature of the other stream are 2000 kg/h, 4.2 kJ/kg·K, and 20°C, respectively. The heat transfer area and overall heat transfer coefficient are 0.50 m2 and 2.0 kW/m2·K, respectively. Find the outlet temperatures of both streams in steady operation using (*a*) the LMTD method and (*b*) the effectiveness-NTU method.

Step 1 of 9

(a)

Using LMTD method:

The rate of heat transfer of hot fluid can be calculated as:

$$\dot{Q} = \dot{m}_h c_{ph} (T_{h1} - T_{h2})$$

Here,

Mass flow rate of tube side stream, $\dot{m}_h$

Specific heat tube side stream, c_{ph}

Inlet temperature of tube side (hot) stream, T_{h1}

Hot fluid exit temperature, T_{h2}

Substitute 3200 kg/h for $\dot{m}_h$, 2.0 kJ/kg·K for c_{ph}, 120°C for T_{h1}, in the above equation

$$\dot{Q} = \dot{m}_h c_{ph} (T_{h1} - T_{h2})$$

$$= \frac{3200}{3600} \times 2.0 \times (120 - T_{h2})$$

$$= 1.77 \times (120 - T_{h2}) \quad \text{..... (1)}$$

The rate of heat transfer of cold fluid is

$$\dot{Q} = \dot{m}_c c_{pc} (T_{c2} - T_{c1})$$

Here,

Mass flow rate of second stream, $\dot{m}_c$

Specific heat of second stream, c_{pc}

Inlet temperature of second stream, T_{c_1}

Cold fluid exit temperature, T_{c2}

Substitute 2000 kg/h for $\dot{m}_c$, 4.2 kJ/kg.K for c_{pc}, 20°C for T_{c_1} in the above equation

$$\dot{Q} = \dot{m}_c c_{pc} (T_{c2} - T_{c1})$$

$$= \frac{2000}{3600} \times 4.2 \times (T_{c2} - 20)$$

$$= 2.333 (T_{c2} - 20) \quad \text{..... (2)}$$

Step 2 of 9

Log mean temperature difference is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)} \quad \text{..... (3)}$$

Where temperature differences at the inlet and exit of the heat exchanger is

$$\Delta T_1 = T_{h1} - T_{c1}$$

Substitute the values of 120°C for T_{h1}, 20°C for T_{c1} in the above equation

$$\Delta T_1 = T_{h1} - T_{c1}$$

$$= 120 - 20$$

$$= 100°C$$

$$\Delta T_2 = T_{h2} - T_{c2}$$

Substitute the values of 120°C for T_{h1}, 20°C for T_{c_1} in the equation (3)

$$\Delta T_{lm} = \frac{100 - (T_{h2} - T_{c2})}{\ln\left(\frac{100}{(T_{h2} - T_{c2})}\right)}$$

Step 3 of 9

Heat transfer can also be determined by using the equation

$$\dot{Q} = UA \times \Delta T_{lm}$$

Here,

Heat transfer area, A

Overall heat transfer coefficient, U

Substitute $0.50\,m^2$ for A, $2.0\,kW/m^2 \cdot K$ for U, ΔT_{lm} values in the above equation

$$\dot{Q} = UA \times \Delta T_{lm}$$

$$= 2.0 \times 0.5 \times \left(\frac{100 - (T_{h2} - T_{c2})}{\ln\left(\frac{100}{(T_{h2} - T_{c2})}\right)} \right)$$

$$= \left(\frac{100 - (T_{h2} - T_{c2})}{\ln\left(\frac{100}{(T_{h2} - T_{c2})}\right)} \right) \quad \text{..... (4)}$$

Step 4 of 9

Solving the equations (1), (2) and (4) by using equation solver

$$\dot{Q} = 63.88\,kW$$

$$T_{h2} = 84.19°C$$

$$T_{c2} = 47.17°C$$

Therefore, the exit temperature of hot fluid T_{h2} is $\boxed{84.19°C}$

Exit temperature of cold fluid T_{c2} is $\boxed{47.17°C}$

Step 5 of 9

(b)

Using effectiveness-NTU method:

The heat capacity of hot fluid is

$$C_h = \dot{m}_h c_{ph}$$

Substitute 3200 kg/h for $\dot{m}_h$, 2.0 kJ/kg·K for c_{ph}, in the above equation.

$$C_h = \dot{m}_h c_{ph}$$

The heat capacity of hot fluid is

$$C_h = \dot{m}_h c_{ph}$$

Substitute 3200 kg/h for $\dot{m}_h$, 2.0 kJ/kg·K for c_{ph}, in the above equation.

$$\begin{aligned} C_h &= \dot{m}_h c_{ph} \\ &= \frac{3200}{3600} \times 2.0 \\ &= 1.77 \text{ kW/K} \end{aligned}$$

The heat capacity of cold fluid is

$$C_c = \dot{m}_c c_{pc}$$

Substitute 2000 kg/h for $\dot{m}_c$, 4.2 kJ/kg.K for c_{pc}, in the above equation

$$\begin{aligned} C_c &= \dot{m}_c c_{pc} \\ &= \frac{2000}{3600} \times 4.2 \\ &= 2.333 \text{ kW/K} \end{aligned}$$

Step 6 of 9

From the above heat capacity ratios the minimum heat capacity rate is

$$C_{min} = C_h = 1.77 \text{ kW/K}$$

Heat capacity ratios

$$\begin{aligned} c &= \frac{C_{min}}{C_{max}} \\ &= \frac{1.77}{2.333} \\ &= 0.758 \end{aligned}$$

Step 7 of 9

Number of transfer units, NTU of this heat exchanger is

$$\text{NTU} = \frac{UA}{C_{min}}$$

Substitute 0.50 m^2 for A, $2.0 \text{ kW/m}^2 \cdot \text{K}$ for U, 1.77 kW/K for C_{min} values in the above equation

$$\begin{aligned} \text{NTU} &= \frac{UA}{C_{min}} \\ &= \frac{2 \times 0.5}{1.77} \\ &= 0.564 \end{aligned}$$

Effectiveness of the parallel flow heat exchanger is

$$\varepsilon = \frac{1 - \exp\left(-\text{NTU}(1+c)\right)}{1+c}$$

Substitute 0.564 for NTU, 0.758 for c in the above equation

$$\begin{aligned} \varepsilon &= \frac{1 - \exp\left(-\text{NTU}(1+c)\right)}{1+c} \\ &= \frac{1 - \exp\left(-0.564 \times (1+0.758)\right)}{1+0.758} \\ &= 0.3577 \end{aligned}$$

Step 8 of 9

Maximum heat transfer rate is

Substitute the values of 120°C for T_{h1}, 20°C for T_{c1} in the above equation

$$\begin{aligned} \dot{Q}_{max} &= C_{min}(T_{h1} - T_{c1}) \\ &= 1.77(120 - 20) \\ &= 177 \text{ kW} \end{aligned}$$

The effectiveness of the heat exchanger is

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$

$$\begin{aligned} \dot{Q} &= \varepsilon \dot{Q}_{max} \\ &= 0.3577 \times 177 \\ &= 63.312 \text{ kW} \end{aligned}$$

Step 9 of 9

The rate of heat transfer of hot fluid can be calculated as:

$$\dot{Q} = \dot{m}_h c_{ph}(T_{h1} - T_{h2})$$

Substitute the values of 3200 kg/h for $\dot{m}_h$, 2.0 kJ/kg·K for c_{ph}, 120°C for T_{h1}, 20°C for T_{c1}, in the equation

$$\begin{aligned} \dot{Q} &= \dot{m}_h c_{ph}(T_{h1} - T_{h2}) \\ 63.312 &= \frac{3200}{3600} \times 2.0 \times (120 - T_{h2}) \\ T_{h2} &= 84.387°\text{C} \end{aligned}$$

Therefore, exit temperature of the hot fluid T_{h2} is $\boxed{84.387°\text{C}}$

The rate of heat transfer of cold fluid is

$$\dot{Q} = \dot{m}_c c_{pc}(T_{c2} - T_{c1})$$

Substitute 2000 kg/h for $\dot{m}_c$, 4.2 kJ/kg.K for c_{pc}, 20°C for T_{c_1} in the above equation

$$\begin{aligned} \dot{Q} &= \dot{m}_c c_{pc}(T_{c2} - T_{c1}) \\ 63.312 &= \frac{2000}{3600} \times 4.2 \times (T_{c2} - 20) \\ T_{c2} &= 47.13°\text{C} \end{aligned}$$

Therefore, exit temperature of the cold fluid T_{c2} is $\boxed{47.13°\text{C}}$

Question: 22.104P

A shell-and-tube heat exchanger with 1-shell pass and 14-tube passes is used to heat water in the tubes with geothermal steam condensing at 120°C (hfg = 2203 kJ/kg) on the shell side. The tubes are thin-walled and have a diameter of 2.4 cm and length of 3.2 m per pass. Water (cp = 4180 J/kg·K) enters the tubes at 18°C at a rate of 6.2 kg/s. If the temperature difference between the two fluids at the exit is 46°C, determine (*a*) the rate of heat transfer, (*b*) the rate of condensation of steam, and (*c*) the overall heat transfer coefficient.

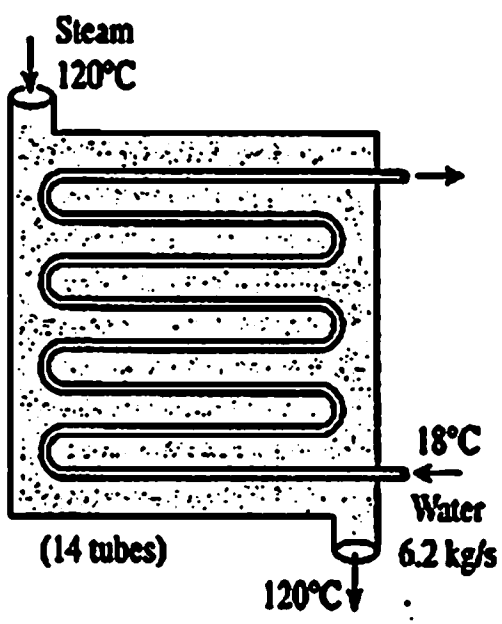

FIGURE P22–104

Step 1 of 5

Given data:

The specific heat of water is $c_p = 4180\ \text{J/kg}\cdot^\circ\text{C}$

Temperature of steam $T_{h,i} = T_{h,e} = 120^\circ\text{C}$

Inlet temperature of water $T_{c,i} = 18^\circ\text{C}$

The temperature difference between the two fluids at the exit is $T_{h,e} - T_{c,e} = 46^\circ\text{C}$

The heat of vaporization of steam is $h_{fg} = 2203\ \text{kJ/kg}$

Mass flow rate of water $\dot{m}_{water} = 6.2\ \text{kg/s}$

The diameter and length of the tube $D = 2.4\ \text{cm}, L = 3.2\ \text{m}$

Step 2 of 5

a) Heat transfer rate is calculated as follows

The outlet temperature of the water is

$T_{h,e} - T_{c,e} = 46^\circ\text{C}$

$T_{c,e} = T_{h,e} - 46^\circ\text{C}$

$T_{c,out} = 120 - 46$

$T_{c,out} = 74^\circ\text{C}$

Then the rate of heat transfer becomes

$\dot{Q} = [\dot{m}C_p(T_{out} - T_{in})]_{water}$

$\dot{Q} = (6.2\ \text{kg/s})(4.18\ \text{kJ/kg.°C})(74^\circ\text{C} - 18^\circ\text{C})$

$\boxed{\dot{Q} = 1451.296\ \text{kW}}$

Therefore, the heat transfer $\dot{Q} = 1451.296\ \text{kW}$

Step 3 of 5

b) The rate of condensation steam is

$\dot{Q} = (\dot{m}h_{fg})$

$1415.296 = \dot{m}(2203)$

$\boxed{\dot{m} = 0.658\ \text{kg/s}}$

Therefore, the rate of mass $\dot{m} = 0.658\ \text{kg/s}$

Step 4 of 5

b) The heat transfer surface area is

$A_i = n\pi D_i L$

$= 14\pi(0.024\ \text{m})(3.2\ \text{m})$

$A_i = 3.3778\ \text{m}^2$

For this counter flow heat exchanger LMTD can be calculated as

$\Delta T_1 = T_{h,i} - T_{c,e}$

$= 120^\circ\text{C} - 74^\circ\text{C}$

$\Delta T_1 = 46^\circ\text{C}$

$\Delta T_2 = T_{h,out} - T_{c,in}$

$= 120^\circ\text{C} - 18^\circ\text{C}$

$\Delta T_2 = 102^\circ\text{C}$

Then LMTD of this heat exchanger is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)}$$

$$= \frac{46 - 102}{\ln(46/102)}$$

$\Delta T_{lm} = 70.32^\circ\text{C}$

Step 5 of 5

We know the correction factor in case of condenser is $F = 1$

Therefore the Overall heat transfer coefficient of the heat exchanger is determined to be

$\dot{Q} = U_i A_i F \Delta T_{lm}$

$$U_i = \frac{\dot{Q}}{A_i F \Delta T_{lm}}$$

$$U_i = \frac{1451.296 \times 10^3\ \text{W}}{3.3778\ \text{m}^2 \times 1 \times 70.32^\circ\text{C}}$$

$\boxed{U_i = 6110.028\ \text{W/m}^2\cdot^\circ\text{C}}$

Therefore the Overall heat transfer coefficient, $U_i = 6110.028\ \text{W/m}^2\cdot^\circ\text{C}$

Question: 22.105P

Geothermal water (*cp* = 4250 J/kg·K) at 75°C is to be used to heat fresh water (*cp* = 4180 J/kg·K) at 17°C at a rate of 1.2 kg/s in a double-pipe counter-flow heat exchanger. The heat transfer surface area is 25 m2, the overall heat transfer coefficient is 480 W/m2·K, and the mass flow rate of geothermal water is larger than that of fresh water. If the effectiveness of the heat exchanger is desired to be 0.823, determine the mass flow rate of geothermal water and the outlet temperatures of both fluids.

Step 1 of 10

Given data:

Specific heat of geothermal water, $c_{ph} = 4250\ \text{J/kg°C}$

Specific heat of freshwater, $c_{pc} = 4180\ \text{J/kg°C}$

Mass flow rate of fresh water is $\dot{m}_c = 1.2\ \text{kg/s}$

Overall heat transfer coefficient $U = 480\ \text{W/m}^2\text{°C}$

Effectiveness of the heat exchanger is $\varepsilon = 0.823$

Heat transfer surface area is $A_s = 25\ \text{m}^2$

Step 2 of 10

Outlet temperatures of the geothermal water and fresh water are determined as

$$\dot{Q} = C_h\left(T_{h,in} - T_{h,out}\right)$$

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h}$$

$$\dot{Q} = C_c\left(T_{c,out} - T_{c,in}\right)$$

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c}$$

Step 3 of 10

The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph}$$
$$= \dot{m}_h\,(4250\ \text{J/kg}\cdot\text{°C})$$
$$C_c = \dot{m}_c C_{pc}$$
$$= (1.2\ \text{kg/s})(4180\ \text{J/kg}\cdot\text{°C})$$
$$= 5016\ \text{W/°C}$$

Step 4 of 10

Therefore $C_{min} = C_c = 5016\ \text{W/°C}$

$$C = \frac{C_{min}}{C_{max}}$$
$$= \frac{5016}{\dot{m}_h\,(4250\ \text{J/kg}\cdot\text{°C})}$$

NTU of this heat exchanger is

$$NTU = \frac{UA_s}{C_{min}}$$
$$= \frac{(0.480\ \text{kW/m}^2\cdot\text{°C})(25\ \text{m}^2)}{5.016\ \text{kW/°C}}$$
$$= 2.392$$

Step 5 of 10

Heat capacity ratio can be calculated as

$$\varepsilon = \frac{1-\exp\left[-\text{NTU}(1-C)\right]}{1-C\exp\left[-\text{NTU}(1-C)\right]}$$

$$0.823 = \frac{1-\exp\left[-2.392(1-C)\right]}{1-C\exp\left[-2.392(1-C)\right]}$$

$$0.823\left[1-C\exp\left(-2.392\left(1-C\right)\right)\right] = 1-\exp\left[-2.392(1-C)\right]$$

By trail and error method

Substituting different values of the C which will satisfy the equation

If $C = 0.2$

$$0.823\left[1-0.2\exp\left(-2.392\left(1-0.2\right)\right)\right] = 1-\exp\left[-2.392(1-0.2)\right]$$

$$0.798 \neq 0.852$$

It is not satisfying the equation so go for next trail

If $C = 0.3$

$$0.823\left[1-0.3\exp\left(-2.392\left(1-0.3\right)\right)\right] = 1-\exp\left[-2.392(1-0.3)\right]$$

$$0.7767 \neq 0.8125$$

It is not satisfying the equation so go for next trail

If $C = 0.4$

$$0.823\left[1-0.4\exp\left(-2.392\left(1-0.4\right)\right)\right] = 1-\exp\left[-2.392(1-0.4)\right]$$

$$0.7018 = 0.7019$$

If $C = 0.494$

$$0.823\left[1-0.494\exp\left(-2.392\left(1-0.494\right)\right)\right] = 1-\exp\left[-2.392(1-0.494)\right]$$

$$0.7018 = 0.7019$$

It is satisfying the equation

$\therefore C = 0.494$

Step 6 of 10

Mass flow rate of the geothermal water is calculated as

$$C = \frac{1.1802}{\dot{m}_h}$$

$$0.494 = \frac{1.1802}{\dot{m}_h}$$

$$\dot{m}_h = \frac{1.1802}{0.494}$$

$$\dot{m}_h = 2.389\ \text{kg/s}$$

$\therefore$ The mass flow rate of geothermal water, $\boxed{\dot{m}_h = 2.389\ \text{kg/s}}$

Step 7 of 10

The maximum heat transfer rate is

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$
$$= (5016\ \text{W/°C})(75\text{°C} - 17\text{°C})$$
$$= 290.928\ \text{kW}$$

The actual heat transfer rate is

$$\dot{Q} = \varepsilon\dot{Q}_{max}$$
$$= (0.823)(290.928\ \text{kW})$$
$$= 239.433\ \text{kW}$$

Step 8 of 10

Heat capacity of the hot fluid is

$$C_h = \dot{m}_h C_{ph}$$
$$= (2.389\ \text{kg/s})(4250\ \text{J/kg}\cdot\text{°C})$$
$$= 10.15325\ \text{kW/°C}$$

Step 9 of 10

By substituting the heat transfer rate outlet temperatures of the geothermal water and fresh water are

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h}$$
$$= 75\text{°C} - \frac{239.433\ \text{kW}}{10.15325\ \text{kW/°C}}$$
$$= 51.4\text{°C}$$

$\therefore$ The outlet temperature of the hot fluid, $\boxed{T_{h,out} = 51.4\text{°C}}$

Step 10 of 10

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c}$$
$$= 17\text{°C} + \frac{239433\ \text{W}}{5016\ \text{W/°C}}$$
$$= 64.7\text{°C}$$

$\therefore$ The outlet temperature of the cold fluid, $\boxed{T_{c,out} = 64.7\text{°C}}$

Question: 22.106P

Hot water at 60°C is cooled to 36°C through the tube side of a 1-shell pass and 2-tube passes heat exchanger. The coolant is also a water stream, for which the inlet and outlet temperatures are 7°C and 31°C, respectively. The overall heat transfer coefficient and the heat transfer area are 950 W/m2·K and 15 m2, respectively. Calculate the mass flow rates of hot and cold water streams in steady operation.

Step 1 of 5

Calculation of mass flow rates of hot and cold water streams:

In order to calculate the mass flow rate of hot and cold water streams, let us calculate the rate of heat exchange

Temperature difference between two fluids at two ends of the heat exchanger is,

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

Here $T_{h,in}$ is the Inlet temperature of hot water, $T_{h,out}$ is the outlet temperature of hot water $T_{c,in}$ is the Inlet temperature of cold water and $T_{c,out}$ is the outlet temperature of cold water

Substitute 60 °C for $T_{h,in}$, 36 °C for $T_{h,out}$, 7 °C for $T_{c,in}$, 31°C for $T_{c,out}$

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= 60 - 31$$
$$\Delta T_1 = 29°C$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= 36 - 7$$
$$\Delta T_2 = 29°C$$

Step 2 of 5

Since $\Delta T_2 = \Delta T_1$, the LMTD is $\Delta T_{lm} = 29$ °C

The correction factor for 1- shell pass and 2- tube passes heat exchanger can be calculated as follows,

We have

Heat transfer area, $A = 15$ m^2

$$P = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$$
$$P = \frac{31 - 7}{60 - 7}$$
$$P = 0.45$$
$$R = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$$
$$R = \frac{60 - 36}{31 - 7}$$
$$R = 1$$

From Correction factor charts for common shell and tube and cross flow heat exchangers at above P and R values, the correction factor

$F = 0.88$

Step 3 of 5

Overall heat transfer coefficient, $U = 950$ W/m^2·K

Now, the rate of heat exchange is expressed as,

$$\dot{Q} = UA_s F(\Delta T_{lm})$$
$$= (950)(15)(0.88)(29)$$
$$= 363660 \text{ W}$$
$$\dot{Q} = 363.66 \text{ kW}$$

Step 4 of 5

Therefore, the mass flow rates of cold stream is,

$$\dot{Q} = \dot{m}_c C_{pc}(T_{c,out} - T_{c,in})$$
$$\dot{m}_c = \frac{363.66}{4.18(31 - 7)}$$
$$\boxed{\dot{m}_c = 3.625 \text{ kg/s}}$$

Step 5 of 5

Similarly the mass flow rate of hot stream is,

$$\dot{Q} = \dot{m}_h C_{pc}(T_{h,in} - T_{h,out})$$
$$\dot{m}_h = \frac{363.66}{4.18(60 - 36)}$$
$$\boxed{\dot{m}_h = 3.625 \text{ kg/s}}$$

Therefore, the mass flow rates of hot and cold water streams, $\boxed{\dot{m}_h = 3.625 \text{ kg/s}}$

And $\boxed{\dot{m}_c = 3.625 \text{ kg/s}}$

Question: 22.107P

Cold water (*cp* = 4180 J/kg·K) enters the tubes of a heat exchanger with 2-shell passes and 20-tube passes at 15°Cat a rate of 4 kg/s, while hot oil (*cp* = 2200 J/kg-K) enters the shell at 130°C at the same mass flow rate and leaves at 60°C. If the overall heat transfer coefficient based on the outer surface of the tube is 220 W/m2-K, determine (*a*) the rate of heat transfer and (*b*) the heat transfer surface area on the outer side of the tube.

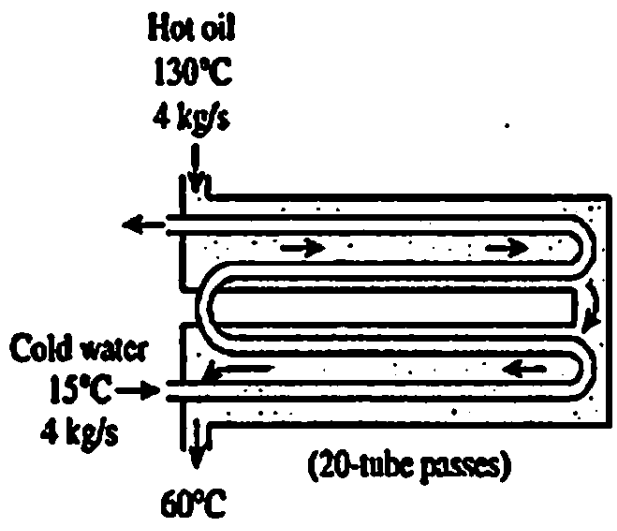

FIGURE P22–107

Step 1 of 6

Given data:

Specific heat of hot oil $c_{ph} = 2200\ \text{J/kg}\cdot\text{K}$

Specific heat of cold water $c_{pc} = 4180\ \text{J/kg}\cdot\text{K}$

Mass flow rate of cold water is $\dot{m}_c = 4\ \text{kg/s}$

Inlet temperature of cold water $T_{c,in} = 15°\text{C}$

Inlet temperature of hot oil $T_{h,in} = 130°\text{C}$

Exit temperature of hot oil $T_{h,out} = 60°\text{C}$

Mass flow rate of hot oil is $\dot{m}_h = 4\ \text{kg/s}$

Overall heat transfer coefficient $U = 220\ \text{W/m}^2\cdot\text{K}$

Step 2 of 6

(a) The rate of heat transfer is

$$\dot{Q} = [\dot{m}_h c_{ph}(T_{h,out} - T_{h,in})]_{heat}$$

$$\dot{Q} = 4\left((2.2\ \text{kJ/kg.°C}) \times (130°\text{C} - 60°\text{C})\right)$$

$$\boxed{\dot{Q} = 616\ \text{kW}}$$

Therefore, the rate of heat transfer is $\dot{Q} = 616\ \text{kW}$

Step 3 of 6

(b) The surface area of the tube can be calculated as follows

Heat transfer surface area on the tube side is determined to be

$$\dot{Q} = UA_s\Delta T_{lm}$$

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

The outlet temperature of the cold water can be calculated as

$$\dot{Q} = \dot{m}_h c_{pc}\left(T_{c,out} - T_{c,in}\right)$$

$$616 = 4 \times 4.18\left(T_{c,out} - 15\right)$$

$$T_{c,out} = 51.84°\text{C}$$

Step 4 of 6

For this counter flow heat exchanger LMTD can be determined as

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$= 130°\text{C} - 51.84°\text{C}$$

$$\Delta T_1 = 78.16°\text{C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= 60°\text{C} - 15°\text{C}$$

$$\Delta T_2 = 45°\text{C}$$

Then LMTD is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)}$$

$$= \frac{78.16 - 45}{\ln\left(\frac{78.16}{45}\right)}$$

$$\Delta T_{lm} = 60.062$$

Step 5 of 6

And correction factor for 2 shell pass and two tube pass heat exchanger can be calculated as follows

$$P = \frac{T_{c,out} - T_{c,in}}{T_{h,in} - T_{c,in}}$$

$$= \frac{51.84 - 15}{130 - 15}$$

$$P = 0.32$$

$$R = \frac{T_{h,in} - T_{h,out}}{T_{c,out} - T_{c,in}}$$

$$= \frac{130 - 60}{51.84 - 15}$$

$$R = 1.90$$

From Correction factor *F* charts for common shell and tube and cross flow heat exchangers at *P* and *R* values

$$F = 0.92$$

Step 6 of 6

By substituting all values in heat transfer surface area

$$A_s = \frac{\dot{Q}}{UF\Delta T_{lm}}$$

$$A_s = \frac{616\ \text{kW}}{(0.22\ \text{kW/m}^2\cdot°\text{C})(0.92)(60.062°\text{C})}$$

$$\boxed{A_s = 50.672\ \text{m}^2}$$

Therefore, the surface area, $A_s = 50.672\ \text{m}^2$

Question: 22.108P

Water (*cp* = 1.0 Btu/lbm-°F) is to be heated by solar- heated hot air (*cp* = 0.24 Btu/lbm-°F) in a double-pipe counter- flow heat exchanger. Air enters the heat exchanger at 190°F at a rate of 0.7 lbm/s and leaves at 135°F. Water enters at 70°F at a rate of 0.35 lbm/s. The overall heat transfer coefficient based on the inner side of the tube is given to be 20 Btu/h-ft2-°F. Determine the length of the tube required for a tube internal diameter of 0.5 in.

Step 1 of 7

Given data:

Specific heat of water $c_{ph} = 1\ \text{Btu/lbm} \cdot {}^\circ\text{F}$

Specific heat of hot air $c_{pc} = 0.24\ \text{Btu/lbm} \cdot {}^\circ\text{F}$

Mass flow rate of hot air $\dot{m}_h = 0.7\ \text{lbm/s}$

Mass flow rate of water $\dot{m}_c = 0.35\ \text{lbm/s}$

Overall heat transfer coefficient $U = 20\ \text{Btu/h} \cdot \text{ft}^2 \cdot {}^\circ\text{F}$

Internal diameter of the tube, $D_i = 0.5\text{in}$

Step 2 of 7

Heat transfer surface area on the tube side is determined to be

$$\dot{Q} = UA_s\Delta T_{lm}$$

$$A_s = \frac{\dot{Q}}{U\Delta T_{lm}}$$

$\dot{Q}$, F & ΔT_{lm} are calculated by the following relations

Heat transfer rate is

$$\dot{Q} = [\dot{m}_c c_{pc}(T_{out} - T_{in})]_{water}$$

$$= (0.7\ \text{lbm/s})(0.24\ \text{Btu/lbm.°F})(190°\text{F} - 135°\text{F})$$

$$= 9.24\ \text{Btu/s}$$

Step 3 of 7

Then the outlet temperature of the oil is

$$\dot{Q} = \left[\dot{m}_h c_{ph}(T_{out} - T_{in})\right]_{oil}$$

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{\dot{m}_c c_{pc}}$$

$$= 70°\text{F} + \frac{9.24\ \text{Btu/s}}{(0.35\ \text{lbm/s})(1.0\ \text{Btu/lbm.°F})}$$

$$= 96.4°\text{F}$$

Step 4 of 7

For this counter flow heat exchanger LMTD determined to be

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$= 190°\text{F} - 96.4°\text{F}$$

$$= 93.6°\text{F}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= 135°\text{F} - 70°\text{F}$$

$$= 65°\text{F}$$

Step 5 of 7

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined from

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$

$$= \frac{93.6 - 65}{\ln(93.6/65)}$$

$$= 78.43°\text{F}$$

Step 6 of 7

By substituting all values heat transfer surface area becomes

$$A_s = \frac{\dot{Q}}{U\Delta T_{lm}}$$

$$A_s = \frac{9.24\ \text{Btu/s}}{(20/3600\ \text{Btu/s} \cdot \text{ft}^2 \cdot °\text{F})(78.43°\text{F})}$$

$$A_s = 21.2\ \text{ft}^2$$

Step 7 of 7

Therefore the length of the tube required becomes

$$A_s = \pi DL$$

$$L = \frac{A_s}{\pi D}$$

$$= \frac{21.2\ \text{ft}^2}{\pi(0.5/12\ \text{ft})}$$

$$= 162.0\text{ft}$$

∴ **The length of the tube required,** $\boxed{L = 162.0\text{ft}}$

Question: 22.109P

By taking the limit as $\Delta T2 \rightarrow \Delta T1$ show that when $\Delta T1 = \Delta T2$ for a heat exchanger, the Tlm relation reduces to $\Delta Tlm = \Delta T1 = \Delta T2$.

Step 1 of 1

In counter flow heat exchanger the temperature difference between the hot and the cold fluids remains constant along the heat exchanger when the heat capacity rates of the two fluids are equal (that is, $\Delta T = \text{constant}$ when $C_h = C_c$).

If $\Delta T_1 = \Delta T_2$ then the log mean temperature difference relation

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)}$$

$$= \frac{0}{0}$$

By applying L'Hospital's rule (taking derivatives of nominator and denominator separately with respect to ΔT_1 or ΔT_2) LMTD becomes

$$\Delta T_{lm} = \frac{d(\Delta T_1 - \Delta T_2)/d\Delta T_1}{d[\ln(\Delta T_1 / \Delta T_2)]/d\Delta T_1}$$

$$= \frac{1}{1/\Delta T_1}$$

$$= \Delta T_1$$

$$= \Delta T_2$$

Question: 22.110P

The condenser of a room air conditioner is designed to reject heat at a rate of 22,500 kJ/h from refrigerant-134a as the refrigerant is condensed at a temperature of 40°C. Air (*cp* = 1005 J/kg·K) flows across the finned condenser coils, entering at 25°C and leaving at 32°C. If the overall heat transfer coefficient based on the refrigerant side is 150 W/m2·K, determine the heat transfer area on the refrigerant side.

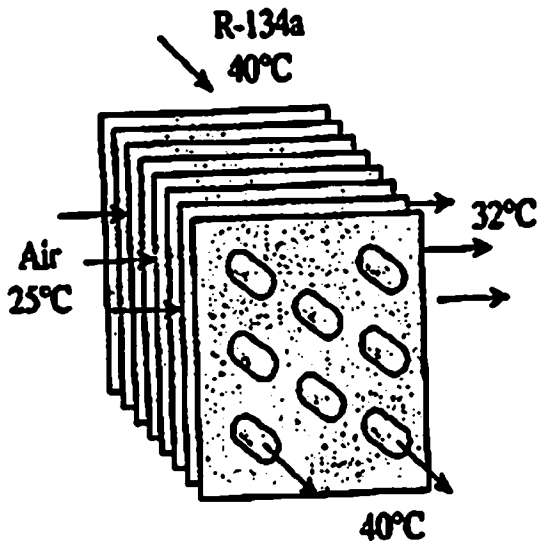

FIGURE P22–110

Step 1 of 4

Given data:

Heat transfer rate is, $\dot{Q} = 22500\,\text{kJ/h}$

$= 6.25\,\text{kW}$

The specific heat of air is $c_p = 1005\,\text{J/kg°}\cdot\text{K}$

Inlet temperature of the R-134a, $T_{in,\text{R-134a}} = 40°\text{C}$

Inlet temperature of the air, $T_{in,air} = 25°\text{C}$

Outlet temperature of the air, $T_{out,air} = 32°\text{C}$

Overall heat transfer coefficient $U = 150\ \text{W/m}^2\cdot\text{K}$

Step 2 of 4

Temperature difference between two fluids at two ends of the heat exchanger is

$$\Delta T_1 = T_{h,in} - T_{c,out}$$
$$= 40°\text{C} - 32°\text{C}$$
$$= 8°\text{C}$$
$$\Delta T_2 = T_{h,out} - T_{c,in}$$
$$= 40°\text{C} - 25°\text{C}$$
$$= 15°\text{C}$$

Step 3 of 4

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined from

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)}$$
$$= \frac{8-15}{\ln(8/15)}$$
$$= 11.136°\text{C}$$

Step 4 of 4

Heat transfer surface area is

$$\dot{Q} = UA_s\Delta T_{lm}$$
$$A_s = \frac{\dot{Q}}{U\Delta T_{lm}}$$
$$= \frac{6250\ \text{W}}{(150\ \text{W/m}^2.°\text{C})(11.136°\text{C})}$$
$$= 3.74172\,\text{m}^2$$

∴ The heat transfer area is $\boxed{A_s = 3.74\ \text{m}^2}$

Question: 22.111P

Air (*cp* = 1005 J/kg·K) is to be preheated by hot exhaust gases in a cross-flow heat exchanger before it enters the furnace. Air enters the heat exchanger at 95 kPa and 20°C at a rate of 0.4 m3/s. The combustion gases (*cp* = 1100 J/kg·K) enter at 180°C at a rate of 0.65 kg/s and leave at 95°C. The product of the overall heat transfer coefficient and the heat transfer surface area is *UAS* = 1620 W/K. Assuming both fluids to be unmixed, determine the rate of heat transfer.

Step 1 of 2

Given data:

The specific heat of combustion gasses is $c_p = 1100\ \text{J/kg} \cdot ^\circ\text{C}$

Mass flow rate of combustion gasses $\dot{m}_{gas} = 0.65\ \text{kg/s}$

Inlet temperature of the gases $T_{in,gas} = 180^\circ\text{C}$

Outlet temperature of the gases $T_{out,gas} = 95^\circ\text{C}$

Step 2 of 2

Heat transfer rate is determined as

$$\dot{Q} = \left[\dot{m}c_p\left(T_{in} - T_{out}\right)\right]_{gas}$$

$$= (0.65\ \text{kg/s})(1.1\ \text{kJ/kg} \cdot ^\circ\text{C})(180^\circ\text{C} - 95^\circ\text{C})$$

$$= 60.775\ \text{kW}$$

∴ The rate of heat transfer, $\boxed{\dot{Q} = 60.775\ \text{kW}}$

Question: 22.112P

In a chemical plant, a certain chemical is heated by hot water supplied by a natural gas furnace. The hot water (cp= 4180 J/kg·K) is then discharged at 60°C at a rate of 8 kg/min. The plant operates 8 h a day, 5 days a week, 52 weeks a year. The furnace has an efficiency of 78 percent, and the cost of the natural gas is $1.00 per therm (1 therm = 105,500 kJ). The average temperature of the cold water entering the furnace throughout the year is 14°C. In order to save energy, it is proposed to install a water-to-water heat exchanger to preheat the incoming cold water by the drained hot water. Assuming that the heat exchanger will recover 72 percent of the available heat in the hot water, determine the heat transfer rating of the heat exchanger that needs to be purchased and suggest a suitable type. Also, determine the amount of money this heat exchanger will save the company per year from natural gas savings.

Step 1 of 6

Given data:

Specific heat of the hot water is $c_{ph} = 4180\ \text{J/kg°C}$

Effectiveness of the heat exchanger is $\varepsilon = 0.72$

Inlet temperature of the hot water, $T_{in,hotwater} = 60°\text{C}$

Inlet temperature of the cold water, $T_{in,coldwater} = 14°\text{C}$

Mass of hot water discharging, $\dot{m}_h = 8\ \text{kg/min}$

Step 2 of 6

The maximum heat transfer rate is determined by

$$\dot{Q}_{max} = \dot{m}_h c_{ph}\left(T_{h,in} - T_{c,in}\right)$$
$$= (8/60\ \text{kg/s})(4.18\ \text{kJ/kg}\cdot°\text{C})(60°\text{C} - 14°\text{C})$$
$$= 25.63\ \text{kW}$$

Step 3 of 6

Actual heat transfer rate becomes

$$\dot{Q} = \varepsilon \dot{Q}_{max}$$
$$= (0.72)(25.63\ \text{kJ/s})$$
$$= 18.45\ \text{kW (or)}$$
$$= 18.45\ \text{kJ/s}$$

Step 4 of 6

Then calculating the annual operating hours

$$\text{hours} = (8\ \text{h/day})(5\ \text{days/week})(52\ \text{week/year})$$
$$= 2080\ \text{h/year}$$

The energy saved during the entire year will be

$$\text{Energy saved} = (\text{heat transfer rate})(\text{operating time})$$
$$= (18.45\ \text{kJ/s})(2080\ \text{h/year})(3600\ \text{s/h})$$
$$= 1.38\times10^{8}\ \text{kJ/year}$$

Step 5 of 6

Then amount of fuel and money saved will be

$$\text{Fuel saved} = \frac{\text{Energy saved}}{\text{Furnace efficiency}}$$
$$= \frac{1.38\times10^{8}\ \text{kJ/year}}{0.78}\left(\frac{1\ \text{therm}}{105,500\ \text{kJ}}\right)$$
$$= 1677\ \text{therms/year}$$

Step 6 of 6

Therefore the amount of money this heat exchanger will save the company per year from natural gas savings

$$\text{Money saved} = (\text{fuel saved})(\text{the price of fuel})$$
$$= (1677\ \text{therms/year})(\$\ 1.0/\text{therm})$$
$$= (1677\ \text{therms/year})(\$\ 1.0/\text{therm})$$

∴ The amount of money saved, $\boxed{\text{Money saved} = \$1677/\text{year}}$

Question:

A shell-and-tube heat exchanger is used for cooling 47 kg/s of a process stream flowing through the tubes from 160°C to 100°C. This heat exchanger has a total of 100 identical tubes, each with an inside diameter of 2.5 cm and negligible wall thickness. The average properties of the process stream are: p = 950 kg/m3, k = 0.50 W/mK, cp = 3.5 kJ/kg·K and μ = 2.0 mPa·s. The coolant stream is water (cp = 4.18 kJ/kg·K) at a flow rate of 66 kg/s and an inlet temperature of 10°c, which yields an average shell-side heat transfer coefficient of 4.0 kW/m2·K. Calculate the tube length if the heat exchanger has (a) a 1-shell pass and a 1-tube pass and (b) a 1-shell pass and 4-tube passes.

Step 1 of 12

Heat transfer rate of the hot fluid is

$$\dot{Q}=\dot{m}_h c_p\left(T_{h,in}-T_{h,out}\right)$$

Here, $\dot{m}_h$ is the flow rate of hot fluid stream, is the specific heat hot water, $T_{h,in}$ is the inlet temperature of the hot fluid, and $T_{h,out}$ is the exit temperature of the hot fluid.

Substitute 47 kg/s for $\dot{m}_h$, 3.5 kj/kg.K for c_{ph}, 160° C for $T_{h,in}$, 100° C for $T_{h,out}$

$$Q=47\times3.5\times(160-100)$$
$$=9870\text{ kW}$$

The exit temperature of the cooling water is

$$\dot{Q}=\dot{m}_c c_{pc}\left(T_{c,out}-T_{c,in}\right)$$

Here $\dot{m}_c$ is the Mass flow rate of cold water, c_{pc} is the specific heat cool water, and $T_{c,in}$ the inlet of temperature of cold water.

Substitute 66 kg/s for $\dot{m}_c$, 4.18 kJ/kgK for c_{ph}, 10°C for $T_{c,in}$

$$\dot{Q}=\dot{m}_c c_{pc}\left(T_{c,out}-T_{c,in}\right)$$
$$9870=66\times4.18\times\left(T_{c,out}-10\right)$$
$$T_{c,out}=45.776\text{ °C}$$

Step 2 of 12

Assume the arrangement is counter flow heat exchanger then temperature difference at The inlet and exit of the heat exchanger is

$$\Delta T_1=T_{h,in}-T_{c,out}$$
$$=160-45.776$$
$$=114.224°C$$
$$\Delta T_2=T_{h,out}-T_{c,in}$$
$$=100-10$$
$$=90°C$$

Step 3 of 12

Then logarithmic temperature difference of the counter flow heat exchanger is

$$\Delta T_{lm}=\frac{\Delta T_1-\Delta T_2}{In\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$
$$=\frac{114.224-90}{In\left(\frac{114.224}{90}\right)}$$
$$=101.63\text{ °C}$$

Step 4 of 12

Velocity of the fluid flowing in the tube is

$$V=\frac{\dot{m}_h}{\rho A}$$

Here $\dot{m}_h$ is the flow rate of hot fluid stream, ρ is the density, D is the inside diameter of the tube, and μ is the Dynamic viscosity, and n is total number of identical tubes

Substitute 47 kg/s for $\dot{m}_h$, 950 kg/m^3 for ρ, 2.5cm for D, 2.0mPa .s for μ.

$$V=\frac{\dot{m}_h}{\rho\times\left(n\times\frac{\pi}{4}D^2\right)}$$
$$=\frac{47}{950\times\left(100\times\frac{\pi}{4}\times0.025^2\right)}$$
$$=1.0078\text{ m/s}$$

Reynolds number of the flow is

$$\text{Re}=\frac{\rho VD}{\mu}$$
$$=\frac{950\times1.0078\times0.025}{2.0\times10^{-3}}$$
$$=11967.62$$

Step 5 of 12

Prandtl number can be calculated by using the formula
Thermal conductivity $k=0.50$ W/m.K

$$\text{Pr}=\frac{\mu c_{pc}}{k}$$
$$=\frac{2.0\times10^{-3}\times3.5\times10^3}{0.5}$$
$$=14$$

Since Reynolds number is greater than 10000,
Assume flow is fully is turbulent flow and
Nusselt number in this case is

$$Nu=0.023\,\text{Re}^{0.8}\,\text{Pr}^{0.3}$$
$$=0.023\times11967.62^{0.8}\times14^{0.3}$$
$$=92.89$$

Step 6 of 12

Tube side heat transfer coefficient can be calculate by using Nusselt number

$$Nu=\frac{h_i D}{}$$

Step 6 of 12

Tube side heat transfer coefficient can be calculate by using Nusselt number

$$Nu = \frac{h_i D}{k}$$

$$92.89 = \frac{h_i \times 0.025}{0.5}$$

$$h_i = 1857.8 \text{ W/m}^2 \cdot \text{K}$$

Conduction resistance is negligible, since negligible wall thickness. Then the overall heat Transfer coefficient can be calculated as

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_0}}$$

$$= \frac{1}{\frac{1}{1857.8} + \frac{1}{4000}}$$

$$= 1268.59 \text{ W/m}^2 \cdot \text{K}$$

Step 7 of 12

For one shell and a one tube pass, the correction factor is 1

$F = 1$

The rate of heat transfer for this arrangement is

$$Q = F \times U \times A \times \Delta T_{lm}$$

$$= F \times U \times (n \times DL) \times \Delta T_{lm}$$

$$9870 \times 10^3 = 1 \times 1286.59 \times (100 \times \pi \times 0.025 \times L) \times 101.63$$

$$L = 9.747 \text{ m}$$

Therefore, the length, L of the tube for one shell pass and a one tube pass is $\boxed{9.747\text{m}}$

Step 8 of 12

(b)

The tube length for 1 shell pass and 4tube passes:

Since total number of tubes is 100, number of tubes per pass is

$$\frac{100}{4} = 25$$

Number of tubes $n = 100$

Therefore, 25 tubes per pass in this heat exchanger and it increases the velocity in 4 tube pass is 4 times the velocity of one tube pass

Then

$$V_4 = 4 \times V$$

$$= 4 \times 1.0078$$

$$= 4.0312 m/s$$

Reynolds number in 4 tube pass is

$$R_e = 4 \times R_e$$

$$= 4 \times 11967.62$$

$$= 47870.48$$

Step 9 of 12

Nusselt number in case of fully turbulent flow is

$$Nu = 0.023 R_e^{0.8} \text{Pr}^{0.3}$$

$$= 0.023 \times 47870.48^{0.8} \times 14^{0.3}$$

$$= 281.59$$

Then tube side heat transfer coefficient can be calculated by using Nusselt number

$$Nu = \frac{h_2 D}{k}$$

$$281.59 = \frac{h_2 \times 0.025}{0.5}$$

$$h_2 = 5631.8 \text{ W/m}^2\text{-K}$$

Step 10 of 12

Conduction resistance is negligible, since negligible wall thickness, and then the overall heat transfer coefficient can be calculated as

Average shell side heat transfer coefficient $h_o = 4.0 W/m^2.K$

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_0}}$$

$$= \frac{1}{\frac{1}{5631.8} + \frac{1}{4000}}$$

$$= 2338.83 \text{ W/m}^2\text{-K}$$

Step 11 of 12

Correction factory for 1 shell and 4 tube passes can be determined as follows

$$R = \frac{T_1 - T_2}{t_2 - t_1}$$

$$= \frac{T_{c,in} - T_{c,out}}{T_{h,out} - T_{h,in}}$$

$$= \frac{10 - 45.779}{100 - 160}$$

$$= 0.596$$

Step 12 of 12

$$p = \frac{t_2 - t_1}{T_1 - t_1}$$

$$= \frac{T_{h,out} - T_{h,in}}{T_{c,in} - T_{h,in}}$$

$$= \frac{100 - 160}{10 - 160}$$

$$= 0.4$$

From correction factor char for 1 shell and 4 tube passes at $P = 0.4 \text{ and } R = 0.596$, the

$$= \frac{T_{c,in} - T_{h,in}}{t_{h,in} - t_{c,in}}$$

$$= \frac{100-160}{10-160}$$

$$= 0.4$$

From correction factor char for 1 shell and 4 tube passes at $P = 0.4$ *and* $R = 0.596$, the correction factor is F = 0.96

Then rate of heat transfer for one shell and 4 tube passes is

$$Q = F \times U \times A \times \Delta T_{lm}$$

$$= F \times U \times (n \times \pi DL) \times \Delta T_{lm}$$

$$9870 \times 10^3 = 0.96 \times 2338.83 \times (100 \times \pi \times 0.025 \times L) \times 101.63$$

$$L = 5.507m$$

Therefore, the length, L of the tube for one shell and a four tube pass is **5.507 m**

Question: 22.114P pg 1

A 2-shell passes and 4-tube passes heat exchanger is used for heating a hydrocarbon stream *(cp* = 2.0 kJ/kg·K) steadily from 20°C to 50°C. A water stream enters the shell- side at 80°C and leaves at 40°C. There are 160 thin- walled tubes, each with a diameter of 2.0 cm and length of 1.5m. The tube-side and shell-side heat transfer coefficients are 1.6 and 2.5 kW/m2·K, respectively, (a) Calculate the rate of heat transfer and the mass rates of water and hydrocarbon streams. *(b)* With usage, the outlet hydrocarbon-stream temperature was found to decrease by 5°C due to the deposition of solids on the tube surface. Estimate the magnitude of fouling factor.

Step 1 of 12

Assume the arrangement is counter flow heat exchanger then temperature difference at The inlet and exit of the heat exchanger are

$$\Delta T_1 = T_{h,in} - T_{c,out}.$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

Here, $T_{h,in}$ is the inlet temperature of the water on the shell side and $T_{h,out}$ is the exit temperature of the water on the shell side, $T_{c,in}$ the inlet of temperature of hydrocarbon stream, $T_{c,out}$ is exit temperature of the hydrocarbon stream

Substitute 20°C for $T_{c,in}$, 50°C for $T_{c,out}$, 80°C for $T_{h,in}$, 40°C for $T_{h,out}$ in the below equation

$$\begin{aligned}\Delta T_1 &= T_{h,in} - T_{c,out}\\ &= 80 - 50\\ &= 30°C\end{aligned}$$

$$\begin{aligned}\Delta T_2 &= T_{h,out} - T_{c,in}\\ &= 40 - 20\\ &= 20°C\end{aligned}$$

Step 2 of 12

Then logarithmic temperature difference of the counter flow heat exchanger is

$$\begin{aligned}\Delta T_{lm} &= \frac{\Delta T_1 - \Delta T_2}{In\left(\frac{\Delta T_1}{\Delta T_2}\right)}\\ &= \frac{30-20}{In\left(\frac{30}{20}\right)}\\ &= 24.66\ °C\end{aligned}$$

Step 3 of 12

Conduction resistance is negligible, since negligible wall thickness.
Then the calculate overall heat Transfer coefficient as below

$$U = \frac{1}{\frac{1}{h_i} + \frac{1}{h_o}}$$

Here, h_i, h_o is the tube and shell side heat transfer co efficient respectively

Substitute 1.6 kW/m^2 for h_i, 2.5 kW/m^2 for h_o

$$\begin{aligned}U &= \frac{1}{\frac{1}{h_i} + \frac{1}{h_o}}\\ &= \frac{1}{\frac{1}{1.6} + \frac{1}{2.5}}\\ &= 0.975\ \text{kW/m}^2\text{·K}\end{aligned}$$

Step 4 of 12

Determine, correction factor for 2 shell and 4 tube passes as follows

$$\begin{aligned}R &= \frac{T_1 - T_2}{t_2 - t_1}\\ &= \frac{T_{c,in} - T_{c,out}}{T_{h,out} - T_{h,in}}\\ &= \frac{20-50}{40-80}\\ &= 0.75\end{aligned}$$

$$\begin{aligned}P &= \frac{t_2 - t_1}{T_1 - t_1}\\ &= \frac{T_{h,out} - T_{h,in}}{T_{c,in} - T_{h,in}}\\ &= \frac{40-80}{20-80}\\ &= 0.666\end{aligned}$$

From above the correction factor is for 2 shells and 4 tubes passes at $P = 0.666, R = 0.75$, is $F = 0.91$.
Number of tubes n is160

Step 5 of 12

The rate of heat transfer for this arrangement is

$$\begin{aligned}Q &= F \times U \times A \times \Delta T_{lm}\\ &= F \times U \times (n \times DL) \times \Delta T_{lm}\end{aligned}$$

Here, L is the length of a tube; D is the diameter of the thin tube

Substitute 1.5 m for L, 2 cm for D, 0.91 for F, 0.975 kW/m^2·K for U, 24.66 for ΔT_{lm} in the above equation

$$\begin{aligned}Q &= F \times U \times (n \times DL) \times \Delta T_{lm}\\ &= 0.91 \times 0.975 \times 10^3 (160 \times \pi \times 0.02 \times 1.5) \times 24.66\\ &= 329.936\ \text{kW}\end{aligned}$$

Therefore, the rate of heat transfer **329.936 kW**

Step 6 of 12

The specific heat of hydrocarbon stream and water are

$$c_{pc} = 2.0\ \text{kJ/kg·K}$$

From the table of properties of water, the specific heat of water is

$$c_{ph} = 4.18\ \text{kJ/kg·K}$$

$c_{pc} = 2.0\ \text{kJ/kg·K}$ 22.114P pg 2

From the table of properties of water, the specific heat of water is

$c_{ph} = 4.18\ \text{kJ/kg·K}$

Step 7 of 12

Calculate mass flow rate of the water stream

$$\dot{Q} = \dot{m}_h c_{p,h}\left(T_{h,i} - T_{h,o}\right)$$

Substitute $329.936\ \text{kW}$ for $\dot{Q}$, $4.18\ \text{kJ/kg·K}$ for c_{ph}, $80°\text{C}$ for $T_{h,in}$, $40°\text{C}$ for $T_{h,out}$ in the above equation

$$329.936\ \text{kW} = \dot{m}_h \times 4.18 \times (80-40)$$

$$\dot{m}_h = 1.97\ \text{kg/s}$$

Therefore, the mass flow rate water $\boxed{1.97\ \text{kg/s}}$

Step 8 of 12

Calculate mass flow rate of the hydro carbon stream

$$\dot{Q} = \dot{m}_c c_{p,c}\left(T_{c,i} - T_{c,o}\right)$$

Substitute $329.936\ \text{kW}$ for $\dot{Q}$, $2\ \text{kJ/kg·K}$ for $c_{p,c}$, $20°\text{C}$ for $T_{c,in}$, $50°\text{C}$ for $T_{c,out}$ in the above equation

$$329.936\ \text{kW} = \dot{m}_h \times 2 \times (50-20)$$

$$\dot{m}_c = 5.49\ \text{kg/s}$$

Therefore, the mass flow rate water $\boxed{5.49\ \text{kg/s}}$

Step 9 of 12

(b)

Outlet temperature of hydrocarbon stream is decreased by $T_{c,out,old} = 45°\text{C}$

Calculate the rate of heat transfer

$$\dot{Q}_{old} = \dot{m}_c c_{p,c}\left(T_{c,out,old} - T_{c,in}\right)$$
$$= 5.498 \times 2.0 \times (45-20)$$
$$= 274.9\ \text{kW}$$

Calculate the exit temperature of hot fluid

$$\dot{Q}_{old} = \dot{m}_h c_{p,h}\left(T_{h,in} - T_{h,out,old}\right)$$
$$274.9 = 1.973 \times 4.18 \times \left(80 - T_{h,out,old}\right)$$
$$T_{h,out,old} = 46.66°\text{C}$$

Calculate the temperature difference at the inlet and exit of the heat exchanger are

Substitute $20°\text{C}$ for $T_{c,in}$, $45°\text{C}$ for $T_{c,out,old}$, $80°\text{C}$ for $T_{h,in}$, $46.66°\text{C}$ for $T_{h,out,old}$ in the below equation

$$\Delta T_1 = T_{h,in} - T_{c,out,old}$$
$$= 80 - 45$$
$$= 35°\text{C}$$
$$\Delta T_2 = T_{h,out,old} - T_{c,in}$$
$$= 46.66 - 20$$
$$= 26.66\ °\text{C}$$

Step 10 of 12

Then logarithmic temperature difference of the counter flow heat exchanger is

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{In\left(\frac{\Delta T_1}{\Delta T_2}\right)}$$
$$= \frac{35 - 26.66}{In\left(\frac{35}{26.66}\right)}$$
$$= 30.641\ °\text{C}$$

Determine, correction factor for 2 shell and 4 tube passes as follows

$$R = \frac{T_1 - T_2}{t_2 - t_1}$$
$$= \frac{T_{c,in} - T_{c,out,old}}{T_{h,out,old} - T_{h,in}}$$
$$= \frac{20-45}{46.66-80}$$
$$= 0.75$$

$$P = \frac{t_2 - t_1}{T_1 - t_1}$$
$$= \frac{T_{h,out,old} - T_{h,in}}{T_{c,in} - T_{h,in}}$$
$$= \frac{46.66-80}{20-80}$$
$$= 0.555$$

From above the correction factor is for 2 shells and 4 tubes passes at $P = 0.666, R = 0.75$, is $F = 0.97$.

Step 11 of 12

Find the overall heat transfer rate

$$\dot{Q}_{old} = F \times U_{old} \times A \times \Delta T_{lm}$$
$$= F \times U_{old} \times (n \times DL) \times \Delta T_{lm}$$

Here, L is the length of a tube; D is the diameter of the thin tube

Substitute $1.5\ \text{m}$ for L, $2\ \text{cm}$ for D, 0.91 for F, $0.975\ \text{kW/m}^2\text{·K}$ for U, 24.66 for ΔT_{lm} in the above equation

$$274.9 = F \times U_{old} \times (n \times DL) \times \Delta T_{lm}$$
$$= 0.97 \times U_{old} \times (160 \times \pi \times 0.02 \times 1.5) \times 30.16$$
$$U_{old} = 0.6133\ \text{kW/m}^2$$

Step 12 of 12

Calculate magnitude of the fouling factor

$$R_f = \frac{1}{U_{old}} - \frac{1}{U}$$

Step 12 of 12

Calculate magnitude of the fouling factor

$$R_f = \frac{1}{U_{old}} - \frac{1}{U}$$

Substitute $0.6133\,\text{kW/m}^2$ for U_{old}, $0.975\,\text{kW/m}^2$ for U in the above equation

$$\begin{aligned} R_f &= \frac{1}{U_{old}} - \frac{1}{U} \\ &= \frac{1}{0.6133} - \frac{1}{0.975} \\ &= 0.0006048\,\text{K}\cdot\text{m}^2/\text{W} \end{aligned}$$

Therefore, the magnitude of the fouling factor is $\boxed{0.0006048\,\text{K}\cdot\text{m}^2/\text{W}}$

Question: 22.115P

Air at 18°C (*cp* = 1006 J/kg·K) is to be heated to 58°C by hot oil at 80°C (*cp* = 2150 J/kg·K) in a cross-flow heat exchanger with air mixed and oil unmixed. The product of heat transfer surface area and the overall heat transfer coefficient is 750 W/K and the mass flow rate of air is twice that of oil. Determine (*a*) the effectiveness of the heat exchanger, (*b*) the mass flow rate of air, and (*c*) the rate of heat transfer.

Step 1 of 5

Specific heats of hot oil and air are $c_{ph} = 2150\ \text{J/kg}\cdot{}^\circ\text{C}$ and $c_{pc} = 1006\ \text{J/kg}\cdot{}^\circ\text{C}$

Product of heat transfer surface area and overall heat transfer coefficient is

$UA = 750\ \text{W/K}$

Temperature of cold air at inlet $T_{c,in} = 18^\circ\text{C}$

Temperature of air at exit $T_{c,out} = 58^\circ\text{C}$

Hot oil inlet temperature $T_{h,in} = 80^\circ\text{C}$

Mass flow rate of air is twice that of oil

$\dot{m}_c = 2\dot{m}_h$

$\dot{m}_h = 0.5\dot{m}_c$

Type of heat exchanger is cross flow heat exchanger with air mixed and oil unmixed

Step 2 of 5

The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h c_{ph}$$
$$= \dot{m}_h (2150\ \text{J/kg.°C})$$
$$= 0.5\dot{m}_c \times 2150$$
$$C_h = 1075\ \text{J/kg.°C}$$

$$C_c = \dot{m}_c c_{pc}$$
$$C_c = \dot{m}_c (1006\ \text{J/kg.°C})$$
$$C_c = 1006\dot{m}_c\ \text{J/kg.°C}$$

Therefore

$$C_{min} = C_c = 1.006\dot{m}_c$$
$$c = \frac{C_{min}}{C_{max}}$$
$$= \frac{1.006\dot{m}_c}{1.075\dot{m}_c}$$
$$c = 0.936$$

Step 3 of 5

a)

Effectiveness of the heat exchanger is

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$
$$= \frac{C_c(T_{c,out} - T_{c,in})}{C_c(T_{h,in} - T_{c,in})}$$
$$= \frac{58 - 18}{80 - 18}$$
$$= 0.645$$

Effectiveness of the heat exchanger is $\boxed{\varepsilon = 0.645}$

Step 4 of 5

b)

Mass flow rate of the air is calculated as follows

From NTU relations for heat exchanger for hot oil unmixed $(C_h = C_{max})$ and air mixed $(C_c = C_{min})$ the NTU expression is

$$NTU = -\frac{\ln[c\ln(1-\varepsilon)+1]}{c}$$
$$= -\frac{\ln[0.936\times\ln(1-0.645)+1]}{0.936}$$
$$NTU = 3.7236$$

NTU for this heat exchanger can also be calculated as

$$NTU = \frac{UA_s}{C_{min}}$$
$$3.7236 = \frac{750}{1006\dot{m}_c}$$
$$3.7236 = \frac{0.7455}{\dot{m}_c}$$
$$\dot{m}_c = 0.2002\ \text{kg/s}$$

Mass flow rate of the air is $\boxed{\dot{m}_c = 0.2002\ \text{kg/s}}$

Step 5 of 5

c)

Heat transfer rate is calculated as

$$\dot{Q} = \dot{m}_c c_p (T_{c,out} - T_{c,in})$$
$$= 0.2002\times 1006(58-18)$$
$$\dot{Q} = 8056.048\ \text{W}$$

Heat transfer rate is $\boxed{\dot{Q} = 8.056\ \text{kW}}$

Question: 22.116P pg 1

During an experiment, a plate heat exchanger that is used to transfer heat from a hot-water stream to a cold-water stream is tested, and the following measurements are taken:

	Hot Water Stream	Cold Water Stream
Inlet temperature, °C	38.9	14.3
Outlet temperature, °C	27.0	19.8
Volume flow rate,L/min	2.5	4.5

The heat transfer area is calculated to be 0.056 m2.

(*a*)Calculate the rate of heat transfer to the cold water.

(*b*)Calculate the overall heat transfer coefficient.

(*c*) Determine if the heat exchanger is truly adiabatic. If not, determine the fraction of heat loss and calculate the heat transfer efficiency.

(d) Determine the effectiveness and the NTU values of the heat exchanger.

Also, discuss if the measured values are reasonable.

Step 1 of 8

Measurements obtained from experiment are:

	Hot water stream	Cold water stream
Inlet temperature, °C(T_{in})	38.9	14.3
Outlet temperature, °C(T_{out})	27.0	19.8
Volume flow rate, L/min	2.5	4.5

Step 2 of 8

(a)

Determine the rate of heat transfer to the cold water

$$\dot{Q}=\dot{m}_c c_{pc}\left(T_{c,out}-T_{c,in}\right)$$

Here $\dot{m}_c$ is the Mass flow rate of cold water, c_{pc} is the specific heat cold water, and $T_{c,in}$ the inlet of temperature of cold water, $T_{c,out}$ is the exit temperature of the cold water.

Substitute 14.3 for $T_{c,in}$, 19.0 for $T_{c,out}$, 0.075 kg/s for $\dot{m}_c$, 4180 for c_{pc}, in the above equation

$$\begin{aligned}\dot{Q}_{cold}&=\dot{m}_c c_{pc}\left(T_{c,out}-T_{c,in}\right)\\&=0.075\times4180\times(19.8-14.3)\\&=1724.25\text{ J/s}\end{aligned}$$

Therefore, the rate of heat transferred to cold water is 1724.25 J/s

Step 3 of 8

Calculate LMTD of the parallel flow heat exchanger is

$$\begin{aligned}\Delta T_1&=T_{h,in}-T_{c,in}\\&=38.9-14.3\\&=24.6^\circ\text{C}\\\Delta T_2&=T_{h,out}-T_{c,out}\\&=27-19.8\\&=7.2\end{aligned}$$

Substitute above obtained values in the following relation

$$\Delta T_{lm}=\frac{\Delta T_1-\Delta T_2}{\ln\left(\Delta T_1/\Delta T_2\right)}$$

$$\Delta T_{lm}=\frac{24.6-7.2}{\ln\left(24.6/7.2\right)}$$

$$\Delta T_{lm}=14.16^\circ\text{C}$$

Step 4 of 8

(b)

The rate of heat transfer in the heat exchanger,

$$\dot{Q}_{cold}=UA_s\Delta T_{lm}$$

Here, the overall heat transfer coefficient of the given counter flow heat exchanger, U

Surface area of the heat exchanger, A_s

Substitute 0.056 m^2 for A_s, 14.16°C for ΔT_{lm}, 1724.25 J/s for $\dot{Q}$ in the above equation

$$\begin{aligned}U&=\frac{\dot{Q}_{cold}}{A_s\Delta T_{lm}}\\&=\frac{1724.25}{0.056\times14.16}\\&=2174.44\text{ W/m}^2\cdot\text{K}\end{aligned}$$

Therefore, the overall heat transfer coefficient is $\boxed{2174.44\text{ W/m}^2\cdot\text{K}}$

Step 5 of 8

(c)

Determine the rate of heat transfer from hot water.

$$\dot{Q}_{hot}=\dot{m}_h c_{p,h}\left(T_{h,in}-T_{h,out}\right)$$

Here $\dot{m}_c$ is the Mass flow rate of cold water, c_{pc} is the specific heat cold water, and $T_{c,in}$ the inlet of temperature of cold water, $T_{c,out}$ is the exit temperature of the cold water.

Substitute 38.9 for $T_{h,in}$, 27.0 for $T_{h,out}$, 0.041 kg/s for $\dot{m}_h$, 4180 for c_{ph}, in the above equation

$$\begin{aligned}\dot{Q}_{hot}&=\dot{m}_h c_{p,h}\left(T_{h,in}-T_{h,out}\right)\\&=\frac{2.5\times4180\times(38.9-27)}{60}\\&=2075.58\text{ J/kg}\end{aligned}$$

Therefore, the rate of heat transferred from hot water is 2075.58 J/kg

Since heat lost by hot fluid is not equal to the heat gained by the cold fluid

Therefore, the heat exchanger is $\boxed{\text{not truly adiabatic}}$

$= 2075.58 \text{ J/kg}$ 22.116P pg 2

Therefore, the rate of heat transferred from hot water is 2075.58 J/kg

Since heat lost by hot fluid is not equal to the heat gained by the cold fluid

Therefore, the heat exchanger is **not truly adiabatic**

Calculate the fraction of heat loss by the heat exchanger

$$Q_{loss} = \frac{\dot{Q}_{hot} - Q_{cold}}{\dot{Q}_{hot}}$$
$$= \frac{2075.58 - 1724.25}{2075.58}$$
$$= 0.169$$

Therefore, the fraction of heat loss is **0.169**

Step 6 of 8

Calculate the heat transfer efficiency

$$\eta_{heat\,transfer} = \frac{\text{heat transfered to the cold fluid}}{\text{heat produced}} \times 100\%$$
$$= \frac{\dot{Q}_{cold}}{\dot{Q}_{hot}} \times 100\%$$
$$= \frac{1724.25}{2075.58} \times 100\%$$
$$= 0.831 \times 100\%$$
$$= 83.1\ \%$$

Therefore, heat transfer efficiency is **83.1 %**

Step 7 of 8

(d)

The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h c_{ph}$$
$$= (0.041)(4180 \text{ J/kg.°C})$$
$$C_h = 171.38 \text{ W/°C}$$
$$C_c = \dot{m}_c C_{pc}$$
$$= (0.075 \text{ kg/s})(4180 \text{ J/kg.°C})$$
$$= 313.5 \text{ W/°C}$$

Therefore

$C_{min} = C_h = 171.38 \text{ W/°C}$

And find the capacity ratio

$$c = \frac{C_{min}}{C_{max}}$$
$$= \frac{171.38}{313.5}$$
$$= 0.54$$

Step 8 of 8

Find maximum heat transfer rate becomes

$$\dot{Q}_{max} = C_{min}\left(T_{h,in} - T_{c,in}\right)$$
$$= (171.38)(38.9 - 14.3)$$
$$= 4215.94 \text{ J/s}$$

Find NTU of the heat exchanger is

$$\text{NTU} = \frac{UA_s}{C_{min}}$$
$$= \frac{2174.44 \times 6.4}{171.38}$$
$$\text{NTU} = 7.105$$

Therefore, the NTU of heat exchanger is **7.105**

From table NTU relations for heat exchanger

Find effectiveness of parallel flow heat exchanger is

$$\varepsilon_p = \frac{1 - \exp\left[-\text{NTU}(1+c)\right]}{1+c}$$
$$= \frac{1 - \exp\left[-7.105(1+0.54)\right]}{1+0.54}$$
$$= 0.649$$

Therefore, the effectiveness of heat exchanger is **0.649**

Question: 22.117P

A shell-and-tube heat exchanger with 2-shell passes and 4-tube passes is used for cooling oil (cp = 2.0 kJ/kg·K) from 125°C to 55°C. The coolant is water, which enters the shell side at 25°C and leaves at 46°C. The overall heat transfer coefficient is 900 W/m2·K. For an oil flow rate of 10 kg/s, calculate the cooling water flow rate and the heat transfer area.

Step 1 of 5

Given data:

Specific heat of hot oil, $c_{ph} = 2000\ \text{J/kg°C}$

Specific heat of water, $c_{pc} = 4180\ \text{J/kg°C}$

Mass flow rates of oil is $\dot{m}_h = 10\ \text{kg/s}$

Overall heat transfer coefficient $U = 900\ \text{W/m}^2\text{°C}$

Step 2 of 5

Heat transfer rate is calculated by

$$\dot{Q} = \left[\dot{m}_h c_{ph}\left(T_{out} - T_{in}\right)\right]_{oil}$$

$$= (10\ \text{kg/s})(2000\ \text{J/kg}\cdot\text{°C})(125-55)\text{°C}$$

$$= 1400\ \text{kW}$$

The mass flow rate of water is determined to be

$$\dot{Q} = \left[\dot{m}c_{pc}\left(T_{out} - T_{in}\right)\right]_{water}$$

$$\dot{m}_{water} = \frac{\dot{Q}}{c_{pc}\left(T_{out} - T_{in}\right)}$$

$$= \frac{1400\ \text{kJ/s}}{(4.180\ \text{kJ/kg}\cdot\text{°C})(46-25)\text{°C}}$$

$$= 15.94\ \text{kg/s}$$

∴ The mass flow rate of the water, $\boxed{\dot{m}_{water} = 15.94\ \text{kg/s}}$

Step 3 of 5

Heat transfer surface area is determined to be

$$\dot{Q} = UA_s\Delta T_{lm}$$

$$A_s = \frac{\dot{Q}}{U\Delta T_{lm}}$$

Where the LMTD for this heat exchanger is determined by

$$\Delta T_1 = T_{h,in} - T_{c,out}$$

$$= (125-46)\text{°C}$$

$$= 79\text{°C}$$

$$\Delta T_2 = T_{h,out} - T_{c,in}$$

$$= (55-25)\text{°C}$$

$$= 30\text{°C}$$

Step 4 of 5

The proper average temperature difference between the two fluids is the logarithmic mean temperature difference which is determined from

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)}$$

$$= \frac{79-30}{\ln(79/30)}$$

$$= 50.61\text{°C}$$

Step 5 of 5

By substituting LMTD heat transfer area is

$$A_s = \frac{1400000\ \text{W}}{(900\ \text{W/m}^2\cdot\text{°C})(50.61\text{°C})}$$

$$A_s = 30.738\ \text{m}^2$$

∴ the heat transfer surface area is $\boxed{A_s = 30.738\ \text{m}^2}$

Question: 22.118P

Consider a water-to-water counter-flow heat exchanger with these specifications. Hot water enters at 90°C while cold water enters at 20°C. The exit temperature of hot water is 15°C greater than that of cold water, and the mass flow rate of hot water is 50 percent greater than that of cold water. The product of heat transfer surface area and the overall heat transfer coefficient is 2200 W/K. Taking the specific heat of both cold and hot water to be *cp* = 4180 J/kg·K, determine (*a*) the outlet temperature of the cold water, (*b*) the effectiveness of the heat exchanger, (*c*) the mass flow rate of the cold water, and (*d*) the heat transfer rate.

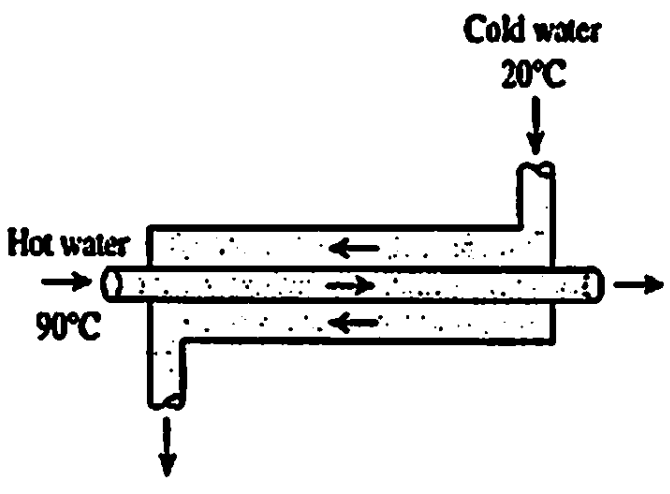

FIGURE P22–118

Step 1 of 8

Specific heat hot water, $c_{ph} = 4180$ J/kg°C

Specific heat cold water, $c_{pc} = 4180$ J/kg°C

Overall heat transfer coefficient $U = 2200$ W/K

And given condition for mass flow rats as $\dot{m}_h = 1.5\dot{m}_c$

Condition for exit temperatures of hot and cold fluids is $T_{h,out} = T_{c,out} + 15°C$

Step 2 of 8

The heat capacity rates of the hot and cold fluids are

$$C_h = \dot{m}_h C_{ph}$$
$$= \dot{m}_h (4180 \text{ J/kg} \cdot °C)$$
$$= 1.5\dot{m}_c (4180 \text{ J/kg} \cdot °C)$$
$$= \dot{m}_c (6270 \text{ J/kg} \cdot °C)$$
$$= 6.27\dot{m}_c \text{ kJ/s} \cdot °C$$
$$C_c = \dot{m}_c C_{pc}$$
$$= \dot{m}_c (4180 \text{ J/kg} \cdot °C)$$
$$= 4.18\dot{m}_c \text{ kJ/s} \cdot °C$$

Step 3 of 8

Therefore $C_{min} = C_c$
$$= 4.18\dot{m}_c$$

And $$C = \frac{C_{min}}{C_{max}}$$
$$= \frac{4.18\dot{m}_c}{6.27\dot{m}_c}$$
$$= 0.667$$

Step 4 of 8

a) Cold fluid outlet temperature is calculated by equating the heat transfer rates of hot and cold fluids as follows

Heat transfer rate of cold fluid is

$$\dot{Q} = C_c (T_{c,out} - T_{c,in})$$
$$= (4.18\dot{m}_c)(T_{c,out} - 20) \quad \ldots\ldots (1)$$

Heat transfer rate of hot fluid is

$$\dot{Q} = C_h (T_{h,in} - T_{h,out})$$
$$= (6.27\dot{m}_c)\left[90 - (T_{c,out} + 15)\right]$$
$$= (6.27\dot{m}_c)(75 - T_{c,out}) \quad \ldots\ldots (2)$$

Step 5 of 8

By equating equations (1) & (2) heat transfer rates of hot and cold fluids

$$4.18\dot{m}_c (T_{c,out} - 20) = 6.27\dot{m}_c (75 - T_{c,out})$$
$$4.18\dot{m}_c T_{c,out} - 83.6\dot{m}_c = 470.25\dot{m}_c - 6.27\dot{m}_c T_{c,out}$$
$$4.18\dot{m}_c T_{c,out} + 6.27\dot{m}_c T_{c,out} = 553.85\dot{m}_c$$
$$10.45\dot{m}_c T_{c,out} = 553.85\dot{m}_c$$
$$T_{c,out} = 53°C$$

∴ The outlet temperature of the cold fluid, $\boxed{T_{c,out} = 53°C}$

Step 6 of 8

b)

Effectiveness of the heat exchanger is determined as

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$
$$= \frac{C_c (T_{c,out} - T_{c,in})}{C_c (T_{h,in} - T_{c,in})}$$
$$= \frac{4.18\dot{m}_c (53 - 20)}{4.18\dot{m}_c (90 - 20)}$$
$$= 0.47143$$

∴ The effectiveness of the heat exchanger, $\boxed{\varepsilon = 0.47}$

Step 7 of 8

c)

Mass flow of the cold water is calculated as follows

NTU of the heat exchanger is

$$NTU = \frac{1}{C-1} \ln\left(\frac{\varepsilon - 1}{\varepsilon C - 1}\right)$$
$$= \frac{1}{0.667 - 1} \ln\left(\frac{0.47143 - 1}{0.47143 \times 0.667 - 1}\right)$$
$$= 0.78094$$

NTU of the heat exchanger can also determined as

$$NTU = \frac{UA_s}{C_{min}}$$
$$0.7809 = \frac{2.2 \text{ kW/°C}}{4.18\dot{m}_c}$$
$$\dot{m}_c = 0.6739 \text{ kg/s}$$

∴ The mass flow rate of cold water, $\boxed{\dot{m}_c = 0.674 \text{ kg/s}}$

Step 8 of 8

d)

Heat transfer rate is calculated as

$$\dot{Q} = C_{min} (T_{c,out} - T_{c,in})$$
$$= (0.674 \text{ kg/s})(4.18 \text{ kJ/kg.°C})(53 - 20)°C$$
$$= 92.97156 \text{ kW}$$

∴ The rate of heat transfer, $\boxed{\dot{Q}_{max} = 92.97 \text{ kW}}$

Question: 22.119P

A single-pass cross-flow heat exchanger with both fluids unmixed has water entering at 16°C and exiting at 33°C, while oil (cp = 1.93 kJ/kg·K and ρ = 870 kg/m3) flowing at 0.19 m3/min enters at 38°C and exits at 29°C. If the surface area of the heat exchanger is 20 m2, determine (*a*) the NTU value and (*b*) the value of the overall heat transfer coefficient.

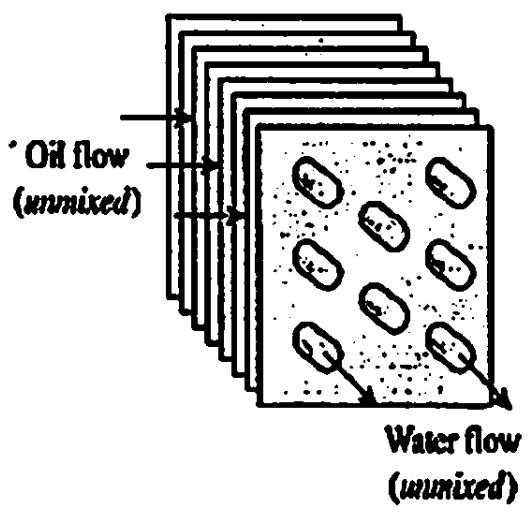

FIGURE P22–119

Step 1 of 8

A single pass cross flow heat exchanger

Find heat transfer rate for oil;

$$\dot{Q} = \dot{m}_{oil} c_{p,oil} \left(T_{oil,in} - T_{oil,out}\right)$$

$$= \frac{\dot{m}_{oil}}{\rho} c_{p,oil} \left(T_{oil,in} - T_{oil,out}\right)$$

Here, Mass flow rate of oil, $\dot{m}_{oil}$, the specific heat of oil, $c_{p,oil}$, Inlet temperature of oil, $T_{oil,in}$, Exit temperature of oil, $T_{oil,out}$

Substitute $0.19\,m^3/min$ for m, $870\ kg/m^3$, $1.93\,kJ/kg\cdot K$ for c_p, $(38-29)°C$ for ΔT in the above equation.

$$\dot{Q} = \frac{\dot{m}_{oil}}{\rho} c_{p,oil} \left(T_{oil,in} - T_{oil,out}\right)$$

$$= \frac{0.19\times 870}{60} \times 1.93 \times (38-29)$$

$$= 47854\ W$$

Determine the mass flow rate of the water from by using above heat transfer rate

$$\dot{Q} = \dot{m}_{water} c_{p,oil} \left(T_{water,out} - T_{water,in}\right)$$

$$47854\ W = \dot{m}_{water} \times 4180 \times (33-16)$$

$$\dot{m}_{water} = \frac{47854}{4180\times 17}$$

$$= 0.673\ kg/s$$

Step 2 of 8

Determine heat capacity rate of water fluid is,

$$C_c = \dot{m}_{water} c_{p,water}$$

Here, Specific heat of cold water, $c_{p,water}$

Mass flow rate of cold water, $\dot{m}_{water}$

Substitute $4180\ J/kg\cdot K$ for c_{pc}, $3.16\ kg/s$ for $\dot{m}_{water}$ in the above equation

$$C_c = \dot{m}_{water} c_{p,water}$$

$$= (0.673\ kg/s)(4180\ J/kg\cdot K)$$

$$= 2814.94\ W/K$$

Step 3 of 8

Determine heat capacity rate of oil,

$$C_h = \dot{m}_{oil} c_{p,oil}$$

Substitute $1.93\,kJ/kg\cdot K$ for c_p, $2.755\ kg/s$ for $\dot{m}_h$ in the above equation

$$C_h = \dot{m}_h C_{ph}$$

$$= (2.755\ kg/s)(1930\ J/kg\cdot K)$$

$$= 5317.5\ W/K$$

Step 4 of 8

Then

$$C_{min} = C_c = 2814.94\ W/K$$

And capacity ratio

$$c = \frac{C_{min}}{C_{max}}$$

$$= \frac{2814.94}{5317.5}$$

$$c = 0.529$$

Step 5 of 8

Determine the maximum heat transfer rate

$$\dot{Q}_{max} = C_{min} \times (\Delta T)_{max}$$

$$= C_{min} \times \left(T_{oil,in} - T_{water,in}\right)$$

$$= 2814.94 \times (38-16)$$

$$= 61928.68\ W$$

Find effectiveness of the heat exchanger is

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$

$$= \frac{47854\ W}{61928.68\ W}$$

$$= 0.772$$

$$= 77.27\%$$

Step 6 of 8

(a)

Determine the number of heat transfer units (NTU) using below relation for single pass cross flow heat exchanger with both fluids unmixed

Use the cross flow with both fluids unmixed chart

For effectiveness $\varepsilon = 77.27\,\%$ and capacity ratio $c = 0.529$

$$NTU = 2.39$$

Therefore, NTU value is $\boxed{2.39}$

Step 7 of 8

(b)

Now determine the overall heat transfer units using the below relation of NTU

$$NTU = \frac{A_s U}{C_{min}}$$

Here, A_s is the surface area of heat exchanger

Step 8 of 8

Substitute $20\,m^2$ for A_s, 2.39 for NTU, $2814.94\ W/K$ for C_{min} in the below relation

$$U = \frac{NTU \times C_{min}}{A_s}$$

$$= \frac{2.39\times 2814.94}{20}$$

$$= 336.38\,W/m^2\cdot K$$

Therefore, the overall heat transfer rate is $\boxed{336.38\,W/m^2\cdot K}$

Question: 22.120P

Saturated water vapor at 100°C condenses in the shell side of a 1-shell and 2-tube heat exchanger with a surface area of 0.5 m2 and an overall heat transfer coefficient of 2000 W/m2-K. Cold water (*cpc* = 4179 J/kg·K) flowing at 0.5 kg/s enters the tube side at 15°C, determine the outlet temperature of the cold water and the heat transfer rate for the heat exchanger.

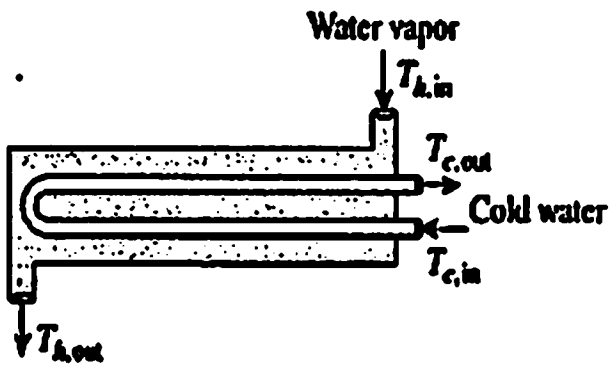

FIGURE P22–120

Step 1 of 4

Temperature of saturated water $T_{h,in} = 100°C$

Mass flow rates of water is $\dot{m}_{water} = 0.5\ kg/s$

Heat transfer surface area is $A_s = 0.5\ m^2$

Overall heat transfer coefficient $U = 2000\ W/m^2 \cdot K$

Temperature of cold water $T_{c,in} = 15°C$

Step 2 of 4

Heat capacity rate of the cold water is

$$C_c = \dot{m} c_{pc}$$

$$C_c = 0.5 \times 4179$$

$$C_{min} = C_c = 2089.5\ W/K$$

And $C = 0$

The maximum heat transfer rate becomes

$$\dot{Q}_{max} = C_{min}(T_{h,in} - T_{c,in})$$

$$= (2.0895\ kW/°C)(100°C - 15°C)$$

$$\dot{Q}_{max} = 177.6\ kW$$

NTU of the heat exchanger is

$$NTU = \frac{UA_s}{C_{min}}$$

$$= \frac{(2\ kW/m^2.°C)\ (0.5\ m^2)}{2.0895\ kW/°C}$$

$$NTU = 0.478$$

(a) Effectiveness of this heat exchanger

$$\varepsilon = 1 - \exp(-NTU)$$

$$= 1 - \exp(-0.478)$$

$$\boxed{\varepsilon = 0.38}$$

Step 3 of 4

(b) The outlet temperature of cold water

The actual heat transfer rate calculated as

$$\dot{Q} = \varepsilon \dot{Q}_{max}$$

$$\dot{m} c_p (T_{c,out} - T_{c,in}) = \varepsilon \dot{Q}_{max}$$

$$0.5(4.179)(T_{c,out} - 15) = 0.38(177.6)$$

$$T_{c,out} = 47.3°C$$

The outlet temperature of cold water is $\boxed{T_{c,out} = 47.3°C}$

Step 4 of 4

(c) The actual heat transfer rate calculated as

$$\dot{Q} = \varepsilon \dot{Q}_{max}$$

$$\dot{Q} = 0.38(177.6)$$

$$= 67.49\ kW$$

The actual heat transfer rate $\boxed{\dot{Q} = 67.49\ kW}$

Question: 22.121P

Oil in an engine is being cooled by air in a cross-flow heat exchanger, where both fluids are unmixed. Oil (*cph* = 2047 J/kg·K) flowing with a flow rate of 0.026 kg/s enters the tube side at 75°C, while air (*cpc* = 1007 J/kg·K) enters the shell side at 30°C with a flow rate of 0.21 kg/s. The overall heat transfer coefficient of the heat exchanger is 53 W/m2·K and the total surface area is 1 m2. If the correction factor is *F* = 0.96, determine the outlet temperatures of the oil and air.

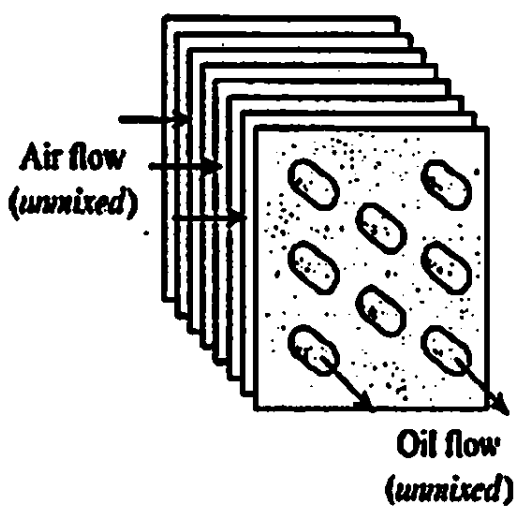

FIGURE P22–121

Step 1 of 6

Find the heat capacity rate of hot fluid by using the expression,

$$C_c = \dot{m}_c c_{pc}$$

Here, $\dot{m}_c$ is mass flow rate of cold fluid (air) and c_{pc} is specific heat of cold fluid.

Substitute 0.21kg/s for $\dot{m}_c$ and 1007 J/kg·K for c_{pc}

$$C_c = (0.21)(1007)$$
$$= 211.47 \text{ W/K}$$

Similarly, find the heat capacity rate of cold fluid by using the expression,

$$C_h = \dot{m}_h c_{ph}$$

Here, $\dot{m}_h$ is mass flow rate of hot fluid (oil) and c_{pc} is specific heat of hot fluid.

Substitute 0.026kg/s for $\dot{m}_h$ and 2047 J/kg·K for c_{ph}

$$C_h = (0.026)(2047)$$
$$= 53.22 \text{ W/K}$$

Therefore, minimum capacity heat rate is

$$C_{min} = C_h = 53.22 \text{ W/K}$$

Step 2 of 6

Find the capacity heat ratio by using the ratio,

$$c = \frac{C_{min}}{C_{max}}$$
$$= \frac{C_h}{C_c}$$
$$= \frac{53.22}{211.47}$$
$$= 0.2517$$

Step 3 of 6

Find the maximum heat transfer rate by using the equation,

$$\dot{Q}_{max} = C_{min}\left(T_{h,in} - T_{c,in}\right)$$

Here, $T_{c,in}$ is inlet temperature of cold fluid and $T_{h,in}$ is inlet temperature of hot fluid.

Substitute 75°C for $T_{h,in}$ and 30°C for $T_{c,in}$

$$\dot{Q}_{max} = 53.22 \times (75 - 30)$$
$$= 2394.9 \text{ W}$$

Find the NTU of the heat exchanger by using the expression,

$$\text{NTU} = \frac{UA_s}{C_{min}}$$

Here, U is overall heat transfer coefficient and A_s is total surface area of the heat exchanger.

Substitute 53 W/m^2-K for U and 1m^2 for A_s

$$\text{NTU} = \frac{53 \times 1}{53.22}$$
$$= 0.9958$$

Step 4 of 6

Then find the effectiveness of the heat exchanger when both fluids unmixed by using the expression,

$$\varepsilon = 1 - \exp\left\{\frac{\text{NTU}^{0.22}}{c}\left[\exp\left(-c\text{NTU}^{0.78}\right) - 1\right]\right\}$$
$$= 1 - \exp\left\{\frac{0.9958^{0.22}}{0.2517}\left[\exp\left(-0.2517 \times 0.9958^{0.78}\right) - 1\right]\right\}$$
$$= 0.585$$

Find the actual heat transfer by using the effectiveness relation,

$$\varepsilon = \frac{\dot{Q}}{\dot{Q}_{max}}$$
$$\dot{Q} = \varepsilon \dot{Q}_{max}$$
$$= 0.585 \times 2394.9$$
$$= 1401.016 \text{ W}$$
$$= 1.401 \text{ kW}$$

Step 5 of 6

Therefore, determine the outlet temperatures of the cold and hot fluids using the equation,

$$\dot{Q} = C_c\left(T_{c,out} - T_{c,in}\right)$$

Here, $T_{c,out}$ is outlet temperature of cold fluid.

Substitute the known values in the above equation,

$$T_{c,out} = T_{c,in} + \frac{\dot{Q}}{C_c}$$
$$= 30 + \frac{1.401 \times 10^3}{211.47}$$
$$= 36.62°\text{C}$$

Therefore, temperature of the hot fluid is $\boxed{36.62°\text{C}}$

Step 6 of 6

Similarly temperature of the cold fluid by using the expression,

$$\dot{Q} = C_h(T_{h,in} - T_{h,out})$$

Here, $T_{h,out}$ is temperature of hot fluid

Substitute the known values in the above equation,

$$T_{h,out} = T_{h,in} - \frac{\dot{Q}}{C_h}$$
$$= 75 - \frac{1.402 \times 10^3}{53.22}$$
$$= 48.656°\text{C}$$

Therefore, outlet temperature of hot fluid is $\boxed{48.656°\text{C}}$
